Results: We reviewed the diagnoses and clinical disposition of patients both before and after SLE-key® testing. In particular, we looked at the ability of the SLE-key® test to enhance our ability to reach a definitive diagnosis across the full cohort of patients, at the disposition of patients who were referred with a suspicion of SLE as part of the differential diagnosis, at the impact of SLE-key® testing on the diagnosis of the subset of patients who presented with minimal symptoms, and at the group of patients who had been referred following an ANA test. Results are summarized in Table 1. In the cases where SLE was ruled out, patients were treated for a variety of disorders including fibromyalgia, joint pain, MCTD, Sjogren's disease and others.

Table 1

Patient Subgroup	Status post SLE-key	Clinical Outcomes
Patients with uncertain diagnosis in our clinic prior to SLE-key® testing.	79% had an actionable diagnosis following SLE-key® test	57% were diagnosed to have SLE. 43% not SLE. Patients treated for a variety of disorders other than SLE
Patients referred to our clinic with SLE as part of differential diagnosis	62% confirmed SLE 32% Ruled Out	> 50% of those RuledOut were diagnosed with myalgia/ fibromyalgia and treated accordingly
Minimally symptomatic patients	65% Ruled Out for SLE	Patients treated for a variety of disorders other than SLE
Patients referred following ANA testing	44% Ruled Out for SLE	Patients treated for a variety of disorders other than SLE

Conclusions: The diagnosis of patients referred in the clinical rheumatology setting remains an ongoing challenge. The SLE-key® RuleOut test provides a laboratory aid to improve the diagnostic and dispositive efficiency saving undue concern, time and resources both to the patient and to the healthcare system. A retrospective analysis of our practices prior to the introduction of SLE-key® is warranted.

AB0490 ANALYSIS OF COMMON GRAM-NEGATIVE BACTERIA AND THEIR DRUG RESISTANCE IN HOSPITALIZED PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

D. Chen, Z. Zhan. *Rheumatology, The first affiliated hospital of SUN YAT-SEN UNIVERSITY, Guangzhou, China*

Background: Infection is an important cause of morbidity and mortality in patients with systemic lupus erythematosus (SLE). The spectrum of infectious agents in SLE patients varies significantly among different ethnic groups. The national surveillance study from the China showed that Gram-negative bacteria (GNB) was the most the common bacterial infection in China, while Gram-positive bacteria (GPB) was predominant in European countries.
Objectives: To identify the spectrum and drug resistant pattern of infection caused by GNB in patients hospitalized with SLE.
Methods: The clinical and microbiological data from hospitalized SLE patients with bacterial infection between June 2005 and June 2015 was collected and then analyzed retrospectively.
Results: Two hundred and sixty-eight episodes of bacteria had been identified from 3815 hospitalized patients. In terms of isolated microorganisms, gram-negative bacteria (GNB) were predominant over gram-positive bacteria (GPB) (178 isolates vs. 90 isolates). In the GNB, *Escherichia coli* (66/178, 37.1%) was the most common isolate, followed by *Acinetobacter baumannii* (36/178, 20.2%), *Klebsiella pneumoniae* (24/178, 13.5%), *Pseudomonas aeruginosa* (20/178, 11.2%), *Haemophilus influenzae* (10/178,5.6%), *Salmonella sp.* (7/178, 3.9%), *Enterobacter aerogenes* (5/178, 2.8%), *Stenotrophomonas maltophilia* (5/178, 2.8%), *Citrobacter freundii* (3/178,1.7%), *Proteus mirabilis* (2/178,1.1%). Resistant isolates (53/178, 30.0%) were more common documented in GNB, mostly extended-spectrum beta-lactamase (ESBL) producing *Escherichia coli* (30/66, 45.5%) and *Klebsiella pneumonia* (6/24, 25%), and multi-drug resistant *acinetobacter baumannii* (36.1%). Susceptibility tests showed that the ESBL-producing strains were highly sensitive to carbapenems, β-lactamase inhibitor compound families, and certain cefalosporin (Cefepime and Ceftazidime) *in vitro*. (the resistance rate <20%), whereas it was highly resistant to ampicillin and Gentamicin. Besides carbapenems and Cefoperazone/sulbactam, *Acinetobacter baumannii* was resistant to most antibiotics.
Conclusions: GNB was predominant in Chinese hospitalized patients with SLE. The drug resistance of GNB has increased significantly. It was necessary to rational use of antibiotics in patients with SLE.

AB0491 THE ASSOCIATION OF BASELINE HYPERURICEMIA IN PREMENOPAUSAL WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND DEVELOPMENT OF NEPHRITIS

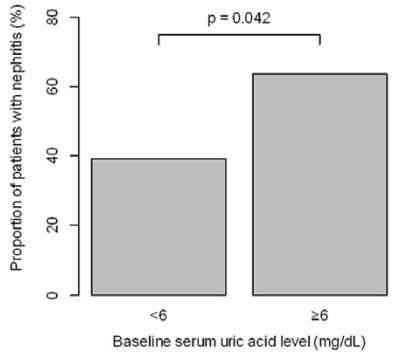
D.H. Lim[1], S. Hong[2], J.S. Oh[3], Y.-G. Kim[2], C.-K. Lee[2], S.W. Choi[1], B. Yoo[2]. *[1]Division of rheumatology, Department of Internal Medicine, Ulsan university hospital, Ulsan; [2]Division of rheumatology, Department of Internal Medicine, Asan Medical Center; [3]Division of rheumatology, Department of Internal Medicine, National Medical Center, Seoul, Korea, Republic Of*

Background: Renal involvement is a common and serious manifestation of SLE. Hyperuricemia may be associated with lupus nephritis as a result of renal

damage. However, it is not yet well known whether hyperuricemia is independently associated with renal involvement even in patients without known predisposing factors for hyperuricemia such as decreased renal function, old age, male gender, menopause, and drugs.

Objectives: The aim of this study was to evaluate the association of baseline serum uric acid level and development of nephritis in patients diagnosed with SLE.

Methods: We retrospectively reviewed electronic medical records of 101 female SLE patients whose ages at the time of diagnosis (baseline) were 45 years old or below in a tertiary medical center from January 2000 to March 2015. SLE with renal involvement was diagnosed when patients met the renal disorder of the 1997 ACR criteria for SLE. We compared baseline serum uric acid levels of the SLE patients who had nephritis at the time of diagnosis or later (nephritis group) with the patients who had not developed nephritis (non-nephritis group) during follow-up period.



Results: Among 101 patients, 22 (22%) had hyperuricemia (serum uric acid ≥6 mg/dL) at baseline and 45 (45%) had developed nephritis during follow-up period (median 6.1 years). There were significant differences in baseline serum uric acid level, glomerular filtration rate (GFR), anti-dsDNA antibody and complement level between non-nephritis group and nephritis group (Table). Interestingly, among 59 patients with normal renal function (baseline GFR ≥90 mL/min/1.73m^2), baseline serum uric acid level was also significantly higher in the nephritis group than non-nephritis group (Table). Moreover, the patients with hyperuricemia at baseline were more likely to develop nephritis than those without hyperuricemia during follow-up period (64% vs. 39%, p =0.042) (Figure).

Table 1. Baseline Characteristics of Study Patients with Systemic Lupus Erythematosus

	Non-nephritis group	Lupus nephritis group	*p*
All patients (%)	56 (55)	45 (45)	
Sex, Female (%)	56 (100)	45 (100)	
Age, years	28.2±8.3	28.9±7.6	0.680
Body Mass Index, kg/m^2	21.2±3.8	22.0±3.0	0.105
Follow-up, years	6.0±4.3	7.5±4.3	0.068
Serum Uric Acid, mg/dL	4.5±1.6	5.5±1.5	**0.003**
GFR, mL/min/1.73m^2	103.1±24.9	85.6±27.0	**0.001**
Anti-dsDNA, IU/mL	56.4±107.9	141.8±163.4	**0.001**
C3, mg/dL	80.1±32.3	48.6±30.2	**0.000**
C4, mg/dL	14.0±8.3	9.8±8.2	**0.005**
Drugs that may increase serum uric acid level[1] (%)	5 (8.9)	2 (4.4)	0.626
Drugs that may decrease serum uric acid level[2](%)	1 (1.8)	0 (0.0)	1.000
Patients with normal renal function (baseline GFR≥90) (%)	39 (66)	20 (34)	
Serum Uric Acid, mg/dL	4.3±1.4	5.1±1.4	**0.047**
GFR, mL/min/1.73m^2	113.0±15.6	106.2±11.7	0.095
Anti-dsDNA, IU/mL	56.2±111.0	135.0±185.2	0.060
C3, mg/dL	76.3±35.0	47.3±30.6	**0.003**
C4, mg/d	13.3±7.8	8.8±7.2	**0.028**

Values are mean ± SD or number (%). [1]Diuretics, aspirin, pyrazinamide, or cyclosporine. [2]Allopurinol, febuxostat, benzbromarone, losartan, fenofibrate, or atorvastatin.

Figure. Proportion of patients who had developed nephritis according to serum uric acid levels at the time of diagnosis with SLE

Conclusions: These findings suggest that high serum uric acid level at the time of diagnosis in premenopausal women with SLE may be independently associated with nephritis. More careful evaluation would be required for development of nephritis in such patients.

AB0492 NUCLEIC ACIDS OXIDATIVE STRESS STATUS IN SJÖGREN'S SYNDROME

D. Tecer[1], R. Tural[2,3], A. Sepici Dincel[2], F. Gogus[1]. [1]*Physical Medicine and Rehabilitation, Division of Rheumatology;* [2]*Medical Biochemistry, Gazi University, Faculty of Medicine, ankara;* [3]*Vocational School of Health Services, Sinop University, Sinop, Turkey*

Background: Although there are many defence systems that protect cellular macromolecules against oxidation, oxidative DNA and RNA damage still occurs. Oxidative damage to nucleic acids has been found to be associated with etiopathogenesis and disease activity of inflammatory disorders. Oxidised guanine species have been recognized as a biomarker of oxidative DNA and RNA damage by endogenously generated oxygen radicals. Sjögren's syndrome (SS) is an autoimmune disorder and associated with overexpression of proinflammatory cytokines. Related to excess expression of proinflammatory cytokines, a prooxidant state could be postulated in SS.

Objectives: We aimed to evaluate levels of nucleic acids oxidative stress products in patients with SS.

Methods: 11 patients with SS diagnosed according to 2012 American College of Rheumatology (ACR) Classification Criteria for Sjögren's Syndrome, 19 patients with psoriatic arthritis (PsA), diagnosed according to Classification Criteria for Psoriatic Arthritis (PSARC), 9 patients with rheumatoid arthritis (RA), diagnosed according to 2010 Rheumatoid Arthritis Classification Criteria, and 12 healthy controls were included. All SS patients were on hydroxychloroquine sulphate 400mg/day. All PsA and RA patients were on methotrexate 15–20mg/week and folic acid 5 mg/week. The serum samples were collected from participants and stored at -30 C until assayed. Three oxidised guanine species, 8-hydroxy-2'-deoxyguanosine as a DNA oxidation marker, 8-hydroxyguanosine as a RNA oxidation marker, and 8-hydroxyguanine as a DNA and RNA oxidation marker, were measured using DNA/RNA Oxidative Damage ELISA Kit (Cayman Chemicals, USA).

Statistics: All data are presented as mean and standard deviation (SD). Differences between groups were examined using Kruskal- Wallis tests. The Mann-Whitney U test was performed to test the significance of pairwise differences using Bonferroni correction to adjust for multiple comparisons. A p-value less than 0.05 were considered as statistically significant. Statistical analysis of correlation was performed by using the Spearman rank test.

Results: There was no statistically significant difference between the groups in terms of age and gender. The average level of serum oxidised guanine species in the PsA, RA, SS and healthy control groups were 2871.77±336.20, 2672.20±292.04, 3375.57±344.21, 2777.55±237.05 pg/mL respectively. Oxidised guanine species levels were significantly higher in patients with SS and positively correlated with CRP levels (p:0.011, r: 0.726) (table 2).

Table 1. Demographic characteristics of individuals

	Psoriatic arthritis	Rheumatoid arthritis	Sjögren's syndrome	Healthy controls	p value
Age	41.05 ± 11.61	51.56 ± 11.17	48.25 ± 10.31	41.17 ± 6.50	0.076
Female/male	8/11	8/1	11/1	5/7	0.096

Table 2. Correlation between oxidised guanine species level and ESR, CRP, IgG, IgA, IgM, C3, C4

		ESR	CRP	IgG	IgA	IgM	C3	C4
oxidised guanine species level	p	0.428	0.01	0.721	0.556	0.04	0.745	0.704
	r	0.253	0.726	0.226	0.189	-0.595	0.105	0.123

ESR: erythrocyte sedimentation rate, CRP: C-reactive protein, Ig: Immunoglobulin, C: Complement

Conclusions: A marked increase in DNA damage leading to oxidative stress may contribute to tissue damage in SS.

AB0493 BLYS UPREGULATION IS RELATED TO LYMPHOPENIA IN SYSTEMIC ERYTHEMATOUS LUPUS PATIENTS

E. Grau Garcia[1], C.M. Feced Olmos[1], E. Labrador Sánchez[1], F.M. Ortiz-Sanjuan[1], M. Fernandez Matilla[2], N. Fernández-Llanio[2], I. Chalmeta Verdejo[1], K. Arévalo Ruales[1], R. Negueroles Albuixech[1], J. Ivorra Cortes[1], J.J. Fragio Gil[1], I. Martínez Cordellat[1], R. González Mazarío[1], L. Gonzalez Puig[1], C. Alcañiz Escandell[1], C. Nájera Herranz[1], I. Cánovas Olmos[1], E. Vicens Bernabeu[1], J.E. Oller Rodriguez[1], J.A. Castellano Cuesta[2], V. Fornés Ferrer[3], D. Hervás Marín[3], J.A. Román Ivorra[1]. [1]*Rheumatology Department, HUP la Fe;* [2]*Rheumatology Section, Hospital Arnau de Vilanova;* [3]*Biostatistics Unit, IIS la Fe, Valencia, Spain*

Background: B lymphocyte stimulator factor (BLyS) is produced by wide range of cells of the immune system, and has proven to be a key factor in the selection and survival of B cells. BLyS is an important factor in the pathology of Systemic Lupus Erythematosus; elevated serum levels (≥20ng/mL) of soluble BlyS are at increased risk of flare.

Objectives: Analyze the association among BLyS levels and clinical manifestations, as well as with SLE clinical activity.

Methods: A cross-sectional and observational study was performed in patients diagnosed of SLE according to SLICC 2012 criteria and healthy controls. The study included a complete blood-test and clinical data collected by personal interview. Disease activity assessment was made by SLEDAI index and for the evaluation of chronic damage we used the validated SLICC damage index. Serum concentration of BLyS was analyzed by colorimetric methods. Lupus patients were dichotomized as high and low BLyS levels based on BLyS levels above 2 SD of the mean in healthy controls. Biostatistical analysis with R (3.3.2.) was performed.

Results: Two hundred forty-two SLE patients were evaluated; 94.4% of them were female. Mean values were as follow: age at diagnosis 33.29±13.53 years, disease duration 15.82±10.56 years, SLEDAI 5.91±5.06, SLICC score 1.06±1.42, BLyS levels 1.811±1.757 ng/mL. The 22.5% of patients displayed increased BLyS levels. The 29.6% of total patients exhibit SLEDAI values up to 6, and only the 7% of them showed SLEDAI values up to 6 and high BLyS levels simultaneously. Higher BLyS levels were significantly correlated to the ANAs positivity (p=0.0006) and lymphopenia (p=0.01) but showed no correlation with hypocomplementemia neither anti-dsDNA. The statistical analysis did not yield differences in the clinical activity or accumulated damage between patients with lower and higher BLyS levels.
Conclusions: In our series we observed a 22.5% of patients with high levels of BLyS, and the 7% of cases had BLyS high levels and SLEDAI>6. BLyS upregulation is related to ANAs positivity and lymphopenia. We have found no statistical evidences on the relationship of BLyS levels and clinical activity in our series of patients.

AB0494 INCREASED LEVELS OF INTERFERON ALPHA AND INTERLEUKIN-10 AS CLINICAL ACTIVITY BIOMARKERS IN SYSTEMIC LUPUS ERYTHEMATOUS PATIENTS

E. Grau Garcia[1], M. Fernandez Matilla[2], C.M. Feced Olmos[1], E. Labrador Sánchez[1], F.M. Ortiz-Sanjuan[1], N. Fernández-Llanio[2], E. Tovar Sugreñes[3], K. Arévalo Ruales[1], R. Negueroles Albuixech[1], J. Ivorra Cortes[1], J.J. Fragio Gil[1], I. Martínez Cordellat[1], R. González Mazarío[1], I. Chalmeta Verdejo[1], L. Gonzalez Puig[1], C. Alcañiz Escandell[1], C. Nájera Herranz[1], I. Cánovas Olmos[1], E. Vicens Bernabeu[1], J.E. Oller Rodriguez[1], J.A. Castellano Cuesta[2], V. Fornés Ferrer[4], D. Hervás Marín[4], J.A. Román Ivorra[1,3]. *[1]Rheumatology Department, HUP la Fe; [2]Rheumatology Section, Hospital Arnau de Vilanova; [3]Medical School, UCV; [4]Biostatistics Unit, IIS la Fe, Valencia, Spain*

Background: Systemic lupus erythematous (SLE) is an autoimmune disease characterized by immune system disruption, including deregulation of cytokine production. Interferon alpha (INF1A) is considered a key molecule in SLE etiopathogenesis, being responsible of the differentiation of dendritic cells from monocytes, and indirectly of interleukin 10 (IL10) upregulation. The B lymphocyte stimulating factor (BLyS) is involved in autoantibodies production and clinical activity, and is regulated by other cytokines as IL10 and INF1A.
Objectives: To analyze the association among INF1A, IL10 and BLyS levels and clinical activity in SLE.
Methods: A cross-sectional, observational study of 142 patients diagnosed of SLE according to SLICC 2012 criteria and 34 healthy controls was performed. A complete blood-test was made, and clinical data by personal interview was collected. We analyzed serum concentration of IL10, BLyS and INF1A by colorimetric methods. Patients were dichotomized as high and low levels for each cytokine based on the cytokine level above 2 SD of the mean in healthy controls. Biostatistical analysis with R (3.3.2.) was performed.
Results: In our SLE patients we observed higher values of IL10, BLyS and INF1A than controls ($P<0.001$, P=0.005 and P=0.043 respectively), showing an average values in patients of 13.39±27.73 pg/mL INF1A, 9.99±15.84 pg/mL IL10 and 1811.31±1757.81 pg/mL BLyS. The mean clinical activity measured by SLEDAI was 5.91±5.06.
Statistical analysis indicate that INF1A levels are correlated to IL10 levels (P=0.001) and BLyS levels (P=0,034). Due to this finding, we categorized SLE patients by low or high level of the three cytokines: 44 INF1A(-)IL10(-)BLyS(-); 61 INF1A(+)IL10(-)BLyS(-); 5 INF1A(+)IL10(-)BLyS(+); 18 INF1A(+)IL10(+)BLyS(-) and 14 INF1A(+)IL10(+)BLyS(+). There is a high association of increased IL10-INF1A levels and the increased of clinical activity by SLEDAI score ($P<0.001$), and to a lesser extent with increased IL10-INF1A-BLyS levels. Patients with high IL10-INF1A and IL10-INF1A-BLyS showed a significant rise in C3-C4 consumption ($P<0.001$ and P=0.001 respectively) and high anti-dsDNA (P=0.001 and P=0.002 respectively). Patients with increased INF1A-BLyS exhibited high anti-dsDNA (P=0.004) and ENA positivity ($P<0.001$). In addition, patients with increased levels of IL10-INF1A-BLyS showed ANAs ($P<0.001$) and antiphospholipid autoantibody positivity (P=0.004).
Conclusions: The 69% of our SLE patients displayed almost one cytokine increased, being the INF1A the cytokine that mainly is increased. However, increased IL10 levels, irrespective of whether there is also increased levels of BLyS and/or INF1A, is the cytokine which best fits to clinical activity in SLE.

AB0495 ASSESSMENT OF FRACTURE RISK IN A COHORT OF EGYPTIAN FEMALE SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

E.A. Hafez[1], S.A. El Bakry[1], S.I. Ibrahim[1], C.S. Morad[1,1], S.A. Hamza[2], D.M. Abd El-Khalik[1]. *[1]Internal medicine and Rheumatology; [2]Geriatric Medicine, Faculty of Medicine, Ain Shams University, Cairo, Egypt*

Background: Survival of systemic lupus erythematosus (SLE) patients has improved dramatically due to improved treatment, and the morbidity pattern has shifted towards long-term complications as osteoporosis. SLE occurs in women during child-bearing years and the disease often persists to the postmenopausal period[1]. Assessment of fracture risk in SLE patients is important as fractures may occur while bone mineral density (BMD) is above the osteoporotic threshold or at the normal range[2]. Osteocalcin measurement helps to assess fracture risk and select patients for treatment.
Objectives: To assess the fracture risk in a cohort of Egyptian female SLE patients by using BMD and osteocalcin level with correlation to disease activity, damage index and drugs in use.
Methods: 70 females with SLE ≥40 years old satisfying the SLICC classification criteria were enrolled with detailed history taking including disease duration, drugs in use, traditional risk factors, regular exercise, history of previous fractures and menstrual history. Assessment of disease activity using Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and disease damage using the Systemic Lupus International Collaborative Clinics/ American College of Rheumatology Damage Index (SLICC/ACR DI). Serum calcium, phosphorus and alkaline phosphatise were measured. BMD measured by dual energy X-ray absorpiometry (DEXA) scans at lumbar spine (LS) (L2-L4) and femoral neck (FN), serum osteocalcin level and World Health Organization fracture risk assessment tool (FRAX®).
Results: 14//70 (20%) patients had LS osteoporosis, 25//70 (35.7%) had LS osteopenia and 6/70 (8.6%) had FN osteoporosis, 30/70 (42.9%) had FN osteopenia. FRAX-Major ≥20% was observed in 10% of patients, FRAX-HIP ≥3% was seen in 27.1% of patients. Serum osteocalcin level was significantly decreased in SLE patients with lower BMD than those with normal BMD, and significantly decreased in patients with osteoporosis than those with osteopenia. A significant negative correlation was found between osteocalcin level and age of patients, disease duration, SLEDAI and SLICC scores, current, IV pulse and cumulative steroids, immunosuppressants, anticoagulants, but there was a positive correlation with antimalarials and calcium supplements.
Conclusions: SLE patients are at greater risk for developing osteoporosis and osteopenia. Ten-year risk of major and hip fractures was high in SLE patients. Increasing age, disease duration, high anti-DNA titres, SLEDAI and SLICC were associated with a higher 10-year probability of major osteoporotic fracture. FRAX predicted incident hip and major osteoporotic fractures among SLE patients with normal and low bone mass not just those with frank osteoporosis. Physicians should be alerted to the higher risk of future fractures in SLE patients for periodic monitoring.

AB0496 VENOUS THROMBOSIS IS MORE PREVALENT IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME (APS) ACCOMPANYING SYSTEMIC LUPUS ERYTHEMATOSUS, WHILE LIVEDO RETICULARIS IN PRIMARY APS

E.N. Hałady, A. Wieczorek, M. Olesińska. *Connective Tissue Diseases, Institute of Geriatrics, Rheumatology and Rehabilitation, WARSAW, POLAND, Warsaw, Poland*

Background:
APS more often overlaps with other systemic autoimmune diseases like systemic lupus erythematosus (SLE) or rheumatoid arthritis (RA) than occur as a distinct disease. Our purpose was to evaluate what are the differences between patients with primary APS and APS accompanying SLE.
Objectives: The objective of this study was to compare patients with primary APS and APS/SLE group whther we can find find any clinical or laboratory parameters that can distinguish them from each other.
Methods: 112 patients with APS were included to the study, 57 of them with primary APS and 55 with coexisting SLE. These patients were followed at the Department of Connective Tissue Diseases, NIGRiR, Warsaw, Poland. At inclusion a full medical history and physical examination data were recorded.
Results: Both groups were similar in age, gender and duration of disease. Among all the clinical manifestations of APS, venous thrombosis was more frequent in patients with concomitant SLE. Skin involvement was significantly more prevalent in primary APS and it was caused mainly by livedo reticularis presence. From neurological manifestations, the occurrence of epilepsy was comparable, when EEG changes were more frequent in APS/SLE group. From laboratory measures, leucopenia, low complement concentrations and proteinuria were more prevalent in APS/SLE group. No differences were observed in thrombocytopenia and elongation of APTT as well as antiphospholipid antibody profile.
Conclusions: In conclusion, arterial thrombosis is more characteristic for primary APS. We found that livedo reticularis is very characteristic feature for primary APS. Although epilepsy occurrence is comparable in APS and APS/SLE, higher frequency of EEG changes in APS/SLE group suggests that the mechanisms

Table 1. Main differences in both groups

	Total N=112	APS N=57 (50,9%)	TRU+APS N=55 (49,1%)	P
Age	48,3±13,7	46,9±14,3	49,7±13,2	0,2187
Gender	96 (85,7%)	45 (78,9%)	51 (92,7%)	0,0698
APS duration (months)	72 [24–144]	48 [13–120]	80 [31–156]	0,2329
Venous thrombosis	61 (54,5%)	25 (43,9%)	36 (65,4%)	**0,0218**
Arterial thrombosis	63 (56,2%)	30 (52,6%)	33 (60,0%)	0,4320
Thrombosis all	97 (86,6%)	47 (82,5%)	50 (90,9%)	0,1891
livedo reticularis	53 (47,3%)	41 (71,9%)	12 (21,8%)	**<0,0001**
EEG changes	18 (16,1%)	5 (8,8%)	13 (23,6%)	0,0323
Epilepsy	20 (17,9%)	8 (14,0%)	12 (21,8%)	0,2823

leading to this feature can be distinct between this two conditions. Additionally, it appears to be more reasonable to add thrombocytopenia to clinical criteria of APS, because its frequency does not depend on SLE presence.

Disclosure of Interest: None declared

AB0497 SIX CASES OF MACROPHAGE ACTIVATION SYNDROME AS PRESENTING MANIFESTATION OF SYSTEMIC LUPUS ERYTHEMATOSUS

F. Dall'ara[1], I. Cavazzana[2], M. Frassi[2], M. Taraborelli[2], M. Fredi[2], F. Franceschini[2], L. Andreoli[1], A. Tincani[1], P. Airò[2]. *[1]Rheumatology and Clinical Immunology, University of Brescia - Dscs; [2]Rheumatology and Clinical Immunology, Spedali Civili of Brescia, Brescia, Italy*

Background: Macrophage Activation Syndrome (MAS) is a life-threatening syndrome characterized by excessive immune activation. It can be triggered by conditions affecting immune homeostasis, such as infections, malignancies and rheumatologic disorders, including Systemic Lupus Erythematosus (SLE). In previous studies, prevalence of MAS among SLE patients ranged from 0.9% to 4.6%.

Objectives: To describe the presentation and treatment of both MAS and SLE in patients with both syndromes.

Methods: Monocentric retrospective evaluation: patients with MAS according to HLH classification criteria were identified in our cohort of SLE patients (classified according to ACR and SLICC criteria)followed for at least 1 year between 1972 and 2014.

Results: Among 511 patients with SLE (mean age at diagnosis:31 years ±2),6 patients (1.2%)with MAS were identified (all female). Their main clinical and laboratory features are reported in table 1.Median HLH score was 226.5 (IQR 204–254),with a probability of having MAS of 96%.In all cases MAS happened simultaneously to the onset of SLE.Median age at diagnosis was 31.5 years, median SLEDAI was 12.All patients had fever above 38°C,lymphadenopathy,hematological involvement,and high titer ANA positivity. Workup for infections and malignancies was negative in all cases.All patients were treated with corticosteroids (100% received intravenous immunoglobulin pulse of methylprednisolone);concomitant medications were: cyclosporin A in 83%, IVIG in 67%, granulocyte colony-stimulating factor in 17%, mycophenolate mofetil in 17%, etoposide in 17% and plasma exchange in 17%. Two patients required haemotransfusion.All cases required hospital admission, and 2 were admitted in intensive care unit. No death from MAS was observed (median follow up: 34.5 months;IQR25–48).One patient died 44 months after after MAS for pulmonary adenocarcinoma.Table 1:main clinical and laboratory features at diagnosis of SLE and MAS

Table 1: main clinical and laboratory features at diagnosis of SLE and MAS

Clinical features of MAS n (%)		SLE ACR classification criteria	
Fever	6 (100%)	§Malar rash/Oral ulcers/Photosensitivity/ LED	5 (83%)
Hemorrhages	1 (17%)		
CNS dysfunction	0 (0%)		
Lymphadenopathy	6 (100%)		
Hepatomegaly	4 (67%)	Arthritis	2 (33%)
Splenomegaly	4 (67%)	Nephritis	0
		Serositis	3 (50%)
		CNS disease	1 (17%)
		Haematological involvement	6 (100%)
MAS Laboratory Parameters median (IQR)		Autoantibodies n (%)	
WBC (x10³/uL)	2.1 (1.8-2.3)	ANA	6 (100%)

Ferritin (µg /L)	4607 (1897-31533)	*Direct Coombs Test +	5 (100%)
Fibrinogen (mg/dL)	97 (35-170)	C3 mg/dl (n.v 80-160)	34 (28-70)
Triglycerides (mg/dl)	511 (317-605)	C4 mg/dl (n.v 10-40)	13 (7-17)
ESR (mm)	17.5 (9-24)		
CRP (mg/dl)	37 (10-49)		

* this test was available only for 5 patients

§at least one of these criteria: malar rash; Oral ulcers; Photosensitivity; LED: Discoid Lupus Erythematosus

CNS: central nervous system; WBC white blood cells; HGB: hemoglobin; PLT: plateletAST: aspartate aminotrasferase; ALT: alanine aminotrasferase; LDH: lactate dehydrogenase; ESR: erytrocyte sedimentation rate; CRP: C-reactive protein; ANA antinuclear antibodies; anti-ds DNA: anti double stranded DNA antibodies; anti-RNP: anti-ribonucleoprotein antibodies; LA: Lupus anticoagulant: n.v.: normal values

Conclusions: MAS is a rare complication in our SLE cohort and can complicate the onset of SLE, but it seems to be a very uncommon manifestation during the course of the disease.Fever may be a red flag for possible MAS, particularly if temperature is persistently above 38° in absence of signs and symptoms of underlying infection.In our series, all cases were treated successfully with immunosuppressive drugs and cytotoxic agents such as etoposide were used only in one case.

AB0498 SOLUBLE CD14 (PRESEPSIN) AS A POTENTIAL BIOMARKER TO DISCRIMINATE INFECTION VS. ACTIVITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

I. Posso-Osorio[1], A. Echeverry[1], D. Aguirre-Valencia[1], G. Castaño[2], G. Tobón[1]. *[1]Rheumatology; [2]Laboratory of inmunology, Fundación Valle del Lili, CALI, Colombia*

Background: Differentiation of Systemic Lupus Erythematosus (SLE) activity and infection in a febrile SLE patient become difficult, since initial clinical presentation may be similar. Several biological markers (including procalcitonin and CRP) have been evaluated, with discordant results. Soluble CD14 (sCD14), also called presepsin, is the receptor for lipopolysaccharide - lipopolysaccharide binding protein (LPS-LBP) complexes. CD14 could activate a series of signal transduction pathways and inflammatory cascades, and lead to systemic inflammatory responses.(1)

Objectives: The aim of this study is to evaluate the utility of sCD14 as a biomarker to differentiate infection *vs.* activity in SLE patients admitted with systemic inflammatory response (SIRS).

Methods: We included 11 patients with SLE (ACR criteria 1997) and SIRS (International conference 2001) admitted to the ER and/or ICU. The measurement of sCD14 in plasma by enzymatic immunoassay of chemiluminescence *in vitro* was performed to differentiate active SLE *vs.* infection. Infection was considered if a positive culture/PCR was obtained. Mann-Whitney test was used to evaluate the association of variables with infection.

Results: All patients were female; mean age 37.9 years. An infectious disease was confirmed in 5 cases (3 bacterial including urinary tract infection, pneumonia and bacteremia; 1 viral infection by Chikungunya virus and 1 fungal by *histoplasma capsulatum*). sCD14 was elevated in the infected SLE patients (median: 1005 pg/mL- RIC: 533–1415-) vs patients with lupus flare (median: 431.5 pg/mL - RIC: 369–579-) (p=0,04).

Conclusions: High values of sCD14 levels seem to be useful to differentiate infections from activity in SLE patients with SIRS. More patients and further analysis are necessary to define the clinical use of this biomarker.

AB0499 TOTAL BODY WATER AND ITS CORRELATION WITH SICCA SYMPTOMS IN PRIMARY SJÖGREN'S SYNDROME

G. Hernandez-Molina[1], P. Almeda-Valdés[2], G. López-Carrasco[2], M. Astudillo-Angel[1], M. González-Acevedo[2], V. Zamora-Legoff[1], P. Sánchez-Fernández[2], C. Aguilar-Salinas[2], I. Cruz Bautista[2]. *[1]Immunology and Rheumatology; [2]Endocrinology Department, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico*

Background: Patients with primary Sjögrens' syndrome (PSS) suffer from severe alterations in both the quality and quantity of saliva and tears. Body water represents around 50–55% of the body weight. Tears contain 98% of water and saliva 99.5%.

Objectives: To evaluate the percentage of total body water (TBW) among patients with PSS and to assess its correlation with sicca symptoms.

Methods: We included 85 patients with PSS and 85 historical non diabetic controls matched by gender, age (±3 years) and body mass index (±1kg/m^2) (BMI). We assessed the presence of sicca symptoms, Schirmer-I test, non-stimulated whole salivary flow (NSWSF) and ocular staining. We also evaluated the ocular and oral domains of the ESSPRI, a validated scale for symptoms (a higher score implies worst symptoms). We obtained the TBW percentage with a bioelectric impedance analysis (BIA-SECA-514, Hamburgo).

Results: 80% were women, mean age 54.8±13.7 years and mean disease duration 11.5±7.52 years. The percentage of TBW was similar among patients and controls (PSS 46.85±4.6 vs. 46.9±4.5, p=0.88). Among the patients, the

TBW negatively correlated with age (ρ=-0.25, p=0.02), disease duration (ρ=-0.30, p=0.005), BMI (ρ=-0.78, p=0.001) and the ocular component of the ESSPRI (ρ=-0.28, p=0.01), but not with the NSWSF or the ESSPRI oral component. When we compared the patients in the 25% percentile (group with the lowest % of water) vs. the remaining patients, the former group was older (56.6±8.1 vs. 54±14.2, p=0.02), with longer disease duration (12.4±5.9 vs. 10.8±7.12, p=0.03), lower scores at the Schirmer test (1 (range 0–8) vs. 2 (range 0–9), p=0.01), higher BMI (31.1±5.1 vs. 23.7±2.9, p=0.001) as well as with higher ESSPRI ocular domain scores (8.3±1.4 vs. 6.7±2.5, p=0.007). With the linear regression analysis, the variables that remained associated with the TBW were disease duration (β -0.22, p=0.001), BMI (β-0.76, p<0.001) and the ocular domain of the ESSPRI (β-0.15, p<0.001).

Conclusions: Patients with PSS had similar TBW percentage than controls. However among patients with PSS, the TBW had a negative correlation with the intensity of ocular symptoms independently of disease duration, age and BMI.

AB0500 TOLERABILITY, EFFICACY AND IMMUNOGENICITY OF 23-VALENT PNEUMOCOCCAL VACCINE IN SLE PATIENTS

G.M. Tarasova, B.S. Belov, M.S. Sergeeva, S.K. Soloviev, E.A. Aseeva, N.G. Klukvina, T.V. Popkova, E.N. Alexandrova, A.A. Novikov, M.V. Cherkasova. *V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Concurrent infections turn out to be the second leading cause of death in systemic lupus erythematosus (SLE) pts after SLE per se. Immunization of SLE pts with pneumococcal vaccine is an important prophylactic approach to prevent severe lower respiratory tract (LRT) infections in SLE pts.

Objectives: To study the relevance of 23-valent pneumococcal vaccine for immunization of SLE pts.

Methods: The study included 30 SLE pts, 27 females, 3 males, aged 19 - 62 y. Duration of follow up (FUP) was 12 months in 24 pts, and 7–10 months – in 6 pts. High disease activity at the time of immunization was documented in 1 patient, low activity – in 20 pts, moderate – in 4 pts, and remission – in 5. 29 pts were treated with glucocorticosteroids (GCs), 23 – with hydroxychloroquine, 14 pts – with cytostatic (CS) agents. Twelve pts were on biological disease-modifying antirheumatic drugs (bDMARDs). One dose (0,5 ml) of 23-valent polysaccharide pneumococcal vaccine was administered subcutaneously. The duration of FUP was 7–12 months. Control visits were scheduled as follows: at baseline (Visit 1), at 1st, 3rd, and 12th months (Visit 4) after immunization. Standard clinical examination and lab tests, including blood immunology, were performed at each visit. Vaccine immunogenicity was evaluated based on the level of serum antibodies (AT) to Streptococcus pneumoniae capsular polysaccharide (VaccZymeTM PCP Ig 2 panels (The Binding Site Ltd, Birmingham, UK)) – 4 times during 1 year.

Results: No post-immunization complications were seen in 11 (36,7%) pts, local reactions of varying intensity lasting from 2 to 7 days were documented in 18 (60%) pts. One patient (3,3%) developed the local *type* III hypersensitivity reaction known as Arthus phenomenon. All symptoms subsided within 7 days after administration of antihistaminic agents and local GCs. Not a single vaccination-related SLE exacerbation episode was documented in 24 pts during the FUP. Significant (≥2-fold vs baseline) increase of serum AT levels to S. pneumoniae polysaccharide was observed during the FUP (Table).

In 10 (41,7%) out of 24 pts ("non-responders") more than 2-fold increase of anti-S. pneumoniae ATs was not achieved by 12th month of FUP. Among them 7 (70%) pts were receiving bDMARDs. 4 (28,6%) out of 14 "responders " were also treated with bDMARDs.

Non-severe pneumonia was documented in 2 out of 24 pts within1 year after vaccination; both cases successfully resolved after 7- and 5-days of oral antibiotic treatment in an out-patient setting. Both pts had episodes of pneumonia in past medical history. One of them had SLE-induced interstitial lung disease. This patient was treated with GCs, mycophenolate mofetil, and rituximab, no post-vaccination response was documented. The second patient had two previous pneumonia episodes, she demonstrated 4–5-fold increase in anti- S. pneumoniae AT titre; her therapy included GCs (10 mg/day) and hydroxychloroquine. There were no clinical or radiological symptoms of pneumonia in remaining 22 pts during the whole FUP.

Table. Anti-pneumococcal AT concentrations in SLE pts, Me (25,75 percentiles), n=24.

Visit	Visit 1 (baseline)	Visit 2 (1 mo)	Visit 3(3 mo)	Visit 4 (12 mo)
AT concentration Mg/L	**97,4[a]** (68,0; 128,1)	**407,8[b]** (231,2; 488,8)	**301,8[c]** (164,3; 424,6)	**265,5[d]** (120,0; 438,7)
		b-a, p =0,00006	c-a, p =0,00008	d-a, p =0,002

Conclusions: Obtained results are indicative of good tolerability, safety and immunogenicity of 23-valent pneumococcal vaccine in SLE pts. Further studies are necessary for more comprehensive evaluation of vaccine clinical efficacy.

AB0501 THE ASSOCIATION BETWEEN GLUCOCORTICOIDS AND DAMAGE ACCRUAL IN PATIENTS WITH SLE USING GLUCOCORTICOID FOR LONG-TERM

G. Wang, X. Li, Z. Dou, W. Wang, R. Liu. *Rheumatology and Immunology, Anhui Provincial Hospital Affiliated to Anhui Medical University, Hefei, China*

Background: Systemic lupus erythematosus (SLE) is a chronic systemic autoimmune disease characterized by a relapsing-remitting course. Long-term prognosis of SLE patients remains poor [1]. Due to the effect of potent anti-inflammatory and immunosuppressive, glucocorticoids (GCs) remain the cornerstone of treatment in SLE. However, GCs produce several adverse reactions, most are time and dose dependent, limiting their clinical usefulness. Increased longevity with prolonged exposure to GCs and inflammatory insults might contribute to organ damage accrual, which retards further improvement of survival in these patients [2]. Assessment the extent of organ damage caused by SLE has been considered an important part of the assessment of prognosis. The Systemic Lupus International Collaborating Clinics/American College of Rheumatology (SLICC/ACR) Damage Index (SDI) is a validated instrument designed to measure irreversible damage resulting from SLE disease activity and its treatment. The study of damage accrual in patients with SLE caused by the long-term treatment of GCs is still not clear.In a large SLE cohort, followed prospectively, we determined to investigate the association between damage accrual with GCs, both cumulative prednisone dose and high-dose prednisone. The results of our study could shed more light on the risk/benefit ratio of GCs in long-term maintenance treatment with SLE patients.

Objectives: To evaluate the association between long-term glucocorticoids use and damage accrual in patients with systemic lupus erythematosus.

Methods: Medical records of 535 SLE patients from Department of Rheumatology and immunology of Anhui Provincial Hospital were reviewed. 512 patients were femal. The cohort's mean age was 38.27±12.84 years with mean disease duration of 7.33±5.75 years. Their Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI) scores were noted. (1) Univariate analysis and multivariable regression analysis were performed to determine factors associated with SDI. (2) Analysis were also performed to determine damage associated with cumulative prednisone dose and high-dose of prednisone (exposure to prednisone at a dosage of 60 mg/day for 1 month).

Results: (1) Among 535 patients in our cohort only 5 paitents (0.9%) had never been treated with glucocorticoids. A total of 192 patients (35.9%) had been treated with high dose of prednisone. In addition, 86.9% of patients had been treated with hydroxychloroquine. (2) The highest organ damage was musculoskeletal (n=79, 14.8%), followed by skin damage (n=35, 6.5%) and renal (n=28, 5.2%). Ninety patients were diagnosed with hypertension. (3) SDI scores were associated with age of onset, exposure to high-dose prednisone, hypertension.(4) Cumulative prednisone dose was associated with osteoporosis, osteonecrosis and hypertension; exposure to high-dose prednisone was associated with osteonecrosis, lupus nephritis and hypertension.

Conclusions: Long-term taking prednisone predicted damage accrual. The most common damage was osteoporosis, osteonecrosis and hypertension.

AB0502 STRONG REDUCTION OF ANTI-MÜLLERIAN HORMONE IN SYSTEMIC LUPUS ERYTHEMATOSUS WOMAN OF REPRODUCTIVE AGE

C. Li, J. Xie, X. Wang, X. Liu, G. Chen. *Division of Rheumatology and Clinical Immunology, the First Affiliated Hospital of Guangzhou University of Chinese Medicine, Guangzhou, China*

Background: Systemic lupus erythematosus (SLE) is a clinically autoimmune disease characterized by production of autoantibodies and immune complex deposition. That induces multiple organ damages such as nephritis, pneumonitis and central nervous system (CNS) lupus et al. Moreover, SLE which mainly occurs in reproductive woman could threaten ovarian function. In recent years, ovarian reserve dysfunction in SLE are attracting increasing attentions. Especially cyclophosphamide (CYC) therapy was already well known as a higher risk to result in premature ovarian failure (POF) 1,2. However, few research has been performed in association between SLE itself and ovarian reserve. POF which is a critical cause of secondary amenorrhea and infertility still has not been treated effectively until now. Accordingly, an early precaution is important to make an informed decision about impaired ovarian reserve in SLE.

Objectives: To study the association between systemic lupus erythematosus (SLE) itself and strongly reduced Anti-Müllerian Hormone (AMH) values.

Methods: SLE women during reproductive ages 18–40 years were recruited compared with age-matched healthy controls (HC). AMH Levels and its relationship to clinical parameters and disease activity were investigated.

Results: Totally 91 SLE patients were enrolled (means ± SD age 28.38±5.80 years; SLE duration 47.15±44.70 months; SLE-2k scores 6.48±7.02). There were 73 subjects without cyclophosphamide therapy (SLE-CYCfree), 18 subjects previously exposed to CYC (SLE-CYC) and 79 HC. AMH values in SLE-CYC cases decreased significantly than HC and SLE-CYCfree (1.38±1.93 versus 4.10±3.40, *P*=0.002; 1.38±1.93 versus 3.62±3.61, *P*=0.013). No different was found between SLE-CYCfree and HC groups (*P*=0.377). Strong reduced AMH values (<0.5 μg/L) were identified in 12 of 73 (16.4%) SLE-CYCfree patients and 1 of 79 (1.3%) HC (*P*=0.001, OR=15.344). Furthermore, 10 (31.2%) SLE-CYCfree women aged ≥30 years had low AMH levels compared with 2 (4.9%) patients less than 30 years (*P*=0.004, OR=8.86). 29.6% (8/27) SLE populations over 3 year-duration of illness and 8.7% (4/46) in cases with less than 3 years were observed (*P*=0.046, OR=4.42). No difference reached statistical significance in SLEDAI-2K, Complement C3 and C4, IgG and IgM between SLE-CYCfree and SLE-CYC groups.

Conclusions: SLE was confirmed to be closely associated with low AMH levels. SLE could play a critical role in development of abnormal ovarian reserve. And moreover, over 3-year disease duration and ages over 30 years in reproductive-aged SLE women might enhance the risk of impaired ovarian reserve.

AB0503 THE OUTCOME OF SYSTEMIC LUPUS ERYTHEMATOUS IN KYRGYZ PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOUS UNDER LONG-TERM OBSERVATION

G. Koilubaeva, E. Karimova, M. Dzhetybaeva, K. Dzhailobaeva, A. Dzhumakadyrova. *Rheumatology, National Center of Cardiology and Internal Medicine Named After Academician M. Mirrahimov, Bishkek, Kyrgyztan*

Background: Systemic lupus erythematosus (SLE) is a devastating disease affecting different organs, ultimately leading to organ failure and death. To date, there are no data regarding the real-life picture of SLE in Kyrgyzstan.

Objectives: Analysis of SLE outcome in Kyrgyz patients under long-term observation.

Methods: The study involved 50 patients under prospective study treated in the NCCIM from January 2012 to August 2016 with SLE at the age of 27 years (median - 27 [23; 36])., with disease duration about 1 year (median - 1 [0.3, 3.0]), including 45 women and 5 men. The outcome of SLE was estimated as the number of exacerbations based on the SFI index (moderate or severe), irreversible organ damage by SDI, death, remission (complete or drug related). Remission was defined as complete if for the patients, who were not receiving any treatment, no clinical and immunological SLE activity was recorded. Drug remission was registered when clinical and immunological disease activity was absent in patients receiving supporting doses of prednisolone (from 5 mg to 10 mg) and receiving the following cytostatic drugs: 200 - 400 mg per day of PLQ or 100 - 150 mg per day of AZA or 7.5 mg of MTX per week.

Results: During the 3-year-long dynamic monitoring, in 50 patients observed 2 years after the initial examination 62 cases of exacerbation of SLE were registered (median, 2.0 [1.5, 2.5]). Out of these there were 36 severe (58%) and 26 moderate outbreaks (42%). Severe exacerbations were mainly related to kidneys - in 42 patients (84%), 7 out of which experienced simultaneous exacerbation of articular syndrome, 5 lupus dermatitis, 2 patients had CNS damage in the form of visual and audial hallucinatory syndrome with encephalopathy and bilateral pyramidal insufficiency (1) and encephalopathy with anxiety disorders (1). Moderate exacerbations were mainly caused by the lesions of skin and joints (20), myositis (1), in one case there was a necrotizing vasculitis of the lower extremities. The main causes of SLE breakouts were: for 33 patients (66%) - low compliance (when the patients themselves stop taking GC and cytostatics), for the remaining 17 patients (34%) - exacerbation of the SLE process.

Towards the end of monitoring the development SDI was the result of accumulation of organ damage caused by the disease itself (61%) as a result of: ischemic stroke (3), reduced GFR less than 50 ml per minute (4) due to heavy lupus nephritis, paresis of the right motor oculi (1), changes in the retina (1), pulmonary fibrosis (1), and pulmonary arterial hypertension (1). Over the entire period of careful dynamic study of the 50 patients no fatalities were recorded. Remission was achieved in 10 patients (20%) out of 50. The majority of patients had drug remission (9), except for one patient with baseline nephritis, dermatitis, arthritis, which was in complete remission during three years.

Conclusions: During the three years of medical observations remission was achieved in 20% of patients, most of them with drug remission (90%). 62 cases of SLE exacerbation were registered, with a predominance of severe outbreaks (58%), mainly caused by low compliance (53.2%). Development SDI was mainly due to the accumulation of organ damage caused by the disease itself (61%).

AB0504 PREGNANCY OUTCOME AND ITS RELEVANT FACTORS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND RHEUMATOID ARTHRITIS

H. Takei[1], Y. Kaneko[2], T. Takeuchi[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine; [2]Division of Rheumatology, Department of Internal Medicine, Department of Internal Medicine, Keio University, Tokyo, Japan*

Background: Pregnancy outcome is one of the major concerns to manage systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) since they often affect women in reproductive ages. However, the predictive factors of poor pregnancy outcome and disease flare during pregnancy have not fully investigated.

Objectives: To elucidate the factors affecting the pregnancy outcome in patients with systemic erythematosus (SLE) and rheumatoid arthritis (RA).

Methods: Patients with SLE and RA in our university between 2012 and 2016 who experienced pregnancy were retrospectively reviewed. Medical information was collected from their chart.

Results: Thirty six pregnancies in 26 SLE patients and 26 pregnancies in 21 RA patients were identified. Among SLE pregnancies, the mean age, disease duration and prednisolone dose were 32.7±4.6, 8.9±7.7 years and 5.6±4.1 mg/day, respectively. The disease activity was well controlled (the mean SLEDAI, 2.4±2.1). Live birth pregnancies were 31 (86.1%) and fetal loss occurred in 5 pregnancies (3 spontaneous abortions, 1 ectopic gestation and 1 hydatidiform mole). The mean dose of prednisolone was significantly lower in the pregnancies with live birth than those with fetal loss (4.9±3.4 vs 11.3±3.3mg/day, p=0.02), while proteinuria, SLEDAI, history of lupus nephritis, positivity of antiphospholipid antibodies and anti-SSA/Ro antibodies were not significantly different between the two groups. Maternal lupus flare occurred in 6 (16.7%) during pregnancy or after the delivery and was significantly associated with proteinuria at the time of conception (p=0.02). Low body birth occurred in 9 (29.0%) and was also significantly associated with proteinuria at the time of conception (p=0.002). Among RA patients, the mean age and disease duration were 33.5±5.6 and 9.9±7.4 years. The mean DAS28-ESR, CDAI and HAQ were 2.18±0.88, 3.07±4.10 and 0.30±0.50, respectively and 14 achieved DAS28-ESR remission (<2.6). Seven (26.9%) discontinued biological agents before conception while 8 (34.6%) continued to use biological agents. Although 5 (19.2%) experienced the disease flare during pregnancy, all 26 pregnancies were live birth. The patients who discontinued biological agents more frequently experienced the disease flare than those who continued, during pregnancy or postpartum within 1 year after delivery (85.7% vs 25%, p=0.04).

Conclusions: High live birth rates were observed in both SLE and RA pregnancies on the condition of well-controlled disease activity. In SLE pregnancies, less prednisolone dose at the time of conception may be associated with live birth. SLE pregnancies with proteinuria and RA pregnancies with discontinuation of biological agents are associated with disease flare and should be cautiously monitored.

AB0505 DOES VITAMIN D DEFICIENCY CONTRIBUTE TO COGNITIVE DYSFUNCTION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS?

H.A. Hussein[1], N.A. Fouad[2], L. Daker[3], A. Elamir[4], S.R. Mohamad[4]. *[1]Internal Medicine, Fayoum University, Cairo; [2]Rheumatology; [3]Neurology; [4]Medical Biochemistry, Fayoum University, Fayoum, Egypt*

Background: Neurocognitive impairment is one of the most common SLE manifestations. However, its pathophysiology remains poorly understood [1]. Vitamin D deficiency is a potential risk factor for cognitive impairment [2,3].
Objectives: Our aim is to evaluate the relationship between 25(OH)D3 level and cognitive performance in patients with SLE.
Methods: Thirty Egyptian patients diagnosed as systemic lupus erythematosus and their age and sex matched controls were subjected to a battery of neuropsychological evaluation by California Verbal Learning Test (CVLT-II), Controlled Oral Word Association Test (COWAT) and Trail making test and evaluation of depression by using Beck Depression Inventory (BDI). Serum level of 25(OH)D3 was measured in cases and controls.
Results: Patients with SLE had a worse performance than controls in verbal memory total recall, executive function and phonemic verbal fluency as there was a statistically significant difference in CVLT-II total recall, Trail making test and phonemic-COWAT respectively. There was no significant difference between the patients and controls in Beck Depression Inventory (BDI). There was a significant positive correlation between the vitamin D level and executive function assessed by trail making test (r =0.399, p=0.03).

Table 1. Comparison of psychometric tests between the patients and controls

Psychometric tests	Patients (n=30)	Controls (n=20)	p value
CVLT- II total recall	39.65±7.43	53.05±11.89	**<0.0001***
CVLT-II –II short term free recall	8.823±2.87	9.94±3.17	0.2
CVLT-II –II short term cued recall	2.04±1.58	2.41±2.52	0.6
CVLT-II –II long term free recall	9.96±3.36	10.52±2.76	0.5
CVLT-II –II long term cued recall	1.47±1.16	2.23±2.79	0.3
Trail Making Test	178.04±86.76	80.53±28.24	**<0.0001***
COWAT- phonemic	17.96±7.63	30.82±7.23	**<0.0001***
COWAT- semantic	11.47±3.16	14.17±4.84	0.05

Table 2. Correlations between vitamin D level and measures of cognitive among cases

	Vitamin D level	
	r	P-value
cvlt-total recall	0.040	0.843
cvlt-short term free recall	0.000	0.999
Cvlt short cued recall	0.219	0.273
Cvlt free long term recall	0.281	0.155
cvlt cued delayed	-0.079	0.695
Trail making test	0.399	0.039*
COWAT semantic	0.024	0.906
COWAT phenomic	-0.198	0.333

Conclusions: Vitamin D deficiency in patients with SLE could have a significant impact on their cognitive performance.

AB0506 PREGNANCY OUTCOMES IN WOMEN WITH RHEUMATIC DISEASES: A SINGLE CENTER-STUDY

I. Añón Oñate, I. Notario Ferreira, P. Morales Garrido, M.Á. Ferrer González, C. Caro Hernández, L. Pérez Albaladejo, M.J. Soto Pino, A. González Utrilla, E. Raya Álvarez, R. Cáliz Cáliz. *Rheumatology, Complejo Hospitalario Universitario de Granada, Granada, Spain*

Background: Systemic Lupus Erythematosus (SLE), Antiphospholipid Syndrome (APS) and Thrombophilia are associated with considerable pregnancy-related morbidity. Multidisciplinary teams allows the application of an experienced protocol to monitor and treat them during pregnancy in order to reduce adverse pregnancy outcomes and this way improve the prognosis of the pregnancy.
Objectives: To investigate pregnancy outcomes in women with rheumatic diseases and thrombophilia from a Spanish cohort.
Methods: A population of 93 patients diagnosed with SLE, APS and Thrombophilia atended in a specialized multidisciplinary unit of Rheumatic Diseases and pregnancy from the Complejo Hospitalario Universitario de Granada, Spain from January 2012 to December 2016. The following variables were collected: age, presence of antiphospholipid antibodies and anti Ro, thrombotic episodes and prior abortions, treatment during pregnancy, obstetric outcomes births/abortion and pregnancy length. The statistical analysis was done using the McNemar Test.
Results: 93 pregnant women were included in the study. 26 were diagnosed with SLE, 32 with APS and 35 with Thrombophilia (mostly, Heterozygotes for MTHFR gene). 47.3% were younger than 35 years and 52.7% were elder than 35 years. 66.7% had one or more prior abortions, meaning a total record of 159 abortions and an average of 1.71±1.76 abortions per patient. The treatment received by the patients is specified in table 1. 9 patients (3 APS and 6 thrombophilia) received a treatment with intravenous gammaglobulin with doses of 400 mg/kg, apart from Low-Molecular-Weight Heparin (LMWH) and Acetylsalicylic Acid (ASA), two days in a row at the beginning and then every three weeks during the whole pregnancy. 90 (96.8%) pregnancies were developed. 6 of them were preterm pregnancies and 84 were term pregnancies. Only 3 abortions (3.2%) occurred in the patients monitored in our unit. The reduction in the number of abortions was statistically significant ($p<0.001$). Regarding those 3 registered abortions, 2 were patients diagnosed with SLE, with no records of previous abortions and they occurred during the second trimester of pregnancy. 1 was diagnosed with APS and she had records of 2 previous abortions and occurred during the first trimester of pregnancy. Those patients who received treatment with gammaglobulin iv showed an mean of 4.88±1.85 previous abortions per patient and all had a term delivery (100%).

Table 1. The treatment received by the patients

	SLE (n=26)*	APS (n=32)*	Thrombophilia (n=35)
Patients treated with LMWH, n*	2	2	23
Patients treated with ASA, n*	9	1	3
Patients treated with LMWH + ASA, n*	5	29	8
Patients without prophylactic treatment, n	10	0	1

*Systemic Lupus Erythematosus (SLE), Antiphospholipid Syndrome (APS), Low-Molecular-Weight Heparin (LMWH), Acetylsalicylic Acid (ASA).

Conclusions: Our results demonstrate a decrease in the number of abortions and a larger number of term pregnancies since the inclusion of patients with high risk pregnancies in our unit. Prophylactic treatment is effective for the prevention of abortions, reaching higher rate live birth pregnancies. The multidisciplinary evaluation is essential to prevent complications in women diagnosed with rheumatic diseases with high obstetric risk.

AB0507 COBALAMIN (VITAMIN B12) STATUS IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME (APS), ITS ASSOCIATION WITH ATHEROSCLEROTIC VASCULAR LESIONS

I. Segeda[1], S. Shevchuk[1], I. Kuvikova[1], O. Shevchuk[2], I. Segeda[3], S. Shevchuk[3], I. Kuvikova[3], O. Shevchuk[3]. *[1]Rheumatology, Institute of Invalid Rehabilitation; [2]Rheumatology, Vinnitsya National Medical University, Vinnitsya, Ukraine; [3]Affiliation not provided*

Background: Cobalamin (vitamin B12) insufficienty is associated with the development of many diseases. It is known that the growth of clinical and subclinical manifestations of atherosclerotic vascular lesions are often associated with low cobalamin level. Cobalamin status is unknown in patients with antiphospholipid syndrome (APS). There are no data about the role of folic acid in the development of atherosclerotic vascular lesions in patients with APS
Objectives: To evaluate vitamin B12 status in patients with APS and to explore its relationship with atherosclerotic vascular lesion.
Methods: We observed 82 patients with APS and 37 healthy individuals. Content of cobalamin (vitamin B12) in serum were determined by immunochemical detection (ECLIA). Cobalamin level above 200 pg/ml was considered as normal within 200–300 pg/mL - both extremely low, below 200 pg/ml - insufficienty. All patients were underwent detection of endothelial dysfunction - dilatation of brachial artery endothelium, investigation of "intima-media" thickness of common carotid artery (IMT) and the presence of atherosclerotic plaques (AP).
Results: In patients with APS we recorded a significant reduction of cobalamin in the serum (351±14,3 pg/mL (95% CI: 148–562 pg/mL) compared to control group (445±18,1 pg/mL (95% CI: 272–622 pg/mL). Indicators of cobalamin status in patients with secondary APS were significantly worse than patients with primary APS. Thus, in patients with secondary APS cobalamin content was on 26.7% lower (95% CI: 140–559 pg/ml) than in the control group. In patients with primary APS cobalamin content was on 13.0% lower (95% CI: 202–565 pg/ml) than in controls, but 18.7% higher than in patients with secondary APS. Cobalamin (vitamin B12) insufficienty is accompanied by significant thickening of the walls of the common carotid artery. Thus, in patients with cobalamin deficiency IMT was on 17% higher than that in patients with optimal levels of the vitamin. Cobalamin deficiency is also associated with endothelial dysfunction. Thus, in patients with vitamin deficiency dilatation of brachial artery was significantly, by 48.6% less than in people with normal vitamin B12 status. The share of people with the presence of atherosclerotic plaques, transient ischemic attack (TIA), stroke, myocardial infarction (MI) and angina in patients with cobalamin deficiency was also higher.
Conclusions: Thus, in patients with APS low cobalamin status is associated with subclinical manifestations of atherosclerotic vascular lesions.

AB0508 EFFECT OF ALCOHOL CONSUMPTION AND SMOKING ON DISEASE DAMAGE IN SYSTEMIC LUPUS ERYTHEMATOSUS: DATA FROM KOREAN LUPUS NETWORK (KORNET) REGISTRY

J.N. Kim, S.-K. Kim, J.-Y. Choe, C.U. Lee. *Division of Rheumatology, Department of Internal Medicine, Catholic University of Daegu School of Medicine, Daegu, Korea, Republic Of*

Objectives: We assessed correlations of smoking habits and alcohol consumption with disease activity or damage in patients with systemic lupus erythematosus (SLE).
Methods: A total of 505 patients with SLE were enrolled in the KORean lupus Network (KORNET) SLE registry from January 2014 to January 2016. Disease activity and organ damage were measured by the Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) and the Systemic Lupus International Collaborating Clinics/American College of Rheumatology (SLICC/ACR) damage index, respectively. Multivariate logistic regression analysis was used to analyze associations with cutaneous lesions.
Results: There are no differences in SLEDAI-2K and SLICC/ACR damage indexes according to either smoking status or alcohol consumption. More frequent cutaneous damage was observed in current alcohol drinkers compared to non-current alcohol drinkers (p=0.020). Cutaneous damage was significantly associated with alcohol consumption [Odds ratio (OR) 4.048, 95% confidence interval (CI) 1.251 – 12.102, p=0.020]. Both low (1–5 glasses/week) and high (≥6 glasses/week) amounts of alcohol consumption had a significant impact on cutaneous damage compared to the absence of current alcohol consumption (p=0.033 and p=0.027, respectively). Pairwise comparison of alcohol consumption and smoking status with cutaneous damage showed that only alcohol consumption was significantly associated with the presence of cutaneous damage, compared to non-current alcohol consumption and non-current smoking (OR 3.513, 95% CI 1.130 – 10.920, p=0.030).
Conclusions: Current alcohol consumption, but not smoking, might influence the development of cutaneous damage in patients with SLE.

AB0509 IDENTIFICATION OF NOVEL BIOMARKERS ASSOCIATED WITH DISEASE ACTIVITY OF PRIMARY SJÖGREN'S SYNDROME AND CLINICAL RESPONSE TO VAY736

J. Doucet[1], R. Kazma[1], M. Cabanski[1], E. Kamphausen[1], P. Maguire[1], A. Avrameas[1], M.-A. Valentin[1], Y. Li[2], A. Auger-Sarrazin[1], S. Kaiser[1], P. Follet[1], S. Oliver[3], A. Vitaliti[1]. *[1]Translational Medicine/Biomarker Development, Novartis Institutes for Biomedical Research; [2]Global Development NPH, Novartis AG; [3]Translational Medicine, Novartis Institutes for Biomedical Research, Basel, Switzerland*

Background: Overexpression of B cell activating factor (BAFF) contributes to the pathogenesis of primary Sjögren's syndrome (pSS) [1]. Treatment of pSS patients with VAY736, an anti-human BAFF receptor mAb, appears promising and was associated with a positive therapeutic effect [2]. Given the complexity and heterogeneity of pSS, there is a need to further identify molecular mechanisms involved in pSS and in response to new therapeutics.
Objectives: To address this question, we assessed a panel of biomarkers in 27 patients from a clinical trial and tested their associations with pSS activity and clinical response to VAY736.
Methods: This study comprised 27 pSS patients treated with a single intravenous dose of VAY736 at 10 mg/kg (n=12), 3 mg/kg (n=6), or placebo (n=9). The disease activity scores included EULAR Sjogren's Syndrome Disease Activity Index (ESSDAI) and Patient Reported Index (ESSPRI), patient's and physician's reported visual analog scales (VAS), Short-Form 36 and Multidimensional Fatigue Inventory (MFI). BAFF and a panel of chemokines in serum and saliva were assessed using immunoassays. Circulating B cells and B cell subsets were measured by flow cytometry. High frequency ultrasound (US) of the parotid and sub-mandibular glands measured gland thickness and quality using a 4 point scoring (de Vita) [3]. Shear wave elastography of the parotid glands was also measured. All biomarkers were measured at baseline (BL) and post-treatment w6, w12, w24. The effect of VAY736 on biomarker levels was assessed by descriptive statistics. Correlations between biomarkers and disease activity scores were calculated at BL and w6, w12, and w24 using levels and relative changes from BL.
Results: In addition to B cell depletion, serum BAFF increase, and improvements in US and elastography measures [2], a subset of serum chemokine tended to be reduced nine weeks after VAY736 treatment. Pooling all 27 patients, salivary BAFF levels correlated with parotid De Vita scores at BL (left: r=0.75, right: r=0.72, $p<10^{-4}$ for both) and w6 (left: r=0.72,; right: r=0.78, $p<10^{-4}$ for both) but not at later time points. Pooling the 18 VAY736 treated patients, increase in salivary BAFF correlated with decrease in MFI at w6 (r=-0.83, $p=3\times10^{-4}$) and high levels of one of the serum chemokines at BL correlated with decrease in ESSPRI at w24 (r=-0.76, $p=3\times10^{-4}$). In the same patients, the B cell count at BL correlated with changes in several clinical outcomes at w12: ESSPRI (r=-0.65, p=0.01), Physician's VAS (r=-0.6, p=0.01), shear wave (r=-0.63, p=0.02), and parotid thickness (r=-0.6, p=0.03).
Conclusions: We identified a set of markers correlated with clinical outcomes in pSS after treatment with VAY736, which have the potential to provide additional insight in pSS and treatment-modifying effects. Further large-scale studies are necessary to confirm the value of these markers.

AB0510 NEUROPSYCHIATRIC MANIFESTATIONS AND DISEASE ACTIVITY IN POLISH COHORT OF SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

K. Pawlak-Bus, M. Spalek, P. Leszczynski. *Department of Rheumatology and Rehabilitation, University of Medical Sciences, Poznan, Poland*

Background: Neuropsychiatric systemic lupus erythematosus (NPSLE) is defined as wide range of neurological and psychiatric symptoms due to inflammation and ischemic processes. It is difficult to recognize primary NPSLE because of multiple central and peripheral symptoms.
Objectives: The aim of the study was to identified and classified the group of NPSLE patients with evaluation of disease activity.
Methods: We observed clinical neuropsychiatric (NP) manifestations in the cohort of 128 Polish patients with SLE. All patients with suspicion of NP symptoms had neuropsychological and imaging examinations. Symptoms of NPSLE were observed in 38 (30%) patients (34 female and 4 male) with average age 38±6 years (range 18–61 yrs), average disease duration 6,6±5,6 years (range 1,0 - 18,0 yrs). Patients were treated with oral and pulse glucocorticoids (GC) and 89% of them standard immunosuppressive drugs (CYC, MMF, AZA,MTX, CsA). As a background therapy 82% of these patients were on chloroquine or hydroksychloroquine (CQ/HCQ). All patients were assessed according to Systemic Lupus Erythematosus Disease Activity Index by SLEDAI (version 2000), Physical Global Assessment (PGA) and damage index (SDI).
Results: Central and peripheral NPSLE symptoms were recognized and categorized (Tab 1). All NPSLE patients had symptoms from central nervous system, but only 16% (n=6) of them had peripheral lupus manifestations. Mean SLEDAI score at NP event was very high 29±9,6, but mean SLEDAI score without NP symptoms was 15±8,3 and was connected with musculoskeletal, mucocutaneous, renal and hematological domains respectively n=29, 76%; n=23, 60%; n=11, 29%; n=8, 21%. Low disease activity was estimated at 3% of patients examined.Most of lupus patients (n=37, 97%) had moderate or high disease activity regardless of NP symptoms. In our study group lupus patients during NPSLE symptoms were immunologically active with increased anti-dsDNA antibodies (n=30, 78%) and/or lower complements C3 and/or C4 levels (n=21, 55%).
Conclusions: In Polish lupus cohort we observed more frequently lupus-related primary neuropsychiatric symptoms from central nervous system, especially cognitive dysfunctions, mood disorders, cerebrovascular events. Clinical activity of NPSLE patients was rather high and definitely most of patients were immunologically active despite aggressive immunosuppressive treatment and with standard background therapy.

AB0511 VITAMIN D: POTENTIAL ROLE IN ANTIPHOSPHOLIPID SYNDROME

L. Riancho-Zarrabeitia[1], M. Cubería[2], S. García-Canale[2], G. Daroca[2], M. García-Unzueta[3], J.L. Hernández[4], M. López-Hoyos[5], P. Muñoz[2], M. Agudo[1], V. Martínez-Taboada[1]. *[1]Rheumatology; [2]Hospital Universitario Marqués de Valdecilla, Santander, Spain; [3]Biochemistry; [4]Internal Medicine; [5]Immunology, Hospital Universitario Marqués de Valdecilla, Santander, Spain*

Background: Vitamin D, due to its immunoregulatory properties, has been implicated in the pathogenesis of autoimmune diseases, such as antiphospholipid syndrome (APS).
Objectives: A) To determine vitamin D levels in patients with primary APS and to compare them with patients with positive antiphospholipid antibodies (aPL), not meeting clinical criteria for APS, and with healthy controls. B) To analyze the association of the vitamin D levels with both the clinical manifestations and the immunological profile of patients with primary APS.
Methods: We conducted a retrospective study including patients attended at the rheumatology clinic from a tertiary facility in Northern Spain. We included 74

patients with primary APS, 54 patients with positive aPL serology not meeting clinical criteria for APS and 326 healthy controls adjusted by the month of vitamin D analysis. We considered 30 ng/ml and 10 ng/ml as the thresholds for vitamin D insufficiency and deficiency, respectively.
Results: Median levels of vitamin D were similar in the three groups: 21 (range 5–69) in primary APS, 25 (4–50) in the aPL-positive group, and 21 (4–105) in controls. Overall, 53.9% of measurements were performed during the sunny season (April to September). Ten percent of patients with primary APS were males, versus 16% in the aPL serology group and 26% among healthy controls (p=0.007). Mean age was 46±15 in primary APS, 49±17 in the aPL-positive group and 53±10 in the control group (p<0.001). Regarding vitamin D insufficiency, 82% of APS patients had levels of vitamin D (<30 ng/ml) versus 70% and 72% of patients with aPL serology and controls, respectively (p=0.168). When analyzing the prevalence of vitamin D deficiency (<10 ng/ml), we found significant differences across the groups: 16.2% in patients with primary APS, 11.1% in patients with positive serology and only 4.9% in healthy controls (p=0.002). There was no significant association between insufficient levels of vitamin D and the presence of thrombotic or obstetric events. Nevertheless, we found a trend for the presence of more thrombotic events in patients with vitamin D deficiency (p=0.097). Regarding the immunological profile, we found no association between vitamin D and either the number of positive antibodies or their serological evolution. However, we found an association between insufficient levels of vitamin D and the presence of lupus anticoagulant (54.7% vs 18.2%, p=0.047)
Conclusions: More than 80% of patients with primary APS have insufficient levels of vitamin D and 16% of them have very low levels of vitamin D.
Primary APS patients show a higher frequency of vitamin D deficiency than healthy controls.
Patients with vitamin D insufficiency have more commonly positivity for lupus anticoagulant.

AB0512 EPIDEMIOLOGICAL, CLINICAL AND IMMUNOLOGICAL CHARACTERISTICS OF ANTIPHOSPHOLIPID SYNDROME: STUDY OF 170 PATIENTS

L. Riancho-Zarrabeitia, S. García-Canale, M. Cubería, G. Daroca, M. López-Hoyos, P. Muñoz, M. Agudo, V. Martínez-Taboada. *Hospital Universitario Marqués de Valdecilla, Santander, Spain*

Background: Antiphospholipid syndrome (APS) is an autoimmune disease defined by the presence of antiphospholipid antibodies (aPL) and thrombosis and/or pregnancy morbidity. Although thrombotic and obstetric APS are considered the same disorder, there are pathogenetic and clinical differences between them.
Objectives: To describe the epidemiological, clinical and immunological characteristics of a cohort of APS patients from a defined population and to study the differences between thrombotic, obstetric and mixed APS.
Methods: Retrospective study including patients attending the rheumatology and the obstetric clinics of a tertiary facility in Northern Spain. All patients met APS classification criteria.
Results: We included 84 patients with thrombotic APS, 76 with obstetric APS and 10 with mixed APS. Main demographical characteristics are showed in table. There were differences in the age of discovery a positive serology (46±15 yr in thrombotic APS, 36±8 yr in obstetric, and 36±14 in mixed APS). Moreover, the prevalence of systemic lupus erythematosus (SLE) was higher in patients with thrombotic and mixed APS (26% and 30% vs 5% in obstetric APS, p=0.001). Anticardiolipin antibodies were, overall, the most frequently positive. Lupus anticoagulant was significantly more common in patients with thrombotic and mixed APS (70% and 71% vs 30% in obstetric APS, p=0.002). We found no differences in the load of antibodies between the three groups. Regarding traditional cardiovascular risk factors (CVRF), tobacco use was the most common, followed by hypertension and dyslipidemia. The last two factors were more frequent in patients with thrombotic and mixed APS than in those with obstetric APS (p<0.001). As expected, treatment with heparin was more frequent in obstetric and mixed APS, while oral anticoagulants were more frequently used in thrombotic APS. Antimalarial drugs were less frequently used in obstetric APS (17% vs 37% and 30%, p=0.020), probably due to a lower prevalence of lupus in this group.

Corticoids	5 (3)	5 (6)	0	0	0.072
Antimalarials	47 (28)	31 (37)	13 (17)	3 (30)	0.020
Immunosuppressants	5 (3)	4 (5)	1 (1)	0	0.371

Conclusions: In our cohort, patients with thrombotic or mixed APS have a higher frequency of SLE than patients with obstetric APS. Positivity for lupus anticoagulant is more common in patients with thrombotic or mixed APS. Regarding traditional CVRF, hypertension and dislypidemia are more common in patients with thrombotic or mixed APS.

AB0513 FATIGUE IN CHINESE PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME: A CROSS SECTIONAL STUDY

L. Li[1], Y. Cui[1], S. Chen[1], Q. Zhao[1], L. Li[2], Z. Gu[1]. *[1]Department of Rheumatology, Affiliated Hospital of Nantong University; [2]School of Nursing of Nantong University, Nantong, China*

Background: Primary Sjögren's syndrome (pSS) is the second most common systemic autoimmune disease, with a female-male ratio of 9:1, and characterized by sicca symptoms of the eyes and mouth, including joint pains and multi-system involvement. pSS affects patients' health-related quality of life (QoL), mental status and relationships with family. In pSS patients, symptoms such as fatigue, depression, arthralgia, fibromyalgia and general loss of well-being are commonly reported. Among them, fatigue is the most common problem that includes physical and mental fatigue, it can be as disabling as pain, which is difficult to manage and has a notable impact on QoL. Fatigue is a tiredness which may be mental, physical, or both, and that results in an inability to function at normal performance levels. However, the underlying pathophysiological mechanisms of fatigue remain unclear. A number of studies have reported the association of fatigue with Primary Sjögren's syndrome (pSS), whereas, because of the small sample size of pSS patients, we still lack large sample studies to find the relationship between pSS and fatigue.
Objectives: To investigate the relationship of fatigue severity to other clinical features in primary Sjögren's syndrome (pSS) and to identify factors contributing to the physical and mental aspects of fatigue in Chinese patients.
Methods: Sixty-seven consecutive patients with PSS according to the American-European Consensus group (AEGG) criteria were included. Demographic, clinical and biological characteristics for all patients were collected. The Fatigue Severity Scale (FSS), Profile of Fatigue (ProF), Visual analogue scale, Hospital Anxiety and Depression Scale (HADS), OHIP-14 Scale, MDADI Scale and PSQI Scale were adopted to assess fatigue, depression, anxiety, xerostomia, xerophthalmia and sleep disturbances. Associations with fatigue were compared using multivariate regression.
Results: 94% of our patients were women. The mean age of patients was 51.13±13.23 years, and the mean disease duration was 4.12±4.49 years. The mean oral dryness was 51±17.82, and the mean ocular dryness was 33.56±26.3. Abnormal fatigue, defined as an FSS score >or=4, was present in 64% of the patients. Dry symptoms, low educational level, Pain and depression had a negative impact on fatigue scores. The regression models explained that Pain and depression were the strongest predictors of fatigue according to the FSS.
Conclusions: Fatigue is a tiredness which may be mental, physical, or both, and that results in an inability to function at normal performance levels. However, the underlying pathophysiological mechanisms of fatigue remain unclear. From our study, we found that psychosocial variables are determinants of fatigue, and fatigue is associated with depression, but depression is not the primary cause of fatigue in primary SS. Therefore, the investigation of the pathophysiologic correlates of physical and mental aspects of fatigue is needed to guide the development of more effective interventions.

AB0514 THE RELATIONSHIP BETWEEN SERUM LEVEL OF C-TERMINAL TELOPEPTIDE OF TYPE I COLLAGEN WITH COURSE OF SYSTEMIC LUPUS ERYTHEMATOSUS AND STRUCTURAL AND FUNCTIONAL STATE OF BONE TISSUE

S. Shevchuk, L. Denyschych, L. Marynych. *National Pirogov Memorial Medical University, Vinnytsya, Ukraine, Vinnytsya, Ukraine*

Background: It is well known, that the incidence of osteoporosis in patients with systemic lupus erythematosus (SLE) is higher compared to the population level. Its severity in patients with SLE is associated with a number of factors: female gender, disease activity, damage index, glucocorticoid therapy etc. One of metabolic factors indicating the reducing bone mineral density (BMD) is the level

of C-terminal telopeptide of type I collagen (CTX). Its place in the formation of osteoporosis in SLE patients is poorly understood, as well as its relationship with the course of the disease.
Objectives: The aim of study was to determine serum level of CTX in the SLE patients and its relationship with structural and functional state of bone tissue, course of the disease.
Methods: The study involved 58 SLE women (study group) and 29 healthy individuals (control group) representative by age and gender. The mean age of patients was 45,11±1,03 years. For every patient data were recorded on age, body mass index (BMI), chronic SLE damage (SLICC/ACR DI) and disease activity score (SLEDAI), cumulative glucocorticoid dose, serum concentrations of interleukin-6 (IL-6) and C-reactive protein (CRP), bone resorption marker (CTX). Serum concentration of CTX was determined using ELISA test system "Nordic Bioscience Diagnostics A/S". Changes in BMD of the lumbar spine and proximal hip were determined by Dual-energy X-ray absorptiometry.
Results: It was established, that in patients with SLE serum level of C-terminal telopeptide of type I collagen was 1,15±0,03 ng/ml, while in the control group – 0,83±0,03 ng/ml, or was higher more than 19,0%. Violation of bone remodeling in patients with SLE was associated with reduced BMD, increased incidence of osteopenia and osteoporosis. Thus, the mean concentration of CTX in patients with osteoporosis was 1,63±0,04 ng/ml, while in patients with normal bone – 1,0±0,03 ng/ml. In SLE patients with osteopenia the level of C-terminal telopeptide of type I collagen was 1,23±0,04 ng/ml (higher more than 23% compared with the control group). Increased CTX practically had no correlation with age, duration of the disease, smoking and BMI. At the same time the serum CTX was associated with chronic SLE damage index (r =0,51), SLEDAI disease activity (r =0,41), concentration of IL-6 (r =0,45) and CRP (r =0,44)
Conclusions: Alterations of bone metabolism were found in 19% female SLE patients in the form of increasing serum CTX and closely associated with the severity and activity of the disease, high levels of CRP and IL-6 and did not depend on the age, disease duration, smoking and body mass index.

AB0515 SKIN MANIFESTATIONS AS INDEPENDENT PREDICTORS AND THE INITIAL RISK FAKTORS FOR SYSTEMIC ANTIPHOSPHOLIPID EVENTS

L. Stojanovich, A. Djokovic, N. Stanisavljevic, M. Zdravkovic. *Internal Medicine Department, University Hospital Center Bezanijska Kosa, Belgrade, Serbia*

Background: Antiphospholipid syndrome (APS) patients express skin manifestations with the presence of various levels of antiphospholipid antibodies (aPL).Several studies have shown the frequency of dermatological manifestations with APS[1,2,3], including livedo reticularis, cutaneous ulcers, acrocyanosis, and other.
Objectives: Dermatological manifestations can be the initial clue in the diagnosis of this disease.
Methods: Our study includes a total of 508 APS patients; 360 were PAPS patients (283 female and 77 male, mean age 44.0±12.9 years),148 had APS associated with SLE/SAPS (133 female and 15 male,mean age 47.7±14.8 years).aPL analysis included:LA, aCL (IgG/IgM), β_2GPI (IgG/IgM).In all patients, we collected data considering frequently occured skin lesions.
Results: Our results showed prevalence of skin manifestations in SAPS group of patinenst regading to PAPS (Table 1). Patients with skin manifestations overall had higher prevalence of thrombosis (Table 2).

Table 1. Prevalence of skin manifestations analyzed in PAPS and SAPS group

	PAPS (N=360)	SAPS (N=148)	p
Livedo	46 (12.8%)	86 (58.1%)	**0.0001**
Skin ulcerations	31 (8.6%)	47 (31.8%)	**0.0001**
Pseudovasculitis lesions	34 (9.4%)	72 (48.6%)	**0.0001**
Superfitial cutaneous necrosis	9 (2.5%)	25 (16.9%)	**0.0001**
Digital gangrene	3 (0.8%)	14 (9.5%)	**0.0001**
Skin manifestations overall	98 (27.2%)	113 (76.4%)	**0.0001**

Table 2. Skin manifestations and thrombosis

	PAPS (p values)	SAPS (p values)
Livedo	0.038	0.062
Skin ulcerations	0.024	**0.004**
Pseudovasculitis lesions	0.007	**0.019**
Superfitial cutaneous necrosis	0.005	0.380
Digital gangrene	1.000	**0.008**
Skin manifestations overall	0.0001	**0.076**

Conclusions: Dermatological manifestations can be very often the initial symptoms of severe manifestations of APS.Our study showed that patients with secondary APS had higher prevalence of skin lesions, and that some aPL types were risk factors for thrombotic manifestations in APS patients

AB0516 INCIDENCE OF CANCER IN A COHORT OF PATIENTS WITH PRIMARY SJÖGREN SYNDROME

M. Brom, S. Moyano, M. Scolnik, L.E. Pompermayer, I.J. Gandino, E.R. Soriano. *Rheumatology, Hospital Italiano de Buenos Aires, Ciudad Autónoma de Buenos Aires, Argentina*

Background: The most severe complication of Sjögren Syndrome is the development of lymphoproliferative processes. Several neoplasia have been associated with the disease, being non-Hodgkin lymphoma the most frequent one.
Objectives: Our objective was to evaluate incidence of cancer in a cohort of patients with primary Sjögren Syndrome.
Methods: A retrospective descriptive study was performed in a university hospital with its own health insurance and captive population. Using electronic medical records and laboratory database were review the entries performed between 01/01/2000 and 12/31/2015. We analyzed those patients with either diagnosis of Sjögren Syndrome, complain of dry mouth/eyes, or positive antibodies anti-Ro/SSA and anti-LA/SSB.
Among these patients, we included those fulfilling either ACR 2012 or EULAR 2002 Sjögren criteria, or those who were diagnosed as Primary Sjögren Syndrome by the treating rheumatologist even if they did not fulfill criteria.
We then proceeded to register and analyze demographic, clinical and histopathologic information available on their clinical records.
Results: One hundred fifty-seven patients with Primary Sjögren Syndrome were identified. Female accounted for 95.5% of the cohort; mean age at diagnosis was 49.4 years (SD 19). Median follow-up time was 7.7 years (IQR 8). The development rate and type of neoplasia was the following:

- Lymphomas: Three (Two MALT lymphomas of the parotid and one disseminated non-Hodgkin lymphoma). Density of Incidence 260/100,000 person/year (CI 95%: 50 – 750/100,000 person/year)
- Multiple Myeloma: One
- Skin (non-melanoma) neoplasia: Four
- Solid organ Neoplasia: Seven (Four breast cancer, one lung cancer, one uterus cancer, one tongue cancer). Density of Incidence 600/100,000 person/year (CI 95% 240 – 1240/100,000 person/year)

Univariate analysis showed association between lymphoma and cryoglobulinemia (p=0.01; OR=5,8), low C4 fraction of complement (p=0.01; OR=5,1), anemia (p=0.02; OR=1,96) and leucopenia (p=0.03; OR=1,67)
Conclusions: Development of cancer is a known complication of Primary Sjögren Syndrome. The association between lymphoma and cryoglobulinemia, low C4 fraction of complement, anemia and leucopenia enhances the importance of periodic screening for neoplasms among this subgroup of patients with Primary Sjögren Syndrome.

AB0517 PREDICTIVE FACTORS FOR INFECTION IN SYSTEMIC LUPUS ERYTHEMATOSUS

M. Kechida[1], N. Lorenzo[2], R. Klii[1], S. Hammami[1], I. Khochtali[1]. *[1]Internal Medicine and Endocrinology Department, Fattouma Bourguiba Hospital, Monastir, Tunisia; [2]Internal Medicine and cancerology Department, Saint-Cyr Hospital, Lyon, France*

Background: it's known that infection could complicate the course of systemic lupus erythematosus (SLE) because of the immune status or the long term steroids and immunosuppressors.
Objectives: This study was aiming at determining the prevalence of infectious complications during SLE and their predictive factors.
Methods: A retrospective bi-centric analyzes of 289 patients diagnosed as SLE between January 2004 and December 2016 according to the ARA criteria of 1997 was conducted. A descriptive analysis of infectious complications was first made, then a comparative study between patients with (group 1) and without (group 2) infectious complications was performed to detect predictive factors.
Results: Mean age was 84.6±13 years (14–72 years) with a sex ratio F/M=6.

Cardiac involvement and lupus nephritis (LN) were developed in 20% of patients. About 13.75% of patients had neurological manifestations, 26.5% articular complications, 16% vascular involvement and 10% of them developed infectious complications. Eight percent of these infections were diagnosed concomitantly with the diagnosis of SLE and 92% of them after the diagnosis of lupus with an average of 25 months. About 52.9% of the patients developed more than 2 episodes of infection. The spectrum of infectious complications was: pulmonary in 33.3%, urinary in 22.2% and cutaneous in 13.9%. Tuberculosis was the most frequent infection 12.5%. Lupus flare complicated the infection in 28.6% of patients with mean SLEDAI score at 10. Comparative study between group 1 and group 2 revealed that LN, corticosteroids and immunosuppressors were associated with a high risk of infection (p=0.002, p=0.017 and p=0.034 respectively). In multivariate analysis only LN was an independent predictive factor (OR=3.5, 95% CI=1.06-12.87, p=0.049).

Conclusions: Infections may complicate the course of SLE with flares presenting in 1/3 of cases. Half of the patients had more than 2 episodes of infection during their follow up. The presence of LN represents a predictive factor of such complication.

AB0518 NEW 2016 ACR/EULAR CLASSIFICATION CRITERIA FOR SJÖGREN SYNDROME: USEFULNESS AND APPLICABILITY IN CLINICAL PRACTICE

M. Retuerto Guerrero[1], L. Sierra Herranz[2], C. Moriano Morales[1], C. Iñiguez Ubiaga[1], M. Garijo Bufort[1], A. Crespo Golmar[1], C. Álvarez Castro[1], E. Díez Álvarez[1], A. López Robles[1], M. Martín Martínez[1], T. Perez Sandoval[1]. *[1]Rheumatology Department; [2]Pneumology Department, University Health Care Complex of León, Leon, Spain*

Background: The Sjögren syndrome (SS) is an autoimmune disease where the cellular and humoral mechanisms affect the exocrine glands. In 2016, new classification criteria validated by ACR and EULAR were established.

Objectives: To compare the new criteria with those used so far in our hospital, as well as to assess the need for changes in the current diagnostic strategy.

Methods: Retrospective observational study in which 65 patients diagnosed with SS at the Hospital of León were randomly included. We reviewed the diagnostic tests performed and the fulfilment of the different classification criteria developed since 1993. Other variables studied were: sex; age at the time of diagnosis and the months from the onset of symptoms; xerostomia and xerophthalmia; extraglandular involvement, ESSDAI; immunosuppression; Raynaud; lymphoma development; and analytical alterations.

Results: The mean age at the time of diagnosis was 54.9 years ±14 | 23–82 |, with an average of months from the onset of symptoms to the diagnosis of 10.2±9.5 | 0–36|. 90.8% were women. 87.7% presented xerostomia; and 91% showed xerophthalmia, being severe in 43.1%. 64.6% had extraglandular manifestations; being the most prevalent the joint manifestation (60%) and the cutaneous one (18.4%). Over the past year, 37% developed haematological alterations in the form of cytopenias, and 73% biological alterations. At the time of the study, 32.8% presented low activity, 38.5% moderate activity and 9.2% high activity, measured by ESSDAI; being higher in anti-Ro positive patients (p=0.011). There was no association between ESSDAI and other antibodies, Raynaud or severe ocular involvement. 10.8% required systemic immunosuppression (RTX 5, AZA 2) and 18.5% needed ocular immunosuppression (topical cyclosporine). Only one patient developed lymphoma.

A Schirmer's test (ST) was performed in 92.3% (positive in 89.2%), saving the Van Bijsterveld test for patients with severe ocular involvement. The Ocular Staining Score (OSS) was not performed in any patient.

The scintigraphy of the salivary glands was positive in 70.8% of the patients and was not performed in 21.5%. The parotid sialography was only performed in two patients and the study of the salivary flow was not stimulated in none of them.

Regarding the autoimmunity, 80% presented positive antiRo; 61.5% antiLa; 89% ANA; 61.5% RF; 43% quadruple positivity.

Labial gland biopsy was performed only in 18.4%, with a positive result in 75%.

All patients met the 1993 European Criteria; 86.2% met the European-American criteria of 2002; and only 10.8% met the SICCA-ACR Criteria. The new criteria validated by ACR and EULAR were verified in 80%. Four patients who fulfilled the European criteria did not meet the new criteria, coinciding with those patients with negative ST, but positive scintigraphy.

Conclusions: In our hospital, the method for electing the xerostomia study was the salivary scintigraphy; therefore, we cannot establish direct comparisons with the new criteria.

The incorporation of non-stimulated salivary flow in our diagnostic strategy is necessary.

We should consider conducting a lip biopsy more systematically for histological confirmation since there are no validated diagnostic criteria.

AB0519 LABORATORY ABNORMALITIES IN PATIENTS WITH PRIMARY SJOGREN'S SYNDROME

M. Fernandez Castro[1], J.L. Andreu[2], C. Sanchez-Piedra[3], V. Martínez Taboada[4], A. Olive[5], J. Rosas[6] on behalf of SJOGRENSER group, part of the Spanish Society of Rheumatology Systemic Autoimmune Diseases Study Group (EASSER). *[1]Rheumatology, Hospital Infanta Sofía; [2]Rheumatology, Hospital Puerta de Hierro Majadahonda; [3]Research unit, Spanish Society of Rheumatology; [4]Rheumatology, Hospital Marqués de Valdecilla, Madrid; [5]Rheumatology, Hospital Hospital Germans Trias i Pujol, Barcelona; [6]Rheumatology, Hospital Hospital Marina Baixa, Alicante, Spain*

Background: Primary Sjögren's syndrome (pSS) is a chronic systemic autoimmune disease often accompanied by analytical abnormalities. Altered levels in serum protein concentration, blood cell count and autoantibodies contribute to the broad spectrum of biological manifestations that characterize pSS.

Objectives: The objective of this study is to evaluate the presence of laboratory abnormalities in patients with pSS from the SjogrenSER registry.

Methods: We conducted a multicentre transversal study of a cohort of pSS patients fulfilling 2002 European/American criteria, from 33 Spanish rheumatology departments. Every patient was interviewed for data collection and signed an informed consent. Data were also collected by reviewing medical records. Local ethics committees approved the study. Variables were analysed by descriptive statistical methods, using means, medians and rates. Chi-square was used to establish the statistical associations. A $p<0.05$ was considered significant.

Results: Four hundred and thirty-seven patients were included. Ninety-five percent of them were women. The median age of the cohort was 58 years. AntiRo antibodies were present in 93.6% of patients and AntiLa antibodies in 67.3% of patients. All patients were ANA+. Rheumatoid factor (RF) was positive in 64.8% of patients. Low levels of C3 and C4 were observed in 14.87% and 14.19% of patients, respectively. Polyclonal hypergammaglobulinemia (HGG) was present in 53% of patients. Thirteen patients had cryoglobulins (2.97%). An increase in β2microglobulin was observed in 22.2% of patients. Fifty-six percent of the patients had hematological involvement: 29% of the patients had anemia, 38% had leukopenia (38% lymphopenia, 10.5% had neutropenia), and 9% had thrombocytopenia. The median ESR was 25 mm. Age at diagnosis and age at onset of symptoms were significantly lower in patients presenting RF+ vs RF- (48.71 vs 53.73, $p<0.001$ and 44.76 vs 49.53, p=0.001, respectively), decreased C3 vs normal C3 (45.66 vs 51.18, p=0.004 and 42.2 vs 46.99, p=0.018, respectively), decreased C4 vs normal C4 (47.02 vs. 50.89, P=0.042, for age at diagnosis) and HGG (47.59 vs 54, $p<0.001$, and 43.44 vs 50.16, $p<0.001$, respectively). ESR was significantly higher in patients with hematological involvement (35.94 vs 26.24, $p<0.001$), RF+ (36.39 vs 22.91, $p<0.001$), decreased C3 (37.8 vs 30.53, p=0.026) and C4 (38.71 vs. 30.42, p=0.04)), HGG (36.21 vs 26.03, $p<0.001$) and increased β2microglobulin (38.80 vs 29.71, p=0.009). ESSDAI (Eular Sjögren Syndrome Disease Activity Index) was significantly higher in patients with haematological involvement (5.58 vs 3.69, $p<0.001$), RF+ (5.40 vs 3.53, $p<0.001$) and HGG (5.31 vs 3.93, P=0.011). The median ESSDAI score was 2 (P25-P75, 0–4).

Conclusions: in SjogrenSER registry all patients were serologically positive. More than half of the patients presented abnormalities in serum proteins and 14% had hipocomplementemia. More than half of the patients had abnormalities, mostly leucopenia and lymphopenia. Patients with analytical alterations were younger at the time of diagnosis and had more often elevated ESR and higher ESSDAI score.

AB0520 THE ROLE OF LEPTIN IN SJOGREN'S DISEASE

M. Erdoğan[1], M.E. Tezcan[2], K. Başak[3]. *[1]Internal medicine division of Rheumatology, Cerrahpaşa Medical Faculty; [2]Internal medicine division of Rheumatology; [3]Pathology, Dr. Lürfi Kırdar Kartal Training and Research Hospital, Istanbul, Turkey*

Background: Sjogren's disease (SD) is a multisystemic disease mostly manifest with sicca symptoms. Lympocytic infiltration of the glandular and extra glanduler organs is the dominant pathologic feature of the disease. Multiple stimulators were accused in the pathogenesis of SD. Leptin, an endogenous peptide, involves in various metabolic processes as well as influence immune system (1). Increased serum leptin level is observed in patients with autoimmune diseases such as SD, systemic lupus erythematosus and rheumatoid arthritis when compared to healthy controls (2).

Objectives: Even if serum leptin level increases in the patient with SD, there is no data about its effect on exocrine glands. We aimed to compare density of leptin in the salivary gland of SD patients with control group. Furthermore we evaluted the relation between intensity of lympocytic infiltration and density of leptin in the salivary glands of SD patients

Methods: We applied leptin immunostain to minor salivary glands samples of 24 SD patientss,who were fullfilled American College of Rheumatology Sjögren's Disease Classification Criteria (ACR-SDCC) and 19 patients who undergo minor salivary gland biopsy due to clinically on suspicion of SD but not fullfilling the ACR-SDCC and had no lymphocytic focus on biopsy. Herein,leptin density in acinar and ductal structures of the salivary glands were evaluated in both groups.Moreover,

minor salivary gland samples of SD patients were also assessed for relationship between focus score, disease progression (evaluated with SSDAI) and leptin immunostaining.

Results: Demographic features of both group were similar. Furhermore, there were no difference in leptin staining features of both group.Additionally, we found that higher focus score (>2) was associated with more diffuse leptin staining and higher SSDAI scores related with diffuse acinar staining.

Figure 1. Total leptin Satining in Different Focus Score Groups

		Total Leptin Staining			
		≤2	3-4	≥5	Total
Focus Score	Focus 1	2	1	3	6
	Focus 2	0	9	3	12
	Focus Score >2	0	0	6	6
	Total	2	10	12	24

*p=0.02

Figure 2. Stromal Leptin Staining in Different Focus Groups

		Stromal staining				
		No Staining	Focal	Modest	Wide	Total
Focus Score	Focus 1	1	3	2	0	6
	Focus_2	0	9	1	2	12
	Focus >2	0	0	0	6	6
	Total	1	12	3	8	24

*p=0.001

Conclusions: Different leptin staining features in higher focus score and higher disease activity might indicate the role of leptin especially in more significant disease. Leptin may locally stimulate chemotaxis and activate infiltration of glands with inflammatory cells. We suggested further studies aimed to understand autocrine effect of leptin and evalute its role in SD pathogenesis

AB0521 ANTIPHOSPHOLIPID SYNDROME - ATHEROSCLEROSIS AND CLINICAL-IMUNOLOGICAL CORRELATIONS

N. Stoilov[1], V. Boyadzhieva[2], R. Rashkov[1]. *[1]Clinic of Rheumatology; [2]Clinic of Rheumatolog, UMBAL "Sv. Ivan Rilski", Sofia, Bulgaria*

Background: Antiphospholipid syndrome (APS) is an autoimmune, multisystem disease characterized by thrombocytopenia, venous and/or arterial thrombosis, pathological course of pregnancy in women (preeclampsia, eclampsia, miscarriage) and the presence of a heterogeneous group of antibodies - antiphospholipid antibodies. Recent studies show that in the pathogenesis of atherosclerotic process relevant inflammatory component of the immune response, as well as elements of autoimmunity (autoantibodies and autoantigens autoreactive lymphocytes). A number of autoimmune rheumatic diseases, including RA, SLE and API are characterized by accelerated atherosclerosis and therefore an increased risk of cardiovascular morbidity and mortality.

Objectives: The aim of the study was to investigate the incidence of cardiovascular events and atherosclerosis in patients with primary and secondary antiphospholipid syndrome, spyamo healthy subjects and patients with systemic lupus erythematosus without antiphospholipid antibodies.

Objectives of the study:

- To compare the damage to aa. Carotes in patients with APS compared to healthy subjects and patients with SLE without antifosfolipindi antibodies.
- To compare Are score in patients with APS compared to healthy individuals without antifosfolipindi antibodies.
- To compare atherosclerosis of aorta in patients with APS compared to healthy subjects and patients with SLE without antifosfolipindi antibodies.
- To compare cutaneous vascular lesions (Raynaud, Livedo reticularis, periungual vasculitis, son pulp gangrene, asphyxia, vasculitis lesions) on the limbs and body in patients with API spyamo healthy subjects and patients with SLE without antifosfolipindi antibodies.

Methods: For the purpose of this study examined 127 patients, 18 men (14%) and 109 women (86%), positive antiphospholipid antibodies. Patients were selected from the Department of Rheumatology, University Hospital "St. Ivan Rilski" – Sofia.

All the patients were tested for: ANA, aPL, standart laboratory tests.

Instrumental methods:

- calcium score of a. coronaria sinister, a. anterior descendens sinister, a. circumflexa sinister, a. coronaria dexter, Aorta, Valva aorte.
- Ultrasonographic examination of aa. Carotes to measure the Intima-media thickness.

Results: It is proved strong, statistically significant correlation between aCL antibodies and the presence of plaques in the left common carotid artery (p=0.041). Absent the dependence between the antibody titers and incidence of carotid plaques.

In the group with APS, 33,3% (14) establishes a positive calcium score of coronary arerii, 11.9% (5) plozhitelnite for aorta. Aortic valve Absent deposits. In the control group positive calcium score is when one person (5.88%).

Conclusions: We found that patients with antiphospholipid syndrome suffer from early developmentof atherosclerosis. In the process of atherogenesis involved inflammatory componentof immune response. Atherosclerosis can be viewed as an inflammatory autoimmune disease.

It is proved strong, statistically significant correlation between aCL antibodies and the presence of plaques in the left common carotid artery (p=0.041). Absent the dependence between the antibody titers and incidence of carotid plaques.

AB0522 CLINICAL FINDINGS AND THEIR RELATIONSHIP WITH THE PROFILE OF ANTIPHOSPHOLIPID ANTIBODIES IN DOMINICAN PATIENTS

R. Vasquez-Colon[1], P. Gottschalk[1], C. Tineo[1], P. Lopez[1], R. Tejada[2], E. Loyo[1]. *[1]Reumatologia, Hospital Regional Universitario Jose Maria Cabral y Baez; [2]Investigaciones Clinicas, Pontificia Universidad Catolica Madre y Maestra, Santiago, Dominican Republic*

Background: There is an increased risk of thrombotic events and obstetric morbidities in individuals with antiphospholipid antibodies (APAs) compared with the general population. The risk of complications is further increased in those patients who have a rheumatic diseases and antibody positivity.

Objectives: The purpose of this study is to determine the clinical findings and their relationship with the profile of antiphospholipid antibodies in patients with rheumatic disease, of the Division of Rheumatology of the Hospital Regional Universitario José Ma. Cabral y Baez, Dominican Republic.

Methods: Patients with 18 years of age and above, with a confirmed rheumatic disease was eligible for enrollment; those with positive titers for APAs, that met the inclusion and exclusion criteria, were included in our study. The institutional review board approved the protocol.

This is a transverse study, with retro-prospective data gathering from patients and their medical records. Demographic information at the time of APA measurement and medical information regarding the rheumatic disease and clinical course were collected from the patient's medical record, with a follow-up of 10 years.

Results: 40 patients were included in this study. The male to female ratio was 19:1; mean age was 36±10 years. A large number of patients (13 patients, 32.5%) were asymptomatic for antiphospholipid syndrome (APS) at the time of this study; eight patients (20%) were carriers without defining manifestations. Ten patients (25%) were categorized as vascular APS and five patients (12.5%) as obstetric APS; three patients (7.5%) had vascular and obstetric APS. One patient presented with catastrophic APS. In evaluating such specific profile of antiphospholipid antibodies, aCL was observed that corresponded to the antibody most frequently identified with IgG isotypes (52.5%) and IgM 47.5%. The lupus anticoagulant (LA) corresponded to the second most common (37.5%). The isotypes of the anti-B2GP-I were identified in less proportion. We report 89 pregnancies during the follow, with 29 abortions and 60 live births, of which 12 were premature and 11 born with intrauterine growth restrictions.

Conclusions: The most frequent clinical manifestations were livedo reticularis, vascular thrombosis in lower extremities, Raynaud's phenomenon, migraine, cerebrovascular disease, thrombocytopenia, leukopenia, and alteration of urine sediment.

AB0523 AN ANALYSIS OF THE FACTORS INFLUENCING THE BODY IMAGE DISTURBANCE WITH SYSTEMIC LUPUS ERYTHEMATOSUS LIVING IN CHINA

Q. Zhao, Y. Cui, L. Li, S. Chen, C. Zhou, Z. Gu. *Department of Rheumatology, Affiliated Hospital of Nantong University, Nantong, China*

Background: Systemic Lupus Erythematosus (SLE) is a chronic, autoimmune rheumatic disease that can affect multiple systems/organs in the body and is characterized by relapses and remission, usually affects women in the reproductive age group. SLE may cause inflammation activity and damage in any of the organs, often resulting in decreased physical, emotional and social abilities, depression, pain, fatigue, visible or invisible changes in appearance. Recent studies have indicated that body image disturbance (BID) can lead to a variety of cognitive, emotional and behavioral changes. BID will cause the individual having a negative perception of the body, negative emotional experience and the corresponding behavior disorders.
Objectives: To explore the relationship between social and economic status, disease activity, mental state, self-esteem, quality of life and the essential BID with Systemic Lupus Erythematosus Living in China.
Methods: The investigation is from in October 2015 to December 2016 at the Affiliated Hospital of Nantong University. There are 109 cases of hospitalized patients, including 8 cases of male, female 101 cases, mean age is 35.3±12.2. Scale including body image disorder scale (BID), respectively. Body image was assessed using the Body Image Disturbance Questionnaire (BIDQ) which contains seven scaled items scored from 0 (not affected) to 8 (extremely affected) pertaining to appearance-related concerns (BIDQ1); mental preoccupation (BIDQ2); emotional distress (BIDQ3); social, occupational, or functional impairment (BIDQ4); social life interference (BIDQ5) and educational, occupational, or other functional interferences (BIDQ6); and behavioural avoidance (BIDQ7). Systemic lupus erythematosus disease activity index (SLEDAI); the hospital anxiety and Depression Scale (HADS) in systemic lupus erythematosus; disease-specific HRQOL measure for adults with SLE (Lupus QOL), including health (PH), pain (PN), planning (PL), intimate relationship (IR), a burden to others (BV), emotional Health (EH), body image (BI), fatigue (F). Spearman's coefficient for nonparametric and Pearson's coefficient for parametric data were computed. Variables that were significant in univariate analysis were included in a multivariate linear regression model. All p-values less than 0.05 were considered statistically significant.
Results: SLE patients were most concerned about their body size (33.38%) and skin (32.23%), 55.34% SLE patients were more concerned about the change of body shape caused by disease. There was significant correlation between BID and disease status, psychological status and quality of life in patients with SLE. Physical health is correlated with BD1, Pain is correlated with BID1, BID4–7, Planning is correlated with BID2, BID4–7, Intimate relationships is correlated with BID4–7, Burden to others is correlated with BID3–7, Emotional health, fatigue are associated with BID3–7. Anxiety and depression also affect BID, anxiety is an important predictor of BIDQ1, BIDQ3–6, depression is a predictor of BIDQ2, BIDQ 3–6.
Conclusions: Patients with Systemic Lupus Erythematosus Living in China are much easier bear with BID, anxiety, depression, less quality of life will lead to BID, in view of the body image perspective, this study will help explore the influence factors of BID in patients with SLE.

AB0524 TRANSLATION AND VALIDATION OF THE FATIGUE SEVERITY SCALE, THE PITTSBURGH SLEEP QUALITY INDEX AND THE MODIFIED HEALTH ASSESSMENT QUESTIONNAIRE INTO THE MALTESE LANGUAGE, IN A COHORT OF MALTESE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

R. Magro[1], A.A. Borg[1], L. Camilleri[2]. *[1]Rheumatology, Mater Dei Hospital; [2]Statistics and Operations Research Department, University of Malta, Msida, Malta*

Background: The Fatigue Severity Scale (FSS), Pittsburgh Sleep Quality Index (PSQI) and Modified Health Assessment Questionnaire (mHAQ) are validated questionnaires that measure fatigue, sleep quality and function respectively. Research in the Maltese population, on systemic lupus erythematosus (SLE) requiring the use of these questionnaires, necessitates their translation and validation into the Maltese language.
Objectives: The aim of the study is to translate, validate and perform cross-cultural adaptation of the FSS, PSQI and mHAQ into the Maltese language, according to the recommended methodology.[1]
Methods: The original instruments were translated into Maltese by two translators whose mother language is Maltese. One of the translators had a medical background and was knowledgeable on the concepts being examined in the questionnaires; while the other did not. The two translated versions of the instruments were then compared and the discrepancies were resolved by reaching a consensus on the best Maltese version that reflects the underlying meaning of the original English version. The preliminary initial Maltese translations were then given to two other translators for back translation into English. English was the native language of these translators and they were totally blind to the original versions. The back translated English versions were then compared to the original English questionnaires and any discrepancies were highlighted. The equivalent statements in the Maltese translations were discussed and changes were made to reflect the original English versions more accurately. The pre-final Maltese translations were produced and pilot tested in a sample of 20 bilingual SLE patients to evaluate the clarity of the questionnaires. These 20 patients were also asked to fill in the original English version of the FSS, PSQI and mHAQ, seven days after filling in the Maltese versions. Psychometric testing was carried out to assess reliability of the translation, internal consistency and validity.
Results: Reliability of the translation of the FSS, PSQI and mHAQ into Maltese was analysed by using Kendall's tau test for statements having an ordinal scale and Pearson's correlation test for variables having a metric scale. The *p* value for each statement in the FSS, PSQI and mHAQ was less than 0.05 showing that the reliability of the translated versions was satisfactory. Internal consistency of the Maltese translations was demonstrated using Cronbach's alpha. This was calculated to be 0.877 for the FSS, 0.859 for the PSQI, and 0.897 for the mHAQ. Validity of the Maltese translation of the FSS was assessed by its correlation with the visual analogue scale for fatigue using Pearson's Correlation test. Pearson's R value was 0.809 and the *p* value was <0.001 confirming a positive significant correlation.
Conclusions: This study has confirmed the reliability and internal consistency of the translated English versions of the FSS, PSQI and mHAQ into Maltese. Moreover the validity of the Maltese version of the FSS has been shown. The Maltese translations can be finalised and used for research purposes.

AB0525 CLINICAL AND RENAL HISTOLOGIAL CHARACTERISTICS OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS WITH ANTI-SS-A AND ANTI-SS-B ANTIBODIES COMPARED TO THOSE WITHOUT

R. Anan, Y. Kaneko, J. Kikuchi, M. Ushikubo, S. Saito, T. Takeuchi. *Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Shinjuku-ku, Tokyo, Japan*

Background: Systemic lupus erythematosus (SLE) is a chronic condition with a broad clinical spectrum, which can affect multiple organs and systems. Although the most featuristic autoantibodies are anti-DNA and anti-Sm antibodies, anti-SS-A antibody and anti-SS-B antibody are detected in 30–40% and 7–45% of SLE patients, respectively. However, the clinical features of those positive patients are unclear.
Objectives: The aim of this study was to clarify the associations of anti-SS-A and anti-SS-B antibodies with the clinical features of SLE and histological findings of lupus nephritis (LN).
Methods: We enrolled consecutive Japanese patients with SLE who had visited Keio University Hospital from 2013 to 2015 and whose anti-SSA and anti-SSB antibodies were measured. The patients were divided according to the presence or absence of anti-SS-A and anti-SS-B antibodies, and their associations of the clinical features and renal biopsy histological findings were examined.
Results: A total of 253 patients were enrolled, 215 (84%) were female, and the mean age was 55.2 years. Anti-SS-A antibody was detected in 152 cases (69%), and anti-SS-B antibody in 40 cases (18%). No difference was found in sex, age, the rates of anti-DNA and anti-Sm positivity between both the anti-SS-A positive group and the anti-SS-A negative group, and between the anti-SS-B positive group and the anti-SS-B negative group. While the frequencies of oral ulcers (38% vs. 37%, p=0.83), arthritis (82% vs. 79%, p=0.58), serositis (23% vs. 22%, p=0.94), neuropsychiatric involvement (14% vs. 10%, p=0.35), LN (51% vs. 63%, p=0.07), leukopenia (74% vs. 69%, p=0.44), and thrombocytopenia (26% vs. 31%, p=0.44) were not different between the anti-SS-A positive group and the anti-SS-A negative group,.mucocutaneous involvement (84% vs. 63%, p=0.002), alopecia (37% vs. 19%, p=0.002), lymphopenia (97% vs. 89%, p=0.020) were significantly higher in the anti-SS-A positive group than the anti-SS-A negative group. The frequencies of neuropsychiatric involvement (24% vs. 10%, p=0.015) was significantly higher in the anti-SS-B positive group than the anti-SS-B negative group. The period from the SLE onset to the LN onset was significantly shorter in the anti-SS-A positive group than the anti-SS-A negative group (4.0 years vs. 9.0 years, p=0.005), and in the anti-SS-B positive group than the anti-SS-B negative group (0.4 years vs. 6.8 years, p=0.008). Focusing on the histological findings of LN patients, the anti-SS-A positive group had significantly lower rate of renal tubular atrophy (8.0% vs. 16%, p=0.042) and interstitial fibrosis (7.6% vs. 16%, p=0.031) than the anti-SS-A negative group. The anti-SS-B positive group had also significantly lower rate of renal tubular atrophy (3.3% vs. 13%, p=0.048) and interstitial fibrosis (2.1% vs. 13%, p=0.016). Finally, chronicity Index was significantly lower in the anti-SS-A positive group (2.37 vs. 4.14, p=0.002) and in the anti-SS-B positive group (1.17 vs. 3.33, p=0.008).
Conclusions: SLE patients positive for anti-SS-A and anti-SS-B antibodies had

characteristics with frequent mucocutaneous involvement, alopecia, neuropsychiatric involvement, and lymphopenia. They should be followed carefully for early onset of LN.

AB0526 B1 CD5+ LYMPHOCYTES IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: RELATION TO DISEASE ACTIVITY

S.I. Nasef[1], H.H. Omar[2], H.H. Omar[3], M.S. Ghaly[1]. *[1]Physical Medicine, Rheumatology and Rehabilitation; [2]Clinical Pathology; [3]Internal Medicine, Faculty of Medicine, Suez Canal University, Ismailia, Egypt*

Background: B cells are essential players in the pathogenesis of Systemic lupus erythematosus (SLE). Membrane CD5 elevates the threshold of B cell receptor mediated responses, and thus prevents the release of antibodies. So, misguided signalling through CD5 could lead to autoimmunity. Hence, $CD5^+$ B cells were considered to play a paradoxical role in preventing rather than inducing autoimmunity. This challenging view differs from the old interpretation that elevated levels of B1 $CD5^+$ cells in SLE patients represent a direct source of autoantibodies responsible for organ damage.

The clinical implications of this new concept for the role of B1 $CD5^+$ cells in SLE have not been fully addressed yet and there is no consensus agreement about the proportions of B1 CD5+ cells in SLE patients. Moreover, the relation of B1 $CD5^+$ cells to disease activity and organ damage is not sufficiently studied.

Objectives: To assess the expression of B1 $CD5^+$ cells in SLE patients and to evaluate their relationship with disease activity and organ damage.

Methods: We recruited 100 SLE patients and 100 healthy control subjects. Based on SLE disease activity index (SLEDAI), patients were divided into two groups; active SLE (n=50) and inactive SLE (n=50). SLE was active when SLEDAI was $\geq$4. The expression of ($CD5^+CD20^+$) B1 cells was evaluated using flow cytometry. Lymphocytes were gated depending on both side and forward scatter. From the gated lymphocytes, B1a cells were identified double positive cells for CD20 and CD5. Percentage and absolute numbers of $CD20^+CD5^+$ (B1a cells) and their mean fluorescence intensity (MFI) were measured. The histogram of CD5 expression was used to assess its expression on CD20 cells (figure 1).

Laboratory work included CBC, ESR, CRP, Serum creatinine, Protein/creatinine ratio, Urine analysis, 24 hour protein collection in urine, Complement levels, (Anti-dsDNA) and (ANA).

Results: Mean age of patients was 31.3±8.8 years. Females constituted 94% (n=94) of patients. Mean disease duration was 5.28±4.8 years. Mean SLEDAI was 10.28±5.16.

The proportions of ($CD5^+CD20^+$) B1 cells were significantly lower in SLE patients versus controls (5.9±4.4% vs 20.2±4%, $p\leq0.001$). Similarly, the absolute numbers of ($CD5^+CD20^+$) B1 cells (cell/mm^3) were significantly lower in SLE patients versus controls (100.2±103.4 vs 557.6±163.3, $p\leq0.001$).

The expression of ($CD5^+CD20^+$) B1 cells was decreased in active SLE patients (4.5±3.8%) in comparison to inactive patients (7.3±4.7%) (p=0.027). B1 ($CD5^+CD20^+$) absolute cell number (cell/mm^3) was significantly lower in active SLE patients (71.4±82.9) compared to inactive ones (129.0±115.1) (P=0.047).

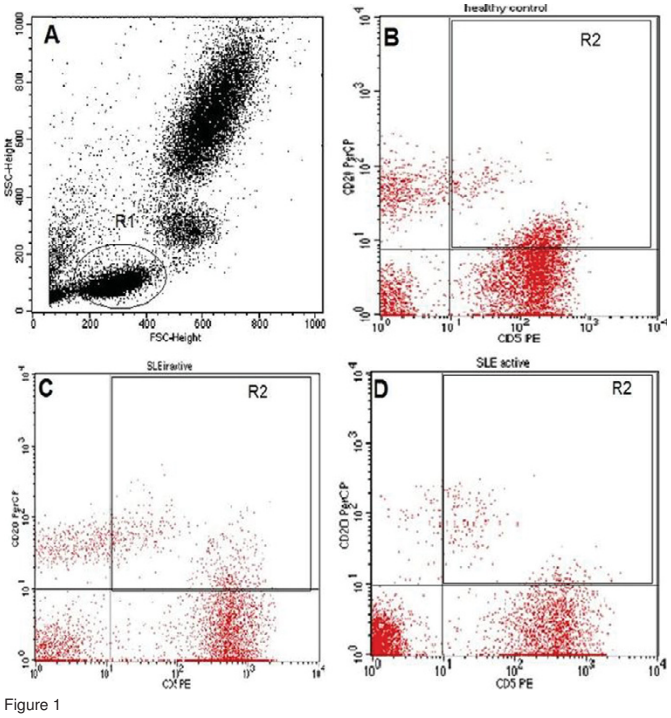

Figure 1

MFI of $CD5^+/CD20^+$ was significantly decreased in SLE patients compared to healthy control (146.9±109 vs 196±48, P=0.033). B1 cells ($CD5^+CD20^+$) correlated positively with C3 (r=0.322, p=0.022) and C4 (r=0.307, p=0.030). No correlation was found between ($CD5^+CD20^+$) B1 cells and disease duration, autoantibodies or any specific system or organ damage.

Conclusions: Expression of B1 $CD5^+$ cells was significantly decreased in SLE patients. Decreased B1 $CD5^+$ cells expression was associated with higher disease activity. B1 $CD5^+$ correlated positively with complement levels. These findings denote that CD5 expression on B cells may play a regulatory role in SLE pathogenesis and decrease occurrence of flares.

AB0527 PROGRANULIN AND INSULIN-LIKE GROWTH FACTOR-2 AS BIOMARKERS FOR DISEASE ACTIVITY AND PATHOLOGICAL CHANGES IN LUPUS NEPHRITIS

S. Goma, M. Abdelaziz, E. El-Hakeim, M. El Zohri, S. Sayed. *Assiut University, Egypt, Assiut, Egypt*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune inflammatory disease (1), characterized by the production of autoantibodies, and formation of immune complexes due to the polyclonal activation of T and B lymphocytes that result in tissue and organ damage (2). During inflammation, neutrophils and macrophages release serine proteases to cleave progranulin (PGRN) into granulin (GRN), which exert their pro-inflammatory effects that counteract the anti-inflammatory effects of intact PGRN (3). Insulin-like growth factor-2 (ILGF-2) binds to insulin-like growth factors (IGFs) with high affinity (4). Although reports suggest that IGFBP-2 is a reliable biomarker of renal deterioration, it is still needed to confirm that it has high sensitivity and specificity in discriminating kidney disease caused by SLE from other origins.

Objectives: The aim of this study was to explore whether PGRN and ILGF-2 can be used as useful markers not only for accurate diagnosis of patients with active lupus nephritis (LN) but also for prediction of the disease activity in these patients.

Methods: Twenty-five patients with systemic lupus erythematosus, twenty-five patients with chronic renal failure and twenty-five age- and sex-matched healthy volunteers were enrolled in the study. Routine laboratory investigations and measurement of serum PRGN and IGFBP-2 levels were done.

Results: Our results showed that the mean age of SLE, CRF and control groups 31.12±12.34, 38.7±9.4 and 32.96±13.66 respectively with no significant difference between the three groups. There was female predominance in the three groups. Disease duration was 4.78±4.26 in SLE patients.The mean of SLEDAI score was 15.04±7.54. All renal biopsy results were class 2, 3, and 5 with a percentage of 32%, 24%, and 44% respectively.

Table 1. Levels of PRGN and ILGF-2 in SLE, CRF and control groups

	SLE	CRF	Control	P	P1	P2	P3
PRGN, pg/ml	2558.92±1170.77	1814.6±330.28	1052±276	<0.001**	<0.001**	<0.001**	<0.001**
ILGF-2, ng/ml	26.44±11.55	6.14±2.25	3.3±1.7	<0.001**	<0.001**	<0.001**	0.148

P: Comparison between all groups. P1: comparison between SLE and CRF. P2: comparison between SLE and control. P3: comparison between CRF and control. Table 2. Levels of PRGN and ILGF-2 in relation to SLEDAI score, renal SLEDAI, and Renal biopsy

	PRGN pg/ml	ILGF-2 ng/ml
SLEDAI score		
Moderate	1945.6±300	26.8±11.7
High	2072.1±545.5	20.1±5
Very high	4269.2±1106.8	37.6±12.6
P value	0.002**	0.006**
Renal SLEDAI		
Inactive	2251.2±841	23.3±8.9
Active	2764.1±1335	28.6±12.9
P value	0.311	0.196
Renal biopsy		
Class 2	2199.31±854.85	24.38±13.31
Class 3	2244.17±767.97	23.75±7.01
Class 4	2992.14±1453.93	29.41±12.41
P value	0.270	0.540

SLEDAI: Systemic Lupus Erythematosus Disease Activity Index. *Statistically significant difference ($p<0.05$) **Statistically significant difference ($p<0.01$).

Conclusions: PGRN and ILGF-2 are significantly elevated in SLE than CRF and control and were associated with SLEDAI. Hence they are considered specific to LN.

AB0528 PATIENT ACTIVATION AND THE FACTORS AFFECTING IT IN PRIMARY SJÖGREN'S SYNDROME

S.T. Souter[1], B. Hargreaves[2], K.L. Hackett[3], W.-F. Ng[3]. *[1]Newcastle University; [2]Freeman Hospital; [3]Institute of Cellular Medicine & NIHR Newcastle Biomedical Science Research Centre, Newcastle upon Tyne, United Kingdom*

Background: Increased patient activation has been associated with reduced costs of treatment[1] and improved patient outcomes[2]. The effect of primary Sjögren's syndrome (pSS) on patient activation however has not been established.
Objectives: This study aims to identify how activated patients with pSS are, and to ascertain whether factors such as ESSPRI score, EULAR dryness score and self-reported quality of life influence this.
Methods: Patient activation in 170 pSS patients was assessed using the 13-item Patient Activation Measure (PAM-13). A PAM-13 score from 0–100 was obtained using the PAM-13 Scoring Spreadsheet, which also gave a corresponding activation level ranging from 1–4. Descriptive statistics of the PAM-13 scores was performed, and frequency analysis of the corresponding activation level. Demographic, clinical and self-reported measures such as age, gender, ESSPRI score and EQ5D-3L score were linked to each patients' PAM-13 scores. Spearman's correlation analysis was performed to assess the relationship between the continuous variables and PAM-13 score, and Fisher's exact test was used to assess the relationship between activation level and the categorical variables.
Results: The mean PAM-13 score of the 170 patients studied was 59.5 (SD 13.5). 17.6% of patients were in level 1 of activation, 26.5% in level 2, 40.0% in level 3, and 15.9% in level 4. The mean age of the sample was 59.6 (SD 13.1), and 83.5% were female.
EQ5D-3L score had the strongest correlation with increased PAM score (r_s 0.405, p 0.000). Increasing self-reported pain in the ESSPRI questionnaire was correlated with a decreasing PAM score (r_s -0.355, p 0.000), as was increasing ESSPRI score (r_s -0.337, p 0.000). Increasing abnormal fatigue (r_s -0.189, p 0.016) and EULAR dryness (r_s -0.190, p 0.013) score were only weakly correlated with a decrease in PAM-13 score. Decreases in patients self-reported mobility (p 0.000), self-care (p 0.002), and ability to perform daily activities (p 0.018) were also associated with differences in activation score.
Conclusions: Factors such as a patients self-reported health and pain have a moderate correlation with activation in pSS patients, while dryness and fatigue are only weakly correlated with changes in activation. This should be considered in the future when devising treatment plans and clinical trials.

AB0529 ROLE OF THE ANTI-RO52 AND RO60 ANTIBODIES QUANTIFICATION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

S. Heredia[1], M. Martinez-Morillo[1], A. Riveros[1], L. Gifre[1], A. Teniente-Serra[2], B. Quirant[2], S. Holgado[1], L. Mateo[1], A. Prior[1], Y. Garcia[1], J. Camins[1], E. Martínez-Cáceres[2], A. Olivé[1]. *[1]Rheumatology; [2]Immunology, Hospital Universitari Germans Trias i Pujol, Badalona, Spain*

Background: Anti-Ro antibodies (Ab) are especially directed against two antigens, Ro52 and Ro60, with different structure and function. Studies in systemic lupus erythematosus (SLE) have been described a relationship between the presence of anti-Ro Ab and dry syndrome, subacute cutaneous lupus, myocardial involvement or minor renal involvement. However, studies about the clinical usefulness of determining the 2 specificities of anti-Ro Ab in SLE are not conclusive. It seems that anti-Ro52 could be associated with joint involvement and lung disease, while anti-Ro60 could be related to late-onset SLE. In this paper we evaluate the clinical usefullness of anti-Ro52 and Ro60 Ab chemiluminescence quantification in patients with SLE.
Objectives: To analyze the presence of anti-Ro52 and Ro60 Ab in a cohort of patients with SLE and evaluate its correlation with clinical, analytical and immunological parameters.
Methods: 152 patients with SLE (according to the SLICC criteria 2013) attended in an university hospital were included. Qualitative immunoblot analysis of anti-Ro Ab was performed on all of them; those with positive values were also assessed by a chemiluminescence quantification of anti-Ro52 and Ro60 Ac (normality <19.9 CU). Other LES specific Ab were also analyzed by immunoblot, indirect immunofluorescence and ELISA. Clinical variables (age, oral ulcers, alopecia, synovitis, serositis, antiphospholipid syndrome (APS), Sjögren's syndrome, cutaneous, neurological and renal involvement), analytical (complement, cytopenia and coombs test) and activity and damage index of SLE (SLEDAI and SLICC) were also evaluated. The study was approved by the Clinical Research Ethics Committee of the center, and all patients signed informed consent.
Results: 91% (138) were women with a mean age of 46±12 years (range, 20–75) and an average SLE evolution of 12±7 years (range, 1–40). 32% (49/138) of the patients had anti-Ro positive determination by immunoblot: 36 were anti-Ro52 positive (mean value 696±726 CU) and 48 anti-Ro60 positive (mean value 504±696 CU) by chemiluminescence. Only one anti-Ro52 positive patient was anti-Ro60 negative. 10.5% had late-onset SLE. The mean SLEDAI was 1.84±2.48 while the SLICC was 0.32±0.7, with a mean anti(ds)DNA Ac values about 207.87±357.15 IU/ml. 37.5% had hypocomplementemia. Anti-Ro positive patients by immunoblot had a higher value of anti(ds)DNA compared to the patients without Ro positive values and patients with both positivity by chemiluminescence had lower prevalence of APS, however the quantitative values of anti-Ro52 and anti-Ro60 were not related with clinical, analytical or immunological parameters.
Conclusions: 32% of patients in the cohort were anti-Ro positive being mostly anti-Ro60 positive. The presence of anti-Ro Ab was associated with higher value of antiDNAds and lower prevalence of APS. However, the quantitative values of anti-Ro52 and anti-Ro60 Ab by chemiluminescence were not related to the different parameters analyzed in the study. These results indicate the need to assess the quantification of anti-Ro Ab in a larger cohort of patients with SLE.

AB0530 PREVALANCE OF OSTEONECROSIS OF BONE IN PATIENTS OF SLE IN A NEWLY ESTABLISHED RHEUMATOLOGY CLINIC IN CENTRAL INDIA

S. Malviya[1], N. Gupta[2], R. Gupta[3]. *[1]Department of Rheumatology, Indore, India, Medanta Superspeciality Hospital; [2]Department of Anaesthesia, SAIMS, Indore, Indore; [3]Department of Rheumatology, Indore, India, MEDANTA Medicity, Gurugram, India*

Background: Osteonecrosis (OCN) is a well recognized complication of SLE. The prevalence rate of AVN in SLE ranges from 8–25% in various studies. It is always debatable if corticosteroids or disease itself causes OCN. Although long term corticosteroids use can cause OCN, but in few cases and studies it has shown disease itself can be the causative event.
Objectives: To study the prevalance of Osteonecrosis of bone among patients of SLE attending the newly established Rheumatology clinic over 2 years time.
Methods: All the patients of SLE with OCN attending the newly established Rheumatology clinic of the town were included in the study.OCN was diagnosed on the basis of MRI after screening with X-ray.Serological data collected. Routine investigations done were collected. Details of patients were included in a set proforma and details noted in the same.
Results: Among 180 patients of SLE were included in the study. Among those, 9 patients (5%) were diagnosed with OCN. Seven patients of OCN had been on steroids but 2 patients never received any drugs, both were male. All the patients were AN A positive (Homegenous pattern in 6 and Speckled in 3), Anti-ds-DNA was positive in 7 and Anti-Smith in 2. Most common site of OCN was Femur head (n=6), Lower femoral condyles in 2 patinets of OCN and head of Talus in 1. Anti-phospholipid antibodies were found in 3 patients.
Conclusions: Osteonecrosis was found in 5% of patients of SLE. Most of the patients had active disease with OCN occurred very early during the course of disease. This suggest OCN can be seen due to disease itself as 2 patients never received any drugs. Most common antibodies associated was anti ds-DNA antibody. So among patients of SLE with hip or pain in joints/bone not explaining active arthritis, OCN should be ruled out.

AB0531 ANTI-CENTROMERE POSITIVE PRIMARY SJÖGREN'S SYNDROME – CHALLENGE TO CLASSIFICATION CRITERIA

S. Palshina[1], V. Vasiliev[1], E. Sokol[1], B. Chaltsev[1], E. Rodionova[1], T. Safonova[2]. *[1]Nasonova research institute or rheumatology; [2]Research Institute of Ophthalmic diseases, Moscow, Russian Federation*

Background: The prevalence of anti-centromere antibodies (ACA) among patients with primary Sjögren's syndrome (pSS) varies from 3,7% till 10,9% [1;2]. They have special course of the disease: 1) with some features of systemic sclerosis (SSc), but rarely evolve to it, 2) higher prevalence of hepatitis and primary biliary cholangitis - PBC.
Objectives: to describe the peculiarities of this subgroup; to evaluate it's conformity to the latest classification criteria for pSS (2012, 2016) [3;4] and prevalence of SSc with ACR2013 criteria [5].
Methods: From 2012 to 2016 in a single rheumatic center 50 ACA positive patients (47 female; 3 male) national (Russian) criteria (1987) and in 68%cases - AECG 2002 criteria for pSS (SSc excluded) [Tabl.1]. The mean age was 59,2±9,6 yrs. All diagnostics methods are listed in the table 1, lymphomas were verified pathomorphologicaly with immunohystochemical staining.
Results: In our study 2/3 (64%) ACA+pts with pSS did't fulfill ACR2012 criteria, because of the lack of aRo or aLa or combination of RF+ANA. According to the criteria, 2016 [4] also just 60–68% pts will have ≥4scores for diagnosing pSS. SSc (limited form) due to new criteria [5] might be revealed in 11/50 (22%) cases. MALT lymphoma of salivary glands arised in 5/6 pts with visible enlargement of parotid glands.

Table 1. Characteristics of pSS patients with positive ACA

Parameters	Value (n, %)
Sialography of parotid gland: sialectasis	47/50 (94%)
Xerostomia (grade I-III) stimulated parotid saliva flow rate <0,5ml/5min (III)	27/43 (62,8%)
Keratoconjunctivitis sicca with ocular staining score ≥5	31/50 (62%)
Schirmer's test ≤5 mm/5 minutes	29/48 (60,4%)
Focal lymphocytic sialadenitis ≥1 foci/4 mm^2	28/30 (92%)
Non-Hodgkin lymphoma (incl. MALT lymphoma)	6 (5) =12% (10%)
aRo/SS-A ≥50 IU/ml	16/50 (32%)
aLa/SS-B ≥50 IU/ml	3/50 (6%)
IgM RF positive ≥2UNL (>30 IU/ml)	9/50 (18%)
AMA positive >10 IU/ml	13/31 (41,9%)

Conclusions: pSS with positive ACA is challenging for diagnostics with comprehensive classification criteria (32–64% doesn't meet it [3;4]). These patients overlaps SSc, some PBC. PBC is not rare among, but biliary tract lesions (AMA+(rarely absent, 2% in our study) with slightly elevated liver enzymes, esp.GGT, and stage 1 typical to PBC without progression) are more common.

AB0532 VITAMIN D IN A MALAYSIAN LUPUS COHORT AND ITS CORRELATIONS WITH CLINICAL AND IMMUNOLOGICAL PARAMETERS

S.G. Ong, H.J. Ding. *Medicine, Kuala Lumpur Hospital, Kuala Lumpur, Malaysia*

Background: Numerous studies have demonstrated that inadequate vitamin D levels are common in systemic lupus erythematosus (SLE) patients and they correlate inversely with disease activity. To date, there is paucity of data on the prevalence of vitamin D status, as well as its clinical and immunological associations in Malaysian SLE patients.
Objectives: Our study aimed to determine the prevalence of vitamin D deficiency and insufficiency in SLE patients, and to examine the associations between vitamin D status with gender, ethnic groups, clinical manifestations of SLE, Schirmer's test, cardiovascular risk factors, bone mineral density and autoantibodies.
Methods: This retrospective study included 216 SLE patients who attended the Rheumatology Clinic of Kuala Lumpur Hospital between January 2013 and December 2015. Data was obtained from patients' medical records. All patients fulfilled the 1997 American College of Rheumatology revised classification criteria for SLE. Serum 25(OH)D concentrations were measured by electrochemiluminescence immunoassay.
Results: A total of 216 SLE patients were included in this study. Eleven (5.1%) were males and 205 (94.9%) were females. There were 141 (65.3%) Malay, 53 (24.5%) Chinese, 19 (8.8%) Indian and 3 (1.4%) of other ethnic group. This corresponded with the pattern of ethnic distribution in the Malaysian population. Their ages ranged from 14 to 75 years, with a mean age of 35.9±7.1 years. Mean duration of SLE at the time of 25(OH)D analysis was 6.9 years (range from 0 to 39 years), and mean age was 35.1±6.4 years (range from 14 to 75 years). Mean 25(OH)D concentration was 51.3±14.8 nmol/L (range from 7.5 to 156.1 nmol/L). Fifty (23.1%) patients had vitamin D deficiency, 120 (55.6%) had vitamin D insufficiency, while 46 (21.3%) had adequate vitamin D levels.
Our study showed statistically significant association between vitamin D status and ethnic group ($p<0.001$). The Chinese ethnic group had the lowest proportion of patients with vitamin D deficiency and insufficiency (60.4%), while Malay had the highest proportion at 86.5%. Mean levels of serum 25(OH)D in Chinese, Indian and Malay SLE patients were 66.3±36.7 nmol/L, 54.9±36.4 nmol/L, and 45.0±27.5nmol/L, respectively. Among the clinical manifestations of SLE, only lupus nephritis showed a statistically significant association with vitamin D status ($p<0.001$). In terms of cardiovascular risk factors, hypertension demonstrated significant correlation with vitamin D status ($p=0.032$).
No significant association was found between vitamin D status and gender. Nonetheless, male SLE patients had higher mean 25(OH)D concentrations at 69.4±36.9 nmol/L, compared to female at 50.2±31.6 nmol/L. There were no significant correlations between vitamin D status and clinical features of lupus such as cutaneous lesions, arthritis and NPSLE; positive Schirmer's test; cardiovascular risk factors, that are, dyslipidemia and diabetes mellitus; osteoporosis; and autoantibodies which included anti-dsDNA antibody, anti-Ro antibody, anticardiolipin antibody and rheumatoid factor.
Conclusions: Sub-optimal vitamin D levels are prevalent among SLE patients in a tropical country and are associated with ethnic group, lupus nephritis and hypertension. It is essential to include vitamin D supplementation in the management of SLE patients.

AB0533 JUVENILE AND JUVENILE-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS: CLINICAL CHARACTERISTICS, DISEASE ACTIVITY AND DAMAGE

T.A. Gheita[1], R.E. Gheith[1], H.S. El-Fishawy[2], D.M.R. Bahgat[3], A.M. Nour El-Din[4]. *[1]Rheumatology and Clinical Immunology; [2]Internal Medicine; [3]Clinical and Chemical Pathology, Faculty of Medicine - Kasr Al-Ainy School of Medicine - Cairo University, Cairo; [4]Pediatrics, National Research Centre (NRC), Giza, Egypt*

Background: The diagnosis of systemic lupus erythematosus (SLE) in children is challenging as the heterogeneous manifestations and disease impact on the child's growth highlighted the importance of timely diagnosis and management.
Objectives: The aim of the present study was to assess and compare the clinical characteristics, disease activity and damage between juvenile (JSLE) and juvenile-onset (JO-SLE) Egyptian patients.
Methods: Seventy-eight SLE patients (26 JSLE and 52 JO-SLE) were included in this study. Disease activity was assessed using the SLE Disease Activity Index (SLEDAI) and organ damage using the Systemic Lupus International Collaborating Clinics (SLICC) index.
Results: The mean age of the JSLE children was 13.25±2.09 years and 23.17±4.26 years for JO-SLE cases. JO-SLE cases were older at disease onset with a higher female-to-male ratio. There were no noticeable gender differences. There was a significantly higher frequency of serositis, nephritis and hematological involvement in the JO-SLE (57.7%, 76.9% and 73.1%) compared to the JSLE cases (15.4%; 30.8% and 30.8%) ($p<0.001$ for all). The erythrocyte sedimentation rate, creatinine and proteinuria were significantly increased in JO-SLE while alkaline phosphatase was higher in JSLE cases. In JO-SLE cases, SLEDAI significantly increased (5.96±6.18 *vs* 3.12±1.97; $p=0.003$) and the SLICC tended to increase compared to the JSLE children. More JO-SLE cases received hydroxychloroquine and azathioprine.
Conclusions: The existence of differences in clinical phenotype has been confirmed, between JSLE and JO-SLE especially as regards serositis, nephritis and heamatological affection. The disease damage was comparable which denotes that the maximum organ involvement occurs in childhood with an almost stationary course. Rheumatologists caring for children with SLE must be aware of the greater risk of major haematological and renal involvement as well as important long-term morbidity.

AB0534 THROMBOTIC MICROANGIOPATHY IN PREGNANT WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS: CHARACTERICTICS AND OUTCOMES

T. Kirsanova[1], M. Vinogradova[1], A. Kolyvanova[2], N. Klimenchenko[1]. *[1]Federal State Budget Institution "Research Center for Obstetrics, Gynecology and Perinatology" MoH, Russian Federation; [2]Moscow State University, Moscow, Russian Federation*

Objectives: to evaluate the impact of thrombotic microangiopathy (TMA) on perinatal and maternal outcomes in patients with systemic lupus erythematosus (SLE).
Methods: This study included 21 SLE patients with pregnancy, who developed TMA signs during pregnancy. Patients underwent general survey, clinical and laboratory assessment for disease activity and APL-antibodies. All of them had low SLE-activity indices.
Results:

Table 1. Laboratory features of pregnant patients with SLE

	TMA (n=7)	Without TMA (n=14)
Hb,g/l	89,8	95,8
LDH, Ed/l	716,39	331,2
ALT, Ed/l	110,9	21,3
AST,Ed/l	69,1	24,3
Creatinine, mkmol/l	113,3	77,3
GFR, ml/min	50,5	81,1
Proteinuria, g/24h	0,65	0,28
Thrombocytes, x10^9	135,5	213,8
sFLT/PLGF	66,6	18,9

Table 2. Perinatal outcomes in pregnant women with SLE

	TMA (n=7)	Without TMA (n=14)
– Livebirth	4	12
– Stillbirth	3	1
Weigh	1363,3	3047,3
Mean gestational age	29,1	36,2

TMA signs were found in 7/21 SLE patients (33%). Patients with TMA had significantly higher systolic and diastolic blood pressure ($P \leq 0.05$), higher serum creatinine and lower estimated glomerular filtration rate ($P \leq 0.05$) than that of those without TMA lesions (tabl.1). APLA positivity was significantly more frequent in patients with TMA (3/7 vs 0/14). TMA onset in 2 patients occurred before 20 gestational weeks, 5/7 have developed PE signs (23–38 weeks), only 3/7 had classical HELLP syndrome. There was no PE in patients without TMA. There was a significant association between the detection of TMA and adverse perinatal outcomes (tabl.2).
Patient with TMA and SLE had a poor outcome and most severe course: 5/7 had a PE (3/7 developed HELLP),3/7 had antenatal fetal death, 3/7had signs of heart damage,5/7 a variety of neurological manifestations. Despite of PE signs in 5/7 with TMA the blood sFlt1/PLGF levels were slightly above normal (average sFlt/PLGF levels in preeclampsia without SLE in our another study is 404,47)
Conclusions: TMA is not an uncommon disorder in pregnant patients with SLE. It is associated with APLA positivity only in 1/3 cases. TMA was significantly associated with renal impairment, systemic hypertension and adverse perinatal outcomes. Less increased ratio of sFlt-1/PlGF in TMA patients than "pure" PE may confirm that PE in patients with TMA is not a condition due to angiogenic factors imbalance. Circulating concentrations of angiogenic factors appear not to be suitable markers to assess the severity of PE and adverse outcomes in SLE patients. Thus, TMA may be an important cause of renal injury and renal dysfunction in a subset of pregnant patients with SLE and associated with worse renal and perinatal prognosis. Complement over-activation via both classical (SLE+APS) and alternative pathways might play an important role in the pathogenesis of TMA in SLE.

AB0535 FATIGUE IS ASSOCIATED WITH HS-CRP IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

T. Aung, L. Sahakian, B. Skaggs, J. Grossman, M. McMahon. *Rheumatology, UCLA, Los Angeles, California, United States*

Background: Fatigue is highly prevalent and has a negative impact on quality of life in patients with Systemic Lupus Erythematosus.[1,2] The 9-item Fatigue Severity Scale (FSS) is one of the commonly used self-report questionnaires to measure fatigue in patients with chronic disease.[3] Although fatigue is one of the most commonly reported symptoms in SLE, previous studies have not consistently found any clear association between disease activity (as measured by the SLEDAI)[4] or with laboratory measures of disease activity.[1]
Objectives: To determine whether fatigue is associated with any laboratory measures of disease activity or inflammation in patients with SLE.
Methods: SLE patients and age-matched controls participating in our longitudinal "Biomarkers of Cardiovascular Disease in SLE" completed FSS questionnaires at study entry. Laboratory measures of cardiovascular risk assessment and lupus disease activity assessments were performed in plasma, including high sensitivity C-reactive protein (hs-CRP), myeloperoxidase (MPO), homocysteine, fasting lipid panels, erythrocyte sedimentation rate (ESR), C3, C4, dsDNA, and urine protein/creatinine ratio (UPCR).
Results: 54 patients and 37 control individuals participated. FSS scores were higher in patients with SLE (4.79±1.63 (mean ± SD) compared to healthy subjects (3.17±1.83, $P<0.001$). There were no significant correlations between FSS and age, gender, or SLE disease duration.
In SLE patients, there was significant correlation between FSS scores and hs-CRP (r=0.56, p=0.004), and an inverse correlation with myeloperoxidase (-0.37, p=0.045). No associations between FSS and C3, C4, dsDNA, ESR, UPCR, fasting lipid levels, or homocysteine were seen in the SLE group. No associations between FSS and laboratory measures of cardiovascular risk assessment were seen in the control group.
Conclusions: Although fatigue is not correlated with traditional laboratory measures of disease activity in SLE patients, we did find significant associations between fatigue, hs-CRP, and myeloperoxidase in our cohort. Future longitudinal studies are underway to determine whether these associations also reflect the risk for progression of cardiovascular disease in patients with high fatigue.

AB0536 ANTICARDIOLIPIN ANTIBODIES IN SYSTEMIC LUPUS ERYTHEMATOSUS

T. Ben Salem, I. Naceur, M. Tougorti, M. Lamloum, I. Ben Ghorbel, M.H. Houman. *Internal Medicine, Rabta university hospital, Tunis, Tunisia*

Background: Anticardiolipin (ACL) antibodies have been independently associated with high incidence of thrombotic diseases and pregnancy associated disorders in patients with systemic lupus erythematosus (SLE).
Objectives: This study aims to assess influence of ACL antibodies in SLE and their association with clinical, biological and immunological features.
Methods: A retrospective study of 246 patients with systemic lupus erythematous (revised ACR criteria) conduced in an internal medicine department over a period time of 14 years. Two groups were compared according to the positivity of ACL antibodies (group1: positive ACL/ group2: negative ACL).
Results: ACL antibodies were positive in 48.8% of SLE patients (screened in 168 patients). This prevalence was similar in female and male. Poor general state at diagnosis was more frequent in the ACL positive group (55.7% vs 38.6%; p=0.02). The following data were comparable in the two groups: joint involvement (91.8% vs 90.8%; p=0.7), pericarditis (33.8% vs 37.8%; p=0.6) and pleural effusion (24.1% vs 29.5%; p=0.44). Alopecia (38.6% vs 27.9%; p=0.2), central nervous system involvement (12.5% vs 18.8%; p=) and peripheral neuropathy (6.4% vs 11.1%; p=) were more frequent in the group 2 without significant difference. Prevalence of lupus nephritis was more important in the group 1 (52.8% vs 38.8%; p=0.07). Thromboembolic complications: deep venous thrombosis (13.8% vs 11.9%; p=0.72) and pulmonary embolism (10.8% vs 7.1%; p=0.51) were more frequent in patients with ACL antibodies without significant difference. Obstetrical complications were more frequent in group 1 but differences were not statistically significant; spontaneous abortions (29.5% vs 20.4%; p=0.29), intra-uterin death (13.6% vs 9.3%; p=0.5), premature birth (6.8% vs 1.9%; p=0.3).
There were no associations between hematologic disorders and ACL antibodies; leucopenia (51.3% vs 39.5%; p=0.13) and), lymphopenia (81% vs 80.2%; p=0.9), anemia (77.2% vs 74.4; p=0.6) and thrombopenia (22.8% vs 23.5%; p=0.9) were comparable in the two groups. Frequencies of anti-ds DNA antibody and of antibodies to extractable nuclear antigens were similar in the two groups. Only anti-B2GP1 antibodies were significantly associated to ACL antibodies (51.3% vs 17.2%; $p<0.001$).
Conclusions: ACL antibodies were found in 30–40% of patients with SLE, this is comparable to our group.
No significant associations of ACL antibodies.to thrombotic events or obstetrical complications were found in our patients
Disclosure of Interest: None declared

AB0537 ACUTE ACALCULOUS CHOLECYSTITIS: A RARE MANIFESTATION OF SYSTEMIC LUPUS ERYTHEMATOSUS

T. Ben Salem, A. Kefi, M. Jedidi, M. Lamloum, I. Ben Ghorbel, M.H. Houman.
Internal Medicine, Rabta university hospital, Tunis, Tunisia

Background: Acute acalculous cholecystitis (AAC) is a rare complication of systemic lupus erythematosus (SLE) but should be recognized
Objectives: The aim was to describe clinical, biological and radiological features of AAC in SLE patients.
Methods: We report four cases of AAC complicating SLE among 246 patients.
Results: Case 1: A 37-year-old woman with one year history of arthralgia and Raynaud's phenomenon was admitted for fever, cutaneous lesions, nausea and abdominal pain. The right upper quadrant of the abdomen was tender and we noted oral ulcerations and wrist synovitis. Laboratory data showed lymphopenia, hemolytic anemia and an inflammatory syndrome. There was no cholestasis or cytolysis. Antinuclear antibodies (ANA), anti-nucleosome, anti-Sm and anti-ribosome antibodies were positive. Abdominal sonography revealed ascites and gallbladder wall was thick and irregular. The diagnosis of AAC complicating a SLE was made and patient was treated with antibiotics and corticosteroids. Two weeks later, she was asymptomatic and abdominal sonography was normal.
Case 2: A 32-year-old woman had SLE with arthralgia, cutaneous manifestations, hematological involvements and pulmonary hypertension; she was treated with corticosteroids and cyclophosphamide. Six month later, at time of the second pulse of cyclophosphamide, she presented with jaundice and tender hepatomegaly without abdominal pain. Liver enzymes rates were normal except bilirubin which was high at 47 UI. Her abdominal sonography showed gallbladder wall thickness without bile ducts enlargement or gallstones. Patient was continued on steroids and cyclophosphamide but she died because of heart failure.
Case 3: A 40-year-old patient with 12-year-history of SLE was admitted for fever and dyspnea. On physical examination, there was tenderness on right upper quadrant of her abdomen. Cholestasis and cytolysis were found. Abdominal sonography showed a striated and thick gallbladder wall (17 mm). Computer tomography confirmed the gallbladder wall thickness and note pericholecystic edema. Patient was also diagnosed with myocarditis and seritis. A new SLE relapse was obvious and she was treated with prednisone 1 mg/kg/day and azathioprine. The outcome was good and she still is asymptomatic.
Case 4: A 56-year-old-woman was admitted with abdominal pain and fever, limbs paresthesia. Abdominal examination was normal. Biological data showed anemia, thrombopenia and cholestasis. ANA, anti-DNA and anti-Sm were positive. Abdominal sonography showed gallbladder wall thickness and pericholecystic edema. SLE diagnosis with peripheral neuropathy, lupus nephritis, hematological manifestations and ACC was made. Patient was given corticosteroids and cyclophosphamide with good outcome.
Conclusions: Only few cases of AAC complicating SLE are reported. Cholecystitis can be an initial manifestation of SLE and reveal the disease or can occur at any time of the disease course. ACC is always associated to other disease manifestations. Patients present with abdominal pain, vomiting and fever. Ultrasonography and computed tomography confirm the diagnosis. The outcome is good with steroids. Sometimes patients are given antibiotics and/or underwent cholecystectomy because of infectious cholecystisis suspicion. None of our patients had surgery.

AB0538 URINARY LEVELS OF VCAM-1 AND TWEAK AS BIOMARKERS OF LUPUS NEPHRITIS

T. Urrego[1], B. Ortiz-Reyes[1], G. Aroca[2], A.L. Vanegas-García[3,4], A.A. Cadena Bonfanti[2], L. Almendrales[2], C.H. Muñoz[3,4], L.A. González[3], A. Iglesias[2], G. Vásquez[1,3], J.A. Gómez-Puerta[1,3]. *[1]Grupo de Inmunología Celular e Inmunogenética, Universidad de Antioquia, Medellín; [2]Grupo investigación Nefrología, Universidad Simón Bolivar, Baranquilla; [3]Grupo de Reumatología, Universidad de Antioquia; [4]Grupo de Reumatología, Hospital San Vicente Fundación, Medellín, Colombia*

Background: TNF-like WEAK inducer of apoptosis (TWEAK) is able to increase the expression of various molecules involved in the inflammatory response with relevant effects also in angiogenesis. The pathological functions of TWEAK are primarily attributed to its ability to induce the expression of several pro-inflammatory cytokines, chemokines and cell adhesion molecules, including vascular cell adhesion molecule-1 (VCAM-1) (1). Some previous studies (most of them in Caucasic, Afro-American and Asiatic cohorts) have demonstrated clinical utility of VCAM-1 and TWEAK as biomarkers in patients with systemic lupus erythematosus SLE (2).
Objectives: To evaluate the diagnostic value of urinary VCAM-1 and TWEAK in a cohort of Latin-American patients with SLE.
Methods: Patients meeting the revised ACR criteria for SLE were recruited from 2 different centers at Medellín and Baranquilla, Colombia. Urinary levels of VCAM-1 (uVCAM-1) and TWEAK (uTWEAK) were measured using an ELISA kit (R&D system, USA). SLE activity was measured with SLEDAI. Inactive LN was defined by the presence of: 24 hours proteinuria $\leq$500 mg/dl, inactive urine sediments and stable serum creatinine. Mann-Whitney tests were used to compare data and Spearman's rank correlations were used to examine associations.
Results: One hundred and fifty eight SLE patients were recruited (89% female) with median age of 32.8±12.1 years and median disease duration of 7.27±6.6 years. Mestizo (77%) and African Latin-American patients (20%) were majority. Mean SLEDAI score was 8.5±8.7. One hundred and four patients (64%) had lupus nephritis (LN). 76 out of 104 patients had biopsy proven LN, in 62% of cases with proliferative forms. uVCAM-1 and uTWEAK were significantly higher in patients with LN than without LN. At the same time, uVCAM-1 and uTWEAK were significantly higher in patients with active vs inactive LN (Figure). uVCAM-1 (581±1197 vs 189±256 ng/ml, p<0.001) and uTWEAK levels (3202±3778 vs 1123±1873 pg/ml, p=0.038) were significantly higher in patients with Class V LN in comparison with other LN classes. uVCAM-1 and uTWEAK levels had a mild positive correlation with SLEDAI (r=0.22 and r=0.16, respectively). In addition, uTWEAK correlated with 24 hours proteinuria (r=0.28). No significant correlation was found between uVCAM-1 and uTWEAK.

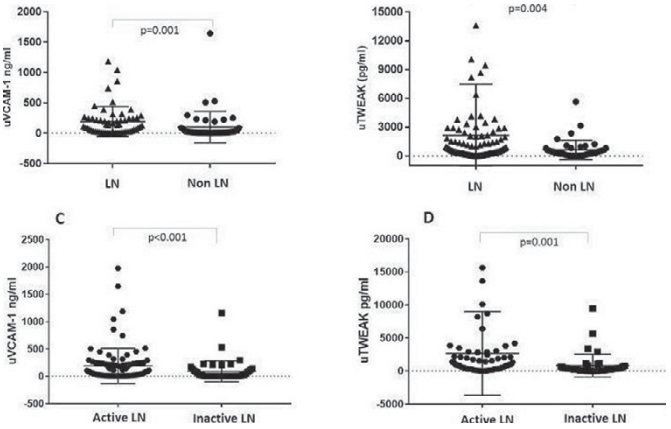

Figure 1. Urinary levels of VCAM-1 and TWEAK in patients with and without LN (A and B) and in patients with active vs inactive LN (C and D).

Conclusions: uVCAM-1 and uTWEAK are useful biomarkers in Latin-American patients with SLE for the identification of patients with LN and active LN. In addition, urinary levels of VCAM-1 and TWEAK were significantly more elevated in patient with membranous LN.

AB0539 DOES ERYTHROCYTE SEDIMENTATION RATE REFLECT DISEASE ACTIVITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATODES? CORRELATION WITH ACUTE PHASE REACTANTS, IMMUNOLOGICAL PARAMETERS AND PROTEINURIA

V.S. Schäfer, K. Weiß, A. Krause, W.A. Schmidt. *Medical Center for Rheumatology and Clinical Immunology Berlin-Buch, Immanuel Krankenhaus Berlin, Berlin, Germany*

Background: Patients with active systemic lupus erythematosus (SLE) are considered to have raised erythrocyte sedimentation rate (ESR) rather than raised C-reactive protein (CRP). Yet published evidence is low for this statement. DsDNA-antibodies, C3 complement, ferritin and proteinuria are also commonly applied to assess SLE.
Objectives: Firstly, to assess how ESR correlates with above mentioned laboratory parameters: in general, in the presence of clinical activity and/or infection or in the absence of both. Secondly, to determine if these parameters are associated with disease flare or infections.
Methods: A retrospective analysis of patients of a tertiary referral centre with SLE who underwent inpatient treatment between 2006 and 2015. Data on laboratory parameters, infection and disease flare, judged by the treating physician, were extracted. Patients were divided in four SLE groups: flare only (n=147), infection only (n=48), both (n=23), and neither infection nor flare (n=153). ESR was correlated to CRP, ferritin, proteinuria, C3-reduction and raised dsDNA-antibodies for the whole cohort and within each SLE group. Further, the association between all laboratory parameters and a) disease activity with and without infection, b) the presence of infection with and without disease activity, was tested.
Results: We identified 203 SLE patients, 26 males, with a total of 371 visits. Mean age was 45.6 years (SD± 16.5 years). Table 1 (top part) shows the correlation

coefficients of ESR with the other laboratory parameters. ESR correlated moderately with CRP amongst all groups (r=0.47–0.58); weakly with ferritin in the general and the flare group (r=0.26); and very weakly with C3-reduction and raised dsDNA-antibodies (r<0.2) in each group. Concerning proteinuria, the correlation was weak for all, for flaring and for silent patients (r=0.22 – 0.35), moderate for patients with both infection and activity (r=0.56). There was no correlation in infected patients (r <0.06). Table 1 (bottom part) displays the p-values for the association of parameters with disease activity or infection, respectively. ESR, reduction of C3, proteinuria and raised dsDNA-antibodies were all associated with disease activity in the whole cohort and in the non-infected group; CRP only in non-infected patients. In the infected group, raised dsDNA-antibodies and proteinuria were the only parameters showing significant relation to disease activity. ESR and CRP were significantly associated with infections when looking at all or at inactive patients, but not in active patients.

Table 1: Correlation of laboratory parameters to ESR and association with disease flare and infection

Parameters	ESR	CRP	Ferritin	C3-reduction	Raised dsDNA-antibodies	Proteinuria
Coefficients for correlation to ESR						
all patients (n=371)		0.498*	0.256*	0.165*	0.134*	0.349*
flare only (n=147)		0.549*	0.268*	0.064	0.101	0.222*
Infection only (n=48)		0.468*	0.109	0.172	0.12	0.056
both (n=23)		0.575*	0.266	0.037	0.205	0.556*
silent (n=153)		0.556*	0.25	0.032	0.082	0.341*
P-value for the association with disease activity						
all patients (n=371)	<0.001 *	0.692	0.405	<0.001*	<0.001*	<0.001*
without infection (n=300)	<0.001*	<0.001*	0.318	<0.001*	<0.001*	<0.001*
with infection (n=71)	0.186	0.321	0.713	0.268	<0.001*	0.007*
P-value for the association with infections						
all patients (n=371)	<0.001*	<0.001*	0.797	0.384	0.023*	0.059
without activity (n=201)	<0.001*	<0.001*	0.642	0.281	0.068	0.088
with activity (n=170)	0.039	0.213	0.576	0.255	1	0.057

Conclusions: Both, ESR and CRP are elevated in patients with SLE flare and are weakly correlated with other laboratory activity parameters. Thus, while normal CRP argues against infection elevation of ESR and CRP is not sufficient to distinguish between SLE flare and infection.

AB0540 ORGAN DAMAGE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

V. Zivkovic[1], B. Mitic[2], B. Stamenkovic[1], S. Milenkovic[1], J. Jovanovic[1], I. Aleksic[1]. *[1]Institute for Treatment and Rehabilitation "Niška Banja", Niska Banja; [2]Clinic of nephrology Clinical centre Nis, Nis, Serbia*

Background: Organ damage in patients with systemic lupus erythematosus (SLE) occurs as the consequence of the disease itself, administered therapy, primarily corticosteroid and cytostatic, as well as the accompanying diseases and complications.

Objectives: Our aim in this paper was to examine the degree of irreversible organ changes in SLE patients using the SLICC/ACR Damage Index (SDI) and to establish the correlation of organ damage with disease activity, quality of life, and severity of fatigue, as well as with the immunological parameters – anti-dsDNA antibodies, anti-nucleosome, anti-C1q antibodies, and MCP1 in the serum and urine.

Methods: The study involved 83 SLE patients (77 women and 6 men), aged 45.8±9.2 years on the average, with average disease duration of 10.6±7.9 years, hospitalized at the Clinic of Rheumatology of the "Niška Banja" Institute, in whom the diagnosis was made based on the revised 1997 ACR criteria. The disease activity was evaluated using the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and a physician's global assessment. The degree of organ damage was evaluated using the SDI. The quality of life was assessed based on The Medical Outcome Survey Short Form 36 (SF-36), and the severity of fatigue was measured using the Fatigue Severity Scale (FSS). The level of antibodies was determined using the ELISA test, and serum and urine MCP1 with the sandwich enzyme immunosorbent assay method according to the manufacturer's instructions (R&D Systems, Inc. Minneapolis, USA).

Results: The mean value of organ damage index in all SLE patients was 1.8±2.0 (median 1, min 0, max 9). Twenty-five (30.1%) patients did not have any organ damage (SDI=0); 21 (25.3%) had SDI=1; SDI=2 or 3 was found in 20 patients (24.1%), and 17 patients (20.5%) had SDI≥4. Neuropsychic and musculoskeletal changes were the most common organ damage manifestations, present in 23 (27.7%) of patients. In 21 patients (25.3%), cardiovascular changes were seen, and ocular lesions in 14 patients (16.9%). Renal and pulmonary changes were found in 13 patients (15.7%), cutaneous changes in 3 patients (3.6%), and gastrointestinal changes in 2 patients (2.4%). In 5 cases (6.0%) malignancies were detected, and diabetes mellitus in 2 patients (2.4%). A statistically significant positive correlation of SDI was established with age (r=0,348, p=0,001), disease duration (r=0,412, p<0,001), SLEDAI (r=0,359, p=0,001), global physician's assessment (r=0,357, p=0,001) and fatigue (r=0,296, p=0,007), and a negative correlation with quality of life (r=-0,386, p<0,001). There were no correlations of SDI with the level of anti-dsDNA, anti-nucleosome, anti-C1q antibodies, nor with serum and urine MCP1 levels.

Conclusions: Musculoskeletal, neuropsychic, and cardiovascular changes were the ones most commonly seen. Organ damage positively correlated with age and disease duration, a higher disease activity, poorer quality of life, and more severe fatigue.

AB0541 CO-MORBIDITY STATUS IN SYSTEM LUPUS ERYTHEMATOSUS PATIENTS

V. Dostanko[1], V. Yagur[2], N. Dostanko[2], K. Chizh[2]. *[1]Infomed; [2]2-d Department of Internal Medicine, BSMU, Minsk, Belarus*

Background: The improved survival of patients with Systemic Lupus Erythematosus (SLE) over the past decades highlighted the problem of co-morbidity (several different chronic pathologies presence) in SLE patients because many of them reach the age when the burden of concomitant diseases could increase and become ordinary.

Objectives: To evaluate the frequency of concomitant diseases and to estimate the total co-morbidity status in SLE patients.

Methods: The retrospective study of co-morbidity in SLE patients was conducted on the database of Byelorussian Republican Rheumatologic Center. It included 212 patients: 192 women and 20 men at the age of 16.1 to 68.3 (mean ± SD: 33.2±12.3 years) at the baseline (first visit). The diagnosis of SLE was in conformance with 1997 ACR modified classification criteria for SLE [1]. The comprehensive assessment of patient co-morbidities was performed by Kaplan-Feinstein co-morbidity index (KFI) [2] which includes twelve pathology categories: arterial hypertension (HT), heart disease (HD) presence, nervous system (ND) involvement, respiratory system (RD) pathology, vascular (VD), kidney (KD), liver (LD) gastrointestinal (GID) and musculoskeletal (MSD) diseases, other pathology (OD), malignancies and alcoholism. A co-morbidity score of 1 indicates low level of co-morbidity, 2 - moderate and 3 - high level of co-morbidity for corresponding pathology. The possible grade of co-morbidity is calculated as a sum score for all categories and varies from 0 to 36 points.

Results: KFI in SLE patients at the first visit varied from 0 to 7 points (Me: 2; 25–75% range: 0–3) and had minor differences in age and sex groups (NS, Fisher's exact test). One-third of patients (n=68) had no co-morbidities.

One of the most common pathology was HT which was diagnosed in 39 patients (18.4%, 95% CI 5.6–26.7%): 34 women and 5 men (p=0.591, NS, Fisher's exact test). Over the 13-year follow-up period the frequency of HT dramatically increased to 52.9% (95% CI 37.0–68.0%) i.e. 2.9 times vs baseline (p<0,001). Prognostic odds ratios (pOR) of HT were 7.6 (95% CI 3.1–18.2) and 3.2 (1.4–7.6) for lupus nephritis presence and signs of glucucorticoid disease ("cushingoid"), correspondingly.

Other common co-morbidities were GID and HD. Coronary HD and congestive heart failure were revealed in 43 (20.3%) patients. GID were registered in 44 (20.8%) patients, among them 9 (4.2%) patients had gastric/duodenal ulcer. VD, ND and RD were revealed in 7 (3.3%) patients for each category, KD and LD frequency was 6 (2.8%) for both pathology. MSD were registered in 8 (3.8%) and OD, including different infections, anemia, diabetes etc. were registered in 39 (18.4%) patients. There were no cases of malignancies or alcoholism in our patients.

Conclusions: Total co-morbidity status revealed in SLE patients at baseline varied up to the 20 percent of the maximal possible level for all age and sex groups. Arterial hypertension was one of the most common pathology which demonstrated significant and predictable growth over the 13-year follow-up period.

AB0542 PRESENTATION AND OUTCOME OF LUPUS NEPHRITIS IN THE MULTICULTURAL SOCIETY OF WESTERN AUSTRALIA – A SINGLE CENTRE EXPERIENCE

W.D. Raymond[1], K. Minas[2], L. Tyack[2], B. Wong[2], A. Douglas[2], A. Kang[3], D. Wong[3], A. Chakera[1,2], J. Nossent[1,4]. *[1]School of Medicine & Pharmacology, University of Western Australia; [2]Renal Medicine; [3]Pathology; [4]Rheumatology, Sir Charles Gairdner Hospital, Perth, Australia*

Background: Lupus Nephritis (LN) is one of the most severe complications that can occur in patients with Systemic Lupus Erythematosus (SLE) as it increases the risk of renal failure, comorbidity and death. As with SLE, there is a significant impact of ethnicity on LN severity and outcome.
Objectives: To investigate the impact of ethnicity of LN presentation and health outcomes in a tertiary referral centre in Western Australia.
Methods: Single centre retrospective cohort study of 104 patients with biopsy confirmed lupus nephritis (LN) collating clinical characteristics, renal histopathology, serology, medication use, disease activity (Systemic Lupus Erythematosus Disease Activity Index - 2K (SLEDAI-2K)), organ damage (SLICC-Damage Index (SDI)), and clinical outcomes from index biopsy event to the last visit. Outcomes included the high serum creatinine ($\geq$150 umol/L), low eGFR ($<$50%), the need for renal replacement therapy (RRT), and death. Outcomes were assessed across ethnicity with comparative statistics, Chi-square, and survival analysis.
Results: Asian (n=17, 16.3%), Caucasian (n=79, 76.0%) and Indigenous (n=8, 7.7%) patients were similar for age (p=0.149), gender (p=0.309) and SLEDAI-2K (8.5 vs. 9.0 vs. 13.0, p=0.897), non-renal SLEDAI-2K (10.5 vs 2 vs. 1, p=0.528). Time to biopsy from the initial SLE diagnosis was shorter in Asian and Indigenous patients (p=0.055). At the index biopsy, ethnic groups were similar for WHO Class distribution (predominantly Classes 3 and 4, p=0.345) and clinical signs of renal disease (the presence of haematuria, proteinuria, pyuria and/or red cell casts) (p=0.874). Indigenous patients trended towards higher creatinine (66.0 vs 71.0 vs. 101.5, p=0.214), lower eGFR (60% vs. 60% vs. 32.5%, p=0.076), lower C3 (0.67 vs. 0.65 vs. 0.47g/L, p=0.375) and C4 (0.15 vs 0.12 vs 0.03g/L, p=0.272), and higher anti-dsDNA antibody levels (16.0 vs 26.5 vs 520.0, p=0.81), albeit non-significantly (due to low numbers).
At the last follow-up, 6.4 years (IQR 3.8, 12.4) after the index biopsy, 10%, 30% and 12.5% of Asian, Caucasian and Indigenous patients had high serum creatinine levels ($\geq$150 umol/L) (p=0.434) and 10%, 28.9% and 25.0% had low eGFR ($<$50%) respectively. Chronic renal replacement therapy (RRT) was needed in 0%, 5.1%, and 12.5%, respectively (p=0.386), while death occurred in 0%, 8.7% and 25.0%, respectively (p=0.115). Indigenous patients had the poorest survival rates at 1, 5 and 10 years compared to Caucasian patients (p=0.002).
Conclusions: This interim analysis demonstrated that Asian patients had a better prognosis regarding serum creatinine, eGFR, commencement of RRT and mortality, compared to Caucasian and Indigenous patients. Indigenous patients were both over-represented in this cohort and showed poorer prognosis in terms of RRT and mortality rates compared to Asian or Caucasian patients in WA.

AB0543 ANXIETY AND DEPRESSION IN CHINESE PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

Y. Cui[1], L. Li[1], Q. Zhao[1], S. Chen[1], L. Li[2], Z. Gu[1]. *[1]Department of Rheumatology, Affiliated Hospital of Nantong University; [2]School of Nursing, nantong University, Nantong, China*

Background: Primary Sjögren's syndrome (pSS) is a multisystem autoimmune disorder characterised by lymphocytic infiltration and exocrine failure of salivary and lacrimal glands, resulting in the classical symptoms of the disease including xerostomia (dry mouth) and keratoconjuctivitis sicca (dry eyes). pSS has the potential to impair both psychological state and the health-related quality of life (HR-QOL). A common mental health problem among adults with pSS is anxiety and depression. In addition, depression is more common in pSS than in the general population and has been associated with enhanced fatigue, reduced health-related quality of life, increased levels of physical disability and increased health care costs. Besides, depressed pSS patients have poorer long-term outcomes, including more complications. Anxiety was more common than depression in pSS. The most affected domains were vitality in the SF-36 and general/physical fatigue in the MFI. Extraglandular systemic involvement was not a major determinant of QoL alteration in patients with pSS.
Objectives: Prevalence of anxiety and depression are high in women with Primary Sjögren's syndrome (pSS). Our aim was to compare anxiety and depression in pSS patients and healthy controls and evaluate its relationship with the disease activity, sleep and quality of life; as well as to analyze potential determinants of anxiety and depression.
Methods: Sixty-seven patients fulfilling the American-European Consensus Group criteria for pSS (mean age 52.76 years (s.d. 13.16)) and 42 age-matched healthy controls were included. Participants completed self-administered questionnaires, namely Hospital Anxiety and Depression Scale (HADS), Short Form 36 (SF-36) scores and the Pittsburgh Sleep Quality Index (PSQI). In addition, the European League Against Rheumatism Sjögren's Syndrome Disease Activity Index (ESSDAI); Patient Reported Index (ESSPRI) and systemic inflammation (erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) level) were recorded in patients. Independent samples t-tests, $\chi 2$ analyses and logistic regression modeling were used to analyze the data.
Results: pSS patients experienced greater anxiety and depression than controls (HADS-A scores: mean± SD 6.5±3.4 for pSS versus 3.8±3.4 for controls; P =0.002. HADS-D scores: mean± SD 6.7±4.1 for pSS versus 4.2±3.5 for controls; P =0.012). And there were significant correlations among fatigue, pain, disease activity, dryness, sleep, quality of life and anxiety/depression. Meanwhile, logistic regression analysis revealed that poor quality of life and ESSPRI were significantly associated with anxiety/depression in pSS patients.
Conclusions: The study suggests that optimal care of pSS patients may include the detection and management of anxiety and depression. Early recognition and appropriate intervention is therefore essential to reduce the negative impact of anxiety and depression on the patient's quality of life and outcome of their disease.

AB0544 LEVELS OF VITAMIN D IN A COHORT OF PATIENTS WITH SYSTEMIC LUPUS ERITHEMATOSUS. RELATIONSHIP WITH DISEASE ACTIVITY AND BONE MASS

Y. Garcia-Mira, S. Heredia, M. Martínez-Morillo, L. Gifre, A. Prior-Español, J. Camins, J. Cañellas, S. Holgado, L. Mateo, A. Olivé. *Hospital Universitari Germans Trias i Pujol, Badalona, Spain*

Background: Vitamin D (vit D) is an immunoregulatory hormone which seems to mediate immune tolerance. Several studies have suggested that vit D deficiency may be related to increased disease activity in patients with systemic lupus erythematosus (SLE).
Objectives: To analyze 25-hydroxyvitamin D (25-OHD) levels in a cohort of patients with SLE and to investigate their relationship with clinical, analytical, immunological and densitometric parameters.
Methods: Prospective study including patients with SLE (according to SLICC criteria 2013) performed in an Academic Hospital with a referral area of 800.000 inhabitants. 152 patients with SLE were included (138 women [46 postmenopausal]/14 men) with a mean age of 46±12 years (range: 20–75). Clinical parameters (including risk factors for osteoporosis, presence of skeletal fractures, treatment with glucocorticoids (GCC) as well as SLE involvement including haematologic, renal, neurological and skin), biochemical determinations (including 25-OHD, parathormone (PTH)), immunological (ANA, DNA and complement) and SLE activity and severity (assessed by SLEDAI and SLICC index) were assessed in all patients. Bone mineral density was performed by DXA (at lumbar spine and proximal femur). Vit D deficiency was defined as 25-OHD values under 20 ng/mL. Low bone mass was considered as T or Z scale $<$-1 SD; and osteoporosis as T $<$-2.5 SD [age$>$50 years] or Z $<$-2 SD [age $<$50 years]. The study was approved by the Clinical Research Ethics Committee and all patients provided informed consent to participate. Statistical analysis was performed by SPSS.20.
Results: The mean values of 25-OHD were 19.8±11.4 (range, 4.2–66.6). 87.5% of patients had 25-OHD levels below 30 ng/mL, 61.2% below 20 ng/mL and 15.1% below 10 ng/mL. The lowest values were in winter (80%) and spring (64.3%). 42.8% of patients received vitamin D supplements. 56.5% of patients had low bone mass (T or Z scale $<$ -1 SD), and 15.8% had osteoporosis. Levels of 25-OHD showed no correlation with SLE disease activity (complement, Ac antiDNAds, SLICC/SLEDAI) neither with bone mass by DXA. Patients with low bone mass (T or Z $<$-1 SD scale) were older (at the time of inclusion and age of SLE diagnosis), had higher SLICC and lower complement levels whereas no differences were observed in SLEDAI and 25-OHD values. 37.5% of the patients were treated with GCC. Patients without GCC treatment had higher prevalence of vit D deficiency (73.9% vs. 55.6%, p=0.034) compared to patients with GCC treatment.
Conclusions: 61.2% of patients with SLE have 25-OHD deficiency, which is more frequent in winter and spring, and mostly in those patients without GCC treatment. 25-OHD values showed no correlation with the disease activity and damage. However, patients with low bone mass had higher SLICC and hypocomplementemia. Thus, our results suggest the need to perform clinical guidelines to assess bone mass and bone metabolism in this clinical condition. Additionally, we recommend quantifying vit D levels in winter/spring and don't forget to assess those patients without GCC treatment.

AB0545 EFFECT OF EMPATHY NURSING ON THE LIFE QUALITY OF THEPATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Y. Wen[1], L. Yan[1], L. LiMin[2]. *[1]Department of Rheumatology; [2]Nursing department, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Background: The patients with Systemic Lupus Erythematosus always had sub-health status in psychology and been troubled by the chronicity of the disease. Empathy nursing is an effective treatment for chronic disease such as cancer or terminal patients.

Objectives: To investigate the effect of empathy nursing on the life quality of patients with Systemic Lupus Erythematosus (SLE).
Methods: 120hospitalized patients with SLE admitted from January 2014 to December 2016 were divided into the control group and the experimental group for 60 people in each randomly. The control group was given routine care and the experimental group was given additional empathy care for 6 months. The World Health Organization Quality of Life (WHOQOL-BREF) Chinese version was evaluated on the 2nd day of hospitalization and 6 months after discharge respectively.
Results: Before intervention, the life quality of the two groups was poor. The scores of the control group and the experimental group in each field had no statistic difference (44.13±16.72 vs 44.08±17.33 in physiology, 51.13±14.38 vs 52.01±13.87 in psychology, 58.12±15.33vs 56.71±8.12in social relation, 54.93±13.2 vs 55.33±11.78 in environment and 52.52±15.6vs 52.03±13.44 overall), ($P>0.05$). After the intervention, the scores of the WHOQOL-BREF scale in the two groups were improved to different extents ($P<0.05$) (59.33±13.76 vs 66.77±16.21 in physiology, 57.43±7.88 vs 64.55±11.76 in psychology, 65.22±13.34 vs 72.11±8.12 in social relation and the overall scores were 59.95±14.32 vs 67.89±6.42).The scores of the four dimensions in physiology, psychology, social relations and environment were significantly different from those before the intervention ($P<0.05$). The improvement of the scores in physiology, psychology, social relations in the experimental group was more obvious than the control group ($P<0.05$).
Conclusions: Empathy nursing can obviously improve the life quality of SLE patients, and it is worthy to be popularized.

AB0546 CLINICOPATHOLOGICAL CHARACTERISTICS OF SJÖGREN'S SYNDROME IN THE PRESENCE OR ABSENCE OF OBJECTIVE SICCA SYMPTOMS

Y. Suzuki[1,2], H. Fujii[1], K. Yamada[1], M. Kawano[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Kanazawa University Graduate School of Medicine; [2]Division of Nephrology and Rheumatology, Department of Internal Medicine, Ishikawa Prefectural Central Hospital, Kanazawa, Japan*

Background: Sjögren's syndrome (SS) is generally diagnosed on the basis of objective criteria, including xerophthalmia, xerostomia, autoantibodies, and labial salivary gland biopsy. Patients without objective sicca symptoms (non-sicca SS) require a biopsy. For such patients, we should evaluate pretest probability using parameters other than sicca symptoms before performing an invasive biopsy. To assess pretest probability, data on clinicopathological characteristics of non-sicca SS are needed.
Objectives: This study aimed to analyze the clinicopathological features of non-sicca SS. Epidemiological data, antibody profiles, organ involvement, and labial salivary gland biopsy results in non-sicca SS patients were compared with those in SS patients with objective sicca symptoms (sicca SS).
Methods: We selected 103 patients with primary SS who met Japanese or American College of Rheumatology criteria; those whose results exceeded the focus score by 1 underwent salivary gland biopsy. Objective xerophthalmia was evaluated with the Schirmer's test, and objective xerostomia with the Saxon's test. Seventeen patients were excluded because neither test was performed. Sicca SS was defined as a positive Schirmer's and/or Saxon's test result. Clinical and laboratory data were compared in 70 sicca SS and 16 non-sicca SS patients.
Results: Non-sicca SS patients were younger at diagnosis (45.9±14.8 vs. 61.4±15.1 years, $p<0.001$), had a shorter disease duration (1.1±1.5 vs. 6.9±8.9 years, $p<0.001$), and had a higher rate of positive anti-SS-A/Ro antibody (100 vs. 74.3%, p=0.023), and a lower rate of positive anti-centromere antibody (6.3 vs. 44.3%, p=0.005). Subjective xerophthalmia and xerostomia rates were similar between the groups, but fewer non-sicca SS patients had sicca symptoms as chief complaints (18.8 vs. 58.6%, p=0.004). There were no significant differences in focus score, leukocyte and lymphocyte counts, serum IgG levels, and positive rheumatoid factor and antinuclear antibody levels. The maximum European League Against Rheumatism Sjögren's Syndrome Disease Activity Index (ESSDAI) score during follow-up showed no significant difference (3.34±4.27 in non-sicca SS vs. 3.83±4.68 in sicca SS, p=0.30). However, more non-sicca SS patients had ESSDAI scores ≥ 1 (100 vs. 71.4%, p=0.015), a positive correlation with the biological domain of the ESSDAI (87.5 vs 58.6%, p=0.03), and articular symptoms (37.5 vs 8.6%, p=0.003).
Conclusions: Non-sicca SS patients were younger, had shorter disease duration, and a higher rate of positive correlation with the biological and articular domains of the ESSDAI. Moreover, all non-sicca SS patients had ESSDAI scores ≥ 1. When we diagnose SS patients without objective sicca symptoms, we should assess age, disease duration, and extraglandular organ involvement before performing labial salivary gland biopsy.

AB0547 THE PREVALENCE AND THE RISK FACTOR OF HYPERTENSION AND DYSLIPIDEMIA IN SYSTEMATIC LUPUS ERYTHEMATOSUS PATIENTS: EXPLORATORY RESEARCH

Y. Miura[1], M. Saito[1], K.-E. Sada[2], N. Yajima[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Showa University School of Medicine, Shinagawa-ku, Tokyo; [2]Department of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama City, Japan*

Background: Hypertension (HT) and dyslipidemia (DL) are the risk factors for all-cause mortality, cardiovascular and cerebrovascular disease, and end-stage renal disease in SLE patients [1)]. Neither disease activity nor chronic damage were associated with the metabolic syndrome in SLE patients [2)] and there were few reports about the risk factors of HT and DL in Japanese SLE patients.
Objectives: We aimed to describe a prevalence of HT and DL and to identify the risk factor of HT and DL in Japanese SLE patients.
Methods: All SLE patients visited at Showa University Hospital and Okayama University Hospital from January 2016 to September 2016, were enrolled in a cross-sectional study. SLE patients who satisfied American College of Rheumatology (ACR) criteria were included. HT was defined as usage of anti-HT drugs and DL was defined as usage of anti-DL drugs. We performed descriptive statistics and binomial logistic regression analysis to identify the risk factors of HT and DL. Variables considered possible risk factors were BMI, drinking status, smoking status (current smoking), current daily dose of glucocorticoids, past maximum dose of glucocorticoids, lupus nephritis, Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K), and Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SLICC/ACR-DI).
Results: In total, 244 participants were enrolled. The mean age was 46.2±15.3 years, and 222 (91%) were female. The mean current daily dosage of glucocorticoids was 6.7±5.9 mg, and the mean SLEDAI-2K was 5.0±5.2 and the mean SLICC/ACR-DI was 1.3±1.7. The prevalence of HT and DL were 29.1% (71/244) and 22.1% (54/244). Both HT and DL were confirmed in 11.9% (29/244) patients. On binomial logistic regression analysis, BMI (regression coefficients (β)= -0.095; 95% confidential interval (CI) = -0.173 to -0.020), drinking status (β =0.443; 95% CI =0.000 to 0.879), past maximum dosage of glucocorticoids (β= -0.018; 95% CI = -0.036 to -0.004) and lupus nephritis (β= -0.727; 95% CI =0.230 to 1.241) were identified as the significant independent risk factors of HT. On the other hand, only age (β= -0.030; 95% CI = -0.055 to -0.006) was identified as the independent risk factor of DL. There was no independent risk factor of having both DL and HT.
Conclusions: Our results could help to identify patients at higher risk of HT and DL.

AB0548 CIRCULATING PROLACTIN LEVEL IN SYSTEMIC LUPUS ERYTHEMATOSUS AND ITS CORRELATION WITH DISEASE ACTIVITY: A META-ANALYSIS

Y.H. Lee, Y.H. Seo. *Rheumatology, Korea University Medicial Center, Seoul, Korea, Republic Of*

Background: Prolactin has an immune stimulatory effect and may promote autoimmunity by encouraging the development of antigen presenting cells expressing MHC class II and co-stimulatory molecules and modulating IFN-γ secretion.
Objectives: This study aimed to evaluate the relationship between circulating prolactin level and systemic lupus erythematosus (SLE), and to establish a correlation between plasma/serum prolactin levels and SLE activity.
Methods: We performed a literature search for studies that examined prolactin status in SLE patients and controls, and the relationship between circulating (serum or plasma) prolactin levels and SLE using PUBMED, EMBASE, and Cochrane databases. We conducted a meta-analysis comparing the plasma/serum prolactin levels in patients with SLE to controls, and examined correlation coefficients between circulating prolactin level and SLE disease activity.
Results: Twenty-five studies with a total of 1,056 SLE patients and 426 controls were included. Prolactin levels were significantly higher overall in the SLE group than in the control group (SMD =0.987, 95% CI =0.512 – 1.463, $p=4.7\text{x}10^{-5}$). Stratification by ethnicity showed significantly elevated prolactin levels in the SLE group in Asian, Latin American, and mixed populations (SMD =0.813, 95% CI =0.137 – 1.490, p =0.018; SMD =0.981, 95% CI =0.307 – 1.655, p =0.004; SMD =1.469, 95% CI =0.443 – 2.495, p =0.005, respectively), but not in the European population. Meta-analysis of correlation coefficients showed

a significantly positive correlation between circulating prolactin level and SLE activity (Correlation coefficient =0.379, 95% CI =0.026–0.487, p=4.0x10^{-9}).
Conclusions: Our meta-analysis demonstrated that circulating prolactin levels are higher in patients with SLE and that a significantly positive correlation exists between prolactin levels and SLE activity.

Vasculitis

AB0549 DEMOGRAPHIC FEATURES AND CLINICAL ASPECTS OF BEHÇET'S DISEASE IN OMANI PATIENTS

A.S. Al Ghafri, H. Al Wahshi. *Rheumatology, Royal Hospital, Muscat, Oman*

Background: Behçet's disease (BD) is a chronic, relapsing, multi-system vasculitis of unknown aetiology. Few reports support the hypothesis that BD has a primarily hereditary basis. It complicated diversified clinical features predominantly involving oral and genital ulcers, ocular and cutaneous lesions. The clinical features of this disease have been described to be different according to geographical areas and gender.
Objectives: The objective of the study is to explore the demographic features and clinical aspects of BD in Omani patients.
Methods: 56 BD patients were recruited and clinical data parameters were recorded including age, sex, age at diagnosis, duration of symptoms till diagnosis, disease characteristics such as oral and genital ulcers, ocular manifestations, the presence of arthritis and cutaneous lesions such as papulopustular lesions and erythema nodosum. Furthermore, other systemic involvement was studied including gastrointestinal, neurological & vascular manifestations. Laboratory tests of BD and treatment used were recorded in each patient.
Results: The onset was between 6–74 years with a male predominance. Oral ulcers were the most common manifestation, followed by genital ulcers, ocular lesions and arthritis. Vascular lesions and GI manifestations were less common. Cutaneous manifestations were rare in patients with BD. The frequency of neurological involvement was significantly high. There were no reported cardiac or urogenital manifestations.
Conclusions: There are quite significant clinical geographical and gender differences among BD patients in which genetic and immunological factors might participate it's aetiopathogenesis.
Acknowledgements: The authors thank Department of research, Oman Medical Specialty Board, Muscat, Oman, for their excellent technical assistance.

AB0550 AN AUDIT OF BEHCET'S SYNDROME RESEARCH: RECENT 6 YEARS

A. Murt[1], A. Ercaliskan[1], H. Yazici[2]. *[1]Internal Medicine, Cerrahpasa Medical Faculty; [2]Rheumatology, Academic Hospital, Istanbul, Turkey*

Background: A previous audit by our group of Behçet's syndrome (BS) research, published in 2011 (1) had revealed a list of problems related to research methodology. They were mainly the relative lack of prospective studies, proper use of control groups, a marked under utilization of power calculations where needed and a paucity of studies reporting negative results.
Objectives: We have reassesed the same items as in the previous survey in articles about BS since published. An additional item looked at was self criticism in manuscript preparation (2).
Methods: Original articles from 15 highest impact factor journals of internal medicine, rheumatology, dermatology and ophtalmology between January 2010 and February 2016 were analyzed by two observers. Study designs, presence of necessary control groups, power calculations and reporting of negative outcomes were tabulated. Presence of self-criticism was assessed both by reading and specific word scanning. Discrepansies between the observers was reconciled in a joint session of all 3 authors.
Results: A total of 188 articles, 149 (79%) clinical and 39 (21%) basic, were analyzed. Of 94 studies in which a time-element classification was appropriate; 14% were prospective, 57% cross-sectional and 29% retrospective studies. There were only 3/188 controlled trials. Out of 71 studies in which the study design necessitated control groups, 69 (97%) had healthy and 30% had diseased while 2 did not have any control groups. 50 of the same 71 studies were about genetic association and 13 (26%) had diseased controls in addition to the usual healthy controls. Out of 107 studies in which power calculations were necessary, only18 (16%) gave power calculations. Of these 13 were belonged to 50 (26%) of the genetic association studies and 3/3 to the controlled drug trials. Among 107 studies in which a negative outcome could be expected only 12 studies (11%) reported scuh outcomes. Finally, by electronic scannnig, a limitation acknowledgement was present in 92/188 (49%) of articles [76/149 (51) for clinical and 16/39 (41%) for basic]. When self critique was assesed by text reading these percentages increased to 113 (60%) for total, 93 (62%) clinical and 20 (51%) for basic science studies.
Conclusions: Similar methodological problems seem to exist in current BS research as compared to what we had noted 6 years ago. The relative lack of basic science articles (21%) in a condition with a yet unknown cause (s) and the paucity of controlled clinical trials with the recent much increased avaliability of biologics are particularly worrisome. On the other hand; there was an increased inclusion of diseased controls in genetic association studies, 26% in the current and 13% in the former surveys. Similarly, an optimistic note might be that the currrent survey showed basic research in BS included more self-criticism (41–51%) as compared to what was noted among the general rheumatology manuscripts (15–20%) (2).

AB0551 THE IMPACT OF TEMPORAL ARTERY BIOPSY ON DIAGNOSIS OF GIANT CELL ARTERITIS IN CLINICAL PRACTICE

E. Kaltsonoudis[1], D. Kirochristos[2], A. Bai-Papoudou[3], P. Voulgari[3], A.A. Drosos[3]. *[1]Rheumatology Clinic, Department of Internal Medicine, Medical School, University of Ioannina; [2]Department of Surgery, University Hospitasl of Ioannina, Department of Surgery; [3]Rheumatology Clinic, Department of Internal Medicine, Medical School, University of Ioannina, Medical School, University of Ioannina, Ioannina, Greece*

Background: Temporal artery biopsy (TAB) is the current gold standard for diagnosis of giant cell arteritis (GCA). Clinical manifestations of GCA include cranial symptoms, features of polymyalgia rheumatica (PMR), fever of unknown origin (FUO) and large vessel involvement, following by elevation of C- reactive protein (CRP) and erythrocyte sedimentation rate (ESR). In these patients TAB confirms diagnosis.
Objectives: In the current study the impact of TAB on diagnosis of GCA in a large number of patients is presented.
Methods: 245 patients who had undergo TAB were evaluated. All patients were more than 50 years old and were admitted in a tertiary University Hospital during the period 2006–2016. More specifically 164 were admitted in the division of internal medicine (DIM), 53 in the rheumatology clinic (RC), 6 in the eye clinic (EC) and 3 in the neurology clinic (NC). All the clinical and laboratory data were recorded and analyzed appropriately.
Results: The mean age of the patients was 68,6±5,6 year and 61,5% were women. 49/245 patients had positive TAB (21,17%). More specifically 5/6 positive TAB (83,3%) were ordered by the EC with signs of visual disturbances, mainly visual loss, diplopia and headache. 12/56 positive TAB (22,6%) were ordered by the RC with clinical features of headache and PMR. 31/164 (18,9%) with positive TAB were ordered by DIM with clinical signs of PMR, FUO and anemia of chronic disease and finally 1/3 with positive TAB (33,3) were ordered by the NC with clinical features of severe headache. All patients with positive TAB had elevated levels of CRP and ESR.
Conclusions: In elderly patients with cranial symptoms, visual disturbances, PMR, FUO and raised acute phase reactants, the possibility of GCA is very high and TAB is necessary to confirm diagnosis.
Disclosure of Interest: None declared

AB0552 ANTIPHOSPHOLIPID ANTIBODIES IN GIANT CELL ARTERITIS

A. Hocevar, R. Jese, Z. Rotar, P. Zigon, S. Cucnik, M. Tomsic. *Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia*

Objectives: The aim of our prospective study was to evaluate the role of antiphospholipid antibodies (aPL) on the clinical presentation of giant cell arteritis (GCA).
Methods: GCA patients diagnosed for the first time between 1. September 2011 and 31. December 2016 at our secondary/tertiary rheumatology center and in whom aPL-Abs were determined at presentation were included. We studied four types of aPL-Abs in patient's sera: lupus anticoagulants (LA), IgG and IgM isotype of anticardiolipin antibodies (aCL), of antibodies to β2-glycoprotein 1 (aβ2GP1) and of antibodies to phosphatidylserine-prothrombin complex (aPS/PT). LA activity was determined only in patients not receiving anticoagulant therapy. A dilute Russell viper venom time test was used and a ratio above 1.2 was considered positive. aCL, aβ2GPI and aPS/PT were measured using an in-house ELISA. A value above the 99th percentile of healthy control population was taken as positive.
Results: During the 64-month observation period we performed all aPL-Abs tests in 121 GCA patients (81 females (66.9%); median (IQR) age 73.8 (66.4; 78.7) years). We found LA, aCL, aβ2GP1 and aPS/PT in 59 (48.8%), 55 (45.5%), 15 (12.4%) and 18 (14.9%) cases, respectively. Fifty-four patients (44.6%) were single, 25 (20.7%) double, 13 (10.7%) triple and 1 (0.8%) quadruple aPL-Abs positive. 28 patients (23.1%) were aPL-Abs negative. Clinical characteristics of individual aPL-Ab type groups are presented in Table 1. There was one case of

concurrent venous thrombotic event in our group (in a patient without aPL-Abs). The presence of aCL was associated with extracranial large vessel vasculitis (RR 1.8 (95% CI 1.1–2.9)). Double- or triple-positivity for any combination of "classic" aPL (LA and/or aCL and/or abeta2GP1) emerged as a marker of severe visual manifestations (RR of 2.1 (95% CI 1.1–4.3) for permanent or transient visual loss in case of double or triple aPL positivity vs. LA, aCL and aβ2GP1 negative cases). At least 1 year follow-up data (median (IQR) of 103 (54; 105) weeks) were available for 73 patients. 32 patients (43.8%) relapsed, most frequently those with positive aβ2GP1 (62.5%).

Table 1. GCA and aPL

	All GCA	aPL	aCL positive	aB2GPI positive	aPS/PT e positive	LA positive
Number of cases	121	28	55	15	18	59
Female (%)	66.9	67.9	72.7	60.0	66.7	66.1
General symptoms (%)	76.0	67.9	78.2	66.7	66.7	81.4
Headache (%)	69.4	82.1	61.8	66.7	61.1	71.2
Jaw claudication (%)	42.1	46.4	43.6	33.3	22.2	44.1
Visual symptoms (%)	24.0	35.7	20.0	13.3	22.2	16.9
PVL or TVL (%)	12.4	14.3	16.4	13.3	5.6	11.9
PMR (%)	14.0	14.3	16.4	6.7	22.2	11.9
Stroke (%)	2.5	3.6	3.6	0	0	0
Venous thrombosis (%)	0.8	3.6	0	0	0	0
LVV (CDS) (%)	38.8	38.5	50.9	33.3	17.6	31.0
TA CDS (%)	80.2	78.6	74.5	80.0	88.9	79.7
TAB (%)	83.0	86.4	92.5	76.9	84.6	76.6
ESR (mm/h)#	86 (65; 110)	75 (61; 95)	83 (64; 107)	108 (94; 115)	88 (71; 118)	94 (73; 116)
CRP (mg/l)#	73 (45; 134)	62 (36; 124)	69 (44; 106)	95 (66; 164)	65 (52; 117)	113 (65; 170)
Relapse during follow up (%)	43.8	47.1	38.2	62.5	30.0	45.5

Legend: aPL antiphospholipid antibodies; TVL transient visual loss (amaurosis fugax); PVL permanent visual loss; TA temporal artery; TAB temporal artery biopsy; CDS color Doppler sonography; LVV large vessel vasculitis; ESR erythrocyte sedimentation rate; CRP C-reactive protein; #median (IQR).

Conclusions: Our results indicate that aCL could identify GCA patients with extracranial large vessel disease. The double- or triple-positivity for any combination of LA and/or aCL and/or aβ2GP1 seems to be a marker of severe visual manifestations.

AB0553 UPDATED SYSTEMATIC REVIEW 2016: EFFICACY AND SAFETY OF BIOLOGICAL THERAPY COMPARED TO SYNTHETIC IMMUNOSUPPRESSANTS OR PLACEBO IN THE TREATMENT OF UVEITIS ASSOCIATED WITH BEHÇET'S DISEASE

A. Urruticoechea-Arana[1], T. Cobo-Ibáñez[2], V. Villaverde García[3], M. Santos Gómez[1], K. Vargas-Osorio[4], L. Fariñas-Padrón[4], F. Díaz-González[5], V. Calvo-Río[6], R. Blanco-Alonso[6]. *[1]Rheumatology, Can Misses Hospital, Ibiza; [2]Rheumatology, University Hospital Infanta Sofía, Madrid; [3]Rheumatology, University Hospital of Móstoles, Móstoles; [4]Family and Community Medicine, Can Misses Hospital, Ibiza; [5]Rheumatology, Hospital of the Canary Islands, Islas Canarias; [6]Rheumatology, University Hospital of Marqués de Valdecilla., Santander, Spain*

Background: Systematic treatment used in ocular involvement of Behçet's disease are corticosteroids, synthetic and biological immunosuppressants. The possible irreversible ophthalmological complications make it a priority to know the efficacy of these drugs.

Objectives: To analyze the efficacy and safety of biological therapy vs. Cyclosporin A (CsA), azathioprine (AZA), or placebo in reducing the number of uveitis relapses and improving visual prognosis in patients with Behçet.

Methods: Systematic search of the literature in MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials from its inception until August 22, 2016. In additional manual search in international conferences and in the references of included studies. Selection criteria: 1) adults with Behçet's disease and uveitis, 2) Biological therapies, 3) placebo or active comparator with CsA or AZA, 4) outcome measures to evaluate efficacy: number of recurrence of uveitis, visual prognosis, cystic macular edema, retinal vasculitis, vitritis, hypopyon and or adverse events. Meta-analyses, systematic reviews, clinical trials, and observational studies of >10 control patients were included. The selection, review and evaluation of the quality of the articles was carried out by 2 independent reviewers. The Oxford scale was used to determine the quality of studies.

Results: Of 256 articles, 9 met the inclusion criteria: 3 retrospective observational and 6 randomized clinical trials in 378 patients with Behçet and refractory uveitis to synthetic corticosteroids and/or immunosuppressants. The age range was 9–63 years, with male dominance and a follow-up period of 6–36 months. The different treatments: 3 observational studies compared infliximab (IFX) with CsA and IFX with CsA associated with AZA or methotrexate (MTX) and IFNα2a with AZA associated with CsA; 2 clinical trial (CT) compared adalimumab (ADA) with placebo; 1 CT RTX associated with MTX with ciclofosfamide (CFM) associated with AZA; 1 CT secukinumab (SECUK) with placebo; Another daclizumab (DACL) with placebo and the last pegIFN-α-2b with systemic and/or immunosuppressive corticosteroids. Adverse events were recorded as secondary outcomes in the 9 studies.

Conclusions: With variable evidence, IFX appears to be safe and more effective than CsA in reducing short-term uveitis relapse and the number of severe long term complications and retinal vasculitis flares. RTX is similar to CYA associated with AZA in improving short term inflammatory activity. ADA is more effective than placebo as a corticosteroid sparing, achieving early and sustained control in patients with intermediate, posterior, or active uveitis. PegIFNα-2b significantly reduced the dose of corticosteroids, and improved the quality of life. Treatment with IFNα-2a reduces the uveitis/year relapse rate and improves visual acuity. SECUK and DACL, are not effective in reducing uveitis flares but could have an effect on immunosuppressants sparing. The results of this review support the benefit of performing more well-designed comparative studies with IFX, ADA, RTX and IFN-α.

AB0554 RELATIONSHIP BETWEEN DISEASE ACTIVITY AND NEUTROPHIL-LYMPHOCYTE RATIO, PLATELET-LYMPHOCYTE RATIO AND MEAN PLATELET VOLUME IN BEHÇET'S DISEASE

I.E. Okatan, M. Torgutalp, A. Ateş, E. Uslu Yurteri, M.E. Yayla, A.B. Keleşoğlu Dinçer, T.M. Turgay, G. Kınıklı. *Department of Internal Medicine, Division of Rheumatology, Ankara University Faculty of Medicine, Ankara, Turkey*

Objectives: Behcet's syndrome (BS) is an autoimmune disease characterized by chronic inflammation and endothelial dysfunction. There are only a few studies examining the relationship between neutrophil-lymphocyte ratio (NLR), mean platelet volume (MPV), platelet-lymphocyte ratio (PLR) and BS. The aim of this study was to determine NLR, PLR and MPV levels and their association with disease activation in BS patients with mucocutaneous, ocular and vascular involvement.

Methods: The study included 259 patients with BS and 41 healthy individuals. Age, sex, total white blood counts, neutrophil, platelet, mean platelet volume and lymphocyte counts of the patients were recorded. Patients with inflammatory bowel, hematological, infectious, cardiovascular diseases, hyperlipidemia, chronic liver, chronic kidney disease, hypertension, diabetes mellitus, chronic obstructive pulmonary disease, malignancy and corticosteroid use were excluded from the study. Of 259 patients, 163 had active disease (75 active mucocutaneous (MC), 40 active ocular, 48 active vascular involvement) and 96 had inactive disease. MPV, NLR and PLR values of the patients were compared between the groups. P value <0.05 was considered significant.

Results: Age and sex were similar between the groups. We compared the MPV, NLR and PLR values of patients with active and inactive disease. NLR and PLR were significantly higher while MPV was lower in the active group than the inactive and control groups (Table 1). Statistically significant higher PLR and NLR were found in the active MC and vascular groups, significantly lower MPV was seen only in vascular active group. This significance was not seen in active ocular group (Table 2). We also evaluated the same patient's active and inactive periods of the disease, lower MPV, higher NLR and PLR values were seen MC and vascular groups (for all groups $p<0,05$). When the active 3 groups were compared within themselves, the MPV value was significantly lower and NLR and PLR values were significantly higher in vascular group than active ocular and active mucocutaneous groups (p=0.033, <0.001, 0.001, respectively).

Table 1. Demografic and laboratoary, characteristics

Baseline characteristics	Active BD n=163	Inactive BD n=96	Control n=41	p
Age, y (IQR)	35,7 (16,2)	31,3 (13,2)	38,4 (11,8)	0,143
Male, n (%)	69 (%42,3)	36 (%37,5)	10 (%24,4)	0,105
CRP, mg/L (IQR)	4,8 (20,9)	2,7 (5,1)	1 (2,9)	**<0,001**
ESR, mm/h (IQR)	24 (30)	12 (16)	11,5 (9)	**<0,001**
MPV (f/L)	8,5±1,1	8,9±1	8,8±0,9	**0,011**
NLR (IQR)	2,4 (1,7)	1,9 (1,0)	1,8 (0,8)	**<0,001**
PLR (IQR)	134 (63)	116 (44)	130 (65)	**0,012**

Table 2. MPV, NLR and PLR values

		MPV	NLR	PLR
Mucocutaneous Involvement	active (n=75)	8,6±1,0	2,4 (1,4)	134 (54)
	inactive (n=96)	8,8±1,1	1,9 (0,9)	118 (51)
	P	0,168	**0,009**	**0,006**
Ocular Involvement	active (n=40)	8,8±1,5	1,9 (1,3)	117 (43)
	inactive (n=96)	8,8±1,1	1,9 (0,9)	118 (51)
	P	0,807	0,716	0,386
Vascular Involvement	active (n=48)	8,1±0,9	3,2 (2)	161 (98)
	inactive (n=96)	8,9±1,1	1,9 (1,0)	116 (44)
	P	**<0,001**	**<0,001**	**<0,001**

Conclusions: The low MPV and the high NLR and PLR are found in the active disease, which is especially significant in vascular and mucocutaneous groups. In the light of our findings, NLR and PLR were associated with the activity of BS especially with vascular involvement. The low MPV and the high NLR and PLR. The low MPV and the high NLR and PLR may be useful disease activity markers in behcet's disease.

AB0555 ANCA VASCULITIS AND CLASSIC CARDIOVASCULAR RISK FACTORS: COINCIDENCE OR CAUSALITY?

C. Busca, J.J. Ríos, Á. Robles, A. Noblejas, E. Martínez, C. Soto, I. Vives, J.A. Troncoso, L. Bailón, F. Arnalich. *Internal Medicine, la Paz Hospital, Madrid, Spain*

Background: Unlike other systemic autoimmune diseases (rheumatoid arthritis or systemic lupus erythematosus), the mechanisms involved and the association between ANCA vasculitis with cardiovascular risk factors (CVRF) or cardiovascular events (CVE) are unknown. There may be a phenomenon of "early" atherosclerosis that contributes to an increased cardiovascular risk. This process would not be explained only by the co-existence of the classics CVRF.
Objectives: We reviewed the prevalence of classical CVRF and CVE in a cohort of patients diagnosed with ANCA vasculitis. We analyzed whether the appearance of these factors was prior to or subsequent to the diagnosis of the disease or during its evolution.
Methods: A descriptive cross-sectional analysis of the classic CVRF and CVE was analyzed in a cohort of patients with ANCA positive vasculitis in follow-up in the Autoimmune Diseases Division of a Spanish hospital. The main demographic characteristics, type of vasculitis and the presence of arterial hypertension, type 2 diabetes mellitus (T2DM), dyslipemia, smoking and obesity were reviewed. Likewise we analyzed CVE (heart failure -HF-, acute coronary syndrome -ACS-, stroke or transient ischemic attack -TIA- and peripheral arteriopathy –PA-) and if each factor was presented at the diagnosis of the disease or they appeared during the evolution after starting immunosuppressive treatment.
Results: A total of 35 patients were studied: 21 women (60%) and the average age was 53 years old. A number of 15 were microscopic polyangiitis, 9 granulomatosis with polyangiitis and 11 allergic granulomatous angiitis. Twenty one patients presented hypertension, 9 of them (42.9%) developed it after the diagnosis of vasculitis. From 7 patients with diabetes mellitus, 5 of them were before diagnosed with vasculitis. Nineteen presented dyslipemia and 9 of them (47.4%) presented lipid alteration during the evolution of vasculitis. Overweight/obesity was evident in 4 of the 11 cases after the diagnosis of vasculitis. Only 5 patients did not have a cardiovascular event. ACS was observed in 3 patients, HF in 2 and PA in 1 patient. There were no cases of TIA or ischemic stroke. Four of them had dyslipidemia (3 after diagnosis of vasculitis) (p=0.18) and 3 had hypertension (2 after diagnosis of vasculitis, p=0.66). Three patients were overweight or obese (p=0.3) and two had T2DM (p=0.2), both of them appeared after the diagnosis. Previous history of smoking was observed in 4 of the 5 patients (p=0.06). In 3 patients (71.4%) the cardiovascular event was recorded prior to vasculitis diagnosis and only in 2 cases it occurred during the evolution.
Conclusions: This study shows that a high percentage of patients with ANCA vasculitis also presents some type of classic CVRF despite of CVE were not elevated. The diagnosis and treatment of ANCA-positive vasculitis did not statiscally correlate with a greater number of CVE, therefore it would be necessary to carry out studies with a larger number of patients in order to establish conclusions. It is not well defined that weight may have these factors in the prognosis of patients with ANCA vasculitis. These data suggest the need to maintain a close monitoring and therapeutic approach of classic CVRF in this relatively young group of patients.

AB0556 INCIDENCE AND RISK FACTORS OF INFECTIONS IN SYSTEMIC NECROTIZING VASCULITIS

C.E. Pena, M. Pera, C. Costi, G. Lucila, P. Castellani, Y. Nuccetelli, M. Garcia. *HIGA San Martin la Plata, la Plata, Argentina*

Background: Infections in patients with systemic vasculitis represent one of the main causes of mortality. Risk factors of infection such as corticosteroid use, intensity of immunosuppressive therapy, age, presence of leucopenia, lymphopenia,hypogammaglobulinemia,associated organic involvement, and dialysis dependence have been identified
Objectives: a)To determine the incidence of infection in patients diagnosed with:Polyangeitis with Granulomatosis (GPA), Eosinophilic Polyangiitis with Granulomatosis (EGPA), Microscopic Polyangeitis (PAM) and Panarteritis Nodosa (PAN), b) clinical characteristics and associated risks factors.
Methods: Analytical, observational,retrospective study. Data source:clinical records of patients diagnosed with ANCA associated vasculitis and Panarteritis Nodosa, evaluated in a center of rheumatology (2000–2016). Variables:Demographic data, clinical manifestations, laboratory data, infectious events serious (requiring hospitalization or prolonged antibiotic/antiviral treatment, recurrences of herpes zoster virus or opportunistic infections), sites of infection, isolated microorganisms, mortality related to the infectious event
Results: 80 patients, 61.25% women. Mean age at diagnosis: 49.2 years (range 18–77). Types of vasculitis: 41.2% GPA, 18.7% EPGA, 26.25% PAM, 3.73% PAN not associated with HBV and 10% ANCA-associated vasculitis that did not met classification criteria. Systemic involvement (68%), pulmonary (59%), renal (58%) and otorhinolaryngology (43.6%) were the most frequent. 36 infectious events were recorded in 28 patients. Follow-up time: Median 22 m (IQR6–64). Incidence of infection:38.4%, with a median of 3 m (IQR 1–18 m) from diagnosis of vasculitis. Low respiratory infections (40.7%), sepsis (39.3%), and urinary tract infections (15%) were the most common. 25% of these patients presented a second infectious event, being low respiratory tract the most frequent site (47%). Two patients had a 3rd event (soft tissue infection, septic shock). Bacterial etiology was the most prevalent (45%).Mortality at the 1st event was 14.3% (n: 4). 71.4% of patients were in the induction phase of treatment. Immunosuppressants used prior to infectious event: cyclophosphamide (48.1%), azathioprine (11.1%), methotrexate (7.4%), mofetil mycophenolate (3.7%), none (22.2%). Corticosteroids $\geq$30 mg/d were observed in 35.7% patients, ranging from 7.5–30 mg/d (10.7%), and $\leq$7.5 mg /d in 35.7%. Presence of leukopenia (26%), lymphopenia (44%), hypoalbuminemia (24%), renal insufficiency (63%) and dialysis dependency (37%) were identified in patients with infectious events. Renal involvement (p0.01) and dialysis dependence (p0.001) were significantly associated with infection.
Conclusions: The incidencia of infection was 38.4%.Lower airway infections, septicemia and urinary tract infections are the most commonly implicated sites. Most infections occurred in the induction phases of the disease. Dialysis dependence and presence of renal involvement were significantly associated with the presence of infection.

AB0557 HEART LESSON IN EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS

D. Rednic[1], R. Rancea[2], F. Cozma[1], L. Damian[1], L. Muntean[1,3], M.M. Tamas[1,3], S.-P. Simon[1,3], I. Felea[1], S. Rednic[1,3]. *[1]Rheumatology, Clinical County Emergency Hospital; [2]Cardiology, Heart Institute "Niculae Stancioiu"; [3]"Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania*

Background: Eosinophilic granulomatosis with polyangiitis (EGPA) is a disorder characterised by systemic small vessel vasculitis, that occurs typical in patients with a positive history of late-onset asthma and allergic rhinitis. Cardiac involvement is the major cause of mortality. There is required a standardised method to assess cardiac involvement in EGPA.
Objectives: To assess the clinical and imagistic caracteristics of EGPA patients with cardiac involvement in a tertiary referral hospital.
Methods: Fourteen patients (pts) with EGPA were retrospectively analysed between 2010–2016, in Rheumathology Departament in Cluj-Napoca. All patients were screened for cardiac involvement by electrocardiogram (ECG) and cardiac ultrasonography (CUS). Cardiac involvement was defined as follows: ventricular hypertrophy, kinetic abnormalities, valvulopathy, pericardial effusion or diastolic dysfunction. Cardiac magnetic resonance (CMR) and coronarographie was assessed in 4 pts with ECG or CUS abnormalities.
Results: Characteristics of EGPA patients is detailed in table 1. Six out of 14 pts had cardiac involvement (table 2). Only one patient was symptomatic. CMR abnormalities were: endocardial fibrosis in 2 pts, subepicardial inflammation

Table 1. Demographic caracteristic of EGPA patients. EGPA, eosinophilic granulomatosis with polyangiitis; Cardiac, patients with cardiac involvement, Non cardiac, pacients without cardiac involvement; ANCA, anti-neutrophil cytoplasmatic antibody

Characteristics of EGPA Patients	n=14	Cardiac (n=6)	Non cardiac (n=8)
Age at onset, yr ± SD	54.57±9.7	53±12.19	55.75±8.04
Female, n	8	4	4
History of astm, n	7	3	4
ANCA (+), n	5	3	2
Organ involvement, n			
Renal	1	1	0
Pulmonary	9	4	5
Neurologic	10	5	5
Ophtalmic	1	0	1
Skin	6	1	5

Table 2. Electrocardiographic and echocardiographic findings in EGPA patients with cardiac involvement

Electrocardiographic and echocardiographic findings	n=6
Conduction disorders	2
Ischemia in inferior leads, n	1
Pericardial effusion, n	4
Kinetic abnormalities, n	3
Septal thickening, n	3
Mitral insufficiency, n	1
Diastolic dysfunction, n	4

and fibrosis in 1 patient, ventricular hypoperfusion in 2 pts and hypertrophic cardiomyopathy (HCM) in 2 pts. The pts with subepicardial inflamation and HCM had a more severe outcome. Three out of the 6 pts with cardiac involvement were pANCA (+). Hypereosinophilia was singnificantly higher in the group with cardiac involvement ($p<0.012$). None of the patients had positive coronarography.
Conclusions: Cardiac involvement is frecvent and is associated with hypereosinophilia. Absence of pANCA was not associated with the cardiac involvement, in contrast with other publications. CMR makes the difference between inflamatory and noninflamatory lesions, beeing useful in clinical assessment and in treatment decisions, therfore this examination could avoid a fatal outcome. Furthermore, in the future, CMR may replace cardiac byopsy.

AB0558 BIOSIMILAR INFLIXIMAB FOR BEHÇET'S SYNDROME

E. Dinçses[1], S.N. Esatoğlu[1], E. Seyahi[1], M. Melikoğlu[1], I. Fresko[1], V. Hamuryudan[1], D. Uçar[2], Y. Özyazgan[2], Z. Kutlubay[3], C. Mat[3], S. Yurdakul[1], G. Hatemi[1]. *[1]Internal Medicine, Division of Rheumatology; [2]Department of Ophtalmology; [3]Department of Dermatology, Istanbul University, Cerrahpasa Medical School, Istanbul, Turkey*

Background: The efficacy and safety of biosimilar infliximab has been studied in several inflammatory conditions and biosimilar was approved for all indications of the reference product in several countries. However, to the best of our knowledge, there was no published reports on its use in Behçet's syndrome (BS).
Objectives: We aimed to report our experience with biosimilar infliximab for the treatment of 3 different types of organ involvements in BS.
Methods: We reviewed the charts of all BS patients who were prescribed infliximab in our multidisciplinary BS clinic. Among the 88 patients who were prescribed infliximab, 4 had used biosimilar infliximab (5 mg/kg) due to refractory disease despite conventional immunosuppressives.
Results: *Case 1:* The first patient was a 28-year-old man who had received azathioprine (AZA), cyclosporine-A and methotrexate for 6 years for ocular involvement. Six months after the immunosuppressives were stopped due to sustained remission he had a stroke with right hemiparesis. Cranial MRI revealed venous infarct extending from posterior limb of left internal capsule to pons and mesencephalon, involving corpus callosum. Cervical MRI revealed a hyperintense lesion between C3-C8 segments. His cranial MR venography excluded sinus thrombosis. He received intravenous pulse corticosteroid followed by biosimilar infliximab. He achieved clinical remission and his MRI at month 3 showed almost total regression of the lesions. He is still in remission at 7th month of therapy. *Case 2:* The second patient was a 24-year-old man using AZA 2,5 mg/kg/day for refractory skin lesions when he developed bilateral external iliac vein and right common iliac vein thrombosis. Biosimilar infliximab was added to AZA. His abdominal superficial collateral vein distension regressed and Doppler ultrasonography at month 4 showed recanalization in bilateral external iliac veins and residual thrombosis only in the right common iliac vein. *Case 3:* The third patient was a 41-year-old man who had used colchicine, AZA, sulfasalazine, interferon-alpha and adalimumab for refractory arthritis. Biosimilar infliximab was started, with only a partial response. After one year treatment was switched to etanercept 50 mg/week and is attack-free for the last 7 months. *Case 4:* The fourth one was a 26-year-old man who was prescribed infliximab for panuveitis refractory to AZA, cyclosporine-A and interferon-alpha. The first infusion was biosimilar infliximab, but the following infusions were reference infliximab due to reimbursement policy of the hospital. There were no adverse events after switching to reference infliximab and the patient is doing well at 8 months of therapy.
Conclusions: Our limited experience showed that biosimilar infliximab may be effective for BS patients refractory to conventional immunosuppressives.

AB0559 IMPROVING THE MANAGEMENT OF GIANT CELL ARTERITIS: A REVIEW OF CARE PATHWAY FOR PATIENTS WITH SUSPECTED GIANT CELL ARTERITIS IN A DISTRICT GENERAL HOSPITAL

F.E. Sin[1], M. Ragheb[2], R. Shah[2], A. Hunter[2], W. Shattles[2], U. Davies[2], R. Makadsi[2], S. Griffith[2]. *[1]Rheumatology Department, Brighton and Sussex University Hospitals NHS Trust, Brighton; [2]Rheumatology Department, East Surrey Hospital, Redhill, United Kingdom*

Background: Giant cell arteritis (GCA) requires prompt diagnosis and treatment to prevent irreversible neuro-ophthalmic complications. Conversely, misdiagnosis leads to unnecessary treatment with high dose glucocorticosteroids (GC) and their associated complications. The British Society of Rheumatologists (BSR) Guideline emphasises early recognition of symptoms and prompt treatment when index of clinical suspicion is high.
At East Surrey Hospital (ESH), we noted that some patients were not managed in accordance with BSR guidelines. Additionally, there is no existing care pathway for patients with suspected GCA to be referred to Rheumatology and for Temporal Artery Biopsy (TAB), often resulting in delayed care provision, or unnecessary use of healthcare resources.
Objectives: This study aims to audit the management of patients with suspected GCA against BSR guidelines. It also aims to evaluate patients' journey, to identify inefficiencies within the management pathway, in order to initiate improvements in service.
Methods: Case notes of patients seen in ESH with suspected GCA between March 2015 and December 2016 were reviewed retrospectively. Cases were identified through keyword search on hospital discharge letters and Rheumatology clinic letters.
Results: Case notes of 67 patients (21M, 46F) were analysed. Of those presenting with suspected GCA, 31% fulfilled ACR classification criteria. 28% had documented visual symptoms at presentation.
Concordance with BSR guidelines: 79% of patients were started on GC at presentation. Of these 15% had a TAB within 7 days of starting GC. 34% were seen by a Rheumatologist within a week of presentation. Of those referred for a TAB 47% were performed within a week of referral.
Care Pathway: The majority of patients (78%) first presented to GPs. Despite this, only 64% of referrals to rheumatology were by GPs. Other referral sources included the Acute Medical Unit (27%) and ophthalmology (5%). 49% were seen by a Rheumatologist within 7 days from referral. 25% had a final diagnosis of GCA.
Conclusions: The small proportion of patients with a final diagnosis of GCA highlighted that early Rheumatology assessment is important to minimise unnecessary TAB and high dose GC. Additionally, the lack of a structured care pathway and a standardised referral system for GCA meant that a large proportion of patients had delay in the diagnosis, inappropriate treatment with GC, and unnecessary TAB. These added to the burden of other already stretched medical specialities.
In light of this; a GCA pathway was implemented to enable rapid access to Rheumatology in patients with suspected GCA. The on-call team was advised to redirect any GP or A&E referrals with suspected GCA to the rheumatology on-call bleep. Patients will be assessed and managed by the rheumatology on-call Registrar or Consultant within 24 hours. The impact of these new implementations will be reaudited in 2017.

AB0560 STUDY ON STREPTOCOCCAL INFECTION RELATIONSHIP WITH HENOCH-SCHONLEIN PURPURA IN CHILDREN

F. Li[1], H. Zeng[2]. *[1]Department of Pediatric Allergy, Immunology and Rheumatolog; [2]Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children's Medical Center, Guangzhou, China*

Objectives: To study hemolytic Streptococcus infection relationship with Henoch-Schonlein Purpura in children.
Methods: 42 cases in children with Henoch-Schonlein Purpura (Observer Group) and healthy children in 40 cases of physical examination (the control group) for blood antistreptolysin O (ASO) detection, observation group at the same time children are divided into (belly-non-abdominal Purpura and Purpura group set and repeatedly attacks groups and the Group of non-recurrent) for statistical analysis.
Results: Observation group in the blood ASO detection positive 22 cases, accounted for 52.4%; normal control group children 40 cases, blood ASO detection positive 2 cases, accounted for 5%, both comparison differences has significantly significance ($\chi^2=22.22$, $p<0.01$); abdominal type Purpura children with 23 cases, blood ASO detection positive 17 cases, accounted for 73.9%; non-abdominal type Purpura children with 19 cases, blood ASO detection positive 5 cases, accounted for 26.3%, both comparison differences has significantly significance ($\chi^2=9.45$, $p<0.01$); 14 cases in children with recurrent Henoch-Schonlein Purpura, ASO blood test positive in 12 cases, 85.7%, non-recurrent attacks of 28 cases of children with Henoch-Schonlein Purpura, ASO blood test positive in 10 cases, 35.7%, comparing the two differences are significant ($\chi^2=9.35$, $p<0.01$).
Conclusions: Streptococcal infections may be the important factor relatated to Henoch-Schonlein Purpura in children.Purpura and Purpura of abdominal type recurrence is related with streptococcal infection, which is the great value to treatment.

AB0561 B CELL THERAPY IN REFRACTORY/ RELAPSED ANCA ASSOCIATED VASCULITIS- A SINGLE CENTRE PROSPECTIVE OBSERVATIONAL STUDY

G.G. Ekbote, R. Gupta, N. Mendiratta, N. Negalur, M. Bindroo, V. Singal.
Rheumatology, MEDANTA, the Medicity, Gurgaon, India

Background: Rituximab (Rtx), a novel biological, having B cell depletion mechanism is an anti- CD 20 antibody and is found to be useful in patients of ANCA associated vasculitis. In AAV the disease activity correlates with increased circulating B cells. Rituximab has been found to be useful in depleting these B cells. According to the RAVE study, Rituximab was shown to be non-inferior to Cyclophosphamide in inducing remission. It also showed that the regimen (Rtx) may be superior to the standard regimen of Cyclophosphamide and glucocorticoids for remission induction in severe relapsing ANCA-associated vasculitis.
In our study, B cell therapy was given in those patients only who had persistent disease activity or relapse.
Objectives: To assess response of Rtx in relapsed /refractory cases of AAV and show that it is a good therapeutic stratergy in such cases.
Methods: In our cohort there were 49 patients of ANCA associated vasculitis, diagnosed by clinical and serological criteria, (by both ELISA and IFA) classified according to ACR criteria and supported, wherever possible, by biopsy. In this prospective study, patients were seen during January 2012 to January 2017. A total of 15 patients received Rituximab for various reasons. Rituximab (Rtx) was given as 1 gram infusion on day 1 and day 15 as induction therapy and subsequently 6 monthly maintenance doses of 500 mg were administered. No other immunosuppression other than steroids were given.
Results: Median follow up was 22 months. All patients had recieved Cyclophosphamide (median dose 6 grams) and 1mg/kg glucorticoids at onset. Among the patients who received Rituximab, all had anti PR3 antibody positive & all were GPA clinically. 14 patients (93.33%) had lung involvement, renal involvement was seen in 7 (46.6%) patients, 13 (86.6%) patients had upper respiratory tract involvement, 6 (40%) had ophthalmic involvement. Nervous system involvement was seen in 5 (33.3%) and myocarditis was seen in 3 (20%) each. 3 (20%) patients had gangrene.
Indications for receiving Rtx were heterogenous. It was given for involvement of lung, renal, ophthalmic, upper respiratory and nervous system in 6 (40%), 3 (20%), 3 (20%), 1 (6.66%) and 1 (6.66%) respectively. Whereas 1 (6.66%) patient received Rtx for persistent disease activity.
12 out of 15 patients (80%) achieved remission at mean follow up of 3 months while one achieved at 6 months follow up & all maintained continued remission. 1 patient was due for 3-month follow up. 1 patient died due to lung infection during the course. 4 patients had permanent morbidities/organ damage which they already had before starting Rtx. Only one patient had infusion reaction at the end of 1st induction however she remained in remission after the first dose itself.
Conclusions: 86.6% patients achieved remission after Rtx and remained in continous remission at median follow up of 22 months. Rtx is a very good therapeutic strategy for refractory/relapsed especially PR3+ AAV also it can be used as a maintenance regimen for long term.

AB0562 CLASSIFICATION OF ANCA ASSOCIATED VASCULITIS BASED ON PR3 AND MPO SEROLOGY & THEIR OUTCOME: A SINGLE CENTRE PROSPECTIVE STUDY

G.G. Ekbote, R. Gupta, N. Mendiratta, N. Negalur, M. Bindroo, V. Singal.
Rheumatology, MEDANTA, the Medicity, Gurgaon, India

Background: It is often difficult to classify small vessel vasculitis, especially AAV, as Granulomatosis polyangitis [GPA], Microscopic polyangitis [MPA], Eosinophilic granulomatosis polyangitis [EGPA] & Idiopathic cresentic glomerulonephritis. But with the discovery of ANCA, rheumatologists divide this as ANCA positive or negative vasculitis.
Objectives: To classify AAV as anti-proteinase 3 (PR3) antibody+ or anti-myeloperoxidase (MPO) antibody + & compare their clinical presentation & outcome.
Methods: 49 patients were included in our study from August 2011 till January 2017. Patients were classified according to PR3 and MPO serology [based on ELISA].
Results: Median follow up was 18 months. PR3 + were 38 and 11 patients were MPO+. GPA was significantly higher in PR3 Group vs MPO group [36 (94.7%) vs 1 (9.1%) p<0.0001*] while MPA was significantly lower in PR3 group as compared to MPO (2 [5.3%] vs 5 [45.45%] p=0.001*). All EGPAs were MP0+ (4 [36.35%]). 48 fulfilled ACR clinical criteria for GPA/MPA or EGPA. 1 patient with arteritic anterior ischemic optic neuropathy without any other major organ involvement had significantly higher titres of MPO antibodies & was sorted as unclassified AAV. None were idiopathic crescentic glomerulonephritis in our cohort. 18 were biopsy proven [15 PR3+vs 3 MPO+]. Lung involvement was significantly higher in PR3 group than MPO group (32 [84.2%] vs 6 [54.5%] p=0.037*).Kidney involvement was also more in PR3 group but was not statistically significant (20 [52.6%] vs 4 [36.4%] p=0.341). Upper respiratory involvement was significantly higher in PR3 group (26 [68.4%] vs 3 [27.3%] p=0.014*).
Comparision between manifestations of ophthalmic, cardiac, peripheral vascular system & nervous systems of PR3+ & MPO+ groups was not statistically significant.
Complete remission without permanent organ damage was seen in 16 (42%) vs 6 (54.5%) in PR3 and MPO groups respectively (p=0.465). Frequency of relapse/refractory disease, though higher in PR3 group, was not statistically significant (PR3 vs MPO, 10 [26.3%] vs 1 [9.1%] p=0.228). Rates of morbidity & mortality were not significant statistically between PR3 & MPO groups (11 [28.9%] vs 2 [18.2%] p=0.476 & 3 [7.9%] vs 1 [9.1%] p=0.899 respectively). Similar comparisons were made between those who were classified clinically as GPA, MPA & EGPA with respect to remission, relapse, morbidity and mortality. All EGPAs achieved remission. Comparison between groups when divided as GPA & PR3 and MPA & MPO did not show statistical significance. 15 patients (all clinically GPA & PR3+) of the cohort [39.5%] received rituximab for relapse/refractory disease during/after initial induction therapy with cyclophosphamide & steroids.
Conclusions: In this study, we did not find any advantage of clinical classification over serological. Wrongly diagnosing patients when disease is still evolving & inter-clinician bias are eliminated when classifying patients according to serology. Classification as PR3 & MPO is simpler and universal.

AB0563 RITUXIMAB IN PATIENTS WITH TAKAYASU ARTERITIS: A SEVEN PATIENTS EXPERIENCE

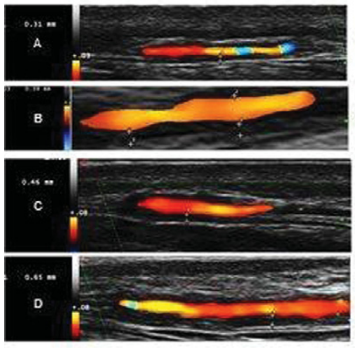
G. Pazzola[1], F. Muratore[1], N. Pipitone[1], F. Crescentini[1], P. Cacoub[2], L. Boiardi[1], L. Spaggiari[3], C. Comarmond[2], S. Croci[4], D. Saadoun[2], C. Salvarani[1]. *[1]Rheumatology, Arcispedale S Maria Nuova, Reggio Emilia, Italy; [2]Internal Medicine and Clinical Immunology, Groupe Hospitalier Pitie-Salpetriere, Paris, France; [3]Radiology; [4]Inflammation Laboratory, Clinical Immunology, Allergology and Advanced Biotechnologies Unit, Arcispedale S Maria Nuova, Reggio Emilia, Italy*

Background: Takayasu arteritis (TAK) is a large vessel vasculitis involving the aorta and its major branches in patients younger than 40 years. Glucocorticoids (GCs) are the mainstay of treatment for TAK, but relapses and GC dependence are seen in more than two-thirds of patients. Increasing evidence supports a role for B cells in the pathogenesis of TAK. Circulating plasmablasts and memory B cells are increased, while naive B cells are decreased in patients with active TAK as compared with inactive and control patients [1]. These findings suggest a potential role for B cell depleting therapy in TAK.
Objectives: Our aim was to assess the efficacy and safety of Rituximab (RTX) in a series of 7 patients with TAK.
Methods: We conducted an open-label study on 7 TAK patients (5 followed prospectively, 2 retrospective cases) treated with RTX. All patients satisfied the American college of Rheumatology classification criteria for TAK. Six of the 7 patients had a disease refractory to high dose GCs and conventional immunosuppressive (IS) and/or biologic agents. One newly diagnosed, treatment naïve TAK patient refused GCs and received RTX alone. RTX was administered according to rheumatoid arthritis scheme (2 infusions of 1.000 mg, 15 days apart). Clinical evaluation, laboratory tests (full blood count, ESR, CRP) and imaging modalities (CTA or MRA, and PET/CT) were performed at first RTX administration and every 6 months thereafter. Disease activity was assessed using Kerr index. Radiographic disease progression was defined as new or worsening lesions at follow-up CTA or MRA. PET/CT was considered positive for active disease if two or more large vessels showed grade 2 FDG uptake or higher.
Results: Seven patients (6 females) were included in the study. Mean (SD) age was 32.4 (±16.1) years. At first RTX administration, all patients had active disease

Table 1. Parameters of disease activity before and after Rituximab treatment

Case	Age/Sex	Disease duration (yr)	Previous therapy	ESR/CRP at first RTX (mm/h, mg/dl)	PDN dose at first RTX (mg/day)	Concomitant IS therapy	RTX cycles	ESR/CRP 6 months after last RTX (mm/h, mg/dl)	Imaging (CTA/MRA) 6 months after last RTX	PET/CT 6 months after last RTX	Kerr index 6 months after last RTX	Outcome 6 months after last RTX	PDN 6 months after last RTX	Therapeutic changes	Follow-up (m)
1	20/F	2y	MTX	38/6.2	25g	MTX 20 mg weekly	2g	6/4.7	No disease progression	Positive	Positive	Active disease	5g	Stop RTX, start ADA	12g
2	32/F	0m	None	48/4.6	0m	None	1g	6/3.4	Disease progression	Positive	Positive	Disease progression	12.5g	Stop RTX, start PDN+TCZ	12g
3	21/F	1y	MMF	12/2.7	50g	MMF 2 gr day	1g	16/2.8	Disease progression	Positive	Positive	Disease progression	5g	Stop RTX, start ADA	12g
4	60/M	20y	MTX, MMF, ADA, IFX	66/2.0	25g	MMF 2 gr day	2g	18/0.5	No disease progression	Negative	Negative	Remission	7.5g	PDN tapering, No changes	36g
5	19/F	3y	MTX, AZA, TCZ, IFX, ADA	98/11.5	50g	None	2g	78/4.0	Disease progression	Positive	Positive	Disease progression	10.75g	Stop RTX, start MMF	24g
6	22/F	1y	AZA, MTX	MD/4.5	10g	None	1g	MD/0.3	No disease progression	ND	Negative	Remission	2.5g	No changes	72g
7	54/F	3y	MTX, AZA, TCZ	MD/1.10	15g	None	3g	MD/0.20	No disease progression	ND	Negative	Remission	10g	PDN tapering, No changes	60g

ESR = erythrocyte sedimentation rate; CRP = C-reactive protein; RTX = rituximab; PDN = prednisone; IS = immunosuppressive; CTA = Computerized Tomography Angiography; MRA = Magnetic Resonance Angiography; PET/CT = positron emission tomography/computerized tomography; MTX = methotrexate; ADA = adalimumab; TCZ = tocilizumab; MMF = mycophenolate mofetil; IFX = infliximab; AZA = azathioprine; MD = missing data; ND = not done.



according to Kerr index (≥2), and had also evidence of active disease at PET/CT. Table 1 summarizes the main results of our study.
Despite RTX treatment, 4 of the 7 patients had evidence of persistent disease activity and/or radiographic disease progression during follow-up.
Three out of 7 patients in whom RTX was employed as rescue therapy achieved complete remission.
Conclusions: Our data do not support a role for RTX as first line biologic therapy in TAK patients, but it may have a role in some patients as second/third line biological therapy.

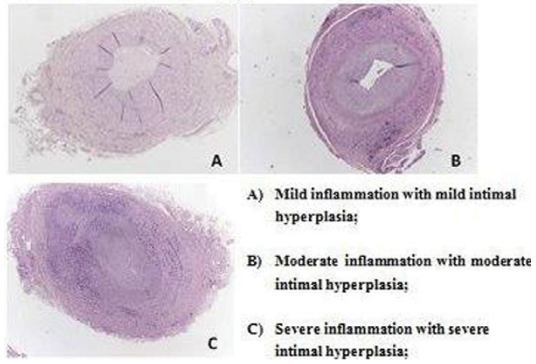
AB0564 TEMPORAL ARTERITIS: IS THERE ANY CORRELATION BETWEEN ULTRASONOGRAPHIC ARTERIAL WALL INVOLVEMENT AND THE INFLAMMATORY CELLULAR INFILTRATE AT HISTOLOGICAL EXAMINATION?



G. Germano[1], P.L. Macchioni[1], A. Cavazza[2], L. Cimino[3], F. Muratore[1], C. Salvarani[1]. [1]*Rheumatology Unit;* [2]*Pathology Unit;* [3]*Ophthalmology Unit, IRCCS Arcispedale Reggio Emilia, Reggio Emilia, Italy*

Background: Ultrasonographic alterations such as the halo sign and the compression test are now accepted as surrogate markers of artery inflammation. No data have yet been published on the correlation between the ultrasonographic grading of arterial wall inflammation and the grading of cellular infiltrate.
Objectives: To compare a semiquantitative ultrasonographic grading (USG) of TA involvement (halo sign and media-intima thickness) with a semiquantitative grading of the inflammatory burden in patients with giant cell (temporal) arteritis (GCA).
Methods: Fiftheen consecutive patients with new onset clinical symptoms and satisfiing ACR criteria for GCA, with positive halo sign in the frontal branch and positive temporal artery biopsy have been enrolled. For each patients we performed power Doppler ultrasonography of temporal artery with a 18–6 MHz linear probe (Esaote MyLab 70) and measured the maximum halo thickness of TA frontal branch in a quantitative and semiquantitave (0–3) grade of involvement (0 = <0.37 mm, 1 = in between 0.38–0.44, 2 = 0.45–0.6 mm, 3 = >0.6). TA biopsy was done in the same frontal branch evalutaed with US. Then we compared the ultrasonographic data with a semiquantitative (0: absent, 1: mild, 2: moderate, 3: severe) grading of the trasmural cellular inflammatory infiltrate and with the intima-media thickness of the TA biopsy specimen. Moreover US results were correlated with the other patterns of histological alterations (giant cells, calcifications, laminar necrosis). Correlation between variables was done by Rho of Spearman method.

Ultrasonography of temporal artery: grading of Halo thickness

Grading of the trasmural cellular inflammatory infiltrate and intima-media thickness of the TA biopsy.

Results: 15 patients, 6 males and 9 females (mean age 71.6±7 years – duration symptoms at onset 1.7±1.3 months – mean ESR 60 mm/h ±29 – mean CRP 8 mg/dl ± 5.2) entered the study. US halo sign was bilateral in 10/15 (66,7%). The mean halo thickness was 0.53 mm ± 0.12. Five patients had USG =1, six patients =2 and four patients =3. The hystological inflammatory grade 1 was present in seven pts, grade 2 in four and grade 3 in four pts. No significant correlation were found between USG and histological inflammatory grade, nor with the presence of giant cells, calcifications, laminar necrosis and intima-media thickness.
Conclusions: No correlation has been found between the size of the halo sign and the hystological inflammatory grading.

AB0565 INSUFFICIENT INFLUENZA VACCINATION COVERAGE IN GIANT CELL ARTERITIS. A FRENCH POPULATION-BASED STUDY

G. Pugnet[1], M. Lapeyre-Mestre[2], M. Mounie[2], G. Moulis[1], L. Sailler[1]. [1]*Service de Médecine Interne, CHU Toulouse Purpan;* [2]*INSERM UMR 1027, Toulouse, France*

Background: French general health insurance scheme has implemented a national influenza vaccination program, including full refund for those 65 years old or more. Despite this program, only 62.6 to 71% of people aged over 65 years are vaccinated and no data are available regarding influenza vaccination coverage (IVC) in GCA.
Objectives: To evaluate the rate and the factors associated with seasonal influenza vaccination coverage in incident giant cell arteritis (GCA) patients compared with controls.
Methods: Using the French National Health Insurance system (SNIIRAM), we included patients with incident GCA from the Midi-Pyrenees region, southern France, and randomly selected 6 controls matched by sex and age at calendar date from January 2005 to December 2008 and followed them till April 2011. The vaccination rate was estimated from vaccine dispensation registered in the SNIIRAM. IVC was compared between GCA and their controls using longitudinal multivariate Poisson regression.
Results: Eighty-seven incident GCA patients over 65 years of age and 509 in the control group were included. Mean follow-up was 4.4±1.2 and 4.2±1.2 years, respectively. During the yearly influenza campaigns from 2005–2006 to 2010–2011, the IVC rates in the GCA group and the control group ranged from 60.8 to 74.7% vs 56.6 to 70.4%, respectively. Incident GCA influenza vaccination rate was 20% higher than controls (RR=1.20; IC 1.09 to 1.32, P<0.001) (Table 1).

Table 1. Associated factors with recommended influenza vaccination (Multivariate longitudinal Poisson analysis)

		Adjusted RR	IC 95%	P
GCA	GCA	1.20	1.09 - 1.32	< 0.001
Comorbidity at baseline				
- High blood pressure		1.13	1.04 - 1.24	0.006
Age, *years*	] 64.4 ; 71.5]	1		
	] 71.5 ; 80]	1.15	1 - 1.32	0.048
	] 80 ; 91.9]	1.13	0.99 - 1.29	0.079
Gender	Female	1.05	0.96 - 1.16	0.259
Time, *Influenza campaigns*	[2005 : 2008]	1		
	[2008 : 2010]	1.11	1.08 - 1.14	< 0.001
	[2010 : 2011]	1.05	1.02 - 1.08	0.002
GCA*Time	GCA * [2008 : 2010]	0.90	0.87 - 0.92	< 0.001
	GCA * [2010 : 2011]	0.77	0.72 - 0.83	< 0.001

GCA: giant cell arteritis, RR: Relative Risk, CI: Confidence Interval. GCA *Time: the interaction term between to have GCA and time variable,

Conclusions: Rates of recommended influenza vaccinations are insufficient in GCA patients over 65 years. More attention should be paid for appropriate vaccination during GCA course.

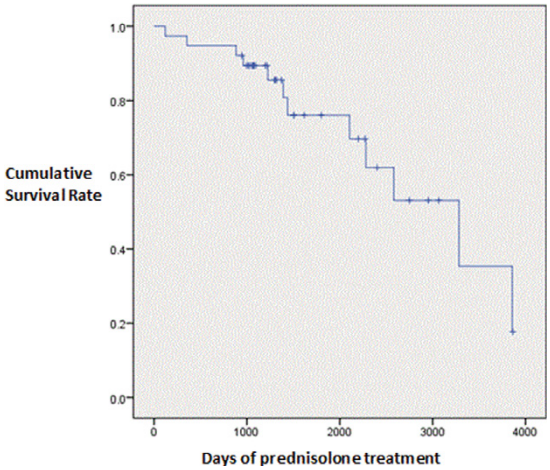
AB0566 18F-FDG-PET-POSITIVE TEMPORAL ARTERY IN GIANT CELL ARTERITIS: A POSSIBLE CORRELATION WITH HISTOPATHOLOGICAL FINDINGS

H. Kono[1], Y. Okada[1], K. Asako[1], H. Kikuchi[1], Y. Oguchi[1], Z.-I. Honda[1], A. Takeuchi[1], T. Tokairin[2], K. Saito[2]. [1]*Department of Internal Medicine;* [2]*Department of Pathology, Teikyo University School of Medicine, Tokyo, Japan*

Background: Giant cell arteritis (GCA) a form of vasculitis in persons older than 50 years, in which cranial and systemic large vessels can be involved. ^{18}F-fluorodeoxyglucose positron emission tomography - computed tomography (^{18}F-FDG-PET-CT) is increasingly used to diagnose inflammation of the large arteries in GCA. But it is very rare to observe an inflammation of temporal arteries of GCA using ^{18}F-FDG-PET.



Objectives: To understand the mechanism and frequency of the positive temporal artery of GCA in ^{18}F-FDG-PET.
Methods: This was a retrospective chart review of 3 patients with giant cell arteritis who underwent all of ^{18}F-FDG-PET, MRI, CT angiogram, ultrasound and histopathologic evaluation of temporal arteries. To investigate the cases of FDG-PET positive temporal arteries in GCA, a systematic literature review was done in Pubmed using ^{18}F-FDG-PET AND ("temporal arteritis" OR "giant cell arteritis").
Results: A case report: An 85-year-old male presented with muscle weakness. Three years before admission, he experienced pain in his neck and both extremities. Rheumatoid arthritis was diagnosed at another hospital, and the patient was treated with methotrexate and prednisolone, which resolved his symptoms. The medication was discontinued after 2 years. Two months before admission he began coughing due to interstitial pneumonitis, and later developed muscle weakness and difficulty walking. On admission a physical examination revealed swelling of the bilateral temporal arteries. A blood test showed accelerated ESR at 54mm/h and a CRP of 4.6 mg/dL. Ultrasound showed an increased diameter, hypoechoic wall thickening (halo), stenosis, and calcification of the arterial wall of the temporal artery. A contrast CT showed wall thickening in the affected segments, calcification, stenosis and enhancement of the soft tissue around the temporal artery. An ^{18}F-FDG-PET scan indicated increased uptake of ^{18}F-FDG at the temporal arteries whereas no uptake was found in the other arteries including the aorta and carotid arteries. A biopsy of the temporal artery revealed necrotizing vasculitis with a few giant cells and the formation of a microscopic neutrophilic abscess. When compared with 2 other cases of temporal arteritis with a negative ^{18}F-FDG uptake, the severity of inflammation and the number of giant cells in the present case were not remarkably high. A systematic literature review identified 4 cases of ^{18}F-FDG-PET positive temporal arteries in 454 cases of GCA of 82 papers. Of note, large arteries were positive for ^{18}F-FDG-PET in 253 cases of GCA in the same series.
Conclusions: The hierarchy for FDG uptake by resting inflammatory cells is neutrophil > macrophage = lymphocyte in vitro, indicating that the sites where neutrophils dominate are more likely to be visualized by ^{18}F-FDG PET in vivo. In addition to the known usefulness of ^{18}F-FDG-PET in visualizing inflammation in large vessels, the increased uptake of ^{18}F-FDG to the temporal artery may help to identify the neutrophilic inflammation.

AB0567 THE LONG TERM HEALTH RELATED QUALITY OF LIFE (HRQOL) IMPACT ON GIANT CELL ARTHRITIS (GCA) PATIENT

H. Horiuchi. *General Medicine, Kurashiki Central Hospital, Okayama, Japan*

Background: Health related quality of life (HRQOL) of Giant cell Arthritis (GCA) patients is improtant because it adds depth to our understanding of how a disease and its treatments affect them. Though only one previous study has addressed the short term impact of GCA on HRQOL, the long term impact has not fully been investigated.
Objectives: The aim of our study is to assess the long term HRQOL outcomes of GCA patients using the Japanese version of EuroQol 5 Dimention (EQ-5D).
Methods: 40 GCA patients who admitted to our hospital from November 2004 to June 2014 were enrolled. All patients were received prednisolone over 2 years. Patients who had lost their eyesight were excluded because vision concern for HRQOL nor it is difficult to mesure by using EQ-5D. This is a retrospective study and deta were collected by telephone interview. Patients evluated their health status using five dimensions. The EQ-5D score were calculated based on the Japanese version of the value set. Primary outcome is the mortality rate and the norm of EQ-5D score. As a secondary analysis, we classified the patients as follows and compare the mortality rate and EQ-5D score between two groups.

Figure1: Kaplan Meier survival estimate

Group 1: GCA patients who received prednisolone over 5 years.
Group 2: GCA patients who received prdnisolone less than 5 years.
Results: There were 16 male (40%) and 24 female (60%). The median age was 83.5 (95% CI 79.24–87.76). The mortality rate was 37.5% (15 patients). Kaplan-Meier curve is shown in Figure1. The median EQ-5D score was 0.746 (95% confidence interval [CI] 0.852–0.640) and it is lower than Japanese norm (0.853 in male and 0.808 in female). In the secondary analysis, the mortality rate was 56.0% (14 patients) in Group1 and 6.6% (1 patient) in Group2. It was significantly higher in Group 1 ($P<0.05$). The median EQ-5D score was 0.764 (95% CI 0.579–0.870) in Group1 versus 0.768 (95% CI 0.621–0.915) in Group2. There was no statistically significant difference between them ($P=0.813$).
Conclusions: This study focused on GCA patients with prednisolone therapy over 2 years. It showed that EQ-5D was decreased compared with the Japanese norm but it didn't clearly decrease after 2 years of treatment. These findings suggest the value of measuring health status in GCA patients by EQ-5D at least first 2 years of treatment, because it would allow comprehensive evaluation of the patient's health condition and add another dimension to the subjective symptoms and laboratory data.

AB0568 APPLICATION OF OZONATED WATER IN ORAL ULCER PATIENTS WITH BEHCET'S DISEASE

H. Miao, L. Zhang, G. Zhang, K. Xu. *Rheumatology, Shanxi Dayi Hospital, Taiyuan, China*

Background: Behcet's disease is a systemic vasculitis disease of unknown etiology. Oral ulcer is the most common symptoms, the ulcer is various, the swelling and pain is obvious, and it is easy to recurrent, these symptoms affected the patient's diet and life seriously.Therefore, it is important to care the patients with Behcet's disease of oral ulcer.The ozonated water had many functions such as immune activation and immune regulation, it can induce the production of many cytokines,promote the repairment of oral epithelium.At the same time,the ozonated water had a direct effect on the nerve endings,it played a better analgesic effect, it was widely used in oral mucositis which induced by chemotherapy.But there were few studies about application ozonated water in the patients with Behcet's disease of oral ulcer, it was not widely used in clinical practice.
Objectives: Apply the ozonated water in patients with Behcet's disease,observe the effectiveness in patients with Behcet's disease of oral ulcer.
Methods: From June 2014 to June 2016,82 cases of hospitalized patients with Behcet's disease were randomly divided into study group and control group (n=41), the control group used nursing method of gentamycin sulfate solution and nystatin solution gargle alternatively,the research group using ozonated water gargle,observe and evaluate the healing effect of two groups of patients.
Results: The research group had significant improvement in healing oral ulcer and relieving pain ($P<0.05$).
Conclusions: Ozonated water had a perfect effect in patients with Behcet's disease of oral ulcer.

AB0569 CHANGE IN SERUM LEVEL OF SOLUBLE E-SELECTIN AND MMP-9 IN CHILDREN WITH KAWASAKI DISEASE

H. Zeng. *Department of Pediatric Allergy, Immunology and Rheumatolog, Guangzhou Women and Children's Medical Center, Guangzhou, China*

Objectives: Kawasaki disease (KD)is a kind of febrile disorder without definite etiology. Coronary artery aneurysms are the major complication of Kawasaki disease (KD). r11le pathogenesis of the vascular damage remains unknown.This study Wfl8 conducted to explore the pathophysiological role of E-selectin (ES), CMatrix metalloproteinase 9 (MMP-9) in KD.and to look for the evidenee of direct relationship between the plasma levels of ES,MMP-9 and the incidence of the coronary artery lesion (CAL).

Methods: Soluble ES and MMP-9,were measured in 68 patients with KD,20 patients with febrile disease and 20 healthy children by using double antibody sandwich enzyme linked immunosorbent assay (ELISA).Patients with KD were separated into acute phase group, subacute phase group, recovery phase group. coronary artery lesion group (CAL), non-coronary artery lesion group (NCAL).
Results: KS and MMP-9 levels in the acute phase group,subacute phase group were significantly higher than those in the healthy group. Plasma ES and MMP-9 levels of CAL group were significanfly higher than those of NCAL group in acute phase. ne peak level of ES and MMP-9 appeared in the acute phase.There Was a significant correlation between KS and MMP-9 levels in KD patients ($r=0.643$, $P<0.01$).
Conclusions: the increase of plasma PS and ES levels in KD acute phase and subacute phase might play an important role in the pathophysiology of the VasCUlax damage.KS and MMP-9 may potentially be a predictor of CAL in patients.

AB0570 CLASSIFICATION, EPIDEMIOLOGY, AND CLINICAL PHENOTYPES OF PRIMARY VASCULITIDES IN COLOMBIA

J.E. Barahona-Correa[1,2], Ó.E. Gómez-Cárdenas[3], J.C. Sarmiento Monroy[1,2], R.D. Mantilla[1,2]. *[1]Rheumatology, Center of Dermatology and Rheumatology (FUNINDERMA); [2]Center for Autoimmune Diseases Research (CREA), Universidad del Rosario; [3]Department of physiological sciences, School of Medicine, Pontifical Xavierian University, Bogotá, Colombia*

Background: Primary vasculitides usually pose a diagnostic challenge. They represent a wide spectrum of heterogeneous vascular disorders characterized by variable target vessel involvement, vascular abnormalities, and end organ damage [1]. Several studies about primary vasculitides expose epidemiologic data, mainly from North America and Europe. Nevertheless, data in Latin America is scarce [2].
Objectives: To describe the prevalence and clinical presentation of primary vasculitides.
Methods: This was an observational cross-sectional study in which well-characterized patients were assessed from 2001 to 2016. Each patient was evaluated by the same rheumatologist in a single rheumatology outpatient center in Bogota, Colombia. Patients were classified either according to ACR 1990 criteria (Granulomatosis with polyangiitis, Eosinophilic granulomatosis with polyangiitis, Henoch-Schönlein purpura, Polyarteritis nodosa, Takayasu arteritis, Giant cell arteritis), EMA algorythm (Microscopic polyangiitis) or 2012 revised Chapell Hill nomenclature criteria (Variable Vessel Vasculitis, Single-Organ Vasculitis). ANCA-Associated Vasculitis (AAV) was used to define Small Vessel Vasculitis (SVV) not fulfilling either ACR 1990 criteria or EMA algorythm.
Results: A total of 56 patients were included. Baseline characteristics of patients were as follows: female gender 75%, mean age 56±15.7 years, and median disease duration 3 (IQR 6) years. Most of patients (73%) were diagnosed at first year of disease onset, and fulfilled international classification criteria (63%). SVV was the most frequent phenotype (55%), and C-ANCA/anti-PR3 were the most frequently identified auto-antibodies (40%). Musculoskeletal manifestations (arthralgia, arthritis, and myalgia), mucocutaneous disorders (including vasculitic/necrotic lesions, mucosal ulcers, and purpura), neurological compromise (peripheral and central), and renal involvement (acute renal failure, glomerulonephritis, and lung-kidney syndrome) were the most frequently reported onset symptoms in 29%, 29%, 23%, and 21%, respectively. Interestingly, most of patients did not develop organic compromise other than the onset manifestation form. Thirteen percent of patients fulfilled polyautoimmunity criteria and 9% presented with multiple autoimmune syndrome. Antiphospholipid syndrome was the most common associated autoimmune disease described. Corticosteroids were the most common treatment used in 93% of patients, followed by azathioprine in 57%, cyclophosphamide, methotrexate, and rituximab in 29%, and antimalarials in 27% (Tab.1). No deaths occurred during follow-up.

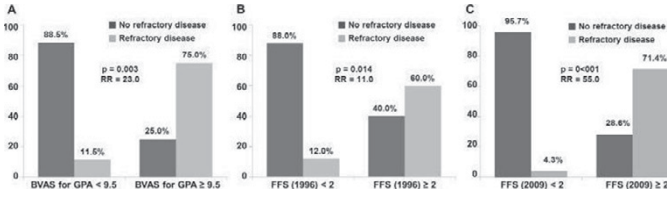
Other	8 [14]
Behçet	3 [5]
Aortitis	1 [2]
Skin-limited	3 [5]
Cogan syndrome	1 [2]



* The presence of more than one autoimmune disease in a single patient. Distribution of autoimmune comorbidities were as follows: antiphospholipid syndrome, systemic lupus erythematosus-SLE like (3 each); autoimmune hepatitis, autoimmune thyroid disease, myasthenia gravis, pyoderma gangrenosum, rheumatoid arthritis, Sjögren's syndrome, and vitiligo (1 each).
** Multiple Autoimmune Syndrome: The presence of three or more well-characterized autoimmune diseases in the same patient.
* A case of TAK with positive C-ANCA was excluded.

Conclusions: Vasculitides are conditions with several subphenotypes, being ANCA-associated the most frequently reported. Onset symptoms seem to be the main drivers of disease evolution. Appropriate and prompt diagnosis is critical to enable timely intervention, aimed to prevent end organ damage and reduce morbidity in these patients. Controlling disease activity and preventing progression is the milestone of treatment. Characterization of Latin America population is pivotal to raise awareness of health-care workers, and policy makers.

AB0571 BIRMINGHAM VASCULITIS ACTIVITY SCORE MORE THAN 9.5 AT DIAGNOSIS IS AN INDEPENDENT PREDICTOR OF REFRACTORY DISEASE OF GRANULOMATOSIS WITH POLYANGITIS

J. You, H.J. Kim, S.-W. Lee. *Division of Rheumatology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea, Seoul, Korea, Republic Of*

Background: Granulomatosis with polyangiitis (GPA), that is identical to what has been called Wegener's granulomatosis, is one of anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV). GPA is characterized by necrotising granulomatous inflammation usually affecting small to medium vessels, and it often involves the upper and lower respiratory tracts and commonly provokes necrotising glomerulonephritis. It has been reported that the mortality rate in untreated patients increased up to 90% within 2 years after diagnosis, and the overall mortality rates were ranging from 12% to 44% within 4 to 10 years. The major causes of death are known as cardiovascular disease, adverse events of immunosuppressive agents and major organ involvement of GPA. If there might be predictors of relapse or refractory disease of GPA during the follow-up duration, they can help physicians to select the induction therapeutic regimens, decide the duration of the maintenance therapeutic regimens and adjust the follow-up interval in order to improve the disease course of GPA.
Objectives: We investigated whether clinical manifestations, anti-neutrophil cytoplasmic antibodies (ANCAs), Birmingham vasculitis activity score (BVAS) for granulomatosis with polyangiitis (GPA) and five factor score (FFS) at diagnosis can predict relapse or refractory disease in 30 histology-proven GPA patients with the follow-up duration ≥12 weeks.
Methods: We reviewed the medical records of 30 GPA patients. We collected clinical data, ANCAs, BVAS for GPA, FFSs at diagnosis, and we compared variables between the two groups based on relapse or refractory disease. The optimal cut-offs were extrapolated. Multivariate logistic regression and Cox hazard model analyses were conducted to identify predictors of refractory disease.
Results: The mean age and follow-up duration of patients were 63.3 years old and 45.2 months. The mean initial BVAS for GPA, FFS (1996) and FFS (2009) were 5.4, 0.6 and 1.0. There were no significant predictors of relapse. The mean BVAS for GPA, FFS (1996) and FFS (2009) of patients with refractory disease were higher than those without ($p<0.05$ for all). Patients having BVAS for GPA ≥9.5, FFS (1996) ≥2 and FFS (2009) ≥2 exhibited significantly enhanced risk of refractory disease than those having not (RR 23.0, RR 11.0, and RR 55.0, respectively), and low cumulative refractory disease free survival rates. Multivariate Cox hazard model analysis proved BVAS for GPA ≥9.5 was an independent predictor of refractory disease during the follow-up duration (OR 12.892).

Conclusions: BVAS for GPA ≥9.5 was an independent predictor of refractory disease during the follow-up duration ≥12 weeks.

AB0572 EFFICACY AND SAFETY OF RITUXIMAB FOR ANCA ASSOCIATED VASCULITIS

K. Fujita[1], M. Hirata[1], S. Oguni[2], Y. Nakashima[2], Y. Nomura[2], Y. Yamamura[3], K. Nonaka[2], N. Shibutou[1,2], N. Momoki[2], A. Ueno[1], T. Ombe[2], K. Maruyama[2], M. Hiramatsu[2], M. Yamamura[1]. *[1]Centre for Rheumatology; [2]Centre for Kidney Diseases, Okayama Saiseikai General Hospital; [3]Okayama University Hospital, Okayama, Japan*

Background: In Japan, rituximab (RTX) has become one of the dominant alternatives for ANCA associated vasculitis (AAV) even for elderly patients.
Objectives: The efficacy and safety of RTX for AAV patients was determined at our hospital.
Methods: Nineteen patients with AAV, including 14 newly diagnosed patients and 6 relapsed patients, had been treated with RTX. There were 10 males and 9 females. They were all MPO-ANCA positive; 16 were diagnosed with microscopic polyangiitis (MPA), 2 with granulomatosis with polyangiitis (GPA), and 1 with undifferentiated, according to the EMA classification of AAV. The mean age at RTX induction was 71.3 years (range: 40 – 82 years). The efficacy was evaluated by the BVAS score at the time of first induction and after 6 month treatment. Adverse events were recorded during the 6-month treatment.
Results: The mean of BVAS decreased from 17.3 (range: 7–35) at the first induction to 1.2 (0–4) at 6 month of RTX treatment. Of the 10 patients who could be followed-up for over 6 months, 7 patients achieved remission (BVAS=0) (remission rate: 70.0%). The titer of mean MPO-ANCA decreased 136.1 IU/mL (9.9–300 IU/mL) to 44.4 IU/mL (1.0–114.0 IU/mL) at 6 month. The dose of prednisolone decreased from 34.4mg/day (5–60mg/day) at baseline to 5.5mg/day (0–10 mg/day) at 6 month. The adverse events were as follows: 3 patients experienced reactivation of cytomegalovirus (CMV) with a CMV colitis, one patient with sepsis following urinary-tract infection, and one patient with bacterial pneumonia. One patient with PMA died of exacerbation of the disease itself.
Conclusions: In Japan, AAV, mostly MPO-ANCA-positive PMA, affects elderly persons. The results suggest that RTX may provide a therapeutic option for elderly patients at the age of over 70 years with severe MPA, with an acceptable safety profile and rapid glucocorticoid tapering. However, careful monitoring for infectious diseases will be needed.

AB0573 AUTOLOGOUS STEM CELL TRANSPLANTATION IN THE MANAGEMENT OF REFRACTORY BEHÇET'S SYNDROME: A CASE SERIES FROM A SINGLE CENTRE OF EXCELLENCE

L. Chadwick[1,2], D. Thong[2], J. Nair[1], N. Goodson[1,2], R. Moots[1,2]. *[1]Aintree University Hospital; [2]Institute of Ageing and CHRonic Disease, University of Liverpool, Liverpool, United Kingdom*

Background: Evidence regarding haematopoietic stem cell transplantation (HSCT) in refractory Behçet's Syndrome (BS) is limited. A systematic review in 2014 identified 20 patients with BS who had undergone HSCT, from which 9 patients underwent HSCT with refractory BS as the primary indication. Of these 20 patients: 15 achieved complete remission, 1 patient achieved partial remission, 2 patients relapsed, 1 patient died and 1 had no outcome reported. Nine patients had reported complications, 5 patients had no complications and 6 patients were missing data. All data was sourced from single case studies (1).
Objectives: Outline the indications, outcomes and complications of HSCT in a case series of 4 patients with BS managed at a single centre of excellence.
Methods: Case notes were reviewed for 4 patients from the Liverpool Behçet's Centre of Excellence (LBCE) who have undergone HSCT.
Results: The primary indication for 3 of the 4 patients who have undergone autologous HSCT at LBCE was refractory BS. Patient 1 underwent HSCT for multiple myeloma, but suffered from severe BS with neurological and venous involvement and is now in partial remission with occasional mild muco-cutaneous ulceration, not requiring systemic immunosuppression. Patient 2 underwent HSCT for severe refractory neuro-Behçet's. This patient is now in complete remission after commencing azathioprine for oral ulceration. The indications for HSCT in patients 3 and 4 were severe muco-cutaneous ulceration and dermatological involvement refractory to numerous biologic agents with high ongoing steroid dependency. Patient 3 also had previous thrombophlebitis and patient 4 had previous gastro-intestinal ulceration. They are both currently in complete remission but follow up time is limited. Patient 3 had a post-HSCT complication of pneumonia and mucositis which resolved without persistent morbidity, patient 4 had an upper limb deep vein thrombosis (DVT) as an inpatient.
Conclusions: HSCT is an effective treatment modality for severe refractory BS and can result in medication free remission. However, the associated risks should be considered and alternative treatment options deliberated or exhausted before opting for this treatment modality.

AB0574 VENOUS INVOLVEMENT IN BEHCET'S DISEASE: A RETROSPECTIVE ANALYSIS OF 75 CASES

L. Belhadj, A. Hariz, I. Boukhris, I. Kechaou, S. Azzabi, L. Ben Hassine, E. Cherif, N. Khalfallah. *Internal medecine B, Charles Nicolle Hospital, Tunis, Tunisia*

Objectives: Behcet's disease (BD) is a chronic multisystem inflammatory disease characterized by recurrent mouth and genital ulcerations. The vascular involvement varies from 7, 7 to 43% depending on ethnicity. Venous lesions are

the most frequent vascular manifestation in BD. In this study, we looked at the pattern and outcome of venous events in BD.
Methods: Seventy five patients, who fulfilled the criteria of the International Study Group for diagnosis of BD, were recruited. We studied the characteristics of patients with thrombotic venous events. Clinical data parameters were recorded, including age at onset, the vascular and extra-vascular manifestations of the disease.
Results: Twenty six from 75 patients had vascular event. Twenty three of these patients had a venous event. The mean age of the patients at the first venous event was 32 years. There were 22 males and 4 females. The first venous event occurred before BD diagnosis in one case and in the same time of onset of the disease in two cases. In the other cases, venous event occurred in patients followed for BD and the mean disease duration was 5, 82 years. The mean number of recurrence of venous events was 1, 46. Deep vein thrombosis was the most frequent single vascular event (76, 92%). The most frequent localizations were in legs (23 cases). Four patients had cerebral vein thrombosis. A pulmonary venousinvolvement, a Budd-Chiari syndrome,an inferior and superior vena cava syndrome and arms thrombosis were found in only one case each one. An arterial event was associated in 2 cases. An association with ocular manifestations was observed in 26, 9% patients and neurologic manifestations in 11, 53%.
Conclusions: Although there is no agreement on the frequency rate of the vascular lesions in the littérature, most the vascular lesions in the litterature, most of the reported series indicate that the venous lesions are by far, more common than the arterial lesions. Kabbaj et al. reported 85% venous, 10% arterial and 5% mixed arterial and venous involvment which is similar to the reported frequency in our patients.
In conclusion, the frequency of vascular complications of BD in our patients is similar to those reported around the world.

AB0575 RETROSPECTIVE SURVEY OF CONCOMITANT AUTOIMMUNE DISEASES AND AUTOANTIBODIES IN A COHORT OF PATIENTS WITH ANCA-ASSOCIATED VASCULITIS (AAV)

M. Casal Moura[1,2,3], S. Prieto-González[3], G. Espígol-Frigolé[3], G. Murgia[3,4], M. Alba[3], J. Hernández-Rodríguez[3], M. Cid[3]. *[1]Department of Internal Medicine, São João Hospital Center; [2]Department of Medicine, Porto Medical School, Porto, Portugal; [3]Department of Autoimmune Diseases, Hospital Clínic. University of Barcelona. IDIBAPS, Vasculitis Research Unit, Barcelona, Spain; [4]University Clinic for Visceral Surgery and Medicine, Bauchzentrum Bern, Bern, Switzerland*

Background: Anti-neutrophil cytoplasmic antibodies (ANCA) associated vasculitis (AAV) – granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA) have heterogenous clinic and biologic phenotypes. Sporadic reports indicate that some AAV patients may have other autoimmune diseases but the frequency of the association is unknown.
Objectives: Our purpose was to assess the frequency of other autoimmune diseases or autoantibodies in a well-defined cohort of AAV patients.
Methods: Retrospective survey of a cohort of patients regularly controlled at outpatient facility of an Autoimmune Disease Department in a 5-year period (2011–2016). Clinical and immunologic data were retrieved from electronic records. All patients were diagnosed and treated by the authors.
Results: We included 110 AAV patients – 36 (32.7%) GPA, 45 (40.9%) MPA and 29 (26.4%) EGPA. Regarding to ANCA specificity – 23 (20.9%) against proteinase 3 (PR3)-ANCA, 68 (61.8%) against myeloperoxidase (MPO)-ANCA and 19 (17.3%) were ANCA negative. Organ-specific auto-immune diseases was actively searched in 73 (81.1%) patients and was present in 43 (58.9%) patients. More prevalent autoimmune diseases diagnosed were: hypothyroidism (15,34.9%), pernicious anemia (12,27.9%), Sjögren syndrome (8,18.6%), hyperthyroidism (4,9.3%) and primary biliar cholangitis (3,7.0%). Autoantibodies more frequently positive were: ANAs 29 (67.4%), ASMA 27 (62.8%), anti-parietal cells 20 (46.5%), anti-thyreoglobulin 6 (14.0%), anti-peroxidase 12 (27.9%), anti-SSa 5 (11.6%), anti-SSb 3 (7.0%) and RF 14 (32.6%). Prevalence of organ-specific autoimmune disease was higher in MPA (67.4vs.32.6%,p=0.001) and ANCA-MPO carriers (81.4vs.18.6%,p<0.001). Pernicious anemia was more prevalent in MPA (41.4vs.0%,p=0.027) and in ANCA-MPO (34.3vs.0%,p=0.054) and myositis was more prevalent in ANCA-PR3 (12.5vs.0%,p=0.037). ANAs positivity was more prevalent in ANCA-MPO carriers (74.3%vs.36.5%,p=0.048). Predictive factors for development of organ-specific autoimmune disease identified were: female gender (OR 2.710,95% CI 1.034–7.099,p=0.043), MPA syndrome (OR 3.578, 95% CI 1.334–9.523,p=0.011) and MPO carriers (OR 3.346, 95% CI 1.166-9.601,p=0.025).
Conclusions: A substantial percentage of AAV patients, particularly MPA and anti MPO carriers, have associated autoimmune diseases and autoantibodies. The limitations of our study (retrospective assessment and lack of comparator) do not allow accurate estimation of prevalence. The severity of AAV and difficulties in management, may lead to overlooking of associated autoimmune diseases which appear to be frequent. Associated autoimmune disease may contribute to additional burden in AAV patients. (Supported by SAF 2014 57708-R).

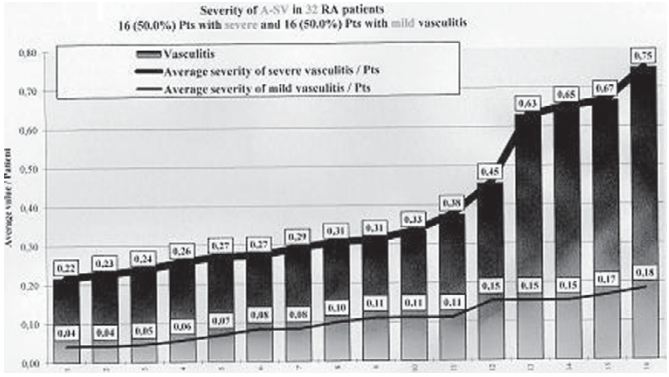
AB0576 ANTINEUTROPHILIC CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS: IS HYPOCOMPLEMENTEMIA A PREDICTOR OF POOR PROGNOSIS?

M. Estévez, A. Argibay, L. Rodriguez, R. Lorenzo, M. Freire, C. Vázquez-Triñanes, I. Villaverde, B. Gimena, J. Fernández-Martín, A. Rivera. *Systemic Autoimmune diseases and Thrombosis Unit, University Hospital Complex of Vigo, Vigo, Spain*



Background: Antineutrophil cytoplasmic antibodies (ANCA) associated vasculitis (AAV) is a necrotizing vasculitis that predominantly affects small vessels and is associated with ANCA specific for myeloperoxidase (MPO-ANCA) or proteinase 3 (PR3-ANCA). The major clinicopathologic variants of AAV include microscopic polyangiitis (MPA), granulomatosis with polyangiitis (GPA) and eosinophilic granulomatosis with polyangiitis (EGPA). Recent studies have demonstrated the crucial role of complement activation in the pathogenesis of AAV. However, the clinical characteristics of AAV with hypocomplementemia (HC) still remain unclear.
Objectives: The aim of our study was to anlyze the demographic, laboratory, treatment and clinical characteristics of AAV using medical records. To compare the AAV patients with and without HC.
Methods: Retrospective study of patients with AAV diagnosed and followed in a specific Systemic Autoimmune Diseases and Thrombosis Unit. We defined HC as the state in which at least one of the following was lower than the lower limit of the normal range: Complement 3 (C3), Complement 4 (C4). Demographic, clinical, treatment and evolution data were recorded and analyzed using SPSS 22.0.
Results: Thirty-six patients with AAV were included (94,4% MPO-ANCA, 5,6% PR3-ANCA). 8 patients were diagnosed of GPA, 21 of MPA and 3 of EGPA. 61,1% of the patients were males and the mean age at the onset of the disease was 63,11±14,38 years [30–85]. 75% of patients had any vascular risk factors. Renal involvement occurred in 32 patients (88,9%): hematuria in 96,9%, proteinuria in 90,6% (>1 gr 68,7%) and glomerular filtration decreased in 81,25%. Biopsy was performed in 22 patients and a focal and segmental necrotizing glomerulonephritis with extracapillary proliferation was the finding more common. Pulmonary disease (61,1%) included interstitial disease 40,9%, alveolar hemorrhage 22,7% and nodules 18,2%. Other clinical manifestations were constitutional syndrome 36,1% (the main symptom was asthenia); ear, nose, and throat manifestations 33.3%; neurologic involvement 27.8% (the main finding was polyneuropathy); articular manifestations 33.3% and skin lesions 16,7%. All the patients received prednisone in combination with cyclophosphamide (69.4%) or rituximab (13.9%). Azathioprine was used as glucocorticoid-sparing agent (41.7%). 83.3% of the patients needed hospital admission and 6 died (16.7%). Eleven patients (30,6%) had HC at their diagnosis of AAV. Compared to the AAV patients without HC (n=25), we found no significant differences in the outcome or severity of the manifestations (evaluated by Five factor score). The small sample size could in part explain these results.
Conclusions: Our patients with HC at diagnosis of AAV did not have different characteristics than those without HC. More studies are needed to determinate if HC is a predictor of poor prognosis in AAV patients.

AB0577 SYSTEMIC AUTOIMMUNE VASCULITIS IN RHEUMATOID ARTHRITIS – A POSTMORTEM CLINICOPATHOLOGIC STUDY OF 161 PATIENTS

M. Bély[1], Á. Apáthy[2]. *[1]Department of Pathology, Policlinic of the Order of the Brothers of Saint John of God; [2]Department of Rheumatology, St. Margaret Clinic Budapest, Budapest, Hungary*

Background: Systemic vasculitis of autoimmune origin (A-SV) may be regarded as a basic histological manifestation of rheumatoid arthritis (RA) [1,2].
Objectives: The aim of this study was to characterize the severity of systemic autoimmune vasculitis at death in RA patients.
Methods: A randomized autopsy population of 161 in-patients with RA was studied.
A-SV complicated RA in 32 (19.88%) patients [3].
RA was confirmed clinically according to the criteria of the ACR [4].
The severity of vasculitis was evaluated by semi-quantitative, visual estimation on a 0 to 3 plus scale in12 organs (heart, lung, liver, spleen, kidney, pancreas, gastrointestinal tract, adrenal gland, skeletal muscle, peripheral nerve, skin and brain) at death) [1]. ("0": no vasculitis, "1": sporadically (scattered) located

vasculitis, "2": less than five, "3": five or more involved blood vessels/microscopic field with a x20 objective)
The age at death, and the onset and duration of RA with mild (<0.2/patient), or severe (0.2A-SV, were compared by Student (Welch) t-probe.
Results: 16 (50.0%) of 32 patients had a "mild" degree of A-SV (females 11, avg age of 70.91 years, range 80 – 63, onset of RA: 62.55, avg disease duration: 8.36 years at death; males 5, avg age of 71.6 years, range 83–58, onset of RA: 57.2, avg disease duration: 14.4 years).
16 (50.0%) of 32 patients had "severe A-SV" (females 8, age of 60.88 years, range 82–32,onset of RA: 52.67, avg disease duration: 13.5 years at death; males 8, avg age of 65.0 years, range 78–53, onset of RA: 53.25, avg disease duration: 11.75 years).
Four (12.5%) of 32 patients had "extremely severe A-SV" (with an average cumulative value of severity/RA patient with SV >0.630) (females 1, age of 82.0 years, onset of RA: 62.0, average disease duration: 20.0 years at death; males 3, average age of 69.7 years, range 78 – 59, onset of RA: 60.7, average disease duration: 9.0 years)
Severity of SV in 32 RA patients with A-SV – according to increasing average values of vasculitis/patient – is summarized in Figure.

Conclusions: A-SV is caused by circulating immune complexes in RA. Immune complexes spread via the bloodstream and provoke vasculitis throughout the body.
We found no differences in the linear and basically parallel development of A-SV between patient groups with mild and severe vasculitis.
The progression of vasculits was the same in both patient groups suggesting differences in production of circulating immune complexes.
Quantitative differences in the production of circulating immune complexes may be related to a "benign" or "aggressive" clinical course of RA, which may be due to genetical and other factors.
In 4 of 32 RA patients the severity of vasculitis showed a "step-wise" growth curve with "extreme severe" A-SV (0.630 or <) according to increasing average values of vasculitis/patient (Figure 1). There was no gradual transition between the "extremely severe" and "severe" degrees A-SV. This profile of "step-wise" general severity in patients with vasculitis may represent a subgroup of patients with a different genetic-immunologic background.

AB0578 ARTERIAL ANEURYSMS MOROCCAN EXPERIENCE STUDY OF 37 CASES

M. Moudatir[1], M. Moudatir[2]. [1]*Internal medicine;* [2]*12 rue la saone, Polo, University hospital ibn rochd, Casablanca, Morocco*

Background: Behcet's disease is a systemic vasculitis with a tropism for the venous system. Arterial involvement is uncommon (1%) and mainly represented by aneurysms that can be life-threatening.
Objectives: This retrospective study was conduced in the internal medicine department of the University Hospital Ibn Rochd of Casablanca, over a period of thirty-five years between 1980 and 2016. Where included all the cases of Behcet's disease diagnosed in our service (1618 case).
Methods: We aimed to determine the epidemiological profile, the different possible clinical manifestations and to discuss both prognosis and treatment in such cases.
Results: 37 patients – 32 men and 5 women – presented arterial involvement in type of arterial aneurysm, which represents a rate of 2.35%.
Mean age at diagnosis was 32 years old (ranges 17–54). This complication was the revealing event for Behcet's disease in 2 cases, concomitant in 3 cases and occurring after an average of 6-year-period evolution of the disease in 32 cases.
The aneurysm affected: the pulmonary artery (22 cases), the abdominal aorta (5 cases), the femoral artery (5 cases), the internal carotid artery (2 cases), the iliac artery (2 cases) and the middle cerebral artery (1 case). The aneurysm was associated with venous disease (18 cases), pulmonary embolism (2 cases) and intracardiac thrombus (1 case).
The medical treatment has relying on anticoagulants (6 cases), anti-aggregating agents (9 cases), corticosteroids (36 cases), immunosuppressive drugs – cyclophosphamide (23 cases) and azathioprine (12 cases), while 7 patients underwent surgical intervention.
Evolution was favorable in 23 patients and with negative outcome in 14 patients (9 relapses and 5 deaths).
Conclusions: Arterial aneurysms are the most common arterial complications in the context of Behcet's disease, while the prognosis remains poor in the absence of early and appropriate management (corticosteroids, immunosuppressive agents, surgery).

AB0579 IMMUNE RELATED DIFFUSE ALVEOLAR HAEMORRHAGE: SINGLE CENTER EXPERIENCE AND LONG TERM OUTCOME – RHEUMATOLOGICAL PERSPECTIVE

M.A. Bindroo, R. Gupta, N. Mendiratta, D. Raval, G. Ekbote, V. Singal.
Rheumatology and Clinical Immunology, Medanat the Medicity, gurgaon, India

Background: Diffuse alveolar haemorrhage (DAH) is a feature of several immune and nonimmune disorders. Failure to diagnose and treat DAH syndromes in their early stages may lead to acute respiratory failure, CKD and death. Prognosis is poor with in-hospital mortality ranging from 20% to 100%. Immune related DAH is monophasic and if treated early and achieved remission, long term outcome is good.
Objectives: To evaluate the therapeutic response and long term outcome in patients with Immune related (AAV & SLE) DAH.
Methods: A retrospective review of medical records of patients admitted under Rheumatology and Clinical immunology department with Immune related DAH was made with regards to their presentation, treatment & response, mortality, morbidity and long term outcome. Study was performed after approval and ethical clearence from IRB.
Results: From June 2012 to Augst 2016, 18 patients (15 were AAV related & 3 as SLE related) were admitted. Amongst AAV patients, PR3 positive were 11 & MPO positive were 4. Fourteen patients were females and 4 males, age ranged from 14 – 68 yrs (median=54.5 yrs). Mean duration of disease before onset of DAH was 3 months. Nine (50%) patients had associated kidney and musculoskeletal involvement. Eleven (61.11%) patients were admitted under ICU care requiring artificial ventilation. Pulse methylprednisolone injections were given in 15 (83.33%), Cyclophosphamide in 13 (72.22%), IVIg in 2 (11.11%), plasmapheresis in 7 (38.88%) patients. Time from first consultation to pulse methylprednisolone was in range from 1 to 5 days. Out of 18, 11 patients achieved remission. In hospital mortality was seen in 5 (27.77%) patients, all were AAV (MPO+=3, PR3+=2), all were complicated with sepsis with MODS before death. Out of 7 who received plasmapheresis, 2 patients (28.4%) died, 2 patients developed CKD (dialysis independent). Duration of ICU& hospital stay in days ranged from 3 to 28 days & 2 to 40 days respectively. Mean follow up was 16 months (range 11–42 months) on OPD visits. Two had relapse on follow up (1 nephritis, 1 persistant cavities with episcleritis) who were given Rituximab. Total 5 (38.46%) received Rituximab out of which 2 were refractory to Cyclophosphamide, 2 had relapse & 1 concomitantly. Eight patients (44.44%) developed morbidity in the form of dialysis independent-CKD in 4 (PR3+ in 2, MPO+ in 1 and Lupus nephritis in 1) with concomitant cataract in 1, ILD in 2, hearing loss in 1 and finger amputation in 1). All 13 patients who survived are in remission. Ongoing maintenance treatment is Azatjioprine in 5, Mycophenolate mofetil in 3 and Rituximab in 3 patients.
Conclusions: High index of suspicion with early diagnosis and treatment results in low mortality and better long term outcome. All mortality was because of delay in diagnosis. Rituximab is effective in achieving remission in refractory as well as relapsed cases

AB0580 CLINICAL CHARACTERISTICS AND RISK FACTORS OF BEHCET'S PATIENTS WITH CONDUCTION DISTURBANCES-DATA FROM A CARDIOVASCULAR CLINICAL CENTER IN CHINA

R. Bai, N. Gao. *Anzhen Hospital, Capital Medical University, Beijing, China*

Background: Behcet's disease is a kind of systemic vasculitis affecting multiple systems. Although symptomatic cardiac involvement in Behcet's disease is uncommon, the fatality rate may reach up to 29%. Conduction disturbances might lead to poor outcome and often need permanent pacemaker implanted. The characteristics of conduction disturbances in Behcet's disease were rarely reported before.
Objectives: To investigate the clinical characteristics of Behcet's patients with conduction disturbances and explore the underlying risk factors.
Methods: We reviewed 57 medical records of Behcet's disease with cardiovascular lesions in Anzhen Hospital, Capital Medical University between January 2002 and July 2015, and analyzed the clinical characteristics.
Results: (1) There were 13 patients with conduction disturbances out of a total of 57 Behcet's disease cases (22.8%) in our research: three patients with first-degree atrioventricular block; one patient with Mobtizs type I second- degree atrioventricular block; four patients with third-degree atrioventricular block; one patient with the left anterior branch block; one patient with complete right bundle branch block; three patients with first-degree atrioventricular block combined with the left anterior branch block or complete right bundle branch block. One patient (7.7%) died from infectious endocarditis and aortic root abscess during hospital stay.
(2) Hemoglobin level was significantly lower in cases than controls (111.23±23.06 vs. 127.16±19.86 g/L, P=0.017); The median of albumin level in cases was higher than controls [34.5 (14.2) vs. 38.5 (9.9) g/L, P=0.032] (Table 1); C reactive protein level was higher in cases than controls [26.12 (21.3) vs. 6.7 (16.4) mg/L, P=0.045] (Table 1).
(3) The aortic valvular insufficiency presented more frequently in patients in the case group than the control group (92.3% vs. 47.7%, respectively; P=0.004).Heart reconstruction can be seen in Behcet'patients with cardiac involvement. The echocardiography showed the following parameters were significantly different between two groups: left ventricular end-diastolic diameter (64.85±10.96 vs. 52.55±10.13 mm, P=0.001); left ventricular end-contraction diameter [48 (15) vs. 31 (13) mm, P=0.001]; left atrial diameter [50 (17) vs. 35.85 (13) mm, P=0.003]; outflow tract of right ventricle [26 (7) vs. 27 (6) mm, P=0.045]
(4) Aortic valvular insufficiency was an independent risk factor for Behcet's disease with conduction disturbances (OR =1.157, 95% CI 1.034, 1.293, P=0.011).
Conclusions: Behcet's disease is one of the unusual etiologies of atrioventricular block. The evaluation of conduction disturbance should be kept in mind when diagnosing BD's patient.

Pereira da Silva[3], C. Afonso[2], J.E. Fonseca[1], H. Canhão[7], R.A. Luqmani[9], M.J. Santos[4,7]. *[1]Hospital Santa Maria-CHLN, Lisboa; [2]Unidade Local de Saúde Alto Minho, Ponte de Lima; [3]Centro Hospitalar Universitário de Coimbra, Coimbra; [4]Hospital Garcia de Orta, Almada; [5]Centro Hospitalar São João, Porto; [6]Hospital Egas Moniz-CHLO; [7]Sociedade Portuguesa de Reumatologia, Lisboa; [8]Hospital de Faro-CHA, Faro, Portugal; [9]NDORMS, University of Oxford, Oxford, United Kingdom*

Background: The vasculitides are a group of relatively rare diseases with different manifestations and outcomes. New therapeutic options have led to the need for long-term registries. The Rheumatic Diseases Portuguese Register, Reuma.pt, is an electronic clinical record, created in 2008, which currently includes specific protocols for 11 diseases and >16000 patients registered from 79 national and international rheumatology centres. Since October 2014, a dedicated protocol to vasculitis has been created as part of the European Vasculitis Society initiative of having compatible European registries.
Objectives: To describe the structure of Reuma.pt/Vasculitis and characterize the patients registered over the last two years.
Methods: We developed a dedicated web-based software to enable prospective collection and central storage of anonymised data from patients with vasculitis. All Portuguese rheumatology centres were invited to participate. Data regarding demographics, diagnosis, classification criteria, imaging and laboratory tests, outcome measures of prognosis, damage, disease activity and quality of life, and treatment were collected. We performed a cross-sectional descriptive analysis of all patients registered up to January 2017.
Results: A total of 492 patients, with 1114 visits, from 11 centres were registered in Reuma.pt/Vasculitis. The mean age was 53±20 years at last visit; 68% were females. The diagnoses followed the 2012 Chapel Hill Consensus nomenclature (Table 1). The most common diagnoses were Behçet's disease (BD) (39%) and giant cell arteritis (GCA) (20%). Patients with BD met the International Study Group 1990 criteria, the International Criteria for BD 2006 and 2013 in 84%, 95% and 95% of cases, respectively. Patients with GCA met the 1990 American College of Rheumatology criteria in 95% of cases. Data on vascular ultrasound was available in 74% of patients; 73% compatible with the diagnosis. Assessment of the Birmingham Vasculitis Activity Score (BVAS) and Vasculitis Damage Index (VDI) was available for all vasculitides and the Five Factor Score calculation of survival rate for ANCA associated vasculitis (AAV) and polyarteritis nodosa (PAN). The mean BVAS at first visit was 18±7 for AAV and 15±9 for PAN; the mean VDI at last visit was 3±2 for AAV and 2±2 for PAN. Health related quality of life assessments (SF-36, EQD5, FACIT and HADS) were also collected. Treatment registry with the disease assessment variables shown in graphics was available for all patients; only 6% were under biologic treatment.

Table 1. Diagnosis, demographics and organ involvement of the vasculitis patients registered in Reuma.pt/Vasculitis.

		Total	TAK	GCA	PAN	MPA	GPA	EGPA	CV	IgAV	BD	CS
Demographics	Number of patients (% of total)	492 (100)	19 (3.8)	99 (20.1)	22 (4.4)	13 (2.6)	31 (6.3)	22 (4.4)	14 (2.8)	11 (2.2)	191 (38.8)	12 (2.4)
	Female/male ratio	2.2	8.5	1.7	1.2	2.3	1.1	2.7	2.8	0.6	2.8	1.4
	Mean age at diagnosis in years (SD)	44.3 (22.9)	31.4 (11.8)	73.7 (7.9)	38.1 (20.9)	60.1 (15.8)	49.1 (11.6)	47.1 (16.3)	53.2 (12.2)	30.0 (19.6)	27.6 (13.4)	28.4 (11.6)
Organ involvement	Generalsymptoms	35%	75%	54%	56%	71%	73%	57%	50%	29%	14%	44%
	Musculoskeletal	53%	43%	55%	67%	71%	76%	57%	75%	63%	50%	44%
	Skin	55%	0%	2%	78%	17%	40%	69%	57%	88%	76%	33%
	Eyes	41%	14%	47%	25%	17%	41%	14%	13%	0%	48%	100%
	ENT	25%	0%	48%	13%	33%	90%	71%	0%	0%	1%	100%
	Chest / pulmonary	13%	0%	0%	38%	43%	61%	100%	0%	0%	4%	11%
	Cardiovascular	42%	90%	87%	63%	33%	13%	31%	13%	0%	23%	0%
	Gastrointestinal	60%	13%	5%	43%	17%	13%	17%	25%	75%	98%	88%
	Genitourinary	55%	44%	6%	33%	71%	69%	29%	0%	63%	83%	17%
	Neurologic	48%	71%	90%	55%	50%	47%	81%	50%	0%	25%	33%

The patients with single-organ vasculitis, vasculitis associated with systemic disease, vasculitis associated with probable etiology, not-classifiable vasculitis or missing diagnosis are excluded.
BD – Behçet's disease; CS – Cogan syndrome; CV – cryoglobulinemic vasculitis; EGPA – eosinophilic granulomatosis with polyangiitis; ENT – ear nose and throat; GCA – giant cell arteritis; GPA – granulomatosis with polyangiitis; IgAV – immunoglobulin A vasculitis; MPA – microscopic polyangiitis; PAN – polyarteritis nodosa; SD– standard deviation; TAK – Takayasu arteritis

Conclusions: Reuma.pt/Vasculitis is a registry adapted for routine care, allowing an efficient data repository at a national level with the potential to link with other international databases. It facilitates research, trials recruitment, service planning and benchmarking.

Nishizaka[14], I. Furugo[15], S. Yoshizawa[2], H. Niiro[16], T. Horiuchi[12], H. Nakashima[4], Y. Tada[1]. *[1]Rheumatology, Saga University, Saga; [2]Rheumatology, National Fukuoka Hospital; [3]Rheumatology, Fukuoka Red Cross Hospital; [4]Rheumatology, Fukuoka University, Fukuoka; [5]Rheumatology, Iizuka Hospital, Iizuka; [6]Rheumatology, Saiseikai Fukuoka Hospital, Fukuoka; [7]Rheumatology, Miyazaki Prefectural Miyazaki Hosipital, Miyazaki; [8]Rheumatology, Matsuyama Red Cross Hospital, Matsuyama; [9]Rheumatology, Hiroshima Red Cross Hospital, Hiroshima; [10]Rheumatology, Hamanomachi Hospital, Fukuoka; [11]Rheumatology, Saiseikai Karatsu Hospital, Karatsu; [12]Rheumatology, Kyushu University Beppu Hospital, Beppu; [13]Rheumatology, Shimonoseki City Hospital, Shimonoseki; [14]Rheumatology, Kitakyushu Municipal Medical Center; [15]Rheumatology, JR Kyushu Hospital, Kitakyushu; [16]Rheumatology, Kyushu University, Fukuoka, Japan*

Background: Recent studies had proven that the genetic backgrounds of ANCA associated vasculitis (AAV) were dependent on ANCAs. We and other groups had shown the differences between MPO-ANCA positive Granulomatosis with polyangitis (MPO-GPA) and Microscopic polyangitis (MPA) (1–3). It is not clear what determine these two phenotypes.
Objectives: To elucidate the etiologies of two phenotypes, we compared the backgrounds and comorbidities between MPO-GPA and MPA.
Methods: Retrospectively we recruited MPO-GPA and MPA patients through the two multi-center cohorts (Cohort A: 2001–2012, Cohort B: 2012–2016). We classified patients with EMEA classification and ANCA. We found 40 MPO-GPA and 126 MPA cases without overlaps. We compared those backgrounds, comorbidities, organ involvements and outcomes.
Results: The average age of MPO-GPA group was similar to that of MPA (69.1 years old vs 72.1 years old). But MPO-GPA preferentially affected female patients (80.0% vs 52.8%) with lower creatinine levels (1.03mg/dl vs 2.7mg/dl). Two year survivals of MPO-GPA were significantly better than MPA (95.8% vs 73.2%, p=0.0424). Interestingly MPO-GPA patients had less atherosclerotic risk

factors, i.e. smoking history (6.3% vs 38.4%), hypertension (10.4% vs 30.5%) and diabetes (12.5% vs 17.9%). Instead these patients had more upper respiratory inflammations (chronic sinusitis, chronic otitis media and allergic rhinitis, 33.3% vs 6.6%) before the disease onset.

Conclusions: We found that MPA had more atherosclerotic risk factors, and MPO-GPA had more upper respiratory inflammations. These factors may determine MPA or GPA phenotypes in MPO-ANCA positive AAV.

AB0583 DIFFERENCES BETWEEN ISOLATED AORTITIS AND NON-INFECTIOUS AORTITIS SECONDARY TO OTHER ENTITIES. STUDY OF 93 PATIENTS FROM A SINGLE CENTER

N. Vegas-Revenga[1], J. Loricera[1], D. Prieto-Peña[1], J.L. Hernández[2], I. Martínez-Rodríguez[3], J.I. Banzo[3], M. Calderón-Goercke[1], V. Calvo-Río[1], L.C. Domínguez-Casas[1], C. González-Vela[4], P. Fuentevilla[1], M.Á. González-Gay[1], R. Blanco[1]. *[1]Rheumatology; [2]Internal Medicine; [3]Nuclear Medicine; [4]Pathology, Hospital Universitario Marqués de Valdecilla. IDIVAL, Santander, Spain*

Background: Non-infectious aortitis is an inflammation of aortic wall which may be isolated or associated with a cluster of diseases.

Objectives: Our aim was to compare the clinical and laboratory findings of patients with isolated aortitis and patients with aortitis secondary to other underlying conditions.

Methods: Retrospective study of 93 patients with non-infectious aortitis diagnosed by PET/CT scan from a referral center from January 2010 to December 2016. We have considered two groups: *group a)* isolated aortitis; and *group b)* secondary aortitis. Distributions of *categorical variables were* compared by the Pearson Chi^2 or Fisher exact test. Quantitative variables were analyzing using the Student t test or Mann-Whitney U test as appropriate.

Results: Ninety-three patients were diagnosed with non-infectious aortitis. One patient was excluded due to missing data. Group a) was composed by 54 patients (34 women/ 20 men) with a mean age of 67±11 years; group b) comprised 38 patients (28 women/ 10 men) with a mean age of 68±11 years. In this group, the underlying conditions we found were: giant cell arteritis (n=24), Takayasu arteritis (n=3), spondiloarthropathy (n=3), Sjögren's syndrome (n=3), ulcerative colitis (n=2), sarcoidosis (n=1), rheumatoid arthritis (n=1), polyarteritis nodosa (n=1). The comparative study between both groups is shown in the TABLE. Only inflammatory low back pain and polymyalgic syndrome yielded statistical signification.

Variables	Group a (isolated aortitis) n= 54	Group b (secondary aortitis) n= 38	p
Age (years), *mean±SD*	67.2 ± 11.1	68.0 ± 11.2	0.73
Age ≥ 70 years, *n (%)*	21 (38.9)	18 (47.4)	0.42
Sex *(M/W), n*	20/34	10/28	0.28
Time from symptoms onset to PET date, *median [IQR]*	12.5 [3-36]	19.5 [6-75.5]	0.29
Symptoms at the time of requesting PET			
- Constitutional symptoms, *n (%)*	15 (27.8)	14 (36.8)	0.24
- Fever, *n (%)*	7 (13.0)	11 (28.9)	0.06
- Inflammatory low back pain, *n (%)*	23 (42.6)	7 (18.4)	**0.015**
- Lower limb pain, *n (%)*	29 (53.7)	13 (34.2)	0.07
- Polymyalgic syndrome, *n (%)*	40 (74.1)	18 (47.4)	**0.016**
- Headache, *n (%)*	7 (13.0)	11 (28.9)	0.06
Laboratory values at the time of requesting PET			
- Anaemia, *n (%)*	8 (14.8)	10 (26.3)	0.16
- ESR (mm/1sth), *mean±SD*	44.7 ± 31.6	42.1 ± 38.3	0.42
- CRP (mg/dl), *median [IQR]*	0.9 [0.6-2.3]	0.9 [0.2-2.6]	0.76
Treatment at the time of requesting PET			
- Patients on corticosteroids, *n (%)*	25 (46.3)	23 (60.5)	0.18
- Prednisone dose (mg), *median [IQR]*	10 [5-10]	10 [7.5-16.9]	0.05
- Patients on traditional IS agents, *n (%)*	4 (7.4)	7 (18.4)	0.11

Conclusions: In this study, we observed that both the presence of inflammatory low back pain and polymyalgic syndrome might have clinical relevance in the clinical suspicion of primary aortitis. However, larger studies are needed to corroborate these findings.

AB0584 UTILITY OF PET/CT SCAN FOR THE DIAGNOSIS OF AORTITIS. A STUDY OF 170 PATIENTS FROM A SINGLE CENTER IN A 6-YEAR PERIOD

N. Vegas-Revenga[1], J. Loricera[1], D. Prieto-Peña[1], I. Martínez-Rodríguez[2], J.I. Banzo[2], M. Calderón-Goercke[1], V. Calvo-Río[1], C. González-Vela[3], J. González-Vela[1], M.Á. González-Gay[1], J.L. Hernández[4], R. Blanco[1]. *[1]Rheumatology; [2]Nuclear Medicine; [3]Pathology; [4]Internal Medicine, Hospital Universitario Marqués de Valdecilla. IDIVAL, Santander, Spain*

Background: Aortitis is the inflammation of the aortic wall. This entity is often under-recognised due to its frequent presentation with non-specific symptoms. PET/CT scan represent a major breakthrough to establish an early diagnosis, but this is an expensive technique.

Objectives: Our aim was to compare the baseline characteristics of patients with a suspicion of aortitis and positive results on PET/CT scan, and those with a negative result, in order to search for predictive factors, that improve the clinical probability of diagnosis aortitis by this imaging technique.

Methods: Retrospective study on 170 patients and PET/CT scans ordered by suspicion of aortitis from a referral center from January 2010 to December 2016. According to a pre-specified protocol, the baseline epidemiological and clinical variables of patients with positive and negative PET/CT scans results for aortitis were reviewed. Distributions of *categorical variables were* compared by the Pearson Chi^2 or Fisher exact test. Quantitative variables were analyzing using the Student t test or Mann-Whitney U test as appropriate.

Results: In 170 patients, PET/CT scans were performed due to clinical suspicion of aortitis, and were positive in 93 (54.7%) cases. Patients (113 women/57 men) had a mean age of 67.7±13.1 years (range, 20–90 years). One patient was excluded because missing clinical or laboratory data.

The underlying diseases at the moment of ordering the PET/CT scan were: giant cell arteritis (GCA) (n=28), spondiloarthropaties (n=7), conectivopaties (n=6), Takayasu arteritis (n=3), ulcerative colitis (n=3), other condition (n=11). The remaining 111 patients did not have any underlying condition suggestive of aortitis. Two out of 170 patients suspected an infectious aortitis (*Brucella* and *Salmonella*); however, PET/CT was negative in both cases.

Characteristics of patients with positive and negative PET/CT scans were summarized in the Table. Patients with GCA had a higher percentage of positive PET/CT scans, whereas they were negative more frequently in patients who did not have any condition suggestive of underlying aortitis. Only inflammatory low back pain and polymyalgic syndrome were significantly more frequent in patients with positive PET/CT scans. The remaining clinical and laboratory variables did not show differences between both groups.

TABLE

	Positive PET n= 92	Negative PET n= 77	p
Age (years), mean±SD	67.4± 11.1	68.1±15.2	0.73

- *Dosage of prednisone (mg), median [IQR]*	10 [5-15]	10 [7.5-15]	0.80
- *Patients with traditional immunosuppressants, n (%)*	11 (12.0)	5 (6.5)	0.21

Conclusions: In this study, we have found that the presence of inflammatory low back pain and polymyalgic syndrome, especially in GCA patients, may have clinical relevance in ordering a PET/CT scan when aortitis was suspected.

AB0585 VASCULITIS DAMAGE INDEX IN LIMITED AND SYSTEMIC GRANULOMATOSIS WITH POLIANGIITIS IN MEXICAN PATIENTS

O. Vera-Lastra, A.G. Angulo-Gonzalez, J. Sepulveda-Delgado. *Internal Medicine, Hospital Especialidades CMN la Raza. Instituto Mexicano Seguro Social, Mexico City, Mexico*

Background: Granulomatosis with polyangiitis (GPA) has been transformed

from life-threatening conditions to chronic relapsing long-term diseases as a result of significant advances in immunosuppressive therapy. Structured clinical assessment using Vasculitis Damage Index (DVI) should form the basis of a treatment plan and be used to document progress.

Objectives: To investigate the Vasculitis Damage Index and clinical manifestations in localized and systemic granulomatosis with poliangiitis in Mexican patients

Methods: We enrolled 61 patients with GPA according to The American College of Rheumatology (ACR) criteria at a referral hospital during the period from 2005 to 2015. Clinical and laboratory data, organ involvement and the Vasculitis Damage Index (VDI) were recorded at baseline. Patients were divide into systemic and localized form for their analysis.

Results: They were 61 GPA (34 men and 27 women) mean age 42 years old at diagnosis. Systemic form was observed in 53% and localized form 47%. Chronic sinusitis was the most frequent manifestation in 33% followed by otologic in 26%. Subglottic stenosis 4 patients, alveolar hemorrhage 1%. Of the patients with the systemic form 22 presented focal and segmental glomerulonephritis and 10 patients (32%) rapidly progressive glomerulonephritis. Distal-symmetric polyneuropathy and cranial neuropathy were present in 24%; scleritis 24.5% and proptosis in 18%, palpable purpura 26.2% and ulcers in 9 patients (14.8%). The VDI score in the systemic form was 3.8 and in the localized 2.6, p= NS. The disease related damage was pronounced in kidneys and upper airways. The majority of patients in the induction to remission phase received steroids plus cyclophosphamide, 7 patients also received plasmapheresis and in maintenance phase they were treated with methotrexate or azathioprine.

Conclusions: In this cohort of patients with GPA, a high chronic damage was found which was similar in both systemic and localized forms of this vasculitis. The VDI was more prominent in kidneys and upper airways in GPA patients

AB0586 EVALUATION OF ASSSOCIATION BETWEEN ANTIPHOSPHOLIPID ANTIBODIES OR LUPUS ANTICOAGULANT POSITIVITY AND SEVERITY OF VASCULAR INVOLVEMENT IN TAKAYASU ARTERITIS PATIENTS

E. Fırat[1], A. Erden[2], A. Sari[2], B. Armagan[2], L. Kilic[2], O. Karadag[2], A. Akdogan[2]. [1]*Internal Medicine, Hacettepe University Faculty of Medicine;* [2]*Rheumatology, Hacettepe University of Medicine, Ankara, Turkey*

Background: Takayasu Arteritis is a rare large-vessel vasculitis variant that affects the aorta and its main branches and the pulmonary arteries. Antiphospholipid syndrome is characterized by obstetric and thrombotic complications in the presence of antiphospholipid antibodies, which consist of anticardiolipin antibody, lupus anticoagulant and anti -β2 glycoprotein I. The association of antiphospholipid antibodies and Takayasu arteritis is very rare and few cases decumented it, while others argued aganist such association.

Objectives: This study was planned to find out the prevelance of immunoglobulin-IgM/G anti-cardiolipinantibodies, anti beta 2 glycoprotein- 1antibodies and lupus anticogulant and evaluate the relationship between these antibodies and disease severity/complications in Takayasu arteritis patients.

Methods: 53 patients with Takayasu arteritis patients were enrolled in this study. We obtained blood samples to detectIgM/G anti-cardiolipin antibodies, anti beta 2 glycoprotein 1 antibodies and lupus anticogulant (LA) levels from all patients during their routine control. ImmunoglobulinIgM/G anti-cardiolipin antibody, anti beta 2 glycoprotein 1 antibodies were measured by using a standardized enzyme-linked immunosorbent assay (ELISA) and lupus anticogulant was measured using the diluteRussell's viper venom time (dRVVT).

Results: No patients was positive forIgM/G anti-cardiolipin antibody. Seven were positive immunoglobulin IgM anti beta 2 glycoprotein 1 antibodies, three were positive immunoglobulin IgG anti beta 2 glycoprotein 1 antibodies, one waspositive LA. All of the antibody titters were low. TA patients who had antibody positivity had longer disease duration ($p<0.05$). Antibody and LA positive patients had superior mesenteric artery and celiac artery involvement more frequently then the antibody negative patients ($p<0.05$).

Conclusions: In this study that there were no association between the antibodies positivity and vascular involvement or disease complications and severity in TA patients. In conclusion we can not suggest the routine evaluation of antiphospholipid antibodies or lupus anticoagulant test during the follow-upTakayasu arteritis patients. These antibodies may only be measured in the presence of clinical suspicion.

AB0587 ANTINEUTROPHILIC CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS AND HYPOCOMPLEMENTEMIA: CLINICAL IMPACT AND OUTCOME

S. Deshayes[1], A. Aouba[1], K. Khoy[2], D. Mariotte[2], T. Lobbedez[3], N. Martin Silva[1]. [1]*Department of Internal Medicine;* [2]*Department of Immunology;* [3]*Department of Nephrology, CHU Côte de Nacre, Caen, France*

Background: Although their pathophysiology are still largely unknown, there are growing evidences that complement (C) alternative pathway activation is implicated in antineutrophilic cytoplasmic antibody-associated vasculitis (AAV) pathogenesis.

Objectives: The aim of our study was to evaluate the clinical characteristics and outcome of AAV patients, according to their serum C levels at diagnosis.

Methods: A retrospective monocentric study carried out in Caen University Hospital led to identify proteinase-3 (PR3) or myeloperoxidase (MPO)-ANCA AAV patients (via an ELISA technique). All patients with available C3 and C4 levels (by nephelemetry) at diagnosis were included, except for eosinophilic granulomatosis with polyangiitis (EGPA), which has a different pathophysiology. AAV were classified between granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA), and limited or severe forms according to respectively European Medicines Agency vasculitis algorithm and WGET group. Patients were categorized in the hypocomplementemia group if the C3 or C4 level at diagnosis was below the lower limit of the normal range (respectively 750–1400 mg/l and 100–340 mg/l). Categorical variables were reported as percentages and compared using Fisher's tests. Continuous variables were expressed as means and analyzed using Student's t-test. Associations between survival, renal survival and relapse-free survival, and low serum C levels were evaluated by the log-rank test. A p-value <0.05 was considered to be statistically significant.

Results: Among the 157 AAV patients identified, 81 were excluded (8 EGPA, 73 without C3 and C4 determinations before treatment initiation). On the 76 AAV included (43 GPA, 33 MPA), median age at diagnosis was 65 years (M/F, 38/38). Clinical presentations included constitutional symptoms (56, 73.7%), pulmonary (52, 68.4%), renal (50, 65.8%), rheumatologic (43, 56.6%), and ear, nose or throat (37, 48.7%) involvements, without statistical differences between groups. Twelve (15.8%) deaths and 41 relapses in 25 (32.9%) patients were noted (median follow-up: 38 months). Four patients (5.3%) had hypocomplementemia: 1 patient had isolated low C3 level, 1 had isolated low C4 level, and 2 had both low C levels. All 4 patients had renal involvement. The C level, controlled in 1 patient, became normal 1 month later. No thrombotic microangiopathy (TMA) features were found on the 2 performed kidney biopsies.

	Hypocomplementemia group (n=4)	Normal complement level group (n=72)	p value
Male %	50	50	1
Age at diagnosis (years), median ± SD	71±9	65±16	0.18
BVAS, median ± SD	21±8	18±7	0.26
Granulomatosis with polyangiitis %	75	57	0.64
PR3-ANCA %	50	60	1
Limited vasculitis %	0	28	0.57
End-stage renal disease %	75	15	0.02
Death %	50	14	0.12
Relapse %	25	36	1

Survival and renal survival were significantly lower in the hypocomplementemia group ($p=0.0011$ and $p<0.001$, respectively), but relapse-free survival was similar ($p=0.1$).

Conclusions: Hypocomplementemia at AAV diagnosis may be responsible for worse survival and renal prognosis. This particular phenotype may confer resistance to common immunosuppressive approaches as in thrombotic microangiopathy caused by abnormalities in the regulation of the C system. These results also argue for larger studies and for investigating C pathway targeting.

Marseille; [13]Department of Internal Medicine, CHU Grenoble, Grenoble; [14]Department of Internal Medicine, Hôpital Archet 1, Nice, France

Background: Giant cell arteritis (GCA) is a large-vessel vasculitis affecting elderly people, and most frequently women (sex-ratio of 2.3). Some studies suggest an increased risk of malignancies in GCA.
Objectives: We aimed to describe the clinical, paraclinical characteristics and outcomes of GCA patients with concomitant malignancy and compare them to a control group without malignancy.
Methods: Patients with a diagnosis of GCA and of solid neoplasm or malignant blood disease, within one year before or after the diagnosis of vasculitis, were included. A random group of age-matched (3:1) control patients from our monocentric inception cohort of GCA patients from Caen University Hospital was constituted.
Results: Twenty-four observations were collected (median age 75.5 years). All fulfilled ≥3/5 ACR criteria. Temporal artery biopsy was positive in 17 cases (70.8%). There were 1 active (4.2%) and 9 former (37.5%) smokers. Only 1 patient had a previous prostate cancer. Malignancies were 10 malignant blood diseases (41.7%, 3 chronic lymphoid leukemias, 3 essential thrombocythemias, 1 myeloma, 1 chronic myelomonocytic leukemia, 1 MALT lymphoma, 1 Waldenström's macroglobulinemia) and 14 solid neoplasms (58.3%, 3 lung, 3 breast, 2 prostate, 1 thyroid, 1 colon, 1 pleural cancers, 1 melanoma, 1 Kaposi's sarcoma and 1 Merkel cell carcinoma). Malignancy was diagnosed at a median of 1 month after GCA diagnosis in 21 patients and before in the other 3. Diagnosis of malignancy was made in consultation in 5 patients (3 skin cancers and 2 breast cancers), on lab tests in 13 (thrombocytosis, anemia or increased prostate specific antigen) and on imaging in 6. Treatments of malignancy included chemotherapy alone in 8 patients (33.3%), simple monitoring in 6 patients (25%), surgery alone in 4 patients (16.7%), surgery and radiotherapy and/or chemotherapy in 4 patients (16.7%), decrease of corticosteroids in 1 patient, and 1 patient was lost to follow-up. Two patients (8.3%) died from infectious complications, 8 patients (33.3%) had a GCA relapse, including one with concomitant malignancy relapse. After a median follow-up of 16 months [0–134], 5 patients (20.8%) were weaned from steroids, all considered in malignancy remission. Seven patients (29.1%) were still under chemotherapy, 9 patients (37.5%) were considered to be in malignancy remission. There were more males in patients with concomitant malignancy, compared to the control group (respectively 15/24 and 21/72, p<0.005).
Conclusions: Our study shows an over-representation of male gender in GCA with concomitant malignancy. Vasculitis outcomes were not influenced by the malignancy treatment. The diversity of malignancies encountered in this study raises the issue of an incidental association. Initial clinical and paraclinical follow-up dictated by vasculitis may have led to an early identification of associated malignancy, and thus represent a lead time bias.

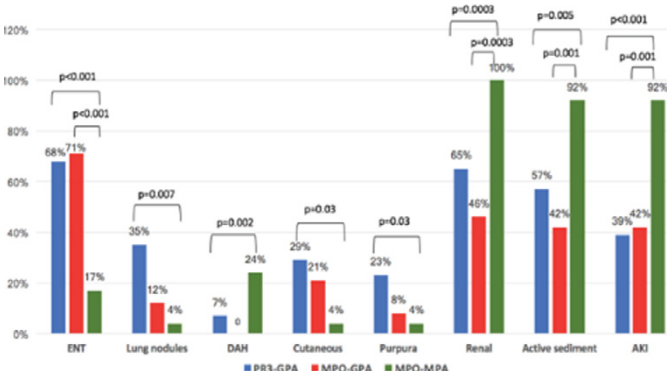
AB0589 THE ROLE OF ANCA SPECIFICITY IN THE CLINICAL MANIFESTATIONS AT DISEASE ONSET: COMPARISON BETWEEN PATIENTS WITH GRANULOMATOSIS WITH POLYANGIITIS AND MICROSCOPIC POLYANGIITIS



S. Monti[1], M. Felicetti[2,3], S. Balduzzi[1], R. Padoan[2], A. Berti[3], G. Paolazzi[3], G. Brunori[3], F. Schiavon[2], R. Caporali[1]. *[1]Rheumatology, University of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia; [2]Rheumatology, Department of Medicine DIMED, University of Padova, Padova; [3]Rheumatology, Santa Chiara Hospital, Trento, Italy*

Background: ANCA specificity, rather than clinical diagnosis, has been suggested to influence the phenotype and clinical course of ANCA associated vasculitis (AAV) (1,2).
Objectives: To investigate differences in clinical presentation at disease onset between MPO-ANCA-positive granulomatosis with polyangiitis patients (MPO-GPA), PR3-ANCA-positive-GPA (PR3-GPA), and MPO-ANCA-positive microscopic polyangiitis (MPO-MPA).
Methods: Clinical records of AAV patients from three third level rheumatologic centers in Northern Italy were retrospectively analyzed.
Results: Of the 133 AAV patients included, 84 were PR3-GPA, 24 MPO-GPA, and 25 MPO-MPA. Patients with MPO-MPA were significantly older at diagnosis compared to both PR3-GPA and MPO-GPA (average age 63±10, 49±15, 55±29, respectively) (Table 1).
Patients with MPO-GPA experienced a significant diagnostic delay compared to PR3-GPA (17±30 vs 7±14, p=0.02). ENT involvement was equally frequent in both GPA groups despite ANCA specificity, and significantly more represented than the MPO-MPA group (68%, 71% and 17% respectively; p<0.001). Figure 1. Renal involvement was significantly more frequent in MPO-MPA patients (100%) compared to GPA (p<0.001), without differences between MPO-GPA (46%) and PR3-GPA (65%). Alveolar haemorrhage (DAH) was an onset manifestation mainly in MPO-MPA compared to the other two groups (24% vs 7% in PR3-GPA; p=0.02). Cutenous manifestations, mainly purpura, were significantly more reported in PR3-GPA compared to MPO-MPA (29% vs 4%; p=0.03).
Conclusions: Clinical phenotype of GPA at disease onset did not seem to be influenced by ANCA specificity. Despite ANCA positivity (PR3 or MPO), GPA patients were significantly different from MPA.

Table 1. Clinical characteristics of patients with GPA and MPA at disease onset according to ANCA specificity

	GPA-PR3 (A) (n=84)	GPA-MPO (B) (n=24)	MPA-MPO (C) (n=25)	p
Male/female n (%)	46 (55%)/38 (45%)	10 (42%)/14 (58%)	10 (40%)/15 (60%)	0.29
Age at disease onset (average ± SD)	49±15	55±19	63±10	**p<0.001** A vs C p<0.001 B vs C p=0.03
Diagnostic delay (months ± SD)	7±14	17±30	10±19	0.07
Systemic symptoms	54 (65%)	16 (67%)	19 (76%)	0.59
ENT	55 (68%)	17 (71%)	4 (17%)	**<0.001**
Pulmonary	57 (69%)	16 (67%)	16 (64%)	0.86
Cutaneous	24 (29%)	5 (21%)	1 (4%)	**0.03**
Ocular	16 (20%)	3 (12%)	2 (8%)	0.34
Cardiovascular	4 (5%)	2 (9%)	1 (4%)	0.77
Gastrointestinal	2 (3%)	0	0	0.56
Renal	53 (65%)	11 (46%)	25 (100%)	**<0.001**
Nervous system	26 (31%)	8 (33%)	8 (35%)	0.94

AB0590 PERFORMANCE OF 2017 ACR/EULAR PROVISIONAL CLASSIFICATION CRITERIA FOR GRANULOMATOSIS WITH POLYANGIITIS IN CHILEAN POPULATION

S.F. Elgueta, L. Ricci Larrea, D. Vargas, P. Wurmann, I. Goecke. *Hospital Clínico Universidad de Chile, Santiago, Chile*

Background: Anca Associated Vasculitis (AAV), are a group of necrotizing primary vascultitis, whith multisistemic manifestation, of unknown etiology. The variants are: Microscopic Polyangiitis (MPA), Granulomatosis with polyangiitis (GPA), Granulomatosis whith Polyangiitis and Eosinophilia (GPE) and AAV limited to one organ. Until now, there are no diagnostic criteria for AAV. Therefore definitions, as Chapell Hill consensus Conference Nomenclature, classification criteria and the physician judgement are used for diagnosis. Currently the DCVAS (Diagnosis and Classification Criteria in Vasculitis) proyect is developing diagnostic criteria for AAV, using data-driven methods. The preliminary DCVAS classification criteria for granulomatosis whith polyangiitis has been recently realesead.
Objectives: To evaluate and compare the acuraccy of ACR/EULAR 2017 provisional Classification Criteria for GPA whith the ACR 1990 Classification Criteria In Chilean patients with AAV.
Methods: All adult patients (>18 yo) with diagnoses of AAV according to their rheumatologist judgment, from 2000–2016 at the University of Chile, Clinical Hospital (UCCH), were included. Clinical variables of interest were extracted form medical chart and AAV database, wich is kept for these patients at the Rheumatology Section of UCCH. Based on that data, the Classification criteria ACR 1990 and 2017preliminary ACR/EULAR (DCVAS) classification criteria for GPA were applied to each individual. Sensibility, especifity, Likehood ratio (LR +/-), predictive values (PPV/NPV) and accuracy were calculated for both sets of Criteria as compared to Clinical diagnosis
Results: 93 patient were included in the study. 59 patients with GPA, 33 with

MPA and 1 with GPE (Patients characteristics are described in Table 1). From the 59 patients with GPA according to clinical judgment, 34 fullfilled the ACR 1990 criteria (57,63%) whereas 51 (86,44%) fullfilled the ACR/EULAR 2007 criteria. From the 33 patients diagnosed as having MPA 9 (27,27%) and and 3 (9.09%) fulfilled classification criteria for GPA according to ACR 1990 criteria and 2017 ACR/EULAR preliminary criteria, respectively.The patient with GPE did no classify as GPA by either set of criteria.The values for Sensibility, Espicifity, LR+ LR-, PPV and NPV in our population for both Criteria sets, are described in table 2.

Table 1. Patient characteristics

	N	Gender (F)	Age, Av (S.D.)	ACR 1990 + for GPA	ACR/ EULAR 2017 + for GPA
GPA	59 (63.44%)	30 (50.85%)	46.54 (13.32)	34 (57,63%)	51 (86,44%)
MPA	33 (35.48%)	23 (69.7%)	62,72 (2.11)	9 (27,27%)	3 (9,09%)
GPE	1 (1.08%)	1	62	0	0
Total	93	39 (41.94%)	52,45 (14.97)	43 (46,24 %)	54 (58,06 %)

Table 2.- Performance of ACR 1999 and ACR/EULAR preliminary Criteria for GPA in Chilean Patients

GPA Clasification Criteria	ACR 1990	ACR/EULAR 2017, preliminary Criteria
Sensitivity	57,6%	91,5%
Especificity	70,6%	91,2%
Positive Predictive Value	77,3%	94%
Negative Predictive Value	49%	86%
Positive Likelihood Ratio	1,96	10,3
Negative Likelihood Ratio	0,6	0,9
accuracy	0,62	0,91

Conclusions: In our population, provisional 2017 ACR/EULAR criteria for classificatión of GPA have better acurracy than ACR 1990 classification criteria.

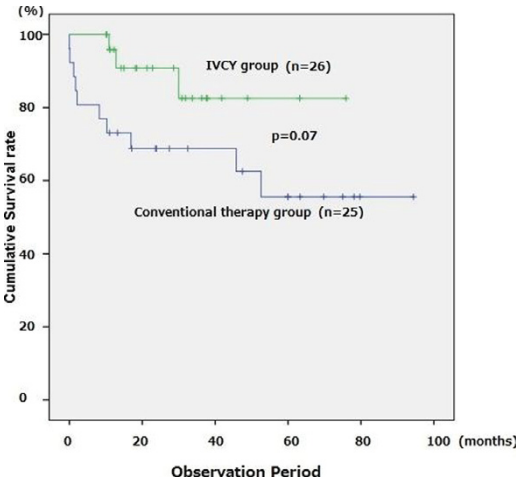
AB0591 EFFICACY AND SAFETY PROFILE OF INTRAVENOUS CYCLOPHOSPHAMIDE TREATMENT IN ELDERLY PATIENTS WITH SYSTEMIC VASCULITIS

S. Shimoyama[1], T. Kurita[1], S. Fukaya[2], M. Kanda[2] on behalf of Japanese Red Cross Kitami Hospital, Hokkaido P.W.F.A.C. Obihiro Kosei Hospital. *[1]Internal medicine/ General medicine, Japanese Red Cross Kitami Hospital, Kitami; [2]3rd Department of Internal medicine, Hokkaido P.W.F.A.C. Obihiro-Kosei General Hospital, Obihiro, Japan*

Background: Intravenous cyclophosphamide is mainstay of remission induction and dose reduction of glucocorticoid in patients with systemic vasculitis. However, little evidence has yet shown the safety profile of intravenous cyclophosphamide, especially in elderly patients.

Objectives: To evaluate efficacy and safety of patients diagnosed as systemic vasculitis and treated with intravenous cyclophosphamide.



Methods: This retrospective study comprised the patients with active systemic vasculitis who were admitted to Kitami Red Cross Hospital and Obihiro-Kosei General Hospital from April 2009 to March 2016. These patients were treated with intravenous cyclophosphamide plus conventional therapy (IVCY group) or only with conventional therapy (glucocorticoid/azathioprine/tacrolimus and methotrexate) (conventional therapy group). The patients treated with oral cyclophosphamide or rituximab were excluded. Primary endpoint was defined as death or serious infections. Prognostic factors in IVCY group were analyzed by multivariate Cox regression methods.

Results: This study comprised 90 patients with active systemic vasculitis (61 microscopic polyangiitis, 9 eosinophilic granulomatosis with polyangiitis, 10 granulomatosis with polyangiitis, and 10 polyarteritis nodosa). Fifty-one patients were over 70-year-old (26 patients in IVCY group). The mean observation period was 30.1 months. IVCY group had a trend for higher event-free survival rate as compared with conventional therapy group (p=0.19). IVCY group had significantly higher cumulative survival rate as well (p=0.04). Age (HR=1.07, 95% CI 1.01–1.14, p=0.03), five factor score (FFS, HR=3.39, 95% CI 1.36–8.44, p=0.01) and glucocorticoid dose at 24 weeks (GC24, HR=1.14, 95% CI 1.05–1.22, p=0.001) were identified as risk factors for events. In patients over 70-year-old, IVCY group had a trend for higher cumulative survival rate as well (p=0.07, Figure1). FFS (HR=3.30, 95% CI 1.19–9.15, p=0.02) and GC24 (HR=1.10, 95% CI 1.02–1.20, p=0.01) were identified as risk factors for events.

Table 1. Background of patients with IVCY group and conventional therapy group

	IVCY group (n=54)	conventional therapy group (n=36)	P value
MPA,n (%)	36 (67%)	25 (69%)	0.95
EGPA,n (%)	6 (11%)	3 (8%)	0.56
GPA,n (%)	8 (15%)	2 (6%)	0.36
PN,n (%)	4 (7%)	6 (17%)	0.19
age (y)	66.4±15.5	72.3±15.9	0.09
Male,n (%)	19 (35%)	13 (36%)	0.93
FFS (d=0)	0.6±0.7	0.7±0.8	0.40
BVAS (d=0)	10.9±5.5	10.5±6.4	0.71
PSL (mg, d=0)	50±11	38±13	0.39
PSL pulse,n (%)	18 (33%)	22 (61%)	0.01
AZA,n (%)	13 (24%)	14 (39%)	0.10
MTX,n (%)	2 (4%)	4 (11%)	0.17

Abbreviation: MPA (microscopic polyangiitis), EGPA (eosinophilic granulomatosis with polyangiitis), GPA (granulomatosis with polyangiitis), PN (polyarteritis nodosa), BVAS (Birmingham Vasculitis Activity Score), AZA (azathioprine), MTX (methotrexate), d = 0 means day 0; the start of the treatment.

Conclusions: Intravenous cyclophosphamide treatment had acceptable safety profile even in elderly patients.

AB0592 PULMONARY ARTERY ANEURYSM IN BEHÇET'S DISEASE: RETROSPECTIVE MONOCENTRIC TUNISIAN STUDY

S. Hammami, A. Sondes, R. Klii, M. Kechida, M. Ben Nasr, I. Kochtali. *Internal medicine, University Hospital F Bourguiba Monastir, Monastir, Tunisia*

Background: Behcet's disease (BD) is a chronic inflammatory disorder. Arterial inflammatory involvement includes predominantly aortic and pulmonary aneurysmal lesions, affects about 10% of patients with BD. They account for the severity of the disease and are a leading cause of death

Objectives: To investigate the frequency of Behcet's disease with pulmonary artery aneurysm (PAA). We aimed to review PAA and other systemic involvements associated with PAA in BD and to provide a review of diagnostic techniques, treatment and prognosis

Methods: 243 BD patients were recruited for this study (152 men, 91 women, mean age 31.7±7 years. Diagnosis of BD was made according to the international study group for Behçet's disease [International Study Group for Behçet's Disease, lancet 1990; 335: 1078–80]. All patients underwent full clinical examination, routine laboratory investigations. Chest X-rays and pulmonary CT angiography were performed on all patients with pulmonary involvement.

Results: Eight of the patients have pulmonary aneurysm, all of them are male, mean age 32.6±13, The mean disease duration until PAA appear was 2.8±3.5 years. The main pulmonary symptoms were as follows: dyspnea 87%, cough 50%, hemoptosis: 75%, fever 37%. Other systemic involvements associated PAA are as follows: buccal (100%) and genital (75%) ophthalmic 25%, neurological 50%, cardiac 25%. 3 patients presented with Hughes Stovin syndrome. The treatment includes corticosteroids, colchicine and immunosuppressant agents (Cyclophosphamid or azathioprine), only two patients reveive coil embolization. At follow up for a median of 4 years (1 to 25 years), three patients died because they stopped their medication.

Conclusions: The prognosis of PAA is poorer than other lesions involved in BD, treatment (immunosuppressant agents, colchicine) seems to improve the prognosis. It is important to maintain the immunosuppressive therapy and a regular follow-up to prevent these complications

AB0593 ANCA-ASSOCIATED VASCULITIS WITH BOTH MPO-ANCA AND PR3-ANCA SHARES CHARACTERISTICS OF ANCA-ASSOCIATED VASCULITIS WITH SINGLE ANCA

S.M. Kim[1], J. Kim[2], S.W. Kang[2], S.-C. Shim[2], S.-J. Yoo[3]. *[1]Internal Medicine, Chungbuk National University Hospital, Cheong-ju; [2]Internal Medicine, School of Medicine Chungnam National University; [3]Internal Medicine, Chungnam National University Hospital, Daejeon, Korea, Republic Of*

Background: The anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides are heterogeneous group of necrotizing inflammation of small vessel and the presence of the ANCA. ANCAs are defined according to the target antigens, leukocyte proteinase 3 (PR3) and myeloperoxidase (MPO). Recently, the ANCA specificity could be better for classification of ANCA-associated vasculitides than the clinical diagnosis. A few patients have both MPO- and PR3 ANCA. However, the clinical characteristics of these patients were not known in detail.
Objectives: To analyze organ involvement of patients with ANCA-associated vasculitis according to ANCA type focusing both MPO- and PR3-ANCA (both-ANCA) positive vasculitis
Methods: The medical records of the patients with positive ANCA and clinical diagnosis or the patients with positive ANCA and vasculitis diagnosis confirmed by biopsy were reviewed at two regional tertiary hospitals. The age at diagnosis, sex, and the organ involvement of kidney, lung, upper airway (nose/sinus/ear), skin, peripheral nervous system, central nervous system, and gastrointestinal tract were collected. The clinical variables were analyzed by ANCA type.
Results: Total 82 patients with positive ANCA and clinical diagnosis or histologic diagnosis of vasculitis were searched. MPO-ANCA positive patients was 63 (76.8%), PR3-ANCA 9 (11.0%), and both MPO- and PR3-ANCA was 10 (12.2%). The age at diagnosis of patients with PR3-ANCA was younger than patients with MPO-ANCA or both-ANCA (PR3-ANCA, 49.6 vs. MPO-ANCA, 66.1 vs. both-ANCA, 62.1, $p<0.05$). Moreover, kidney involvement were MPO-ANCA was 77.8%, PR3-ANCA 22.2%, and both-ANCA 80% ($p<0.05$). Upper airway involvement was also significantly associated with ANCA type (PR3-ANCA, 66.7% vs. MPO-ANCA, 23.8% vs. both-ANCA, 50.0%, $p<0.05$). The involvement of skin, central or peripheral nervous system, gastrointestinal tract or the presence of lung fibrosis and lung nodule or mass did not differ according to ANCA type.
Conclusions: ANCA-associated vasculitis with both MPO-ANCA and PR3-ANCA has more kidney involvement than ANCA-associated vasculitis with PR3-ANCA and more upper airway involvement than ANCA-associated vasculitis with MPO-ANCA.

AB0594 RELATION OF CERTAIN BLOOD PICTURE PARAMETERS AND VASCULAR ENDOTHELIAL GROWTH FACTOR TO CLINICAL MANIFESTATIONS AND DISEASE ACTIVITY IN BEHÇET'S DISEASE PATIENTS

T.A. Gheita[1], R.E. Rabea[1], B.R. Sakr[1], S.M. Abd ElHamid[2]. *[1]Rheumatology and Clinical Immunology; [2]Clinical Pathology, Faculty of Medicine - Kasr Al-Ainy School of Medicine - Cairo University, Cairo, Egypt*

Background: Behçet's disease (BD) is a systemic inflammatory condition sharing the clinical features of both auto- inflammatory diseases and variable vessel vasculitis. Endothelial dysfunction (ED) plays an important role in the pathogenesis of BD. Several markers can be used to evaluate ED as mean platelet volume (MPV), red cell distribution width (RDW), neutrophil-lymphocyte ratio (NLR) and vascular endothelial growth factor (VEGF).
Objectives: The aim of the present study was to measure the MPV, RDW, NLR and serum level of VEGF in BD patients and to study their relation with disease manifestations and activity.
Methods: Ninety six BD patients and 60 matched controls were enrolled in this study. The MPV, NLR, RDW and serum VEGF level were measured. Disease activity was assessed by the BD Current Activity Form (BDCAF). The influence of an associated metabolic syndrome (MetS) was also considered.
Results: The mean age of the 96 patients was 34.9±10.1 years (18–73 years), male:female 4.7:1 and the disease duration was 9±7 years (0.6–40 years). MetS was present in 13.7%. Two patients were siblings and 5 had juvenile-onset BD. The RDW and NLR were significantly higher in patients (15.5±2% and 2.7±2.9) than controls (14.3±1.03% and 1.5±0.8) ($p<0.001$ each), while the MPV and VEGF were comparable. The MPV was significantly decreased in patients with vascular involvement (p=0.04) and increased in those with psychiatric disorders (p=0.02). The RDW was significantly higher in patients with vascular involvement (p=0.04) especially those with venous thrombosis and in those with neurological manifestations (p=0.03). The NLR was higher in males (p=0.01) and in those with retinal vasculitis (p=0.03) and vein occlusion (p=0.02). None of the parameters significantly correlated with the BDCAF. However, the NLR was the most valuable parameter to predict disease activity at a cut-off level of 1.69 ng/L (sensitivity 75%, specificity 55.6%). The MPV significantly correlated with the body mass index (BMI) (p=0.008), cholesterol (p=0.01) and low density lipoprotein (LDL) ($p<0.001$); the RDW correlated with the erythrocyte sedimentation rate (ESR) (p=0.003) and total leucocytic count (TLC) (p=0.04); the NLR with TLC (p=0.001) and blood urea (p=0.001) and VEGF with the TLC (p=0.048) and high density lipoprotein (HDL) (p=0.02). None of the parameters was significantly different according to the presence of MetS. Regarding the medications received, the RDW was significantly higher in patients who received cyclophosphamide and warfarin than those who did not (p=0.003 and $p<0.001$ respectively) and the level of VEGF tended to be lower in patients who received colchicine (p=0.06).
Conclusions: In BD, only the RDW and NLR were significantly increased raising the possibility of a potential role in the disease susceptibility and pathogenesis with no obvious relation to the disease activity or to an associated MetS. Together with the serum VEGF, they may all serve as useful markers to reveal the pattern of organ involvement while the NLR was the most valuable cost effective parameter to signify the disease activity. The influence of medications warrants further studies.

AB0595 NOVEL APPROACHS BASED IN CURRENT EVIDENCE IN ANCA-ASSOCIATED VASCULITIS WITH RENAL INVOLVEMENT TREATMENT

V. Vazquez[1], G. Gonzalez[2], J. Robaina Sindin[2]. *[1]Nephrology, Hospital Simplemente Evita, Gonzalez Catan, Pcia Buenos Aires; [2]Nephrology, Hospital de Clínicas José de San Martín, Universidad de Buenos Aires, Ciudad Autonoma de Buenos Aires, Argentina*

Background: ANCA-associated vasculits (AAV) are a group of multi-system autoinmune diseases characterized by inflamation and necrosis in small and medium vessels.AAV could respond to diferent therapeutics protocols depends on diverse levels of clinical severity and early treatment could improve the outcome of the disease.In spite of recognized efficay of regimens consisting of cyclophosphamide and high-dose corticosteroids to control the AAV,efforts to minimize drugs-related toxicity led to consider targeted therapies.
Objectives: Considering the currently quality evidence in therapies novely proposed to AAV and the severity of renal disease presentation,we suggest new rational approaches emphasizing targeting B-cells therapy and preventing disease relapse
Methods: We identified the latest quality evidence using methodological search filters,assessed the evidence quality with Cochrane Renal Goup check list and determinated the strenght of recommendations by Levels of Evidence (Oxford Centre for Evidence-based Medicine)
Results: Rituximab (RTX), a monoclonal anti-CD 20antibody, has emerged as the biologic agent more using in AAV patients in current publications and unlike latest Guides and Recommendations published,RTX would be recommended in induction and maintenance AAV with renal involvement treatment (Table 1).

Table 1

AAV Induction Therapy	Early systemic (GF>60 ml'):MTX + GC (Ib,B) Severe generalised (Cr>5.68 mg/dl):CFM IV/PO + MPS (Ia,A) Generalised with contraindication to CFM:RTX + GC (Ib,B) Prophylaxis against *Pneumocystis jirovecii* (in CFM or RTX therapy):Cotrimoxazol PO (IIb,B) Severe with RPGN: Plasma Exchange-adjuvant therapy (Ia, B)
AAV Maintenance Therapy	Low-dose GC + AZA up 18 months (IIb,B) Low-dose GC + LF (less safer) (Ib,B) Low-dose GC + MTX with GF >60 ml/'(Ib,B) Avoid use CFM long-term (higher relapse risk) (Ia,A) In GPA:RTX + GC low-dose each 6 months up18 months (Ib, B)
AAV Relapse	Minor Relapse:increase GC dose (IIb,C) Major Relapse:RTX + GC (Ia,A) Major Relapse with CFM cumulative dose <36 gr:CFM + GC (Ib,B) Plasma Exchange and/or MPS (IIb,C)
VAA Refractaria	RTX + GC,specially patients whose never recived RTX (II,B) Plasma Exchange in RPGN and/or dialysis-dependen (Ia,B)

GF: glomerular filtrate, MTX:metotrexate, GV: glucocorticoids, Cr: creatinine, CFM: ciclophosphamide, IV: intravenous, PO: oral, MPS: metilprednisolone, RTX: rituximab, RPGN: rapidly progressive glomerulonephritis, AZA: azathioprine, LF: leflunomide, GPA: granulomatosis with polyangiitis.

Conclusions: Current therapeutical protocols for AVV with renal involvement show that emerging therapies like RTX could improve rates of relapses and treatment-related toxicity. Further studies would provide target-therapeutical options

AB0596 INTERFERON-Γ RELEASE ASSAY (T-SPOT.TB) IN THE DIAGNOSIS OF TUBERCULOSIS INFECTION IN PATIENTS WITH BEHCET'S DISEASE: A SINGLE CENTER EXPERIENCE IN CHINA

W. Zheng[1], X. Wu[2], P. Chen[3], L. Zhao[1], J. Liu[1], L. Zhang[4], X. Liu[4], Y. Zhao[1], X. Zeng[1]. *[1]Rheumatology, Peking Union Medical College Hospital, BEIJING; [2]Rheumatology, General Hospital of Tianjin Medical University, Tianjing; [3]Rheumatology, Affiliated Mindong Hospital of Fujian Medical University, Fujian; [4]Infectious Diseases, Peking Union Medical College Hospital, BEIJING, China*

Background: In many aspects Behcet's disease (BD) is correlated with tuberculosis (TB). They may mimic each other on clinical manifestations. For example erythema nodosa, arthritis, gut lesions could be occurred in both disease and it is difficult for differential diagnosis. Some patients with newly-diagnosed BD were found to have active or latent or old TB and anti-TB therapy could relieve some of the symptoms. In etiology, it has been postulated that tubercle bacilli may act as a trigger of BD through the mechanism of molecular mimicking. Vice versa, defective cell-mediated immunity in BD patients may increase individual susceptibility of TB.It is extremely important to clarify TB existence or not in BD patients. Since BD patients commonly need glucocorticoid and immunosuppressant or even biologic agent such as anti-TNFa. And these medications may increase the risk of occurrence or flare of TB. But positive result of PPD shows little value in this special population due to acupuncture reaction in BD patients.In this pilot study, the values of interferon-γ release assay (T-SPOT-TB) in diagnosing active TB in BD patients were explored.
Objectives: To investigate the diagnostic value of the T-SPOT.TB in BD patients complicated with tuberculosis infection.
Methods: The clinical, radiology and laboratory data were collected and analyzed in 175 hospitalized BD patients from the Peking Union Medical College Hospital between January 2010 and March 2015. Statistical analysis was carried out using IBM SPSS version 20.
Results: Of the 175 BD patients, the positive rate of tuberculosis infection in BD patients was 34.3%. The sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of the T-SPOT.TB test for the diagnosis of ATB were 87.5%, 73%, 36.8%, 98.3%, respectively. Positive likelihood ratio (PLR) and negative likelihood ratio (NLR) were 3.24 and 0.17. The median number of SFCs in the BD-ATB group was higher than that in the BD-LTB group and BD-OTB ($p<0.001$ and p=0.012). By ROC method, it was suggested that 70 SFCs act as a cutoff for diagnosing BD-ATB with the sensitivity, specificity, PPV, NPV, PLR and NLR were 87.5%, 85%, 24.6%, 98.5%, 5.79 and 0.15, respectively. The rates of LTB infection had no significant difference between BD patients and healthy controls. Agreement between T-SPOT.TB and TST in BD patients measured by the kappa coefficient was poor (kappa =0.37).Multiple logistic regression analysis revealed that BD patients with positive T-SPOT.TB had the highest likelihood of ATB (OR 11.93, 95% CI 2.108–67.508, p=0.005).
Conclusions: T-SPOT.TB is a promising test in the diagnosis of BD complicated with tuberculosis infection, and higher number of SFCs may has a higher risk of ATB.

AB0597 LOW-DOSE RITUXIMAB AS INDUCTION THERAPY FOR JAPANESE PATIENTS WITH ANCA-ASSOCIATED VASCULITIS

Y. Takakuwa, H. Hanaoka, T. Kiyokawa, K. Ishimori, H. Iida, H. Nagafuchi, T. Okazaki, S. Ozaki. *Division of Rheumatology and Allergy, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan*

Background: Four times of once-weekly doses of 375 mg/m^2 rituximab (RTX) are frequently used as remission induction therapy for ANCA-associated vasculitis (AAV). Since this regimen has been basically generated from experience of B-cell non-Hodgkins' lymphoma in the Europe and North America, appropriate dose and interval for patients with AAV in other population have been poorly investigated. Here we comprehensively analyzed the efficacy and tolerability of high or low dose regimen of RTX in Japanese patients with AAV.
Objectives: We investigated the efficacy and safety issue of low dose RTX for Japanese patients with AAV.
Methods: We retrospectively examined AAV patients who met the 2012 Chapel Hill classification from 2006 to 2016. We divided them into 2 groups, those treated with high-dose (HD) and low-dose (LD) RTX. HD RTX was the original regimen and LD RTX consisted of twice of one-weekly dose of 375 mg/m^2. We evaluated cumulative complete remission (CR) rate and relapse-free rate for 1.5 years. CR was defined as BVAS=0 and relapse was defined as BVAS$\geqq$1.
Results: We evaluated 17 patients with HD and 11 patients with LD RTX. Higher percentage of elderly patients was observed in LD group ($p<0.01$). No significant difference was found in BVAS (p=0.49) and VDI (p=0.15) before treatment. No significant difference was found in cumulative CR rate (p=0.90) (Fig. 1A), relapse-free rate (p=0.48) (Fig. 1B), B cells counts and serious adverse events. We found patients with nasal involvement and pulmonary nodule/cavity formation had higher relapse rate in LD group than those with HD group (p=0.05,and p=0.09 respectively).

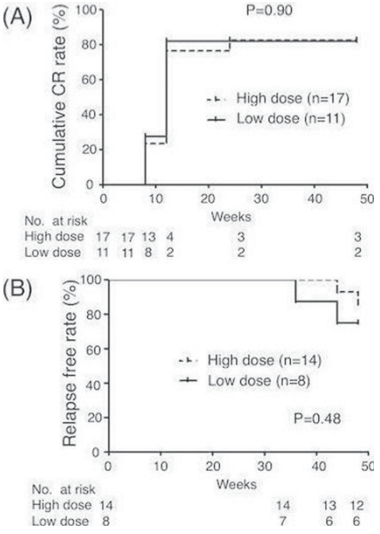

Figure 1

Conclusions: LD regimen of RTX, especially in elderly patients, might be effective in remission induction therapy in AAV.

Scleroderma, myositis and related syndromes

AB0598 SERUM DEFENSIN LEVEL IN SYSTEMIC SCLEROSIS PATIENTS

T. Emiroglu[1], H. Küçük[2], B. Goker[2], S. Haznedaroglu[2], H. Pasaoglu[3], Ö. Varan[2], M.A. Öztürk[2], O.T. Pasaoglu[3], A. Tufan[2]. *[1]Department of Internal Medicine; [2]Department of Internal Medicine, Division of Rheumatology; [3]Department of Biochemistry, Gazi University Faculty of Medicine, Ankara, Turkey*

Background: Skleroderma is an autoimmune disease characterized by fibrosis of skin and lung as well as involvement of kidney, gastrointestinal system and heart (1). Etiology and exact mechanism of disease is poorly understood. A small number of studies have examined the role of AMPs on autoimmune diseases. It has been demonstrated that the amount of alfa- and beta-2 defensin serum levels are increased in systemic lupus erythematosus patients (2.3). Likewise, the association between AMPs and other diseases such as idiopathic pulmonary fibrosis, diffuse panbronchiolitis, pulmoner alveolar proteinosis and psoriasis has been reported (4).
Objectives: No study investigated the role of AMPs on scleroderma patients. Hence, we aimed to investigate AMP serum levels and their possible association in these patients.
Methods: There were 42 patients (40 female, mean age 42 years) and 38 healthy subjects (32 female, mean age 38 years) in the study. For SSc patients, the following data were recorded at enrollment: disease subset (limited/diffuse), autoantibodies (antinuclear, anti-centromere (ACA), and anti-scl), blood tests, erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP), modified Rodnan skin score, presence and history of digital ulcers, presence and history of involvement kidney and gastrointestinal system, interstitial lung disease detected by chest HRCT and pulmonary function tests, estimated pulmonary arterial systolic pressure at echocardiography.
Results: There were 42 patients (40 female, mean age 42 years) and 38 healthy subjects (32 female, mean age 38 years) in the study. Twenty-nine of the patients had diffuse systemic sclerosis and thirteen of the patients had limited systemic sclerosis. Average disease duration is 5.5 years. Pulmonary involvement was detected in twenty patients. The levels of beta 1 and beta 2 defensin that are epitelyal defensins were higher than control group but it has not reached statistical significance. (beta-1 defensin 235±178 vs 185±24 pg/ml, p=0.08 and beta2 defensin 253±453 vs 152±101 pg/ml, p=0,1). Alpha defensin levels in scleroderma patients were significantly higher than control group (563±415 vs 377±269 ng/mL,p=0.02). In sub-group analysis patients with interstitial lung disease had a higher level of alpha defensive than those without involvement (684±473 vs430±299 ng/ml, p=0.04). There was an negative correlation between alfa defensin and Rodnan score (r=0.30) and CRP (r=0.34).
Conclusions: Alpha defensin levels in scleroderma patients were significantly higher than control group, There may be an increase in the level of alpha defensin in a cause of vasulopathy in scleroderma patients

AB0599 COMBINATION OF CAPILLAROSCOPIC AND ULTRASONOGRAPHIC EVALUATIONS OF THE HAND TO DETECT SEVERE VASCULOPATHY IN SYSTEMIC SCLEROSIS: RESULTS OF A CROSS-SECTIONAL STUDY

A. Lescoat[1], G. Coiffier[2], M. de Carlan[1], C. Droitcourt[3], C. Cazalets[1], A. Perdriger[2], P. Jégo[1]. *[1]Internal Medicine; [2]Rheumatology; [3]Dermatology, CHU, Rennes, France*

Background: Although micro-vessel alterations have been largely described, macrovascular involvement is also frequent in Systemic Sclerosis (SSc). Macrovascular damages specifically involve narrowing or occlusions of proper palmar digital arteries and ulnar artery. On the contrary, radial artery is rarely concerned. Ulnar artery occlusion (UAO) assessed by power doppler ultrasonography (PDUS) has proven to be predictive of the onset of new ischaemic DUs in longitudinal studies (1). PDUS could also be a reliable tool to evaluate finger pulp blood flow (FPBF). Only few studies have explored the association between macrovascular damages evaluated by PDUS and microvascular involvement assessed by nailfold capillaroscopy (NC) (2). The association between macrovascular disease and calcinosis or Acro-osteolysis is still to be determined in SSc.
Objectives: to confront microvascular damages on NC with macrovascular manifestations evaluated by PDUS in SSc patients. Micro and macro-vascular damages were confronted with the main digital manifestations of the disease: digital ulcers (DU), Acro-osteolysis and Calcinosis.
Methods: NC, hand X-Rays and PDUS were systematically performed in 64 unselected SSc patients. PDUS evaluation with assessment of Ulnar Artery Occlusion (UAO) and finger pulp blood flow (FPBF) was performed blinded for the results of X-Rays and NC.
Results: UAO and pathologic FPBF were associated with severe capillary loss (<4 capillaries/mm) on NC (respectively OR=4.04 (1.23–13.29); $p<0.05$ and OR=3.38 (1.03–11.05); $p<0.05$). UAO was significantly associated with Cutolo's late NC pattern (OR=3.80 (1.31–11.01); $p<0.05$). A DU history was associated with UAO (OR=10.71 (3.36–34.13); $p<0.0001$), pathologic FPBF (OR=7.67 (2.52–23.28); $p<0.0001$), late pattern (OR=6.33 (2.03–19.68) and severe capillary loss (OR=8.52 (2.15–33.78); p=0.001). Acro-osteolysis was also associated with UAO (OR=15.83 (3.95–63.54); $p<0.001$), pathologic FPBF (5.52 (1.71–17.90) p=0.003), late NC pattern (OR=6.86 (2.18–21.53); p=0.001) and severe capillary loss (OR=7.20 (2.16–24.02), p=0.001). Calcinosis on X-rays were associated with late NC pattern (5.41 (1.82–16.12); p=0.002), severe capillary loss (OR=12.69 (3.14–51.26); $p<0.0001$) and UAO (3.19 (1.14–8.92); 0.025) but not with pathologic FPBF. Combination of UAO and severe capillary loss in a same patient was especially associated with DU history (OR=18.60 (2.24–154.34); p=0.001) and Acro-osteolysis (OR=10.83 (2.56–45.88); p=0.001).
Conclusions: The combination of macro and microvascular evaluations by PDUS and NC may help to detect patients with a more severe vasculopathy.

AB0600 CLINICAL RELEVANCE OF AUTOANTIBODY PROFILES IN SYSTEMIC SCLEROSIS

A. Burlui[1,2], A. Cardoneanu[1,2], E. Rezus[1,2]. *[1]Rheumatology, "Grigore T. Popa" University of Medicine and Pharmacy; [2]Rheumatology, Clinical Rehabilitation Hospital, Iasi, Romania*

Background: Systemic sclerosis (SSc) is a connective tissue disease accompanied by immune abnormalities. A number of autoantibodies such as anti-centromere, anti-topoisomerase I, anti-RNA polymerase III and anti-U3 (fibrillarin) antibodies were proven to be of great diagnostic and prognostic factors in patients with scleroderma. Certain studies have reported the presence of antinuclear, anti-SSA (Ro) and/or anti-SSB (La), anti-Pm/Scl, anti-endothelial cell and anti-nucleosome antibodies in patients with systemic sclerosis. However, the clinical relevance of these autoantibodies is yet to be fully elucidated.
Objectives: Our aim was to assess clinical features, capillaroscopic abnormalities and autoantibody titers in patients with systemic sclerosis as well as analyze relationships between these parameters.
Methods: We conducted a prospective observational study on 36 adult patients who satisfied ACR/EULAR 2013 criteria for systemic sclerosis.We recorded disease duration. current symptoms and classified patients as limited cutaneous (lc) SSc and diffuse cutaneous (dc) SSc. Skin involvement was assessed using the modified Rodnan skin score (mRSS). We performed nailfold videocapillaroscopy using a FEDMED Digitale 100N at a magnification of 200X. Thoracic Xrays were done to establish the presence of pulmonary fibrosis. Ultrasounds were performed by a single examiner to evaluate pulmonary artery pressure. Blood samples were drawn to measure anti-topoisomerase 1, anti-centromere, anti-SSA (Ro), anti-SSB (La), anti-U1RNP and anti-nucleosome antibody titers (ELISA). Patient characteristics were included in a database and analyzed using IBM SPSS Statistics v20.
Results: Our study group was composed of 20 dc SSc (55.6%) and 16 lc SSc (44.4%) patients. Severity of capillary changes correlated with mRSS values (p,0.01), anti-topoisomerase I (p=0.006), anti-SSA (p=0.01) and anti-nucleosome antibodies (p=0.02). We found positive associations between the presence of dysphagia, anti-centromere (p=0.009) and anti-SSA ($p<0.01$) titers in patients with lc SSc. Anti-centromere antibody positivity also correlated with pulmonary hypertension (p=0,011) and pulmonary fibrosis (p=0,04) in these patients. Anti-SSA antibodies correlated with pulmonary hypertension ($p<0.01$) and capillaroscopic changes (p=0.024) in dc SSc.
Conclusions: Our findings support the relationship between autoantibody titers, systemic involvement and microvascular changes in scleroderma patients. Non-specific autoantibodies such as anti-nucleosome and anti-SSA antibodies were associated with microvascular changes in our study group. Further studies in this field may provide new information on SSc pathogenesis and possibly novel targets for treatment in scleroderma patients.

AB0601 ANATOMIC AND FUNCTIONAL ASSESSMENT OF PERIPHERAL PERFUSION IN PATIENTS WITH SYSTEMIC SCLEROSIS. IS THERE ANY CORRELATION BETWEEN CAPILLAROSCOPIC FINDINGS AND ERGOSPIROMETRY?

A. Sarantopoulos[1], I. Gkougkourelas[1], A. Pataka[2], I. Stanopoulos[2], I. Koulas[1], P. Boura[1]. *[1]Clinical Immunology Unit, 2nd Dpt of Internal Medicine; [2]Pulmonary Department, "G. Papanikolaou" General Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece*

Background: Microvasculopathy of systemic circulation in patients with Systemic Sclerosis (SS) is widely assessed by digital capillaroscopy (DC), a method that evaluates the architecture of capillary network and reveals changes of vascular anatomy. On the other hand, ergospirometry (ERG) reveals functional impairment of microcirculation by assessing indirect measures of peripheral tissue ischemia (most suitable VE/VCO2). Since today, there have been studies correlating DC findings with spirometric parameters (respiratory volumes)[1,2]; nevertheless, no reports have been published correlating the same DC findings with ERG parameters (functional microvascular perfusion).
Objectives: To propose the use of DC as a screening tool for impaired functional microvasculopathy by investigating correlations between patterns of capillaroscopic findings with ergospirometric values of peripheral tissue blood perfusion.
Methods: 11 patients (11 women mean age 43+/- 12 ys) with SS were evaluated contemporary with High Resolution Computed Tomography of the chest, ERG, and DC. Parameters were correlated with multiple regression analysis. Statistic significance was considered $p<0.05$.
Results: Patient data are shown in the table.
Patients with late pattern in capillaroscopy had less endurance in exercise test ($P<0.05$) but no correlation was found between capillaroscopic pattern and VE/VCO2 ($P>0.05$). Age was a crucial confounding factor.
Conclusions: The correlation of late pattern capillaroscopy findings with reduced ergospirometric endurance in 11 patients indicates that in a larger cohort, specific parameter associations between DC and ERG are probable to emerge.

Diffuse scleroderma	6/11
Limited scleroderma	5/11
Pulmonary hypertension	4/11
History of digital ulcers	5/11
Time of endurance in minutes (ergospirometry)	5':32" (±65")
Diffusion capacity (%pred)	82±15
Pulmonary fibrosis	7/11
VE/VCO2 (mean values ± sd)	32±5
Patterns of capillaroscopy	1/11 normal 1/11 early 4/11 active 5/11 late

AB0602 CAROTID ATHEROESCLEROTIC PLAQUES DETECTED BY ULTRASOUND IN SYSTEMIC SCLEROSIS PATIENTS UNDER 55 YEARS OLD

I. Sanz Pérez[1], F. Martínez Valle[1], A. Guillén del Castillo[1], N. Pizzi[2], R. Solans Laque[1], E. Callejas Moragas[1], I. Gonzalez Nieto[1], V. Fonollosa Pla[1], C.P. Simeón Aznar[1]. *[1]Internal Medicine; [2]Nuclear cardiology, Hospital Universitari Vall d'Hebron, Barcelona, Spain*

Background: In Systemic sclerosis (SSc), as in other autoimmune diseases such as rheumatoid arthritis or systemic lupus erythematosus, cardiovascular events are one of the most frequent causes of mortality not attributed to the disease itself.
Objectives: The aim of this study was to assess the presence of subclinical atherosclerosis by carotid Doppler ultrasound in SSc patients under 55 years.
Methods: We conducted a cross-sectional study that included 78 SSc patients without cardiovascular events from H. Vall d'Hebron cohort (Barcelona). Carotid Doppler ultrasound was performed to measure the Carotid Intima Media Thickness (CIMT) of common carotid artery (CCA) and detection of cholesterol plaques in CCA, bulb and internal and external carotid arteries, according to Mannheim consensus criteria. The results were compared to a healthy cohort from Barcelona, adjusted to age and sex[1]. We used SCORE for populations with low risk and REGICOR as cardiovascular risk assessment charts.
Results: Risk factors and SSc related features are described in table 1. Twenty three patients (29.5%) had carotid plaques (CP) being the presence of CP statistically significant compared to the healthy cohort (29.5% vs 15.6%; $p<0.05$; IC 0.04–0.24). None of the patients were catalogued as high risk according to SCORE chart. According to REGICOR chart, 4 patients (5.1%) were catalogued as intermediate risk and none as high risk. The four intermediate risk patients had CP. Carotid Intima Media Thickness mean (CIMTm) and maximum (CIMTmax), were statistically significant increased compared to the healthy cohort (CIMTm 0,57 vs 0,53; $p<0,05$ and CIMTmax 0,74 vs 0,61; $p<0,05$).
We performed multivariate regression analysis. Age, CIMTmax, low High Density Lipid (HDL), the presence of pulmonary hypertension, and Diffuse cutaneous SSc patients were independent factors for the presence of CP.

Female	62 (79.5%)
Age	44 (20–55)
Disease duration	14 (0–38)
Limited cutaneous SSc	41 (57.7%)
Diffuse cutaneous SSc	17 (23.9%)
Sine Scleroderma SSc	8 (11.3%)
Initial Scleroderma	5 (7%)
Arterial Hypertension	18 (23.1%)
Diabetes mellitus	2 (2.8%)
Statin treatment	14 (17.9%)
Smokers	15 (19.2%)
Digital ulcers	30 (42.3%)
Pulmonary Hypertension*	4 (5.1%)
Interstitial lung disease	32 (41%)

*Mean pulmonary artery pressure >25 mm Hg at right heart catheterization.

Conclusions: SSc patients under 55 years old often have subclinical atheromatous disease which could be detected by carotid ultrasound. Risk charts do not correlate with the presence of subclinical atheromatous disease. The presence of carotid plaque is more frequent in SSc patients with pulmonary hypertension, diffuse cutaneous subtype and patients with low HDL. CIMT could be useful although it is currently not recommended in cardiovascular risk guidelines.

AB0603 QUANTITATIVE VIDEOCAPILAROSCOPY STUDY IN SYSTEMIC SCLEROSIS

A. Guillén-Del Castillo, C.P. Simeón-Aznar, E.L. Callejas-Moraga, S. Alonso-Vila, V. Fonollosa-Pla, A. Selva-O'Callaghan. *Department of Systemic Autoimmune Diseases, Hospital Universitari Vall d'Hebron, Universitat Autònoma de Barcelona, Barcelona, Spain*

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized by immunological features, microvascular disturbances and fibrosis as a consequence of a massive production of extracellular matrix.
Objectives: The aim of this study was to analyse the alterations of the capillary nailfold bed and describe their correlation with clinical variables.
Methods: 134 patients were selected with SSc according to LeRoy and Medsger diagnostic criteria from the Hospital Universitari Vall d'Hebron cohort. Patients underwent an echocardiogram, pulmonary function test and nailfold videocapillaroscopy (NVC) within a 3 months period. NVC was performed from 2nd to 5th finger of both hands. NVC features were quantitatively measured. Informed consent was obtained by all the participants. SPSS 20.0 were used for statistical analysis. A P-value <0.05 was considered as significant.
Results: Female was the predominant gender (113, 84.3%). The most common cutaneous subtypes were limited SSc, diffused SSc (88, 65.7% and 28, 20.9%, respectively). Almost 80% of patients met the ACR/EULAR 2013 classification criteria. The age (± standard deviation) at NVC was 38.5 (± 15.7) years, and the interval from the first SSc symptom and NVC was 16 (± 12.6) years. Anticentromere antibodies (ACA) were the most frequent in 36.6% of patients, followed by anti-topoisomerase I in 23.1%. Regarding organ involvement, 62 (46.3%) patients suffered from digital ulcers, 58 (43.3%) interstitial lung disease (ILD), 11 (8.2%) pulmonary hypertension, 110 (82.1%) gastrointestinal disturbances and 103 (76.9%) some cardiac alterations. The forced vital capacity was 80.8 (± 20.1) % and diffusion capacity for carbon monoxide (DLCO) was 66.2 (± 23.7) %. Regarding echocardiography results, the tricuspid regurgitation velocity (TRV) was 2.8 (± 0.3) m/s and the right ventricular systolic pressure 30.7 (± 12.0) mmHg. NVC findings were described as follows: the median of number of capillaries was 5.4 /mm, enlarged capillaries 0.8/mm, giant capillaries 0.2 /mm, microhemorragies 0.1 /mm, ramified capillaries 0.3 /mm, tortuous capillaries 0.6 /mm and disorganized capillaries 0.0 /mm. SSc-ILD patients presented lower capillary density 4.8 /mm compared with 5.8 /mm in the other group (P=0.005), and also more frequent ramified capillaries 0.3 /mm compared with 0.2 /mm (P=0.013). With respect to the correlations, the number of capillaries was related with the DLCO (rho =0.26, P=0.003) but negatively with the RVSP (rho = - 0.21, P=0.03). Giant capillaries were correlated with LVEF (rho =0.27, P=0.001) and greater tricuspid annular plane systolic excursion (TAPSE) (rho =0.21, P=0.01). Microhemorraghies were associated with LVEF (rho =0.29, P=0.001) although negatively with age at NVC (rho = - 0.25, P=0.003) and time from first symptom (rho = - 0.25, P=0.003). Disorganized capillaries were related with age at NVC (rho =0.17, P=0.04) but negatively with DLCO (rho = - 0.18, P=0.035).
Conclusions: The existence of a correlation between NVC features and clinical variables suggests that microvascular alterations may play a role as a pathogenic link with the cardiopulmonary SSc manifestations.

AB0604 RITUXIMAB EXPERIENCE IN PATIENTS WITH LONGSTANDING SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE: A SERIES OF 14 PATIENTS

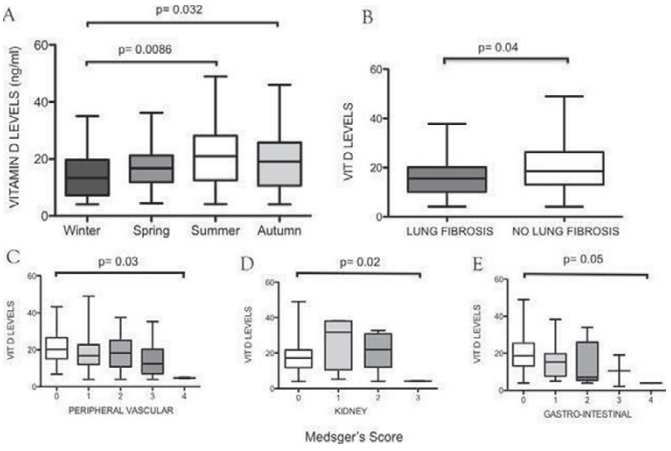
A. Sari[1], D. Guven[2], B. Armagan[1], L. Kilic[1], A. Erden[1], A. Akdogan[1]. *[1]Rheumatology; [2]Internal Medicine, Hacettepe University School of Medicine, Ankara, Turkey*

Background: Interstitial lung disease (ILD) is the leading cause of mortality in systemic sclerosis (SSc) patients. Treatment options are rather limited in SSc associated ILD (SSc-ILD).
Objectives: Objective of this study was to report the experience of RTX treatment in a series of patients with longstanding SSc-ILD in whom unsatisfactory response in lung functions was noted under conventional treatments.
Methods: We retrospectively reviewed charts of 197 SSc patients evaluated between April 2015 and November 2016. 14 patients who received rituximab (RTX) for SSc-ILD participated in this analysis. The severity of ILD based on PFTs was defined as follows; mild (FVC between 71% and 80% of predicted), moderate (FVC between 51% and 70% of predicted) and severe (FVC $\leq$50%). The extent of skin disease was clinically measured by using Modified Rodnan Skin Score (mRSS) tool. End of follow-up was considered as six months after the last RTX dose.
Results: Median (IQR, interquartile range) age was 53.2 (46.8–55.5) and median disease duration was 9.1 (5.1–13.6) years. Median FVC was 52.5 (41.5–64.0)

prior to RTX. At the end of follow-up, no significant change was revealed in FVC when compared with pre-RTX values [58.0 (44.7–58.7), p=0.065]. FVC was improved in four patients and stabilized remaining ten patients. All of the patients with improvement of PFTs had moderate or severe restrictive lung disease. High resolution thorax computed tomography (HRCT) findings remained stable in 7 and showed progression of ILD in 3 patients. In total, mRSS remained stable at the end of follow-up when compared with baseline [8.0 (5.2–12.2) vs. 6.0 (4.0–12.2),p=0,026].

Table 1. Demographic, clinical and laboratory data of patients

Age/ Sex	Disease duration, years	Cutaneous subset	Auto-antibodies	Previous immuno-supresive treatment	RTX cycles	Follow-up after RTX, months	FVC (predicted%)	
							Before RTX	After RTX
52/F	7.0	Diffuse	ANA, Scl-70	CYC, MMF	2	12	44	44
39/M	10.1	Diffuse	ANA, Scl-70	MMF	4	24	75	79
55/F	5.0	Diffuse	ANA, Scl-70	MMF	4	24	75	70
43/F	16.6	Limited	ANA, Scl-70	CYC, MMF	1	6	38	47
50/F	4.6	Limited	ANA, Scl-70	CYC, MMF	4	24	52	57
65/F	13,0	Diffuse	ANA, Scl-70	CYC, MMF	1	6	42	41
48/F	5.7	Limited	ANA, Scl-70	CYC	4	24	67	64
54/F	18.9	Diffuse	ANA, Scl-70	CYC, MMF	2	12	39	57
53/F	15.0	Limited	ANA, Scl-70	CYC, MMF	5	30	53	44
56/F	5,1	Limited	ANA, Scl-70	CYC	1	6	40	45
52/F	8.2	Limited	ANA	–	3	12	59	59
18/F	11.2	Diffuse	ANA, Scl-70	MMF	1	6	63	73
62/F	4.6	Limited	ANA, Scl-70	CYC, MMF	3	18	51	61
54/F	13.1	Limited	ANA, Scl-70	CYC, MMF	5	30	54	67



FVC, forced vital capacity; ANA, antinuclear antibody; Scl-70, antitopoisomerase-1 antibody; CYC, cyclophosphamide; MMF,mycophenolate mofetil; RTX, rituximab.

Conclusions: In this case series of SSc patients treated with RTX, improvement or stabilization of pulmonary functions was observed in most of SSc patients. RTX may be useful in SSc-ILD patients with longer disease duration and resistant to conventional immunsupresive therapies.

AB0605 VITAMIN D SERUM CONCENTRATION IN EUROPEAN SYSTEMIC SCLEROSIS PATIENTS: CORRELATIONS WITH SEASONALITY, ORGAN INVOLVEMENT AND STANDARD ORAL SUPPLEMENTATION

A.C. Trombetta [1], V. Smith [2], E. Gotelli [1], M. Ghio [1], S. Paolino [1], C. Pizzorni [1], A. Sulli [1], M. Cutolo [1]. *[1]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, Genoa, Italy; [2]Department of Internal Medicine, Faculty of Medicine and Health Sciences; Department of Rheumatology, Ghent University Hospital, Ghent University, Ghent, Belgium*

Background: Vitamin D deficiency is reported to interfere with immune responses and to correlate with course and outcome in several autoimmune diseases. In systemic sclerosis (SSc), low 25-hydroxyvitamin D (25(OH)D) serum concentration has been recognized.
Objectives: To investigate relations between 25(OH)D serum concentration and seasonality, clinical parameters as well as standard oral supplementation, in SSc patients.
Methods: 154 SSc patients (mean age 59±15 years, 24.7% diffuse form and 75.3% limited form) were evaluated, at any time of the year, in a retrospective survey. Serum 25(OH)D quantification was performed using the LIAISON 25-OH vitamin D assay (Diasorin, Italy). Pulmonary function test, chest x-ray, lung CT scan, electrocardiography, Doppler echocardiography, renal artery resistive index by eco color Doppler, Dual X-ray absorptiometry, were performed at the time of sample collection. Disease severity scale (DSS) was performed according to Medsger. Drug assumption (glucocorticoids, calcium channel blockers, cyclic intravenous iloprost, endothelin receptor antagonists) and supplementation with vitamin D analogues, were recorded. Non-parametric tests were used for statistical analysis.
Results: Average 25(OH)D serum concentration was found to be 18.7±9 ng/ml (<20 classified as deficiency). A significant difference was observed among seasonal 25(OH)D serum concentration (winter: 14.6±7.8 ng/ml, spring: 17.2±7.9 ng/ml, summer 21.43±10 ng/ml, autumn 20.2±10; p=*0.032*) (Figure 1). A significant correlation was found between 25(OH)D serum concentration and presence/absence of bi-basal fibrotic changes at lung computed tomography (CT) scan (average values: 16.1±8 ng/ml and 20±10 ng/ml, respectively, *p=0.04*). Peripheral vascular *(p=0.03*), kidney (*p=0.02*), gastrointestinal (*p=0.05*) Medsger's DSS parameters also were found to correlate with 25(OH)D serum concentration (Figure 1). Interestingly, no influence of treatment with vitamin D analogues (1,000 UI daily) was found regarding 25(OH)D serum concentration in treated (18.8±10 ng/ml) and in not treated (18.7±9 ng/ml) SSc patients (p=0.81).
Conclusions: In SSc is confirmed a serum 25(OH)D deficiency that we report to be associated with lung involvement, peripheral vascular, kidney and gastrointestinal Medsger's DSS parameters, as well as with seasonality. Supplementation with vitamin D analogues did not influence present results.

Therefore, for successful replacement, supra-physiological oral vitamin D3 doses or programmed UVB light exposure should be considered.

AB0606 MORTALITY ASSOCIATED FACTORS TO IDIOPATHIC INFLAMMATORY MYOPATHIES (IIMS)

A.C. Costi [1], P. Sansinanea [1], C. Pena [1], A. Testi [1], A. Salas [1], J. Marcos [1], V. Arturi [1], A. Vulcano [1], M. Pera [1], R. García Salinas [2], R. Aguila Maldonado [1], L. García Var [1], V. Nagua [1], M.A. García [1]. *[1]Rheumatology, HIGA San Martín; [2]Rheumatology, Hospital Italiano, la Plata, Argentina*

Background: Idiopathic inflammatory myopathies (IIMs) include a group of muscular diseases characterized by the presence of muscle inflammation. The mortality of the IIMs has been estimated between 13 and 50%.
Objectives: To evaluate mortality rate and associated factors in patients with IIMs.
Methods: Retrospective, observational study, where patients with IIMs (Bohan & Peter 1975) were included. Data were obtained from medical records from patients with myopathy (Increase CK, muscle weakness, cutaneous involvement, interstitial lung involvement) evaluated in a reference rheumatology center of Argentina (1992–2016). Descriptive statistics were performed. Chi2 test, Student's test or Mann Whitney as appropriate multivariate logistic regression analysis.
Results: From 102 patients evaluated 89 enter the study, 73% were female. Mean age at diagnosis 48±14 years. Clinical Manifestations: Skin involvement 77% (erythema Heliotrope 51%, rash on the neck and V-sign 60%, back and shoulders 50%, photosensitivity 60%, Gottron's papules 50%, pruritus 33%, erythema peri nail 21%), pulmonary involvement 19% Raynaud 28%, muscle weakness 86%, muscle weakness of the neck 33%, respiratory muscles 13%, myalgias 60% and dysphagia 53%.
Muscle biopsy: performed in 36/89 with pathological findings in 83%, electromyogram performed in 35%. Intensive care unit admission 14/89 (16%). Laboratory: raised CPK 68% with an mean value 3527 IU/ml, raised Transaminase 60%, ANA positive 65%, SSA/RO 25%, Jo1 4.4%, RNP 7%, increased CRP 28% and ERA 59%.
Clinical Subtypes IIMs: Dermatomyositis (DM): 61%, Antisynthetic syndrome (AS): 6%, Myopathy associated with connective tissue disease: 19%, Associated with statins: 4, 4%, Polimyositis: 10%. Association with neoplasia was observed in 15%. Treatments: Corticoids pulses 21%, corticoids 97% (mean starting dose 45 mg meprednisone), methotrexate 77%, hydroxychloroquine 36%, azathioprine 30%, cyclophosphamide 16%, intravenous immunoglobulin 15%, biological 10% and cyclosporine 3%.

Univariate analysis

Variables	Mortality (Odds Ratio)	95% IC	
Male sex	3	1,03–8,4	P<0,039
Respiratory muscle weakness	5,47	IC: 1,4–20,59	p<0,007
ANA positive	6	1,27–27	P<0,01
Neoplasms	3,8	1,1–1,3p	P<0,026
Glucocorticoid pulses	5,7	1,81–17,8	P<0,001
Intravenous immunoglobulin	3,67	1,06–12,6	P<0,03
Serious infections	17	4,6–61,5	P<0, 0000012

Multivariate analysis of logistic regression

Variable	OR	IC (95,0%)		p
Malignant neoplasm	8,785	1,229	62,797	**0.03**
Serious infections	69,168	10,079	474,666	**0.0001**
Glucocorticoid pulses	3,745	0,635	22,092	0.145
Male sex	5,899	1,141	30,504	**0.034**
Intravenous immunoglobulin	0,906	0,100	8,217	0.93
Respiratory muscle weakness	0,524	0,050	5,527	0.59
ANA positive	4,247	0,638	28,259	0.135

Mortality was 22.5% (20/89 patients), CI95 (14.3–32.5). Mean time from diagnosis to the event was 18 months. The primary cause of death was sepsis 14/20 (70%).
Conclusions: Mortality of patients with inflammatory myopathies was 22%, and the primary cause was infectious. In the analysis of multiple variables, male sex, presence of neoplasms and serious infectious complications were significantly factors associated with mortality.

AB0607 PULMONARY EMBOLISM IN SYSTEMIC SCLEROSIS – ONE YEAR FOLLOW UP

A.C. Duarte[1], I. Cordeiro[1], M. Ferreira[2], T. Judas[2], M.J. Loureiro[3], J. Santos[4], S. Carmona[4], M.J. Santos[1], A. Cordeiro[1]. *[1]Rheumatology; [2]Internal Medicine; [3]Cardiology; [4]Nuclear Medicine, Hospital Garcia de Orta, Almada, Portugal*

Background: Risk of pulmonary embolism (PE) in systemic sclerosis (SSc) has been estimated between 2.51–3.47 fold higher when compared to non-SSc patients (pts). Proinflammatory state, vasculopathy and vascular injury may contribute to a prothrombotic state in SSc and increased risk for venous thromboembolism.
Objectives: Calculate frequency and identify possible risk factors for PE among SSc pts;analyse efficacy of longterm anticoagulation (ACO) in these pts.
Methods: We conducted a retrospective analysis of 110 pts with SSc followed in our Rheumatology department and selected those who performed lung ventilation/perfusion scintigraphy (V/Q scan) or CT pulmonary angiography due to worsening dyspnea/fatigue or isolated reduction of the carbon monoxide diffusing capacity (DLCO). We collected demographic features, comorbidities, age at SSc diagnosis, anti-nuclear antibody specificities, dyspnea according to New York Heart Association (NYHA) classes and results of cardiopulmonary exams. PE and related variables were assessed at baseline and after 12 months of ACO.
Results: PE was diagnosed in 12 out of 29 (41.4%) SSc pts that met inclusion criteria, with the majority presenting bilateral peripheral multisegmental defects. Most were females (91.7%), mean age of 59.4 (±12.7) years (yrs). Two thirds were diagnosed with limited SSc with mean disease duration of 13.3 (±12.9) yrs. Mean time between SSc and PE diagnosis was 8.5±8.2 yrs, although one third of the pts was diagnosed within the first year of SSc diagnosis. One patient was taking oral contraceptives and none had thrombophilia, previous surgery or cancer.
One third was classified as having NYHA class≥3, with a mean N-terminal pro-brain natriuretic peptide (NTproBNP) of 1108pg/mL (19 to 8069). Six pts had concomitant interstitial lung disease (ILD) and 8 had an estimated pulmonary artery systolic pressure (PASP)≥35 mmHg (6 of them had concomitant ILD). From these only 2 had pulmonary hypertension confirmed by right heart catheterization and 1 died.
When comparing SSc pts with and without PE, Scl70 positivity was more common in pts with PE (p=0.041). No significant associations were found between PE and several cardiovascular risk factors.
From the 12 pts with PE, 10 were on longterm ACO:5 on rivaroxaban, 4 on warfarin and 1 on apixaban. Clinical reassessment after 12 months of ACO is shown in figure 1.

Patient	Anticoagulant	Symptoms*	NT-pro BNP	V/Q scan	PASP (mmHg)	DLCO
1	Warfarin	Discrete improvement	Reduction (>100 pg/mL)	Not available	Not available	Identic
2	Rivaroxaban	Identic	Identic	Identic	Identic	Identic
3	Non-pplicable§					
4	Rivaroxaban	anticoagulated for < 6 months				
5	Warfarin	Identic	Identic	Identic	Identic	Discrete improvement (29»36)
6	Apixaban	Discrete improvement	Discrete raise (±100 pg/mL)	Decrease in perfusion defects	Worsening (28»40)¥	Identic
7	Warfarin	Discrete improvement	Identic	Identic	Improvement (51»30)	Not available
8	Warfarin	Identic	Marked raise (>5000 pg/mL)¥	Not available	Not available	Not available
9	Non-pplicable§					
10	Rivaroxaban	Identic	Raise (±200 pg/mL)	Identic	Not available	Identic
11	Rivaroxaban	Discrete improvement	Identic	Identic	Not available	Not available
12	Rivaroxaban	anticoagulated for < 6 months				

*Symptoms evaluated were fatigue and dyspnea; § V/Q scan defects are too subtle and the risk is considered to outweigh the benefit of anticoagulation; ¤ Cardiac catheterization demonstrated important coronary disease; ¥ In relation with worsening of ILD
Figure 1 – Patients' reassessment after 12 months of ACO

Conclusions: Our results suggest that PE is frequent in SSc and must be considered in the differential diagnosis of worsening fatigue and dyspnea and/or reduction of DLCO/PASP increase. PE may occur more frequently in Scl70 positive pts and early in disease course, probably due to vasculopathy and vascular injury being more prominent in the early phase of the disease. Although there is no consensus regarding the optimal ACO, the disease's vasculopathy seems to be an important contributor, potentially preventing improvement in perfusion defects, regardless of the anticoagulant used.

AB0608 PREDICTIVE FACTORS FOR LONG-TERM SURVIVAL AND DISEASE PROGRESSION OF SYSTEMIC SCLEROSIS – A LONGITUDINAL ANALYSIS

A.M. Gheorghiu[1,2], A. Radu[1,2], R. Oneata[1,2], A. Soare[1,2], R. Dobrota[1,2], S. Magda[2,3], T. Constantinescu[2,4], R. Jurcut[2,5], R. Sfrenţ-Cornăţeanu[2,6], M. Bojincă[1,2], V. Stoica[1,2], C. Mihai[1,2]. *[1]Internal Medicine and Rheumatology, Cantacuzino Hospital; [2]Carol Davila University of Medicine and Pharmacy; [3]Emergency University Hospital; [4]Marius Nasta Institute of Pneumology; [5]C.C. Iliescu Institute for Cardiovascular Diseases; [6]Physiopathology and Immunology Department, Bucharest, Romania*

Background: Systemic sclerosis (ScS) has unpredictable course and high mortality. Generalised Estimating Equations (GEE) is a technique useful for longitudinal data analysis, using data from all time points and adjusting for within-patient correlation,i.e. correlation between time points within the same patient. GEE does not require a normal distribution of dependent variables, making it attractive for analyzing SSc data.
Objectives: To identify predictive factors for death and unfavorable outcomes.
Methods: Data of SSc patients with ≥2 visits in our EUSTAR centre in 2004–2016 were analyzed. GEE investigated the relationship over time between outcomes (death, digital ulcers (DUs), forced vital capacity (FVC), modified Rodnan skin score (mRSS)) and potential predictors (age, gender, disease duration, cutaneous subset, mRSS at baseline, DUs history, DLCO, left ventricle ejection fraction (LVEF), proteinuria), separately for each predictor and in combined models.
Results: 89 patients (12.4%males, mean±SD age 49.2±12.2years, disease duration 4.1±7.5years) were included, with a follow-up of up to 13years. There were 14deaths, most due to lung involvement (7/14). In multivariable GEE analysis (Table 1), predictors of death were a shorter disease duration, DUs history, and a lower LVEF. Predictors for FVC decrease over time were difuse cutaneous subset (dcSSc), younger age and lower DLCO. Younger age, shorter disease duration and higher baseline mRSS were the most important predictors for higher mRSS at follow-up. The only predictor for the development of new DUs was a history of DUs.

Table 1. Prediction factors for death and for evolution over time of parameters reflecting disease severity in SSc

Predictors	Death	DUs	FVC	mRSS
	OR (95% CI)	OR (95% CI)	B (95% CI)	B (95% CI)
Age	1.1 (0.9, 1.3)	0.9 (0.9, 1.0)	0.3 (0.1, 0.6)*	-0.1 (-0.2, -0.01)*
Disease duration	0.8 (0.7, 0.9)***	1.0 (0.9, 1.1)	-0.0 (-0.3, 0. 3)	-0.1 (-0.3, -0.03)**
mRSS baseline	0.9 (0.9, 1.1)	1.1 (0.9, 1.1)	0.2 (-0.2,0.7)	0.4 (0.3, 0.6)***
DLCO	0.9 (0.9, 1.0)	1.0 (0.9, 1.0)	0.5 (0.3, 0.6)***	0.1 (-0.0, 0.0)
LVEF	0.9 (0.90, 0.98)**	0.9 (0.9, 1.1)	0.2 (-0.2, 0.7)	0.0 (-0.2, 0.2)
Male gender	1.9 (0.3, 11.2)	0.5 (0.1, 1.9)	0.7 (-9.3, 10.7)	-1.2 (-3.9, 1.5)
dcSSc	6.8 (0.6, 81.7)	0.7 (0.2, 2.9)	-16.5 (-28.9, -4.9)**	1.7 (-0.1, 3.4)
DUs history	13.1 (3.1, 55.8)***	28.4 (2.3, 356.4)**	3.2 (-2.1, 8.4)	0.2 (-1.4, 1.7)
Proteinuria	1.1 (0.6, 1.8)	0.9 (0.4, 1.9)	2.2 (-2.5, 6.8)	1.7 (-0.1, 3.5)

*p<0.05, **p<0.01, ***p<0.001.

Conclusions: Patients with shorter disease duration, dcSSc, higher mRSS, lower DLCO and LVEF and a history of DUs had a more unfavorable course. GEE is a robust technique for longitudinal data analysis, excellent for identifying prediction factors in SSc.

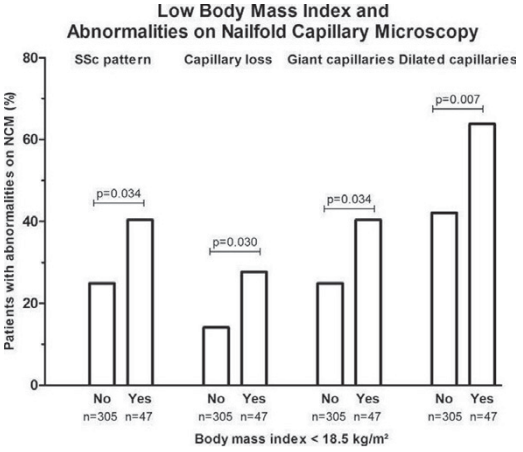
AB0609 CORRELATION OF PSYCHOLOGICAL PROFILE (MMPI-II A BDII TESTS) OF SCLERODERMA PATIENTS WITH ORGAN MANIFESTATION AND IMMUNOLOGICAL PROFILE

A. Smržová[1], L. Hubáčková[2], S. Kreiselová[2], J. Zapletalová[3], P. Horák[4]. *[1]3Rd Department of Internal Medicine – Nephrology, Rheumatology and Endocrinology; [2]Department of Psychology; [3]Department of Medical Biophysics; [4]Faculty of Medicine and Dentistry, Palacký University Olomouc, Olomouc, Czech Republic*



Background: There is high prevalence of mood disorders in patients with systemic scleroderma. Psychical distress can influent some of clinical manifestations and can worse the course of the disease and socioeconomicall status of patients.
Objectives: The aim of study is detection of correlations of depression and psychological profile measures by MMPI-II (The Minnesota Multiphasic Personality Inventory) and BDI-II (The Beck Depression Inventory-II) and organ manifestation and immunological profile of patients with systemic sclerosis.

Methods: From March 2015 to July 2017 we examined 42 patients with scleroderma, from which 37 filled the valorisation criteria of MMPI-II test. The data of MMPI-II scales and BDI-II was correlated with antropometric data, form of disease, disease duration, duration of RP, organ major manifestation, comorbidities, use of medication and immunological profile.
Results: In this study 37 patient were included (6 men, 31 women, mean of age – 58.8±10.6y., duration of disease 8,9±9.1y, duration of RP 13.9±13.4y.), 10 patient have diffuse, 27 patient limited form. Subjective perceived depression detected by BDI II test was present in 11 patients (35%, mild 6, moderate 3 and 2 severe). Total BDI-II score correlated with anticentromer Abs (p=0.05), total cholesterol (p=0.008), LDL (p=0.05) and gastrointestinal manifestation (p=0.002). Positivity in domain - Hypochondria, Depression, Hysteria, Psychastenia and Social introversion was highly prevalent (47–13%). This results of MMPI-II suggest a specific psychological profile of SSc patients. There was no correlation for age, subset of disease, cardiovascular manifestation, valvular damage and myositis. Smokers are much more introvert (p=0.012). Positivity of anti Scl70 Ab correlated with incredulity (p=0.038), schizophrenia, hypomania and family disharmony (p=0.046). Positivity of anticentromer antibodies was connected with incredulity (p=0.038), hypomania, alienation to family, egocentrism (p=0.042), psychotic thinking, psychomotoric retardation (p=0.037) and subscales of BDI-II test (Loss of pleasure, Self-Criticism, Self-Dislike). From organ manifestation, pulmonary hypertension correlated with himself degradation (p=0.037). Gastrointestinal manifestation has the same correlation and BDI-II subscale-Guilt Feelings (p=0.042). It is interesting, that absence of lung damage demonstrated with alienation self and family (p=0.049), posttraumatic stress disorder (p=0.025), problems in family (in more scales, p=0.028,0.03,0.029), schizophrenia (p=0.03). Patients without digital ulceration have much more neurologic symptoms (p=0.023). Using of antidepressant and anxiolitic medication correlated with a lot of scales in domain of depression, anxiety, social introversion, family distress and self devaluation. Disease duration and duration of RP correlated with psychomotoric retardation.
Conclusions: Patients with scleroderma may have special psychological profile. MMPI-II test shows specific psychologic abnormalities of scleroderma patients. Psychiatric and psychologic intervention can be very useful in complex care of these patients.

AB0610 NAILFOLD CAPILLARY MICROSCOPY AND LOW BODY MASS INDEX IN RAYNAUD'S PHENOMENON PATIENTS

A.M. Van Roon[1], A. Eman Abdulle[1], A.M. van Roon[1], A.J. Stel[2], A.J. Smit[1], H. Bootsma[2], D.J. Mulder[1]. [1]*Internal Medicine - Vascular Medicine;* [2]*Rheumatology and Clinical Immunology, University of Groningen - University Medical Center Groningen, Groningen, Netherlands*

Background: Underweight patients develop Raynaud's phenomenon (RP) more frequently. [1] In a small study, skin temperature and perfusion in RP patients was positively associated with body mass index (BMI). [2] In clinical practice, we frequently observe an abnormal nailfold capillary microscopy (NCM) in underweight subjects with presumably primary RP, from which the implications are unknown.
Objectives: The aim is to study whether being underweight is associated with the presence of more abnormalities on NCM.
Methods: NCM, assessed by widefield videocapillaroscopy, was retrospectively assessed in consecutive patients with suspected RP. Patients were included when they had negative serology and did not develop any definite connective tissue disease or organ involvement after a maximum of 5 years follow-up. NCM pattern was classified as normal, non-specific, early, active or late, based on the Cutolo patterns. Weight and height were measured for clinical practice and patients were divided by BMI category: underweight (BMI$<$18.5 kg/m^2), normal weight (BMI 18.5–25 kg/m^2), and overweight (BMI $>$25 kg/m^2). Dilated and giant capillaries were counted as well as the total number of capillaries.
Results: A total of 352 patients were included (median age 40.6 years (24.9–52.9), male/female: 111/241), of which 47 were underweight, 220 normal weight and 85 overweight. Patients who were underweight presented more abnormalities (dilated capillaries, capillary loss or giant capillaries) on NCM, as shown in figure 1. BMI was negatively associated with NCM pattern, number of dilated capillaries and number of giant capillaries (r=-0.247, r=-0.225 and r=-0.221 respectively, all p$<$0.001) and positively with the total number of capillaries (r=0.260, p$<$0.001).
Conclusions: In addition to well-known thermoregulatory abnormalities, clear NCM pattern abnormalities are more frequently observed in underweight patients with primary RP. BMI was negatively associated with the number of dilated capillaries and positively with capillary density. These data potentially suggest that damage to the microvasculature in underweight patients with primary RP may occur independently of the presence or development of a CTD and may be explained by other mechanisms.

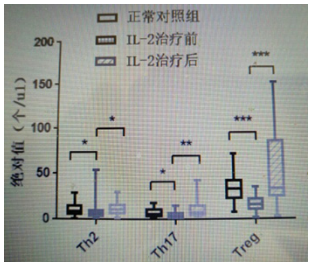
AB0611 MYCOPHENOLATE MOFETIL FOR THE TREATMENT OF INFLAMMATORY MYOPATHY RELATED INTERSTITIAL LUNG DISEASE: A SYSTEMATIC REVIEW



B. Lopez[1], D.A. Isenberg[2], P.A. Gordon[1]. [1]*Rheumatology, King's College Hospital;* [2]*Rheumatology, UCL, London, United Kingdom*

Background: Inflammatory myopathies (IIM) are a heterogeneous group of rare autoimmune rheumatic diseases in which extramuscular manifestations, especially interstitial lung disease (ILD), are common and may occur in the absence of muscle symptoms. ILD has been identified as a marker of poorer prognosis, with sparse, mainly observational evidence, supporting the use of immunosuppressant therapies.
Despite the lack of clinical trial evidence, corticosteroids are considered first-line therapy. Cyclophosphamide is frequently used for severe disease and Azathioprine as maintenance therapy. Mycophenolate Mofetil (MMF) has emerged as a promising treatment, encouraged by data published from a randomised controlled trial comparing Cyclophosphamide with MMF in patients with systemic sclerosis and ILD, which showed similar efficacy and better tolerability in the MMF group (1).
Objectives: To examine the evidence supporting the use of MMF in patients with IIM associated ILD.
Methods: An electronic literature search was performed using the Ovid platform. Population: Adults diagnosed with IIM according to validated criteria (2, 3) or antisynthetase syndrome (defined by the presence of anti-synthetase antibodies), with ILD demonstrated by HRCT or lung biopsy and treated with MMF, with extractable outcomes regarding ILD. Outcomes were recorded as positive (improvement/stabilisation) and negative (deterioration) as defined by the American Thoracic Society consensus guidelines (4).
Results: 506 initial citations were identified, with 23 studies included in the review comprising a total of 82 patients. Median follow up was 12 months, median age 55 years. There was sufficient data to apply America Thoracic Society criteria in 37 patients: improvement/stabilisation n=29, deterioration n=8. Although the criteria could not be applied in 45 patients, improvement/stabilisation was reported in 44 with deterioration in one patient. A non-significant trend to better outcomes was observed when MMF was prescribed as first line therapy, in Jo-1 positive patients and non-Usual Interstitial Pneumonia pattern. Mean Prednisolone dose reduced from 40 mg/day to 10.1 mg/day. No significant toxicity was reported.
Conclusions: Mycophenolate Mofetil is a promising drug with encouraging results, but randomised controlled clinical trials are needed to prove its efficacy.

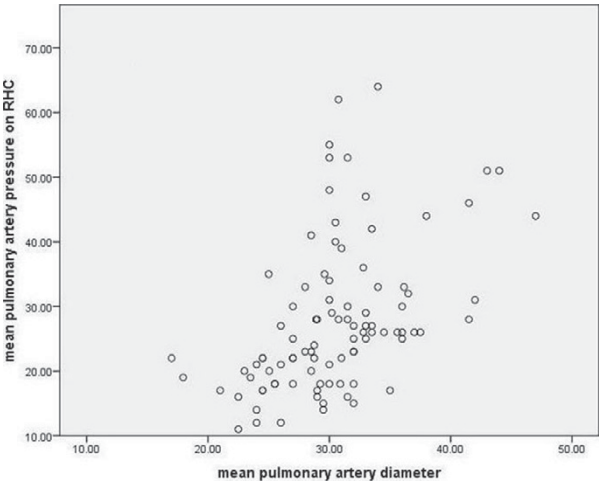
AB0612 EFFICACY OF LOW DOSE AND SHORT-TERM IL-2 TREATMENT TO EXPAND ENDOGENOUS REGULATORY T CELLS IN PATIENTS WITH MIXED CONNECTIVE TISSUE DISEASE

B. Zhang[1], L.L. Shang[1], J.P. Cao[2], H.Y. Gao[2], C. Gao[3], X.F. Li[2]. *[1]The Second Hospital of Shanxi Medical University, Taiyuan, China; [2]Rheumatology, The Second Hospital of Shanxi Medical University, Taiyuan, China; [3]Brigham and Women's Hospital/Children's Hospital Boston, Harvard Medical School, Boston, American Samoa*

Background: The concept of Mixed Connective Tissue Disease (MCTD) was first proposed by Sharp and his colleagues in 1972.[1] MCTD has overlapping features between at least two autoimmune diseases, such as SLE, SSc, PM/DM and RA. Regulatory T cells (Treg cells) play a critical role in the maintenance of immune tolerance and the regulation of immune responses. Treg cell dysfunction contributes to the initiation of pathogenesis and the maintenance of high disease activity in RA and SLE.[2] Recently, some studies have indicated that the proportion of Treg cells was different from healthy controls in SSc patients.[3] Therefore, MCTD may be associated with Treg cells.
Objectives: To explore the status of CD4+T cells in peripheral blood of patients with MCTD; to explore the effect of low dose interleukin -2 (IL-2) treatment on the balance of Treg cells and Th17 cells in patients with MCTD, and to observe the short-term curative effect.
Methods: CD4+T cells in the peripheral blood of 58 MCTD patients and 33 healthy controls were analyzed by flow cytometry. All of 58 cases were treated with standard therapy, including corticosteroids, NSAIDs, immunosuppressants, or combination therapy. Among them, 26 cases of MCTD without using immunosuppressant (CYC, MTX, LEF, MMF), were as untreated group, another 32 cases were as treated group. Then we compared the difference of CD4+T cells between two groups. In 58 patients with MCTD, a total of 27 patients were treated with low-dose IL-2 (50WIU) on the basis of standard treatment for 5 days. The difference of CD4+T cells before and after treatment with IL-2 was compared.
Results: The absolute count of CD4+CD25+FOXP3+Treg cells in peripheral blood of patients with MCTD was significantly lower than those in healthy controls. There was no significant difference in the absolute count of CD4+CD25+FOXP3+Treg cells in the peripheral blood between the treated group and the untreated group. The absolute count of CD4+CD25+FOXP3+Treg cells was significantly higher than those before treatment with IL-2.



Conclusions: The absolute count of CD4+CD25+FOXP3+Treg cells in peripheral blood of patients with MCTD were significantly reduced, which may be the mechanism of immune imbalance in MCTD patients. The decrease of the absolute count of CD4+CD25+FOXP3+Treg cells in peripheral blood of patients with MCTD was not associated with the use of immunosuppressive agents. Low dose and short-term IL-2 treatment may increase the absolute count of CD4+CD25+FOXP3+Treg cells in the peripheral blood in patients with MCTD, so as to restore the immune balance in patients with MCTD.

AB0613 PULMONARY ARTERY DIAMETER AND PULMONARY HYPERTENSION IN SYSTEMIC SCLEROSIS

B.E. Schreiber[1], C.P. Denton[2], G. Robinson[3], A.U. Wells[4], G. Keir[4], N. Sverzelatti[5], J. Suntharalingam[3], G. Coghlan[1]. *[1]Royal Free Hampstead NHS Trust; [2]University College London, London; [3]Royal United Hospital, Bath; [4]Royal Brompton Hospital, London, United Kingdom; [5]Parma University Hospital, Parma, Italy*

Background: Systemic sclerosis may be complicated by pulmonary hypertension. CT-determined pulmonary artery diameter has been shown to correlate with presence of pulmonary hypertension in idiopathic patients and in interstitial lung disease but not in scleroderma.
Objectives: To determine the utility of CT-determined main pulmonary artery diameter (MPAD) for predicting pulmonary hypertension (PH) in 97 patients with systemic sclerosis who had CT chest within six months of right heart catheterisation.
Methods: Retrospective review of right heart catheter and CT data done within six months in 97 patients. The CT scans were blindly scored by two radiologists.
Results: 97 patients (75 female, 22 male) with systemic sclerosis who underwent CT scan and right heart catheterization were analysed. About 2/3 had the limited subtype (64 limited, 24 diffuse, 6 undefined).
Pulmonary hypertension was present in 55 patients (57%) and interstitial lung disease affecting 20% of the lung or more was present in 42 patients (43%).
Survival was worse in those with pulmonary hypertension. Median survival was 9.3 years in those without pulmonary hypertension (8.1–10.5) and 4.4 years in those with pulmonary hypertension (2.6–6.2). Presence of interstitial lung disease and pulmonary hypertension were independent predictors of survival.
An ROC curve shows area under the curve of 0.864. MPAD threshold of 25 mm or greater has a sensitivity of 98% and a specificity of 33% for the presence of pulmonary hypertension; 30 mm has a sensitivity of 73% and a specificity of 81% for the presence of pulmonary hypertension; 32 mm has a sensitivity of 56% and a specificity of 88% for the presence of pulmonary hypertension and 34 mm has a sensitivity of 35% and a specificity of 98% for the presence of pulmonary hypertension.
Survival was worse in those with a MPAD of 30mm or greater, with median survival of 5.5 years (3.8–7.2) compared to survival of 9.3 years (7.9–10.7) in those with MPAD smaller than 30mm. It was not a significant predictor of survival after adjustment for presence of pulmonary hypertension and interstitial lung disease.

Conclusions: The CT determined MPAD correlates strongly with the presence of pulmonary hypertension in patients with systemic sclerosis.

AB0614 ANTISYNTHETASE SYNDROME: AUTOANTIBODIES, CLINICAL PATTERN AND MANAGEMENT OF 17 SPANISH PATIENTS

C. Busca, Á. Robles, I. Vives, J.A. Troncoso, L. Bailón, J.J. Ríos, A. Noblejas, F. Arnalich. *Internal Medicine, la Paz Hospital, Madrid, Spain*

Background: Antisynthethase syndrome (ASS) is a heterogeneous rare inflammatory condition characterized by myopathy, intersticial lung disease (ILD), arthritis, mechanic hands and Raynaud phenomenon (RP). The hallmark of ASS is the presence of antibodies against aminoacyl-transfer RNA synthetases (anti-ARS). Eight different anti-ARS have been described: anti-Jo1, anti-PL7, anti-PL12, anti-EJ, anti-OJ, anti-KS, anti-Zo, anti-Tyr/YRS. Despite recent publications, correlation between autoantibodies clinical pattern and management in ASS is not entirely well-known.
Objectives: The aim of this study was to define clinical features, autoantibodies and outcomes of a series of ASS patients.
Methods: We retrospectively analyzed the epidemiology, clinical data, lung function parameters, muscle enzymes, electromyogram (EMG) and autoantibodies pattern and its relationship with clinical manifestations, treatment management and outcomes of 17 patients recruited between 2005 and 2016 from the Autoimmune Diseases Division of a Spanish hospital.
Results: A total of 17 patients were reviewed (15 female). Mean age at diagnosis was 55 years. Median time delay to diagnosis was 5 months. Median follow-up was 65 months. Main clinical symptoms were dyspnea (76.5%), polyartrhitis (58.6%), muscle weakness and myalgias (52.9%), RP (41.1%) and mechanic

hands (23.5%). Lung involvement was defined by HRCT compatible with ILD (64.7%) and abnormal functional exploration (47.1%): restrictive pattern (87.5%) and diminished DLCO (61%). Muscle involvement was defined by elevated CK (52.9%) with a median maximum value of 517 IU/L, myopathic pattern on 8 of 13 performed EMG (61.1%) with myositis found in 4 of them (50%), and inflammatory myositis in 5 of 8 performed biopsies (62.5%). Anti-ARS findings were anti-Jo1 (11), PL12 (2), PL7 (1), anti-EJ (2) and one patient with both PL7 and PL12. Anti-Jo1 predominant clinical pattern was ILD (72.7%), followed by myopathy (63.6%) and concomitant myopathy and ILD (45.5%). Anti-PL12 was associated with ILD, RP, and esophageal involvement and no myopathy. Anti-PL7 patient showed mild myopathy and cutaneous association alone. A combination of anti-PL12 and PL7 was described in one patient who developed ILD with severe myopathy. Anti-EJ patients had pulmonary involvement but no evidence of muscle disease. There was no evidence of cancer in any of our patients. Corticosteroids therapy was administered in most of them (88.2%), and corticodependence was highlighted, being necessary at times to associate one or more immunosuppressants.

Conclusions: Regardless of ASS being a rare disease, 17 patients were collected. Anti-Jo1 was the most described antibody. It is important to note that one patient was found to be positive for both anti-PL7 and PL12 meanwhile they were described as exclusive, showing overlap of clinical pattern with severe muscle injury. This finding suggests that positive results for more than one ASS antibody infer more severity. In contrast with previous literature, pulmonary was more frequent than muscle involvement. The coexistence of both was observed in a small group (35.3%), mostly in anti-Jo1 patients (45.5%). Therefore, we suggest the need to request ASS antibodies in patients with pulmonary or/and muscle involvement at onset although classic clinical pattern is missing.

AB0615 PERSISTENCE OF HUMAN PAPILLOMAVIRUS IN THE CERVIX OF WOMEN WITH SYSTEMIC SCLEROSIS

C. Vacchi, M. Colaci, G. Cassone, C. Esposito, F. Lumetti, D. Giuggioli, C. Ferri.
Rheumatology Unit, University of Modena and Reggio Emilia, Modena, Italy

Background: Persistent infection by high-risk oncogenic Human Papillomavirus (HPV) is the main cause of the development of dysplastic or malignant lesions of the cervix. Furthermore, a few life habits, such as smoking, sexual habits and hormonal contraception, are known risk factors for cervical HPV infection. In addition, increased frequency of persistent HPV infection or high-grade intra-epithelial lesions rates was anecdotally described in patients affected by immune-mediated diseases, such as systemic lupus erythematosus, rheumatoid arthritis and systemic sclerosis (SSc), in comparison with the general population.

Objectives: To determine the prevalence of persistent HPV infection in an SSc patients series and its possible correlation with the disease clinical features.

Methods: The study retrospectively evaluated 52 consecutive female SSc patients (age 56.7±11.2SD years, disease duration 12.1±7.4SD years), classified according to the ACR/EULAR 2013 criteria, referring to our university-based Rheumatology Unit. Detection of HPV DNA and viral genotyping in cervical swabs were carried out. Moreover, abnormal Papanicolau test smears were classified using the Bethesda system.

Results: Fourteen(26.9%) patients presented a cervical swab positive for HPV infection,including12 infected by high risk or probable-high risk HPV types. Six (11.5%) patients presented multiple infection ($\geq$2 HPV types), including one case with high-grade intra-epithelial lesion.

Only tabagism was significantly correlated to HPV infection; namely,smoking habit was observed in 41.6% of SSc patients with and in 21.7% of those without HPV infection, respectively; p=0.006); moreoverimmunesuppressive therapies, namely mofetil mycophenolate, cyclophosphamide or rituximab, tended to be associated withHPV infection (presence/absence 21.4 vs 21.7%; p=0.055).

More interestingly, amongSSc patients over 50, HPV infection was found in 9/38 (23.7%) individuals, a frequency markedly higher than that expected in age-matched general population from the same geographical area (5%).

Conclusions: Persistent HPV infection was observed in over a quarter of SSc patients, notably in women over 50. The HPV positivity was not related to SSc clinical features, while a significant association with tabagism and immunesuppressive therapies was evidenced. Considering the possible clinico-prognostic implication on the overall disease outcome, routinely gynaecological screening of SSc female patients ishighly recommendable.

AB0616 COST ANALYSIS RELATED TO SUBCUTANEOUS IMMUNOGLOBULINS IN PATIENTS WITH INFLAMMATORY MYOPATHIES AND IMMUNE-MEDIATED CHRONIC NEUROPATHIES. RESULTS OF AN OPEN LABEL STUDY

C. Vacchi, M. Sebastiani, A. Manfredi, G. Cassone, F. Campomori, C. Ferri.
Rheumatology Unit, Universita di Modena e Reggio Emilia, Modena, Italy

Background: Intravenous Immunoglobulins (IVIg) represent a relevant treatment option in various immune-mediated disorders such as idiopathic inflammatory muscle diseases (IIMD), immune-mediated chronic neuropathies (IMCN), hematologic autoimmune diseases, Still disease, Felty syndrome, systemic lupus erythematosus, vasculitis, some organ-specific autoimmune disease, and atopic diseases. The IVIg treatment is expensive and need of hospital-based assistance for administration; the recent avaibility of home-therapy with subcutaneous immunoglobulins (SCIg) may significantly reduce costs and improve the patient's quality of life.

Objectives: The primary objective was to perform an analysis of costs of SCIg administration in patients affected by IIMD or IMCN compared to that of previous IVIg treatments.

Methods: We prospectively evaluated 6 consecutive patients (3 males and 3 females, mean age 65,3 years, range 63 - 77), 2 affected by IIMD in the context of polymiositis and 4 by IMCN, 3 in the context of vasculitis and 1 in the context of undifferentiated connective tissue disease. All patients were previously treated with IVIg at the dosage of 2g/Kg monthly, (mean monthly dosage 143 g, range 98 – 160, average patient weight 71,5 kg, range 49 - 80), with good clinical and humoral response. After a mean therapy duration of 49.8 months (range 12 – 125) all patients were shifted to SCIg at the dosage of 10 g twice a week (80 g monthly). Each patient was followed-up by humoral and clinical evaluation, including Medical Research Council (MRC) score to quantify muscle strength and INCAT Sensory Score to evaluate sensory symptoms. The costs of the two therapeutic strategies were also compared, excluding indirect costs (absences from work and productivity losses, transport and parking, health care sector costs).

Results: In 5/6 patients, we observed the maintenance of clinical and humoral status after a mean follow-up of 21 months (range 4 - 51), in particular we observed a stability in MRC score in patients presenting loss of strenght and INCAT score in patients presenting sensory symptoms. Furthermore, the treatment with SCIg was well-accepted and preferred to IVIg by all patients. In one patient SCIg were discontinued after 2 weeks, because of the appearance of a haemorrhagic lesions nearby the injection site (in the same patient IVIg have been stopped because of a hypertensive crisis during the infusion). Direct cost associated to IVIg amount to 252€ for 5 g of immunoglobulins (7,056€ monthly, considering a protocol of 2 g/kg/monthly and a patient-weight of 70kg), while direct costs associated to SCIg (20g weekly) amount to 6,400€/monthly, with a saving of 656€/monthly and 7,872€/yearly. In our case-series the annual saving was 9,686.40€/patient (from 86,486.40€ to 76,800€, for IVIg and SCIg, respectively).

Conclusions: Our experience suggests that the shift to SCIg from IVIg in patients affected by IIMD and IMCN is feasible, cost-effective, safe and well-accepted by patients. Further studies are needed to evaluate the effectiveness of SCIg in first-line therapy of these diseases.

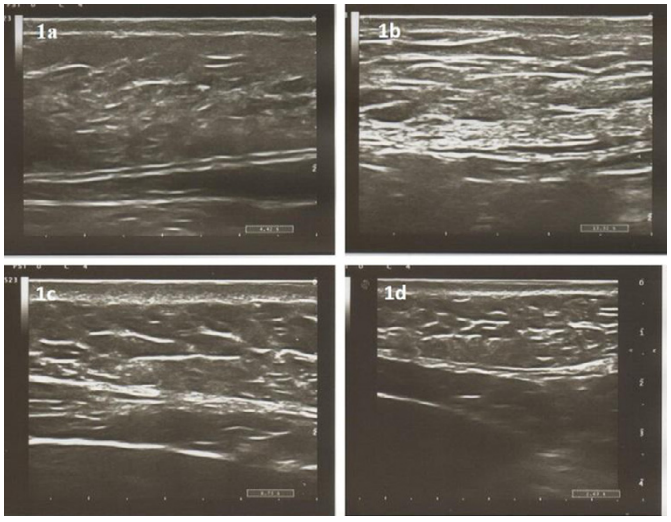
AB0617 CLINICAL CHARACTERISTICS OF DIABETES MELLITUS PATIENTS WITH AND WITHOUT SCLEREDEMA BUSCHKE SKIN DISORDER

C. Varjú [1], D. Kovács [1], B. Gábris [1], E. Kálmán [2], L. Czirják [1], B. Bódis [3], V. Csonka [1]. *[1]Department of Rheumatology and Immunology; [2]Department of Pathology; [3]1st Department of Internal Medicine, University of Pécs, Pécs, Hungary*

Background: Scleredema adultorum of Buschke is a rare disorder characterized by non-pitting hardening of the skin around the neck, shoulders, occasionally the face and the trunk. The most frequent form of scleredema is associated with diabetes mellitus (DM). The histopathologic features of scleredema are characterized by thickened collagen bundles within the reticular dermis that are separated by mucopolysaccharides (mainly mucin) containing fenestrations.

Objectives: To compare clinical data of patients with Buschke-scleredema-DM to diabetic patients without skin involvement patients (Control-DM) with a focus on the late vascular and neurological complications.

Methods: Clinical data of 105 diabetic patients were investigated based on their medical histories and physical examinations. All subjects met the following inclusion criteria: each of their disease duration time of DM had to be more than three years. Twenty-eight patients with Scleredema-DM were collected (three of type 1 and 25 of type 2 diabetes, 19 female, nine male; their mean age (±SD) was 63.0±9.3 and mean DM-duration time was 17.9±9.6 years). Seventy-seven consecutive, age and DM-duration matched patients without skin involvement were investigated as controls (nine patients with type 1 and 68 with type 2 M, 50 female, 27 male, their mean age was 63.3±11.9 and mean DM-duration time was 17.4±10.7 years). For statistical analysis Pearson's Chi-squared, Fisher and Mann-Whitney U tests were used.



Results: In the medical history of the Scleredema-DM group stroke occurred more frequently (8 of 28 cases, 28.6%) compared to the Control-DM group (5/77, 6.5%, /$p<0.01$/). There were no significant differences in the occurrence of myocardial infarction (5/28, 17.9% vs. 10/77 cases, 13.0%), nephropathy (5/28, 17.9% vs. 10/77 cases, 13.0%), retinopathy (13/28 cases 46.4% vs. 28/77, 36.3%) and of peripheral neuropathy (21/28 patients, 75.0% vs. 49/77, 63.6%) respectively. Higher level of cholesterol and triglycerides was present in the Scleredema-DM group compared to the Control-DM cases (mean cholesterol was: 5.7±1.5 mmol/l vs. 4.6±1.2 mmol/l, /$p<0.01$/; triglyceride: 2.3±1.1 mmol/l vs. 1.84±1.6 mmol/l

/p<0.01/), though there were no significant differences in the mean actual level of hemoglobin A1c in the sera, or comparing the body mass index (BMI) between the two investigated groups.
Cholesterol levels were significantly higher in both Scleredema-DM patients group taking /p<0.01/ or not taking /p<0.05/ statins compared to similar control diabetic patient groups. Concerning the triglyceride, also a higher levels of triglyceride were found in Scleredema-DM patients who were taking statins /p<0.05/, compared Control-DM patients who were also taking statins, but no difference were shown in triglyceride levels between the Scleredema-DM group and the Control-DM group both who were not treated by statins.
Conclusions: Scleredema can be assessed by a simple skin-examination and might be a risk factor for stroke in patients with DM. Patients with scleredema are associated with increased cholesterol and triglyceride levels and a higher incidence of stroke compared to matched DM control population.

AB0618 A UNIQUE ULTRASOUND PATTERN OF ADIPOSE TISSUE IN SYSTEMIC SCLEROSIS PATIENTS: A COMPARISON WITH RHEUMATOID ARTHRITIS PATIENTS AND HEALTHY CONTROLS. TWO SIDES OF ADIPOSE TISSUE INVOLVEMENT IN SYSTEMIC CHRONIC INFLAMMATORY DISEASES

C. Rotondo[1], R. Fanizzi[1], A. Chialà[2], M.G. Anelli[1], G. Righetti[1], M. Nivuori[1], E. Praino[1], L. Dinoia[1], S. Lopriore[1], G. Laselva[1], C. Scioscia[1], F. Cacciapaglia[1], G. Lapadula[1], F. Iannone[1]. [1]*Deto - Rheumatology Unit, Bari University, Bari;* [2]*Internal Medicine Unit, P.O. Valle d'Itria, Martina Franca (TA), Italy*

Background: Systemic sclerosis (SSc) and rheumatoid arthritis (RA) are both chronic and systemic inflammatory diseases, involving connective tissue. The adipose tissue is acknowledged as an immune organ that secretes numerous inflammatory signals and it is supposed playing an important role in up-regulation of inflammatory status. A few data are published on altered white adipose tissue (WFT) distribution in patients (pts) with RA. None data are available about WFT distribution in SSc pts
Objectives: We aimed to characterize the subcutaneous adipose tissue (total (sWFT); superficial (SsWFT); inner (IsWFT)) and visceral adipose tissue (vWTF) thickness, evaluated by ultrasound (US) of abdominal adipose tissue, in SSc pts, with different body mass index classes (BMI), comparing with RA pts and healthy controls (HC).
Methods: 42 SSc pts, 57 RA pts and 12 HC were recruited in this study. WFT measurements were assessed, using US (7.5 MHz probe), along the xiphoumbilican line: sWFT thickness (distance between the inner edge of the skin at the outer edge of the alba line (AL)), SsWFT (lobular upper zone of sWFT), IsWFT (sWFT- SsWFT); vWFT thickness (distance between the inner edge of the AL and the peritoneal line).
Results: No subject enrolled had metabolic syndrome. RA pts had thicker vWFT (15.6±7.6mm) than SSc pts (10.8±5.8mm) or HC (10.1±3.8mm) (p=0.001). In particular, the upper-weigh RA pts had vWFT 88% thicker than upper-weight HC and the RA obese pts had vWFT 87% thicker than obese HC. While, the upper-weight SSc pts had vWFT 22% thicker than upper-weight HC, and the SSc obese pts had vWFT 16% thicker than obese HC. Positive correlations were found between all WFT measures and BMI in RA pts and HC (p≤0,05). In SSc pts we found lack of correlation between SsWFT and BMI (r=0.232; p=0.145). Of note, only in SSc pts we observed different US WFT patterns (fig. 1a, fig. 1b) characterized by rearrangement of normal sWFT structure (HC fig. 1c and RA pts fig. 1d). These structural rearrangements consisted in the absence of adipose lobules, replaced by hypoechoic – anechoic areas (fig.1a) (attributable to edema), or by hyperechoic lines and spots (fig.1b) (attributable to fibrotic replacement of subcutaneous abdominal fat), independently by SSc diffuse or SSc limited skin subset.

Conclusions: In SSc and RA the WFT is abnormal. The WFT in RA seems be altered just for dimension and distribution, in particular the vWFT is overexpressed; it might be due to vWFT hyperactivity induced by inflammatory status. In SSc, the WFT is altered in the structure of sWFT. A direct involvement of sWFT in pathologic mechanism of SSc is supposed. An edema phase and a fibrotic phase of abdominal sWFT can be hypothesized, independently by skin involvement. If these findings will be confirmed by fat histological analysis, the US of WFT might be an important tool for the clinicians to identified the earlier stage and/or the active phase (edema) of SSc, in order to support physicians in the decision making about the treatment management.

AB0619 CONNECTIVE TISSUE DISEASE-ASSOCIATED INTERSTITIAL LUNG DISEASE TREATED WITH CYCLOPHOSPHAMIDE OR RITUXIMAB: A UNICENTRE, OPEN-LABEL AND COMPARATIVE STUDY

C. LóPez-Medina[1], F.J. Godoy-Navarrete[2], P. Peinado-Villén[2], P. Font-Ugalde[1], M.C. Castro-Villegas[1], R. Ortega-Castro[1], J. Calvo-Gutiérrez[1], L. Ladehesa-Pineda[1], L. Bautista-Aguilar[1], A. Escudero-Contreras[1], E. Collantes-Estévez[1]. [1]*Rheumatology, Hospital Universitario Reina Sofía de Córdoba/ Imibic/ Universidad de Córdoba;* [2]*Universidad de Córdoba, Córdoba, Spain*

Background: To date, rheumatologists do not have curative treatments for connective tissue disease-associated interstitial lung disease (CTD-ILD) (1), therefore an stabilization of the disease is considered as a therapeutic success. One of the most frequent drugs used for achieving this goal is Cyclophosphamide (CYC); however, in the last years there has been an increasing interest in the use of Rituximab (RTX) as a treatment for CTD-ILD.
Objectives: To compare long-term effectiveness of CYC vs. RTX as a treatment in patients with CTD-ILD.
Methods: Unicentre and retrospective study in which it was analyzed clinical and image data of 26 CTD-ILD patients treated with CYC or RTX between June 2004 and December 2016.
Previously, we checked that baseline characteristics and baseline levels of Pulmonary Function Tests (PFTs) in both groups were similar by using Fisher and T-student tests.
The primary outcome of the study was the stabilization of PFTs or HRTC (High Resolution Tomography Computed Tomography) considering as relapse: a) a deterioration ≥10% in FVC (Forced Vital Capacity), or b) a decrement ≥15% in DLCO (diffusing capacity of carbon monoxide), or c) a worsening in HRCT. The prognostic effect of each treatment on stabilization was evaluated using the Kaplan-Meier method and Long Rank test.
Subsequently, values of FEV1 (forced expiratory volume in one second), FVC, DLCO and DLCO/VA were compared 12 months after the beginning of the treatment with their corresponding baseline levels in both groups, using paired T-test. Finally, direct comparison between the CYC and the RTX groups was performed at the 12-months time point using T-test.
Results: The study includes 20 women and 6 men with an average age of 58.9±14.2 years. 14 patients had a diagnosis of Systemic Sclerosis whereas 12 had other types of CTD.
From the 26 patients, 15 received CYC and 11 RTX, according to the physician's decision. Both groups presented similar baseline characteristics and levels in PFTs.
The Kaplan-Meier method showed that the treatment had an influence on the stabilization of CTD-ILD, although long Rank test was non-significative. The average of months without relapse in CYC and RTX group was 59.79±9.50 and 79.27±7.81 respectively.
Patients in the CYC group did not present any changes in FEV1, FVC, DLCO and DLCO/VA levels during the first year of treatment. In contrast, patients in RTX group showed an increase of all PFTs levels during the first year of monitoring, although these differences were non-significatives. A direct comparison between both treatment groups after 12 months showed lower levels of all PFTs in CYC vs RTX, been DLCO/VA (67.30±10.69 and 86.25±4.59, respectively) statistically significative.
Conclusions: This study suggests, in patients with ILD-CTD, that CYC treatment stabilizes the lung function, whereas RTX shows a tendency to improve it. Also, patients with RTX treatment shows a larger mean time of stabilization than CYC group. However, large scale randomized controlled trials are needed to confirm these results.

AB0620 ORAL HEALTH IN PATIENTS WITH SYSTEMIC SCLEROSIS: AN EUSTAR CENTER EXPERIENCE

C. Ancuta[1,2], M. Antohe[2], E. Ancuta[3], R. Chirieac[4], C. Iordache[2].
[1]Rheumatology 2, Clinical Rehabilitation Hospital; [2]University of Medicine and Pharmacy Grigore T Popa Iasi; [3]Research Department, Elena Doamna Clinical Hospital; [4]Sanocare Medical and Research Center, IASI, Romania

Background: Although the orofacial manifestations are commonly reported among patients with systemic sclerosis (SSc), only few studies have adequately addressed the issue of oral health-related quality of life (QoL) in such pathobiological settings.
Objectives: The aim was to characterize the oral health status (OHS) of adults with SSc and to compare with the general population.
Methods: A cross-sectional prospective observational study in 37 consecutive SSc in a EUSTAR cohort (EUSTAR 162 center) and 37 gender and age-matched controls without SSc.
A standardized oral exam meaning OHS (periodontal, dental, mucosal and microbial), oral health-related behaviors and oral HRQoL (Oral Health Impact Profile, OHIP) were evaluated in all recruited individuals, while oral manifestations such as size of oral aperture, oral dryness, manual dexterity for oral hygiene and HRQoL only in SSc.
Multivariable regression analysis was done to evaluate association between SSc, oral abnormalities, oral health status and QoL.
Results: Overall, SSc had significantly reduced oral HRQoL compared with controls ($p<0.05$).
We demonstrated lower resting salivary flow rates ($p<0.05$) and pH ($p<0.05$), reduced maximal mouth opening ($p<0.05$), smaller interincisal distance ($p<0.05$) in SSc group as compared to their controls. Moreover, despite comparable oral health-related behaviors (e.g. same level of daily tooth-brushing), the majority of SSc experienced caries ($p<0.05$) and presented with more periodontal disease ($p<0.05$) comprising periodontal pockets (pocket depth PD>3 mm) ($p<0.05$), clinical attachment level (CAL) $\geq$5.5 mm ($p<0.05$).
Finally, SSc was documented as a significant independent predictor of OHIP, missing teeth, periodontal disease, interincisal distances as shown by multivariate regression ($p<0.05$).
Conclusions: SSc patients are at risk to develop impaired oral health and oral HRQoL compared with the general population.

AB0621 DEVELOPMENT OF SYSTEMIC SCLEROSIS IN TRANSGENDERED FEMALES: A CASE SERIES

C. Campochiaro, C. Fonseca, E. Derrett-Smith, V.H. Ong, C.P. Denton. *Centre for Rheumatology and Connective Tissue Diseases, Royal Free Hospital and UCL Division of Medicine, London, United Kingdom*

Background: Scleroderma (SSc) is an autoimmune connective tissue disease with a female preponderance (female to male ratio of 9.7:1) [1]. Sex hormones are thought to play a role in the susceptibility to autoimmune diseases [2].
Objectives: We report 3 cases of SSc in male-to-female transsexuals diagnosed following their male-to-female transition
Methods: Medical records of 3 patients diagnosed with SSc after male-to-female transition were reviewed. Disease features, hormonal therapies and surgical interventions related to gender reassignment were collected.
Results: At our tertiary University Hospital clinical service, 3 male-to-female transsexual patients were diagnosed with SSc following their surgery between May 1997 and October 2016. All 3 patients had started their transition before the onset of the disease and had not been diagnosed with any autoimmune disease before either starting the hormonal therapy required for the transition or before undergoing plastic surgery interventions. The first case was diagnosed with anti-RNA pol III +ve diffuse cutaneous SSc at the age of 35 yearsa year after the first surgical intervention for infected silicone buttock implants and approximately 5 years of hormonal therapy with combination of mestranol and norethisterone (Norinyl-1®). She experienced scleroderma renal crisis 2 years after the diagnosis and severe vascular involvement with frequent and severe digital ulcers (DU), Raynaud's phenomenon (RP), gastroesophageal reflux disease (GERD), pulmonary arterial hypertension and telangiectasiae. She required chronic dialysis and was treated with mycophenolate mofetil (MMF), rapamycin, bosentan and proton-pump inhibitors (PPI). She eventually died 8 years after the diagnosis. The second case was diagnosed at the of 49 years, approximately 6 months following her gender reassignmentand 5 years after having started hormonal therapy initially with conjugated estrogen isolated from pregnant mares (Premarin®) and later with ethinylestradiol and gestodene (Femodene®). She developed ANA –ve, antiCCP antibody and rheumatoid factor positive limited cutaneous SSc/rheumatoid arthritis overlap syndrome and experienced severe DUs, RP, GERD, inflammatory arthritis and pulmonary fibrosis (PF). She was treated with MMF, PPI, calcium-channel blocker (CCB) and low-dose steroid therapy with good response. The third case was diagnosed at the age of 43 years, 2 years after having started triptorelin (Decapeptyl®) and oestradiol valerate. She had not undergone any surgical intervention prior to her diagnosis. She developed anti-PM/Scl +ve limited cutaneous SSc/myositis overlap syndrome and experienced RP, GERD and PF. She has only been treated with PPI and CCB prior to her reconstructive surgery.
Conclusions: Although still debated, the role of sex hormones in triggering autoimmunity has been suggested in animal models and human studies [2]. The development of SSc in our case series supports the notion that altered profile of sex hormones may modulate autoimmunity in genetically susceptible individuals with distinct clinical and laboratory characteristics.

AB0622 RENAL RESISTIVE INDEX (RRI): PROPOSAL FOR AGE-ADJUSTED CUT-OFF VALUES IN SYSTEMIC SCLEROSIS PATIENTS

C. Bruni[1], V. Maestripieri[2], G. Tesei[1], M. Chiostri[3], C. Sambalino[3], S. Guiducci[1], S. Bellando-Randone[1], M. Boddi[3], M. Matucci-Cerinic[1].
[1]Department of Experimental and Clinical Medicine, Division of Rheumatology; [2]Department of Internal Medicine, Division of Medicine for Care Complexity III, University of Florence; [3]Department of Heart and Vessels, Division of Cardiology I, Azienda Ospedaliera Universitaria Careggi, Firenze, Italy

Background: Renal resistive index (RRI) by Doppler ultrasound, reflects changes in both renal vascular and tubular-interstitial compartments and systemic vascular compliance related to physiological (age) and pathological conditions among which hypertension, diabetes mellitus, hyperuricaemia, dyslipidaemia and chronic kidney disease play a major role [1]. Because of the age-related changes in RRI reported in literature [2,3] the use of a 0.70 cut-off to detect renal damage, as proposed [4], was questioned: renal injury in younger decades (<60yrs) may occur also for RRI value <0.70 and be underestimated. In systemic sclerosis (SSc), RRI was previously correlated with disease duration, glomerular filtration rate and nailfold-videocapillaroscopy pattern [5–7], although tested on small samples and not investigating the possible confounding role of age-related RRI values.
Objectives: to describe RRI in a larger scleroderma population and to test both the fixed 0.70 RRI cut-off and age-adjusted cut-offs in reflecting renal and other disease-related organ damage.
Methods: SSc patients attending classified according to ACR/EULAR 2013 criteria were enrolled. Data on renal arteries Doppler ultrasound (RRI), autoantibodies status and biochemical tests for renal function/damage, subset and extent of skin fibrosis, instrumental assessment for internal organ involvement were collected and analysed as appropriate with SPSS vers 20.0. Considering that age-adjusted mean values were higher in the SSc population compared to literature values for the general population, we created SSc-specific age-adjusted pathologic cut-offs dividing our SSc population in quartiles and considering RRI values above the 75th percentile as pathologic (Table 1).
Results: 190 SSc patients (age 56.3±15.0 years, disease duration 6±8,20 men) were eligible for the study. In the SSc population significant positive correlations between RRI and age, as well as significant associations between RRI and above mentioned general population comorbidities [1], were confirmed. When considering absolute value of RRI, the 0.70 pathologic cut-off and age-adjusted cut-offs validated in the general population [1], only renal function, systolic PAP, DLCO and late nailfold scleroderma pattern were associated with RRI (Figure 1). Pathologic RRI identified according to age cut-offs could not detect early renal damage, but was significantly associated with various fibrotic [interstitial lung disease (p=0.015), tendon friction rubs (p=0.032), skin fibrosis vs no skin involvement ($p<0.001$),

Age	Proposed SSc age-adjusted pathologic cutoff
1st quartile, ≤48 years	≥0,68

AB0623 PROGNOSTIC VALUE OF RENAL RESISTIVE INDEX (RRI) IN SYSTEMIC SCLEROSIS: PRELIMINARY DATA FROM A SINGLE CENTRE

C. Bruni[1], V. Maestripieri[2], G. Tesei[1], M. Chiostri[3], C. Sambalino[3], S. Guiducci[1], S. Bellando-Randone[1], M. Boddi[3], M. Matucci-Cerinic[1].
[1]Department of Experimental and Clinical Medicine, Division of Rheumatology; [2]Department of Internal Medicine, Division of Medicine for Care Complexity III, University of Florence; [3]Department of Heart and Vessels, Division of Cardiology I, Azienda Ospedaliera Universitaria Careggi, Firenze, Italy

Background: Renal Resistive Index (RRI- measured with Renal arteries Doppler ultrasound) is a useful technique to evaluate vascular and tubular-interstitial damage in both general and systemic sclerosis (SSc) population, where increased RRI values correlates with longer disease duration [1], lower glomerular filtration rate and more advanced nailfold-videocapillaroscopy pattern [2]. Moreover, higher RRI values were seen in SSc patients with new occurrence of digital ulcers [3].
Objectives: to test the prognostic value of RRI [absolute, ≥0.70 and SSc age-adjusted pathologic value (Table1)] and RRI delta change in predicting general and organ-specific worsening in scleroderma patients.
Methods: SSc patients classified according to ACR/EULAR 2013 criteria were enrolled. Demographics data and renal ultrasound data were collected. Data on clinical worsening had been collected as herewith specified: a) Skin worsening as an increase of mRSS≥5 units, b) Peripheral vascular worsening as the appearance of new digital ulcers or the worsening of nailfold videocapillaroscopy scleroderma pattern, c) Lung worsening as decline of FVC≥15% or FVC<80% with new detection of ILD on chest HRCT or worsening of HRCT-ILD extent, d) Cardiac worsening as new onset of left ventricular failure requiring treatments or new onset of PAH confirmed on RHC or detection of severe ventricular arrhythmias on 24h EKG, e) Renal worsening as a new scleroderma renal crisis or reduction of creatinine clearance ≤30 ml/min. General worsening was recorded in case of death due to SSc or for any of the above organ-specific worsening. Data were analysed as appropriate with SPSS vers. 20.0.
Results: 190 SSc patients (age 56.3±15.0 yrs, 170 women, disease duration 6±8yrs, 65 with a follow up RRI measurement after 2.8±0.9 years) were enrolled. After a mean clinical follow-up of 3.6±2.6 years, 89 (46.8%) pts showed general worsening. Skin, peripheral vascular, cardiac, lung and renal worsening were detected in 14 (7.4%), 40 (21%), 32 (16.8%), 38 (20%) and 11 (5.8%) patients respectively. We registered 10 (5.2%) deaths and 43 (22.6%) patients with multiple organ worsening. Both absolute value of RRI and ≥0.70 RRI cut-off showed no significant association with organ or global clinical worsening, At the opposite, RRI cut-offs adjusted for age were associated with cardiac worsening (p=0.065 =- Figure 1). When in 65 patients the pattern of delta RRI and clinical worsening were analysed (Table 1), wider RRI changes were associated with general worsening (p=0.029) and cardiac worsening (p=0.006). The significance of these associations increased when sub-analyse was repeated focused on patients with normal SSc age-adjusted RRI values at baseline evaluation (p=0.017 and p<0.001 respectively, Figure 1).

Age	Proposed SSc age-adjusted pathologic cutoff
1st quartile, ≤48 years	≥0,68
2nd quartile, 49–58 years	≥0,69
3rd quartile, 59–67 years	≥0,75
4th quartile, ≥68 years	≥0,77

	RRI basal value (190 pts)		RRI>0,70 (85 pts)		SSc age-adjusted pathologic (61 pts)		ΔRRI (available 65 pts)		ΔRRI in baseline SSc age-adjusted normal RRI (45 patients)	
	n (%)	p value	n (%)	p value	n (%)	p value	(n) mean±SD	p value	(n) mean±SD	p value
General Worsening	89 (46,8)	N.S.	37 (43,5)	N.S.	31 (50,8)	N.S.	(33)+0,03±0,05 vs (42) 0,00±0,04	0,029	(24)+0,04±0,04 vs (21) +0,01±0,03	0,017
Cardiac Worsening	32 (16,8)	N.S.	16 (18,8)	N.S.	15 (24,5)	p<0,001	(13)+0,05±0,05 vs (52) +0,01±0,04	p=0,006	(7)+0,08±0,03 vs (38) +0,02±0,04	p<0,001

Conclusions: increase in RRI could be used as a sentinel sign for general and cardiac worsening in SSc patients, especially when age-related RRI variations are taken into account.

AB0624 INTERSTICTIAL LUNG DISEASE IN SCLERODERMA: SEVERITY ASSOCIATED FACTORS. OBJETIVES

D. Sanchez Cano[1], N. Ortego Centeno[2], M.T. Cruces Moreno[1], L. Sáez Comet[3], M. Freire[4], J.A. Todlí Parra[5], M. Rodríguez Caballeira[6], C. Simeón Aznar[7] on behalf of RESCLE. *[1]Internal Medicine; [2]Sistemic Autoimmune Diseases Unit, Hospital Campus de la Salud, GRANADA; [3]Internal Medicine, Hospital Universitario Miguel Servet, Zaragoza; [4]Unidad Trombosis y Vasculitis, Hospital Xeral de Vigo, VIGO; [5]Internal Medicine, Hospital Universitario la Fe, Valencia; [6]Internal Medicine, Hospital Universitari Mútua de Terrassa, Terrassa; [7]Sistemic Autoimmune Diseases Unit, H. Universitari General de la Vall D'hebron., Barcelona, Spain*

Background: Systemic sclerosis (SSc) can virtually affect any organ system (such as lungs, kidneys, gastrointestinal tract, and heart). However, it is the pulmonary manifestations that account for the majority of deaths, especially interstitial lung disease (ILD) and pulmonary arterial hypertension (PAH).
Objectives: Our aim was to assess the differences between severe and mild-to-moderate ILD in SSc.
Methods: A descriptive study was performed, using the available data from the Spanish Scleroderma Study Group (RESCLE). ILD was deemed as serious when forced vital capacity (FVC) was <50%. Patients were classified attending the modified classification criteria proposed by LeRoy and Megdsger.
Results: Fourteen referral centers for SSc participated in the registry. By April 2014, 1374 patients with SSc had been enrolled, 541 of whom (39.4%) had ILD, which was severe in 72 of them (13.2%). There were no significant differences as far as sex and age at onset is concerned. Patients with diffuse SSc presented with severe ILD more frequently than those with limited SSc (57% vs. 35%, p=0.002), as well as those who had tested positive for ATA (51% vs. 33%, p=0.005). Additionally, prevalence of FVC<50% was higher in patients with myopathy (32% vs. 15%, p=0.002). Mean FVC was 40.2±6.4 in the severe ILD group, whilst it was 80.3±18.9 in the mild-to-moderate one (p<0.001), and mean DLco was 36.7±15.2 and 62.9±34.5, respectively (p<0.001). Likewise, DLco<70% was also more frequent among patients with severe ILD (100% vs. 69%, p<0.001), as well as mean DLco/VA (56.2±24.2 vs. 74.2±42.0, p=0.002). PAPs was equally higher when FVC<50% (42.2±18.2 vs. 35.1±13.4, p=0.034), and so was the frequency of PAPs>40mmHg (66% vs. 29%, p<0.001) and PAH by right heart catheterism (19% vs. 11%, p=0.050). Finally, by means of a multiple logistic regression, both ATA positivity [OR 0.17 (0.05–0.58), p=0.005] and low DLco [0.93 (0.91–0.95), p=0.000] were found to be related with FVC<50%
Conclusions: Patients with ACA positivity and with a limited variant of SSc seem to be at lower risk of severe interstitial lung involvement. Furthermore, the presence of myopathy may contribute to explain the decrease of FVC in SSc patients.

AB0625 AUTOANTIBODY PROFILE IN PATIENTS DIAGNOSED WITH IDIOPATHIC INFLAMMATORY MYOPATHY: MULTICENTER REGISTRY ON INFLAMMATORY MYOSITIS FROM THE RHEUMATOLOGY SOCIETY IN MADRID, SPAIN

D.C. Hernández Flórez[1], L. Valor[1], J. Martinez[1], B. Joven[2], L. Nuno[3], C. Larena[4], I. Llorente[5], C. Barbadillo[6], P. Garcia de la Pena[7], L. Ruiz[8], H. Moruno[9], T. Cobo[10], R. Almodovar[11], L. Lojo[12], M. Garcia[13], F. Lopez-Longo[1]. *[1]H. Gregorio Maranon; [2]H.12 de Octubre; [3]H.La Paz; [4]H.Ramon y cajal; [5]H.La Princesa; [6]H.Puerta de Hierro; [7]H.Norte Sanchinarro; [8]H.Nino Jesus; [9]H.Principe de Asturias, Madrid; [10]H.Infanta Sofia, Asturias; [11]H.F.Alcorcon; [12]H.Infanta Leonor; [13]InMusc, Madrid, Spain*

Background: Inflammatory myopathies (IIM) are a heterogeneous group of autoimmune rheumatic diseases characterized by muscle inflammation and progressive weakness. They include any kind of primary inflammatory muscle disease that is not otherwise better explained by metabolic, toxic, infectious, neurologic or inherited causes. The presence of autoantibodies (AA) in IIM is variable and they can recognize nuclear and cytoplasmic cellular components.
Objectives: To evaluate the AA profile in patients diagnosed with IIM.
Methods: We evaluated 479 patients that included 12 hospitals belonging to the IIM registry of the Rheumatology Society in Madrid (SORCOM-REMICAM) with diagnosis from January 1980 to December 2014. All patients were diagnosed of IIM according to Bohan and Peter criteria. The AAs evaluated were ANA (n=476), anti-Jo1 (n=457), anti-RNP (n=427), anti-MI2 (n=159) and ACA (n=293), according to the standard techniques in the respective laboratories. The presence of ANA was considered valid with at least two positive determinations. The AAs were compared according to the classification I) as dermatomyositis (primary

and secondary dermatomiositis) (DM) and polymyositis (PM) including the rest of the patients. Also, IIM were classified (II) as primary polimiositis (PPM), primary dermatomyositis (PDM), overlap syndrome (OSd), juvenile myopathies (JM), cancer-associated myopathies (CAM), autoimmune necrotizing myopathy and inclusion body myositis (these were grouped as other myositis; OM).
Results: In the PM and DM groups 250 and 229 (52.2% and 47.8%) patients were included respectively. Positive ANA, anti-Jo1 and anti-RNP were higher in the PM than in the DM group (67, 22 and 19% vs. 56, 11 and 6%) (p=0.21, p=0.002, p=0.0001, respectively). The presence of anti-MI2 was higher in the DM group (p=0.024), according to the classification II, we found statistically significant differences in ANA, anti-Jo1, anti-RNP and anti-ACA. The OSd group had the highest proportion of ANA, anti-RNP and ACA positive AA and the JM group had the lowest frequency of Anti-Jo1 (see Table 1).

Table 1. Autoantibodies profile in IIM according to classification II

AA	Comparison between groups		Frequency	P
ANA	OSd vs.	PPM	91% vs. 54%	0,0001
		PDM	91% vs. 63%	
		JM	91% vs. 40%	
		CAM	91% vs. 63%	
	PDM vs.	JM	63% vs. 54%	
Anti-Jo1	JM vs.	PPM	3% vs. 25%	0,0001
		PDM	3% vs. 19%	
		OM	3% vs. 36%	
Anti-RNP	OSd vs.	PPM	40% vs. 6%	0,0001
		PDM	40% vs. 3%	
		JM	40% vs. 7%	
		CAM	40% vs. 5%	
ACA	OSd vs.	PDM	18% vs. 3%	0,002

Conclusions: The AA associated with the IIM subtypes is consistent with published scientific evidence on other cohorts for ANA, anti-Jo1, anti-RNP and anti-MI2, in spite of the small sample size. The OSd group showed higher ANA and anti-RNP frequencies which might be explained by the coexistence of SLE and MCTD patients. It could be interesting to follow up those PPM patients with positive AA because they could be in the future diagnosed with a connective tissue disease. Carrying out longitudinal studies that include a greater proportion of patients may help to evaluate and predict the clinical course of IIM.

AB0626 EPITOPE PROFILING OF ANTI-RO52 ANTIBODIES IN PATIENTS WITH SYSTEMIC SCLEROSIS, SYSTEMIC SCLEROSIS-ASSOCIATED PRIMARY BILIARY CIRRHOSIS, AND PRIMARY BILIARY CIRRHOSIS ALONE

C. Liaskos[1], A. Gkoutzourelas[1], T. Simopoulou[1], E. Marou[1], T. Scheper[2], W. Meyer[2], L. Sakkas[1], D.P. Bogdanos[1]. [1]*Rheumatology and Clinical Immunology, University of Thessaly, School of Health Sciences, Larisa, Thessaly, Greece;* [2]*Institute of Immunology, Euroimmun AG, Lubeck, Germany*

Background: Anti-Ro52 antibodies are detected in patients with Sjogren's syndrome (SjS), systemic sclerosis (SSc) and other autoimmune rheumatic diseases. Epitope mapping studies of anti-Ro52 in autoimmune rheumatic diseases have failed to find any difference on epitope recognition suggesting a common stimulus for the loss of tolerance to Ro52. Such epitope differences, however, were noted between SjS and non-rheumatic diseases and in particular, SjS-associated primary biliary cirrhosis (SjS-PBC) or PBC alone (1).
Objectives: To assess whether or not the Ro52 epitope profile in anti-Ro52+ SSc patients differs from that of SSc-associated PBC (SSc-PBC) or PBC.
Methods: Serum samples were obtained from 63 anti-Ro52-positive (by ELISA) patients (33 SSc, 10 SSc-PBC, 20 PBC alone). Antibody reactivity to full length recombinant Ro52 and 5 baculovirus expressed Ro52 fragments spanning the whole sequence [Ro52–1 (aa 1–129), Ro52–2 (aa 125–268), Ro52–3 (aa 269–475), Ro52–4 (aa 57–180, partly overlapping with Ro52–1 and Ro52–2), and Ro52–5 (aa 181–320, partly overlapping with Ro52–2 and Ro52–3)] were tested by a line immunoassay.
Results: Reactivity was present to: full length Ro52 in all anti-Ro52 positive SSc, PBC-SSc, or PBC patients by line immunoassay; Ro52–1 in 6/33 (18.2%) SSc, 3/10 (30%) SSc-PBC, and 3/20 (15%) PBC; Ro52–2 in 33/33 (100%) SSc, 10/10 (100%) SSc-PBC and 20/20 (100%) PBC; Ro52–3 in 0/33 (0%) SSc, 0/10 (0%) SSc-PBC and 0/20 (0%) PBC; Ro52–4 in 4/33 (12.1%) SSc, 2/10 (20%) SSc-PBC, and 4/20 (20%) PBC and Ro52–5 in 11/33 (33.3%) SSc 4/10 (40%) SSc-PBC, and 9/20 (45%) PBC respectively ($p>0.05$ for all epitopes amongst the 3 cohorts). No statistically significant correlation was found.
Conclusions: The major epitope of anti-Ro52 does not differ among SSc, PBC-SSc and PBC and is localized on aa125–268, the major epitopic region of anti-Ro52 antibodies in SjS and other rheumatic diseases. Our epitope mapping data suggest that the mechanisms responsible for the loss of tolerance to Ro52 is common amongst diseases.

AB0627 RISE-SSC: A DOUBLE-BLIND, RANDOMISED STUDY EVALUATING THE EFFICACY AND SAFETY OF RIOCIGUAT FOR THE TREATMENT OF PATIENTS WITH DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS

D. Khanna[1], Y. Allanore[2], C. Denton[3], M. Matucci-Cerinic[4], J. Pope[5], Z. Yao[6], J. Curram[7], J. de Oliveira Pena[8], O. Distler[9]. [1]*University of Michigan, Ann Arbor, United States;* [2]*Paris Descartes University, Paris, France;* [3]*University College London, London, United Kingdom;* [4]*University of Florence, Florence, Italy;* [5]*University of Western Ontario, Ontario, Canada;* [6]*Bayer AG, Beijing, China;* [7]*Bayer plc, Newbury, United Kingdom;* [8]*Bayer AG, Whippany, New Jersey, United States;* [9]*University Hospital of Zürich, Zürich, Switzerland*

Background: Diffuse cutaneous systemic sclerosis (dcSSc) is a severe subtype of SSc, a rare, chronic autoimmune connective tissue disease associated with significant morbidity and mortality, and with reduced quality of life. Currently, there are no approved disease-modifying therapies to treat the vascular and fibrotic damage in patients with dcSSc. Soluble guanylate cyclase stimulators, such as riociguat, target the transforming growth factor beta pathway, inhibiting signalling through non-SMAD pathways. They have been shown to inhibit dermal fibrosis in several animal models and to ameliorate fibrosis of the skin and intestine in bleomycin-induced fibrosis and experimental chronic graft-versus-host disease.[1] These preclinical data suggest that riociguat has vascular and antifibrotic properties that may be beneficial in dcSSc, potentially delaying disease progression.
Objectives: RISE-SSc (NCT02283762) is an international, multicentre, randomised, double-blind, placebo-controlled, parallel-group, Phase II study to assess the efficacy and safety of treatment with riociguat versus placebo in patients with dcSSc. The primary efficacy endpoint is change in modified Rodnan skin score (mRSS) from baseline to Week 52.
Methods: Eligibility criteria include a disease duration of ≤18 months and mRSS of 10–22, parameters identified to be predictors of progression of skin fibrosis.[2] Patients were randomised (1:1) to treatment with riociguat (adjusted up to 2.5 mg tid over the first 10 weeks) or placebo for a total of 52 weeks. The double-blind phase will be followed by an open-label extension phase for up to 6 years where all patients receive riociguat.
Results: Study recruitment was completed on 30 Dec 2016 and 121 patients have been randomised. Mean±SD age at inclusion was 50.7±12.3 years (range 18–79) and 76% (n=92) were female. At baseline the mean±SD mRSS was 16.8±3.7 (range 10–22) and disease duration was 8.8±5.5 months (range 0.5–18.5). Almost 70% of the patients tested positive for either anti-SCL-70 (43%) or anti-RNA polymerase III (25%) antibodies, while 32% of patients tested negative for these two antibodies. Swollen and tender joint counts were present in 38 (31.4%) and 51 (42.1%) patients, respectively, while 35 patients (28.9%) had tendon friction rubs. Digital ulcers were present in 15 patients (12.4%) at baseline.
Conclusions: RISE-SSc has a unique trial design with a cohort enriched for disease progressors,[2] which is reflected in the baseline characteristics of the randomised patients. Results of the RISE-SSc study will provide data to inform not only the efficacy, safety and tolerability of riociguat treatment in patients with dcSSc, but also the feasibility of a new trial design based on cohort enrichment.

AB0628 MACROVASCULAR DYSFUNCTION OF UPPER AND LOWER LIMBS CORRELATES WITH DIGITAL ULCERATIONS IN PATIENTS WITH SYSTEMIC SCLEROSIS

E. Moradkhan[1], S. AleSaeidi[2], F. Gharibdoost[3]. *[1]Shahid Beheshti University of Medical Siences; [2]Rheumatology, Internal medicine, Tehran university of medical sciences, Medical Faculty; [3]Tehran university of medical siences, Tehran, Iran, Islamic Republic Of*

Background: Systemic sclerosis (SSc) is a chronic connective tissue disorder of unknown etiology characterized by tissue fibrosis and vascular damage [1]. Digital ulcerations (DUs) are common manifestations of vascular involvement [2]. Althoughthe vascular dysfunction of SSc has been considered mainly to affect microvasculature [3], there is recent evidence showing that SSc is associated with the prevalence of large vessel disease [4]. However, only a few studies investigated the relationship between macrovascular disease and its role in the clinical manifestations of SSc such as ulcers.
Objectives: To assess the relationship between the Macrovascular dysfunction of upper and lower limbs with digital ulcerations in patients with systemic sclerosis.
Methods: Ninety patients with SSc (45 cases with DUs and 45 cases without DUs) enrolled in this study. Patients with other rheumatologic diseases and diabetics patients were excluded from the study. Data which were collected from the patients, included, age, past medical history of cardiovascular disease and dyslipidemia, SSc disease duration, type of SSc (lcSSc or dcSSc), Raynaud's phenomenon (RP), RP duration and digital ulcerations (DUs), Body weight (BW), Height, Waist circumference (WC), Body mass index (BMI), Blood pressure (BP), serum levels of SCL-70 antibody and Anti β2 microglobulin antibody. Then Doppler sonographies were performed. The outcome variables were the peak systolic velocity (PSV) and resistance index (RI) of ulnar, radial, popliteal, dorsalis pedis and tibia artery.
Results: The SSc patients with DUs have significantly lower PSV and higher RI in the ulnar (PSV:52.1±7.9 vs 55.7±4.1, p=0.006 and RI: 0.58±0.15 vs 0.52±0.06, p=0.003), dorsalis pedis (PSV: 33.9±1.9 vs 34.5±0.4, p=0.027 and RI: 0.54±0.11 vs 0.50±0.04, p=0.045) and tibial artery (PSV: 32.6±3.1 vs 34.4±0.9, p<0.001 and RI: 0.62±0.16 vs 0.51±0.07, p<0.001) in comparison to SSc patients without DUs. PSV and RI of ulnar artery were significantly correlated with age (p=0.012 and p=0.019), disease duration (p=0.001and p=0.001) and Raynaud's phenomenon (RP) duration (p=0.048 and p=0.028). PSV and RI of tibial artery had significant correlation with age (p=0.038 and p=0.009), systolic blood pressure (p=0.022 and p=0.037) and diastolic blood pressure (p=0.015 and p=0.010).
Conclusions: We concluded that digital ulceration in patients with SSc might be frequently related to the macrovascular dysfunction in below the elbow and knee.

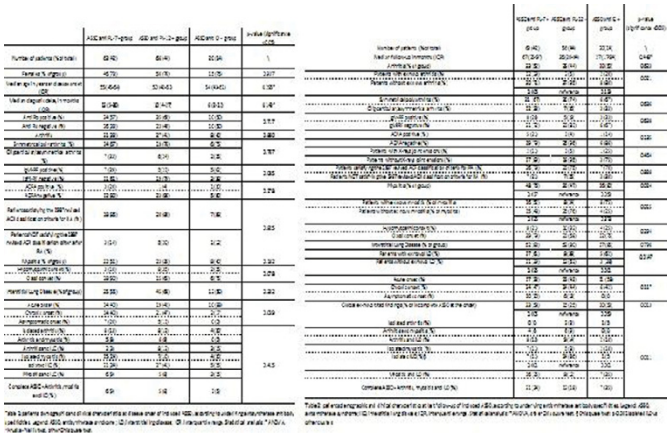
AB0629 FROM LOCALIZED SCLERODERMA TO SYSTEMIC SCLEROSIS: A POSSIBLE EVOLUTION

E. Cocchiara, C. Esposito, V. Raimondo, A. Spinella, F. Lumetti, M. Colaci, D. Giuggioli, C. Ferri on behalf of Rheumatology Unit, University of Modena and Reggio Emilia, Modena, Italy. *Ospedale Policlinico di Modena, Modena, Italy*



Background: Systemic Sclerosis (SSc) is a connective tissue disease characterized by skin fibrosis and visceral organ involvement. Localized Scleroderma (LoS), also known as morphea, is a fibrosing condition limited to the skin, subcutaneous tissue, underlying bone, and rarely central nervous system if present on face and head. SSc and LoS may share some aspects, such as histopathological findings, presence of autoantibodies and systemic symptoms, especially Raynaud phenomenon (RP). In this perspective they may represent two ends of a spectrum of disease.
Objectives: The aim of our study is to evaluate the evolution from LoS to SSc in our case series of SSc patients.
Methods: We retrospectively investigated 330 patients fulfilling the SSc-ACR/EULAR criteria referred to our University-based Rheumatology Unit. The occurrence of LoS preceding the SSc diagnosis was evaluated for each patient on the basis of medical records; clinical, laboratory, and instrumental features were analyzed, from the presenting symptoms at the disease onset to the first visit and during the follow-up, with particular attention to very early cutaneous manifestations.
Results: Five SSc patients (1.5% of our SSc series) had a clinical history of LoS prior to SSc diagnosis. All were women with mean age at time of LoS onset of 39±16.1SD years and time interval between LoS and SSc diagnosis of 19.2±16SD months. Skin biopsy was performed in 4/5 patients showing nonspecific inflammatory infiltrate, collagen fiber deposition and dermis sclerosis. In all patients RP was the first extra-dermal symptom, preceding LoS in 2/5 patients. Cutaneous involvement was represented by patches of skin sclerosis localized in limbs, trunk and face; while scleroderma was classified as cutaneous limited SSc in 4/5 patients and sine scleroderma in one. Following the SSc onset 2/5 patients had a history of digital ulcers, 1/5 esophagopathy, 1/5 interstitial lung disease; while capillaroscopy evidenced a SSc pattern in 4/5 patients. ANA were detected in all patients with anti-ENA positivity in 3/5 (1 ACA, 1 anti-Scl70, 1 anti-U1RNP); the presence of autoantibodies was observed in 3/5 individuals before SSc onset. None referred exposure to toxics or cigarettes smoke, while autoimmune thyropathy was the most frequent comorbidity. No local treatments had been employed for LoS but only low dosage of systemic steroids.
Conclusions: LoS and SSc are two distinct clinical entities that may share some clinical features; however, LoS is characterized by the absence of sclerodactyly, RP, digital ulcers, and typical SSc capillaroscopic changes; while possible internal organs involvement is much less frequently observed and the transition to SSc is exceptional and reported in only pediatric population. At our knowledge, this is the first observation of well-documented evolution from LoS to SSc in adult population as shown by updated review of the literature. The presence of RP and ANA positivity observed before the SSc onset can be considered as red flags of LoS evolution towards SSc, as reported in literature in pediatric population. SSc following LoS seems to be characterized by higher prevalence of vasculopatic symptoms compared to fibrotic complications. Finally, a careful clinical and laboratory monitoring of patients with LoS is recommendable to early identify the possible evolution to overt SSc.

Background: Arthritis, myositis and Interstital lung disease (ILD) represent the classic clinical triad of antisynthetase syndrome (ASSD). In anti Jo-1 positive patients, these findings may appear also during the follow-up. Even if a similar cumulative trend has been showed also in non anti Jo-1 positive ASSD, a head to head comparison of clinical spectrum time course in these patients is still lacking
Objectives: To assess the clinical spectrum time course in non anti Jo-1 positive ASSD, according to different underlying non anti Jo-1 specificities
Methods: Clinical, laboratory and instrumental data collection of anti PL-7, PL-12, and EJ positive patients from an international database of ASSD
Results: We identified 63 (42%) anti PL-7, 66 (44%) anti PL-12 and 20 (14%) anti EJ positive patients, reporting their characteristics in table 1 (disease onset) and 2 (last follow-up). At disease onset, no substantial differences were observed. At the end of follow-up, we observed some differences between anti PL-12 and both anti PL-7 and anti-EJ positive patients. In particular, anti PL-12 positive patients presented less frequently ex-novo triad findings and had a reduced prevalence of

myositis. From the clinical point of view, the main pattern of disease presentation was an isolated ILD in all groups at the onset and only in anti-PL12 positive ASSD at last follow-up.

Conclusions: Our study seems to indicate that clinical spectrum time course of anti PL-12 positive ASSD is different from that of anti PL7 and of anti EJ positive ASSD. The clinical pattern associated with these two latter antibodies was very similar. Furthermore, anti PL-12 positive patients seems to have a more stable disease, with a less common occurrence of ex-novo triad findings during the follow-up

AB0631 THE CLINICAL CONSEQUENCES PRESENCE OF ANTI-PM/SCL ANTIBODIES IN SYSTEMIC SCLEROSIS

E. Wielosz, M. Dryglewska, M. Majdan. *Department of Rheumatology and Connective Tissue Diseases, Medical University of Lublin, Lublin, Poland*

Background: Anti-PM/Scl (a-PM/Scl) antibodies are found in different systemic autoimmune disease such as polymyositis, dermatomyositis, systemic sclerosis (SSc), and overlap syndromes. According to literature they are detected in about 2% of patients with SSc, but their presence are more common in SSc with myositis overlap. Features positively associated with the presence of a-PM/Scl antibodies included younger age at disease onset, skeletal muscle involvement, calcinosis, inflammatory arthritis, and overlap disease. On the other hand interstitial lung disease and gastrointestinal symptoms were less frequent in SSc patients with a-PM/Scl.

Objectives: The aim of the study was to assess the clinical consequences presence of a-PM/Scl antibodies in patients with SSc.

Methods: The study was performed in 126 European Caucasian SSc patients (98-female and 28-male) hospitalized consecutively in the Department of Rheumatology and Connective Tissue Diseases. Patients fulfilled the ACR classification criteria of SSc (59 have diffuse cutaneous SSc and 67 limited SSc). The study group were studied according to the presence of a-PM/Scl antibodies applying commercial test – EUROLINE Systemic Sclerosis Profile. Detection and interpretation of results was carried out electronically using the specific program Euroimmun– EUROLINEScan. The subtype of SSc, incidence of internal organ involvement and serological profile were determined in the whole group. Due to the presence of a-PM/Scl antibodies, patients were divided into two groups a-PM/Scl (+) SSc - 22 pts and a-PM/Scl (-) SSc- 104 pts.

Results: a-PM/Scl antibodies were detected in 22/126 patients with SSc (17,5.%) We showed a significant positive association with a-PM/Scl antibodies and myalgia or myosistis (p=0,0379), contractures (p=0,0002) and prevalence of overlap syndrome (p=0,0142). There were no relationship between the presence of a-PM/Scl antibodies and subtypes of SSc, other organ involvement, digital ulcers or calcinosis.

Conclusions: In SSc anti-PM/Scl antibodies are frequently associated with myalgia or myositis, contractures and overlap syndrome.

AB0632 ASSESSMENT OF VEGF AND OTHER CYTOKINES IN THE TEAR OF PATIENTS WITH SYSTEMIC SCLEROSIS

A. Rentka[1], J. Hársfalvi[2], K. Köröskényi[3], G. Szücs[4], Z. Szekanecz[4], P. Szodoray[5], A. Berta[1], Á. Kemény-Beke[1]. *[1]Department of Ophthalmology, University of Debrecen, Faculty of Medicine, Debrecen; [2]Department of Biopsysics and Radiation Biology, Semmelweis University, Budapest; [3]Department of Biochemistry and Molecular Biology; [4]Department of Rheumatology, University of Debrecen, Faculty of Medicine, Debrecen, Hungary; [5]Institute of Immunology, Rikshospitalet, Oslo, Norway*

Background: Systemic sclerosis (SSc) is an autoimmune disease, characterized by widespread small vessel vasculopathy, immune dysregulation with production of autoantibodies, and progressive fibrosis. SSc may be associated with sicca syndrome. Changes in levels of proangiogenic and proinflammatory cytokines had already been determined largely in serum, however, the local inflammatory and cytokine milieu in the tear of SSc patients has not yet been evaluated.

Objectives: We wished to determine VEGF and other cytokine and chemokine levels in tear samples of SSc patients.

Methods: First, forty-three patients (40 female and 3 men, mean (SD) age 61 (48–74) years) with SSc and 27 healthy controls were enrolled in the VEGF study. Basal tear sample collection and tear velocity investigations were carried out followed by an ophthalmological examination. Total protein concentrations and VEGF levels were determined in tear samples. In the multiple cytokine study, unstimulated tear samples were collected from nine patients with SSc and 12 age- and gender-matched healthy controls. The relative levels of 102 different cytokines were determined by a cytokine array, and then absolute levels of four key cytokines were determined by a magnetic bead assay.

Results: In the first study, the mean collected tear fluid volume developed 10.4 L (1.6–31.2) in patients and 15.63 L (3.68–34.5) in control subjects. The mean total protein level was 6.9 g/L (1.8–12.3) and 4.1 g/L (0.1–14.1) in tear samples of SSc patients and controls, respectively. In patients with SSc, the mean VEGF tear concentration was 4.9 pg/L (3.5–8.1) compared to 6.15 pg/L (3.84–12.3) in healthy samples. Multicytokine-array studies revealed shifted cytokine profile characterized by predominance of proinflammatory mediators in the tear samples of SSc patients. Out of the 102 analyzed proteins, nine were significantly increased in tears of patients with SSc. Based on the multiplex bead results, CRP, interferon-inducible protein 10 (IP-10) and monocyte chemoattractant protein-1 (mcp-1) levels were significantly higher in tears of patients with SSc compared to controls.

Conclusions: Impaired angiogenesis has been found by other investigators in SSc. This is reflected by lower VEGF levels in the tear samples of SSc patients compared to controls. The multi-cytokine array study revealed increased production of CRP and two important pro-inflammatory chemokines in the tear of SSc patients. Our current data depict a group of inflammatory mediators, which may play a significant role in ocular pathology of SSc.

AB0633 RITUXIMAB IN SCLERODERMA RELATED INTERSTITIAL LUNG DISEASE: A SINGLE CENTRE EXPERIENCE FROM NORTH INDIA

G. Naidu, S.K. Sharma, V. Dhir, S. Jain. *Internal Medicine, PGIMER, Chandigarh, India*

Background: Pulmonary involvement is one of the major causes of morbidity and mortality in patients with progressive systemic sclerosis (PSS). Clinically significant interstitial lung disease (ILD) is noted in 25% of patients and accounts for 33% of deaths in PSS patients [1, 2]. Cyclophosphamide (CYC) and mycophenolate mofetil (MMF) have been shown to retard progression of ILD [3, 4]. The limited data on rituximab indicate that rituximab might be effective in PSS related ILD [5].

Objectives: To study the efficacy of rituximab in patients with PSS related ILD.

Methods: The clinical details of all patients of PSS related ILD who were treated with rituximab were noted retrospectively from the case files. Forced vital capacity (FVC) value before and 1 year after administration of rituximab were noted. Increase in FVC by 10% from baseline was considered as improvement and fall in FVC by 10% or absolute value less than 40% of predicted was considered as worsening. Patients with FVC ±10% from baseline were considered to have stabilized lung functions.

Results: A total of 11 patients received rituximab between 2013 and 2016. Six (54.5%) patients were females. Median age of the subjects was 44 years (range: 31–75 years). All patients received intravenous CYC at least 1 year before rituximab administration and had either not responded to CYC or worsened after initial response to CYC. All patients received 2 doses of rituximab (1gram each) at 2 weeks interval. Median FVC before rituximab was 57% of predicted. Two patients did not have post rituximab FVC values. Median FVC 1 year after rituximab was 54% predicted. Out of the remaining 9 patients, 2 (22.2%) patients had improvement in FVC, 6 (66.7%) patients had stabilization of FVC and 1 patient worsened. One patient, who had stabilization of FVC with rituximab expired after 2 years of receiving rituximab.

Conclusions: Rituximab was effective in stabilization of lung functions in patients of PSS with ILD who did not have favourable outcome with intravenous CYC.

Efficacy of rituximab in treatment naive PSS related ILD patients needs to be studied.

AB0634 RITUXIMAB IN SYSTEMIC SCLEROSIS-INTERSTITIAL LUNG DISEASE, A CASE SERIES OF 18 PATIENTS

G. Guzelant[1], M. Melikoglu[1], B. Musellim[2], D.D. Yilmaz[2], I. Fresko[1], E. Seyahi[1], G. Hatemi[1], S. Ugurlu[1], V. Hamuryudan[1]. *[1]Cerrahpasa Medical Faculty Department of Internal Medicine Division of Rheumatology; [2]Cerrahpasa Medical Faculty Department of Pulmonology, Istanbul University, Istanbul, Turkey*

Background: Interstitial lung disease (ILD) is a severe complication of systemic sclerosis (SSc). Immunosuppressives such as cyclophosphamide (CYC) and mycophenolate mophetil (MMF) are used in its treatment with no proven efficacy (1). Rituximab (RTX) appears to be an emerging agent according to case series.

Objectives: This retrospective study aims to evaluate the efficacy of RTX on SSc-ILD in a group of patients followed in our center.

Methods: A chart review revealed 18 patients (16 women, 2 men; mean age 50.3±12.1 SD years (range 30–72), mean disease duration 8.3±9.3 SD years) with SSc who have been diagnosed as having ILD (confirmed by high-resolution thorax computed tomography and pulmonary function tests) and have been treated with one or more cycles of RTX. Efficacy was evaluated according to the criteria of the American Thoracic Society: improvement= an increase in FVC≥10% or DLCO≥15%; worsening= a decrease in FVC≥10% or DLCO≥15%; stabilization= changes in FVC less than 10% or DLCO less then 15% (2).

Results:

Table 1 Demographic findings of the patients and their response to RTX treatment

	Group 1 (ILD with short duration and naive to treatment)	Group 2 (ILD with long duration and previous IS therapy)	All patients
Number of patients	4 (22.2%)	14 (77.7%)	18
Sex (F/M)	3/1	13/1	16/2
Mean disease duration	2±0.8 SD years	10.2±9.8 SD years	8.3±9.3 SD years
Follow-up time after initiation of RTX	12.2±6.8 SD months	21±12.4 SD months	19±11.8 SD months
Baseline FVC%	69.2±20.9	65.1±14	
Last FVC%	66.7±13	61.6±19.6	
Baseline DLCO%	57.7±24.1	43.5±12.2	
Last DLCO%	52±18	41.2±21.8	
Outcome: Stable/ Improvement (n)	2	7	9
Worsening (n)	2	5	7
Death	0	1	1
Unable to do PFT (n)	0	1	1

Four patients were treatment naive for ILD when they received RTX (Group 1). The mean duration between the diagnosis of ILD and RTX treatment in Group 1 was 3.5 months (range 0–14 months). The average RTX cycle in this group was 2 with 1 patient also receiving mycophenolate mophetil in combination with RTX. The mean follow-up time after the initiation of RTX in this group was 12.2±6.8 SD months (range 7–22 months). FVC/DLCO was stable or improved in 2/4 compared to baseline and worsened in 2/4 at the end of follow-up at group 1.

Fourteen patients had a 10.2 years-history of SSc and have been treated with immunosuppressives (cyclophosphamide, azathioprine, methotrexate, MMF) for ILD before RTX (Group 2). The mean duration between the diagnosis of ILD and RTX treatment in Group 2 was 71.2 months (range 5–246 months). These patients received a mean of 3 cycles of RTX with 5 receiving MMF (n=3) or AZA (n=2) in addition to RTX. One patient died after 3 months following the first RTX cycle (unknown reason) and 1 was unsuitable for spirometry because of microstomia. Of the remaining 12 patients in Group 2, improvement or stabilisation was seen in 7 and worsening was seen in the remaining 5 patients.

Conclusions: RTX appears to be modestly effective for ILD of SSc. The duration of ILD as well as the presence or absence of previous immunosuppressive therapy do not appear as playing a role in response.

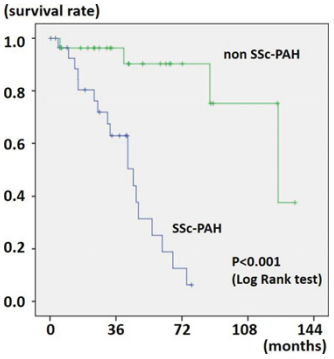
AB0635 THE CLINICAL FEATURES AND PROGNOSIS OF PULMONARY ARTERIAL HYPERTENSION ASSOCIATED WITH SCLERODERMA AND OTHER CONNECTIVE TISSUE DISEASE DURING THE MODERN MEDICAL ERA IN JAPAN



H. Maki[1], M. Hatano[2], S. Minatsuki[1], T. Inaba[1], I. Komuro[1], Y. Asano[3], S. Sato[3]. *[1]Cardiovascular Medicine; [2]Therapeutic Strategy for Heart Failure; [3]Dermatology, The University of Tokyo, Tokyo, Japan*

Background: Due to the recent progress of vasodilators for pulmonary arterial hypertension (PAH), the prognosis of PAH has been getting better for the past 10 years. Among them, idiopathic PAH (IPAH) well improved but PAH associated with connective tissue disease (CTD-PAH) especially scleroderma (SSc-PAH) have poorer prognosis than IPAH.

Objectives: This study intended to clarify the clinical features and prognosis of CTD-PAH in modern era when multiple PAH drugs are available, in addition, compare between SSc-PAH and PAH associated with other CTD-PAH (non SSc-PAH).

Methods: Fifty-seven consecutive CTD-PAH patients were enrolled to this study, who received hemodynamic examination with right heart catheterization between 2004 and 2016. Thirty of 57 patients were SSc-PAH patients and other 27 patients were non SSc-PAH patients (11 mixed connective tissue disease, 8 systemic lupus erythematosus, 5 primary sjogren syndrome, 1 polymyositis, 1 rheumatoid arthritis and 1 Still's disease were included). We retrospectively analyzed the relationship between clinical parameters at baseline and the prognosis of CTD-PAH patients.

Results: Mean age at entry were 65.3±10.3 and 48.3±15.5 years old each other (SSc-PAH vs non SSc-PAH $P<0.001$). Twenty-eight SSc-PAH (93%) and 26 non SSc-PAH patients (96%) took at least one vasodilator, among them, 18 SSc-PAH (60%) and 13 non-SSc-PAH (48%) patients took multiple vasodilators at the end of follow-up period. Comparing the baseline clinical parameters between two groups, vital capacity and diffusing capacity of the lung for carbon monoxide (DLCO) were significantly lower in SSc-PAH patients than non SSc-PAH patients and brain natriuretic peptide and creatinine level were higher in SSc-PAH patients than non SSc-PAH patients ($P<0.05$). However, there were no significant differences in hemodynamic indices between two groups. During a mean follow-up period of 42.5±31.5 months, 22 patients (18 SSc-PAH and 4 non SSc-PAH) died or received lung transplantation. The SSc-PAH patients had worse prognosis than non SSc-PAH patients (figure: $P<0.001$). Only 6 of 18 SSc-PAH patients and 1 of 4 non SSc-PAH patient died of PH related cardiovascular event and other principal causes of death included interstitial lung disease (ILD), neoplasm and infection. Applying multivariate Cox-proportional hazard regression, mean pulmonary arterial pressure, right atrial pressure, creatinine level and %DLCO were extracted as the independent risk for all-cause mortality.

Conclusions: SSc-PAH patients had poor prognosis among CTD-PAH patients despite the progression of PAH drugs. As well as the report from REVEAL registry, not only PAH severity but also respiratory dysfunction may predict the prognosis of CTD-PAH patient. Scleroderma is multiorgan disease affected by complex pathology of vasoconstriction (ischemia), proliferation, inflammation, autoimmune disorder and fibrosis. Our data suggest that vasodilator alone is not enough to improve the prognosis of CTD-PAH patients. Comprehensive therapeutic strategy for scleroderma is needed.

AB0636 A COMPARISON STUDY OF PREVALENCE OF TRADITIONAL CARDIOVASCULAR RISK FACTORS AND FRAMINGHAM RISK SCORE IN SYSTEMIC SCLEROSIS PATIENTS AND MATCHED CONTROLS

J. Sousa-Neves, M. Cerqueira, D. Santos-Faria, J. Leite Silva, C. Afonso, F. Teixeira. *Rheumatology, Hospital Conde de Bertiandos, ULSAM, Ponte de Lima, Portugal*

Background: In Systemic Sclerosis (SSc), data on prevalence of traditional cardiovascular (CV) disease risk factors is scarce and conflicting (1). Therefore, SSc patients CV risk attributed to traditional CV risk factors remains an issue of debate.
Objectives: To evaluate if patients with SSc have a higher prevalence of traditional CV disease risk factors and a higher risk of long-term CV events based on the risk prediction tool of the Framingham risk score (FRS) in comparison with age, race and sex matched control subjects.
Methods: The study comprised patients diagnosed with SSc, fulfilling both the 1980 ACR and the 2013 ACR/EULAR criteria for the disease, and followed-up at our Rheumatology Department and a group of age, race and sex-matched controls. Inclusion criteria were age 30 to 74 and no history of CV events in order to calculate FRS. In total, 46 out of 62 patients were eligible for the study. Traditional CV disease risk factors (diabetes, arterial hypertension and smoking) were compared among the 46 patients with SSc and 51 matched controls. Systolic blood pressure (SBP) values and total and high-density lipoprotein (HDL) cholesterol levels were also collected. The 10-year risk for CV events according to FRS was calculated and means of patients and controls were compared. Subjects' distribution into 3 categories of risk – low (<10% risk), medium (10–20% risk) and high (>20% risk) was also compared. Parametric and nonparametric tests were used for comparison between groups. P value <0.05 was defined as statistically significant.
Results: Mean risk for CV events in 10-years assessed by FRS was 10.00%±8.61 for SSc patients and 7.76%±8.30 for matched controls. Differences were not statistically significant (p=0.196). Additionally, prevalence of diabetes, arterial hypertension and smoking did not differ significantly between the two groups (p=0.890, p=0.443, p=0.651, respectively). Total and HDL cholesterol levels were also similar between groups (p=0.963 and p=0.506, respectively). Only SBP values (mmHg) of SSc patients were significantly higher (128.50 mmHg [113.5 to 139.3]) (median [interquartile range]) compared with controls (120.00 [110 to 130]), p=0.031. Subjects' distribution into the 3 groups of risk defined was similar for both groups (p=0.205).
Conclusions: In our study, prevalence of traditional CV disease risk factors and 10-year risk for CV events based on FRS assessment tool did not differ significantly between SSc patients and age, sex and race matched controls.

AB0637 SUBCLINICAL ATHEROMATOSIS AND VITAMIN D DEFICIENCY IN PATIENTS WITH SCLERODERMA

J.J. Gonzalez Martin[1], O. Carrion[2], A. Abdelkader[2], E. Calvo[1], F. Aramburu[1], F. Sainz[2], P. García de la Peña[1]. *[1]Rheumatology; [2]Angiology and Vascular Surgery, Hospital Universitario HM Sanchinarro, Madrid, Spain*

Objectives:
To study whether patients with systemic sclerosis (SSc) have an increased cardiovascular risk (CVR), measured on the basis of analytical, angiodinamic and/or vascular lesions on carotid ultrasound.
The carotid IMT is a marker of cardiovascular morbidity and mortality, allowing measurement and monitoring of atherosclerosis in asymptomatic individuals, being surrogate markers of future coronary disease, stroke and general death in the general population and in inflammatory rheumatologic diseases.
Methods: Epidemiological and analytical data were collected, including the determination of the RCV SCORE index.
Vascular ultrasound protocol included assessment of carotid intima-media thickness (IMT), presence of atheromatous plaques, and exploration of peripheral arteriopathy using the ankle arm index (ABI).
Results: Seventy adult patients with ES diagnosis (ACR-EULAT 2013 criteria) were included.
94% of the women had a mean age of 50.2±12.5 years, and an average evolution time of 3.0±4.4 years.
The distribution by subgroups was: limited SSc (48%), diffuse SSc (34%), pre-SSc (4'2%), sine SSc (2.8%), MCTD (5'7%) and overlap syndrome 4'2%). The mean SSRm was 9.3±7.0 (range 0–42).
The ANA were positive in 91.4%, ACA (51.4%), ATA (10%), RNA polymerase (4'2%).
4% were DM, 7% were obese, 11% were active smokers, 13% were HTN, and 28% were ex-smokers.
28% had hypercholesterolemia with a mean total cholesterol of 192.5 (SD ± 31.9) and LDL of 102.4 (SD ± 29.4 mg/dL).
57% received vasodilators, most of them ARA-II. 10% bosentan, 4.2% sildenafil, and a 2.8% combination therapy.
The percentage of immunosuppressive drugs was corticoid (50%), MTX (34%), mycophenolate (3%), AZA (11%), HCQ (14%), CP %).
The IMT presented pathological values (>0.9 mm) in 39% of the sample, 23% had atheroma plaques (being bilateral in 40%). Subclinical atheromatosis affected 41.4% (patients without cardiovascular events, pathological IMT and/or atheroma plaques). The ABI had pathological values (<0.9) in 17% of the patients.
In the bivariate analysis, the pathological GIM was related to the presence of ACA antibodies (OR =3.80, 95% CI: 1.15–12.52, p=0.028) and with the SCORE index of CVR (OR =2.93, 95% CI: 1.12–7, 64, p=0.028); And the presence of atherosclerotic plaques was associated with increased SSRm score (OR 1.09, 95% CI 1.00–1.19, p=0.046), and the highest CVR SCORE index (OR 3.90, 95% CI: 1.31–11.56, p=0.014.
In the multivariate analysis, the serum vitamin D concentration showed a protective effect on IMT (OR =0.94, 95% CI 0.89–0.99, p value =0.025); And the main determinant of atheromatous plaques is the SCORE index, since the increase of one unit in SCORE index multiplies by 4 the probability of presenting plaques (OR =4.06, 95% CI: 1.31–12.60; P=0.015), once the effect of SSRm was controlled.
Conclusions:
- 40% of the patients had pathological IMT values, showing association with the presence of positive AAC and the SCORE risk index.
- The serum concentration of 25-OH-vitamin D showed a protective effect on IMT. Sixty percent of the sample had vitamin D deficiency.
- The presence of atheromatous plaques (23% of patients) was associated with higher SSRm indexes and SCORE cardiovascular risk.

AB0638 CARDIAC TRANSPLANT IN SYSTEMIC SCLEROSIS-ASSOCIATED CARDIOMYOPATHY: MONOCENTRIC EXPERIENCE OF 3 CASES

J. Lenaerts[1], J. Lenaerts[2], R. Westhovens[2], W. Droogne[3], A. Ciarka[3], J. Van Cleemput[3], E. De Langhe[2]. *[1]Internal Medicine; [2]Rheumatology; [3]Cardiology, UZ Leuven, Leuven, Belgium*

Background: Cardiac involvement in systemic sclerosis (SSc) is a frequent complication, but end-stage cardiac failure remains uncommon and represents a poor prognosis. Heart-lung and lung transplant is an established treatment option for SSc-related pulmonary disease. Due to the limited published data, no recommendations exist for cardiac transplant in the context of SSc.
Objectives: We present our monocentric experience of 3 patients with SSc who underwent cardiac transplant for SSc-related end-stage heart disease (multiple hospitalisations due to failure of medical therapy and life-threatening complications).
Results: *Case 1* is a 59-year-old male with limited cutaneous SSc. Antinuclear antibody (ANA) was negative. He had vascular (digital ulcers) and cardiac (heart failure (left ventricular ejection fraction (LVEF) 20%, NYHA class IV)) involvement, without major gastrointestinal or pulmonary involvement (no interstitial lung disease (ILD) or pulmonary arterial hypertension (PAH: assessed by right heart catheterization (RHC))). He underwent a cardiac transplant at the age of 51, after a disease duration of 6 years. Post-transplantation immunosuppressant therapy consists of tacrolimus and mycophenolic acid, initially associated with methylprednisolon, which is the standard immunosuppression protocol at our institution.
Case 2 is a 55-year-old male with limited cutaneous SSc. ANA was positive,

	Case 1	Case 2	Case 3
Sex, age	Male, 59 years	Male, 55 years	Male, 50 years
Type of SSc	Limited	Limited	Diffuse
Disease duration at Tx	6 years	7 years	4 years
ANA	Negative	1/320, speckled, no SSc-specific antibody	Negative
Pre-Tx			
NYHA class	IV	III	III
LVEF	20%	40%	40%
RHC: mPAP in mmHg	26	20	31
RHC: PCWP in mmHg	20	14	28
Post-Tx			
NYHA class	I	I	I
LVEF	60%	55%	60%
RHC: mPAP in mmHg	19	13	21
RHC: PCWP in mmHg	12	8	12

Tx: Transplant; mPAP: Mean pulmonary artery pressure; PCWP: Pulmonary capillary wedge pressure.

1/320, speckled pattern, but no SSc-related autoantibody has been identified. He had gastrointestinal (upper gastrointestinal tract dysmotility), muscular (myositis) and cardiac (heart failure with secondary cardiac cirrhosis (LVEF 40%, NYHA class III)) involvement, without major pulmonary involvement (no ILD or PAH). He underwent a cardiac transplant at the age of 54, after a disease duration of 7 years. Standard immunosuppressants were initiated.

Case 3 is a 50-year-old male with diffuse cutaneous SSc. ANA was negative. He had vascular (digital ulcers), gastrointestinal (upper gastrointestinal tract dysmotility) and cardiac (heart failure with secondary cardiac cirrhosis (LVEF 40%, NYHA class III)) involvement, without major pulmonary involvement (no ILD or PAH). He underwent a cardiac transplant at the age of 49, after a disease duration of 4 years. Standard immunosuppressants were initiated.

At present, 1,5 years (case 2 and 3) and 8 years (case 1) after transplant, the donor hearts are still functioning well. No other SSc-related organ manifestations have occurred.

Conclusions: We present 3 patients with SSc who successfully underwent cardiac transplant for SSc-related end-stage heart disease. None had other major SSc-related organ involvement. This supports the limited published data that cardiac transplant is feasible and can be considered in end-stage SSc-related cardiomyopathy.

AB0639 SUPERIOR TREATMENT RESPONSE OF INTERSTITIAL LUNG DISEASE IN INFLAMMATORY MYOPATHIES COMPARED TO OTHER CONNECTIVE TISSUE DISEASES – A PROSPECTIVE COHORT STUDY

J.J. Maya[1], A. Borja[2], A. Abril[1], I. Mira-Avendaño[2]. [1]*Rheumatology;* [2]*Pulmonary, Mayo Clinic Florida, Jacksonville, United States*

Background: Interstitial Lung Disease (ILD) associated to Connective Tissue Disease (CTD) represent a challenge for clinicians and researchers because of their significant morbidity and mortality. Although the different types of ILD associated to CTD are often studied and managed as one because of their autoimmune background, there are considerable differences in their etiopathogenesis and therefore it can be assumed that there are differences in their response to treatment (1). Even though previous studies have analyzed the impact of immunosupipression in ILD secondary to sclerodema, additional studies are needed in order to determine the response to treatment of the different forms of ILD associated to CTD (2–3).

Objectives: To characterize and analyze the response to treatment of different types of ILD associated to CTD. The primary endpoint is the Functional Vital Capacity (FVC) change at 6 months and 1 year, and secondary endpoints arere the change in Diffusion Capacity of the Lung for Carbon Monoxide and in a 6 Minute Walk Test.

Methods: A prospective cohort study is being carried out where all patients who present to the Mayo Clinic Florida pulmonary clinic, age 18 to 80, with established CTD and diagnosed with ILD, and all patients with ILD who meet the criteria for immunologic mediated process, are being followed for a year in order to evaluate the clinical and functional outcomes to treatment. Patients with moderate to severe Pulmonary Hypertension, and active smokers with bronchiolitis pattern are being excluded. Exploratory analysis were performed on the first group of patients enrolled in the study, continuous variables were described with central tendency measures and the mean absolute difference in adjusted 12-month FVC was analyzed between the different types of CTDs using student's t test.

Results: Thirteen patients with ILD were enrolled in the study's initial phase. Five of the patients had been diagnosed with an Inflammatory Myopathy (IM), 2 with Rheumatoid Arthritis, 1 with an Undifferentiated Connective Tissue Disease, 1 with Churg-Strauss Syndrome, and one with Systemic Sclerosis. One patient was treated with Rituximab only; 2 with Rituximab and a steroid; 3 with Mycophenolate Mofetil (MMF) only; 2 with steroids, MMF, and Rituximab; 1 with a TNF inhibitor and MMF; 1 with MMF and steroids; 1 with Azathioprine and steroids; and 1 received only steroids. IMs were compared to the rest. At 1 year follow-up FVC mean absolute difference for the IMs demonstrated and improvement of 0.43 while the other CTDs had worsen by a mean of 0.04 (p=0.01). There were no statistical differences at 6 months for all outcomes or at 1 year for DLCO and 6MWT.

Conclusions: To our knowledge, this is the first time that a cohort of ILD associated to CTD patients is followed and analyzed after 1 year of treatment. Our results suggest that there is a difference in the response to treatment of ILD depending on the underlying CTD. Specific types of ILD associated to CTD likely benefit from early and aggressive treatment, but longer follow ups and larger studies are needed in order to be able to validate and further understand these pathologies.

AB0640 DOES MIXED CONNECTIVE TISSUE DISEASE WITHOUT ANTI-U1RNP EXIST?

J. Martínez-Barrio[1,2], E. Estrada[3,4], J.G. Ovalles-Bonilla[1], L. Valor[1], D. Hernández-Flórez[1], T. del Río[1], I. Janta[1], J.C. Nieto Gonzalez[1], B. Serrano[1], R. González Benítez[1], C. Sáenz Tenorio[1], L. García-Montoya[1], M. Correyero[1], A. Silva[1], A. López-Cerón[1], C. Gonzalez[1], I. Monteagudo[1], F.J. López-Longo[1]. [1]*Department of Rheumatology, Hospital General Universitario Gregorio Marañón;* [2]*Universidad Complutense de Madrid;* [3]*Facultad de Salud, Universidad Camilo José Cela;* [4]*Facultad de Psicología, Universidad Autónoma de Madrid, Madrid, Spain*

Background: Mixed Connective Tissue Disease (MCTD) is a systemic autoimmune rheumatic disease (SARD) characterized by clinical manifestations of systemic lupus erythematosus (SLE), systemic sclerosis (SSc) and polymyositis (PM) and the presence of anti-U1-RNP antibodies.

Objectives: To determine whether there are patients with symptoms of MCTD in the absence of anti-U1-RNP antibodies.

Methods: This was a monocentric, prospective, observational study of patients with SARD. All patients diagnosed of MCTD according to Kasukawa and/or Alarcón-Segovia's criteria, SLE, SSc, PM, overlap syndromes (simultaneous or sequential criteria of 2 or more SARD), Sjögren's syndrome, Antiphospholipid syndrome, systemic vasculitis and undifferentiated or incomplete SARD (at least one clinical criterion of the classification criteria and a related antibody of any of the SARD) were included in the "Autoimmune Systemic Rheumatic Diseases Registry" of the Hospital General Universitario Gregorio Marañon Rheumatology Department from 1986 to 2012. The registry includes 2406 patients diagnosed with SARD. Patients with rheumatoid arthritis were excluded. Patients with clinical MCTD criteria were divided into seropositive (MCTD, with anti-U1RNP) and seronegative (possible MCTD, without anti-U1RNP). The registry counts with the local Institutional Ethics Board approval.

Results: A total of 692 patients were recruited, 608 women (87.9%). Seventy (70, 10.1%) patients were classified as seropositive and 75 (10.8%) as seronegative by Kasukawa's criteria. Sixty-two (62, 8.9%) patients were classified as seropositive and 54 (7.8%) as seronegative according to Alarcón-Segovia's criteria. There were no significant differences in age at disease onset, age at diagnosis or disease duration ($p>0.05$) between seropositive and seronegative patients. Seropositive patients with Kasukawa's criteria presented more frequently: lymphadenopathy, malar rash, leukopenia, Raynaud's phenomenon, muscle weakness and increase of muscle enzymes (Table 1). By Alarcón-Segovia's criteria, patients who developed myositis were more frequent in the seropositive group (p=0.007, OR 3.25, 95% CI, 1.44–7.32).

Kasukawa criteria	Seropositive MCTD		Seronegative MCTD		*P*	OR	95% CI OR	
	n	%	*N*	%			Inf	Sup
Lymphadenopathy	28	40%	17	23%	0.038	2.275	1.105	4.681
Malar rash	25	36%	8	11%	0.001	4.653	1.928	11.231
Leucopenia	41	59%	17	23%	<0.001	4.824	2.348	9.909
Muscle weakness	32	50%	24	32%	0.042	2.125	1.083	4.171
Increase of muscle enzymes	45	64%	35	47%	0.049	2.057	1.056	4.008

Conclusions: Some patients with SARD manifestations fulfill MCTD clinical criteria, both Kasukawa's and Alarcón-Segovia's, in the absence of anti-U1-RNP antibodies from the onset of the disease and throughout its evolution (seronegative MCTD). The frequency of seronegative MCTD was similar to the frequency of seropositive MCTD. Patients with seropositive MCTD presented more frequently manifestations of SLE (lymphadenopathy, malar rash and leukopenia) when using Kasukawa's criteria and of PM when using both criteria.

AB0641 ARTERIAL STIFFNESS AND CLINICAL ASSOCIATION IN PATIENTS WITH SYSTEMIC SCLEROSIS

K. De La Cruz Rodríguez[1], G. Martínez Bonilla[2], V. González Díaz[2], K. García Osuna[2], J. Reyes Rueda[2], C. Gómez López[2], J. Polanco Cruz[2], A. Bernard Medina[2], E. Cardona[3], A. Macías Chumacera[4], C. Ramos Becerra[4], S. Gutiérrez Ureña[2], S. Cerpa Cruz[2]. [1]*Rheumatology Service;* [2]*Hospital Civil Fray Antonio Alcalde;* [3]*Mechanical Vascular Service;* [4]*CUCS, Guadalajara, Jalisco, Mexico*

Background: Systemic sclerosis is an autoimmune disease characterized by microvascular damage and fibrosis. There are several studies that shown macrovascular damage with arterial stiffness (AS) and the risk of cardiovascular complications. Carotid-femoral pulse wave velocity (CF-PWV) and augmentation index (AIx) are two competent methods to determine AS and predictors of cardiovascular disease. Association between AS and microvascular damage is unknown in systemic sclerosis patients.

Objectives: To determine the frequency of arterial stiffness in patients with systemic sclerosis and its association with clinical manifestations.

Methods: We performed a cross-sectional study; patients with diagnosis of systemic sclerosis according to ACR/EULAR 2013 criteria were included and the control group was selected from a database of mechanical vascular service. AS

was non-invasively assessed by Pulse pen device and AIx was evaluated by tonometry. Statistical analysis was done with SPSS v22 software, we calculated mean and standard deviation, for continuous variables we used Student t test, categorical variables were analyzed by using chi-square or Fisher's exact test. The correlation of AS and clinical variables was assessed with Spearman's correlation.

Results: Forty seven patients were included and compared with 39 healthy subjects; mean age of study group was 48±14. vs control group 47±13.7 (p=0.08) 93% were female. Prevalence of AS was 11% vs 3% p=0.039. AS was more frequent in limited systemic sclerosis sub-group and we found correlation with abnormal capillaroscopy, Rho 0.292 p=0.04.

Conclusions: Arterial stiffness is more prevalent in patients with limited systemic sclerosis and association with abnormal caillaroscopy suggest that both macro and microvascular damage is present in these patients and could explain the presence of early atherosclerosis and increased risk of cardiovascular disease.

AB0642 THICKNESS OF THE INTIMA-MEDIA COMPLEX AND DOPPLER VELOCITY PARAMETERS IN SCLERODERMA PATIENTS

K. Rutka[1], E. Gindzienska-Sieskiewicz[2], R. Milewski[3], S. Sierakowski[2], U. Lebkowska[1]. *[1]Radiology; [2]Rheumatology; [3]Statistics and Medical Informatics, Medical University of Bialystok, Bialystok, Poland*

Background: Systemic sclerosis (Ssc) is a chronic inflammatory autoimmune disease, that involves various tissues and organs, including the cardiovascular system. Ssc patients might suffer from a number of complications – including cardiovascular system diseases. Diagnostic imaging is an important tool in assessment of vascular lesions, and ultrasound (including Doppler ultrasound) is one of the most important examinations, which allow to scan for presence of atherotic lesions, assess the intima-media complex thickness as well as provide measurements of the blood flow parameters.

Objectives: The aim of study was to determine if there is any difference in the intima-media complex thickness as well as in blood flow parameters measured using Doppler ultrasound examination in scleroderma patients and the general population.

Methods: 35 patients, aged 19–75, with diagnosed systemic scleroderma were examined using a Doppler ultrasound examination. Thickness of intima-media complex (IMT) approximately 2 centimeters from the carotid bulb was assessed for both right and left common carotid artery (CCA). The standard parameters of blood flow were measured – including peak systolic velocity (PSV), end diastolic velocity (EDV), as well as resistive index (RI), pulsative index (PI) and standard deviation (SD) was measured in the common carotid arteries, internal carotid arteries (ICA) as well as in the vertebral arteries (VA).

Results: The mean IMT value in CCA was approximately 0.63mm (0.35 – 0.9mm).

The mean, minimal and maximal values measured in CCA equalled respectively: PSV – 68.7 cm/s (22.4–94 cm/s), EDV – 19,7 cm/s (4.7–30.35 cm/s), PI – 1.95 (0.41–2,09) and RI – 0.68 (0.28–0.81). In ICA the measured values were as follows: PSV – 68.4 cm/s (38.65–96.9 cm/s); EDV – 23.6 cm/s (9,05–38.6 cm/s), PI – 1.16 (0.76–1.71) and RI – 0.65 (0.37–0.79); in VA PSV – 46.5 cm/s (26.75–75.35 cm/s); EDV – 12.4 cm/s (6.1–22 cm/s), PI – 1.38 (0.6–2.28) and RI – 0.73 (0.34–1.33).

A positive correlation between the age of examined subjects and the IMT was found (p=0.002; R=0.49). Additionaly, a negative correlation between the IMT and the EDV was found (p=0.008, R=-0.44).

Conclusions: The mean thickness of intima-media complex in the examined group of SSc patients is within the values that were established for a healthy population, however a further investigation, including a control group study will allow to evaluate whether there is no correlation between systemic sclerosis and increased IMT.

A negative correlation between IMT and EDV was shown, which is an interesting finding, and could be confirmed in a control group study and on a larger group of patiens.

AB0643 MALIGNANCY SCREENING IN AUTOIMMUNE MYOSITIS AMONGST AUSTRALIAN RHEUMATOLOGISTS

K. Dutton[1], M. Soden[2]. *[1]Rheumatology, RBWH, Brisbane; [2]Rheumatology, Townsville Hospital, Douglas, Australia*

Background: The association between cancer and autoimmune myositis is well established and has lead to the common practice of malignancy screening in asymptomatic individuals. The international literature advocates widely for cancer screening in autoimmune myositis however no consensus or guideline has been published to set forth a process for screening standardisation (1). Malignancy screening is a complicated topic and recommendations in favour of screening should in principle be based on a judicious assessment of the evidence in terms of the benefits, risks and costs. In inflammatory myositis there is currently insufficient evidence to support any recommendation with respect to cancer screening. In the absence of clinical guideline and quality evidence, our study aimed to establish the current trends in malignancy screening amongst Australian Rheumatologists.

Objectives: To explore the current trends in malignancy screening in autoimmune myositis amongst Australian Rheumatologists using an online questionnaire.

Methods: Research approval was granted by The Townsville Hospital. An invitation email containing the survey weblink was sent twice to 386 Australian Rheumatologists between August 2015 and August 2016. Voluntary participation and anonymity were guaranteed. The questionnaire contained a fixed set of multiple choice questions that requested data on respondent demographics, practice setting and screening preference, practice and concerns. Open entry comment was an option throughout the questionnaire. Fifty-eight Rheumatologists, 1 Immunologist and 1 Paediatric Rheumatologist responded (16% response rate). There were 3 survey dropouts. The data was pooled, coded and analysed using statistical software. All data was included in the analysis.

Results: Most respondents (N=58) were in private (67%) and/or public practice (68%), in practice for >10 years (70%), conducted cancer screening (93%) and were "very" or "somewhat" confident in their screening practice (90%). The majority (72%) performed cancer screening independent of patient characteristics. Determinants that triggered screening (in descending order of popularity) were: tobacco use (N=11), history of cancer (N=10), age >40 (N=7), cancer family history (N=7), age >50 (N=3) and age >60 (N=1). Most respondents indicated preference to order screening tests (in descending order of popularity): mammogram (81%); CT chest & abdomen (78%); myeloma screen (70%); chest x-ray (69%), serum PSA (67%), PAP smear (54%), colonoscope (44%), LDH (41%), pelvic USS (33%), gastroscope (33%), FOBT (33%), tumour markers (28%), CT neck (17%), nuclear bone scan (15%), PET CT (4%) & testicular USS (2%). Respondents (N=57) indicated that cancer screening was problematic due to a lack of clinical practice consensus & guideline (77%), test selection knowledge (37%) and knowledge regarding repeated screening (53%). The potential for harm in conducting screening was identified to be a problem by most respondents (62%).

Conclusions: The practice of malignancy screening in autoimmune myositis amongst Australian Rheumatologists is highly variable. Practice is driven by patient factors and clinician preferences. The cancer screening process is felt on several fronts to have inherent problems. Guideline, consensus and further research is needed in this area to address the challenges and evidence gap.

AB0644 FINGERPRINT ABNORMALITIES IN SYSTEMIC SCLEROSIS: A SINGLE CENTER SURVEY FROM INDIA

K. Chanakya, P.K. Devarasetti, R.V.P. Irlapati, L. Rajasekhar. *Rheumatology, Nizams institute of medical sciences, Hyderabad, India*

Background: Fingerprint [FP] abnormalities are known in patients with Systemic Sclerosis [SSc]. Little has been described about their frequency, systemic associations and social impact in literature.

Objectives: To study the fingerprint abnormalities in Systemic Sclerosis patients

Methods: Raynaud's phenomenon [RP] was taken as the inclusion criteria. Patients with SSc [limited LcSSc and diffuse DcSSc], SSc overlap with other Connective Tissue Diseases [CTDs] and other CTDs with RP were screened for FP abnormalities using a Standardization Testing and Quality Certification (STQC) Directorate certified biometric FP scanner. FP quality assessment was done by recording The National Institute of Standards and Technology [NIST] finger print image quality [NFIQ] scores[1]. NFIQ's 5 levels of quality are intended to be predictive of fingerprint matching. NFIQ=1 indicates high quality samples and NFIQ=5 indicates poor quality samples. Other associated systemic features of

the disease were noted. Also the social difficulties due to fingerprint abnormalities were noted. Healthy controls with no RP were included for comparison.
Results: 40 consecutive patients with RP attending Rheumatology outpatient services of our institute were screened for FP abnormalities. 29 with SSc [20-DcSSc, 9-LcSSc], 8 with overlap syndromes and 1 each of SLE, Undifferentiated Vasculitis and Undifferentiated CTD. It was noted prior to screening that 19 patients experienced some difficulty in the past with biometric recognition of their FPs at various times. On screening with biometric scanner, 15 of 40 [37.5%] had FP abnormalities in the form of non recognition of at least one finger with a median of 2 [range 1–6 fingers]. Of these 15, seven had DcSSc, six had LcSSc and two with overlap syndromes. The mean NFIQ score of these 15 patients was 4.5 [poor] and the mean NFIQ scores in SSc was 3.8. Eleven [27.5%] patients could not get government Identity cards based of FP scanning, four could not avail various government benefit schemes which needed their fingerprints as identity. Sixteen [40%] had history of digital vasculopathy in the form of digital pits, digital ischemia or ulcers. PAH was found in one and eight had Interstitial lung disease. Among the 10 controls all FPs were recognized and the mean NFIQ score was 2.2 indicating a better quality of FPs.
Conclusions: Fingerprint abnormalities occur frequently in patients with systemic sclerosis causing social disabilities in few. The quality of FPs in SSc patients is poor. Raynaud's phenomenon and vasculopathy are frequently associated. Documentation of this abnormality should allow the use of other biometric tools for personal identification.

AB0645 LYMPHOCYTE SUBSETS T, B AND NK CELLS IN SYSTEMIC SCLEROSIS

L. Schneider[1], V. Hax[1], N. Marcondes[1], R.M. Xavier[2], R. Chakr[1].
[1]Rheumatology; [2]Rheumatologi, HCPA, Porto Alegre, Brazil

Background: Systemic sclerosis (SSc) is a rare multisystem disease with underlying immune mechanisms, whose pathogenesis remains unclear. Few previous reports have evaluated lymphocyte subpopulations in SSc and your results are conflicting.
Objectives: The present study aimed to analyze the lymphocyte subsets in SSc patients in comparison to healthy individuals.
Methods: Peripheral blood (PB) samples to analyze lymphocyte subsets were obtained from a non-random convenience sample of 20 SSc patients. Twenty healthy individuals recruited from the blood bank were used as sex and age-matched controls. Blood samples were analyzed by flow cytometry for total T cells, CD4+ and CD8+ T cells subsets, CD19+ B cells and total NK cells. Statistical analyses were performed using the IBM Statistical Package for Social Sciences (SPSS 18.0). Data are expressed as mean ± SD and median and range. Non-parametric Mann–Whitney U test was used for analyses of the flow cytometry. A probability $p<0.05$ was considered statistically significant.
Results: The mean (SD) age of SSc patients was 57.9 (14.2) years, 95% were female and 31.6% presented diffuse cutaneous SSc (dcSSc). Patients presented a lower mean total lymphocyte count compared to healthy controls (23.7% vs. 29.6%, p=0.026) (Table 1.). No statistically significant differences were found in the percentages or the absolute numbers of T, B or NK cells.

		Patients	Controls	p[a]

Conclusions: Our data support previous reports indicating that depletion of lymphocyte in the PB of SSc patients. However, we found no significant difference in relation to lymphocyte subtypes, which differs from the literature data.

AB0646 DETERMINANTS OF QUALITY OF LIFE IN SYSTEMIC SCLEROSIS AND PATIENT'S PERCEPTION OF THEIR ILLNESS

L. Groseanu[1,2], A. Balanescu[1,2], D. Predeteanu[1,2], D. Opris-Belinski[1,2], V. Bojinca[1,2], I. Saulescu[1,2], A. Borangiu[1,2], D. Mazilu[1,2], C. Constantinescu[1,2], F. Berghea[1,2], R. Ionescu[1,2]. *[1]Internal Medicine and Rheumatology, Sf Maria Clinical Hospital; [2]Department 5- Internal Medicine, University of Medicine and Pharmacy Carol Davila, Bucharest, Romania*

Background: Systemic sclerosis (SSc) is a chronic multi-system autoimmune disease associated with disability and reduced quality of life.
Objectives: The purpose of this study was to assess health-related quality of life and disease perception in a group of SSc patients.
Methods: We performed a case-control study on 50 SSc patients from EUSTAR cohort 096. Socio-demographic data, disease characteristics and self-assessment questionnaires: Health assesment questionnaire (HAQ), EuroQol-5D (EQ5D) and the Brief Illness Perception Questionnaire were collected.
Results: The group included 41 females,31 limited SSc subsets.
Medium HAQ value was 0.9 (0.6). Patients with higher Rodnan score (p=0.002), synovitis (p=0.02), late capillaroscopic pattern (p=0.02), muscle weakness (p=0.001), gastrointestinal involvement (p=0.01) and those on immunosuppressants (p=0.02) have a poor life quality.
According to EQ-5D, the quality of life was related to specific organ involvement. 48% of the patients had some mobility problems, 6% were confined to bed; mobility was influenced by lung involvement (p=0.008), digital ulcers (p=0.03) and Medsger score (p=0.01). 48% of the patients had some self-care problems and 8% were not able to wash/dry themselves; self-care was influenced by the Rodnan score (p=0.02), diffuse subset (p=0.02), muscle weakness (p=0.03) and gastrointestinal involvement (p=0.021). 64% of the patients had some problems in performing usual activities and 16% were not able to perform them; the performance was influenced by disease subset (p=0.01), Medsger score (p=0.02), cardiac involvement (p=0.02) and the use of immunosuppressants (p=0.01). 52% of the patients had some and 38% had extreme pain/disconfort; 66% of the patients were moderately and 20% were extremly anxious/depressed. Both were related to digital ulcers (p=0.01, respectively p=0.045)
The illness had a great impact on patients life 7.3 (2.5)/10. The main determinant was pulmonary fibrosis (p=0.04). The patients consider that their disease will continue for quite a long time 8.7 (2.6)/10. Most of the patiens do not feel to have a good control on their disease 6.3 (3.3)/10 and unfortunately they do not think that the treatment is very helpful 7.9 (2.7)/10. The intensity of the symptoms is quite severe 7.5 (2.7)/10,related to digital ulcers (p=0.04) and gastrointestinal involvement (p=0.02). Patients are very concerned about their disease 9.1 (2.3)/10, most of them being emotionally affected 7.6 (2.6).
Conclusions: This study confirms the presence and magnitude of impaired life quality in patients with SSc with impact on mobility, self-care, usual activities. The major determinants were the extend of skin involvement, musculoarticular, gastrointestinal involvement and digital ulcers. Often patients are anxious/depressed, had a high pain intensity and the perception of this illness is pessimistic.

AB0647 DIAGNOSIS OF SYSTEMIC SCLEROSIS – "A TANGLED STORY"

L. Groseanu[1,2], A. Dima[1], T. Gudu[1], A. Balanescu[1,2], D. Predeteanu[1,2], D. Opris-Belinski[1,2], I. Saulescu[1,2], A. Borangiu[1,2], C. Constantinescu[1,2], D. Mazilu[1,2], M.M. Negru[1,2], F. Berghea[1,2], V. Vlad[1], C. Cobilinschi[2], M. Abobului[1,2], R. Ionescu[1,2]. *[1]Internal Medicine and Rheumatology, Sf Maria Clinical Hospital; [2]Department 5 - Internal Medicine, University of Medicine and Pharmacy Carol Davila, Bucharest, Romania*

Background: Proper diagnosis of scleroderma is often long and difficult, since it is such a rare disease, and one which few doctors or patients are familiar with.
Objectives: To establish the interval between the symptoms' onset of systemic sclerosis (SSc) and what type of investigations are performed until the patients reach the final diagnosis of a rheumatologist
Methods: This is a cross-sectional study that included randomly selected patients with a a diagnosis of SSc which were evaluated based on a questionnaire about symptoms at onset, specific consults and investigations. Descriptive statistics were used.
Results: The study group included 47 patients, of which only 5 were males and 17 from rural areas.The medium age was 53 (14.4) years.

First symptom of onset was Raynaud phenomena 91.3% of the cases, followed by skin changes (56.5%), puffy fingers (52,2%), gastrointestinal and musculoarticular symptoms (23.9% each).
The medium duration between the first symptom and a medical consult was 6 (63.5) months. The first medical consult was done by a internal medicine specialist -38.3%, by a rheumatologist-29.8%, a gastroenterologist-12.8%, a dermatologist-8.5%, a nephrologist and a pneumologist-4.2% and neurologist 2.1%
The first suspected diagnosis was SSc in 14 cases, Raynaud syndrome in 8, connective tissue disease in 5, rheumatoid arthritis in 4, cancer, autoimmune hepatitis, idiopathic pulmonary fibrosis each in 2 cases and none in 10 cases.
The medium number of consults until final diagnosis was 3.4 (1.7). The medium duration from the first symptom until the correct diagnosis was 39.2 (74) months.
The first investigations recommended were blood tests in almost all of the patients (95.7%), but only a third of them included specific scleroderma autoantibodies. Capillaroscopy was performed as an initial diagnostic test in only 6 patients (12.8%). The mean interval from disease onset until the patient was referred to the first capillaroscopy was 13.5 (28.8) months, to specific autoantibodies was 40.17 (61.3) month, to echocardiography was 36.38 (54) months, to lung function tests and lung CT – 41.76 (65.8) months.
There were no significant statistical differences between patients coming from rural environment and those coming from urban environment. The only significant statistical difference between diffuse and limited subset was the time the patient was referred to echocardiography (19.8 (47.6) months for the diffuse subset, 66.8 (94.6) months for the limited subset, p=0.04).
The only statistical difference between males and females was related to the interval that capillaroscopy was performed (14 (20.5)months in females, 4.8 (5) months in males, p=0.02).
Conclusions: Scleroderma is a less well-known disease. This lack of awareness contributes to delayed diagnosis and delayed onset of therapy. Often such diagnostic uncertainty and frustration takes a huge toll on the psychological well-being of these patients, who describe their journey to diagnosis as being one of the most difficult part of their illness. One of our missions as rheumatologist is to increase recognition of this disorder.

AB0648 DISEASE-RELATED AUTOANTIBODY PROFILE IN SYSTEMIC SCLEROSIS IN GREECE

C. Liaskos[1], E. Marou[1], T. Simopoulou[1], M. Barmakoudi[1], G. Efthymiou[1], T. Scheper[2], W. Meyer[2], D.P. Bogdanos[1], L. Sakkas[1]. *[1]Rheumatology and Clinical Immunology, University of Thessaly, School of Health Sciences, LARISSA, Greece; [2]Institute of Immunology, Euroimmun AG, Lubeck, Germany*

Background: Autoantibodies (autoAbs) help in diagnosis and predicting clinical phenotypes in systemic sclerosis (SSc).
Objectives: To determine the clinical utility of 13 SSc-related autoAbs in SSc patients in Greece.
Methods: 131 consecutive patients with SSc (111 female, mean age 58.1±14 years; 49 with diffused cutaneous SSc [dcSSc] and 82 with limited cutaneous SSc [lcSSc]) were analyzed by a multiplex line immunoassay (Euroimmun) for autoAbs against 13 SSc-related antigens. Twenty two patients with primary Raynaud phenomenon (RP), and 22 healthy controls were also analyzed
Results: ANA by indirect immunofluorescence was present in 128 (97.7%) patients with SSc. Excluding anti-Ro52, 113 (89.3%) SSc patients were positive for at least one autoAb: anti-Topo I abs in 54 (41.2%), anti-CENPA in 37 (28.2%, all reactive with CENPB), anti-RNA polymerase III (RP11) in 19 (14.5%), anti-RNA polymerase III (RP155) in 13 (9.9%), anti-fibrillarin in 4 (3.1%), anti-Ku in 6 (4.6%), anti-NOR90 in 8 (6.1%), anti-PM/Scl100 in 2 (1.5%), and anti-PM/Scl75 in 4 (3.1%). There was no immunoreactivity for Th/To or PDGFR. Overall, 102 (77.9%) SSc patients had autoAbs against Topo I, CENPA or CENPB, RP11 or RP155. Anti-Topo I abs were strongly associated with dcSSc, interstitial lung disease (ILD) ($p<0.001$), and pulmonary arterial hypertension (PAH) (p=0.019). Anti-CENB abs were associated with lcSSc, and negatively associated with ILD. Anti-RP11 and anti-NOR90 abs were associated with male gender, and anti-NOR90 associated with ILD. In PR individuals and healthy individuals anti-Ro52 immunoreactivity was found in 9.1% and 13.6%, respectively, but no other immunoreactivity was detected.
Conclusions: Anti-Scl70, anti-CENP and anti-RNA pol III are the most prevalent autoAbs in SSc. Anti-Topo I and anti-NOR90 abs are associated with ILD and/or PAH.

AB0649 SYSTEMIC SCLEROSIS IN ARGENTINA: EVALUATION OF A SINGLE CENTER COHORT AND COMPARISON WITH INTERNATIONAL SERIES

M. Garcia Carrasco[1], L.O. Roa Prerez[1,2], R. Gomez[1,2], S. Leal[1,2], F. Paniego[1], N. Perez[1], G.G. Nasswetter[1], D. Diana[1]. *[1]Rheumatology Division; [2]Hospital de Clinicas José de San Martín, Buenos Aires, Argentina*

Background: Systemic sclerosis (SS) is an autoimmune disease with generalized vascular dysfunction and a myriad of clinical and laboratory manifestations. Spreading of thickening of the skin, serological characteristics and the pattern of compromise of the internal organs help to classify them as diffuse scleroderma, localized sclerosis and systemic sinus scleroderma. Reports of Latin American cohorts published to date are scarce.
Objectives: To describe the clinical and serological data for a single center cohort and to compare those with national and international cohorts.
Methods: Descriptive, observational, cross-sectional study. We analyzed our SS database. Patients were evaluated since 01/15 to 05/2016 and fulfilled SS classification criteria (ACR 1980/ACR-EULAR 2013).Patients were classified according to Le Roy criteria in Limited Systemic Sclerosis (lSS), Diffuse Systemic Sclerosis (dSS), Systemic Sclerosis sine scleroderma (SsnS) and pre-systemic sclerosis (pSS). Organic compromise was defined as follows: Gastrointestinal (GI): esophagic dismotility by manometry or esophagitis by endoscopy; Lung: Pulmonary hypertension (PH): PSAP>25 mmHg by right heart catheterization; Intersticial Lung Disease (ILD): compatible HRCT or <70% predicted FVC or<80% predicted DLCO; Heart: Left ventricle dysfunction without PH or arterial hypertension, pericardial effusion; Digital ulcers and pitting scars; History of sclerodermic renal crisis (RSC); calcinosis. Anti-Scl-70 was determined by ELISA and anti-Centromere (ACA) by IIF.
Results: 123 patients were included.74% with lSS,24% dSS and 2% SsnS; age at diagnosis (years): 49.7 (18–79 DS: 12.27) and 48.7 (27–79 DS: 13.01) in lSS and dSS respectively. Raynaud's phenomenon previous to diagnosis (years) 7,7 (0–54 DS: 12.81) in lSS and 4.03 (0–22 DS: 5.5) in dSS. 49.5% lSS were ACA positive vs 17% in dSS as well also 41,4% had Scl-70 positive ($p<0.05$). Lung:58.6% of dSS presented ILD and 3,4% RSC, according to published reports. No statistically significant differences were found about the presence of calcinosis, digital tip ulcers or PH between dSS and lSS. GI: was studied in only 39/123 patients with 84,6% affected among those.

Table 1. Comparison of main variables among different cohorts

	Diffuse				Limited systemic sclerosis					
	US, n		EUSTAR, n		Spain, n		Germany, n		Argentina*, n	
	119	128	2838	4481	243	568	484	674	29	91
Oesophageal dysmotility (%)	67	67	70	66	71	57	69	59	31.5	38.5
ILD (%)	63	37	52	11	70	39	56	21	59	22
PH (%)	2	31	6	ND	14	9	19	15	3.4	3.3
RSC (%)	17	2	4	1	8	1	16	9	3	0
Digital ulcers (%)	ND	ND	20	33	64	39	34	24	10.3	5.5
Calcinosis (%)	23	42	ND	ND	24	20	ND	ND	14	19

*HCJSM.

Conclusions: Our data showed similar results to the local and european cohorts. We found fewer calcinosis and digital tip ulcers in both lSS and dSS than international cohorts. A lower prevalence of PH was reported in lSS respect to other series, and it might be atributed to the method wich it was measured. (right heart catheterism).

AB0650 ANTI-TOPOISOMERASE POSITIVE SYSTEMIC SCLEROSIS PROGNOSIS INFAUST?

M. Boonstra, G.A. Beerends, H.U. Scherer, J.K. de Vries-Bouwstra.
Rheumatology, LUMC, Leiden, Netherlands

Background: Anti-topoisomerase antibodies (ATA) in systemic sclerosis (SSc) have been associated with poorer prognosis including diffuse skin involvement, pulmonary fibrosis, cardiac involvement and increased mortality. However, 30–60% of ATA-positive SSc patients demonstrate only limited skin involvement and some have only mild disease course. In SSc, optimal risk stratification is of utmost importance for tailored clinical management at the patient level.
Objectives: We aimed to determine the prevalence of mild disease among ATA positive patients and to investigate which readily available clinical parameters best identify patients with highest disease severity.
Methods: Clinical baseline data from SSc patients included in the Combined Care In Systemic Sclerosis (CCIS) cohort of the Leiden University Medical Center were extracted. Patients fulfilling ACR 2013 criteria and ATA positive were included. Descriptive statistics were used to summarize sociodemographic, clinical and serological features. Patients with grade 3 or 4 disease on any of the Medsger severity subscales were considered to be severely diseased. We compared presence of diffuse cutaneous involvement, Raynaud's, pitting scars, calcinosis, proximal muscle weakness, >10% weight loss, interstitial lung disease and pro-BNP between the severity groups and corrected for confounding by disease duration (time since non-Raynaud) by stratifying into quartiles.

Results: Of 422 SSc patients in the database, 344 patients had SSc meeting ACR criteria. 89 patients were exclusively ATA-positive, of which n=42 with mild disease and n=47 with severe disease. Patients with severe disease appeared to be younger (mean age 50 vs 55 yr), more often non-caucasian (51 vs 12%), with a longer time since non-Raynaud (median 4 vs 2 yr) and more often diffuse skin involvement (dcSSc;62 vs 41%), calcinosis (6 vs 0%) and weight loss (23 vs 7%). Stratification by disease duration, however revealed there are no real differences between mild en severe disease. Overall 47% of ATA+ patients in our cohort presented with mild SSc. When stratifying patients according to time of non-Raynaud, 55% of ATA+ patients presented with mild disease in the first disease duration quartile (median follow-up 0.5 years, range 0–0.8 years). In the forth disease duration quartile, according non-Raynaud time (median follow-up 12.7 years, range 8.2–44.1) the percentage with mild disease was still 27% (Figure 1).

Figure 1. Medsger scores of ATA patients stratified by duration non-Raynaud

Conclusions: In our cohort, 47% of ATA-positive patients presented with mild systemic sclerosis, which could not be explained by disease duration. This suggests that solely the presence of ATA is of limited clinical relevance. Readily available sociodemographic and clinical parameters including type of skin involvement seem to have only limited value in identifying ATA patients with more severe SSc. More complex serological findings as antibody titers and fine-specifity of ATA should be defined for optimal serological subsetting.

AB0651 THE EFFECT OF CYCLOPHOSPHAMIDE ON PULMONARY FUNCTION AND DEPENDENCE ON DISEASE ACTIVITY OF INTERSTITIAL LUNG DISEASE ASSOCIATED WITH SYSTEMIC SCLEROSIS

M. Vonk[1], W. van den Hombergh[1], H. Knaapen[1], S. Simons[2], J. Fransen[1], F. van den Hoogen[1]. *[1]department of Rheumatology; [2]department of Pulmonology, Radboud University Nijmegen, Nijmegen, Netherlands*

Background: The pathogenesis of interstitial lung disease associated with systemic sclerosis (SSc-ILD) is not completely elucidated, although it is believed that chronic alveolar inflammation leads to increasing fibrosis. Treatment strategies using cyclophosphamide (CYC) have been focusing on the inflammatory pathway of SSc-ILD. We hypothesized that CYC is more effective in patients that are in the early, inflammatory phase.

Objectives: The objectives of this study are to analyze the effects of intravenously CYC pulses (750mg/m^2) on pulmonary function (FVC, DLCO) in SSc-ILD after 12, 24 and 36 months, and whether this effect is dependent on the extent of ILD, the proportion of ground glass compared to fibrosis, SSc disease duration or baseline DLCO <60%.

Methods: Patients with SSc-ILD receiving CYC pulses between 2003 and 2015 were classified by the Goh (2008) criteria in either limited or extensive ILD, using HRCT at baseline independently judged by two raters. Pulmonary function tests were performed at 0, 6, 12, 24 and 36 months. Missing outcome data due to drop-out were replaced by last observation carried forward, except in case of death.

Results: Seventy-five patients were included, 33 with limited ILD, 42 with extensive ILD. There were no baseline differences in age, gender, SSc subtype classification, disease duration or autoantibody status. Mean FVC and DLCO were stable after 12, 24 and 36 months of follow-up (figure 1).

There was no effect in the degree of change in mean FVC and DLCO for the different effect modifiers (table 2): the extent of ILD, proportion of ground glass compared to fibrosis, short SSc disease duration or baseline DLCO <60%.

Conclusions: Mean FVC and DLCO in SSc-related ILD was stable during 36 months of follow-up after cyclophosphamide pulse therapy. The extent of ILD, proportion of ground glass, SSc disease duration and baseline DLCO <60% did not influence the effect of CYC on pulmonary function. CYC did not appeare to be more effective in the early phase of SSc-ILD.

AB0652 EARLY ORGAN INVOLVEMENT, SURVIVAL AND CAUSES OF DEATH IN AN UNSELECTED COHORT OF DUTCH PATIENTS WITH SYSTEMIC SCLEROSIS

M. Vonk, W. van den Hombergh, H. Knaapen, F. van den Hoogen, J. Fransen. *Department of Rheumatology, Radboud University Nijmegen, Nijmegen, Netherlands*

Background: Systemic sclerosis (SSc) patients are at risk for organ involvement and premature death. The occurrence of organ involvement that is reported differs widely between various long term cohort studies; ILD 25–90%, PAH 8–32%, CI 5–30%, and SRC 4–12%. Differences in findings also apply to survival, the 5- and 10-year survival rates between studies vary from 80% to 90% and from 60% to 85% respectively (1–3).

Objectives: To assess the occurrence of organ involvement and death in a large, unselected cohort of Dutch SSc patients at the moment of diagnosis and during 5 years of follow-up, stratified by disease subtype and auto-antibodies.

Methods: Up to 2015, 690 SSc patients were included in the Nijmegen SSc cohort. Occurrence of interstitial lung disease (ILD), pulmonary arterial hypertension (PAH), cardiac involvement (CI), scleroderma renal crisis (SRC) and occurrence of death were determined using survival analysis, stratified by disease subtype (limited cutaneous SSc and diffuse cutaneous SSc) and auto-antibodies (ACA, ATA, anti-RNP).

Results: Organ involvement was already present at SSc diagnosis in 32% of patients. In 25%, organ involvement developed during follow-up, mostly ILD (22%). Significant differences between lcSSc and dcSSc were found in SRC at baseline and ILD, PAH and SRC during follow-up. Between the autoantibody subgroups, the occurrence of ILD, PAH and SRC at baseline and ILD during follow-up differed. There were no differences in survival between subtypes and auto-antibodies. The overall 5-year survival rate was 89%. Patients without organ involvement at SSc diagnosis had a better 5-year survival rate than patients with organ involvement at SSc diagnosis: 95% versus 73% respectively ($p<0.001$). (figure 1)

Conclusions: In many SSc patients, organ involvement is already present at diagnosis or develops in the first 5 years after diagnosis.

Survival is significantly worse in patients who already have involvement at the moment of SSc diagnosis.

AB0653 EFFICACY OF AN INTENSIVE 24-WEEK PHYSIOTHERAPY PROGRAMME IN MYOSITIS PATIENTS - PRELIMINARY DATA FROM A SINGLE-CENTER CONTROLLED STUDY

M. Spiritovic[1,2], S. Oreska[1], H. Storkanova[1], P. Cesak[2], A. Rathouska[1], K. Kubinova[1], M. Klein[1], L. Vernerova[1], O. Ruzickova[1], R. Becvar[1], H. Mann[1], K. Pavelka[1], L. Senolt[1], J. Vencovsky[1], M. Tomcik[1]. *[1]Department of Rheumatology, 1st Medical Faculty, Charles University, Institute of Rheumatology; [2]Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic*

Background: Involvement of musculoskeletal system (inflammatation, atrophy and permanent damage to the muscle) in idiopathic inflammatory myopathies (IIM) leads to impaired function and reduced muscle strength, endurance, aerobic capacity and decreased quality of life. Data on efficacy of non-pharmacologic care in IIM is very limited due to variety in studied interventions/outcomes.

Objectives: To address the limitations of existing studies, and evaluate the effect of a controlled, long-term (24-week intervention, 24-week follow-up), intensive (1h physiotherapy twice weekly, and home-exercise for 1h 5x weekly), tailored physiotherapy program to improve muscle strength, endurance and deep stabilizer system, and quality of life/disability in cohorts with a substantial number of IIM patients.

Methods: All patients fulfilled the Bohan and Peter 1975 diagnostic criteria for dermatomyositis (DM) or polymyositis (PM), had skeletal muscle involvement, and were consecutively recruited from 2014 to 2016 at the Institute of Rheumatology in Prague. Both groups received educational materials and instructions for home exercise at baseline, however, only intervention group underwent the intensive physiotherapy programme. At months 0,3,6,12 all patients were assessed by a physician [physical examination, Myositis intention to treat index (MITAX), Myositis disease activity assessment visual analogue scale (MYOACT), and Myositis damage index (MDI)], and a physiotherapist blinded to intervention [standardized tests evaluating the level of muscle strength [Manual muscle test-8 (MMT-8)], and endurance [Functional index-2 (FI-2)], patients filled out patient reported outcomes (PRO)/questionnaires [HAQ, SF-36, Beck's depression inventory-II

(BDI-II), PROs assessing nutrition and fatigue], body composition was analyzed using densitometry (iDXA Lunar) and bioelectric impedance (BIA2000-M), and patients provided blood for routine laboratory analysis and biobanking. Normality of data was tested and inter-group analysis performed with 2-way ANOVA and intra-group analysis by Friedmann's test with Dunn's post hoc test.
Results: 27 IIM patients (22 female/5 male, 10 DM/12 PM/5 IMNM (immune mediated necrotizing myopathy), median of age 58.0 and disease duration 7.0 years) were recruited into the intervention group (IG) and 27 patients into the control group (CG) (24 female/3 male, 13 DM/12 PM/2 IMNM, median of age 56.5 and disease duration 4.7 years). Compared to observed statistically significant deterioration in CG over the period of months 0–6, we found statistically significant improvement in FI-2, MMT8, HAQ, BDI-II (Table 1). Only numerical improvement in IG compared to numerical deterioration in CG, which has not reached statistical significance, was observed in SF-36 and fatigue PROs.

AB0654 AN ULTRASOUND ASSESSMENT OF THE HAND AND WRIST IN EGYPTIAN PATIENTS WITH SYSTEMIC SCLEROSIS

M. Hassanien, S. Rashad, A. Aljohee. *Rheumatology Department, assuit, Egypt*

Background: Systemic sclerosis (SSc, scleroderma) is a systemic disease characterized by fibrosis, progressive vascular obliteration and the production of autoantibodies.Ultrasound (US) imaging has advantages of simplicity, low cost, noninvasiveness, real-time capability and portability compared with traditional EDX. US imaging also offers high temporal and spatial resolutions, and can potentially provide dynamic anatomical information regarding local structures and kinesiology, few studies evaluate joint and tendons involvement in SSc by US the incidence and abnormality are differs among studies
Objectives: describe and determine possible correlations between US abnormalities of hand and wrist and clinical findings in SSc Egyptian patients
Methods: Randomly selected 50 Egyptian SSc patients were enrolled in the study in outpatient clinic Rheumatology department, Assuit university hospital. Clinical examination and US evaluation (Gray Scale and Power Doppler (PD)) of the tendons and joints of hands and wrists, were performed bilaterally on both dorsal and palmar sides. Joint assessment was performed on all MCP and PIP joints as well as the wrist and tendon assessment included finger flexors and extensors, wrist extensors and flexors. The scoring for synovitis was based on the EULAR/ OMERACT scoring system
Results: Within the cohort, 100% of the patients were female; mean age and range disease duration were 40.93±11.71 (20–61) years and 8.13±5.56 (0.5–25)years, respectively. Modified Rodnan Skin Score mean and range were 23.17±9.14 (13–43), 22 patients were diffuse type (44%) and 28 patients were limited type (56%), 67% had inflammatory arthralgia as reported by patients. US examination revealed abnormalities in 76% of all cases. Synovitis was present in 74% of patients (22% wrist; 15% MCP/PIP, 63% both); with a grade 2 and 3 synovitis in 29% cases. The grade 2 or 3 synovitis was associated with a higher age ($p<0.05$) and disease duration ($p<0.03$) but not with inflammatory markers (CRP, ESR) and C3 nor with anti-CCP antibodies.
Furthermore, patients with US proven grade 2 or 3 synovitis had interstitial lung disease involvement (ILD) (74%) and elevated systolic pulmonary artery pressure >35 mmHg in (46%). Grade 1 synovitis did not correlate with tenderness or joint swelling. Synovitis using PD abnormalities were present in 20% patients, but only a 25% had concomitant clinical synovitis. Bone erosions (>1mm) were observed in 15%, which located at the second and third MC heads and at the styloid process of the ulna. The presence of bone erosions was associated with the presence of grade 2 or 3 synovitis. US identified tenosynovitis in 40% of patients, involving the wrist extensors in the vast majority of cases (70%), especially of the 2nd extensor compartment.
Conclusions: US examination detects significant synovitis of the hand and wrist in the absence of clinical findings, and reveals structural damage in a number of patients. The grade 2 or 3 synovitis was associated with a higher age, and ILD involvement. Tendon involvement is frequent with specific pattern of wrist extensors. Thus, US seems to be a valuable tool to identify subclinical joint manifestations in Egyptian SSc patients.

AB0655 ULTRASOUND B-LINES IN THE EVALUATION OF INTERSTITIAL LUNG DISEASE IN PATIENTS WITH SYSTEMIC SCLEROSIS: CUT-OFF POINT DEFINITION FOR THE PRESENCE OF PULMONARY FIBROSIS

M. Tardella[1], M. Di Carlo[1], M. Carotti[2], E. Filippucci[1], W. Grassi[1], F. Salaffi[1].
[1]*Rheumatology Department, Università Politecnica delle Marche, Jesi;*
[2]*Radiology Department, Università Politecnica delle Marche, Ancona, Italy*

Background: Although in Systemic Sclerosis (SSc) the cutaneous manifestations are the most noticeable features, lung involvement guides the disease prognosis. High resolution computed tomography (HRCT) is the mainstay for the detection of the interstitial lung disease (ILD). However, exposure to ionising radiation is a major limitation for the repetition of this examination. Over the last years, lung ultrasound (US) gained an intriguing potential in the evaluation of several pulmonary condition, and in previous studies was found a significant correlation between US score and HRCT score [1].
Objectives: To establish the cut-off point of the US B-lines number for detecting the presence of SSc-ILD.
Methods: Patients with SSc-ILD underwent chest HRCT, lung US, pulmonary function test, and clinical assessment. Exclusion criteria were represented by the presence of a coexisting congestive heart failure and other lung or pleural diseases (i.e., pneumonia, pleural effusion). HRCT were scored for the presence of ILD by an experienced radiologist, in accordance with the Warrick method. US assessment was performed by a US skilled rheumatologist, blinded to the HRCT results, and included the bilateral evaluation of 14 lung intercostal spaces (LIS) [2]. In each LIS the number of B-lines was recorded and summed. To test discriminant validity we used the receiver operating characteristic (ROC) curve analysis applying a Warrick score of 7 as external criterion for the presence of SSc-ILD.
Results: Forty patients completed the study. The US B-lines number and the Warrick score confirmed an excellent correlation (Spearman's rho: 0.819, $p<0.001$). The ROC curve analysis revealed that the presence of 10 US B-lines is the cut-off point with the greatest positive likelihood ratio (12.52) for the presence of SSc-ILD (Table).

US B-lines number	Sensitivity	95% CI	Specificity	95% CI	+LR	95% CI	–LR	95% CI
≥2	100.00	87.2–100.0	0.00	0.0–24.7	1.00

>20	59.26	38.8–77.6	92.31	64.0–99.8	7.70	5.4–10.9	0.44	0.06–3.1
>21	55.56	35.3–74.5	92.31	64.0–99.8	7.22	5.0–10.5	0.48	0.07–3.3
>22	51.85	31.9–71.3	92.31	64.0–99.8	6.74	4.5–10.0	0.52	0.08–3.6

Conclusions: The detection of 10 B-lines is highly predictive for the HRCT presence of SSc-ILD. In SSc patients, a lung US follow-up can optimize the employment of chest HRCT.

AB0656 NAILFOLD VIDEOCAPILLAROSCOPY FEATURES OF PATIENTS WITH ANTISYNTHETASE SYNDROME

M. Sebastiani[1], V. Codullo[2], A. Manfredi[1], A. Selva O'Callaghan[3], F. Furini[4], A. Iuliano[5], A. Schwarting[6,7], L. Cavagna[2], K. Triantafyllias[7] on behalf of NASCAR Study Group. [1]*Policlinico di Modena, University of Modena and Reggio Emilia, Modena;* [2]*University of Pavia, Pavia, Italy;* [3]*Universidad Autonoma de Barcelona, Barcelona, Spain;* [4]*University of Ferrara, Ferrara;* [5]*Azienda Ospedaliera San Camillo-Forlanini, Roma, Italy;* [6]*University Mainz, Mainz;* [7]*ACURA Rheumatology Clinics, Bad Kreuznach, Germany*

Background: Antisynthetase syndrome (ASSD) is an autoimmune disease characterized by the clinical triad arthritis, myositis, and interstitial lung disease (ILD). As in inflammatory myopathies, nailfold videocapillaroscopy (NVC) alterations have been sporadically described also in ASSD patients, but no elucidating data are available.
Objectives: To investigate the possible specific NVC features of ASSD patients.
Methods: Within the framework of a multicenter study, we retrospectively analyzed NVC images of ASSD patients, after excluding patients with overlap syndrome with systemic sclerosis. Two operators in a blind manner re-evaluated all

patients with at least one image per finger. For each patient, we examined number of capillaries (mean number of capillaries per mm in the distal row), enlarged and giant capillaries, micro-hemorrhages, avascular areas, ramified capillaries, and the presence of a scleroderma (SSc)-like pattern, according to Manfredi et al. Finally, we correlated NVC features with clinical and serological findings of ASSD patients.
Results: The NVC of 54 ASSD patients were analyzed (males/females 1/6.8, mean age 55.79, CI95% 51.9–59.9 years, mean disease duration 59.4, CI95% 27.9–90.9 months). Raynaud's phenomenon (RP) was recorded in 51.9% of patients, arthritis in 79.6%, myositis in 53.7%, and ILD in 92.6%. NVC alterations were observed in 53.7% of AASD patients. Nineteen patients (35.2%) showed a SSc-like pattern; the main features were disarrangement of hairpin and angiogenetic aspects (42.6%), avascular areas (38.9%), giant capillaries (27.6%), and microhemorrhages (20.4%). Finally, the mean number of capillaries was reduced (7.8±2/mm). No significant association was recorded between SSc-like pattern and the presence of arthritis, myositis, and ILD, nor with RP. Among other NVC features, angiogenesis was significantly associated to female gender (p=0.031), while microhemorrhages were inversely associated to the presence of arthritis (0.033). No association was observed between NVC features and autoantibodies profile. Of interest, in 58% of patients with ILD we observed at least a NVC alteration vs no patients without ILD (p=0.04). Finally, in patients with RP NVC alterations were recorded in 15/28 patients (53.6%) and a SSc-like pattern in 11/28 (39.3%), while only 57.9% of patients with SSc-like pattern had a clinically manifest Raynaud's phenomenon.
Conclusions: Despite preliminary, the present is the first study concerning NVC in AASD patients. Regardless of the presence of Raynaud's phenomenon, NVC alterations are frequently observed; in particular, a SSc-like pattern is recorded in more than 1/3 of patients. NVC should be performed in all ASSD patients at diagnosis regardless of the presence of RP in the patient history and during follow-up. ASSD should be always considered in the screening of RP. A prospective multicenter study has been planned to identify specific patterns and possible associations between NVC findings and clinical and serological features of ASSD.

AB0657 SMALL INTESTINAL BACTERIAL OVERGROWTH IN RELATION TO GASTROINTESTINAL SYMPTOMS IN SYSTEMIC SCLEROSIS

M.D.P. Cruz-Dominguez[1], G. Garcia-Collinot[1], E.O. Madrigal-Santillan[2], A. Carranza-Muleiro[1], L.J. Jara[3], D.H. Montes-Cortes[4], G. Medina-Garcia[1], O. Vera-Lastra[5]. *[1]Research Division, Instituto Mexicano del Seguro Social, Hospital de Especialidades CMN la Raza; [2]Posgrade, IPN, ESM; [3]Research and Education Direction, Instituto Mexicano del Seguro Social, Hospital de Especialidades CMN la Raza; [4]Emergency Room, Hospital General CMN la Raza; [5]Internal Medicine, Instituto Mexicano del Seguro Social, Hospital de Especialidades CMN la Raza, Mexico, Mexico*

Background: Autonomic dysfunction, smooth muscle fibrosis and vascular damage lead to small intestinal bacterial overgrowth (SIBO) in Systemic Sclerosis (SSc). SIBO is characterized by diarrhea, abdominal pain, bloating, malabsorption and malnutrition.
Objectives: To evaluate by NIH PROMIS® gastrointestinal symptoms scales and SIBO by hydrogen breath test (HBT) in patients with SSc.
Methods: We include 68 patients with SSc (ACR-EULAR 2015) who signed informed consent. NIH PROMIS®questionarie was applied to evaluated gastrointestinal symptoms and classified in not symptomatic, least, mildy, moderately and most symptomatic. Glucose HBT was applied after 14 hours fast, oral hygiene and 30 days free of antibiotics. Patients who has a negative HBT with symptoms associated to glucose ingestion we repeat test with lactulose.
Results: We applied questionnaire to 58 SSc patients, age 52 (26–75)years, 65 (96%) female and 3 (4%) males, disease duration 13 (1–40) years, limited SSc 41 (59%) and diffuse 27 (41%), body mass index 24 (12–39).
They are using prednisone (28%), micofenolate (14%), methotrexate (19%), azatioprin (5%), amlodipine or nifedipine (33%). Patients had continuous and very high increase of parts per millon (ppm) of exhaled Hydrogen: min0: 13 ppm (5–21), min15:17 ppm (5–43), min30:17 (3–49), min45:18ppm (7–103), min 60:22ppm (8–145), min90:18ppm (2–250), min120:25ppm (3–212), min150:71ppm (3–235). Normal values: <10 ppm during total test (Figure1).
Frequency of gastrointestinal symptoms were flatulence (87.5vs81.2%), nausea/vomiting (72.7vs37.6%), constipation (65.6vs40%), diarrhea (45.2vs33.4%), abdominal pain %) and incontinence (39.4vs31.3%) respectively between SCB (+) positive and negative.
Hyperproduction of hydrogen in breath had a direct correlation to severity of their symptoms ($p \leq 0.05$). The severity of diarrhea was in close relation to the severity of its rectal incontinence (r=0.73,p=0.001), and greater abdominal pain with flatulence (r=72, p=0.001).
Conclusions: Gastrointestinal symptoms are common in SSc regardless of whether they have SIBO. However, a higher Row Score SGI or moderate severe status (NIH PROMIS) correlates with high H scores from the 30th minute, therefore, the questionnaire is useful within the SSc assessment.

AB0658 FACTORS INFLUENCING ELAPSED TIME TO A DEFINITIVE DIAGNOSIS OF SYSTEMIC SCLEROSIS AND THEIR RELATIONSHIP WITH THE NUMBER OF ATTENDING PHYSICIANS AND THEIR MEDICAL SPECIALIZATION

Y. Erez[1], H. Yarkan Tugsal[2], G. Kenar[2], B. Zengin[2], D. Solmaz[3], M. Ozmen[3], G. Can[2], N. Akkoc[2], F. Onen[2], M. Birlik[2]. *[1]Internal Medicine; [2]Rheumatology, Dokuz Eylul University School of Medicine; [3]Rheumatology, Katip Celebi University School of Medicine, Izmir, Turkey*

Background: The diagnosis of Systemic Sclerosis (SSc) can be difficult due to its rarity and heterogeneity. In addition, not all physicians are expert in the identification of patients with early SSc features.
Objectives: The aim of this study was to investigate factors influencing the time elapsed since a proper diagnosis of SSc and their relationship with the number of attending physicians and their specialization, among Turkish patients. In Turkish healthcare system,each patient may directly go to the hospitals and choose appropriate care facility and physician.
Methods: The study covers 240 SSc patients who were diagnosed according to 1980 ACR criteria in the rheumatology database at the University of Dokuz Eylul, Izmir. Data included demographics, SSc duration, SSc subtype, physical examinations (mRodnan Score-mRS), and a face-to-face structured interview. Cases were excluded if they couldn't recall date of initial symptoms and all the prior attending physicians including their specialization until a definitive diagnosis of SSc. As clinical characteristics are different than pure SSc patients, overlap syndromes were excluded. Mann-Whitney U test was used to assess the difference between dependent and independent variables. The association between mRS and dependent variables was evaluated by Spearman correlation test.
Results: Remaining 135 patients (F:88.8%), mean age±SD (52.14±11.58 years) identified. 55 (41%) patients had diffuse and 80 (59%) patients had limited disease. 119 (88%) patients SSc diagnosed by a rheumatologist however, 48 patients (35%) were first seen by an internist. Median time to diagnosis was 36 months (1–588) from the onset of Raynaud Phenomenon (RF) and 11 months (0–397) from the onset of the first non-RF symptom for our cases. Relation between some parameters and time to diagnosis were shown in Table.1. Mean number of attending physicians until SSc diagnosis was calculated as 3,54 (SD±1,66). None of the demographic and clinical parameteres (SSc subtype, mRS, symptom duration) were related with the number of attending physician. There was no correlation detected between mRS and time to diagnosis and number of attending physicians. Nevertheless it was established that median number of physicians was less for patients who were referred to a proper clinician by their familier healthcare practitioners (p: 0,019).

Table 1. Time to diagnosis from Raynaud's and first non-Raynaud's symptom onset stratified clinical and demographic parametres

	Time to diagnosis from RF median-months	p	Time to diagnosis from first non-RF median-months	p
Sex				
Female	19 (4-299)	>0,05	11 (0-397)	>0,05
Male	39 (1-588)		15 (0-277)	
Education situation				
Less than highschool	44(0-588)	>0,05	11(0-397)	>0,05
Highschool and more	20(0-288)		14(0-297)	
Scl subtype				
Diffuse	23 (1-299)	***0.013****	11(0-297)	>0,05
Limited	45 (1-588)		11.5(0-397)	
Referred by healthcare practitioner				
Positive	24 (1-349)	>0,05	11(0-191)	>0,05
Negative	42 (1-588)		11(0-397)	
Initial symptom				
RF	49 (0-588)	***0.001***		
RF-non-RF together	21 (0-470)			

RF-non-RF together: less than one year between onset of RF and first non-RF symptom

Conclusions: Time to diagnosis from onset of RF is significantly shorter in diffuse SSc. Although mRS is typically higher in diffuse SSc, no correlation has been found between mRS and time to diagnosis. Therefore, duration of diagnosis may be influenced by internal organ involvement and other complications rather than skin changes due to lack of awareness of physicians about SSc related early skin changes. Referral to a proper physician by a familier healthcare practitioner decreased the number of physicians attending till the diagnosis, although it did not affect the time to diagnosis.

AB0659 ASSOCIATION BETWEEN -12518A/G GENE POLYMORPHISM ENCODING MONOCYTE CHEMOATTRACTANT PROTEIN 1 (MCP-1) AND SERUM LEVEL OF C-REACTIVE PROTEIN IN DIFFERENT CLINICAL AND SEROLOGICAL PHENOTYPES OF SYSTEMIC SCLEROSIS IN THE RUSSIAN COHORT OF PATIENTS

M. Krylov, L. Ananieva, O. Koneva, M. Starovoytova, O. Desinova, O. Ovsaynnikova, E. Samarkina, A. Novikov, E. Aleksandrova. *V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Immune system activation with associated up-regulation in the production of extra-cellular matrix proteins by fibroblasts are known specific features in the pathogenesis of systemic scleroderma (SSc). Most recent data indicate that MCP-1 and MCP-3 chemokines from the family of monocyte chemoattractant proteins are also involved into SSc pathogenetic process. C-reactive protein (CRP) is known as the marker of acute-phase inflammation. The association between increased CRP levels and SSc clinical and serological parameters has been reported recently.

Objectives: To study the association between -2518 A/G gene polymorphism, encoding *MCP-1*, and CRP levels in different clinical SSc phenotypes in the Russian cohort of pts.

Methods: PCR-RFLP method was used to identify *MCP-1* genotype in 81 SSc pts aged 49,4±12,6 years, with mean SSc duration 11,1±9,0 years. CRP concentrations were measured with highly sensitive immunoturbidimertry method.

Results: CRP levels were correlated with *MCP-1* genotypes in pts with limited (lcSSc) and diffuse (dcSSc) phenotypes, with interstitial lung disease (ILD+), with SSc duration >3 years, with increased CRP level (>5 mg/L), with positive antibody titers to DNA topoisomerase I (ATA+) and antibody to centromeres (ACA+). A total cohort analysis showed that carriers of -2518AA genotype had higher mean CRP level versus G allele carriers (12,6±7,5 mg/L vs 4,9±4,8 mg/L, respectively, p=0,009), although similar trend was found in dcSSc phenotype (16,4±19,5 mg/L vs 6,1±4,4 mg/L, respectively, p=0,040). In pts with -2518AA genotype and SSc duration >3 years mean CRP level was significantly higher than in G allele carriers (1,1±16,7 mg/L vs 4,5±4,4 mg/L, respectively, p=0,025). In (ILD+) and (ATA+) subgroup pts with -2518AA genotype demonstrated higher mean CRP levels as compared to G allele carriers (12,4±15,6 mg/L vs 5,5±5,1 mg/L, respectively, p=0,018; and 17,6±20,9 mg/L vs 5,5±5,5 mg/L, respectively, p=0,010). CRP levels (>5 mg/L) were found in 31 (38%) pts and were significantly different between AA genotype carriers and G allele carriers (27,4±19,2 mg/L vs 10,4±3,8 mg/L, respectively, p=0,003). No associations between genetic variations in the *MCP-1* gene and CRP levels in lcSSc phenotype, SSc duration <3 years, CRP levels <5mg/L and (ACA+) pts were established.

Conclusions: Our data demonstrate that -2518A/G *MCP-1* gene polymorphism is closely associated with CRP levels, thus, it can be considered as a new marker, reflecting the severity of the disease and unfavorable SSc prognosis.

AB0660 CHARACTERISTICS OF AL-I LIGHT-CHAIN AND AMYLOID A DEPOSITION IN PROGRESSIVE SYSTEMIC SCLEROSIS – A COMPARATIVE POSTMORTEM CLINICOPATHOLOGIC STUDY OF 12 PATIENTS

M. Bély[1], Á. Apáthy[2]. *[1]epartment of Pathology, Policlinic of the Order of the Brothers of Saint John of God; [2]Department of Rheumatology, St. Margaret Clinic Budapest, Budapest, Hungary*

Background: Different types of amyloid deposits may be present in systemic sclerosis (SSc), as consequences (complications) of basic or associated diseases.

Objectives: The aim of this study was to determine the type, prevalence and extent of amyloid deposits on different tissue structures in various organs in SSc.

Methods: We studied histopathologically 12 SSc patients (females 11, average age: 54.82 years, range 66–32, onset of SSc: 48.86, average disease duration: 6.43 years; one male, age 65.0 years at death, onset of SSc and average disease duration not known, who died at the National Institute of Rheumatology. SSc was diagnosed clinically according to the criteria of the ACR [1]. In 1 (8.0% of 12) 67 year old female patient (onset of SSc: 66 years, disease duration: 1 year) SSc was accompanied by B-cell lymphoma and complicated by systemic AL-l light-chain amyloidosis. In 1 (8.0% of 12) 53 year old female patient (onset of SSc: 41 years, disease duration: 12 years) SSc was complicated by systemic amyloid A (aA) deposition.

Amyloid deposits on different tissue structures [arteriole, small artery, medium size artery, venule, small vein, medium size vein, interstitial collagen fiber, reticulin fiber (collagen IV), and nerve] of 6 organs [heart, lungs, kidney, gastrointestinal tract, skin and brain] were determined histologically. The extent of amyloid deposition was evaluated by semi-quantitative, visual estimation on a 0 to 3 plus scale, based on the number of involved tissue structures per light microscopic field [2].

The prevalence and extent of amyloid-l light-chain and amyloid A deposits on different tissue structures were compared by Student (Welch) t-probe.

Results: The involvement of different tissue structures (prevalence in %) and the average extent of AL-l light-chain and amyloid A deposits (absolute value) are summarized in Table 1.

Table 1

Tissue structures	SSc-l Prevalence in %	SSc-aA Prevalence in %	p<	SSc-l Average extent	SSc-aA Average extent	p<
Arteriole	83,33	66,67	0,2749	2,00	1,33	0,1709
Small artery	83,33	66,67	0,1709	2,17	1,00	0,0414
Medium size artery	83,33	66,67	0,1520	2,33	0,67	0,0090
Interstitial collagen	66,67	50,00	0,2998	0,83	0,83	0,5000
Medium size vein	50,00	50,00	0,2735	1,17	0,50	0,1476
Small vein	50,00	50,00	0,5000	0,58	0,50	0,4088
Venule	33,33	33,33	0,5000	0,33	0,33	0,5000
Collagen IV	33,33	16,67	0,2749	0,50	0,33	0,3671
Nerve	0,00	0,00		0,00	0,00	
Average/Structure	53,70	44,44	0,232	1,10	0,61	0,075

Conclusions: In SSc patients the prevalence and extent of l light-chain and amyloid A deposits on different tissue structures changed parallel.

The higher prevalence and extent of l light-chain deposits in contrast to amyloid A may be explained with qualitative differences of l light-chain and amyloid A; l light-chain seems to have greater affinity for tissues than amyloid A protein.

Infiltration of the vessel walls – regarding the amount of l light-chain and amyloid A deposits in arterioles and arteries in contrast to the veins – showed a converse tendency in SSc patients with AL-l or AAa. This may be related to sluggish blood flow or stasis (backward congestion and accumulation of circulating precursors) in both diseases.

AB0661 ORAL HEALTH-RELATED QUALITY OF LIFE MEASURED WITH OHIP 49 HIGHLY CORRELATES WITH DISEASE ACTIVITY AND SEVERITY IN SYSTEMIC SCLEROSIS PATIENTS

K. Parat[1], M. Radić[2], K. Borić[2], D. Perković[2], D. Biočina Lukenda[1], D. Martinović Kaliterna[2]. *[1]Department of Oral Medicine and Periodontology, Study of Dental Medicine, School of Medicine, University of Split; [2]Division of Rheumatology and Clinical Immunology, Center of excellence for Systemic Sclerosis in Croatia, University Hospital Split, Split, Croatia*

Background: Systemic sclerosis (SSc) is associated with decreased saliva production and interincisal distance, more missing teeth, and periodontal disease. Orofacial manifestations of SSc contribute greatly to overall disease burden and still are regularly overlooked and under-treated. Previous studies did not confirm correlation between disease severity and oral health-related quality of life in SSc patients.

Objectives: The aim of this study was to determine possible correlation of the SSc clinical parameters with oral health-related quality of life measured with the Oral Health Impact Profile 49 (OHIP 49).
Methods: Subjects were recruited from the Center of excellency for systemic sclerosis in Croatia cohort. Detailed dental by the same dentist and clinical examinations were performed according to standardized protocols. Associations between oral health-related quality of life and disease charachteristics were examined. We evaluated the disease severity using clinical and laboratory parameters according to the Medsger Severity Scale. The level of SSc activity was evaluated according to Valentini activity score. Oral quality of life was measured using the OHIP 49, which consists of 49 questions on the frequency of adverse oral conditions such as toothache, mouth pain, difficulty chewing or pronouncing words and discomfort related to appearance (higher scores indicating worse oral health-related quality of life). The study was approved by the University Hospital Split Ethics Committee.
Results: Thirty-one SSc patients (29 women and 2 men, mean age 56.45±13.60 years, median disease duration 7 years with minimum–maximum range 1–28 years) were consecutively enrolled for this study between January 2014 and December 2015. All patients fulfilled the ACR criteria for the diagnosis of SSc. The distinction between limited cutaneous SSc (lcSSc) and diffuse cutaneous SSc (dcSSc) was made according to the Leroy et al. criteria (28 dcSSc, 3 lcSSc). OHIP 49 scores highly positively correlated with disease activity (p=0.005, r=0.4872, Spearman's rank coefficient) and severity (p=0.016, r=0.4303, Spearman's rank coefficient). Furthermore, oral health-related quality of life positively correlated with the skin involvement evaluated by modified Rodnan skin score (p=0.003, r=0. 5207, Spearman's rank coefficient). Impaired quality of oral health positively correlated with the severity of general involvement, skin, gastrointestinal and joint/tendon involvement (p=0.003, r=0.506 for general involvement, p=0.003, r=0.511; $p<0.001$, r=0.591 and p=0.02, r=0.391 for skin, gastrointestinal and joint/tendon involvement, respectively, Spearman's rank coefficient). OHIP 49 score was highly variable between anti-topoisomerase I antibodies positive or negative SSc patients ($p<0.001$, Fisher's exact test).
Conclusions: Contrary to previous studies in our study disease severity and activity were related to OHIP 49 scores. Our data suggest that OHIP scores correlate with severity of general involvement, skin, gastrointestinal, and joint/tendon involvement in SSc patients. Disease subset and autoantibodies profil could play a role in the oral manifestation of SSc. Better collaboration between rheumatologists and the dental team is required to improve access to dental care and oral health outcomes for SSc patients.

AB0662 SYSTEMIC SCLEROSIS (SSC) COHORT IN ABU DHABI: FOCUS ON DIGITAL ULCERS (DU)

M. Al-Maini[1], H. Al-Mashari[1], T. Khan[1], N. Abutaha[1], R. Aneja[1], A. Las Alas[1], S. Gonuguntla[1], M. Cerinic[2], K. Khawaja[1]. *[1]Adult and Pediatric Rheumatology, Allergy and Immunology, Al-Mafraq Hospital, Abu Dhabi, United Arab Emirates; [2]Rheumatology, University of Florence, Florence, Italy*

Background: DU are a significant burden for SSc patients affecting approximately 40–50% of patients (1). No data are available on the frequency of DU on SSC patients living in the United Arab Emirates.
Objectives: To identify the frequency of DU in a cohort of SSC in Abu Dhabi which is the capital city of the United Arab Emirates (UAE).
Methods: SSC patients identified according to ACR EULAR criteria through the hospital electronic medical records system, which was implemented from January 2011 for medical documentation in all public hospitals in Abu- Dhabi and districts. Using the International statistical classification of diseases and related health problems, usually called by the short form name international classification of Diseases (ICD), version 9 (710.1) from 1st of January 2011 to 31st of December 2016. Retrospective review of electronic medical records and paper case notes was performed on patients who presented during this period. The frequency of DU was searched. DU were defined (1) and categorised (2) (no digital ulcers, episodic (rarely recurrent), recurrent (frequently recurrent) and chronic ($\geq$1 DU at every follow up). Results and the incidence of gangrene were compared to data from DUO registry (3).
Results: 47 SSc patients (Male to female ratio 12 (25.5%) to 35 (74.5%) (Duration of disease from 2 to 24 years with peak age for ulcers between 40–50 years) were identified. No ulcers were detected in 34 patients (72.3%) while DU were found in 13 patients (27.7%): they were episodic in 9 patients (19%) and chronic in 4 patients (8.5%) of the total patients. No recurrent ulcers were found. Only one patient (2%) evolved to gangrene (she was a smoker). The other 12 patients with DU were non-smokers and three of them were under 16 years of age.
Conclusions: In Abu Dhabi SSc population, the incidence of DU is 27.7%. This differs from the incidence in the western literature where it peaks from 40 to 50% (3). Our patients had episodic (19%) and chronic DU (8.5%) of the total patients. The incidence of gangrene in our cohort was lower when compared to the data reported in the DUO registry (20%) (2). Although patients live in a very warm climate, DU are still experienced in SSc in Abu Dhabi. Likely, the chronic exposure to air conditioning may explain this paradox.

AB0663 THE RELATIONSHIP OF SERUM LEVEL OF ANTICCP ANTIBODY WITH SEVERITY OF SKIN INVOLVEMENT IN SYSTEMIC SCLEROSIS PATIENTS REFERRED TO TOHID HOSPITAL

N. Moghimy[1], A. Saeidi[2]. *[1]Liver and Digestive Research Center; [2]Master of clinical Psychologist, Kordestan Medical Scienses, Sanandaj, Iran, Islamic Republic Of*

Background: Systemic sclerosis is a chronic systemic disease of unknown etiology. There are a number of autoantibodies that correlated with disease severity and severity of skin involvement (1). Various studies have shown that AntiCCP Ab can also be seen in other autoimmune diseases such as systemic sclerosis (2–4). Results Polimen et al (4) and Morita et al (3) studies showed no relationship was found between AntiCCP Ab with skin Rodnon score.
Objectives: This study aimed to determine the relationship between serum levels of AntiCCP Ab with severity of skin involvement in systemic sclerosis patients referred to Tohid Hospital.
Methods: This study is a cross - sectional study, in the study population included all patients diagnosed with systemic sclerosis according to ACR 1980 criteria and subtypes according to Le Roy, that between 2013 and 2014 referred to Tohid hospital. We used from MRSS index to determine the extent of skin involvement. Sampling was available and we used to determine this association from chi-square statistics and to determine the amount of the connection from Phi statistics. Serum antibodies directed against CCP were assessed by ELISA.
Results: The results showed that the patients who were evaluated at the end of study were 50 patients, of whom 48 were women (96%) and (2%) 2 were male. The mean age of subjects is 38±10 years. The subtype of systemic sclerosis in 15 (%30 percent) of the patients were diffuse systemic sclerosis and 35 patients (%70 percent) have limited systemic sclerosis. Serum Anti CCP Abntibody was positive in 10% (5 patients). Also, there is no statistically significant relationship between the severity of skin involvement with Anticcp Ab (p=0.164).Severity of skin involvement in both groups was more severe form, and there is no statistically significant relationship between the severity of skin involvement and subtypes of systemic sclerosis (p=0.233). Also we didn't find no association between levels AntiCCP and joint symptoms and other symptoms.
Conclusions: In this study wasn't observed a significant correlation between serum levels of Anti CCP Antibody with severity of skin involvement in patients with systemic sclerosis (p=0.164),also serum level of AntiCCP Antibody couldn't as a predict factor to determine the severity of the disease. It seems that the relationship between other symptoms of systemic sclerosis and serum level of AntiCCP Antibody may be result from overlapping with RA.

AB0664 LEVEL OF SATISFACTION IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

N. Loghin-Oprea[1], S. Vetrila[2], L. Mazur-Nicorici[2], M. Cebanu[3], V. Salaru[4], M. Mazur[1]. *[1]Internal Medicine; [2]Cardiology; [3]Emergency Medicine; [4]Family Medicine, PI SUMPh Nicolae Testemitanu, Chisinau, Moldova, Republic of*

Background: Idiopathic Inflammatory Myopathies (IIM) are the group of rare diseases that carry a significant impact on patient's quality of life, influenced by the level of patient's satisfaction regarding medical services.
Objectives: To assess the patient's satisfaction and quality of life.
Methods: A cross-sectional study was performed from December 2015 to December 2016. There were included consecutive patients that fulfilled the Bohan and Peter[1] criteria for IIM. The collected information was about demographic data, clinical and laboratory findings. The patient's satisfaction was assessed by self-administered Patient Satisfaction Questionnaire (PSQ III)[2], which is a 50-item tool, covering 7 domains: general satisfaction, technical quality,

interpersonal aspects, communication, financial aspects, time spent with doctor, access/availability/convenience. To estimate the quality of life we applied Short Form-8 questionnaire with 8 items for 8 domains and two components: mental and physical.

Results: There were 32 patients enrolled in the study, including 23 females and 9 males, mean age 52.5±14.26 (range 25–78), the disease duration was 8.3±5.3 (range 0.5–12) years. The physical component was lower 37.49±8.49, than the mental component 44.96±6.24 points, we determined that the quality of patient's life was reduced. The PSQ III results were: general satisfaction 20±2.93, technical quality 36.8±5.93, interpersonal aspects 26.50±4.92, communication 19.7±3.25 and access/availability/convenience indicated 44.75±6.29 score. The time spent with doctor was 7±1.15, a border score. The average result in the financial aspects domain was 21.6±6.6, lower than the midpoint scoring (24). We identified correlation between the quality of life and the access/availability/convenience PSQ III domain. For the mental compound the correlation was moderate ($r=0.5$ $p<0.005$) and for physical domain it was weak ($r=0.27$ $p<0.005$), these results can be explained by the fact that patients got accustomed with the disease, but they are more interested in access to care and require increasement of the duration of medical consultation.

Conclusions: Patients with idiopathic inflammatory myopathies have reduced quality of life; however they are satisfied of the medical attendance. The dissatisfaction was with the financial aspect, due to the long-term disease course and high indirect costs.

AB0665 ASSOCIATION BETWEEN MICROVACULATURE CHANGES AND PULMONARY INVOLVEMENT IN SYSTEMIC SCLEROSIS: A FOLLOW-UP STUDY

R. Bečvář[1], M. Tomčík[2], J. Štork[3], A. Slováková[4]. *[1]Department of Rheumatology; [2]Institute of Rheumatology; [3]Department of Dermatovenerology; [4]Department of Pneumology, General Teaching Hospital, Praha 2, Czech Republic*

Background: Lung involvement is the major cause of mortality in patients with systemic sclerosis (SSc). Gas transfer (DLCO) and FVC levels have traditionally been used as measures of disease severity and reductions of both parameters have been associated with increased mortality. In SSc repeated attacks of Raynaud's phenomenon lead to the reduced capillary density leads with reduced blood flow and tissue ischemia. Raynaud's phenomenon can occur also in the lungs. Tissue hypoxia usually initiates the formation of new blood vessels from the pre-existing microvasculature. Nailfold capillaroscopy is a safe, noninvasive routine way for the microvascular investigation.

Objectives: The aim of this study was to assess the correlation between capillaroscopic abnormalities and parameters of interstitial lung involvement at baseline and after one year follow-up in patients with SSc.

Methods: All patients underwent routine clinical examination (dyspnea, cough, crepitus), pulmonary function tests, DLCO (alveolitis grade and fibrosis), blood gases and HRCT scan of chest (1). Microvasculature changes were assessed using nailfold videocapillaroscopy (NVC) which was performed by two independent examiners. The obtained images were analysed anonymously by two investigators blinded for the clinical and serum status of SSc patients and classified as early, active and late pattern, non specific or normal picture (2). For statistical evaluation Poisson's correlation coefficient and T-test were used. All examinations were performed at baseline and after 12 months.

Results: Total 42 patients (38 females) were investigated: 30 individuals with limited form, 7 with diffuse form, 3 patients with scleroderma sine scleroderma, 1 with overlap syndrome and 1 with undifferentiated connective tissue disease. The mean age ± standard deviation (SD) of the whole cohort was 51±22 years and the mean disease duration ± SD was 10±7 years. 3 patients (7.5%) had early NVC pattern, 12 patients (30%) had active, 10 (58%) late pattern, and 17 (37.5%) had nonspecific changes or normal picture. The patients with late NVC pattern exhibited more often mild to moderate alveolitis, decreased FEV1 and FVC and DLCO. When correlating NVC patterns with clinical findings, pulmonary function test and HRCT scans we found only an association of low significance with dyspnea and alveolitis grade (both $p<0.1$). After one year follow-up similar results were obtained ($p<0,001$ and $p<0,01$, respectively).

Conclusions: In our study NVC patterns did not seem to correlate with severity of interstitial lung disease in SSc patients even after one year follow-up.

AB0666 MYOPATHIES ASSOCIATED WITH SYSTEMIC SCLEROSIS: CLINICAL AND IMMUNOLOGICAL FEATURES FROM A TERTIARY CENTRE COHORT

R. Nichitean, A. Mociran, I. Szabo, L. Damian, I. Felea, S. Siao-Pin, S. Rednic. *Rheumatology, Scju Cluj Napoca, Cluj Napoca, Romania*

Background: Systemic sclerosis (SSc) is a connective tissue disease characterized by skin and internal organ fibrosis due to immune activation, vascular damage and excessive synthesis of collagen [1]. Muscle involvement is still a variable feature, with prevalence from 14% to 79% due to the lack of diagnostic consensus criteria [2].

Objectives: The aim of this study was to characterize the clinical, biochemical and immunological features of SSc patients with muscle involvement and to find any correlations amongst them.

Methods: We retrospectively analysed data for 18 SSc patients with myopathy out of 254 SSc patients followed between 2000 and 2016 in a Romanian academic hospital centre. All patients fulfilled the ACR/EULAR criteria for the diagnosis of SSc and had a history of myopathy. Myopathy was defined as the presence of muscle weakness, myalgia, with creatine kinase (CK) and/or lactate dehydrogenase (LDH) level >2N (two times the upper normal range). Clinical, biochemical and immunological parameters were assessed by descriptive statistics, logistic regression and Chi-square test.

Results: The prevalence of myopathy was 7.0%. General features in myopathy-SSc patients are detailed in Table 1. Male sex represents a risk factor for muscle involvement (OR=38.2, p-value<0.001). The ratio of diffuse subtype to the limited subtype was 0.8. The major organ involvement associated with myopathy was lung fibrosis (55.5%). Most prevalent autoantibody was anti-Scl70 (44.4%). The onset of muscle symptoms occurred within a median of 1.6 years (range 0–12 years) after SSc diagnosis. Among the studied patients, 12 (66.6%) had muscle weakness, and 13 (72.2%) had myalgia. CK and LDH levels were elevated in 16 (88.88%) and 18 (100%) cases, respectively. AST level values were found to be slightly higher than ALT ones but not statistically significant (p-value=0.15). A positive correlation was found between levels of LDH and AST (Pearson coefficient=0.72) and between CK and LDH (Pearson coefficient=0.66). No association was identified with inflammatory parameters.

Table 1.

SSc general data and associated features		Number out of 18 (total) and %
Female sex		12 (66.6%)
Diffuse SSc form		8 (44.4%)
Age at SSc diagnosis		43 ye ars
Digital ulcers		3 (16.6%)
Calcinosis		6 (33.3%)
Autoantibodies	Anti-nuclear	16 (88.8%)
	Anti-Scl70	8 (44.4%)
	Anti-centromere	0
	Anti-RNP	2 (11.1%)
	Anti-PM/Scl	1 (5.5%)
Heart involvement		2 (11.1%)
Lung fibrosis		10 (55.5%)
Scleroderma renal crisis		2 (11.1%)
Arthritis		4 (22.2%)
Oesophagus involvement		6 (33.3%)
Motor weakness		12 (66.6%)
Myalgia		13 (72.2%)

Conclusions: This study emphasizes the fact that male SSc patients are at increased risk of developing myopathy. Although the prevalence of muscle involvement was quite low than reported in other cohort series, the results are similar to the more recent publications [3]. We showed that myopathy occurred more often in anti-Scl70 positive patients and that anti-centromere wasn't present at all. All patients should be carefully assessed for muscle involvement in the first years of SSc diagnosis and screened for lung fibrosis, regardless of cutaneous subtype of the disease.

AB0667 CLINICAL AND THERAPEUTIC DIFFERENCES BETWEEN POLYMYOSITIS AND DERMATOMYOSITIS IN A COLOMBIAN COHORT WITH IDIOPATHIC INFLAMMATORY MYOPATHY

R. Fuentes[1], F. Vargas[1], M.A. Alzate[2], D. Hernandez-Parra[2], J.C. Salazar-Uribe[3], P. Ortiz-Salazar[2], R. Pineda[2] on behalf of Artmedica IPS, Medellin, Colombia. *[1]Rheumatology division; [2]Clinical information group, Artmedica IPS; [3]School of Statistics, Faculty of Sciences, National University of Colombia, Medellin, Colombia*

Background: The idiopathic inflammatory myopathies (IIM) are a group of immune-mediated systemic conditions characterized by chronic muscle inflammation, resulting in muscle weakness (1).
Objectives: To characterize the disease in a Colombian cohort with idiopathic inflammatory myopathy, assessing differences in its classification, cutaneous and systemic manifestations, laboratory results, and therapeutic approach, according to the type of myopathy.
Methods: A cross-sectional study was conducted in 112 patients, in whom sociodemographic, clinical and therapeutic characteristics were analyzed based on the type of myopathy. Statistical association was examined by means of Chi-square tests, Mann-Whitney test, and logistic regression analyses.
Results: From the 112 patients recruited, 59 had polymyositis (PM) and 53 had dermatomyositis (DM). The patients were classified with Peter & Bohan criteria as: "definite" diagnosis 67 (60%), "probable" 35 (31%) and "possible" 9 (10%). A high proportion of males were found in this cohort. Our most notable findings are listed in Table 1, noticing for this population a high rate of polyautoimmunity associated to PM (OR 3.81 95%IC 1,003–14,53) and an association between ANAs antibodies positivity and DM (OR 7.03 95%IC 2,16–22,9). Patients with PM presented higher values of CK, LD and transaminases. Also, according to the therapeutic approach, PM was positively associated with the use of azathioprine and immunoglobulins (OR 2,59 95%IC 1,18–5,69 and OR 3,21 95%IC 1,19–8,19, respectively), while chloroquine and hydroxychloroquine were mainly used in DM patients.

Table 1. Sociodemographic and clinical characteristics of Colombian patients with idiopathic inflammatory myopathy

	Polymyositis N=59		Dermatomyositis N=53		p-value
	N	%	N	%	
Female	41	69,5	35	66	0,69
Age (mean)	54,3		49,4		0,09
Clinical characteristics					
Symmetrical muscle weakness	59	100	51	96,2	0,13
Gottron's papules	0	–	49	92,4	**<0.0001**

AB0668 CALCINOSIS CUTIS AND ITS ASSOCIATION OF SERUM LEVELS OF OSTEONECTIN, OSTEONECTIN, NITRIC OXIDE AND TGF-B IN SYSTEMIC SCLEROSIS

R.A. Carranza Muleiro[1,2], M.D.P. Cruz-Domínguez[2], L.M. Apolinar[3], A.A. Reséndiz-Albor[2], A.L. Vázquez-Martínez[3], G. García-Collinot[2], L.J. Jara-Quezada[4], I.M. Arciniega[1]. *[1]Sección de Estudios de Posgrado e Investigación, Escuela Superior de Medicina Instituto Politécnico Nacional; [2]División de Investigación en Salud, Instituto Mexicano del Seguro Social Hospital de Especialidades Centro Medico la Raza; [3]Hospital de Especialidades Centro Medico Siglo XXI Laboratorio de Enfermedades Endocrinológicas, Instituto Méxicano del Segúro Social; [4]Jefatura de Investigación en Salud, Instituto Mexicano del Seguro Social Hospital de Especialidades Centro Medico la Raza, México city, Mexico*

Background: Systemic sclerosis (SSc) is characterized by fibrosis, autoimmunity and vasculopathy. ES is classified subtypes: diffuse (dSSc) and limited (ISSc). More than 35% develop calcinosis. Calcium, phosphorus, parathormone, vitamin D, TGF-β, nitric oxide and osteonectin and osteopontin involved in bone mineralization.
Objectives: The aim was to compare osteonectin (ON), osteopontin (OP), TGF-β, nitric oxide (NO), Paratohormone (PTH), Vitamin D and minerals concentrations in ES with and without calcinosis.
Methods: Cross-sectional study in ES patients (ACR criteria). We quantified OP, ON, TGF-β, ON, Calcium, Phosphorus, PTH and vitamin D in serum by ELISA. We performed descriptive statistics, Student t, Pearson correlation (significance $p<0.05$) in SPSSv21 program.
Results: We included 71 patients, age 52.94 (± 11.47); 28 (40%) with calcinosis (18 dSSc/10 ISSc), and 43 (60%) without calcinosis (13 dSSc/30 ISSc). Biochemical parameters between two groups. In the whole population the higher PCR had moderate positive correlation (r =0.41, p=0.042), and serum calcium level had a moderate negative correlation (r = -0.47, p=0.021); ON increased in direct relation to OP (r =0.3, p=0.014) and the serum levels of VitD had lower indirect relation with the evolution time of SSc (r = -0.28, P=0.025) and the ON increase in direct relation to serum creatinine (r =0.039, p=0.006).
Conclusions: Patients with a longer time evolution of SSc have less serum levels of VitD and those with higher inflammation (PCR) have a higher TGF-β than a potent inducer of fibrosis. PCR and TGF-B have a moderate direct correlation, PCR and Calcium have moderate indirect correlation, ON and OP have a low direct correlation, VitD and evolution of diseases (years) had a low indirect correlation and NO and creatinine had a very low direct correlation.

Background: Patient reported outcome measures (PROM) are required as key outcomes in therapeutic trials in systemic sclerosis (SSc). Given the unmet need of a validated, comprehensive PROM in SSc, the ScleroID questionnaire was developed by a team of patients with SSc and medical experts in the field. This is intended as a brief, disease-specific, patient-derived, disease impact score for scientific and clinical use in SSc.
Objectives: To present a preliminary analysis from the ongoing ScleroID validation study.
Methods: This EULAR-endorsed project involves 11 European centers special-

Abstract AB0669 – Table 1

ScleroID weighting (out of a total of 100 points)	Raynaud phenomenon	Hand function	Upper gastrointestinal tract symptoms	Pain	Fatigue	Lower gastrointestinal tract symptoms	Limitations of life choices and activities
Median (IQR)	15 (20)	10 (15)	6 (10)	10 (10)	10 (10)	5 (10)	5 (10)

ized in SSc. Patients fullfilling the ACR/EULAR 2013 criteria were prospectively included since 05/16 in the ongoing observational cohort study. Patients filled in the ScleroID questionnaire (Figure 1), as well as selected comparators SHAQ, EQ5D, SF36. Additionally, they weighted the 10 dimensions of the ScleroID by distributing 100 points according to the perceived impact on their health. The final score calculation will be based on the ranking of the weights. The study includes a reliability arm (follow-up questionnaire 7–10 days from baseline), as well as a longitudinal arm, looking at sensitivity to change at follow-up visits after 6 and 12 months from baseline.

Results: As of 01/2017 the study cohort included 224 patients with valid baseline data, 44 also had a reliability visit and 6 a 6-months follow-up visit. 84.4% of patients were female, 54.4% had limited SSc, median age 58, and median disease duration 8 years. The highest preliminary median weights for ScleroID domains were for Raynaud, impaired hand function, fatigue and pain (Table 1). Except for pain, these dimensions were also scored most highly in the ScleroID questionnaire at baseline.

The EULAR Scleroderma Impact of Disease Score (ScleroID)

How much have the different aspects of systemic sclerosis affected you during the last week? Please mark your responses on the scale by choosing the appropriate number for each of the following dimensions:

Raynaud's phenomenon:
Circle the number that best describes the severity of your Raynaud's phenomenon during the last week:
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Hand function:
Circle the number that best describes your hand function limitations due to your systemic sclerosis during the last week:
No limitation 0 1 2 3 4 5 6 7 8 9 10 Extreme limitation

Upper gastrointestinal tract symptoms (e.g. swallowing difficulties, reflux, vomiting):
Circle the number that best describes the severity of your upper gastrointestinal tract symptoms due to your systemic sclerosis during the last week:
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Pain:
Circle the number that best describes the pain you felt due to your systemic sclerosis during the last week:
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Fatigue:
Circle the number that best describes the impact of overall fatigue due to your systemic sclerosis during the last week:
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Lower gastrointestinal tract symptoms (e.g. bloating, diarrhea, constipation, anal incontinence):
Circle the number that best describes the severity of lower gastrointestinal tract symptoms during the last week:
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Limitations of life choices and activities (e.g. social life, personal care, work):
Circle the number that best describes how severe the limitations of life choices and activities due to your systemic sclerosis were during the last week:
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Body mobility:
Circle the number that best describes how much your body mobility was affected due to your systemic sclerosis during the last week:
Not affected 0 1 2 3 4 5 6 7 8 9 10 Extremely affected

Breathlessness:
Circle the number that best describes how severe your breathlessness due to systemic sclerosis was during the last week:
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Digital ulcers:
Circle the number that best describes how much your digital ulcers affected you overall during the last week:
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Conclusions: The EULAR ScleroID score is a novel tool designed for use in clinical practice and clinical trials to display the disease impact of SSc. In this preliminary analysis, Raynaud syndrome, impaired hand function, and fatigue were the main patient reported drivers of disease impact, however, further recruitment and validation of this new instrument is ongoing.

AB0670 CLINICAL AND LABORATORY MANIFESTATIONS OF RNP-POSITIVE PATIENTS WITH SYSTEMIC SCLEROSIS

L.P. Ananyeva, R.U. Shayakhmetova, O.A. Koneva, M.N. Starovoitova, O.V. Desinova, O.B. Ovsyannikova. *Department of vasculopathy, V.A.NASONOVA Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Among patients, who meet the classification criteria for systemic sclerosis (SSc), there are the patients without specific SSc anti-nuclear antibodies and who are positive for antibodies to ribonucleoprotein (RNP). The clinical significance of the RNP antibodies in SSc is not clear.

Objectives: To investigate clinical and laboratory characteristics of SSc patients positive for antibodies to RNP.

Methods: The study included 52 patients (49 women and 3 men, mean age 44.2±15 years, median disease duration from the beginning of Raynaud's phenomenon 11.2±7years) who met the classification criteria of SSc (ACR/EULAR 2013) and have high level (>200 U/ml) of antibodies to RNP-70 (determined by ELISA, range 0–25 U/ml). Clinical, laboratory, and immunologic data were collected on all patients.

Results: All the patients met the criteria for classification of SSc ACR/EULAR 2013 (table 1). Other prevalent clinical manifestations were gastroesophageal reflux in 63, 5% of patients, joints involvement in 58%, myositis in 30, 7%, serositis in 27.5% (including 23% of pericarditis). All patients were positive for antinuclear factor (Hep-2) and in some cases RF, anti-SS-A, anti-SS-B, anti-Sm and anti-dsDNA antibodies were identified. The increased levels of CRP and/or ESR were found in 56% of cases. Among the SSc patients, there were 38 (73%) who satisfied for the classification criteria for mixed connective tissue disease (MCTD) proposed by Kasukawa et al. (1987).

Table 1. Frequency of items of SSc classification criteria (ACR/EULAR 2013) in the group under study

Items	52 patients
Skin thickening of the fingers extending proximal to the metacarpophalangeal joints	9 (17,3%)
Skin thickening of the fingers:	41 (78,8%)
puffy fingers	29 (55,7%)
sclerodactily	14 (27%)
Fingertip lesions	22 (42,3%)
Telangiectasia	25 (48%)
Abnormal nailfold capillaries	45 (86,5%)
Lung involvement:	37 (72%)
Pulmonary arterial hypertension	2 (4%)
Interstitial lung disease	35 (68%)
Raynaud's phenomenon	52 (100%)
SSc-related autoantibodies:	12 (23%)
ACA	4 (7,7%)
Anti-Scl-70	8 (15,4%)

Conclusions: In the group under study the limited form of SSc dominated, with high frequency of the different manifestations of vasculopathy, esophagus, joint and muscle disorders symptoms. A subtype of RNP-positive SSc patients often met the criteria for MCTD. This fact makes it reasonable to discuss the possibility of overlap-syndrome between these two diseases.

AB0671 INCREASED BODY FAT BUT DECREASED LEAN BODY MASS AND BONE MINERAL DENSITY IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES ARE ASSOCIATED WITH DISEASE DURATION, INFLAMMATORY STATUS, SKELETAL MUSCLE INVOLVEMENT AND PHYSICAL ACTIVITY

S. Oreska[1], M. Spiritovic[1,2], P. Cesak[2], O. Marecek[2], H. Storkanova[1], K. Kubinova[1], M. Klein[1], L. Vernerova[1], O. Ruzickova[1], R. Becvar[1], K. Pavelka[1], L. Senolt[1], H. Mann[1], J. Vencovsky[1], M. Tomcik[1]. *[1]Department of Rheumatology, 1st Medical Faculty, Charles University, Institute of Rheumatology; [2]Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic*

Background: Idiopathic inflammatory myopathies (IIM) are characterized by inflammation and atrophy of skeletal muscles, pulmonary and articular involvement, which limit the mobility/self-sufficiency of patients, and can have a negative impact on body composition.

Objectives: To assess body composition and physical activity of IIM patients and healthy controls (HC).

Methods: 54 patients with IIM (45 females/9 males; mean age 57.3; disease duration 5.8 years; polymyositis (PM,22)/dermatomyositis (DM,25)/necrotizing

myopathy (IMNM,7)) and 30 age-/sex-matched HC (25 females/5 males, mean age 54.9) without rheumatic/tumor diseases or manifest cardiovascular event were included. PM/DM patients fulfilled Bohan/Peter criteria for PM/DM. Anthropometric parameters and body composition were assessed (by densitometry-iDXA Lunar, and by bioelectric impedance-BIA2000-M), and physical activity was evaluated using Human Activity Profile (HAP) questionnaire. Routine biochemistry analysis was performed after 8 hours of fasting. Muscle involvement was evaluated by manual muscle test (MMT)-8. Data are presented as mean±SD.

Results: Compared to HC, patients with IIM had significantly increased body fat % as assessed by iDXA (BF%: 38.7±6.7 vs. 42.5±7.1%, p=0.015), but decreased lean body mass as assessed both by iDXA (LBM: 45.7±6.6 vs. 40.3±7.0 kg, p=0.0005) and BIA (LBM: 53.2±8.5 vs. 48.7±9.0 kg, p=0.0295), and increased ECM/BCM ratio (extracellular mass/body cell mass: 1.00±0.12 vs. 1.43±0.42, p<0.0001), which reflects worse muscle predispositions for physical exercise, aerobic fitness/performance, and also increases with deteriorating nutritional status. Compared to HC, IIM patients had significantly lower bone mineral density (BMD: 1.16±0.10 vs. 1.05±0.11 g/cm^2, p=0.0010), and were currently able to perform less energetically demanding physical activities according to HAP score (86.3±5.9 vs. 49.0±20.2, p<0.0001). Disease duration negatively correlated with BMD (r=-0.392, p=0.004) and LBM-BIA (r=-0.272, p=0.047). CRP was positively associated with BF% assessed both by DEXA (r=0.276, p=0.035) and BIA (r=0.306, p=0.025). MMT-8 score negatively correlated with ECM/BCM ratio (r=-0.385, p=0.006), and physical activity (HAP) negatively correlated with BF%>DEXA (r=-0.292, p=0.032).

Conclusions: Compared to healthy age-/sex-matched individuals we found significant negative changes in body composition of our IIM patients, which are associated with their disease duration, inflammatory status, skeletal muscle involvement, and physical activity, and could reflect their impaired nutritional status and predispositions for physical exercise, aerobic fitness and performance.

AB0672 RISK FACTORS AND TREATMENT OF RECURRENT DERMATOMYOSITIS AND POLYMYOSITIS

S. Yamada, H. Yamashita, Y. Takahashi, H. Kaneko. *Division of Rheumatic Diseases, National Center for Global Health and Medicine, Tokyo, Japan*

Background: Patients with polymyositis (PM) and dermatomyositis (DM) often have repeated exacerbations of myositis. Sometimes immunosuppressive agents are added to induce remission in steroid-resistant cases, with steroid reduction in maintenance therapy, and to prevent exacerbations. However, comparative clinical studies are difficult to conduct and the appropriate immunosuppressive agents are not known [1–2]. There are also no studies of the treatment in recurrent cases with repeated relapses.

Objectives: In this study, we defined myositis that relapses more than once as recurrent myositis and examined its risk factors and re-induction treatments.

Methods: Patients from our PM and DM database who were hospitalised between January 1991 and September 2016 were reviewed. We included only patients who had been followed for more than 1 year.

Results: There were 14 cases (13.1%) with recurrent myositis. The average observation period was 11.3 and 8.0 years in the relapsing and non-relapsing groups, respectively (P =0.18), and the average ages at onset were 46.2 and 55.0 years (P =0.17). The myositis relapse rate was significantly higher in the anti-aminoacyl-tRNA synthetase (ARS) antibody-positive group than in the group with other antibodies [8/24 (33.3%) *vs.* 0/14 (0.0%) cases; P =0.02]. The myositis relapse rate was significantly lower in the group in which one more immunosuppressive agent was combined in the initial treatment than in the group without any [3/53 (5.7%) *vs.* 11/48 (22.9%) cases; P =0.02]. The myositis relapse rate did not differ significantly between DM and PM, men and women, the groups with or without malignancy, the groups with or without interstitial pneumonia (IP), and groups with or without the following initial findings: fever, joint pain, dysphagia, constipation, bedridden, muscle pain, distal muscle weakness, cutaneous symptoms (*e.g.*, heliotrope rash, Gottron's sign, V signs, Raynaud's phenomenon, skin ulcers and necrosis, and itching sensation), cardiac complications, hypertension, diabetes, and smoking history. There was no significant difference in the serum creatine kinase and C-reactive protein between the relapse and no-relapse groups. Only 3 of 14 cases (21.4%) had successful re-remission induced and were on maintenance therapy. In two of these cases, two immunosuppressive agents other than glucocorticoid were added: tacrolimus and methotrexate in one and tacrolimus and mycophenolate mofetil in the other. The other 11 patients were treatment-resistant.

Conclusions: The presence of anti-ARS-antibody and initial treatment with glucocorticoid only (without any other immunosuppressive agent) were the only two risk factors for recurrent myositis; none of the other factors examined were significant. Recurrent myositis is often treatment-resistant; if one immunosuppressive agent cannot introduce remission, it is worth trying two agents.

AB0673 TESTING FOR ANTIBODIES SPECIFIC TO FIBRILLARIN (U3 RNP) SHOWS ADDED VALUE FOR DIAGNOSIS OF SYSTEMIC SCLEROSIS

I. Gehring[1], S. Sjölander[2], P. Höpfl[1], S. Swiniarski[1], L. Vinderslev Iversen[3], G. Gallo[4]. *[1]Thermo Fisher Scientific, Freiburg, Germany; [2]Thermo Fisher Scientific, Uppsala, Sweden; [3]Department of Dermatology, Aarhus University Hospital, Aarhus, Denmark; [4]Thermo Fisher Scientific, Milano, Italy*

Background: Systemic sclerosis (SSc) is a heterogeneous and often systemic autoimmune disorder characterised by specific autoantibody subsets. The disease is associated with anti-nuclear antibodies (ANA) and the detection of each of the autoantibodies is useful during diagnosis. Most SSc patients are positive for anti-centromere or anti-Scl70 antibodies. The presence of more rare antibodies to, e.g. Fibrillarin (U3 RNP), RNA-polymerase III and PM-Scl are often indicative of a systemic or a limited skin involvement.

Objectives: In this in-house study the prevalence, and clinical sensitivity and /specificity of anti-Fibrillarin antibodies in a subset of patients diagnosed with SSc was investigated. The major aim was to find out whether Fibrillarin testing would identify patients which are negative for standard parameters and therefore add value forin the diagnosticis workup for patients with suspected SSc.

Methods: Sera from 187 SSc patients, 53 blood donors and 177 disease controls were analysed for the presence of antibodies to CENP, Scl-70s, PM-Scl, RNA Pol III and Fibrillarin using the EliA platform (Thermo Fisher Scientific, Freiburg, Germany).

Results: In 149 out of the 187 patients one or more of the tested parameters were detected. Fibrillarin was identified in 7 out of the 149 patients including 6 solely positive for Fibrillarin. Overall sensitivity within this study is 79,68% with an overall specificity of 92,17%; for Fibrillarin sensitivity of 3,74% and specificity of 98,70% was shown within this cohort.

Conclusions: Increased diagnostic sensitivity was shown in this cohort of 187 patients with SSc by adding the analysis of antibodies against Fibrillarin. Testing allowed additional identification of 6 SSc patients which correlates to an increase of 3,74% in sensitivity.

AB0674 YKL-40 IS THE BIOMARKER FOR THE PRESENCE OF INTERSTITIAL PNEUMONIA AND PULMONARY ARTERIAL HYPERTENSION IN SYSTEMIC SCLEROSIS

T. Furukawa, K. Matsui, M. Kitano, Y. Yokoyama, M. Sekiguti, N. Azuma, H. Sano. *Division of Rheumatology, Department of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Japan*

Background: SSc is a refractory of connective tissue disease that causes fibrosis of the skin and various organs. Recently, it is attention to 2013 ACR/EULAR classification criteria because can diagnose early phase before causing skin involvement in SSc. Thus, we considered that YKL-40 which is known to be involved in inflammation, tissue fibrosis and remodeling, is useful marker for evaluating early diagnosis and complications in SSc. YKL-40 is a chitinase-like protein and expressed in the synovial membrane and cartilage fibroblast cells in Rheumatoid Arthritis. Several cases of relationship between SSc and YKL-40 have been reported overseas, but it is unclear. Our report is the first in Japan.

Objectives: We investigated serum YKL-40 levels and examined immunohistochemistry (IHC) with YKL-40 of cutaneous tissue in SSc patients. To clarify YKL-40 is useful biomarker in early diagnosis in the presence or absence of complications in Japanese SSc patients.

Methods: Between August 2014 and March 2016, we treated 57 SSc patients in our department. We excluded infection, malignant disease, and other active complication may be a factor that increases YKL-40 levels. The patients were divided into 4 groups depending on whether suffered IP or PAH, which can affect the prognosis. Group1 (n=30) did not suffer from either IP or PAH, Group2 (n=12) suffered from IP, Group3 (n=7) suffered from PAH, and Group4 (n=8) suffered from both IP and PAH. YKL-40 levels in 4 groups and a control group of healthy individuals (n=13) were measured by ELISA. And age percentile strata of YKL-40 were calculated because serum YKL-40 levels have reported to rise with age; YKL-40 age percentile = $100/(1 + (\text{Serum YKL-40 levels}^{-3}) \times (1.062^{\text{age}}) \times 5000)$. IHC with YKL-40 of skin biopsy tissue from patients and controls was performed to investigate YKL-40 expression.

Results: YKL-40 age percentile were elevated in Group1 compared to controls (42.0±24.5 vs 21.8±15.6), and were elevated due to complications (Group2, 3, 4: 61.8±21.4, 88.9±8.2, 94.4±8.7), with a tendency for PAH to cause greater elevation. There was no significant difference between Group3 and Group4, and

a significant difference was found between the other groups ($p<0.05$). IHC with YKL-40 revealed staining of the vessels in the superficial dermis in SSc and normal skin remained unstained. The ROC curve for PAH showed an AUC=0.959, and the most valid cut-off levels of YKL-40 age percentile was 85.2 (sensitivity 86.7% and specificity 92.8%).

Conclusions: Our report is the first report of IHC with YKL-40 in SSc. IHC suggest that YKL-40 may be further elevated by angiogenesis caused by microcirculatory damage in SSc. Our results suggest that YKL-40 may be very useful biomarker for diagnosing SSc and complications associated with microvascular lesions.

AB0675 ANTI-MDA5 POSITIVE DERMATOMYOSITIS: AN EMERGING ENTITY

V. Ortiz-Santamaria, A. Ponce, N. Busquets, N. Del Castillo, X. Surís.
Rheumatology Unit, Granollers General Hospital, Granollers. Barcelona, Spain

Background: Hypo or amyopathic dermatomyositis (DM) represent about 20% of the classic DM. Melanoma differentiation-associated gene 5 antibody or anti-MDA5 antibody, formerly known as anti-CADM140 antibody, has been reported in the last decade. This antibody is detected in more than 50% of patients with hypo or amyopathic DM and it has specific features such as the presence of ulcerative vascular lesions and rapid progression of the interstitial lung disease.

Objectives: To report anti-MDA5 positive DM cases diagnosed at a university county hospital, between 2012 and 2016.

Methods: Design: Retrospective descriptive study. Location: University county hospital. Reference area: ?350.000 inhabitants. Clinical manifestations, analytical results, diagnostic approach, treatment administered and follow-up have been exposed.

Results: We report four anti-MDA5 positive DM with a mean age at diagnosis of 54 years (35–77). Caucasian origin in 2 men and Maghreb origin in 2 women. They had no relevant medical history neither neoproliferative process was detected.

ANA were negative and CK values were normal in all the cases. Nailfold capillaroscopy was characteristic of DM pattern. Case B did not present cutaneous manifestations and he was diagnosed as anti-MDA5 DM after his death.

Discussion: B and C cases showed abnormal heart rhythm that could be related to myocardial involvement, as suggested in a recent publication of anti-MDA5 DM (1). In case C, sinus tachycardia was resolved with the clinical response to treatment.

In the literature reviewed, anti-MDA5 positive DM has been reported as a dermato-pulmonary syndrome, but probably the clinical profile of these patients remains to be defined. In our cases, one of them did not present skin lesions and another case did not develop pulmonary involvement 18 months after the diagnosis.

Conclusions: Keep in mind anti-MDA5 antibody in patients with cutaneous manifestations of DM with vasculopathy lesions, minimal or absent muscular disease, heart rhythm abnormalities not explained by other causes and/or rapidly progressive pulmonary involvement.

Anti-MDA5 positive DM may have a poor response to treatment and fatal outcome. It remains to be seen if early diagnosis could improve the life expectancy of these patients.

Abstract AB0675 – Table 1

	A	B	C	D
Sex	Female	Male	Female	Male
Age at disease onset	43	77	35	62

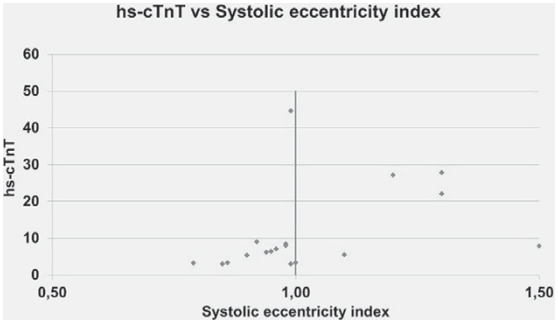
AB0676 RELATIONSHIP BETWEEN BIOLOGICAL BIOMARKERS AND CHANGES IN RIGHT VENTRICLE THAT PRECEDE PULMONARY HYPERTENSION IN PATIENTS WITH SYSTEMIC SCLEROSIS



V. Márquez Fernández [1], C. Soto [1], A. Robles [1], A. Noblejas [1], E. Mártínez [1], G. Gúzman [2], C. Busca [1], F. Arnalich [1], J.J. Ríos [1]. *[1] Internal Medicine; [2] Cardiology, Hospital Universitario la Paz, Madrid, Spain*

Background: A higher prevalence of Pulmonary Hypertension (HP) has been described in patients with Systemic Sclerosis (ES) diagnosis, so this fact significantly overshadows the prognosis, since it leads to the failure of the right ventricle (RV). In this context, it could be very useful to identify ES patients who are at greater risk of developing PH in the future to make an early diagnosis of this complication, and prescribing an early theraphy to improve their prognosis.

Objectives: The purpose of this study is to investigate if certain fibrosis, inflammation and vasculopathy biomarkers could be associated to early functional changes in RV, assessed by echocardiography and cardiac nuclear magnetic resonance (MRI) in ES patients.

Methods: A cross-sectional study was performed on a cohort of ES patients diagnosed according to the LeRoy modified criteria, who were being following-up in the Systemic Autoimmune Diseases Unit of the Internal Medicine Service of La Paz Universitary Hospital. Serum levels of inflammation (IL-13, IL-6, TNF alpha), vasculopathy (VEGF), fibrosis biological markers (endoglin, PDRFR, TGFB1, TGFB2, TGFB3) and cardiac biomarkers (NT-proBNP, High sensitivity T troponin) were determinated as well as hemodynamic and cardiac morphological variables, were mesured by transthoracic echocardiography (systolic and diastolic eccentricity index, E/E' ratio, E/A, pulmonary artery systolic pressure, RV thickness) and cardiac MRI (Mean pulmonary artery velocity). We investigated how many patients had these markers elevated and how many of them had hemodynamic and morphological cardiac alterated measurements.

Results: Twenty patients with a diagnosis of ES (18 females/2 males) aged between 41 and 77 years, with a mean of 56 years, were included. A control group of 9 patients with similar demographic characteristics was included. ES subjets had higher levels of PDGFR (fibrosis marke) compared to the control group. In addition, in the group of ES patients, two statistically significant associations were observed: troponin T levels (hs-cTnT), endoglin and TGFB2 had higher leves in pacients with a systolic eccentricity index >1; a negative correlation was evidenciated between levels of NT-proBNP and the mean pulmonary artery velocity measurement (VELAP).

Conclusions: Hs-cTnT, Endoglin and TGF beta are biomarkers that could appear

elevated in patients with systolic eccentricity index >1. NT-proBNP is elevated in patients with decreased VELAP. This study demonstrates the association between certain cardiac biomarkers, fibrosis and vasculopathy peptids and early finding suggesting cardiac remodeling that occurs in some ES patients, which may help to predict the development of PH in those patients.

AB0677 INDIVIDUAL IMMUNOLOGICAL PREDICTORSOF THE RISK OF LUNG DAMAGE IN PATIENTS WITH SYSTEMIC SCLEROSIS

V. Hayevska, V. Chopyak, V. Hayevskyy on behalf of Chopyak Valentyna, Hayevskyy Volodymyr. *Department of clinical immunology and allergology, Lviv National Medical University named by Danylo Halytskyy, Lviv, Ukraine*

Background: A significant role in the formation and development of systemic sclerosis (SSc) belongs to immunogenetic factors and immunopathological mechanisms, so nowadays become important to find immunological predictors of early diagnosis of the disease. An urgent task is timely diagnosing the pulmonary complications as the main causes of high mortality and appointment of adequate therapy and objective assessment of its effectiveness.
Objectives: The main purpose was to develop a personal way of forecasting the risk of damage of the lungs, including its subtype – pneumofibrosis (PF) and pulmonary hypertension (PH) in patients with SSc.
Methods: To address this goal, the following studies performed: clinical, general laboratory, instrumental, immunological, molecular genetics, statistical methods. Adequacy and reliability of the results of mathematical model of the risk of damage the lungs were using criteria Wald and Xi-square. The results show that our model is correct with a probability of error less than 1% (p=0.001).
Results: We found that among the analyzed complex interrelated factors in the development of lung damage in patients with SSc significantly influenced: the duration of the disease, miRNA29b, expression levels in the blood concentration of IL17 in serum and blood, neutrophil phagocytic index t that we include in the predictive model.
We know that the most significant complications associated with damage to their lungs are pneumofibrosis and pulmonary hypertension, which threatened the rapid development of respiratory failure and a high mortality of these patients. In this regard analyzed immunological and molecular genetic parameters of patients with SSc depending on the development of PF and LH.
We found that among the complex of interrelated factors of the development of PF in patients with SSc significantly influenced the following factors: patient age, miRNA 29b, MCP-1, IFN-γ, TGF-β in serum, oxidative indicator “explosion” of neutrophils, which we have included in the predictive model.
At the same time, the development of PH in patients with SSc significantly affected other clinical and immunological factors: patient age, levels of endothelin-1, IL17 in serum, the number of CD4 + CD25 + Fox P3 + -lymphocytes, CD3 +/CDHLA-DR + -lymphocytes, CD4 + IL17 + -lymphocytes in peripheral blood, which we have included the following predictive model.
Conclusions: The application withdrawn prognostic clinical and immunological and molecular genetic criteria of lungs damage (pulmonary hypertension and pneumofibrosis) will enable medical practitioners to verify early visceral lesions in patients with SSc in time and justified the appointment of basic therapy.

AB0678 ACCELERATED ACTIVATION OF 25-HYDROXYVITAMIN D TO 1,25-DIHYDROXYVITAMIN D IN SYSTEMIC SCLEROSIS PATIENTS- A RETROSPECTIVE STUDY

V.R. Mehta[1], J.F. Farrell[2], R. Peredo[1], L.S. Shapiro[3]. *[1]Rheumatology, Albany Medical Center; [2]Rheumatology, Albany College of Pharmacy and Health Sciences; [3]Rheumatology, Steffens Scleroderma Center, Albany, United States*

Background: There have been multiple reports of low vitamin D in Systemic Sclerosis (1, 2). The majority of these reports only measured 25-hydroxyvitamin D (calcifediol) and not 1,25-dihydroxyvitamin D (calcitriol). In our clinical observation, we noted that there may be a population of patients with low calcifediol but normal or high calcitriol.
Objectives: We aim to evaluate the frequency of normal or high calcitriol level in systemic sclerosis patient with low calcifediol levels.
Methods: We performed a retrospective analysis using data collected from a large private practice. We collected data from systemic sclerosis patients who had calcifediol and calcitriol levels ordered between January 2014 and January 2017, patients with sarcoidosis overlap were excluded.
Results: We identified 90 scleroderma patients with documented calcifediol and calcitriol levels and no history of sarcoidosis. Mean calcifediol level was 32.7 ng/mL (SD 20.2) and mean calcitriol level was 60.9 pg/mL (SD 27.6). Total of 42 patients were identified as having calcifediol level of less than 30 (normal >30), only 1 of these patients had calcitriol levels below 10 pg/mL (normal >10) and 6 patients had calcitriol levels above 75 pg/mL. Twenty-three out of 41 patients who had low calcifediol but high calcitriol level also had a CT chest with no diagnostic findings suggestive of sarcoidosis.
Conclusions: Our study suggests that while low calcifediol levels are common in systemic sclerosis patients, not all patients are truly vitamin D deficient and a calcitriol level should be checked before supplementation is initiated. There is some documented evidence of sarcoid and scleroderma overlap at greater than expected frequency which is under recognized and elevated calcitriol level in a systemic sclerosis patient should prompt further evaluation for sarcoidosis (3). We have identified a population of scleroderma patients with low calcifediol, elevated calcitriol level, but no evidence of sarcoidosis. Based on this observation we are planning a prospective study to investigate this further.

AB0679 THE CLINICAL VALUE OF NAILFOLD CAPILLAROSCOPY IN THE EARLY DIAGNOSIS OF SYSTEMIC SCLEROSIS

W. Gao, G. Zhang, L. Zhang, K. Xu, B. Li, Y. Yang, M. Yan. *Rheumatology, Shanxi Dayi Hospital, Shanxi Academy of Medical Sciences, taiyuan, China*

Background: Vascular changes was early pathological changes of SSc, gradually appearing with irreversible fibrosis of the skin and internal organs. Early diagnosis and assessment of the development and efficacy timely, could improve survival in patients with SSc.
Objectives: To assess the value of nailfold capillaroscopy in the early diagnosis of systemic sclerosis (SSc).
Methods: 60 patients with SSc and 55 patients with other connective tissue diseases.Data were extracted on clinical and laboratory parameters.2013 ACR/EULAR classification criteria and 1980 ACR criteria for SSc were evaluated.
Results: The sensitivity of the 2013 criteria was 91.7% compared to 56.7% for the 1980 criteria ($P<0.001$). The specifiity of two criteria was no significant difference. This sensitivity of the 2013 criteria was higher compared to the 1980 criteria among those with lcSSc (95.5% versus 50%).The pattern was consistent among those with disease duration <3 years (90.5% versus 57.1%,$P<0.05$),and disease duration ≥3 years (92.3% versus 56.4%, $P<0.05$). The sensitivity and specificity of nailfold capillaroscopy to determine SSc were 86.7% and 43.6%. Patients not fulfilling the two classification criteria were met the very early diagnosis of systemic sclerosishe, and often suffering from RP, and had an SSc pattern on nailfold capillaroscopy.
Conclusions: The sensitivity of 2013 ACR/ EULAR classification criteria was higher compared with 1980 ACR classification criteria.The specificity of two classification criteria was no significant difference. This sensitivity of two criteria was higher among those with lcSSc and short disease duration.Scleroderma pattern were significantly associated with the development of systemic sclerosis.

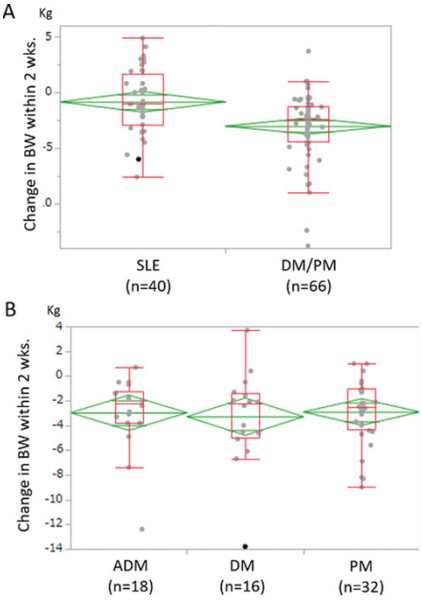
AB0680 ANALYSIS THE CAUSES AND COUNTERMEASURES OF IGNORING SWALLOWING DYSFUNCTION IN PATIENTS WITH POLYMYOSITIS AND DERMATOMYOSITIS



Y. Wen, Q. MinLi, L. Yan. *Department of Rheumatology, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Background: The patients with Polymyositis and Dermatomyositis always ignored swallowing dysfunction and most of them eventually had no enough knowledge of this. For this situation, to find out the reasons and take appropriate measures was necessary.
Objectives: To analyze the causes of ignoring swallowing dysfunction in patients with Polymyositis and Dermatomyositis and to explore the corresponding preventive measures.
Methods: The clinical data of 47 patients with Polymyositis and Dermatomyositis in hospital from September 2012 to December 2013 was analyzed retrospectively. The swallowing function was evaluated by the water swallow test, and the patients' knowledge of swallowing dysfunction was surveyed.
Results: Only 2 patients complained of choking during swallowing, with ignorance rate of 95.74%. Positive rate was 40.43% in water swallow test, of which grade II dysphagia proposition was 58%, III grade was 32%, IV grade was 10%. 100% of patients believed that sternal obstruction or dysphagia as swallowing dysfunction. 89.36% of patients didn't think drinking water with bucking as swallowing dysfunction.
Conclusions: The symptoms of limb weakness in patients with Polymyositis and Dermatomyositis may obscure the presence of dysphagia. In addition, the patients do not have enough knowledge about dysphagia that to neglect the swallowing dysfunction. To improve detection rate of swallowing dysfunction in patients with Polymyositis and Dermatomyositis, earching detailed history by listing dysphagia performance and providing water swallow test is necessary.

AB0681 HIDDEN GENERALIZED EDEMA IN INFLAMMATORY MYOPATHY; GENERALIZED EDEMA IS AN UNRECOGNIZED CLINICAL FEATURE OF MYOSITIS?

Y. Namiki[1], K. Kurasawa[2], A. Tanaka[2], R. Yamazaki[1], H. Okada[2], S. Arai[2], T. Owada[1], R. Maezawa[1], M. Arima[1]. *[1]Department of Rheumatology, Dokkyo Medical University, Mibu, Tochigi; [2]Department of Rheumatology, Dokkyo Medical University, Mibu, Tochigi, Japan*

Background: Dermatomyositis (DM)/ polymyoitis (PM) are systemic diseases characterized by muscle inflammation, which shows varieties of clinical symptoms and signs. We have experienced cases of DM/PM with generalized edema as reported previously by others (1). Moreover, we found that there were many myositis patients who lost their body weight (BW) after starting of high dose glucocorticoid (GC) therapy. Thus, we hypothesized that hidden generalized edema is a characteristic clinical feature of myositis.
Objectives: To determine whether generalized edema is a hidden clinical feature of myositis. If so, what myositis patients have the feature.
Methods: The study was a retrospective observation study. The subjects were consecutive 67 of DM/PM and 53 of SLE patients who diseases for the first time, admitted our department from April 2007 to September 2016 and received immunosuppressive therapy including over 30mg/day GC. The patients were excluded who had cardiogenic or nephrogenic edema or whose BW data was not available. To detect hidden generalized edema caused by inflammation, we examined the change in BW within 2 weeks after starting immunosuppressive therapy. The clinical features of DM/PM patients with/without BW change were examined through reviewing medical record.
Results: The included subjects were DM/PM 66 patients (M/F; 18/48 with a mean age of 59.4 y.) and SLE 40 patients (M/F;14/26 with a mean age of 49.8 y.). The body weight of DM/PM and SLE were 56.4±14.0 and 54.7±10.9 kg, respectively. Decrease in BW within 2weeks after starting the therapy were 3.02±2.99kg of DM/PM and 0.85±2.87 kg of SLE, which was larger in DM/PM compared to SLE (Fig A). The numbers of patients who lost BW more than 2kg within the 2 weeks were 42 in DM/PM (64%) and 14 in SLE (35%).
Serum albumin levels were slightly decreased by 0.18 g/ dl (0.06 to 0.30; 95% CI) in DM/PM, while no significant change was detected in SLE.
In myositis, change in BW was similar among DM, amyopathic DM (ADM) and PM (Fig.B). Moreover, no differences were found in the change of BW between patients with and without male sex, malignancy, interstitial pneumonia, anti-ARS Ab and anti-MDA5Ab. Additionally, between patients with and without BW loss more than 2kg, no differences were found in age, serum TP, Alb and CRP levels before and after treatment and prognosis.

Conclusions: DM/PM patients lose BW by immunosuppressive therapy including GC, which indicates the existence of hidden generalized edema that might be a characteristic clinical feature in inflammatory myopathy.

AB0682 THE INCIDENCE RATE OF INFLAMMATORY MYOPATHIES IN SLOVENIA

Ž. Rotar[1], A. Hočevar[1], M. Krošel[1], S. Praprotnik[1], M. Tomšič[1,2]. *[1]Department of Rheumatology, University Medical Centre Ljubljana; [2]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia*

Background: Annual incidence rates of inflammatory myopathies (IM) vary widely from 1.16–19.0 per 10^6 of adults.1 Our aim was to, for the first time, determine the incidence rate of IM in our population.
Objectives: To determine the incidence rate of IM in our population.
Methods: We retrospectively collected incident cases of IM from 1 January 2005 to 31 December 2016 at our department of rheumatology which is a part of an integrated secondary/tertiary university teaching hospital that is the only referral center for two well defined regions representing roughly a third of the national adult population. Tertiary cases are referred to our department from the entire country. We identified the cases by searching the electronic patient records (PRs) for ICD-10 codes M05, M33–35, M60, G73.7, G72.4. The paper and electronic PRs were scrutinized to assess clinical, laboratory and histopathological data. Descriptive statistics was used to describe our group of patients. The adult population size of the two regions served by our department was obtained from the national statistics institute database. The annual incidence rate for IM was then calculated.
Results: During the 12-year observation period we identified 117 new cases of IM from a well-defined adult white Caucasian population aged 18 or above. 38 cases were excluded from analyses since they were referred to our department from outside the two regions we serve on the secondary and tertiary level. Thus, we analyzed 79 cases of IM (63% female; median (IQR) age 67 (55–75) years; 44% ever smokers). The median time to diagnosis was 5 (IQR 3–12) months. We diagnosed 29% patients with dermatomyositis, 25% with anti-synthetase syndrome, 18% with polymyositis, 9% with statin induced necrotizing autoimmune myopathy, 9% with concomitant myositis as a part of connective tissue disease, 6% with paraneoplastic myositis, and 4% with undifferentiated myositis. The IM cases were most often diagnosed in the summer months (32.9%), followed

by spring (24.1%), fall (22.8%), and winter (20.3%). The clinical and laboratory characteristics at presentation are shown in Table 1. Muscle biopsy was performed in 93% of patients. Notably, patients with swallowing difficulties had more commonly had Raynaud phenomenon (RR 3.7 (95% CI 1.4–9.4), p=0.008).

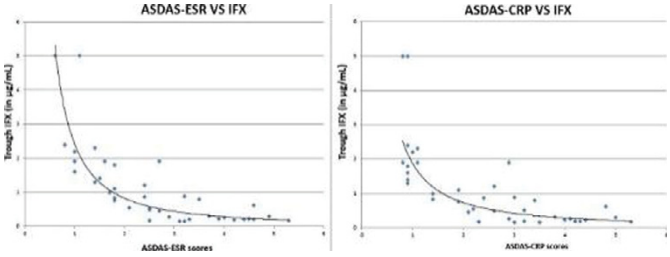
Spondyloarthritis - treatment



AB0683 TROUGH INFLIXIMAB LEVELS AND ANTI-INFLIXIMAB ANTIBODIES IN SPONDYLOARTHRITIS PATIENTS ON TREATMENT WITH LOW DOSE INFLIXIMAB: A SINGLE CENTRE CROSS-SECTIONAL STUDY

A. Patil[1], S.K. Upadhyaya[1], R. Dawar[2], B. Vaishnav[1], N. Dadhaniya[1], S.J. Gupta[1], R. Handa[1]. *[1]Rheumatology; [2]Microbiology, Indraprastha Apollo Hospitals, Delhi, India*

Background: Infliximab (IFX) is an anti-TNF, chimeric, monoclonal antibody approved for use in refractory spondyloarthritis (SpA). Studies done in patients with Rheumatoid arthritis[1] and Inflammatory bowel disease[2] have demonstrated the clinical utility of the measurement of serum trough IFX and antibodies to IFX (ATI). In India, many centres including ours use IFX at lower doses of 3–5 mg/kg and on demand IFX treatment without the use of the loading dose IFX in SpA patients[3]. Data on the utility of measuring trough IFX and ATI levels and their correlation with disease activity in such group of patients is lacking.
Objectives: To evaluate the co-relation between trough Infliximab levels and disease activity measures, viz ASDAS ESR and ASDAS CRP in SpA patients on low dose IFX therapy
To compare the mean ASDAS- ESR/CRP scores between ATI positive and ATI negative patients
Methods: Thirty-nine adult spondyloarthrtitis patients in the age group of 18–70 years, meeting the ASAAS classification criteria for peripheral and/or axial spondyloarthritis were recruited into the study. The inclusion criteria required the patients to have had received three or more infusions of IFX at 3–5 mg/kg/dose over the past 6 to 9 months. Blood samples were collected between two to three months after the previous IFX infusion for the measurement of the ATI and the trough IFX levels using the Matriks Biotek Shikari Q-ATI ELISA and Q-IFLIXI ELISA kits respectively. At the same time, disease activity of the patients was quantitated using ASDAS ESR and ASDAS CRP scores.
Correlation between the ASDAS scores and the trough IFX levels was analysed by Pearson's product moment correlation assay. The difference in mean trough IFX and ASDAS scores between the ATI positive and ATI negative patients were assessed using Welch two sample t-test.
Results: There was a moderately significant negative correlation between the trough IFX levels and the ASDAS-ESR ($r = -0.69$, $p<0.001$), ASDAS-CRP scores ($r = -0.67$, $p<0.001$) (Fig 1). ATI positive patients in comparison to ATI negative, had significantly higher ASDAS ESR and ASDAS CRP scores (Table 1).

Table 1. Table showing differences in ASDAS scores between ATI positive and negative patients

	ATI +ve patients	ATI –ve patients	P value
Mean ASDAS ESR	3.13	1.56	<0.001
Mean ASDAS CRP	3.06	1.45	<0.001

Conclusions: SpA patients from India on low dose, on demand IFX therapy, have both the trough IFX and ATI correlate significantly with the measures of disease activity. Therefore, these may be used in addition to clinical activity scores for a more cost effective on demand IFX therapy in SpA patients, especially in an expense constrained country like India.

AB0684 CLINICAL RESPONSE AND RADIOGRAPHIC PROGRESSION IN ANKYLOSING SPONDYLITIS PATIENTS UNDER ANTI-TNF THERAPY: IMPACT OF HIP INVOLVEMENT

A.Y. Shimabuco[1], F.M. Milanez[1], J.C.B. Moraes[1], G.V. Perico[2], C.R. Gonçalves[1], M.G. Waisberg[1], P.D. Sampaio-barros[1], C.G.S. Saad[1]. *[1]Rheumatology Division, Faculdade de Medicina da Universidade de São Paulo, São Paulo; [2]Unidade Radiológica Criciúma, Criciuma, Brazil*

Background: Hip involvement is considered an important prognostic factor associated with radiographic progression in ankylosing spondylitis (AS) patients. However, there are no studies regarding hip involvement impact on clinical response and radiographic progression in AS patients under anti-TNF therapy.
Objectives: Compare clinical and radiographic progression in AS patients receiving anti-TNF therapy with and without moderate-severe hip involvement.
Methods: Forty-seven AS patients referred to receive anti-TNF treatment were included and classified according to baseline hip involvement based on Bath Ankylosing Spondylitis Radiology Hip Index (BASRI-Hip): none-minimal hip disease (hip grade <3) or moderate-severe disease (hip grade ≥3). Demographic data, presence of HLA-B27, extra-articular involvement, DMARD and NSAID use, clinical and laboratorial disease parameters (BASDAI, BASMI, BASFI, ASQol, mSASSS and inflammatory markers) were assessed at baseline and two years after anti-TNF treatment.
Results: Thirty-four (72.3%) patients were classified as none-minimal hip disease and 13 (27.7%) as moderate-severe hip involvement. Both groups were similar at baseline considering age, HLA-B27, extra-articular involvement and comedication use. Laboratorial markers (ESR, CRP) and disease parameters (BASDAI, BASFI and mSASSS) showed no difference at baseline. Moderate-severe group had longer disease (10.0±7.6 vs. 14.9±8.6, P=0.002, years), higher BASMI (3.8±2.4 vs. 6.5±2.5, P=0.002) and lower ASQoL (13.7±4.4 vs. 9.9±4.9, P=0.007). After two-years of anti-TNF therapy, both groups presented similar BASDAI response (delta BASDAI, p=0.134; final BASDAI, p=0.324) and an increase in mSASSS [no-minimal involvement: 13.6±18.3 vs. 16.1±19.4, P<0.001); moderate-severe involvement: 21.7±19.9 vs. 28.6±18.5, P=0.003]. At final evaluation patients with moderate-severe hip involvement presented higher mSASSS (28.6±18.5 vs. 16.1±19.4, P=0.02), despite similar delta BASDAI and final BASDAI.
Conclusions: Our study provides evidence that hip involvement did not impact on clinical response in AS patients under anti-TNF therapy but may have an effect on radiographic progression of these patients.

AB0685 SECUKINUMAB PROVIDES SUSTAINED IMPROVEMENTS IN WORK PRODUCTIVITY AND HEALTH RELATED QUALITY OF LIFE IN PATIENTS WITH ANKYLOSING SPONDYLITIS: LONG-TERM RESULTS FROM MEASURE 1 AND MEASURE 2

A. Deodhar[1], P.G. Conaghan[2], V. Strand[3], A. Boonen[4], G. Ferraccioli[5], F. Van den Bosch[6], V. Bhosekar[7], B. Porter[7], K. Gandhi[7], S. Jugl[8]. [1]*Oregon Health & Science University, Portland, Oregon, United States;* [2]*University of Leeds, Leeds, United Kingdom;* [3]*Stanford University School of Medicine, Palo Alto, CA, United States;* [4]*Maastricht University Medical Centre, Maastricht, Netherlands;* [5]*Catholic University of the Sacred Heart, Rome, Italy;* [6]*Ghent University Hospital, Ghent, Belgium;* [7]*Novartis Pharmaceuticals Corporation, East Hanover, United States;* [8]*Novartis Pharma AG, Basel, Switzerland*

Background: Patients (pts) with ankylosing spondylitis (AS) experience significant restrictions in work productivity and health-related quality of life (HRQoL). Secukinumab (SEC) demonstrated rapid improvements in signs, symptoms and physical functioning in pts with AS.[1]
Objectives: To assess whether the beneficial effects of SEC on AS signs and symptoms were reflected in improvements in work productivity and HRQoL in the overall population and in TNF inhibitor (TNF)-naïve pts and pts with an inadequate response or intolerance to TNF inhibitors (TNF-IR) for up to 52 weeks (wks) in MEASURE 2 and 104 wks in MEASURE 1.
Methods: 371 and 219 pts were randomized to SEC or placebo (PBO) in MEASURE 1 (10 mg/kg IV followed by 150 or 75 mg SC) and MEASURE 2 (150 or 75 mg SC), respectively. At Wk 16, PBO pts were re-randomized to SEC 150 or 75 mg SC (PBO pts with ASAS20 response at Wk 16 were switched to SEC at Wk 24 in MEASURE 1). Productivity was measured using the Work Productivity and Activity Impairment-General Health (WPAI-GH) questionnaire, which includes questions to assess absenteeism, presenteeism and overall work productivity impairment in employed pts, and general activity impairment in all pts during the preceding 7 days (0–100%). HRQoL was assessed with the ASQoL questionnaire (0–18 points). Across both studies, approximately 69% of pts were TNF-naïve and 31% were TNF-IR. Observed data are presented from the full analysis set and in subgroups stratified by prior TNF exposure. Only data with the approved dose (SEC 150 mg) are shown.

Table. WPAI-GH and ASQoL outcomes in MEASURE 1 and MEASURE 2 through Week 104

	MEASURE 1			MEASURE 2[a]		
	Overall	TNF-naive	TNF-IR	Overall	TNF-naive	TNF-IR
WPAI GH[b] (change from BL)						
Absenteeism (% work time missed due to health)[c]						
Wk 52	−2.1 (n=60)	−3.5 (n=47)	3.0 (n=13)	−4.9 (n=38)	−12.8 (n=23)	7.1 (n=15)
Wk 104	1.3 (n=49)	0.2 (n=41)	6.8 (n=8)	–	–	–
Presenteeism (% impairment while working due to health)[c]						
Wk 52	−20.2 (n=57)	−21.6 (n=45)	−14.9 (n=12)	−19.2 (n=37)	−25.5 (n=22)	−10.0 (n=15)
Wk 104	−25.1 (n=49)	−27.8 (n=41)	−11.3 (n=8)	–	–	–
Work Productivity (% overall work impairment due to health)[c]						
Wk 52	−21.2 (n=57)	−23.2 (n=45)	−13.8 (n=12)	−21.3 (n=37)	−29.5 (n=23)	−7.9 (n=14)
Wk 104	−23.0 (n=49)	−26.1 (n=41)	−6.9 (n=8)	–	–	–
Activity Impairment (% activity impairment due to health)[d]						
Wk 52	−25.4 (n=107)	−26.7 (n=83)	−20.8 (n=24)	−26.4 (n=61)	−30.5 (n=40)	−18.6 (n=21)
Wk 104	−27.3 (n=85)	−27.5 (n=67)	−26.7 (n=18)	–	–	–
ASQoL (change from BL)[c,e]						
Wk 52	−4.7 (n=109)	−5.0 (n=85)	−3.4 (n=24)	−5.2 (n=61)	−6.0 (n=40)	−3.7 (n=21)
Wk 104	−4.8 (n=86)	−5.0 (n=68)	−4.1 (n=18)	–	–	–

[a] WPAI-GH and ASQoL were not assessed at Week 104 of MEASURE 2; [b] In all categories, higher scores indicate higher impact on patients, employers, and society; a decrease from baseline represents improvement; [c] Assessed in 'employed' subjects only; [d] Assessed regardless of subject's employment status; [e] Higher scores represent greater impact on patients' QoL. A decrease from baseline represents improvement

BL, baseline; n, number of patients with sufficient data for evaluation; s, number of responders; SEC, secukinumab

Results: At baseline (BL), 77 of 125 and 45 of 72 randomized pts were employed and working in the SEC groups in MEASURE 1 and 2, respectively. Improvements in all WPAI domains were observed with SEC in the overall, TNF-naïve and TNF-IR populations at Wk 16 in both studies, and effects were generally sustained through Wks 52 and 104 (Table). In MEASURE 1, activity impairment in the total group improved by 49% and overall work productivity in those employed improved by 45% from BL at Wk 104. Improvements were 51%/49% in TNF-naïve and 42%/19% in TNF-IR pts, respectively. In MEASURE 2, activity impairment and work productivity improved by 43% and 40% vs BL, respectively at Wk 52; improvements in activity impairment/work productivity in TNF-naïve and TNF-IR pts were 49%/54% and 32%/16%, respectively. Similar responses were seen in the other WPAI scores across both studies. Early improvements in ASQoL were sustained through Wk 104 in MEASURE 1 and Wk 52 in MEASURE 2. At Wk 104 of MEASURE 1, ASQoL scores had improved by 48% vs. BL with SEC; improvements were 50% and 39% in TNF-naïve and TNF-IR pts, respectively.
Conclusions: SEC provides sustained improvements in work productivity and ASQoL for up to 104 wks among AS pts, regardless of prior TNF exposure.

AB0686 ASSOCIATION BETWEEN DRUG SERUM LEVELS AND DISEASE ACTIVITY IN ESPONDILOARTHRITIS PATIENTS TREATED WITH GOLIMUMAB

C. Redondo[1], A. Martínez[2], C. Plasencia[1], A. Jochems[2], D. Pascual-Salcedo[2], V. Navarro-Compán[1], M.G. Bonilla[1], I. Monjo[1], A. Balsa[1]. [1]*Rheumatology;* [2]*Immunology Unit, la Paz University Hospital, Madrid, Spain*

Background: Efficacy and safety of Golimumab (Glm) has been demonstrated for spondiloarthritis (SpA). Nonetheless, there is little data determining an association between an optimal drug levels concentration and the maintenance of a good control of disease activity. In Spa-Paz cohort we defined previously an optimal Glm levels concentration associated with a good clinical response.
Objectives: To investigate the association between serum levels of Glm, based on the optimal concentration defined previously in Spa-Paz cohort, and disease activity in a larger cohort of SpA.
Methods: Observational prospective SpA-Paz cohort study treated with Glm. Disease activity was measured by ASDAS and clinical improvement using Delta-ASDAS at baseline, 6 and 12 months of biologic therapy. ASDAS$<$2.1 was considered as low activity and clinically important improvement as Delta-ASDAS$\geq$1.1. Drug levels were measured by ELISA at 6 and 12 months of therapy and classified in 3 groups based on the optimal concentration range previously defined in our cohort: Group 1:$<$0.7 mg/L, group 2: 0.7–1.4 mg/L, group 3: $>$1.4 mg/L. At 12 months we made a LOCF analysis to include patient data (11 patients) with less than 12 months of treatment. We used the software Graph-Pad Prism 6 for statistical analysis.
Results: 46 patients of 79 with SpA treated with Glm were included in this study. The average age was 49 years old (age range 22–72 years old), 31 men (67%) and 15 women (33%). 22 patients (48%) were non-smokers and 13 (28%) active smokers. 25 (54%) were HLA-B27 positive. In total, 17 patients (37%) were classified in group 1, 16 (35%) in group 2 and 13 (28%) in group 3. At 12 months of therapy, most patients in low disease activity were in groups 2 and 3 but nevertheless, the majority of high disease activity patients were in group 3 (76% in groups 2 and 3 vs. 41% in group 1 with ASDAS$<$2.1; 24% in group 2 and 3 vs. 53% in group 1 with ASDAS$\geq$2.1; $p<0.0001$). Likewise, clinical improvement was significantly higher in groups 2 and 3 patients (62% in groups 2 and 3 vs. 35% in group 1, $p>0.0002$). There were no differences in clinical improvement between group 2 and 3. 11 patients (24%) discontinued the treatment, 1 for adverse effect and 10 for inefficacy, 50% of which (5 patients) were in group 1 at the suspension moment.
Conclusions: In our Glm treated SpA cohort, the majority of low activity patients and higher clinical improvement were classified in optimal or supraoptimal concentration group. Overoptimal concentration drug levels do not seem to contribute to major benefit in clinical improvement.

AB0687 ASSOCIATION BETWEEN GOLIMUMAB TAPERING STRATEGY AND DRUG SERUM LEVELS IN SPA-PAZ SPONDILOARTHRITIS COHORT

C. Redondo[1], A. Martínez[2], C. Plasencia[1], V. Navarro-Compán[1], L. Nuño[1], D. Peiteado[1], A. Villalba[1], A. Jochems[2], D. Pascual-Salcedo[2], A. Balsa[1].
[1]Rheumatology; [2]Immunology Unit, la Paz University Hospital, Madrid, Spain

Background: Golimumab (Glm) is a tumour necrosis factor (TNF) inhibitor used as Spondiloarthritis (SpA) treatment. There is more and more evidence of tapering therapies used in maintained low disease activity patients, avoiding overtreatments and adverse effects. Up to now, there are no studies concerning SpA patients with Glm tapering therapy and serum drug levels measured prior to tapering strategy.
Objectives: To analyze clinical and analytical course of SpA patients with Glm interval prolongation in SpA-Paz cohort. Associate pre-tapering Glm serum levels with flare occurrence along tapering treatment.
Methods: Observational prospective SpA-Paz cohort study of 22 patients treated with Glm that remained with low disease activity, so they started tapering strategy (Tap-S). We measured clinical activity with ASDAS and ∆ASDAS at baseline, pre-tapering visit (v-pre)and at 6, 12, 18 and 24 months after tapering starting (v-end). All of them had a clinically important improvement determined as ∆ASDAS≥1'1. We registered flares, defined as clinical worsening based on patient anamnesis and physical examination and on diverse activity indexes made from the beginning until the last visit. Drug serum levels in v-pre were measured by ELISA and classified following optimal concentration previously defined in our laboratory: <0'7 mg/L, 0'7–1'4 mg/L, >1'4 mg/L. We used the software Graph-Pad Prism 6 for statistical analysis.
Results: 22 of 79 patients from our cohort (28%) initiated Tap-S. The age range was between 25 and 70 years, 73% men and 27% women. 52% were non-smokers. 5 patients (23%) received another antiTNF drug previously (4 Infliximab, 1 Etanercept). All of them had a 6 months visit prior to tapering, 18 patients had 12 months visit, 8 had 18 months visit and 5 had 24 months visit. ASDAS and ∆ASDAS were similar in v-pre and v-end (ASDAS: 1'3±0'4 v-pre vs 1'2±0'7 v-fin, p=0'3; ∆ASDAS: 2'3±0'7 v-pre vs 2'4±0'9 v-end, p=0'6). 13 patients (59%) had 1 or 2 flares along tapering therapy. The occurrence of flare average was 14 months. In all the patients with flares, disease activity was controlled returning to previous tapering dose (4/13, 31%), to monthly schedule (6/13, 46%) or remaining tapering dose with symptomatic treatment adjustments (3/13, 23%). None of them discontinued the treatment. At v-end, ASDAS and ∆ASDAS were similar between patients with and without flares along Tap-S (ASDAS v-end: 1±0'7 in patients without flares vs 1'3±0'7 in patients with flares, p=0'4, ∆ASDAS v-fin: 2'7±0'7 in patients without flares vs 2'2±1 in patients with flares, p=0'3). All the patients (4/4, 100%) that were under optimal drug concentration (<0'7mg/L) had at least one flare along Tap-S; however, only 23% (3/9) of those who were in optimal drug concentration in v-pre (0'7–1'4 mg/L) had flares.
Conclusions: The tapering strategy in our SpA cohort treated with Glm results in similar disease activity control after 24 months of monitoring. The activity disease in patients with flares was controlled with symptomatic or biologic treatment adjustments avoiding therapy discontinuation. Flares incidence was more frequent in patients under optimal drug concentration in v-pre.

AB0688 EFFECT OF TREATMENT WITH NON-STEROIDAL ANTI-INFLAMMATORY DRUGS ON DISEASE ACTIVITY IN PATIENTS WITH EARLY AXIAL SPONDYLOARTHRITIS BASE ON DATA FROM 2 YEARS FOLLOW UP OF CORSAR COHORT

D. Rumiantceva, T. Dubinina, O. Rumyantseva, A. Demina, E. Agafonova, S. Erdes, S. Krasnenko. *Laboratory of spondyloarthritis, Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation*

Background: Currently non-steroidal anti-inflammatory drugs (NSAIDs) are the first-line drugs for treatment of axial spondyloarthritis (axSpA) and much discussed question of influence frequency of intake NSAIDs on axSpA disease activity.
Objectives: To compare the frequency of intake NSAIDs with early axSpA disease activity.
Methods: The research included 65 patients (pts) with axSpA (criteria ASAS 2009) with disease duration <5 years and age at onset <45 years. Pts at least 2 years follow up, 32 (49,2%) males, pts mean age was 28,5 (5,8) y., average disease duration - 24,1 (15,4) mo, 60 (92,3%) pts were HLA-B27 positive. At baseline all pts were NSAID-naïve, DMARD-naïve, anti-TNF-naïve. For 2 years pts taking NSAIDs at therapeutic doses. The dosages of NSAIDs accounted by the ASAS NSAID index. 1 year after baseline – 9 (13,8%) pts started treatment with anti – TNF because of high activity of the disease and absence of effect from 2 NSAIDs. 2 years after baseline number of pts with anti-TNF equal - 15 (23,0%).
Results: Compared with baseline characteristic after 2 years have significantly reduced disease activity and increased the number of ASAS partial remission (PR) in patients with axSpA (Table 1).
There were no statistical differences between the frequency of NSAIDs intake and early axSpA disease activity (Table 2).

Table 1. Outcome parameters at baseline and after 2 years of NSAID treatment

	Baseline, NSAID naïve (n=65)	2 years after baseline with NSAIDs (n=50)	p
BASDAI, mean (s.d)	3,6 (1,9)	2,4 (1,9)	0,6
BASDAI≥4, % pts	29 (44,6%)	10 (20,0%)	0,05
BASDAI <3, % pts	26 (40,0%)	46 (92,0%)	0,01
ASDAS-CRP, mean (s.d)	2,4 (1,1)	1,7 (1,1)	0,0009
ASDAS-CRP≥2,1, % pts	39 (62,9%)	22 (44,0%)	0,4
ASDAS<1,3, % pts	11 (16,9%)	27 (54,0%)	0,004

Table 2. Outcome parameters at 1 and 2 years after baseline depend on NSAID index >50 or NSAID index <50

	1 year after baseline (n=56)			2 years after baseline (n=50)		
	NSAID index >50 n=40 (61,5%)	NSAID index <50 n=16 (23,0%)	P	>50 n=28 (56,0%)	NSAID index <50 n=22 (44,0%)	p
BASDAI, mean (s.d)	2,3 (1,5)	1,9 (1,8)	0,4	2,3 (1,5)	1,8 (1,3)	0,6
BASDAI≥4, % pts	3 (7,5%)	1 (6,2%)	1,0	4 (14,2%)	2 (9,1%)	0,8
BASDAI <3, % pts	28 (70,0%)	12 (75,0%)	0,8	20 (71,4%)	21 (95,4%)	0,5
ASDAS-CRP, mean (s.d)	1,6 (0,7)	1,3 (0,8)	0,4	1,7 (0,9)	1,4 (0,7)	0,2
ASDAS-CRP≥2,1, % pts	12 (30,0%)	3 (18,7%)	0,7	9 (32,1%)	8 (36,3%)	0,7
ASDAS<1,3, % pts	15 (37,5%)	6 (37,5%)	0,8	13 (46,4%)	10 (45,4%)	0,9
ASAS PR, % pts	15 (37.5%)	8 (50,0%)	0,6	12 (42,8%)	9 (40,9%)	1,0

Conclusions: Long reception of NSAIDs in patients with early axSpA reduces disease activity, however, the receive frequency does not affect the activity of the disease.

AB0689 METABOLIC SYNDROME IN ANKYLOSING SPONDYLITIS AND THE EFFECT OF ANTI-TNF THERAPY

F. Atzeni[1], L. Gianturco[2], I.F. Masala[3], S. Bongiovanni[1], L. Boccassini[1], P. Sarzi-Puttini[1], M. Turiel[1]. *[1]Rheumatology Unit, L.Sacco University Hospital; [2]Cardiology Unit, Department of Biomedical Sciences for Health, IRCCS Galeazzi Orthopedic Institute, Milan; [3]Orthopedic and Trauma, Santissima Trinità Hospital, Cagliari, Italy*

Background: Metabolic syndrome (MeS) is a cluster of cardiovascular (CV) risk factors (obesity, dyslipidemia, hypertension, alterations in glucose metabolism, and insulin resistance) whose prevalence is increasing particularly in devoloped countries. In comparison with the general population, patients with ankylosing spondylitis (AS) are at increased risk of cardiovascular (CV) disease, which is one of the main causes of mortality among them.
Objectives: The aim of this study was to identify the relationship between MeS and disease activity in AS patients, and evaluate the the effect of anti-tumour necrosis factor (TNF) therapy.
Methods: The study involved 30 outpatients who met the New York diagnostic criteria for AS: 14 males and 16 females; mean age 53.07±10.73 years; mean disease duration 5.03±4.06 years. All of the patients were being treated with DMARDs and anti-inflammatory drugs, but none had received any biological agents or steroids at baseline. The patients underwent laboratory tests (lipid profile and glucose levels), a clinical and standard echocardiographic examination, carotid ultrasonography (including the assessment of intima-media thickness and pulse wave velocity), and speckle tracking echocardiography (STE) of the left ventricle (LV) using Philips QLAB software to evaluate their CV risk profiles. Functional impairment and disease activity were assessed using the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and the Bath Ankylosing Spondylitis Functional Index (BASFI). All of the patients were evaluated at baseline and after 12 months of anti-TNF treatment. The data were statistically analysis using non-parametric chi-squared and Mc-Nemar tests, and the Wilcoxon-Mann-Whitney test.
Results: Before starting anti-TNF therapy, the cohort was divided into two groups: those with MeS (25%) and those without. The patients with MeS higher BASDAI scores (chi-squared test: 4.85; p=0.03). After 12 months of follow-up, there was a statistically significant improvement in global longitudinal strain (GLS) in both groups: from a baseline median of 19.94 (IQR 18.66–20.78) to a median of 21.46 (IQR 20.37–22.69) (p=0.02) in the non-MeS group, and from a baseline median of 18.88 (IQR 16.00–19.35) to 19.54 (IQR 18.21–19.98) (p=0.04) in the MeS group. No other changes in CV parameters were observed. The improvement in BASDAI scores was greater in the MeS group, but the difference was not statistically significant. The prevalence of MeS decreased after 12 months of anti-TNF therapy, although the McNemar test showed that the decrease was of borderline significance (p=0.048).
Conclusions: AS patients are affected by MeS. The effects of anti-TNF drugs on MeS are still controversial, but our findings suggest that they improve CV markers such as GLS as well as disease activity. The main limitation of this study is its small sample size and short follow-up; further studies are required in order to clarify the influence of MeS on clinical therapeutic outcomes.

AB0690 CLINICAL EXPERIENCE WITH INFLIXIMAB BIOSIMILAR (BOW015) IN ANKYLOSING SPONDYLITIS- EFFICACY AND SAFETY ANALYSIS FROM AN INDIAN PERSPECTIVE

I. Agrawal[1], A.N. Roy[2], R. Kiran[3], V.K. Rao[4], R.N. Sarkar[5], S. Naorem[6], A. Ray[7], M. Shamil[8]. *[1]Department of Rheumatology, Paras Hospital, Delhi; [2]Department of Rheumatology, Yashoda Hospital; [3]Department of Rheumatology, Star Hospital, Hyderabad; [4]Department of Rheumatology, Manipal Hospital, Bengaluru; [5]Department of Rheumatology, Medical college of Kolkata, Kolkata; [6]Department of Medicine, Regional Institute of Medical Sciences, Imphal; [7]Department of Rheumatology, Radiant Medical Centre, Kolkata; [8]Medical Affairs Manager, Sun Pharma Laboratories Ltd, Mumbai, India*

Background: The regulatory phase III trial supporting the approval of biosimilar infliximab (BOW015) in India included only rheumatoid arthritis patients. Consequently there is paucity of data on the effectiveness of BOW015 in Ankylosing Spondylitis (AS).[1,2,3] Hence, we decided to objectively quantify the effectiveness and safety of BOW015 in AS patients.
Objectives: To determine safety, efficacy and tolerability of BOW015 in Indian AS patients.
Methods: We retrospectively collected data from seven centres to get a comprehensive picture of the Indian population. The protocol along with data collection form was designed by the investigators and ethics committee approval was obtained. Biologic naïve patients diagnosed with AS as per Assessment of Spondylo Arthritis International Society criteria who were having six months of follow up data during January-November 2016 were included in the study. Percentage of patients achieving major clinical improvement (Ankylosing Spondylitis Disease Activity Score C-reactive protein ($ASDAS_{CRP}$) >2 from the baseline to six months of follow up) was the primary variable. Secondary variables included; clinical improvement criteria ($ASDAS_{CRP}$>1.1 from the baseline to six months of follow up), change in $ASDAS_{CRP}$, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), CRP and Erythrocyte Sedimentation Rate (ESR) from the baseline to six months. Variables were reported as mean ± Standard Deviation (SD), absolute change in variable were reported along with their Confidence Interval (CI) and data was analyzed using Statistical Package for the Social Science V-22.
Results: A total of 68 patients treated with BOW015 having follow-up data for six months were analyzed. Mean age of patients was 32.63±11.73 (SD) years with mean body mass index of 25.72±7.48 (SD) kg/m^2 and about 32 (47%) patients had peripheral arthritis. Of the treated patients, 52 (76%) patients were administered four doses while 6 (9%) patients administered three doses, 3 (5%) patients administered two doses and 7 (10%) patients administered single dose as they were loss to follow up. As per the primary variable, 67.9% patients achieved major clinical improvement, 9.4% patients achieved clinical improvement and 22.6% were non-responders. There was an absolute change of -2.54 (95% CI -1.92, -3.17) in BASDAI and -1.77 (95% CI -1.43, -2.11) in $ASDAS_{CRP}$ right from first follow up corresponding to post 1st dose visit which was statistically significant (see Table-1). This trend was observed in the subsequent visits in BASDAI, $ASDAS_{CRP}$, ESR and CRP which continued till the end of six months. One patient developed pulmonary tuberculosis and marginally elevated liver enzymes were seen in two patients.

Table 1: Change in the primary and secondary variables

	Baseline (mean±SD)	Δ Baseline to 1st follow up (Mean Difference; 95% CI)	Δ Baseline to 2nd follow up (Mean Difference; 95% CI)	Δ Baseline to 6 months follow up (Mean Difference; 95% CI)	p value compared to previous visit and baseline vs. 6 months FU
BASDAI	5.83±1.90	-2.54 (95% CI -1.92, -3.17)	-3.44 (95% CI -2.79, -4.09)	-3.77 (95% CI -3.05, -4.48)	<0.05
$ASDAS_{CRP}$	3.88±0.80	-1.77 (95% CI -1.43, -2.11)	-2.212 (95% CI -1.86, -2.55)	-2.13 (95% CI -1.78, -2.47)	<0.05
ESR (mm/h)	39.45±27.04	-20.82 (95% CI -14.08, 27.55)	-26.137 (95% CI -19.05, -33.22)	-26.087 (95% CI - 17.89, 34.28)	<0.05
CRP(mg/L)	25.06±22.84	-18.408 (95% CI -12.01, 24.80)	-18.918 (95% CI -12.69, -25.14)	-15.702 (95% CI -9.38, 22.02)	<0.05

Conclusions: BOW015 showed significant improvement in $ASDAS_{CRP}$ and BASDAI in patients with AS on a six month follow up period and the clinical benefits were apparent as early as first dose of BOW015.

AB0691 METFORMIN THERAPY CAN RESTORE THE BALANCE OF TH17 AND TREG CELLS IN PATIENTS WITH SPONDYLOARTHRIT

J. He[1], J. Xie[1], H. Niu[1], R. Jia[1], J. Cao[1], Y. Liu[1], J. Li[1], J. Luo[1], X. Sun[1], X. Li[1], C. Lu[2], C. Gao[3]. *[1]Rheumatology, The Second Hospital of Shanxi Medical University, Taiyuan; [2]Rheumatology, West China Hospital of Sichuan Universit, Sichuan, China; [3]Pathology, Brigham and Women's Hospital, Harvard Medical School, Boston, United States*

Background: Spondyloarthrit (SpA) is a chronic autoimmune disease and is associated with immunological function disorder. Previous studies have observed that increased number of T17 cells and decreased number of Regulatory T (Treg) cell in patients with S [1,2]. However, the current therapy for SpA, focusedon NSAID, biological agents and glucocorticoid, can't correct the imbalance of Th17 and Treg cells. Metformin has been demonstrated a reducing effect on Th17 cells but an increasing effect on Treg cells, regulating the Thl7/Treg ratio [3].
Objectives: The study is to explore the effect of metformin therapy on the balance of Th17 and Treg cells in patients with SpA.
Methods: SpA patients (n=27) (from August 1st to November 30th in 2016, both outpatients and inpatients in our department, according to American-European Consensus Group criteria for SpA), who were given metformin (750mg/day for 6 weeks). Laboratory indicators were compared before and after metformin treatment.
Results: The number of Treg cells [25.37 (18.31,45.78) vs.34.43 (25.91,50.31), P=0.015] significantly increased after the treatment. At the same time, there was a significantly decrease in the ratio of Th17/Treg cells [0.26 (0.15,0.48) vs. 0.22 (0.1,0.33), P+0.037]. Besides, Th17 cells were also decreased [7.85 (4.95,10.65) vs. 6.42 (3.7,10.63)].
Conclusions: Metformin can restore and maintain the balance of Th17 and Treg cells in the patients with SpA. And it may be a potential therapy for SpA.

AB0692 EFFECTS OF INTRAVENOUS GOLIMUMAB ON PATIENT-REPORTED OUTCOMES IN ACTIVE ANKYLOSING SPONDYLITIS: 28-WEEK RESULTS OF THE PHASE III GO-ALIVE TRIAL

J.D. Reveille[1], A. Deodhar[2], E.K. Chan[3], S. Peterson[4], N. Li[4], E. Hsia[4,5], L. Kim[4], K.H. Lo[4], D.D. Harrison[4], C. Han[6]. *[1]University of Texas Health Sciences Center, Houston; [2]Oregon Health & Science University, Portland; [3]Janssen Global Services, LLC, Raritan; [4]Janssen R&D, LLC, Spring House; [5]University of Pennsylvania School of Medicine, Philadelphia; [6]Janssen Global Services, LLC, Malvern, United States*

Objectives: To evaluate patient-reported outcomes (PRO) of physical functioning, mental health functioning, health state, and health-related quality of life (HRQoL) in patients (pts) w/active Ankylosing Spondylitis (AS) treated w/intravenously administered (IV) golimumab (GLM), an anti-TNFα monoclonal antibody.
Methods: GO-ALIVE is a Phase 3, multicenter, randomized, double-blind, placebo-controlled trial. Pts (aged ≥18 years) had a diagnosis of definite AS (per modified New York criteria) and BASDAI ≥4, total back pain visual analogue scale ≥4, and CRP ≥0.3mg/dL. At baseline, 208 pts were randomized either to IV GLM 2mg/kg (N=105) at Wks 0, 4, and every 8 wks or placebo (PBO, N=103) at Wks 0, 4, and 12, w/crossover to GLM at Wk 16.
Three PRO instruments were included: 1) SF-36, a generic instrument designed to measure physical & mental health functioning, 2) EQ-5D visual analogue scale (VAS), a generic measure of current health state & 3) Ankylosing Spondylitis Quality of Life (ASQoL) questionnaire, a disease-specific instrument designed to measure the impact of AS on HRQoL. The scores for SF-36 range from 0–100 w/higher scores indicating better functioning. It has Physical (PCS) and Mental Component Summary (MCS) and eight subscales (physical functioning, role-physical, body pain, general health, vitality, social functioning, role-emotional, & mental health). EQ-5D has a scale of 0–100 (0=worst health you can imagine to 100=best health you can imagine). ASQoL assesses sleep, mood, motivation, ability to cope, activities of daily living, independence, relationships, & social life in pts w/AS. The scores range from 0–18 w/higher scores indicating worse HRQoL. Unadjusted p-values of least square mean differences (LSMD) between treatment groups were based on analysis of covariance (ANCOVA) controlling for prior anti-TNF therapy.
Results: Table 1 summarizes the mean changes from baseline at Wks 8, 16, & 28. Improvements from baseline in SF-36 PCS & MCS were greater in the GLM group than PBO at Wk 8 (6.83 vs. 2.07, p<0.001; 5.56 vs. 1.67, p=0.006, respectively) and maintained through Wk 16 (8.52 vs. 2.87, p<0.001; 6.47 vs.

0.84, p<0.001, respectively). Improvements in all SF-36 subscales were observed in the GLM group at Wks 8 & 16 compared to PBO (p<0.01, with the exception of the role-emotional subscale [p=0.058]). The percentage of pts achieving clinically meaningful change (5 points or greater) in SF-36 PCS & MCS were higher in GLM than PBO in Wks 8 & 16 (PCS: 58.1 vs. 27.2, 67.6 vs. 35.9, respectively; MCS: 48.6 vs. 34.0, 54.3 vs. 29.1, respectively; p<0.05 for all). Mean EQ-5D VAS improvements were greater (p<0.001) in GLM than PBO at Wks 8 & 16 (17.61 vs. 6.63, 20.32 vs. 4.79, respectively). Greater improvements in ASQoL were observed in GLM compared to PBO at Wks 8 & 16 (-4.5 vs. -1.5, p<0.001, -5.4 vs. -1.8, p<0.001, respectively). By Wk 28, after PBO crossed-over to GLM, improvement in PCS, MCS, EQ-5D VAS, & ASQoL were similar between the two treatment arms.

Table: Summary of mean (standard deviation) changes in SF-36, EQ-5D, and ASQoL.

		IV GOLIMUMAB 2mg/kg	PLACEBO
Patients		105	103
Mean (SD) change from baseline in SF-36 PCS:	Week 8	6.83 (6.90) (p<0.001)	2.07 (5.66)
	Week 16	8.52 (7.54) (p<0.001)	2.87 (6.11)
	Week 28	9.08 (8.02)	9.29 (7.09)
Mean (SD) change from baseline in SF-36 MCS:	Week 8	5.56 (9.26) (p=0.006)	1.67 (8.80)
	Week 16	6.47 (9.12) (p<0.001)	0.84 (9.82)
	Week 28	6.16 (10.91)	5.60 (9.70)
Mean (SD) change from baseline in EQ-5D VAS:	Week 8	17.61 (24.02) (p<0.001)	6.63 (19.881)
	Week 16	20.32 (24.59) (p<0.001)	4.79 (23.47)
	Week 28	20.52 (27.86)	22.45 (23.08)
Mean (SD) change from baseline in ASQoL:	Week 8	-4.5 (4.71) (p<0.001)	-1.5 (3.90)
	Week 16	-5.4 (5.01) (p<0.001)	-1.8 (4.50)
	Week 28	-5.3 (5.24)	-5.3 (4.84)

Conclusions: Adult pts w/active AS treated w/IV GLM showed marked improvements in physical functioning, mental health functioning, health state, & HRQoL.

AB0693 PATIENTS WITH CHRONIC INFLAMMATORY ARTHROPATHIES TREATED WITH GOLIMUMAB ACHIEVE A HIGHER SERUM LEVEL OF DRUG IF USED AS THE FIRST OR SECOND BIOLOGICAL DRUG

J. Rosas[1], M. Marco-Mingot[2], J.M. Senabre-Gallego[1], F. Llinares-Tello[2], A. Pons[1], X. Barber[3], G. Santos-Soler[1], E. Salas[1], C. Cano[1], M. Lorente[1], M. Sanchís-Selfa[3], J. Molina[2], M. García-Carrasco[4] on behalf of AIRE-MB Group. *[1]Rheumatology Department; [2]Laboratory Department, Hospital Marina Baixa, Villajoyosa (Alicante); [3]CIO, Universidad Miguel Hernández, Elche, Spain; [4]Rheumatology Department, Universidad Autómoma de Puebla, Puebla, Mexico*

Objectives: To know the influence of the order of introduction of Golimumab (GLM), on clinical efficacy in ankylosing spondylitis (AS), psoriatic arthritis (PSA) and rheumatoid arthritis (RA).

Methods: A prospective, observational study, in 46 consecutive patients with AS, APS and RA, treated with GLM. Data: epidemiological, concomitant DMARD, time of disease evolution, HLA-B27, RF and ACPA; from GLM: order of introduction, time in treatment, serum level and anti-GLM Ab. The clinical response was assessed in AS patients using BASDAI, BASFI, ASDAS-VSG. In patients with RA or peripheral APS, DAS28-VSG, DAS28-PCR and SDAI. Serum levels of GLM and anti-GLM Ab were determined by ELISA (Progenika, Grifols SA, Spain). Serum cutoff levels for serum GLM levels: 36 ng/mL and for anti-GLM Ab: UA>20 AU/mL. Samples were extracted just prior GLM administration (trough level) and stored frozen at -80ºC until analysis.

Results: Of 33 (72%) AS patients: 52% were males, mean age 53±12 years, mean BMI 28±4, disease mean evolution 16±12 years and in GLM: 1.3±1.1 years, 30% received DMARD, being GLM the first anti-TNF in 25%, second 37%, third 25% and fourth in 13%. The mean GLM level was 0.77±0.62 mg/mL and the prevalence of anti-GLM antibodies was 6%. In the 5 patients with RA and 8 with APS: 23% were men, mean age of 55±11 years, mean BMI 28±6, mean disease evolution of 10.5±8 years and in GLM of 2±1.5 years, the 85% of patients received DMARD, being GLM the first anti-TNF in 31%, second 15%, third 31% and fourth 23%. The mean GLM level was 0.703±0.53 mg/L. No anti-GLM Ab were detected.

Table 1. Characteristics of patients with receiving GLM, according to the order of introduction

Golimumab (GLM) RA-APS (n: 13)	1°–2° anti-TNF (n: 7)	3°–4° Anti-TNF (n: 6)	p
BMI, kg/m^2: mean (SD)	28,72 (6,62)	28,93 (6,66)	0,95
Disease evolution (years): mean (SD)	10,1 (7,64)	11,53 (10)	0,78
DMARD, n (%)	7 (100)	4 (67)	0,13
Years on GLM: mean (SD)	2,27 (1,86)	2,5 (2,04)	0,84
anti-GLM Ab, U/L, n (%)	0	0	–
DAS28-VSG, mean (SD)	1,74 (0,83)	2,12 (0,94)	0,47
DAS28-PCR, mean (SD)	1,82 (0,85)	2,28 (0,93)	0,39
SDAI, mean (SD)	3,92 (5,17)	7,67 (6,58)	0,30
Golimumab (GLM) AS (n: 33)	**1°–2° anti-TNF (n: 21)**	**3°–4° anti-TNF (n: 12)**	**p**
BMI, kg/m^2: mean (SD)	27,46 (4,20)	29,26 (3,09)	0,16
Disease evolution (years): mean (SD)	14,25 (10,55)	20,65 (14,27)	0,21
DMARD, n (%)	8 (38%)	2 (17)	0,57
Years on GLM: mean (SD)	1,75 (1,47)	1,13 (0,89)	0,14
GLM level, mg/dL: mean (SD)	0,919 (0,63)	0,448 (0,47)	**0,025**
anti-GLM Ab, U/L, n (%)	0	2 (17)	–
BASDAI: mean (SD)	5,96 (2,48)	6,10 (2,23)	0,86
ASDAS: mean (SD)	2,92 (0,87)	3,79 (2,68)	0,64

Conclusions: 1. The overall prevalence of anti-GLM Ab was 6% and 17% in AS patients. Not detecting in patients with RA or PSA. 2. Serum GLM level was higher among the patients receiving it as the 1st or 2nd anti-TNF. 3. In AS GLM as 3rd or 4th anti-TNF were able to achieve clinical remission, similar to that achieved as 1st or 2nd drug.

AB0694 RHEUMATOLOGISTS' ATTRIBUTION OF PATIENT-REPORTED SYMPTOMS IN AXIAL SPONDYLOARTHRITIS (AXSPA): IMPACT ON RESPONSE TO TNF-INHIBITORS (TNFI) IN 508 PATIENTS

L. Gossec, A. Moltó, A. Etcheto, N. Boudersa, P. Claudepierre, N. Roux, F. Berenbaum, A. Martin, L. Sparsa, P. Coquerelle, M. Soubrier, S. Perrot, M. Dougados. *Predict-SpA Study Group, Paris, France*

Background: In axSpA, treatment decisions are mainly based on patient-reported symptoms: recommendations are to initiate TNFi in patients with active disease and with physician conviction that treatment is needed (ref). However, the attribution of symptoms to inflammation is difficult to establish in axSpA.

Objectives: The objective of the present analysis was to explore the link between physician-attributed causality for symptoms and treatment response to TNFi.

Methods: The PredictSpA study (ClinicalTrials.gov: NCT03039088) was a longitudinal observational multicenter study in France in 2015. Patients with physician-defined definite axSpA and starting a TNFi treatment were included, a TNFi was prescribed according to usual practice and efficacy was assessed at 12 weeks by BASDAI50 response. At baseline, symptoms levels including BASDAI and ASDAS were collected and the physician evaluated the causality of symptoms by answering the following 3 questions: how convinced are you that the symptoms of this patient are due to (A) inflammatory axSpA activity (B) to axSpA severity (eg syndesmophytes, kyphosis) and NOT to disease activity and (C) to other diseases and NOT axSpA. Each question was assessed 0–10 (not convinced at all to absolutely convinced). The link between a score ≥4/10 on each of the 3 questions and BASDAI50 response was assessed by univariate logistic regression. Patients interrupting the TNFi before 3 months were considered as non-responders and missing data were imputed using non-responder imputation.

Results: In all, 519 patients were included and 508 had data over 3 months: mean age 41.3 (SD 11.6) years, mean disease duration 6.1 (SD 8.4) years, 237 (46.7%) were women, 424 (83.5%) satisfied the ASAS criteria for axSpA of whom 379 (74.6%) were in the imaging arm and 45 (8.9%) in the clinical arm. Symptom levels were high: mean BASDAI was 5.7 (SD 1.8) and mean ASDAS-CRP was 3.3 (SD 0.9) with only 6 (1.2%) patients in inactive disease state according to ASDAS. The physician-attributed causality of symptoms was mostly related to inflammatory activity: mean scores for (A), (B) and (C) were respectively, 7.4 (SD 2.0), 2.3 (SD 2.5) and 2.1 (SD 2.2). When physicians attributed causality to non-axSpA (score (C) ≥4/10), BASDAI50 response was less frequent: 45/118 (38.4%) vs 213/390 (54.6%), odds ratio 0.5 [95% CI 0.3, 0.8].

Conclusions: In axSpA patients starting a TNFi with high symptom levels, physician-attributed causality of symptoms was mainly related to inflammatory activity of the axSpA. When physician-attributed causality was more oriented towards non-axSpA causes, BASDAI50 response after 3 months of a TNFi was lower. This confirms the validity of the ASAS-EULAR recommendations for starting a TNFi which rest on a level of symptoms but associated to physician conviction of the indication.

AB0695 DOSE TAPERING OF INFIXIMAB IN PATIENTS WITH SPONDYLOARTHRITIS

M. Correyero, J.C. Nieto, C.M. González, A. López, R. González, C. Saenz, L. García-Montoya, F.J.L. Longo, I. Monteagudo. *Rheumatology Department, Hospital General Universitario Gregorio Marañon, Madrid, Spain*

Background: Infliximab have proven to be effective in spondyloarthritis. Previous studies suggest that patients in clinical remission may benefit from dose reduction or pharmacological tapering without relapse.
Objectives: To study the evolution of clinical activity and physical function in patients with spondyloarthritis, ankylosing spondylitis (AS) and psoriatic arthritis (PsA) under Infliximab (IFX) tapering strategy.
Methods: This is a prospective single-centre observational study of patients diagnosed with AS and PsA treated with IFX (5 mg/kg/infusion) between January 1, 2012 and December 31, 2015. We included patients who achieved clinical remission or low activity index (expressed with BASDAI and BASFI) and decided to lower the dose of 5 to 4 mg/kg/infusion, maintaining the periodicity of the treatment in each patient. Demographic data (age, gender, time with IFX) daily activities, physical activity (BASDAI and BASFI) and laboratory data (ESR and CPR) were collected at the baseline visit prior to tapering, at the next infusion following dose reduction and the last infusion (between November 1st 2014 and December 31st, 2016).
Results: We included 18 patients (16 men) on IFX treatment with EA (16) or axial APs (2). The medians of age and time of evolution were 50.79 years (41.8–55.1) and 9.5 years (7.2–11.5), respectively. Table 1 shows the clinical and laboratory data obtained at the baseline visit, the next infusion and the last infusion. Fourteen patients (87.9%) continued with the dose of 4 mg/kg/infusion and are maintained in clinical remission. Four patients returned to the dose of 5 mg/kg/infusion due to loss of efficacy at dose reduction, with a mean follow-up of 17.6 months (17.0–19.1). Clinical remission was again achieved in the 4 patients, although one of them changed biological therapy due to loss of efficacy of IFX after 3 infusions with 5 mg/kg/infusion.

Table 1. Clinical and laboratory data during follow-up

	Baseline	Next Infusion	Last Infusion
BASDAI median (RI)	3,1 (1,45–4,45	4 (1,4–4,25)	4,1 (1,65–6,15)
BASFI median (RI)	2,8 (1,1–4,5)	3,6 (1,8–4,25)	2,8 (1–5)
ESR (mm/h) median (RI)	6,5 (3–11,25)	4,5 (3–11,5)	12,5 (6,5–16,75)
CPR (mg/dl) median (RI)	0,2 (0,2–0,55)	0,3 (0,1–0,4)	0,2 (0,1–0,72)

Conclusions: In our patients with spondyloarthritis dose reduction of IFX was well tolerated and safe, maintaining the clinical response measured by BASDAI and BASFI. In 3 out of 4 patients who worsened upon dose reduction, the 5 mg/kg/infusion dose recovered clinical remission.

AB0696 RETENTION RATES OF ADALIMUMAB, ETANERCEPT, AND INFLIXIMAB AS FIRST- OR SECOND-LINE BIOTHERAPIES FOR SPONDYLOARTHRITIS PATIENTS IN DAILY PRACTICE IN AUVERGNE (FRANCE)

M. Soubrier[1], B. Castagné[1], B. Pereira[2], A. Fan[1], T. Frayssac[1], M. Couderc[3], S. Malochet-Guinamand[1], S. Mathieu[1], Z. Tatar[1], A. Tournadre[3], J.-J. Dubost[1]. *[1]Rheumatology, C.H.U. HÔPITAL GABRIEL MONTPIED; [2]DRCI, CHU Gabriel Montpied; [3]Rheumatology, CHU Hopital Gabriel Montpied, Clermont-Ferrand, France*

Background: The use of tumour necrosis factor alpha (TNF-α) inhibitors – or anti-TNFs – has considerably improved the treatment of spondyloarthritis (SpA). The first three of these available anti-TNFs (infliximab, adalimumab, and etanercept) are the most widely used in the treatment of SpA. Their efficacy and safety have been demonstrated in extensive randomised controlled trials (RCTs).Nevertheless, the randomized studies were of short duration and included a selected population that differed from patients treated in daily practice
Objectives: To compare, in real-life settings, the retention rates of the initial anti-TNF treatment (etanercept [ETN], adalimumab [ADA],and infliximab [IFX]) used as first-line biotherapy for spondyloarthritis (SpA), and to evaluate treatment switches to another anti-TNF inhibitor in the event of treatment failure.
Methods: Monocentric retrospective cohort including all SpA patients starting an initial anti-TNF therapy between 2001 and 2015.
Results: Of the 249 SpA patients analysed (135 radiographic cases, 114 non-radiographic), 102 were given ETN, 62 ADA, and 85 IFX. In total, 103 discontinued treatment. The median retention duration was 69.7 months (17–∞) (ETN: 55.4 [17.6–94.6], ADA 57.6 [13.9–∞], and IFX: not reached). Retention was longer for IFX compared with ETN (HR=0.62 [0.39–0.99]) but non-significant compared with ADA (HR: 0.91 [0.56–1.48]). The percentage of patients continuing treatment after 5 years was 47% for ETN, 46% for ADA, and 62% for IFX. In multivariate analysis, the predictive factors for retention were a low BASDAI score (HR: 1.02 [1.01–1.04]), high CRP levels (HR 0.98 [0.97–0.99]), the concomitant use of disease-modifying therapy (HR: 0.4 [0.21–0.75]), and radiographic SpA (HR: 1.5 [1.0–2.52]). In total, 61 patients switched to another anti-TNF therapy. No difference was observed among the three anti-TNF therapies with regard to the median retention duration, but the retention rate was higher in the event of treatment switches from one monoclonal antibody to another.
Conclusions: The retention rate in SpA patients proved high, and retention for IFX was superior to that of ETN.

AB0697 IMPACT OF THE BASELINE BATH ANKYLOSING SPONDYLITIS RADIOLOGY HIP INDEX ON THE STRUCTURAL HIP JOINT PROGRESSION AFTER TNFα BLOCKING THERAPY IN SPONDYLOARTHRITIES PATIENTS

K. Maatallah[1], M. Sahli[1], I. Mahmoud[2], W. Hamdi[1], O. Saidane[2], M. Kchir[1], R. Tekaya[2], L. Abdelmoula[2]. *[1]Rheumatology, Kassab university hospital; [2]Rheumatology, Charles Nicolle university hospital, Tunis, Tunisia*

Background: One of the major goals of treatment of spondyloarthrites (SpA) is to prevent or slow the radiographic damage.The results of clinical trials raised expectations that TNFi are effective not only on clinical and biological parameters of the disease but may also have structural effect.
Objectives: We assessed whether the baseline Bath Ankylosing Spondylitis Radiology (BASRI) hip index had effect on structural hip progression under TNFα blockers in SpA patients with hip disease.
Methods: This was a multicentric longitudinal study including SpA patients (ASAS2009) with hip disease under TNF α blockers. Anteroposterior X-rays of the pelvis obtained at baseline were compared with X-rays obtained after 5 years [3–10] of continuous TNF α blockers treatment. Radiographic progression of the hip was evaluated by the Bath Ankylosing Spondylitis Radiology Hip Index (BASRI-h), scoring system (min 0 = no change, 1 = focal joint space narrowing, 2 = circumferential joint space narrowing >2 mm, 3 = circumferential joint space narrowing ≤2 mm or bone-on-bone apposition of <2 cm and max 4 = bone deformity or bone-on-bone apposition of ≥2 cm) and the hip joint space width (assessed by the average of measurements at three distinct sites between the acetabulum and femoral head)[1]. The median progression of the hip joint space was chosen as cut-off to define the structural evolution, it was 0.3mm. A good response of the hip was defined by a stabilization or a decrease of the hip joint space less than 0.3 mm (RH+).A poor response was defined by a decrease of the hip joint space >0.3mm (RH-).
Results: 48 patients were included (81% male). The average age was 40.7±11years. The mean age at the onset of the disease was 25.8±10 years. Hip involvement was bilateral in 77% of cases. At baseline, the mean BASRI hip index was 2±0.8. The BASRI hip score was 1 in 26%, 2 in 51%, 3 in 18% and 4 in 5% of patients. The average of hip joint space width at baseline was 3.4±1.2mm. Infliximab was the most prescribed TNFα blocker (48%) followed by Etanercept (37.5%) and Adalimumab (14.5%).After 5years, the mean BASRI hip index remained stable 2±0.8, the BASRI hip score was 1 in 23%, 2 in 50%, 3 in 14% and 4 in 13% (p=ns). The variation of hip joint space width was-0.294 mm (p=ns). 29 patients were RH+. The BASRI hip index 2±0.8 and 2.1±0.9 in RH+ and RH- patients respectively with no statistically significant difference.
Conclusions: According to our study the structural hip joint progression under TNFα blockers is not influenced by the baseline BASRI hip index.

AB0698 COMPLEMENTARY AND ALTERNATIVE MEDICINE USAGE AND ASSOCIATED FACTORS IN ANKYLOSING SPONDYLITIS: PRELIMINARY RESULTS OF A CROSS-SECTIONAL STUDY

F.I. Cinar[1], O. Ozdemir[2], S. Yilmaz[3], N. Ozen[4], G. Bagcivan[5], I. Aydoğan[6], A.G. Yalcin[6], E. Tekgoz[3], M. Cinar[3]. *[1]Gulhane School of Nursing, University of Health Sciences; [2]Department of Nursing, Ankara Yildirim Beyazit University, Faculty of Health Sciences; [3]Department of Internal Medicine, Division of Rheumatology, University of Health Sciences, Gulhane Medical Faculty, Ankara; [4]University of Health Sciences, Okmeydani Training and Research Hospital, Kasimpasa Building, Istanbul; [5]Department of Internal Medicine; [6]Division of Rheumatology, Gulhane Training and Research Hospital, Ankara, Turkey*

Background: Several surveys indicate that the complementary and alternative medicine (CAM) use is especially prevalent in patients with chronic painful

conditions like ankylosing spondylitis (AS). Despite good treatment options such as tumor necrosis factor alpha (TNFα) inhibitors in AS, it is seen that patients have applied for CAM use for many reasons including local regulatory funding requirements, potential risks and accessibility of biological treatments. Few studies have examined the frequency of CAM use, and associations between demographic and disease-related factors of it in AS.

Objectives: To investigate the CAM usage of patients with AS and to determine the associated factors.

Methods: Total of 123 patients with AS, who were being followed in a tertiary rheumatology outpatient clinic, were included to the study. The demographic and clinical features along with the behaviors about the CAM usage of the patients agreeing to participate were recorded to the "Patient Assessment Form". The activity of the disease were determined with doctor global assessment (numeric visual analog scale (nVAS; 0–10), and Routine Assessment of Patient Index Data (RAPID)-3 score. The treatment adherence of the patients was assessed with the Morisky Green Levine Scale.

Results: One hundred eleven patients (%90.2) were male, and mean age was 36.5±8.8 years. The mean disease duration and mean delay in diagnosis were 10.9±6.4, and 3.7±3.9 years, respectively. The mean RAPID3 score, doctor and patient global assessment were; 9.9±5.3, 2.8±1.9, and 4.6±2.7, respectively. While 79 patients (%64.2) were on anti-TNF treatment, 76 patients were receiving NSAIDs, and 35 patients (%28.5) reported an adverse event related with the treatment. Forty-five patients (%36.6) reported to use any CAM (previous or current) (Table1). The reasons reported by the patients for the usage of CAM; media in %13, recommendations from family members or relatives in %10.6. It has been found that in married patients, the ones with lower the Morisky Green Levine Scale score (high adherence), CAM usage was statistically high ($p<0.05$). Receiving NSAIDs or anti-TNF agents was not statistically associated with CAM usage. The underlying expectations for the usage of CAM were; considering it might be helpful in %27.6; considering it might heal in %17.9; to relieve the pain in %14.6; and preventing to deteriorate the disease status in %12.2.

Table 1. Types of CAM use

CAM Type	n*	%
Plants and herbs	31	25.2
Massage	13	10.6
Spa	10	8.1
Praying/spiritual approach	6	4.9
Cupping	3	2.4
Imagining	2	1.6
Naturapati	2	1.6
Acupuncture	1	0.8

CAM, complementary and alternative medicine. *There are patients marked the method more than one.

Conclusions: In our study, we found that approximately one third of our AS patients were using CAM. When compared with the literature related with other diseases, CAM usage in AS patients was somewhat lower. Our results have demonstrated that treatment adherence was higher in those using concomitantly CAM in their therapy.

AB0699 EFFECTS OF GLOBAL POSTURAL REEDUCATİON EXERCISE AND ANTI-TNF TREATMENTS ON DISEASE ACTIVITY, FATİGUE, MOBİLİTY, SLEEP QUALİTY AND DEPRESSİON IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS (PROSPECTIVE-CONTROLLED TRIAL)

N.H. Coksevim, D. Durmus, O. Kuru. *Physical Therapy and Rehabilitation, 19 Mayis University Medical Faculty, Samsun, Turkey*

Background: Ankylosing spondylitis (AS) is chronic inflammatory disease that affects primarily the spine and the sacroiliac joints. ASAS/EULAR guidelines describe regular exercise as the cornerstone of non-pharmacological treatment and pharmacological treatments including non-steroidal anti-inflammatory drugs as first-line therapy, and a tumour necrosis factor (TNF) alpha inhibitor (anti-TNFα) as second-line medication in patients with persistently high disease activity despite conventional pharmacological treatment in patients with AS.

Objectives: The purpose of this study was to investigate the effects of combination therapy with global postural reeducation exercise (GPR) and Anti-TNF treatments on pain, disease activity, mobility, fatigue, sleep quality, and depression in patients with active AS.

Methods: 60 active AS patients who meet the criteria of Modified New York and/or ASAS axial spondyloarthropathy were included in the study. Patients were divided into 3 groups. The first group was given anti-TNF therapy plus GPR exercise program. The 2nd group was given anti-TNF and conventional exercise therapy. The 3rd group was given routine exercise program along with their existing treatments (NSAIDs and/or SLZ). Following inventories are used for clinical evaluation: for disease activity – Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), for functionality – Bath Ankylosing Spondylitis Functional Index (BASFI), for mobility – lumbar Schober, chest expansion, hand-finger to floor distance, for fatigue – fatigue Multidimensional Assessment Questionnaire (MAF), for sleep quality – Pittsburgh sleep quality index (PSQI), for depression – Beck depression Inventory (BDI). All patients were evaluated before treatment and at 3 months.

Results: The demographic characteristics of the patients were compared and there was no significant difference between the groups. The improvements in all parameters were better in both groups receiving exercise and anti-TNF therapy than in the control group after treatment compared with baseline. The Anti-TNF + GPR exercise therapy resulted in greater improvements than the anti TNF+ conventional exercise therapy in pain, and mobility parameters.

Conclusions: Anti-TNF therapy and exercise were efficient in both groups on improving pain, disease activity, fatigue, sleep quality, and depression. However, the improvements in pain and mobility were greater in the active AS patients with GPR exercise method. Therefore motivated patients should be encouraged to perform this exercise program.

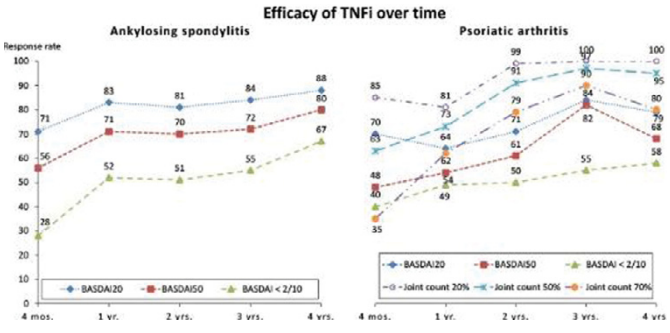
AB0700 EFFICACY AND DRUG SURVIVAL OF ANTI-TUMOUR NECROSIS FACTOR-ALPHA THERAPIES IN PATIENTS WITH SPONDYLO-ARTHRITIS: ANALYSIS FROM THE THAI RHEUMATIC DISEASE PRIOR AUTHORIZATION (RDPA) REGISTER



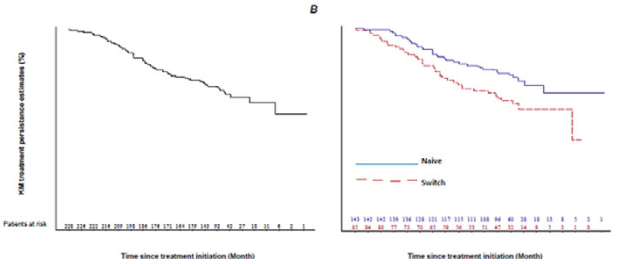
P. Chiowchanwisawakit [1], W. Katchamart [1], P. Chevaisrakul [1], P. Narongroeknawin [2], W. Louthrenoo [3], M. Osiri [4] on behalf of the Thai Rheumatism Association. *[1]Mahidol University; [2]Phramongkutklao Hospital and College of Medicine, Bangkok; [3]Chiang Mai University, Chiang Mai; [4]Chulalongkorn University, Bangkok, Thailand*

Background: Treatment recommendations for patients with spondyloarthritis (SpA) who inadequately respond to non-steroidal anti-inflammatory drugs (NSAIDs) and/or traditional disease-modifying antirheumatic drugs (DMARDs) are anti-tumour necrosis factor-alpha therapy (TNFi). There has been no data on the long-term efficacy and safety of TNFi in Thai patients with SpA.

Objectives: To evaluate the long-term efficacy and safety of the first TNFi in real-life practice and to identify the risk factors related to drug discontinuation in Thai patients with SpA from the RDPA registry.

Methods: Patients who fulfilled the 1984 Modified New York criteria for ankylosing spondylitis (AS), CASPAR criteria or Moll and Wright criteria for psoriatic arthritis (PsA) and the European Spondyloarthropathy Study Group Criteria or Modified Amor criteria for undifferentiated SpA (uSpA), and were prescribed the first TNFi between December 2009 and October 2014 in the RDPA registry were enrolled. Baseline demographic and clinical data were retrieved. A Cox proportional hazard model was used to identify the factors associated with discontinuation. The P-value of <0.05, two-sided was considered statistically significant.

Results: Of the 142 patients included, 97 had AS, 41 had PsA, and 4 had uSpA. Most AS patients were male (54.6%) with mean (SD) age of 44.6 (10.6) years, median (P_{25}–P_{75}) baseline BASDAI was 6.5 (5.6, 8.2) [from a 10-cm visual analog scale (VAS)], and median baseline patient global assessment (bPGA) was 7.2 (P_{25}–P_{75} 6.0, 8.0) (from a 10-cm VAS). For PsA patients, most were female (68.3%) with mean age of 52.6 (SD 12.2) years, median baseline BASDAI was 6.6 (P_{25}–P_{75} 4.9, 7.4) in patients with active axial involvement and median baseline number of joint involvement was 13.5 (P_{25}–P_{75} 6, 18.3) joints per patient with active peripheral joint involvement. The Efficacy of the TNFi treatment was good and it was increased over time in AS and PsA patients (figure 1). During the 5-year follow-up, AS, PsA, and uSpA patients had comparable discontinuation rate of their first TNFi treatment [25 (26%) in AS, 14 (34%) in PsA, and 1 (25%) in uSpA; p=0.82]. In univariate analysis, leflunomide use, and bPGA <3 comparing to >6 (from a 10-cm VAS) were associated with the discontinuation of TNFi in AS patients with hazard ratio (HR) (95% CI) of 2.56 (1.13, 5.81) and 8.59 (1.82, 40.65), respectively. For the patients with PsA, only infliximab use was associated with TNFi discontinuation with HR of 4.79 (95% CI 1.33, 17.20) in univariate analysis. The reasons for TNFi discontinuation were good response (38%), serious adverse effects (SAE) (30%), non-adherence (20%), and lack of efficacy (13%). Among SAE, 58% was infectious causes (57% tuberculosis and 43% non-mycobacterium infections). The others were non-infectious causes.



Conclusions: During the 5-year follow-up period, patients with SpA responded well to TNFi and the response rate increased over time. Tuberculosis was the most common SAE in this registry therefore surveillance of TB should be done.

AB0701 THE REAL-LIFE USE OF GOLIMUMAB IN PATIENTS WITH IMMUNE-MEDIATED RHEUMATIC DISEASES: ONE YEAR RESULTS OF THE GO-PRACTICE STUDY

R.-M. Flipo[1], F. Tubach[2], J. Ouaniche[3], P. Goupille[4], E. Lespesailles[5], N. Gouyette[6], P. Bertin[7], B. Fautrel[8]. *[1]Rheumatology, CHU Roger Salengro, Lille, Lille; [2]Epidemiology Departement & Clinical Research, CHU Pitié Salpêtrière, Paris; [3]Private practice, Private practice, Toulon, France, Toulon; [4]Rheumatology, CHU Tours, Tours; [5]Rheumatology, CHR Orléans, Orléans, France; [6]Rheumatology, Msd France, Courbevoie Cedex; [7]Rheumatology, CHU Limoges, Limoges; [8]Rheumatology, CHU Pitié Salpêtrière, Paris, Paris, France*

Background: The GO-PRACTICE study was initiated to describe the use of Golimumab (GLM), a human anti-TNFα monoclonal antibody, in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA), and ankylosing spondylitis (AS) in French clinical practice.
Objectives: The primary objective of this interim analysis was to assess the persistence of GLM at 1-year.
Methods: Observational, multicenter, prospective, national study. Adult patients with RA, PsA and AS were included consecutively at GLM after the decision for GLM therapy has been taken or at least after GLM initiation, and followed-up for 2 years. We present here baseline characteristics for overall population (n=754) and interim results for patients with 1-year follow-up (n=228 patients with available data regarding persistence of GLM)
Results: A total of 754 patients (134 sites) were included between January 2015 and March 2016. Most of them had AS (64%), and 22% and 13% had RA and PsA, respectively. Mean age was 46±13 years and 61% were female. Almost 37% had received prior biotherapy.
Nearly all patients (99%) were prescribed GLM as 50 mg-monthly injections. GLM was mostly co-prescribed with other antirheumatic treatments (84%).
Of the 163 patients with available data at strictly 1-year, 56.4% were still treated with GLM; (61.9% in biotherapy-naïve patients); the persistence rate was similar across the three groups. The Kaplan-Meier duration curves of GLM are presented in figure 1. The main reason for GLM discontinuation was primary non-response, reported in 42% of patients.
Among patients who continued GLM treatment, a meaningful improvement in disease activity was observed at 1-year in 71.9% of RA, 63.2% of PsA and 68.0% of AS patients. Patients-reported outcomes, including pain and functional disability, also showed improvement

Figure 1: Kaplan–Meier duration curve of treatment with golimumab for A) the global population (n=228) and B) by prior biotherapy: biotherapy naïve patients (n=143, blue line) and biotherapy experienced patients (n=85, red dotted line).

Conclusions: In real-life practice in France, GLM was prescribed according to recommendations in terms of dosage and therapeutic strategy. One-year interim analysis, performed in one third of the cohort, suggests that GLM treatment is associated with clinical improvements leading to persistence of treatment. These results need to be confirmed in the final overall analysis planned in 2018.

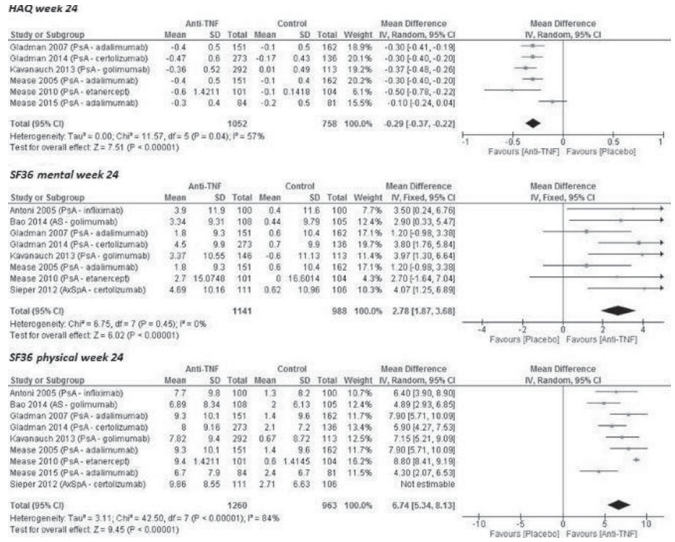
AB0702 IMPROVEMENT OF FATIGUE IN PATIENTS WITH SPONDYLOARTHRITIS TREATED WITH ANTI-TNF THERAPY: A PROSPECTIVE STUDY IN A REAL-LIFE SETTING

S. Desouches, E. Gaigneux, K. Louati, L. Lemeunier, C. Beauvais, J. Sellam, F. Berenbaum. *Rheumatology, APHP Saint-Antoine, paris, France*



Background: Besides randomized controlled trials evaluating biologic agents on fatigue, the impact of anti-TNF therapy on this crucial symptom has been poorly assessed in a real-life setting (1).
Objectives: To assess the early effect of etanercept (ETN) on fatigue-related outcomes in spondyloarthritis (SpA) patients in a real-life setting.
Methods: This prospective study included patients with active SpA fulfilling ASAS 2009 axial or peripheral criteria requiring an anti-TNF. All patients were treated with ETN 50mg weekly. BASDAI, BASFI, functional assessment of chronic illness therapy-fatigue (FACIT-F) (0 maximum and 52 the minimum of fatigue) and visual analogic scale of fatigue (VAS-F) (0 the minimum -100 maximum of fatigue) were assessed at inclusion at the time of ETN beginning (M0) and 4±1 months later (M4).
The primary outcome was the M0-M4 change of VAS-F. The secondary outcomes were i) the M0-M4 change of FACIT-F ii) the frequency of patients who met improvement according to FACIT-F (defined as the minimal clinically important difference of FACIT-F corresponding to a 4-points decrease (FACIT-F responders). To determine whether fatigue change was related to disease activity improvement, a correlation between M0-M4 changes of BASDAI and VAS-F or FACIT-F was determined.
Results: 30 SpA patients were enrolled (60% women, mean age ± standard deviation 39±8 years-old, axial SpA 83%, mean BMI 26±4, 80% ETN as a 1st line). Mean BASDAI improved at M4 (M0 48±20 versus M4 36.5±22; p=0.04) as well as VAS-F (M0 69±18 vs M4 52±24; p=0.01). The frequency of patients having VAS-F>50/100 was 86% at M0 and decreased at 36% at M4. Conversely, no significant change was observed concerning FACIT-F (M0 24.5±24 versus M4 28.8±11: p=0.36). At M4, 64% patients were FACIT-F responders. FACIT-F and VAS-F M0-M4 changes were highly correlated (r=0.78, p<0.0001).
Despite no correlation between BASDAI and FACIT-F M0-M4 changes (r=0.36, p=0.1), a trend was observed for BASDAI and VAS-F M0-M4 changes in the same fashion (r=0.36, p=0.07). Interestingly, there was no baseline clinical characteristic associated with subsequent better fatigue improvement.
Conclusions: This real-life study investigating the early effect of etanercept therapy on fatigue in SpA patients showed that fatigue (according to VAS-F) significantly improved while effect on FACIT-F was less pronounced. This improvement was explained, only in part, by disease activity improvement.

AB0703 IMPACT OF ANTI-TNF AGENTS ON PATIENT-REPORTED OUTCOMES IN SPONDYLOARTHRITIS: A SYSTEMATIC REVIEW OF THE LITERATURE AND META-ANALYSIS

S. Laclau[1], A. Constantin[1,2], A. Cantagrel[1,2], T. Barnetche[3], A. Ruyssen-Witrand[1,4], Y. Degboe[1,2]. *[1]Rheumatology Center, Hospital Pierre Paul Riquet, Toulouse University Hospital; [2]CPTP, INSERM UMR 1043, Toulouse; [3]Rheumatology Department, Fhu Acronim, Bordeaux University Hospital, Bordeaux; [4]Pharmaco-épidémiologie, Evaluation de l'utilisation et du risque médicamenteux, INSERM UMR 1027, Toulouse, France*

Background: Disability, alteration in quality of life and fatigue are frequently reported in spondyloarthritis (SpA). Anti-TNF demonstrated clinical efficacy in SpA. However efficacy on patient-reported outcomes (PROs) may differ from medical assessment.
Objectives: To assess the impact of anti-TNF on quality of life, disability and fatigue reported by SpA patients.
Methods: *Design:* systematic review and meta-analysis of the literature. *Data sources:* two authors (SL and YD) independently screened PubMed-Medline, Cochrane library and EMBASE databases until November 2016. *Key words:* ("Patient reported" OR "quality of life" OR fatigue OR FACIT) AND (spondyloarthritis OR "psoriatic arthritis" OR "ankylosing spondylitis") AND (anti-TNF OR certolizumab OR etanercept OR adalimumab OR infliximab OR golimumab). *Articles selection:* randomized controlled trials (RCTs), published in English, assessing efficacy of anti-TNF on PROs, in ankylosing spondylitis (AS), psoriatic arthritis (PsA) or SpA according to the ASAS criteria. *Data collected:* fatigue assessed by FACIT score, quality of life assessed by Short Form 36 (SF36) mental and physical component or by Health AssessementQuestionnary Disability Index (HAQ). *Data analysis:* Article quality was evaluated by the JADAD scale. For SF36 and HAQ outcomes, pooled variations at 12 and 24 weeks were computed by meta-analysis. Heterogeneity was measured by I^2 index.
Results: Of the 604 articles identified, 37 references were eligible for systematic review and 13 for meta-analysis. Our systematic review identified 10 RCTs concerning AS, 20 concerning PsA and 7 concerning axial SpA. However due to the heterogeneity in available statistical data, references eligible for meta-analysis were mainly related to PsA.
HAQ assessment was available for a meta-analysis in 8 studies. HAQ was significantly improved at 12 and 24 weeks with anti-TNF. The impact on HAQ variation at week 24 was -0.29 points [95% CI: -0.37, -0.22]. Heterogeneity was important (I^2 =57%; see figure).
Ten studieswere eligible for a meta-analysis of anti-TNF effect on SF36 mental form. An improvement was observed at 12 and 24 weeks, although superior at 24 weeks. The effect at week 24 was 2.78 [95% CI: 1.87 - 3.68], without heterogeneity (I^2 =0%; see figure).

Twelve studies were eligible for a meta-analysis of anti-TNF effect on SF36 physical form. We observed a similar and significant improvement at 12 and 24 weeks. The effect at week 24 was 6.74 [95% CI: 5.34 – 8.13], with an important heterogeneity (I^2 =84%; see figure)
Fatigue was evaluated in 3 studies. Adalimumab induced a significant improvement in FACIT score at 12 and 24 weeks in one study. Two studies using different scores (Fatigue Assessment Scale, BASDAI fatigue item) to assess certolizumab effect highlighted similar findings: an early improvement in fatigue at week 12, remaining significant and stable at week 24.

Conclusions: Anti-TNFs agents significantly improve disability, quality of life and fatigue in patients with PsA.
Acknowledgements: Abbvie France pharmaceutical company provided logistic support by organizing a meta-analysis methods workshop, but played no further role in the project.

AB0704 HIP ARTHROPLASTY IN PATIENTS WITH ANKYLOSING SPONDYLITIS - CLINICAL AND FUNCTIONAL EFFICIENCY

S. Lapshina[1,1], I. Akhtyamov[1,2], I. Gilmutdinov[2], L. Myasoutova[1]. *[1]Kazan State Medical University; [2]Republic Clinical Hospital, Kazan, Russian Federation*

Objectives: To evaluate the results of the hip joints replacement in patients with SpA under the dynamic supervision of a rheumatologist and orthopedic within the first year after the operation.
Methods: As part of special program for rheumatology patients hip endoprosthesis was done in 12 patients (mean age - 44,2±15,3 years) with SpA, 8 of them with ankylosing spondylitis (AS) and 4 with psoriatic arthritis (PsA). Duration of the disease - 13,3±7,9 years, positive for HLA B27 in 9 (75%) patients. High activity for ASDAS was at 58.3% of the patients. Took NSAIDs at the time of the operation - 11 (91.6%) patients, sulfasalazine 5 (41.6%), methotrexate- 2 (16.7%). 1 (8.3%) patient received etanercept,1 (8.3%) patient - infliximab. Dynamic observation of rheumatologist and orthopedic was carried out before, just after surgery, after 6 and 12 months, with the assessment of VAS, BASDAI, ASDAS, BASFI.
Results: The reduction of pain intensity on the VAS was observed in the first month after the surgery (47,3±18,6 mm), initially it was 74,0±24,1 mm, 42.5±9 after 6 months ($p<0.05$), after 12 months - up to 22,5±9,9 mm ($p<0.05$). ASDAS significantly ($p<0.05$) reduced from 2,94±2,01 to 1,68±1,35 - in 6 months and 1,26±0,88 - 12 months after operation; BASDAI: from 6,24±3,91 to 2,75±2,20 - 6 months, 2,65±1,53 at 1 year follow-up. BASFI index before surgery - 5,48±3,29, 6 months - 2,78±2,31, 1 year - 2,32±1,60 points. No complications after surgery were registered.
Conclusions: Hip joints endoprosthesis in patients with SpA is effective not only in improving functional ability and pain relief, but also a reduction of disease activity. Dynamic rheumatologist observation in perioperative period leads to positive dynamics in relation to the activity of SpA and quality of life of patients during the first year after surgery

AB0705 CONTINUED EFFECTIVENESS OF A BIOSIMILAR ADALIMUMAB AFTER STOPPAGE OF INITIAL TREATMENT IN PATIENTS WITH ANKYLOSING SPONDYLITIS

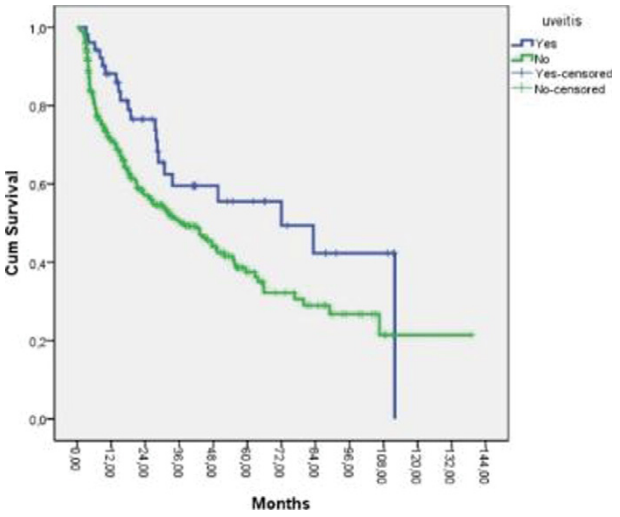
S. Bandyopadhyay[1], A. Ray[2], R.N. Sarkar[3], S. Dash[1], S. Mondal[1]. *[1]Medicine, Apollo Gleneagles Hospital; [2]Medicine, Fortis Hospital, Kolkata; [3]Medicine, Calcutta Medical College, Kolkata,, India*

Background: Adalimumab, an anti TNF-α agent, has been proven to be safe and effective in treatment of ankylosing spondylitis (AS). A biosimilar adalimumab was approved for use by Indian regulators in 2014. It is a "fingerprint match" of the reference adalimumab in terms of purity, potency, safety and clinical efficacy.[1,2] In the absence of availability of adalimumab in India, this biosimilar adalimumab currently serves as an accessible, cost-effective option for treatment of AS patients.
Objectives: This retrospective analysis evaluates effectiveness of biosimilar adalimumab (bADA), in terms of disease activity, safety and outcomes in real-life Indian AS patients treated for initial 24 weeks and then followed for next 24 weeks off biologic treatment.
Methods: Medical records of AS patients with Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Bath Ankylosing Spondylitis Functional Index (BASFI) >4, who were prescribed bADA therapy between January to December 2015 were analysed. For patients, who stopped bADA treatment after 24 weeks, standard AS outcome-measurement scores including ESR, CRP, BASDAI, BASFI, and Health Assessment Questionnaire (HAQ) at baseline, week 24 and at week 48 were measured to evaluate ongoing efficacy, were compared using paired Student's T-test. Patients were allowed to continue methotrexate and salazopyrin as part of routine medical care.
Results: During the study period, 52 AS patients were prescribed bADA 40 mg s/c; 24 of these patients, who had stopped treatment after 6 months, were considered for this analysis. Mean age for this group was 36.57±10.81 years; 10 females. At the end of 24 weeks' treatment, there were significant reductions in levels of inflammatory markers ESR, CRP, as well as in BASDAI, BASFI and HAQ scores. Eight patients continued to receive methotrexate and 8 patients sulfasalazine as concomitant medications. After week 48 (24 weeks post stoppage), BASDAI and BASFI scores did not deteriorate despite discontinuation of bADA treatment. The patients' HAQ scores were also indicative of similar trends of continuing improved health status post the therapy.

Table 1. Disease activity scores and patient outcomes at 24 weeks after completion of biosimilar adalimumab therapy

Parameters	Baseline	Week 24 (last dose)	P value (baseline – week 24)	Week 48 (24 weeks bADA free period)*	P value (baseline – week 48)
BASFI	8.35±0.72	2.87±0.77	p<0.001	2.55±0.65	p<0.001
BASDAI	7.70±0.84	2.45±0.58	p<0.001	2.41±0.58	p<0.001
ESR	49.50±28.78	13.97±11.19	p<0.001	30.33±26.23^	p=0.02
CRP	19.71±12.24	3.58±3.6	p<0.001	6.13±9.41	p<0.001
HAQ (Pain)	67.71±7.22	27.08±8.2	p<0.001	28.13±9.42	p<0.001
HAQ (Health)	60.83±8.43	28.13±8.45	p<0.001	25.63±10.56	p<0.001

Data presented as Mean±standard deviation. *p = not significant for any parameter when compared for changes from week 24 to week 48. ^p=0.006 as compared to week 24 for rise in ESR during the bADA free period.



Conclusions: Biosimilar adalimumab therapy was effective in treating AS patients. The disease activity and health assessment scores continued to remain stable with no worsening after the stoppage of treatment for 6 months, indicating a post-therapy effectiveness in these patients with no reported adverse event.

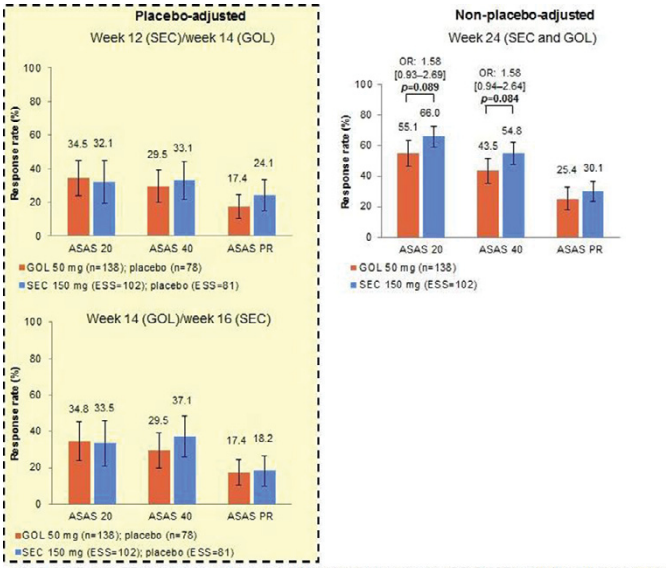
AB0706 ANKYLOSING SPONDYLITIS PATIENTS WITH UVEITIS HAD BETTER ADALIMUMAB RETENTION RATE: HUR-BIO REAL LIFE RESULTS

B. Armagan[1], A. Sari[1], A. Erden[1], L. Kilic[1], D.C. Guven[2], T. Pashayev[2], E. Bilgin[2], C. Simsek[2], E.C. Erdat[2], O. Karadag[1], A. Akdogan[1], S. Apras Bilgen[1], S. Kiraz[1], I. Ertenli[1], U. Kalyoncu[1]. *[1]Hacettepe University, Department of Internal Medicine, Division of Rheumatology; [2]Department of Internal Medicine Hacettepe University, Ankara, Turkey*

Background: Retention of biological drugs in inflammatory arthritis may be affected from different obvious and unknown factors. It can be related with patient characteritics or disease features. In ankylosing spondylitis (AS), retention rate of biological drugs may be related with extra-articular presentation of AS such as uveitis, as well.
Objectives: The objective of this study was to assess whether uveitis affected retention of adalimumab in AS patients in our single center biological cohort.
Methods: Hacettepe University Biological registry is single-center biological registry since 2005. HURBIO had 2165 spondyloarthritis patients of which 1190 patients had AS according to NY criteria. Until now, in 510 of 1190 patients have used adalimumab and 350 of 510 patients had available for uveitis. Patients

were assessed for demographic characteristics, disease duration, HLA-B27, DMARD and biological usage, biological switch ratio. Baseline disease activity was assessed with BASDAI, BASFI VAS (pain, fatigue and patients global assessment), ESR and CRP. Patients were compared according to having uveitis or not. Retention rate of adalimumab assessed by Kaplan-Meier survival analysis.
Results: Total 350 (59.4% male) AS patients analyzed. Mean age was 43 (12), mean disease duration and symptom duration were 10.5 (7.8) and 14.8 (9.6) years, respectively. 52 patients (14.8%) had uveitis. Median adalimumab survival time according to having uveitis were 71.9 (95% CI 25.4–118.6) months vs 36.4 (95% CI 23.3–49.4) months (log-rank p=0.014) (figure). Patients with uveitis were more frequently male (18.2% vs 9.8%, p=0.03), HLA-B27 positive (75.0% vs 49.5%, p=0.022). Patients with uveitis had more frequently SpA family history, as well (23.1% vs 10.8%, p=0.003). Age (49 (11) vs 41 (11) years, p<0.001), disease duration (14.4 (10.1) vs 9.8 (7.1) years, p<0.001), and symptom duration (22 (12) vs 14 (8) years, p<0.001) were higher in patients with uveitis. Baseline and last visit disease activities were similar regarding to uveitis.



Conclusions: Determination of possible risk factors for retention of TNFi drugs is an important clinical problem for routine practise. It is well known that adalimumab is one of the treatment option for uveitis whether uveitis related with SpA or not. Our biological cohort supported that AS patients with uveitis had better adalimumab survival. For routine practise, adalimumab could be considered for AS patients with uveitis.

AB0707 COMPARATIVE EFFECTIVENESS OF SECUKINUMAB AND GOLIMUMAB IN ANKYLOSING SPONDYLITIS ASSESSED BY MATCHING-ADJUSTED INDIRECT COMPARISON USING PIVOTAL PHASE 3 CLINICAL TRIAL DATA

W. Maksymowych[1], E. Choy[2], Y. Yazici[3], J. Walsh[4], H. Thom[5], C. Kalyvas[6], T. Fox[7], K. Gandhi[8], S. Jugl[7]. *[1]University of Alberta, Edmonton, Canada; [2]University of Cardiff, Cardiff, United Kingdom; [3]New York University School of Medicine, New York; [4]University of Utah, Salt Lake City, United States; [5]University of Bristol, Bristol, United Kingdom; [6]MAPI Group, Houten, Netherlands; [7]Novartis Pharma AG, Basel, Switzerland; [8]Novartis Pharmaceuticals Corporation, East Hanover, United States*

Background: No data are available from head-to-head RCTs between secukinumab 150 mg (SEC; an anti-IL-17A) and golimumab 50 mg (GOL; a TNFi) in patients with active ankylosing spondylitis (AS). Matching-Adjusted Indirect Comparison (MAIC) can be used to estimate comparative effectiveness and enables treatment outcomes to be compared across effectively balanced trial populations. MAIC is an established method in health technology assessments and NICE have published guidance on appropriate methodology, and especially for addressing imbalances in observed covariates between trials.[1]
Objectives: To assess the comparative effectiveness of SEC and GOL up to week 24 using MAIC with pooled individual patient data (IPD) from the RCTs MEASURE 1 (M1) and MEASURE 2 (M2) and published aggregate data from the RCT GO-RAISE.
Methods: Pooled M1 and M2 data were used to maximize the effective sample size (ESS) for SEC. IPD from the SEC arms of M1 and M2 (n=197) were weighted to match the published baseline characteristics of the GOL arm of GO-RAISE (n=138). Placebo arms were matched in the same way; placebo-adjusted comparisons were possible only until week 16 because patients could receive active treatment from this time onwards. Logistic regression was used to determine weights for age, sex, BASFI, disease duration, CRP and previous TNFi therapy. Recalculated outcomes from M1 and M2 (SEC, ESS=102; placebo, ESS=81) were compared with data from GO-RAISE (GOL, n=138; placebo, n=78). Pairwise comparisons – reported as odds ratios (ORs [95% CIs]) – were performed for ASAS 20, ASAS 40 and ASAS PR responses at nearest-equivalent time points across trials: week 12 (SEC)/14 (GOL), week 14 (GOL)/16 (SEC) and week 24 (SEC and GOL). Non-responder imputation (NRI) was available for all binary outcome data. Strict thresholds were avoided when interpreting *p* values, in line with American Statistical Association 2016 guidance.
Results: There was no evidence of differences in ASAS 20 and ASAS 40 responses between SEC and GOL at weeks 12/14 and 14/16 (both placebo-adjusted). At week 24, non-placebo-adjusted ASAS 20 and ASAS 40 responses using NRI were higher with SEC than GOL (OR [95% CI]: 1.58 [0.93–2.69], *p*=0.089 and 1.58 [0.94–2.64], *p*=0.084, respectively). There was no evidence of differences in ASAS PR responses between SEC and GOL at weeks 12/14, 14/16 and 24. A sensitivity analysis conducted after adding BASDAI score to the matching parameters yielded similar results.

ASAS 20/40 and PR responses are the absolute mean response rate (GO-RAISE) and the predicted mean response rates (MEASURE 1 and MEASURE 2). Error bars shown are 95% CIs.
ASAS, Assessment of SpondyloArthritis International Society; ASAS 20/40, at least a 20%/40% improvement according to ASAS response criteria; ASAS PR, ASAS partial remission; CI, confidence interval; ESS, effective sample size; GOL, golimumab; OR, odds ratio; SEC, secukinumab.

Conclusions: There was no evidence of differences in ASAS responses between SEC and GOL in placebo-adjusted analyses. In non-placebo-adjusted analyses, SEC showed higher ASAS 20 and ASAS 40 responses than GOL at week 24.

AB0708 TRANSITION FROM ONGOING INFLIXIMAB REFERENCE PRODUCT TO ITS BIOSIMILAR: CAN WE TALK ABOUT A FAILURE?

W. Akrout[1], A. Bosycot[1], R. Levet-Labry[1], E. Gazaix-Fontaine[2], M. Paul[1], P. Claudepierre[2]. *[1]Clinical Pharmacy Department; [2]Rheumatology Department, Henri Mondor University Hospital AP-HP, Créteil, France*

Background: Some recent publications support the fact that there is no clinically meaningful difference between infliximab biosimilar and the originator in naïve patients, but sole a few of them actually assessed the transition itself. Since May 2016, according to the European guidelines, the French Health Authorities have allowed interchangeability between a biotherapy reference product and its biosimilar. According to the last studies focusing on the safety and efficacy issues, avoiding the transition to biosimilar looks no longer justified.
Objectives: This work aimed to understand to which extent the use of infliximab biosimilar may result in the failure of the switch strategy in spondyloarthritis patients.
Methods: This is a retrospective study conducted from June to December

2016. Only were included the adult patients with rheumatoid arthritis (RA), spondyloarthritis (SpA) or psoriatic arthritis (PsA) having accepted the transition from Infliximab reference product (IFX^R) to its biosimilar (IFX^B). For SpA patients, transition monitoring was based on the end-of-dose "wearing off" (WO) phenomenon assessment before and after the switch, disease activity score BASDAI and also the inflammatory marker CRP. Transition was considered as unsuccessful after 2 IFX^B infusions with patient complain. In this case, the drug level was determined using ELISA before switching back to IFX^R, and any spacing infusions because a concomitant health disorder was sought.

Results: Of the 99 patients treated with IFX^R for more than 2 years, 91% (90/99) accepted the transition: 53 SpA, 23 RA and 14 PsA. Fourteen patients (12 SpA, 2 RA) didn't reach the 3rd IFX^B administration. SpA patients reported the occurrence of arthralgia (12/12) and a partial (8/12) or total (4/12) efficacy loss. Only 5 patients reported a 2 point-increase or more regarding the BASDAI score, and only 3 patients had an increase in the CRP level (*Cf.*Table 1). Except for P1, the efficacy loss was associated in each case with WO phenomenon already reported before the transition (8/12) or undetectable IFX level (3/12). For these 3 last patients, the IFX^B drug administration rate was increased by at least 2 weeks than usual because of a concomitant infection.

Table 1: SpA patients discontinued IFXB outcomes

SpA patients	P1	P2	P3	P4	P5	P6	P7	P8	P9	P10	P11	P12
Arthralgia	+	+	+	+	+	+	+	+	+	+	+	+
Partial or total efficacy loss	+	+	+	+	+	+	+	+	+	+	+	+
↗BASDAI	-	+	+	+	-	-	-	+	-	-	-	+
↗ CRP	+	-	-	-	-	+	-	+	-	-	-	-
Existing WO	-	+	+	-	+	+	+	-	+	+	-	+
Undetectable IFX level	-	-	-	+	-	-	-	+	-	-	+	-
Spacing infusions	-	-	-	+	-	-	-	+	-	-	+	-

+: Yes: - : No

Conclusions: This observational study showed a transition failure rate at 16% (76/90) in global, which reached 23% (12/53) if limited to SpA. All SpA patients with supposed transition failure reported either a disease escape beforehand or a concomitant infection requiring to spacing infusions. In order to complete these results, an anti-IFX antibodies monitoring is in progress so to highlight any IFX activity loss. Any failure observed with the transition would be actually more complex than the presumably inefficacy of the biosimilar IFX^B especially for SpA patients. So, it seems difficult to assess robustly the inefficacy of the transition to IFXB in SpA patients only according to patient complain.

Spondyloarthritis - clinical aspects (other than treatment)

AB0709 THE RELATIONSHIPS BETWEEN THORACIC REGION INVOLVEMENT AND FUNCTIONS OF UPPER EXTREMITY, SCAPULAR KINEMATICS IN PATIENTS WITH ANKYLOSING SPONDYLITIS: PILOT STUDY

O. Mete[1], D. Oskay[1], A. Tufan[2]. [1]*Physiotherapy and Rehabilitation;* [2]*Internal Medicine, Division of Rheumatology, Gazi University, Ankara, Turkey*

Background: Ankylosing spondylitis (AS) is a chronic inflammatory rheumatic disease that mainly affects the axial skeleton. As the disease progresses, increased thoracic kyphosis can be seen in these patients. Because of increase in thoracic kyphosis, the orientation of the scapula on the thorax and thus the functions of upper extremity may change.

Objectives: The aim of the study is to investigate the relationships between thoracic region involvement and functions of upper extremity, scapular kinematics in patients with AS.

Methods: Fifteen (15) patients with AS and eleven (11) healthy control were participated in the study. Thoracic kyphosis angle and shoulder range of motions were assessed by using digital inclinometer, scapular and shoulder muscle strength were assessed by using digital dynamometer, three dimensional (3D) scapular kinematics were assessed by using electromagnetic tracking system, disability level of upper extremity were assessed by Turkish Version of Disability of Arm, Shoulder and Hand Questionnaire (DASH-T). Spearman correlation coefficient, Pearson correlation coefficient, Mann-Whitney U Test and Independent Sample T-test were used for statistical analysis.

Results: DASH-T, thoracic kyphosis angle, shoulder abduction, internal rotation, external rotation of dominant side, shoulder abduction, internal rotation of non-dominant side, anterior deltoid, middle deltoid, serratus anterior, downward trapezius muscle strengths of dominant and non-dominant side, upward rotation of scapula during 30,60,90 degrees humerothoracic elevations at sagital plane of dominant and non-dominant side showed significantly differences between two groups. Thoracic kyphosis angle showed correlations with DASH-T ($p<0,05$,r:0,619), shoulder flexion, abduction, internal rotation, external rotation of dominant side ($p<0,05$,r:-0,867), ($p<0,05$,r:-0,580), ($p<0,05$,r:-0,657), ($p<0,05$,r:-0,599) and shoulder flexion, abduction, internal rotation of non-dominant side ($p<0,05$,r:-0,813), ($p<0,05$,r:-0,665), ($p<0,05$,r:-0,741), respectively. Thoracic kyphosis angle showed correlations with anterior deltoid, middle deltoid, serratus anterior, middle trapezius, downward trapezius muscle strengths of dominant side and non-dominant side, respectively ($p<0,05$,r: -0,899), ($p<0,05$,r:-0,854), ($p<0,05$,r:-0,805), ($p<0,05$,r:-0,791), ($p<0,05$,r:-0,633), ($p<0,05$,r:-0,877), ($p<0,05$,r:-0,796), ($p<0,05$,r:-0,884), ($p<0,05$,r:-0,724), ($p<0,05$,r:-0,673). Correlations between thoracic kyphosis angle and anterior tilt of scapula during 90 degree humerothoracic elevations at sagital plane of dominant side were obtained ($p<0,05$, r:0,522).

Conclusions: Scapulothoracic joint biomechanics and functions of upper extremity were affected by kyphotic posture in patients with AS. One of the most important causes of biomechanical impairment in AS patients is the deterioration of scapular kinematics with kyphosis. For preventing functional impairment, treatment programs should be supplemented with scapular kinematic exercises.

AB0710 REVIEW OF PREGNANCY OUTCOMES IN SPONDYLOARTHROPATHY IN A UNIVERSITY TEACHING HOSPITAL

A. Shajpal[1], M. Khare[2], A. Moorthy[3]. [1]*Obstetrics;* [2]*Maternal Fetal Medicine;* [3]*Rheumatology, University Hospitals of Leicester, Leicester, United Kingdom*

Background: Spondyloarthropathy (SpA) is a chronic inflammatory condition of the spine affecting mainly the male population however the incidence amongst the female population is increasing. The peak incidence of SpA is in the reproductive age group. There has been a lack of focus on pregnancy in SpA as compared to other autoimmune condition such as Lupus and Rheumatoid arthritis, but this is changing. There is a paucity of information (1) on fertility and pregnancy outcomes in this condition compared to other diseases and this may lead to inequality in healthcare delivery.

Objectives:
- To review the pregnancy outcomes in women with SpA in our unit
- To review ankylosing spondylitis activity during pregnancy
- To improve the quality of care in this group of patients by developing local pathways and appropriate MDT involvement

Methods: This is a retrospective case review of pregnancies in women with SpA booked at a large tertiary teaching hospital over three years between January 2014 and December 2016. We have an annual delivery rate of 11,000 maternities. The maternity electronic database and clinic diaries were used to identify the cases. A standardised proforma was used to collect and collate the data for demographics, pre pregnancy counselling, disease activity and pregnancy outcome.

Results: Six pregnancies were identified in the study period. All patients were under the care of a Rheumatologist. The maternal age range was between 28 and 35 years. The BMI ranged between18 and 37. Ethnicity included 5 caucasian and one Asian woman. Five women had previous pregnancies and one was in her first pregnancy. Two of the multiparous women had previously delivered by caesarean section. Three of the six women suffered from anxiety and/or depression and one had fibromyalgia. Two of the six patients were not on any medication at the start of pregnancy and didn't require any during pregnancy. Four women needed various analgesics and one patient was on sulfasalazine but stopped this at 5 weeks' gestation. NSAIDs was stopped in 3 women after confirmation of pregnancy. One patient who was on Anti TNF therapy discontinued the drug preconception. We observed 50% attended specialist maternal-fetal medicine and anaesthetic services. One patient saw a physiotherapist and accessed hydrotherapy during pregnancy.

Two of six patients delivered preterm (<37 weeks) and 4 delivered at term (>37 weeks). Of the preterm deliveries, 1 went into spontaneous labour not related to disease flare and the other was delivered electively for fetal concerns. All the women delivered by caesarean section. One was planned as an elective caesarean for maternal request due to difficulty abducting legs. All the remaining caesarean deliveries were for obstetric indications not related to SpA.

Conclusions: This small observational case series did not highlight any worsening SpA disease activity or poor pregnancy outcome. Further larger studies are required. However a care pathway for managing this group of patients would help to standardise the care during pregnancy. A multidisciplinary approach is essential to optimise the quality of care for these patients.

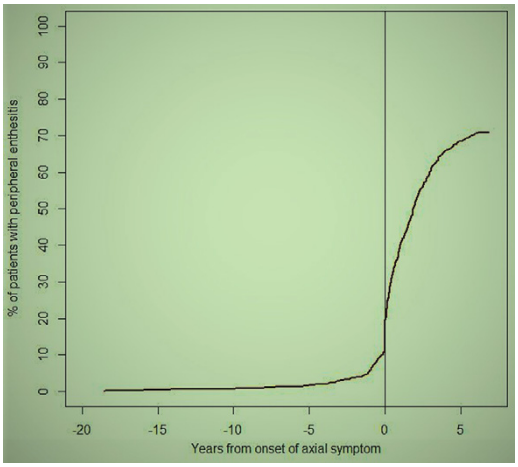
AB0711 REVIEW OF MANAGEMENT OF HLA B27 POSITIVE UVEITIS PATIENT ATTENDING A TERTIARY HOSPITAL – HOW GOOD ARE WE?

B. Kapoor[1], K. Periyasamy[1], M. Babbington[1], A. Moorthy[2]. [1]*Ophthalmology;* [2]*Rheumatology, Leicester Royal Infirmary, Leicester, United Kingdom*



Background: Delay in diagnosing Spondyloarthroapthy is well documented. One of the reasons for the delay is the presentation of these group of patients to different specialties due to variety of extra articular manifestations. Acute anterior uveitis (AAU) is the most common extra-articular manifestation in HLA B27 positive spondyloarthropathies, occurring in 30–50% of cases [1]. It can occur before the onset of rheumatologic symptoms [2,3]. However quite often this group of patients is not routinely referred to or seen by the rheumatologist for further evaluation.
Objectives:
- To assess the ophthalmologist practice in evaluating patients with AAU for inflammatory back pain or other Rheumatological diagnoses.
- To identify the number of HLA B27 requests made for uveitis patients.
- To identify the referral rate of HLA B27 uveitis patients to Rheumatologists for evaluation.

Methods: We conducted a retrospective pilot study to assess all patients with AAU presenting over a period of one-week to our busy teaching hospital eye casualty which serves over one million population. All patients with Iritis were identified from eye causality records and medical case notes were obtained. A standard proforma was designed and piloted with few case notes initially. Modified proforma was subsequently used to collect the data which was collated and analysed using EXCEL spread sheet.
Results: A total of 62 patients (n=62) with AAU presented to eye casualty over a one-week period. Case notes of 49 patients could be procured. Majority of the patients were Caucasians (n=35) while the rest were Asians (n=12) and blacks (n=2). Sex ratio was nearly equal with 25 patients being males and the rest females. Most of our patients' age ranged between 20 to 60 years. 60% patients had a history of recurrent iritis. Out of these 9 patients had bilateral uveitis and 14 were unilateral. In 6 patients, the laterality was not documented. A history for spondyloarthropathy was elicited in only 14 patients by the ophthalmologist at the time of initial assessment. Out of these 14 patients Inflammatory back pain history was positive in 10 patients. Only 17 out of 62 (27%) patients had HLA B27 checked and it was noted to be positive in 5. Amongst the 5 HLA B27 positive patients 2 patients were referred to rheumatology whereas 2 patients were already under rheumatology.
Conclusions: We observed that there is a clear lack of understanding in eliciting effective rheumatology history in patients with recurrent anterior uveitis and requesting HLA B27 appropriately. Therefore, a need for a clear pathway for managing patient presenting with recurrent uveitis and HLA B27 positivity for evaluation of Inflammatory back pain. Clear local guidelines and pathway need to be developed to provide effective care. Good communication between the Ophthalmologist and Rheumatologist is key in early diagnosis and effective management of this deforming condition.

AB0712 CLINICAL CHARACTERISTICS OF SPONDYLARTHRITIS (SPA) WITH AND WITHOUT PERIPHERAL ENTHESITIS – DATA FROM THE DESIR COHORT

V. Nadon[1], A. Molto[2], A. Etcheto[2], L. Bessette[3], L. Michou[3], P. Claudepierre[4], D. Wendling[5], C. Tkaczyk[6], B. Haraoui[1], M. Dougados[2]. [1]*Institut de Rhumatologie de Montreal, Montreal, Canada;* [2]*Hôpital Cochin, Paris, France;* [3]*CHUL, Quebec, Canada;* [4]*Hôpital Henri Mondor, Créteil;* [5]*CHRU, Besançon, France;* [6]*Janssen, Montreal, Canada*

Background: Peripheral enthesitis, mostly in the lower limbs, is a major feature of spondyloarthritis (SpA). Its prevalence is highly variable depending on the population studied, estimated between 10% and 70%. The probability to develop a peripheral enthesitis over time and the factors associated with it are mostly unknown.
Objectives: The aims of the present study were: 1) To describe the prevalence and characteristics of peripheral enthesitis in early axial SpA population, at the inclusion in the DESIR cohort; 2) to estimate the incidence of peripheral enthesitis over time; 3) to determine the factors associated with the presence of peripheral enthesitis.
Methods: We used data from the DESIR cohort, a prospective multi-center, longitudinal French cohort of 708 patients with inflammatory back pain suggestive of early axial SpA (<3 years since axial symptoms onset). We performed a descriptive analysis to evaluate the prevalence and characteristics of the peripheral enthesitis at time of inclusion (location, number of enthesitis, and mean time between first enthesitis and axial symptoms). We also estimated the incidence of peripheral enthesitis over a follow up period of 60 months, using Kaplan-Meier curves. Finally, we determined the baseline characteristics associated with the presence of a peripheral enthesitis by multivariable analysis (logistic regression, including the variables significantly associated in the univariable analysis).
Results: At inclusion, 395 patients (55.8%) had peripheral enthesitis in their past medical history. The locations were mainly the plantar fascia (212/395, 53.7%) and the Achilles tendon (152/395, 38.5%). Seventy-seven (19.4%) of these patients developed peripheral enthesitis before their axial symptoms, with a mean time interval of 773 days. During the 5-year follow-up period, 109/708 (15.4%) patients developed new peripheral enthesitic symptoms, resulting in 504/708 (71.2%) patients who had presented with at least one episode of peripheral enthesitis at 5 years. Variables associated to peripheral enthesitis according to the univariable analysis were: older age, male gender, HLA B27 positivity, MRI sacroiliitis, Modified NY criteria fulfilled, presence of either anterior chest wall pain, peripheral arthritis, dactylitis or psoriasis, high BASDAI, BASFI or mean score ASAS-NSAID. Only the history of anterior chest wall pain and of peripheral arthritis were significantly and independently associated with the presence of peripheral enthesitis in the multivariable analysis (Odds Ratio (OR) =1.6 [95% Confidence interval (1.6 [1.1–2.3], and OR=2.1 [1.4–3.0], respectively)

Conclusions: This prospective study highlights the high prevalence of peripheral enthesitis in early axial SpA and stresses the importance of researching any signs and symptoms of enthesitis, especially in those patients with anterior chest wall pain and peripheral arthritis.

AB0713 UVEITIS SECONDARY TO SPONDYLARTHRITIS IN AN OCULAR INFLAMMATION INTERDISCIPLINARY UNIT

D. Peiteado[1], A. Pieren[1], A. Schlinker[2], V. Hidalgo[2], C. Millán[1], E. De Miguel[1], A. Balsa[1]. [1]*Rheumatology;* [2]*Ophthalmology, Hospital Universitario la Paz, Madrid, Spain*

Objectives: To describe the characteristics of ocular involvement in spondyloarthritis in an ocular inflammation interdisciplinary unit.
Methods: This descriptive study include the patients with uveitis secondary to spondyloarthritis or inflammatory bowel disease (IBD) treated by the rheumatologist from January 2012 to December 2016 in an ocular inflammation multidisciplinary unit. Demographic characteristics, aetiology, ocular involvement pattern, and systemic therapy data were collected and analysed.
Results: From 276 patients evaluated by the rheumatologist, 111 (40.2%) were uveitis secondary to systemic inflammatory diseases. Within this group, the uveitis

associated with spondyloarthritis (including also IBD) were the most frequent (68 patients, 61%). Focusing on this group, 57.4% were male with a mean age of 49±15.8 years. 73.5% were HLAB27 positive and 76% had radiologic sacroiliitis. In 24 patients (35.3%) the diagnosis of spondyloarthritis was made after the anamnesis in the uveitis unit. The diagnosis was already known in the other cases. The spondyloarthritis subtypes are described in the table.

Diagnosis	n (%)
Ankylosing spondylitis	33 (48.5)
Non radiographic axial spondyloarthritis	13 (19.1)
Psoriatic arthritis	5 (7.4)
IBD spondyloarthritis	5 (7.4)
Peripheral spondyloarthritis	4 (5.9)
Juvenile idiopathic arthritis	4 (5.9)
IBD (without Joint involvement)	3 (4.4)
Reactive arthritis	1 (1.5)
Total	68 (100)

According to the anatomical distribution, 95.6% were anterior uveitis (AU), followed by the intermediate and posterior ones (1,5% both). 85.3% has unilateral involvement and 10.3% bilateral. Relapsing acute AU was the most frequent pattern (73.5%), followed by non-relapsing acute AU (16.2%) and chronic AU (7.4%).

24 patients (35.3%) required treatment with DMARD to achieve uveitis control. The most commonly used drugs were salazopyrine (7 patients), methotrexate (6 patients), mycophenolate (1), and in another 6 patients anti-TNF treatment was started or the previous dose of the biological was adjusted.

The visual acuity (VA) was not perfect (VA≠1 in both eyes) in 35% in the first collected visit. 28% (19 patients) had cataract, and 19% (13) had ocular hypertension. Only 1 patient had bilateral cystoid macular edema. Follow-up data were available for 43 patients and VA was stable in 47%, worsening in 23% and improving in 30% (median follow-up time 23 months, IQR: 6–41)

Conclusions: Our work confirms that in spondyloarthritis the most frequent pattern of ocular involvement is relapsing acute AU. Spondyloarthritis diagnosis was made at the uveitis unit in 35% of patients. More than one-third of patients required systemic therapy for ocular involvement control. Thirty-five percent of the patients had a reduced VA, remaining stable or improving in most, during the follow-up.

AB0714 DIFFERENTIATING CHARACTERISTICS IN PATIENTS WITH SPONDYLOARTHRITIS WHO HAVE RECEIVED DIFFERENTS ANTI-TNF THERAPIES

E. Moral[1], C. Plasencia[1], D. Pascual Salcedo[2], C. Tornero[1], P. Bogas[1], V. Navarro[1], A. Villalba[1], D. Peiteado[1], I. Monjo[1], A. Balsa[1]. *[1]Rheumatology; [2]Inmunology, la Paz University Hospital, Madrid, Spain*

Background: The term spondyloarthritis (SpA) encompass a group of crhonic inflammatory disease with predominant axial involvement. Anti-TNF therapy (AT) has stirred up the management of these diseases. Nevertheless, according to nationwide registries of the drug continuation rate in several countries, the rate of treatment failure is considerable. Nowdays there are insufficient data to evaluate the differences between responders (Resp-AT) and non-responders (Nonresp-AT) to anti-TNF therapy.

Objectives: To compare the main sociodemographic, clinical and analytical features at baseline, after 6 months of treatment and at the end of the first anti-TNF therapy of responders to a first anti-TNF therapy and non-responders to several anti-TNF therapies form our cohort of patients diagnosed with SpA. We also analized the association between drug levels (DL) and antidrug antibody (ADA) in non-responders to several anti-TNF.

Methods: 181 patients were included, 155 (85%) kept receiving their first AT therapy (responders) and 26 (15%) had discontinued at least two different AT therapies. The main demographic features, disease activity (BASDAI, ASDAS, CRP and ESR) were measured at baseline, after 6 months (v-6) and when the first AT was discontinued. Serum drug levels and/or ADA were measured at drug discontinuation of anti-TNF treatment and last visit in non-responders and responders respectively.

Results: The mean age was 55.3±15 and 50±10.8 in the resp-AT and nonresp-AT groups, respectively. The demographic and clinical characteristics of both groups are shown in Table 1. At baseline, a lower BMI was observed in the resp-AT group (25.6±5 resp-AT, 28.7±5 nonresp-AT, p=0.013); 59% and 35% were in concomitant treatment with DMARDS at baseline in the resp-AT and nonresp-AT groups respectively (p=0.032); 33% of the resp-AT were in monotherapy in the last visit compared to 62% of the nonresp-AT when discontinued the 1st AT (p=0.008). There were no differences in BASDAI (5.6±2 resp-AT, 6.1±1.9 nonresp-AT, p=0.2) and ASDAS (3.3±1.1 resp-AT, 3.4±1.1 nonresp-AT, p=0.8) at baseline. In v-6, the resp-AT group had a better clinical response in terms of BASDAI (3.2±2.3 in resp-AT, 4.7±2.4 in nonresp-AT, p=0.004) and ASDAS (1.7±0.9 in resp-AT, 2.7±1.2 in nonresp-AT, p=0.00), as well as in the delta-ASDAS (ΔASDAS) (1.56±1.2 resp -AT, 0.7±0.9 nonresp-AT, p=0.04). However, delta-BASDAI (ΔBASDAI) showed no difference between the two groups (2.3±2.3 resp-AT, 1.5±1.6 nonresp-AT, p=0.1).

Table 1. DEMOGRAPHIC CHARACTERISTICS

Population=181	Controls (n=155)	Cases (n=26)	p
Baseline			
Age	55.3±15	50±10.8	0,009
Sex (male)	104 (67%)	16 (62%)	0,6
B27+	93 (74%)	15 (62%)	0,3
BMI	25,5±5,3	28,7±5	0,013
Smokers	26	8	0,056
Disease duration (years)	9,5 ±12	7,6±9,3	0,4
RX (133): Sacroiliitis	65	14	0,6
MRI (37): Sacroiliitis	16	2	1
Uveitis	27	6	0,5
Enthesitis	53	16	0,015
Dactylitis	8	0	0,6
Peripheral	88	11	0,2
Psoriasis	16	5	
CRP baseline	16,7±23,7	12,3±21,3	0,4
ESR baseline	25,6±23,5	22±16	0,5
BASDAI baseline	5,6±2	6,1±1,9	0,2
ASDAS baseline	3,3±1,1	3,3±1,1	0,8
FAMES baseline	91	9	0,03
At 6 months			
BASDAI	3,2±2,3	4,7±2,4	0,004
ASDAS	1,7±0,9	2,7±1,2	0,00
ΔBASDAI	2,3±2,3	1,5±1,6	0,1
ΔASDAS	1,5±1,2	0,7±0,9	0,004
At drug discontinuation			
Monoterapia	51	16	0.08
Drug levels	138	13	0,02
ADA	1	4	0,00

24% of the nonresp-AT were ADA + at drug discontinuation, while only 0.7% of the AT-resp (AT) were ADA + (p=0.00) at last visit.

Conclusions: In our cohort of patients with axial SpA, a significant improvement in BASDAI, ASDAS and ΔASDAS after 6 months of treatment is associated with a lower frequency of drop-out of the first AT. Moreover a lower BMI, DMARDS at baseline and absence of ADA determine a better response to AT treatment.

AB0715 DIFFERENCES IN THE CO-MORBIDITIES DESCRIBED FROM SPONDYLOARTHRITIS PATIENTS WITH OR WITHOUT CONCOMITANT FIBROMYALGIA

E. Roussou, M. Karela, A. Georgiou. *Rheumatology, Barking, Havering and Redbridge University Hospitals NHS Trust, London, United Kingdom*

Objectives: To assess the differences in the occurrence of co-morbidities from cardiovascular, respiratory, renal/urological and Central nervous systems (CNS) between patients with spondyloarthritis (SpA) not having headache as presenting symptom and those having headache assuming that those describing headache represent secondary (s) fibromyalgia (FM). (previous submitted abstract provides justification on headache as presenting symptom associated with secondary sFM).

Methods: Data obtained through a questionnaire from 776 patients seen in clinic with SpA was analysed with reference to headache as symptom at presentation. From the total 776 patients 13 patients did not record an answer to the question and were hence excluded. The remaining 763 patients were divided in 2 groups: Those having headache at presentation (n=117) considered having sFM, and those not having headache at presentation (n=656).

	Headache at presentation (n=117)	No headache at presentation (n=656)	Statistical significance (p)	CI
Age (mean ± SD)	47.7 (13.16)	48.3 (14.3)	0.1	-5.757 to 0.912
Gender (M:F) ratio	28:89 1:3.1	219:419 1:1.9	0.3	-0.025 to 0.077
Disease duration	11.4 (12.1)	10.9 (10.8)	0.4	-1.905 to 4.470
Delay in diagnosis	6.43 (8.9)	6.3 (8.1)	0.7	-3.151 to 2.151
ESR	15.5 (14.8)	18.2 (18)	0.07	-11.064 to 0.582
CRP	10.4 (36)	8.2 (9.8)	0.4	-6.106 to 12.536
BASDAI score	7.31 (3.7)	6.06 (2.08)	0.000 (<0.005)	0.783 to 2.624
BASFI score	5.6 (2.7)	5.04 (2.7)	0.09	-0.143 to 1.626
Main problem				
Fatigue	77/116 (66.4%)	340/608 (55.9%)	0.018	0.029 to 0.299
Pain with pressure	71/117 (61.2%)	257/807 (42.4%)	0.000	0.122 to 0.378
Co-morbidities				
Heart	16/100 (16%)	59/479 (12.3%)	0.002	0.44 to 0.196
Lungs	11/99 (11.1%)	52/475 (10.9%)	0.1	-.014 to 0.135
Dizziness	50 (104) 48.1%	147/408 (30.1%)	0.000	0.220 to 0.453
Numbness	58 (105) 55.2%	199/505 (39.4%)	0.000	0.188 to 0.441
Kidneys/urology	23 (102) 22.5%	100/479 (20.9%)	0.1	-0.31 to 0.188

The data of patients with sFM were compared with the data of patients who did not report headache as a presentation symptom therefore not having FM with regards to age, disease duration, delay in diagnosis, disease activity (BASDAI) functional ability (BASFI), ESR, CRP and associated co morbidities from cardiovascular, respiratory, renal/urinary, and CNS systems. Central nervous system was evaluated by symptoms of dizziness and numbness.
Independent sample T test was used to explore differences between the 2 groups and confidence intervals obtained.
Results: Table shows demographics and disease characteristics as well as differences between SpA patients presenting with headache (indicating secondary FM), and those not presenting with headache. A greater proportion of patients with SpA and headache (sFM) report cardiovascular and CNS co-morbidities. There was no significant difference noted in the respiratory or renal/ urological co-morbidities amongst the 2 sub-groups.
Conclusions: A significantly higher proportion of patients described cardiovascular and CNS co-morbidities in the sFM group of SpA. No significant difference was noted in the 2 sub-groups with regards to the respiratory or renal systems.

AB0716 PREVALENCE OF STRUCTURAL LESIONS TYPICAL FOR AXIAL SPONDYLOARTHRITIS IN YOUNG MILITARY RECRUITS BEFORE AND AFTER MECHANICAL STRESS

G. Varkas[1,2], M. de Hooge[1], T. Renson[1], P. Carron[1,2], S. De Mits[3], G. Souverijns[4], D. Elewaut[1,2], F. Van den Bosch[1,2]. *[1]Department of Rheumatology, Ghent University Hospital; [2]VIB Inflammation Research Centre; [3]Department of Rehabilitation Sciences and Physical Therapy, Ghent University, Gent; [4]Department of Radiology, Jessa Ziekenhuis, Hasselt, Belgium*

Background: Magnetic resonance imaging (MRI) has become the imaging modality of choice in early SpA. Not only has this imaging technique proven useful in the identification of inflammatory lesions on T2 FS/STIR sequences, also structural lesions such as erosions, sclerosis, fat infiltration and ankylosis can be seen on T1 sequences. There is still ongoing debate concerning the possible inclusion of any structural lesion in the definition of a positive MRI in order to improve specificity. However, erosions and fat infiltration have also been found in respectively more than 10% and 17% of non-SpA patients on MRI of the sacroiliac joints. [1]
Objectives: To evaluate the presence of structural lesions on MRI of the sacroiliac joints (MRI-SIJ) in young, asymptomatic subjects.
Methods: Twenty-five military recruits volunteered to perform a MRI-SIJ before and after 6 week of intense physical training, of which 22 recruits underwent imaging at both time points. The MRIs were scored for structural lesions by 3 trained readers MdH, GV and TR, blinded for time sequence and clinical findings. Regarding the number of lesions a consensus was made by agreement of 2 out of 3 readers.
Results: At baseline, structural lesions were present in 36.4% (8/22) of subjects of which 5 subjects presented with at least 1 erosion, one subject with sclerosis and 3 subjects presented fatty lesions. This increased to 50% subjects (11/22) with structural lesions on MRI-SIJ after 6 weeks of mechanical stress, of which 8 subjects with at least 1 erosion, one subject with sclerosis and 3 subjects with fatty lesions (P=0.453). The change scores for sclerosis, erosions and fatty lesions were respectively 0.0 (±0.0), 0.2 (±0.1) and 0.3 (±0.2). None of the subjects displayed ankylosis. The lesion distribution is visualized in Table1.

Table 1. Number of structural lesions in young military recruits before and after intensive training

N=22	Baseline	Week 6	P-value
Sclerosis			
Mean (±SD)	0.05 (±0.05)	0.05 (±0.05)	1.00
Median (25, 75 percentile)	0.0 (0.0, 0.0)	0.0 (0.0,0.0)	
Erosions			
Mean (±SD)	0.32 (±0.14)	0.55 (±0.17)	0.096
Median (25, 75 percentile)	0.0 (0.0, 0.25)	0.0 (0.0, 1.0)	
Fatty lesions			
Mean (±SD)	1.0 (±0.86)	1.3 (±1.0)	0.285
Median (25, 75 percentile)	0.0 (0.0, 0.0)	0.0 (0.0, 0.0)	

Conclusions: Although not prevalent, structural lesions such as erosions, sclerosis and fatty lesions can be found in young asymptomatic subjects. However, these lesions do not seem to increase after 6 week of intense physical training.

AB0717 CONDUCTION DISTURBANCES IN A GROUP OF PATIENTS WITH AXIAL SPONDYLOARTHROPATHY

H.S. Park[1], A. Laiz[1], C. Alonso[2], A. Garcia-Guillén[1], M. Millán[1], B. Magallares[1], P. Moya[1], I. Castellví[1], C. Díaz-Torné[1], J.M. De Llobet[1]. *[1]Rheumatology; [2]Cardiology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain*

Background: Cardiac conductance disturbances are known to be one of the many extra-articular manifestations of Ankylosing Spondilitis but not as well related to axial spondyloarthropathies.
Objectives: Description of conduction disturbances found in a group of patients with Axial Spondyloarthropathy (AxSpa) that met ASAS criteria.
Methods: Clinical and demographic variables of 78 patients with AxSpa were registered. It included cardiovascular risk factors as well as cardiacvascular adverse events. All of them had a routine electrocardiogram done which were analized by a cardiologist.
Results: 48 of the 78 patients were men, with a mean age of 61 with standard deviation (SD) of 14. The mean time of evolution of the disease was 23 years (SD ±16). HLA-B27 was prevalent in 54 (69.2%). The sacroileitis was found in radiologic examination of 72 (92.2%), and 6 (7.7%) of them presented edema in magnetic resonance imaging. Other clinical traits were: 43 (55.1%) peripheric arthritis 43, 8 (10.3%) dactilitis, 33 (42.3%) enthesitis, 16 uveitis (20.5%), 2 (2.6%) inflammatory bowel disease and psoriasis 34 (43.3%). The following cardiovascular risk factors were registered: 25 (32%) smokers, 42 (53%) hypertension, 32 (41%) dislipemia, 9 (12%) diabetes, 9 (12%) hyperuricemia and 20 (20%) obesity. 14 patients had structural cardiopathy (11 ischemic cardiopathy and 3 aortic valvulopathy). The electrocardiographic register showed conductance disorders in 20 patients (25.6%). The details of these findings are specified in table 1.

First grade auriculoventricular block	5
Second and third grade auriculoventricular block	2
Left anterior fascicular block	1
Right bundle branch block	2
Unspecific intraventricular conduction disorder	4
Bachmann interatrial conduction disorder	1

Conclusions: A quarter of our series of presented conduction disturbances in electrocardiography. The relation with disease evolution, as in Ankylosing Spondilitis remains yet to be analized.

AB0718 PREVALENCE OF RISK FACTORS FOR FRACTURES IN AXIAL SPONDYLOARTHRITIS: A SYSTEMATIC REVIEW

J. Ramírez García[1], R. Curbelo[2], J.C. Nieto[3], S. Castañeda[4], L. Carmona[2]. *[1]Rheumatology, Hospital Clínic, Barcelona; [2]Instituto de Salud Músculoesquelética; [3]Rheumatology, Hospital G.U. Gregorio Marañón; [4]Rheumatology, Hospital de la Princesa, Madrid, Spain*

Background: Spinal fractures occur more than expected in axial spondyloarthritis (Ax-Sp). However, it is not totally clear whether fracture risk depends solely on biomechanical problems of the spondyloarthritic spine or whether the prevalence of risk factors for fracture is larger than expected in these patients.
Objectives: To describe the prevalence of risk factors for osteoporotic fractures (both axial and peripheral) in Ax-Sp.
Methods: A systematic literature search was conducted. Medline, Embase and Cochrane Library databases were searched with a sensitive strategy including type of study and synonyms of Ax-Sp. All contemporary cross sectional studies or baseline results from representative cohorts of Ax-Sp published between January 2006 and 2016 were selected for detailed review. Only studies that fulfilled a minimum quality for survey data were included. Data on bone mineral density, prevalence of osteoporosis, and risk factor for fractures in Ax-Sp patients were collected.
Results: After screening 3597 titles and abstracts, only 43 studies (34 cross-sectional, 3 prospective and 6 retrospective) were reviewed in detail. Of these, 20 studies compared Ax-Sp patients with a control group, either healthy individuals (17 studies) or subjects with other diseases (6 studies). Reported prevalence of osteoporosis varied from 2% to 39.6%. Alcohol intake (58–61%), use of corticosteroids (11.7–67%), and 25-OH vitamin D deficit (26–76%) were unexpectedly high in Ax-Sp patients. All other factors were within expected frequencies for a not too old population.
Conclusions: Our systematic review found that alcohol intake, steroid use and 25-OH-vitamin D deficit should be taken into account when assessing comorbidity in Ax-Sp in order to avoid excess fractures.

AB0719 BASELINE CHARACTERISTIC OF NEWLY DIAGNOSED PATIENTS WITH AXIAL SPONDYLOARTHRITIS: RESULTS FROM THE SINGLE CENTRE LITHUANIAN COHORT

J. Sabaliauskiene[1], A. Baranauskaite[2]. [1]*Rheumatology;* [2]*Lithuanian University of Health Sciences, Kaunas, Lithuania*

Background: The prevalence rates for spondyloarthropathies has been investigated in an epidemiological study in Lithuania (1), but no studies are analysing the demographics, clinical characteristics of SpA in Lithuania. Changes in spondyloarthritis (SpA) concept and application of the new criteria for classification should improve spondyloarthritis diagnostic standards in routine clinical practice.
Objectives: To assess demographics and clinical manifestations of firstly diagnosed axial spondyloarthritis, to compare ankylosing spondylitis (AS) with non-radiographic axial spondyloarthritis (nr-axSpA) using standardized clinical assessment tools.
Methods: In September 2014 our centre began to collect a cohort of patients with newly diagnosed axial spondyloarthritis, according to ASAS criteria. Statistical analysis was performed with SPSS 20.0. A $p<0,05$ was considered statistically significant.
Results: 97 patients (60 men, 37 women) have been included. All of them (100%) suffered from chronic back pain. Inflammatory back pain (according to ASAS criteria) was present in 77%. 34 (35,1%) patients already had definite radiographic changes in the sacroiliac joints (SIJ), therefore AS (based on modified New York criteria) was diagnosed. The mean age at first visit was similar: 34,3 (±10,0) in nr-axSpA and 36,1 (±11,0) in AS group. Duration of symptoms was significantly longer in AS group (mean 106,6 months in AS versus 44,8 months in nr-axSpA). The prevalence of HLA-B27 was similar: 74,6% vs 91.2% for nr-axSpA and AS, respectively. There were more males in AS group (76,5% vs 54,0%, p 0,03). The frequency of clinical features (peripheral arthritis, dactylitis) and extra-articular manifestations (enthesitis, uveitis, psoriasis, inflammatory bowel disease, preceding infection) was similar between the two subgroups ($p>0,05$). Mobility was slightly more impaired in AS patients, but it did not reach a significant level. No differences in the level of global pain, patient's global assessment were found. BASDAI did not show the significant difference between AS and nr-axSpA (mean 4,5±2,1 vs 3,9±2,0), as well CRP (mean CRP 17,33 mg/l vs 17,75 mg/l (p 0,2) and ESR.
Conclusions: Diagnosis of axial SpA in Lithuania remains delayed. The proportion of patients with AS among newly diagnosed axial SpA is high.There are more women in the nr-axSpA group. Both groups do not differ regarding clinical features, disease activity.

AB0720 CHARACTERISTICS OF TUNISIEN SPONDYLOARTHRITIS PATIENTS WITH HIP DISEASE

K. Maatallah[1], F. Essafi[1], I. Mahmoud[2], K. Ben Abdelghani[3], O. Saidane[2], W. Hamdi[1], M.M. Kchir[1], R. Tekaya[2], L. Abdelmoula[2]. [1]*Rheumatology, MOHAMED KASSAB Orthopedics National Institute, manouba;* [2]*Rheumatology, Charles Nicolle hospital;* [3]*Rheumatology, Monji Slim hospital, tunis, Tunisia*

Background: spondyloarthritis (SpA) is characterized by inflammation of spine and sacroiliac joints. Hip involvement is the most frequent extra spinal arthritic manifestation of SpA and may lead to a worse functional outcome.
Objectives: The objective of this study was to assess clinical, biological and radiological characteristics of SpA patients with hip disease.
Methods: This is a transversal multicenter study, including SpAs patients (satisfying ASAS criteria2009) with hip disease Demographic, clinical, radiographic, and laboratory data were collected and analyzed. Radiographic forms of hip disease were assessed according to Netter classification (early, condensing, destructive, combined and synostosante forms). Radiographic severity was assessed by the modified Stokes Ankylosing Spondylitis Spine Score (mSASSS) and BASRI (Bath Ankylosing Spondylitis Radiologic Index).
Results: ninety four patients were evaluated (77men). The mean age was 41.53±11.97 years. The median age at disease onset was 26.23±10.29 years.The mean diagnostic delay was 6.48 years. 46% of patients were smoker. HLA B27 was positive in 50% of cases. A peripheral joint involvement was found in 33% of cases. Extra-articular manifestation was seen in 57% of patients: osteoporosis (16 patients), uveitis (15 patients), psoraisis (10 patients), chronic inflammatory bowel disease (12 patients). 78 patients had bilateral hip involvement and 147 hips were evaluated. The median BASDAI and BASFI scores were respectively 5,4 and 5,5. The mean index of severity for osteoarthritis for the hip (ISH) was 12.24 (±6.84). Patients had an early form of hip disease in 22% of cases, Condensing form in 3% of cases, combined forms in 22% of cases and destructive form in 53% of cases. BASRI-hip score was 1 in 24%, 2 in 49%, 3 in 19% and 4 in 8% of hips. Sacoiliac joint grade was 2 in 17%, 3 in 37% and 4 in 46% of cases. The mean mSASSS score was 15.34±16.22.
TNF inhibitors were indicated in 49% of patients (infliximab 23, Adalimumab 7 and Etanercept 18).31 patients received csDMARDs and 46 NSAID.
Conclusions: Our finding confirm previous observation that clinical and radiological hip involvement is associated with a more severe disease with a high activity and pronounced functional impairments.

AB0721 THE EVALUATION OF ULTRASONOGRAPHIC AND CLINICAL ENTHESOPATHY IN PATIENTS WITH INFLAMMATORY RHEUMATIC DISEASES

E. Suleyman[1], H. Harman[2], K. Nas[1]. [1]*Division of Rheumatology and Immunology, Department of Physical Medicine and Rehabilitation, Sakarya University, Faculty of Medicine, Sakarya;* [2]*Rheumatology Clinic, Bolu İzzet Baysal State Hospital, Bolu, Turkey*

Background: Enthesitis is considered as the primary anatomical lesion in spondyloarthropathy (SpA) but it can be seen in other rheumatologic diseases. Its locations and clinical relationships have not been studied well in the literature.
Objectives: We aimed to investigate the frequency of ultrasonographic, clinical enthesopathy and the relationship between enthesopathy and disease activity, functional status in patients with rheumatoid arthritis (RA) and axial SpA.
Methods: Thirty three axial SpA, 21 RA patients and 30 healthy subjects were included in the study. The clinical and functional evaluations relied on the BASDAI, BASFI, ASQoL, DAS28, and HAQ, and on a VAS for entheseal pain, as well as on the MASEI. Knee, ankle and elbow were examined with US bilaterally in 172 joint regions.
Results: The physical examination scores for enthesitis were 1.97±2.68, 2.43±1.80, 0.23±0.12 in axial SpA, RA and healthy subjects, respectively. There was no statistically significant difference between axial SpA and RA about enthesitis physical examination scores (p=0.123). A statistically significant difference was not found between axial SpA and RA in quadriceps tendon enthesitis and distal patellar ligament enthesitis according to MASEI index (MASEI 3,4,5) (p=0.993, p=0.124, p=0.652). Other MASEI enthesit scores were statistically higher in axial SpA group than RA and healthy subjects (p=0.008). Positive correlations were found between BASDAI scores and enthesitis pyhsical examination scores, MASEI total scores (r=0.739, p=0.0001, r=0.516, p=0.002). There was moderately positive correlation between ASQoL total scores and MASEI total scores (r=0.466, p=0.006). HAQ total scores were not correlated with MASEI total scores (r=0.213, p=0.065).
Conclusions: Ultrasonographic enthesitis was associated with impaired quality of life in axial SpA. MASEI 1 and 2 was spesific entheseal regions in MASEI index for axial SpA. Different from RA, the calcaneal enthesitis region for clinical investigation and ultrasonographic enthesopathy should be focused on in axial SpA.

AB0722 THE IMPACT OF A REFERRAL STRATEGY FOR AXIAL SPONDYLOARTHRITIS IN YOUNG PATIENTS WITH CHRONIC LOW BACK PAIN: SHORT TERM OUTCOMES OF THE IMPACT STUDY

L. Van Hoeven[1,2], A. Korver[1,2], C. Appels[3], J. Hazes[1], F. van den Hoogen[4], M. van Oosterhout[5], J. Oostveen[6], J. Spoorenberg[7], I. Tchetverikov[8], T. Kuijper[2], B. Koes[9], A. Weel[1,2]. [1]*Rheumatology, Erasmus University Rotterdam;* [2]*Rheumatology, Maasstad Hospital, Rotterdam;* [3]*Rheumatology, Amphia Hospital, Breda;* [4]*Rheumatology, Sint Maartenskliniek, Ubbergen;* [5]*Rheumatology, Groene Hart Hospital, Gouda;* [6]*Rheumatology, ZGT, Almelo;* [7]*Rheumatology, UMCG, Groningen;* [8]*Rheumatology, Albert Schweitzer Hospital, Dordrecht;* [9]*Primary Care, Erasmus University Rotterdam, Rotterdam, Netherlands*

Background: A substantial amount of young patients with chronic low back pain (CLBP) have axial spondyloarthritis (axSpA), but early recognition of these patients is difficult for general practitioners (GPs). Recently, the CaFaSpA referral rule has been published and externally validated. It is an easy to use referral strategy that has shown to be able to identify patients with CLBP at high risk for axSpA in a primary care setting. The CaFaSpA referral rule consists of 4 items: inflammatory back pain, family history of axSpA or related disease, good reaction to NSAIDs and duration of back pain $\geq$5 years. If at least 2 out of 4 items are present, the referral rule is positive and a referral to a rheumatologist is advised.
Objectives: To assess the effect of the CaFaSpA referral rule on disability in young CBPP patients by comparing it with usual care, using the format of an impact analysis.
Methods: A cluster randomized controlled trial with GP practices as clusters. GP practices were randomized to either the intervention (use of the referral strategy) or control (usual care) group. Within these GP practices, patients aged 18–45 years with current CLBP were recruited. The primary outcome was disability caused by low back pain, measured with the Roland Morris Disability Questionnaire (RMDQ) scale 0–24. RMDQ score was obtained at baseline and 4 months after a referral advice was made. A higher RMDQ score means more disability. For statistical analysis a linear mixed effects regression model was used.

Results: 92 primary care practices were randomized, 679 patients participated (64% women, mean age 36.2 years (SD7.5) and median CLBP duration 9 years (IQR 4–15 years). 333 patients were randomized to the intervention group, both groups had similar characteristics at baseline. Sixty percent of participants had a positive referral rule. RMDQ scores are shown in table 1. Sub scores are shown for patients with a positive outcome of the referral rule (PRR) and a negative outcome of the referral rule (NRR). The change in RMDQ score after 4 months in the intervention group was -0.74 (95% confidence interval (CI) -1.31 – -0.18) and in the control group -0.46 (95% CI -0.98 – 0.05). There was no significant difference between groups.

Table 1. Estimated RMDQ scores with linear mixed effects regression model in young chronic low back pain patients by application of the CaFaSpA referral rule versus usual care*

	RMDQ at baseline	RMDQ after 4 months
Use of referral rule, mean (95% CI)	8.38 (7.58 - 9.18)	7.64 (6.78 - 8.49)
PRR^, mean (95% CI)	8.51 (7.56 - 9.45)	7.77 (6.74 - 8.79)
NRR±, mean (95% CI)	8.19 (7.02 - 9.35)	7.44 (6.18 - 8.69)
Usual care, mean (95% CI)	8.61 (7.82 - 9.39)	8.14 (7.33 - 8.96)
PRR^, mean (95% CI)	8.58 (7.65 - 9.50)	7.83 (6.87 - 8.79)
NRR±, mean (95% CI)	8.65 (7.55 - 9.76)	8.74 (7.54 - 9.93)

*= There were no significant differences between use of the referral rule and usual care; RMDQ=Roland Morris Disability Questionnaire; ^PRR=positive referral rule; ±NRR= negative referral rule

Conclusions: Compared with usual care, use of the CaFaSpA referral rule in CLBP patients in a primary care setting did not significantly impact disability in these patients, 4 months after a referral advice was made. Results after 12 and 24 months should be awaited before definitive conclusions about the impact of the CaFaSpA referral rule for axSpA in CLBP patients can be made.

[1]Rheumatology, HU Gregorio Marañón; [2]InMusc, Madrid; [3]Rheumatology, HU Monte Naranco, Oviedo; [4]Rheumatology, HU Reina Sofía, Córdoba; [5]Rheumatology, HU la Princesa, IIS-IP, Madrid; [6]Rheumatology, HU Clinic i Provincial, Barcelona; [7]Rheumatology, H Can Misses, Ibiza; [8]Rheumatology, HU 12 de Octubre, Madrid; [9]Rheumatology, H de Plasencia, Plasencia; [10]Internal Medicine, HU la Princesa, IIS-IP; [11]Cardiology; [12]Gastroenterology, HU la Paz; [13]Psychology, UCJC, Madrid; [14]Centro de Salud Ciudades, Getafe; [15]Centro de Salud Alcobendas, Alcobendas, Spain

Background: The management of comorbidity in patients with axial spondyloarthritis (Ax-SpA) needs improvement; the implementation of clinical practice guidelines is still deficient and heterogeneous.
Objectives: To prioritise comorbidities in Ax-SpA and to elaborate practical aids for their identification and follow-up.
Methods: A multidisciplinary panel [10 rheumatologists (6 experts in Ax-SpA), 2 family doctors, 1 internist, 1 cardiologist, 1 gastroenterologist, 1 psychologist and 3 methodologists] prioritised, in a discussion group, a list of comorbidities based on frequency and impact. Each comorbidity was discussed largely and systematic reviews were performed to support or discard items. In a second meeting, items to be included were presented, discussed, and those with lower priority disregarded.
Results: The panel produced a checklist for health professionals and another for patients. Each item is supported by arguments and references. Table 1 shows, schematically, the items included in the checklists.

Table 1. Items included in the checklist

Usual treatment	Of note: oral anticoagulants, antihypertensive drugs, ASA, steroids and NSAIDs.
Specific comorbidities	Hypertension, heart failure, renal failure, liver cirrhosis, gastric ulcer, infections, tuberculosis, neurological disease, and fracture risk.
Vaccine schedule and dental hygiene	Patient's vaccination status; prevention of infections.
Life-style	Physical activity (amount and type). Alcohol consumption. Detect possible abuses; important risk factor for other comorbidities.
Depression, quality of sleep and sexual life	The impact of Ax-SpA in the psychosocial sphere is relevant and should be carefully evaluated. Specific questionnaires are recommended.
Non-preventable diseases	Frequent association with uveitis, inflammatory bowel disease and cardiac pathology; systematise questions

Conclusions: These checklists are intended to facilitate the systematic evaluation of co-morbidity associated with Ax-SpA, thus allowing an earlier detection and better control and management of these patients by the rheumatologist.

AB0724 HIGHER LIKELIHOOD OF ANTI-TNF PRESCRIPTION IN MEN VS WOMEN WITH ANKYLOSING SPONDYLITIS DESPITE SIMILAR DISEASE BURDEN: RESULTS FROM ROUTINE CARE AT TWO ACADEMIC RHEUMATOLOGY CENTERS OF USA AND SPAIN

M. Blasco-Blasco[1], I. Castrejón[2], M. Ruiz-Cantero[1], V. Joaní[3], E. Pascual[4], J. Block[2], T. Pincus[2]. *[1]Public Health, University of Alicante, Alicante, Spain; [2]Rheumatology, Rush University Medical Center, Chicago, United States; [3]Rheumatology, Alicante University General Hospital; [4]Rheumatology, Miguel Hernandez University, Alicante, Spain*

Background: Ankylosing spondylitis (AS) has been considered to be more prevalent in men compared to women. Besides, the clinical presentation in women is thought to be milder and more peripheral than in men. Some studies have suggested a higher burden of disease in women[1,2] but others not confirm these differences[3,4].
Objectives: To evaluate possible gender differences in men and women with AS seen in routine care at two academic rheumatology centers of the USA and Spain.
Methods: Sixty one men and 30 women with AS in Spain and 61 men and 31 women in the USA completed a Multidimensional Health Assessment Questionnaire (MDHAQ). The MDHAQ includes (0–10 scores) for physical function, pain, patient global estimate (PATGL), compiled into a 0–30 RAPID3, and fatigue scores. Furthermore, demographic data, biological (anti-TNFα) and DMARD therapies, were obtained from the medical records. A comparative analysis of men and women was performed by Mann-Whitney U tests for non-parametric quantitative data (median/interquartile range), and Chi square tests for qualitative data (frequencies/percentajes).
Results: We have not detected significant differences in men and women for function, pain, PATGL, or fatigue although a trend towards higher RAPID3 values was seen in females in both sites (Table). Anti-TNFα medications were prescribed more often in men than in women (81.2% vs 65.6%, in all patients p=0.02), statistically significant in Spain (82% vs 60%, p=0.02), and numerically higher in the USA (80.3% vs 71%, p=0.31). DMARD medications tend to be more prescribed in women than men in all patients (17.2% vs 23%, p=0.35) although no statistically significant.

Table 1. Health status and treatment of patients with SpA at two academic centers (*p<0.05)

	USA		Spain	
	Men (N=61)	Women (N=31)	Men (N=61)	Women (N=30)
Age, years	41.5 (31.7–56.9)	36.2 (31.7–56.8)	52.0 (46.0–65.4)	54.6 (43.3–61.4)
Education, years	16 (12–17)	16 (11–18)	9 (8–12)	8 (8–12)
White	31 (51%)	17 (55%)	56 (92%)	30 (100%)
Duration disease, years	12.1 (6.1–21.5)	6.3 (4–16.6)	22 (12.1–34.8)	21.4 (12.1–30.1)
HLA-B27+	26 (68%)	21 (88%)	49 (86%)	20 (69%)
MDHAQ				
Function, (0–10)	2 (0.3–4)	2.3 (0.3–4)	1.2 (0–2.7)	0.8 (0–2.3)
Pain, (0–10)	4 (1–7)	5 (2–7.5)	3 (1.5–6)	4 (1–5)
PATGL, (0–10)	3 (1.5–6.3)	5 (2–6.5)	4 (2–5.5)	3.5 (1–5.5)
RAPID3, (0–30)	8.5 (4.2–15.3)	11.8 (4–16.8)	6.8 (3.5–14.2)	8.1 (3.3–12.7)
Fatigue, (0–10)	3 (0–6.5)	5 (3–8)	3 (1–4.5)	2.8 (1–5.5)
Treatment				
Anti-TNFα	49 (80%)	22 (71%)	50 (82%)	18 (60%)*
DMARD	9 (15%)	7 (23%)	13 (21%)	7 (23%)

Conclusions: Men with SpA receive anti-TNFα more likely than women; although disease burden appears somewhat higher in women. This pattern is similar in both Spain and the USA, though statistically significant only in the Spanish population. Other parameters may be having weight in the management of SpA, such as radiographic signs versus peripheral manifestations.

AB0725 USING A REDUCED JOINT COUNT IN MEASURING DISEASE ACTIVITY IN PSORIATIC ARTHRITIS, IS IT LEGIT?

M. Vis[1], K. Wervers[2], I. Tchetverikov[3], A. Gerards[4], M. Kok[5], C. Appels[6], L.-A. Korswagen[7], M. Hazes[1], J. Veris[8], H. van Groenendaal[9], J. Luime[1] on behalf of DEPAR. *[1]Rheumatology; [2]Erasmus MC; [3]Rheumatology, Alber Schweitzer hospital; [4]Vlietland ziekenhuis; [5]Rheumatology, Maasstad ziekenhuis, Rotterdam; [6]Rheumatology, Amphia ziekenhuis, Breda; [7]Rheumatology, Sint Franciscus Gasthuis, Rotterdam; [8]Rheumatology, RZWN, Goes; [9]Rheumatology, RZWN, Roosendaal, Netherlands*

Background: In Psoriatic arthritis (PsA) the pattern of joint involvement seems to be more heterogenic than Rheumatoid Arthritis (RA). Therefor the 66/68 joint count is frequently used in PsA scores. In this study we would like to investigate whether using less extensive joint counts influences PsA disease activity measures
Objectives: To evaluate the effect of using a 28, 44 or 66/68 joint count on Minimal Disease Activity (MDA).
Methods: Newly diagnosed PsA patients were included in the Dutch Early south-west Psoriatic Arthritis Registry (DEPAR) study between August 2013 and January 2017. Joint scores at baseline and 6 months were calculated using a 28, 44 and 66/68 joint count. Consecutively MDA was calculated using each of these joint counts. MDA is defined as minimal disease activity in 5 out of 7 domains (swollen joints, tender joints, PASI, patient vas pain, patient vas global, HAQ, enthesitis)
Results: In total, 413 patients were included into the study, of which 320 had reached 6 months follow-up at the time of this abstract. Half of the patients were male (49%), and mean age was 50 years (SD 13.8).
The percentage of patients with at least one involved joint (swollen or tender) at baseline decreased from 91% using the 66/68 score to 88% with 44 joints and then to 80% with a 28 joint count (Table 1). At 6 month these scores were 66% 63% and finally 56% respectively for the 66/68, 44 and 28 joint count. After 6 months, 96 patients (30%) had achieved MDA using the original 66/68 joint count. Using a 28 joint count, 10 more patients (10% of the MDA population) were classified as having achieved MDA.

Table 1. Joint scores and MDA at baseline (n=421) and 6 months (n=320) using 66/68, 44 and 28 joint counts in a population of newly diagnosed PsA patients

	Joints		
T0	66/68	44	28
Swollen joint score, median	2	1	1
Tender joint score, median	3	2	2
Swollen joint score >0, n (%)	311 (75)	298 (72)	256 (62)
Tender joint score >0, n (%)	346 (84)	331 (80)	290 (70)
Involved joint >0 (swollen and/or tender), n (%)	375 (91)	363 (88)	329 (80)
MDA, n (%)	56 (14)	65 (16)	70 (17)
T6	66/68	44	28
Swollen joint score, median	0	0	0
Tender joint score, median	1	1	0
Swollen joint score >0, n (%)	125 (41)	117 (38)	100 (32)
Tender joint score >0, n (%)	183 (59)	175 (57)	149 (48)
Involved joint >0 (swollen and/or tender), n (%)	204 (66)	195 (63)	171 (56)
MDA, n (%)	96 (30)	98 (31)	106 (33)

Conclusions: Using reduced joint count joints in PsA misclassifies around 10% of patients as having no joint involvement. It also misclassifies about 10% of the MDA population of having achieved MDA while they have not. Full 66/68 joint counts remain recommended for measuring disease activity in PsA.

AB0726 SUBCLINICAL ATHEROSCLEROSIS IN PATIENTS WITH ANKYLOSING SPONDYLITIS

M. Ismail, A. Mosallam, M. Abdelaziz, A. Moshrif. *Rheumatology, Faculty of Medicine, Al Azhar University, Assiut, Egypt*

Background: Systemic inflammatory response of various autoimmune diseases has been reported as a cause of accelerated atherosclerosis which is a risk factor for cardiovascular complications.
Objectives: This study aimed to evaluate atherosclerosis in patients with ankylosing spondylitis (AS) and its relation to disease activity.
Methods: The study was carried out on thirty AS patients, who fulfilled the modified New York criteria. Thirty apparently healthy normal volunteers, age and sex matched served as control. Complete History taking, General and systemic examination, Body mass index (BMI), Bath AS disease activity index (BASDAI), Bath AS functional index (BASFI), lipid profile, inflammatory markers and serum glucose level were done. Based on BASADI score, patients were then classified to active and inactive groups comprised 11 patients (37%) and 19 patients (63%) respectively. Carotid intima-media thickness (CIMT) was measured using real-time gray-scale sonography. The intima-media thickness (IMT) of common carotid artery, carotid bulb and internal carotid artery was determined.
Results: 25 males (83.3%) and 5 females (16.7%) with mean age 39.1±12.38, their mean disease duration 13.13±8.03 while controls were 21 males (70%) and 9 females (30%) with mean age 39.7±12.6.
While IMT was found significantly increased in patients (0.87±0.49) versus controls (0.5±0.12) ($P<0.001$), there was no significant difference regarding the presence of plaques and there was no stenosis found in cases or controls. No significant difference was found between active and inactive cases as regard to components of lipid profile. The mean IMT in active and inactive cases was 0.74±0.11 and 0.72±0.17 respectively with no significant difference. we found no significant correlation between IMT and different disease scores, ESR or CRP.
Conclusions: AS patients have a higher risk for developing atherosclerosis. IMT of common carotid artery could be added as a further investigation for detection and follow up of atherosclerosis in AS patients.

AB0727 HIP OSTEOPOROSIS AND VERTEBRAL FRACTURES ARE ASSOCIATED WITH YOUNGER AGE AT DIAGNOSIS OF SPONDYLOARTHRITIS: RESULTS FROM THE COMOSPA STUDY

M.H. Derakhshan[1], N.J. Goodson[2], J. Packham[3], R. Sengupta[4], H. Marzo-Ortega[5], A. Molto[6], S. Siebert[1] on behalf of BRITSpA and COMOSPA investigators. *[1]Institute of Infection, Immunity & Inflammation, University of Glasgow, Glasgow; [2]Academic Rheumatology Department, University of Liverpool, Liverpool; [3]Haywood Rheumatology Centre, Keele University, Keele; [4]Royal National Hospital for Rheumatic Diseases, Bath; [5]NIHR, Leeds Teaching Hospitals Trust and LIRMM, University of Leeds, Leeds, United Kingdom; [6]Paris Descartes University, Hôpital Cochin, Paris, France*

Background: Spondyloarthritis (SpA) is associated with adverse bone health outcomes. It is not known whether age at disease diagnosis is associated with osteoporosis and fracture in later life.
Objectives: To examine the relationship between "younger age at SpA diagnosis" and risk of osteoporosis and fractures (vertebral and low-trauma peripheral).
Methods: COMOSPA is a large global cross-sectional study comprising 3984 patients with SpA from 23 countries1. We evaluated the association between "younger age at SpA diagnosis" (categorised into 5-year blocks) and vertebral fracture, low-trauma peripheral fracture, and osteoporosis (t<-2.5 on bone densitometry) using logistic regression. Models were adjusted for age, sex, BMI, smoking, alcohol, NSAIDs, DMARDs, biologics, steroids and vitamin D level. Subgroup analysis was performed, stratified by peripheral and/or axial joint involvement.
Results: Data were available for 3923 participants (64% male). Median age at SpA diagnosis was 33 (IQR 25–43) years. Younger age at SpA diagnosis was not associated with the risk of vertebral fractures in the entire cohort (OR=1.11, p=0.143) nor in the subgroup with axial SpA involvement, but was increased in those with peripheral arthritis (OR=1.26, p=0.014) indicating 26% excess risk for each 5-year younger age at time of SpA diagnosis.
There was no significant association between younger age at diagnosis and the risk of low trauma peripheral fractures or spinal osteoporosis in the entire cohort or any subgroups. Younger age at SpA diagnosis was associated with higher risk of hip osteoporosis in the entire cohort (OR=1.34, p=0.004) and both subgroups. Femoral neck osteoporosis demonstrated similar associations (Table).

Table 1. Association between "younger age at SpA diagnosis" and the risk of fractures and osteoporosis (multivariable)

	OR	95% CI for OR	*p* value
Vertebral Fractures (All)	1.11	0.96–1.29	0.143
Peripheral arthritis* subgroup	1.26	1.05–1.51	0.014
Axial disease* subgroup	1.07	0.92–1.24	0.370
Low trauma peripheral fracture (All)	1.01	0.85–1.20	0.924
Spinal Osteoporosis (All)	1.07	0.93–1.22	0.362
Peripheral arthritis* subgroup	1.09	0.92–1.28	0.338
Axial disease* subgroup	1.04	0.90–1.20	0.611
Hip Osteoporosis (All)	1.34	1.10–1.64	0.004
Peripheral arthritis* subgroup	1.30	1.02–1.64	0.031
Axial disease* subgroup	1.41	1.14–1.75	0.002
Femoral neck Osteoporosis (All)	1.32	1.12–1.54	0.001

*Subgroups overlap as many patients will have both axial and peripheral arthritis.

Conclusions: Younger age of SpA diagnosis was associated with higher risk of vertebral fracture in patients with peripheral arthritis but not axial disease in this study. Lack of association with vertebral fracture and spinal osteoporosis in axial disease may reflect difficulty in detecting spinal disease and osteoporosis in the presence of spinal pain and syndesmophytes. An association between hip osteoporosis and younger age at SpA diagnosis was noted.

AB0728 RHEUMATIC MANIFESTATIONS OF INFLAMMATORY BOWEL DISEASES, STUDY FROM MIDDLE EAST

M. Hammoudeh[1], S. Alkaabi[1], M. Sharma[1], E. Al-Sayed[1], P. Chandra[2], M. Elbadri[1], S. Hammoudeh[3], N. Abu Nahya[2]. *[1]Medicine; [2]Research center, HMC; [3]Research center, Weill Cornell College-Qatar, Doha, Qatar*

Background: Musculoskeletal symptoms accompanying the diagnoses of Inflammatory bowel diseases (IBD), are seen in 6 -46% of cases1. There are very limited data about prevalence of rheumatic manifestations of IBD from the Middle East 2.

Objectives: The goal of this study is to examine the prevalence of rheumatic manifestations among patients diagnosed with IBD.

Methods: Between 1/2/2015 and 30/7/2016 all consecutive IBD patients were approached. A total of 127 adult patients signed the consent form. The diagnosis and extent of IBD (ulcerative colitis or Crohn's disease) had to be confirmed by a colonoscopy and histopathology. Patients were then interviewed and examined by one of two expert rheumatologists. A set of questions were used, complete rheumatological examination, X-rays of the lumbosacral and SI joints, and HLA-B27 test were done.

Results: Among our sample; 66% were Arabs and 34% are Asians, 58.3% were males, 52% fell in the age category of 30–49 years, 83.1% were married, 25.6% had a graduate degree, 36.5% had a history of smoking, and 15.2% had a family history of IBD.

The sample had 36%% with Crohn's disease, and 64% with ulcerative colitis. Any type of rheumatic manifestations were present in of 57.5% with no significant differences between the the two types of IBD diseases ($p>0.05$). The majority of these patients had peripheral manifestations (arthralgia, arthritis, enthesitis) (43.3%), while only 3.1% had axial alone, and 11% had both types. Among those with peripheral manifestations; 7.2% had type 1 arthritis (Pauciarticular), while 1.4% had type 2 arthritis (polyarticular). There were no significant differences between the two types of IBD diseases in regards to the presence of peripheral manifestations ($p>0.05$). However, the two diseases were significantly different in the presence of axial manifestations as more people with Crohn's have axial manifestations (19.6%) compared with Ulcerative colitis (12.3%). Those with Crohn's had more people with rheumatic manifestations 4–7 years before the diagnosis of IBD. HLA-B27 was positive in 5 patients 3 with Crohn's and 2 with ulcerative colitis. Logistic regression analysis of the data did not reveal any significant predictor or potential risk (type of IBD, gender, age group, BMI, smoking, family history, duration or extent) for the development of musculoskeletal manifestations in our patients.

Conclusions: In this study of musculoskeletal manifestations of patients with IBD from the Middle East 57.7% of them have any rheumatic manifestations.Peripheral manifesations occurred in 43%, axial alone in 3.1%, axial and peripheral manifestations in 11.5%, type I arthritis in 7.2% and type II in 1.4%. More patients with Crohn's has axial spondyloarthropathy (19.6%) compared with patients with ulcerative colitis (12.3%).

AB0729 BENEFITS OF ADDITIONAL SPINAL MAGNETIC RESONANCE IMAGING COMPARED TO SACROILIAC JOINTS IMAGING ALONE IN THE DIAGNOSIS OF SPONDYLOARTHROPATHY

N. Ahmad[1], A. Khan[1], P. Yoong[2], J. Kitchen[1]. *[1]Department of Rheumatology; [2]Department of Radiology, Royal Berkshire NHS Foundation Trust, Reading, United Kingdom*

Background: Axial spondyloarthritis (AxSpA) is a chronic inflammatory condition predominantly involving the axial skeleton including the spine and sacroiliac joints. Magnetic resonance imaging (MRI) demonstrates inflammatory and structural changes in patients with both ankylosing spondylitis and non-radiographic (nrAxSpA) forms of SpA and has become widely used in diagnosing SpA.

Sacroiliitis is a prominent feature of SpA but up to 24% of patients with clinically active SpA can have normal MRI of their sacroiliac joints (SIJ).[1] Spinal inflammation is well recognized in SpA and studies have shown that 49% of clinically active nr-AxSpA patients have spinal lesions alone but no lesions in SIJ.[2] Thoracic spinal lesions are as common as SIJ lesions.[3] Therefore using spinal in addition to SIJ MRI should improve the overall sensitivity and specificity for the detection of the disease.

Prior to publication of the 2015 EULAR recommendations,[4] an evidence-based MRI protocol had been adopted in our hospital, using STIR and T1-weighted sequences of the whole spine and SIJs in patients with suspected SpA.

Objectives: To determine the additional diagnostic benefit of including limited sequence whole spine imaging with SIJ MRI to SIJ MRI alone in patients with suspected SpA.

Methods: MRI scans performed for suspected SpA over twelve months from November 2015 to November 2016 were reviewed retrospectively (n=203). Reports were analysed for presence and location of lesions suggestive of SpA. HLA-B27 status of the patients and the presence of SpA associated clinical features as defined by ASAS criteria were recorded.

Results: MRI scans from 203 patients with suspected SpA were reviewed. 81 (40%) were male and 122 (60%) were female. The age range was 13 to 78 years (mean =41). 130 (64%) were less than 45 years of age. 157/203 (77%) patients had been tested for HLA B-27 alleles of whom 46 (29%) were HLA-B27 positive. All patients had inflammatory back pain and 76 (37%) had one or more additional SpA features as per ASAS criteria.

Overall 43 (21%) patients had a positive MRI spine and/or SIJs for inflammatory or structural changes. 21/43 (49%) patients had inflammatory lesions in their sacroiliac joints only. 18/43 (42%) patients had inflammatory changes involving both SIJ and Spine and 4/43 (9%) had spinal inflammatory changes only with normal SIJs (Table 1). In these four patients the thoraco-lumbar spine was involved. In HLA-B27 positive patients (n=46), 25 (54%) had a positive MRI.

Positive Imaging Findings	Number of patients	Percentage of patients
SIJ & Spine	18	42
SIJ lesions alone	21	49
Spinal lesions alone	4	9
Total	43	–

Conclusions: The majority of patients with SpA can have their diagnosis confirmed on SIJ MRI. However a proportion of patients (9%) had spinal changes only. Additional spinal MRI has been shown to increase the diagnostic yield for axial spondyloarthropathy in our cohort.

AB0730 CELL CHOLESTEROL TRANSPORT IN SPONDYLOARTHRITIDES AND ITS RESPONSE TO ANTI-RHEUMATIC DRUGS

N. Ronda[1], I. Hokstad[2], G. Deyab[3], D. Greco[1], S. Agewall[4,5], G. Hjeltnes[6], J.E. Whist[3], F. Bernini[1], I. Hollan[2,7,8,9]. *[1]Department of Food and Drug, University of Parma, Parma, Italy; [2]Lillehammer Hospital for Rheumatic Diseases; [3]Department of Medical Biochemistry, Innlandet Hospital Trust, Lillehammer; [4]Oslo University Hospital, Ullevål; [5]Institute of Clinical Sciences, University of Oslo, Olso; [6]Department of Medicine; [7]Innlandet Hospital Trust, Lillehammer, Norway; [8]Department of Medicine, Brigham and Women's Hospital; [9]Harvard Medical School, Boston, United States*

Background: Spondyloarthritis is associated to accelerated atherosclerosis, possibly due to chronic inflammation and lipid metabolism disturbances. Circulating lipoprotein function may be more important than concentration. In particular, cholesterol efflux capacity (CEC) of high density lipoproteins (HDL) opposes to foam cell formation and correlates inversely with cardiovascular risk[1]. Instead, the capacity of low density lipoproteins (LDL) to load cells with cholesterol (CLC) favors atherosclerosis. CEC and CLC may be altered independently from lipoprotein serum levels, *e.g.* due to chronic autoimmune inflammation or to medical therapies[2].

Objectives: Our aim was to compare CEC and CLC in patients with ankylosing spondylitis (AS) and psoriatic arthritis (PsA). We also aimed to evaluate CEC and CLC modification upon anti-rheumatic therapy and their relationship to lipoprotein levels.

Methods: Patients with AS (n=24) and PsA (n=36) were from the observational PSARA study. Treatment was: anti-TNF agents for AS; MTX alone or in combination with an anti-TNF agent for PsA.

Serum was drawn before, after 6 weeks and after 6 months of anti-rheumatic therapy to measure CEC with a validated cell model (radioisotopic technique to measure % cholesterol efflux on total cell cholesterol[3]) and CLC (with a macrophage model and fluorimetric measurement of cell cholesterol[2]).

Results: At baseline serum LDL and total cholesterol were higher in PsA than in AS patients. LDL, total cholesterol and HDL increased after treatment in AS, but not in PsA.

In AS, CEC increased after 6 weeks of treatment (4.9±0.3 vs. 5.5±0.3, 95% CI: -1.09 to -0.03, $p<0.05$), in parallel with HDL serum levels. In PsA, CEC did not differ between any of the time points.

CLC did not change with treatment in AS nor in PsA, but was overall higher in PsA than in AS patients. Despite the LDL serum level increase in AS, after 6 months of treatment the difference between CLC in PsA and AS was the most significant (34.0±1.8 in PsA vs 27.8±1.5 in AS, CI 95%: 3.28 to 6.67, $p<0.05$). In addition, after 6 months of therapy the correlation of CLC with LDL levels, present before treatment, was lost in the AS group. In the PSA group CLC did not correlate with LDL serum levels at any time point.

Conclusions: Our novel data indicate that pro-atherogenic lipoprotein dysfunction is more marked, and less responsive to anti-rheumatic treatment, in PsA than AS patients.

In AS, CEC improved significantly during anti-TNF therapy, probably due to increase in anti-atherogenic HDL. Despite the LDL increase associated with the anti-TNF therapy in AS patients, CLC stayed constant, standing against a hypothetical pro-atherogenic effect of such LDL increase.
These data may be useful for atherosclerosis prevention and treatment with tailored strategies for AS and PsA patients.

AB0731 OVERCOMING THE PROBLEMS OF UNTRANSLATABILITY: A MOBILE PHONE APPLICATION IN THE EXAMPLE OF TURKISH VERSION OF BASDAI

Y. Özmen[1], E. Mammadov[1], Y. Yalçınkaya[1], A.U. Ünal[1], Z. Ertürk[1], Ü.G. Gazel[1], S. Kaymaz[1], A. Aksoy[1], F. Alibaz-Öner[1], N. İnanç[1], H. Direskeneli[1], A. Gökduman[2], P. Atagündüz[1]. *[1]Rheumatology, Marmara University Faculty of Medicine, Istanbil; [2]Pleksus Information Technologies Inc., Ankara, Turkey*

Background: Patient-reported outcomes (PROs) are important in monitoring and making treatment decisions.Recently,we reported that the translation of"tender points" in the fourth question of the Turkish version of BASDAI was not correctly understood,and replacing this question with an entheses examination (BASDAI-Q4) decreased the score (∆BASDAI:0.99,p<0.0001,95% CI0.54–1.44).[1]
Objectives: We report here the results of an investigator initiated clinical trial using a self-developed mobile phone application (MPA)[2] to overcome the problem of untranslability.
Methods: Out of 135 invited 95 axSpA patients participated.Initially,BASDAI self-report forms (BSRF) were administered.Thereafter,patients were randomized into two groups (2:1).GroupA completed a second set of BSRF after using the MPA with embedded videos defining terms and grading for each domain.GroupB completed a second set of BSRF under guidance of an inexperienced family physician (FP).A third set of BSRFs were completed by GroupB with the same FP after he went through the MPA.Afterwards,an entheses examination (EE) was performed by a blinded rheumatolgist and patients graded enthesis pain between 0–10.StandartQ4 was replaced with the EE scoring (BASDAI-Q4).Patients older than 45 years of age were excluded.
Results: Fifththree male (%55.7) and 42 female (%44.3)patients,with a mean disease duration of 13 years (SD=8.7)were studied.Sixtyfour and 31 patients were randomized to Groups A and B, respectively.Nine patients reported the Q4 as"not understood".32 patients had no enthesitis on EE,but of those only 21 scored"0" for Q4 during the unassisted-PRO.Eleven reporting no enthesitis had so on EE.In GroupA,out of six"not understood" responders forQ4,five reported enthesitis after MPA assistance and four had enthesitis at the final EE.Nineteen patients had no enthesitis on physical examination,but of those only 12 scored"0" for Q4 during the unassisted PRO,and an additional nine scored"0" forQ4 after MPA assistance.Six out of seven patients reporting no enthesitis,but with enthesitis on EE reported,enthesitis after MPA assistance.In GroupB,scoring forQ4 was similar after both the unassisted- and FP's first assistance PRO.Out of four "not understood" responders for Q4,two reported enthesitis after the second assistance of FP and both had enthesitis at the final EE.Six patients had no enthesitis on EE,but of those only4 scored"0" for Q4 during the unassisted-PRO,and an additional two scored"0" for Q4 after second FP-assistance.Two out of four patients reporting no enthesitis,but with enthesitis on EE,reported enthesitis after second FP-assistance.Mean BASDAI was significantly higher in both groups then BASDAI-Q4 (Group A=3.97±1.95 vs. 2.84±1.98, p<0.0001,95% CI0.58–1.52, Group B=3.81±2.05 vs. 2.98±2.25, p<0.0001,95% CI0.48–1.31). In both groups, MPA for both, patients and FPs resulted in more reliable overall BASDAI scores with BASDAI-Q4 as the gold standard (Group A=3.05±2.25 vs. 2.84±1.98, p=0.081, 95% CI0.71–1.45, Group B=3.21±1.87 vs 2.98±2.25, p=0.075,95% CI0.71–1.63).
Conclusions: Mobile applications may improve the quality of collected data in cases of untranslability even in previously validated PROs.

AB0732 SPONDYLOARTHRITIS IN THE DEMOCRATIC REPUBLIC OF CONGO

P. Lebughe[1], K. de Vlam[2], R. Westhovens[3], J.-M. Mbuyi-Muamba[1], J.-J. Malemba[1]. *[1]Rheumatology, University Hospital of Kinshasa, Kinshasa, Congo, The Democratic Republic of the; [2]Rheumatology; [3]Department of Development and Regeneration, Skeletal Biology and Engineering Research Center, Division of Rheumatology, University Hospitals Leuven, Leuven, Belgium*

Background: While spondyloarthritis (SpA) is intensively studied in the Western world, data are scarce in sub-Saharan Africa.
Objectives: To determine the spectrum of SpA in outpatients with rheumatological complaints attending two rheumatology practices in Kinshasa, Democratic Republic of Congo.
Methods: A descriptive cross-sectional study over six months (December 1st, 2012 till May 31th, 2013) in consecutive patients attending the two rheumatology practices of Kinshasa; diagnosis was based on Amor or the ESSG criteria, and a clinical evaluation by a rheumatologist. Sacroiliac joint radiographic lesions were scored with the modified New York criteria. BASDAI and BASFI were evaluated in axial SpA.
Results: One hundred five patients (10.7%) were diagnosed among 984 rheumatologic outpatients with a sex ratio (male to female) of 1.4. The average age at the onset of the disease was 41.3±12.4 years. Non-radiographical axial spondyloarthritis was the most frequent subtype (4.98%) followed by reactive arthritis (4.27%). Other subtypes were: ankylosing spondylitis (1.02%), psoriatic arthritis (0.1%), SAPHO syndrome (0.1%) and IBD associated arthritis (0.1%). Mean BASDAI and BASFI in axial SpA were 42.7/100 and 46.4/100 respectively. Peripheral enthesitis was found in 43% of SpA patients and uveitis (10.4%) was the most frequent extra-articular manifestation. We did not detect any family history. Median erythrocyte sedimentation rate and C reactive protein were 37 (range: 7–110) mm/h and 22 (range: 4–48) mg/l respectively.

Subtypes of SpA	*N* (Rf)	Sex distribution			P	Mean age (years) ±SD
		M	F	Ratio		
Nr-axSpA	49 (46.7)	27	22	1:0.8	0.23	40.5±7.5
ReA	42 (40.0)	20	22	1:1.1	0.47	40.2±13.1
AS	10 (9.5)	6	4	1:0.7	0.45	46.2±4.7
PsA	1 (0.95)	0	1			32
SAPHO Syndrome	1 (0.95)	1	0			35
Enteropathic arthritis	1 (0.95)	0	1			25
Juvenile SpA	1 (0.95)	1	0			13

Conclusions: This hospital-based study suggests a substantial occurrence of some subtypes of SpA in central Africa. A population-based study is needed.

AB0733 ASSOCIATIONS OF SERUM OSTEOPROTEGERIN AND IL-18 CONCENTRATIONS WITH CARDIOVASCULAR RISK IN ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS PATIENTS

E. Kontny[1], K. Bonek[2], P. Gluszko[2]. *[1]Department of Pathophysiology and Immunology; [2]Department of Rheumatology, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warszawa, Poland*

Background: Inflammatory spondyloarthropathies (SpAs), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) are associated with cardiovascular (CV) disorders. In both diseases cytokines of IL-17/IL-23 axis are thought to play a pathogenic role. PsA, but not AS, is usually preceded by psoriasis, suggesting contribution of skin inflammation-related cytokines to disease manifestation and CV risk.
Objectives: To search in AS and PsA patients for the association between CV risk and serum concentrations of select cytokines, i.e. of IL-17/IL-23 axis, IL-18 and osteoprotegerin (OPG) related to skin inflammation and/or cardiovascular disease (CVD) pathogenesis, respectively.
Methods: Twenty patients with AS (15M/5F) and 18 patients with PsA (10M/8F) of similar age (mean±SD, 42±7 vs 46±10 years) and disease duration (6.5±10 vs 6.1±7 years) were evaluated. A group of 38 sex and age-matched healthy volunteers was used as a control. Routine laboratory tests, i.a. measurement of serum C-reactive protein (CRP) concentrations were performed. Clinical data, including evaluation of disease activity by $ASDAS_{CRP}$ and BASDAI indices, calculation of SCORE (Systemic Coronary Risk Evaluation) index and atherogenic index (AI=total cholesterol/HDL) were collected. Serum concentrations of IL-17AF, IL-21, IL-23, IL-27, IL-18 and OPG were measured by specific commercially available enzyme-linked immunosorbent assays (ELISA) and were expressed in pg/ml. The Mann-Whitney U-test was applied for intergroup comparison, and correlation was assessed using a Spearman's Rank two-tailed test (*R* value is shown).
Results: Compared with control, total group of SpAs patients was characterized by significantly elevated serum concentrations of OPG (1757±852 vs 1062±406 pg/ml), IL-18 (273±235 vs 164±195 pg/ml) and IL-21 (68±127 vs 20±49 pg/ml). Interestingly, while up-regulation of OPG (1517±387) and IL-18 (324±291)

was attributed to PsA, IL-21 increase (90.6±158) was found in AS group. Nevertheless, there was no significant difference between patients' groups in the tested cytokines concentrations. Despite of less active disease in PsA than in AS patients ($ASDAS_{CRP}$ 2.76±1 vs 3.44±0.89), PsA patients had higher AI (4.44±1.3 vs 3.37±1). Importantly, in both AS and PsA groups, OPG concentration positively correlated with SCORE values (*R*=0.613 and 0.792, respectively). However, in PsA patients also IL-18 concentration showed similar noxious associations, correlating positively with AI (*R*=0.705), and triglycerides level (*R*=0.679) but inversely with HDL level (*R*= - 0.525) and HDL/LDL ratio (*R*= -0.623). On the other hand, neither in AS nor in PsA patients the cytokines of IL-17/IL-23 axis were significantly related to CV risk.

Conclusions: By showing positive correlation of serum OPG with CV risk expressed by SCORE in AS and PsA patients we support opinion of an important role of OPG in CVD pathogenesis. Our results may also suggest that in PsA patients IL-18, up-regulated owing to skin inflammation, contributes to dyslipidemia and thus further increases CV risk.

AB0734 EVALUATION OF CARDIOVASCULAR RISK PROFILES IN A POPULATION OF PATIENTS WITH ANKYLOSING SPONDYLITIS: A CROSS-SECTIONAL STUDY

A. Ghrbel[1], M. Turki[1], A. Feki[2], B. Belhasan[3], R. Akrout[2], M. Chtourou[1], M. Neifar[1], H. Fourati[2], S. Baklouti[2], F. Ayedi[1]. *[1]Unit of Research "Molecular Bases of Human Diseases", 12ES17, Sfax Medicine University Biochemistry laboratory Habib Bourguiba Hospital; [2]Hedi Chaker Hospital; [3]Unit of Research "Molecular Bases of Human Diseases", 12ES17, Sfax Medicine University, Sfax, Tunisia*

Background: ankylosing spondylitis (AS), like the other chronic inflammatory rheumatic diseases, is considered to have higher cardiovascular (CV) risk (1). The Etiopathogenesis is not clearly defined.

Objectives: assess the early biological markers of atherosclerosis in Tunisian patients with AS compared with healthy controls and evaluate the relationship between Systematic Coronary Risk Evaluation (SCORE) for CV-related mortality and biological markers (2).

Methods: This was a cross-sectional study conducted since June 2015 until October 2016 including patients with AS in the South of Tunisia and matched controls with sex, age, body mass index (BMI) and smoking. Patients diagnosed with AS should fulfill the modified New York criteria. For patients and controls, we measured total cholesterol (TC), high density lipoprotein (HDL) cholesterol, triglycerides, apolipoprotein (Apo) AI, ApoB, lipoprotein (a) [Lp(a)] and C-Reactive Protein (CRP). Low-density lipoprotein (LDL) cholesterol was calculated with the Friedewald formula. SCORE was calculated through the use of sex, age, systolic pressure, smoking and TC. Comparisons were performed using two sample t-tests for parametric values and Wilcoxon Mann-Whitney Test for non-parametric values. Correlation analyses were performed with Spearman rank.

Results: Overall 79 patients with AS and 79 controls were included. The mean age was (43.81±14.29 vs 44,27±14 years). The sex ratio (M/F) was 2/1 and the mean BMI was (25.9±5.3 vs 25.76±3.5 kg/m^2). AS patients had significantly lower levels of HDL and TC and a higher level of CRP and atherogenic index (TC/HDL, ApoB/ApoA). AS patients had higher CV mortality than controls (1.1±1.8 vs 0,51±1.13%, p=0.01). The frequency of high cardiovascular risk was higher in AS patients (5 vs 2, p=0.4). The correlation between SCORE's risk and biological markers were positive with TC, LDL, Lp (a), TC/HDL ratio and LDL/HDL ratio.

Conclusions: AS patients are at a greater cardiovascular risk due to a higher CRP rate, atherogenic index and 10-year risk SCOREs of CV mortality. So, the dyslipidaemia and inflammation could be the aetiology of cardiovascular risk.

AB0735 EVALUATION OF PSYCHOLOGICAL STATE OF PATIENTS WITH ANKYLOSING SPONDYLITIS: REGIONAL REGISTRY AS A TOOL FOR IMPROVEMENT OF MANAGEMENT

S. Lapshina, D. Abdulganieva, L. Myasoutova. *Kazan State Medical University, Kazan, Russian Federation*

Background:
According to modern conception "T2T" a patient with ankylosing spondylitis (AS) takes an active part in the disease treatment that determines the importance of his psychological state.

Objectives: To evaluate interconnection between the psychological state of the patient with AS and the disease course.

Methods: Within the regional registry which is a part of epidemiological study of clinical diversity of AS in Russian population, 40 patients (32 males and 8 females) at the age of 21 to 56 years (average age 40,3±10,0) were examined. The average disease duration on the day of examination was 12,7±9,9 years, BASDAI - 5,54±1,8, BASFI – 5,34±2,48. Functional status (range of motion) was evaluated by means of BASMI. EQ-5D questionnaire was used for psychological state evaluation.

Results: A total of 17 (42,5%) patients had anxiety and depression: moderate – 15 (88,2%), severe – 2 (11,8%) responders. With the disease duration of less than 5 years propensity for depression and anxiety was noted by 6 out of 11 (54,5%) patients, 5 to 10 years – 2 out of 12 (16,7%), more than 10 years – 9 out of 17 (52,9%).

In patients with mild disease activity anxious and depressive states were not observed, with moderate disease activity they were revealed in 3 out of 7 patients (42,8%), with severe activity – in 9 out of 21 (42,8%), with very severe activity – in 5 out of 10 (50%) responders.

Among the patients without limitation of motion (BASFI) anxiety and depression was revealed in 2 out of 11 (18,2%), with moderate limitation –6 out of 18 (33,3%), with severe limitation –9 out of 11 (81,8%) patients. According to BASMI 1 out of 2 patients without limitation of motion had anxiety and depression, 6 out of 19 (31,5%) – with moderate limitation and 10 out of 19 (52,6%) with severe limitation.

The direct correlation was revealed between EQ-5D score and BASFI (r=0,996) and between EQ-5D and BASDAI (r=0,855), concurrently such correlation was absent between BASMI and EQ-5D.

Among the patients without anxious and depressive states 14 out of 23 (60,8%) patients take NSAIDs regularly while among the patients who noted propensity for anxiety and depression only 7 out of 17 (41,17%) take NSAIDs regularly.

Conclusions: Patients with short (less than 5 years) and long (more than 10 years) AS duration, severe disease activity and functional limitation are more prone to anxiety and depression. Patients with anxious and depressive states are less compliant with therapy which influences its efficacy. These data should be considered when the programs of AS patients' management are developed.

AB0736 THE DATA OF CENTRAL AORTIC PRESSURE AND PULSE WAVE VELOCITY IN PATIENTS WITH ANKYLOSING SPONDYLITIS

T. Aksenova[1,2], N. Ivashhenko[1,2], S. Tsarenok[1], V. Gorbunov[1], P. Gromov[2]. *[1]therapy, Chita State Medical Academy; [2]The hospital within the Russian Railroad Network, Chita, Russian Federation*

Background: Pulse Wave Velocity (PWV) is the main determinant of arterial stiffness. In recent years the increased arterial stiffness in Ankylosing Spondylitis was shown [1]. The most of investigations of arterial stiffness in ankylosing spondylitis were performed on the treatment by anti TNF-therapy [2]. However, today this issue has not been adequately studied.

Objectives: To evaluate the data of central aortic pressure and PWV and their relationship with Ankylosing Spondylitis.

Methods: 49 patients with Ankylosing Spondylitis aged between 19 and 60 (mean age 39.6±10.6) were examined. This group (group 1) included 38 men, 11 woman. Ankylosing Spondylitis Disease Activity Score (ASDAS-CRP) was 3.11±0.55. Duration of Ankylosing Spondylitis was from 0.5 to 20 years (mean 5.87±4.76 years). X-ray stage sacroiliac joints (according Modified New York Criteria) was 2.59±1.42. The control group included 33 healthy individuals. The groups were similar in age and sex. 10 patients with ankylosing spondylitis have history of arterial hypotension, however, at the time of inclusion in this study their blood pressure was stabilized. The groups did not differ by office blood pressure parameters and heart rate. Indicators of central aortic pressure and PWV were determined by applanation tonometry by SphygmoCor, Australia. For statistical analysis we used Mann-Whitney criteria and Spirmen correlation method. The study was based on GCP principles.

Results: Increased levels of central systolic blood pressure (118.02±14.02 vs 101.1±10.2, p=0.00001), central diastolic blood pressure (80.23±11.86 vs 71.8±7.3, p=0,001) were determined in patients with Ankylosing Spondylitis.

Patients with Ankylosing Spondylitis demonstrated the increase in central mean pressure compared to control groop on 17.2% (108.5±13.6 vs 92.6±9.4 p=0.0001). Pulse Wave Velocity (PWV) in the carotid-femoral segment in patients with ankylosing spondylitis was 6.5±1.3 m/sec vs 5.2±0.96 m/sec (p=0.0001) in the control group. The levels of augmentation pressure and Subendocardial viability ratio (SERV) were similar in the examined groups.

PWV was directly correlated with trangulus-to-wall (r=0,41; p=0,005) and with X-ray stage of sacroiliitis (r=0,31; p=0,043) and negative correlated with Lumbar flexion (Shober test) (r= - 0,38; p=0,009).

Conclusions: Increasing indicators of arterial stiffness, such as, PWV, central systolic blood pressure, central diastolic blood pressure, central mean pressure were determined in patients with Ankylosing Spondylitis. The relationship between clinical data, X-ray stage and PWV was demonstrated.

Psoriatic arthritis

AB0737 AA AMYLOIDOSIS IN RHEUMATOID ARTHRITIS AND IN PSORIATIC ARTHRITIS – A POSTMORTEM CLINICOPATHOLOGIC STUDY OF 173 PATIENTS

Á. Apáthy[1], M. Bély[2]. [1]*Department of Rheumatology, St. Margaret Clinic Budapest;* [2]*Department of Pathology, Hospital of the Order of the Brothers of Saint John of God, Budapest, Hungary*

Background: Rheumatoid arthritis (RA) and psoriatic arthritis (PsA), like all chronic autoimmune arthritides, may be complicated by AA amyloidosis (AAa).
Objectives: The aim of this study was to determine the prevalence and extent of AAa in RA and PsA patients, furthermore appraise the extent of amyloid A deposits in various organs.
Methods: At the National Institute of Rheumatology 11860 patients died between 1968 and 1998; among them 161 patients with RA and 12 with PsA. All of them were autopsied. RA and PsA were diagnosed clinically according to the criteria of the ACR [1,2].
Amyloid deposits on different tissue structures [arteriole, small artery, medium size artery, venule, small vein, medium size vein, interstitial collagen fiber, reticulin fiber (collagen IV), basal laminas, nerve, renal glomerulus] of 6 organs [heart, lungs, liver, kidney, skin and brain] were determined histologically.
The extent of amyloid A deposition was evaluated by semi-quantitative, visual estimation on a 0 to 3 plus scale, based on the number of involved tissue structures per light microscopic field [3]. ("0": no amyloid deposits, "1": Sporadic, minimal amyloid deposits on different tissue structures, "2": less than five, "3": five or more involved tissue structures per microscopic field at objective magnification of x20)
The average prevalence and extent of amyloid A deposits of RA and PsA patients and the average prevalence and extent of amyloid A deposits in various organs were compared by Student (Welch) t-probe.
Results: The prevalence (in %) and the average extent of amyloid A deposits (absolute value) in various organs of RA and PsA patients are summarized in Table 1.

Table 1

Organs	RA-AAa Prevalence in %	PsA-AAa Prevalence in %	p<	RA-AAa Average extent	PsA-AAa Average extent	p<
Kidney	48,49	68,18	0,0611	0,99	1,41	0,0706
Heart	56,97	38,89	0,0651	0,97	0,67	0,1065
Liver	29,17	38,89	0,3014	0,60	0,67	0,3945
Lung	29,80	15,00	0,0852	0,44	0,13	**0,0002**
Skin	10,83	50,00	**0,0000**	0,18	1,00	**0,0027**
Brain	0,00	0,00	–	0,00	0,00	–
Average/Organ	29,21	35,16	0,332	0,529	0,645	0,341
Average/Patient	32,27	36,21	0,244	0,585	0,668	0,198

Conclusions: Based on the nearly same 0,585 versus 0.668, significantly not different: $p<0.198$) average amount of amyloid A deposits/patient, the immune processes (producing amyloid A deposition) of our RA and PsA patients may be similar.
The more prominent amyloid deposition in the lungs of RA patients (in contrast with PsA patients) may be associated with more frequent and pronounced pulmonary complications of RA (vasculitis, interstitial pneumonitis and fibrosis, etc.), than by PsA.
Extreme severe amyloid deposition in the skin of PsA patients may be due to local factors, namely severe systemic dystrophic changes of the skin in psoriasis. A diverse affinity of amyloid A to qualitative changed collagens cannot be ruled out in PsA in comparison with RA. In systemic sclerosis patients such change of collagens has been demonstrated [4].

AB0738 PRECLINICAL IMPAIRMENT OF MYOCARDIAL FUNCTION AND ENDOTHELIAL VASCULAR MARKERS IN EARLY PSORIATIC ARTHRITIS: ASSOCIATION WITH VITAMIN D LEVELS AND INFLAMMATION

A. Lo Gullo[1], G. Mandraffino[2], C.O. Aragona[2], V. Cairo[2], A. Saitta[1]. [1]*Clinical and Experimental Medicine;* [2]*Policlinico G Martino, Messina, Italy*

Background: Patients with psoriatic arthritis (PsA) have an increased prevalence of cardiovascular risk factors such as hypertension, myocardial dysfunction, and type 2 diabetes mellitus, and cardiovascular diseases (CVD) are the leading cause of death in these patients.
Furthermore, PsA patients have a high prevalence of vitamin D (vit-D) deficiency, considered an independent predictor of cardiovascular diseases and all-cause mortality in several clinical settings.
Objectives: We aimed to evaluate left ventricular (LV) mechanics in patients diagnosed with PsA and no clinical evidence for cardiovascular disease (CVD) using a more sensitive technique, which evaluates myocardial deformation in multidimensional planes for the detection of impaired LV function. Furthermore we evaluated carotid intima media thickness (cIMT) and pulse wave velocity (PWV), circulating proangiogenic haematopoietic cells (PHCs),as markers of endothelial dysfunction. We investigated the association between vitamin D levels, inflammatory mediators, markers of endothelial and myocardial dysfunction in patients with PsA.
Methods: The study enrolled 19 PsA patients and 16 sex- -age matched healthy controls. All participants underwent conventional echocardiography and 2-dimensional speckle tracking echocardiography (STE). Global longitudinal, circumferential, and radial strain were measured. PHCs,Vitamin D levels, C-reactive protein (CRP), fibrinogen, (PWV), (cIMT) were also evaluated.
Results: PHCs count and vitamin D levels were lower in PsA patients as compared to controls, while fibrinogen, CRP, PWV and cIMT were higher in PsA patients. STE analysis showed that PsA patients had significantly lower global longitudinal strain (-16.11±2.89% and -19.15±1.9%, respectively, p=0.05) and global circumferential strain (-14.21±2.7% and -20.22±4.13%, respectively, $p<0.01$) versus control group.
No correlation was found between longitudinal and circumferential strains and disease-related risk factors.
Vitamin D levels was found to correlate with longitudinal strain, ejection fraction, PHCs, diseases activity markers, and fibrinogen levels.
Conclusions: Subclinical impaired myocardial deformation and endothelial dysfunction were common in patients with PsA even when there is no clinical evidence for CVD. Furthermore, vitamin D seems to may have a role in the endothelial homeostasis and myocardial function.
Further studies on larger sample sizes could clarify whether a supplementation of Vitamin D could modify PHCs levels inflammatory indices, myocardial function and arterial stiffness in patients affected by PsA, therefore contributing to reduce cardiovascular risk in this patients.

AB0739 MHAQ RESPONSE AMONG PATIENTS WITH PSORIATIC ARTHRITIS INITIATING A TNFI

A. Ogdie[1], L. Palmer[2], D. Solomon[3], A. Kavanaugh[4], J. Greenberg[2,5], J. Curtis[6], L. Harrold[2,7], J. Kremer[2,8], P. Mease[9]. *[1]University of Pennsylvania, Philadelphia, Pa; [2]Corrona Research Foundation, Albany, NY; [3]Brigham and Women's Hospital, Boston, MA; [4]University of California San Diego, San Diego, CA; [5]New York University, New York, NY; [6]University of Alabama, Birmingham, AL; [7]University of Massachusetts, Worcester, MA; [8]Albany Medical College, Albany, NY; [9]Swedish Medical Center, Seattle, WA, United States*

Background: Improved functional ability is among the most relevant outcomes for patients with psoriatic arthritis (PsA).[1] The modified health assessment questionnaire (mHAQ) is one of the most commonly used patient reported outcome measures used in PsA and addresses the domains of disability and physical function.

Objectives: We examined the change in mHAQ over one year among patients with PsA initiating a TNFi and examined predictors of a clinically meaningful improvement in disability and physical function, as measured by the mHAQ.

Methods: Patients with PsA enrolled in the Corrona Registry between 2005–2013 were followed from initiation of a TNFi (etanercept, adalimumab, infliximab, certolizumab, or golimumab) to the visit closest to 12 months. Patients were required to have at least three tender or swollen joints for inclusion for this study (this is not an inclusion criteria for Corrona), mHAQ within six months prior to TNFi initiation date, and at least one follow up visit 5–13 months after TNFi initiation with mHAQ. The primary outcome was the proportion of patients with a decrease of 0.35 or more in the mHAQ score, the minimal clinically important improvement in PsA[2]. Predictors of mHAQ response were measured in the six months before TNFi initiation. Covariates with p-value $\leq$0.10 in univariable logistic regression models and $\leq$5% missing values were included in a multivariable model and removed individually until all remaining variables were significant ($p<0.05$).

Results: Among 1742 TNFi initiations, 721 initiations (623 patients) met inclusion criteria. Mean age at initiation was 51.5 years (SD 12.3), 56% were female, median PsA duration was 5 years (IQR 2–11), and median baseline mHAQ was 0.375 (IQR 0.125–0.875). The mean change in mHAQ was -0.098 (SD 0.38) and median change in mHAQ was 0 (IQR: -0.25 to 0.125); 23% had a mHAQ decrease of 0.35 of more. In univariable models, college education and being married or partnered were inversely associated with mHAQ response (baseline scores were lower in patients with these characteristics) while patient global, patient pain, baseline clinical disease activity index (CDAI) and swollen joint count were positively associated with the outcome. However, in a multivariable model, only age (0.96 per year, 0.94–0.98) and baseline mHAQ score (17.7 per one point, 10.6–29.4) were associated with a decrease of 0.35 or more in the mHAQ.

Table: Predictors of modified Health Assessment Questionnaire (mHAQ) decrease of 0.35 or greater at follow up visit closest to one year*

	Univariable			Multivariable		
Predictor	OR	95% CI	p	OR	95% CI	p
Female Gender	0.90	0.63-1.28	0.64			
Age at Initiation	0.97	0.96-0.98	<0.0001	0.96	0.94, 0.98	<0.0001
BMI >30 (versus =30)	0.83	0.58-1.17	0.35			
Baseline mHAQ	16.24	9.91-26.61	<0.0001	17.7	10.6, 29.4	<0.0001
Hypertension	0.71	0.48-1.04	0.09			
Cardiovascular disease	0.72	0.34-1.51	0.36			
Work Full Time	0.91	0.64-1.29	0.50			
Smoker (Prev/Current)	1.10	0.77-1.56	0.60			
Alcohol	0.86	0.61-1.23	0.45			
Previous biologic use	1.06	0.75-1.51	0.65			
College Education	0.68	0.47-0.97	0.03			
Married/Partnered	0.58	0.40-0.84	0.005			
Prednisone	1.59	0.998-2.52	0.06			
Patient Global	1.02	1.01-1.03	<0.0001			
Patient Pain	1.02	1.01-1.03	<0.0001			
Baseline CDAI	1.03	1.01-1.05	0.0002			
Tender joint count	1.02	0.995-1.05	0.13			
Swollen joint count	1.04	1.004-1.07	0.03			

Conclusions: A clinically meaningful change in mHAQ occurred in 23% of patients and was strongly associated with age and baseline mHAQ score. In this real world population, there was little change in mHAQ scores over one year, despite treatment. These analyses are limited by the floor effect of the mHAQ among patients with established PsA. Despite having at least 3 tender and 3 swollen joints, many patients in this cohort had a low mHAQ at baseline which did not allow for sufficient change to meet the MCII.

AB0740 SECUKINUMAB IN PSORIATIC ARTHRITIS: HIGH DISEASE BURDEN OBSERVED IN THE CORRONA PSORIASIS REGISTRY

A.B. Gottlieb[1], V. Strand[2], C. Karki[3], M. Mason[3], J. Greenberg[3], S. Jugl[4], K.K. Gandhi[5], P.J. Mease[6]. *[1]NY Medical College, New York; [2]Stanford University School of Medicine, Stanford; [3]Corrona LLC, Southborough, United States; [4]Novartis Pharma AG, Basel, Switzerland; [5]Novartis Pharmaceuticals Corp., East Hanover; [6]Swedish Medical Center and University of Washington, Seattle, United States*

Background: Secukinumab (SEC), a fully human anti–IL-17A monoclonal antibody, has significant efficacy in the treatment of moderate-to-severe psoriasis (Ps) and psoriatic arthritis (PsA), with a favourable safety profile. The Corrona Psoriasis Registry is an independent observational registry of Ps patients (pts) receiving FDA-approved systemic treatments (TNFis, anti–IL-17s and IL-12/23 and non-biologics) in the United States.

Objectives: To assess demographics, clinical features and pt reported outcomes (PROs) of Ps pts with concomitant PsA receiving systemic treatments at registry enrolment.

Methods: Adult Ps pts who initiated a systemic therapy at enrolment or in the previous 12 months, and concomitant PsA reported by a dermatologist, were included. Demographics (e.g. age, gender, BMI), disease activity (body surface area, investigator global assessment, psoriasis area severity index) and PROs (pain, fatigue, itch, EQ-VAS 0–100, work productivity and activity impairment and dermatology life quality index) were evaluated at enrolment and stratified by therapy: SEC, etanercept (ETN), adalimumab (ADA), ustekinumab (UST), and non-biologics (Non-B).

Results: As of October-2016, 2073 Ps pts were enrolled in the registry; 823 (39.7%) had a PsA diagnosis (mean disease duration 7.6 years) of which 37% were biologic naïve. Of the 823 pts with PsA, 25.4% received SEC, 6.2% ETN, 21.5% ADA, 17.6% UST, and 24.8% Non-B. Pts on SEC had a mean age 53.2 years, mean BMI 32.4; 45% were female; all comparable across the treatment groups. PsA pts treated with SEC had higher Ps disease activity than other treated groups (Table). A higher proportion of SEC treated PsA pts had diabetes and cardiovascular disease (25% and 19% respectively). Mean pain scores were higher in the SEC group; however other PROs assessed at enrolment were similar across treatment groups (Table).

WPAI - % overall work affected by Ps^	16.8±22.8	19.8±23.8	15.3±25.9	12.8±21.5	14.8±23.5	15.5±23.8

[1]Data on infliximab and ixekizumab not presented due to small sample sizes; #Mean scores were higher in incident users compared to prevalent users; *Non-biologics include: apremilast, cyclosporine, MTX; ^Assessed only in employed: n=124 (SEC); 37 (ETN); 121 (ADA); 98 (UST); 105 (Non-B); 510 (Overall).

Conclusions: These data show that Ps pts with concomitant PsA who initiated SEC in the Corrona Psoriasis Registry had higher disease activity, more comorbidities and suffered from more severe pain at enrolment. These differences need to be factored in for future analyses between treatment groups as data mature in this registry.

AB0741 PSORIATIC ARTHRITIS QUALITY OF LIFE QUESTIONNAIRE: TRANSLATION, CULTURAL ADAPTATION AND VALIDATION INTO PORTUGUESE LANGUAGE

A. Barcelos[1], C. Ambrósio[1], J. da Silva[2,3], S. McKenna[4], J. Wilburn[4], P.L. Ferreira[5,6]. *[1]Rheumatology Department, Centro Hospitalar Baixo Vouga, Aveiro; [2]Rheumatology Department, CHUC; [3]Faculdade de Medicina, Universidade de Coimbra, Coimbra, Portugal; [4]Galen Research, Manchester, United Kingdom; [5]Faculdade Economia, Universidade de Coimbra; [6]Centro de Estudos e Investigação em Saúde, Faculdade Economia - Universidade de Coimbra, Coimbra, Portugal*

Background: Psoriatic Arthritis (PsA) has a strong negative impact in the quality of life of patients, through pain, stiffness, functional disability, deformity and a variety of other dimensions. The Psoriatic Arthritis Quality of Life (PsAQoL) questionnaire is a disease-specific instrument developed to measure quality of life in patients with PsA.

Objectives: The aims of this study were to culturally adapt the questionnaire for Portugal, and evaluate its reliability and validity in patients with PsA.

Methods: The original UK English version of PsAQoL was translated into Portuguese by a bilingual translation panel. An independent lay panel reviewed the instrument's item phrasing to ensure appropriateness in colloquial European Portuguese. Structured cognitive debriefing interviews were conducted with ten PsA patients to assess the acceptability, the understanding and the redundancy or ambiguity of the questionnaire. The Portuguese PsAQoL was subsequently applied to PsA patients followed at the Rheumatology Department of Centro Hospitalar do Baixo Vouga, E.P.E. To assess reproducibility, thirty patients with PsA completed the Portuguese PsAQoL on two occasions, two weeks apart. A larger sample was recruited to determine internal consistency and construct validity. Descriptive statistical analysis was used to characterize the data. The Nottingham Health Profile (NHP) was used as a comparator instrument.

Results: Translation and adaptation were successful. The validation sample included 104 patients, 67% of whom were men. Their median age was 50.2 (SD=12.1) years and most were married. Cronbach's alpha for the Portuguese version of the PsAQoL was 0.91 and the test-retest reliability was 0.92, indicating that the measure has good internal consistency and produces low random measurement error. The PsAQoL could distinguish between groups of patients defined by self-reported general health status, self-reported severity of PsA and flare of arthritis. Duration of arthritis did not influence PsAQoL scores. There was a positive correlation between the total score of APsQoL and each of the dimensions of the NHP.

Conclusions: The Portuguese version on the PsAQoL was found to be relevant, understandable and easy to complete, reliable and valid. It should be considered for use in clinical practice and research settings to asses PsA-specific QoL.

AB0742 ULTRASONOGRAPHY OF THE NAIL UNIT IN PSORIASIS AND PSORIATIC ARTHRITIS: A QUALITATIVE AND QUANTITATIVE ANALYSIS

A. Fassio[1], L. Idolazzi[1], A. Zabotti[2], E. Vantaggiato[1], C. Benini[1], O. Viapiana[1], M. Rossini[1], D. Gatti[1]. *[1]Rheumatology, Aoui Verona Reumatologia, Verona; [2]Rheumatology, University Hospital "Santa Maria della Misericordia", Udine, Italy*

Background: the nail unit is a shared topic of interest both for dermatologist and rheumatologist [1]. It is easy to study using imaging techniques such as ultrasonography. The nail was considered one of the possible target of assessment for the disease, especially when ultrasonography is performed. Ultrasound imaging of nails is a quite new technique, available since high frequencies probes were introduced in musculoskeletal examination and nail was considered one of the possible target for assessing the disease and defining its prognosis [2,3].

Objectives: to evaluate the presence of the nail involvement and subclinical alterations using ultrasonography in psoriasis and psoriatic arthritis.

Methods: the study sample included 82 patients affected by psoriasis and/or psoriatic arthritis and 50 healthy controls (HC). The patients were consecutively enrolled during their routine visit in the outpatient clinic and they performed clinical and ultrasonographic evaluation of the nail. Activity indexes (DAPSA, PASI, NAPSI) and other clinimetric parameters were considered.

Results: multivariate analysis of variance (mANOVA) was performed between groups and the nail plate and nail bed thickness, PASI, NAPSI, age and BMI were considered (table 1). Post hoc analysis underlined the differences between groups, in particular between healthy and affected. The lesions for nail plate and nail bed in the PASI score were analyzed using Pearson's chi square test and, secondary, odd ratios for significant results were calculated. Nail plate thickness and nail bed thickness were correlated with PASI, NAPSI, BMI and DAPSA. ROC curves were calculated obtaining also quantitative cut offs for nail plate and nail bed thickness in the affected vs healthy ones.

Table 1. patient groups and ANOVA results

	HC N=50 (M/F 22/28)	PSOs N=31 (M/F 22/9)	PsAs) N=51 (M/F 26/25)
	Mean ± SD	Mean ± SD	Mean ± SD
Eta	48.44±13.95	48.22±14.7	50.92±13.9
BMI	24.61±3.92	28.61±4.95*	28.64±5.84*
Thickness NAIL PLATE	0.051±0.006	0.063±0.011*	0.065±0.014+
Thickness NAIL BED	0.22±0.02	0.25±0.05*	0.25±0.04*

Conclusions: the application of ultrasonography is of potential advantages supported by the data of this study and strengthens the information available in literature, also adding quantitative parameters for the ultrasonography of the nail.

AB0743 LOW RATES OF MAJOR ADVERSE CARDIAC EVENTS, MALIGNANCIES, AND SERIOUS INFECTIONS IN PATIENTS WITH PSORIASIS AND PSORIATIC ARTHRITIS TREATED WITH APREMILAST FOR ≥156 WEEKS: POOLED ANALYSIS FROM THE ESTEEM AND PALACE 1-3 PHASE 3 TRIALS

A. Kavanaugh[1], M. Augustin[2], E. Lespessailles[3], K.A. Papp[4], M. Paris[5], R. Chen[5], D.D. Gladman[6], D.M. Pariser[7], K. Peris[8]. *[1]University of California, San Diego, School of Medicine, la Jolla, United States; [2]Institute for Health Care Research in Dermatology and Nursing (IVDP), University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]University of Orléans, Orléans, France; [4]Probity Medical Research, Waterloo, Canada; [5]Celgene Corporation, Summit, United States; [6]Toronto Western Hospital, Toronto, Canada; [7]Eastern Virginia Medical School and Virginia Clinical Research, Inc., Norfolk, United States; [8]Catholic University of Rome, Rome, Italy*

Background: Apremilast (APR), an oral PDE4 inhibitor, was effective in phase 3, randomized, placebo (PBO)-controlled trials assessing treatment of moderate to severe plaque psoriasis (ESTEEM 1 and 2) and psoriatic arthritis (PsA; PALACE 1–3).

Objectives: We report incidence of MACE, malignancies, and serious infections (SIs; opportunistic and non-opportunistic) in pts receiving APR 30 mg BID (APR30) for ≥156 wks in a pooled analysis of these studies.

Methods: Incidence rates and exposure-adjusted incidence rates (EAIR)/100 pt-yrs of MACE, malignancies, SIs, and serious opportunistic infections (SOIs) are reported for 0 to 16 wks, 0 to ≤52 wks, and the APR-exposure period (0 to ≥156 wks) for pts receiving APR30 any time during the studies, through February 2015; ~30% (n=575) of pts received >3 yrs (>156 wks) of APR exposure.

Results: 2,242 pts were included in the safety analysis for 0 to 16 wks (PBO n=913, pt-yrs exposure [py]=260.2; APR30 n=1,329, py=377.8); 1,905 pts received APR30 during the APR-exposure period, representing 3,527.5 py; exposure during 0 to ≤52 wks was 1,524.5 py. At baseline 64.2% of PsA pts (PALACE 1–3) in the APR30 group were receiving concomitant DMARDs (including methotrexate). Incidence of MACE with APR30 was low and comparable to PBO during 0 to 16 wks. During 0 to ≤52 wks and the APR-exposure period, incidence of MACE (EAIR/100 pt-yrs) remained low (Table). Incidence rates (EAIR/100 pt-yrs) of hematologic malignancies, non-melanoma skin cancers, and solid tumors were similar with PBO (0.0, 1.2, 0.4) and APR30 (0.0, 1.3, 0.3) during 0 to 16 wks; incidence rates remained low during 0 to ≤52 wks and the APR-exposure period (Table). During 0 to 16 wks, the overall rate of infections (serious and non-serious) was low and comparable between pts receiving PBO (20.6%) and APR30 (24.8%). The overall rate of infections (serious and non-serious) was 42% during 0 to ≤52 wks and comparable to rates during the PBO-controlled period (0 to 16 wks); the majority of reported infections (URTI, nasopharyngitis, sinusitis) were not serious. During the PBO-controlled period (0 to 16 wks), rates of SIs with APR30 were low and comparable to PBO; no SOIs were reported. During 0 to ≤52 wks, the overall rate of SIs was low (0.6%; EAIR/100 pt-yrs: 0.7). The rate of SIs remained low (1.8%; EAIR/100 pt-yrs: 1.0) during the long-term cumulative APR-exposure period (0 to ≥156 wks) (Table). No clustering of any particular event was noted with respect to SIs; most events occurred in only 1 pt. No clinical reactivation of tuberculosis was reported with long-term APR30 exposure (0 to ≥156 wks). The rate of marked hematologic abnormalities remained low with long-term APR exposure.

	Treatment Period	
	0 to ≤52 Weeks	APR-Exposure Period 0 to ≥156 Weeks Cumulative Events*
	APR30 n=1,905 Pt-Yrs=1,524.5	APR30 n=1,905 Pt-Yrs=3,527.5
	EAIR/100 Pt-Yrs	EAIR/100 Pt-Yrs
Major adverse cardiac events§		
Acute myocardial infarction	0.1	0.1
Myocardial infarction	0.1	0.1
Subarachnoid hemorrhage	0.1	0.1
Cardiac arrest	0.0	0.1
Cerebral infarction	0.0	0.1
Malignancies		
Hematologic	0.0	0.1
Non-melanoma skin cancer	0.9	0.5
Solid tumors‡	0.3	0.4
Serious infections	0.7ǂ	1.0#
Pneumonia	0.1	0.1
Urinary tract infection	0.1	0.1
Appendicitis	0.1	0.1
Diverticulitis	0.1	0.1
Sepsis	0.0	0.1
Bronchitis	0.0	0.1

*Each patient's total exposure is defined as the time interval between the date of the first and last dose of APR30, regardless of when treatment was initiated, through February 2015.
§No adjudication of major adverse cardiac events for the APR-exposure period.
‡Including malignant melanoma.
ǂSerious infections occurring in patients included pneumonia (n=2), urinary tract infection (n=2), appendicitis (n=1), and diverticulitis (n=1).
#Serious infections occurring in ≥2 patients included pneumonia (n=5), appendicitis (n =3), bronchitis (n=3), diverticulitis (n=2), sepsis (n=2), and urinary tract infection (n=2).
APR30=apremilast 30 mg BID; EAIR=exposure-adjusted incidence rate; PBO=placebo; Pt-Yrs=patient-years.

Conclusions: Incidence of MACE, malignancies, and SIs was low in pts with psoriasis and PsA receiving APR30 for ≥156 wks. No new safety signals or SOIs were observed over time with APR30.

AB0744 DOES TIMING OF INITIATION OF ANTI-TNF AGENTS AFFECT THE QUALITY OF LIFE OUTCOMES IN PATIENTS WITH PSORIASIS AND PSORIATIC ARTHRITIS?

P.W. Barnes[1], N. Rich-Garg[2], D. Choi[3], A. Deodhar[2]. *[1]School of Medicine; [2]Division of Arthritis & Rheumatic Diseases; [3]Public Health & Preventative Medicine, Oregon Health and Science University, Portland, United States*

Background: Psoriatic Arthritis (PsA) affects up to 30% of people with psoriasis[1]. While Tumor Necrosis Factor inhibitors (TNFi) are effective agents for PsA, the relationship between early treatment and patient reported outcomes in a real world setting has not been reported previously.

Objectives: To assess whether timely treatment with TNFi leads to better improvement in quality of life outcomes than delayed treatment.

Methods: This was a retrospective analysis of patients with PsA and/or Psoriasis (PsO) using TNFi with or without methotrexate, and who had a minimum of 2 visits at the Center of Excellence for Psoriasis and Psoriatic Arthritis at our university. Detailed demographic and clinical characteristics of this cohort have been published previously[2]. Demographics, quality of life measures (e.g. Routine Assessment of Patient Index Data – RAPID3, Psoriasis Quality of Life – PQoL12, Short Form 12 – SF-12), and clinical data (percent of body surface area involved with PsO – BSA%) were collected from patient-reported questionnaires and electronic medical records. Only those patients who had a chronological overlap of treatment exposure and QoL measures such as RAPID3, BSA, SF12 and PQOL were included. To ascertain treatment effects, a mixed-effects model was fitted to estimate the trend of each QoL outcome of a patient separately. Then, for all estimated trends of an outcome, a linear regression model was employed to explore the association between the magnitude of estimated trends and timeliness of TNFi treatments.

Results: The quality of life measures were not affected by how early after the disease onset TNFi treatment was started (in other words, no statistically significant associations between the effectiveness of TNFi treatment and disease duration) for RAPID3 (p=0.285), SF-12 (p=0.674), or BSA (p=0.078). For PQoL, there was a significant association between the trend of treatment effects and timeliness of treatment. A day of delay into treatment was resulted in a reduction of 4.4×10^{-4}/day in the trend of PQoL scores (p=0.007).

Conclusions: In this sample of PsA & PsO patients, timing of starting TNFi in patients with PsA had significant impact on improvements in the PQoL but not other quality of life measures such as RAPID3, SF-12 and BSA. A relatively short treatment history might have led to the negative correlations.

AB0745 SUBCLINICAL ATHEROSCLEROSIS EVOLUTION IN PSORIATIC ARTHRITIS PATIENTS TREATED WITH ANTI-TNF ALPHA: 5 YEARS FOLLOW UP

A. Ortolan[1], M. Puato[2], G. Boschetti[3], M. Lorenzin[1], A. Hoxha[1], L. Punzi[1], R. Ramonda[1]. *[1]Rheumatology Unit, Department of Medicine DIMED, University of Padova; [2]Clinica Medica III, Department of Medicine DIMED, Universityof Padova; [3]Clinica Medica III, Department of Medicine DIMED, University of Padova, Padova, Italy*

Background: Psoriatic arthritis (PsA) is associated with increased morbility and mortality and an accelerated atherosclerosis. Influence of anti-TNFalpha treatment (a widely used therapy in PsA) in subclinical atherosclerosis is still unclear.

Objectives: The aim of this study was to evaluate subclinical atherosclerosis progression before, during and after 5 years of anti-TNFalpha treatment.

Methods: Twenty-seven consecutive PsA patients were evaluated before TNF blockers therapy (T0), after 2 years (T1) and after 5 years (T2) of treatment. Subclinical atherosclerosis was evaluated through carotid duplex scanning, analyzing intima-media thickness (IMT) and flow-mediated dilation (FMD). IMT values were expressed as IMT mean (cumulative mean of all the IMT mean in every analyzed carotid segment) and M-MAX (cumulative mean of all the higher IMT in every analyzed carotid segment). Response to therapy was studied by the evaluation of tender and swollen joints (Tj and Sj), DAS 28 (disease activity score), erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP). Metrologic and metabolic data were collected. For the statistical evaluation of parameters over time (T0 vs T1, T1 vs T2) Student's T test for paired data was used.

Results: From T0 to T1 a deterioration in IMT-mean and M-MAX ($p<0.01$) was

Table

	T0	T1	T2
IMT-mean	0.72±0.15	0.91±0.37*	0.92± 0,34
M-MAX	0.89±0.18	1.06±0.39*	1.10±0.35**
FMD	5.40±1.93	5.37±1.66	5.40±1.89
Tender joints (n)	8.10±5.56	2.09±2.32*	1.72± 2.05
Swollen joints (n)	3.85±3.84	0.25±0.72*	0.50±0.92
CRP	11.25±9.16	2.91±1.72*	2.73 ±2.51
DAS28	4,16±0.67	2.30±0.82*	2.40±0,9

Legend: IMT= intima-media thickness; M-MAX= cumulative mean of all the higher IMT in every analyzed carotid segment; FMD= flow-mediated dilation; CRP= C Reactive Protein; DAS28=Disease Activity Score 28joints; *= p<0.01 with respect to the previous determination; **=p<0.05 with respect to the previous determination

noted. At T2 IMT-mean remained stable, M-MAX worsened further ($p<0.05$). No significant variation in FMD was observed (Table). Noteworthy, from T0 to T2 systolic blood pressure and Body Mass Index remained stable (p=ns), while diastolic blood pressure decreased (p=0,001). A good response to PsA treatment was confirmed by a significant decrease (T0 vs T1) in Tj, Sj, DAS 28 and CRP ($p<0.01$); treatment efficacy was preserved from T1 to T2 (p=ns) (Table).

Conclusions: Our data revealed that in patients with PsA, despite treatment with TNF blockers, there is still a gradual, albeit slight progression of subclinical atherosclerosis assessed by ultrasonography. Other inflammatory mechanisms not related to TNF may be responsible of the progression in atherosclerotic disease.

Disclosure of Interest: None declared

AB0746 PRELIMINARY RESULTS OF A TWO-YEAR FOLLOW UP OF SUBCLINICAL ATHEROSCLEROSIS IN PATIENTS WITH PSORIATIC ARTHRITIS

C. Vergara-Dangond[1], M. Robustillo-Villarino[1], V. Núñez-Monje[1], M. Aguilar-Zamora[1], L. Montolio-Chiva[1], E. Valls-Pascual[2], A. Ybáñez-García[1], Á. Martínez-Ferrer[2], J.J. Alegre-Sancho[1]. [1]*Rheumatology;* [2]*Hospital Universitario Dr. Peset, Valencia, Spain*

Background: Psoriatic arthritis (PsA) is a disease associated with an increased cardiovascular (CV) risk, due to early atherosclerosis, which is comparable to a rheumatoid arthritis population. However, there is a lack of studies that evaluate the progression of subclinical atherosclerosis over a year in these patients.

Objectives: To explore the progression of the vascular damage by different techniques in patients with PsA and the factors related with these changes.

Methods: Pre-post study with analytical components. 44 patients with PsA (CASPAR criteria) and peripheral joint involvement of more than one year since diagnosis were consecutively included. We gathered demographic (age, gender, BMI), clinical (traditional CV risk factors, previous CV event), and analytical variables (atherogenic index [AI], GFR [MDRD], fibrinogen, glycated hemoglobin, CRP, ESR, ultrasensitive CRP, apoB/apoA1 ratio) and basal CV risk was estimated with SCORE tool. Other variables were collected retrospectively from patients electronic medical record. The extracranial branches of carotid artery were explored by ultrasonography (US) using an Esaote MyLab70XVG with a 7–12 MHz linear transducer and an automated program measuring intima-media thickness (IMT) through radiofrequency (^{RF}QIMT), and the presence of atheroma plaques, as per the Mannheim consensus, was registered. Pulse wave velocity (PWV) was determined, as an arterial stiffness marker, by a validated MobilOGraph® device. Patients were followed during a 2-year period between may 2014 until december 2016. All of the tests were repeated after 2 years. Statistical analysis was performed using SPSS 17.0 software.

Results: We analyzed 38 patients, excluding those with high CV risk (previous CV event, GFR<60mg/dl, and/or type II or type I diabetes with organ affection) and followed during 2 years. At baseline, the mean and median of age was 59,2 and 60,5 years (39–88), respectively, mostly women (65,8%). The median BMI was 28 (17–35). 28,9% were smokers and 36,8% had hypertension. 26,3% received glucocorticoids, 57,9% NSAIDs, 84,2% DMARDs and 31,6% biologic therapies. The median CRP, ESR and DAS 28 were 5mg/L (1–19,1), 7mm/h (2–28) and 2,17 (1,24–3,7), respectively. The median SCORE was 1 (0–7), the PWV was 8 m/s (5,6–13,5) and basal IMT was 728 μ(462–1087); the presence of atheroma plaques was detected in 35,1% of the patients.

After 2 years, plaque appearance was seen in 15% more of patients, as well as worsening of PWV and IMT in 56,8% and 38,9% of patients, respectively.These changes were not significant. No patient developed a CV event.

In the bivariate analysis, PWV progression at 2 years related with advanced age ($p<0,002$), and with elevated SCORE ($p<0,044$), and showed a tendency with higher arterial systolic pressure (ASP). We also observed a tendency to an association between plaque appearance, age and ASP; as well as lower apolipoprotein A1 levels with IMT.

Conclusions: The progression over time of the vascular damage in patients with PsA relates with traditional CV risk factors. These preliminary results must be confirmed in a posterior analysis with a greater number of patients.

AB0747 THE EFFECT OF CERTOLIZUMAB PEGOL ON RADIOGRAPHIC PROGRESSION OVER 4 YEARS OF TREATMENT IN PATIENTS WITH PSORIATIC ARTHRITIS

D. van der Heijde[1], R. Fleischmann[2], J. Wollenhaupt[3], A. Deodhar[4], L. Bauer[5], B. Hoepken[5], L. Peterson[6], P.J. Mease[7]. [1]*Leiden University Medical Center, Leiden, Netherlands;* [2]*UT Southwestern Medical Center and Dallas Metroplex Clinical Research Center, Dallas, United States;* [3]*Schön Klinik, Hamburg, Germany;* [4]*Oregon Health and Science University, Portland, United States;* [5]*UCB Pharma, Monheim, Germany;* [6]*UCB Pharma, Raleigh;* [7]*Swedish Medical Center and University of Washington, Seattle, United States*

Background: The RAPID-PsA trial (NCT01087788) investigated the efficacy and safety of certolizumab pegol (CZP) in patients (pts) with psoriatic arthritis (PsA). It demonstrated that CZP treatment inhibits radiographic progression over 96 weeks (wks).[1]

Objectives: We report the long-term effect of CZP treatment on radiographic progression in pts with PsA over 4 years.

Methods: The RAPID-PsA phase 3 trial was double-blind and placebo-controlled to Wk24, dose-blind to Wk48, and open-label (OL) to Wk216. Pts had active PsA and had failed ≥1 DMARD. Pts randomized to CZP (200mg Q2W or 400mg Q4W, following 400mg loading dose at Wks0, 2, 4) continued their assigned dose in the OL period. Radiographs taken at baseline (BL), and at Wks96, 168, 216, were read in a single reading campaign using the modified Total Sharp Score (mTSS) for PsA by 2 readers, blinded to patient information and time point sequence. The mean of the scores of the 2 readers was used. Outcomes reported are the least squares (LS) mean mTSS score, change from BL (CFB) in mTSS score, and the percentage of pts assessed for radiographic damage who achieved mTSS non-progression (defined either as CFB in mTSS score ≤0.5 or ≤0), for all Wk0 CZP-treated pts, irrespective of dose regimen. mTSS score and CFB were estimated using Mixed Model Repeated Measures (MMRM) estimates; proportions of pts with radiographic non-progression are presented as observed case.

Results: 409 PsA pts were randomized, of whom 273 received CZP from Wk0. The LS mean BL mTSS score was 16.0 and there was little increase from BL in mTSS score to Wk216 (Table). Amongst those who completed the study to Wk216, the majority of CZP-treated pts achieved radiographic non-progression to Wk216, both with non-progression defined as CFB in mTSS score ≤0.5 or ≤0 (Table). The change in LS mean mTSS score over time for Wk0 CZP-treated pts was consistently low throughout the trial: 0.14 (95% CI: 0.02–0.26) per 48 wks from BL to Wk96, and 0.18 (95% CI: 0.08–0.28) per 48 wks from Wk96 to Wk216.

Table: mTSS score and radiographic non-progression to Week 216 for patients treated with CZP from Week 0

	Week 0 CZP dose combined (N=273)			
	Week 0	**Week 96**	**Week 168**	**Week 216**
mTSS score, LS mean (SE) [95% CI] [a]	16.0 (2.2) [11.6–20.4]	16.2 (2.2) [11.8–20.6]	16.6 (2.3) [12.1–21.0]	16.7 (2.3) [12.2–21.1]
CFB in mTSS score, LS mean (SE) [95% CI] [a]	–	0.3 (0.1) [0.0–0.5]	0.6 (0.2) [0.3–1.0]	0.7 (0.2) [0.3–1.1]
Non-progression rate, n (%) [b]				
Patients with CFB in mTSS ≤0.5, n/N (%)	–	180/214 (84.1)	158/196 (80.6)	145/186 (78.0)
Patients with CFB in mTSS ≤0, n/N (%)	–	157/214 (73.4)	131/196 (66.8)	121/186 (65.1)

[a] Mixed Model Repeated Measures (MMRM) estimates; [b] Observed case; percentage of patients with non-progression, as a proportion of the number assessed for progression. CFB: change from baseline; LS: least squares; SE: standard error.

Conclusions: There was little radiographic progression in CZP-treated PsA pts, as measured by mTSS, throughout the 4-year RAPID-PsA trial.

AB0748 HYPERURICEMIA IN PSORIATIC ARTHRITIS: A NEW LOOK AS A RISK FACTOR FOR CARDIOVASCULAR EVENTS

D.S. Bublikov. *Altay State Medical University, Barnaul, Russian Federation*

Background: According to various authors, the prevalence of hyperuricemia in patients with psoriatic arthritis constitutes up to 35% of the total patient population. Thus, seronegative spondylarthritis patients, as it is known, possess a higher incidence of cardiovascular mortality than the population in general, in particular due to life-threatening cardiac arrhythmias.
Objectives: To study the effect of hyperuricemia on the development of ventricular extrasystole in patients with psoriatic arthritis and the interrelation of uric acid levels and gradation of ventricular extrasystole.
Methods: The study involved patients with psoriatic arthritis, confirmed by CASPAR criteria (2006), n=59. The average age – 57.15±12.11 years. All patients underwent the study of myocardial contractility and treadmill test. Inclusion criteria - the presence of psoriatic arthritis for the period of at least one year, uric acid levels over 360 mkmol/L for women and more than 420 mkmol/L for men. The exclusion criteria included the presence of coronary heart disease, myocardial contractility disorders and decreased ejection fraction according to Simpson less than 55%. For all patients was recorded Holter ECG for the period of 24 hours on an outpatient basis. The level of uric acid was measured by means of the standard method of biochemical analyzer.
Results: The prevalence of ventricular extrasystole in patients with psoriatic arthritis and grading are shown in Table 1.
Moreover, there has been discovered a direct correlation of medium strength between the uric acid levels and frequency and Lown-Wolf gradation of ventricular extrasystole (Table 1).

Table 1

Lown-Wolf gradation of ventricular extrasystoles	Percentage of patients with with psoriatic arthritis	Average level of uric acid	Coefficient of correlation, r
I	25,40%	546,52+12,24	0,54
II	22,03%	622,15+28,11	0,47
III	1,69% (1 patient)	511,21	Small sample
IV a	20,34%	784,22+55,16	0,68
IV b	25,42%	774,13+22,60	0,33
V	5,08%	894,23+13,90	0,57

Conclusions: 1. Hyperuricemia in patients with psoriatic arthritis by exclusion of cardiogenic causes of cardiac extrasystole is an independent risk factor for ventricular extrasystole.
2. The level of hyperuricemia correlates directly with the Lown-Wolf gradation of ventricular extrasystole.

AB0749 AXIAL INVOLVEMENT IN THE RUSSIAN COHORT OF EARLY PERIFERAL PSORIATIC ARTHRITIS PATIENTS AND ITS ASSOCIATION WITH ARTHRITIS ACTIVITY, PATIENT'S ASSESSMENT AND SEVERITY OF SKIN LESION

E.E. Gubar, E.Y. Loginova, L.N. Denisov, A.V. Smirnov, S.I. Glukhova, T.V. Korotaeva. *V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: The association of axial involvement with peripheral arthritis activity and skin lesion severity in early psoriatic arthritis (ePsA) patients (pts) has not been studied properly.
Objectives: to study the prevalence of axial involvement detected by magnetic resonance imaging (MRI) and X-ray of sacroiliac joints (SIJs) and its correlation with peripheral arthritis activity and skin lesion severity in peripheral ePsA pts.
Methods: 89 pts (M/F–42 /47) with peripheral ePsA according to CASPAR criteria were included; mean age 36.5±10.9 yrs, disease duration 12.1±10.1 mo., disease activity index (DAS)28 8.8±1.7, patient's pain VAS 55.0±17.9, patient's global disease activity VAS 56.9±17.1, C-RP16.1 [6.6; 31.0] mg/l, ESR 22.5±19.2 mm/h. All patients were evaluated for the presence of inflammatory back pain (IBP) by ASAS criteria. In pts having IBP disease activity was measured by BASDAI. The examination included X-ray of sacroiliac joints (SIJs), HLA B27 antigen, MRI of SIJs was performed in 79 pts, both with and without IBP, on Signa Ovation 0,35T. Bone marrow edema on MRI (STIR), considered as active MRI sacroiliitis (MRI-SI), was evaluated by an independent reader. Radiographic sacroiliitis (R-SI) was defined at 2 grade changes, at least in one SIJ, while definite radiographic SI (dR-SI) was considered according to New York criteria (unilateral grade $\geq$3 or bilateral grade $\geq$2). Skin lesion area was measured according to BSA. BSA $>$10% was defined as extensive.
Results: IBP was found in 58 out of 89 (65.1%) pts, 35 (60.3%) of them had short-term (episodic) IBP, and 23 (39.7%) pts had long-term IBP. MRI-SI was observed in 28 out of 79 (35.4%) pts. R-SI was determined in 42 out of 89 (47.2%) pts, while dR-SI was found in 27 out of 89 (30.3%) pts. 34 (38. 2%) pts were HLA-B27 positive. In pts having IBP disease activity by BASDAI was 4.5±1.6. An association was detected between the presence of MRI-SI and activity of peripheral arthritis by DAS28 (r=0.25; p=0.03). Correlation was detected between the presence of MRI-SI and the value of patient's global disease activity (r=0.23; p=0.047) as well as patient's pain (r=0.31; p=0.007). An association was found between the presence of MRI-SI and the skin lesion area. Among the group of 28 pts with MRI-SI, 6 (21.0%) pts had an extensive skin lesion area, while out of the group of 51 pts without MRI-SI only 2 (4.0%) pts had an extensive skin lesion area (p=0.033). A positive trend has been found between the presence of R-SI and erosive arthritis of hands and feet. Among the 42 pts having R-SI erosive arthritis was found in 18 (43.2%) pts while in 47 pts without R-SI–in 11 (23.9%) pts (p=0.06).
Conclusions: in the Russian cohort of early peripheral PsA pts, careful examination quite often revealed high prevalence of axial involvement. Active inflammation of the SIJ detected by MRI (in 35% of pts) is more often found in pts with higher peripheral arthritis activity measured by DAS28, with higher values of patient's pain /patient's global disease activity, with more extensive skin lesion area. There is a tendency that pts with more severe (erosive) peripheral arthritis more often develop R-SI.

AB0750 THE GO-DACT PROTOCOL: A RANDOMIZED CONTROLLED TRIAL TO COMPARE THE EFFICACY OF GOLIMUMAB IN COMBINATION WITH METHOTREXATE (MTX) VERSUS MTX MONOTHERAPY, IN IMPROVING DACTYLITIS AND ENTHESITIS, IN MTX NAÏVE PSORIATIC ARTHRITIS PATIENTS

E. Vieira-Sousa[1], H. Canhão[2], J.E. Fonseca[1] on behalf of GO-DACT research team. *[1]Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa and Rheumatology Department, Hospital de Santa Maria, Lisbon Academic Medical Centre; [2]CEDOC, NOVA Medical School, Universidade Nova de Lisboa, Lisbon, Portugal*

Background: Dactylitis is a hallmark manifestation of psoriatic arthritis (PsA) and a key feature for PsA diagnosis. Active dactylitis is associated with a higher risk of erosions and can severely impact function. The therapeutic strategies for dactylitis are however largely empirical, with a profound absence of knowledge regarding efficacy, as primary endpoint, and impact on disease progression. The use of biologic disease modifying anti-rheumatic drugs (DMARDs) in patients with dactylitis, refractory to non-steroidal anti-inflammatory drugs (NSAIDs) or local corticosteroids, is recommended by EULAR guidelines, over the use of conventional DMARDs, based in the scarcity of evidence and properly designed studies in this field.
Methods: GO-DACT is an investigator initiated ongoing multicentric trial, involving 13 national Rheumatology departments. Patients older than 18 years, with the diagnosis of PsA and active dactylitis (tenderness score$\geq$1), refractory to NSAIDs, for 3 months, were included. Patients were randomized on a 1:1 ratio, to either MTX in combination with golimumab or placebo, for a period of 24 weeks. The primary aim of this trial is to determine differences of efficacy between the two treatment arms, in improving dactylitis (and enthesitis), as assessed by the dactylitis severity score (DSS) at 24 weeks. Key secondary outcomes include: Leeds dactylitis index (LDI), Leeds enthesitis index (LEI), joint counts, psoriasis area and severity index (PASI) and nail psoriasis severity index (NAPSI), health assessment questionnaire (HAQ), Dermatology life quality index (DLQI) and composite indexes for disease activity. The effect of treatment arms, on different tissue compartments, will be analysed by contrast-enhanced magnetic resonance imaging (MRI), with high resolution images for dactylitis, at baseline and 24 weeks.
Results: The results from GO-DACT are expected to have implications in clinical practice, bringing robust and valid data for the definition of dactylitis treatment stratification and algorithm.GO-DACT will also contribute to understand dactylitis pathogenesis through the assessment of treatment efficacy, namely in distinct tissue compartments as defined by MRI. https://www.clinicaltrials.gov (NCT02065713)

AB0751 THE DIFFERENCES AND SIMILARITIES BETWEEN PATIENTS AND PHYSICIAN GLOBAL ASSESSMENT IN PATIENTS WITH PSORIATIC ARTHRITIS

K. Nas[1], E. Kilic[2], R. Cevik[3], A.Z. Dagli[3], G. Kilic[4], S. Sag[1], A. Kamanli[1], I. Tekeoglu[1]. *[1]Div. of Rheumatology and Immunology, Dept of PM&R, Sakarya University Faculty of Medicine, Sakarya; [2]Rheumatology Clinic, Afyonkarahisar State Hospital, Afyon; [3]Div. of Rheumatology, Dept of PM&R, Dicle University Faculty of Medicine, Diyarbakir; [4]Dept. of PM&R, Afyon Kocatepe University Faculty of Medicine, Afyon, Turkey*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis associated with psoriasis, axial involvement, enthesitis, dactylitis and uveitis. The differences and similarities between patient's global assessment (PtGA) and physician's global assessment (PhGA) were not assessed clearly in PsA.
Objectives: The aim of this study was to assess differences and similarities between patient's and physician's perspective of global assessment in patients with PsA.

Methods: Patients with PsA over the age of 18-year-old who met the CASPAR classification criteria were underwent clinical and laboratory evaluation by using standardized protocol and case report form, from two universities outpatient's clinics. PtGA and PhGA, VAS-pain, fatigue, BASDAI, BASFI, health-related QoL were recorded at baseline visit. Pearson correlation coefficient were calculated for PtGA and PhGA. Linear regression model were used to asses relationship between global assessments and clinical finding.
Results: A total 144 patients with PsA (male 51, female 93) were included. Symptom duration (7.8±7.5 vs 11.3±11.2), VAS-pain (4.4±2.6 vs 4.9±2.6), PtGA (4.7±2.5 vs 5.0±2.4) and PhGA (4.0±2.2 vs 4.4±2.2) were similar between male and female patients with PsA ($p>0.05$). VAS-fatigue was higher in female patients with PsA than male ones (5.9±2.7 vs 4.4±2.8, p=0.001). Disease activity measurements such as, tender and swollen joint count, DAS28, BASDAI and acute phase reactant were similar for both sex. Correlation coefficient of Physician's global assessment was higher than PtGA in various clinical findings. The highest correlation coefficient was observed in VAS-pain (r=0.784) and followed by SF36-bodily pain (r=-0.613), BASDAI (r=0.587), NHP-physical activity (r=0.584), VAS-fatigue (r=0.555), BASFI question 5 (r=0.551) for PhGA ($p<0.0001$). However the highest correlation coefficient was observed in VAS-pain (r=0.690) and followed by NHP-physical activity (r=0.536), BASFI question 10 (r=0.512), BASDAI (r=0.499), SF36 (r=-0.490) and BASFI total score (r=0.484) for PtGA ($p<0.0001$). Statistically significant positive linear relation was observed between global assessment and clinical parameters (VAS-pain, fatigue, BASDAI, BASFI, DAS28, NHP-physical activity) by using simple linear regression model. VAS-pain and BASDAI question 1 explained 83.3% of PtGA as a predictor in multiple linear regression model. However, VAS-pain and DAS28 explained 68.4% of PhGA as a predictor in multiple linear regression model (table 1).

Table 1. Results of multiple linear regression of PtGA and PhGA

	R^2	B	SE	t	p
Patient's global assessment					
Constant	0.833	0.597	0.311	1.920	0.060
VAS-pain		0.665	0.061	10.939	?0.0001
BASDAI-1 How would you describe the overall level of fatigue/tiredness you have experienced in the past week?		0.205	0.063	3.243	0.002
Physician's global assessment					
Constant	0.684	0.399	0.310	1.285	0.201
VAS-pain		0.587	0.050	11.846	?0.0001
DAS 28		0.332	0.096	3.453	0.001

Conclusions: Assessment of disease activity as well as clinical parameters is considered to be complex in PsA. Patient's and physician's have different perspective of disease activity. Severity of pain and fatigue may be predictor of PtGA whereas; pain and objective disease activity measurement may be predictor of PhGA in patient with PsA.

DOI: 10.1136/annrheumdis-2017-eular.5396

AB0752 CONSENSUS STATEMENT ON THE USE OF METHOTREXATE IN PSORIATIC ARTHRITIS PATIENTS

J. Tornero[1], E. Loza[2], J.D.D. Cañete[3]. *[1]Rheumatology, Hospital de Guadalajara, Guadalajara; [2]Instituto de Salud Musculoesquelética, InMusc, Madrid; [3]Rheumatology, Hospital Clínic e IDIBAPS, Barcelona, Spain*

Background: Methotrexate (MTX) is the cornerstone in rheumatic diseases, including psoriatic arthritis (PsA), but the complexity of PsA and the paucity of randomised controlled studies and strategic trials need a clear analysis.
Objectives: To develop recommendations for the management of MTX in PsA (musculoskeletal manifestations) based on best evidence and experience
Methods: The coordinators formulated 14 questions about MTX use (indications, efficacy, safety) in patients with PsA. A systematic literature review was performed to answer these questions. Using this information, inclusion and exclusion criteria were stablished as well as the search strategies (Medline, Embase and the Cochrane Library), that were designed by an expert librarian. Two different reviewers selected the articles, first by title and abstract, then by detailed review, and collected data independently. Evidence tables were produced. With this evidence the coordinators proposed 12 preliminary recommendations that will be discussed and voted in a nominal group of expert meeting. The level of evidence and grade of recommendation will be defined using the Oxford Center for Evidence Based Medicine. Agreement will be stablished if at least 80% of the experts voted yes (yes/no).
Results: A total of 12 preliminary recommendations on the use of MTX in PsA were proposed (see table).
Conclusions: This document aims to help to answer usual clinical questions and facilitate decision making when treating PsA patients with MTX.

Abstract AB0752 – Table 1

#	Recommendation	LE; GR
1	In patients with active peripheral disease (oligo-polyarthritis), the use of a csDMARD is recommended, MTX preferred, principally in cases of relevant skin involvement	1b; A
2	A starting dose of at least 10–15 mg/w is recommended, taking into account disease severity and patients prognostic factors	5; C
3	In case of insufficient response to MTX starting dose, a quick dose increase should be performed up to 25–30 mg/w in approximately 8 w	5; C
4	Oral MTX is recommended, but parenteral MTX should be considered in patients with high disease activity, those needing >15 mg oral/week, in those with low adherence to oral MTX, polypharmacy, obese patients, in order to avoid dosing errors, and always taking into account patients preferences	5; C
5	When the treatment target is reached for at least 6 months, then a dose adjustment is recommended in order to maintain the treatment target with the minimal MTX dose	5; D
6	Despite of lack of well designed clinical trials to demonstrate the efficacy of MTX in PsA, data coming from clinical trials using MTX as placebo, treat to target studies and years of rheumatologist accumulated clinical experience, all are in favor of MTX efficacy in peripheral PsA	1b; A
7	In patients with peripheral PsA and enthesitis/dactylitis, MTX could be an option along with steroids injections (if needed)	2a; B
8	In general, combined therapy with MTX and other csDMARD is not recommended	2a; B
9	If a biologic therapy is indicated, MTX continuation should be individually evaluated in each patient	1b; A
10	MTX improves anti-TNFα survival (monoclonal antibodies, mainly chimeric antibodies)	2a; B
11	No special safety problems, regarding to rheumatoid arthritis patients, have been reported with MTX in PsA patients	1b; A
12	PsA is a chronic disease in which MTX discontinuation is not recommended if there is maintained efficacy and the drug is well tolerated	3a; C

AB0753 ARTERIAL STIFFNESS INCREASE IN THE EARLY PHASE OF ARTHROPATHY RELATED WITH PSORIATIC ARTHRITIS IS NOT FURTHER MODIFIED BY STABLE PROLONGED RETENTION OF A MINIMAL DISEASE ACTIVITY CONDITION

F. Fischetti, F. Bozzao, M. Rovina, G. Simon, M. Bardelli, R. Carretta. *University of Trieste Italy, Trieste, Italy*

Background: Increased large arteries wall stiffness (AS) is a well known independent morbidity and mortality cardiovascular risk factor, not only related to hypertension and diabetets, but also induced by long standing systemic inflammation, as observed in inflammatory rheumatic or gut chronic diseases. Psoriatic arthritis (PsA) was also shown to increase cadiovascular morbidity, but this observation was commonly related with the associated occurrence of long term arthritis, disease activity and CV traditional risk factors
Objectives: To assess whether in a selected group of PsA patients, affected by recent onset (4–12 months) arthritis, not suffering from CV disease risk factors, evidence could be obtained of an early alteration of arterial wall function as expressed by an increased arterial pulse wave velocity (aPWV) and secondary reduced tonometric subendocardial viability ratio (tSEVR).
Further, we evaluated if a 18 months (Mth) treatment with synthetic disease modifying antirheumatic drugs (sDMARD) other than cyclosporine, leading to a demonstrable target of clinical "minimal disease activity"(MDA) could modify such possible modifications
Methods: Conclusive data were obtained in a selected goup of 12 PsA patients (Pts) (CASPAR criteria classified) (M/F, 6/5; mean age, 50.8; range, 40–65) not suffering from axial spondylitis who firsly underwent (without any previous treatment) aPWV measurement (PulsePen, Diatecne Srl, Milan) and tSEVR calculation, and then were re-evaluated for the same calculations after a 18 Mth time of sDMARD treatment. Each of the PsA Pts had a 3–4 Mth follow up and showed to reach the target of stable MDA (with also ultrasound confirmed remission of active synovitis) after a 4–8 Mth treatment. Before treatment, the group of PsA Pts was compared with an age, body weight, CV parameters and risk factors–matched control group of voluntary 22 healthy subjects (M/F, 11/11; mean age, 51.3; range, 41–67)
Results: Before any treatment, aPWV was higher in the group of patients with PsA than in control subjects (median, 8.667 m/s vs 6.963 m/s, $p<0.02$) while tSEVR was decreased (median, 1.44 vs 1.50, $p<0.05$). Aortic PWV was not modified after the sDMARD treatment (median m/s, before=8.691, after=8.048, p=0.55), despite statistically significant improvements of the disease activity scores (DAS28; modified CPDAI; DAPSA) as well as cutaneous PASI, and stable retention of a MDA condition. A direct correlation (Spearman rank) between aPWV and DAS28 (rho=0,70; p-value=0,04), BASDAI (rho=0,77; p-value=0,01), and HAQ (rho=0,66; p-value=0,05) was found, not instead between aPWV and ESR or CRP. Pts with PsA, at the end of the follow up, had increased levels of systolic (134,1±14,3 vs 122±11,2, $p<0,05$) and diastolic (82±7,4 vs 73,5±6,6, $p<0,05$) blood pressure, with unmodified heart rate
Conclusions: Early onset of PsA seems to be associated with already established and stable increase of AS. Subclinical previous phase of inflammation and length of psoriatic disease could be addressed as possible causes
Disclosure of Interest: None declared

AB0754 COMPARISON OF COMPOSITE INDICES TAILORED FOR PSORIATIC ARTHRITIS TREATED WITH CSDMARDS AND BDMARDS: A LONGITUDINAL OBSERVATIONAL STUDY

F.M. Perrotta, A. De Socio, E. Lubrano. *Medicina e scienze della salute, Università degli studi del Molise, Campobasso, Italy*

Background: Remission or low disease activity should be the target of therapy in chronic inflammatory arthritis as well as in Psoariatic arthritis (PsA). In a complex disease such as PsA, several methods are available to define remission that comprise the assessment of different clinical features.
Objectives: The aim of this study was to compare the composite indices tailored for PsA in both patients treated with csDMARDs and bDMARDs.
Methods: Adult PsA patients classified with CASPAR criteria and with >6 months follow up treated with first csDMARDs and bDMARDs were consecutively enrolled in our outpatient clinic. To assess disease activity, composite indices tailored for PsA namely DAPSA, cDAPSA, PASDAS, MDA (5/7) and MDA (7/7) were used. DAPSA and cDAPSA score ≤4, MDA 7/7 and PASDAS ≤1.9 identified remission while MDA 5/7and PASDAS <3.2 the minimal disease activity and inactive disease criterion[1–5].
Results: One hundred nine PsA patients were enrolled. Of this, 79 patients were in stable treatment with bDMARDs and 30 with csDMARDs. Overall, 28 (25.6%), 23 (21.1%), 19 (17.4%), 54 (49.5%), 13 (11.9%) and 35 (32.1%) PsA patients were in cDAPSA remission, DAPSA remission, MDA 7/7, MDA 5/7, PASDAS ≤1.9 and PASDAS <3.2. Patients in bDMARDs had a significantly low median DAPSA, cDAPSA and PASDAS score than patients treated with csDMARDs (table 1). Overall, the concordance between the indices ranging from slight to good.

Table 1. Demographic and clinical disease activity characteristics in patients treated with bDMARDs and csDMARDs

	bDMARDs (n=79)	csDMARDs (n=30)	P value
Female/male	38/41	16/14	ns
Mean age (SD), years	52.7 (12.4)	51.6 (12.3)	ns
Disease duration (SD), years	7.8 (9.3)	6.6 (8.2)	ns
PASI, median (25th-75th percentile)	0.3 (0–0.6)	1.5 (0–3.2)	0.02
Enthesitis (LEI) median (25th-75th percentile)	0 (0–1)	1 (0–3)	<0.01
CRP, mg/dl (25th-75th percentile)	0.3 (0.16–0.49)	0.3 (0.2–0.76)	ns
PASDAS, median (25th-75th percentile)	3.28 (2.69–3.72)	4.43 (3.73–4.76)	<0.01
MDA 5/7, n (%)	49 (62)	5 (16.6)	<0.01
MDA 7/7, n (%)	16 (20.2)	3 (10)	ns
DAPSA, median (25th-75th percentile)	6.8 (3.7–9.57)	18.1 (16.5–31.5)	<0.01
cDAPSA, median (25th-75th percentile)	6.5 (3.5–9.5)	17.5 (11.2–26.9)	<0.01

PASI: psoriasis area severity index; LEI: Leeds enthesitis index; CRP: C-reactive protein; PASDAS: psoriatic arthritis disease activity score; MDA: minimal disease activity, DAPSA: disease activity index for psoriatic arthritis.

Conclusions: PsA patients in bDMARD are more likely to reach a status of MDA and remission in respect to csDMARDs. PASDAS ≤1.9 and MDA 7/7 seem to be stringent remission criteria.

AB0755 DEPRESSION AND ANXIETY MAY CONTRIBUTE TO HIGHER DISEASE ACTIVITY AND WORSE QUALITY OF LIFE IN PSORIATIC ARTHRITIS

F. Farkas[1], N. Ikumi[1], A. Szentpetery[1], B. Kirby[2], O. FitzGerald[1]. *[1]Department of Rheumatology; [2]Department of Dermatology, St. Vincent's University Hospital, Dublin, Ireland, Dublin, Ireland*

Background: Psoriatic arthritis (PsA) is a heterogeneous disease with variable types of joint involvement, extra-articular features, including skin psoriasis, and with well-known comorbidities such as depression and anxiety[1]. Composite Psoriatic Disease Activity Index (CPDAI) adequately assesses disease activity in this complex condition[2]. To date, no study has evaluated the relationship between depression/anxiety scores and CPDAI in PsA.
Objectives: The aim of this study was to compare 1) depression/anxiety scores; 2) physician-assessed and patient-reported outcome measures (PROMs) between patients with CPDAI≤4 suggesting low disease activity versus with CPDAI>4 reflecting moderate or severe disease activity in PsA.
Methods: PsA patients fulfilling the CASPAR criteria were recruited. Patients underwent musculoskeletal and skin assessments (TCJ68, SJC66, Leeds enthesitis index, dactylitis digit score and PASI) and they have completed questionnaires on physical function and health-related quality of life (HAQ, PsAQoL, DLQI, EQ-5D, BASDAI, BASFI, ASQoL, BRAF-NRS, pain and general health VAS). Patients were assessed for depression/anxiety using the Hospital Anxiety and Depression Scale (HADS-A and HADS-D) and Penn State Worry Questionnaire (PSWQ). Data were analyzed using Mann Whitney, Chi-square tests and linear regression model.
Results: 100 PsA patients were recruited; 57 presented with CPDAI≤4 (age 52.7±9.46 years) and 43 with CPDAI>4 (age 52±11.82 years). Patients with CPDAI>4 had significantly higher TCJ68 (p<0.001), Leeds enthesitis index (p=0.015) and significantly worse HAQ, BASDAI and ASQoL scores. There was no significant difference in other items of CPDAI between the two groups. Patients with CPDAI>4 had significantly higher HADS-D, HADS-A and PSWQ scores (p<0.001; p<0.001; p=0.001, respectively) and significantly worse PROMs, including PsAQoL, EQ-5D score, BASFI, BRAF-NRS, pain and general health VAS (Table 1). Multiple regression analysis revealed significant relationship between PsAQoL, BASFI and CPDAI (B=0.311, p=0.0093; B=0.568, p<0.0001, respectively).

Table 1. Comparison of patient-reported outcome measures between CPDAI ≤4 and CPDAI >4 groups

PROMs	CPDAI <4 n=57	CPDAI >4 n=43	p value
HADS-D	2.32±2.53	5.27±3.13	**<0.0001**
HADS-A	3.44±2.74	5.98±2.81	**<0.0001**
PSWQ	38.7±13.23	46.95±12.22	**0.001**
PAIN VAS	2.07±2.02	4.41±2.07	**<0.0001**
ghVAS	76.73±20.95	66.6±20.15	**0.005**
BRAF-NRS	12.35±4.51	16.41±4.76	**<0.0001**
PsAQoL	1.68±2.47	6.17±5.15	**<0.0001**
EQ-5D SCORE	0.82±0.15	0.66±0.19	**<0.0001**
BASFI	1.53±1.33	4.26±1.74	**<0.0001**

Mann-Whitney test. Results are presented as mean ± SD.

Conclusions: This is the first study assessing the relationship betweeen depression/anxiety and CPDAI in PsA. We have found significantly higher HADS-D, HADS-A, PSWQ scores and worse PROMs in patients with CPDAI>4 compared to those with CPDAI≤4. Based on our results there is significant relationship between depression/anxiety, physical function, quality of life and disease activity in psoriatic arthritis.

AB0756 PRIMARY EFFICACY AND SAFETY OF ADALIMUMAB IN NAIL PSORIASIS FROM THE FIRST 26 WEEKS OF A PHASE-3, RANDOMIZED, PLACEBO-CONTROLLED TRIAL WITH SUBANALYSIS IN PATIENTS WITH AND WITHOUT PSORIATIC ARTHRITIS

B.E. Elewski[1], P.A. Rich[2], F. Behrens[3], G. Guillet[4], Z. Geng[5], O. Reyes Servin[5]. *[1]University of Alabama at Birmingham, School of Medicine, Birmingham; [2]Oregon Health and Science University Hospital, Portland, United States; [3]Goethe University Medical Center, Frankfurt, Germany; [4]Hopital la Miletrie, Service de Dermatologie, CHU Poitiers, France; [5]AbbVie Inc., North Chicago, United States*

Background: Psoriasis (Ps) disease burden for patients (pts) with psoriasis (Ps) and concomitant fingernail Ps plus psoriatic arthritis (PsA) is higher compared with pts with Ps alone.
Objectives: We report safety and efficacy of originator adalimumab (ADA) in pts with fingernail Ps, and also for pts with or without concomitant PsA.
Methods: Results are reported from the double-blind PBO-controlled, Period A in which 217 pts with moderate to severe plaque Ps and fingernail Ps were included and randomized 1:1 to receive 40 mg ADA every other week (eow) from wk 1 (initial 80 mg dose at wk 0), or matching PBO, for 26 wks. The primary endpoints were the proportion of pts with ≥75% improvement in modified Nail Ps Severity Index (mNAPSI 75) and the proportion of pts with Physician's Global Assessment of Fingernail Psoriasis (PGA-F) of clear (0) or minimal (1) with ≥2-grade reduction from baseline (primary in US only; for regulatory purposes). Missing data were handled by multiple imputation. Safety was assessed using treatment-emergent adverse events (AEs).
Results: Of the 217 randomized pts (108 PBO, 109 ADA), 84.3% were male; mean age was 46.7 years; 188 (86.6%) completed 26 wks of treatment or early escaped to Period B according to protocol. Both primary endpoints were met: total fingernail mNAPSI 75 was achieved by 3.4% PBO vs 46.6% ADA (p<0.001), and PGA-F 0 or 1 with ≥2 grades improvement was achieved by 6.9% vs 48.9% (p<0.001). At baseline, 28.6% had PsA (29.6% PBO, 27.5% ADA) with mean

duration 7.91 years [SD 8.314]. Total fingernail mNAPSI 75 was achieved by 0.5% PBO vs 61.5% ADA of pts with PsA and 4.6% PBO vs 40.9% ADA without PsA ($p<0.001$ for both groups). PGA-F 0 or 1 with $\geq$2-grade reduction was achieved by 4.4% PBO vs 59.3% ADA with PsA and 7.9% PBO vs 44.9% ADA without PsA ($p<0.001$ for both groups). Adverse events (AEs) in Period A were reported by 55.6% PBO vs 56.9% ADA (with PsA: 56.3% PBO vs 56.7% ADA; without PsA: 55.3% PBO vs 57.0% ADA without PsA); serious AEs by 4.6% PBO vs 7.3% ADA (with PsA: 9.4% PBO vs 10.0% ADA; without PsA: 2.6% PBO vs 6.3% ADA).

Conclusions: The primary results demonstrated that in this population, ADA was more effective than PBO for the treatment of fingernail Ps, and significantly improved signs and symptoms, both overall and regardless of the presence or abscense of PsA; no new safety risks were identified with ADA eow treatment for 26 wks.

AB0757 IMPACT OF DISEASE ACTIVITY ON PHYSICAL FUNCTION AND HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH PSORIATIC ARTHRITIS

K. Nas[1], G. Kilic[2], R. Cevik[3], A.Z. Dagli[3], E. Kilic[4], S. Sag[1], U. Erkorkmaz[5], A. Kamanli[1], I. Tekeoglu[1]. *[1]Division of Rheumatology and Immunology, Department of Physical Medicine and Rehabilitation, Sakarya University Faculty of Medicine, Sakarya; [2]Physical Medicine and Rehabilitation, Afyon Kocatepe University Faculty of Medicine, Afyon; [3]Division of Rheumatology, Department of Physical Medicine and Rehabilitation, Dicle University Faculty of Medicine, Diyarbakir; [4]Rheumatology Clinic, Afyonkarahisar State Hospital, Afyon; [5]Department of Biostatistic, Sakarya University Faculty of Medicine, Sakarya, Turkey*

Background: Psoriatic arthritis (PsA) is a chronic progressive inflammatory disease characterized by peripheral arthritis, dactylitis, axial joint involvement and extraarticular features. Disease consequences such as chronic pain, severe joint damage and fatigue may adversely effect on a patient's physical function and health-related quality of life (QoL) to perform daily activities.

Objectives: The aim of this study was to investigate the potential relationship between physical function and health-related QoL and disease activity measures in patients with PsA.

Methods: For all participating patients, quality of life, functional and disease activity measures were measured by different ways: Nottingham Health Profile (NHP), psoriatic arthritis quality of life (PsAQoL), Ankylosing Spondylitis Quality of Life (ASQoL), SF36 health survey, Health Assessment Questionnaire (HAQ), BASFI, VAS pain, DAS28, BASDAI and acute phase markers including ESR and CRP.Patients with PsA were discriminated into low and high disease activity according to BASDAI ($\geq$6 vs $\leq$4).

Results: A total of 186 patients with PsA (116 female, 70 male, mean age 43,9±12,6) who met CASPAR criteria were included. Their mean symptom duration was 7.9±9.1 years. Patients with higher BASDAI score ($\geq$6) had significantly higher scores on all important items including health related QoL, fatigue, pain, and functional status. Correlation coefficients between disease activity and various health related QoL measurements were given in Table1. SF36 physical component score was significantly correlated with VAS-pain, BASDAI and DAS28 compared to SF36 mental component. Also, physical activity subscore of NHP was found higher correlated with disease activity indices for PsA in all NHP sections. Other quality of life measurements including PsQoL, HAQ and ASQoL were also significantly correlated with disease activity measurements.

Conclusions: Psoriatic arthritis has a major impact on patients' lives. Variable disease activity measurements were found correlated with all important QoL measurementss including NHP, SF36, PsQoL, HAQ and ASQoL. In patients with PsA, high disease activity may lead to severe impairments in daily activities and influence on participation in society.

AB0758 AUDIT ON USTEKINUMAB DRUG SURVIVAL IN A DISTRICT GENERAL HOSPITAL VERSUS PSUMMIT 1 TRIAL RESULTS

G. Tracey, S. Webber. *Rheumatology, Weston General, Bristol, United Kingdom*

Background: Psoriatic arthritis (PsA) is an immune mediated inflammatory disorder that affects 10–30% of patients with psoriasis. Ustekinumab, a monoclonal anti–IL-12/23p40 antibody, is approved for the treatment of PsA and plaque psoriasis[1] PSUMMIT 1 was one of two phase 3 trials of ustekinumab in adults with active PsA[2]In England, use of medication is subject to guidance from National Institute for Health and Care Excellence (NICE). [TA340] recommend that Ustekinumab is a possible treatment, alone or with methotrexate, for adults with active psoriatic arthritis when treatment with non-biological disease-modifying antirheumatic drugs has not worked well enough if: treatment with tumour necrosis factor (TNF) alpha inhibitors is not suitable for them, or the person has had a TNF alpha inhibitor before[3] We audited the survival data from our cohort of patients in district general hospital (DGH) against data from PSUMMIT trial.

Objectives: Our objectives were to evaluate drug survival of Ustekinumab in PsA, to compare real world data with that from PSUMMIT trial.

Methods: Our biologics database was searched for patients currently receiving Ustekinumab treatment for Psoriatic Arthritis and those who have had treatment failures. Length of treatment was recorded and any adverse effects which caused the treatment to be stopped. Analysis of treatment non-responders was performed including previous biologics/drug use. We then compared our results to those in the treatment arms (Ustekinumab 45mg or 90mg)of the PSUMMIT trial at week 24 and 52.

Results:

Table 1

	Ustekinumab 45mg	Ustekinumab 90mg
DGH (n=20)	15	5
PSUMMIT (n=409)	205	204

Table 2

	DGH		PSUMMIT	
	(Ust 45mg)	(Ust 90mg)	(Ust 45mg)	(Ust 90mg)
Week 24 withdrawal	4/15	0/5	8/205	7/204
Reasons:				
Adverse effects	3		4	3
Inefficacy	1		2	1
Other (consent, lost follow up)			4	3
Week 52 withdrawal	0/8	0/3	17/197	15/197
Reasons:				
Adverse effects			2	5
Inefficacy			7	3
Other (consent, lost follow up)			8	7

Treatment Failure group (DGH): All patients had had at least one anti-TNF agent prior to Ustekinumab therapy. One patient had trialled 3, two had two, one had one. They had been stopped either due to inefficacy or intolerance.

Conclusions: Ustekinumab has been shown to be a generally well tolerated drug. Our treatment group had proportionally more treatment failures than the PSUMMIT trial (4/20 20% vs 24/409 5.8%). There is the obvious criticism that our patient numbers are very small. For eligibility in PSUMMIT trial the patients had to be anti-TNF naïve. In NHS ENgland, Ustekinumab is not NICE approved as a first line agent except in certain circumstances.Therefore, our patients have had

Abstract AB0757 – Table 1. Correlation coefficients between disease activity and various health related QoL measurements in patients with PsA [r (p)]

AB0759 NEUROPATHIC PAIN PREVALENCE IN PSORIATIC ARTHRITIS AND ITS CORRELATION WITH DISEASE ACTIVITY

H.E. Öz[1], S. Tuna[1], Ü. Gürbüz Uçar[2], N. Vedin Balcı[1]. *[1]Physical Therapy and Rehabilitation, Akdeniz University, Antalya; [2]Rheumatology, Izmir Bozyaka Training and Research Hospital, Izmir, Turkey*

Background: Psoriatic arthritis (PsA) is a systemic chronic inflammatory disease associated with psoriasis. Neuropathic pain is defined as pain which is produced by a primary lesion or dysfunction of peripheral or central nervous system.
Objectives: The aim of this study is to investigate the neuropathic pain component of chronic joint pain in psoriatic arthritis and to detect its correlation with disease activity and functional capacity.
Methods: During the patients' routine outpatient clinic visit, we gain information about patients' demographics. We used Pain Detect questionnaire to detect neuropathic pain component, Visual Analogue Scale for joint pain, Disease Activity Score 28-Joint (DAS28) for disease activity evaluation and Health Assessment Questionnaire (HAQ) for functional capacity evaluation.
Results: There were 48 PsA patients and 34 control patients in this study. Mean age was 52 (21–79), mean BMI is 27.5 kg/m^2 (20.8–53) and mean disease duration was 5 year in PsA group. Mean age was 54 (20.8–53), mean BMI was 27.6 kg/m^2 (20.8–53) in control group. Neuropathic pain component was positive in 22.9% of PsA and negative in 45.8% of PsA and unclear in 31.2% of PsA group. In control group, neuropathic pain component was positive in 35.3% of patients and negative in 41.2% of patients and unclear in 23.5% of patients. Mean pain detects score was 13 in PsA and 14 in control group. There was no statistically important difference between the PsA and control group's neuropathic pain prevalence (p=0.601) and mean PD score (p=0.24). Mean DAS 28 score was 3.5 (1–3.56) and mean HAQ score was 0.65 (0–2.05) in PsA group. There was a statistically important positive correlation between the PD score and HAQ score in PsA patients (Ro=0.460, p=0.001). In addition, there was a statistically unimportant positive correlation between the PD score and DAS28 score in PsA patients. There was a statistically unimportant positive correlation between the PD score and HAQ score in control group (Ro=0.411, p=0.016).
Conclusions: We detected neuropathic pain component in 22.9% of PsA patients but there was no difference between the PsA group and control group. Diagnosis of concomitant neuropathic pain by Pain Detect Questionnaire may be useful for pain management in PsA patients.

AB0760 EFFICACY OF USTEKINUMAB IN A COHORT OF PATIENTS AFFECTED BY PSORIATIC ARTHRITIS IN REAL-LIFE

I. Notario Ferreira, M. Ferrer González, P. Morales Garrido, I. Añón Oñate, L. Perez Albaladejo, C. Caro Hernández, A. González Utrilla, E. Raya Álvarez, R. Cáliz Cáliz. *Rheumatology, Complejo Hospitalario Universitario de Granada, Granada, Spain*

Background: Psoriatic arthritis (APs) is a chronic inflammatory joint disease, that can be treated effectively with synthetic disease modifying anti-rheumatic drugs (DMARDs) and biological agents. Ustekinumab is a monoclonal antibody that inhibits IL-12 and 23 that has recently demonstrated efficacy and safety for the treatment of patients with APs in the PSUMMIT 1 and PSUMMIT 2 studies.
Objectives: To evaluate the efficacy of Ustekinumab in our patients with psoriatic arthritis with peripheral involvement in clinical practice conditions.
Methods: Descriptive, prospective, longitudinal and open study including patients diagnosed with psoriatic arthritis with peripheral involvement. All patients were given ustekinumab at an initial dose of 45 mg administered subcutaneously followed by another 45 mg dose 4 weeks later and then every 12 weeks. Clinimetric scores (DAS28, MASES, Pain VAS, Clinicians VAS) were assessed and CRP was measured al baseline and after 6 months of treatment.
Results: 52 patients were included, 25 were female (48.1%) and 27 male (51.9%). They had a mean age of 46.96±11.39 years, a disease duration of 5.03±5.08 years, and moderate disease activity (DAS 28 of 3.95±0.87), the number of tender and swollen joints were 6.24±4.9 and 2.82±2.36, respectively. The patients had received an average of 1.42±1.75 biological therapies previously. Ustekinumab was prescribed as a first line treatment in 42.3% of patients, 19% after failure of a TNF inhibitor and 38% of patients had received 2 or more biological therapies previously. Ustekinumab was administered alone in 51% of the patients, 36.5% in combination with methotrexate and 11.5% in combination with leflunomide. 23.1% of the patients had dactylitis and 36.5% had enthesitis (mean MASES 1.31±0.86). At 6 months of treatment, there were improvements in the number of tender and swollen joints (mean NAD 4.84±6.4 and NAT 2±3.4 at 6 months, respectively) and MASES index (mean at 6 months, 0.35±0.96). 15 patients had completed at least 6 months of treatment. Improvements in DAS28-CRP scores were observed at 6 months of treatment (3.26±1.62), with a mean DAS28 change after 6 months (∆DAS28) of -0.65±1.88. At month 6, 71.4% of the patients had low disease activity, and 35.7% were in clinical remission according to the DAS28 index.
Conclusions: Ustekinumab is effective in patients with psoriatic arthritis with peripheral involvement in routine clinical practice.

AB0761 THE BIOLOGIC THERAPY USE FOR ENTHESITIS AS A PREDICTOR OF PSORIATIC ARTHRITIS IN PSORIATIC PATIENTS

I. Litovchenko[1], O. Golovchenko[2]. *[1]Medical Clinical Investigational Center of Medical Center "Health Clinic", Medical Center Health Clinic; [2]Medical Clinical Investigational Center of Medical Center "Health Clinic", Medical Center "Health Clinic", Vinnytsia, Ukraine*

Background: According to ACR data 15–20% patients (PTN) with psoriasis are developed with psoriatic arthritis (PsA). Herewith the enthesitis (ETS) as usual is the first signs of PsA manifestations. It is usually asymptomatic at the beginning of the disease, however it is successfully diagnosed with Doppler ultrasound (DU). In average, it takes about 2 years from beginning of the disease till diagnosis PsA is established. PsA treatment is low effective with DMARD, and middle effective with biologic therapy. Wherein no treatment restores the articular changes that have occurred. Thus the actual is to find some resolution to the effective therapy for PTN with psoriasis and also to identify the factors preceding the development of the PsA.
Objectives: Consider the application of biologic therapy before the articular changes in PTN with psoriasis and predictors of psoriatic arthritis.
Methods: Observed 82 PTN with pustural psoriasis without clinical manifestations of PsA. A physical examination (including PASI), a series of laboratory tests (hematology, CRP, RF, anti -ccp, HLA-B27, uric acid), DU to identify the PsA, its activity, as well as to the exclusion of other types of arthritis were used.
Results: 3,7% PTN were diagnosed with PsA with articular changes. 23,1% PTN were founded with enthesitis. The remaining 73,2% PTN had no signs of enthesitis during physical examination and DU. PTN with enthesitis were divided into 2 groups. I – 47% PTN (22% of them had clinical manifestations of enthesitis; the average group PASI– 42,4±8,2) received a 52-weeks course of ustekinumab (45 mg administered subcutaneously initially and 4 weeks later, followed by 45 mg administered subcutaneously every 12 weeks). II group – 53% people (20% PTN had clinical manifestations of enthesitis; the average group PASI– 43,6±9,0) did not receive biological therapy, but only standart treatment for psoriasis. After 1 year follow-up after completion of the treatment course – 11% PTN from group I developed PsA with articular changes. From the group II in 80% PTN developed PsA with articular changes. The average group I PASI– 7,6±1,5; the average group PASI– 6,2±1,3. ($p < 0,05$)
Conclusions: Thus, the ustekinumab use in psoriatic PTN with enthesitis possibly may be reasonable and will hinder the development of PsA. Ustekinumab is also high effective for the improving of the psoriasis skin symptoms.
DU is the high effective diagnostic method for detecting enthesitis without clinical manifestations.
Frequency of screening DU in PTN with psoriasis, for the early detection of enthesitis is the perspective for further study.

AB0762 THE RELATIONSHIP BETWEEN SERUM PENTRAXIN-3 LEVELS, CARDIOVASCULAR DISEASE RISK AND DISEASE ACTIVITY IN PSORIATIC ARTHRITIS PATIENTS

I. Sunar[1], A.E. Ozdemirel[2], Z.S. Sürmeli[3], G. Yilmaz[1], E. Üstüner[4], H. Tutkak[5], A.P. Yalçin[1], S. Ataman[1]. *[1]Rheumatology, Ankara University Faculty of Medicine Physical Medicine and Rehabilitation, Rheumatology Division; [2]Rheumatology, Health Ministry Ankara Dışkapı Trainig and Research Hospital, Rheumatology Clinic, Ankara; [3]3. Health Ministry Istanbil Trainig and Research Hospital, Rheumatology Clinic, Istanbul; [4]Radiology, Ankara University Faculty of Medicine; [5]Immunology and Allergy, Ankara University Faculty of Medicine, Immunology an Allergy Department, Ankara, Turkey*

Background: Psoriatic arthritis (PsA) is an immune-mediated disease affecting skin, joints, entheses, spine, and the vasculature [1,2]. Increased inflammatory mediators are held responsible for impacts on the skin and musculoskeletal system as well as comorbid situations including cardiovascular disease (CVD) and metabolic syndrome [3]. PTX 3 is an acute phase reactant that has prognostic value for rheumatoid arthritis (RA), vasculitis, and psoriasis that also stands out as a novel biomarker for CVD in new researches [4].

Objectives: This study aims to assess the association between PTX 3 levels, disease activity and CVD risk in patients with PsA.
Methods: A total of 38 PsA patients applying to Ankara University Faculty of Medicine, Rheumatology Polyclinic and 32 age and sex-matched controls were enrolled in the study. tender and swollen joint counts, patient's and doctor's global assesment on VAS, ESR, CRP, fasting insulin, fasting glucose, total cholesterol, HDL, and LDL were noted. Also body mass index (BMI) and HOMA-IR score were calculated. Carotid intima media thickness (cIMT) was bilaterally assessed by Doppler ultrasound.
Results: The mean age was 49.5 in patients and 48.9 in controls. Sixty percent of the patients and 50% of controls were female. Of the patients, 15 (39%) used DMARD monotherapy, 8 (21%) used DMARD combination therapies, and 15 (39%) used anti TNF therapies. There was no statistically significant difference between groups in terms of hypertension, LDL levels, and smoking status (p:0.775, p:0.228, p:0.136 respectively). PsA patients had significantly higher BMI scores (p:0.03). Insulin levels and HOMA-IR scores were significantly higher among PsA patients compared to controls (p:0.001, p:0.005). There was statistically significant difference between groups in terms of PTX 3 ($p<0.001$). PTX 3 was significantly correlated with HOMA-IR and cIMT (r:0.243 p:0.043 and r:0.421 p:0.001 respectively). However no correlation between PTX 3 and disease activity parameters such as ESR, CRP, SJC, TJC, and VAS-pain was detected (p:0.824, 0.662, 0.922, 0.924, 0.410 respectively). There was not significant difference in terms of PTX-3 levels between PsA patients on biologic treatment or other treatment strategies (p:0.27).
Conclusions: Elevated levels of PTX 3 may be associated with cardiovascular involvement in PsA patients independent from the disease activity. This marker might be used for risk prediction for CVD or may represent a target for new therapies.

AB0763 USTEKINUMAB FOR THE TREATMENT OF PSORIATIC ARTHRITIS – RESULTS OF THE FIRST INTERIM ANALYSIS OF THE NON-INTERVENTIONAL STUDY SUSTAIN

J. Wendler[1], I. Schwarze[2], H. Schwenke[3], J. Behrens[4], T. Gruppe[4], F. Behrens[5]. *[1]Rheumatologische Schwerpunktpraxis, Erlangen; [2]Praxis für Internistische Rheumatologie, Leipzig; [3]Rheumatologisches MVZ Dresden, Dresden; [4]Janssen-Cilag GmbH, Neuss; [5]CIRI/Rheumatology & Fraunhofer TMP, Frankfurt, Germany*

Objectives: SUSTAIN is a prospective, multi-center non-interventional study in Germany to observe long term efficacy and safety, quality of life and further patient reported outcomes in patients with active psoriatic arthritis under treatment with Ustekinumab in routine clinical care.
Methods: In this study treatment with Ustekinumab is according to the label (Stelara®). It is planned to observe 400 patients at 75 centers for 160 weeks with documentation intervals at week 0 and 4 and then every 12 weeks. Besides demographic data, the following data will be documented: Amount of swollen and tender joints, tender entheses, skin symptoms (BSA and PASI), patient reported outcome concerning disease activity and pain, Health Assessment Questionnaire (HAQ), quality of life (SF-12), sleep quality (VAS), satisfaction with therapy of patient and physician, safety (adverse events [AE]/serious adverse events [SAE]), pharmacoeconomic aspects, number of patients with "Minimal Disease Activity" (MDA), number of patients with MDA at week 28 und 52.
Results: Overall, there have been 189 patients (56% women) at 59 centers documented after 11 months. At week 4 154 patients and at week 16 112 patients. At baseline, the patients had a mean age of 56 years (29–85), body weight 87 kg (50–147), BMI 30 (19–47), showed arthritis at small (68.8%) and/or big (51.3%) joints, skeletal involvement (19%), enthesitis (13.2%). The number of tender joints improved from a mean of 8,6 (CI 95% 7.1/10.2) to 4.7 (3.1/6.3) at week 16, number of swollen joints from 3,4 (2,6/4,2) to 1,4 (0.9/1.9). The patient reported global disease activity (0–100) decreased from 55.1 to 38.6 at week 16. Further improvements were documented for enthesitis, PSA, BSA, PASI, and pain. Efficacy of the therapy with Ustekinumab after 16 weeks was assessed as "very good" by 32.3% and as "good" by 44.8% of the treating physicians and by 34% and 40.2%, respectively, of the patients. In total, 60 adverse events were reported, of which four were serious. All in all safety of therapy with Ustekinumab after 16 weeks was assessed as "very good" by 51% and as "good" by 43.8% of the treating physicians, and by 55% and 37%, respectively, of the patients.
Conclusions: The non-interventional study SUSTAIN showed relevant improvements with elevated therapy satisfaction and good safety in patients with active psoriatic arthritis after 16 weeks under real world condition.

AB0764 MALIGNANCY AND SERIOUS INFECTIONS AMONG PSORIATIC ARTHRITIS PATIENTS TREATED WITH BIOLOGICAL DRUGS IN A REGIONAL REGISTRY IN THE NORTHWEST OF SPAIN

J. Pinto-Tasende[1], F.J. Maceiras-Pan[2], L. Guerra-Vazquez[3], L. Fernandez-Dominguez[4], J.A. Mosquera-Martínez[5], C. García-Porrúa[6]. *[1]INIBIC-Rheumatology, Complejo Hospitalario Universitario A Coruña, A Coruña; [2]Rheumatology, Complejo Hospitalario Universitario de Vigo, Vigo; [3]Rheumatology, Complejo Hospitalario Universitario de Ferrol, Ferrol; [4]Rheumatology, Complejo Hospitalario Universitario de Ourense, Ourense; [5]Rheumatology, Complejo Hospitalario Universitario de Pontevedra, Pontevedra; [6]Rheumatology, Hospital Universitario de Lugo, Lugo, Spain*

Background: Biological treatments have provided new opportunities for disease control for patients with psoriatic arthritis. However, it is important to evaluate their safety, since they expose them to an increased risk of developing malignant tumors and serious infections.
Objectives: To examine the rate of solid tumors and serious infections among patients diagnosed with psoriatic arthritis (PsA) treated with biological drugs (BD) in 2011–2015.
Methods: We included all PsA patients (CASPAR criteria) under treatment with BD followed in our regional registry (reference population 2.055.000) between January 2011 and December 2015. In order to capture the incidence of new malignancy we excluded patients with a prior history of malignancy. Medical records were fulfilled for patients and were recorded solid tumors diagnosed (date of diagnosis and histology information) and all serious infections (requiring hospitalization or intravenous antibiotics) in this time. Incidence rates (IRs) were calculated per 1000 Person-year (py). We used for this analysis sex, age, disease duration, current BD with or without current DMARD associated. Continuous variables were reported as mean ± standard deviation (SD). Categorical variables were reported as percentages and frequencies. Differences were considered statistically significant if $p<0.05$ (two-tailed).
Results: Among 604 patients 329 (54.5%) of whom were men, with a mean age of 53.3±12.6 years and a time since the diagnosis of PsA of 12.4±8.7 years. There were 14 cancers diagnosed during treatment (2.3%), with an IR of 0.48 cases per 1000 patient-years. Patients who developed cancer had a higher age, 63.4±10.0 years vs 53.1±12.6, than those who did not developed (p=0.010). Etanercept was the most used (42%) and no differences were observed among BDs (p=0.214) or between naïve and non-naïve to BD (p=0.384). Current DMARD associated (56.2%) had not differences in tumors (p=0.429). Prostate tumor was the most frequent (21.4%). There were 42 had serious infection (6.2%), with an IR of 13.9 cases per 1000 patient-years, and was more common in men (4.7% vs 8.8%, p=0.049). Severe infections were more frequent in patients non-naïve to BD (10.4% vs 5.4%, p=0.026). Pneumonia (28.6%), varicella-zoster virus infection (16.6%) and soft tissue infections (14.3%) were most frequent. Latent tuberculosis infection was positive in 133 patients (22.0%) and 3 developed tuberculosis.
Conclusions: Patients older than 60 years with psoriatic arthritis treated with BDs had a higher incidence of tumor development. Most of patients were men and prostate tumor was the most frequent. Pneumonia was the most frequent serious infection and non-naïve to BD patients had a higher IR of serious infections.

AB0765 SECUKINUMAB PROVIDES SUSTAINED IMPROVEMENT IN FUNCTION, QUALITY OF LIFE AND FATIGUE OVER 2 YEARS IN PATIENTS WHO ACHIEVED DISEASE ACTIVITY INDEX FOR PSORIATIC ARTHRITIS (DAPSA) REMISSION

J.S. Smolen[1], I.B. McInnes[2], L. Gossec[3], V. Strand[4], L. Pricop[5], T. Fox[6], S. Jugl[6], C. Gaillez[6] on behalf of the FUTURE 2 Study Group. *[1]Medical University of Vienna, Vienna, Austria; [2]University of Glasgow, Glasgow, United Kingdom; [3]UPMC Université Paris 06, Paris, France; [4]Stanford University School of Medicine, Stanford; [5]Novartis Pharmaceuticals Corp., East Hanover, United States; [6]Novartis Pharma AG, Basel, Switzerland*

Background: Disease Activity index for Psoriatic Arthritis (DAPSA) states are associated with functional impairment levels in patients (pts) with psoriatic arthritis (PsA).[1] Secukinumab demonstrated sustained improvements in disease activity assessed with DAS28-CRP, physical function and pt-reported outcomes (PROs) among active PsA pts over 104 weeks (wks) in the FUTURE 2 study.[2]

Abstract AB0765 – Table 1. Core components by DAPSA states with secukinumab or placebo at Wk 16

Mean ± SD	SJC (66)		TJC (68)		PtGA (cm)		PP (cm)		CRP (mg/dl)	
	300mg/150mg	PBO	300mg/150mg	PBO	300mg/150mg	PBO	300mg/150mg	PBO	300mg/150mg	PBO

*n=14 (300mg), 10 (150mg) and 4 (PBO); ^n=27 (300mg), 34 (150mg) and 12 (PBO); #n=26 (300mg), 24 (150mg) and 22 (PBO); $n=30 (300mg), 32 (150mg) and 49 (PBO).

Objectives: To explore the relationship between DAPSA states and function, health-related quality of life and PROs, and the individual DAPSA components in the different states in pts treated with secukinumab through 104 wks using *post-hoc* analysis.

Methods: FUTURE 2 study design has been reported.[3] DAPSA was derived as sum of five core components: tender joint and swollen joint counts (TJC 68, SJC 66), pt global assessment (PtGA) and pain (PP) assessed by a 10cm VAS and CRP (mg/dl). Four DAPSA states were: remission (REM:≤4), low (LDA:>4–≤14), moderate (MDA:>14–≤28) or high disease activity (HDA:>28). Mean±SD of each core component of DAPSA were analysed at Wks 16, 24, 52 and 104 using observed data. The relationship between HAQ-DI, SF-36 PCS and MCS, PsAQoL, DLQI and FACIT-Fatigue with DAPSA states was assessed in the pooled treatment arms at each time point using a mixed-effect model for repeated measures (MMRM) analyses.

Results: Baseline characteristics were similar across treatment groups.[3] DAPSA scores at baseline (mean±SD) were 42.0±17.4, 46.8±24.3 and 44.9±25.3 in the secukinumab 300mg, 150mg and placebo groups, respectively. Mean scores of each component by DAPSA states at Wk 16 are shown in table and were sustained through Wk 104. Significant differences were observed among secukinumab treated pts between REM vs. HDA and LDA vs. HDA states for PRO scores through Wk104 (Figure).

Figure: Mean change in PRO scores by DAPSA states at Wks 16 and 104

*P <0.0001; †P <0.001; ‡P <0.01; §P <0.05 versus HDA. P-values are from a mixed-effects model for repeated measures (MMRM) analysis.
DLQI, Dermatology Life Quality Index; FACIT-Fatigue, Functional Assessment of Chronic Illness Therapy-Fatigue; HAQ-DI, Health Assessment Questionnaire Disability Index; HDA, high disease activity; LDA, low disease activity; LS, least squares; PsA QoL, PsA-specific quality of life; MDA, moderate disease activity; REM, remission; SF-36 MCS, Short Form-36 Mental Component Summary; SF-36 PCS, Physical Component Summary

Conclusions: In pts treated with secukinumab 300 or 150mg, the five individual components related to DAPSA REM were <1 in contrast with other disease states and were sustained through Wk 104. DAPSA REM was associated with significantly greater improvement in physical function, health related quality of life and fatigue indicating that it is an important target to be achieved and sustained in PsA pts.

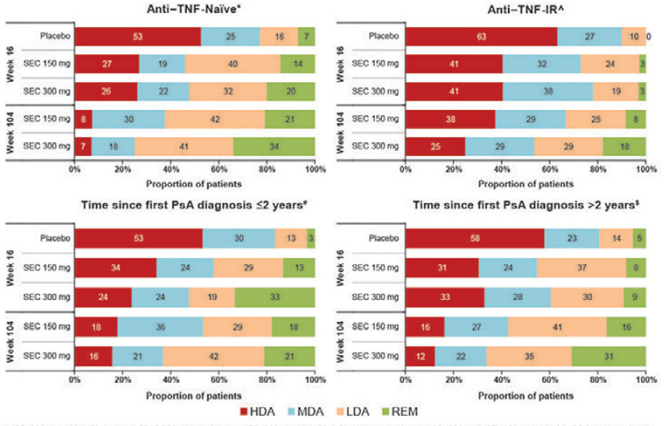
AB0766 SECUKINUMAB PROVIDES SUSTAINED REMISSION AND LOW DISEASE ACTIVITY RELATED TO DISEASE ACTIVITY INDEX FOR PSORIATIC ARTHRITIS (DAPSA): 2 YEAR RESULTS FROM THE FUTURE 2 STUDY

J.S. Smolen[1], I.B. McInnes[2], T.K. Kvien[3], L. Pricop[4], T. Fox[5], L. Rasouliyan[6], S. Jugl[5], C. Gaillez[5] on behalf of the FUTURE 2 Study group. *[1]Medical University of Vienna, Vienna, Austria; [2]University of Glasgow, Gasgow, United Kingdom; [3]Diakonhjemmet Hospital, Oslo, Norway; [4]Novartis Pharmaceuticals Corp., East Hanover, United States; [5]Novartis Pharma AG, Basel, Switzerland; [6]RTI Health Solutions, Barcelona, Spain*



Background: Disease Activity Index for Psoriatic Arthritis (DAPSA) is a validated tool to measure disease activity states, focussing on peripheral joint involvement in psoriatic arthritis (PsA), and can be used to assess targets such as remission (REM) or low disease activity (LDA).[1]

Objectives: Secukinumab, a fully human anti–interleukin-17A monoclonal antibody, significantly improved American College of Rheumatology responses vs. placebo at Week (Wk) 24 that were sustained through Wk 104 in active PsA patients (pts) in the FUTURE 2 study[2]. This *post-hoc* exploratory analysis assessed DAPSA states through Wk 104.

Methods: In total, 397 active PsA pts were randomised to subcutaneous (s.c) secukinumab (300, 150 or 75mg) or placebo at baseline and Wks 1, 2, 3 and 4, and every 4 wks (q4w) thereafter. Placebo pts were re-randomised to secukinumab 300 or 150mg s.c q4w from Wk 16 or 24, depending on Wk 16 clinical response. DAPSA was derived as the sum of five variables: tender joint and swollen joint counts (TJC 68 and SJC 66); pt global and pain assessed on a 10cm visual analogue scale; and C-reactive protein levels (mg/dl) with validated cut-offs to indicate REM (≤4), LDA (>4 and ≤14), moderate disease activity (MDA; >14 and ≤28) and high disease activity (HDA; >28). DAPSA was assessed in the overall population and in pts stratified by prior anti-tumour necrosis factor (anti-TNF) therapy use (anti–TNF-naïve vs. inadequate response/intolerance to these agents [anti–TNF-IR]) and time since first PsA diagnosis (≤2 vs. >2 years) using observed data. Only data for secukinumab 300 and 150mg (approved doses) are reported.

Results: Baseline demographics and clinical characteristics were similar across treatment groups and previously reported.[3] DAPSA score at baseline (mean [SD]) was 42.0 (17.4), 46.8 (24.3) and 44.9 (25.3) in the secukinumab 300mg, 150mg and placebo groups, respectively. In the overall population, at Wk 16, REM was achieved in 14/97 (14.4%) with secukinumab 300mg and 10/100 (10%) with secukinumab 150mg vs. placebo 4/87 (4.6%); LDA in 27/97 (27.8%) and 34/100 (34%) vs. 12/87 (13.8%), respectively. REM or LDA were sustained through Wk 104 with secukinumab 300 and 150mg (55/84 [65.5%; REM + LDA] and 41/ 77 [53.2%; REM + LDA], respectively). The proportion of pts achieving each DAPSA state at Wks 16 and 104 by anti-TNF status (anti–TNF-naïve vs. anti–TNF-IR)

Figure. DAPSA at Wks 16 and 104 by anti-TNF status and Disease duration

*n= 65 (300 mg), 63 (150 mg) and 57 (PBO) at Wk 16 and n= 56 (300 mg) and 53 (150 mg) at Wk 104; ^n= 32 (300 mg), 37 (150 mg) and 30 (PBO) at Wk 16 and n= 28 (300 mg) and 24 (150 mg) at Wk 104; #n= 21 (300 mg), 38 (150 mg) and 30 (PBO) at Wk 16 and n= 19 (300 mg) and 28 (150 mg) at Wk 104; $n= 76 (300 mg) 62 (150 mg) and 57 (PBO) at Wk 16 and n= 65 (300 mg) and 49 (150 mg) at Wk 104

and by time since diagnosis (≤2 vs. >2 years) for secukinumab 300 and 150mg is presented in the figure.
Conclusions: In the overall population, a higher proportion of pts treated with secukinumab at Wk 16 achieved DAPSA REM than those treated with placebo, with REM and LDA sustaining through Wk 104. At Wk 16, a higher proportion of anti–TNF-naïve pts treated with secukinumab achieved and sustained DAPSA REM than anti–TNF-IR pts and a higher proportion of pts with early diagnosis (≤2 years) achieved DAPSA REM vs. pts diagnosed later (>2 years).

AB0767 IL-17-22-23 PATHWAYS IN PSORIATIC ARTHRITIS AND PSORIASIS

K. Nas[1], R. Cevik[2], I. Yildiz[3], J. Rech[4], G. Schett[4]. *[1]Division of Rheumatology and Immunology, Department of Physical Medicine and Rehabilitation, Sakarya University, Faculty of Medicine, Sakarya; [2]Division of Rheumatology, Department of Physical Medicine and Rehabilitation; [3]Department of Biostatistic, Dicle University, Faculty of Medicine, Diyarbakir, Turkey; [4]Department of Internal Medicine and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany*

Background: Psoriatic arthritis (PsA) is an immune-mediated chronic inflammatory arthropathy-associated with psoriasis. T helper 17 pathway has been shown to play an important role in PsA.
Objectives: In this study, we aimed to investigate concentrations of TH17 pathway cytokines such as IL-17, IL-22 and IL-23 in psoriasis (PsO) with/and without structural bone damage and psoriatic arthritis (PsA), and their relationship with disease activity and clinical findings.
Methods: A total number of 74 patients, 24 patients with PsA (mean age 57.5±11.37; 13 women, 11 men) and 25 patients with PsO and structural bone damage (mean age 49±13.92; 11 women, 14 men) and 25 patients with PsO and no structural bone damage (mean age 41±16.77; 7 women, 18 men), were recruited from the Department Internal Medicine 3 of the University of Erlangen-Numberg. Both PsO and PsA patients were evaluated according to the CASPAR criteria. Demographic and disease specific variables were recorded. Bone architecture of the metacarpal heads II and III were assessed by high-resolution peripheral quantitative computed tomography (HR-pQCT, XtremeCT, Scanco, Switzerland). Disease activity was assessed with Disease Activity Score (DAS28). Psoriatic skin and nail disease activity were measured by the PASI.
Results: The ages of the patients in the three groups were similar. *IL-17A concentrations were significantly differed between the* groups (p=0.000). However, for other cytokines there was no difference between PsA and PsO groups. Serum levels of IL-17A were significantly correlated to patient pain of VAS (r=-0.318, p=0.06), VAS patient global assessment (r=0.272, p=0.021), DAS28 (r=-0.394, p=0.001) and PASI (r=0.519, p=0.000) in PsA and PSO. PASI score were also positively correlated with IL23 (r=-0.286, p=0.015) and S100A8 (r=0.298, p=0.011).
Conclusions: IL-17A seems to play an important role in development of PsA and bone damage in PsO. This role should be elucidated by further and larger clinical studies.

AB0768 CLINICAL FEATURES OF RHEUMATOID FACTOR- OR ANTI-CYCLIC CITRULLINATED PEPTIDES-POSITIVE PATIENTS WITH PSORIATIC ARTHRITIS

K. Inui[1], T. Okano[1], H. Yoshimura[1], Y. Sugioka[2], K. Mamoto[1], T. Koike[2,3], M. Tada[4], H. Nakamura[1]. *[1]Orthopaedic Surgery; [2]Center for Senile Degenerative Disorders, Osaka City University Graduate School of Medicine, Osaka; [3]Search Institute for Bone and Arthritis Disease, Shirahama Foundation for Health and Welfare, Shirahama Cho; [4]Orthopaedic Surgery, Osaka City General Hospital, Osaka, Japan*

Background: Although rheumatoid factor (RF) negativity is among the Classification Criteria for Psoriatic Arthritis (CASPAR) for the diagnosis of psoriatic arthritis (PsA), not all patients with PsA are seronegative. Measurement of anti-cyclic citrullinated peptides (ACPA) is another key test for rheumatoid arthritis and PsA; however, the prevalence of ACPA in patients with PsA is unclear.
Objectives: We analyzed the clinical features of RF- or ACPA-seropositive patients with PsA in comparison with seronegative patients with PsA using the ISLAND registry (UMIN000024292).
Methods: One hundred patients with psoriasis referred from dermatologists for assessment of synovitis or enthesitis from July 2015 to August 2016 were enrolled. PsA was diagnosed by CASPAR, and synovitis or enthesitis was confirmed by ultrasound assessment. Factors compared between seropositive and seronegative patients included age, sex, comorbidities, use of disease-modifying antirheumatic drugs, prevalence of enthesopathy, eye symptoms, duration between skin onset and musculoskeletal onset, psoriasis area severity index, composite psoriatic disease activity (CPDAI), psoriatic arthritis screening and evaluation (PASE), disease activity score-28 (DAS-28), and laboratory data.
Results: In total, 52 patients had PsA and 48 patients had psoriasis without any musculoskeletal manifestations. Significant differences were observed in the age at onset of psoriasis (37.4 vs. 47.9 y, respectively; $p<0.01$) and several clinical parameters (CPDAI: 14.60 vs. 4.55, respectively [$p<0.01$], PASE: 50.8 vs. 32.0, respectively [$p<0.01$], DAS-28: 3.77 vs. 2.72, respectively [$p=0.009$]). ACPA positivity was observed in 15.9% of patients with PsA and in 0.0% of patients with psoriasis (p=0.04). Among 44 of the 52 patients with PsA whose ACPA data were available, the duration from skin onset to joint onset was shorter in the 7 ACPA-positive patients (54.3±52.8 months) than in the 37 ACPA-negative patients (147.8±158.0 months), although the difference was not statistically significant (p=0.30). There were no statistically significant differences in the PASE, DAS-28, C-reactive protein concentration, or matrix metalloproteinase-3 concentration. The differences between RF positive and negative patients were not also statistically significant.

Table 1

	ACPA Positive (n=7)	ACPA Negative (n=37)	p value
PASE	45.8±16.1	51.1±13.4	0.42
IBP positivity	28.6	40.5	0.69
DAS28-ESR	4.24±0.93	3.76±1.56	0.45
DAS28-CRP	3.78±0.73	3.67±1.39	0.84
CRP (mg/dl)	0.56 [0.02–20.39]	0.48 [0.00–16.05]	0.79
MMP-3 (ng/ml)	133.6 [42.8–184.2]	69.1 [13.5–245.1]	0.14
Duration (skin/SpA) (mo)	54.3±52.8	147.8±158.0	0.26

Data are presented as mean ± standard deviation or median [range] unless otherwise indicated.

Conclusions: Among the patients with PsA in this series, ACPA positivity occurred in 15.9% and RF positivity occurred in 12.8%. Seropositive patients with PsA tended to have a shorter duration between skin onset and joint onset. Clinical and laboratory findings were not significantly different between ACPA-positive and -negative patients. One possible explanation for this is that 40.4% of patients with PsA received biological disease-modifying antirheumatic drugs; therefore, their disease activity was stable.

AB0769 SONOGRAPHIC SIGNS OF ENTHESITIS IN ESTABLISHED PSORIATIC ARTHRITIS AND HEALTHY VOLUNTEERS

K. Werversr[1], I. Herrings[1], J.J. Luime[1], M. Moed[1], I. Tchetverikov[2], A.H. Gerards[3], J.M.W. Hazes[1], M. Vis[1]. *[1]Rheumatology, Erasmus MC, Rotterdam; [2]Rheumatology, Albert Schweitzer Hospital, Dordrecht; [3]Rheumatology, Vlietland Hospital, Schiedam, Netherlands*

Background: Previous research in our group showed that sonographic signs of enthesitis are present in early and established PsA, but in young healthy volunteers as well. The Madrid Sonographic Enthesitis Index (MASEI) was only able to differentiate between patients and healthy volunteers after excluding knee enthesis thickness from the score and semi-quantitative scoring of Power Doppler (PD) signal (1).
Objectives: We aim to validate the modified MASEI in a larger cohort of established PsA patients and healthy volunteers.
Methods: Established PsA patients and healthy volunteers aged 35–55 were asked to participate in this cross-sectional study, irrespective of presence of enthesitis complaints. The triceps, quadriceps, proximal and distal patellar and Achilles tendon and plantar fascia (i.e. the locations of the MASEI) and the common extensor insertion at the lateral epicondyle of the elbow were evaluated sonographically for structural changes (i.e. erosions, calcifications and structure) and active inflammation (thickness, bursitis and PD).
Results: 84 established PsA patients and 25 healthy volunteers participated. Sonographic structural changes and one or two spots of PD signal were common in both groups. The modified MASEI was significantly higher in PsA patients

(median 12 (IQR 7.25–17) vs. 7.5 (5–9), P<0.001), while the original MASEI did not differ significantly (Table 1). Confluent PD over a larger area was only seen in 8% of the established PsA patients. Structural damage on ultrasound was more pronounced in the patients compared to the healthy volunteers. Number of PD locations and PD score did not distinguish the two groups.

Table 1. Participant characteristics and sonographic enthesitis scores

	PsA patients (n=84)	Healthy Volunteers (n=25)
Male, n (%)	45 (54)	12 (48)
Age, mean (SD)	55 (11)	47 (6)*
Disease duration, median years (IQR)	8.0 (4.9–12.3)	
LEI, median (IQR)	0.5 (0–2)	0 (0–0)**
Ultrasound		
MASEI, median (IQR)	15.5 (11–22)	13 (9–18)
Modified MASEI, median (IQR)	12 (7.25–17)	7.5 (5–9)**
structural components	7 (3–10)	3 (1–6)**
inflammatory components	6 (3.5–8.5)	3.5 (2–5.5)
Power Doppler		
in any enthesis, n (%)	74 (88)	22 (88)
score 3, n (%)	7 (8%)	0 (0%)
locations, median (IQR)	2 (1–3)	2 (1–3)
if positive, median (IQR)	1.5 (1.25–1.75)	1.5 (1.25–1.5)

PsA: Psoriatic Arthritis; SD: standard deviation, IQR: interquartile range; LEI: Leeds Enthesitis Index; MASEI: Madrid Sonographic Enthesitis Score; modified MASEI: MASEI with new PD scoring method (1: one spot of PD, 1.5: some spots of PD, 2: confluent signal, 3: severe signal) and without knee entheses thickness. Structural components: erosions, calcifications, structure. Inflammatory components: bursitis, thickness and PD signal. PD: Power Doppler. *P<0.01, **P<0.001 (Wilcoxon rank sum test).

Conclusions: Inflammatory and structural changes of the enthesis measured with ultrasound are common in both unselected PsA patients and healthy volunteers, but more pronounced in established PsA patients.

AB0770 CHANGE OF PSORIATIC ARTHRITIS IMPACT OF DISEASE (PSAID12) QUESTIONNAIRE RELATED TO CHANGE IN DISEASE ACTIVITY IN EARLY PSORIATIC ARTHRITIS

K. Wervers[1], J.J. Luime[1], I. Tchetverikov[2], A.H. Gerards[3], M.R. Kok[4], C.W.Y. Appels[5], W. van der Graaff[6], J.H.L.M. van Groenendael[7], L.-A. Korswagen[8], J.J. Veris-van Dieren[9], J.M.W. Hazes[1], M. Vis[1] on behalf of Cicero. *[1]Rheumatology, Erasmus MC, Rotterdam; [2]Rheumatology, Albert Schweitzer Hospital, Dordrecht; [3]Rheumatology, Vlietland Hospital, Schiedam; [4]Rheumatology, Maasstad Hospital, Rotterdam; [5]Rheumatology, Amphia Hospital, Breda; [6]Rheumatology, Rivas Hospital, Gorinchem; [7]Rheumatology, Reumazorg Zuid West Nederland, Roosendaal; [8]Rheumatology, Sint Franciscus Gasthuis, Rotterdam; [9]Rheumatology, Reumazorg Zuid West Nederland, Goes, Netherlands*

Background: The Psoriatic Arthritis Impact of Disease 12-item questionnaire (PsAID12) has been developed to measure impact of Psoriatic Arthritis (PsA) for purposes of monitoring and clinical management. Although validated in patients with longstanding disease, data on validity and sensitivity to change in early PsA is lacking.

Objectives: We aim to relate change in disease activity to change in PsAID12 score in early PsA and evaluate which PsAID domains are more likely to change.

Methods: Patients with a new diagnosis of PsA were included in the Dutch southwest Early Psoriatic Arthritis cohoRt (DEPAR). For this analysis, patients that have PsAID12 (range 0–10) and Composite Psoriatic Disease Activity Index (CPDAI, range 0–15) data at two consecutive visits (i.e. 3 months apart) within the first year were included. In case multiple periods per patients were available, the first time period was chosen. The change in PsAID is compared to the change in disease activity over this period, measured with the CPDAI using Spearman's correlation coefficient. Change in score on individual domains of the PsAID was analysed in subgroups of patients that perceived improvement in health and those that perceived worsening. The SF-36 question on self-perceived change in health was used to determine these subgroups.

Results: 143 unique patients had at least one period with two PsAID and CPDAI measurements (67 from baseline-3 months, 26 3–6 months, 25 6- 9 months and 25 9–12 months). Mean age was 51 (SD 13.7) and 70 (49%) were male. The initial median PsAID was 3.35 (IQR 1.4–5.1) and the subsequent score was 2.25 (0.95–4.8 with a mean delta of 0.52 (P<0.01). Median first CDPAI score was 4 (2–7) and 3 (1–5) for the second with a mean delta of 0.45 (P<0.05). The difference in PsAID score was significantly but moderately correlated with the difference in CPDAI (Spearman's rho 0.267, P=0.0013). 58 patients (41%) report a better health status compared to 3 months ago. Figure 1 shows that patients with self-perceived improvement of health have the highest improvement in pain and only domains of skin problems and embarrassment/shame did not improve significantly. Patients reporting worsening of health (n=29) only have significantly lower scores in fatigue, discomfort and social domains.

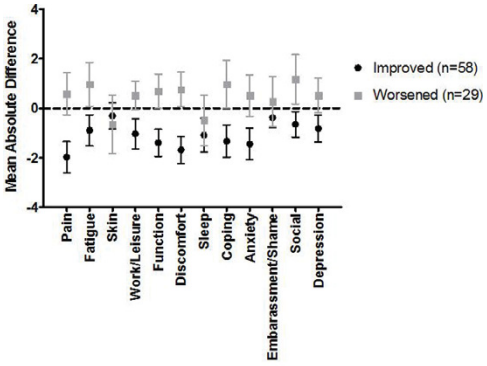

Figure 1. Mean absolute differences in PsAID12 domains in patients with self-perceived improvement of health (n=58, black) and patients reporting worsening of health (n=29, grey). Shown as mean value and 95%-Confidence Interval

Conclusions: Improvement in CPDAI disease activity is significantly but moderately associated with improvement in PsAID score, with the biggest improvement in the pain domain in patients with a self-reported improvement of health.

AB0771 SAFETY AND EFFICACY OF APREMILAST THROUGH 104 WEEKS IN PATIENTS WITH MODERATE TO SEVERE PSORIASIS WHO CONTINUED ON APREMILAST OR SWITCHED FROM ETANERCEPT TREATMENT IN THE LIBERATE STUDY

K. Reich[1], M. Goodfield[2], L. Green[3], K. Nograles[4], R. Chen[4], E. Levi[4], R.G.B. Langley[5]. *[1]Dermatologikum Hamburg, Hamburg, Germany; [2]Leeds General Infirmary, Leeds, United Kingdom; [3]George Washington University School of Medicine, Washington, DC; [4]Celgene Corporation, Summit, United States; [5]Dalhousie University, Halifax, Canada*

Background: Many patients (pts) with chronic plaque psoriasis exhibit nail and scalp involvement that can markedly affect quality of life and be difficult to treat.

Objectives: The phase 3b LIBERATE (Evaluation in a Placebo-Controlled Study of Oral Apremilast and Etanercept in Plaque Psoriasis) study (NCT01690299) evaluated the efficacy and safety of apremilast or etanercept vs. placebo in biologic-naive pts with moderate to severe plaque psoriasis. Efficacy assessments included effects on preexisting nail and scalp disease and skin lesions.

Methods: In this double-blind, double-dummy study, pts were randomized (1:1:1) to placebo (PBO), apremilast 30 mg BID (APR), or etanercept 50 mg QW (ETN) through Week 16; thereafter, all pts switched to or continued APR (PBO/APR, ETN/APR, APR/APR) through Week 104. The primary end point was achievement of a ≥75% reduction from baseline in Psoriasis Area and Severity Index (PASI) score (PASI-75) at Week 16 with APR vs. PBO; the secondary end point was PASI-75 achievement at Week 16 with ETN vs. PBO. Physician assessments were also conducted for overall disease activity (static Physician's Global Assessment [sPGA]); scalp disease activity (Scalp Physician Global Assessment [ScPGA], limited to patients with score ≥3 at baseline, indicating moderate to very severe scalp disease); and nail disease (Nail Psoriasis Severity Index [NAPSI], limited to patients with active disease [NAPSI ≥1] in the target nail at baseline). Responses were assessed at Week 104 using the last-observation-carried-forward (LOCF) methodology.

Results: The APR extension phase (Weeks 16 to 104) included 226 pts (PBO/APR n=73; APR/APR n=74; ETN/APR n=79). At Week 16, PASI-75 scores vs. PBO were significant for both APR and ETN; long-term treatment with APR maintained both PASI-75 and sPGA 0 or 1 response levels (Table). Improvements were seen in nail and scalp disease at Week 16, and responses continued to improve with APR treatment over 104 weeks and in pts who switched from ETN to APR (Table). ScPGA 0 or 1 was achieved by 50.0% to 59.2% of pts across treatment arms, and mean percent improvement from baseline NAPSI score ranged from –48.1% to –51.1% (Table); the proportion of pts achieving NAPSI-50 response ranged from 48.6% to 65.2%. Adverse events (AEs) occurring in ≥5% of pts during Weeks 0 to 16 were diarrhea, nausea, nasopharyngitis, upper respiratory tract infection, and headache; long-term assessment by exposure-adjusted incidence rates (EAIR)/100 pt-yrs showed no increase with longer-term APR exposure. No increase in EAIR/100 pt-yrs of serious AEs occurred during the APR extension phase (3.45 to 5.49, across groups) vs. Weeks 0 to 16 (PBO 0.0; ETN 7.91; APR 12.57). Changes in laboratory parameters were infrequent and transient; EAIR/100 pt-yrs remained low across groups through 104 weeks.

Conclusions: APR demonstrated efficacy through Week 104 in pts who continued APR and pts who switched from PBO or ETN to APR at Week 16. The AE profile remained consistent with prolonged APR exposure, and no new safety or tolerability issues were observed through Week 104 in pts with moderate to severe plaque psoriasis.

Table. LIBERATE Efficacy Outcomes

Pts Achieving Response, % (LOCF)	PBO n=84	APR n=83	ETN n=83

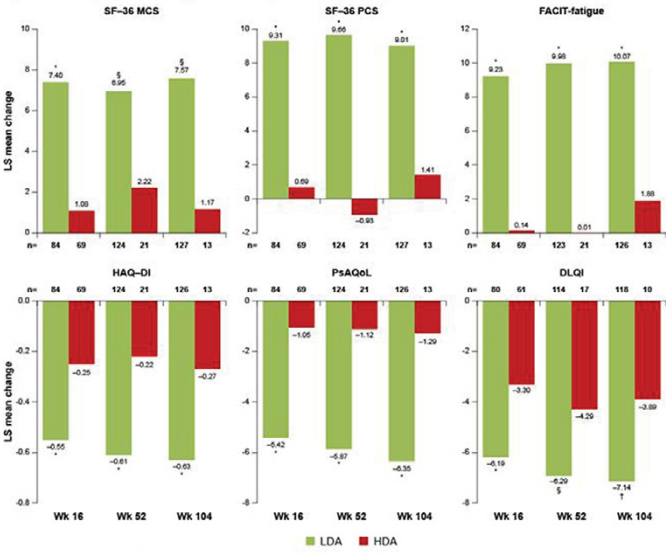
AB0772 SECUKINUMAB PROVIDES SUSTAINED IMPROVEMENT IN FUNCTION, QUALITY OF LIFE AND FATIGUE OVER 2 YEARS IN PATIENTS WHO ACHIEVED LOW DISEASE ACTIVITY RELATED TO PSORIATIC ARTHRITIS DISEASE ACTIVITY SCORE (PASDAS)



L.C. Coates[1,2], T.K. Kvien[3], P. Nash[4], L. Gossec[5], V. Strand[6], L. Pricop[7], L. Rasouliyan[8], K. Ding[7], S. Jugl[9], C. Gaillez[9] on behalf of the FUTURE 2 study group. *[1]University of Leeds; [2]Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; [3]Diakonhjemmet Hospital, Oslo, Norway; [4]University of Queensland, Brisbane, Australia; [5]UPMC Université Paris 06, Paris, France; [6]Stanford University School of Medicine, Palo Alto; [7]Novartis Pharmaceuticals Corporation, East Hanover, United States; [8]RTI Health Solutions, Barcelona, Spain; [9]Novartis Pharma AG, Basel, Switzerland*

Background: PASDAS is a composite index measuring disease activity in psoriatic arthritis (PsA), well correlated with HAQ and health related quality of life[1].
Objectives: To report the impact of secukinumab on individual core components of PASDAS and its relationship with function (HAQ-DI), health related quality of life (SF36-PCS and MCS, DLQI, PsAQoL) and fatigue in patients (pts) who achieved PASDAS low disease activity (LDA) vs. high disease activity (HDA) through Week (Wk) 104 using *post-hoc* analysis from FUTURE 2 trial.
Methods: 397 pts with active PsA were randomised to s.c. secukinumab (300, 150, or 75mg) or placebo in FUTURE 2 study.[2] PASDAS is derived from physician's global VAS, pts global VAS, SF-36 PCS, tender and swollen joints (TJC68 and SJC66), Leeds enthesitis count, dactylitis count and CRP level and has cut-points for HDA (≥5.4), LDA (<3.2) and remission (REM≤1.9).[3] PASDAS was assessed at Wks 16, 52 and 104 and reported as observed using non-mutually exclusive categories at group level. Additionally, the SF-36 PCS, SF-36 MCS, HAQ-DI, FACIT-Fatigue, PsAQoL, and DLQI were assessed by PASDAS LDA and HDA at Wks 16, 52 and 104 using MMRM analyses.
Results: Pts presented similar baseline characteristics. Mean±SD score of each PASDAS component among pts reaching LDA and HDA at Wk 16 for each treatment group are shown in table and were similar at Wk 104. Secukinumab treated pts achieving PASDAS LDA had significantly greater improvements in function, physical and mental health quality of life and fatigue compared to HDA through Wk 104 (Figure).
Conclusions: In pts treated with secukinumab, the most improved individual components with PASDAS LDA were related to dactylitis, enthesitis, SF36-PCS, Physician global VAS and SJC at Wk 16 and Wk 104. PASDAS LDA was associated with better improvement in function, quality of life and fatigue than HDA confirming the importance to reach stringent target in a PsA pts with multifaceted disease.

Table 1. Scores of PASDAS components at Wk 16

Core components, Mean ± SD	Secukinumab/PBO (s.c.), mg	LDA 300mg: n=37; 150mg: n=34; PBO: n=14	HDA 300mg: n=12; 150mg: n=23; PBO: N=34

AB0773 EFFECTIVENESS OF GOLIMUMAB IN TNF-INHIBITOR INADEQUATE RESPONDER PATIENTS WITH SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS

L. Santo[1], F. D'Onofrio[2], M.G. Anelli[3], N. Maruotti[2], R. Bucci[4], A. Semeraro[5], C. Zuccaro[6], G. Carlino[7], A. Marsico[5], L. Quarta[8], O. Casilli[8], P.C.F. Falappone[9], F. Iannone[3]. *[1]O.U. of Rheumatology, ASL Barletta, Bari; [2]UOC Reumatologia Universitaria, University of Foggia, Foggia; [3]DETO - Rheumatoly Unit, University of Bari, Bari; [4]Rheumatology Hospital Unit, AOU Foggia, Foggia; [5]O.U. of Rheumatology, ASL Taranto, Taranto; [6]Ambulatorio Reumatologia, Ospedale "Perrino", Brindisi; [7]ASL LECCE - DSS Casarano and Gallipoli, Rheumatology Service, Casarano; [8]OU of Rheumatology, "V.Fazzi" Hospital, Lecce; [9]Ambulatorio Reumatologia, Ospedale di Mesagne, Mesagne, Italy*

Background: In real-life world settings, failure of a first TNF-inhibitor (TNFi) put rheumatologists against a crossroad to choose a further TNFi or a biologic drug with a different mechanism of action.
Objectives: Aim of this study was to assess effectiveness of golimumab (GOL) as second line drug after failure of a first TNFi as treatment of patients affected with rheumatoid arthritis (RA), psoriatic arthritis (PsA), or axial-spondyloarthritis (Ax-SpA).
Methods: GOAREL is a prospective cohort of patients starting GOL in community-based care rheumatology centers in Apulia (south Italy) since 2013. Of 494, we selected 368 patients (RA n.73, PsA n.168, and n. Ax-SpA 127) commencing GOL as first ever biological (n.206, 56%) or second treatment (n.161, 44%) after inadequate response to a first TNFi (adalimumab (ADA, n.51), etanercept (ETA, n.81), or infliximab (IFX, n.29). Three patients failing certolizumab were excluded. Primary endpoint was to compare the drug retention rate of biological naïve and TNFi inadequate responders (TNFi-IR) patients on treatment with GOL. In addition, drug retention of second line GOL patients according to the firs TNFi was assessed. Drug survival was estimated by Kaplan-Meier life table analysis. Estimates hazard ratios (HRs) of 2- years drug discontinuation adjusted for demographics, type of disease, disease characteristics, body mass index, co-therapy with glucocorticoids or methotrexate, and prior TNFi were computed by backward selection Cox-regression model.
Results: 2-year drug survival on GOL of naïve and TNF-IR patients was not significantly different (Figure 1). Mean survival time was 20.0 months (95% CI 18.9–21.0) for naïve and 20.4 months (95% CI 19.3–21.6) for TNFi-IR patients. Likewise, drug retention rates on GOL of TNFi-IR patients subdivided by previous TNFi was not significantly different and similar to naïve patients (Figure 1). Mean survival time was 19.0 months (95% CI 16.7–21.4) for prior-ADA, 20.5 months (95% CI 18.9–22.1) for prior-ETA, and 22.0 months (95% CI 19.6–24.3) for prior-IFX. Multiple Cox-regression model showed gender female as the only independent factor positively associated to the risk of GOL discontinuation (HR 2.5, 95% CI 1.5–4.2, p 0.0001).

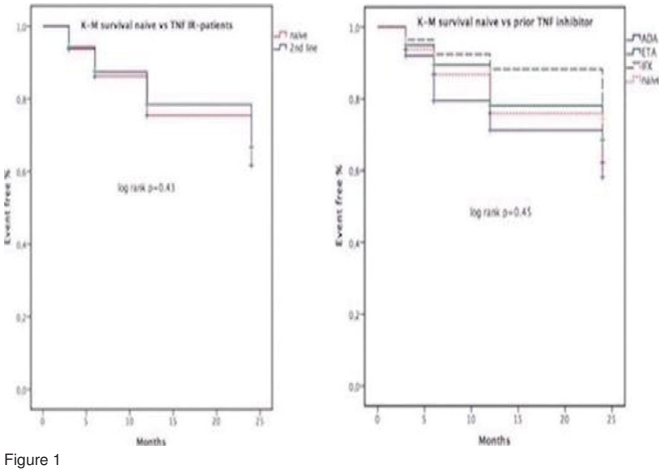

Figure 1

Conclusions: In real-life setting effectiveness of GOL seems to be similar in naïve or TNFi-IR patients with RA, PsA, and Ax-Spa. Furthermore, clinical outcomes were not influenced by the previous TNFi.

AB0774 PREVALENCE, CLINICAL AND RADIOGRAPHIC CHARACTERISTICS OF SACROILITIS IN PATIENTS WITH PSORIASIS

L. Stefanović[1], D. Veljković[2], E. Mahmutović[3], V. Skakić[4]. *[1]Dom zdravlja Kraljevo; [2]Odsek za sanitetsko obezbeenje, Odred Žandarmerije, Kraljevo; [3]Državni Univerzitet Novi Pazar, Departman za biomedicinske nauke, Novi Pazar; [4]Institute Niska Banja, Nis, Serbia*

Background: Psoriasis is a skin disorder that is associated with arthritis. Sacroiliac joint involvement is considered to be less frequent than the other types of psoriatic arthritis.
Objectives: im of the study was to investigate the prevalence of sacroilitis in patients with psoriasis (Ps) in region of Kraljevo, Novi Pazar and Niška banja.
Methods: A multicenter, noninterventional, retrospective, cross-sectional study was conducted at 3 care centers in region of Kraljevo, Novi Pazar and Niška banja. Diagnosis of sacroilitis was based on clinical and antero-posterior pelvic X-rays Prevalence of sacroilitis and its clinical and radiologic characteristics were examined.
Results: Sacroilitis was documented in 24/100 (24%) patients with Ps. There was no significant difference in average age between Ps patients without sacroilitis (47,83) and Ps patients with sacroilitis (49,9). Sacroiliitis appeared to be unilateral in 12,5% and bilateral in 87.5% of patients. Ps preceded sacroilitis in 62,50% and sacroilitis preceded Ps in 29,17% of cases; concomitant onset of Ps and sacroilitis was present in 8,33%. Peripheral arthritis was found in 67,89% patients with sacroilitis.
Conclusions: The prevalence of sacroilitis and related spondylitis is high in patient with Ps. We found predominantly bilateral sacroilitis which is characteristic of ankylosing spondylitis. This is in contrast to present knowledge about the association of psoriasis and sacroiliitis. In 68% sacroilitis patients we found associated peripheral arthritis.

AB0775 UNDERESTIMATED AXIAL AND ENTHESIAL INVOLVEMENT IN PATIENTS WITH PSORIATIC ARTHRITIS IN A RUSSIAN DERMATOLOGICAL DAILY PRACTICE: COMPARED WITH RHEUMATOLOGICAL PRACTICE

M. Chamurlieva, E. Loginova, T. Korotaeva. *Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Psoriatic arthritis (PsA) is frequently underdiagnosed by dermatologists due to it's heterogeneous clinical manifestations such as peripheral arthritis, dactylitis, spondylitis and enthesitis. For the correct early diagnosis, choice of treatment and for better outcomes proper evaluation of all symptoms is required.
Objectives: to compare the definition of the main clinical symptoms of PsA by dermatologists and rheumatologists in daily clinical practice.
Methods: 103 pts (male-47/female-56) with different forms of plaque psoriasis (PsO), mean age 44±13.69 years (yrs.), mean psoriasis duration 10.7±10.2 yrs., mean PASI 5.05±1.23 were included. In dermatological clinic, all pts completed a PEST questionnaire and underwent clinical evaluation by a dermatologists in order to identify the main clinical symptoms of PsA such as peripheral arthritis, dactylitis, spondylitis and enthesitis. Later all pts were subsequently evaluated by rheumatologists to confirm/exclude the diagnosis of PsA based on CASPAR criteria and underwent standard clinical examination to identify the same symptoms - peripheral arthritis, dactylitis, spondylitis (based on inflammatory back pain (IBP) ASAS criteria) and enthesitis (based on Leeds Enthesial Index (LEI) plus Plantar Fascia (PF). M±m, %, t-test were peformed. All $p<0.05$ were considered to indicate statistical significance.
Results: 61 out of 103 pts with PsO (59.2%) had PsA based on rheumatological evaluation and CASPSR criteria. Dermatologists diagnosed peripheral arthritis in significantly less cases compared to rheumatologists: in 15 (24.6%) and in 35 (57.4%) out of 61 pts ($p<0.001$) accordingly. No significant difference was seen in clinical evaluation of dactylitis by dermatologists or rheumatologists - in 37 (60.7%) and in 40 (65.6%) out of 61 pts accordingly (p=0.32). Heel pain was noted by dermatologists in 32 out of 61 pts (52.5%) according to PEST questionnaire. Dermatologists could not find enthesitis according to LEI. Rheumatological examination based on LEI scale identified lateral epicondyles in 11 out of 61 pts (18%), enthesitis of medial femoral condyles in 8 out of 61 pts (13.1%), enthesitis of Achilles tendon insertions – in 25 out of 61 pts (41%). Enthesitis of PF were observed in 15 out of 61 pts (24.6%). Dermatologists noted back pain using PEST questionnaire in 30 out of 61 pts (49.2%). IBP based on ASAS criteria was not detected by a dermatologists in any case. In these 30 pts having back pain IBP was diagnosed by a rheumatologists in 21 (70%) cases; and in the rest 9 out of 30 pts (30%) mechanical back pain was observed. On the basis of clinical examination tendinitis was not noted by dermatologists, while rheumatologists found hand tendinitis in 13 out of 61 pts (21.3%).
Conclusions: Perypheral arthrtitis, axial and enthesial involvement were underestimated by dermatologists using PEST screening questionnaire, because it does not cover these symptoms in detail. ASAS criteria for IBP and standard enthesitis assessment should be implemented into Russian dermatological clinical practice. In order to improve early PsA diagnosis in dermatological practice, interdisciplinary educational training programmes and collaboration with rheumatologists are needed.

AB0776 THE EFFECT OF PREGNANCY ON DISEASE ACTIVITY OUTCOMES IN PSORIATIC ARTHRITIS PATIENTS

M. Berman[1], D. Paran[1], D. Zisman[2], J. Wollman[1], D. Levartovsky[1], O. Elkayam[1]. [1]*Rheumatology, Tel Aviv Sourasky Medical Center, Tel Aviv;* [2]*Rheumatology, Carmel Medical Center, Haifa, Israel*

Background: Psoriatic arthritis often affects patients at a childbearing age. The relationship between pregnancy and psoriatic arthritis, in terms of pregnancy outcomes and its effect on disease activity, has not been well studied
Objectives: To evaluate the effect of pregnancy on disease activity in psoriatic arthritis
Methods: A retrospective review of files of female patients followed at Psoriatic arthritis clinic at the Tel Aviv Medical center was performed, patients with at least 1 pregnancy during follow up and one visit during or soon after pregnancy were included. A review of files was performed which included the following data: age, disease duration, pattern of PsA, disease activity before during and after pregnancy, record of treatment, including IA injections. Postpartum period was defined as up to 1 year after pregnancy. PsA activity was defined as follow: no disease activity (no active synovitis), mild disease (up to 1 joint involved), moderate to severe disease (more than 2 joints involved). The follow-up during and after pregnancy was classified as: improvement, worsening or stable
Results: 25 PsA women and 35 pregnancies were identified. 33 resulted in live healthy babies. One pregnancy was interrupted on week 23, so partial follow up was available. The mean age at pregnancy was 32.5 years. Table 1 summarizes status of disease activity before, throughout pregnancy and during the postpartum period in the whole group. No significant change in disease activity was noticed throughout pregnancy while significant proportion of patients flared at postpartum. Before 21 pregnancies patients were treated with biologic agents. In 15, biologic treatment was discontinued close to pregnancy or during the first trimester. In this group, 5 (33%) of patients were classified as mild to severe activity prior to pregnancy. This number increased up to 8 (53%), 7 (47%) and 14 (93%) during the 1st, 2nd trimester and postpartum period respectively. In 6 patients in whom biologics were continued beyond first trimester, no significant change in degree of disease activity was noticed. Interestingly, in the group of non-biologics treated patients, an improvement in disease activity was observed – the proportion of patients with mild to severe disease activity decreased from 85% close to pregnancy to 69% in the 1st and 2nd trimester and 58% in the 3rd one while an increase to 83% was observed after pregnancy. During 6 pregnancies, corticosteroids were initiated or the dosage increased- 83% in pregnancies where biologics were stopped before pregnancy.

Table 1. Disease activity during pregnancy

N (%)	Before	1st trimester	2ndtrimester	3rd trimester	Postpartum
No	15 (44%)	14 (41%)	13 (38%)	16 (48%)	6 (18%)
Mild	9 (26%)	10 (29%)	10 (29%)	9 (27%)	9 (27%)
Moderate to severe	10 (29%)	10 (29%)	11 (32%)	8 (24%)	18 (55%)

Conclusions: Patients with PsA definitively flare after pregnancy. Our results suggest that stopping treatment with biologic agents before pregnancy is associated with flare during pregnancy and the postpartum period. It seems that in terms of PsA disease activity, it may be recommended to continue treatment with biologic agents throughout pregnancy

AB0777 CHARACTERISTICS OF AMYLOID A DEPOSITION IN PSORIATIC ARTHROPATHY AND IN RHEUMATOID ARTHRITIS – A COMPARATIVE POSTMORTEM CLINICOPATHOLOGIC STUDY OF 161 RHEUMATOID AND 12 PSORIATIC ARTHRITIS PATIENTS

M. Bély[1], Á. Apáthy[2]. [1]*Department of Pathology, Policlinic of the Order of the Brothers of Saint John of God;* [2]*Department of Rheumatology, St. Margaret Clinic Budapest, Budapest, Hungary*

Background: The aim of this study was to determine the prevalence and extent of amyloid A deposition on different tissue structures in various organs of rheumatoid arthritis (RA) and psoriatic arthritis (PsA) patients.
Methods: AAa was detected in 34 (21.1%) (females: 29, average age: 64.3 years, range: 83–32, onset of RA: 48.6, average disease duration: 15.7 years; males: 5, average age: 51.2 years at death, range: 88–19, onset of RA: 41.3, average disease duration: 14.8 years) of 161 RA, and in 2 (16%) female: 2, average age: 57.5 years, range: 63–52, onset of PsA: 47.5, average disease duration: 11.0 years) of 12 PsA patients.
RA and PsA were diagnosed clinically according to the criteria of the American College of Rheumatology (ACR) [1,2].
Amyloid deposits on different tissue structures [arteriole, small artery, medium size artery, venule, small vein, medium size vein, interstitial collagen fiber, reticulin fiber (collagen IV), basal laminas, nerve, renal glomerulus] of 6 organs [heart, lungs, liver, kidney, skin and brain] were determined histologically. The extent of amyloid A deposits was evaluated by semi-quantitative, visual estimation on a 0 to 3 plus scale, based on the number of involved tissue structures per light microscopic field [3].
The prevalence and extent of amyloid A deposits on different tissue structures were compared by Student (Welch) t-probe.
Results: The average prevalence (in %) and the average extent of amyloid A deposits (absolute value) on different tissue structures of analyzed 6 organs in RA and PsA patients are summarized in Table.

Tissue structure	RA-AAa Prevalence in %	PsA-AAa Prevalence in %	p<	RA-AAa Average extent	PsA-AAa Average extent	p<
Arteriole	61,33	58,33	**0,28**	1,34	1,33	**0,49**
Small artery	50,28	58,33	**0,46**	0,94	1,21	**0,25**
Collagen IV	30,39	**41,67**	**0,36**	0,56	**0,83**	**0,21**
Interstitial collagen	**45,86**	33,33	**0,22**	**0,78**	0,58	**0,24**
Small vein	26,52	33,33	**0,42**	0,39	0,42	**0,44**
Medium size vein	21,55	25,00	**0,47**	0,37	0,33	**0,43**
Medium size artery	24,86	25,00	**0,42**	0,34	0,25	**0,27**
Venule	22,10	16,67	**0,32**	0,32	0,25	**0,35**
Nerve	4,97	16,67	**0,17**	0,08	0,17	**0,24**
Average/Structure	**31,98**	**34,26**	**0,388**	**0,57**	**0,60**	**0,444**
Average/Patient	**32,27**	**36,21**	**0,244**	**0,585**	**0,668**	**0,198**

Conclusions: The difference between average prevalence ($p<0.388$) and average amount ($p<0.444$) of amyloid A deposits/structures in RA and PsA patients was not significant.
The prevalence and extent of amyloiod A deposits on different tissue structures of analyzed organs changed parallel in RA or PsA patients except for collagen IV and interstitial collagen.
The reverse prevalence and extent of amyloid A deposits on collagen IV and interstitial collagen fibers between RA or PsA patients may be due to structural (qualitative) changes of collagen IV resulting in its increased affinity of amyloid A in PsA patients. Qualitative change of collagens in systemic sclerosis patients has been demonstrated [4].

AB0778 PATIENT AND PHYSICIAN GLOBAL ASSESSMENTS ARE POORLY CONNECTED IN INDIVIDUAL PATIENTS WITH PSORIATIC ARTHRITIS AND ONLY POORLY EXPLAINED BY OTHER CLINICAL MARKERS OF DISEASE ACTIVITY

E.M. Egsmose[1,2], O.R. Madsen[1,2]. [1]*Department of Rheumatology, Copenhagen University Hospital Rigshospitalet Gentofte, Hellerup;* [2]*The DANBIO registry, Copenhagen University Hospital Rigshospitalet Glostrup, Glostrup, Denmark*

Background: Assessment of disease activity is important in the evaluation and monitoring of patients with psoriatic arthritis (PsA) in clinical care and research. As there is no single “gold standard” variable for assessment of disease activity several markers of disease activity are used, among these “global assessment” by the patient (PaGl) and by the physician (PhGl). The agreement and interplay between PaGl and PhGl are not well clarified in patients with PsA, however.
Objectives: The objective of the study was to examine associations on the group level and agreements on the individual patient level between PaGl and PhGl as scored on visual analogue scales (VAS) in the daily clinic by patients with active PsA and their rheumatologists.
Methods: Traditional disease activity data on 76 PsA patients with active disease planned to initiate biological treatment were extracted from the Danish DANBIO registry. Data comprised swollen joint count (SJC), tender joint count (TJC), CRP, patient and physician global assessment (PaGl and PhGl) and pain (VAS), HAQ-DI and DAS28-CRP (4v). Parametric statistics was used. The predictability of PaGl and PhGl, respectively, by all other disease markers mentioned and by age and sex was examined using stepwise multiple regression analysis. Agreement between the VAS scores was expressed as the bias (mean difference between intra-individual scores) and the 95% lower and upper limits of agreement (LLoA;ULoA) according to the Bland-Altman method.
Results: Mean age was 52.2±11.1 years and mean DAS28-CRP 4.7±1.1. 59.2% were of the patients were women. Mean PaGl was 63.7±23.2 and PhGl 39.9±19.8 ($p<0.0001$). PaGl was significantly but weakly correlated with PhGl ($r=0.42$, $p<0.0001$) with a high standard error of estimation (SEE) =21.2. PaGl was independently predicted by pain (beta =0.76, $p<0.0001$) and HAQ-DI (beta =0.19, $p<0.01$) and was not predicted by PhGl (p=0.61) (R =0.78, SEE =10.5, $p<0.0001$). PhGl was independently predicted by SJC (beta =0.43, $p<0.0001$) followed by pain (beta =0.41, $p<0.0001$) and CRP (beta =0.20, $p<0.05$) (R =0.70, SEE =14.4, $p<0.0001$) with no significantly contribution by PaGl (p=0.49). Differences between the patient-reported VAS-scores were small on the group level but on the individual level they were pronounced: LLoA;ULoA [bias] for PaGl

vs. PhGl was -21.9;69.5 [23.8], for PaGl vs. pain -17.1;22.0 [4.9], and for PhGl vs pain -60.8;23.0 [-18.9].
Conclusions: In patients with PsA, PaGl was in general scored considerably higher than PhGl. The two scores were poorly connected not only on the individual level but also on group level with no systematic differences between the scores. PaGl was best predicted by pain, and PhGl by SCJ reflecting patients and physicians diverging attitudes to the importance of the different disease manifestations. The findings highlight the challenge of understanding and dealing with discrepancies between assessments and attitudes by physicians and patients.

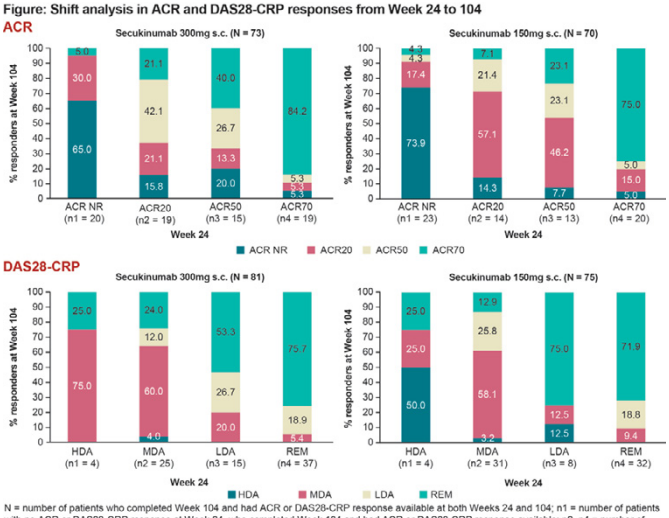
AB0779 CLINICAL MANIFESTATIONS AND PARAMETERS AFFECTING THERAPEUTIC RESPONSE IN A COHORT OF 411 PSORIATIC ARTHRITIS PATIENTS

M.P. Migkos, T.-E. Memi, T.E. Markatseli, A.A. Drosos, P.V. Voulgari.
Rheumatology Clinic, Department of Internal Medicine, Medical School, University of Ioannina, Ioannina, Greece



Background: Psoriatic arthritis (PsA) has various clinical manifestations. The therapeutic response of patients may be affected by epidemiological parameters such as body mass index (BMI), disease duration, sex and the choice of therapy.
Objectives: To illustrate the clinical manifestations of psoriatic arthritis and to assess the impact of epidemiological features and treatment choice on therapeutic response.
Methods: We retrospectively studied 411 patients diagnosed with PsA and we recorded the clinical manifestations of the disease. Data of 254 out of 411 patients were analyzed to examine the possible effect of BMI, disease activity, sex and treatment choice on therapeutic response. Patients were followed up at predefined time points [baseline, 12 weeks (wks), 24 wks, 48 and 240 wks after initiation of therapy]. The treatment response was assessed using Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), disease activity score-28 (DAS) -C-Reactive Protein (CRP), DAS28-erythrocyte sedimentation rate (ESR) and Health Assessment Questionnaire (HAQ). Patients were categorized in three groups: patients treated with biological synthetic disease modifying anti-rheumatic drugs (DMARDs) (anti-tumor necrosis factor alpha (TNFa) agents), patients treated with synthetic DMARDs and combined therapy (biological and synthetic DMARDs).
Results: The interval between psoriasis and PsA in women is shorter (p=0,041). PsA presented predominantly as asymmetric oligoarthritis (41,60%), followed by symmetric polyarthritis (24,57%). Arthritis of distal phalangeal joints was established in 3,16%, while 4,37% showed only enthesitis or dactylitis. Axial involvement was recorded in 26,27%7.Twenty-eight patients had only axial disease and 80 had axial and peripheral joint involvement. 23/411 patients (5,60%),had eye involvement, 8/411 (1,95%) and 6/411 (1,46%) had involvement of the urogenital and gastrointestinal system, respectively. Eleven patients had pulmonary fibrosis. In the subgroup analysis of 254 patients, disease duration was positively correlated in all time points (p<0,005) with all disease activity scores. Statistical significant differences with respect to gender was observed for DAS28-CRP (3,93–2,96, 3,54–2,64 p<0,001) and DAS28-ESR (3,37 – 2,82 p=0,001, 3,06–2,62 p=0,023) at 12 and 24 wks respectively. More specifically women showed higher disease activity than males the first 6 months after treatment. BMI was not significantly correlated with the disease activity. Treatment with biological DMARD showed a statistically significant difference in all disease activity scores early in the disease course (p<0,05) in comparison with those receiving conventional DMARD. After the first 12 wks all disease activity scores were rather stable with no differences between the treatment groups.
Conclusions: PsA manifests predominantly as asymmetric oligoarthritis. Extraarticular manifestations are less frequent. Higher disease duration was associated with higher disease activity. Women early on disease course had higher DAS-28 scores. Treatment with biological DMARD showed better response in PsA patients compared with synthetic early in the disease course. However, after the first 12 wks there were no significant differences in treatment response with respect to treatment choice.

AB0780 SECUKINUMAB SUSTAINS INDIVIDUAL CLINICAL RESPONSES OVER TIME IN PATIENTS WITH PSORIATIC ARTHRITIS: 2-YEAR RESULTS FROM A PHASE 3 TRIAL, FUTURE 2

P. Emery[1], I.B. McInnes[2], P.J. Mease[3], M. Schiff[4], L. Pricop[5], S. Shen[5], Z. Wang[5], C. Gaillez[6] on behalf of the FUTURE 2 study group. *[1]University of Leeds, Leeds; [2]University of Glasgow, Glasgow, United Kingdom; [3]Swedish Medical Centre and University of Washington, Seattle; [4]University of Colorado, Denver; [5]Novartis Pharmaceuticals Corporation, East Hanover, United States; [6]Novartis Pharma AG, Basel, Switzerland*

Background: Achieving sustained clinical response to biologics is part of treat-to-target recommendations in psoriatic arthritis (PsA) and is aimed at optimising treatment goals.[1]
Objectives: To evaluate patient (pt)-level secukinumab data and report the likelihood of improving, sustaining or worsening of American College of Rheumatology (ACR) response and disease status (disease activity score 28 based on C-reactive protein [DAS28-CRP]) from Week (Wk) 24 to 104 in pts with active PsA from the FUTURE 2 trial.[2,3]
Methods: The findings of the FUTURE 2 trial through Wk 104 have been previously reported.[3] *Post-hoc* shift analyses were performed on ACR response between Wks 24 and 104 for subgroups of secukinumab-treated pts, based on their higher response rate at an earlier time point in 1 out of 4 categories (ACR non-responders [NR], ACR20, 50 or 70) by evaluating whether the response improved, sustained or worsened at a later time point using exclusive categories and as observed analyses. Similar shift analysis on DAS28-CRP derived criteria were performed in 4 exclusive categories extrapolated from rheumatoid arthritis: high, moderate, low disease activity (HDA, MDA, LDA) or remission (REM) only.[4]
Results: In total, 86/100 (86%) and 76/100 (76%) pts in the secukinumab 300 and 150mg groups, respectively, completed the 104-wk treatment. Of which, 73/70 and 81/75 pts in secukinumab 300/150mg were eligible for ACR and DAS28-CRP shift analysis, respectively, from Wk 24 to 104. Baseline demographics and clinical characteristics were balanced across the two dose groups.[2,3] Most secukinumab-treated pts who achieved at least an ACR20, 50 or 70 response and Psoriasis Area and Severity Index (PASI) 75 or 90 response at Wk 24, improved or sustained their response at Wk 104 (Figure, data not shown for PASI response). Similarly, a majority of pts who were in the MDA, LDA or REM category at Wk 24 sustained or improved their disease status related to DAS28-CRP score at Wk 104 (Figure).

Figure: Shift analysis in ACR and DAS28-CRP responses from Week 24 to 104

N = number of patients who completed Week 104 and had ACR or DAS28-CRP response available at both Weeks 24 and 104; n1 = number of patients with no ACR or DAS28-CRP response at Week 24, who completed Week 104 and had ACR or DAS28-CRP response available; n2–n4 = number of patients with ACR or DAS28-CRP response at Week 24, who completed Week 104 and had ACR or DAS28-CRP response available.

Conclusions: In this *post-hoc* analysis, a majority of secukinumab-treated pts who achieved at least ACR20 and PASI 75 response or at least MDA at Wk 24 sustained or improved their ACR and PASI responses or sustained or reduced their disease status at Wk 104. Numerically higher sustained response and LDA or REM rate was observed for secukinumab 300mg, thereby extending the sustainability of response and lowering the disease activity that has been previously reported at group level.[2,3]

AB0781 PSORIATIC ARTHRITIS IN PSORIASIS PATIENTS: RESULTS OF A FRENCH SURVEY

P. Claudepierre[1], P. Richebé[2], S. Benkhalifa[3], D. Sid Mohand[4], B. Charles[4], Y. Braults[3], M. Lahfa[5]. *[1]Department of Rheumatology, Université Paris Est Créteil, Chenevier-Mondor Hospital, Créteil; [2]Department of Rheumatology, Université Paris Est Créteil, Chenevier-Mondor Hospital; [3]Pfizer; [4]France Psoriasis, Paris; [5]Private dermatology practice, Biarritz, France*

Background: Early detection of psoriatic arthritis (PsA) in patients with skin psoriasis (Pso) is critical to reduce the risk of joint damage, disability, and comorbidities. However PsA is mostly under-diagnosed in patients with Pso.
Objectives: first to compare characteristics of patients with Pso without PsA with those of patients with Pso and PsA, then to compare patients with Pso and potential but undiagnosed PsA (puPsA) to the other patients.
Methods: 817 patients completed an online questionnaire published by the French Psoriasis Patients Association, including multiple-choice questions regarding in particular past and current symptoms. For analysis, a first comparison was performed between patients with Pso without known PsA and patients with Pso and PsA, then between patients with symptoms suggestive of PsA (puPsA group), i.e., patients with past or current joint or back pain accompanied by waking up at night and/or morning stiffness, with PsA patients on the one hand, and with patients without known PsA and without symptoms suggestive of puPsA, on the other hand.
Results: 746 patients reported having Pso of which 192 (25.7%) had also PsA. Among the 554 patients without known PsA, 190 (34.3%) had symptoms suggestive of PsA, 101 (18.2%) had rheumatologic symptoms not suggestive of PsA, and 263 (47.5%) had no rheumatologic symptoms. The comparison, in multivariate analysis, between patients with Pso and PsA and patients with Pso without known PsA showed significant differences ($p<0.05$): Pso and PsA patients had more often current bone or joint pain at any time (OR=7.8), joint pain during the day (OR =2.45), stiff back or joints on waking (OR=1.77), painful and swollen fingers and toes (OR=3.15), past joint pain during the day (OR=3.05), and drug in tablet form (OR=2.07), biotherapy alone (OR=5.45) or with DMARDs (OR=16.06); conversely they had less often guttate psoriasis (OR=0.54). Results of the multivariate analysis comparing patients with puPsA to the other patients are shown in Tables 1 and 2 (comparison with patients with Pso and PsA in Table 1; comparison with patients with Pso without known PsA in Table 2).

Table 1. Multivariate analysis, patients with puPsA and Pso compared with patients with Pso and PsA

Covariates ($p<0.05$ for all OR)	OR [95% CI]
Current skin pain	OR=1.85 [1.12; 3.08]
Current bone or joint pain	OR=0.25 [0.15; 0.44]
Current joint pain during the day	OR=0.49 [0.29; 0.84]
Current back pain	OR=2.55 [1.52; 4.29]
Current painful and swollen fingers and toes	OR=0.29 [0.17; 0.51]
Past joint pain during the day	OR=0.39 [0.19; 0.79]
Biotherapy/Neither biotherapy nor DMARD	OR=0.28 [0.12; 0.67]
Biotherapy + DMARD/Neither biotherapy nor DMARD	OR=0.15 [0.04; 0.55]

Table 2. multivariate analysis, patients with Pso without known PsA compared with patients with puPsA

Covariates ($p<0.05$ for all OR)	OR [95% CI]
Current nail changes	OR=1.53 [1.02 ; 2.29]
Current fatigue	OR=2.53 [1.72 ; 3.72]
Other current symptoms	OR=0.33 [0.18 ; 0.60]
Hydration	OR=1.48 [1.01 ; 2.18]

Conclusions: That survey on Pso patients showed that a fourth of them also had PsA, but more importantly that about another fourth had puPsA, highlighting the underdiagnosis of PsA. It suggests that presence of fatigue and nail changes might raise suspicion of PsA in Pso patients.

AB0782 PSORIATIC ARTHRITIS EARLY ULTRASONOGRAPHIC CHANGES IN PATIENTS WITH PSORIASIS AND NAIL PSORIASIS. A COMPARATIVE STUDY WITH SUBJECTS WITHOUT PSORIASIS

P. Rodriguez Henriquez[1], M.L. Cardenas-Hernandez[2], L. Lammoglia-Ordiales[2], L.T. Becerril-Mendoza[3], R.M. Lacy-Niebla[2]. *[1]Rheumatology; [2]Dermatology, Hospital General Dr. Manuel Gea González; [3]Rheumatology, Hospital Juarez de Mexico, Mexico, Mexico*

Background: Psoriatic Arthritis (PsA) has a prevalence of 30% amongst Psoriasis (Ps)patients. However in patients with ungueal Ps the prevalence has been reported in up to 68% of cases. In muskuloskeletal ultrasound (MSUS) studies the lesion most frequently reported is enthesitis followed by synovitis in early PsA patients.
Objectives: To determine the presence of psoriatic arthritis early ultrasonographic changes in patients with psoriasis, nail psoriasis, and subjects without psoriasis.
Methods: Analytic, comparative, prospective and transversal study, in which patients with psoriasis, nail psoriasis, and subjects without psoriasis paired by age, were recruited. Each group underwent a skin and joint checkup, which included demographic data, comorbidities, psoriasis severity and joint signs and symptoms. The ultrasonographic evaluation consisted in a gray scale detection and classification according to severity scales, of synovitis, enthesitis, synovial effusion and bone erosions in the distal interphalangeal joints of both hands.
Results: A total of 16 patients, 8 with psoriasis and 8 with nail psoriasis, as well as 9 subjects without psoriasis, were recruited. The psoriasis group included mostly men (87.5%), unlike the subjects without psoriasis (44.4%) and the nail psoriasis group (37.5%) (p=0.09). The mean age for the study population was 55.16 + 8.09 years. There was no statistical significance between groups (p=0.430). The greatest prevalence of comorbidities was found in both groups with psoriasis. The mean time of disease duration in the nail psoriasis group was 20.12 + 14.54 years, vs 13.37 + 14.45 years in the psoriasis group (p=0.247). Synovitis was found in 100% of patients in the psoriasis group, vs 37.5% in the nail psoriasis group, and 62.5% in the subjects without psoriasis group (p=0.028). No enthesitis was observed in any group

Prevalence of synovitis

	Synovitis	Grade 1	Grade 2	Grade 3
Control group	62.5 %	12.5 %	37.5 %	12.5 %
Ungueal Psoriasis	37.5 %	62.5 %	25 %	12.5 %
Psoriasis	100 %	25 %	50 %	12.5 %

Chi-square test for synovitis between groups p= 0.28.
Chi-square test for synovitis grading p=0.269

Conclusions: Synovitis was more frequent than enthesitis in our population as an ultrasonographic finding of psoriatic arthritis. No association was found between other variables with synovitis, such as age, sex, disease duration and comorbidities.

AB0783 THE RELATIONSHIP BETWEEN THE DEGREE OF SKIN INVOLVEMENT AND JOINT ACTIVITY IN PATIENTS WITH PSA: EXPERIENCE FROM THE CORRONA REGISTRY

P.J. Mease[1], C.J. Etzel[2,3], J.R. Lisse[4], A.W. Armstrong[5], W.J. Huster[4], S. Rebello[2], R. Dodge[2], T. Muram[4], S. Al Sawah-Folian[4], M.J. Murage[4], J.D. Greenberg[2,6], W. Malatestinic[4]. *[1]Swedish Medical Center, University of Washington School of Medicine, Seattle; [2]Corrona, LLC, Southborough; [3]UT MD Anderson, Houston; [4]Eli Lilly and Company, Indianapolis; [5]University of Southern California, Los Angeles; [6]NYU School of Medicine, New York, United States*

Background: Prior studies have shown inconsistent relationships between skin and joint symptoms in patients with comorbid psoriasis (PsO) and psoriatic arthritis (PsA)[1–3].
Objectives: To characterize the relationship between skin severity and joint activity in patients with comorbid PsA and PsO at enrollment.
Methods: Data from the U.S. Corrona PsA/spondyloarthritis (PsA/SpA) registry were obtained from the period 3/21/2013– 9/30/2016. Inclusion criteria included a diagnosis of PsA, a history of PsO, and age greater than 18 years. PsA patients were evaluated for skin severity as defined by Body Surface Area (BSA) and joint activity as defined by the level of clinical disease activity index (CDAI). Patient characteristics, including current and prior PsA medication use, were obtained during the enrollment visit. We evaluated the relationship of skin severity (BSA) and joint activity (CDAI) with multi-variable linear regression.
Results: 1,542 patients met inclusion criteria: 52.9% were women with mean (SD) age 53.7 (13.2) years, with median 9.0 years PsA disease duration, and 71 (4.6%) with fibromyalgia. 266 (18%) patients were on no DMARD therapy, 430 (29%)

were on csDMARDs only, 616 (42%) were on first line biologic/targeted synthetic (ts)DMARD therapy, and 172 (12%) were on second line biologic/tsDMARD therapy. The relationship between skin severity and joint activity was statistically significant ($p<0.0001$) with a correlation of 0.183. Results were similar when adjusting separately for treatment and for duration of PsA and PsO. Greater age, female gender, higher dactylitis count, not achievement of MDA, higher HAQ, and patient reported pain and fatigue affected the relationship.

Conclusions: The relationship between skin severity and joint activity is statistically significant and varies by age, gender, MDA, HAQ, and patient reported pain and fatigue. This suggests degree of skin involvement is important to take into account when evaluating PsA patients.

AB0784 EFFECTIVENESS OF ANTI-TNFS ON DACTYLITIS AND ENTHESITIS IN PATIENTS WITH PSORIATIC ARTHRITIS: RESULTS FROM THE CORRONA PSORIATIC ARTHRITIS/SPONDYLOARTHRITIS REGISTRY

P.J. Mease[1,2], R. Singh[3], K. Douglas[3], D. Hua[4], H.J. Litman[4], C. Karki[4], J. Griffith[3]. *[1]Swedish Medical Center; [2]University of Washington, Seattle; [3]AbbVie, Inc., Abbott Park; [4]Corrona, LLC, Southborough, United States*

Background: Dactylitis and enthesitis are common disease manifestations encountered in nearly 10–30% of patients with psoriatic arthritis (PsA). Previous clinical trial data suggests that anti-tumor necrosis factors (aTNFs) are effective in controlling dactylitis and enthesitis among PsA patients, however there are limited data from real world studies.

Objectives: To evaluate the effectiveness of aTNFs on dactylitis and enthesitis in patients with PsA enrolled in Corrona, a large US observational cohort of patients with PsA and spondyloarthritis.

Methods: Adult PsA patients who initiated or were currently on an aTNF at registry enrollment (baseline) between 3/2013–9/2016 and had a 12 month follow-up visit were included. Dactylitis was defined as a non-zero total dactylitis score on a scale 0–20 and enthesitis was defined by a non-zero score on the SPARCC enthesitis index, 0–16. The primary outcome was change in dactylitis and enthesitis scores at 12 months from baseline. Descriptive analysis of patient characteristics at baseline was examined and change in outcomes was evaluated using t-tests.

Results: There were 28 patients with dactylitis and 77 patients with enthesitis who met the inclusion criteria. Patients with dactylitis and enthesitis had a mean (SD): age of 48.2 (14.8) and 53.5 (11.5) years, body mass index of 30.8 (6.6) and 31.4 (7.6), disease duration of 9.3 (9.1) and 8.1 (7.7) years, and 28.6% and 45.5% were on methotrexate combination therapy respectively. Patients had a mean clinical disease activity index of 15.1 in both groups, 40.0% and 17.1% were in minimal disease activity, mean (SD): body surface area was 4.4 (4.4) and 5.2 (9.7), pain was 33.1 (29.5) and 43.3 (27.5) on a visual analogue scale (VAS) of 0–100, and more than 80% and 90% of patients had some morning stiffness in the dactylitis and enthesitis groups, respectively. At 12 months from baseline, there were significant improvements in both dactylitis and enthesitis scores in patients with PsA treated with aTNFs (Table).

Table: Primary outcomes in PsA patients on aTNFs at 12 months from baseline

	At enrollment	At 12 month visit	Change in score (enrollment – 12 month visit	p-value*
Dactylitis Count (0-20)	n=28	n=28	n=28	
Mean (± SD)	2.1 (±1.5)	0.5 (±1.1)	-1.6 (±1.8)	0.001
SPARCC Enthesitis Count (0-16)	n=77	n=77	n=77	
Mean (± SD)	4.1 (±3.2)	1.9 (±2.8)	-2.2 (±3.2)	<0.001

SPARCC: Spondyloarthritis Research Consortium of Canada; *Calculated based on a t test assessing whether the change in counts differs from 0.

Conclusions: In this clinical registry, aTNF therapy significantly improved both dactylitis and enthesitis at 12 months. Further evaluation of secondary outcomes and larger studies with comparator cohorts will further validate the effectiveness of aTNFs in improving the outcomes in PsA patients.

*Includes all patients who received APR during the time interval relative to the start of APR treatment. §Motor vehicle accident on Day 489. ‡Cerebrovascular accident on Day 1330 in a 69-year-old man, considered unrelated to study drug; patient had history of myocardial infarction, atrial fibrillation, and cerebrovascular accident. ‖Stroke on Day 1224 in a 58-year-old woman, considered unrelated to study drug; patient had a history of chronic ischemic heart disease, hypertension, alcoholism, and atrial fibrillation. APR30=apremilast 30 mg BID; AE=adverse event; n/m=number of patients with ≥1 occurrence of the abnormality at any time point/number of patients with ≥1 post-baseline value; ULN=upper limit of normal.

to APR30 or APR20 at Week 16 (early escape) or Week 24. Double-blind APR treatment continued to Week 52; patients could continue APR during an open-label, long-term treatment phase for up to 5 years treatment. Visits in years 2, 3, and 4 were scheduled at 13-week intervals. Safety was assessed at each visit throughout the study, and results are summarized here by exposure.

Results: A total of 1493 patients were randomized and received ≥1 dose of study medication (PBO: n=495; APR30: n=497; APR20: n=501). At the 4-year data cut, the numbers of patients receiving APR30 and APR20 in each exposure period were 1441 in Weeks 0 to ≤52, 1028 in Weeks >52 to ≤104, 865 in Weeks >104 to ≤156, and 767 in Weeks >156 to ≤208. During the 0- to ≤52-week APR-exposure period, adverse events (AEs) occurring in ≥5% of APR30-exposed patients were diarrhea, nausea, headache, upper respiratory tract infection, and nasopharyngitis (Table). Most diarrhea and nausea AEs were reported within the first 2 weeks of treatment and usually resolved within 4 weeks; the frequency of gastrointestinal AEs decreased with longer APR30 exposure, and the frequency of other common AEs either decreased or remained stable with prolonged exposure (Table). Most AEs were mild/moderate in severity. During Weeks >156 to ≤208 of APR exposure, the discontinuation rate due to AEs was 1.7% with APR30, and the rate of serious AEs (SAEs) was 7.0%, consistent with earlier periods; most SAEs occurred in 1 patient each. Rates were very low for major cardiac events, malignant neoplasms, and serious opportunistic infections, comparable to the first year of treatment. Rates of depression remained very low in Weeks >156 to ≤208. Marked laboratory abnormalities were infrequent, and most returned to baseline with continued treatment.

Conclusions: APR30 demonstrated a favorable safety profile and was well tolerated for up to 208 weeks, marked by the lack of accumulation of immunosuppression or need for specific laboratory monitoring. The incidence of AEs remained stable or decreased with long-term exposure to APR30.

AB0786 SYSTEMATIC REVIEW OF MEASUREMENT PROPERTIES OF PATIENT REPORTED OUTCOME MEASURES IN PSORIATIC ARTHRITIS: A GRAPPA-OMERACT INITIATIVE

P. Højgaard[1,2], L. Klokker[1], A.-M. Orbai[2], K. Holmsted[1], E.M. Bartels[1], Y.Y. Leung[2], N. Goel[2], M. de Wit[2], D. Gladman[2], P. Mease[2], L. Dreyer[1], L.E. Kristensen[1], O. FitzGerald[2], W. Tillett[2], L. Gossec[2], P. Helliwell[2], V. Strand[2], A. Ogdie[2], C. Terwee[2], R. Christensen[1,2] on behalf of GRAPPA-OMERACT PsA Core Set Working Group. *[1]The Parker Institute, Frederiksberg and Bisbebjerg Hospital, Copenhagen, Denmark, Frederiksberg, Denmark; [2]GRAPPA-OMERACT PsA Core Set Working Group, International organisation, -*

Background: An updated psoriatic arthritis (PsA) core domain set (COS) for randomized controlled trials (RCTs) was endorsed at the Outcome Measures in Rheumatology (OMERACT) meeting in 2016 and reflects the patient and physician perspectives.[1]

Objectives: To synthesise the evidence on measurement properties of Patient Reported Outcome Measures (PROMs) in PsA in order to contribute to the development of a PsA core outcome measurement set (COMS) for RCTs adhering to the OMERACT filter 2.0 Framework.[2]

Methods: A systematic literature search was performed in EMBASE, MEDLINE and PsycINFO to identify studies published in English on PROM measurement properties in PsA. Two independent reviewers rated the quality of studies according to COnsensus-based Standards for the selection of health Measurement INstruments (COSMIN) guidelines,[3] extracted data on measurement properties and performed a qualitative evidence synthesis.

Results: Of 4703 identified references, 162 were read in full-text and 44 included in the systematic review (SR). Thirty-nine instruments, consisting of one or more scales, were analysed. PROMs measuring core set domains with at least fair quality evidence for good validity and reliability (and without evidence for inadequate measurement properties) were: Stockerau Activity Score for PsA (German) for the *Musculoskeletal Disease Activity* domain; the Psoriatic Symptom Inventory for *Skin Disease Activity*; the 36-Item Short Form Health Survey Physical Function scale and to a lesser extent the Health Assessment Questionnaire Disability Index and Bath Ankylosing Spondylitis Functional Index for *Physical Function*; the Psoriatic Arthritis Quality of Life Questionnaire, the Psoriatic Arthritis Impact of Disease questionnaire and VITACORA-19 (Spanish) for *Health related Quality of Life/Life Impact;* the Functional Assessment of Chronic Illness Therapy-Fatigue Scale for *Fatigue*, and the Social Role Participation Questionnaire for *Participation*. Evidence for content validity was lacking for most of these PROMs.

Conclusions: At least one PROM with some evidence for good validity and reliability was available for five out of eight inner circle domains of the PsA COS. Lack of content validity evidence constitutes a critical barrier for application to the PsA COS per the OMERACT Filter 2.0 Instrument Selection Algorithm [2]. This SR serves as a guide for additional research to increase knowledge of PROM measurement properties in PsA followed by stakeholder consensus for developing a PsA COMS.

AB0787 STUDY OF SERUM SCLEROSTIN LEVELS IN ASSOCIATION TO ENTHESIAL ULTRASONOGRAPHY IN EGYPTIAN PSORIATIC ARTHRITIS PATIENTS

R. Elmallah[1], E. EL Attar[1], D. Farrag[1], D. Samaha[2] on behalf of responsible for part of clinical measuring of sclerostin level. *[1]Rheumatology & Rehabilitation; [2]Clinical & Chemical Pathology, Faculty of Medicine Ainshams University, Cairo, Egypt*

Background: Psoriatic arthritis (PsA) is characterized by focal bone erosions and new bone formation, suggesting an uncoupling of osteoblast–osteoclast homeostasis [1]. Serum sclerostin is a protein inhibitor of wnt signaling pathway of bone formation implicated in the suppression of bone repair in inflammatory arthritis. The role of sclerostin in osteoimmunology and inflammatory arthritides is still controversial [2].

Objectives: This study aimed at measuring serum sclerostin in psoriatic arthritis men and to correlate its levels with disease activity scores, ultrasonographic findings and bone mineral density in those patients

Methods: This study included 30 male patients diagnosed with Psoriatic arthritis (PsA), 15 healthy age and sex matched volunteers as control group. Patients disease activity index measured. Clinical assessment by Leed's enthesitis Index (LEI) [3], Spinal manifestations scored according to Bath Ankylosing Spondylitis Activity Index [4], Serum sclerostin measured using enzyme linked immunosorbent assay. Ultrasonography of enthesis at Leeds enthesitis sites [5] and dual energy x-ray absorbiometry (DEXA) at the lumbar spine.

Results: The study included 30 PsA male patients with a mean age of 43.33±8.33 mean, body mass index (BMI) of 26.87±2.63 and 15 healthy age and sex matched

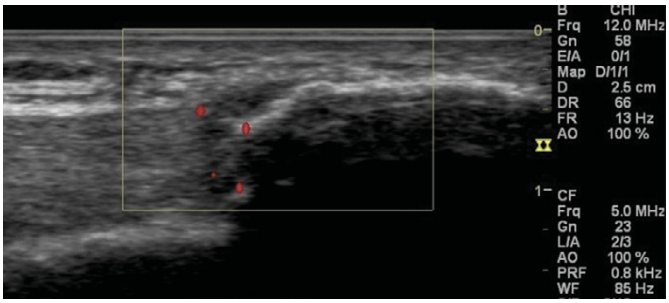

Figure 1. Ultrasonographic longitudinal scan of the tendoachillis showing hypoechoic area of edema & power Doppler signal at insertion.

controls with a mean age of 42.12±7.22 mean BMI of 25.87±3.51 with an unsignificant difference between two groups.
Serum sclerostin level significantly higher in PsA patients compared to controls with a mean of (0.64 and 0.37ng/ml) respectively, positive significant correlation with patients' age, disease activity scores, ultrasonographic findings of inflammation and damage at the enthesis as well as negative correlation with DEXA at lumbar spine. A positive though non-significant correlation detected between serum sclerostin and Leeds clinical enthesitis index (LEI) and CRP.
Conclusions: sclerostin plays important role in pathogenesis of psoriatic arthritis and associated with bone damage either systemic or localized. Further studies for the effect of treatment on serum sclerostin, ultrasonographic and bone mineral density findings is recommended

AB0788 DIFFERENCES IN THE PHENOTYPIC EXPRESSION OF RECENT ONSET PSORIATIC ARTHRITIS AMONG MEN AND WOMEN: BASELINE DATA FROM THE REAPSER STUDY

R. Queiro, A. Laiz Alonso, H.S. Park, C. Montilla Morales, E. Galíndez Agirregoikoa, J.J. Bethencourt Baute, S. Bustabad Reyes, P. Tejón Menéndez, M.Á. Belmonte, J.A. Pinto Tasende, E. Alonso Blanco Morales, J. Ramír. *Rheumatology, Hospital Universitario Central de Asturias (Coordinating Center), Oviedo, Spain*

Background: The natural history of psoriatic arthritis (PsA) according to gender of patients is an aspect of the disease only partially studied. In prospective PsA cohorts such information is barely known.
Objectives: To analyze baseline gender differences in the REAPSER cohort (Psoriatic Arthritis Registry of the Spanish Society of Rheumatology).
Methods: Observational, multicenter study (34 centers), with consecutive inclusion. We included adults of both sexes 18 years of age or older with PsA that met CASPAR criteria, and duration of less than two years since the appearance of symptoms attributed to PsA. Annual follow-up visits will be carried out for 5 years. Measurements: socio-demographic data; employment status and impact of the disease; family history of PsA and other inflammatory diseases; comorbidities and treatment; lifestyle; use of health services; clinical status at the time of diagnosis of PsA; anthropometric data; clinical evaluation of PsA manifestations; radiographic evaluation; analytical determinations; treatment of PsA. The study has been approved by the Ethical committees of the participating centers. Comparative statistical analysis: for qualitative variables, the χ-square or the Fisher exact statistic were used. For non-normal quantitative variables, non-parametric tests were used and for normal quantitative variables, Student's t-test was used.

Parameter	Men (N=142)	Women (N=68)	P values
Age (years)	50.2 (13.8)	49.6 (14.1)	NS
University studies	18.3%	16.2%	NS
Active worker	65%	49.3%	<0.001
BMI	27.3 (4.8)	28.5 (6)	NS
Waist-hip index	0.94 (0.1)	0.87 (0.1)	<0.001
Smoker	29.6%	32.4%	NS
Alcohol consumption	45.1%	16.2%	<0.001
Psoriasis family history	40.1%	45.6%	NS
PsA family history	8.5%	10.3%	NS
Charlson's CI (>3)	18.3%	17.6%	NS
Depression	7.7%	19.4%	0.014
Common Psoriasis	81%	61.8%	0.003
Pustular Psoriasis	2.1%	11.8%	0.006
Onicopathy	59%	49%	NS
PASI	1.5 (0.6–4.4)	1.2 (0.6–3)	NS
Peripheral pattern	80.3%	83.8%	NS
Axial pattern	7%	1.5%	NS
Mixed Pattern	12.7%	14.7%	NS
BASDAI (0–10)	4.1 (2.2–6)	4.8 (2.4–7.3)	0.008
BASFI (0–10)	1.8 (0.4–4.5)	2.9 (1.4–4.7)	0.065
Dactylitis	31.4%	47.1%	0.028
Pain (0–10)	4.5 (2–7)	6 (4–7.5)	0.021
PGA (0–10)	5 (3–7)	6 (3.5–8)	0.042
ESR (mm/h)	12 (5–20)	21 (10–29.5)	0.001

CI: comorbidity index. PASI: Psoriasis Area and Severity Index. PGA: Patient's Global Assessment. Data are expressed in percentages, means with SD (Standard Deviation), medians and IQR (Interquartile Range). There were no significant differences in SJC, TJC or PsAID (Psoriatic Arthritis Impact of Disease).

Results: The results are expressed in the table.
Conclusions: The baseline data from this prospective cohort point to significant differences in the phenotypic expression of PsA between men and women. Thus, in women, the prevalence of dactylitis and pustular psoriasis was higher, there were higher rates of depression and a perception of higher disease activity. Women scored higher on the pain linked to their arthritis and the activity of axial disease. They also had biological activity parameters (ESR) higher than that of men. It is necessary to determine if these differences are maintained or change over time.

AB0789 THE PSORIATIC ARTHRITIS PATIENT'S JOURNEY: SPECIAL EMPHASIS ON DIAGNOSIS AND TREATMENT DELAYS

S. Moyano, M. Brom, F.B. Mollerach, L.E. Pompermayer, M.L. Acosta Felquer, M. Scolnik, J. Marin, L.G. Ferreyra Garrott, L.J. Catoggio, J.E. Rosa, E.R. Soriano. *Rheumatology, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina*

Background: A delay in diagnosis and treatment of Psoriatic Arthritis (PsA) is associated with increased disability and damage in the long term. There is currently scarce data available about diagnosis delay, referrals delays, and time to first treatment in patients with PsA in developing countries.
Objectives: To describe the journey of patients with psoriatic arthritis, with special emphasis on diagnosis and treatment delays.
Methods: All patients with PsA registered in the Rheumatology Unit data base (between 2000–2016), with complete data, were included. Electronic medical records were manually revised, and the following data were obtained: date of first visit to a Dermatologists due to Psoriasis (PsO) symptoms, date of PsO diagnosis, date and type of first musculoskeletal symptom, specialty of physician seen at first visit for musculoskeletal symptoms, date of PsA diagnosis, date and reason for prescription of first Disease Modifying anti-Rheumatic Drug (DMARD). Primary outcome variable was mean lag time between first musculoskeletal symptom and diagnosis of PsA. Other variables calculated were: mean lag time between first musculoskeletal symptom and first physician encounter because of those symptoms, mean lag time to first DMARD and mean lag time between PsO diagnosis and PsA diagnosis. Variables associated with a delay in PsA diagnosis (more than one year delay) were analyzed in multivariable analysis (logistic regression).
Results: 93 patients were included, mean age 60.8 years (SD: 15.3), 61% males. Mean age at time of PsA diagnosis was 52 years (SD: 14.8). The most common musculoskeletal symptom was arthralgia (46%), followed by arthritis (37%), enthesitis (6%), low back pain (6%), and dactylitis (4%). Mean lag time between first musculoskeletal symptoms and visit to a physician because of those symptoms was 16,8 months (SD: 44,4) (median: 1,92 (IQR: 0,35–11,6). In Only 33% of the cases the first specialist seen was a Rheumatologist. Mean lag time between first musculoskeletal symptom and diagnosis of PsA was 19,2 (SD: 28,8) months (Median: 7,2 (IQR: 2,4–21,6 months). In 90 patients (97%), the diagnosis of PsO preceded the diagnosis of PsA, a mean time of 15.1 years (SD: 14.4). 83 patients (89%) received traditional DMARDs, 82% because of the musculoskeletal symptoms, with a mean lag time between PsA diagnosis and initiation of DMARDs of 11,4 months (SD: 31,2) (Median: 0,48 (IQR: 0–4,3) months). Forty-three patients (46.2%) had a delay on PsA diagnosis equal or greater than 1 year. In logistic regression analysis, including age, sex, first specialist seen and type of musculoskeletal symptom, none was independently associated with a delay equal or greater than 1 year in PsA diagnosis.
Conclusions: Mean time between symptoms' onset and PsA diagnosis was relatively short. However, a delay greater that one year was observed in almost half of patients. As none of the variables studied was associated with a delay in diagnosis, more studies are needed to identify potential actions that would help reducing this delay.

AB0790 HYPERURICEMIA IN PSORIATIC ARTHRITIS: PREVALENCE AND ASSOCIATED FACTORS

T. Gudu, A. Peltea, A. Balanescu, V. Bojinca, D. Opris, D. Predeteanu, R. Ionescu. *Rheumatology, Sf Maria Hospital, UMF Carol Davila, Bucharest, Bucharest, Romania*

Background: Hyperuricemia is frequent in psoriatic arthritis (PsA) and it seems to be related to metabolic syndrome rather than to extensive psoriatic skin disease [1].

Objectives: The objective of this study was to evaluate the prevalence of hyperuricemia in PsA patients and to identify the associated factors.
Methods: Design: cross-sectional study, including consecutive, unselected, adult PsA patients. Data collection: demographic variables (age, gender, disease duration), clinical variables (affected joints, current moderate/severe psoriasis, nail disease, axial involvement, enthesitis, dactylitis), biological factors (acute phase reactants), treatment-related variables (non-steroidal antiinflamatory drugs, corticosteroids, synthetic and biologic disease modifying drugs) and comorbidities [2]. Hyperuricemia was defined as uric acid level above 6.8 mg/dl [3]. Statistical analysis: the factors that were potentially associated with hyperuricemia were assessed by Spearman correlation and uni- and multivariate logistic regressions.
Results: In all, 120 PsA patients were included in the study: 69 (57.5%) women, mean age±standard deviation 54±11.8 years, mean disease duration 7±7.4 years; 24 (20%) had moderate/severe psoriasis and 30 (25%) were taking a biologic. A high percentage of patients had cardiovascular comorbidities, i.e., dyslipidemia 80%, hypertension 51.7%, obesity 34.2% and cardiovascular events 34.2%. Around a quarter of patients had hyperuricemia (33; 27.5%). Hyperuricemia was significantly associated with obesity, diabetes, ischemic heart disease and hypertension, but there was no correlation with current skin psoriasis. In the multivariate analysis, it was best explained by diabetes (odds ratio: 4.95, [95% confidence intervals: 1.47; 16.67]), ischemic heart disease (3.61 [1.00; 12.98]) and obesity (1.86 [1.04; 3.32]).
Conclusions: Hyperuricemia in PsA is associated with metabolic syndrome rather than skin psoriasis, but further longitudinal studies are needed to identify causal relationships.

AB0791 HIGH PREVALENCE OF METABOLIC DISORDERS AND OBESITY IN PSORIATIC ARTHRITIS COMPARED TO PSORIASIS ALONE: A RETROSPECTIVE DERMATOLOGICAL CLINIC-BASED STUDY

N. Batkaeva[1], T. Korotaeva[2], E. Batkaev[1]. [1]*Department of dermatology, RUDN University;* [2]*V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: An association between increased adiposity, obesity (Obs), and psoriasis has emerged. In addition to obesity, patients with psoriasis are more likely to have metabolic syndrome.
Objectives: to evaluate the prevalence of endocrine diseases, nutritional and metabolic disorder (ENMD) comorbidity in patients (pts) with PsA and Psoriasis (PsO) patients without arthritis in the dermatological hospital cohort.
Methods: 889 pts (Male-516/Female-329) with moderate-to-severy plaque PsO, mean age 50.4±17.6 years, mean PsO duration 21.5±14.7 were included. PsO pts with Endocrine, nutritional and metabolic diseases (E00-E90) (ENMD), including Disorders of thyroid gland (E00–E07), Obesity and other hyperalimentation (E65-E68), Diabetes mellitus (E10-E14) (DM) were identify in the hospital Database reporting and coding by International Statistical Classification of Disease and Related Health Problems (ICD-10) between 2010 - 2015 years. M±m, t-test, χ^2, (%) were calculated. All $p<0.05$ were considered to indicate statistical significance.
Results: 302 out of 889 pts (33.9%) had PsA and 587 out of 889 pts (66.1%) had PsO alone. PsA pts were older then PsO pts – 55.3±13.7 and 50.4±17.6 ($p<0.001$). 155 out of 889 pts (17.4%) had ENMD. In PsA pts ENMD were found in significantly more cases than in PsO pts – in 76 out of 302 pts (25.2%) and in 79 out of 587 pts (13.5%) accordingly (χ^2=18.986, df=2, $p<0.00001$). In PsA pts ENMD coding as E00–E07 were found in significantly more cases than in PsO pts – in 25 out of 302 pts (8.3%) and in 23 out of 587 pts (3.9%) accordingly (χ^2=7.4211, df=2, p=0.00645). Obs coding as E65-E68 were found in significantly more cases in PsA pts compare to PsO pts - in 54 out of 302 pts (17.9%) and in 64 out of 587 pts (10.9%) accordingly (χ^2=8.4345, df=2, p=0.00368).
DM coding as E10-E14 were found in more cases in PsA pts compare to PsO pts - in 54 out of 302 pts (17.9%) and in 83 out of 587 pts (14.1%) accordingly (χ^2=2.1410, df=2, p=0.14341).
Conclusions: ENMD comorbidities are common for PsA and PsO without arthritis pts. Obs and disorders of thyroid gland were found in significantly more cases in PsA pts compare to PsO pts. Obesity and PsA are an unhealthy combination. Obesity may represent an additive cardio-metabolic risk factor in PsA subjects. High frequency of ENMD in PsA than PsO could be due to share inflammation pathways with insulin resistance and age. Patients with more severe psoriasis are at higher odds of endocrine, nutritional and metabolic diseases compared with those with mild psoriasis.

AB0792 CURRENT STATUS AND UNMET NEEDS IN THE MANAGEMENT OF PSORIATIC ARTHRITIS WITH CONVENTIONAL SYNTHETIC AND BIOLOGICAL DISEASE MODIFYING ANTI-RHEUMATIC DRUGS: TAIWANESE NATIONWIDE PHYSICIANS' PERSPECTIVES

T.-H. Li[1], C.-C. Lai[2], C.-Y.T. Tsai[2]. [1]*Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Chiayi Branch, Taichung Veteran General Hospital, Chiayi City;* [2]*Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taipei Veteran General Hospital, Taipei City, Taiwan, Province of China*

Background: Psoriatic arthritis (PsA) contributes to enormous burden of disease and thus early correct diagnosis and adequate therapeutic management are essential for physicians in practice; however, There have been several studies highlighting the inadequate diagnosis and suboptimal therapies for PsA worldwide and physicians generally report difficulties in managing psoriasis.
Objectives: To analyze the real-world clinical practice of PsA in Taiwan, and assess physicians' adopted methods and difficulties of diagnosis, therapeutic consideration and strategy, in addition to rationales for biologic agents and unmet needs.
Methods: A nationwide cross-sectional observational study in Taiwan was conducted by means of the face-to-face in depth interviews with the 80 physicians, composed of 50 rheumatologists and 30 dermatologists, from November 2014 to January 2015.
Results: The major adopted diagnostic examinations for PsA are arthritis performance, psoriasis and nail dystrophy, roentgenological studies, personal and family history; however, more dermatologists rely on RF for initial diagnosis ($p<0.05$). The difficulties for diagnosis, considerations on therapeutic management and current prescription were reported and displayed some interdisciplinary difference. Rationales for biological agent selection were investigated and physicians generally favored etanercept in terms of milder symptoms or more conservative treatment. The main unmet needs for current biologic therapies for PsA included the aspects of better efficacy, safety, sustainability and oral administration.
Conclusions: The nationwide study is the first survey for real-world clinical practice of PsA in Asia and provides detailed messages about the diagnostic difficulties and therapeutic consideration, especially rationales and unmet needs on current biologic therapies, which may offer possible directions for new drug development. We also made interdisciplinary comparison, hence in order to improve comprehensive care.

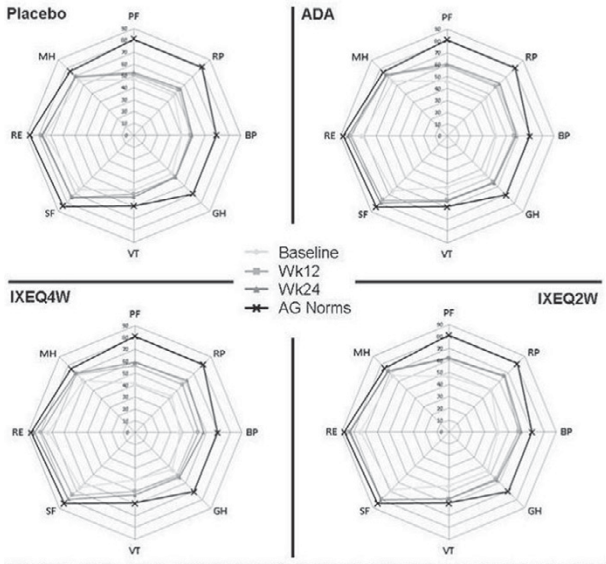
AB0793 EFFICACY OF IXEKIZUMAB IMPROVING SF-36 SCORES IN BIOLOGIC DMARD-NAIVE PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: RESULTS FROM A PHASE 3 STUDY (SPIRIT-P1)

V. Strand[1], A.B. Gottlieb[2], T.K. Kvien[3], A. Naegeli[4], C.-Y. Lin[4], O. Benichou[4], J. Birt[4]. [1]*Stanford University School of Medicine, Palo Alto;* [2]*New York Medical College, Valhalla, United States;* [3]*Diakonhjemmet Hospital, Oslo, Norway;* [4]*Eli Lilly and Company, Indianapolis, United States*

Background: In a phase 3 randomized controlled trial (RCT), ixekizumab (IXE), a high affinity mAb that selectively targets interleukin-17A, significantly improved signs and symptoms of psoriatic arthritis (PSA)and health status vs placebo (PBO)[1].
Objectives: To evaluate the efficacy of IXE improving patient (pt)-reported health status, assessed by Short Form Survey (SF-36) physical and mental component summary (PCS and MCS) and domain scores in pts with active PSA vs PBO, compared with age-and gender (A/G)-matched population normative scores[2].
Methods: In phase 3 RCT (SPIRIT-P1; NCT01695239), bDMARD-naive pts with active PSA (N=417) randomly received IXE 80 mg either once every 4 Wks (Q4W) or 2 Wks (Q2W) after a 160 mg starting dose, or 40 mg adalimumab (ADA) Q2W, or PBO (all subcutaneous). Health status was assessed by SF-36 at baseline, Wk 12, and Wk 24. Treatment comparisons were by mixed model for repeated measures for continuous data and logistic regression for categorical data. Missing values were imputed by nonresponder imputation.
Results: Baseline SF-36 scores were similar across treatment groups. At Wk 24, significant improvements vs PBO were observed with ADA and IXEQ2W for PCS, and 5/8 domains (PF, RP, BP, GH, and RE), and with IXEQ4W for PCS and 6/8 domains (except VT and MH) (Figure) (post hoc for individual domains). In pts with baseline scores <A/G norms, significant improvements vs PBO were observed with ADA and IXEQ4W for PCS, MCS, and 5/8 domain scores (PF, RP,



BP, VT and RE) and with IXE Q2W for PCS, MCS, and 7/8 domains (except MH) (post hoc). Within the same subgroup, a greater percentage of pts in each of the 3 active groups reported SF-36 scores ≥normative values at Wk 24 vs PBO, with statistical significance for PCS, MCS, and majority of the individual domains (Table) (post hoc).

Table 1. Percentage of patients with SF-36 scores ≥normative values at week 24 (n) among the patients reporting SF-36 scores <normative values at baseline (N) (nonresponder imputation)

SF-36 Scores, n/N (%)	PBO	ADA	IXEQ4W	IXEQ2W
Physical Component Summary	4/101 (4.0)	20/93 (21.5†)	12/98 (12.2*)	19/95 (20.0**)
Mental Component Summary	10/53 (18.9)	21/52 (40.4*)	21/58 (36.2*)	21/55 (38.2*)
Physical Functioning Domain	5/94 (5.3)	22/91 (24.2†)	14/97 (14.4*)	19/87 (21.8**)
Role Physical Domain	5/98 (5.1)	19/91 (20.9**)	16/93 (17.2*)	19/86 (22.1**)
Bodily Pain Domain	12/95 (12.6)	28/87 (32.2**)	27/96 (28.1*)	28/93 (30.1**)
General Health Domain	8/97 (8.2)	14/88 (15.9)	16/92 (17.4)	21/91 (23.1*)

AB0794 **EFFECT OF TOFACITINIB ON PATIENT-REPORTED OUTCOMES IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: RESULTS FROM TWO PHASE 3 STUDIES**

V. Strand[1], K. de Vlam[2], J.A. Covarrubias-Cobos[3], P.J. Mease[4], D.D. Gladman[5], T. Hendrikx[6], E. Kudlacz[7], D. Graham[7], J. Wu[7], L. Chen[8].

Background: Tofacitinib is an oral Janus kinase inhibitor under investigation for treatment of psoriatic arthritis (PsA). The safety and efficacy of tofacitinib for the treatment of PsA has been investigated in two Phase 3 randomised controlled trials (RCTs: OPAL Broaden [12 months; NCT01877668]; OPAL Beyond [6 months; NCT01882439]).

Objectives: To evaluate patient-reported outcomes (PROs) in patients (pts) with active PsA enrolled in OPAL Broaden (N=422) and OPAL Beyond (N=394). OPAL Broaden pts had an inadequate response (IR) to ≥1 conventional synthetic disease-modifying antirheumatic drug and were naïve to tumour necrosis factor inhibitors (TNFi) whilst OPAL Beyond pts had an IR to ≥1 TNFi.

Methods: Pts were randomised to tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID, placebo (PBO)→ tofacitinib 5 mg BID, PBO→ tofacitinib 10 mg BID and, in OPAL Broaden, also to adalimumab 40 mg subcutaneously every two weeks (active comparator). Pts receiving PBO advanced to either tofacitinib 5 mg BID or 10 mg BID at month 3 (M3) in both RCTs. Least squares mean changes from baseline in: Patient's Global Assessment of Arthritis (PtGA; Visual Analogue Scale [VAS]); Arthritis Pain (Pain; VAS); Short Form-36 Health Survey (SF-36); Functional Assessment of Chronic Illness Therapy–Fatigue (FACIT-F); Dermatology Life Quality Index (DLQI) and Ankylosing Spondylitis Quality of Life (ASQOL) questionnaires are reported. Nominal p values are reported without adjustments for multiple comparisons.

Results: Patients with active PsA in OPAL Broaden and OPAL Beyond RCTs receiving tofacitinib 5 mg and 10 mg BID reported improved PROs compared with PBO (Table 1). Greater improvements in PtGA and Arthritis Pain were observed as early as Week 2 through M3 with both tofacitinib doses compared with PBO in both studies (p≤0.05). Greater improvements were also reported in SF-36 Physical Component Summary, DLQI and ASQOL scores at M1 and M3 with both tofacitinib doses compared with PBO (p≤0.05). There were greater improvements in SF-36 physical functioning, bodily pain and vitality domains with both tofacitinib doses compared with PBO in both studies (p≤0.05) at M3. SF-36 social functioning domain showed greater improvement with tofacitinib 5 mg BID in OPAL Broaden and both tofacitinib doses in OPAL Beyond compared with PBO at M3 (p≤0.05). SF-36 role-physical domain showed greater improvement with tofacitinib 10 mg BID in OPAL Beyond at M3 compared with PBO (p≤0.05). FACIT-F showed a greater improvement in both studies at M3 with both tofacitinib doses compared with PBO (p≤0.05). In OPAL Broaden, improvements in PROs were similar between tofacitinib and adalimumab.

Osteoarthritis

AB0795 OSTEOARTHRITIS AND COMORBIDITY: ASSOCIATION BETWEEN MENTAL FEATURES AND CYTOKINES LEVELS

E. Trifonova, O. Sazonova, E. Zonova. *Novosibirsk State Medical University, Novosibirsk, Russian Federation*

Background: Studies of mental health in patients with osteoarthritis (OA) are topical at the present time. This applies especially to OA patients with such comorbidity as obesity, metabolic syndrome (MS) and type 2 diabetes mellitus (T2DM). Psychological features, quality of life (QoL) and depression degree also can be linked with immunopathogenesis of OA with obesity, MS, T2DM.

Objectives: To explore the mental health in knee OA patients with obesity, MS, T2DM and to estimate association between psychological and immunological features.

Methods: Patients (n=128) with bilateral knee OA according to ACR criteria were divided into four groups. Group 1 (n=17) had obesity, group 2 (n=17) had MS, group 3 (n=56) had T2DM and group 4 (n=38) had only knee OA without comorbidity. All patients were comparable by age, sex and duration of OA. We assessed serum cytokine levels (IL-1b, IL-6, IL-10, IL-18), NO and adipokines (adiponectin, leptin) using ELISA. The parameters of QoL, mental health and depression degree were measured by short form 36 (SF-36), Knee injury and Osteoarthritis Outcome Score – (KOOS) and with patient health questionnaire-9 (PHQ-9). We also studied coping strategies to overcome pain by Coping Strategy Questionnaire (CSQ). U-Mann-Whitney test was applied to detect differences between groups. Correlation was assessed using Spearman correlation coefficient (r_s).

Results: During comparative analysis, we found many statistically significant differences in such indexes and questionnaires as SF-36, KOOS, PHQ-9, CSQ between groups knee OA patients with comorbidity and group knee OA patients without concomitant diseases. Patients with OA and obesity were characterized by low values of mental health (SF-MH) (median (Me) 52; interquartile range (IQR) 38–64; p=0.01). Patients from group 2 (MS) and 3 (T2DM) had significant impairment of QoL parameters, mental health values. Patients of these groups also had the higher degree of depression and built coping strategies to overcome pain of OA worse than patients of OA group. Differences in serum cytokine levels were found in patients with OA and T2DM (IL-6 p=0.0018; IL-18 p=0.0006; NO p<0.001). Significant high leptin level had OA patients with obesity (p=0.03) and OA patients with T2DM (p=0.0002). Correlation analysis identified the association between mental health and cytokines in OA patients with obesity and OA patients with T2DM. Some data are presented (Table).

Table. Correlations between mental parameters and serum cytokine levels in studied groups.

Cytokines	OA patients with obesity n=17	OA patients with T2DM n=56		
	Social Functioning (SF36-SF)	Vitality (SF36- VT)	Social Functioning (SF36-SF)	Coping Strategy Questionnaire (CSQ)
IL-1ß (pg/ml)	-0.51	-0.06	0.08	-0.15
IL-6 (pg/ml)	**-0.89***	**-0.33***	**-0.27***	-0.03
IL-10 (pg/ml)	-0.75	-0.18	-0.09	**-0.41***
NO (pg/ml)	-0.39	0.10	0.14	0.11
Leptin (ng/ml)	-0.27	**-0.28***	-0.22	**0.43***

Table legend: * r - p<0.005;

Conclusions: This study suggests that OA patients with obesity, MS and T2DM have special mental features which may be linked with immunological parameters. This data should be verified by larger studies and can be the part for an integrated program of treatment and rehabilitation of OA patients with comorbidity.

AB0796 THE PREDICTIVE ROLE OF INTERLEIKINE 6 AND 10 IN IMPAIRMENT OF MENTAL HEALTH IN PATIENTS WITH KNEE OSTEOARTHRITIS AND UNCONTROLLED TYPE 2 DIABETES MELLITUS

E. Trifonova, O. Sazonova, E. Zonova. *Novosibirsk State Medical University, Novosibirsk, Russian Federation*

Background: The influence of different interleukins on development and progression of osteoarthritis (OA) has been proved. However, there is lack of data on relationship between mental health and immunological features in OA patient with type 2 diabetes mellitus (T2DM).

Objectives: To estimate the relationship between mental health and the proinflammatory serum cytokine levels in patients with knee OA and T2DM depending on glycemic control.

Methods: A study was performed on 45 persons who had bilateral knee OA according to the ACR criteria and T2DM. Then patients were divided into two groups according to the compensation degree T2DM taking into account parameters of glycated hemoglobin concentrations (HbA1c) which were assessed using liquid chromatography. Group 1 (n=26) had controlled T2DM. Group 2 (n=19) had uncontrolled T2DM. All patients were comparable by age, sex and duration of OA. Serum cytokine levels (IL-1b, IL-6, IL-10, IL-18), NO, and adypokines (adiponectin, leptin) using ELISA were measured. Blood glucose level was also estimated. The parameters of QoL, mental health, depression degree and coping strategies to overcome pain were measured by short form 36 (SF-36), Knee injury and Osteoarthritis Outcome Score – (KOOS) and with patient health questionnaire-9 (PHQ-9), Coping Strategy Questionnaire (CSQ). We used U-Mann-Whitney tests to detect differences between selected groups. Correlation was assessed using Spearman correlation coefficient (r_s).

Results: Patients with OA and uncontrolled T2DM had significant low values of role limitations due to emotional problems (SF-RE) (median (Me) 38; interquartile range (IQR) 25–52.3; p=0.02). Serum cytokines levels were not different between studied groups. Correlation analysis identified the relationships between parameters of mental health and serum cytokine levels in OA patients with uncontrolled T2DM. Certain data are presented (Table).

Table. Correlations between clinical parameters and serum cytokine levels in studied groups.

Cytokines	OA patients with uncontrolled T2DM n=19						
	Vitality (SF36-VT)	Social Functioning (SF36-SF)	Mental Health (SF36-MH)	Role Emotional (SF36-RE)	General Mental Health (SF36-MH)	Patient Health Questionnaire (PHQ-9)	Coping Strategy Questionnaire (CSQ)
IL-6 (pg/ml)	**-0.60***	**-0.62***	**-0.54***	-0.25	**-0.51***	**0.43***	-0.20
IL-10 (pg/ml)	**-0.48***	**-0.42***	**-0.64***	-0.25	**-0.56***	0.29	**-0.53***

Table legend: * r - p<0.005;

Conclusions: It follows from these results mental and immunology parameters of OA patients with uncontrolled T2DM can be linked. Such interleukins as IL-6 and IL-10 may play a role of potential biomarkers of mental impairment in this category of patients. These data should be verified by larger studies and may allow in future to develop programs of treatment and rehabilitation of OA patients with uncontrolled T2DM within personalized medicine.

AB0797 LONG TERM PROSPECTIVE MULTICENTER RANDOMIZED PLACEBO-CONTROLLED STUDY OF HYALURONIC ACID IN SMALL JOINTS OSTEOARTHRITIS (SJOA)

E. Tsvetkova[1], L. Denisov[1], E. Panasyuk[1], E. Nasonov[2]. *[1]Clinical Research laboratory; [2]Scientific Leader, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation*

Objectives: Assessment of the efficacy, tolerability and period of aftereffect of the single administration into 1st carpometacarpal and 1st metatarsophalangeal OA joints of 1.0 ml (20mg) of hyaluronic acid (Durolane) as compared with placebo.
Methods: The study included 120 pts with OA of small hand joints or feet, pain intensity >40 mm by VAS and consisted of two phases: "blind" phase up to 24 weeks, period of assessment of long term efficacy results – 48 weeks. The efficacy was assessed by 40% pain subsiding, index AUSCAN (for the hand), dose of NSAID, total effect assessment.
Results: Both groups were comparable by basic clinical criteria, 40% pain subsiding by VAS (mm) was noted in experimental group to 24th week in 79.7%, in the placebo group – 30% (chi-square: $p<10^{-5}$), relation of chances (OR) equal to 9.1 (3.9–21.1). Dispersion analysis of pain, stiffness and function of AUSCAN index revealed reliable differences between Durolane and placebo. Statistically significant difference ($p<0.0001$) according to assessment of general condition by the doctor and patient were found out in experimental group from the 4th week and were stable till 48th week. Adverse effects related to the therapy were not found. NSAID dose was decreased in 45.7% in experimental group and in 30% in placebo group.
Conclusions: efficacy and considerable duration of aftereffect of single administration of Durolane SJ (small joints) as compared with placebo was demonstrated in 24 and 48 weeks.

AB0798 AMTOLMETIN GUACIL-EFFECTIVE AND GOOD SAFE NONSTEROIDAL ANTI-INFLAMMATORY DRUG IN KNEE OSTEOARTHRITIS PATIENTS WITH DYSPEPSIA

E. Tsvetkova[1], L. Denisov[1], E. Nasonov[2] on behalf of AGATA group. *[1]Clinical Research laboratory; [2]Scientific Leader, V.A.Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation*

Objectives: To investigate the efficacy and tolerability of amtolmetin guacil (AMG; Niselat®, Dr. Reddy's Laboratories Ltd, India) versus previous therapy with nonsteroidal anti-inflammatory drugs (NSAIDs) in patients with knee osteoarthritis (OA) and signs of dyspepsia.
Methods: The open-label observational study included 220 patients aged 30–65 years who suffered from knee OA and intense pain during NSAID intake and had symptoms of dyspepsia in the absence of contraindications to the use of AMG. Among the comorbidities that generally occurred in 68% of the patients, there was a preponderance of hypertension (42%), lower extremity varicose veins (6.4%), and diabetes mellitus (6%).
Treatment efficacy was evaluated using three domains of the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), by also taking into account pain intensity and general health assessment on the visual analogue scale. A Severity of Dyspepsia Assessment (SODA) scale was used to rate dyspepsia.
Results: AMG had a marked analgesic effect confirmed by 40% or more pain reduction thatoccurred in 72.5% of the patients. The high analgesic effect of AMG was confirmed by a statistically significant ($p<0.001$) reduction in the WOMAC index (pain and stiffness) and by an increase in functional activity. Therewas a significant decrease in painless and painful signs of dyspepsia, as well as positive changes in the measures"overall assessment of dyspepsia severity" ($p<0.001$) and "satisfaction with treatment". Overall assessment ofAMG tolerability was only positive: excellent (33%), good (56%), and satisfactory (11%). There were no seriousadverse events (AE). AE were graded as moderate and mild in 8 and 82% of cases, respectively. AE were recordedin 7.7% of the patients.
AMG had a marked analgesic effect confirmed by 40% or more pain reduction that occurred in 72.5% of the patients. The high analgesic effect of AMG was confirmed by a statistically significant ($p<0.001$) reduction in the WOMAC index (pain and stiffness) and by an increase in functional activity. There was a significant decrease in painless and painful signs of dyspepsia, as well as positive changes in the measures "overall assessment of dyspepsia severity" ($p<0.001$) and "satisfaction with treatment". AB0799 DECREASED RATIO OF TIMP1/MMP-9 IS ASSOCIATED WITH HIGHER PAIN SENSITIVITY IN A SUBSET OF OSTEOARTHRITIC PATIENTS WITH LOW MECHANISTIC TARGET OF RAPAMICIN GENE EXPRESSION IN THE PERIPHERAL BLOOD

E.V. Tchetina[1], G.A. Markova[1], E.A. Taskina[2], N.G. Kashevarova[2], E.P. Sharapova[2], L.I. Alekseeva[2]. *[1]Immunology & Molecular Biology; [2]Osteoarthritis, Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Progression of osteoarthritis (OA) produces loss of articular cartilage that may culminate in pain, loss of joint function, and disability. Osteoarthritic changes in articular cartilage are associated with progressive proteolytic degradation of the extracellular matrix due to excessive expression of metalloproteinases (MMPs) over their tissue inhibitors (TIMPs). At the same time, decrease in TIMP concentration versus MMP has been previously associated with an increase in pain sensitivity.
Objectives: Here we hypothesized that imbalance in TIMP1 and MMP-9 gene and protein expressions in the peripheral blood might contribute to pain perception in OA patients.
Methods: We examined whole blood of 65 OA outpatients and 27 healthy subjects. Clinical testing comprised physical examination, radiographic and WOMAC scoring, and ultrasonography. Total RNA isolated from the whole blood was used for gene expression examination of mTOR, mechanistic target of rapamycin, a major regulator of cell growth and proliferation, metalloproteinase MMP-9, and tissue inhibitor of metalloproteinase, TIMP1 using quantitative Real-time RT-PCR. p70-S6K (mTOR read-out), MMP-9, and TIMP1 protein levels were quantified by ELISA.
Results: 23 OA outpatients exhibited significant downregulation of mTOR gene expression (subset "Low mTOR") while other 42 OA outpatients have demonstrated upregulation of mTOR gene expression (subset "High mTOR") in the peripheral blood compared to healthy controls. Although both OA outpatient subsets had comparable radiographic severity according to Kellgren-Lawrence grading, similar age, disease duration, and body mass index, "Low mTOR" patients experienced significantly higher pain at joint function versus "High mTOR" subset. This was associated with a significant upregulation of MMP-9 gene expression in "Low mTOR" patients versus healthy subjects while TIMP1 expression remained equal to controls. In a "High mTOR" subset, both gene expressions were significantly upregulated. p70-S6K and TIMP1 protein concentrations measured in the peripheral blood mononuclear cells were significantly lower in "Low mTOR" patients versus that in "High mTOR" while MMP-9 protein expression was significantly higher compared to healthy subjects in both examined OA subsets.
Conclusions: Our results show that TIMP1 and MMP-9 gene expressions measured in the peripheral blood might be associated with pain sensitivity in OA outpatients while low level of TIMP1/MMP-9 ratio indicates increased pain perception.

AB0800 KNEE OSTEOARTHRITIS PATIENTS' USE OF AND COMPLIANCE TO AN ORTHOTIC INTERVENTIONS

E. Mauricio, M. Sliepen, D. Rosenbaum. *Universitätsklinikum Münster, Münster, Germany*

Background: Knee osteoarthritis (KOA) is the most common form of arthritis with an estimated lifetime prevalence of 44.7% (1). The use of orthotic devices (knee braces, insoles, wedged shoes) is a generally accepted conservative therapy for KOA patients (2). However, it is suggested that their effectiveness is detrimentally affected by poor patient compliance due to discomfort while wearing these devices (3).
Objectives: The aim of this study is to objectively establish the compliance to an orthotic intervention using a thermal sensor (TS) and comparing it to patients' self-reported wear time.
Methods: Ten medial KOA patients (mean±SD age 57.6±13.4 years, BMI 27.3±3.2 kg/m^2), clinically diagnosed according to the ACR Guidelines, were recruited for this study. A small, light-weight TS with the size of an average lithium battery (0.5℃ resolution) was placed in a newly developed ankle-foot-orthosis (AFO) that patients were asked to wear as often as possible during a period of six weeks. The TS measured the temperature every 5 minutes for 4 weeks. Patients rated the comfort of the orthosis during the first visit using a scale from 1 to 5 (1 being the most comfortable).
Additionally, the patients reported during these six weeks how many hours per day they had worn the orthosis and rated which amount of pain they felt each day (from 0=no pain to 10=most painful). To determine the patients' compliance, the AFO wear time, derived from the TS, was compared to the wear time per day recorded in the patients' diaries. The threshold to differentiate the wear

and non-wear times was set at 25℃. Timeframes during which the temperature rose above 25℃ were classified as wear time. A Wilcoxon signed-rank test was performed between the different wear times and Spearman's correlations between pain, comfort and wear time were determined.

Results: On average, patients wore the device for 143±80 h according to the form they filled out, whereas the TS measured only 83±86 h, leading to an overestimation of 72%. Patients reported an average pain level of 3±1.4 during the six weeks period and the AFO's comfort was rated with 1.9±0.3.

Statistical differences were found between the wear time reported by the patients and the wear time derived from the TS (p=0.005). Additionally, a significant correlation between the AFO comfort and the wear time derived from the TS was found (r = -0.81; p=0.001). No significant correlation was found between pain and wear time.

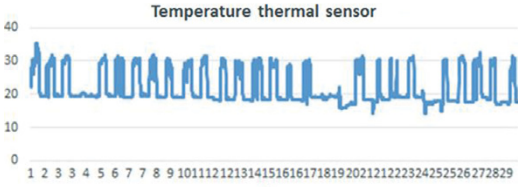

Figure 1: Data set from one of the patients.

Conclusions: As can be expected, patients who found the AFO more comfortable were the ones who wore the orthosis for longer periods. The wear time recorded by the TS was significantly lower compared to the self-reports. This might be due to a social desire bias, overestimating the amount of hours of wearing the AFO as we asked the patients to wear it as often as possible. Secondly, patients might have trouble to accurately recall the amount of wear hours, thereby inducing an overestimation of wear time. As the reliability of self-reported measures seems to be questionable, such data should be interpreted with care.

AB0801 EVALUATION OF EFFECTIVITY OF RADIOTHERAPY FOR PAIN CONTROL IN OSTEOARTHRITIS AND SOFT TISSUE PATHOLOGY

F. Aramburu, Á. Montero, R. Silvia, J. González, E. Calvo, M. Valero, C. Rubio, P. Garcia de la Peña on behalf of Rheumatology and Radiotherapy services.
Rheumatology, HM hospitales, Madrid, Spain

Background: Osteoarthritis and soft tissue pathology are diseases that produce important pain and disability in many patients. Some studies support that the low-dose radiotherapy may be effective in refractory diseases.

Objectives: The main objective of this study is to evaluate whether the treatment with radiotherapy is long-term effective to reduce the pain in osteoarthritis and soft tissue pathology. The secondary objective is to evaluate the analgesic requirements before and after the treatment.

Methods: A prospective and observational study was designed. 38 patients were included. 53 different pathologies were treated including knee osteoarthritis, trochanteric bursitis, calcinosis, rizartrosis, pyramidal syndrome, rotatory cuff pathology and shoulder osteoarthritis, plantar fasciitis, epicondylitis, hand osteoarthritis, tibialis posterior tendonitis, ankle osteoarthritis, hip osteoarthritis and hand tendonitis. All these pathologies did not respond to conventional therapy (non steroidal antiinflamatory drugs, rehabilitation or infiltrations). Initially, the patients received a treatment of radiotherapy with a dose of 6 Gray divided in 6 sessions during 2 weeks. The patients that did not respond after 6 weeks received a second treatment with the same characteristics. The modification in Visual Analogic Scale (VAS) of pain was evaluated as well as analgesic intake before and after the treatment.

Results: No side effects were observed. 92% were women and 8% men. Mean age was 66,82, standard deviation (SD): 12,97 (42–89). 44 locations responded to one treatment and 19 needed a second one.

The mean VAS prior treatment was 7,38, SD: 1,49, (10–4). Mean VAS after the first treatment was 3,81 SD: 2,84 (9–0).

The mean VAS after the first treatment in locations that received 2 treatments was 6,65 SD: 1,46 (9–5), and mean VAS after the second one was 4,56 DE: 2,66 (8–1).

By pathology, the difference in means was: 4,8 in knee osteoarthritis (N=11), 4,78 in trochanteric bursitis (N=10), 5 in calcinosis (N=3), 5,33 rizartrosis (N=8), 4 in pyramidal syndrome (N=2), 3,87 in rotatory cuff pathology and shoulder osteoarthritis (N=6), 6 in plantar fasciitis (N=1), 7 in epicondylitis (N=1), 3,22 in hand osteoarthritis (N=11), 6 in tibialis posterior tendonitis (N=2), 4 in ankle osteoarthritis (N=2), 2 in hip osteoarthritis (N=1) and 2,2 in hand tendonitis (N=5).

Until November 2016, 12 patients (17 pathologies) were followed-up for 6 months. The mean VAS before treatment of these pathologies was 7,29 SD: 1,21; (9–4). After 6 months mean VAS reduced to 1,47 SD: 1,42; (5–0).

The analgesic intake was reduced in 37,98% of patients, 10,34% used the same amount and 34,48% was not known. 17,24% did not take analgesic drugs at all after treatment.

Conclusions: The treatment with low dose radiotherapy was long-term effective for reducing the pain level in our study.

AB0802 EFFECTS OF DIETARY MAGNESIUM SUPPLEMENTATION AND INTRA-ARTICULAR MAGNESIUM SULFATE ON EXPERIMENTAL OSTEOARTHRITIS AND POTENTIAL MOLECULAR MECHANISMS BY MRNA AND LNCRNA EXPRESSION PROFILES SCREENING

G. Lei[1], C. Zeng[1], H. Li[1], J. Wei[2], T. Yang[1], B. Wise[3], X. Ding[1], Y. Zhang[1], Y. Yang[1], Z. Deng[1], J. Li[4], Y. Cui[5]. *[1]Department of Orthopaedics; [2]Health Management Center, Xiangya Hospital of Central South University, Changsha, Hunan Province, China; [3]Department of Internal Medicine and Department of Orthopaedics, University of California, Davis School of Medicine, Sacramento, CA; [4]Division of Rheumatology, Department of Internal Medicine, Rush University Medical Center, Chicago, IL, United States; [5]International Medical Center, Xiangya Hospital, Central South University, Changsha, Hunan Province, China*

Background: Epidemiological studies of ours and other groups have reported an inverse association between dietary and serum Mg with knee radiographic osteoarthritis (OA) [1–4].

Objectives: To investigate the effects of dietary magnesium supplementation and intra-articular $MgSO_4$ on the development of experimental rat osteoarthritis, and explore the underlying potential molecular mechanisms by mRNA and lncRNA expression profiles screening.

Methods: Rat osteoarthritis model was induced by surgery. Articular cartilage damage was evaluated by modified Mankin score system after intervention of dietary magnesium supplementation or intra-articular $MgSO_4$ injection. Microarray was performed to reveal alteration of expression profiles of mRNA and lncRNA after intervention of $MgSO_4$ on human osteoarthritis chondrocytes. Bioinformatics analyses including gene ontology analysis, pathway analysis, target gene predictions and network analysis were used.

Results: Comparing with normal diet, dietary Mg supplementation showed significantly ameliorated cartilage damage at the medial femoral condyle, lateral tibial plateau and medial tibial plateau ($P \leq 0.05$), and approaching significance at the lateral femoral condyle (P=0.06). All four locations exhibited mitigated cartilage damage in the intra-articular $MgSO_4$ group compared with intra-articular saline ($P \leq 0.05$). 1767 lncRNAs and 2558 mRNAs were upregulated while 994 lncRNAs and 1512 mRNAs were downregulated in chondrocytes with intervention of 50mM MgSO4 compared with control group (fold change ≥ 2.0). The top 6 lncRNAs which showed the largest difference were ENST00000425914.2, ENST00000419881.1, ENST00000561231.1, ENST00000609062.1, TCONS_00029212 and ENST00000429530.1. Bioinformatics analyses indicated that the differentially expressed lncRNA target genes of chondrocyte after intervention of 50mM $MgSO_4$ are enriched in negative regulation of phosphatidylinositol 3-kinase signaling.

Conclusions: Both dietary magnesium supplementation and intra-articular $MgSO_4$ injection may exert cartilage protective effects by causing widespread changes in the profile of lncRNAs and mRNAs of chondrocytes.

AB0803 DOES INTRA-ARTICULAR INJECTION OF PLATELET-RICH PLASMA PROVIDE CLINICALLY PREFERABLE OUTCOMES IN THE KNEE OSTEOARTHRITIS? A DOUBLE-BLIND, RANDOMIZED CONTROLLED PILOT STUDY

J. Moghimi[1,2], R. Ghorbani[1], H. Beiki[1]. *[1]Social Determinants of Health Research Center; [2]Department of Internal Medicine, Semnan university of medical sciences, Semnan, Iran, Islamic Republic Of*

Background: Knee osteoarthritis (OA) symptoms Improvements with platelet-

rich plasma (PRP) have been ascribed to its ability to rectify intra-articular inflammatory processes.
Objectives: The aim of this study was to determine the safety, feasibility and changes in symptom severity, sports activity, lower limb function, and function in daily living activities following intra-articular injections of PRP in mild to moderate knee OA.
Methods: In this double-blind randomized controlled pilot study, 34 patients with knee OA grade 2 or 3, from March 2013 to February 2016 were selected. Participants were randomly assigned one knee as the case and other knee was considered as control to receive three injections of either PRP or placebo. The administering doctor and the patients were blinded to group allocation. Outcomes included safety and recruitment data, 100 mm the EuroQol-visual analogue scales (EQ-VAS), the international knee documentation committee (IKDC), the Western Ontario and McMaster Universities Arthritis Index (WOMAC) and the Tegner Activity Score (TAS) at three and six months.
Results: Twenty four (100%) participants met the inclusion criteria. No treatment-related major adverse events were reported. The PRP group demonstrated significant improvements at all follow up time points in the WOMAC (3 months: p=0.017; 6 months: p=0.029, ETA=0.601). For the PRP group, the 11.47 mm reduction in EQ-VAS at 6 months (p=0.040) and the 7.35 mm at 3 months (p=0.035) was statistically significant improvement from baseline. The PRP group also significantly improved IKDC (p=0.039, ETA =0.619) and TAS (p=0.028, ETA =0.641) at three months. The placebo group showed improvements on only the IKDC Function at 3 months (p=0.019, ETA =0.591). There were no significant between-group differences for any of the self-reported measures at either time-point.
Conclusions: The study provides proof-of-concept evidence about the safety and feasibility of intra-articular injections of PRP necessary to appraise a larger clinical trial knee OA. Our preliminary findings also suggest PRP improves self-reported symptom severity, sports activity, and function in daily living activities, however no between-group differences were found. PRP may provide an effective and safe novel treatment for knee OA.

AB0804 SINGLE-NUCLEOTIDE POLYMORPHISM (SNP) RS143383 GROWTH AND DIFFERENTIATION FACTOR 5 (GDF5) IN KNEE OSTEOARTHRITIS IN EGYPTIAN POPULATION

M. Hassanien[1], N.A. Mohamed[2], S.A. Mahran[1]. *[1]Rheumatology Department; [2]Medical Biochemistry, Assuit University, assuit, Egypt*

Background: Osteoarthritis (OA), is an age-related common polygenic disease characterized by the thinning and loss of the articular cartilage in synovial joints such as knees. The etiology and pathogenesis of OA is largely unknown, the single-nucleotide polymorphism (SNP) rs143383 (C/T) influencing OA susceptibility across a range of ethnic groups.
Objectives: The present study investigated to identify the association of polymorphism in GDF-5 gene with osteoarthritis in Egyptian population.
Methods: This Case control study of 100 women and 100 male $\geq$40 years that fulfilled American College of Rheumatology (ACR) for Knee OA and 100 controls recruited from the outpatient clinic of Department of Rheumatology, Asyut university, Egypt. Clinical symptoms were assessed with WOMAC index and VAS for knee pain. The severity of disease was determined by radiological grades (Kellgren Lawren). Body Mass Index (BMI) was recorded. DNA isolation and genotype analysis the method of (Southam *et al.*, 2007) was followed for determining the GDF-5 gene (T/C; rs143383) polymorphism. Amplification was performed.
Results: There were weak but significant associations present between the GDF5 polymorphism and knee OA at the allele level (C vs. T: 0.85, 95% CI =0.78–0.93) and genotype level (CC vs. TT: 0.72; CT vs. TT: 0.81; CC/CT vs. TT: 0.83; CC vs. CT/TT: 0.78) in the overall population. A stronger significant association was observed for CC vs. TT (OR =0.83, P$<$0.001) in comparison with other models. In males we identified a second polymorphism, located in the 3'-UTR of *GDF5*, that influenced allelic expression of the gene independent of rs143383.
Conclusions: GDF5 is an OA susceptibility gene with association between the GDF5 polymorphism and clinical symptoms of knee OA in Egyptian population.

Background: This consensus derives from a previous study of Demographic and Clinical Characteristics by the PANLAR OA study group, reporting significant differences in handling these patients and in which it was evident the need of reaching an agreement in the management of hand, hip and knee OA in Latin America (2)
Objectives: The aim is to update the recommendations for the treatment of hand, hip and knee OA by agreeing on key propositions relating to the management of hand, hip and knee OA,identifying and critically appraising research evidence for the effectiveness of the treatments and by generating recommendations based on the available evidence and expert opinion.
Methods: Recommendations were developed by a group of 40 specialists made up of rheumatologists and members of other medical disciplines. A systematic review of articles, meta-analyses and guidelines for the management of hand, hip and knee OA published from 2008 and January 2014 was done. The level of evidence and strength of recommendation were classified according to the Jadad scale (3).The level of agreement was established through a Delphi technique.
Results: Both "strong" and "conditional" recommendations are given for management of hand, hip and knee OA and non-pharmacological, pharmacological and surgical modalities of treatment are presented according to the different levels of agreement.
Conclusions: These recommendations are based on the consensus of clinical experts from a wide range of disciplines considering the available evidence, while balancing the benefits and risks of non-pharmacological, pharmacological and surgical treatment modalities. It is hoped that these recommendations will be utilized by healthcare providers involved in the management of patients with hand, hip and knee OA.

AB0806 THE EFFECT OF REPETITIVE ACTIVE RANGE OF MOTION VERSUS CONTINUOUS PASSIVE MOTION ON EARLY FUNCTIONAL OUTCOMES AFTER PRIMARY TOTAL KNEE REPLACEMENT

M. Erduran[1], M. Eymir[2], B. Ünver[2]. *[1]Faculty of Medicine Surgery Medicine Department of Orthopaedics and Traumatology, Dokuz Eylül University, Izmir, Turkey; [2]School of Physical Therapy and Rehabilitation, Dokuz Eylül University, Izmir, Turkey, Izmir, Turkey*

Background: Continuous passive motion (CPM) is a common procedure in total knee replacement (TKR), but its effectiveness is controversial at early stage after TKR. Some studies have claimed that CPM promoting rapid postoperative recovery and the range of motion (ROM). However, some studies have demonstrated that CPM have any benefit on ROM, length stay of hospital and postoperative recovery (1, 2). Several studies have examined the use of CPM, but there is not any study that compared the effect of repetitive active range of motion (AROM) vs. CPM on early functional outcomes after TKR.
Objectives: The aim of this study was to compare the effect of AROM vs. CPM on early functional outcomes after TKR.
Methods: The study group consisted of 71 patients, who underwent primary TKR because of arthrosis were consecutively allocated to a AROM group (n=40, with

median age; 70.8±7.9 years), and were allocated to a CPM group (n=31, with median age; 69.7±8.4 years). Patients were evaluated regarding knee function score (Hospital for Special Surgery (HSS) score), pain (Numeric Pain Rating Scale (NPRS)), knee circumference, knee range of motion, length of hospital stay, the day of knee flexion angle achieved 70 degrees and quality of life (Short-Form 12 Health Survey (SF-12). Functional activities were evaluated using the Iowa Level of Assistance Scale and walking speed was evaluated using the Iowa Ambulation Velocity Scale. Also functional outcomes were evaluated with timed up and go (TUG) test and 10-meter walk test (10 MWT). Patients were evaluated preoperatively and at discharge.
Results: At baseline, demographic and anthropometric characteristics were similar in groups and there was no statistically difference between groups ($p>0.05$). It was determined that; the AROM group had better results in terms of reduction of pain severity ($p<0.001$). When the HSS knee scores were compared there was statistically difference between groups ($p<0.001$) and the HSS knee scores were lower in CPM group after surgery. There were no statistical differences in knee circumference, knee range of motion, the day of achieved active straight leg raise, length of hospital stay, the day of knee flexion angle achieved 70 degrees, quality of life, the IOWA help level score, IOWA walking speed score, 10 MWT score and TUG test score between groups after TKR ($p>0.05$).
Conclusions: In patients with TKR, application of repetitive AROM has better results than CPM to decrease pain severity, improve the HSS knee score. However, AROM has no effect on the early functional outcomes and the other early patients' outcomes. The current results suggest that application of AROM might be an effective method to decrease pain severity, improve the HSS knee score.

AB0807 VALIDITY OF THE QUADRICEPS ANGLE MEASUREMENT IN PATIENTS WITH VARUS KNEE OSTEOARTHRITIS: COMPARE THE GONIOMETRIC AND PHOTOGRAMMETRY METHOD TO RADIOGRAPHY METHOD

M. Erduran[1], M. Eymir[2], B. Ünver[2], N.D. Demirkıran[3]. *[1]Faculty of Medicine Surgery Medicine Department of Orthopaedics and Traumatology, Dokuz Eylül University, Izmir, Turkey; [2]School of Physical Therapy and Rehabilitation, Dokuz Eylül University, Izmir, Turkey; [3]Department of Orthopaedics and Traumatology, Dokuz Eylül University, Izmir, Turkey, Izmir, Turkey*

Background: Various measurement methods have been defined to assess the alignment of the lower extremities. The Q-angle measurement is reported to be associated with knee injury and patellofemoral dysfunction. The Q-angle has been assessed using radiography scans, goniometer and photogrammetry methods in supine and standing positions. The radiography method is accepted to be the most accurate and valid measurement technique in measurement the Q-angle. But as a result of being expensive and time-consuming, this invasive method is not mostly preferred in research and clinics. The goniometric measurement of Q-angle is practical because it is simple, requires inexpensive equipment (only a goniometer), and can be applied in a short time. Photogrammetry measurement technique is also an advantageous method for reducing measurement errors caused by goniometers and reduction of investigator errors.
Objectives: The aim of the present study, was to compare the clinical assessment of the Q-angle (goniometric and photogrammetric measurement methods) to a radiological assessment using radiograph (criterion validity) in patients with varus knee osteoarthritis.
Methods: The study group consisted of 15 (median age 68.6±11.9 years) patients with unilateral and bilateral varus knee osteoarthritis. Q-angle measurements were assessed on both lower extremities with three different goniometric methods (goniometric measurement method in standing position with quadriceps muscle relaxed; goniometric measurement method in supine position with quadriceps muscle relaxed; and contracted) using a 360° universal goniometer. After the goniometric measurements, photographs were taken with quadriceps muscle relaxed in standing position. For radiographic assessment, we used patients' lower extremity scanograms, which had been taken to determine the diagnosis and treatment from the Computer Patient Archiving System database.
Results: There was a good correlation between the radiographic assessment and photogrammetric measurement ($r=0.623$, $p<0.001$). Also a good correlation was observed between radiographic assessment and goniometric measurement (in standing position with quadriceps muscle relaxed; in supine position with quadriceps muscle relaxed; and contracted) ($r=0.676$, $p<0.001$, $r=0.616$, $p<0.001$, $r=0.676$, $p<0.001$, respectively).
Conclusions: According to our result, the photogrammetric measurement and the goniometric measurement appear to be valid alternatives to the radiographic measurement for determining the Q-angle. These alternative measures might be used by clinicians and researchers to measure the Q-angle of patients with varus knee osteoarthritis in orthopaedic clinics.

AB0808 COMPARING THE EFFECTS OF PHYSICAL THERAPY AND NON-STEROIDAL ANTI-INFLAMMATORY TREATMENT ON SLEEP QUALITY, QUALITY OF LIFE AND CLINICAL STATUS IN KNEE OSTEOARTHRITIS

M. Sezgin[1,1], E. Yeşildal[1], H. Ankaralı[2], G. Sahin[1]. *[1]Department of Physical Medicine and Rehabilitation, Mersin University Medical Faculty, Mersin; [2]Department of Biostatistics and Medical Informatics, Duzce University Medical Faculty, Düzce, Turkey*

Objectives: We aimed to compare the effectiveness of physical therapy (PT) and non-steroidal anti-inflammatory drug (NSAID) therapy on sleep quality, quality of life and clinical status in patients with knee osteoarthritis (OA).
Methods: Demographic characteristics of the participants were recorded. MOS sleep scale, Nottingham Health Profile (NHP) and Western Ontario ve McMaster Universities Osteoarthritis Index (WOMAC) were used to evaluate sleep quality, quality of life and clinical status of patients before and after the treatment.All patients were divided into two groups as PT (57 patients) and NSAID (43) groups. The patients in the drug group were administered oral dexketoprofen (50 mg/day, for two week) and the patients in the PT group were administered five times a week, total 15 seances hot-pack, ultrasound and transcutaneous electrical nerve stimulation therapy.
Results: Demographic characteristics, MOS sleep scale and NHP were similar at baseline in both groups ($p>0.05$). WOMAC pain, stiffness, and physical function scores before treatment were significantly poorer in the PT group than the NSAID group ($P<0.05$). There were statistically significant improvements on the MOS sleep scale (except snoring subscore, $p=0.05$, table 1), NHP (except social isolation, $p=0.209$) and and WOMAC pain, stiffness, physical function and total scores of both groups after the treatments ($p<0.05$). Improvement was also similar when both groups were compared after the treatment ($p>0.05$). After the two treatment, significantly side effect was not observed.
Conclusions: PT and NSAID therapy has good effectiveness on sleep quality, quality of life and clinical status in knee OA.

AB0809 FALL RISK AND RELATED FACTORS IN KNEE OSTEOARTHRITIS

M. Alkan Melikoglu[1], A. Kul[2]. *[1]Rheumatology; [2]Physical Medicine and Rehabilitation, Ataturk University Faculty of Medicine, Erzurum, Turkey*

Background: Balance, as a complex task, may be affected in knee osteoarthritis (KOA) and this may cause postural instability and fall risk.
Objectives: The aim of this study was to determine the fall risk in patients with KOA with an objective computerized technique and to evaluate the potential risk factors for falls in these patients.
Methods: Patients with KOA and controls were included in this cross-sectional study. Gender, age, and body mass index (BMI) were recorded. Pain was evaluated with a visual analog scale (VAS). The Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) was used to assess the patients and the Falls Efficacy Scale International (FES-I) was used for the evaluation of fall efficacy. Knee radiographs were recorded with the Kellgren–Lawrence grading scale. Fall risk analysis was performed by using the Tetrax Interactive Balance System, which is a computerized posturography device.
Results: One hundred patients with KOA and 30 controls were included. The age, gender, and BMI scores were similar between the groups. FES-I scores were significantly higher in the cases than in the controls ($p<0.000$). Using a computerized system, significantly higher fall risk results ($p<0.000$) and significantly low, moderate, and high fall risk distribution were recorded in the cases than in the controls ($p<0.000$). Fall risk was significantly related to age, pain, and the WOMAC scores of the patients.

Conclusions: Using an objective computerized technique, our study demonstrated a higher fall risk in patients with KOA than in healthy individuals. This higher risk was shown even in the early radiographic phases of the disease related to age, pain, and dysfunction. An understanding of factors on postural control seems to be critical in successful fall prevention in these patients.

AB0810 CORRELATION BETWEEN KNEE EXTENSOR MUSCLE STRENGTH AND GAIT ENDURANCE AFTER TOTAL KNEE ARTHROPLASTY

M.J. Suh, B.R. Kim. *Jeju National University Hospital, Jeju, Korea, Republic Of*

Objectives: This study was undertaken to identify the relationship of objective physical performance and gait endurance after 1 month after total knee arthroplasty.
Methods: One-hundred ninety-five patients (32 males and 163 females; average age 72.6±6.1 years) who underwent a primary total knee arthroplasty (TKA). Patients completed 6-minute walk test (6MWT) to assess gait endurance. Additional physical performance test including timed up and go (TUG) test, timed Stair Climbing Test (SCT), instrumental gait analysis for spatio-temporal parameters, and isometric knee flexor and extensor strength of the surgical and nonsurgical knees 1 month after TKA were measured. To evaluate self-reported physical function, self-reported disease-specific physical function measured by using the Western Ontario McMaster Universities Osteoarthritis Index (WOMAC) and self-reported quality of life measured by using EuroQOL five dimensions (EQ-5D) questionnaire. Visual analog scale (VAS) of post-operative knee pain was recorded each patient.
Results: In the bivariate analyses, the postoperative gait endurance had a significant positive correlation with the postoperative gait speed ($r=0.48$, $p<0.001$), cadence ($r=0.40$, $p<0.001$), stride length ($r=0.58$, $p<0.001$), postoperative peak torque (PT) extensor of surgical knee ($r=0.36$, $p<0.001$), postoperative peak torque (PT) flexor of surgical knee ($r=0.25$, $p<0.001$), postoperative peak torque (PT) extensor of non-surgical knee ($r=0.49$, $p<0.001$), postoperative peak torque (PT) flexor of non-surgical knee ($r=0.34$, $p<0.001$), EQ5D ($r=0.33$, $p<0.001$) and a significant negative correlation with TUG ($r=-0.46$, $p<0.001$), SCT-ascent ($r=-0.63$, $p<0.001$), SCT-descent ($r=-0.68$, $p<0.001$), WOMAC pain score ($r=-0.29$, $p<0.001$), WOMAC stiffness score ($r=-0.35$, $p<0.001$), WOMAC function score ($r=-0.43$, $p<0.001$).
In the linear regression analyses, the postoperative Visual analog scale (VAS) ($\beta=-6.91$, $p=0.03$), peak torque (PT) extensor of surgical knee ($\beta=0.56$, $p=0.04$) and peak torque (PT) extensor of non-surgical knee ($\beta=0.77$, $p<0.001$) were a factors predictive of the postoperative 6MWT.

Abbreviations: 6MWT, 6-minute walk test, TUG, timed up and go, SCT, timed stair climbing test, PT, peak torque, ROM, range of motion, VAS, Visual Analog Scale, WOMAC, Western Ontario McMaster Universities Osteoarthritis Index, EQ-5D, EuroQOL five dimensions,

Conclusions: This study demonstrated that quadriceps muscle strength significantly influenced on gait endurance 1 month after TKA. Using variables measured after surgery, it may be possible to predict with good accuracy for postoperative gait speed. In addition, these results could be of importance in determining effective rehabilitation strategies focusing on resistance training for improvement of gait speed early after TKA.

AB0811 HYALURONIC ACID INTRA-ARTICULAR INJECTION VERSUS ORAL ATORVASTATIN IN THE TREATMENT OF KNEE OSTEOARTHRITIS

M. Jokar, Z. Mirfeizi, K. Hashemzadeh, H. Zarei. *Mashhad University of Medical Sciences, Mashhad, Iran, Islamic Republic Of*

Background: Osteoarthritis is a degenerative joint disorder of articular cartilage and is the most common type of arthritis in the elderly. Some studies have suggested that Hyaluronic acid[1] and atorvastatin[2] may have a role in the treatment of osteoarthritis.
Objectives: The purpose of the present study was to investigate and compare the potential effects of Hyaluronic acid and Atorvastatin on the symptoms of knee osteoarthritis.
Methods: We conducted an open, randomized, parallel study on patients with knee osteoarthritis. Eligible patients were those who met the ACR criteria of primary knee osteoarthritis, radiologically ascertained grade I or II of knee osteoarthritis on the Kellgren-Lawrence scale, had a pain score≥60 (maximum 100) and age 50–70 years. Patients are not eligible if they had secondary osteoarthritis, systemic disease like diabetes, history of inflammatory arthritis, sever knee deformity (varus or valgus >50 degree), history of coagolopathy, sever cardiovascular disease, and active infections. Patients were enrolled from outpatient clinic of Imam Reza Hospital, Mashhad, Iran. We divided them randomly into two groups; Group 1 (n=35) received intra-articular Hyaluronic acid each week for three weeks, and group 2 (n=35) received oral atorvastatin 40 mg/day orally for six months. Symptoms were assessed by the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) at baseline and every month up to 6 months.
Results: Twenty eight patients (40%) were male and 42 patients (60%) were female. There was not a significant difference between 2 groups regard to sex (P=0.626). Mean age of patients was 57.9±1.1 years. Groups mean age did not differ significantly (P=0.710). The pain and function scores were significantly decreased only in the Hyaluronic acid group in the second month (P<0.001). There was not any significant improvement in any group in the next months (figure 1).

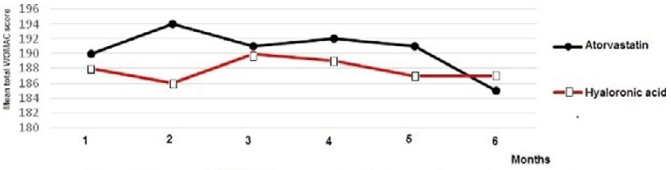

Figure 1 Mean total WOMAC score during the interventions in the studied patients

Conclusions: Intra articular Hyaluronic acid improved the pain and function of patients with knee osteoarthritis in the second months after injection. Atorvastatin did not have any effect on the knee osteoarthritis symptoms during 6 months.

AB0812 DIFFERENTIATED APPROACH TO THE TREATMENT OF OSTEOARTHRITIS WITH COMORBIDITIES

N. Shuba, A. Krylova, T. Khambir, A. Pilipenko, T. Voronova. *Shupyk National Medical Academy of Postgraduate Education, Kyiv, Ukraine*

Background: A significant prevalence of osteoarthritis (OA), the most disability joint disease in the world, which is important in the search for the new treatment. Analysis of modern therapy of OA was the reason for research efficacy of NSAIDs and SYSADOA on biochemical, inflammatory and immunological signs in the treatment of OA.
Objectives: Differentiated approach to the treatment of OA depending of presence of hyperuricemia.
Methods: 176 patients (144 women, 32 men) was exanimated, aged (59,71±0,86) years with confirmed radiographic OA according to Kellgren and Lawrence scale. Division into groups was performed depending on treatment. For 14 days group 1 (n=30) received nimesulide 100 mg twice daily, and group 2 (n=30) - meloxicam

15 mg 1 per day. For 6 months 3rd group (n=54) received diacerein 50 mg twice a day and the 4th group (n=32) - chondroitine sulfate (CS) 500 mg twice daily. 5th group (n=30) received glucosamine sulfate (GS) 400 mg 3 times per week for 1.5 months. It was estimated dynamics of VAS, WOMAC, Lequesne, uric acid (UA), CRP, IL-1β, IGF-1, NO, ESR, biochemical indicators. Statistical analysis - SPSS Statistics.

Results: Nimesulide compared to meloxicam found more effective for WOMAC index, the reduction of pain, stiffness and functional failure 53.93% vs 37.3%, 29.7% vs 13.5%, 41.6% vs 26.6% respectively. Only nimesulide decreased NO by 40.2%, and showed a decrease trend of UA from 375,33±24,6 to 321,57±19,6 mkmol/l while meloxicam had no effect on their levels. In 60% of patients with OA was found hyperuricemia with nephrolithiasis. Was showed the relation between the severity of OA and the presence of hyperuricemia by VAS, Lequesne, WOMAC, lesions more number joints, higher stage of X-ray progress. Diacerein, CS and GS showed clinical effect on pain reduction by VAS, Lequesne, WOMAC ($p<0.05$), respectively. Was showed lower levels of CRP, IL-1, NO during treatment by diacerein (CRP from 5,6 (IQR: 3,6–8,0) to 3,0 (IQR: 1,95–4,3) mg/l, IL-1 from 19,47 (IQR: 15,22–23,81) to 12,0 (IQR: 9,0–16,2) pg/ml, NO of 4,09 (IQR: 3,0–4,19) to 2,2 (IQR: 1,0–3,44) mmol/l), CS (CRP from 6,0 (IQR: 3,25–9,0) to 3,10 (IQR: 1,81–6,0) mg/l, IL-1 20,0 (IQR: 11,5–26,52) pg/ml to 16,7 (IQR: 9,80–18,62) pg/ml, NO of 3,0 (IQR: 2,05–4,00) to 2,0 (IQR: 2,0–3,0) mmol/l) and GS (CRP from 6,0 (IQR: 4,0–8,45) to 4,0 (IQR: 4,0–6,0) mg/l, IL-1 from 4,69 (IQR: 2,5–7,59) to 2,52 (IQR: 1,75–3,94) pg/ml, NO 3,28 (IQR: 2,02–4,79) to 2,37 (IQR: 1,59–3,03) mmol/l) ($p<0,05$). Diacerein reduced UA from 415,5 (IQR: 347,0–452,5) to 374,0 (IQR: 318,75–423,5) mkmol/l ($p=0.001$) and glucose from 5,1 (IQR: 4,8–5,8) mmol/l to 4,88 (IQR: 4,00–5,40) mmol/l ($p=0.0001$). CS in patients with hyperuricemia ($p=0.001$) increased the level of UA, which reduced the efficacy of CS, but without hyperuricemia didn't influence the level of UA and efficacy of CS.

Conclusions: Was showed that nimesulide is more effective than meloxicam during first 14 days, and reduces NO, an important proinflammatory factor. The presence of hyperuricemia in 60% patients with OA, resulted in a more severe OA. Diacerein decreases UA and glucose, given an advantage in treatment these patients, which isn't presented with CS (which increased UA).

AB0813 PROPOSAL FOR THE CONSTITUTION IMPLEMENTATION AND DEVELOPMENT OF THE PROGRAM OF CENTERS OF EXCELLENCE IN OSTEOARTHRITIS IN LATIN AMERICA

P. Santos-Moreno[1], R. Arape[2], R. Chacon[2], L. Franco[2], H. Riera[2], C. Caballero[3], M. Quintero[2]. *[1]Rheumatology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia; [2]Rheumatology, Center for Osteoarthritis, Caracas, Caracas, Venezuela, Bolivarian Republic Of; [3]Rheumatology, Universidad del Norte, Barranquilla, Colombia*

Background: Osteoarthritis (OA) is the most prevalent disease in the Americas, with an estimated prevalence of 5–10% of the population. These patients have difficulties accessing the clinic, as well as poorly successful therapeutic programs. We plan to develop a program of Centers of Excellence (CoE) in OA, to meet and respond to these needs, generate data and local research applicable to our health systems.

Objectives: In a first phase: To create OA pilot centers in Venezuela and Colombia under the CoE scheme, defined in REAL-PANLAR project (Panamerican league of associations for rheumatology project for implementation of CoE in Rheumatoid Arthritis). In a second phase under the auspices of PANLAR to create the Pan American Network of Centers of Excellence in OA (CEOA).

Methods: A systematic review of the literature in global and regional databases (Pubmed, Medline, Scopus, Lilacs) was conducted and through a Delphi-modified methodology and a consensus of experts, naming a coordinator by subject, we established the conceptual bases and defined OA Center of Excellence.

Results: The group proposes: 1. Clinical detection and early diagnosis of OA, discarding false positives and diagnosing early OA; 2. Model of patient-centered and multidisciplinary care: frequency of care are to be established according to the conditions of the patient and the multidisciplinary team. 3. Implementation of a specific clinical register of OA with indexes such as WOMAC, Lequesne and also EuroQol and definition of socioeconomic characteristics. 4. Paraclinics and Imaging: Each patient will be given a general laboratory study at admission and then every two years including a metabolic profile. Conventional Rx of hands, hips, knees or lumbosacral column depending on the location and then annual or depending on the evolution. Ultrasound, upon admission to the program, six month later, if synovitis was detected, for redefining the treatment and then annually for evaluation of the articulatory damage; CT and MRI when deemed necessary (OMERACT) 5. Definition of the disease management program in axes: treatment protocol of pain with sequential treatment lines, DMOADs, viscosupplementation, Glucosamine + Chondroitin, Strontium Ranelate, Piascledin; Alternative Medicine and Surgical Treatment 6. Establishment of a management program that includes Structure, Process and Outcome Indicators to define the CEOA as Standard, Optimal and Model. 7. Education modules for patients and families; Continuing Medical Education for all members of the multidisciplinary team; Generation of research in the areas above mentioned.

Conclusions: The unmet needs in OA determine the implementation of units of CEOAs, to promote management knowledge, and define T2T strategies, in order to improve clinical outcomes, reducing disability and consequently economic and social costs.

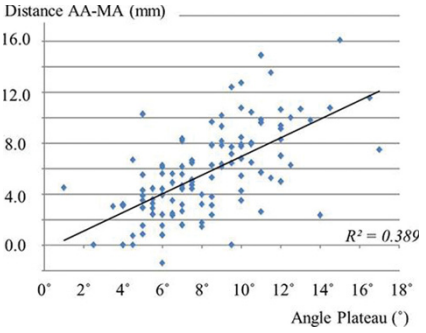
AB0814 MEDIAL SHIFT OF THE TIBIAL ARTICULAR SURFACE SHOULD BE TAKEN INTO ACCOUNT FOR ONE FACTOR OF MEDIAL OSTEOARTHRITIS OF THE KNEE



R. Nagamine. *Center of Artificial Joint and Rheumatism, Fukuoka Tokushukai Medical Center, Kasuga, Japan*

Background: Varus knee is one factor of medial osteoarthritis of the knee. According to the concept of the constitutional varus[1)], the bone growth disturbance at the growth plate in the medial proximal metaphysis of the tibia results in proximal tibia vara. In this situation, the tibia is bent at the proximal metaphysis and the tibial articular surface (TAS) may be shift medially. The medial shift of the TAS will increase the mechanical loading in the medial side of the knee. The medial shift of TAS will also influence the value of the Hip-knee-ankle (HKA) angle because the tibial plafond that is the end point of the mechanical axis (MA) of the tibia will shift laterally.

Objectives: The purpose of this study was to assess the extent of the medial shift of TAS in knees with medial osteoarthritis, and to assess the effect of this medial shift of TAS on the value of HKA angle.

Methods: This study consists of 116 knees with medial osteoarthritis. The mean age was 75.3 years old. The mean standing femorotibial angle (FTA: lateral angle between femoral and tibial anatomical axes) was 183.6°. The anatomical axis (AA) was the central line of the femoral and the tibial shaft. On the anteroposterior view radiograph of the tibia, AA, MA and tibial plateau tangent were drawn. MA is the line between the center of the tibial spines notch and the center of the tibial plafond. Two angle parameters and two distance parameters were measured. Those are angle between AA and MA (Angle AA-MA) (the value was positive when MA located medial to AA), angle between the tibial plateau tangent and the line perpendicular to AA (Angle plateau), distance from AA to the center of the tibial spines notch on the tibial plateau (Distance AA-MA) (the value was positive when Point M located medial to AA), and the length of MA.

Results: The mean (±SD) Angle AA-MA and Angle plateau was 1.0° ± 0.6° and 8.2° ± 2.9°, respectively. The mean Distance AA-MA and length of MA was 5.6±3.4mm and 347.3±3.4mm, respectively. Figure 1 shows the relationship between Angle Plateau and Distance AA-MA. The correlation coefficient between two parameters was 0.62. The more proximal tibia had varus deformity, the more the tibial articular surface shifted medially. The maximum Distance AA-MA was 16.1mm. In this case, HKA angle underestimated varus deformity up to 3°.

Conclusions: The knees with proximal tibia vara have medial shift of the tibial articular surface. There are three factors to influence the evaluations of the medial osteoarthritis of the knees. Firstly, varus knees have higher loading condition in medial compartment because of proximal tibia vara and medial shift of the tibial articular surface. Secondly, HKA angle under-estimates varus deformity in knees with medial shift of the tibial articular surface. Thirdly, FTA cannot reveal the exact loading condition, either. Even with the same FTA, it is clear that loading in the medial compartment is larger in knees with medial shift of the tibial articular surface compared with knees with simple medial osteoarthritis. The medial shift of the tibial articular surface should be taken into account for one factor of medial osteoarthritis of the knee.

AB0815 PREVALENCE OF DORSAL AND LUMBAR VERTEBRAL OSTEOARTHRITIS IN WOMEN OVER 50 YEARS OF AGE EVALUATED USING THE LANE RADIOGRAPHIC SCORE IN FIVE LATIN-AMERICAN COUNTRIES

S.M. Carrillo[1], D.X. Xibillé[2], E. Granados-Sandoval[3], D. Curiel-Quiroz[4], E. Denova-Gutierrez[4], M.G. Olvera-Soto[5], P. Clark[4]. *[1]Rheumatology, Hospital Regional 1ro de Octubre ISSSTE, CDMX; [2]SEIC-Investigación, Servicios de Salud de Morelos, Cuernavaca; [3]Radiology Unit, Hospital Regional 1ro de Octubre ISSSTE; [4]Unidad de Epidemiologia Clinica, Hospital Infantil Federico Gómez Facultad de Medicina UNAM; [5]Unidad de Investigación, Colegio Mexicano de Reumatologia, CDMX, Mexico*

Background: Osteoarthritis is the most common musculoskeletal disease worldwide. Spinal osteoarthritis (OA) is a frequent cause of back pain and disability in patients over 60. The frequency of radiographically-evident dorsal and lumbar OA in Latin America is unknown
Objectives: To determine the prevalence of dorsal and lumbar vertebral OA in a database-driven random sample of women 50 years of age and older from the Latin-American Vertebral Osteoporosis Study (LAVOS) in 5 LA countries (México, Brazil, Argentina, Colombia and Puerto Rico)
Methods: Lumbar and Dorsal X-rays were performed per a standardized protocol and analyzed independently by two trained radiologists and a general practitioner using the Lane score to establish diagnosis and degree of vertebral OA severity. Inter and intra observer agreement was determined to be $k>0.6$. Descriptive statistics were used to analyze demographic variables. Prevalence was determined using means and standard deviations for quantitative variables and simple frequencies and percentages for qualitative variables. Bivariate analysis was performed to associate age, BMI and other variables with the presence of OA, using c^2 and the magnitude of association through OR and 95% CI, carrying out a multivariate analysis to adjust the frequency of OA to other variables
Results: 405 women, mean age 69.4 (58–80), median weight 64 kg (56.9–73.4) mean height 151.8 cm (±7.6) were analyzed. 5.65% were underweight, 21% had normal weight, 41.6% were overweight and 31.5% were obese. Argentina contributed 19% of the sample, Brazil 14.8%, Colombia 20.1%, México 33.3% and Puerto Rico 12.8%. OA prevalence per age group was 76.3% (95% CI 68.4–84.2) in those 50–59, 83.8% (95% CI76.6–91.2) in those 60–69, 84.3% (95% CI 76.7–91.7) in those 70–79 and 94.9% (95% CI 90.4–99.3) in those 80 or older (p=0.003). Prevalence per country was as follows: Brazil 93%, Colombia 90%, México 85%, Puerto Rico 79% and Argentina 74%. Prevalence per BMI was 80% in normal weight, 82.5% in overweight and 87.5% in obese. 72.6% of sampled women had dorsal OA (Argentina 48.1%, Brazil 65%, Puerto Rico 73.1%, México 79.3%, Colombia 90.1%). Obesity was a risk factor for the development of dorsal OA (OR 2.46) when compared to normal BMI (p=0.01). Lumbar OA was found in 44.9% of the sampled women (Argentina 68.8%, Brazil 65%, Colombia and Puerto Rico 42.3% each, México 37%). Adjusting for age, BMI, height loss, steroid use and physical activity, the OR for presenting OA is 6.45 ($p<0.001$) in women over 80 compared to those 50–59
Conclusions: Radiographic OA is highly prevalent in Latin American women over 50 and associated with progressing age and BMI. Brazil has the highest prevalence of OA.

AB0816 COMPREHENSIVE ANALYSIS OF A NEW CHEMICAL COMPOUND FOR THE TREATMENT OF OSTEOARTHRITIS BY A PROTEOMIC APPROACH IN HUMAN CHONDROCYTES

S. Cheleschi[1], V. Calamia[2], M. Fernandez-Moreno[3], A. De Palma[1], M. Galeazzi[1], M. Anzini[4], A. Fioravanti[1], F.J. Blanco[5]. *[1]Department of Medicine, Surgery and Neuroscience, Rheumatology Unit, University of Siena, Policlinico le Scotte, Siena, Italy; [2]2Servicio de Reumatología, Grupo de Proteómica; [3]2Servicio de Reumatología, Grupo de Genomica, INIBIC-Hospital Universitario A Coruña, A Coruña, Spain; [4]3Department of Biotechnology, Chemistry and Pharmacy, Università di Siena, Siena, Italy; [5]2Servicio de Reumatología, Grupo de Proteómica y Genomica, INIBIC-Hospital Universitario A Coruña, A Coruña, Spain*

Background: Selective cyclooxigenase (COX)-2 inhibitors were developed to prevent NSAIDs gastro-intestinal adverse effects. VA692, a new hydroxyetyl selective COX-2 inhibitor, showed anti-inflammatory, anti-nociceptive and chondroprotective properties. Proteomics is being applied for the study of drug mode of action, toxicity and to identify new drugs targets.
Objectives: The aim of this study was to analyze the anti-inflammatory effect of VA692, in comparison with celecoxib. By iTRAQ methodology, we quantitatively analyzed the different expressed profiles in T/C-28a2 cell line treated with the studied drugs in presence of IL-1β.
Methods: Human T/C-28a2 chondrocytes cell line were generated by Goldring group. Human articular cartilage was obtained from femoral heads of five OA patients. Cells were incubated with VA692 and celecoxib (1, 0.5 and 0.2μM) in presence of Interleukin (IL)-1β (5ng/ml) for 48h. The expression of inflammatory cytokines and anti-oxidant enzymes was evaluated by quantitative qRT-PCR, PGE_2 release by ELISA, and apoptosis and ROS production by flow cytometry. T/C-28a2 cell line was also processed to carry out western blot tests and finally employed for the iTRAQ analysis. Statistical analysis was performed by ANOVA and Bonferroni multiple comparison tests.
Results: IL-1β-stimulated chondrocytes showed a significant increase ($p<0.001$) of COX-2, IL-1β, IL-6, IL-8, superoxide dismutase (SOD)-2 and catalase (CAT) gene expression, as well as of PGE2 levels. The tested drugs significantly counteracted the effect of IL-1β, with a better modulation by VA692 1μM in T/C-28a2 cell line ($p<0.01$ for COX-2, IL-1β, IL-8, CAT; $p<0.001$ for IL-6, SOD-2). Regarding apoptosis and ROS production, the new drug was able to significantly reduce ($p<0.05$) their increase induced by IL-1β ($p<0.05$). Proteomic analysis led to identification of 797 proteins in T/C28a2 cell line, 123 of which were significantly modulated by VA692 in presence of IL-1β ($p<0.001$), and 34 by IL-1β alone ($p<0.05$). 22 proteins were commonly modulated in both groups, thus indicating that 101 proteins were regulated by VA692 in a specific manner. Among the proteins down-regulated by VA692, some with structural function were detected, responsible for cytoskeleton riorganization, as well as chaperones (heat shock proteins) and glycolitic enzymes. Proteins involved in calcium metabolism and in ribosome biogenesis resulted up-regulated instead, as well as SOD-2 as confirmed by western blot analysis.
Conclusions: Our data demonstrated the anti-inflammatory effect of VA692, suggesting also its anti-apoptotic and anti-oxidant role. The proteomic profile showed that VA692 induced not only an anti-inflammatory effect in chondrocytes but, interestingly, this compound also seemed to regulate their anabolic response.

AB0817 IMPROVING CARE FOR PATIENTS WITH OSTEOARTHRITIS IN FIVE EUROPEAN COUNTRIES: THE JIGSAW-E PATIENT PANEL

S. Blackburn[1], J. Meesters[2], M. De Wit[3], L. Campbell[1], C. Rhodes[1], D. Schiphof[2], T. Vliet Vlieland[2], S. Bierma-Zeinstra[4], N. Østerås[5], S. Pais[6], E. Roos[7], N. Evans[1], K. Dziedzic[1]. *[1]Keele University, Keele, United Kingdom; [2]Leiden University Medical Center (LUMC), Leiden; [3]VU University Medical Centre, Amsterdam; [4]Erasmus MC - University Medical Centre Rotterdam, Rotterdam, Netherlands; [5]Diakonhjemmet Hospital, Oslo, Norway; [6]University of Algarve, Algarve, Portugal; [7]University of Southern Denmark, Odense, Denmark*

Background: EULAR guidelines for osteoarthritis (OA) endorse high quality care and support to self-manage with core recommended treatments such as exercise, weight loss and the provision of written information and education. An EU-funded project, Joint Implementation of Guidelines for oSteoArthritis in Western Europe (JIGSAW-E)[1], aims to improve the management of OA across five European countries (UK, Netherlands, Norway, Denmark, Portugal) by implementing an intervention to enhance the OA consultation.
Coordinated, cross-border Patient and Public Involvement and Engagement (PPIE), working in active partnership with the project team, is an essential component of JIGSAW-E.
Objectives: To describe the PPIE in the JIGSAW-E project.
Methods: A two-day international workshop established the JIGSAW-E Patient Panel to act as the voice of patients and the public in the project and to co-develop clear information and resources for patients. Panel members meet regularly with the project teams in each country. The Patient Panel is coordinated and supported by dedicated PPIE teams in the UK and Netherlands.
Results: The JIGSAW-E Patient Panel consists of Patient Champions and patient representatives from newly established or existing patient groups in each of the five countries. The Patient Champions form a core group of seven patient representatives who work closely with the Patient Panel and the JIGSAW-E team. PPIE activities have included:
- One Patient Champion sits on the JIGSAW-E project steering committee.
- In the Netherlands, Patient Panel members substantially contributed to the translation and cultural adaptation of a guidebook for patients with OA. This process will continue as JIGSAW-E is rolled out in each of the five countries.
- Patient Panel members in the UK have helped refine an OA Quality Indicator questionnaire[2] for use in JIGSAW-E.

A glossary of terms has been developed to support the involvement of Patient Panel members throughout the project.
Conclusions: Effective and meaningful PPIE is a central component to delivery and success of raising awareness and implementing the OA management

recommendations on a national level. The Patient Panel represents a step forward in international collaboration of PPIE within implementation projects. The Patient Panel is producing culturally appropriate and relevant information and resources for patients in five European countries. Future activities may include the development of patient stories to support increased adoption of JIGSAW-E, providing the patient perspective during training of health care professionals, and the digitisation of patient resources into Smartphone or tablet Apps.

AB0818 PERSONALIZED ARTICULATING JOINT DISTRACTION FOR TREATMENT OF TIBIOFEMORAL OSTEOARTHRITIS: CLINICAL FEASIBILITY

T. Struik[1], R.J. Custers[2], N.J. Besselink[1], J.E. Jaspers[3], A.K. Marijnissen[1], F.P. Lafeber[1], S.C. Mastbergen[1]. *[1]Rheumatology & Clinical Immunology; [2]Orthopedics; [3]Medical Technology & Clinical Physics, University Medical Center Utrecht, Utrecht, Netherlands*

Background: Osteoarthritis (OA) patients encounter progressive pain and functional disabilities, including joint stiffness, due to degeneration of the joint tissues. For knee OA, the most prevalent form, available treatment strategies are limited in number and focus primarily on minimizing the functional disability, inflammation, and pain in a conservative manner since still no unambiguously proven effective disease modifying approaches are available. Progress in the development of joint sparing procedures however, has demonstrated the regenerative capacity of the osteoarthritic knee and with that the delay for conventional last resort therapy such as total knee arthroplasty (TKA). Knee Joint Distraction (KJD) is a joint preserving procedure that can postpone knee arthroplasty in case of knee osteoarthritis for over 5 years [1]. Distraction is applied with an external fixator for 6–8 weeks.
Objectives: To reduce the burden on patients during treatment originating from a restriction in joint flexion during KJD, we evaluated an articulating frame. A personalized articulating KJD-device was developed, biomechanically tested, and technical feasibility was evaluated in cadaveric legs. Reproduction of joint specific motion was demonstrated and articulating KJD was concluded to be technically feasible. In this study, clinical feasibility was tested in 3 patients.
Methods: Patients received rigid knee joint distraction treatment in general practice. After 2–4 weeks, the frame was removed in the outpatient clinic and the joint was flexed in a continuous passive motion (CPM) device until 30° flexion was reached, or motion became painful. Subsequently, the articulating frame was attached to the bone pins (figure 1), followed by computerized personalization of the hinge from a non-invasive motion measurement. After assembling the custom parts, weight-bearing and non-weight-bearing radiographs were taken at 0, 15, and 30° flexion for joint space width measurements. Finally, the articulating device was replaced by the rigid frame and treatment was continued according to clinical practice.
Results: For none of the three patients, the articulating distractor could be personalized. In the first patient, 15° flexion was achieved on the CPM, but pin positions did not allow for positioning of the frame. In the other patients, 8° and 15° flexion was measured, which was too little motion for the custom software to generate personalized hinge parts. Pain at the pin sites during motion was reported by all patients.

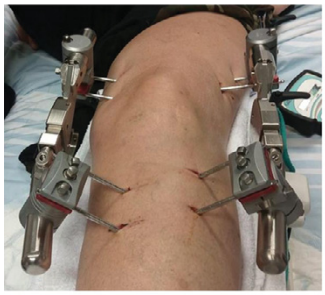

Figure 1 *The articulating frame assembled to the same bone pins and bone pin clamps as used for rigid joint distraction in clinical practice, and previous to measurement of joint-specific motion and customization of joint specific hinge parts.*

Conclusions: Despite confirmation of joint-specific articulating distraction on cadaveric legs, clinical feasibility could not be demonstrated, mainly due to painful motion of soft tissues along the bone pins.

AB0819 IS INCREASING THE TREND OF PRIMARY TOTAL HIP ARTHROPLASTIES FOR THE PATIENTS WITH OSTEOARTHRITIS, BUT DECREASING THE RATE OF WOMEN IN SUPER-AGING AREA OF JAPAN IN LAST TWELVE YEARS?

Y. Takakubo[1], K. Sasaki[1], H. Oki[1], Y. Naganuma[1], A. Narita[1], J. Ito[1], H. Kawaji[2], M. Ishii[2], M. Takagi[1]. *[1]Department of Orthopaedic Surgery, Yamagata University Faculty of Medicine; [2]Department of Orthopaedic Surgery, Yamagata Saisei Hospital, Yamagata, Japan*

Background: Elderly people over 65 year-old have increased year by year in many countries[1]. Because their rate was from 19.5% at 2004 to 26.8% at 2015 in Japan and 30.8% at 2015 in our super-aging area, the numbers of total joint arthroplasties have increased too[2]. In fact, the numbers of total hip arthroplasty predicted increasing from six hundred fifty-six thousand cases at 2010 to one million three hundred seventy-six thousand cases at 2020 in USA[3]. The rate of total joint arthroplasty, including primary total hip arthroplasty, may reflect trends in management and health outcomes of elderly people with osteoarthritis (OA) in our super-aging area of Japan[1,4].
Objectives: The aim of this study was to analyze the trend of primary total hip arthroplasties for the patients with OA in our institutes in the last twelve years.
Methods: We surveyed the number and rate of orthopaedic surgeries and primary total hip arthroplasties in our two institutes from 2004 to 2015.
Results: We had 19,862 cases of orthopaedic surgeries, including 3,782 primary total hip arthroplasties in the last twelve years. They have increased year by year ($r=0.92$, $p<0.05$, Fig. 1). Mean age was 64.5 old-year (62.4–66.8) in last twelve years, had become older year by year ($r=0.78$, $p<0.05$), 62.4 old-year at 2004 vs 66.8 old-year at 2015. Mean rate of female was 87% (85–91) in last twelve years, had gradually decreased year by year ($r= -0.68$, $p<0.05$), 91% at 2004 vs 85% at 2015.

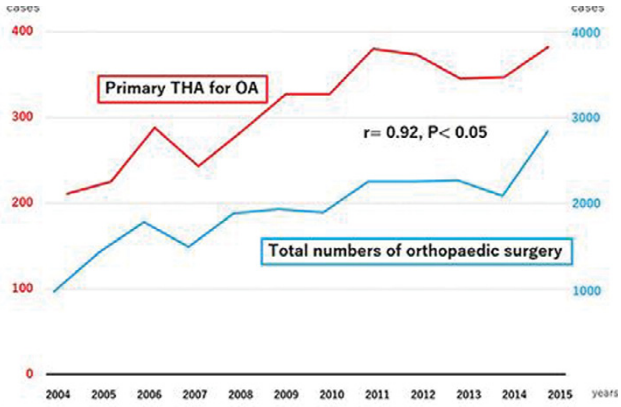

Fig. 1

Conclusions: The rate of total joint arthroplasties including primary total hip arthroplasty increased year by year, and related to total numbers of orthopaedic surgeries in our super-aging area of Japan. Mean age at receiving primary total hip arthroplasty was older annually but mean rate of women had gradually decreased year by year. Although majority of OA hip consist of female which have secondary dysplastic acetabulum in our country[2], it might increase gradually the patients of man with OA hip in super-aging time in Japan.

Osteoporosis

AB0820 FREQUENCY OF OSTEOPOROSIS AND ASSOCIATED RISK FACTORS IN MEXICAN PATIENTS WITH RHEUMATOID ARTHRITIS

A.N. Rangel-Botello[1,2], A. Gallegos-Posada[2], F. Jasso-Ávila[2], D. Ramos-Bello[1,2], C. Villa-Calderón[3], M.U. Martínez-Martínez[1,2], C. Abud-Mendoza[1,2]. *[1]Rheumatology, Hospital Central "Dr. Ignacio Morones Prieto"; [2]Faculty of Medicine, Autonomous University of San Luis Potosí, San Luis Potosí; [3]Faculty of Medicine, Autonomous University of Aguascalientes, Aguascalientes, Mexico*

Background: The risk of osteoporosis in patients with rheumatoid arthritis (RA) is well described and may be associated with genetic and environmental factors. The frequency of generalized osteoporosis in different studies is variable.
Objectives: The aim of the study was to investigate the frequency of osteoporosis as well as to describe the risk factors in RA population.
Methods: Retrospective study, including patients with RA who had at least 2 densitometries in their follow up. We collected demographic characteristics, use of glucocorticoids (GC), other medications and antibody profile. Variables were compared between groups with or without osteoporosis. The frequency of osteoporosis was calculated according to the T-score and logistic regression was performed to explore the association of osteoporosis and relevant variables. Statistical analysis was performed using R software version 3.2.1. Baseline characteristics were compared between groups of patients (osteoporosis in the lumbar spine, femoral neck and hip) defined according to the T-score results. We used x^2 or Fisher test for categorical variables as appropriate and Wilcoxon test for continuous variables. A logistic regression model was used to explore the relationship between osteoporosis and variables that could contribute as risk factors.
Results: One hundred and five patients were included, 96.2% were women, RA evolution of 7 (IQR 8) years. The frequency of osteoporosis was: lumbar spine 55.2%, hip 12%, and femoral neck 25.7%. Patients with lumbar spine osteoporosis had higher age (62 vs 58 years, p=0.13), lower weight (57 vs 63.8 kg, p=0.00004) and higher FRAX scores (26.5 vs 11.5, p=0.004; 8.5 vs 2.4, p=0.02). The associated risk factors were: weight (OR 1.09, 95% IC 1.03–1.15, p=0.001), GC use (OR 4.36, 95% IC 1.0–19.89, p=0.049), menopause (OR 22.78, 95% IC 2.73–190.12, p=0.003). There was no association with disease activity (DAS28-ESR) (OR 0.64, 95% IC 0.42–0.96, p=0.049).

Multivariate logistic regression analysis of osteoporosis associated factors

	OR	95% IC	P value
Age	1.01	0.96–1.07	0.553
Weight	1.09	1.03–1.15	0.001
DAS28-ESR	0.64	0.42–0.96	0.034
Glucocorticoids	4.36	1.00–18.89	0.049
Menopause	22.78	2.73–190.12	0.003
ACCP	2.00	0.38–10.47	0.409

OR: odds ratio, IC: confidence interval, DAS28-ESR: Disease Activity Score, ESR: erithrosedimentation rate.

Conclusions: The frequency of lumbar spine osteoporosis in our population was similar to that reported in previous studies (38.9%>50%). In our study only significant association with weight, GC use and menopause was observed

AB0821 HIGH PREVALENCE OF VITAMIN D3 DEFICIENCY IN PATIENTS WITH RHEUMATIC DISEASES AND MUSCULOSKELETAL DISORDERS IN CYPRUS

A. Tsirogianni[1], P. Hadjicostas[2]. *[1]General Hospital of Larnaca, LARNACA; [2]Agios Panteleimon Orthopedic Clinic, NICOSIA, Cyprus*

Background: Vitamin D3 (vitD) deficiency has been associated with an increased risk of a wide range of acute and chronic diseases including rheumatic diseases. Low serum 25(OH)D levels has been reported in mediterranean countries but little is known about the sunny island of Cyprus.[1,2]
Objectives: To assess vitamin D status among Cypriot patients with various rheumatic diseases (RD) and non-inflammatory musculoskeletal disorders (MSD).
Methods: Serum levels of 25(OH)D were randomly measured in 277 Cypriot patients with RD and MSD who attended the rheumatology outpatient clinics at the General hospitals of Larnaca and Ammochostos in 2016. 84/277 patients were receiving vitD supplements and excluded from analysis. From the rest 193 patients (female/male [F/M]:151/42, mean age:58, rage:21–89), 69 had rheumatoid arthritis (RA) (F/M:54/15, mean age:62, range 27–83), 31 seronegative spondyloarthropathies (SpA) (F/M:13/18, mean age:54, rage:21–73), 65 MSD (e.g. osteoarthritis, back pain, neck pain, arthralgia) (F/M:61/4, mean age 56, range 21–82), 16 autoimmune diseases (lupus, sjogren's, scleroderma) (F/M:15/1, mean age:61, rage:45–79)) and 12 various other RD (F/M:8/4, mean age 55, rage 21–89). 20 patients had additionally Hashimoto's thyroiditis (F/M:18/2, mean age:56, rage:28–73).
Results: The mean serum vitD levels in all patients were 20.4 ng/ml (range 3.2–56.8 ng/ml). VitD deficiency (<20 ng/ml) was found in 122/193 patients (63%), insufficiency (21 to 29 ng/ml) in 49/193 patients (25%) and sufficiency (>30 ng/ml) in 22/193 patients (11%).[3] The mean values (range) of vitD levels and the percentage of patients that had vitD deficiency, insufficiency and sufficiency per disease category were; RA: 19.8 ng/mL (8.1–53.3 ng/ml), 64%, 28% and 9% respectively, spa: 21.9 ng/ml (7.2–54.0 ng/mL), 48%, 35% and 16% respectively, MSD: 20.3 ng/ml (6.6–48.0 ng/ml), 63%, 28% and 9% respectively, autoimmune diseases: 17.9 ng/ml (3.20–37.00 ng/ml), 81%, 6% and 13% respectively, other RD: 22.7 ng/ml (9.0–56.8 ng/ml), 75%, 0%, 25% respectively and Hashimoto's thyroiditis: 18.8 ng/ml (7.2–37.0 ng/ml), 80%, 5% and 15% respectively. Analysis of the total number of patients showed significant differences in vitD levels and rates of vitD deficiency among females and males (19.3 ng/mL, [range 3.2–54.0 ng/mL], vs 23.7ng/mL, [range 7.2–56.8 ng/mL] [p=0.009] and 70% vs 43% respectively). Seasonal variations or age-related differences in vitD levels were not observed in this study.
Conclusions: High rates of vitD deficiency were observed in patients with RD and MSD in the island of Cyprus despite the sunny climate. Avoidance of sun exposure is presumed to be the main reason. Further studies are needed.

AB0822 CLINICAL FEATURES AND PREDICTIVE FACTORS OF ORAL BISPHOSPHONATE-RELATED OSTEONECROSIS OF THE JAW: AN ANALYSIS OF 8 CASES IN A SINGLE INSTITUTION

A. Suzuki[1], M. Yoshida[1], M. Mori[2], Y. Sakamoto[3]. *[1]Department of Rheumatology; [2]Department of Pathology; [3]Department of Oral Surgery, Mitsui Memorial Hospital, Tokyo, Japan*

Background: Oral bisphosphonates (BPs) have been increasingly prescribed for the treatment of and prophylaxis for osteoporosis over the past decade. More than 190 million prescriptions for oral BPs have been dispensed worldwide, and, thus, the number of patients that develop oral BP-related osteonecrosis of the jaw (BRONJ) is expected to increase in the future. Although previous studies have investigated oral BRONJ, predictive factors have not yet been identified [1].
Objectives: The aim of the present study was to clarify the clinical features and predictive factors of oral BRONJ.
Methods: We included 8 patients who had taken oral BPs and were diagnosed with BRONJ at Mitsui Memorial Hospital (Tokyo, Japan) between 2011 and 2016. The following details were collected for each patient from a review of medical charts: sex, age, type of BP used, duration of BP administration, co-morbidities, laboratory values at presentation including hemoglobin, albumin, and serum creatinine values, clinical stage of the lesion, site affected, and pathological findings. Laboratory values of patients with BRONJ were compared with those of 242 patients (as a control group) who were prescribed BPs in October 2016 at our hospital. The Mann-Whitney U-test and chi-squared test were used for statistical comparisons between the oral BRONJ and control groups. Risk factors for BRONJ were assessed using multivariate analyses with a logistic regression analysis. All analyses were performed using SPSS ver. 21.
Results: The mean age and female ratio in the oral BRONJ and control groups were 74.5±13.8 years and 75.0%, and 71.1±12.7 years and 66.1%, respectively (p=0.26, p=0.61). The mean interval between the initiation of BP therapy and a confirmed diagnosis was 45.9±35.5 months. Seven patients had lesions in the mandibular bones and alendronate was used in six cases. Oral BPs were administered to three patients with rheumatoid arthritis or multiple sclerosis, all of whom were given a maintenance dose of corticosteroids. The remaining three out of 5 oral BP users developed BRONJ after dental extraction. Regarding laboratory results, serum albumin values were significantly lower in the oral BRONJ group than in the control group (3.7±0.3 g/dl and 4.2±0.4 g/dl, respectively, p<0.01). Serum hemoglobin levels were slightly lower in the oral BRONJ group than in the control group (11.3±1.3 g/dl and 12.4±1.7 g/dl, respectively, p =0.06). A multiple logistic regression analysis identified serum albumin levels as the only significant predictive factor for oral BRONJ (OR=0.14; 95% CI 0.03–0.71, p<0.05). A pathological examination was available in six patients, with Actinomycetes being identified as the causative species in 4.
Conclusions: Oral BRONJ mainly developed in patients with long-term corticosteroid use for an underlying illness or those who underwent dental extraction, and hypoalbuminemia was the only laboratory marker identified as a predictive factor for BRONJ.

AB0823 EVALUATION OF OSTEOPOROSIS AND FRACTURES IN PATIENTS WITH DIABETES MELLITUS TYPE 2: RESULTS OF A 5-YEAR FOLLOW-UP

V.L. Masenko[1], A.N. Kokov[1], S.E. Semenov[1], T.A. Raskina[2], O.L. Barbarash[1]. *[1]Federal State Budgetary Scientific Institution Research Institute for Complex Issues of Cardiovascular Diseases; [2]Kemerovo state medical academy of Federal Agency of Healthcare and Social Development, Kemerovo, Russian Federation*

Objectives: The aim of the study is to determine the characteristics of bone mineral density (BMD) and the the prevalence of fractures of the vertebral fractures and long bones in men with diabetes mellitus type 2 on the basis of 5-year prospective study.
Methods: 251 males (60.56±8.7years) were examined. The patients were divided into 2 groups: patients with type 2 diabetes mellitus (n=65) and patients without disorder of carbohydrate metabolism (n=186). All patients underwent DXA-definition of BMD (g/cm^2), T-score of the spine and bones of the femur. Dynamic observation for 5 years and the determination of vertebral fractures and long bones.
Results: BMD measured in lumbar spine and proximal femur were analyzed. According DXA BMD of femur in patients with diabetes is significantly higher than that of non-diabetics (0,928 [0,847;1,029]; 0,858 [0,779 0,928]; p=0,000005). T-score is also higher in diabetics (-1,47 [-2,12;-0,63]; -2,01 [-2,71;-1,49]; p=0,000020). BMD and T-score of the lumbar vertebrae in diabetic patients was also is significantly higher: BMD (Group I =1,002 [0,902;1,182]; Group II =0,969 [0,879;1,106]; p=0,008). T-score (-0,94 [-1,43; -0,05]; -1,07 [-1,54; -0,40]; p=0,014). After 5 years, spine or long bones fractures marked in 12 patients (18%) from I group. In Group II was observed only 5 episodes of bone fracture (2.6%).
Conclusions: BMD in men with diabetes are higher, but they often develop bone fractures. Perhaps this is due to pathological remodeling of bone tissue on a background of metabolic disorders, when bone is more dense, but fragile.

AB0824 THE METHOD OF CALCULATING THE PROBABILITY OF OSTEOPENIA IN PATIENTS WITH MULTIFOCAL ATHEROSCLEROSIS

A.N. Kokov[1], V.L. Masenko[1], S.E. Semenov[1], T.A. Raskina[2], O.L. Barbarash[1]. *[1]Federal State Budgetary Scientific Institution Research Institute for Complex Issues of Cardiovascular Diseases; [2]Kemerovo state medical academy of Federal Agency of Healthcare and Social Development, Kemerovo, Russian Federation*

Objectives: To determine probability of the presence of osteopenic syndrome in patients with multifocal atherosclerosis based on the multislice computed tomography (MSCT) evaluation of vascular calcification.
Methods: 186 male (60±6,7 years) with multifocal atherosclerosis. All the patients underwent the measurement of BMD with X-ray absorptiometry. Moreover, calcium scores (CS) of coronary and brachiocephalic arteries were obtained using Agatston method.
Results: Among the patients had a high prevalence of osteopenia syndrome (87.1%). According to X-ray absorptiometry T-score values of lumbar vertebrae -1.07 [-1.54; -0.40], T-score of the proximal femur -2.01 [-2.71; -1.49]. We also found a large amount of calcification of the coronary arteries according MSCT: calcium score (CS) 471.8 [118.2; 916,8]. Calcification of the carotid arteries in patients of the study group was less pronounced: CS 113.9 [44.5; 300.8], but noted significant direct relationship between the degree of calcification of different vascular beds (r=0,35, p<0,05). We have data on the significant inverse association between bone density and a coronary artery calcification (r=-0,29, p<0,05), and the carotid artery (r=-0,22, p<0,05) by using Spearman rank correlations. Factors that affect the probability of osteopenic syndrome (according X-ray absorptiometry) in patients with known rates of calcification of the coronary and carotid arteries were obtained by regression analysis. These factors were coronary CS (p=0.012), carotid CS (p=0.034), the mass of calcifications of the carotid arteries (p=0.025) and the presence of a stenosis of the carotid arteries (p=0.026). The predictive model for estimating the probability of the presence of osteopenia in patients with multifocal atherosclerosis has been is designed using regression coefficients of each of the factors. As a result, ROC-analysis of the area under the ROC-curve for this prediction model was 0.792 (p=0.0001). The model was tested in the study sample. The specificity of the model was 72.1%, sensitivity of the model was 80.2%.
Conclusions: The study results suggest that indicators of calcification of the carotid and coronary arteries resulting from a routine examination by MSCT of patients with multifocal atherosclerosis have a high predictive capacity for assessing the probability of the presence of osteopenic syndrome in this category of patients.

AB0825 COMPARISON OF BONE DENSITY CHANGES ONE YEAR AFTER TREATMENT WITH ZOLEDRONIC ACID VERSES DAILY TERIPARATIDE

A.K. Aggarwal, D. Jain, N. Aggarwal. *Rheumatology, Institute of Rheumatology & Pain, Ghaziabad, India*

Background: The treatment of Osteoporosis is difficult to monitor and so usually incomplete resulting in inadequate response.[1]
Objectives: To evaluate the minimum period of treatment required with Bisphosphonates and Parathyroid hormone in order to see a significant change in serial Bone Mineral Density analysis (BMD).
Methods: Low BMD patients were subjected to yearly infusion of Zoledronic Acid 5mg (ZA) verses daily Subcutaneous injections of Teriparatide 20 μg (PTH). A single center pencil beam bone densitometer was used to measure serial BMD at baseline and yearly. Average BMD measures from the Spine L2, L3 and L4 (BS) and Total Hip (BH) were evaluated. The percentage change in the mean BS and BH readings was calculated to look for the least significant change (LSC) in the density scores.
Results: Significant change of 4.65% was seen (LSC=2.6%)[2] in the Spine in the PTH group after one year of treatment while it took two years in the ZA group for a 2.77% change. There was no significant change (LSC=3.6%)[2] in both groups in the BH. A p>0.05 was considered statistically significant. The finding is summarized in Table 1.

Table 1

Study group of 100 patients					Percentage Change in BMD			
Treatment Group	N	Gender		Age range	BS*		BH**	
		Males	Female	Years	After 1 yr	After 2 yrs	After 1 yr	After 2 yrs
ZA - Zoledronic Acid	50	12	38	42–79	2.19	2.77	0.02	2.47
PTH -Teriparatide	50	10	40	40–75	4.651	X	2.272	X
LSC - Least Significant Change for single DXA machine					2.50%		3.60%	

*Average of L2,3,4 Spine; **Total Hip.

Conclusions: Significant result of treatment with PTH requires a period of one year of therapy while with ZA it needs two years. The LSC in BMD is seen in the Spine and not in the Total Hip BMD.

AB0826 RESULTS OF BONE MINERAL DENSITY IN COELIAC DISEASE: ABOUT 30 CASES

H. Kchir[1], D. Kaffel[2], R. Zgolii[1], D. Issaoui[1], H. Chaabouni[1], H. Sahli[3], N. Maamouri[1], M. Elleuch[3], M.M. Kchir[2], N. Ben Mami[1]. *[1]gastroenterology B, Rabta hospital, Tunis; [2]Rheumatology, Kassab institute, Manouba; [3]Rheumatology, Rabta hospital, Tunis, Tunisia*

Background: The link between Coeliac disease (CD) and low bone mass has been established in several large international studies.
Objectives: To determinate the prevalence and risk factors of osteopenia and osteoporosis in a Tunisian population of coeliac patients.
Methods: We carried a retrospective study from January 1991 to December 2015 including all cases of CD diagnosed in the departement of Gastroenterology B in Rabta's Hospital. We retained all patients having a bone mineral density (BMD). We used the WHO criteria for the diagnosis of osteoporosis and osteopenia.
Results: During the period of the study, 78 cases of CD were included. Thirty among them, performed a BMD: 25 women and 5 men with an average age of 35.8 years. Malnutrtion was found in 14 patients with a BMI <20Kg /m^2. Smoking was found in one case. Among women, 2 were menopaused. BMD showed a low bone mass in 76,3% of patients: osteoporosis in 43.3% and osteopenia in 33.3%. The mean T score was -2.08 DS in the lumabr spine (LS) and -1DS in the Femur (F). The mean Z score was -1.66DS in LS and -0.73DS in femur. Osteoporosis was found in 13 patients: 3 men and 10 women (2 among them were menopaused). The research of risk factors of osteoporosis found a smoking (N=1), and an associated autoimmune disease in 5cases: A diabetes Mellitus in 3 patients, and an autoimmune hepatitis an Sjogren Syndrome in 1 case. Finally, a marked villous atrophy was associated to osteoporosis in 9 cases.
Conclusions: Our study showed that approximately ¾ of coeliac patients had a low bone mass. Osteoporosis was found in 33% of our patients and was associated to a marked villous atrophy.

AB0827 COMPARISON OF THE CAPABILITY OF RADIAL BONE MINERAL DENSITY AND CALCANEAL QUANTITATIVE ULTRASOUND VARIABLES IN THE IDENTIFICATION OF MEN WITH OSTEOPOROSIS

A. Oral, D. Sindel, A. Yaliman, S. Asghari Kaleibar, S. Esmaeilzadeh. *Physical Medicine and Rehabilitation, Istanbul University Istanbul Faculty of Medicine, Istanbul, Turkey*

Background: Bone mineral density (BMD) as measured by dual-energy X-ray absorptiometry (DXA) is considered the gold standard for the management of osteoporosis. Recently, quantitative ultrasound (QUS), which is easy to use, inexpensive, portable, does not use ionizing radiation, and has also been shown to provide information about bone quality and to predict fracture risk, has gained growing interest in this area.
Objectives: The aim of this study was to compare the capability of one-third radius (33% radius) DXA BMD measurements and calcaneal QUS (cQUS) variables for identifying axial osteoporosis as measured by DXA in men.
Methods: Axial BMD measurements at the lumbar spine and at the hip (femoral neck and total hip), 1/3 radius BMD of the non-dominant forearm were made using DXA and cQUS variables at both sides as measured twice were obtained in 179 men aged between 24 and 85 years. Osteoporosis was defined based on the WHO criteria in men aged 50 and over, a man having been considered as osteoporotic in the presence of a T-score $\leq$-2.5 in any of the axial regions measured. For defining axial osteoporosis or BMD below the expected range for age, Z-scores of $\leq$-2.0 were used in men younger than the age of 50 years. Receiver operating characteristic (ROC) analysis was used to assess the osteoporosis identification capability of measurements.
Results: The areas under ROC curves (AUCs) for 1/3 radius BMD, its T-score, the lowest means (as calculated as the mean of the two calcaneal QUS measurements for each heel) of quantitative ultrasound index (QUI), QUI T-score, broadband ultrasound attenuation (BUA), speed of sound (SOS), and estimated heel BMD (eBMD) for identifying axial osteoporosis or BMD below the expected range were found as 0.755, 0.767, 0.760, 0.758, 0.717, 0.768, and 0.764 ($p<0.001$ for all), respectively.
Conclusions: In conclusion, AUCs pointed to similar (for QUI, QUI T-score, and eBMD) or even better (for SOS) osteoporosis discriminative capability of cQUS variables in comparison to radial DXA BMD variables. These findings may have implications that cQUS variables, particularly SOS, may be used for the identification of osteoporosis in men whose axial BMD cannot be measured by DXA due to certain circumstances as well as in circumstances where DXA is not available.

AB0828 MAJOR RISK FACTORS OF OSTEOPOROSIS IN RA FEMALE PATIENTS WITH NORMAL MENSTRUAL CYCLE

E.A. Taskina, L.I. Alekseeva, I.S. Dydykina, M.M. Podvorotova, A.V. Smirnov, S.I. Glukhova, E.L. Nasonov. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation*

Background: Only postmenopausal women were in the researcher's focus in the majority of publications on osteoporosis (OP) risk factors (RF) in RA female patients (pts). Meanwhile the data on OP RF in menstruating women presented in the rare available papers are not consistent.
Objectives: To identify the major OP RF in RA female pts with normal menstrual cycle.
Methods: 51 RA (based on ACR criteria) female pts with normal menstrual cycle aged 20 to 51 years (mean age 41,1±7,9) were examined. The following info was included in each individual pts' files: anthropometric parameters, social and demographic data, case history, clinical examination and lab findings, traditional OP RF, pts' joint status, comorbidities status, pain intensity assessments and VAS evaluation of pts' general health status. Axial bone mineral density (BMD) was measured with DEXA scan using Z-score calculator. Based on the OP status all pts were divided into 2 groups:pts with OP–16 (31,4%), and pts without OP–35 (68,6%).
Results: Comparative analyses of the groups showed that: OP pts were younger vs the pts without OP (36,9±10 vs 42,8±6,3 years, p=0,02). Disease duration was comparable in both groups. Clinical manifestations of inflammation activity (mean DAS 28 score and hsCRP) were statistically significantly more pronounced in the OP group vs the pts without OP (4,91±1,39 vs 4,19±1,06, p=0,049; 27,8 (10,8–43,5) vs 7,4 (1,4–22,7) mg/L, p=0,02, respectively). High DAS 28 (50 vs 20,6%, RR=2,43, 95% CI 1,07–5,53, p=0,03) scores were more often documented in the OP pts. Pronounced feet and hand bone destruction based on the radiographic findings was documented in the majority of pts in both groups, although in the OP pts the joint space narrowing counts (97 (62,5–121) vs 73,5 (53–87), p=0,02) and the total Sharp score (98 (64,5–183) vs 89,0 (63–112), p=0,03) were statistically significantly higher. The OP pts were more often administered oral GCs (81,3 vs 37,1%, RR=2,19, 95% CI 1,34–3,57, p=0,004), as well as GCs -pulse therapy (56,3 vs 25,7%, RR=2,18, 95% CI 1,08–4,45, p=0,04), had higher GCs cumulative dose (18,8 (8,1–30,7) vs 6,4 (0,8–14,1)g, $p<0,01$), higher GC daily dose at the time of examination (8,8 (6,3–10) vs 5 (3,8–6,3)mg/day, p=0,01) and higher average daily dose in the previous year (8,8 (5–10) vs 3,8 (2,5–6,3)mg/day, p=0,01) versus the pts without OP. Analysis of traditional RF (low body weight/BMI, long immobilization periods, smoking, family history of OP and others) showed no difference between the two groups. Discriminant analysis revealed the following major OP RF in the RA female pts before menopause: RA activity (based on the Das 28 score) and GCs dose at the time of examination (given GCs therapy lasts $\geq$3 months). Meanwhile the patient's body weight and age at the onset of RA were identified as protective factors for BMD. Based on the abovementioned risk and protective factors and the derived coefficients the authors designed a formula allowing to predict of OP in female RA pts before menopause with high accuracy (area under the ROC-curve=0,833). The model accuracy is 85,1%.

Factors	Discriminant function coefficients
RA activity (DAS 28)	0,667
GCs dose at the time of examination	0,257
Age at RA onset	-0,09
Body weight	-0,034
Constant	1,319

Conclusions: RA activity and GCs dose (GCs therapy duration $\geq$3 months) were identified as the major OP RF in young RA female pts before menopause, thus adequate and timely therapy aimed at obtaining RA control and achieving remission should be considered as key OP prevention strategy.

AB0829 BONE METABOLISM IN LIVER TRANSPLANT PATIENTS TWO-YEAR STUDY. INFLUENCE OF MEDICAL INTERVENTION PRIOR TO SURGERY AND ANTIRESORPTIVE TREATMENT

E. Labrador Sánchez [1], E. Grau Garcia [1], K. Arévalo Ruales [1], J.J. Fragio Gil [1], R. González Mazarío [1], C. Alcañiz Escandell [1], I. Cánovas Olmos [1], I. Chalmeta Verdejo [1], C.M. Feced Olmos [1], L. Gonzalez Puig [1], J. Ivorra Cortes [1], I. Martínez Cordellat [1], C. Nájera Herranz [1], R. Negueroles Albuixech [1], J.E. Oller Rodriguez [1], F.M. Ortiz-Sanjuan [1], E. Vicens Bernabeu [1], A. Villota Bello [2], V. Fornés Ferrer [3], D. Hervás Marín [3], D. Moya Nájera [4], A. Moya Herraiz [5], J.A. Román Ivorra [1,2]. *[1]Rheumatology Department, HUP la Fe; [2]Medical School, UCV; [3]Biostatistic Unit, IIS la Fe; [4]Health and Sport Group, UV; [5]Hepatology Department, HUP la Fe, Valencia, Spain*

Background: Osteoporosis is a frequent complication in patients with chronic liver diseases, mainly in advanced stages or with evidence of cholestasis. During the first few months after liver transplant (LT) it seems that there is an accelerated bone mass loss and greater fracture risk.
Objectives: To study the antiresorptive treatment effect in bone metabolism in patients undergoing LT and to evaluate whether medical intervention prior to LT decreases the risk of osteoporosis
Methods: We recruited patients from the LT Protocol of Osteoporotic Risk Assessment. The patients were evaluated 3–6 months before surgery, shortly after transplant (month 0) and 6–12–18–24 months after surgery. Data of bone metabolism biomarkers, densitometric values and antiresorptive treatment was collected. Biostatistical analysis with R (3.3.2.) was performed.
Results: We selected 163 LT patients of which 86 completed 24 months follow-up. From the total cohort, 77.8% were men and the mean age at transplantation 54.53±9.4 years old. 92.6% of patients were supplemented with vitamin D after surgery and 19.6% initiated antiresorptive treatment. We observed that 25-OHVitamin D, PTH, beta-CTX and P1NP levels were corrected through the follow-up. T-score during the first year of follow-up decreased slightly and at 24 months the tendency was towards increase. This pattern was stronger in lumbar spine (t-score -1.48±1.34 after surgery and -1.28±1.06 at 24 months). Statistical analysis showed that antiresorptive treatment significantly influence lumbar and hip densitometric values ($P<0.001$ and $P<0.001$ respectively) as well as P1NP levels (P=0.003 and P=0.012 respectively). Moreover, obesity (P=0.0004), as well as beta-CTX (P=0.029) and 25-OHVitamin D (P=0.024) standardization improved hip densitometric values. Finally, LT patients evaluated before surgery showed better lumbar densitometric values than those evaluated after the transplant (P=0.007).

Conclusions: We observed 25-OHVitamin D levels and bone metabolism biomarkers correction during the first two years after LT. Medical intervention prior to LT as well as antiresorptive treatment seem to play a decisive role in bone mineral density improvement.

AB0830 BONE MINERAL DENSITY IN MULTIPLE MYELOMA: 39 CASES

Z. Saoussen, H. Mouanaa, A. Arfa, M. Jguirim, B. Ismaiel, M. Touzi, N. Bergaoui.
Rheumatology departement of Monastir University Hospital, Monastir, Tunisia

Background: In multiple myeloma (MM), osteolysis affects more than 80% of patients. This leads to bone pain, pathological fractures and hypercalcemia. These lesions result from an alteration of bone remodeling by increased osteoclast activity and decreased osteoblasts one. The real impact of this osteolysis on bone mineral density remains largely understudied. To the best of our knowledge the impact of MM on bone mineralization was studied worldwide only for 6 times where our study is the second biggest one.
Objectives: The aim of the study was to evaluate bone mineralization in the patients with multiple myeloma according to the criteria of diagnostic (IMWG: International Myeloma Working Group 2014, during a period of 5 years (2011–2016).
Methods: This is a transverse and descriptive study. The bone mineral density was measured by dual-energy X-ray absorptiometry with Lunar Prodigy in spine (L2-L4) and femoral neck.
Results: Thirty-nine patients were collected. The average age was 63±10 years [50 years, 86 years] upon them 26 men and 13 women. The sex-ratio is equal to 2. 11 patients were smoking (35%), 9 of them had diabetes and only 2 were alcoholic (6%). The Body Mass Index (BMI) average was 29 kg/m^2. Only one case was underweight (3%). The reason of seeking health carewas poor general state in 14 cases (49%), bone pain in 22 cases (78%),5 cases among them of generalized bone pain (23%) and 12 cases of rachialgia (4.5%) and only 4 cases of pathological fracture (15%). The distribution of patients according to the Durie and Salmon Classification was as follows: 25 cases (84%) in stage III, 3 cases (10%) in stage II, 2 cases (7%) in stage I, and 27 cases (90%) Type A and 3 cases (10%) type B. The average of the monoclonal spike was 34g/L [2.5g/L, 88g/L] The heavy chains antibodies were IgG type in 19 cases (64%), IgA type in 7 cases (24%), IgM type in only one case (4%) and IgD type in only one case (4%). The light chains were Kappa type in 19 cases (64%) and Lambda type in 11 cases (37%). The ISS score was equal to 1 in 6 cases (23%), equal to 2 in 13 cases (34%) and equal to 3 in 8 cases (30%).The average bone mass in the spine was 0.998±0.254g/cm^2 [0.632g/cm^2; 1.892g/cm^2] and in the femoral neck 0.869±0.254g/cm^2 [0.632g/cm^2; 1.892g/cm^2]. The average of the Z-score in the spine was -0.762±1.895 [-4.4; 5.7] and in the femur -0.438±0.962 [-2.8; 1.4]. The mean T-score in the spine was -1.626±2.025 [-4.9; 5.6] and in the level of the femur -1.567±1.178 [-3.7; 1]. There was a decrease of bone mineral density noticed in 15 patients (39%) in at least one place (T-score more than 2.5 SD below normal of young healthy persons. Seventeen patients (58%) were candidates for *autogenous bone graft*. They had *induction chemotherapy* (Dexamethasone-thalidomide). Others was treated by MPT protocol (Prednisone-Thalidomide-Dexamethasone) in 8 cases (28%), CDT protocol (Cyclophosphamide-Thalidomide-Dexamethasone) in one case (4%) and MP protocol (Melphalan -Prednisone) for the remaining (10%).
Conclusions: BMD analysis suggests that MM is associated with systemic bone disease with progressive loss of bone mass at both the spinal and lumbar levels. In order to better study the impact of multiple myeloma and chemotherapy on bone densitometry, a densitometry controlin about 5 years is favorable.

AB0831 FRAX SCORE: AN INTERESTING WAY FOR GASTROENTEROLOGISTS TO ASSESS FRACTURE RISK IN PATIENTS WITH LONG-TERM PROTON PUMP INHIBITORS

H. Romdhane[1], M. Cheikh[1], K. Abdelghani[2], R. Ennaifer[1], N. Bel Hadj[1], A. Laatar[2]. *[1]Gastroenterology and hepatology; [2]Rhumatology, Mongi Slim Hospital, TUNIS, Tunisia*

Background: Proton pump inhibitors (PPI) are effective in many indications. Nevertheless, some serious adverse effects associated with prolonged exposure, including an increase in fracture risk, have occurred. This would be explained by two main mechanisms: decreased absorption of calcium secondary to decreased gastric acidity and inhibition of proton pump of osteoclasts reducing bone resorption.
The Frax score assess the 10-year probability of osteoporotic fracture or hip fracture in subjects older than 40 years.
Objectives: The aim of our study was to evaluate the usefulness in our practice of this score in patients under long-term PPI.
Methods: We included patients who had been taking PPI for at least one year. In all patients, we specified the indication and duration of PPI. We then looked for the main personal or family risk factors for osteoporosis. Bone mineral density (BMD) was performed in all patients and frax score was calculated for those older than 40 years.
Results: Fifty-two patients were included in our study. The mean age was 49.5±14.55 years [21 - 84 years] with a sex ratio of 0.48. Long-term PPI were indicated in 75% (n=39) of patients for gastroesophageal reflux, in 11.5% (n=6) for chronic gastritis with failure of Helicobacter Pylori eradication, in 3.8% (n=2) for persistent epigastralgia, in 5.7% (n=3) for functional dyspepsia and finally in 3.8% (n=2) of patients in prophylaxis of gastroduodenal lesions in chronic use of NSAIDs. The mean duration of intake was 45.4 months [12–240 months]. The main osteoporotic risk factors were tobacco in 25%, alcohol in 12%, physical inactivity in 42% and dysthyroidism in 6% of cases. In our study, 20 women among the 35 included (57% of cases) were already menopausal. An osteoporotic fracture in a first-degree relative was noted in 23% of cases, including one parent reporting two fractures. A history of fragility fracture was observed in 11 patients (21%) including 3 men and 8 women. The mean daily calcium intake was 567.2±327.6 mg /d [230 -2315 mg /d]. Calcium intake was insufficient in 94% of patients. BMD was normal in 15 patients (29% of cases) while 71% (n=37) had low BMD. In our population, age (p=0.02), calcium intake (p=0.029) and menopause ($p<0.0001$) were significantly related to low BMD. The duration of PPI intake was negatively correlated with BMD. Patients taking PPI for at least 30 months were 6.5 times more likely to have low BMD (95% CI [1.5–27.4]). The mean FRAX score for major osteoporotic fractures in 37 patients older than 40 years was 1.08±0.84% [0.3–3.3%]. For hip fractures, the mean score was 0.26±0.29% [0–1.4%]. There was a significant correlation between mean Frax score and BMD ($p<0.0001$). None patient had a patent or subclinical fracture during the follow-up period.
Conclusions: Our study shows an increased risk of fracture in patients under long-term PPI, especially if they have other osteoporotic risk factors. In this context, Frax score is a simple and non-invasive tool for assessing fracture risk in these patients and to adapt screening strategy for sub-clinical fractures.

AB0832 EFFECT OF LONG-TERM PROTON PUMP INHIBITORS ON BONE MINERAL DENSITY

H. Romdhane, M. Cheikh, H. Ben Nejma, R. Ennaifer, N. Bel Hadj.
Gastroenterology and hepatology, Mongi Slim Hospital, TUNIS, Tunisia

Background: Proton pump inhibitors (PPI) are widespread nowadays. Recent concerns have emerged about possible bone complications of long-term use of PPIs, such as low bone mineral density (BMD) and an increased risk of fractures.
Objectives: The aim of our study was to evaluate the effect of long-term use of PPIs on bone by measuring the BMD in order to estimate the frequency of osteopenia and osteoporosis, and to determine the risk factors associated to this complication.
Methods: It was a prospective study including consecutive patients who where taking proton pump inhibitors for at least one year. In all patients we realized a bone densitometry in order to evaluate the bone strength and we calculated the FRAX score to estimate the risk of osteoporotic fracture at ten years.
Results: We included 52 patients. The mean age was 49,5 years old. The male-female ratio M/F was 0,48. At least three risk factors were found in more than 50% of the population. The calculated daily calcium intake was insufficient in 94% of the patients. The mean duration of PPIs intake was 45 months. The most frequent indication was gastro esophageal reflux disease (75%). The PPI prescription was appropriate in 94% of the cases. The prevalence of osteopenia and osteoporosis was respectively 52% and 19%. The predictive factors of low BMD were an age $\geq$50 years old (p=0,03), the menopause ($p<0,0001$), a calcium intake $\leq$550 mg/day ($p<0,038$), and a PPI use duration $\geq$30 months ($p<0,006$). The multivariate study could not be undertaken because of co linearity of the factors.
Conclusions: The long term PPI use is associated to the risk of bone complications, especially among patients at risk for osteoporosis. It seems reasonable to be more vigilant in prescribing PPIs and use lowest effective dose for patients with appropriate indications, and to screen these complications if necessary.

AB0833 BONE MINERAL DENSITY IN TUNISIAN PATIENTS WITH AUTOIMMUNE HEPATITIS

M. Cheikh, H. Romdhane, H. Bennejma, R. Ennaifer, N. Bel Hadj.
Gastroenterology and hepatology, Mongi Slim Hospital, TUNIS, Tunisia

Background: Bone loss in autoimmune hepatitis (AIH) is scanty and conflicting. The pathogenic mechanisms are not completely elucidated.
Objectives: This study aimed to assess the prevalence and risk factors for bone loss in patients with AIH.
Methods: Bone mineral density (BMD) using X-ray absorptiometry at both lumbar spine and femoral neck sites was measured in patients with AIH. Were excluded patients with diseases disturbing the bone density. Osteopenia was considered if T-score <-1.5 DS and osteoporosis if T-score <-2.5 DS.

Results: Twenty eight patients were enrolled in the study. They were 19 women (sex-ration M/F=0.6), with a mean age of 54 years [extremes: 13 - 73 years]. Most patients had type 1 AIH (89.2%). Seventeen patients were diagnosed at stage of cirrhosis (60.7%). Associated auto-immune manifestations were observed in 42.8% of cases. Overlap syndrome with primary biliary cirrhosis was noted in 21.4% of cases. Fifty five percent of patients were on steroid treatment with or without azathioprine. BMD was low in 9 patients (32%) as fellow: osteopenia in 6 cases and osteoporosis in 3 cases. There was a correlation between bone loss and use of steroid treatment but it wasn't statistically significant (p=0.07).
Conclusions: In our series, the prevalence of bone loss in AIH is high (45%). This data suggests that bone status should be assessed routinely in patients with AIH, especially in those on steroid treatment.

AB0834 RISK FACTORS FOR DECREASED BONE MINERAL DENSITY IN INFLAMMATORY BOWEL DISEASE IN A TUNISIAN COHORTE

H. Romdhane[1], M. Cheikh[1], K. Abdelghani[2], R. Ennaifer[1], N. Bel Hadj[1], A. Laatar[2]. [1]*Gastroenterology and hepatology;* [2]*Rhumatology, Mongi Slim Hospital, TUNIS, Tunisia*

Background: Patients with inflammatory bowel disease [IBD] are at risk for metabolic bone disease. Many studies have identified various risk factors but most of them have involved western patients.
Objectives: The aim of this study was to investigate the prevalence and the risk factors for metabolic bone disease in Tunisian IBD patients.
Methods: Retrospective study including patients with IBD admitted in our department between January 2011 and December 2015. Demographic and clinical characteristics of patients were analysed. Bone mineral density of the femoral neck, total femur and lumbar spine was quantified by dual-energy X-ray absorptiometry.
Results: Among 82 patients followed for IBD (70.7% with Crohn's disease; 29.3% with Ulcerative colitis), a bone densitometry was performed in 56% of cases (n=46). 16 patients have osteopenia and 7 had osteoporosis, as assessed by T-score. Univariate analysis showed that Crohn'n disease in particular ileal disease, high steroid dose and the presence of extra-intestinal manifestations were significantly associated with a low bone mineral density (for all $p<0.05$). In the other hand, IBD duration since diagnosis, sexe, tabagism were not associated with bone loss.
In multivariate regression analysis, risk factors for decreased bone mineral density were IBD duration since diagnosis, high steroid dose, ileal crohn's disease and extra-intestinal manifestations.
Conclusions: In our Tunisian cohort of IBD patients, Crohn's disease, high steroid dose and extra-intestinal manifestations were associated with increased risk for metabolic bone disease. High risk patients should be identified and appropriate therapies should be started early to improve long term quality of life.

AB0835 DENOSUMAB AS A FIRST CHOICE DRUG FOR GLUCOCORTICOID INDUCED OSTEOPOROSIS TREATMENT INSTEAD OF BISPHOSPHONATE

I. Yoshii[1], T. Chijiwa[2]. [1]*Orthopaedic Surgery, Yoshii Hospital, Shimanto City;* [2]*Rheumatology, Kochi Memorial Hopsital, Kochi, Japan*

Background: Glucocorticoid induced osteoporosis (GIO) is serious problem for raising risk of bone fragile fracture. In general, first choice drug for GIO is bisphosphonate (BPH), however, denosumab (dMAB), a monoclonal antibody of receptor activator of nuclear factor kappa-B ligand, is closed up as a alternative selection for GIO recently.
Objectives: The aim of this study is to evaluate effectiveness of dMAB in bone mineral density (BMD) for GIO treatment compared to BPH.
Methods: In the patients in whom glucocorticoid steroid (GCs) have been administered for more than three months, who met indication criteria for GIO what was determined by the Japanese Society for Bone and Mineral Research in 2014, that is matrix calculated in adding points of past fracture history, age, dosage of GCs, and BMD value (1), were enrolled. Before March 2013, data was lacking, so patients who have been administrated GCs after April 2013 were picked up. Patients BMD at GCs administration, at 6 months after initial treatment, if drug was changed, also at 6 months after second treatment, for minimum lumbar spine (LS), femoral neck (FN), and greater trochanter (GT) were measured with dual-energy X-ray absorptiometry (DEXA). Patients were classified by drug for initial treatment and second drug if administered. Patients age, initial, average, and total dose of GCs, term length of administration, and BMD and its gain for each chance were compared with Mann-Whitney U-test and Student's paired T-test.
Results: 149 patients in whom 48 with no drug administrated (N), 24 for BPH naïve and continued (BB), 22 for BPH naïve and changed to dMAB (BD), 21 for dMAB naïve and continued (DD), 34 for dMAB naïve and changed to BPH (DB) were counted. In these, sex distribution was 26 for men and 123 for women. Underlying disease for administration of GCs were rheumatoid arthritis for 114, polymyalgia rheumatica for 12, idiopathic thrombocytopenic purpura for 9, systemic lupus erythematosus for 6, and others for 8. For groups, age at baseline, initial, average, and total dose, and term length of administration of GCs demonstrated no significant difference between any pairs of the groups. BMD at baseline for Group N demonstrated significant greater per-cent of young adult mean (%YAM) than Group DD ($p<0.01$) in all parts, yet greater than the other groups but not statistically significant. In Group N, BMD had significantly decreased from the baseline to 6 months later in all parts ($p<0.01$). In the other groups, BMD had shown gain at 6 months after drug administration in all part, however, in Group DB showed mean %YAM loss for GT after first and second drug administration compared to Group BD had shown %YAM loss after first but gain after second drug for FN (Table 1).

First Drug (FD)	none	bisphosphonate		denosumab	
Second Drug (SD)	none	none	denosumab	none	bisphosphonate
Cases	48	24	22	21	34
age at baseline	69.7±10.8	73.7±16.5	81.8±12.2	72.5±11.5	71.5±10.8
initial dose of GCs	6.78±8.98	6.88±8.25	5.58±6.95	5.21±3.47	6.95±2.25
average dose of GCs	3.77±2.13	5.49±3.76	5.06±1.61	3.49±1.49	5.12±2.06
term length of administration	53.6±45.3	84.7±44.9	38.2±46.4	51.9±58.7	65.2±46.0
total dose of GCs	3836.6±4444.3	7170.2±10923.8	2447.1±6365.9	5017.1±9057.3	7898.2±772.9
BMD of lumbar spine at baseline	89.1±16.9	78.1±17.7	80.2±12.4	70.9±9.3	75.9±12.4
BMD of LS at six months after administration of FD	86.5±19.1	79.3±10.5	81.8±15.2	72.9±13.5	75.9±15.5
BMD of LS at six months after administration of SD			81.2±12.8		77.3±9.2
BMD of FN at baseline	90.8±12.8	77.3±9.3	70.6±12.9	66.8±7.6	72.1±8.8
BMD of FN at six months after administration of FD	87.8±15.4	80.0±14.6	69.1±12.2	65.9±12.4	74.3±11.4
BMD of FN at six months after administration of SD			71.2±11.3		74.4±15.3
BMD of GT at baseline	85.8±9.8	80.8±10.1	71.2±12.7	67.1±12.6	75.2±9.4
BMD of GT at six months after administration of FD	83.5±14.5	80.1±12.9	71.2±12.7	68.9±12.6	75±9.3
BMD of GT at six months after administration of SD			74.2±13.3		74.2±10.3

Table 1: Results of glucocorticoid induced osteoporosis (GIO) patients for each group classified by used drugs. GCs : glucocorticoids, BMD : bonemineral density, LS : lumbar spine, FN : femoral neck, GT : greater trochanter. Unit in BMD is per cent of young adult mean (%YAM).

Conclusions: From these results, dMAB is effective role in raising BMD for GIO as a initial drug, and a second drug even after inadequate response to BPH. dMAB could be possible to be chosen as a first choice drug for GIO treatment.

AB0836 PERFORMANCE OF QUANTITATIVE ULTRASOUND AND SIX OSTEOPOROSIS RISK INDEXES IN MENOPAUSAL WOMEN: VALIDATION AND COMPARATIVE EVALUATION STUDY

I. Ghozlani[1], A. El Maataoui[2], M. Ghazi[3], A. Kherrab[3], R. Niamane[3]. [1]*Rheumatology Department, Military Hospital;* [2]*Chemistry-Biochemistry Department, Faculty of Medicine and Pharmacy, Ibn Zohr University, Agadir;* [3]*Rheumatology Department, Military Hospital Avicenne, Marrakech, Morocco*

Background: A number of questionnaire-based systems and the use of portable quantitative ultrasound scanners (QUS) have been devised in an attempt to produce a cost-effective method of screening for osteoporosis.
Objectives: to assess the sensitivity and specificity of different techniques and their ability to act as screening tools in relation to dual energy X-ray absorptiometry (DXA).
Methods: 295 white postmenopausal women aged over 60 were enrolled. Each subject completed a standardized questionnaire which permits the measure of six osteoporosis indexes and had bone mineral density (BMD) measured using QUS and DXA. Sensitivity and specificity of the different techniques in relation to DXA were plotted as receiver-operating characteristic (ROC) curves at DXA T-score total hip $\leq$ -2.5 (osteoporosis).
Results: BUA sensitivity and specificity values were respectively 76.8% and 51.2% at the total hip. The optimal cut-off T-score for QUS was -2 at the total hip. The osteoporosis self-assessment tool (OST) provided consistently the highest AUC (0.80) among the clinical tools and had the best sensitivity and specificity balance (90.2%>44.5%). OST negative likelihood ratio was 0.22.
Conclusions: OST (based only on the weight and the age) performed slightly better than QUS and other risk questionnaires in predicting low BMD at the total hip.

AB0837 BONE METABOLISM AND OSTEOPOROSIS RISK FACTORS ANALYSIS IN SPINAL CORD INJURY PATIENTS AT TWELVE MONTHS FOLLOW UP

I. Martínez Cordellat[1], F. Torralba Collados[2], C. Grao Castellote[2], E. Grau García[1], V. Fornes Ferrer[3], E. Labrador Sánchez[1], K. Arévalo Ruales[1], J. Fragio Gil[1], R. González Mazarío[1], C. Alcañiz Escandell[1], I. Chalmeta Verdejo[1], C. Feced Olmos[1], L. González Puig[1], J. Ivorra Cortés[1], R. Negueroles Albuixec[1], J.E. Oller Rodríguez[1], F. Ortiz Sanjuán[1], E. Bernabeu Vicens[1], C. Nájera Herranz[1], I. Cánovas Olmos[1], J.A. Román Ivorra[1]. [1]*Rheumatology Department;* [2]*Spinal Cord Injury Unit;* [3]*Biostatistics Unit IIS la Fe, Hup la Fe, Valencia, Spain*

Background: The spinal cord injury associated with the immobilization of the

patient leads to a decrease in bone mass. The bone loss greater is observed in the 6 months after the spinal cord injury, and stabilizing between 12–16 months after the same. The incidence of fractures oscillates between 1.5% and 6%.
Objectives: To assess bone metabolism and bone fracture incidence in SPI patients.
Methods: Prospective study of SPI patients from the Spinal Cord Injury Unit of La Fe Hospital. In all cases densitometry, x-ray image, bone metabolism biomarkers and clinical evaluation have been performed according protocol. Statistical techniques was carried out using R software 3.2.3, using mixed linear regression models.
Results: We studied 40 patients with SCI, 54% of them men and 46% women, with a mean age of 59.5 years (57.3- 63.5). The 58% of patients showed thoracic injuries, 48.6% paraparesis and 46.7% presented level C in Asia scale. The baseline study was performed in 100% of patients (n=40), 65% in month 6 (n=26), 30% in month 12 (n=12), and in 22.5% in month 18 (n=9). The 32.4% of patients received supplementation with calcium and vitamin D at month 0, 66.7% at month 6 and 100% at month 12.
In month 6, the 11.1% was treated with antiresorptive drugs.
An increase in vitamin D values can be observed in the population with follow-up (values of 16.82 in month 0 to 39.33 in month 12), justified by the supplementation, and there is an increase in Calcium and a decrease in phosphorum values.
There was also a decrease in PTH levels in month 12 (32.3) compared to month 0 (34.08), as well as a decrease in bctx levels. Probably related to the increase of vitamin D.
Despite a decrease in the densitometric parameters at month 6, a slight recovery in bone mineral density at month 12 was observed. No bone fractures were seen during Follow-up in none of the patients.
Results from biochemical markers and densitometry are showed in the table

Parameter	Month 0	Month 6	Month 12
	Mean (SD)	Mean (SD)	Mean (SD)
Calcium	9.04 (0.47)	9.57 (0.36)***	9.39 (0.34)***
Phosphorus	3.83 (0.62)	3.42 (0.45)***	3.4 (19.94)***
25OH Vitamin D	16.82 (10.4)	37.27 (15.52)***	39.33 (19.94)***
PTH	34.08 (21.74)	36.16 (19.46)	32.3 (12.6)
P1NP	76.1 (79.18)	64.27 (28.11)	65.87 (25.76)
BCTX	0.94 (0.46)	0.62 (0.87)**	0.34 (0.21)***
Lumbar spine tscore	-0.24 (1.58)	-0.25 (1.11)	-0.3 (1.27)
Femoral neck tscore	-0.73 (1.34)	-1.35 (1.03)**	-1.26 (1.25)**
Hip bone tscore	-0.74 (1.25)	-1.56 (1.29)***	-1.52 (1.4)***

*p<0,05, **p<0,01,***p<0,001.

Conclusions: A high percentage of our patients with spinal cord injury has a vitamin D deficiency. In addition, the lower levels are associated with cases where the mobility limitation is higher. As patients increase vitamin D values, a decrease in the bctx and PTH parameters is observed.
No fractures were detected during follow-up.

AB0838 EPIDEMIOLOGY AND ANALYSIS OF FALLS IN PATIENTS DURING BALNEOTHERAPY IN DANUBIUS HEALTH SPA PIESTANY

I. Rybar[1], V. Kolnikova[2], T. Zimanova[2], R. Gaspar[2]. *[1]Department of Rheumatology, National Institute of Rheumatic Diseases; [2]Department of Physiotherapy, Danubius Health Spa, Piestany, Slovakia*

Background: Patients falls in hospitals are frequent and undesirable complications that may lead to negative outcomes such as injuries, prolonged hospitalization and legal liability.
Objectives: To investigate the incidence and characteristics of patients hospitalized in the Health Spa Piestany.
Methods: Prospective analysis of falls in the group of in-patients of health spa during a year since 01.01.2015 to 31.12.2015.
Results: Overall there were hospitalized in the health spa 25 774 in-patients. The mean age of patients was 64,02±13,16 years. There were women - 15 301, mean age (63,61±11,57 years) and men 10 473, with mean age (64,43±9,22 years). Falls were confirmed in 131 patients (women 94, mean age 68,55±10,22 years and men 37 males, mean age 70,39±7,62 years. Fractures have been confirmed in 19 patients, all of them non-vertebral. The ankle distortion were in 11 patients and lacerated wounds in 10 patients. There were collapse status in 8 and commotio cerebri in 1 patient. Spa therapy had to be discontinued only in 5 from 131 patiens due to falls. The annual incidence of falls reached 5,08 cases/1000 patients. In women there were - 6,14 cases/1000 women a year and in men 3,53 cases/1000 men a year. The annually incidence of fractures reached 0,69/1000 pacients. The most common locations of falls were hotel rooms, especially bathtub in the bathroom (49%), slightly less facilities for balneotherapy (22%), the area outside the spa (21%) and at least in the park area of health spa 8%. Women and men who have suffered falls had significantly higher age and had also high rate of cardio-vascular morbidity (87%).
Conclusions: The annual incidence of falls among patients in a balneotherapy reached to 5.08 cases per 1,000 patients per year. Incidence of falls in women was almost twice as high compared to men. The age of women and men with falls was significantly higher (p<0,001) compared to other patients and they also had higher rate of cardiovascular morbidity. The most common locations of falls were bathtubs in the bathroom.

AB0839 THE EFFICACY AND SAFETY OF DENOSUMAB LOCAL EXPERIENCE)

J. Al-Saleh, N. Salah, A.S. Hasan, S. Mohamad, F.A. ElBadawi, M. Khamashta. *Rheumatology Department, Dubai Hospital, Dubai, United Arab Emirates*

Background: Denosumab was introduce to the United Arab Emirates Market in 2013.Given the limited experience in using Denosumab in the region we have explored it efficacy and safety in daily practice.
Objectives: To assess the efficacy and safety of Denosumab in our practice.
Methods: *Inclusion criteria:* All patients received Denosumab in a dose of 60mg every six months. Underwent DEXA scan in Dubai Health Authority. *Exclusion from analysis:* Other Doses of Denosumab, who received less than 3 doses, and those with no follow up DEXA scan. *Outcome measures:* 1) Efficacy: Proposed Criteria for Assessing Clinical Response [1,2]. a) "inadequate": incident fracture and significant BMD decrease. b) "possible inadequate": incident fracture or significant BMD decrease. c) "appropriate": no fracture and stability or increase in BMD. 2) Safety: Reviewing the medical records and conduct patients interview for occurrence of the following adverse events. *Statistical analysis:* Descriptive statistical analysis, Graphpad Prism 6 was used.
Results: 143 patient identified. Out 139 patients 86 were eligible for analysis (See table 1). At baseline 39% had normal vitamin D level, 57% had insufficiency and 4% had deficiency. 20 of 86 did not undergo repeated DEXA scan. 9% had osteopenia and 91% had osteoporosis before initiating Denosumab in comparison 8% had normal bone mineral density, 45% had osteopenia and 47% post four injections of Denosumab. Table 2 summarize the comparison between the responders and non-responders. There was a significant positive correlation in the increase in bone mineral density among the responders at the femoral neck and the lumbar spine, (r=0.56, 95% confidence interval: 0.31–0.74, P-value <0.0001 No report of any of the adverse events 86 patients who completed 2 years or more on treatment.

Table 1. Patients characteristics at baseline

Variables	Number	Percentage
Age (yrs) median, (1st Quartile- 3rd Quartile)	65, (58–67)	
51- 65	48	35%
>65	76	55%
Female	126	91%
UAE	121	87%
Comorbidities	72	52%
Received 4 Denosumab doses or more	86	62%
DEXA scan in DHA at Baseline	136	98%
Osteopenia	12	9%
Osteoporosis	124	91%
Fractures	12	9%

Table 2. Comparison between the appropriate Response group "Responders" and inadequate response group "Non-responders"

Variables	Responders	Non-responders	Odds Ratio	P-value	95% CI
Number	52	14			
Rheumatic Diseases	6	36	0.1	0.0001	0.05–0.2
Fracture	0	3	0.2	NS	
Pre-treatment fractures	9	1	9.5	0.02	2.0–70

Conclusions: Denosumab was effective and safe in our patients. Long-term follow up is required to verify these findings in our population.

AB0840 LOCAL FRACTURE LIAISON SERVICE (FLS): CHARACTERISTICS AND FIRST 6 MONTHS OF EVOLUTION IN PATIENTS AFTER HIP FRACTURE: PRELIMINARY RESULTS

J. Rosas[1], C. Cano[1], M. Lorente[1], A. Pons[1], E. Salas[1], T. Llinares[2], M. Hernández[3], J.M. Senabre-Gallego[1], M. Marco-Mingot[4], J.D. Alvarado[3], G. Santos-Soler[1], H. Arcos[3], A. García[3], J.I. Hernández[3], J.J. Jiménez[3], X. Barber[5], C. López[3], M.D. López[3], A.M. Molinos[3], B. Statti[3], M. Sanchís-Selfa[5] on behalf of FLS-HMB and AIRE-MB Groups. *[1]Rheumatology Department; [2]Traumatology Department; [3]Radiology Derpartment; [4]Laboratory Department, Hospital Marina Baixa, Villajoyosa (Alicante); [5]CIO, Universidad Miguel Hernández, Elche, Spain*

Background: Hip fracture has great impact on morbi-mortality, but a large percentage of patients do not receive treatment.
Objectives: To know the characteristics of patients whith hip fracture and its evolution in the first 6 months.
Methods: A prospective, 6-month follow-up study of patients over 60 years old admitted for hip fracture, evaluated in a local FLS. At 3 months after discharge, patients are evaluated for: epidemiological data, fracture income (days of admission, prior and discharge of osteoporosis (OP) drugs, general biochemistry and vitamin D), OP records and possible diseases or osteopenizing drugs, lumbar spine and hip Bone densitometry (BMD) lateral dorsal and lumbar spine radiology and the treatment was decided. The electronic history before and after 6 months of the fracture were reviewed.
Results: Of 152 patients >60 years old, admitted in 2016 due hip fracture, 77 (51%) were during the first 6 months. However, radiology or BMD data were not available for 30 (39%) patients, 16 (21%) for death and 14 (18%) for loss of follow-up. Mean BMI was 26.02±6.2. The mean age of menopause was 49±5 years. 1% of the patients received corticosteroids and 2% of patients an osteopenizing disease (COPD) was found. Mean time of admission was 7.57±2.51 days. In 3% of the patients, before the fracture were receiving OP treatment, which continued to discharge. The mean level of calcium, phosphorus and alkaline phosphatase was normal. However, the mean level of 25OH vitamin D was 13.55±8.63 ng/ml (median: 12 ng/ml, range: <4 to 29 ng/ml).
In 11 of the 27 (41%) patients, in whom radiology was available, the presence of vertebral fracture was demonstrated. The mean T-score for lumbar BMD was 1.8±1.65 DE (32%: the result was normal, 36% osteopenia, 32% OP), femoral neck 2.59±0.77 DE (27%: osteopenia, 77% OP) and in total hip: 2.56±0.86 DE (56%:osteopenia and 44% OPand In Ward of 3.2 DE. 100% of patients evaluated in Rheumatology, initiated treatment for OP: zoledronate: 40%, alendronate: 20%, denosumab: 25%, PTH: 15%.
Conclusions: In patients with hip fracture: 1) Mortality is high (21%), in the first 6 months after fracture. 2) The prevalence of vertebral fracture is 40%. 3) It is accompanied by very low blood levels of vitamin D. 4) In a high percentage the result of BMD is normal or osteopenia. 5) A minimum number of patients receive specific treatment for osteoporosis after fracture. 6) Evaluation in a FLS, ensures the evaluation and treatment of patients.

AB0841 MEDICAL AND SOCIAL CONSEQUENCES IN HIP FRACTURES DEPENDING ON THE METHOD OF TREATMENT

J.V. Averkieva, T. Raskina. *State Medical University Kemerovo, Kemerovo, Russian Federation*

Background: medical and social significance of osteoporosis is determined by its consequences - fractures of the vertebrae and the bones of the peripheral skeleton leading to high rates of mortality and disability among older adults. Purpose: to follow basic health and social consequences among the surviving patients with hip fractures aged 50 years or older at 6, 24 months.
Objectives: The study included 432 patients (328 women and 104 men) with radiographic evidence of hip fractures that occurred with minimal trauma.
Methods: Surgical treatment was performed in 171 (40,04%) patients, conservative treatment-261(59.96%).
Results: tracked mortality in hip fractures in 432 patients. It was found that in the first 6 months in the surgical treatment of deaths registered in 11 (6,43%) patients and in 84 (32.18%) - the conservative ($p<0.0001$). After 12 months after fracture increased mortality rate after the surgical treatment and after conservative (12.9% and 44.81%, respectively, $p<0.0001$). It was revealed that in the first 6 months in patients with surgical treatments bedridden were 10 (8.0%) men and 78 - a group with conservative treatment (66.67%) ($p<0.0001$).
Restriction of physical activity within the room was observed in 86 (68.8%) patients with surgery, and in 30 (25.64%) patients - with conservative treatment ($p<0.0001$). Aids used after surgical treatment of 105 (84.0%) patients after conservative - 34 (29.0%) ($p<0.0001$). Social impact showed that after 6 months of observation revealed a low proportion of patients with complete recovery of function after a surgery, or after conservative treatment (8.0% and 5.13%, respectively; p=0.5). After 24 months from the time of the fracture using surgical methods bedridden stayed only 1 (0.4%) and 16 patients (13.68%) - with conservative methods (χ^2 =18,3; $p<0.0001$). There was a significant decrease in the number of patients with limited motion activity within the room in the group with surgery and in the group with conservative (10.4% and 26.5%, respectively, p=0.002). When surgical treatment aids continued to use 38.4% (48 patients) under conservative treatment - 58.97% (69 people) (χ^2=10,24; p=0.002). Full restoration of function was observed in 72 (57.6%) and 32 (27.35%) patients who received surgical and conservative treatment, respectively (χ^2 =4,62; $p<0.0001$).
Conclusions: the obtained during this study data suggest that the immediate and long-term consequences in patients with a fracture of the proximal femur depends on the method of treatment. Surgical treatment is the method of choice for the treatment of patients with this type of fracture.

AB0842 SARCOPENIA AND OSTEOPOROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Aminov. *Medical Radiology, Tashknet Institute for Postgraduate Medical Education, Tashkent, Uzbekistan*

Background: Musculoskeletal disorders in RA are characterized by lesions of the peripheral joints, the development of local and systemic osteoporosis (OP), as well as a decrease in muscle mass and strength, which are currently being considered within the framework associated with chronic diseases syndrome sarcopenia and cachexia.
Objectives: To determine the prevalence and the relationship between sarcopenia and OP in patients with RA.
Methods: 156 RA patients were examined, of whom 83 postmenopausal women (mean age-61.7 years) and 73 males (mean age, 59 years). The control group consisted of 35 healthy subjects matched for age and sex. Exclusion criteria were: other rheumatic and endocrine diseases, severe somatic diseases, cancers, etc. The states of bone mineral density (BMD) at the lumbar spine (L1-L4) and femoral bone were assessed by dual-energy X-ray absorptiometry (DXA).
Results: Most RA patients (83% women and 63% men) were observed to decrease in BMD of osteopenia/OP level. BMD were negatively correlated with radiographic stage of RA, the DAS 28 and HAQ. IPC also revealed significant correlations with laboratory parameters such as creatinine, total protein, albumin, rheumatoid factor, and 1,25 (OH) D. Investigation of body composition showed a statistically significant reduction ITM RA patients compared to the control group, with no differences between the groups for fat mass. Sarcopenia had 25% of women and 55% men with RA, whereas the control groups, 8.7% and 0%, respectively. The majority of patients of both sexes sarcopenia observed on the background of the normal range of body fat index. Status of TM in patients with RA was statistically significant ($p<0,05$) associated with femoral BMD and lumbar spine (r=0,3), BMI (r=0,5), force brush compression (r=0,4) RA radiographic stage (r= -0,4), indicators of total protein (r=0,5).
Conclusions: Patients with RA, together with OP/osteopenia have a significant reduction in muscle (lean) mass. Sarcopenia in patients with RA was observed in the majority of men (55%) and 25% of women, significantly more than the control groups. Implementation of the DRA with the program “whole body” will allow time to identify not only bone, but also muscle loss in RA patients, which will help to intensify targeted therapy.

AB0843 RELATIONSHIP BETWEEN THE HISTOLOGICAL CLASSIFICATION OF MARSH AND THE AFFECTATION OF THE BONE METABOLISM IN PATIENTS WITH A RECENT DIAGNOSIS OF CELIAC DISEASE

L. López[1], M. Larrea[2], A. Erra[1]. *[1]Rheumatology; [2]Gastroenterology, Hospital San Rafael, Barcelona, Spain*

Background: Celiac disease is a chronic autoimmune pathology that affects people with genetic predisposition, caused by a permanent intolerance to gluten. Its prevalence has been estimated at around 1% but about 30% of patients are diagnosed after age 60.Its diagnosis is made through clinical data, serological markers, study of duodenal biopsy (BD) and response to the gluten-free diet. The histological study (Marsh classification) remains the gold standard to the diagnosis and allows classification of the disease in 4 types: grade I (less histological lesion) to grade IV (total duodenal mucosal atrophy).In these patients the deficiency of 25-OH vitamin D (vit D) is very frequent and is one of the causes of osteomalacia associated with malabsorption.
Objectives: To evaluate if there is a relation between the histological classification of Marsh and the bone metabolism in patients with a recent diagnosis of celiac disease.
Methods: Prospective study, which included all patients with a recent diagnosis of celiac disease by the Digestive Service during the period 2014–2016. This diagnosis was made through a clinical, serological (anti-transglutaminase IgA, anti-endomysium IgA), histological BD and genetic study (HLA DQ2 and HLA DQ8).
All patients underwent a study of phospho-calcium metabolism including: calcemia, phosphataemia, vit D, PTH, alkaline phosphatases, 24-hour calciuria and a densitometric study (BMD). We present the inclusion data of these patients

Results: 15 patients were included: 11 women and 4 men, with a mean age of 42.2 years (SD+/-16)
The genetic study was performed in 12 patients: 75% were positive for HLA DQ2 and 25% for HLA DQ8.
The determination of antibodies was positive in 12 patients (73%) and negative in 3 (27%). These 3 were positive for the genetic study (2 HLA DQ2 and 1 HLA DQ8).
The study of BD showed: type I in 4 patients; Type IIIa in 2 patients; Type IIIb in 6 patients; Type IIIC in 3 patients.
BMD showed normal values in 33%, osteopenia in 47% and osteoporosis (OP) in 20% of patients. Thus, 67% had an alteration in BMD at the time of diagnosis.
100% had a Vit D deficit, with a mean value of 14.3 ng/mL (range 4.15–26.8). 75% of them had values below 20 ng/mL (40% less than 10 ng/mL).
40% had secondary hyperparathyroidism (SHP), 83% of which had an alteration in BMD (67% osteopenia and 16% OP). The BD of the patients with SHP and alteration of the BMD showed a histological pattern type Marsh III.
No patient presented an alteration in the values of calcemia, phosphataemia or calciuria.
The relationship between the degree of alteration in BMD and the Marsh classification (table) was studied.
72% of patients with a Marsh III had an alteration in BMD (3 OP and 5 osteopenia vs 3 normal).

DMO	Marsh I	Marsh IIIa	Marsh IIIB	Marsh IIIc	Total
Osteoporosi	0	0	2	1	3
Osteopenia	2	2	1	2	7
Normal	2	0	3	0	5
Total	4	2	6	3	15

Conclusions: Most patients with celiac disease have an alteration in BMD.
In our study, all patients with celiac disease had a Vit D deficiency with no alteration of calcemia or calciuria.
Only in patients with SHP, there is a correlation between alterations in BMD and a higher degree of Marsh.
Most patients with a histological Marsh III have abnormalities in BMD.

AB0844 FALLS: RISK AND PREVENTION IN PRIVATE RHEUMATOLOGY PRACTICE

L. Poulain[1], V. Strotz[2], X. Grapton[3], P. Lemesle[4] on behalf of Groupe CREER. *[1]Private Rheumatology Practice, la Garenne-Colombes; [2]Private Rheumatology Practice, Antony; [3]Private Rheumatology Practice, Colombes; [4]Private Rheumatology Practice, Bois-Colombes, France*

Background: Menopaused and osteoporotic women have a higher risk of fractures when falling. Fall prevention is important when taking care of those women.
Objectives: After identifying fall risk factors, defining the % of fractured fallers and the part of osteoporotic women in this population, we want to evaluate the relevance of balance tests and to favor prevention measures for those patients.
Methods: 110 patients, 60 years and older (including 24 controls), having falled within a year, have seen 28 private practice rheumatologists in the larger Paris area and were subject of our multicentre retrospective study.
Results: Fallers mean age was 75 years.
37% of the fallers within a year fractured after falling. Among them, 95% were post-menopausal fractures versus 64% when including the control group.
Post-fall or post menopausal fracture sites are identical. In order: spine 26%, wrist 18%, ribs 6%.
The circumstances of the falls are: 1) lack of attention 2) slipping 3) stumbling.
61% of the fallers have at least one physical activity, among them 71% a weight-bearing physical activity. The most common physical activity was walking (46%).
Among the fractured, 32% had physical activity, 42% hadn't.
72% of the fallers had at least one fall risk factor: 94% had intrinsic risk factors, 28% extrinsic, and an average of 2 risk factors within the older than 80 years.
Intrinsic factors: 1) osteo-articular 2) eye-vision 3) postural 4) drugs, out of 13 items.
Extrinsic: 1) obstacles 2) footwear out of 7 items.
45% of the fallers within a year had at least one osteoporosis risk factor: 1) low body mass index
2) cortico-steroids 3) early menopausis 4) smoking, out of 9 items.
70% of our patients had vitamin D level>30 ng/l (as recommanded)
69% of the patients had recent bone density measures: bone density was lower only at femoral neck of fractured fallers versus non fractured fallers.
The unipodal balance test (positive when standing less than 5 seconds) was relevant in 42% of the patients with or without fractures. Get up and go test was not relevant in our study population.
94% of the rheumatologists participating in the study recommend at least 2 fall prevention measures: 1) correct vitamin D levels 2) physical activity 3) reeducation 4) eye vision correction, out of 12 items.
Conclusions: A significant part of menopaused women with anteriority of falls and fractures will refracture after falling again. Beside treating osteoporosis, we should identify potential fallers by doing unipodal tests, consider and correct fall risk factors, encourage those patients to keep on physical activity and prescribe reeducation.

AB0845 TECHNETIUM-99 CONJUGATED WITH METHYLENE DIPHOSPHONATE AMELIORATES GLUCOCORTICOID INDUCED OSTEOPOROSIS IN RATS

L. Shi[1], Y. Ning[2], J. Li[1], F. Hu[2], X. Zhang[2]. *[1]Peking University International Hospital; [2]Peking University People's Hospital, Beijing, China*

Background: ^{99}Tc-MDP has been used in Chinese RA patients for over 15 years and many more studies have focused on this agent in RA. However, the previous studies limited in its effect on the effects of anti-inflammation. As a special form of bisphosphonate, the anti-osteoporotic effect of ^{99}Tc-MDP is unclear.
Objectives: To systematically investigate the effect of technetium-99 conjugated with methylene diphosphonate (^{99}Tc-MDP), an anti-inflammatory drug effective in treating rheumatoid arthritis (RA), on cortical and cancellous bones in glucocorticoid-induced osteoporotic (GIO) rats, as well as comparing the effect of ^{99}Tc-MDP with that of methylene diphosphonate (MDP).
Methods: Forty-eight Sprague-Dawley rats were randomly divided into six groups: blank, negative control, high dose, medium dose, low dose, and positive control groups. After dexamethasone was given to all groups except the blank group to induce osteoporosis, the rats in different groups were treated with saline, MDP, or different doses of
Results: Micro-CT analyses showed that: (1) ^{99}Tc-MDP reversed glucocorticoid induced bone microarchitecture destruction by increasing vBMD, BV/TV, Tb.Th, Tb.N and decreasing BS/BV, Tb.Sp and TBPf; (2) effect of ^{99}Tc-MDP increased as its dosage increased; and (3) ^{99}Tc-MDP could improve cortical bone thickness while MDP failed to do so. Micro-CT spatial structure analysis and histology also yielded consistent results, indicating ^{99}Tc-MDP increased trabecular number and connectivity morphologically. Finally, biomechanics revealed ^{99}Tc-MDP can enhance the extrinsic stiffness of bone by changing bone geometry.
Conclusions: ^{99}Tc-MDP has anti-osteoporotic effect by improving both cancellous and cortical bone, as well as increasing extrinsic bone stiffness. The dual effect of ^{99}Tc-MDP, anti-inflammatory and anti-osteoporotic, may suggest a potential clinical application for patients with both GIO and RA.

AB0846 OSTEOPOROSIS AND ATHEROSCLEROSIS - ALTERNATIVE OR COEXISTENCE

L. Lagvilava. *Rheumatology, Clinic " Consilium Medulla", Tiblisi, Georgia*

Background: The majority of scientific research data promote the idea that OP and Atherosclerosis are inter-connected via OPG system. Scientists have speculation that OPG is the molecular bond between artery hardening and bone resorbtion. Thus the mechanism explained above makes obvious the co-existence of two: Artery hardening and Osteoporosis.
Objectives: There are number of ongoing Clinical trials on Denosumab therapy in patients with diagnosis of Osteoporosis and Atherosclerosis. The increase of Bone mineral density is associated with less intensive hardening of arteries. This fact inspired us to study bone mass in patients with cardiovascular events and atherosclerosis.
Methods: 1675 men, age range 38–78 years, mean age 59±4.3 Disease duration 6,4±1,75 with the diagnosis of Atherosclerosis (revealed on coronarography, assessed lipid profile).At the moment of research Stabile Angina Pectoris (Stable Angina) found in 20% (335); unstable angina non S-T elevation in 48% (804); -Myocardial Infarction 32% (536) Bone Mass was assessed by DXA Absorbtiometry technique (Hologic 1000) using T and Z Scores (WHO 1994). As a control group 680 healthy Georgian men 40–70 age range were assessed.
Results: Men having atherosclerosis are rather predisposed to Osteoporosis than health individuals.In Atherosclerosis subgroup normal bone mass was measured in 23% (385.25 patients) of patients; Osteopenia was diagnosed in 19% (315.25 patients), Osteoporosis was detected in 58% (971.5%) according to T-Score SD BMD records are shown in table 1.
Conclusions: 1.According to our research more than 50% of men with verified Atherosclerosis are diagnosed to have Osteoporosis 2.The lowest BMD values were observed in Lumbar Spine L1-L4, indicating that trabecular bone is more

Table 1

	Stable Angina n=335	Unstable angina nont S-T n=804	Myocardial Infarction n=536	Healthy N=680
L2- L4	-2.6±11 *	-2.9±1.4 **	-3.1±1.1 **	-0.6±0.2
Prox. Femur Neck	-1.8±0.5*	-2.6±1.4**	-2.5±1.6**	-1.14±0.26
Prox. Femur Total	-2.7±1.48**	-2.7±0.2**	-2.7±1.25**	-1.05±0.5

AB0847 ACCURATE ASSESSMENT OF FEMORAL ECHOSOUND APPROACH PERFORMANCE THROUGH DXA ERROR ANALYSIS

M. Muratore[1], F. Conversano[2], P. Pisani[2], M. Peccarisi[3], A. Greco[3], T. De Marco[3], E. Quarta[1], L. Quarta[1], A. Grimaldi[1], S. Casciaro[2]. *[1]OU of Rheumatology Galateo Hospital, San Cesario di Lecce, ASL-LE; [2]National Research Council, Institute of Clinical Physiology; [3]Echolight Spa, LECCE, Italy*

Background: Currently, the accepted "gold standard" method for bone mineral density (BMD) measurement and osteoporosis diagnosis related to the reference axial anatomical sites is dual-energy X-ray absorptiometry (DXA). However, actual DXA effectiveness is limited by several factors, including intrinsic accuracy uncertainties and specific errors in patient positioning, image segmentation, and post-acquisition data analysis, as documented by very recent literature [1]. This may affect the comparative evaluation of the effectiveness of novel diagnostic methods whose validation studies adopt DXA outcomes as standard reference to assess diagnostic performance.

Objectives: To assess the impact of DXA errors on the performance of an innovative ultrasound parameter for osteoporosis diagnosis on the femoral site, known as Osteoporosis Score (OS).

Methods: 202 patients aged in 46–75 years underwent two diagnostic investigations on the femoral neck: a conventional femoral DXA and an echographic scan performed by employing the innovative EchoSound technology [2]. Initially, the performance of the OS parameter was evaluated considering all the available DXA reports as reference in the data analysis, and calculating the corresponding accuracy in patient classification (osteoporotic, osteopenic, or healthy) and the correlation coefficient between the DXA-measured BMDs and the OS-derived BMD values. At a later stage, the DXA errors were taken into account by performing a strict quality control on DXA reports: all those cases affected by a typical inaccuracy [1] were excluded from the analysis and the actual diagnostic accuracy of the EchoSound technology was re-assessed by analysing only the reliable DXA reports. Intra- and inter-operator repeatability of OS-derived BMD values were also measured in a group of patients.

Results: A diagnostic accuracy of 84.4% (r =0.78, p<0.001) was obtained for the EchoSound approach when all the DXA reports were included in the analysis. In the second part of the study, 61 out of the initial 202 (30.4%) patients were excluded from the analysis because their DXA reports were affected by specific errors. An actual diagnostic accuracy of 94.2% was then obtained on the remaining 141 patients, together with a high correlation between DXA-measured BMDs and OS-derived BMD values (r =0.88, p<0.001). Intra- and inter-operator repeatability of OS-derived BMD values, expressed in terms of the root mean square coefficient of variation (RMS-CV), resulted equal to 0.29% and 0.34% for intra- and inter-operator variability, respectively, therefore documenting a very good measurement repeatability.

Conclusions: Undetected DXA errors had an impact on the accuracy evaluation of EchoSound femoral neck densitometry, causing an underestimation of OS performance in osteoporosis diagnosis. The quality control analysis on DXA reports can be useful to study the actual performance of different ultrasonic methods that considered routine DXA reports as the gold standard reference.

AB0848 DENTAL PANORAMIC RADIOGRAPHY AS A TOOL FOR IDENTIFICATION OF OSTEOPOROSIS: AMONG TUNISIAN WOMEN

M. Brahem[1], M. Jguirim[1], M. Khemiss[2], I. Chaabani[2], E. Chebil[3], M. Younes[4], T. Ben Alaya[2], M. Ben Khelifa[2], I. Bejia[1], M. Touzi[1], S. Zrour[1], N. Bergaoui[1]. *[1]Rheumatology; [2]Stomatology, Fattouma Bourguiba Hospital Monastir, Monastir; [3]Maxilla-Facial; [4]Rheumatology, Taher Sfar Mahdia, mahdia, Tunisia*

Background: Osteoporosis is defined as a skeletal disorder characterized by low-bone mass predisposing to an increased risk of fracture. At present, the evaluation of bone mineral density (BMD) is the main diagnostic tool in osteoporosis, and it is the most effective and accurate measurement for identifying and monitoring the disease. However, several studies have been conducted with the object of detecting whether these skeletal changes in the mandible are specific to the osteoporotic stage.

Objectives: The purpose of this study was to determine whether the madibular indices on panoramic radiographs are useful for identifying women with osteoporosis or osteopenia (low BMD).

Methods: Tunisian women aged from 30 to 60 years,who consulted the Rheumatology department of Fattouma Bourguiba university hospital in2017.The measure the BMD using the dual-energy X-ray absorptiometry (DEXA), were recruited to participate in this case-control study.Among the 60 women selected, 30 were diagnosed with osteoporosis or osteopenia (T-score <-1; cases) and 30 with normal T-score (T-score >-1; controls). The mandibular cortical index (MCI), the mental index (MI), the panoramic mandibular index (PMI) and the alveolar crest resorption degree (M/M ratio)were measured from digital panoramic radiographs in the right and left mandibles and the mean was calculated for each subject.The MI, PMI and M/M ratio values were evaluated using the Z test, and MCI values were analysed using the Chi^2 test.

Results: The mean age of patients with osteoporosis/osteopenia was 58.61±8.11and 56.07±9.72 in the control group.The mean bone miniral density (BMD)in vertebral site was 0.856±0.090g/cm^2 and 1.216±0.185g/cm^2 in control group.In femoral site,it was 0.877±0.221g/cm^2 and 1.061±0.142g/cm^2 respectively.The mean T-score in vertebral site was -2.38±0.81DS in osteoporosis/ osteopenia group and 0.64±1.58DS in control group.In femoral site,it was -1.57±0.97DS and 0.21±1.16 respectively.

The analysis of the panoramic radiography showed that in the osteoporosis/osteopenia group: the mean value of MI was 3.56±0.89, the mean PMI was 0.25±0.06 and the mean M/Mratio was 0.71±0.14; concerning the MCI: 46.7% were classified C2 stage and 53.3% were classified C3 stage.

In the control group, the mean MI was 4.42±0.98, the mean PMI was 0.30±0.07 and the mean M/Mratio was 0.77±0.11; 30.1% were classified C1 stage, 53.3% were classified C2 stage and only 16.6% were classified C1 stage.

This study showed that the MI and the PMI were significantly smaller in the group with osteoporosis/osteopenia. However, the M/M ratio was not significantly different.Therefore, the MCI was significantly more affected in the osteoporosis/osteopenia group.

Conclusions: In our study, we proved that the MI, PMI and MCI values were affected in women with osteoporosis/osteopenia, compared with normal patients. Therefore, these indices could be used as an ancillary method in the diagnosis of osteoporosis in women.

AB0849 ASSOCIATION BETWEEN PERIODONTITIS AND OSTEOPOROSIS

M. Brahem[1], M. Jguirim[1], M. Khemis[2], E. Chebil[3], D. Chaabouni[2], M. Younes[4], T. Ben Alaya[2], M. Ben Khelifa[2], I. Bejia[1], M. Touzi[1], S. Zrour[1], N. Bergaoui[1]. *[1]Rheumatology; [2]Stomatology; [3]E.N.T. Head Neck Surgery, Fattouma Bourguiba Hospital Monastir, Monastir; [4]Rheumatology, Taher Sfar Mahdia, mahdia, Tunisia*

Background: Both periodontitis and osteoporosis have similar sign of bone resorption in nature and have multifactorial etiologic factors, although the mediator factors or mechanism may be different. How to prevent and treat these two bone-loss diseases is always an important issue in public health. However, the relationship of them is still uncertain.

Objectives: The aim of our study is to evaluate the relationship between periodentitis and osteoporosis.

Methods: Tunisian women aged from 30 to 60 years, who consulted the Rheumatology department of Fattouma Bourguiba university hospital between Febrary to December 2017. The measure the bone mineral density (BMD) using the dual-energy X-ray absorptiometry (DEXA), were recruited to participate in this case-control study. Among the 60 women selected, 30 were diagnosed with osteoporosis or osteopenia (T-score< -1; cases) and 30 with normal T-score (T-score> -1; controls). The oral examination was done by a dentist in the stomatology department in the same hospital.

Results: The mean age of patients with osteoporosis/osteopenia was 58.61±8.11

[51–81 and 56.07±9.72 [40–76] in the control group.the mean bone miniral density (BMD)in vertebral site was 0.856±0.090g/cm^2 and 1.216±0.185g/cm^2 in control group. In femoral site, it was 0.877±0.221g/cm^2 and 1.061±0.142g/cm^2 respectively. The mean T-score in vertebral site was -2.387±0.814 DS in osteoporosis/ osteopenia group and 0.643±1.587 DS in control group. In femoral site, it was -1.577±0.970 DS and 0.213±1.162 respectively.The oral examination showed an excessive tooth mobility in 60% and 36.7% of controls without a significant difference, a gingival recession in 50% and 30% of controls, the presence of periodontal pockets in 23.3% and 16.7% of controls without a significant difference, a plaque index $\geq$2 in 53,3% of osteoporosis/osteopenia patients and 63,3% of controls and a non rectilinear trajectory of mouth opening in 13,3% and 3,3% of controls.

Conclusions: Our study showed that patients with osteoporosis or osteopenia have a poor oral hygiene, but without significant difference with control group.However, patients who were diagnosed as osteoporosis must pay more attention to their periodontal health. Good oral hygiene maintenance might be a crucial factor for preventing the deterioration of osteoporosis progressing.

AB0850 HELICOBACTER PYLORI INFECTION AND OSTEOPOROSIS IN POST MONOPAUSAL WOMEN

N. Abdolahi, M. Aghaei, M. Naghdi. *Golestan Rheumatology Research Center, Golestan University of Medical Sciences, Gorgan, Iran, Islamic Republic Of*

Background: Osteoprosis is a health problem that if is left untreated,can lead to serious health & economical complications.It is also very common in postmenopausal women. Mineral deficiency, smoking, low BMI, some certain diseases and some medications can also cause osteoprosis. H.Pylori infection can also increase levels of inflammatory cytokines and bone turn over regulatory cytokines,as a result, it is likely that H. pylori infected patients are at increased risk for osteoprosis.

Objectives: the present study was done to understanding the association between H.Pylori seropositivity and osteoprosis in postmenopausal women.

Methods: The study population consisted of 34 osteoporotic patients and 73 healthy controls. Serum levels of h.pylori antibody (IgA,IgG) were measured by ELISA method.

Results: There was no difference in levels of IgA and IgG h.pylori antibody between patients and healthy controls

IgA seropositivity was 70.6% in osteoporotic women and 54.8% in healty women (p value: 0.1). Also H. pylori IgG seropositivity was 82% in osteoporotic women and 75.3% in healthy women (p value: 0.4). We didnot find any correlation between H. pylori seropositivity and bone mineral density in post menopausal women.

Conclusions: In this study, we found that Helicobacter pylori infection does not increase the osteoporotic chance and is not a reliable risk factor for osteoporosis. greater sampele size, gastric biopsy to detect atrophic gastritis, bone turn over factors and Cag detection is recommended in order to achieve more accurate results

AB0851 ZOLEDRONATE AUDIT – ARE WE MEETING EUROPEAN GUIDELINES?

N. Begum[1], A. Khan[1], A. Nandagudi[2]. *[1]Rheumatology/General Medicine; [2]Rheumatology, Basildon & Thurrock NHS Foundation Trust, Basildon, United Kingdom*

Background: Zoledronate is recommended by European guidelines for the treatment of osteoporosis particularly where first-line oral drugs are ineffective or contraindicated. EULAR's guidelines are complimented by UK organisations including the National Institute of Health and Care Excellence (NICE), National Osteoporosis Guidelines Group (NOGG), British Society of Rheumatology (BSR) and the National Osteoporosis Society (NOS).

Objectives: The aim of our audit was to ascertain whether our use of zoledronate was compliant with current guidelines and review the real life experience.

Methods: We performed a retrospective audit of fifty patients who were commenced on zoledronate for the treatment of osteoporosis during 2012–2016 in our Trust. Data gathered included the reasons for commencement, whether patients had appropriate monitoring and the effect it had on DEXA and FRAX scores.

Results: The age ranged from 44–88 years; 67% were between 60–80 years with 80% females. Vertebral fragility fractures were the most common type of fracture (42%). Zoledronate was commenced primarily because of either intolerance or inefficacy to oral anti-osteoporotic treatment (Table 1). It was commenced as first line in 20% because of contraindications to oral drugs. Almost 70% of our patients received zoledronate for two or three years. There was an improvement by 43% and 38% in the DEXA t-score for the spine and hip respectively. Stable t-scores were recorded for the spine and hip in 49% and 54% respectively, whereas 8% deteriorated. Three patients sustained a fragility fracture and a further 11 experienced side effects (Table 2); five patients consequently stopped treatment. Only 3% had recorded FRAX scores pre- or post-zoledronate treatment. All of our patients had their calcium and renal function measured before each zoledronate infusion whilst over 80% had their vitamin D checked. All of our patients had dental checks prior to treatment. Following post-treatment DEXA scans 46% continued zoledronate and 16% were on a drug-free holiday. A third were switched to denosumab due to ineffectiveness, side effects or contraindications.

Table 1. Rationale for Zoledronate Commencement

Rationale	Number	%
Intolerance	24	38%
GI Contraindication	11	17%
Inefficacy	24	38%
Other Contraindication	4	7%

Table 2. Side Effects of Zoledronate

Side Effect	Number	%
Bony Pain	1	9%
Flu-Like Symptoms	5	46%
Aches	1	9%
Acid-Reflux	1	9%
Rash	1	9%
Other	2	18%

Conclusions: The majority of our patients had improvements or stability in bone mineral density T-scores with only 20% experiencing side effects. Our results show that the vast majority of our patients are treated with zoledronate in concordance with guidelines. Nonetheless we can make improvements in recording FRAX scores and monitoring vitamin D levels. This has been highlighted to the multidisciplinary osteoporosis team and changes have been instigated. We plan to re-audit in due course.

AB0852 INCREASED INFECTION RATE WITH CONCOMITANT RANK LIGAND INHIBITOR DENOSUMAB AND BIOLOGIC THERAPIES FOR RHEUMATIC DISEASES: REALITY OR ILLUSION? EXPERIENCE WITH 40 PATIENTS OVER 66 MONTHS AT THE UNIVERSITY OF SOUTHERN CALIFORNIA

P.S. Chhibar, G. Ehresmann. *Rheumatology, University of Southern California, Los Angeles, United States*

Background: Patients with autoimmune diseases are at increased risk of early onset osteoporosis due to multiple reasons including prolonged exposure to corticosteroids and the disease process itself in RA patients. Same patients are more likely to be on TNF inhibitors or other biologics, which causes them to be at an increased risk of infections. Denosumab, an anti-RANK ligand inhibitor, itself a biologic, used to treat osteoporosis, is associated with increased infection risk as Receptor activator of nuclear factor kappa B ligand (RANKL) is also expressed on activated T and B lymphocytes (1). It is unknown if there is an added risk of infections when TNF inhibitors/biologic agents and denosumab are used concomitantly.

Objectives: To determine if denosumab and biologics are associated with increased infection risk.

Methods: Data was collected and analyzed on 40 patients in the rheumatology clinic who had been on denosumab and TNF inhibitor/ other biologic for 66 months at the Keck Medical Center of USC.

Results: Patient characteristics: Mean age: 70±9.8 SD years, Gender: 98% were females, 2% Males. 75% had RA, 10% SLE, 15% had other rheumatic diseases. 70% on TNF inhibitors, 30% on other biologics. Before Denosumab (over 2 years): cumulative infection rate 17.5%, which is 8.75 cases per 100 person-years. 9% hospitalization rate. Post Denosumab: After 12 months: No infections within the first year. After 60 months: incidence rate of infections=12.5 cases/100 person-years. After 66 months, incidence rate of infections=15.9 cases/100 person-years. Urinary tract infection (UTI) accounted for the most common infection (17.5%). No opportunistic infections, and no reactivation of latent TB found in our patients.
Conclusions: No infections developed within the first year, suggesting a cumulative effect of increased infection risk, if any. We cannot attribute the overall infection rate solely to the combination of denosumab and biologics as patients who developed infections either had Diabetes Mellitus, urinary incontinence, recent surgery, underlying pulmonary disease. Patients did not develop infections beyond what would be expected for their comorbidities and medications. Whether prophylactic antibiotics are indicated in patients with recurrent infections PRIOR to denosumab is uncertain, but may be a consideration in certain patients.

AB0853 DENOSUMAB: CLINICAL PERSPECTIVE AND DRUG SURVIVAL IN A SECONDAY CARE SET UP IN UK

R. Laxminarayan, U. Dissanayake, N. Sayed, K. Narangoda. *Rheumatology, Queen's Hospital, Burton on Trent, United Kingdom*

Background: Denosumab has become a useful parental therapy for the treatment of osteoporosis. FREEDOM extension study has shown safety and effectiveness of denosumab beyond 8 years. Real life data on the efficacy and safety of denosumab is lacking. There are no studies looking at the drug survival in the osteoporosis population either. Observational data from clinical practice can provide unique clinical perspective for novel therapies like denosumab.
Objectives: 1. To look at the baseline characters of patients receiving denosumab in a secondary care unit in UK.
2. To study the drug survival rate, analyse the reasons for discontinuation of therapy.
3. To assess fractures during the course of denosumab therapy.
Methods: We looked at the case records retrospectively of all the patients receiving denosumab therapy from 01/01/2011 to 31/12/2016. A database to record baseline characters, indications and previous fracture was prepared. Renal function, calcium, alkaline phosphatase (ALP), vitamin D levels at baseline and renal function, calium and ALP levels for each injection visit were noted. Vitamin D status was assessed at least once a year. Reasons to stop therapy were recorded.
Results: 237 patients were offered the treatment. One patient declined the treatment at the beginning.
5 (2.1%) patients had fracture on treatment. 2 had a hip fracture and one of them had a previous fracture (humerus). Other fracture sites were ankle, humerus and metatarsal. None of them had any further fractures during the follow up period.
61 patients discontinued therapy during the course of treatment over 3 years. 8 (4.2%) had infections, 7 (3.6%) due to declining eGFR and 9 (4.7%) were lost to follow up. 1 patient had jaw necrosis after the first injection. 1 developed hepatitis after the first injection which resolved on withdrawal of therapy. 6 (3.1%) patients withdrew consent for therapy. 19 (8%) patients died causes unrelated to denosumab therapy. 23 (9.7%) patients moved away. Treatment was stopped due to other side effects in 3 patients (2 had rash and 1 headache). There were no episodes of hypocalcaemia.
Conclusions: 1. Majority patients were elderly and female. Majority were high risk and had received osteoporosis treatments previously.
2. Denosumab therapy was well tolerated and nearly 2/3rd were stll receiving therapy at 3 years. Treatment was withdrawn due to an adverse event in only 14 (6%) patients.
3. Fracture rate was very low and there were no repeat or multiple fractures.

AB0854 THE BMD CHANGE AFTER IBANDRONATE (BONVIVA®) TREATMENT IN OSTEOPENIC POSTMENOPAUSAL WOMEN

S.E. Park, K. Choi. *Orthopaedic Surgery, Dongguk University International Hospital, Seoul, Korea, Republic Of*

Background: Ibandronate (Bonviva®) is effective in the treatment of postmenopausal women with osteoporosis. But, there were few datas about Ibandronate (Bonviva®) treatment in Korea. We evaluated the effect of Ibandronate (Bonviva®) therapy on bone mass and compared the effectivity on bone mineral density (BMD) in 1-year treatment group
Objectives: The aim of the study is to assess the effect of 1-year treatment with Ibandronate (Bonviva®) on bone mineral density (BMD) in postmenopausal women with osteopenia or osteoporosis.
Methods: The BMD was assessed in 118 postmenopausal women with osteopenia or osteoporosis from March 2007 to January 2011, 42 patents who treated with 2.5 mg per day of Ibandronate (Bonviva®) were enrolled to study. BMD of lumbar spine (L2-L4) and femur was assessed by dual energy absortiometry at baseline, 12 months after treatment.
Results: The annual BMD of the lumbar spine showed a 9.11% increase, while also positive changes were noted in the proximal femur as a 1.89% increase. The BMD changes were 11% (L: Lumbar spine) and 1.1% (F: Femur) for the T-scores <-4.0, 6.3% (L) and 0.9% (F) for the T-scores -3.0∼-4.0, and 3.8% (L) and 0.5% (F) for the T-scores >-3.0 respectively.
Conclusions: This study suggests that Ibandronate (Bonviva®) treatment in postmenopausal women with osteopenia or osteoposis is effective in terms of improving BMD.

AB0855 THE DISPARITIES BETWEEN FRACTURE RISK ASSESSMENT (FRAX) WITH BMD AND WITHOUT BMD IN KOREAN PATIENTS WITH ANKYLOSING SPONDYLITIS- MULTICENTER TRIAL

S.-R. Kwon[1], S.T. Choi[2], C.-H. Suh[3], H.-A. Kim[3], J.-Y. Jung[3], S.-S. Kim[4], S.-H. Kim[5], J.-M. Kim[5], S.-Y. Lee[1]. *[1]Division of Rheumatology/Dept. of Internal Medicine, College of Medicine, Inha University, INCHEON; [2]Division of Rheumatology/Dept. of Internal Medicine, College of Medicine, Chung-Ang University, Seoul; [3]Division of Rheumatology/Dept. of Internal Medicine, College of Medicine, Ajou University, Suwon; [4]Division of Rheumatology/Dept. of Internal Medicine, College of Medicine, Ulsan University, Gangneung Asan Hospital, Gangneung; [5]Division of Rheumatology/Dept. of Internal Medicine, College of Medicine, Keimyung University, Daegu, Korea, Republic Of*

Objectives: The aims of this study are to determine the proportion of patients with ankylosing spondylitis (AS) at high risk for major osteoporotic and hip fractures of Fracture risk assessment (FRAX) in Korean and to determine if a care gap exists for high risk.
Methods: This study is a multicenter study including 163 AS patients in 5. All of the AS patients fulfilled the modified New York criteria. The classification of osteoporosis according to WHO criteria was based on T-score ≤ -2.5. The FRAX criteria for high risk of osteoporotic fracture, which is 10-year probability of ≥20% for major osteoporotic fracture or ≥3% for hip fracture, were calculated by the FRAX tool including the bone mineral density (BMD) values. We assessed various demographic factors, clinical and laboratory findings of AS, and medication use for AS and osteoporosis, and then evaluated the risk factors for osteoporotic fracture.
Results: The mean age of AS patients was 44.3 years, and 42 patients were female (25.2%) with 23 postmenopausal women 56.1%. Osteoporotic fracture was detected in 16 (9.8%) patients with AS. Among the 16 patients ≥65 years of age, 2 (12.5%) and 8 (50%) were at high risk for a major osteoporotic fracture (10-year probability >20%) and hip fracture (>3%), respectively.
Among patients with BMD measurements (n=106), the 10-year risk of a major osteoporotic fracture and hip fracture calculated with BMD was significantly higher than in those without BMD measurements (P=0.001, P=0.002) respectively. The 10-year risk of a major osteoporotic and hip fracture fracture calculated with BMD was significantly higher than in those without BMD measurements (P<0.001, P=0.003) respectively among male patients with BMD measurements (n=74). There is no statistic difference of the 10-year risk of a major osteoporotic fracture

and hip fracture between those calculated with BMD and those without BMD measurements (P>0.05) respectively among female patients (n=32).
Conclusions: A substantial gap exists between FRAX with BMD and without BMD in Korean patients with AS.
Disclosure of Interest: None declared

AB0856 T-SCORE OF THE SPINE AS PREDICTOR OF THE FEMORAL NECK FRACTURE

S.D. Jandric. *Department for FRM, Faculty of Medicine, University of Banjaluka, Banja Luka, Republic of Srpska, Bosnia and Herzegovina*

Background: Osteoporosis is defined as a progressive, systemic skeletal disorder characterized by low bone mass and micro-architectural deterioration of bone tissue with a consequent increase in bone fragility and susceptibility to fracture. There are numerous hip fracture risks. Bone mineral density (BMD) and T-score measured by dual-energy X-ray absorptiometry (DXA) are the main determinants of the clinical evaluation of hip fracture risk. World Health Organization classification defined osteoporosis as T-score below –2.5 SD.
Objectives: The aim of this study was to estimate differences in DXA measurements (BMD and T-score of the spine) and potential predictors of the femoral neck fracture in the patients with osteoporosis.
Methods: This study included 181 patients with osteoporosis (165 female and 16 male), average age of the 65, 6±8.5 years (range of 44.1 to 87.3 years). Eighty one patients had fracture of the femoral neck. All patients in this group were managed operatively by hip arthroplasty, after clinical and radiological diagnostic procedures. DXA measurement was performed on Advanced Prodigy Lunar device for these patients postoperatively. BMD of the femoral neck was measured on the no operated side. Age, sex, height, weight, BMI, BMD and T-score of the spine at the level of L1-L4, BMD of the right and left femoral neck were estimated. The control group included 100 patients with osteoporosis (93 female and 7 male), average age of the 65.1±8, 5 years. Student's t-test and Logistic regression were used for statistical analysis. Dependent variable was presence of the fracture of the femoral neck and independent variables were age, sex, height, weight, BMI, BMD and T-score of the spine and BMD of the femoral neck.
Results: Results of our study showed statistically significant difference between T-score of the spine (t=-2,973, p<0.01) as well as between BMD of the spine (t=-12,376, p<0.001) of patients with and without fracture of the femoral neck. T-score of the spine was significant predictor of fracture of the femoral neck (p<0, 01) when controlled by age, sex, height, weight, BMI, BMD of the spine, BMD of the femoral neck.
Conclusions: T-score and BMD of the spine were statistically significantly lower in patients with fracture of the femoral neck than in patients with osteoporosis without fracture. T-score of the lumbar spine was significant predictor of fracture of the femoral neck in patients with osteoporosis. Probability of femur neck fractures increased with the decrease of T-score of lumbar spine in patients with osteoporosis. These results can help in predicting femur neck fractures.

AB0857 PROBLEMS OF DIAGNOSTICS AND PROPHYLAXIS OF GLUCOCORTICOID-INDUCED OSTEOPOROSIS IN REAL CLINICAL PRACTICE

S. Yakupova, R. Demidov. *Kazan State Medical University, Kazan, Russian Federation*

Background: Oral glucocorticoids (GC) are used in different medicine fields and appear as risk factors of glucocorticoid-induced osteoporosis (GIO).
Objectives: The aim is to estimate the frequency of use of prophylaxis of OP, use drugs that are approved for GIO and also an awareness of GIO of patients with prolonged intake of GC.
Methods: 50 patients (10 men and 40 women), taking GC, took part in research. 30 patients (60%) were from rheumatology department, 5 patients (10%) from pulmonology department, 5 patients (10%) from gastroenterology department, 10 patients (20%) from nephrology department of Republic Clinical Hospital. Mean age of patients - 48,84±14,03 years (from 26 to 73). The following signs were estimated: clinical data, osteoporosis risk factors, instrumental tests (X-ray, densitometry). FRAX assessment of fracture risk was performed, the questionnaires of patients' awareness of GIO was completed.
Results: The duration of intake GC – 5,93±4,86 years. Minimal dose of GC per day (if receiving prednisone) – 7.5 mg; maximal dose – 60 mg. 10-year risk of major osteoporotic fractures by FRAX, adjusted according to GC dose - 18,11±11,01. 32 patients (64%) were given recommendations for changing lifestyle and diet for GIO prophylaxis, 40 patients (80%) - recommendations for intake of calcium and vitamin D medications, but only 31 patients (62%) followed recommendations and started the intake of calcium medications. From the said number of patients only 14 patients (45,2%) used appropriate daily dose of calcium and vitamin D.
Drugs that are approved for GIO were have to be prescribed for 18 patients, but only 6 patients (33,3%) underwent treatment, principally bisphosphonates. Only half of them underwent densitometry after starting the therapy. 72,2% patients with GIO used calcium and 30,7% were taking appropriate daily dose of calcium and vitamin D. 70% rheumatologic patients knew about GIO and in 90% cases calcium and vitamin D drugs were recommended. Only 50% of patients from non-rheumatologic departments knew about GIO and in 65% cases calcium and vitamin D drugs were recommended.
Conclusions: Clinical recommendations in real clinical practice are rarely fulfilled. Less than 60% patients were taking calcium and vitamin D, which are recommended for all patients, who started the GC therapy; only 33% of patients received osteoporosis therapy, only half of them underwent densitometry. Patients are insufficiently informed about necessity of changing lifestyle and diet for GIO prophylaxis. Education for patients taking GC and training for rheumatologic and non-rheumatologic specialties are necessary.

AB0858 ASSOCIATION OF BONE MINERAL DENSITY WITH DEVELOPMENT OF HEART FAILURE IN DIABETIC PATIENTS

V. Vasilkova[1], T. Mokhort[2], E. Naumenko[3], M. Zmailik[4]. *[1]Endocrinology, Gomel State Medical University, Gomel; [2]Endocrinology, Belarusian State Medical University, Minsk; [3]Functional Diagnostics; [4]Endocrinology, The Republican Research Center for Radiation Medicine and Human Ecology, Gomel, Belarus*

Background: Diabetes mellitus has shown to be a significant risk factor for the development and prognosis of heart failure (HF) and associated with an increased risk of fractures [1]. Osteoporosis and heart failure are generally considered two distinct diseases, but recent evidence suggests a link between both diseases.
Objectives: The aim of the study was to investigate the association of bone mineral density with the risk of developing heart failure in diabetic patients.
Methods: 85 patients both sexes with type 2 diabetes aged 58.69±9.07 years were studied. Besides standard laboratory parameters, the echocardiographic and BMD measurements were performed. Estimated glomerular filtration rate was measured.
Results: Among diabetic subjects, 8 patients (9.4%) had osteoporosis, 21 (24.8%) had osteopenia and 56 (65.8%) had a normal BMD. Increased serum NT-proBNP (p<0.001) and decreased left ventricular ejection fraction (EF) (p=0.03) were significantly correlated with low T-score L1-L4 cutoff points between groups (normal, osteopenia, and osteoporosis). Multivariate stepwise linear regression analysis of the significant variables revealed that NT-proBNP, EF were independent predictors of lumbar BMD among female patients with diabetes mellitus. After adjusting for age, gender, and related comorbidities, the osteoporosis group was associated with a significantly higher risk of coronary artery disease in women with diabetes. However, no association between BMD and HF was found in men.
Conclusions: Osteoporosis may be an independent factor for HF in women with diabetes mellitus. Our data suggested that early detection of abnormal BMD should warrant for early search of undetected HF in diabetic women. A further study is needed to elucidate the effects of BMD on cardiac function in diabetic patients.

AB0859 CAN ZOLENDRONIC ACID USE LEAD TO IMPAIR RENAL FUNCTION IN OSTEOPOROSIS PATIENTS?

Y.-C. Chen, C.-H. Ko. *Rheumatology, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, Province of China*

Background: Bisphosphonates are recommended in patients with osteoporosis patients. clinical concerns had been considered in kidney safety.
Objectives: This study investigated the safety of bisphosphonate effects on renal function in patients with magnetic resonance imaging (MRI)-proven acute osteoporotic vertebral fractures after vertebroplasty.
Methods: This retrospective study was conducted in osteoporotic patients with acute vertebral fractures treated with vertebroplasty between January 2001 and December 2015. Their gender, age, body mass index (BMI, kg/m^2), co-morbidities were recorded, as well as their use of zolendronic acid. Those with increase in creatinine was defined as progress of renal function. Logistical regression was used to adjust the variables.
Results: There were 989 patients (783 females; mean age, 74.08±9.26 years).

71patients accepted zolendronic acid, the others accept other anti-osteoporotic agents. 35 (49.3%) of zolendronic acid had increased creatinine, while 379 (41.3%) of non-zolendronic acid had creatinine changes (p=0.117). After adjust variables, zolendronic acid did not increase creatinine (*p*=0.291; OR: 0.750; 95% CI: 0.440–1.279).(Table 1)

Table 1. Risk of increase in renal function in zolendronic acid after adjust variables

	Regression coefficient	S.E.	Wald	P value	OR	95% C.I.for OR	
						Lower	Upper
Zoledronic acid	-0.288	0.273	1.116	0.291	0.750	0.440	1.279
Smoking	0.250	0.343	0.533	0.465	1.284	0.656	2.513
Alcohol	0.025	0.065	0.147	0.702	1.025	0.903	1.164
BMI	0.007	0.017	0.160	0.689	1.007	0.974	1.040
DM	-0.165	0.164	1.022	0.312	0.848	0.615	1.168
HTN	-0.418	0.149	7.856	0.005	0.658	0.491	0.882

Conclusions: Zolendronic acid use did not lead to increase in creatinine as compared with the control group. However it need more cases to confirm this findings.

AB0860 THE PREDICTORS FOR 24 MONTHS EFFICACY OF DENOSUMAB, AN ANTI-RANKL ANTIBODY, ON OSTEOPOROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS FROM MULTICENTER STUDY (TBCR-BONE)

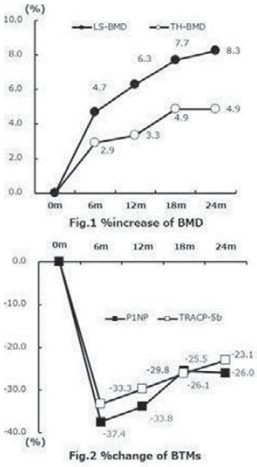
Y. Hirano [1], Y. Kanayama [2], N. Takahashi [3], N. Ishiguro [3], T. Kojima [3].
[1] Rheumatology, Toyohashi Municipal Hospital, Toyohashi; [2] Orthopaedic Surgery and Rheumatology, Toyota Kosei Hospital, Toyota; [3] Orthopaedic Surgery and Rheumatology, Nagoya University Graduate School of Medicine, Nagoya, Japan

Background: Although medication of rheumatoid arthritis (RA) has been improved by early intensive treatment using csDMARDs, tsDMARDs and bDMARDs for decades, treatment of concomitant disease in RA patients, such as osteoporosis (OP), will be more important to improve activity of daily living of RA patients. Although denosumab (DMB), an anti-RANKL antibody, was approved for treatment of OP in Japan in 2013, clinical data in real world is lacking in patients with RA. We reported 12 months efficacy of denosumab on osteoporosis in patients with RA at EULAR 2016 in London [1]. Here we report results for 24 months.

Objectives: To investigate the 24 months efficacy of denosumab (DMB) on osteoporosis in patients with rheumatoid arthritis (RA-OP) and to explore predictors of efficacy from multicenter study (TBCR-BONE).

Methods: 59 female cases with RA-OP treated with DMB for 24 months were included in this study. Bone mineral density (BMD) of lumbar spine (LS-BMD) and total hip (TH-BMD) and serum bone turnover markers (P1NP and TRACP-5b) were measured at baseline and every 6 month until 24 months. Spearman's rank correlation coefficient was calculated between %increase of BMD at 24 months and various data (baseline patients' characteristics, parameters of RA disease activity [DAS28-CRP, SDAI, CRP, MMP-3] and bone turnover markers (BTMs) [P1NP and TRACP-5b]). Time averaged data (ta-data) which was averaged data of every 6 month was utilized for analysis with respect to data of RA disease activity and BTMs besides baseline data.

Results: Mean age was 59 years old. Mean RA duration was 16 years. Rates of concomitant prednisolone use was 33.9%. Mean DAS28-CRP was 2.7. 44% of cases had the past history of fracture. Mean FRAX was 28%. Daly teriparatide was used in 11 cases before DMB treatment. %increase of LSBMD at every 6 month was significantly increased (4.7%>6.7%>7.7%>8.3%) and %increase of THBMD at every 6 month was significantly increased (2.9%>3.3%>4.9%>4.9%) (Fig1). %decrease of P1NP and TRACP-5b was 37.4%>33.8%>25.5%>26.0% and 33.3%>29.8%>26.1%>23.1%, respectively (Fig2). Fig3 showed that parameters (correlation coefficient) which were correlated with %increase of LSBMD at 24 months were %increase of LSBMD at 6 months (0.61), baseline P1NP (0.33) and time averaged %decrease of TRACP-5b (0.30). Parameters (correlation coefficient) which were correlated with %increase of THBMD at 24 months were %increase of LSBMD at 6 months (0.42), %increase of THBMD at 6 months (0.69), baseline P1NP (0.36), time averaged %decrease of P1NP (0.37), baseline TRACP-5b (0.29) and time averaged %decrease of TRACP-5b (0.29). Although %increase of BMD at 24 months was not correlated with disease activity of RA, taCRP was significantly correlated with taP1NP (0.57) and taTRACP-5b (0.45).



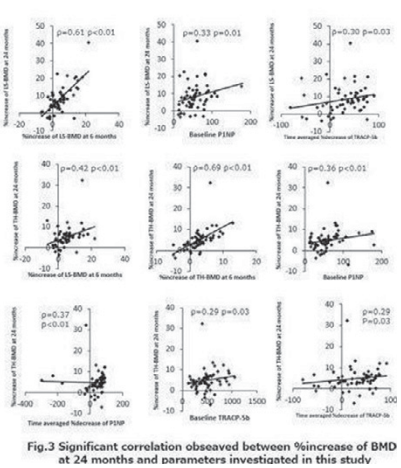


Fig.1 %increase of BMD

Fig.2 %change of BTMs

Fig.3 Significant correlation obseaved between %increase of BMD at 24 months and parameters investigated in this study

Conclusions: DMB was effective in RA-OP. Early response of BMD, baseline values of BTMs and response of BTMs were suggested to be the predictors of the efficacy of DMB in RA-OP. Inflamation of RA was correlated with not BMD but BTMs.

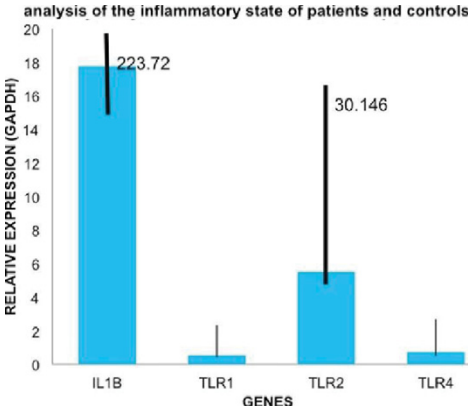
Crystal diseases, metabolic bone diseases and bone diseases other than osteoporosis

AB0861 EXPRESSION CONTROL BY METHYLATION OF THE TLR1, TLR2, TLR4, IL1B, ALPK1 SLC2A9 AND SLC22A12 GENES IN MONOCYTES OF PATIENTS WITH GOUT

N. Paniagua Díaz [1], E.G. Tranquilino Batres [1], A.P. López Flores [2], A. Lozano Cardenas [2], E. Vallarino Reyes [2], A.L. Alvarez Grijalva [2], L. Sanchez Chapul [1], C. Hernández Díaz [3], L. Ventura Ríos [3], A. Lopez Macay [1]. *[1] Enfermedades Neuromusculares, Instituto Nacional de Rehabilitacion; [2] Ciencias de la vida, Instituto de Estudios Superiores Monterrey; [3] LUMA, Instituto Nacional de Rehabilitacion, Mexico City, Mexico*

Background: The gout is an inflammatory multifactorial disorder where the diet, age, sex, absorption regulation of uric acid in kidney and genetic, contribute to the onset of the disease. The balance of uric acid concentration not only depends on metabolism of purines but also on the clearance of uric acid, in which many proteins participate in the reabsorption and transport of urate. Is unknown if the peripheral blood leukocyte cells can change their expression and regulation mechanism of the urate transporters by the presence of uric acid in gout patients [1–4].

Objectives: Analyze changes in gene expression and the methylation pattern of the TLR2, TLR4, SLC2A9, SLC22A12, SLC22A3 and ABCG2 in neutrophils and peripheral blood monocytes from patients with gout and controls



Methods: The isolation of peripheral blood neutrophils and monocytes cells was performed by negative immunomagnetic selection (MACxpress kit, EUA). By flow citometry were analyzed the previously separate cell populations, mononuclear (MN), polymorphonuclear (PMN) cells and neutrophils (N) (CD15, CD16, CD14). The DNA and RNA extraction was realized with a without columns kit and with Trizol technique. The gene expression analysis will be performed from total RNA by RT-PCR kit (Promega). Methylation analysis will be carried out the bisulfite conversion (ABCAM) from total DNA and HRM-PCR. For both studies, gene expression and methylation analysis are designed specific primers

Results: The biggest difference between asymptomatic gout patients (n=12) and controls (n=12), in the biochemical parameters (Table 1), is in the higher levels of uric acid and triglycerides that the patient presents. Actually, we've already evaluated the genetic expression of TLR1, TLR2, TLR4 and IL1b in mononuclear cells of 5 asymptomatic gout patients and 5 controls (Plot 1). Interestingly, IL1b is UP-regulated in sample group bye a mean factor of 16.350 and TLR2 is UP-regulated in sample group in comparison to control group by a mean factor of 3.686.

Table 1. Characteristics of patients and controls

	Patients	Controls
Participants (n)	12	12
Age (years)	40.75	29.75
BMI (kg/m^2)	29.27	24.05
SM n (%)	8.33	0
Hypertension, n (%)	58.33	0
Urate (mg/dL)	8.35	4.87
Glucose (mg/dL)	84.83	81.33
Cholesterol (mg/dL)	196.33	175.25
Tryglicerides (mg/dL)	276.67	109.42
Creatinine (mg/dL)	1.02	0.79

Conclusions: The asymptomatic patients with a higher mean of uric acid (8mg/dL) and tryglicerides (145.60 mg/dL) had a higher expression of IL1b and TLR2 compared to controls.

AB0862 THE SENSITIVITY OF THE DOUBLE CONTOUR SIGN IN HAND JOINTS WOULD BE BETTER BY THE DORSAL SURFACE EXAMINATION

A.M. Mahdi [1,2], H. Rkain [1], M. Erraoui [1], R. Watfeh [3], S. Aktaou [3], L. Tahiri [1], R. Bahiri [1], F. Allali [1], N. Hajjaj-Hassouni [1]. *[1]Rheumatology, Faculty of Medicine and Pharmacy; [2]University Mohamed V, Rabat; [3]Faculty of Medicine and Pharmacy, Rabat, Morocco*

Objectives: To compare the prevalence of ultrasonographic gout specific sign double contour between the dorsal and palmar surfaces of the hand joints.
Methods: This is a cross-sectional study which includes 15 patients with chronic gout, defined according to the American College of Rheumatology criteria (ACR 1977). Ultrasound (US) examination was performed using a high-frequency linear probe (Toshiba Xario®, frequency (8–14 MHz)) in B and Doppler modes. 560 articular sites were studied at their dorsal and palmar surfaces. We compared the prevalence of the hyperechoic band over the superficial margin of the articular cartilage described as a double contour (DC) between the dorsal and palmar surfaces at each site studied.
Results: The mean age at onset was 54.7±12,6 years, and the median diagnosis duration was 0 (0.3) years).
The results of the US examination are summarized in Table 1

Table 1. comparison of double contour prevalence between the dorsal and palmar surfaces of wrist, MCP, PIP and DIP joints in the studied population

Joints (N=540)	Dorsal surface (%)	Palmar surface (%)	P
Wrist joints (N=120)	12,6	7,3	**<0.001**
Radiocarpal (N=30)	20	6,7	0,6
Ulnocarpal (N=30)	13,3	6,7	**0,01**
Scaphotrapezial (N=30)	3,3	13,3	0,8
Trapeziometacarpal (N=30)	13,3	3,3	0,1
MCP (N=150)	8	6,6	**<0.001**
MCP 1 (N=30)	3,3	10	0,1
MCP 2 (N=30)	13,3	6,7	**0,014**
MCP 3 (N=30)	6,7	6,7	**0,002**
MCP 4 (N=30)	6,7	0	**<0.001**
MCP 5 (N=30)	10	10	**<0.001**
PIP (N=150)	4	7,3	**<0.001**
IP (N=30)	3,3	10	0,1
PIP 2 (N=30)	6,7	3,3	0,9
PIP 3 (N=30)	6,7	13,3	**0,01**
PIP 4 (N=30)	3,3	10	0,1
PIP 5 (N=30)	0	0	**<0.001**
DIP (N=120)	0,8	3,3	**0,033**
DIP 2 (N=30)	0	0	**<0.001**
DIP 3 (N=30)	3,3	3,3	**0,002**
DIP 4 (N=30)	0	3,3	**<0.001**
DIP 5 (N=30)	0	6,7	**<0.001**

Conclusions: Our study suggests that globally, DC predilect significatily in dorsal than in palmar surfaces of hand joints. These results should be verified on a larger population.

AB0863 THE POPLITEUS GROOVE IN THE LATERAL FEMORAL CONDYLE: A SHELTER FOR MONOSODIUM URATE CRYSTALS?

A. Di Matteo, E. Cipolletta, M. Ausili, E. Filippucci, W. Grassi. *Clinica Reumatologica, Università Politecnica delle Marche, Jesi (AN), Italy*

Background: Gout is a crystal related arthropathy characterized by deposition of monosodium urate (MSU) crystals at articular and periarticular structures. Ultrasound (US) has gained an important role in the diagnosis of gout due to its capability to clearly detect various expressions of MSU crystal depositions in joints, tendons and bursae [1]. The popliteus tendon inserts in a depression on the outer side of the lateral femoral condyle. It has a close connection to the lateral meniscus and is surrounded by the popliteal recess which is in direct communication with the knee joint cavity [2].
Objectives: To evaluate the prevalence of US findings indicative of MSU crystal deposition at the popliteus groove in patients with gout.
Methods: Consecutive patients with gout, diagnosed according to the 2015 ACR/EULAR criteria, and disease controls diagnosed according to the corresponding diagnostic/classification criteria were enrolled. All the patients underwent a bilateral US examination (carried out using a Logiq 9 US system working with a linear probe operating at 15 MHz) at the popliteus groove level. The US examination was performed with the patient lying supine on the examination bed. A knee flexion of approximately 45° was necessary to visualize the popliteus groove in the lateral aspect of the femoral condyle just deep to the proximal part of the lateral collateral ligament. The following US abnormalities indicative of MSU crystal depositions were evaluated: isolated shining dots, aggregates (heterogeneous hyperechoic foci that maintain their persistent high degree of reflectivity which occasionally may generate posterior acoustic shadow) and tophi (inhomogeneous hyperechoic/hypoechic material surrounded by a small anechoic rim which may generate posterior acoustic shadows).
Results: We enrolled 17 patients with gout and 22 disease controls: 9 calcium pyrophosphate deposition disease (CPPD), 8 rheumatoid arthritis and 5 psoriatic arthritis. A total 78 popliteus groove were examined by US. US findings indicative of MSU crystal deposition were detected in at least one knee in 13 out of 17 gout patients (76.5%) and in 7 out of 22 controls (31.8%). Table 1 shows the prevalence of the US abnormalities indicative of MSU crystal deposition in the two groups. Six out of the 10 US abnormalities (60%) found in controls were detected in CPPD patients.

Table 1

	Gout	Controls
Patients	17	22
Popliteus grooves assessed by US	34	44
Popliteus grooves "positive" for US findings indicative of MSU crystal deposits	23 out of 34 (67.6%)	10 of out 44 (22.7%)
Isolated shining dots	9 out of 23 (39.1%)	8 out of 10 (80%)
Aggregates	8 out of 23 (34.8%)	2 out of 10 (20%)
Tophi	6 out of 23 (26.1%)	0 (0%)

Conclusions: These preliminary results suggest that the popliteus groove could be regarded as a sentinel area for detecting MSU crystals. These findings should lead to further investigations aimed at identifying the factors and associated with MSU crystals deposition at popliteus groove level.

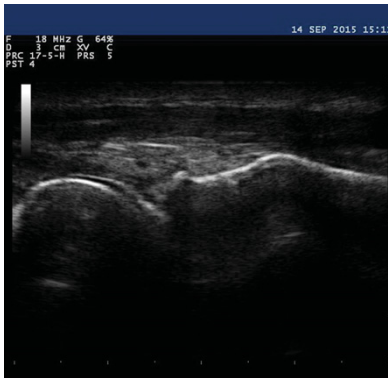
AB0864 SENSITIVITY AND SPECIFICITY OF SONOGRAPHIC DETECTION OF URATE CRYSTAL DEPOSITS IN HYALINE CARTILAGE IN PATIENTS WITH GOUT IN YEARLY STAGE

A. Petrov, V. Fursova, A. Petrov. *Medical Academy named after Georgievsky, Crimean Federal university named after V.I. Vernadsky, Simferopol, Russian Federation*



Background: In some cases differential diagnosis between yearly gouty arthritis and other types of arthritis is very difficult. In 2015 the sonographic detection of urate crystal deposits in hyaline cartilage as a new criterion was included in set of classification criteria of gout [1]. But diagnostic value of that ultrasound marker in first month of disease is underinvestigated.
Objectives: To investigate sensitivity and specificity of sonographic detection of gouty hyperechoic deposits in hyaline cartilage in patients with gout in comparison with other signs of gout in debut of arthritis.
Methods: The 104 patients with yearly arthritis (duration of symptoms less

than 6 month) was examined by clinical, laboratory, X-Ray and ultrasonography. After investigation the following diagnoses were made: Gout in 32 patients, Osteoarthritis in 28 patients, Rheumatoid arthritis in 28 patients, Psoriatic arthritis in 16 patients. Ultrasound investigation of affected joints was performed in all subjects by linear probe 18 MHz. Urate crystal deposits were seen on the surface of the hyaline cartilage as a hyperechoic thin line or dots on the cartilage, wich sometimes imitate double contour of bones [2, 3]. Sensitivity and specificity of ultrasound sign were compared with subcutaneous tophi, bone cysts (X-Ray sign) and hyperuricemia.

Results: The urate crystal deposits in gyalinic cartilage of at least one of affected joints were revealed in 28 of 32 (87,5%) patients with Gout, in 3 of 28 (10,7%) patients with Osteoarthritis and 1of 16 (6,3%) patients with Psoriatic arthritis. Comparative data of sensitivity and specificity of crystal deposits, bone cysts, subcutaneous tophi and hyperuricemia are represented in table below.

Table 1. Sensitivity and specificity of different diagnostic markers in yearly stage of gout

Diagnostic marker	Sensitivity, %	Specificity, %
Hyperechoic lineal urate deposits in gyalinic cartilage	87,5	94,4
Bone cysts	21,7	88,8
Subcutaneous tophi	25,0	98,6
Uric acid level from 360 mkmol/l up to 480 mkmol/l	46,9	86,1
Uric acid level more than 480 mkmol/l	34,4	97,2

Conclusions: Ultrasound detection of urate crystal deposits in hyaline cartilage in patients with gout in yearly stage has a high sensitivity and comparable level of specificity with other diagnostic markers of Gout.

AB0865 SERUM URATE AND ITS ASSOCIATION WITH RACE IN YOUNG ADULTS: BASELINE ANALYSIS FROM A RANDOMIZED CLINICAL TRIAL

M.B. Saddekni[1,1], A.L. Gaffo[2], P.J. Foster[1], S.R. Biggers[2], E.J. Rahn[2], P. Li[3], K.G. Saag[1]. *[1]UAB School of Medicine, Division of Clinical Immunology and Rheumatology; [2]Department of Medicine, Division of Rheumatology and Immunology; [3]UAB School of Public Health, Department of Biostatistics, University of Alabama at Birmingham, Bimringham, United States*

Background: Increased levels of serum urate (sUA) have been reported in association with hypertension, chronic kidney disease and obesity. All these conditions are over-represented in US African Americans, who also have greater environmental risk factors for hyperuricemia development including elevated fructose intake. Our group has previously reported that young African Americans have lower sUA concentrations than Caucasians after adjustment for clinical and demographic factors.

Objectives: To determine whether there is a differential association between sUA and race in young adults.

Methods: We examined baseline data on consecutively enrolled individuals (age 18 – 40 years) in an interventional study aimed at lower blood pressure (BP) through the administration of urate-lowering therapy. African Americans were over-represented in the sample by study-design. Inclusion criteria included a sUA of $\geq$5.0 mg/dL for men or $\geq$4.0 mg/dL for women. After means comparisons between races, we performed multivariable adjustments for age, gender, BP, and body mass index (BMI) a multiple linear regression model. Data reported are mean ±standard deviation.

Results: 86 participants recruited from Birmingham, AL were included in the analysis. Participants had a mean age of 28.5±6.9 years, 36% were female, 41% were African Americans (AAs), and the mean BMI was 29.2±6.8 kg/m^2. The mean sUA was 5.9±1.2 mg/dL (n=77, range: 3.9 to 8.5 mg/dL). We found a significantly lower sUA for African Americans compared to persons of other races (5.4±1.2 mg/dL vs 6.2±1.1 mg/dL, p=0.005). After multivariable analysis the difference in sUA between AAs and other races was attenuated to non-significance (p=0.33) due to the effects of BMI and gender. As expected, the association between sUA and gender was significant (Table).

Table 1. Multivariable regression model on the association between serum urate and race among young adults (n=86)

Variable	Estimate (95% confidence interval)	p
Race (African-Americans versus other races)	-0.34 (-0.82 , 0.15)	0.18
Age (per year)	0.02 (-0.02, 0.05)	0.34
Gender (men versus female)	1.36 (0.87, 1.85)	$<$0.001
BMI (per unit of kg/m^2)	0.04 (0.00, 0.07)	0.035

BMI = Body-mass index.

Conclusions: In this cross-sectional analysis of young adults, AAs had lower sUA concentrations than other races. However, this difference is explained by the effect of gender differences in sUA and BMI. A potential limitation is that participants were enrolled after they met a sUA threshold so not all the ranges of sUA in a normal population are represented in this analysis. Larger studies will be needed to fully address this question.

AB0866 EVALUATION OF THE ACHIEVEMENT OF A THERAPEUTIC TARGET OF<6 MG/DL IN ALGERIAN PATIENTS TREATED FOR GOUT

B. Bengana[1], S. Slimani[2], K. Testas[3], F. Rahal[4], M. Makhloufi[5], A. Ladjouze[4], S. Lefkir-Tafiani[1]. *[1]Rheumatology, Derpartement of Rheumatology -University Medical Centre Beni Messous, ALGIERS; [2]Rheumatology, University of Batna, Batna; [3]Rheumatology, El kherroub Hospital, Constantine; [4]Rheumatology, Ben Aknoune Hospital, ALGIERS; [5]Medicine, University of Batna, Batna, Algeria*

Background: Gout is one of the most prevalent rheumatic conditions in the developing world, due of the aging of the population and the modifications in the life style. The 2014 EULAR recommendations for the management of gout have defined the therapeutic target of 60 mg/L for gouty patients (recommendation 8). The aim of the study was to assess the adherence of Algerian patients with gout to these recommendations.

Methods: We have retrospectively analyzed patients files aged 18 and more, followed in a rheumatology setting for gout, in 4 centers in Algeria. Demographic, clinical and lab data were collected. We have excluded files with missing data. Were noted the used therapeutics and serum uric acid in every patient through time. Tolerance was noted.

Results: We have analyzed 145 complete files: 98 men (68%), with a mean age of 65.4±11.4 years. All patients except two had rheumatic manifestations, 20 patients had renal insufficiency and 15 had tophi. Main comorbidities were hypertension (40 patients) and diabetes (25 patients). The mean serum uric acid level was 96±14 mg/L. Concerning symptomatic drugs, 81 patients have taken colchicine and 15 NSAIDs, the remaining patients have taken other drugs or combination therapy. All patients but one have received serum uric acid lowering therapy (allopurinol in majority of cases), with a median dosage of 200 mg/day, and only 5 patients taking more than 300mg/day. The mean serum uric acid level at 6 months was 58±14 mg/L, with 58% of patients achieving a level of $<$60 mg/L.

Conclusions: In rheumatology settings in Algeria, more than 93% of gouty patients received allopurinol, with an excellent tolerance. However, it seems that dosage is insufficient, with only 58% of patients achieving the EULAR recommendation 8. More efforts have to be provided to optimize this therapy.

AB0867 PEGLOTICASE RE-TREATMENT AFTER A GAP IN THERAPY: DATA FROM TWO PHASE III TRIALS AND AN OPEN-LABEL EXTENSION STUDY

H.S. Baraf[1], A. Morton[2], B. LaMoreaux[3], J. Kent[3]. [1]*Medicine, George Washington University, Washington DC;* [2]*Internal Medicine, Michigan State University School of Osteopathic Medicine, East Lansing;* [3]*Medical Affairs, Horizon Pharma, Lake Forest, United States*

Background: Pegloticase is a PEGylated recombinant uricase approved in the US for treating adult patients with chronic refractory gout. As a biologic medication, pegloticase is administered intravenously every 2 weeks. It is currently not known whether a gap in the standard biweekly regimen can be tolerated or would be associated with a loss of efficacy. During the pivotal trial testing of pegloticase, some patients experienced a delay between participation in the randomized controlled trial (RCT) and the open-label extension (OLE) that followed. Analysis of the clinical impact of this gap was carried out to understand whether therapeutic benefit would be affected.
Objectives: The objective of this analysis was to determine, among pegloticase responders, the effect of a 28 or more day gap between doses of pegloticase on the subsequent urate lowering response and frequency of infusion reactions.
Methods: These analyses utilized results from two RCTs of pegloticase and a 2-year OLE. In the RCTs, 36 of 85 patients, who were dosed with pegloticase every two weeks, were classified as responders (persistent urate lowering during intensive monitoring at 3 and 6 months of the RCT), and went on to enroll in the OLE and receive additional doses of pegloticase. Of these 36 patients, 14 had a gap between pegloticase doses of more than 28 days.
Results: Among the 14 patients with a gap of more than 28 days between doses of pegloticase therapy the length of the gap ranged from 34 to 167 days (mean =72.5 days, median =59.5 days). Of these 14 patients, 8 received pegloticase on an every-4-week dosing schedule in the OLE and 6 remained on every-2-week dosing. Ten of the 14 patients maintained their serum urate level <6mg/dL in the OLE. Five of 6 that remained on every 2 week dosing and 5 of 8 that went to every 4 week dosing continued to have serum urate <6mg/dL. (see table 1). By logistic regression analysis, the length of the gap had no significant effect on the subsequent urate lowering effect of pegloticase. Of the fourteen patients with a gap in pegloticase therapy, 2 (14%) had infusion reactions during a total of 632 infusions in the OLE yielding a re-treatment IR rate of 0.32%.

Table 1. Continued responder proportions and infusion reaction rates by OLE dosing group

Dosing Group	Total	Continued Responders	Percentage	Infusion Reaction Rate
Combined	14	10	71%	0.32
Every 2 weeks	6	5	83%	0.30
Every 4 weeks	8	5	62.5%	0.34

Conclusions: The majority of patients in this limited dataset who were previously responders to pegloticase dosed every 2 weeks continued to maintain a serum urate lowering response to pegloticase after a gap in therapy. Infusion reactions during re-treatment occurred in 2 patients with a re-treatment infusion reaction rate of 0.32%.

AB0868 IS IT APPROPRIATE TO DISCONTINUE COLCHICINE THERAPY IN GOUT PATIENTS IN REMISSION?

Y. Özdem İnan[1], N. Alpay Kanıtez[2], S. Çelik[2], S. Yılmaz Öner[2], C. Bes[2]. [1]*Bakırköy Dr Sadi Konuk Training and Research Hospital, Istanbul, Turkey;* [2]*Rheumatology, Bakırköy Dr Sadi Konuk Training and Research Hospital, Istanbul, Turkey*

Background: Colchicine can reduce the risk of recurrent attacks and it is an appropriate first-line gout attack prophylaxis therapy. There is limited data in the literature about duration of colchicine treatment in patients with gout disease.
Objectives: In this study, we aimed to investigate the frequency of gout attacks between patients with colchicine treatment and patients who are colchicine terminated.
Methods: 54 gout patients under colchicine treatment were enrolled to the study. The subjects were divided into 2 groups. Group 1 (n=19) was consisted of patients whom colchicine therapy was terminated because of remission for three months; group 2 (n=35) was consisted of patients on colchicine treatment. Groups were compared according to the existing of newly gout attacks after the 3rd month. Baseline and the third months of the uric acid levels were also analyzed in each group.
Results: The body mass indexes, the disease intervals, the number of the attacks, and the duration of the attacks were not significantly different ($p>0.05$ for all) (Table 1). Compared to the group 2, the newly gout attacks were not found to be different in group 1 for 3 months ($p>0.05$) (Table 1). The uric acid levels were significantly decreased both in two groups (both $p<0.05$) (Table 2).

Table 1. Demographical and clinical characteristics of patients

Patient variables	Group 1 (n=19)	Group 2 (n=35)	p
Gender, F/M	0/19	12/23	0.040
Age, years	53.36±14.06	62.11±12.72	0.024
BMI	28.22±3.57	30.29±5.63	0.153
Uric acid, mg/dL	7.40±1.30	8.21±1.92	0.108
Disease age, months	111.63±172.70	53.48±59.75	0.170
Number of the attacks, one year	2.68±2.35	3.37±3.75	0.413
Duration of the attacks, days	16.73±16.32	10.91±14.50	0.202
Newly attacks in 3 months	5/14	7/28	0.734

Table 2. Before and after treatment comparisons of the uric acid levels

Variables	Baseline	3rd month	p
Group1	7.40±1.30	6.47±1.19	0.008
Group 2	8.21±1.92	6.74±1.70	<0.001

Conclusions: The colchicine is the mainstay treatment for gout disease. It not only prevents the attacks of the gouts also prevents the development of uric acid nephropathy that exaggerates the kidney disease in gout patients. This study showed that, in gout patients in remission, termination of the colchicine treatment does not affect the development of the new attacks as shown similar attacks were also observed in non-terminated patients.

AB0869 STRESS FRACTURES, A RETROSPECTIVE STUDY OF 325 FRACTURES IN 227 PATIENTS IN RHEUMATOLOGY PRACTICE BETWEEN 2000 AND 2015

C. Nourisson, J.-J. Dubost, B. Pereira, A. Tournadre, S. Malochet-Guinamand, M. Soubrier. *CHU Clermont Ferrand, Clermont-Ferrand, France*

Background: Stress fractures are common in both young and active patients (fatigue fracture) as well as in elderly osteoporotic patients (insufficiency fractures).
Objectives: The aim of this study was to describe characteristics of stress fractures treated in rheumatology at the Clermont-Ferrand University Hospital, to compare them according to their anatomic location (pelvis, lower limb or feet/ankle) and their diaphyseal or metaphyseal/epiphyseal location.
Results: Between 01/01/2000 and 12/31/2015, 325 fractures were identified in 227 patients divided in 176 women (including 116 postmenopausal women) and 51 men. Population averaged age was 65.2 years [15–99 years]. 142 (43.7%) fractures occurred at pelvis, 93 (28.6%) at lower limbs and 87 (26.8%) at feet and ankles. The fracture was spontaneous in 63.6% of cases. History of pain was recorded in 92.3% with more frequently (90.3%) mechanical pain. Diagnostic delay was on average 70 days.
In 51 patients (22.5%) an orthopedic factor could have promoted stress fracture. 54 patients (23.8%) had a history of chronic inflammatory rheumatism, 28 (12.3%) of cancer, and 20 (8.8%) had chronic renal failure.
Among the possible iatrogenic factors, 51 patients (23.4%) received oral corticosteroid therapy, 20 (9.2%) methotrexate, 59 (27%) proton pump inhibitor and 17 (7.8%) serotonin reuptake inhibitor. 49 patients (22.5%) already had vitamin-calcium supplementation, 37 (17%) received biphosphonate therapy. 56.6% were osteoporotic and 29.5% were osteopenic.
First-line medical imaging was in 87% conventional radiography, positive in 37%. 106 patients (46.7%) performed bone scan with a sensibility of 99%. MRI sensibility (n=65, 28.7%) was 88% and CT-scan sensibility (n=47, 20.7%) 65.2%. Compared to other sites, pelvic fractures were more frequent ($p<0.001$) and occurred more frequently in postmenopausal women ($p=0.03$). These patients were older ($p<0.001$) and had more fracture history ($p=0.006$). Hip bone mineral density ($p=0.03$) was lower, and osteoporosis prevalence higher ($p=0.004$).
Pelvic fractures occurred more frequently after fall ($p<0.001$), lower limb fractures spontaneously ($p=0.03$) and those of the feet-ankles group after an unusual activity ($p<0.001$). Patients from metaphyseal-epiphyseal fracture group were older ($p=0.05$) than those from the diaphyseal fractures group and delay in completing complementary examinations was longer ($p=0.04$).
Conclusions: In conclusion, pelvic stress fractures are more frequent in a rheumatology department and suggest insufficiency fracture. Stress fracture should be more often suspected when mechanical pain of the pelvis and lower limbs occurs, even spontaneously. Regardless of the site, an assessment of fracture risk factors and bone mineral density evaluation seems necessary.

AB0870 METABOLIC AND CARDIOVASCULAR GOUT ARE THE MOST FREQUENT CLINICAL VARIANTS OF THE DEBUTING GOUT

E. Mikhnevich[1], T. Pavlovich[1], E. Mytnik[2]. [1]*Department of Internal Medicine, University of Medicine;* [2]*Diagnostic Center, Rheumatology Clinic, Minsk, Belarus*

Background: Gout is phenotypically and genotypically heterogeneous. In most cases, renal mechanism plays an important role in the development of gout. At the same time, gout, as a rule, occurs on the basis of pre-existing comorbid pathology.
Objectives: To determine clinic-pathogenetic variants of gout depending on a leading comorbid pathology at the gout onset.
Methods: We included 604 patients with confirmed gout from our Center database. During 2010–2016, comorbidities were registered before the gout onset, at its appearance, during and at the last examination. Metabolic syndrome (MS) was defined by 5 components. CVD included CHD, atrial fibrillation, CHF and stroke. Patients after organ transplantation and with terminal renal failure observed in specialized centers were not recruited.
Results: In 67,1% (n=405) of patients, the gout developed on the basis of pre-existing MS, thus, this variant may be called a metabolic gout (MG) and considered as a component of MS. The patients with MG were younger, the mean age of symptoms onset was 42 (35–48) years. At the first gout attack, all patients had BMI≥25 kg/m^2, 8,2% (n=33) had pre-existing HTN, and in 14,3% (n=58) of cases the diagnosis of HTN was firstly made. No one patient had diabetes mellitus (DM). Frequent regular or single abundant alcohol intake together with overeating as factors more often favoring gout attack were revealed in all patients. At the last examination, only 38,1% (n=230) of patients had MS without any CVD, the mean age was 50 (45–55) years; 98,7% (n=227) had BMI≥25 kg/m^2; 73,9% (n=170) presented with HTN; 59,1% (n=136) showed dyslipidemia; 6,5% (n=15) had DM. In 8,3% (n=19) of patients, changing the lifestyle and normalizing the weight resulted not only in decreased hyperuricemia but lower attacks rate or even their total disappearance during a 5 year follow-up. The second variant of gout onset developing in patients with pre-existing CVD, can be called a CV gout or cardiorenovascular (CRV) gout. This type of gout was revealed in 28,5% (n=172) of patients, the disease debuted later, at the age of 60 (55–64) years (p<0,001). 97,7% (n=163) had HTN (χ^2=30,1, p<0,001) and 27,3% (n=47) – DM (χ^2=32,65, p<0,001), both features were more common in CV gout. 85,5% (n=147) had BMI≥25 kg/m^2 (F=0,066, p<0,001). Regular alcohol intake was considerably lower – 33,7% (n=58) (χ^2=167,4, p<0,001), but medication use was higher – diuretics in 14,5% (n=25) (χ^2=21,77, p<0,001) and low-dose aspirin in 37,2% (n=64) of patients (F=0,24, p<0,001). At the last examination, the mean age of patients was 63 (59–69) years (p<0,001), chronic GFR <60 ml/min was observed in 47,7% (n=82) of patients (F=0,34, p<0,001).
The secondary gout developed in 4,4% (n=27) of patients with various diseases: myelo-, lymphoproliferative and other blood diseases - 6 cases, renal gout - 13, gut gout after partial gut resection - 2, and anorexic gout - 2. Alcoholic gout without MS was diagnosed in 4 patients, all men with body mass deficiency.
Conclusions: In our opinion, there are two main clinic-pathogenetic variants of debuting gout – metabolic and cardiovascular, the both with different conditions of occurrence, progression and prognosis. In clinical practice, it is reasonable to differentiate these variants, that is determined by the need to simplify complex multimodal diagnostic and therapeutic approach to the patients with gout.

AB0871 NSAIDS AND LIVER FUNCTION IN PATIENTS WITH GOUTY ARTHRITIS

E. Mikhnevich[1], T. Rayeuneva[1], K. Leonchik[1], E. Mytnik[2]. [1]*University of Medicine;* [2]*Rheumatology Clinic, Diagnostic Center, Minsk, Belarus*

Background: Nonsteroidal anti-inflammatory drugs (NSAIDs) have been associated with hepatotoxicity. Drug-induced liver injury (DILI) in patients under NSAIDs is more frequently presented by hepatocellular damage with elevated serum alanine aminotransferase (ALT) levels (1).
Objectives: To evaluate the hepatocellular toxicity due to NSAIDs on the basis of changes in serum ALT levels in patients with gouty arthritis (GA).
Methods: 376 patients with GA registered in our database were included in our retrospective study. Males made 92,8% (n=349). Mean age was 57 (50–62) years; mean duration of gout – 7 (3–10) years. NSAIDs were prescribed to the patients with gouty attack by generalists, and then all patients were addressed to the Rheumatology Clinics. Serum ALT levels were determined at the onset of gout attack and 3–10 days after starting NSAIDs therapy. All NSAIDs used were generics. The hepatotoxicity was considered when ALT level was 2 times (or more) upper limits of normal values (42 U/l for men and 35 U/l for women) according to DILI criteria. ALT level at baseline was within the normal limits in 80,8% (n=304) of cases, its elevation was identified in 19,2% (n=72).
Results: We divided the patients into 3 groups according to the type of changes in serum ALT levels after receiving NSAIDs:
Group 1: 69,4% (n=261) of patients with normal ALT 24 (17–30) U/l before and 24 (18–32) U/l after treatment (p>0,05).
Group 2: 11,4% (n=43) of patients with normal basal ALT 26 (21–35) U/l and its elevation to 77 (72–88) U/l (p<0,001) after NSAIDs therapy.
Group 3: 19,2% (n=72) of patients with elevated basal ALT 57 (46–91) U/l, who had different type of ALT response to NSAIDs therapy. We identified 3 subgroups within the third group:
Subgroup A: 7% (n=5) of patients with elevated ALT level at the beginning of gout attack – 92 (62–123,5) U/l and higher value after treatment – 151 (129–215) U/l (p<0,001). Subgroup B: 23,6% (n=17) of patients with elevated ALT before treatment – 53 (47,5–62) U/l and non-significant changes after therapy – 51 (44,5–63,5) U/l (p >0,05). Subgroup C: 69,4% (n=50) of patients with elevated ALT before treatment – 59 (49–89) U/l and reduced and/or normal ALT level after therapy – 42 (29–57) U/l (p<0,001). While the patients from subgroup A have demonstrated supplementary hepatotoxicity due to NSAIDs on the basis of pre-existing liver injury, the absence of changes in ALT levels in subgroup B has been suggested in favor of a chronic liver injury. Subgroup C has reflected the effect of NSAIDs to decrease and even normalize the elevated basal ALT value. This may be linked to a hepatic inflammation, which is likely associated with alcohol intake, but hyperuricemia could also be involved.
Conclusions: 69,4% (261 from 376) of patients with GA having normal basal ALT values did not demonstrate any changes in ALT level after NSAIDs treatment; in 11,4% of patients, hepatocellular NSAIDs–induced hepatotoxicity was revealed. In the group of patients with elevated basal ALT level, the response of ALT to NSAIDs treatment was as follows: no significant changes – 23,6%, elevated value – 7%, reduced or normalized value – 69,4%. The last subgroup (C) requires more detailed study.

AB0872 DIAGNOSTIC EFFICIENCY OF DETERMINING THE PURINE METABOLISM ENZYMES ACTIVITY IN THE DIFFERENTIATION OF GOUT

E. Mozgovaya, A. Trofimenko, S. Bedina, I. Zborovskaya. *Federal State Budgetary Institution " Research Institute of Clinical and Experimental Rheumatology", Volgograd, Russian Federation*

Background: Serum uric acid (UA) level is the most important risk factor for gout. At the same time many people with hyperuricemia do not suffer from gout, and UA level can return to normal during gout exacerbation.
Objectives: to improve the diagnostics of the gout.
Methods: 53 gout patients were the target group. The mixed control group was consisted of 150 rheumatoid arthritis patients, 95 osteoarthritis patients, 55 ankylosing spondylitis patients. The diseases were diagnosed in accordance with the international standards. Adenine deaminase, Adenosine deaminase (ADA), AMP-deaminase (AMPDA), Guanine deaminase, Guanosine deaminase, Guanosine phosphorylase, 5'-nucleotidase, Xanthin dehydrogenase (XDG), Xanthin Oxidase, Purine nucleoside phosphorylase activities were determined in blood serum with subsequent evaluation of sensitivity (Se), specificity (Sp), likelihood ratio of positive (LRP) and, likelihood ratio of negative (LRN) result, predictive value of positive and negative results.
Results: The AMFDA and ADA activities were defined as a screening marker to diagnose of the gout from a joint syndrome another genesis. Threshold AMPDA activity 1,67 IU was characterized with the predictive value of negative results (without taking into account the prevalence) near 100%, Se 98%, Sp 62,45%.
Cutoff value (CV) of ADA activity (9,57 IU) was characterized with LRN 0,104, Se 92,45%, Sp 72,65%, the sum (Se+Sp 165,10%), which was maximum not only for this test but for all the studied enzymes. The predictive value of negative results (without taking into account the prevalence) was 98,20%. The clinically significant CV of positive result for the ADA activity definition was identified also: LRP was 6,93 (Se 22,64%, Sp 96,73%) for the range of 12.58 IU and above. This fact allows the use of this test not only for the screening, but also, in some cases, for the verification of gout with significant pretest probability of this disease.
Two CV were selected for the XDG activity: 7,49 μM/l×min (Se 47,17%, Sp 97,14%) and 8,39 μM /l×min (Se 39,62%, Sp 99,59%). The result of XDG activity determining in the range of 7.49 - 8.39 μM /l×min is an important argument in favor of the gout presence, but this may be useful for differential diagnosis only at high pretest probability of the gout.
Conclusions: Determination of the ADA activity was gave way to AMPDA activity determination at the gout screening and to XDG activity determination at gout verification. However, the ADA multifunctionality, evidenced clinically significant presence of the second CV (positive results) and a small proportion of the cases, which covered a "grey area" between CV (27.48%), provided the ability to use this marker as a backup in the absence of diagnostically relevant AMPDA and XDG activities.

AB0873 CHARACTERISTICS OF ADHERENCE, PERSISTENCE AND THERAPEUTIC ALLIANCE IN PATIENTS WITH GOUT

E. Alvarez-Hernandez[1], L.D. Upegui-Arango[2], J. Vazquez-Mellado[1], E. Aranda-Arreola[1], R. Burgos-Vargas[1], I. Pelaez-Ballestas[1]. *[1]Rheumatology, Hospital General de Mexico, Mexico DF, Mexico; [2]Rheumatology, 2.Universidad Industrial de Santander, Bucaramanga, Colombia*

Background: Adherence is the extent to which the patient takes their medications and follow the directions prescribed by their doctor. It has two components: compliance (the degree or extent of conformity to the recommendations about day-to-day treatment by the provider with respect to the timing, dosage, and frequency) and persistence (the duration of time from initiation to discontinuation of therapy). The therapeutic alliance is the patient physician relationship that allows the patient to participate actively in their treatment. The reported adherence varies from 43 to 78% in patients with chronic diseases. In gout, the adherence varies from 10 to 46%.
Objectives: To evaluate the characteristics of adhesion in patients with gout.
Methods: Patients with gout from the GRESGO cohort were included. Sociodemographic, clinical, and treatment data were collected and the HAQ-DI, EuroQol-5d and a specific questionnaire of adherence and therapeutic alliance were applied.
Results: The study included 238 patients (97.1% male), whit a mean age of 47.7±12.7 years, educational level 9.2±4.2 years. The adherence index (prescribed doses/doses taken) was 86%. Only 28.6% never stopped treatment. 4.6% took the doses at the correct time. Most frequent causes of suspension were lack of supply (37%) and forgetfulness (30%). Only 5% buy all of their medications, 10% follow the lifestyle changes. 49.6% do not take the medication when they disagree with their doctor.
Conclusions: Despite having a good adherence index there are discrepancies with the qualitative answers, since more than 70% did not have good persistence and more than 90% did not comply with the schedule.

AB0874 CHARACTERISTICS OF GOUT IN CAMEROON, CENTRAL AFRICA: A HOSPITAL-BASED STUDY

M.S. Doualla, F. Kamdem, F. Kemta Lekpa. *Service de Médecine Interne, Douala General Hospital, Douala, Cameroon*

Background: Few data are available on the characteristics of gout in sub-Saharan Africa (1).
Objectives: We performed this study with the aim to present the clinical, laboratory and imaging characteristics of gout at the time of diagnosis in Cameroon.
The results obtained will be compared with data from the Western literature.
Methods: We performed a cross-sectional study among the 10,186 out patients seen at the Rheumatology unit of Douala General Hospital, Douala, Cameroon, between 2004 and 2014. We included patients with gout diagnosis (ACR criteria 1977). The main socio-demographic and clinical data on gout at the time of diagnosis were collected.
A $p<0.05$ was significant.
Results: We included 511 patients (5.02%) including 415 men and 96 women. The mean age was 55.9±10.8 years.
Joint pain (n=508, 99.4%), joint effusion (n=198, 38.7%) and fever (n=20, 3.9%) were the main reasons for consultation at diagnosis. Knees (n=300, 62.6), ankles (n=187, 39.0%) and MTP1 joints (n=128, 26.7%) were the most affected joints. Tophi were mainly located at the elbows (n=72, 66.0%), MTP1 (n=20, 18.3%), and ears (n=18, 16.5%) [Table 1].
Gout was as acute (n=255, 49.9%) as it was chronic (n=256, 50.1%). The clinical presentation was oligoarticular in 195 patients (38.7%), monoarticular in 172 patients (34.1%), and polyarticular in 137 patients (27.2%).
The mean uric acid level was 82.4±22.3 mg/L, with hyperuricemia found in 401 patients (78.4%). Elevated acute phase reactants was present in 81.9% of patients. Structural involvements related to gout were present in 181 (74.8%) of the 241 patients who had performed an X-ray.
Comorbidities were present in 344 patients (67.3%), hypertension (n=208, 40.7%), obesity (n=151, 29.5%), osteoarthritis (n=111, 21.7%), oesogastroduodenal complaints (n=74, 14.5%), diabetes (n=52, 10.2%), and chronic kidney diseases (n=42.8.2%).
Associated factors ($p<0.05$) in the occurrence of gout were obesity, alcohol intake, diuretics intake, and menopause (in women).
Conclusions: Gout has the same clinical, laboratory and imaging characteristics in Cameroon than in Western countries. The main difference comes from the place of the knee as the main joint involved by gouty arthritis at the time of diagnosis in our study.

AB0875 DO WE CONTROL GOUT IN PRIMARY CARE FOLLOWING EULAR RECOMMENDATIONS?

F. Leon Vazquez[1], C. Sanz Rodrigo[2], C. Muñoz Martínez de Salinas[2], M. Ferruelo Magán[2], M. Metola Gómez[2], A. Del Caño Garrido[1], C. González Fernández[2]. *[1]CS San Juan de la Cruz, Servicio Madrileño de Salud, Pozuelo de Alarcón (Madrid); [2]CS Puerta Bonita, Servicio Madrileño de Salud, Madrid, Spain*

Background: Inadequate control of hyperuricaemia in gout patients can lead to more arthritis, activity limitations and higher gout-related treatment costs. General Practitioners can use well tolerated urate-lowering drugs, but some patients are inadequately controlled. European League against Rheumatism (EULAR) has published new guidelines[1] in 2016 with similar serum Uric Acid (sUA) goals.
Objectives: To evaluate sUA control in patients diagnosed with gout who were attended in primary care and to compare them to EULAR 2016 guidelines[1].
Methods: Retrospective analysis, carried out in 2 primary care health centres (8 family doctors) in Spain. We selected patients that have consulted in the last year diagnosed with gout at any time. Demographic variables, gout-related drugs and last sUA level were collected. Adequate control was defined as sUA level <6 mg/dL.
Limitations: We used only one isolated sUA value. No drug doses were analyzed. We did not distinguish severe from mild gout.
Ethical-legal aspects: We did not identify the patients. There was no intervention.
Results: We analyzed 231 patients diagnosed with gout, mean 70.1 years-old (Confidence Interval $CI_{95\%}$ 68.3–72.0), 189 (81.8%) were men. The mean sUA was 6.55 mg/dL ($CI_{95\%}$ 6.31–6.79 mg/dL).
39% were adequately controlled according to EULAR (sUA <6 mg/dL), 25.5% were close to the objective (6–7mg/dL) and clearly inadequate (>7mg/dL) in 35.5%. 10% had really bad control (sUA >9 mg/dL).
There was no difference between control in male 6.58 mg/dL ($IC_{95\%}$ 6.33–6.83) and female 6.40 mg/dL ($CI_{95\%}$ 5.73–7.07). Control improves in elder people: <60 years 7.01 mg/dL ($CI_{95\%}$ 6.60–7.42) vs.>70 years 6.30 mg/dL ($CI_{95\%}$ 6.00–6.60)
The only 14 patients receiving febuxostat achieved similar control using allopurinol (6.5 versus 6.7 mg/dL).
Conclusions: The degree of control of sUA in primary care patients in our area is mostly between optimal and acceptable, but it can be optimized in more than half of the cases. In a few patients the control is lousy. The worst-controlled patients were the youngest.

AB0876 OSTEOMALACIA: MODALITIES OF PRESENTATION AND ETIOLOGY OF 20 CASES

H. Mouanaa, Z. Saoussen, A. Arfa, M. Jguirim, I. Bejia, M. Touzi, N. Bergaoui. *Rheumatology Unit of the Monastir University Hospital, Monastir, Tunisia*

Background: Osteomalacia is a defect of mineralization of the protein framework of the skeleton.
Objectives: We try through our series to determine the presentation modalities and the various causes of this fragile benign osteopathy.
Methods: It is a descriptive retrospective study of cases collected in our rheumatology department between 2001 and 2016, concerning patients with osteomalacia
Results: Twenty patients were collected: 13 women and 7 men with an average age of 53±19 years [22 years, 80 years]. The mean duration of the disease is 45 months [5–172]. The findings were: bone pain in 55% of cases, pelvic pain in 45% of cases, a waddling gait in 5 cases (25%), fractures with low energy in 40% of cases, Functional impotence of the lower limbs in 35% of cases and a biological discovery in 2 cases (10%). Hypocalcemia, phosphorus deficiency and hypocalciuria were found in 14 cases, ie 70%. Alkaline phosphatases were elevated in 12 cases, with a variable rate of 2 to 7 times normal.The PTH, performed in 17 cases, was elevated in 53% of the cases. In our series, all

patients had hypovitaminosis D. In addition, an associated iron deficiency anemia was detected in 50% of the cases, biological stigma of digestive malabsorption in 40% of the cases and renal insufficiency in 15% of the cases. Standard radiographs showed diffuse demineralization in 90% of cases, Looser-Milkman streaks in 40% of cases and fractures in 30% of cases. Bone scintigraphy among 8 patients revealed diffuse hyperfixation in 4 cases (50%), localized hyperfixation in 3 cases (37%) and non conclusive images in only one case (12.5%). Bone densitometry performed in 5 patients showed secondary osteoporosis in 80% of cases. The diagnosis of osteomalacia was retained in 2 cases, celiac disease in 5 cases, renal insufficiency in 1 case, phosphate diabetes in 3 cases including Fanconi syndrome, hypophosphatasia in one case and tubular involvement as part of ankylosing spondylitis In one case. Etiology was a neoplastic cause in 4 cases including multiple myeloma. All the patients had a vitamin-calcium treatment (calcium intake between 500mg and 2g per day with an average of 2.5 cp/d, phosphorus in 3 cases and an etiological treatment in 3 cases. The resection of the tumor was the reason behind a clinical-biological improvement in the case of thyroid tumors. The outcome was favorable in the short term for all cases.

Conclusions: Osteomalacia is a generalized benign osteopathy, essentially linked to a deficiency in vitamin D often unrecognized. The diagnosis is simple and the treatment is easy, but the ignorance of the etiological forms can be responsible for an unfavorable evolution.

AB0877 APPLICATION OF GOUT DIARY IN HEALTH EDUCATION OF GOUT PATIENTS

H. Miao, L. Zhang, G. Zhang, K. Xu. *Rheumatology, Shanxi dayi hospital, Taiyuan, China*

Background: Gout is a heterogeneous disease characterized by increased levels of blood uric acid. It is difficult to achieve a comprehensive and effective control of gout only by drugs, drug therapy must be combined with health education, diet and lifestyle changes. However, most of the gout patients had wrong thinking about their disease, diet and drug therapy.The status of China's health education in gout patients:the research teams were dispersed and unstable, the content of health education needed to be further refined, the models of health education were very simple.Based on the traditional models of health education,the purpose of this study is to explore the effect of gout diary in gout patients, by recording gout diary in order to improve their daily life behaviors and related laboratory indexes,aim to provide a new method for health education of gout patients.

Objectives: In order to explore the effect of gout diary,we applied the gout diary in gout patients.

Methods: From January 2015 to December 2015,110 cases of gout hospitalized patients were randomly divided into study group and control group (n=55).The control group used traditional education models:patient education forum,gout handbook,patient group discussion,etc.Based on the control group,the research group used not only the traditional education models,but also added gout diary,the patient can record the diary by themselves.In order to evaluate the effect of gout diary,we used questionnaires and related laboratory indexes.

Results: The research group had significant improvement in laboratory indexes,healthy behaviors and life style ($P<0.05$),such as quit smoking, quit drinking, according to the doctors' suggestions, pay more attention to their blood uric acid and other laboratory indexes, see the doctor regularly, maintain ideal body weight,exercise regularly,working and resting regularly,keeping happy mood.

Conclusions: Apply the gout diary in gout patients, we can achieve a perfect effect.

AB0878 EFFECT OF DIALYSIS AND LOW DOSE URATE-LOWERING ON SERUM URATE LEVELS IN PATIENTS WITH GOUT

I. Urionagüena[1,2], S.P. Chinchilla[2,3], G. Garcia Erauzkin[4], M.L. Muñiz-Gomez[4], F. Pérez-Ruiz[1,2,3]. *[1]Rheumatology Division, Cruces University Hospital; [2]BioCruces Health Research Institute, Barakaldo, Biscay; [3]University of the Basque Country, Basque Country; [4]Nephrology Division, Cruces University Hospital, Barakaldo, Biscay, Spain*

Background: The effect of dialysis on urate levels (sUA) in patients with gout has not been well characterized. No prospective series are available from the literature, and no recommendation has yet been made by either EULAR or ACR on the topic.

Methods: Exploratory, observational, prospective study. Patients with crystal-proven gout and at least one flare the previous year to entrance into dialysis program, either hemodialysis (HD) or home peritoneal dialysis (PD), were followed-up. No urate-lowering drug was prescribed for the first 3-month period, but low-dose allopurinol (50 mg/day) was to be prescribed from 6-month visit onwards if tophi (any subcutaneous or ultrasonographic >10 mm longest diameter) were present or febuxostat in case allopurinol was not clinically suitable. sUA levels previous to the first dialysis procedure were recorded, along with sUA levels pre-dialysis (pre-sUA) and immediately post-dialysis (for patients on hemodialysis) sUA (post-sUA) were obtained during follow-up at 3, 6, and 12 months of follow-up. No prophylaxis was prescribed, and only adrenocorticotropic hormone (ACTH) analogue or corticosteroids were to be used for the treatment of flares.

Results: 17 patients studied to date: 12 men, mean age 69 (IQ range 62–78). Time from onset of gout was 7years (IQR 1–10) pre-dialysis, and 2 patients entered into dialysis due to prolonged use of NSAIDs because recurrent, longstanding gout over 20 years. Allopurinol (n=6) and febuxostat (n=2) had been prescribed previously to dialysis procedures. ULT was prescribed to 10 patients: 4/4 patients on PD and 6/13 on HD as per in methods; patients treated were prescribed allopurinol 50 mg/day but one who showed HLA-B58 antigen and was treated with febuxostat 80 mg every 3 days. After 12 months 5 patients were lost for follow-up: 2 underwent a renal transplant, 3 were dialyzed at private centers. Follow-up ranged from 12 to 30 months.

There was a significant reduction in sUA at 3-month (Δ - 2.6 mg/dl), compared to baseline sUA. Reduction of sUA from 3–6-month and 3–12 month was greater in patients treated with ULT (Table).

The rate of flares at 3-month was similar in patients on HD (5/13) than in patients on PD (2/4), only one flare was reported at 6 month follow-up visits, none afterwards. No serious side effect was observed.

Table 1. Change in pre-sUA and post-sUA (mg/dl) globally and with interventions

Patients/sUA	0 month	3rd month	PostHD-3rd month	6th month	PostHD-6th month	12th	PostHD-12th month
All (N=17)	9.8	7.2	2.8	5.8	3.1	5.5	1.2
Not treated (N=10)	9.4	6.2	3.1	5.7	3.2	5.8	1.2
Treated from 6-month (N=7)	10.0	7.7	2.7	5.8	3.0	5.3	1.2
PD	10.2	8.0		6.0		5.0	
HD	9.7	6.9	2.8	5.7	3.0	5.7	1.2

Conclusions: In this exploratory study, dialysis is effective in reducing sUA levels. In hemodialysis, both sUa and postHD-sUA may be needed to better estimate the effect of interventions on sUA. Low dose ULT seems to be effective and may be considered to properly control sUA, but only to be considered in patients with severe (tophaceous) gout.

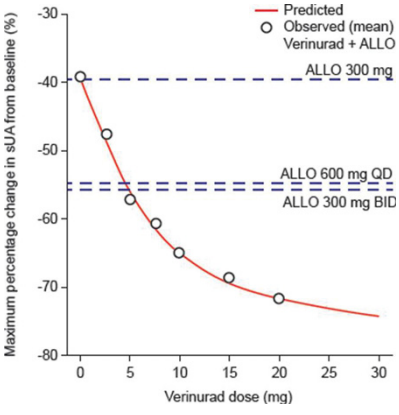
AB0879 AN INTERNET TRIAL OF CHERRY EXTRACT VS. DIET MODIFICATION: PATIENT CHARACTERISTICS, GOUT SEVERITY AND DIET CHARACTERISTICS

J. Singh[1], G. Mcgwin[2]. *[1]Rheumatology; [2]Biostatistics, University of Alabama at Birmingham, Birimingham, United States*

Background: Gout is often treated with life-long pharmacological therapies. Patients are interested in non-pharmacological interventions as adjunct to these therapies. To our knowledge, non-pharmacological have not been studied in detail.

Objectives: To describe the baseline characteristics of patients with gout enrolled in an Internet pilot study comparing the benefits and harms of diet modification to cherry extract intake.

Methods: Patients were enrolled over an 8-month period using the Internet. Diagnosis of gout was confirmed by contacting their health care provider. We describe the baseline characteristics of patients with physician-confirmed gout, who were randomized in the Internet gout study.



Results: We randomized 83 participants in an Internet gout pilot study, randomized to diet modification (n=43) or cherry extract (n=40); 3 patients withdrew before receiving intervention. The mean age of study participants was 56 years, (SD,

16), mean body mass index was 33 kg/m^2 (SD, 10), 73% were male; 67% were white Americans, 25% were African Americans and 7% other/mixed race/ethnicity. Participants took a median of 35 minutes to complete study assessment.
Almost half of the participants were taking medications for the treatment of gout: allopurinol, 42%; febuxostat, 1%, probenecid, 0%; colchicine, 29%. Forty-five percent participant were taking none of these medications. 41% smoked ever, 27% were using a special diet and participants had alcohol use an average of 2 days in the last week. Average number of gout flares were four in the last year. Dietary assessments showed that average daily intakes were as follows: calories, 2005; carbohydrate, 221 gm; fat, 82 gm; fiber, 19 gm; caffeine, 197 ml. The HEI2010 score of 64 was comparable to what was observed with NHANES for people in the average age range of this study.
Conclusions: Patients recruited in an Internet gout study, successfully responded to assessments, and had patient characteristics similar to gout populations described previously. The dietary assessments in this provide may provide a unique insight to design interventions to improve diet to improve gout outcomes.

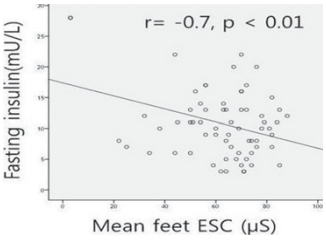
AB0880 PHARMACODYNAMIC EFFECTS AND SAFETY OF VERINURAD (RDEA3170) IN COMBINATION WITH ALLOPURINOL VERSUS ALLOPURINOL ALONE IN ADULTS WITH GOUT: A PHASE 2A, OPEN-LABEL STUDY

R. Fleischmann[1], P. Winkle[2], J.N. Miner[3], X. Yan[3], L. Hicks[3], S. Valdez[3], J. Hall[3], M. Hernandez-Illas[4]. *[1]University of Texas, Southwestern Medical Center, Metroplex Clinical Research Center, Dallas, TX; [2]Anaheim Clinical Trials, Anaheim, CA; [3]Ardea Biosciences, Inc., San Diego, CA; [4]QPS MRA (Miami Clinical Research), Miami, FL, United States*

Background: Verinurad (RDEA3170) is a high-affinity, selective URAT1 inhibitor in development for the treatment of gout and asymptomatic hyperuricemia.
Objectives: This Phase 2a, randomized, open-label, multicenter study investigated the multiple-dose pharmacodynamics (PD), pharmacokinetics (PK), and safety of oral verinurad in combination with allopurinol versus allopurinol alone in adults with gout (NCT02498652).
Methods: Patients aged ≥18 and ≤75 years with gout and serum uric acid (sUA) ≥8 mg/dL were randomized to 1 of 2 cohorts to receive allopurinol (300 mg) in combination with verinurad (dose range 2.5 mg to 20 mg) and allopurinol 300 mg or 600 mg alone (each treatment period was 7 days). Medications were administered once daily ~30 min after breakfast (for allopurinol 300 mg b.i.d. group, the second allopurinol dose was in the evening). Colchicine 0.6 mg for gout flare prophylaxis was initiated at approximately Day -14 (start of urate-lowering therapy [ULT]) washout) or Day -7 if not on ULT. Serial blood and urine samples were measured on Days -1, 1, 7, 14, 21, 28, and 35 for PD and PK endpoints. Safety assessments included adverse events (AEs) and laboratory, electrocardiogram, and vital sign parameters.
Results: Forty-one patients were randomized (n=20–21 per cohort). Serum PD data pooled across cohorts demonstrated maximal % decrease in sUA from baseline (Emax)at 6–10 h after verinurad and allopurinol combination treatment. Addition of verinurad (2.5 mg to 20 mg) to allopurinol decreased sUA in dose-dependent manner (Figure). Greater sUA reductions were observed for dose combinations of verinurad ≥5 mg with allopurinol 300 mg versus allopurinol 600 mg alone, while allopurinol 600 mg once daily was equivalent to allopurinol 300 b.i.d. Emax was 46.9%, 58.9%, 59.9%, 67.1%, 68.4%, and 74.3% for verinurad at doses of 2.5, 5, 7.5, 10, 15, and 20 mg in combination with allopurinol 300 mg, versus 39.7%, 53.8%, and 54.4% with allopurinol 300 mg, allopurinol 600 mg, and allopurinol 300 mg b.i.d. alone. No drug-drug interaction on verinurad and allopurinol plasma PK parameters was observed.



Conclusions: Verinurad coadministered with allopurinol dose-dependently decreased sUA. All dose combinations of verinurad and allopurinol in this study were generally well tolerated with no serious AEs or renal-related events during combination treatment.

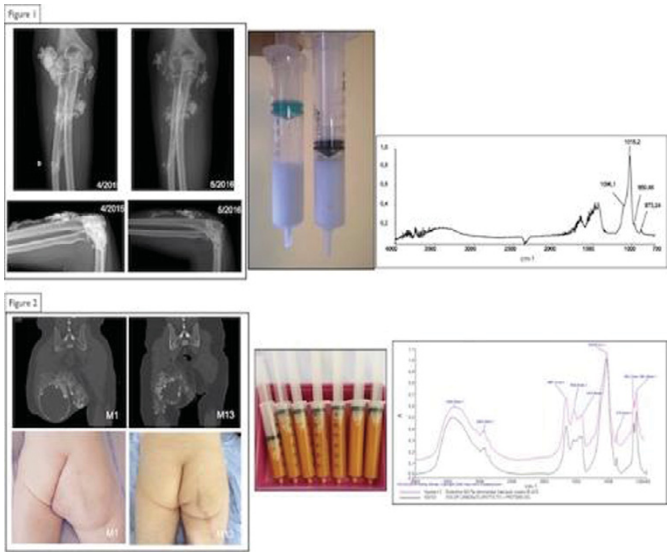
AB0881 ASSESSMENT OF SUDOMOTOR FUNCTION IN PATIENT WITH GOUT

J.W. Lee[1], H.O. Kim[2], S. Lee[3], G. Kim[4]. *[1]Busan St. Mary's Hospital, Busan; [2]KyungSang University, ChangWon; [3]Busan National University; [4]Gosin univeristy, Busan, Korea, Republic Of*

Background: Sodorimetry is a non-invasive device measures sweat gland dysfunction using electrochemical skin conductance (ESC) of hands and feet and is useful for assessing peripheral small fiber nerve function. Little is known about the dysfunction of peripheral small fiber nerve in patients with gout.
Objectives: To evaluate the prevalence and characteristics of small fiber neuropath (SFN) in patients with gout compared with a healty control group and to identify factors associated with SFN in gout.
Methods: 80 male patients with well symtom controlled gout (age: 58±12) and 80 healthy controls were enrolled. Each patient was required to fast over 8 hours before blood samples. Serum fasting glucose, fasting insulin, uric acid, serum 25-(OH) D, lipid profiles, Creatinine (Cr) and r-GTP were measured. Body mass index (BMI) and Homeostatic model assessment insulin resistance (HOMA IR) were calculated. Patients already diagnosed with hypertension and diabetes were excluded.
Results: The mean feet and hands ESC were significantly lower in the gout group than the control group. Mean Hands ESC was irrelevant to age, BMI, fasting glucose and insulin, HOMA-IR, vit D, uric acid, Cr, and lipids. However, mean feet ESC showed significant correlation with fasting glucose (r=-0.7, p<0.01) and HOMA-IR (r=-0.25, p=0.03).



Conclusions: Sudomotor function was significantly lower in patients with gout than the control group. Mean feet ESC was correlated with fasting glucose and insulin resistance in patients with gout. These results suggest that dysfunction of SFN in gout patients is associated with insulin resistance and impaired fasting glucose.

AB0882 EFFICACY OF INTRALESIONNAL SODIUM THIOSULFATE IN DISABLING TUMORAL CALCINOSIS: ABOUT TWO CASES

J. Goossens[1], M. Courbebaisse[2], V. Ratsimbazafy[3], D. Bazin[4], M. Daudon[5], V. Frochot[5], P. Richette[1], F. Lioté[1], H.-K. Ea[1], V. Guigonis[6]. *[1]Rheumatology department, LARIBOISIÈRE Hospital; [2]Physiology Department, Georges Pompidou European hospital, Paris; [3]Pharmacy department, Mother and Child hospital, Limoges; [4]Functional explorations department, TENON Hospital; [5]Laboratoire Chimie de la Matière Condensée de Paris, UMPC, Paris; [6]Pediatric Department, Mother and Child hospital, Limoges, France*

Background: Tumoral Calcinosis (TC) is a difficult-to-treat complication that can occur during the course of several diseases such as dermatomyositis or genetic hyperphosphatemia. It is a painful and disabling condition that can give rise to local complications including joint mobility reduction, cutaneous ulceration and superinfection. Until now, many treatments have been used with inconstant efficacy.
Objectives: Intravenous sodium thiosulfate gives promising results in calciphylaxis and ectopic calcifications, and intra-lesional injections could be effective for tumoral calcinosis.

Methods: We report two cases of successful intra-lesional injections of sodium thiosulfate (STS).
Results: Case 1: A 44-years old woman, with history of dermatomyositis developed in 2009 several TC involving the extensor surfaces of the right elbow and forearm, the two ischiatic regions, fingers and lumbar back. As TC kept growing despite successive treatments, including intravenous STS, we proposed weekly intra-lesional injections of 10% STS in the elbow's lesion. The injected volume varied from 10 to 30 mL at each session. Fourrier transform infrared spectroscopy (FTIR) of the aspirations confirmed that TC was composed of carbonated-apatite crystals. After 6-month treatment, we observed clinical and radiological regression of elbow TC whereas bottom TC and finger calcifications were unchanged (Fig 1). No side effect was observed except a subcutaneous infection occurring after an injection during the fifth month. This infection resolved with anti-staphycoccal antibiotics. Calcium, bicarbonate and chlorus serum levels, anion gap and eGFR remained unchanged during STS treatment.
Case 2: A 42-year old male presented with a prolonged history of hyperphosphatemic familial TC, confirmed by genetic analysis revealing homozygous mutations in the gene encoding the fibroblast growth factor 23. The extraosseous calcifications comprised a plain lesion on the right side of the left tibia and a massive heterogeneous lesion in the right buttock, making it the sitting position impossible. Treatment with maximal dose of phosphate binders, diet prescription and an attempt to surgically remove of the buttock's lesion were unsuccessful. Topical application of STS led to a near complete disappearance of the tibial lesion but was inefficient to treat the TC at the buttock. Considering the potential efficacy of STS in this patient, local injections of 25% STS (12 mL every week) were performed. The calcified material aspiration's analysis confirmed that TC was composed of carbonated-apatite crystals. Calcium and bicarbonate serum levels, anion gap and eGFR remained unchanged. After a 12-month treatment of STS injections, the lesion had significantly regressed (Fig 2), allowing the patient to sit again with no pain.

Conclusions: Intra-lesional injection of STS seems to be a promising treatment for TC. More studies are needed to confirm these results, and to understand the mechanisms implicated in the calcinosis resorption.

AB0883 THE SENSITIVITY OF GOUT SPECIFIC ULTRASOUND SIGNS AT METATARSOPHALANGEAL JOINTS WOULD BE BETTER BY THE DORSAL SURFACE EXAMINATION

M.A. Mahdi[1], H. Rkain[1], M. Erraoui[1], R. Watfeh[2], S. Aktaou[1], L. Tahiri[1], R. Bahiri[1], F. Allali[1], N. Hajjaj-Hassouni[1]. *[1]Rheumatology; [2]Faculty of Medicine and Pharmacy, University Mohamed V, Rabat, Morocco*

Objectives: To compare the prevalence of ultrasonographic gout specific signs at the dorsal and plantar surfaces of the metatarsophalangeal joints (MTP).
Methods: This is a cross-sectional study which includes 15 patients with chronic gout, defined according to the American College of Rheumatology criteria (ACR 1977). Ultrasound (US) examination was performed using a high-frequency linear probe (Toshiba Xario®, frequency (8–14 MHz)) in B mode. 150 articular sites were studied at their dorsal and plantar surfaces. The ultrasound has objectified the presence of two signs: hyperechoic band over the superficial margin of the articular cartilage described as a double contour (DC) and the tophaceous deposits at the joint cavity. We compared the prevalence of the two signs between the dorsal and palmar surfaces at each site studied.
Results: The mean age at onset was 54.7±12,6 years, and the median diagnosis duration was 0 (0.3) years).
The results of the US examination are summarized in Table 1.

Table 1. Prevalence comparison of DC and tophaceous deposits between dorsal and plantar surfaces at MTP joints

Joints (N=150)	Double contour (%)			Tophaceous deposits (%)		
	Dorsal surface	Plantar surface	P	Dorsal surface	Plantar surface	P
MTP 1 (N=30)	33,3	10	0,03	56,7	6,7	0,01
MTP 2 (N=30)	13,3	0	<0.001	13,3	0	<0.001
MTP 3 (N=30)	6,7	0	<0.001	3,3	0	<0.001
MTP 4 (N=30)	0	0	<0.001	6,7	0	<0.001
MTP 5 (N=30)	3,3	0	<0.001	10	0	<0.001

Conclusions: Our study suggests that globally, DC predilect significatily in dorsal than in plantar surfaces of MTP joints. These results should be verified on a larger population.

AB0884 PREVALENCE OF ULTRASONOGRAPHIC GOUT SPECIFIC SIGNS OF HAND AND FINGERS JOINTS

M.A. Mahdi[1], H. Rkain[1], M. Erraoui[1], R. Watfeh[2], S. Aktaou[1], L. Tahiri[1], R. Bahiri[1], F. Allali[1], N. Hajjaj-Hassouni[1]. *[1]Rheumatology; [2]Faculty of Medicine and Pharmacy, University Mohamed V, Rabat, Morocco*

Objectives: To evaluate the prevalence of ultrasonographic gout specific signs of hand and fingers joints.
Methods: This is a cross-sectional study which includes 15 patients with chronic gout, defined according to the American College of Rheumatology criteria (ACR 1977). Ultrasound (US) examination was performed using a high-frequency linear probe (Toshiba Xario®, frequency (8–14 MHz)) in B mode. 540 articular sites were studied at their dorsal surface. The ultrasound has objectified the presence of two signs: hyperechoic band over the superficial margin of the articular cartilage described as a double contour (DC) and the tophaceous deposits at the joint cavity.
Results: The mean age at onset was 54.7±12,6 years, and the median diagnosis duration was 0 (0.3) years).
The results of the US examination are summarized in Table 1.

Table 1. Prevalence of ultrasonographic gout specific signs of the wrist, MCP, PIP and DIP joints in the studied population

Joints (N=540)	Double contour (%)	Tophaceous deposits (%)
Wrist joints (N=120)	12,6	36
Radiocarpal (N=30)	20	43,3
Ulnocarpal (N=30)	13,3	50
Scaphotrapezial (N=30)	3,3	16,7
Trapeziometacarpal (N=30	13,3	43,3
MCP (N=150)	8	18
MCP 1 (N=30)	3,3	16,7
MCP 2 (N=30)	13,3	33,3
MCP 3 (N=30)	6,7	16,7
MCP 4 (N=30)	6,7	3,3
MCP 5 (N=30)	10	20
PIP (N=150)	4	16,6
IP (N=30)	3,3	30
PIP 2 (N=30)	6,7	16,7
PIP 3 (N=30)	6,7	20
PIP 4 (N=30)	3,3	10
PIP 5 (N=30)	0	6,7
DIP (N=120)	0,8	10
DIP 2 (N=30)	0	13,3
DIP 3 (N=30)	3,3	13,3
DIP 4 (N=30)	0	6,7
DIP 5 (N=30)	0	6,7

Conclusions: This study showed a predilection for the gout specific ultrasound signs (DC and tophaceous deposits) of the wrist and MCP joints. The contribution of musculoskeletal ultrasound seems to be very interesting to objectify the presence of gout specific signs in the hand and fingers joints.

AB0885 PREVALENCE OF ULTRASONOGRAPHIC GOUT SPECIFIC SIGNS OF FOOT JOINTS

M.A. Mahdi[1], H. Rkain[1], M. Erraoui[1], R. Watfeh[2], S. Aktaou[1], L. Tahiri[1], R. Bahiri[1], F. Allali[1], N. Hajjaj-Hassouni[1]. *[1]Rheumatology; [2]Faculty of Medicine and Pharmacy, University Mohamed V, Rabat, Morocco*

Objectives: To evaluate the prevalence of ultrasonographic gout specific signs of foot joints.
Methods: This is a cross-sectional study which includes 15 patients with chronic gout, defined according to the American College of Rheumatology criteria (ACR 1977). Ultrasound (US) examination was performed using a high-frequency linear probe (Toshiba Xario®, frequency (8–14 MHz)) in B mode. 330 articular sites were

studied at their dorsal surface. The ultrasound has objectified the presence of two signs: hyperechoic band over the superficial margin of the articular cartilage described as a double contour (DC) and tophaceous deposits at the joint cavity.
Results: The mean age at onset was 54.7±12,6 years, and the median diagnosis duration was 0 (0.3) years).
The results of the US examination are summarized in Table 1.

Table 1. Prevalence of ultrasonographic gout specific signs of hind-foot, mid-foot and Metatarsophalangeal joints in the studied population

Joints (N=330)	Double contour (%)	Tophaceous deposits (%)
Hind-foot	8,8	10
Talocrural (N=30)	13,3	13,3
Subtalar:		
Lateral (N=30)	3,3	10
Medial (N=30)	10	6,7
Mid-foot	14,4	32,2
Talonavicular (N=30)	13,3	13,3
Intertarsal (N=30)	6,7	43,3
Tarsometatarsal (N=30)	23,3	40
MTP (N=150)	11,3	18
MTP 1 (N=30)	33,3	56,7
MTP 2 (N=30)	13,3	13,3
MTP 3 (N=30)	6,7	3,3
MTP 4 (N=30)	0	6,7
MTP 5 (N=30)	3,3	10

Conclusions: This study showed a predilection for the gout specific ultrasound signs (DC and tophaceous deposits) in the tarsometatarsal and metatarsophalangeal joints, especially in the first MTP. The contribution of musculoskeletal ultrasound seems to be very interesting to objectify the presence of gout specific signs of the foot joints.

AB0886 PHARMACOKINETICS, PHARMACODYNAMICS, AND TOLERABILITY OF VERINURAD (RDEA3170), A SELECTIVE URIC ACID REABSORPTION INHIBITOR, IN HEALTHY ADULT MALE SUBJECTS

M. Gillen[1], Z. Shen[2], J.N. Miner[2]. *[1]AstraZeneca, Gaithersburg, MD; [2]Ardea Biosciences, Inc., San Diego, CA, United States*

Background: Verinurad (RDEA3170) is a selective uric acid reabsorption inhibitor in clinical development for the treatment of gout and asymptomatic hyperuricemia.
Objectives: The aim of this study was to evaluate the pharmacokinetics, pharmacodynamics, and tolerability of verinurad following single and multiple doses in healthy adult males.
Methods: This was a Phase 1, randomized, double-blind, placebo-controlled, single- and multiple-ascending dose study. Panels of 8 male subjects (6 active, 2 placebo) received a single oral dose of verinurad or placebo in either a fasted (2 mg, 5 mg, 20 mg, 40 mg) or fed (5 mg, 20 mg) state and panels of 12 male subjects (9 active, 3 placebo) received ascending doses of once-daily verinurad (1 mg, 5 mg, and 10 mg) or placebo in a fasted state for up to 10 days. Verinurad was administered as an oral solution for 1 and 2 mg doses and in tablet form for doses >2 mg. Serial plasma/serum and urine samples were assayed for verinurad and uric acid at predetermined time points. Safety was assessed by adverse event (AE) reports, laboratory tests, vital signs, and electrocardiograms (ECGs).
Results: A total of 81 adult males aged 18–54 years enrolled and completed the study. Following single oral doses of verinurad, absorption was rapid and exposure (maximum plasma concentration [C_{max}] and area under the plasma concentration-time curve [AUC]) increased in a dose-proportional manner up to the maximum dose tested; C_{max} was achieved at 0.5–0.75 hours post-dose in the fasted state, and was slightly delayed to 1.25 hours post-dose in the fed state. Food appeared to decrease AUC by about 23% and C_{max} by about 50%. Following multiple daily doses, there was modest accumulation of verinurad. Urinary excretion of verinurad accounted for approximately 2% of the administered dose, suggesting that renal excretion is a minor elimination pathway for unchanged verinurad. Reductions in serum uric acid (sUA) correlated with dose. Under fasted conditions, single-dose administration of verinurad 2, 5, 20, or 40 mg reduced sUA levels by 16%, 24%, 48%, and 62%, respectively. Following multiple once-daily dosing for 10 days, verinurad reduced sUA levels by 22%, 44%, and 61% for the 1, 5, and 10 mg doses, respectively. A persistent pharmacologic effect (>15% fractional excretion of uric acid relative to baseline) was evident for at least 24 hours after dosing for verinurad doses of 2 mg or above. Verinurad was well tolerated at all doses. No serious AEs, severe AEs, discontinuations due to AEs or clinically significant laboratory or ECG abnormalities were reported.
Conclusions: Single and multiple doses of verinurad were well tolerated, absorption was rapid and exposure was dose-proportional. Verinurad increased urinary uric acid elimination and resulted in sustained reductions in sUA. These data support further clinical evaluation of once-daily verinurad as a treatment for gout.

AB0887 PHARMACOKINETICS, PHARMACODYNAMICS, AND TOLERABILITY OF VERINURAD (RDEA3170), A SELECTIVE URIC ACID REABSORPTION INHIBITOR, IN HEALTHY JAPANESE MALE SUBJECTS

M. Gillen[1], J.N. Miner[2], S. Valdez[2]. *[1]AstraZeneca, Gaithersburg, MD; [2]Ardea Biosciences, Inc., San Diego, CA, United States*

Background: Chronic gout is a significant clinical problem in Asia, including Japan, where many patients remain suboptimally treated with currently available therapies. Verinurad (RDEA3170) is a selective uric acid reabsorption inhibitor in clinical development for the treatment of gout and asymptomatic hyperuricemia.
Objectives: The aim of this study was to evaluate the pharmacokinetics, pharmacodynamics, and tolerability of verinurad in healthy Japanese and non-Asian adult male subjects.
Methods: This was a Phase 1, randomized, single-blind, placebo-controlled study (NCT01872832). Panels of 8 Japanese male subjects were randomized in a 3:1 ratio to receive a modified-release formulation of oral verinurad (2.5 mg, 5 mg, 10 mg, 15 mg) or placebo administered as a single dose in a fasted state and as multiple once-daily doses in a fed state for 7 days. A panel of 8 non-Asian male subjects received single and multiple doses of oral verinurad (10 mg) or placebo. Serial plasma/serum and urine samples were assayed for verinurad and uric acid at predetermined time points. Safety was assessed by adverse event (AE) reports, laboratory tests, vital signs, and electrocardiograms (ECGs).
Results: Of 48 randomized subjects, 46 (Japanese: 39, non-Asian: 7) completed the study. Treatment groups were generally well balanced; however, mean body weight and body mass index were approximately 14% and 7% lower, respectively, in Japanese than non-Asian subjects. Following single- or multiple-oral doses of verinurad in Japanese subjects, exposure (maximum plasma concentration [C_{max}] and area under the plasma concentration-time curve [AUC]) increased in a near dose-proportional manner under fasted or fed conditions. The time to C_{max} (T_{max}) was approximately 1.25–2.0 hours post-dose under fasted conditions. A moderate-fat meal delayed T_{max} up to 5 hours post-dose and increased plasma verinurad exposures up to 109%. Following once-daily multiple doses, there was modest accumulation of verinurad. C_{max} and AUC were 38% and 23% higher, respectively, in Japanese versus non-Asian subjects, largely due to the difference in body weight. Mean reductions in serum uric acid following once-daily multiple dosing of verinurad 10 mg were 62% and 58% at maximum reduction and 46% and 44% at 24 hours post-dose in Japanese and non-Asian subjects, respectively. Verinurad was well tolerated at all doses. One Japanese subject discontinued verinurad due to an AE of urticaria that resolved after 11 days. No serious AEs, Grade 3 or 4 AEs, or clinically significant laboratory or ECG abnormalities were noted.
Conclusions: Verinurad significantly lowered serum uric acid and was well tolerated in both healthy Japanese and non-Asian males, despite small differences in plasma pharmacokinetics. These data support further evaluation of once-daily verinurad as a treatment for hyperuricemia with or without gout in the Japanese population.
Acknowledgements: The authors thank Caroline Lee and Zancong Shen of Ardea Biosciences, Inc., for critical review of the abstract.

AB0888 TENOFOVIR INDUCED OSTEOMALACIA: A PROFILE BASED ON THREE PATIENTS WITH LOW PHOSPHORUS AND NORMAL LEVELS OF VITAMIN D AND PARATHYROID HORMONE

M. Lovy. *Desert Oasis Healthcare, Palm Springs, California, United States*

Background: Tenofovir can induce proximal renal tubular changes that result in varying expression of Fanconi syndrome[1,2]. Less commonly, osteomalacia related to hypophosphatemia[2,3] can occur and has been documented with bone biopsy[3]. The clinical details of 28 reported cases of tenofovir induced osteomalacia, some of whom had vitamin D deficiency and secondary hyperparathyroidism, was recently summarized[3].
Objectives: To describe the clinical presentation and course of three HIV patients with tenofovir induced hypophosphatemic osteomalacia and compare to cases previously reported.
Methods: The clinical, laboratory, and radiologic features of three HIV patients referred for evaluation of pain and osteoporosis were reviewed.
Results: All three patients were male, had diffuse pain, suffered multiple clinical fractures, and were on combination long and short acting opioids at the time of presentation. Two were in wheelchairs and two had neuropathy.
All patients had hypogonadism and proteinuria and case 1 had glycosuria. All patients had normal 25-OH vitamin D, vitamin B12, PTH, serum protein electrophoresis, magnesium, CBC, calcium, CPK, sedimentation rate, TSH. Case 1 had fractures of the hip, sacrum, and humerus; case 2 hip and ribs; and case 3 ribs, pelvis and knee. The technetium bone scan showed a similar pattern of increased uptake in multiple ribs, calcaneus, metatarsal bones, knees, and

Case	Age	HIV, Y	TN, Y	Sx	VAS	BMI	alkphos	PO4	Cr	K+	NTX	FemN	LS
1	49	10	4	8	80	20.4	309	2.2	1.80	2.9	128	-3.5	-4.2
2	69	32	10	8	70	18.0	245	1.5	1.33	4.2	57	-2.6	-2.3
3	61	30	7	36	84	20.0	576	1.2	1.18	3.3	98	-3.2	-3.8

Y = years, Sx = symptoms in months, VAS = visual analogue scale, alkphos = alkaline phosphatase (39–117 IU/L), PO4 = phosphorus (2.5–4.5mg/dL), Cr = creatinine (0.76–1.27mg/dL), K+ = potassium (3.5–5.2mml/L), FemN = femoral neck T-score, LS = lumbar spine T-score.

sacrum in all three patients. A MRI of the knee showed bone marrow edema in case 2 and an atypical longitudinal fracture of the femur in case 3. Tenofovir was withdrawn, oral phosphates given, and resolution of pain and biochemical changes occurred in 4–8 months. Bone mineral density in case 1 repeated 1 year after presentation increased 16% in the femoral neck and 19% in the lumbar spine.

The laboratory and clinical features in our cases shared with those previously reported include long duration of HIV and tenofovir treamtent, severe pain and disability, low BMI, neuropathy, hypogonadism in men, elevation of alkaline phoshatase and varying degrees of renal tubular dysfunction.

Conclusions: Long term tenofovir therapy in HIV patients can induce a devastating disabling osteomalacia caused by hypophosphatemia with features of Fanconi syndrome with or without vitamin D deficiency. A long standing history of HIV infection, low BMI, neuropathy, and hypogonadism in male patients may predispose or be associated with this complication. A serum phosphorus, alkaline phosphatase, and urinalysis should be followed regularly in all tenofovir treated patients to avoid the consequences of osteomalacia.

AB0889 FACTORS CONTRIBUTING TO LENGTH OF INPATIENT HOSPITAL STAY FOR PATIENTS WITH ACUTE GOUT ARTHROPATHY AT THE NORTHERN HOSPITAL: AN OBSERVATIONAL STUDY

M. Mian [1,2], M.N. Hossain [3], M. Omair [1], D. Liew [1,2], C.E. Owen [1,4], A.M. Foote [1,2], R.R.C. Buchanan [1,2,4]. *[1]Department of Medicine, Austin Health; [2]Department of Medicine, Northern Health; [3]School of Public Health and Preventive Medicine, Monash University; [4]Department of Medicine, University of Melbourne, Melbourne, Australia*

Background: Gout is a common inflammatory arthropathy with a reported prevalence ranging from 1.7% to 4% within Australia – one of the highest in the world, second only to New Zealand.[1] Epidemiological studies have established that its prevalence has increased steadily over recent years, with the impact of the disease on the rise.[2]

Gout has painful and debilitating effects on patients leading to impact on their quality of life. Even though usually managed in the primary care setting, many patients are ultimately admitted as inpatients to hospital with the associated increased resource utilisation and cost. There is a growing recognition of the economic burden of gout.[3] A Canadian study estimated 5-year total health costs of patients with gout at $10,332 more than comparable gout free patients.[4]

Objectives: To identify factors potentially contributing to increased length of inpatient hospital stay for acute exacerbations of gout in a teaching hospital in Melbourne, Australia.

Methods: Patients admitted to The Northern Hospital, Melbourne, Australia with a discharge diagnosis of gout as their only acute medical problem between 1st July 2014 and 30th June 2016 were identified using ICD-10 disease coding from institutional compensation reports. Retrospective chart review was performed identifying length of stay and for variables which may potentially affect it.

Results: 121 patients were discharged with an acute gout flare over the 2 years with a mean age of 66±15 years. The vast majority of patients in this cohort were male (86%). The mean length of stay was 2.3 days (95% CI 1.83–2.78 days), with a median of 1 day. The median length of hospital stay was increased by 2 days if patients lived alone (p=0.042) and 1 extra day if the C-Reactive Protein (CRP) measured at admission was >100 mg/L (p=0.001). Hospital stay was similarly prolonged by a single day if more than one joint was involved in the flare (p=0.003).

Conclusions: Gout without antecedent acute medical comorbidity is a common acute medical presentation to hospital with a large corresponding economic burden. Factors affecting length of inpatient stay include social status, marked elevation of CRP and polyarticular involvement. This study identifies factors which warrant further investigation as to how they may be ameliorated in order to improve health resource utilisation.

AB0890 SYSTEMIC LUPUS ERYTHEMATOSUS AND GOUT: REALLY AN UNUSUAL ASSOCIATION?

N. Quilis [1], M. Andrés [2,3]. *[1]Seccion de Reumatologia, Hospital Universitario Vinalopó, Elche; [2]Seccion de Reumatologia, Hospital General Universitario de Alicante; [3]Departamento de Medicina Clínica, Universidad Miguel Hernández, Alicante, Spain*

Background: Patients with systemic lupus erythematosus (SLE) often suffer from cardiovascular comorbidity such as hypertension, dyslipidemia or coronary heart disease. However, the association with gout – an independent cardiovascular risk factor – is considered unusual - it is not reported in the EULAR textbook (1)-, and might not be taken into account when acute arthritis occurs in SLE patients, also due to the predominance of women in this disease.

Objectives: To review our experience regarding SLE patients who developed gout, and to perform a literature review of reported cases to date.

Methods: Retrospective review of patients with SLE and crystal-proven gout in our Rheumatology Unit, a tertiary care center. We recorded clinical and laboratory variables related to both diseases. Then, we performed a bibliographical review in Pubmed (1965 – 2016) to identify reported cases of coexistence of both diseases.

Results: Out 189 SLE patients seen in our Unit, we have identified two cases with crystal-proven gout: 1) A 68 years-old woman with SLE and nephritis diagnosed 30 years ago, who developed polyarthritis affecting her hands. 2) A 47 years-old man with lupus for 22 years with nephritis and renal failure, who developed acute arthritis involving right knee and ankle. In both cases, urate crystals were demonstrated at synovial fluid. The table shows the results of the literature review together with our two cases. To date, 36 cases with coexistent SLE and gout have been reported. Median age at time of gout diagnosis was 43.5 years (p25–75 32.5–52.0), being 26 females (72%). SUA levels were found notably high (median 13.5mg/dL), and tophi, a marker of gout severity, were demonstrated in almost half of cases (44.4%). The majority of patients (91%) were on glucocorticoids at time of gout diagnosis. According to common factors leading to hyperuricemia, lupus-related renal damage (86%) and use of diuretics (83%) predominated in the series.

Conclusions: Data supports including gout into the differential diagnosis of episodes of acute arthritis in SLE patients. This makes crucial the routine analysis of all synovial fluid samples, but especially in patients with long-term disease, renal impairment, and diuretic use.

AB0891 HIGH FREQUENCIES OF CVD RISK FACTORS, OBESITY, METABOLIC SYNDROME, AND VITAMIN DEFICIENCIES IN A DANISH COHORT OF GOUT PATIENTS

O. Slot. *Copenhagen Center for Arthritis Research, Rheumatology, Copenhagen University Rigshospitalet Glostrup, Glostrup, Denmark*

Background: Gout is associated with increased risk of Cardio-Vascular Disease and death.
Objectives: To measure the frequencies of a number of potentially modifiable CVD risk factors in gout patients.
Methods: Comorbidities and CVD risk factors were measured and registered in a cohort of 100 consecutive new crystal proven gout patients.
Results: 88 males (62.1±13.6 years) and 12 females (74.1±6.9 years) were included. See table for results.

Comorbidities	
Previous CVD (n=36/100)	36%
Hypertension (BT>140/90 mmHg) (n=80/100)	80%
Hypertension without antihypertensive treatment (n=22/100)	22%
Diabetes (n=28/100)	28%
Nephropathy (eGFR<60 ml/min) (n=29/99)	29%
One or more comorbidities	86%
Comorbidity risk factors	
BMI, mean±SD (n=95)	29.6±5.3
BMI ≥30 (n=44/95)	46%
Metabolic Syndrome (Int Diab Fed 2006) (n=68/95)	72%
P-High Density Lipoprotein <1.00 mmol/l (n=30/96)	32%
P-Low Density Lipoprotein >3.0 mmol/l (n=39/91)	43%
P-Triglyceride >2.00 mmol/l (n=48/96)	50%
Homocysteine >15 μmol/l (n=28/71)	40%
Homocysteine ≥20 μmol/l (n=17/71)	24%
Cobalamine <200 pmol/l (n=14/90)	16%
Folate ≤9 nmol/l (n=22/86)	26%
25 (OH)-vitamin D3 <50 nmol/l (n=45/94)	48%
25 (OH)-vitamin D3 <20 nmol/l (n=18/94)	19%

Conclusions: Nephropathy, obesity, and dyslipidemia are known to correlate to hyperuricemia and gout. Reciprocally hyperuricemia and gout may lead to development of comorbidities, i.e. hypertension, CVD, and nephropathy.
Almost half the patients in this study were obese emphasizing the correlation between hyperuricemia and gout and obesity. Weight reduction is beneficial for control of hyperuricemia and gout, and is an important lifestyle factor that may be addressed in the treatment of hyperuricemia.
Metabolic Syndrome is characterized by abdominal obesity and at least two of the following criteria: hypertension, diabetes, hypertriglyceridemia, and low blood levels of high-density-lipoprotein. Metabolic Syndrome is associated with a two-fold risk of CVD and was present in 72% of the gout patients.
High homocysteine levels are correlated to endothelial dysfunction and increased risk of CVD. In this study the majority of patients had levels of homocysteine in the upper normal range, and a quarter had hyper-homocysteinemia. Elevated homocysteine has previously been reported in gout correlated to impaired renal function, but hyper-homocysteinmia can also be induced by low blood levels of cobalamin, which was present in 16%, and low levels of folate, which was found in 26%. In addition, low folate has been associated with endothelial dysfunction and CVD independently of homocysteine.
Low levels of 25(OH)-vitamin D3 were observed in nearly half of the gout patients and deficiency were found in 19%. Obesity is known to be associated with low levels of vitamin D. Negative correlation between uric acid and Vitamin D has though been reported after correction for weight. Uric acid suppresses 1-alpha hydroxylase leading to low levels of 1,25(OH)2-vitamin D3 which is correlated to dyslipidemia and Metabolic Syndrome. Urate Lowering Therapy has been shown to counteract suppression of 1-alpha hydroxylase.
Due to the increased risk of CVD and death associated with gout and the high prevalence of comorbidities and CVD risk factors in gout patients - comprehensive evaluation, information, and treatment of reversible co-morbidities and risk factors is recommended to be a part of the clinical management of gout.

AB0892 PROGRESSIVE CLINICAL BENEFIT IN CHRONIC REFRACTORY GOUT PATIENTS ACHIEVING A PERSISTENT URATE LOWERING EFFECT FROM PEGLOTICASE TREATMENT

P. Khanna[1], B. Mandell[2], R. Fleischmann[3], J. Kay[4], A. Yeo[5], P. Lipsky[6]. *[1]Rheumatology, University of Michigan, Ann Arbor, MI; [2]Dept. of Medicine, Cleveland Clinic, Cleveland, OH; [3]Metroplex Clinical Research Center, Dallas, TX; [4]U Mass Memorial Medical Center, Worcester, MA; [5]Horizon Pharma, Lake Forest, IL; [6]AMPEL BioSolutions, LLC, Charlottesville, VA, United States*

Background: Pegloticase is a recombinant uricase conjugated to polyethylene glycol approved for treatment of patients with chronic refractory gout. It profoundly decreases serum uric acid (UA) and resolves tophi, but the quality of the clinical benefit in patients achieving long-term UA lowering has not been assessed.
Objectives: To assess the clinical benefit of long-term UA-lowering with pegloticase in patients with gout.
Methods: This analysis used results from two randomized controlled trials (RCTs) of 6- months duration and the 2-year open-label extension (OLE) of these studies.[1,2] Efficacy was assessed in responders to the approved treatment regimen (8 mg pegloticase every 2 weeks [q2w]) in the RCTs (i.e., patients with plasma UA <6.0 mg/dL for ≥80% of the assessments around the 3 and 6 month time periods.) Clinical assessments included serum UA, frequency of gout flares, Patient Global Assessment (PGA), tender and swollen joints (TJC and SJC), pain measured with a 100-mm visual analog scale (VAS), Health Assessment Questionnaire Disability Index, bodily pain and the Arthritis-Specific Health Index from the Medical Outcomes Study Short Form 36 item, and reduction of target tophi.
Results: 33 patients who responded to pegloticase in the RCTs were followed throughout the OLE. Of these, 20 received 8 mg pegloticase q2w and 13 q4w. Both groups maintained markedly decreased serum UA levels during the OLE. Results for patients who received pegloticase q2w indicated significant improvements between RCT baseline and the final OLE evaluation for serum UA (P<0.0001), PGA (P=0.02), TJC (P=0.04), SJC (P=0.01), and pain VAS (P=0.01); 61.5% of patients in this group had complete target tophus resolution (P<0.0001). Results for those treated q4w indicated significant improvements between RCT baseline and the final OLE evaluation for serum UA (P<0.001), PGA (P=0.004), TJC (P=0.004), SJC (P=0.012), and pain VAS (P=0.01); 100% of patients in this group had complete tophus resolution (P<0.001). After an initial increase in gout flares during the initial 3 months of the RCT, there was a persistent decrease throughout the OLE. Maximal target tophus reduction was observed after 13–25 weeks of the OLE. Two of 20 (10%) patients receiving pegloticase q2w and 4 of 13 (31%) treated q4w lost the persistent UA-lowering effect during the OLE.
Conclusions: There were significant sustained clinical benefits with long-term pegloticase treatment in patients with chronic refractory gout achieving a UA lowering effect during the first 6 months of therapy. Significant decreases in TJC, SJC, and pain were noted along with significant improvements in PGA, suppression of gout flares, and resolution of tophi. In most patients, maximal benefit was noted after 6–12 months of pegloticase therapy, with many patients meeting newly proposed criteria for gout remission.[3]

AB0893 DISEASE RELATED KNOWLEDGE IN GOUT PATIENTS AND THE RELATIONSHIP WITH ADHERENCE TO URATE-LOWERING THERAPY IN EAST CHINA

R. Yin[1], T. Fu[1], Q. Zhang[1], L. Zhang[1], L. Li[2], Z. Gu[1]. *[1]Department of Rheumatology, Affiliated Hospital of Nantong University; [2]School of Nursing, Nantong University, Nantong, China*

Background: Gout is a chronic rheumatic disease caused by deposition of monosodium urate crystals in and around the joint, with a reported prevalence of 1.1% in mainland China and 6.24% in Taiwan, making it the most common form of inflammatory arthritis. With the disease progression, gout can cause permanent joint destruction, bone erosion, and organ damage. Urate-lowering therapy (ULT) is necessary to lower and maintain serum urate (sUA) levels at a therapeutic target of <360 μmol/L as this is associated with fewer gout flares, reduction of tophus size, and depletion of urate crystal stores in synovial tissues, making gout the only chronic arthritis that can be "cured". Disease related knowledge of gout patients should be assessed before attempting to improve health education.To date, except one study from south China, all other published papers about gout knowledge and medication adherence are from other countries. To our knowledge, there is no survey from east China.
Objectives: The current study aimed to investigate knowledge related to gout and it's risk factors, and the relationship with adherence to urate-lowering therapy in patients with gout in east China.
Methods: A cross-sectional study of 229 gout patients recruited from the Affiliated Hospital of Nantong University between August 2015 and November 2016 was conducted with two questionnaire, Gout Knowledge Questionnaire (GKQ) and Compliance Questionnaire on Rheumatology (CQR). Chi-square analysis, t-test, rank sum test, as well as logistic regression analysis were used to analyze data.
Results: 21.5% (49/228) of gout patients in east China had knowledge of gout, and 9.1% (13/143) adhered to ULT. Age, employment, income, alcohol use, family history, acute flares in preceding 1 year, and colchicine use were associated with awareness of gout-related knowledge, and age, income, alcohol use, and colchicine use were the predictors. Among patients with ULT, patients adherent to ULT tended to have gout-related knowledge, compared with non-adherent patients. Awareness of the cause of gout attack, flare prevention induced by ULT and comorbidity were correlated with medication adherence, and the cause of gout attack as well as flare prevention induced by ULT were predictors of adherence to ULT in gout patients in east China.

Conclusions: In this study, 78.5% of patients in east China didn't have gout-related knowledge. Patients' knowledge on gout is a significant independent determinant of adherence to ULT.

AB0894 TREATMENT ADHERENCE TO URATE-LOWERING THERAPY IN CHINESE GOUT PATIENTS

R. Yin[1], H. Cao[1], T. Fu[1], Q. Zhang[1], L. Zhang[1], L. Li[2], Z. Gu[1]. *[1]Department of Rheumatology, Affiliated Hospital of Nantong University; [2]School of Nursing, Nantong University, Nantong, China*

Background: Gout, which is characterised by deposition of monosodium urate monohydrate (MSU) in synovial fluid and other tissues, is the most common form of inflammatory arthritis in man and older women. In addition to recurrent acute arthritis, subcutaneous tophi and chronic painful arthritis, gout also affects morbidity and premature mortality. Previous studies have reported that effective ULT can decrease sUA levels enough to prevent further crystal formation, dissolve existing urate crystals and eliminate the causative agent, thus reducing the frequency of acute gout attacks and preventing urate nephropathy, uric acid nephrolithiasis, and the deposition of tophi: a common cause of progressive joint damage, deformity and functional impairment, making gout the only chronic arthritis that can be "cured". However, gout patents' adherence rate to ULT is low, ranged from 10 to 46%. Emerging data suggest that poor adherence to long-term ULT use may be an important contributor to the suboptimal outcomes seen in gout and nonadherence may be worse in gout than in any other chronic disease. This suggests that there is a strong need to make a further study on drug adherence and its risk factors.

Objectives: Non-adherence in gout patients using urate-lowering therapy (ULT) may lead to joint destruction and permanent disability. Purpose of this cross-section survey was to explore Chinese gout patients' adherence rates and investigate potential risk factors for medication non-adherence.

Methods: A total of 129 gout patients were recruited from the Affiliated Hospital of Nantong University from August 2015 to September 2016. Patients were asked to complete a standardized self-report questionnaires (Compliance Questionnaire on Rheumatology, Treatment Satisfaction Questionnaire for Medication version II, Health Assessment Questionnaire, Confidence in gout treatment questionnaire, Gout Knowledge Questionnaire, Patient Health Questionnaire-9, Generalized Anxiety Disorder-7, and 36-Item Short Form Health Survey). Data was analyzed by independent sample t-test, rank sum test, chi-square analysis as well as logistic regression modeling.

Results: Based on CQR, 9.6% of gout patients were adherent to ULT. Adherence was associated with HAQ, GKQ, treatment satisfaction for medication, confidence in gout treatment and MCS. Other demographic, clinical and psychological characteristics were not related to adherence. Logistic regression models identified HAQ, GKQ and MCS as predictors of medication non-adherence.

Conclusions: In the current study, 90.4% of gout patients didn't adhere to their ULT prescription. HAQ, GKQ, treatment satisfaction for medication, confidence in gout treatment and MCS were relevant to medication adherence, and HAQ, GKQ and MCS were independent predictors of medication non-adherence in patients with gout. These findings could help medical personnel develop useful interventions to improve gout patients' medication adherence and quality of life.

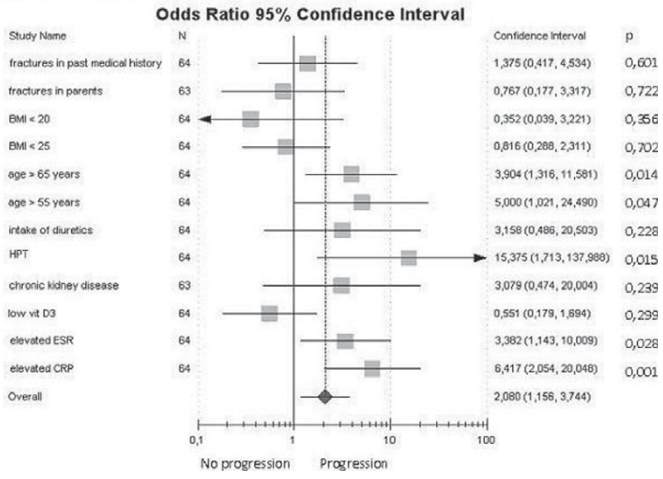
AB0895 OSTEOPOROSIS RISK FACTORS IN PATIENTS WITH CALCIUM PYROPHOSPHATE CRYSTAL DEPOSITION DISEASE (CPPD)

S. Vladimirov, M. Eliseev, O. Zhelyabina, A. Smirnov, S. Glukhova. *V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Osteoporosis (OP) risk factors (RF) in CPPD patients are not sufficiently studied, although some of these RFs may be more prevalent in CPPD pts than in general population [1]

Objectives: To identify the input of individual RFs into OP development in pts with *CPPD*

Methods: 64 patients with CPPD (35 males and 29 females), but without OP were included into open prospective study. CPPD was confirmed based on McCarty criteria (detection of calcium pyrophosphate crystals in the synovial fluid using polarized light microscopy and detection of chondrocalcinosis based on joint radiography or US examination). 40 pts of those had acute and/or chronic arthritis, and 24 pts had osteoarthritis with CPP crystal depositions. Mean age was 57.6±10.2 years, mean follow up – 4.85±0.96 years. Bone mass density (BMD) was measured by dual energy X-ray absorptiometry (DXA) at the forearm, lumbar spine and total hip was performed in all pts at baseline. OP was diagnosed by BMD (T-criterion $\leq$2,5). The following OP risk factors were evaluated in this study: sex, age $>$55 years for females and $>$65 years for males, smoking, alcohol, fractures in past medical history, fractures in parents, BMI $\leq$20 kg/m^2, BMI $\leq$25 kg/m^2, serum levels of calcium, magnesium, vitamin D, hypoparathyroidism (HPT), chronic kidney disease (GFR $\leq$60 mL/min), intake of diuretics and glucocorticosteroids (GCs), Erythrocyte sedimentation rate (ESR) $>$20 mm/h, C-reactive protein (CRP) $>$5,0 mg/L. Odds ratio (OR) (95% confidence interval, CI) was estimated for each risk factor and logistic regression analysis was performed. Statistical analysis was made using SPSS v. 11 package, *p* values of $<$0.05 were considered statistically significant.



Results: OP was identified in 22 (34%) out of 64 pts with CPPD (13 males and 9 females) by the end of the study. The following factors were associated with OP: age $>$55 years in females (odds ratio (OR) 5.0, 95% CI; 1.021–24,49; *p*=0.047), age $>$65 years in males (OR 3.9, 95% CI 1.3–11.5; *p*=0.014), HPT (OR 15.38, 95% CI 1.7–137.9; *p*=0.015), elevated ESR (OR 3.38, 95% CI 1.14–10.0; *p* =0.028) and CRP (OR 6.42, 95% CI 2.05–20.05; *p*=.001) (Fig.1).

Only hypoparathyroidism was identified by logistic regression analysis (sensitivity-71%, specificity -82%) as OP-associated risk factor (OR 14.24, 95% CI 1.05–194.05; *p*=0.046) (Table 1).

Table 1. Data from multiple logistic regression analysis

Study	OR	Lower	Upper	p
sex	1,215	0,259	5,709	0,805
BMI$<$25kg/m^2	1,483	0,325	6,774	0,611
Age$>$65	1,293	0,274	6,093	0,745
Diuretics intake	2,771	0,189	40,617	0,457
HPT	14,245	1,046	194,055	0,046
CKD	1.025	0.082	12.876	0.985
lower vit.D3	0,503	0,116	2,173	0,357
elevated ESR	3,830	0,764	19,214	0,101
elevated CRP	3,855	0,608	24,44	0,152

Fig 1. Risk factors for osteoporosis (forest plot).

Conclusions: Hypoparathyroidism is the key risk factor for OP in CPPD pts. Among other risk factors chronic inflammation (ESR and CRP levels) is of highest importance.

AB0896 THE EFFECT OF SERUM URIC ACID LEVELS ON TOPHUS STATUS AND FLARES IN PATIENTS WITH GOUT: A SYSTEMATIC REVIEW

S. Mitchell[1], L. Manounah[1], H. Liedgens[2], E. Johannes[3]. *[1]Decision Resources Group, Bicester, United Kingdom; [2]Head Health Economics and Outcomes Research, Market Access, SBU Europe?; [3]Head Market Access Europe, Grünenthal GmbH, Aachen, Germany*

Background: Gout is a chronic, progressive, inflammatory disease characterised by elevated serum uric acid (sUA) levels. sUA levels above its saturation point result in the deposition of monosodium urate crystals, which lead to gout flares and tophi (1). Multiple studies support the use of sUA levels as a marker for clinical improvements; hence the therapeutic goal is to lower sUA levels ($<$6.0 mg/dL) to improve the symptoms of gout and reduce the risk of associated comorbidities (2,3).

Objectives: To conduct a systematic review to identify studies reporting the effect of sUA levels on the incidence of gout flares and tophus status in adult patients with gout/hyperuricaemia, with a focus on publications reporting a correlation between the parameters.

Methods: Publications were identified by interrogating electronic databases; Medline & MEDLINE In-Process, EMBASE and the Cochrane Library (accessed 6 Sept 2016). Eligibility criteria included adult patients with a diagnosis of acute/chronic gout or hyperuricemia, with no restriction on publication date, study design or geography.
Results: In total, 59 studies met the pre-defined inclusion criteria and were reviewed; of these, 17 reported the relationship between sUA levels and flares (n=12) and/or tophus status (n=11). Two studies were multinational (North America), and 15 were single country (US [n=10]; Spain [n=2]; New Zealand [n=1]; Germany [n=1]; Japan [n=1]). The majority of studies had a follow-up period of ≤1 year, with one reporting 10 years' follow-up. All 12 studies evaluating flares reported that achieving sUA levels ≤6 mg/dL was associated with a decreased risk of gout flares, compared with sUA levels >6 mg/dL ($p<0.05$ in 8 studies). All 11 studies evaluating tophus status reported that achieving sUA levels ≤6 mg/dL was associated with improvements in tophus status, compared with sUA levels >6 mg/dL ($p<0.05$ in 4 studies). The remaining 42 studies reported the impact of urate lowering therapy on sUA levels and gout flares or tophus status, but not the correlation between the parameters. The qualitative results in these studies indicated that increases in sUA levels were associated with an increased risk of gout flares and worsening of tophus status.
Conclusions: Maintenance of sUA levels <6 mg/dL is associated with improvements in tophi resolution and flare reduction in adult patients with gout/hyperuricaemia. Whilst longer-term follow up studies (>5 years) are warranted, this review further supports that decreases in sUA levels are a marker for clinical improvements.

AB0897 FUNCTIONAL DISABILITY AND HEALTH-RELATED QUALITY OF LIFE IN CHINESE PATIENTS WITH GOUT: A CROSS-SECTIONAL STUDY

T. Fu[1], R. Yin[1], L. Zhang[1], Q. Zhang[1], Y. Xia[1], J. Ji[1], Z. Da[1], X. Zhu[1], L. Li[2], Z. Gu[1]. [1]*Department of Rheumatology, Affiliated Hospital of Nantong University;* [2]*School of Nursing of Nantong University, Nantong, China*

Background: As the most common arthritis in adults, gout is a painful, inflammatory disease that may cause functional disability and decreased health-related quality of life (HRQoL). However, there are currently no known reported studies related to functional disability and HRQoL of gout patients from China.
Objectives: This cross-sectional study aims to investigate the effect of demographic variables, disease parameters, and psychological status on functional disability and HRQoL of Chinese gout patients.
Methods: A self-report survey was administered to 226 gout patients and 232 healthy individuals using the Short Form 36 health survey (SF-36) for HRQoL and the Health Assessment Questionnaire-Disability Index (HAQ-DI) for functional disability. Gout patients were asked to complete the 10 cm Visual Analog Scale (VAS) for total pain, the Patient Health Questionnaire (PHQ-9) for depression, and the Generalized Anxiety Disorder (GAD-7) questionnaire for anxiety. Blood samples were taken to examine the level of uric acid (UA). Independent samples t-tests, Chi square tests, spearman and/or pearson correlation and multiple linear regression were used to analyze the data.
Results: Our results found that individuals with gout have poorer HRQoL compared to healthy controls and the mean disability score was 0.32 (SD 0.54), representing mild disability. SF-36 and almost all components of the SF-36 score were associated with place of residence, hypertension, DM, cardiovascular disease, disease duration, number of flares/last year, total pain, number of tophi, presence of tender joints, colchicines use, corticosteroids use, depression, and anxiety ($p<0.05$). This variable was also significantly related to the HAQ-DI score ($p<0.05$). Additionally, there were significant relationships among age, income/year, allopurinol use and HAQ-DI ($p<0.05$). Stepwise multiple linear regression identified number of flares/last year, place of residence, depression and DM as predictors of functional disability. Disease status (total pain, number of flares/last year, presence of tender joints, cardiovascular disease, colchicine and corticosteroids use) and psychological disorders (depression and anxiety) were significantly accounted for poor HRQoL.
Conclusions: Chinese gout patients experienced mild disability and poor HRQoL. Disease status and psychological status were important risk factors linked to functional disability and HRQoL in Chinese gout population. These data suggest medical personnel should pay more attention to functional disability and HRQoL of gout patients and make suitable interventions to relieve their psychological disorders and finally to reduce their functional ability and improve their HRQoL.

AB0898 SLEEP QUALITY IS ASSOCIATED WITH ALCOHOL USE AND FUNCTIONAL CAPACITY IN CHINESE PATIENTS WITH GOUT: A CROSS-SECTIONAL STUDY

T. Fu[1], R. Yin[1], L. Zhang[1], Q. Zhang[1], Y. Xia[1], J. Ji[1], Z. Da[1], X. Zhu[1], L. Li[2], Z. Gu[1]. [1]*Department of Rheumatology, Affiliated Hospital of Nantong University;* [2]*School of Nursing of Nantong University, Nantong, China*

Background: Poor sleep quality is common in patients with chronic diseases and may lead to disease aggravation and decreased quality of life. The increasing prevalence of poor sleep in individuals with chronic medical conditions is associated with adverse demographic, clinical, and psychological characteristics. However, there are currently no known reported studies related to the sleep quality of gout patients.
Objectives: This study aims to evaluate the prevalence of poor sleep quality and investigate the contributors of poor sleep in Chinese gout patients.
Methods: A self-report survey was administered to 226 gout patients and 232 healthy individuals using the Pittsburgh Sleep Quality Index (PSQI) for sleep quality, the Patient Health Questionnaire (PHQ-9) for depression, and the Generalized Anxiety Disorder (GAD-7) questionnaire for anxiety. Gout patients completed the 10 cm Visual Analog Scale (VAS) for total pain, and the Health Assessment Questionnaire-Disability Index (HAQ-DI) for functional capacity. Blood samples were taken to examine the level of uric acid (UA). Independent samples t-tests, Chi square analyses, and logistic regression were used to analyze the data.
Results: Our results found that the prevalence of poor sleep (PSQI≥5) was 55.3% and the mean global score of PSQI was 6.69 (SD 3.48) in patients, which were significantly higher than the controls (17.7% and 3.83 (SD 1.88), respectively). There were significant correlations among alcohol use, HAQ-DI, PHQ-9, GAD-7 and sleep quality in gout patients. Patients with yellow rice wine and wine use preferred to have better sleep quality. While, disease stage was associated with hypertension, total pain, number of tophi, presence of tender joints and swollen joints. Meanwhile, logistic regression models identified alcohol use and depression as predictors of poor sleep quality.
Conclusions: More than half of Chinese gout population suffered from poor sleep, which significantly higher than healthy individuals. These findings suggested medical personnel should pay more attention to the sleep quality of gout patients, especially those with depression. Additionally, it is beneficial for the patients with normal UA level to take moderate yellow rice wine and wine to improve their sleep quality.

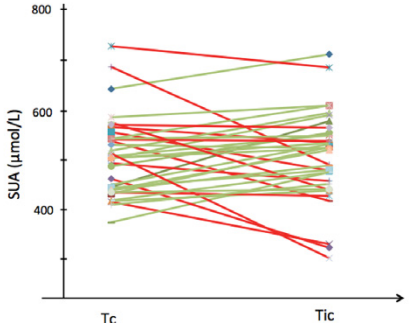
AB0899 DEPRESSION AND ANXIETY CORRELATE WITH DISEASE-RELATED CHARACTERISTICS AND QUALITY OF LIFE IN CHINESE PATIENTS WITH GOUT: A CROSS-SECTIONAL STUDY

T. Fu[1], H. Cao[1], R. Yin[1], L. Zhang[1], Q. Zhang[1], L. Li[2], X. Feng[3], Z. Gu[1]. [1]*Department of Rheumatology, Affiliated Hospital of Nantong University;* [2]*School of Nursing of Nantong University;* [3]*Department of Stomatology, Affiliated Hospital of Nantong University, Nantong, China*

Background: Depression and anxiety are common worldwide and may lead to disease aggravation and decreased health-related quality of life (HRQoL). The increasing prevalence of depression and anxiety in gout patients is associated with demographic and gout characteristics. However, there are currently no known reported studies related to the association between HRQoL and depression/anxiety.
Objectives: This cross-sectional study aims to evaluate the prevalence of depression and anxiety and investigate the potential risk factors for depression and anxiety in Chinese gout patients.
Methods: A self-report survey was administered to 193 gout patients and 208 healthy individuals from September 2015 to September 2016. Patients were asked to complete a set of standardized self-report questionnaires [Visual Analog Scale (VAS), Health Assessment Questionnaire-Disability Index (HAQ-DI), Patient Health Questionnaire (PHQ-9), Generalized Anxiety Disorder (GAD-7) questionnaire, Short Form 36 health survey (SF-36)]. Independent samples t-tests, χ^2 analyses, and logistic regression were used to analyze the data.
Results: We found 15% of gout patients had depression, and 5.2% had anxiety, which were significantly higher than the healthy controls (1.4 and 1.0%, respectively). There were significant correlations among education, pain, disease duration, stage of gout, disability, number of tophi, presence of tender joints, HRQoL, and psychological status. Meanwhile, logistic regression analysis identified number of tophi, HAQ-DI, and MH scale as predictors of depression in gout patients. Education, GH, and VT domains were significantly accounted for anxiety.



Conclusions: The prevalence of depressive and anxious symptoms among gout patients was higher than healthy individuals. Education, disability, tophi and HRQoL were important risk factors linked to this disorder in Chinese gout population. These findings suggested medical personnel should pay more attention to the psychological health of gout patients and make objective interventions to relieve their depression and anxiety, especially those with low education level, more than two tophi, severe disability, and poor HRQoL.

AB0900 SERUM URIC ACID LEVEL VARIATIONS DURING GOUT ATTACKS ARE LINKED NEITHER TO INFLAMMATION NOR TO URIC ACID FRACTIONAL EXCRETION: A PROSPECTIVE STUDY OF 35 PATIENTS

V. Masson Behar[1], C. Desthieux[1], C. Aparicio[2], P. Manivet[3], T. Bardin[1], P. Richette[1], F. Lioté[1], A. Ostertag[1], H.-K. Ea[1]. *[1]Service de rhumatologie, hôpital Lariboisière, AP-HP, centre Viggo Petersen, University Paris Diderot, INSERM UMR 1132, Bioscar; [2]Policlinique, hôpital Lariboisière, AP-HP; [3]Crb Bb-0033–00064, BioBanking and Analytics Systems, APHP, Paris, France*

Background: Acute gout is usually associated with a decrease in serum uric acid (SUA) level but the mechanism responsible for this phenomenon remains unclear.
Objectives: We aimed to investigate relationships between changes in SUA level, urinary excretion of uric acid and biochemical markers during gout attack.
Methods: SUA, eGFR (estimated glomerular filtration rate), serum CRP level and urinary excretion of UA, expressed as fractional excretion of UA (FeUA), from 35 ULT (urate-lowering therapy)-free and diuretic-free gout patients were prospectively measured during acute gout attack (Tc) and intercritical (Tic) phase. In 11 patients, data were available after achievement of SUA target (Tt) (<360 μmol/l) under ULT. Demographics data and waist circumference (WC) were collected. Data are expressed as mean ± SD.
Results: There were 32 men, mean age 57.9 years, mean body mass index 28.6 kg/m^2, and mean waist circumference 104 cm. Overall 17.1% had type 2 diabetes, 37.1% dyslipidemia, 54.3% hypertension, 34.4% obesity, 74.3% abdominal obesity and 51.4% chronic kidney disease (CKD, 31.4% CKD 2 and 20% CKD 3–5). Gout duration was 3.9±6.7 years, 28.6% of patients had tophus and 31.4% gout arthropathy. SUA, eGFR and FeUA values were similar between Tc and Tic phases: SUA: 504.9±79.9 and 507.6±89.7 μmol/l; eGFR: 78.1±28.8 and 81.4±33.8 ml/min/1.73m^2; FeUA: 4.90±2.3 and 4.45±3.3%, respectively. Moreover, the FeUA values were identical between Tt, Tic and Tc in 11 patients who achieved SUA target (296.0±37.8 μmol/l) under ULT. CRP levels were higher at Tc (44.8±69.4 mg/dL) than Tic (5.2±3.3 mg/dl) and Tt (4.6±1.2 mg/dl). While mean SUA levels were similar between Tc and Tic, SUA levels were lower in Tc than Tic in 21 patients (mean difference: 56.9±33.7 μmol/l) (figure1). In contrast, 14 patients had a SUA level higher in Tc than in Tic (mean difference: 78.6±71.5 μmol/L) (figure 1). SUA variations between Tc and Tic were not correlated with FeUA modifications in these two groups (p=0.15). Similarly, SUA and FeUA variations were not correlated with CRP variations between Tc and Tic (p=0.29 and p=0.30, respectively).

Figure 1. Variations of SUA between gout attack (Tc) and intercritical (Tic) phases (Green color: patients (N=21) with lower SUA level at Tc than at Tic; red color: patients (N=14) with higher SUA level at Tc than at Tic)

Conclusions: SUA levels during gout attack can be either higher or lower than SUA during intercritical phase. These variations are linked neither to inflammation level nor to FeUA. It would be interesting to assess the intestinal excretion of uric acid, xanthine oxidase activity and diet intake during these different gout phases.

AB0901 CLINICAL SIGNIFICANCE OF URATE DEPOSITION IN TENDON: A DUAL-ENERGY CT STUDY

Y. Eun[1], I.Y. Kim[1], H. Jeong[1], E.-J. Park[2], H. Kim[1], J. Lee[1], E.-M. Koh[1], H.-S. Cha[1]. *[1]Department of Medicine, Samsung Medical Center, Seoul; [2]Department of Medicine, Jeju National University Hospital, Jeju, Korea, Republic Of*

Background: Dual-energy computed tomography (DECT) is advanced imaging modality that shows the deposition of monosodium urate (MSU) crystal in tissue as a color signal. The MSU crystal deposit around the symptomatic joint is considered as positive finding, but the clinical significance of urate deposition around the tendon is still unclear.
Objectives: The aim of this study was to compare the clinical characteristics and DECT findings in people with MSU crystal deposition in the joints and people with urate deposition in the tendons.
Methods: DECT was performed in 71 patients who complained of recurrent painful swelling of the joints, and 35 of them showed MSU crystal deposition in the joints on DECT. Clinical manifestation and serum uric acid level data were collected.
Results: Most of the included patients were middle-aged (mean age 50 years, SD 15) and 67 patients (94%) were male. All patients who had MSU crystal deposition in joints on DECT had a history of typical gout attacks, and 29 patients (81%) had a history of gout attacks among patients with urate deposition only in tendons (p=0.011). The mean uric acid level of patients included in the study was as high as 7.5±2.2 mg/dL. In the highest uric acid level, the absolute value was higher in patients with urate deposition in joints, but there was no statistical significance. The correlation between the gout attack site and the urate deposit sites was 91% in patients with joint involvement, but only 6% in patients without joint involvement (p<0.001). There were 4 patients (11%) who showed gouty erosion without MSU crystal deposition in joints on DECT.
Conclusions: The MSU crystal deposition in the tendon was not correlated well with clinical features, suggesting that it is more likely to be associated with artifact or asymptomatic hyperuricemia. However, in some patients, MSU crystal deposition may be observed only in the tendon, even with gouty erosion. Therefore, careful interpretation of the DECT results is necessary.

Infection-related rheumatic diseases

AB0902 TUBERCULOSIS SCREENING IN PATIENTS RECEIVING BIOLOGIC THERAPY

S. Bouden, A. Fazaa, K. Oueniche, S. Saidi, S. Kassab, S. Chekili, K. Ben Abdelghani, A. Laatar. *Rheumatology, Hopital Mongi Slim, la Marsa, Tunisia*

Background: The advent of biological treatments has greatly improved the management of chronic inflammatory diseases (CID). However, these biologics increase the risk of infection including the possible development of tuberculosis (TB). Screening of latent tuberculosis infection (LTBI) is therefore necessary prior to their initiation, especially in Tunisia, which is considered as a high-incidence area of TB.
Objectives: The aims of this study were to identify the prevalence of LTBI among patients candidate to initiate biologics, to analyze the tolerance of preventive therapy and to detect active TB or conversions of immunodiagnostic tests under biologics.
Methods: A retrospective study was conducted, over a period of 14 years (2002–2016). Patients with CID, candidate to initiate biological treatment, were included. The screening of LTBI was performed according to the national Tunisian guidelines. Clinical data, screening and follow-up information on biological therapy were assessed.
Results: A total of 76 patients were enrolled in the study, 32 men and 44 women with a mean age of 66 years [17–80]. Rheumatoid arthritis (RA) was the most common CID (44%). The diagnosis of LTBI was established in 16 cases (21%). Among them, 3 had a Tuberculin Skin Test (TST) more than 10mm associated with a positive Interferon Gamma Release Assay (IGRA), 11 had only a positive TST, and 2 had only a positive IGRA. One of them had a history of pulmonary TB but adequately treated. All patients with positive screening were considered for preventive treatment. Thirteen (81%) received an association of isoniazid-rifampicin for 3–6 months, and 3 (19%) received isoniazid for 6 months. Toxicity was reported in 4 cases (25%): hepatotoxicity (n=1), dermatologic toxicity (n=1), fever (n=1) and stomachache (n=1). During the follow-up period, no case of reactivation has been reported among patients with LTBI. Out of the 60 patients with negative baseline screening, only 4 have been re-screened (6%) and none had conversions in immunodiagnostic tests. However, among patients who screened negative, one case of active pulmonary TB has been reported in a woman who had an ankylosing spondylitis (AS) and who was receiving infliximab during 22 weeks. She hadn't previous TB history or new TB exposure.
Conclusions: Our study showed that the Tunisian recommendations allowed detecting a LTBI in 21% of biologic therapy candidates. The initial screening and the prophylactic treatment improve the safety of these treatments. However, we noted a low rate of re-screening, as the Tunisian guidelines do not recommend

annual screening. Wide studies should be designed in order to evaluate the efficacy of re-screening.

AB0903 LABORATORY FINDINGS IN PATIENTS WITH CHIKUNGUNYA FEVER AND CHRONIC JOINT SYMPTOMS – A LONGITUDINAL ASSESSMENT

A. Ranzolin[1,2], R.M. Correia[2], H.D. de Lima[2], M.R.D.A. Freitas[2], A.F.R. de Oliveira[2], A.L.B.P. Duarte[1], C.D.L. Marques[1], P.R.S. de Melo[2], L.F. da Rocha Jr[1,2]. *[1]Hospital Das Clínicas of Pernambuco; [2]Instituto de Medicina Integral Professor Fernando Figueira, Recife, Brazil*

Background: Chikungunya Fever (CF) is an arbovirosis with a high attack rate, affecting large proportion of the population in its outbreaks (85%>90% of infected are symptomatic). In general, it is recommended to carry out laboratory tests when patients reach subacute phase or show signs of severity at the beginning of the disease. There are few studies showing which laboratory results are relevant and their clinical applicability.
Objectives: To recognize the most frequent findings of laboratory tests in a cohort of patients with CF and chronic joint symptoms and to correlate laboratory results with clinical data.
Methods: Patients with diagnosis of CF (clinical and epidemiological criteria) were followed in a cohort study. Clinical data and laboratory tests were collected in a regular schedule in the first months of the disease.
Results: A total of 54 patients were enrolled during 10 months, persistent changes in some patients were recorded (table).

Table 1. Persistent laboratory findings in patients with Chikungunya Fever in subacute/chronic phases

> 50%	Decreased vitamin D (53.8%)
40%>50%	Increased CRP (43.3%)
30%>40%	Decreased: HDL cholesterol (36.5%), eosinophil (37.3%),
20%>30%	Increased: glucose (28.3%), GGT (27.4%), γ globulin (27.4%), glycated hemoglobin (26.4%), calcium (25.4%), alkaline phosphatase (24.5%), β globulin (23.5%), cholesterol (23.0%) Decreased: total bilirubin (20.0%)
10%>20%	Increased: triglycerides (17.6%), LDH (17.3%), ferritin (13.7%), ALT (13.2%), direct bilirubin (12.0%), α2 globulin (11.7%) Monocytosis (11.1%), Limphocytosis (10.0%)
5%>10%	Hyperchloremia (8.0%) Increased: neutrophils (7.54%), LDL (5.88%), folic acid (5.88%), uric acid (5.76%), platelets (7.54%) Decreased: CPK (7.54%), albumin (5.88%), neutrophils (9.43%) Hyponatremia (5.88%),

CRP = C reactive protein, GGT = gamma glutamyl transferase, LDH = lactate dehydrogenase, ALT = alanine aminotransferase, CPK = creatine phosphokinase.

In the subacute phase, the ESR (erythrocyte sedimentation rate) correlated with number of swollen joints (r=0.45, p=0.03), VAS (visual analogue scale) of pain (r=0.72, p=0.0002), VAS patient's general health (r=0.50 p=0.02), VAS by physician (r=0.45, p=0.03) and with HAQ (r=0.51, p=0.01). In subacute phase the VAS of morning stiffness correlated with CRP (r=0.46, p=0.02). In chronic phase, CRP correlated with VAS of pain (r=0.47, p=0.02) and there was a reversal in the correlations between ESR and VAS of general health of the patient (r=-0.54, p=0.03), VAS of physician (r=-0.52, p=0.02), swollen joints (r=-0.46 p=0.03) and HAQ (r=-0.56, p=0.01). ESR and SF-12 (mental component) were correlated (r=0.61, p=0.01).
Conclusions: Levels of ESR correlated with measures of pain and worsening of functional capacity in subacute phase. In chronic phase, there was reversal of this correlation, indicating that ESR does not reflect clinical worsening of patients at this stage. Further clinical studies are needed to better analize other alterations.

AB0904 FUSOBACTERIUM NECROPHORUM MASQUERADING AS NEISSERIA IN SEPTIC ARTHRITIS

C.H. O'neill[1], H. McCormick[2], M. Leith[1], L. McCorry[3], J. McKenna[2], A. Pendleton[3], Y. Protaschik[3], A. Loughrey[2], P.V. Coyle[2], D. Fairley[2]. *[1]Rheumatology; [2]Microbiology; [3]Belfast Health and Social Care Trust, Belfast, United Kingdom*

Background: Infective arthritis with fusobacterium is rare and difficult to diagnose & initially can be misidentified as Neisseria arthritis based on microscopy results. It is associated with Lemierre's Disease & is important to recognise.
Objectives: To demonstrate that a "linked up" approach between culture and PCR in the analysis of joint fluids will provide timely identification of the organism and allow for appropriate antibiotic use & to show the utility of bacterial 16S rRNA PCR in sterile site fluid analysis.
Methods: This is a case study of a pyogenic wrist infection with *Fusobacterium necrophorum* in the rheumatology department
Results: Our report follows a 17 year old caucasian female presenting with a history of left wrist pain, swelling and flu-like symptoms. Microscopy of joint aspirate revealed gram negative diplococci. Empirical antibiotic therapy, Ceftriaxone, was used to cover for potential gonococcus. Real-time PCR testing was negative for both gonococcus and meningococcus. However a real-time PCR assay targeting the bacterial 16S ribosomal RNA gene detected bacterial DNA[1]. The patient did not clinically improve and further aspirate remained positive for the 16S rRNA gene target. As all joint aspirates and other specimens remained culture negative, the decision was taken to attempt bacterial 16S rRNA PCR and sequencing on DNA extracted directly from the joint aspirate. The sequences recovered were identified as *F necrophorum.* This was eventually confirmed by anaerobic culture of the initial joint aspirate. A suspicion of Lemierre's disease (thrombophlebitis of the internal jugular vein and/or bacteraemia) was raised, however jugular venous dopplers were normal.
The outcome was favourable following guided antibiotic treatment.
Conclusions: This case illustrates that *F. necrophorum* infection may occur with unusual or disseminated presentation, but in the absence of the classical features of Lemierre's syndrome. The possibility of Neisseria was recognised early & appropriate empirical antibiotic cover was used. This is important given the emergence of virulent meningococcal serogroup W ST11 strains causing infections with unusual presentation (including septic arthritis) in the UK[2]. Reliance on microscopy findings alone could have led to an incorrect diagnosis of gonococcal septic arthritis – a condition with very low complication rates and excellent prognosis. In contrast, non-gonococcal septic arthritis is a medical emergency with significant morbidity and mortality[3]. The *F. necrophorum* infection in this case could have had fatal complications if it had been managed as a gonococcal infection. Secondly this case highlights the utility of bacterial 16S PCR and sequencing directly from a normally sterile site, allowing accurate diagnosis and appropriate treatment.

AB0905 THE EFFICACY OF TRIMETHOPRIM/SULFAMETHOXAZOLE TO PREVENT ACUTE-ONSET DIFFUSE INTERSTITIAL LUNG DISEASES WITH CONNECTIVE TISSUE DISEASE PATIENTS

F.Y. Chen, K. Setoguchi, M. Ogawa, S. Kamei. *Systemic Immunological Disease, Tokyo Metropolitan Komagome Hospital, Tokyo, Japan*

Background: Acute-onset diffuse interstitial lung diseases (AoDILD) are highly mortal condition and their cause are often difficult to discriminate. Trimethoprim 80mg/sulfamethoxazole 400mg single strength (TMP-SMX SS) has been used for Pneumocystis Pneumonia (PCP) prophylaxis and highly effective but the dose was originally developed in pediatric cancer patient's study and there is possibility that in connective tissue disease (CTD) patients, less dose can be as effective.
Objectives: The aim of this study is to examine hypothesis that taking TMP-SMX for PCP prophylaxis with CTD also have prophylactic effect against AoDILD and how about those effect in under dose patients for some reason
Methods: We retrospectively investigated data from 621 patients with TMP-SMX for PCP prophylaxis during and 43 patients who admitted for either acute respiratory failure/acute interstitial pneumonia/PCP/drug induced pneumonitis during 2004–2016 in our department.
Results: There was no single case who admitted to hospital due to AoDILD with TMP-SMX for PCP prophylaxis. There were 34 cases admitted for AoDILD and 9 cases (26%) were dead. Among 25 cases, 5 cases developed AoDILD after TMP-SMX cessation. 70 cases ware taking under dose prophylaxis for some reasons but there was also no AoDILD case.
Conclusions: Taking TMP-SMX for PCP prophylaxis may also have prophylactic effect against AoDILD. And those effect may also exist even under dose.

AB0906 PYOGENIC SEPTIC ARTHRITIS: IS THERE A DIFFERENCE WHEN GERM IS NOT IDENTIFIED?

H. Sahli[1], M. Sahli[1], R. Tekaya[2], O. Saidane[2], R. Khalfallah[1], I. Mahmoud[2], L. Abdelmoula[2]. *[1]Rheumatology Departement, Mohamed Taher Maamouri University Hospital, nabeul; [2]Rheumatology Departement, Charles Nicolle Hospital, tunis, Tunisia*

Background: Pyogenic septic arthritis (PSA), defined by the presence of living microorganisms in the affected joint, is a therapeutic emergency. Germ isolation is a primordial step in the diagnostic and therapeutic approach.
Objectives: The aim of this study was to study the differences between PSA with positive and negative bacteriology.
Methods: This is a retrospective study which included medical records of patients treated for PSA in a rheumatology department over seventeen years. The epidemioclinical and paraclinical data were recorded. We used the SPSS 11.5 for the statistical analysis to compare patients with (group 1) and without an isolated causative agent (group 2).
Results: We evaluated 49 patients with a diagnosis of PSA. They were 26 (53.1%) men and 23 (46.9%) women. The average age was 55+/-18.7 years (ranging from 15 to 95 years). Comorbidities were observed in 31 (63.3%) patients. The onset of symptoms was acute in 37 (75.5%) patients and progressive in 12 (24.5%) patients. The most common symptoms were joint pain and stiffness (100%) and functional impotence (87.8%). All patients were treated with double or triple antibiotics. Among the studied patients, 27 (55.1%) had negative culture results. Statistical analysis used to compare cases with an isolated pathogen to those cases without an isolated pathogen, noted female predominance in group 2 but there was no statistically significant difference (p=0.252). Patients in group 1 and group 2 had a comparable mean age (p=0.08). Patients in both groups had comparable risk factors for PSA (p=0.549). Acute onset was more common in group 2 (51.4% versus 48.6%) but without a significant difference (p=0.507). Biological inflammatory syndrome was more frequent in group 2 but with no statistically significant difference (p=0.235). The study of the appearance of the synovial fluid did not demonstrate a statistically significant difference between the two groups (p=0.125). The abnormalities of standard x-rays were similar in both groups (45.2% in group 1 versus 54.8% in group 2, (p=1)). The statistical study of all other variables didn't show differences between the two groups.
Conclusions: PSA was not associated with major differences if the germ was or not isolated.

AB0907 CONTRIBUTION OF IMAGING IN THE DIAGNOSIS OF INFECTIOUS SPONDYLODISCITIS

H. Sahli[1], A. Bachali[1], R. Tekaya[2], I. Mahmoud[2], O. Saidane[2], L. Abdelmoula[2]. *[1]Rheumatology Department, Mohamed Taher Maamouri University Hospital, nabeul; [2]Rheumatology Department, Charles Nicolle hospital, tunis, Tunisia*

Background: Infectious spondylodiscitisis represents a diagnostic and therapeutic emergency. Imaging is fundamental in the management of the disease.
Objectives: The aim of this study is to analyze the contribution of imaging in the diagnosis of infectious spondylodiscitis.
Methods: This is a retrospective study which included medical records of patients treated for psoas abcess during the twelve past years [2006–2016]. Epidemiologic, clinical, and imaging data (Standard X ray, Computed tomography (CT), magnetic resonance imaging (MRI)) were recorded and analysed.
Results: Ninety patients were included in this study. The average age was 55 years [16–86] with an even distribution between males and females. Mean symptom duration was of 4 months. The most frequently isolated pathogen was Mycobacterium tuberculosis (63.3%), followed by pyogenic germs (21.2%) and Brucella (15.5%). Standard X ray were pathological in 89% of cases: showed narrowing of intervertebral space (72.2%), endplate destruction (42.2%), erosions of vertebra (13.3%), opacity (12.2%), vertebral fracture (10%), paravertebral spindle (5.5%) and posterior archlysis lesion (2.2%). Standard radiographswere normal in 12 cases and in 1 case, spinal CT showed vertebral destruction wirh " mirror-image ". Spinal MRI, performed in the remaining 11 cases, confirmed the diagnosis in all cases and showed paravertebral collections (n=3), epiduritis (n=3), psoas abscess (n=2), microabscess (n=1) and spinal compression (n=1). In case of posterior archlysis lesion and vertebral fracture, MRI confirmed the diagnosis by showing paravertebral collections.
Conclusions: Management of infectious spondylodiscitis has benefited from advancements in imaging allowing an early diagnosis and treatment.

AB0908 BIOLOGICAL AND RADIOGRAPHIC FINDINGS IMPACT ON GERM IDENTIFICATION DURING SEPTIC ARTHRITIS

H. Sahli[1], M. Sahli[2], R. Tekaya[2], R. Khalfallah[1], O. Saidane[2], I. Mahmoud[2], L. Abdelmoula[2]. *[1]Rheumatology Departement, Mohamed Taher Maamouri University Hospital, nabeul; [2]Rheumatology Departement, Charles Nicolle Hospital, tunis, Tunisia*

Background: Septic arthritis may cause damage and inflammation in short period of time. The germ determination must be the first objective to allow targeted treatment. Bacteriological tests remain negative in 7–35% of cases of septic arthritis.
Objectives: The aim of this study was to determine the impact of biological and radiographic findings on germ identification during septic arthritis.
Methods: This a retrospective study which included medical records of patients treated for septic arthritis during the seventeen past years. Epidemiologic, clinical, biologic, bacteriologic and therapeutic data were recorded and analysed. We made a comparison between patients who had a germ identified (Group 1) with whom who hadn't (Group 2).
Results: Fifty nine patients with septic arthritis were included in this study. The mean age of the patients was 54.6±19 years and a sex ratio (F/M) of 0.9. Causative agents were isolated in 27 patients (45.7%). Biological data showed leukocytosis in 25 (42.4%) patients. Mean leukocyte count was 10673±5003. Leukopenia was noted in 1 case. One patient had neutropenia. Lymphopenia was observed in 4 patients (6.7%). Two patients had hyperlymphocytosis. Anemia, mainly of the inflammatory type, was noted in 47 cases (79.66%). The mean Creactive protein (CRP) was 150.6±106, and the mean erythrocyte sedimentation rate (ESR) was 104.9. Twenty three patients (38.9%) had other perturbations of the biological balance: cholestasis (n=1), cytolysis (n=4) and renal perturbation (n=15). Radiological signs suggestive of septic arthritis were observed in 40 cases (67.8%): articular pinching (28.8%), geodes and erosions (14%), total destruction of the joint (0.67%) or thickening f the soft parts at the beginning (11.86%). Ultrasound exam, performed in 22 cases, showed articular effusion (n=15), synovial thickening (n=8), a soft tissue collection (n=3), and periarticular erosion (n=2). CT, performed in 6 patients, was normal in one case. The abnormalities noted were: collection of soft parts (n=2), joint effusion (n=2), bone demineralization (n=1), bone erosion (n=1) and osteochondritis (n=1). MRI, performed in 2 patients, was pathological in both cases and showed synovitis and cortical erosion with medullary edema. The comparison of the 2 groups according to germ identification showed that biological inflammatory syndrome was more frequent in group 2 (100% versus 96.8%) but without a statistically significant difference (p=0.346). Mean value of CRP and ESR were comparable in the two groups (p=0.65 and 0.19). The mean value of hemoglobin was comparable in the two groups (10.87 versus 10.54 g/dl) (p=0.566). It was similar about the blood count. Abnormalities of standard x-rays were similar in both groups (70.4% in group 1 versus 65.5% in group 2) (p=0.784). The most frequent radiological abnormality in the two groups was articular pinching (40.7% in group 1 and 46.8% in group 2).
Conclusions: In our study, the biological and radiological data had not shown any impact on the identification of the germ.

AB0909 SEPTIC PSEUDARTHROSIS OF THE HUMERUS TREATMENT USING ORTHFIX EXTERNAL FIXATION

S. Daas[1], H. Sahli[2], M.A. Sbai[1], M. Souissi[1], A. Khorbi[1]. *[1]Orthopedic Departement; [2]Rheumatology Departement, Mohamed Taher Maamouri University Hospital, nabeul, Tunisia*

Background: The septic pseudarthrosis of the humerus is a very difficult process that poses a towfold challenge: the infection eradication while trying to get consolidation.
Objectives: The aim of this study was to analyze the results of the treatment of septic pseudarthritis of the humerus with Orthofix monolateral axial external fixator.
Methods: This is a retrospective study which included 17 medical records of patients treated for septic pseudarthritis of the humerus debridement and stabilization by Orthofix over a period of 7 years.
Results: They were 13 women and 4 men with a mean age 44 years. The fracture site was most often at the distal half of the humerus. The initial treatment of the fracture was pinning or intramedullar nailing. Surgical management of pseudoarthrosis was performed 3.5 months after the first surgical procedure. All cases had a bone debridement and stabilization with a monoplane Orthofix axial external side. Fifteen cases had also a bone graft. The mean period of stabilization was 7months. Patients were evaluated clinically and radiologically each month. At the mean of three years of follow-up, we obtain osseous consolidation for all patients in the average of seven months. All patients underwent rehabilitation of the shoulder and elbow after treatment. The functional result were excellent results in 47% of cases, good results in 35,3% of cases and poor results in 17,7%. The Quick DASH score average was 28±5. The average of the elbow motion was 109 ° of flexion with an average of 30 °of deficit in extension. The useful range of motion of the elbow was preserved in 14 patients. There was a shaft angulation under 20 ° in 3 cases and over 20 ° in 3 other cases. We noted

in four cases a bone shortening consolidations of 2 cm. We had a case of radial nerve neuraprexie which regressed spontaneously.
Conclusions: Orthofix is the method of choice for the treatment of septic pseudarthritis of the humerus.
Associate eradication of the germ antibiotic and steroid intake spongy it allows the consolidation of the bone. Furthermore, the monolateral axial external fixator is tolerated well and allows movement of the shoulder and elbow throughout the period of treatment.

AB0910 INFECTIOUS SPONDYLODISCITIS IN THE SANITARY AREA OF TORRELAVEGA BETWEEN 2000 AND 2016: 62 CASES

I. Morante Bolado[1], M. Santos-Gómez[1], I. Villa Blanco[1], E. Aurrecoechea Aguinaga[1], T. Ruiz Jimeno[1], J. Calvo Alén[2]. *[1]Rheumatology, Sierrallana Hospital, Torrelavega; [2]Rheumatology, University Hospital of Araba, Vitoria, Spain*

Objectives: To analyze the clinical characteristics, most frequent diagnostic methods and different treatments used in spondylodiscitis (SD) in our sanitary area.
Methods: Descriptive and retrospective study of patients with the diagnose of infectious SD (clinical or microbiological) from 2000 to 2016. In each case we studied the presence of underlying diseases, an episode of infection in the previous 6 months, way of presentation, location, diagnostic methods, treatment and evolution, comparing among different etiologies.
Results: 62 patients were diagnosed of spondylodiscitis. 41 men (24–90 years: mean 71,7). 58 were pyogenic, 3 tuberculous (TBC) SD, and 1 candida. The patients with TBC were younger (mean age: 45.3; $p<0.05$). An underlying disease was observed in 51 patients, specially Diabetes Mellitus (DM) (31% of SD). 4 patients were Rheumatoid Arthritis patients. A previous episode of bacteriemia or a primary source of infection was identify in a 33% of the cases, obtaining a microbiological isolation in 47/62 (75.8%) SD (43 bacterial, 3 TBC and 1 Candida). The most frequent pathogens were Gram +(G+) (50% of the total SD) being S. aureus and S epidermidis responsible of 21/62 cases (33.8%). In the 94% of SD caused by G+, hemocultures positive were obtained, in comparison to a 55% of SD caused by G- (p=0.016).
The most frequent presentation symptoms were: lumbar pain (95.1%), fever (50%) and neurological deficit (18%). Leucocytosis was present in only a third of the SD, observing an increase of ESR and CRP in the pyogen etiology (p no significative for low number of patients in SD group caused by TBC) and lower levels of hemoglobin, cholesterol and albumin. Lumbar area was affected in the 77% of SD (77% in G+ and 50% in G-). In a 13% of patients, more than one intersomatic space was affected, being visible the presence of an abscess in 44/62 cases (71%). It was necessary surgical treatment in 7/44 (16%). 5 patients died due to pathology related to SD (8%), without any correlation with a risk factor and other 5 presented a relapse in the subsequent months.
Conclusions:
- the bacterial SD are the predominant group, being DM the most frequent risk factor.
- The incidence of SD due to TBC and fungi is scarce in our environment, being absent the Brucella etiology.
- The G+ SD usually have a previous associated bacteriemia.
- The majority of the patients had pain in the presentation, but only half of them had associated fever.
- The most frequent location of SD was lumbar.
- We established a 8% of mortality rate in our sanitary area.

AB0911 ACUTE RHEUMATIC FEVER CASE SERIES PRESENTING WITH ARTHRITIS IN ADULTS

I. Dogan[1], O.N. Koyun[2]. *[1]Rheumatology; [2]Internal medicine, Hitit University Corum, CORUM, Turkey*

Background: Acute rheumatic fever (ARF) is an inflammatory reaction to group A hemolytic streptococcus that emerging 2–3 weeks after infection; presenting with joint, cardiac, neurological and dermatological symptoms. The incidence is reported to be 0.5–3: 100.000 in developed countries and 20–100: 100.000 in developing countries.[1] ARF is a common disease in Turkey. It is most common between the ages of 6 and 20 years. It is rare in adults and arthritis is common with carditis in adults.[2]
Objectives: Due to the ARF is rarer at adulthood, ARF-associated arthritis at adults has been reported as a case report series.
Methods: Five patients who were admitted to our rheumatology policlinic in a tertiary medical center located in Corum province, with early arthritis between 2014 and 2016 were diagnosed with ARF associated arthritis.
Results: The age of ARF associated arthritis patients ranged from 35 to 56 years (Mean age 45.6 years). Two of these patients were male and three were female. One patient has atrial fibrillation and coronary artery disease in other one as a comorbidity. All of patients had tonsillitis in the last 15 days. Two of the patients had a previous ARF story.

The results of the laboratory and the clinical findings are given in table:

Patient	Age/ Gender	Previous ARF Diagnosis	Echocardiography Findings	Arthritis	Sydhenam chorea/ subcutaneous nodule/erythema marginatum	Anti-STREPTOLYSINO Antikoru (0–200 IU/ml)
1	35/F	–	2. MI	+	–/–/–	430
2	42/M	+	mild MS	+	–/–/–	472
3	42/F	–	1–2. AI	+	–/–/–	500
4	53/F	–	mild MS 2. AI, 2. TI	+	–/–/–	320
			2. AI, 2. TI	+		
5	56/M	+	1. AI	+	–/–/–	456

F: Female, M: Male, AI: Aortic valve insufficiency, MI: Mitral valve insufficiency, MS: Mitral valve stenosis, TI: Tiricuspit valve insufficiency.

Acute rheumatic fever associated arthritis was diagnosed according to Jones criteria due to migratory arthritis, carditis findings with Echocardiography, and ASO titer elevation. The ANA, anti-CCP, RF, and Brucella agglutination tests were negative. Non-steroidal anti-inflammatory drugs, oral methyl prednisolone 16 mg per day and benzathidine penicillin G 1.2 million units per month were initiated as treatments. Methyl prednisolone dose was taperde gradually. In one patient using warfarin, depo peniciline i.m. was not given because it could be risky for hematoma. In another patient with coronary artery disease, methylprednisolone 4 mg per day was started because coronary bypass was planned. Symptoms of all patients were improved after treatment.
Conclusions: Acute rheumatic fever associated arthritis is not a common condition in adult patients,and should be kept in mind with poststreptococcal reactive arthritis in arthritis developed after upper respiratory tract infections in adults.

AB0912 ASSESMENT OF CLINICAL AND RADIOLOGICAL PROGNOSTIC VARIABLES IN PATIENTS WITH SPONDYLODISCITIS

J.J. Fragio Gil[1], R. Gonzalez Mazarío[1], M. Tasias Pitarch[2], E. Calabuig Muñoz[2], J. Ivorra Cortes[1], C.M. Feced Olmos[1], F.M. Ortiz-Sanjuan[1], E. Labrador Sánchez[1], K. Arévalo Ruales[1], E. Grau Garcia[1], I. Chalmeta Verdejo[1], L. Gonzalez Puig[1], I. Martínez Cordellat[1], R. Negueroles Albuixech[1], C. Alcañiz Escandell[1], J.E. Oller Rodriguez[1], E. Vicens Bernabeu[1], C. Nájera Herranz[1], I. Cánovas Olmos[1], D. Hervás Marín[3], M. Salavert Lleti[2], J.A. Román Ivorra[1]. *[1]Rheumatology Department; [2]Infectious Disease Unit, HUP la Fe; [3]Biostatistic Unit, IIS la Fe, Valencia, Spain*

Background: Spondylodiscitis is an infectious disease of the intervertebral space, often caused by hematological spreading from a distance septic focus, especially Endocarditis. Because of its low incidence combined with an ambiguous symptoms, delay diagnosis and treatment of this condition, raising probability of an undesirable outcome.
Objectives: To identify poor prognosis variables in patients with Spondylodiscitis
Methods: Observational retrospective study with non-quirurgic spondylodiscitis patients from 2010 to 2016 was performed. Demographic information, clinical history, laboratory test and radiological data were compiled from the clinical history management software. Statistical analysis was performed with the software R (version 3.3.2).
Results: We included 55 patients, with a mean age of 63.47 (16.11) years old. Males predominated (69%). The average time with axial pain was 64.44 (80.63) days. Mean length of hospital stay was 64.44 (80.63) days and readmission rate was 32.7%. 20% of patients required further surgical procedures. Most of patients showed high CRP levels at their admission, with an average value of 112.97 (83.64) mg/L. Underlying endocarditis proportion was 16.4% and in this patients hospital stay was significative higher; nevertheless, it was not correlated with worse prognosis. 50% of patients showed vertebral destruction on MRI; 14.8% cord compression and 20.4% of patients developed neurological complications (7 of them paraparesis). Furthermore, vertebral destruction was statistically correlated with epidural abscess (P=0.026). Isolation and microbiological identification in blood cultures was possible in 83.6% of patients. Most frequent bacteria was Gram positive (50.09%), then Gram negative (18.2%), mycobacteria (10,9%) and fungi (3.6%).
Conclusions: Delay in diagnosis is an important issue in Spondylodiscitis patients. Higher complications rates are mainly in relation to greater vertebral destruction. Underlying infectious endocarditis was described in a small proportion of patients in contrast to other studies. Presence of epidural abscess was also correlated with vertebral destruction, for this reason, patients with this finding should be more carefully follow-up.

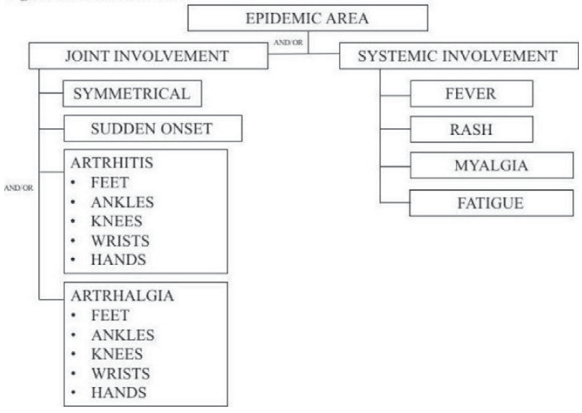
AB0913 AGREEMENT STUDY AND EXPERT CONSENSUS FOR THE CLINICAL PICTURE OF CHIKV INFECTION



J.C. Rueda[1], J.-I. Angarita[1], C. Pinzon[2], A.M. Santos[1], E.-L. Saldarriaga[1], J.M. Rueda[3], D.L. Saaibi[4], E. Forero[5], I. Pelaez-Ballestas[6], P.X. Pavía[7], J. Londono[8]. *[1]Reumatología; [2]Departamento de Investigación Clínica, Facultad de Medicina, Universidad de la Sabana, Chia; [3]Unidad de Reumatología, Centro Médico Imbanaco, Cali; [4]Reumatología Ubit, Centro Médico Carlos Ardila Lulle, Bucaramanga; [5]Medicina Interna, Reumatología, Universidad del Norte, Barranquilla, Colombia; [6]Reumatología, Hospital General de México, México, Mexico; [7]Unidad de Investigación Científica, Hospital Militar Central; [8]Reumatología, Universidad de la Sabana-Hospital Militar Central, Bogotá, Colombia*

Background: World Health Organization suggested case definitions to suspect and diagnose chikungunya virus infection which are: possible case, probable case and confirmed case. Although useful, when applied in practice, its lack definition for specific joint involvement and absence of other systemic symptoms apart from fever, leads to a broad clinical spectrum which increases the need for laboratory tests.
Objectives: To establish agreement on clinical criteria of CHIKV infection based on clinical expertise of specialists from affected areas of Colombia and to develop a set of clinical criteria.
Methods: A group of specialists in rheumatology, epidemiology and bacteriology from different parts of Colombia with experience in diagnosis and treatment of CHIKV patients from the epidemic of 2014–2015 met to reach agreements on clinical characteristics of CHIKV infection. A series of questions were formulated and agreement in percentage was calculated on the following answers: totally agree, agree, not in agree or disagree, disagree and totally disagree. Agreement was set when the sum to the answers totally agree and agree or disagree and totally disagree of was ≥50%. When agreement was not reached, the moderator performed a discussion with the opinions of the confronting members of the group and after that reformulated the question. This procedure was made until agreement was reached. With the results a set of clinical criteria was proposed.
Results: The agreement percentage to the formulated questions are depicted in table 1. Disagreement was achieved with mucosal imvolvement (100%), G/I involvement (88%), and arthralgia and arthritis in shoulders (63% and 100%) and in elbows (100%).
Conclusions: Agreement was achieved in abrupt onset of symptoms, and the presence of fever, rash, myalgia, fatigue, and symmetrical arthritis or arthralgia of wrists, hands, knees, ankles and feet. A set of clinical criteria was proposed (figure 1).
Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.1882

Table 1. Agreement Percentage to Formulated Questions on CHIKV Clinical Characteristics

Do you consider as clinical criteria:	Totally Agree	Agree	Not in Agree or Disagree	Disagree	Totally Disagree	Type of Agreement (Total)
Symmetrical joint involvement	100	0	0	0	0	Agree (100)
Abrupt onset of symptoms	100	0	0	0	0	Agree (100)
Fever	38	50	12	0	0	Agree (78)
Rash	13	75	0	12	0	Agree (88)
Myalgia	25	75	0	0	0	Agree (100)
Fatigue	63	25	12	0	0	Agree (88)
Arthralgia in wrists	50	25	13	0	12	Agree (75)
Arthritis in wrists	75	13	0	12	0	Agree (88)
Arthralgia in hands	88	12	0	0	0	Agree (100)
Arthritis in hands	88	12	0	0	0	Agree (100)
Arthralgia in knees	13	63	0	12	12	Agree (76)
Arthritis in knees	13	63	12	0	12	Agree (76)
Arthralgia in ankles	100	0	0	0	0	Agree (100)
Arthritis in ankles	100	0	0	0	0	Agree (100)
Arthralgia in feet	50	38	0	12	0	Agree (88)

AB0914 CUTANEOUS LEISHMANIASIS IN PATIENTS TREATED WITH BIOLOGICAL THERAPY

J. Lluch[1], M. López de Recalde[1], X. Michelena[1], J. Marcoval[2], X. Juanola[1]. *[1]Department of Rheumatology; [2]Department of Dermatology, Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Barcelona, Spain*

Background: Leishmaniasis is a chronic protozoal disease endemic in several areas of the world. In the Mediterranean basin cutaneous leishmaniasis is caused by *Leishmania infantum* and usually produces localized skin lesions. Biological therapy (BT) may increase the risk of reactivation or development of infections such as tuberculosis, mycoses and protozoan diseases. However, there is scarce literature on *Leishmania* infections in patients treated with anti-TNF drugs. We have diagnosed five cases of cutaneous leishmaniasis in patients treated with anti-TNF drugs in the last four years.
Objectives: To show the clinical characteristics and the evolution of cutaneous leishmaniasis in patients treated with BT at a tertiary level hospital.
Methods: We reviewed the clinical characteristics, previous treatments, the complementary tests used for the diagnosis, the main disease, the therapy used for the treatment of the infection, the clinical evolution and the reintroduction of the BT.
Results: In the last four years we have diagnosed five cases of cutaneous leishmaniasis in patients treated with BT. Four of them were men and one a woman, the age range was 35 to 61 years old. In four of them the symptoms were only cutaneous, but one of them also had systemic impairment, basically hepatosplenomegaly. For the diagnosis skin biopsy, positive PCR for *Leishmania* DNA from skin samples, serology and response to treatment were all needed. Three cases were patients treated with adalimumab and two treated with infliximab. Three patients had Crohn's disease, one psoriatic arthritis and the other ankylosing spondylitis. The diagnostic delay was between 5 and 24 months. All patients were treated with EV liposomal amphotericin B, and two of them also received intralesional injections of meglumine antimoniate. In all cases resolution was achieved, and there have been no relapses to date after reintroduction of BT.

Conclusions: We have to consider cutaneous leishmaniasis in patients with BT who present compatible skin lesions, especially in endemic areas. It is important to be aware of this type of condition in order to make a fast and accurate diagnosis.

Abstract AB0914 – Table 1

Gender	Age	Disease	Biologic therapy	Time with BT	Affection	Evolution until diagnosis	Treatment	Evolution
Man	35	Crohn disease	Adalimumab	4 years	Cutaneous	12 months	Intralesional injections of meglumine antimoniate EV liposomal amphotericin B.	Resolution. Reintroduction of BT.
Woman	55	Crohn disease	Infliximab	3 years	Cutaneous	24 months	Intralesional injections of meglumine antimoniate EV liposomal amphotericin B.	Resolution. Reintroduction of BT.
Man	61	Crohn disease	Adalimumab	3 years	Cutaneous and hepatosplenomegaly	5 months	EV liposomal amphotericin B	Resolution. Reintroduction of BT.
Man	58	Psoriatic arthritis	Adalimumab	19 months	Cutaneous	8 months	EV liposomal amphotericin B	Resolution.
Man	51	Ankylosing spondylitis	Infliximab	12 years	Cutaneous	5 months	EV liposomal amphotericin B	Resolution. Reintroduction of BT.

AB0915 FREQUENT CONVERSION AND REVERSE CONVERSION OF TUBERCULIN SKIN TEST BUT NOT OF AN INTERFERON GAMMA RELEASE ASSAY (T-SPOT.TB) DURING LONG TERM BIOLOGIC TREATMENT OF RHEUMATIC PATIENTS

K. Thomas, A. Makris, C. Tsalapaki, A. Lazarini, K. Klavdianou, K. Antonatou, C. Koutsianas, C. Hatzara, E. Hadziyannis, D. Vassilopoulos. *Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, 2nd Department of Medicine and Laboratory, National and Kapodistrian University of Athens, Hippokration General Hospital, Athens, Greece*

Background: There are limited data regarding the value of tuberculosis (TB) rescreening in rheumatic patients on biologic (bDMARD) therapies who had a negative baseline TB screening.
Objectives: To examine the rates of conversion and reverse conversion at repeated TB screening testing with 2 available assays (tuberculin skin testing-TST and an interferon gamma release assay-IGRA: T-SPOT.TB) in rheumatic patients with negative baseline screening during long term bDMARD treatment.
Methods: Rheumatic patients with negative baseline screening (TST and T-SPOT.TB) were re-screened one year after TNF inhibitor (TNFi) therapy (1st rescreening) and ~6 years later on bDMARDs (2nd re-screening). The rate of conversion and reverse conversions of the 2 assays were recorded. Only patients who did not receive isoniazid (INH) therapy between the 1st and 2nd rescreening were analyzed.
Results: Among 70 patients with negative TB baseline screening, 21 patients with 2 re-screenings available were identified; one patient with TST conversion at the 1st rescreening who converted back to negative at the 2nd rescreening after INH treatment, was excluded from the study. 20 patients were finally included in the study (RA=7, PsA=6, AS=5, other diseases=2). 50% were women with a mean age of 57.1±12.4 years and mean disease duration at the last screening of 13.1±6.2 years. The mean interval between the 1st and 2nd rescreening was 68.6±13 months. At the last evaluation, 90% (18/20) were still on bDMARDs (TNFi=55%, non-TNFi=45%), 45% (9/20) on non-biologic DMARDs and only one patient (5%) on corticosteroids. None of the patients displayed conversion or reverse conversion with T-SPOT.TB compared to 6 (30%) with TST at the 2 rescreenings (p=0.02). At the 1st rescreening, 4/20 (25%) had converted their TST to positive; at the 2nd rescreening, 2 reverted back to negative (1 patient with PsA on etanercept and 1 with RA on steroids, methotrexate and golimumab) while the other 2 remained TST positive (1 with PsA on etanercept and 1 with Still's disease exposed to etanercept, tocilizumab and canakinumab). Among the 16 patients who remained TST and T-SPOT.TB negative at the 1st rescreening, 2 (12.5%) became TST positive at the 2nd rescreening (12 mm and 7 mm, respectively). Both patients were on long term infliximab treatment without history of TB exposure. After thorough evaluation, no evidence of active TB infection was found in any of the 6 patients who converted TST either in the 1st or 2nd rescreening.
Conclusions: Among rheumatic patients with negative baseline TB screening, conversion or reverse conversions were much more frequent with TST compared to an IGRA (T-SPOT.TB) at repeat testings during long term bDMARD therapy. These preliminary findings need to be taken into account while designing the appropriate repeat TB screening strategy for this group of patients.

AB0916 WHIPPLE DISEASE: A RARE DISEASE DIFFICULT TO DIAGNOSE

L. Ferrieres, L. Alric, M. Laroche, D. Bonnet, S. Thebault. *CHU Toulouse France, Toulouse, France*

Background: Whipple disease is a very rare disease needing a long term treatment. The most frequent symptoms are recurrent arthralgia or arthritis, chronic diarrhoea, abdominal pain and weight loss.
Objectives: In this work, we have highlighted the main clinical features and diagnostic procedures that lead to the diagnosis and comment on the clinical response, treatment, and the factors of relapse.
Methods: Subjects were recruited from the Internal Medicine and Rheumatologic Departments of an University Hospital from November 1997 to January 2016. Overall, 12 subjects were finally diagnosed.
Results: Mean age was 54.3 years (age range: 30–81), with more male patients (58.3%). Almost all patients had articular symptoms and impaired general condition (91.7%); and a majority had digestive symptoms (75%). Regardless of the symptoms, the most efficient diagnostic tools were the PCR screening on the gastrointestinal biopsies and saliva (83.3% and 72.7% positive results, respectively). More than half of the patients relapsed (55.6%). The relapsing patients were older (63.2 (44–81)) and mostly male with a majority (60%) of digestive symptoms and a delayed diagnosis.
Conclusions: In current practice, it is highly difficult to diagnose Whipple disease. In order to decrease the delay between the first symptoms and the diagnosis, effective tools such as saliva and stools PCR should be used since higher delays of diagnosis lead to a higher number of relapses.

AB0917 SAFETEY AND EFFICACY OF DIRECT-ACTING ANTIVIRAL AGENTS FOR THE TREATMENT OF HCV IN RHEUMATIC DISEASES: CASE SERIES

M.C. Ditto[1], R. Talotta[1], S. Parisi[2], M.C. Gerardi[1], A. Batticciotto[1], F. Rigamonti[1], P. Sarzi Puttini[1], E. Fusaro[2], M. Antivalle[1]. *[1]Rheumatology Unit, Luigi Sacco Universitary Hospital, Milan; [2]Rheumatology Unit, Azienda Ospedaliera Universitaria Città della Salute e della Scienza di Torino, Turin, Italy*

Background: Until approximately 5 years ago interferon (IFN) associated with Ribavirina (RBV) was the gold standard of HCV therapy. Literature data shown that IFN could exacerbate symptoms related to the autoimmune diseases, and flares or intolerance are reported. Recent advances in antiviral therapy had completely modified the HCV infection approach. Direct acting antiviral agents (DAAs) are more efficacious, safer and more tolerable of IFN-HCV treatment.
Objectives: To show safety and efficacy of IFN-free HCV eradication in inflammatory arthritis patients with concomitant immunosuppressive treatment.
Methods: We evaluated 5 patients (M:F=4:1; median age 50±13.4), affected by inflammatory arthritis and concomitant HCV infection requiring eradication, treated with cDMARDs or bDMARDs (anti-TNFα) and DAAs. Demographic data and concomitant medications are showed in table 1.
Results: Patient 01 and 02 were affected by psoriatic arthritis with severe cutaneous and articular involvement. The first one was also under Lamivudina treatment because concomitant HBV infection and cirrhosis. Patient 03 was affected by enteropathic arthritis (RCU), treated with AZA 100 mg. Patient 04 was affected by rheumatoid arthritis and latent TBC under Nicizina 300 mg daily treatment. Patient 05 was affected by ankylosing spondylitis. Before starting DAAs he was treated with Telaprevir/Peg-IFN/RBV but during the treatment vulgar psoriasis with diffuse and severe involvement appeared. IFN-therapy was interrupted and DAAs therapy started with no flares or other adverse events.
Four patients (01, 02, 04, 05) were under anti-TNF-α treatment and 1 patient (03) was under Azatioprina treatment. During therapy with DAAS any flare of autoimmunity disease or adverse events were observed. HCV-RNA was undetectable after 3 months in 4 patients and after 6 months in 1 patient.
Conclusions: For all of patients IFN-free therapy was efficacious (blood-HCV-RNA undetectable after treatment) and safe (no adverse events). DAAs therapy could be the best choice to HCV eradication in patients affected by autoimmune rheumatic diseases treated with immunosuppressive drugs.

AB0918 REACTIVE ARTHRITIS POST VIRAL – AN UNUSUAL PRESENTATION IN AN EPIDEMIC IN NORTH INDIA

N. Mendiratta, R. Gupta, D. Rawal on behalf of Dr Dhiren Raval. *MEdanta, MEdcity, New Delhi, India*

Background: This study was performed at a Private hospital in New Delhi, India during the epidemic phase of Viral fever. The peak months of viral fever from mosquitoes (Aedes Aeygpti) like Dengue and Malaria (Anopheles)has been from July to October, till the holy festival of Diwali arrives. Chikungunya came like a wave this time along with dengue and Malaria.The worst epidemic since the last 6 years.A disease common in South India, took North India by a storm. 15–20 deaths were also reported due to Chikungunya virus. Apart from Chikungunya (serology negative) there were a lot of other viruses causing arthritis. Our study deals with post viral arthritis, a new variant which has never been described before.
Objectives: 1. To study the pattern of arthritis after viral fever. Is it reactive or a new variant
2. To observe for the evolution of Acute viral arthritis into chronic arthritis
3. The management of Post viral arthritis
Methods: It is a retrospective study conducted at the end of the epidemic. The patients are being followed up over next 3 months to observe for resolution of symptoms, persistent arthritis or evolution into chronic form. 100 patients are being included which were examined and independently assessed by 3 different consultants.
Inclusion criteria: 1. All patients who presented with complaints of persistent joint pains and swelling preceded by fever (Average duration 4–8 weeks). 2. Documented synovitis (Oligoarticular and polyarticular)
Exclusion criteria: 1. Known case of Rheumatoid Arthritis, Connective tissue disease, Vasculitis and Spondyloarthopathy 2. Arthalgia with no documented synovitis 3. Patients on DMARDS previously
Results: Detailed results are still under compilation as patients are under follow up (6 months) for further course.
No of patients: 100
Average Age: 47
Average Disease Duration: 6 weeks (after fever)
Average No of Joints involved: 3–4
Symmetry: All Asymmetrical (Large+ Small)
80% patients had asymmetrical joint involvement. Most common joints were: MCP followed by PIP and then the large joints: shoulders and ankles. It was associated with significant early morning stiffness (30 minutes) like other inflammatory arthritis. 60% had response to short course of NSAIDS and low dose steroids (Injection Depomedrol 80 mg intramuscular once a week) and recovered in 2 weeks, 30% had a prolonged course of 4–6 weeks, butdid not need any further medications. 5% developed into Chronic arthritis (Further follow up pending)
Conclusions: Reactive arthritis is a known entity and it has typical involvement of the lower limbs, usually preceded by urinary tract infection or GI infection. Even with Viral arthritis, the presentation of joint pains and swelling is usually during the acute fever episode. The pattern described here was different. All the patients had fever at presentation which lasted for 3–5 days and 4–6 weeks later they developed synovitis. There was characteristic involvement of Small joints of the hands (PIP and MCPS) (different from reactive).We are still in process of collecting follow up data which will give us a clue on prognosis of this arthritis and future prospects. So, what do we label it as ... Reactive arthritis-a new variant or a post viral arthritis.

AB0919 THE PROGNOSTIC FACTORS DURING OSTEOARTICULAR TUBERCULOSIS

O. Saidane [1], M. Sellami [1], S. Cheikhrouhou [2], I. Mahmoud [1], R. Tekaya [1], L. Abdelmoula [1]. *[1]Rheumathology; [2]Parasitology, Charles Nicolle Hospital, Tunis, Tunisia*

Background: Osteoarticular tuberculosis (OAT) is still common in Mediterranean countries such as Tunisia.The incidence of OAT is increasing, mainly related to expanding immunosuppressive factors and comorbidities.
Objectives: This study aimed to analyze the prognostic factors and therapeutic outcomes of OAT.
Methods: Over a period of 20 years [1996- 2016], patients with the diagnosis of OAT were retrospectively identified. Clinical, laboratory and radiology features in these patients were analyzed to identify the prognostic factors.
Results: Sixty patients (29 men) fulfilled the diagnostic criteria, admitted to the Rheumatology Service with an average of 54 years (range: 16 to 86).We did not find any significant association between prognosis and an advanced age (>60years) at the time of diagnosis, a long diagnostic delay or initial neurologic involvement.However, we found that cervical localization in tuberculous spondylodiscitis, classified as an only infection site or in multi-level vertebral damage, was significantly associated to a poor prognosis.Our study revealed that hyperleucocytosis higher than 11500 elements/mm^3 at the initial blood count constituted the only biological bad prognostic factor during OAT. Based on radiological findings, the presence of abscess or vertebral compression fractures on bone imaging (MRI)and the presence of vertebral deformity (kyphosis or kyphoscoliosis) were strongly linked to a bad outcome.The following table (Table1) summarizes the poor prognostic factors during OAT.

Table 1. The poor prognostic factors during OAT

PROGNOSTIC FACTOR	p	Odds Ratio
White blood cell counts >11500 elements/mm^3	0,041	22
Presence of abscess on MRI	0,024	13
Presence of vertebral compression fractures	0,018	Indefinite
Vertebral deformity	<0,001	Indefinite
Cervical localization	0,033	15
Age>60years	0,078	–
Long diagnostic delay	0,062	–
Initial neurologic damage	0,053	–

Conclusions: This study revealed that cervical localization in tuberculous spondylodiscitis, initial hyperleucocytosis, and the presence of abscess on MRI as well as vertebral compression fractures and vertebral deformity are associated with a bad outcome in OAT.

AB0920 TUBERCULOSIS OSTEOMYELITIS OF THE PUBIC SYMPHYSIS: REPORT OF TWO CASES

R. Sonia, S. Boussaid, I. Abdelkafi, S. Hela, C. Ilhem, E. Mohamed. *Rheumatology, la Rabta, Tunis, Tunisia*

Background: Infection of the symphysis pubis is a rare complication for less than 1% of cases of osteomyelitis. The predisposing causes reported are pelvic surgery, trauma and intravenous drug abuse. We report cases of osteomyelitis of the pubic symphysisdue to mycobacterium tuberculosis which is extremely
Results: The two patients were 47 and 75 year-old women. They were admitted because of three month's history of progressive perineal pain and a hypogastric mass without fever in the first case, and bilateral inguinal pain with limited flexion and rotation of the right hip in the second one. Blood tests showed an elevated erythrocyte sedimentation rate (ESR) of 27 mm and 75 mm. The leucocytes rates were at 5580/mm^3 and 6000/mm^3. Plain X-ray revealed irregularity and widening of the symphysis pubis. Tuberculin skin test was positivein one case and negative in the other. Chest radiograph was normal. The bacteriological cultures for tubercule bacillus in sputum and urines negative. The typhic and brucellian serological diagnosis as well as blood cultures were negative. CT scan showed irregular destruction and erosion of the pubic bone with a soft tissue mass. A biopsy of the symphysis was performed. Histologic examination of the bone material revealed a granulomatous inflammation with caseous necrosis confirming the diagnosis of tuberculosis. Anti-tuberculous treatment was prescribed and led to full recovery.
Conclusions: Tuberculosis is a major health problem in mediterranean countries,including Tunisia. These two cases present a timely reminder that tuberculosis should always be considered as part of the differential diagnosis of treatment of tuberculosis osteomyelitis of the pubic symphysis. Radiological investigations with plain X-rays, CT, MRI and bone scan are hepful. Treatment of tuberculous osteomyelitis of the pubic symphysis is based mainly on anti-tuberculous drugs.

AB0921 INFECTIOUS SPONDYLODISCITIS: EPIDEMIOLOGICAL, CLINICAL, PARACLINICAL AND THERAPEUTIC ASPECTS

A. Feki, R. Akrout, I. Sellami, M. Ezzeddine, H. Fourati, S. Baklouti. *Hedi Chaker Hospital, -Sfax, Tunisia*

Background: Spondylodiscitis is an infection of a disc and the two adjacent vertebrae due to the introduction of a pyogenic, usually by the haematogenous route. It's quite a rare disease accounting for 2–7% of all cases of septic osteomyelitis [1, 2].
Objectives: To study the clinical, microbiological, radiological, therapeutic and evolving of infectious spondylodiscitis
Methods: A retrospective descriptive study conducted over years in the department of rheumatology, including all patients with infectious spondylodiscitis. Clinical given were collected from paper patients records.
Results: We included 67 patients. There were 38 men and 29women. The mean age was 55 years. The male to female ratio was 38:29.Risk factors of spondylodiscitis were observed in 19 patients. The approximate time from onset of symptoms to diagnosis was from 3 to 365 days (median, 132 days). Back pain was the most common symptom. Spinal syndrome was found in all patients. The most frequent location of spondylodiscitis was lumbar spine. Signs of spinal cord compression including paraplegia or paraparesis of the lower limbs were observed in 31 patients. Pachymeningitis was associated in 1

case. The paravertebral abscess was associated to the disc involvement in 23 cases. Epiduritis was associated in 21 cases. Plain radiography, performed in in the majority of cases (63 cases, 94%), demonstrated pathological pictures in 56 (83.5%) patients. MRI, performed in 60 (89.5%) patients, disease was in all patients. Pathogens were isolated in 43 (64.1%) cases. Tuberculosis was the most common cause. The leading causative agents in non tuberculousspondylodiscitis were: Staphylococcus aureus (8 isolates, 11.9%), brucella (7 isolates, 10.4%), Escherichia coli (2 isolates, 2.9%) and streptococcus B (1 isolates, 1.4%).Two microorganisms combined (mycobacterium tuberculosis and a pyogenic) was found in one case. Medical treatment was adapted to the prescribed seed. Surgical treatment was performed in 6 patients. After therapy, 59 (88%) patients had regression of symptoms, two patients had a permanent neurological impairment (paraplegia), one patient had recurrence of infection and one patient was dead.

Conclusions: Infectious spondylodiscitis has been diagnosed with increasing frequency. It should be taken into consideration in differential diagnosis in patients with significant back pain and laboratory evidence of an acute inflammatory process, especially metastatic spinal disease or inflammatory spondyloarthritis

AB0922 CLINICAL MANIFESTATIONS AND OUTCOMES OF ACUTE SEPTIC ARTHRITIS IN SONGKLANAGARIND HOSPITAL: A 10-YEAR RETROSPECTIVE STUDY

T. Yaowmaneerat, D. Aiewruengsurat. *Internal Medicine, Prince of Songkhla University, Hadyai, Songkhla, Thailand*

Background: Septic arthritis is a rheumatologic emergency. Its delayed diagnosis and treatment cause joint morbidity and mortality.[1] Cases involving antimicrobial-resistant bacteria have been reported.[2,3]

Objectives: To determine the clinical manifestations and outcomes of septic arthritis, find the factors associated with mortality, and discover the incidence of drug-resistant organisms in our institution

Methods: A retrospective study was performed. Septic arthritis was defined as the presence of acute inflammatory arthritis indicated by a positive synovial fluid or synovial tissue culture for bacteria. A total of 116 septic arthritis patients, who visited Songklanagarind Hospital from January 2005 to December 2014, were reviewed.

Results: The patient median age was 58 (IQR: 46, 72). Sixty-one patients (52%) were female. The median onset of symptoms and symptoms until diagnosis were 5 (IQR: 2, 7) and 6 (IQR: 3, 10) days, respectively. Eighty-eight cases (76.7%) had underlying diseases that might predispose to joint infection. Sixty-nine cases (59.5%) had pre-existing joint disease. Joint pain was the most common presenting symptom, and 58% of the cases had fever. The most common presentation was monoarthritis (87%), which was predominantly associated (78%) with knee joint involvement. The median synovial fluid leukocyte counts were 64,460 cells/μL (IQR: 30,300; 129,000). Blood cultures were positive in 53 patients (49.1%). Synovial fluid cultures commonly had *Streptococcus spp.* growth (41%). Seven cases (7%) involved drug-resistant organisms. All of them either were diagnosed with septic arthritis during hospitalization or had a history of previous surgery. Twenty-five percent of the cases obtained the empirical antibiotic, ceftriaxone, and 86 patients (80%) underwent arthrotomy drainage. The mortality rate was 12%, and its associated factors were cancer, liver disease and advanced age.

Conclusions: *Streptococcus spp.* is an emerging cause of septic arthritis in Southern Thai patients. Physicians should be aware of this in patients presenting with fever and acute monoarthritis, particularly those with comorbidities and underlying joint diseases. The proper empirical antibiotic of choice is ceftriaxone.

Fibromyalgia

AB0923 MEETING THE FIBROMYALGIA CRITERIA HAS A NEGATIVE IMPACT ON TNF INHIBITORS EFFICACY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

A. Dantu[1,2], J. Michaud[2], M. Gauthier Prieur[1], F. Da Silva[1], S. Pouplin[2], T. Lequerre[2], O. Vittecoq[2], M. Verdet[1]. *[1]Rheumatology, Elbeuf Louviers Val de Reuil Hospital, Saint Aubin les Elbeuf; [2]Rheumatology, Rouen University Hospital, Rouen, France*

Background: Fibromyalgia and spondyloarthritis can coexist and the overlap between the two diseases could have consequences on TNF inhibitors efficacy.

Objectives: To evaluate TNF inhibitors efficacy in patients with axial spondyloarthritis fullfilling or not fibromyalgia criteria.

Methods: Prospective observational bicentric study on 25 patients who met ASAS 2009 axial spondyloarthritis criteria. Fibromyalgia was defined by ACR 2010 fibromyalgia criteria or by a ≥5/6 score of the Fibromyalgia Rapid Screening Tool. Following items were recorded before and after a 6 months treatment with TNF inhibitors: Visual Analog Scale for pain and for patient global disease activity, values of ESR and CRP, number of tender joints, MASES score, number of Yunus tender points. All patients filled a self-questionnaire with BASDAI, BASFI, FiRST and ACR 2010 fibromyalgia scale items using SSS and WPI. Criterion of judgment: an ASAS partial remission state was compared in patients with or without fibromyalgia.

Results: Of the 25 patients enrolled, 15 (60%) fulfilled ACR 2010 fibromyalgia criteria and 9 (36%) had a ≥5/6 FiRST score. The proportion of patients fulfilling an ASAS partial remission state was significantly lower in patients with fibromyalgia according to the ACR 2010 criteria (20% vs 70%, p=0,034) or to the FiRST score (0% vs 62,5%, p=0,0028). These patients had more severe disease activity and physical fonction than the patients without fibromyalgia. In this study, some factors were related with absence of ASAS partial remission: female gender, prior TNF inhibitor failure, ACR 2010 fibromyalgia criteria positivity, to have more than 11 Yunus points and to have a ≥5/6 FiRST score.

Conclusions: Meeting the fibromyalgia criteria might have an impact on ASAS partial remission state and on efficacy of TNF inhibitors in patients with axial spondyloarthritis. The FiRST score was more specific to predict an absence of ASAS partial remission than the ACR 2010 fibromyalgia criteria. TNF inhibitors should be used with circumspection in case of FiRST score ≥5/6 in patients with axial spondyloarthritis.

AB0924 THE ROLE OF SELF LIMITING BEHAVIOUR, DEPRESSION AND SLEEP IN THE SEVERITY OF FATIGUE IN PATIENTS WITH FIBROMYALGIA

M. Fernandes[1], M.P. Guzzo[2], C. Iannuccelli[2], L. Mallia[1], F. Lucidi[3], M. Di Franco[2], C. Violani[1]. *[1]Department of Psychology; [2]Department of Internal Medicine and Medical Specialties; [3]Department of Developmental and Social Psychology, "Sapienza" University, Rome, Italy*

Background: Fatigue and sleep disturbances are prominent symptoms in Fibromyalgia (FM) and significantly affect the level of the patients' impairment. Some studies reported a synergic interaction of depression and poor sleep quality associated with fatigue (e.g. [1]); while Marques et al. [2] showed a significant association of the fatigue severity with a limiting behaviour self-regulatory style of the patients, i.e. reducing daily activities and excessive resting.

Objectives: The purpose of this cross-sectional study was to analyse the predictors of severity of fatigue in Italian patients with FM.

Methods: Outpatients with a FM diagnosis who fulfilled both ACR/EULAR 1990 and 2010 criteria [3,4], after a medical visit at the Fibromyalgia center at Sapienza University Hospital "Umberto I", were invited to participate in a study on their cognitions and behaviours wearing for one week a wrist actigraph (AMI Motionlogger Watch). Actigraphic sleep parameters were averaged over six days. After 7 days the participants returned the actigraph and answered a structured interview conducted by a trained psychologist which included validated scales measuring depression (Brief Symptom Inventory [5]), perceived fatigue (Checklist of Individual Strength [6]), sleep habits (Sleep Disorder Questionnaire [7]) and behaviour regulation patterns (All-or-nothing and Limiting behaviour scales from Behavioural Responses to Illness Questionnaire [8]). In the previous month and during the study, pharmacological and non-pharmacological treatments were unchanged.

Results: Actigraphic monitoring and structured interview were completed by 39 female FM patients, with a mean age of 44.9 years (SD=8.55) and an illness mean duration of 6.5 years (SD=5.72). The majority of the patients reported insomnia complaints, and 29 (74.4%) met the DSM criteria for chronic insomnia. Fatigue severity resulted as the best subjective measure of fatigue, and was positively and significantly correlated with self-management through limiting behaviour, and with Total Time in Bed (TTB) measured through actigraphy. The correlation between TTB and Total Time Slept (TTS) and depression were not significant. Hierarchical regression considering TTB, Depression and Limiting behaviour, showed that all these variables give a significant independent contribution to the prediction

of perceived severity of fatigue (47% of variance): limiting behaviour (β=0.52, p<0.01), TTB (β=0.31, p<0.05), Depression (β=0.29, p<0.05).
Conclusions: These correlational findings suggest that self-regulation through limiting activity should be given priority attention in cognitive behavioural interventions aimed at reducing subjective fatigue.

AB0925 GENDER DIFFERENCE IN FIBROMYALGIA: COMPARISON BETWEEN MALE AND FEMALE PATIENTS FROM AN ITALIAN MONOCENTRIC COHORT

M.P. Guzzo[1], C. Iannuccelli[1], M.C. Gerardi[2], B. Lucchino[1], G. Valesini[1], M. Di Franco[1]. *[1]Dipartimento di Medicina Interna e Specialità Mediche, Sapienza Università di Roma, Rome; [2]Unità di Reumatologia, ASST-Fatebenefratelli Sacco – Polo Universitario, Milan, Italy*

Background: Fibromyalgia (FM) is one of the main causes of chronic widespread pain (CWP). It is characterized by CWP, which is the cardinal symptom, and the presence of more than 11 tender points (hyperalgesia). [1] Other symptoms such as fatigue, sleep disturbances, difficulties with memory and concentration, irritable bowel syndrome, headache, depression are frequent. Worldwide mean prevalence of FM is 2,7% with female/male ratio of 4:1. In Italy the prevalence is 3,7% with the same female/male ratio. [2]
Objectives: The aim of the study is to analyze clinical features of a cohort of male patients with CWP and to evaluate gender differences in patients diagnosed as FM.
Methods: The study population consisted of 101 consecutive male subjects referred to the Clinic for the Diagnosis and Therapy of Fibromyalgia, in the period between January 2007 and October 2016, matched with a control group of 101 females with CWP referred to the clinic in the same period. Complete clinical evaluation was performed in all patients.
Results: Ninety-seven male subjects (96%) were referred to the clinic for a history of musculoskeletal pain, among these 53% reported fatigue and 60% complained about sleep disorders. A stressful trigger (work or family problems, bereavement, infections) at the onset of pain was reported by 42% of patients. Fifty-two percent of patients reported mood changes. Physical examination showed hyperalgesia in 15% of the subjects and a mean tender points' (TP) count was 4.6 (range 0–18). The diagnosis of FM was performed according to ACR 1990 criteria, since the enrollment included patients referred to the clinic before the publication of the latest ACR criteria [3, 4]. Only 18 male subjects (18%) fulfilled the classifying criteria. In the female group CWP was reported by 97%, fatigue by 65%, and sleep disorders by 72% of patients. Stressful events were reported by the 50% of female population. Mood changes were described by 54% of female subjects and were predominantly depressive. Physical examination revealed hyperalgesia in 48 subjects (47%) and the mean TP count was 11 (range 0–18). The diagnosis of FM was confirmed in 60% of subjects. Comparing the two cohorts of patients with FM, mean age at the time of the visit and mean age of onset of symptoms resulted significantly higher in females than in males (p=0.02 and p=0.04 respectively). There was no statistically significant difference in the number of TP, in fatigue, sleep and mood disorders and in the percentage of stressors considered as a trigger for the disease. Hyperalgesia was the only feature more common in females than in males (p=0.03).
Conclusions: The significant higher frequency of hyperalgesia in women suggests a different presentation of CPW, that is the cornerstone of FM, in the two sexes. Moreover, the prevalence of FM was higher in females than in males when 1990 ACR criteria were used. It can be assumed that further gender differences could be showed applying 2010 ACR criteria.

AB0926 AUTONOMIC DYSFUNCTION IN FIBROMYALGIA MAY BE MEDIATED BY HYPERMOBILITY SYNDROME

D. Aslanyan[1], Z. Cipinova[2], N.A. Harrison[1], H.D. Critchley[1], K.A. Davies[1], J.A. Eccles[1]. *[1]BSMS; [2]BSUH, Brighton, United Kingdom*

Background: Neuropsychiatric symptoms are common in Fibromyalgia (FMS). FMS is associated with dysautonomia, particularly orthostatic intolerance, in which there is a phenomenological overlap with anxiety. FMS and dysautonomia are both associated with joint hypermobility (JHS).
Objectives: To investigate whether signs and symptoms of dysautonomia in FMS are mediated by JHS.
Methods: Eighteen patients with FMS (all female; mean age 41.06 years) and 19 controls (14 female; mean age 46.42 years) were recruited. JHS was assessed by Brighton Criteria. Multi-systemic symptoms suggestive of dysautonomia were quantified using Autonomic Symptoms and Quality of Life Scale (ASQoLS). Neuropsychiatric symptoms were formally quantified including anxiety level (BAI), depressive symptom level (BDI), panic disorder symptom severity (PDSS) and dissociative experiences (DES). All participants underwent autonomic function testing (9 minute tilt table with heart rate (HR) recording).
Statistical comparison between groups was performed using independent samples t test and chi squared as required, correlations were explored using pearson or spearman rho as appropriate. Formal mediation analysis was performed using the method of Baron and Kenny (1), which stipulates that a mediator variable must reduce the statistical relationship between the independent and dependent variable.
Results: FMS patients had significant objective features of dysautonomia including higher baseline HR (p=.001) and maximal HR during tilt (p=.002) compared to controls and reported significantly higher autonomic symptom burden (p=.001). Symptoms correlated with changes in physiology during autonomic challenge in patients (r=.536, p=.039), but not controls. Across the study anxiety score correlated with absolute change in pre-tilt and average HR during tilt (r=.483, p=.050) and symptoms of dysautonomia (r=.813, p=.001). Dysautonomia symptoms correlated with DES (r=.793, p=.001), PDSS (r=.742, p=.001), interoceptive sensibility (r=.627, p=.007) and BDI (r=.502, p=.040). There was a significant association between JHS and FMS (p=.001), but not generalized joint laxity. Across all participants, dysautonomia symptoms correlated with Beighton score (r=.353 p=.032) and JHS participants reported higher heart rates during autonomic challenge (p=.002) and greater symptom burden (p=.001). The significant relationship between autonomic symptoms and maximum HR during tilt was fully mediated by presence of JHS or FMS (Figure 1). JHS partially mediated the relationship between FMS and increased anxiety scores and fully mediated the relationship between FMS and maximum HR during tilt (Figure 2).

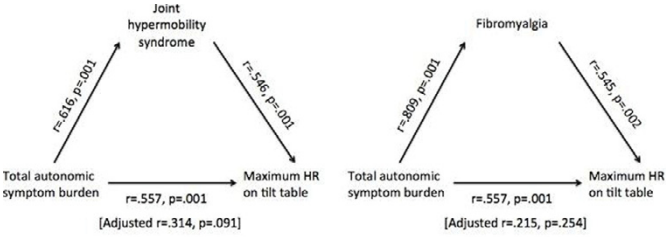

Figure 1: The significant relationship between autonomic symptoms and maximum HR during tilt was fully mediated by presence of JHS or FMS

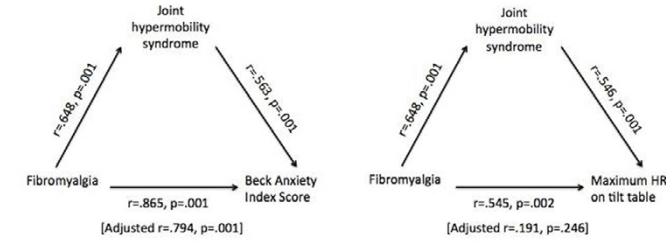

Figure 2: JHS partially mediated the relationship between FMS and increased anxiety scores and fully mediated the relationship between FMS and maximum HR during tilt

Conclusions: This study confirms that objective and subjective measures of dysautonomia are more common in FMS, and associated with JHS in this cohort, suggesting a common underlying mechanism which requires further exploration. We highlight the importance of assessing patients with FMS for both JHS and dysautonomia, which may inform further management of this often challenging condition.

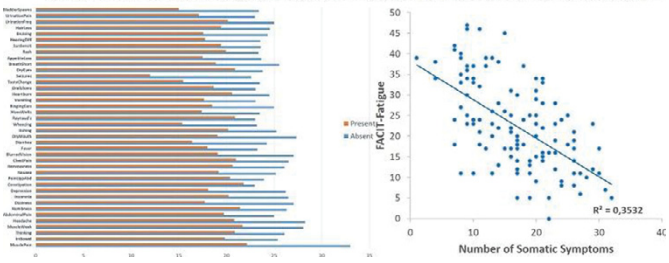
AB0927 RELIABILITY AND VALIDITY OF TURKISH VERSION OF FIBROMYALGIA PARTICIPATION QUESTIONNAIRE

L. Altan[1], R. Çeliker[2], I. Ercan[3], M. Birtane[4], K. Akgün[5], C. Zateri[6], N. Taştekin[7], A. Rezvani[8], I. Aktaş[9], S. Özdolap[10], E. Dursun[11], N. Dursun[11], S. Sarıkaya[10]. *[1]Physical Medicine and rehabilitation, Uludağ University Medical Faculty, Bursa; [2]Physical Medicine and rehabilitation, Acibadem University, Faculty of Medicine, Istanbil; [3]Uludağ University Medical Faculty, Bursa; [4]Trakya University, Faculty of Medicine, Edirne; [5]Istanbul University, Cerrahpaşa Faculty of Medicine, Istanbul; [6]Physical Medicine and rehabilitation, Canakkale Onsekiz Mart University, Faculty of Medicine, Çanakkale; [7]Physical Medicine and rehabilitation, Trakya University, Faculty of Medicine, Edirne; [8]Physical Medicine and rehabilitation, Bezmialem University, Faculty of Medicine; [9]Physical Medicine and rehabilitation, Fatih Sultan Mehmet Teaching and Research Hospital, Istanbul; [10]Physical Medicine and rehabilitation, Bulent Ecevit University, Faculty of Medicine, Zonguldak; [11]Physical Medicine and rehabilitation, Kocaeli University, Faculty of Medicine, Kocaeli, Turkey*



Background: Fibromyalgia (FMS) is a chronic health problem characterized by a wide range of physical and psychological symptoms. There are few high-quality instruments to evaluate the participation and social functioning of fibromyalgia patients. Farin et al. designed the Fibromyalgia Participation Questionnaire (FPQ) as an instrument for measuring the participation and social functioning of FMS patients. The original version of FPQ has been demonstrated to have acceptable internal consistency, reliability and criterion validity.
Objectives: To test reliability and validity of Turkish version of Fibromyalgia Participation Questionnaire (FPQ-T)
Methods: One hundred and eighty-four female fibromyalgia syndrome patients were included in the study. All patients filled FPQ-Turkish (FPQ-T) questionnaire which was obtained by translation from German according to the guideline for the cross-cultural adaptation process.
The patients filled the revised Fibromyalgia Impact Questionnaire (FIQ) and reevaluated FPQ-T two hours later. Internal consistency reliability of FPQ-T was assessed by calculating "if item deleted" using Cronbach alpha and "item-total correction" coefficient for each item of the questionnaire. Consistency of sub-scales and correlation of test-retest values were assessed. Test-retest values were compared using Wilcoxon test. Criterion validity was measured using FIQ scales by Spearman's rho correlation coefficient.
Results: For internal reliability, Cronbach alpha coefficient was calculated as 0.957 for non-working and 0.958 for working patients. Cronbach alpha values of 0.939, 0.871, and 0.914 were obtained for daily, social, and work life, respectively. Correlation coefficients were 0.888 for daily life, 0.859 for social life, and overall 0.901 in non-working group versus 0.896 in working group. Comparison of scores obtained from test-retest measurements showed no significant difference except for Item-3. Correlation of symptom severity score (SSS) and FPQ-T were r=0.385 ($p<0.001$) and r=0.390 ($p<0.001$) for the non-working and working sub-groups, respectively. Construct validity evaluation showed significant correlation between SSS and FPQ-T.
Conclusions: The results of our study showed that FPQ-T is reliable and valid for assessing participation and social functioning in fibromyalgia patients in our society.

AB0928 FATIGUE IN FIBROMYALGIA REFLECTS OVERALL BURDEN OF DISEASE

M. Antivalle, A. Batticciotto, F. Rigamonti, M.C. Ditto, M.C. Gerardi, R. Talotta, A. Mutti, P. Sarzi-Puttini. *Rheumatology, L. Sacco University Hospital, Milano, Italy*

Background: Fatigue in fibromyalgia is a very common and disabling symptom, being reported by over 75% of patients. However, the relationship between fatigue and the different manifestations of fibromyalgia has not been convincingly elucidated.
Objectives: Aim of the our work was to study the relationship between fatigue, pain, and somatic symptoms in fibromyalgia.
Methods: 123 patients with fibromyalgia classified according to 2010 criteria were studied, 113 Females and 10 Males, mean age 47.41±11.21 years, mean disease duration 6.83±6.52 years. Fatigue was assessed by FACIT-Fatigue questionnaire (13 items, score 0–52, higher values representing less fatigue), and results were correlated to the number of Tender points (TP), to Widespread Pain Index (WPI), to Symptom severity Scale (SSS), and to Polysymptomatic Distress Scale (PDS) values. Correlations were computed by parametric or non parametric methods as appropriate.
Results: Average FACIT-Fatigue score (22.51±10.6) was lower than the 25th percentile of the general population (35), and was not correlated to age or to disease duration ($p>0.05$). FACIT-Fatigue showed statistically significant inverse

Fig. 1. Left panel: FACIT-Fatigue score according to the presence or absence of individual somatic symptoms. Right panel: Correlation between FACIT-Fatigue score and the number of reported somatic symproms.

correlations with the number of tender points (r = -.303, p=0.001), WPI score (r=-0.329, $p<0.001$), SSS score (r=-0.651, $p<0.001$), PSD score (r=-0.522, $p<0.001$), and with the total number of somatic symptoms (r=-0.594, $p<0.000$) (Fig. 1, right panel). Furthermore, for each of the 40 somatic symptoms suggested by 2010 criteria, the presence of the symptoms was associated with higher levels of fatigue (Fig 1, left panel).
Conclusions: The results of our study confirm that fatigue is a prominent feature of fibromyalgia. Higher levels of fatigue reflect higher levels of widespread pain, and a higher burden of somatic symptoms.

AB0929 BALANCE IN FIBROMYALGIA IS NOT RELATED WITH LOWER LIMB STRENGTH

P. Serra-Añó, M. Aguilar-Rodríguez, S. Cortés-Amador, G.V. Espí-lópez, N. Sempere-Rubio. *Physical Therapy, University of Valencia, Valencia, Spain*

Background: Postural control, that depends on many sensory contributors and motor skills, is altered in people with fibromyalgia (FM) [1–3]. Knowing those contributors that could be impaired in this population is important to design an appropriate balance therapy.
Objectives: Due to the fact that people with FM use to present a strength loss [7], our main goal was to explore the relation between postural control and lower limb strength in this population. Further, the sensory inputs contributors to the postural control were assessed.
Methods: A cross-sectional study was conducted in a sample of 40 FM patients. A force platform was used to assess postural control under five bipedal conditions: i) eyes-open (EO); ii) dual task (recalling a typical day in their life) (DT); iii) eyes-close (EC); iv) eyes-open over a foam (FEO); v. eyes-close over a foam (FEC). Three variables, "Ellipse", "RMS" and "Sample Entropy" (SampEn), were recorded (for both directions). Further, maximal quadriceps (qdc) and hamstring (hmsg) isometric strength were assessed using a dynamometer. Spearman correlations were conducted to establish the relationship between postural control and strength and a repeated-measures MANOVA, to analyze differences between conditions.
Results: When EO and DT (performed with eyes open) were compared, no significant differences were obtained. However when patients closed their eyes, an increase in ellipse and RMS_AP and a decrease in variability were obtained. The same was true when the tests were performed over a foam (altering proprioception), Table 1.

Table 1. Comparison of sensory inputs results

	Ellipse (mm^2)	RMS_AP (mm)	RMS_ML (mm)	SampEn_AP	SampEn_ML
EO	295.66 (460.93)	5.58 (3.66)	2.46 (2.30)	0.74 (0.14)	0.90 (0.10)
DT	388.92 (530.23)	5.77 (4.22)	2.79 (2.18)	0.67 (0.15)	0.86 (0.13)
EC	508.18 (801.69)[1]	6.77 (3.94)[12]	3.08 (2.04)	0.65 (0.15)[1]	0.85 (0.14)[1]
FEO	815.32 (981.44)[123]	7.63 (4.19)[12]	4.81 (3.04)[123]	0.61 (0.14)[12]	0.79 (0.10)[123]
FEC	1425.54 (1291.53)[1234]	10.87 (4.20)[1234]	6.48 (2.95)[1234]	0.53 (0.11)[1234]	0.69 (0.13)[1234]

EO: eyes-open; DT: dual task; EC: eyes-close; FEO: Eyes-open over a foam; FEC: Eyes-close over a foam; Superscript 1, 2, 3, 4: Significant differences with test 1, 2, 3 and 4, respectively ($p<0.05$).

Furthermore, no significant correlations ($p>0.05$) were observed between strength and balance except for a weak significant correlation between hmsg strength and RMS_AP ($r_s=-0.33$, $p<0.05$) in the EC test.
Conclusions: Postural control worsens in FM people when some sensory inputs are altered or missed. Further, there is no correlation between lower limb strength and balance in this population.

AB0930 CROSS-SECTIONAL ANALYSIS OF THE AUTONOMIC NERVOUS SYSTEM (HEART RATE VARIABILITY): CORRELATIONS WITH PSYCHOLOGICAL DIMENSIONS IN WOMEN WITH FIBROMIALGIA, RHEUMATOID ARTHRITIS AND HEALTHY CONTROLS

T.L. Santiago, D. Peixoto, C. Costa, J.A. Pereira da Silva. *Rheumatology, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal*

Background: Autonomic nervous system (ANS) dysfunction has been proposed to play a role in the pathophysiology and maintenance of rheumatic diseases, including fibromyalgia (FM) and rheumatoid arthritis (RA). Heart rate variability (HRV) analyses provide a quantitative marker of ANS activity. Some studies suggest an association between reduced HRV parameters and psychological dimensions, namely a negative emotional state. This led us to hypothesize an association between rheumatic diseases and higher sympathetic activity mediated by a negative emotional state.
Objectives: To establish correlates between HRV parameters with rheumatic disease groups and psychological dimensions.
Methods: Sixty women (FM, *n*=20; RA, *n*=20; healthy controls (Ct), *n*=20) completed a self-reported questionnaire addressing demographic characteristics, the Eysenck Personality Questionnaire, the Hospital Anxiety and Depression Scale, and the Beck Depression Inventory-II (BDI-II).
HRV analysis was performed by photopletismography between 8:00 and 10:00am, after an overnight fast, in a sitting position, for 5-minutes. We obtained the time and frequency-domain indices of HRV, including SDNN (standard deviation of the NN intervals), RMSSD (root-mean square differences of successive R-R intervals), high frequency power (HF), low frequency power (LF) and very low frequency (VLF). LF/HF ratio reflects sympathetic to parasympathetic balance.
Statistical analysis were performed considering: A) Rheumatic disease groups (FM/RA/Ct), and B) Psychological scores (irrespective of disease group): higher versus lower tertile in the personality questionnaires and score above (depression) versus below 20, in BDI-II. Between-groups comparisons were performed with Kruskal-Wallis test and analysis of covariance (age was adjusted during analyses), as appropriate.
Results: Neuroticism, anxiety and depression scores were significantly higher in FM and RA patients compared with controls ($p<0.05$). However, no statistically significant difference was observed in HRV parameters between disease groups. No statistically significant difference was observed in HRV parameters between tertile groups for psychological dimensions, except for depression. The values of HF power (parasympathetic activity) were lower in the high depression group compared to the low depression group ($p<0.05$). The ratio of LF/HF was higher among the depression group than the control group ($p<0.05$).
Conclusions: This study did not found significant differences in the HRV between the three rheumatic disease groups. The results confirm that depression is accompanied by dysfunction of the autonomic nervous system, specifically lower parasympathetic activity. These results suggest that psychological dimensions, namely depression, must be taken into account when evaluating the ANS and its impact in disease pathogenesis.

AB0931 EFFECTS OF MANUAL THERAPY ON PAIN, POSTURE, FLEXIBILITY, QUALITY OF SLEEP AND DEPRESSIVE SYMPTOMS IN FIBROMYALGIA SYNDROME

T. Duymaz[1], G. Sakınç Toprak[2]. *[1]Physiotherapy and Rehabilitation, Istanbul Bilim University, Şişli-Istanbil; [2]Physiotherapy and Rehabilitation, Acıbadem Hospital, Izmit-Kocaeli, Turkey*

Background: Fibromyalgia syndrome (FMS) is a chronic musculoskeletal pain condition characterized by widespread and a constellation of other symptoms.
Objectives: The purpose of this study was to investigate the therapeutic effects of a Manual Therapy (MT) protocol for improving pain, posture, flexibility, tender points, impact of FMS symptoms, sleep quality and depressive symptoms with FMS.
Methods: Patients completed demographic information, a number of self-report measures including Visual Analog Scale for assessing pain, Fibromyalgia Impact Questionnaire, the Pittsburgh Quality of Sleep Questionnaire Index and the Hospital of Anxiety and Depression Scale.The patients underwent a protocol of MT for a 60-minute session for 3 weeks (5/wk). The protocol was as the following release and mobilisation. All analyses were performed with the SPSS (version 22.0)statistical program
Results: 16 women,3 men patients who had FMS were treated with MT.Demographic variables of the participants are provided in Table 1.While there was a favorable change in all measurement parameters after treatment ($p<0.001$).There was a statistically significant difference between before and after the treatment measurement parameters (Table 2)

Table 1.Demographic variables of the participants

Variables	Mean ±SD (min-max)
Age (year)	36.05±8.16 (20–58)
BMI (kg/m^2)	24.19±4.16 (19.49–33.06)
Duration of symptoms (year)	4.81±2.41 (1–9)

Conclusions: This study found that the application of a MT protocol was effective for improving pain, posture, flexibility,tender points, impact of FMS symptoms, sleep quality and depressive symptoms in individuals with FMS.

AB0932 PREVALENCE OF TYPE D PERSONALITY IN TURKISH PATIENTS WITH FIBROMYALGIA SYNDROME

Y. Garip[1], T. Guler[1], O.B. Tuncer[2], S. Onen[3]. *[1]Physical Medicine and Rehabilitation, Ankara Numune Training and Research Hospital, Ankara; [2]Physical Medicine and Rehabilitation, Medipol University Medical School, Istanbul; [3]Psychiatry, Sevket Yılmaz Eğitim ve Araştırma Hastanesi, Bursa, Turkey*

Background: Type D personality is a distressed personality type involving two personality traits, namely negative affectivity and social inhibition, which are described as tendency to experience negative emotions and to inhibit self-expression in social relationships, respectively (1).
Objectives: The present study investigated the prevalence of type D personality in Turkish patients with fibromyalgia (FM) and evaluated the association between type D personality and clinical parameters of FM. Although there is adequate number of studies focusing on the relation between FM and psychological conditions such as depression and anxiety; this topic has been rarely addressed in the literature.
Methods: A total of 100 patients with FM fulfilling 1990 American College of Rheumatology (ACR) diagnostic criteria and 50 healthy controls were included. Type D personality was assessed by Type D Scale-14 (DS-14). FM disease severity was determined by Fibromyalgia Impact Questionnaire (FIQ), functional status by Stanford Health Assessment Questionnaire (HAQ), and health-related quality of life (HRQoL) by Nottingham Health Profile (NHP). Severity of pain and fatigue were measured by Visual Analog Scale (VAS).

Abstract AB0931 – Table 2. Comparison of before and after treatment in all measurement parameters

Variables	Before Treatment Mean ± SD (min–max)	After Treatment Mean ± SD (min–max)	z	p
Number of tender points	12.10±1.24 (10–15)	7.31±2.26 (2–11)	-3.840	0.000**
VAS at night	6.84±1.30 (3–9)	0.91±0.64 (0–2)	-3.843	0.000**
VAS in activity	7.31±1.24 (4–9)	1.11±0.81 (0–2.20)	-3.850	0.000**
VAS in rest	6.42±1.46 (3–9)	0.49±0.81 (0–2.40)	-3.834	0.000**
Distance of Tragus-Wall (cm)	12.08±1.95 (9–17)	10.72±1.90 (8.20–15.60)	-3.529	0.000**
Distance of processus spinosus-Skapula (cm) (R)	10.65±3.03 (6.50–17)	10.26±2.76 (7–15)	-2.007	0.045*
Distance of processus spinosus-Skapula (cm) (L)	11.21±3.17 (7–17)	10.26±2.76 (7–15)	-2.842	0.004**
Trunk Lateral Flexion (°) (R)	36.47±3.35 (30–41)	37.00±3.39 (30–41)	-1.821	0.069
Trunk Lateral Flexion (°) (L)	33.47±4.01 (27–41)	36.68±3.28 (30–41)	-3.534	0.000**

FIQ	56.25±18.74 (19.79–85.58)	46.39±17.99 (19.59–67.98)	-3.724	0.000**
HAD-A	10.89±3.91 (5–19)	4.73±3.49 (0–10)	-3.849	0.000**
HAD-D	9.78±3.29 (2–15)	5.05±2.06 (0–9)	-3.632	0.000**
PSQI	10.52±3.40 (5–15)	3.63±2.47 (0–8)	-3.830	0.000**

Wilcoxon Test. *p<0.05; **p<0.001.VAS: Visual Analog Scale;FIQ: Fibromyalgia Impact Questionnaire; HAD-A: Hospital Anxiety and Depression-Anxiety; HAD-D: Hospital Anxiety and Depression-Depression; PSQI: Pittsburgh Quality of Sleep Questionnaire Index.

Results: Prevalence of type D personality was 33% in FM patients, and 12% in controls. It was higher in the patients with FM (Odds ratio (OR) =3.612 confidence interval (CI) 95% (1.398–9.333)) ($p<0.01$) compared with controls. Type D FM patients scored higher in tender point count (TPC), FIQ, HAQ, VAS-pain and all NHP subgroups except energy ($p<0.01$) (Table 1). Type D personality was found as correlated with FIQ, TPC, HAQ, VAS-pain and NHP subgroups except energy ($p<0.01$).

Table 1. The comparison of clinical variables and HRQoL between type D and non-type D patients

	Type D FM patients (*n*=33) mean ± standard deviation	Non-type D FM patients (*n*=67) mean ± standard deviation	*p* value
Pain (VAS,10 cm)	8.55±0.75	5.80±1.19	<0.00001*
Fatigue (VAS,10 cm)	4.45±3.18	4.01±3.54	0.549
TPC	15.72±2.33	12.91±1.84	<0.00001*
FIQ	86.27±8.43	64.07±11.47	<0.00001*
HAQ	1.24±0.80	0.52±0.51	<0.00001*
NHP-pain	89.17±10.73	64.33±14.07	<0.00001*
NHP-physical mobility	53.41±16.91	22.57±21.01	<0.00001*
NHP-energy	45.45±42.13	37.31±41.14	0.358
NHP-sleep	80.00±19.36	56.23±22.55	<0.00001*
NHP-social isolation	60.60±37.24	15.52±25.06	<0.00001*
NHP-emotional reactions	83.71±14.14	51.52±25.06	<0.00001*

HRQoL: Health-related quality of life, FM: Fibromyalgia, VAS: Visual analog scale, TPC: Tender point count, FIQ: Fibromyalgia Impact Questionnaire, HAQ: Stanford Health Assessment Questionnaire, NHP: Nottingham Health Profile. *$p<0.01$ (significant).

Conclusions: Type D personality is prevalent among Turkish patients with FM, with a rate of 33%. It is associated with poor HRQoL regarding pain, physical mobility, sleep, and social and emotional functions. Based on our findings, assessment of personality characteristics of the patients with FM may hold the key for the treatment of the disease. Presence of type D personality should be taken into account in FM in order to develop new treatment strategies for the patients who have inadequate response to conventional therapies.

Back pain, mechanical musculoskeletal problems, local soft tissue disorders

AB0933 PREDICTIVE MODEL FOR SHOULDER PAIN USING CLINICAL AND EPIDEMIOLOGICAL VARIABLES

C. Feced Olmos [1], E. Labrador Sánchez [1], J. Ivorra Cortes [1], E. Grau Garcia [1], E. Vicens Bernabeu [1], J.J. Fragio Gil [1], R. González Mazarío [1], C. Alcañiz Escandell [1], I. Cánovas Olmos [1], I. Chalmeta Verdejo [1], L. Gonzalez Puig [1], I. Martínez Cordellat [1], C. Nájera Herranz [1], R. Negueroles Albuixech [1], J.E. Oller Rodriguez [1], F.M. Ortiz-Sanjuan [1], D. Hervás Marín [2], J.A. Román Ivorra [1,3].
[1] Rheumatology Department, HUP la Fe; [2] Biostatistics Unit, IIS la Fe; [3] Medical School, UCV, Valencia, Spain

Background: Shoulder pain is a very common complaint with poor prognosis and high recurrence. To evaluate the shoulder pain, anamnesis and physical examination are used, but a diagnosis of certainty is difficult. Clinical history and specific exploration maneuvers tend to be poorly correlated with the underlying problem. There are few studies that assess the predictability of shoulder pathology using patient characteristics and exploration.

Objectives: To assess if the combination of exploratory maneuvers and clinical data predicts the type of affection of the painful shoulder in a sensitive and specific way.

Methods: We conducted a prospective study with patients who attended to the Rheumatology Department of HUP La Fe by painful shoulder between February 2016 and January 2017, excluding those with known inflammatory diseases. A rheumatologist performed the anamnesis and the selected exploratory maneuvers: Jobe and Gerber test and palpation of the acromioclavicular joint. A second rheumatologist, blind to physical examination and medical history, performed the shoulder ultrasound scan. Biostatistic analysis was performed using software R version 3.3.2.

Results: 119 patients (66.4% women) with a mean age of 60±12.56 years and shoulder pain were collected. Time of pain evolution was 20.43±24.09 months and the right shoulder was the most affected one (71.4%). The association between the maneuvers of Jobe and the involvement of the supraspinatus (SE), as well as the Gerber maneuver with the affectation of the subscapular were statistically significant. However the sensitivity and specificity of both maneuvers are very low, so that alone is not suitable to identify the affected tendon or the type of alteration. Thus, a predictor model (nomogram) of the most common shoulder pathologies (subacromiodeltoid bursitis, tendinosis or SE tears) was developed using epidemiological and clinical examination variables.

Conclusions: Based on our results, the predictor model performed using epidemiological and clinical examination variables would be able to predict the most frequent pathologies of the shoulder. Imaging tests have a certain delay time, and by applying this predictor model, a diagnosis of presumption could be established in primary care, giving the opportunity to institute an early treatment. In addition, patients could be referred more efficiently to the appropriate specialty (rheumatology, traumatology or rehabilitation), avoiding delays.

AB0934 TREATMENT OF LATERAL EPICONDYLITIS WITH ESWT: A SHAM-CONTROLLED DOUBLE BLINDED RANDOMISED STUDY

E.A. Gokmen [1], O. Karatas [2], E. Gilgil [3]. *[1] Physical Medicine and Rehabilitation, Antalya Training and Research Hospital; [2] Physical Medicine and Rehabilitation, Korkuteli Public Hospital; [3] Physical Medicine and Rehabilitation, Akdeniz University Hospital, Antalya, Turkey*

Background: Lateral epicondylitis is a term describing the clinical condition that causes pain and sensitivity in musculotendinous adhesion sites of the wrist extensor muscles originating from the lateral epicondyle of the humerus, resulting in repetitive stresses due to overuse (1,2).

Objectives: The aim of this study was to investigate the efficiency of extracorporeal shockwave therapy (ESWT) in the treatment of lateral epicondylitis as randomized, prospective, controlled and double blind.

Methods: 47 patients (35 women, 12 men) with lateral epicondylitis were included in the study. The mean age of patients was 45.94±10.46 years. Patients were randomized into two groups: active ESWT (n=22) and *sham* ESWT (n=25). Patients were randomly allocated to receive 1 session per week for 3 weeks of either sham or active ESWT.

Patients were evaluated before the treatment, and at the end of the first week, first month and third month after the last treatment session with Patient-rated Tennis Elbow Evaluation Questionnaire (PRTEE), Visual Analogue Scale (VAS) for pain assessment and physical examination of lateral epicondyle of the elbow with special clinical tests.

Results: Compared with pretreatment values in ESWT group, significant improvement was observed in all parameters after treatment. At the first week after the therapy significant improvement was observed in *sham* group but at the first and third month after the therapy no significant difference was found. In comparison of ESWT and *sham* over 3 months after the treatment, significant improvements were observed in ESWT group in all parameters.

Conclusions: there was a significant decrease in pain and a significant improvement in function following ESWT. Although there was a reduction in pain and improvement in function with sham treatment as well, this difference was not as significant as in active group.

AB0935 THE ROLE OF EPIDURAL INJECTIONS IN PATIENTS WITH CHRONIC SCIATICA: A REVIEW BASED ON THE EVIDENCE OVER THE PAST 5 YEARS

G. Ferreira Dos Santos, M. Amaral Silva, E. Marques, M. De Fátima Carvalho.
Physical and Rehabilitation Medicine Department, Hospital de Curry Cabral - Centro Hospitalar de Lisboa Central (CHLC), Lisbon, Portugal

Background: Among various modalities applied in the management of painful conditions of the spine, epidural injections (EI) are one of the most commonly utilized interventions. EI can be administered in the lumbar spine by either caudal (CEI), interlaminar (IEI), or transforaminal (TEI) approaches and various steroids have been used in these injections[1,2]. The purpose of EI is to provide analgesia for a varying duration, whilst making it easier for the patient to undergo a rehabilitation program during this time[1].

Objectives: The aim of this review is to evaluate the efficacy of the different types of EI in patients suffering from chronic sciatica, based on the evidence published over the past 5 years.

Methods: Relevant studies were retrieved by searching PubMed, Medline, The Cochrane Library and UpToDate. Publications from 2012 to 2016 which specified the use of EI to treat chronic sciatica were considered, and all the studies selected were written in the English language only.

A total of 11 articles were gathered, of which 5 were excluded after analysis of their title and abstract. Of the 6 papers included in this study, 5 are systematic reviews and 1 is a meta-analysis of 10 randomized controlled trials.

The outcomes measured were improvement in pain and functional status. The Numeric Rating Scale (NRS) and Visual Analogue Scale (VAS) were the most commonly used baseline scales for pain evaluation. The Oswestry Disability Index (ODI) was the most used scale for the functional disability scoring system in the literature.

Results: 4 of the 6 papers included in this review reported improvements in pain ranging from 30 to 83% and in functional status ranging from 26 to 86% from the pre-injection state, with follow-up periods lasting up to 2 years after the EI. 2 of these 4 studies showed Level II evidence for EI for long-term efficacy in managing chronic sciatica, with no significant difference among CEI, IEI or TEI.
The remaining 2 papers (out of the total 6) associated EI with immediate improvements in both pain and function, but found the benefits to be unsustained. 1 paper reported 1 serious adverse event in one of the trials analyzed and found the data on harms to be sparse on most trials. Another paper concluded that injecting local anesthetic alone might be preferable to injecting local anesthetic with steroid as omitting the steroid could lessen the risk of rare, but possibly fatal complications.
Conclusions: Despite variability in the studies included and methods used for data synthesis, most of the articles included in this review showed positive results for both pain relief and improvement in functional status with EI.
Although no studies found significant difference among CEI, IEI or TEI in terms of efficacy, each approach has its advantages and these should be taken into account when choosing the best approach for each patient.
As supporting evidence, this review shows that EI with or without steroids are a fast, safe and clinically effective treatment method for patients with chronic sciatica.

AB0936 FLEXIBILITY AND STRENGTH OF THE TRUNK IN CHRONIC LOW BACK PAIN TWO YEARS AFTER A FUNCTIONAL RESTORATION PROGRAM

R. Maaoui[1,1], S. Zrida[1], I. Ksibi[1], N. Mouhli[1], H. Rahali[1], M. Sghir[2], W. Kossomtini[2]. *[1]Physical and Rehabilitation Medicine, military hospital Tunis, tunis; [2]Physical and Rehabilitation Medicine, regional hospital Tahar Sfar of Mahdia, Mahdia, Tunisia*

Background: Low-back pain affects significatively the flexibility and the muscular strength of the trunk. It was demonstrated in literature the positive effect of restoration programs in these parameters at short-term evaluation.
Objectives: Evaluate the flexibility and the muscular strength and endurance of the trunk two years after a functional restoration program
Methods: Prospective study on patients with low back pain evaluated before, at the end of the restoration program and two years later. We have evaluated the following parameters: trunk flexibility by use of the Schöber index and the finger–ground distance test (FGD), hamstring flexibility by measurement of the thigh-leg (TL) angle, back flexor and back extensor endurance, assessed with the Shirado test and the Sorensen test, respectively.
Results: Thirty patients were evaluated. Initially, the results reported decreased flexibility: 53% with FGD >15.53 cm; 37% with the thigh-leg (TL) angle >15° and decreased muscle endurance: Schirado 30.26±29.662s; Sorensen 26.3860±18.5208s. The short-term efficacy of the program showed significatively improvement in all parameters (p=0,01). However, this improvement decreased 2 years later but it remains significant. This loss can be attributed to the fact that 70% of patients abandoned self-rehabilitation exercises
Conclusions: The restoration program seems to have good effect in short and long term evaluations in the flexibility and muscular strength of the trunk.

AB0937 DUPUYTREN'S CONTRACTURE: 15 YEARS OF EXPERIENCE WITH 36 CASES

H. Mouanaa, M. Jguirim, A. Arfa, A. Farhat, M. Brahim, A. Mhenni, Z. Saoussen, I. Bejia, M. Touzi, N. Bergaoui. *Rheumatology Unit of the Monastir University Hospital, Monastir, Tunisia*

Background: Dupuytren's contracture is characterized by thickening and retraction of the palmar aponeurosis due to fibroblastic proliferation leading to progressive and irreducible fingers' flexion. Dupuytren's contracture appears to be a disease with poor clinical symptomatology and the therapeutic progress, in particular the needle aponeurotomy, continues to increase.
Objectives: We propose to describe the epidemiological, clinical and therapeutic characteristics- particularly the needle fasciotomy- of Dupuytren's contracture diagnosed and treated in our Rheumatology department.
Methods: This is a retrospective descriptive study that collected patients with Dupuytren's disease over a 15-year period from 2001 to 2016.
Results: Thirty-six patients were collected. The mean age was 63±10 years (46 years, 83 years) and the sex ratio was 5. 34% of the patients were manual workers, of whom 42% were masons, 25% were farmers and 17% were carpenters. 8% Of longshoremen and 8% of dressmakers. The personal history was diabetes in 63% of cases, of which 26% were unbalanced, hypertension in 31% of cases and hypercholesterolemia in 14% of cases. 6% of patients were epileptic. 23% of patients were ethyl and 13% were smokers. 6% had an associated Leddherhose disease. 9% of our patients had a family history of Dupuytren's disease. The mean time to diagnosis was 60 months [03 months to 180 months]. The clinical examination showed an exclusive involvement of the left hand in 22% of cases, right hand in 12% of cases and bilateral involvement in 66% of cases. The fingers affected were: 59% the ring finger, 49% the little finger, 23% the middle finger, 12% the index and 5.5% the inch, in order of frequency of mention. The stages of Dupuytren's disease at their discovery were as follows: stage 4 (25%), stage 3 (34%), stage 2 (24%) and stage 1 (17%). Skin examination showed that 58% of the skin was inflicted and 42% of the skin was soft. From a therapeutic point of view, 86% of the patients benefited from a needle aponevrotomy with a good progression in 97% and a recurrence in 8% of the cases. In all stages combined, the average postoperative therapeutic gain was 0.83 stage at the Left hand and 1.43 stage at the right.
Conclusions: The Dupuytren's contracture is the object of a scientific subject whose wealth grows exponentially. These range from the paternity of his first description, to the place of the last therapeutic modalities.

AB0938 AN ATYPICAL CASE OF SARCOIDOSIS REVEALED BY A BILATERAL PREPATELLAR BURSITIS

J. Perrier-Cornet[1], R. Ouichka[1], S. Moawad[2], I. Chary-Valckenaere[1]. *[1]Rheumatology; [2]Dermatology, CHU Nancy, NANCY, France*

Background: Prepatellar bursitis is not very frequent in daily practice and the main causes are infections, crystal arthropathies or trauma.
We report the case of a 49-year-old man presented to our department with bilateral anterior knee pain. Pain started 3 months ago without any triggering factor. He denied any trauma or infection. The patient also denied any history of gout, rheumatoid arthritis or systemic lupus.
Objectives: On clinical exam, bilateral knee swellings were noticed consistent with prepatellar bursitis with no wound or abrasion, no fever, signs of arthritis or lymphadenopathy.
Methods: Knee ultrasonography and skeletal scintigraphy confirmed symmetrical prepatellar bursitis. Laboratory findings showed elevated ESR and CRP but no other abnormalities.
Few days later, the patient presented with subcutaneous painful nodules that appeared on his forearms. Biopsy was done and showed deep subcutaneous sarcoid nodules of Darier-Roussy, confirming the diagnosis of sarcoidosis.
Further work up revealed typical sarcoid pulmonary involvement. Bilateral hilar and mediastinal lymphadenopathy with beaded appearance of interlobular septa were noticed on CT-scan of the chest.
The Positron Emission Tomography showed abnormally high ^{18}F-fluorodeoxy glucose uptake in the thoracic lymph nodes.
Results: All the diagnostic work up confirmed the diagnosis of systemic sarcoidosis. The decision was to start oral corticosteroids. Few days after starting the systemic steroids, the skin lesions and the knees pain improved significantly.
Conclusions: The conclusion is that after excluding the main causes of bursitis (infection, trauma and inflammatory arthritis) (1), it's necessary to keep in mind sarcoidosis as possible diagnosis.
This clinical observation is important because involvement of the bursa is a rare musculoskeletal manifestation of sarcoidosis (2). Moreover, it's very uncommon to diagnose sarcoidosis presenting with just bilateral prepatellar bursitis with no other musculoskeletal or rheumatological symptoms (3).
The association of bursitis, inflammatory skin lesions and thoracic lymphadenopathy is uncommon but may suggest the diagnostic of sarcoidosis.

AB0939 CHANGE IN THE SURGICAL TREATMENT FOR CERVICAL SPINE DISORDERS RELATED TO RHEUMATOID ARTHRITIS DURING RECENT 15 DECADES

K. Sakuraba, K. Kai, H. Miyahara. *National Hospital Organization Kyushu Medical Center, Fukuoka, Japan*

Background: Since the appearance of biological DMARDs in Japan, disease control of rheumatoid arthritis has been ameliorated. Inflamed synovitis and destructive arthritis declined dramatically, which resulted in a decrease in the number of synovectomy and joint prosthesis gradually. On the other hand,

surgeries for hand or foot disorders have been increasing. However, it is unclear about the surgery for cervical spine disorder.
Objectives: We clarified the change in the surgical treatments for cervical spine disorder related to RA patients at our institution.
Methods: From 2001 to 2015, we identified 71 RA patients with a cervical spine surgery. The mean age was 65.4 years (range, 44–90 years). The patients consisted 11 males and 60 females. The mean disease duration was 20 years (range, 0–52 years). They were classified into three subgroups according to the affected level: the upper lesions (UL) such as atlantoaxial subluxation, the middle and lower lesions (MLL) including subaxial subluxation, and the expanded lesions (EL) which have both features. Individual groups were assessed the change of the number of surgical treatment. In addition, we divided the period into first seven years (from 2001 to 2007) and last eight years (from 2008 to 2015), and compared each other.
Results: There were 38 patients in UL, 25 patients in MLL and 8 patients in EL. Most patients in UL were underwent atlantoaxial fixation by Magerl and Brooks procedure, and the number of them was constant throughout the entire period. Occipito-cervical fusion has been decreasing. Although there were much surgeries of MLL disorder in last 8 years than that in first 7 years, most of them did not have RA change such as endplate erosion and subluxation.
Conclusions: There was no significant change in EL throughout all periods. In conclusion, surgeries for cervical spine disorder of RA patients remained in our institute. However, disorders related to RA within them, especially MLL, were decreasing. it indicates that expansion of RA remission has led to the reduction of cervical spine surgeries with RA change.

AB0940 EFFICACY AND SAFETY OF PLATELET RICH PLASMA PERI-NEURAL INJECTION IN TREATMENT OF DIABETIC NEUROPATHY: DOUBLE BLIND RANDOMIZED CONTROLLED TRIAL

M. Hassanien [1], Y. Saad [1], A. Alawamy [2], W.A. Khalifa [3], D. Abdelkarem [4].
[1] Rheumatology Department; [2] Anathesia department Assuit university; [3] Internal Medicine; [4] Clinical Pathology, Assuit University, assuit, Egypt

Background: Neuropathy is a common complication of diabetes mellitus (DM) not only leads to an impaired quality of life, but also to an increased morbidity and mortality.Autologous platelet-rich plasma is easy and cost-effective method. Platelet-derived angiogenesis factor capable of stimulating new capillary growth by inducing migration of endothelial cells, influence the process of angiogenesis and revascularisation.
Objectives: evaluate the clinical efficacy and safety of perineural PRP injection in the treatment of diabetic neuropathy (DN) compared to tradition medical treatment.
Methods: Sixty patients were selected from Endocrinology unit Department of Internal medicine, Assuit university Hospital, Egypt had type II diabetes mellitus neuropathy (DN) of at least 5 years duration of symptoms, regardless of age and gender double blindly divided into two groups, both groups had control blood glucose. Group I underwent PRP preineural injection under ultrasound guidance and group II underwent medical treatment. Baseline pain and nerve conduction study of upper and lower limb nerves and sural nerve conduction studies, F-wave. nerve conduction study were determined at 3 months after the procedure. Primary outcome was the total effective rate. The total effective rate = (the number of patients with significant effect+ the number of patients with effect)/total number of patients. A “significant effect” meant that limb pain, numbness, and fatigue were significantly reduced, nighttime sleep was improved, and NCV from electromyography increased $>$5 m/s or returned to normal. An “effect” meant that the symptoms mentioned above were relieved, and NCV compared with pre-treatment increased $<$5 m/s. “Failure” meant that the symptoms did not improve, and there were no changes in NCV electromyography
Results: We recruited 60 diabetic patients (type II) with peripheral neuropathy with a mean age 35.27±12.86 years with disease duration of 7.42±3.51 years. Of these, 56% cases with upper limb nerves neuropathy only while the rest 44% had sural nerve plus upper limb nerves neuropathy. Nerve conduction study showed axonal affection in only 26% and all had delayed distal latency and prolonged motor conduction velocities. generalized DN is found in 70% of total patients and 30% of had focal Entrapment of the nerve includes median neuropathy at the wrist 50%, ulnar neuropathy at the elbow 30% and peroneal neuropathy at the knee 20% and no patients had radiculoplexus neuropathies.

	Group I		P-value
	Baseline	3 months Post injection	
Mean motor NCV ± SD	35.6±12.67	46.38±10.68	$\leq$0.05*
Mean DL ± SD	9.19±8.16	4.55±5.66	0.09
Sural conduction velocity	17.00±10.86	34.00±6.84	$\leq$0.001**
	Group I	Group II	P-value
Effect	85.47±9.91%	79.38±12.40%	0.16
Significant effect	95.29±15.28%	81.00±9.64%	$\leq$0.001**
Total effective rate	22/30 (73.3%)	11/30 (36.6%)	$\leq$0.05*
Failure	7.00±2.86/30	18.00±2.84/30	$\leq$0.001**

Conclusions: Autologous platelet-rich plasma is an easy and cost-effective method as a treatment of diabetic peripheral neuropathy.

AB0941 PATIENTS PROFILE AT ORTHOGERIATRIC UNIT: NEW MODEL OF CARE

S. Hammami, A. Meziani, A. Ioana, C. Dumont, V. Latteur. *Geriatric, GHdC Belgium, Charleroi, Belgium*

Background: Fractures in elderly patients its a prevalent problem. Older patients due their characteristics requires a specific care. The orthogeriatric Unit has been shown to be one of the most beneficial units. It is important to evaluate the model of care
Objectives: Evaluate the main variables of fractures patients treated at a orthogeriatric Unit and their complications
Methods: This is a partially concurrent prospective study, taking place in a large urban academic hospital GHdC in Belgium. The participants were 87 consecutive elderly people, admitted directly to a geriatric-based orthogeriatric ward.
Results: A total of 87 patients were included. The average age was 85.2±5.2 years, 20 male, 67 female. Most of them (n=44,52%) were admitted for a hip fractures, 44% (n=38) were transferred from emergency department, ISAR score was 3.9±1.1, Preoperative stay was less than 24 h for 54% of our population, Mini nutritional assessment was 18.7±4.3, Mini mental state examination was 20.6±6.4, the Cumulative Illness Rating Scale was 17.1±4.5, the mean number of medicine was 6.8±3.3, Activity of Daily Living 15 days after admission was 12.2±5.5. Delirium was the principal complication 55% (n=44). Mean hospital stay between admission and discharge/transfer to convalescence unit was 23.8±12.9. In-hospital mortality was 11% (n=10)
Conclusions: Fractures is a frequent and disabling pathology among geriatric fragile population, its treatment requires an interdisciplinary approach. This must be managed by the collaboration between geriatrician and orthopedist. We believe that the orthogeriatric Unit providing subacute and acute care will improve the general outcome of fragile geriatric patients

AB0942 EFFECT OF CORTICOSTEROID INFILTRATIONS ON DIABETES. A MONOCENTRIC RETROSPECTIVE STUDY

S. Mathieu, M. Couderc, Z. Tatar, J. Lopez, S. Malochet-Guinamand, J.-J. Dubost, A. Tournadre, M. Soubrier. *Rheumatology, CHU Gabriel Montpied, Clermont-Ferrand, France*

Background: Corticosteroid therapy can unbalance diabetes, particularly when administered orally, but also during articular infiltration. Corticosteroid infiltrations are an integral part of the therapeutic arsenal in rheumatology. They are utilized to treat congestive articular flare-ups of osteoarthritis or inflammatory rheumatic diseases. Periarticular or ductal pathologies, such as trochanteric bursitis, rotator cuff pathology and carpal-tunnel syndrome, may require the use of these infiltrations. Caution is often required when using corticosteroid infiltrations in diabetics.
Objectives: The purpose of our study was to evaluate whether or not diabetic patients undergoing a corticosteroid infiltration during hospitalization had a diabetes imbalance.
Methods: Diabetic patients having undergone a corticosteroid infiltration during hospitalization between 2009 and 2015 were sought. We collected data regarding their rheumatological pathology, glycated hemoglobin (HbA1c), and fasting glycemia on the day of the infiltration, the next day and after 48 hours.
Results: A total of 114 patients were included in our study. The average age was 72.1±9.4 years. All of them had Type 2 diabetes, and 35 of them were treated with insulin. Average HbA1c was 7.3±0.1%. Overall, 47 (41.2%) patients had an HbA1c below 7%. A total of 31 (27.2%) patients had a diabetes imbalance after infiltration, and 19 of these, who were taking oral antidiabetics, required 48 hours of rapid insulin to balance their glycemia. Overall, 12 patients increased their insulin dose. Out of the 47 patients with good HbA1c, 7 (14.9%) of them had a glycemia imbalance, versus 24 (35.8%) who were unbalanced out of the 67 patients whose HbA1c exceeded 7% (p=0.013).
Conclusions: Corticosteroid infiltrations can lead to a diabetes imbalance, thus making it necessary to administer a few days of rapid insulin or to increase the insulin dose. A patient whose HbA1c is below 7% has a low risk of unbalancing his/her diabetes after corticosteroid infiltration.

AB0943 SIGNIFICANCE OF MUSCLE VOLUME & FATTY DEGENERATION OF LUMBAR PARASPINAL MUSCLE IN SPINAL IMBALANCE

Y.-S. Park, J. Lee, J.-S. Park. *Department of Orthopaedic Surgery, Hanyang University Guri Hospital, Guri city, Korea, Republic Of*

Background: Spinal sagittal imbalance which is closely associated with low back pain is considered as a factor in a variety of spinal disorders.
Objectives: The present study was to determine the relationship between the sagittal imbalance and sarcopenia, especially cross sectional area (CSA) and fatty degeneration (FD) of muscle around the spine.
Methods: Overall, 165 patients are included in this study, classified by three groups according to the distance from sagittal vertical axis to posterior end of upper end plate of sacrum.
38 patients were classified as group 1 (distance ≥9cm), 50 and 53 patients as group 2 (distance 5–9cm) and group 3 (distance <5cm), respectively. For measurement of CSA and FI of paraspinal muscles, five transverse T1W images of S1-S5 were obtained from PACS and measured with Adobe Photoshop 7.0®, by counting the number of pixels included in each selected muscle area. A variance analysis on average muscle surface area of those five images was done with SPSS 19.0 Windows version (SPSS Inc., Chicago, IL, USA).
Results: The average age of total patients was 69.1, average BMI was 22.57 and bone density was -2.34 (T-score).
No significant differences were detected on ages, BMI, and bone density. Each correction coefficient of multifidus, erector spinae and psoas muscle was 0.80, 0.75 and 0.81, respectively.
CSA of paraspinal muscles has significant differences between group I and III, II and III. Psoas has significant differences between all groups. FI has significant differences between all groups in multifidus and between I and III, II and III in erector spinae. But, psoas has no significance between three groups.
Conclusions: Authors were able to detect significant muscle atrophy in the group with severe imbalance. And degeneration of paravertebral muscle has significant increased with sagittal imbalance. Effort for preventing weakness of muscle around spine might cause influence to alignment of spine.

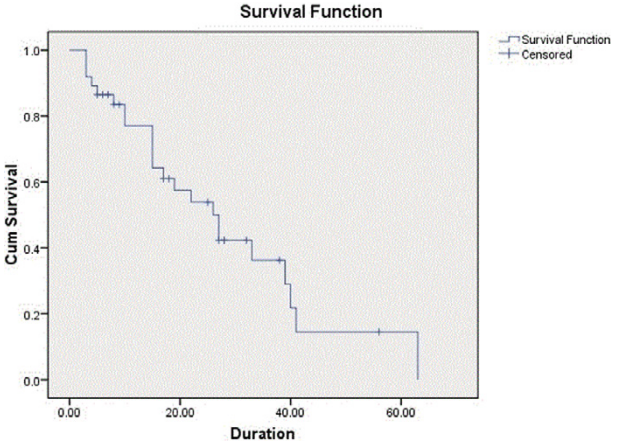
Paediatric rheumatology

AB0944 USE,SAFETY AND EFFICACY OF ETANERCEPT IN JIA–A SINGLE CENTRE RETROSPECTIVE STUDY FROM NORTH INDIA

A. Shivpuri[1], S. Mittal[1], M. Agarwal[2], S. Sawhney[2]. *[1]Fellow in Training, Pediatric Rheumatology; [2]Consultant, Sir Ganga Ram Hospital, New Delhi, India*



Background: The treatment paradigm for Juvenile Idiopathic Arthritis (JIA) has changed in last decade:Early diagnosis,objective assessment & appropriate use of biologic response modifiers (BRMs) are common place.Etanercept (Et) is available in India for 15yrs. BRM use in developing world is fraught with challenges: cost, high burden of Tuberculosis (TB) & retention. In view of the cost & safety concerns regarding TB, at our centre, full dose Et is used for 3–6 mths, followed by dose tapering as tolerated.
Objectives: 1. To determine the use, safety & efficacy of Et in JIA. 2. To determine the factors that determine responders vs non responders. 3. To determine the factors that determine disease free survival on stopping Et
Methods: This study was done from 15thJune'15 to15thDec'16 (18mths) at Sir GangaRam Hospital. *Inclusion criteria:* All JIA pts who took Et for min 12 wks & attended the outpatients during the study period. *Outcome:* All pts who achieved the Wallace criteria of inactive ds, clinical remission on (CRoM) or off medication within 4 months were termed as responders.
Results: *Use:* 46pts recd Et (29M,17F). Median (Md) age at JIA onset: 9.08yrs (1.16–16.5).Md delay to diagnosis: 4mths (0.5–63). Md age at initiation of Et: 11.6yrs (4.25–20.3). *Indications:* Partial response to Intraarticular steroids/bridging steroids & DMARD-32; Started upfront for high ds.burden: 14. *Diagnoses:* ERA30 (65%), Poly JIA8 (17%), OJIA 3 (7%), SOJIA 3 (7%) & UJIA 2 (4%). *Safety:* Screening: Mantoux +ve: 6, Quantiferon+ve: 2,antitubercular therapy for latent TB: 8. Side effects: 41 (88%) had no adverse event. 5 pts - 1 each had enteric fever, varicella, uveitis, hemolysis, malaria. *Follow up:* Md duration of follow up-47.5 mths (2–147). *Medications at last follow up:* Et ongoing in 20 (43.5%), 12 on 2nd BRM, 12 off BRM & 2 lost to follow up. *Status at last follow up:* Of 37 responders - 8 currently active.
Responders vs non responders: 37 responded (2 excluded duration <12 wks). In all responders drug was tapered/stopped. No demographic, clinical, lab criteria could predict responder from non responder (Table 1).

	Responders (37/44)	Non Responders (7/44)	p value
Md time to inactivity post Et	9wks (1–52)	–	
Md time to flare	15m (3–63)	–	
Md duration of taking Et	18m (3–56)	5.5 m (2–22)	0.01
Md Time to first taper Et	5m (1–34)	2m (1.5–16)	0.44
Median ESR	38 (4–125)	63 (22–125)	0.08
SJC ≤4 jts >4 jts	29 (78.4%) 8 (21.6%)	4 (57.1%) 3 (42.9%)	0.34
TJC ≤4 jts >4 jts	32 (86.5%) 5 (13.5%)	4 (57.1%) 3 (43%)	0.10

Of 37 responders, 15 (40.5%) did not show any flare (Table 2).

	Flared (22/37)	Never flared (15/37)	p value
Md time to inactivity post Et	11wks (1–36)	6 wks (2–52)	0.43
Md time to flare	15m (3–63)	18m (3–33)	0.74
Md duration of Et	17.5m (3–53)	25m (6–56)	0.64
Md Time to first taper	5.5m (1–12)	4m (2–34)	0.58
Md time to stop steroids	3m (1–12)	2m (1–4)	0.16
Median ESR	28 (4–120)	45 (15–125)	0.29
SJC≤4 jts >4jts	17 (77.3%) 5 (22.7%)	12 (80%) 3 (20%)	1
TJC≤4 jts >4jts	19 (86.4%) 3 (13.6%)	13 (86.7%) 2 (13.3%)	1

Disease free survival on Et: Of 37 responders, 22 flared. No factors could predict flare in pts who recd tapering Et dose or after stopping Et. Some needed repeat cycles of Et/2nd BRM. Kaplan Meier curve of responders confirmed that no pt would be flare free at 63mths of follow up.

Conclusions: Et is safe to use & had no adverse events in 89%. Needed most for ERA. Effective in 84%. On using shortterm Et, 59% flared either on tapering/stopping. These pts responded to reinitiation of Et/BRM. On long term follow up (63mth) there were no flare free pts.

AB0945 COHORT STUDY OF 112 PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS DURING TRANSITION FROM PEDIATRIC TO ADULT CARE

A.-C. Debrach[1], A. Beaumel[2], A. Rougelot[2], J.-P. Larbre[2], M. Couret[1], F. Coury[2]. *[1]Rheumatology, CHUV, Lausanne, Switzerland; [2]Rheumatology, HEL, Lyon, France*

Background: Juvenile idiopathic arthritis (JIA) is the most common chronic inflammatory arthritis in children. The International League of Associations for Rheumatology 2001 (ILAR) classification includes 7 subgroups: systemic JIA, polyarticular JIA, oligoarticular JIA, enthesitis related arthritis (ERA), psoriatic arthritis and undifferentiated arthritis. Most paediatric inflammatory arthritides persist into adulthood. Therefore, a transition from paediatric to adult rheumatology is a necessary step. Transition is defined as an active process by which a young patient with a chronic disease develops skills and resources to gradually take control of their condition. The transition phase should be anticipated and structured because of the risk of failure in monitoring. However difference in classification criteria in paediatric and adult rheumatology can cause significant difficulty for adult rheumatologists.
Objectives: The aim of this study was to determine the characteristics of juvenile-onset arthritis seen during the transition period and to compare *paediatric* classification criteria to those of adults.
Methods: A retrospective *bi-centre* study was performed. Patients with JIA according to ILAR classification were included and had a consultation at transition. JIA classification criteria were compared to ACR/EULAR 2010 criteria

for rheumatoid arthritis (RA), Yamaguchi criteria for adult Still's disease and ASAS criteria for spondyloarthritis.
Results: 112 patients were included: 17 systemic JIA, 26 polyarticular JIA, 19 oligoarticular JIA, 41 ERA and 9 psoriatic arthritis. The median age of transition was 19 years old. Eight cases of uveitis were observed among patients with oligoarticular JIA and 7 with ERA. Radiographic structural damages were assessed and showed 15% of patients with erosions or carpitis, mainly in polyarticular and systemic JIA patients. 29% of patients with ERA displayed sacroiliitis. In comparison with adult rheumatism, 42% of patients with systemic JIA fulfilled Yamaguchi criteria and 23% of patients with polyarticular JIA fulfilled ACR/EULAR criteria for RA. 41% of patients with oligoarticular JIA, 73% with ERA and 100% with psoriatic arthritis fulfilled ASAS criteria for spondyloarthritis.
Conclusions: Our study confirmed the articular destructive potential of polyarticular and systemic JIA and an ocular risk in oligoarticular JIA. Comparison of JIA criteria to adult rheumatism criteria showed that polyarticular JIA with positive rheumatoid factor fulfilled ACR/EULAR criteria for RA. However, oligoarticular JIA and polyarticular JIA without rheumatoid factor did not fulfill any adult rheumatism criteria and seem to be paediatric entities. Finally, most patients with ERA and psoriatic arthritis fulfilled the ASAS criteria for spondyloarthritis.

AB0946 CALCINOSIS IN CHILDREN WITH JUVENILE DERMATOMYOSITIS FROM A SINGLE-CENTRE IN NORTH INDIA

A. Sharma, A. Jindal, A. Gupta, D. Suri, S. Singh. *Pediatrics, Post Graduate Institute of Medical Education and Research, Chandigarh, India, Chandigarh, India*

Background: Juvenile dermatomyositis (JDM) is a rare childhood autoimmune inflammatory muscle disorder that can result in severe disability or death. Calcinosis is a unique and a poorly understood long-term complication of JDM (1). Calcinosis can present in various forms like nodular calcinosis, tumoral deposits, calcinosis universalis.
Objectives: We present here the images of calcinosis in children with JDM
Methods: All children diagnosed to have JDM and registered in Pediatric Rheumatology Clinic at Post Graduate Institute of Medical Education and Research, Chandigarh, India, were evaluated for presence of calcinosis. Consent was taken from patients or caregivers
Results: A total of 36 patients were evaluated. Twelve (33.33%) patients had calcinosis (Fig 1). Interestingly, 4 children had calcinosis at the time of diagnosis

Figure 1. Calcinosis in children with JDM. Radiographs showing Calcinosis in children with JDM

Conclusions: Calcinosis is a distinct complication of JDM which is uncommon in inflammatory myopathies in adults (2). Calcinosis can be disabling and disfiguring. It may not be obviously visible in all patients and radiographs help reveal the extent of involvement.

AB0947 CHARACTERISTICS OF A TRANSITION CLINIC FOR YOUNG PEOPLE WITH RHEUMATIC DISEASES

B. Serrano-Benavente[1], J.C. López-Robledillo[2], D. Clemente[2], I. Monteagudo[1], J.C. Nieto-González[1]. *[1]Rheumatology, Hospital General Universitario Gregorio Marañón; [2]Paediatric Rheumatology, Hospital Niño Jesús, Madrid, Spain*

Background: Paediatric rheumatologic diseases can still be active in the adulthood. Transitional care units are very important for the transition from paediatric to adult health care system.
Objectives: To describe the demographic characteristics, paediatric rheumatologic diseases distribution and active treatments in a Rheumatologic Transitional Care Unit (RTCU).
Methods: We included all new patients who attended the RTCU of a tertiary level hospital from 1st September 2015 until 31st December 2016. These patients were remitted from the paediatric rheumatology unit of two tertiary level hospitals. We retrospectively analyzed their demographic, laboratory and treatment characteristics. The connective tissue diseases (CTD) group included systemic lupus erythematosus, Behçet disease, dermatomyositis and scleroderma. Patients were considered active according to the physician opinion.
Results: We attended 81 new patients. 59 were female (72.8%) and the median age (range) was 19 years (18.1–20.7). 65.43% were diagnosed with Juvenile Idiopathic Arthritis (JIA) and 12.35% with CTD. Table 1 shows the main baseline characteristics of the patients. In the first visit at the unit, half of the patients did not have any systemic treatment (41 patients [50.62%]). From the remaining 40 patients with systemic treatment, 16 patients (40%) were under biologic treatment, mostly anti-TNFα. In any of the two first appointments, 20 patients (24.7%) were active, most of them from the JIA group. Seven (35%) of these patients increased or changed the treatment, 6 of them initiating a biologic treatment.

Table 1. Demographic and treatment characteristics

	Total (n: 81)	Juvenile Idiopathic Arthritis (n: 53)	Connective Tissue Diseases (n: 10)
Gender, Women (%)	59 (72.83)	39 (73.58)	9 (90)
Age of disease onset - Median (IQR)	10.3 (4.5–14.2)	6.5 (2.1–12.9)	14.4 (11.5–15.6)
Arrival age at the unit - Median (IQR)	19 (18.1–20.7)	19.1 (18.1–21)	19 (18.4–20.5)
Active in the 2 first appointments N (%)	20 (24.69)	15 (28.30)	4 (40)
Antinuclear antibodies, N (%)	32 (39.50)	20 (37.73)	5 (50)
Uveitis at any time, N (%)	11 (13.58)	9 (16.98)	0
Without treatment at the arriving time, N (%)	41 (50.61)	23 (43.39)	5 (50)
sDMARD at arriving, N (%)	30 (37.03)	25 (47.17)	5 (50)
Biologic therapy at arriving, N (%)	16 (19.75)	13 (24.53)	0

sDMARD: synthetic disease-modifying antirheumatic drugs. IQR:Interquartile range.

Conclusions: Our RTCU received mostly JIA patients. Median age at arriving was slightly higher than expected. A fourth of patients were active in the transition moment. All this data highlights the need of an strict control of these patients in the transitional period.

AB0948 INSUFFICIENT CALCIUM INTAKE IN PEDIATRIC POPULATION WITH RISK FACTORS FOR OSTEOPOROSIS

B. Magallares López[1], J. Betancourt[2], G. Fraga[2], N. Pardo[3], M. Torrent[2], A. Marin[4], S. Herrera[4], E. Carreras[2], J. Casademont[4], J. Malouf Sierra[4]. *[1]Rheumatology; [2]Pediatrics; [3]Hospital Santa Creu I Sant Pau, Barcelona, Spain; [4]Internal Medicine, Hospital Santa Creu I Sant Pau, Barcelona, Spain*

Background: Compliance with daily calcium requirements in paediatric and young age is necessary to acquire peak bone mass, especially in populations that meet one or more risk factors for fractures
Objectives: To study the characteristics of the pediatric population with at least one risk factor for developing low bone mass/osteoporosis and to measure their calcium intake
Methods: Demographic and clinical data were prospectively collected from patients aged 2 to 20 years that met at least 1 risk factors for bone fragility, including: inflammatory diseases, treatment with Immunosuppressants and/or

corticoesteroids, malabsortive disorders, chronic systemic disorders such as nephropathies or hematologic diseases, etc. The patients or their legal tutors signed the Informed Consent in order to participate in the study. The average daily calcium intake was collected through the Spanish INDICAD 2001 study survey, together with a comprehensive anamnesis. If patients or their family reported taking food not included in the survey, its calcium content were consulted in the Spanish Food Composition Database published by the BEDCA Network of the Ministry of Health Science and Innovation

Results: Data were collected from 50 patients, with a mean age of 9.2 years (2–20), 28 (56%) female, 86% Caucasian, 6% Arab, 2% Asian and 6% Latin. The most frequent diagnoses were: Food intolerances/malabsorption: 32%, nephropathies: 22%, JIA: 16%, vasculitis: 10%, other inflammatory diseases: 8%. 42% had received systemic corticosteroids at some point, and 16% were receiving corticosteroids at present. Average daily calcium intake was 718 mg/d. They were divided by age groups, attending to daily calcium needs per group. In Table 1 we can observe the Recommended Daily Amount (RDA) of calcium by the Spanish Association of Pediatrics and the consumption collected, by age group.

Age group	% Age group	RDA (mg/d)	Average intake (mg/d) ± SD	Range: min–max (mg/d)	% That reaches RDA
Pre-escholar (2–3 a)	14%	700	819±280	513–1346	57.1%
Escholar (4–9 a)	32%	1000	702±240	254–1075	18.8%
Teenagers (10–17a)	48%	1300	689±350	350–1925	8.3%
Young (18–20 a)	6%	1100	797±182	621–985	0%

Only 3 children with low calcium intake were taking supplements.A decrease in calcium RDA adherence was observed with increasing age, statistically significant (p=0.009). There was also a lower calcium intake in the non-Caucasians compared to Caucasians statistically significant (p=0.044), which was not associated with age.

Conclusions: Calcium intake in the population under 21 years old with at least 1 risk factor for developing low bone mass/osteoporosis is lower than recommended. In addition, recommendations are based on the physiological needs of the healthy population and it could be expected to be insufficient for those with chronic diseases. It should be noted that calcium intake in the groups with higher requirements (adolescents and young people) is lower, with a reduction in the proportion of patients who meet the compliance with the RDA as age increases. Studies with a larger population are needed to ratify these results together with serum calcidiol levels

AB0949 THE ANNUAL COST OF PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

B. Serpen[1], O. Altug-Gucenmez[1], C. Acari[1], M.K. Sozmen[2], B. Makay[1], S.E. Unsal[1]. [1]*Faculty of Medicine, Unit of Pediatric Rheumatology, Dokuz Eylul University;* [2]*Faculty of Medicine, Department of Public Health, Izmir Katip Celebi University, Izmir, Turkey*

Background: The management of juvenile idiopathic arthritis (JIA) includes various methods including such as medication, hospitalization, rehabilitation.

Objectives: To determine how much juvenile idiopathic arthritis cost; the components of this cost; how new treatments, i.e. biologics, improve the disease course and hospital expenditures.

Methods: This study was conducted in Dokuz Eylul University, Pediatric Rheumatology Unit between March 2015-March 2016. One-hundred six JIA patients who had a follow-up period of at least 1 year according to International Edmonton 2001 criteria were included. This retrospective cost study evaluated the data of these patients and calculated the direct cost for the follow-up period. Clinical data was collected from patient files that were in department's archive and cost data was gathered from Probel Hospital Information Management system. Patient data form covering sociodemographic and clinical information, patient drug form and annual medical cost form was filled out for each patient.

Results: 58.5% (n=62) of patients was female and 41.5% (n=44) was male. The mean age was 12.0±4.3 years. 34.0% (n=36) of patients was oligoarticular type, 28.3% (n=30) was poliarticular type, 22.6% (n=24) was enthesitis related arthritis (ERA), 8,5% (n=9) was psoriatic type and 6.6% (n=7) was systemic type. The cost of medication counted for 88.3% (453244.94 TL) of total direct annual cost. Total direct medical cost was highest for ERA (n=7742.55±9891 TL). While the annual cost was calculated as 10451 TL per person for biologic using patients, for the patients using non-biologic treatments it was determined as 1472 TL per person. 1 TL=0.32 € 1 TL =0.35 $

Conclusions: Medication is responsible for most of the total direct medical cost in patients with JIA. Our results showed concordance with previous studies on the subject. This situation could be attributed to biologic agents that are being used in treatment in recent years. More prospective studies on the effectiveness of cost of treatment, with greater amount of patient and more homogenous subgroups are needed.

AB0950 PREDICTORS OF RESPONSE TO ETANERCEPT TREATMENT DEPENDING ON JUVENILE IDIOPATHIC ARTHRITIS CATEGORY

E. Kashchenko[1], E. Alexeeva[1,2], T. Bzarova[1,2], S. Valieva[1], R. Denisova[1], O. Lomakina[1], K. Isaeva[1], M. Soloshenko[1], A. Karaseva[1]. [1]*Federal State Autonomous Institution "National Scientific and Practical Center of Children's Health" of the Ministry of Healthcare of the Russian Federation;* [2]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*

Background: Anti-TNF biologics are highly effective and widely used in clinical practice for the treatment of JIA. However, some children lack of response with few reliable predictors of a good or poor response to treatment found [1–3]. As clinical picture patterns are significantly differ for 7 JIA subclasses, we propose to found predictors of response to therapy for each of JIA category.

Objectives: To identify clinical and laboratory parameters associated with response to etanercept treatment in 12 months in patients with different JIA category.

Methods: Patients from four JIA categories (n=195) were divided to groups with excellent, intermediate and poor response after 12 month treatment with etanercept according to ACRPedi criteria, achieving inactive disease by Wallace criteria and JADAS-71 cut-off point. For each of JIA category univariate and multivariate logistic regression analysis was conducted to identify potential baseline factors associated with treatment response. Baseline factors included clinical, laboratory and anamnestic data.

Results: From total cohort 91/90/85/68.5 percent of patients achieved ACR30/50/70/90 in one year etanercept treatment; 45.5% patients were considered excellent responders, 30% - intermediate responders, and 24.5% - poor responders. Highest efficacy of therapy was shown in persistent oligoarthritis patient, lowest – in enthesitis-related arthritis and polyarthritis patients. Potential baseline predictors of excellent and poor response which were significant are described in the table.

JIA category	Predictors of excellent response	Predictors of poor response
Persistent oligoarthritis	smaller amount of DMARD	–
Extended oligoarthritis	shorter disease duration (DD)	–
Enthesitis-related arthritis	–	– longer DD
RF-negative polyarthritis	– smaller number of joints with limited range of motion (LOM) – lower CRP level at the baseline – younger age at disease onset (ADO)	– longer DD – older ADO

Analysis showed that poor response in all JIA categories was mainly associated with demographic data (longer DD and older ADO). However, factors associated with excellent response significantly differed depending on JIA category (anamnestic factors, number of involved joints, laboratory factors, and demographic factors).

Conclusions: Response to etanercept therapy is strongly associated with JIA category. Shorter disease duration and lower number of DMARDs used before start of etanercept, lower number of joints with LOM, and lower C-reactive protein at baseline are predictors of better response to etanercept.

AB0951 FACTORS ASSOCIATED WITH RESPONSE TO ADALIMUMAB TREATMENT IN JUVENILE IDIOPATHIC ARTHRITIS

E. Kashchenko[1], E. Alexeeva[1,2], T. Bzarova[1,2], S. Valieva[1], R. Denisova[1], O. Lomakina[1], K. Isaeva[1], M. Soloshenko[1], A. Karaseva[1]. [1]*Federal State Autonomous Institution "National Scientific and Practical Center of Children's Health" of the Ministry of Healthcare of the Russian Federation;* [2]*I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*

Background: Tumor necrosis factor inhibitors are highly effective and safe in treatment of juvenile idiopathic arthritis (JIA). Nonetheless, to select the optimal therapy and to achieve maximum therapeutic effect it is necessary to consider the individual characteristics of the patient. Adalimumab (ADA) is widespread use for mild and severe polyarticular JIA especially in the presence of uveitis, but there is lack of data about clinical and laboratory predictors of response to ADA in different JIA categories.

Objectives: To identify clinical and laboratory parameters associated with

Abstract AB0951 – Table 1

Factors	Excellent response to ADA	Poor response to ADA
CHAQ score	lower at start of ADA (ExtOligo)	–
VAS disease activity by patient/parent	higher at start of ADA (ERA)	lower at start of ADA (ERA)
VAS disease activity by physician	–	lower at start of ADA (PersOligo)
Need for corticosteroid eye drops (for uveitis patients)	Absence in anamnesis (PersOligo)	–
Morning stiffness	Shorter at start of ADA (ERA), longer at start of ADA (PersOligo)	–
Joints with active arthritis	–	higher at start of ADA (PolyRF-)
erythrocyte sedimentation rate (ESR)	–	lower at start of ADA (PolyRF-)

response to adalimumab treatment in 12 months in patients with different JIA category.

Methods: Analysis include patients with enthesitis-related arthritis (ERA, n=56), RF-negative polyarthritis (polyRF-, n=50), extended oligoarthritis (extOligo, n=30), and persistent oligoarthritis (persOligo, n=62) with median age 10.5 (IQR 7–14) and median JADAS-71 19.5 (IQR 15–28). Patients were divided to response groups after 12 month treatment with ADA according to ACRPedi criteria, achieving inactive disease by Wallace criteria and JADAS-71 cut-off point as excellent, intermediate and poor responders. For each of JIA category univariate and multivariate logistic regression analysis was conducted to identify potential baseline factors associated with treatment response. Baseline factors included clinical, laboratory and anamnestic data.

Results: ADA was shown to be effective in all groups with 90%/89%/82%/63% children with ACR30/50/70/90 during one year therapy. The most significant factors ($p<0.05$) associated with response to ADA treatment are presented in summarized table.

Our findings demonstrated that different predictors corresponded with different JIA categories. Interestingly subjective scales of disease activity was shown to be strongly associated with response to therapy. At the same time VAS severity at baseline were inversely correlated with achievement of good response. Duration of morning stiffness correlated with excellent response in children with 2 different categories. However, for ERA patients shorter duration was associated with better response to treatment while vice versa for PersOligo patients.

Conclusions: Predictors of response to ADA treatment differ in JIA categories. Low disease activity parameters (clinical and laboratory) at baseline not always predict good response to therapy.

AB0952 EXPERIENCE OF TOCILIZUMAB USE IN TREATMENT OF JUVENILE IDIOPATHIC ATRTRITIS IN CHELYABINSK REGIONAL CHILDREN HOSPITAL

G.A. Glazyrina[1], N.A. Kolyadina[2]. *[1]South Ural Governmental Medical University; [2]Chelyabinsk Regional Children Hospital, Chelyabinsk, Russian Federation*

Background: Recently due to application of interleukin (IL)-6 inhibitors prognosis for systemic juvenile idiopathic arthritis (sJIA) has significantly improved. 526 children with JIA are under monitoring in Chelyabinsk region, 42 children have sJIA. Tocilizumab is the drug of choice for sJIA treatment. It is registered within the Russian Federation for use in children older than 2 years. In Chelyabinsk Regional Children Hospital tocilizumab has been used for 5 years.

Methods: 18 children (12 boys, 6 girls) aged from 2 to 17 (mean age 10.7 years) diagnosed with sJIA were under monitoring. Disease duration was from 6 months to 15 years (mean duration 6 years). JIA was diagnosed based on ILAR diagnostic criteria. SJIA was diagnosed in 16 children, sero-negative polyarthritis was diagnosed in 2 children. Tocilizumab was introduced intravenously every 2 or 4 weeks in dose of 12 mg/kg for children <30 kg or 8 mg/kg for children ≥ 30 kg. Therapy duration was from 3 months to 5 years (average duration 23 months). Assessment of disease activity and therapy efficiency was conducted in accordance with ACR pedi criteria. Nonparametric statistical methods were used to compare results.

Results: Prior to tocilizumab use high disease activity was observed in all children. Average number of joints with active arthritis was 13,5 [6;15] (Me [25;75%]). Average number of joints with functional impairments – 12,5 [6;15]. Average ESR (according to Panchenkov) – 50 [40;60]mm/h, CRP 98,6 [55;139]g/L. Assessment of functional activity according to CHAQ questionnaire- 2,09 [2;2,5]. Activity assessment according to VAS by doctor – 82 [75;90]. Assessment of parents according to VAS 84 [80;90]. No eye lesions were found in children under monitoring. All 16 children with sJIA had fever, hepatosplenomegaly and lymphadenopathy, the rash had 11 children, polyserositis - 8. In 5 children there was a complication in the form of a syndrome of macrophage activation.

During the tocilizumab therapy a decrease in disease activity was observed in all patients. Mean number of joints with active arthritis was 1 [0;2] (Me [25;75%]) (P=0.0002). Mean number of joints with functional impairments – 3 [0;3] (P=0.0003). Average ESR was 4 [3;5]mm/h (P=0.00002), CRP 0,75 [0;1]g/L (P=0.0003). Assessment of functional activity according to CHAQ questionnaire was 0,25 [0;0.5] (P=0.0004). Activity assessment according to VAS by doctor – 16 [10;20] (P=0.0002). Assessment of parents according to VAS 18 [10;20] (P=0.0002).

Clinical disease remission (according to ACR pedi criteria– $\geq$90%) was observed in 11 patients after 6–9 months of treatment. Remission duration up to now is from 3 months to 4 years. Efficiency according to ACR pedi criteria is 70% in 6 children, 50% in 1.

The drug was well-tolerated. Undesirable effect such as allergic skin reactions were observed only in one child. In one child the lack of efficiency produced by switching to canakinumab. Drug was cancelled in 3 patients due to long-term remission (3–4 years), but 2 of them after a year needed the resumption of therapy in connection with the aggravation of the disease.

Conclusions: Tocilizumab therapy was highly effective and safe in patients with JIA. Clinical remission was achieved in 61,1% children. Decrease in disease activity was observed in 39,9% of children. No serious undesirable effects were reported.

AB0953 ARTHRITIS FOLLOWING PARASITIC INFECTION IN THE DIFFERENTIAL DIAGNOSIS OF JUVENILE IDIOPATHIC ARTHRITIS

M. Maschio[1], S. Pieropan[2], F. Caldonazzi[1], G. Dallagiacoma[2], V. Ravagnani[3], D. Degani[1], G. Piacentini[1], D. Biasi[2], M. Rossini[2]. *[1]UOC pediatria; [2]UOC reumatologia, AOUI, Verona; [3]Reumatologia, Azienda Ospedaliera Carlo Poma, Mantova, Italy*

Background: According to literature arthritis is a rare complication following parasitic infection. In the italian pediatric population parasitic infection is manly caused by Enterobius Vermicularis; it is often asymptomatic but common symptoms can be anal nocturnal itching, insomnia, irritability, abdominal pain together with arthralgia

Objectives: To describe cases of mono or poliarthritis due to parasitic infection in young patients followed at the Verona's Pediatric Rheumathology Clinic from 2010 to 2016

Methods: Medical records of 8 patients followed at the Pediatric Rheumatology were analyzed. The mean age of 8 patients was 8 (F:M 3:5). The following data were evaluated: anamnesis data, clinical symptoms (anal itching, irritability, arthralgia, abdominal pain and arthritis), Blood test and scotch tape test. All patients underwent joint ultrasound (US). Physical symptoms of joint's involvement were evaluated in all children by an experienced rheumatologist.

Results: 6 patients had symmetrical poliathirtis, 2 patients had monoarthritis (knee and hand). Symptom's complaint were systemic (12,5%), abdominal (25%), and general pruritus (25%).Blood test confirmed high inflammation indices (25%) and hypereosinophilia (12,5%).Serological tests and stool investigations allowed to diagnose the following infections: Enterobius vermicularis (6 cases) giardia lamblia (1 case); dientaomeba fragilis (1 case).Joint US evidenced synovium hyperplasia in 75% of the cases and tenosynovitis in 50% of the cases.After appropriate antiparasitic treatment complete articular and systemic symptomatic remission was observed (100% cases); also joint US control normalized.2 cases, after about 6 months, were re-evaluated for arthritis relapse and in both cases a parasitic reinfection was confirmed.

Conclusions: Analysis of this series of patients underlines the following data: arthritis can be a manifestation of parasitic infection; treatment must be aimed against the parasite involved in order to achieve complete clinical and laboratory data remission; reinfection must always be considered in cases of relapse; differential diagnosis of this form of arthritis with other chronic polyarthritis is fundamental due to the risk of disseminated infection in case of immunosuppressive treatment

AB0954 RELATIONSHIP BETWEEN SERUM COMPLEMENT LEVELS AND RENAL PATHOLOGICAL CLASSIFICATION IN CHILDREN WITH SILENT LUPUS NEPHRITIS

H. Wakiguchi[1], T. Kubota[2], S. Takei[3]. *[1]Department of Pediatrics, Yamaguchi University Graduate School of Medicine, Ube; [2]Department of Pediatrics, Kagoshima University Graduate School of Medical and Dental Sciences; [3]School of Health Science, Faculty of Medicine, Kagoshima University, Kagoshima, Japan*

Background: Silent lupus nephritis is defined by some pathological evidence of lupus nephritis with normal urinary findings. It is therefore apparent only upon renal biopsy. Serum complement levels have been associated with overall lupus disease activity. Despite recent progress in understanding the pathogenesis of lupus nephritis, including complement, our understanding of silent lupus nephritis, especially in children, remains limited.
Objectives: To search whether serum complement levels are associated with renal pathological classification in children with silent lupus nephritis.
Methods: We determined serum C3 and C4 levels and International Society of Nephrology/Renal Pathology Society classification in 25 patients with paediatric silent lupus nephritis before initial therapy who were admitted to our hospital. Patients were classified as having silent lupus nephritis based on normal urinary findings at baseline renal biopsy in juvenile systemic lupus erythematosus.
Results: Serum C3 levels varied between International Society of Nephrology/Renal Pathology Society classes, with significantly lower levels for silent lupus nephritis patients in class III compared to class II, and for class II compared to class I. There was no significant difference in serum C4 levels between International Society of Nephrology/Renal Pathology Society classes in patients with silent lupus nephritis.
Conclusions: Our results suggest that serum C3 levels were associated with renal pathological classification in children with silent lupus nephritis. We propose that serum C3 levels would provide a useful tool for predicting latent severe nephritis in patients with juvenile systemic lupus erythematosus who have normal urinary findings before initial therapy.

AB0955 NEW ONSET OF UVEITIS, PSORIASIS OR IBD AS PARADOXICAL EFFECTS OF BIOLOGICS IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS: SINGLE CENTER EXPERIENCE

I. Nikishina, O. Kostareva, M. Kaleda, S. Rodionovskaya, S. Arsenyeva, D. Alekseev, E. Fedorov, A. Shapovalenko. *V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Biological agents (BA) are high efficacy options for current therapy for patients (pts) with juvenile idiopathic arthritis (JIA). They are successfully used not only for the arthritis but also for uveitis, psoriasis and inflammatory bowel disease (IBD). However, paradoxical induction of these conditions in pts treated with BA is a well-established phenomenon.
Objectives: To evaluate the frequency of new onset of uveitis, psoriasis or IBD occurring under BA therapy in JIA pts, to establish clinical features, which may be associated with development of such effects.
Methods: Retrospective cohort study involved all JIA pts (740) who were treated with BA in our clinic from 2004 to 2016. All cases of new onset (*no*)-uveitis/psoriasis/IBD collected; clinical features of disease onset and course, activity level, JIA category, exposure to Methotrexate (MTX) and BA, presence of ANA, HLA B27 were studied.
Results: We identified 20 (2.7%) pts (11 female/9 male) with *no*-uveitis under BA, mostly during etanercept (ETA) therapy (18 cases from 285 ETA courses, 6.3%), 1/112 - in abatacept (ABA) and 1/233 - in adalimumab (ADA); 2.46 events/100 patient-year (PY) vs 0.31 in ABA, and 0.15 in ADA), ETA exposure was 14.9±9.9 months (mo). JIA subtypes were as follows: RF-neg polyarthritis 5 (25%), persistent oligoarthritis 3 (15%), extended oligoarthritis 10 (50%) ERA - 2 (10%). JIA started in this group at the age of 4.5±3.9 yrs.18/20 patients had high laboratory activity (CRP 55±25 mg/l) and severe arthritis before BA initiation. Most of pts (16/20) achieved 90–100% ACRpedi-response by the uveitis development. 1 pt was treated by ADA for the 71 mo *and* switched to ABA. in 1 pt *no*-uveitis was obseved under ABA. 12/20 pts were ANA-positive, 10/20 pts had HLAB27, 1 pt did not have ANA or HLAB27. Uveitis was occurred earlier in ANA plus B27 positive pts (mean exposure - 10.7 mo vs 27.4 in ANA+ and 21.6 in B27+ pts). 17/20 (85%) of pts received MTX. In all cases of *no*-uveitis BA was switched. 5 pts from 740 (0.7%) developed *no*-psoriasis under BA: INF - 2 cases (0.62/100PY), ADA - 2 (0.15/100PY), ABA -1 (0.31/100PY). JIA subtypes were presented by RF-negative polyarthritis (1), extended oligoarthritis – 3. All received MTX. 1/5 pts was ANA+, 2/5 - HLAB27+. Average age of disease onset was 9.8±7.8 years; BA exposure before psoriasis was 25±11.5 mo. Therapy was continued in 3/5 pts; switched from INF to ADA in 2. Only 1 case of *no*-IBD was occurred in female patient fulfilled to systemic-onset JIA criteria years. She was treated by INF for the 62 months and switched to ADA due to secondary inefficiency presented by active polyarthritis and sacroiliitis (HLAB27neg), but 2 months later severe gastrointestinal symptoms appeared and diagnosis of Crohn's disease was established by endoscopy.
Conclusions: Our study suggested that new onset of uveitis, psoriasis and IBD is rare adverse event during BA therapy in JiA. It seemes to be as delayed implication of disease natura. but not therapy complication. Uveitis observed mostly in pts receiving ETA, unlike the psoriasis mainly developed during TNF-monoclonal antibodies using. High activity aggressive manifestations at disease onset and good initial response to BA are typical features for all pts, who developed paradoxical effects under BA therapy.

AB0956 INFLUENCE OF BIOLOGICAL THERAPY ON BONE MINERAL DENSITY IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

I. Chyzheuskaya[1], L. Byelyaeva[2], N. Vasiljeva[2], R. Filonovich[1], L. Zajtseva[1]. *[1]Department of pediatrics, 4th City Children's Clinical Hospital of Minsk; [2]Department of pediatrics, Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus*

Background: Juvenile idiopathic arthritis (JIA) is one of the most common and most disabling rheumatic diseases in children. JIA is a systemic chronic inflammatory immunopathological disease, which leads to dysfunction of the joints, their deformation and limitations of life of the child, violates the child's growth and development. One of the complications of systemic JIA in children is osteoporosis. In the pathogenesis of osteoporosis important place is given to the use of glucocorticoids. In world Rheumatology successfully used drugs aimed at the major pro-inflammatory cytokines such as tumor necrosis factor (TNF), interleukin-1 (IL-1), interleukin-6 (IL-6), and others.
Objectives: The purpose of research - to determine the influence of biological therapy on bone mineral density in children with JIA.
Methods: 15 children with systemic JIA (mean age 11,9±3,4 years) were examined in the rheumatological department of 4th city clinical hospital of Minsk. Bone mineral density was assessed by 2-energy X-ray absorptiometry (DEXA) at two points of the skeleton. The level of mineralization of skeletal mineral content was estimated in the bone tissue (BMC), bone mineral density (BMD) and the parameter Z-score. Z-score was used to determine the incidence of osteopenia and osteoporosis in children surveyed. In accordance with the WHO criteria for normal bone mineral density was diagnosed with the Z-score> -1 SD, osteopenia - at Z-score <-1 SD, but> - 2,5 SD, osteoporosis - with Z-score <-2,5 SD. Statistical data processing carried out using an integrated application package "Statistics 6 for Windows".
Results: In a study of children osteopenia was diagnosed in 9 patients with systemic JIA (mean Z-score -2,3 SD) Osteoporosis was diagnosed in 6 patients with systemic JIA (mean Z-score -2,7 SD). All children received a mean dose of methotrexate 12.7 mg/m^2 of body surface area, an average dose of methylprednisolone 0.34 mg/kg body weight per day and treatment of IL-6 inhibitor - tocilizumab 8 mg/kg body weight every 2–4 weeks. Bone mineral density was measured prior to initiating therapy tocilizumab and after 2 years of therapy.
During tocilizumab therapy achieved remission of the disease, all children was canceled methylprednisolone. After re densitometry of 2 years after the beginning of therapy improvement noted tocilizumab Z-score in children with osteopenia with Z-score -2.3 SD to Z-score -1.4 SD, in children with osteoporosis a Z-score -2 7 SD to Z-score - 2,1 SD.
Conclusions: The results indicate a positive influence tocilizumab therapy to bone mineral density in children with JIA.
Acknowledgements: This study would not have been possible without the collaboration of numerous Belarusian pediatric rheumatologists, patients and their parents.

AB0957 IS THERE A DIFFERENCE IN THE CLINICAL PRESENTATION OF JUVENILE SYSTEMIC SCLERODERMA PATIENTS ACCORDING THE AGE OF ONSET: RESULTS FROM THE JUVENILE SCLERODERMA INCEPTION COHORT WWW.JUVENILE-SCLERODERMA.COM

I. Foeldvari[1], J. Klotsche[2], O. Kasapçopur[1], A. Adrovic[1], V. Stanevicha[1], M.T. Terreri[1], E. Alexeeva[1], M. Katsicas[1], V. Smith[1], R. Cimaz[1], M. Kostik[1], T. Lehman[1], J. Anton[1], W.-A. Sifuentes-Giraldo[1], F. Sztajnbok[1], T. Avcin[1], M. Janarthanan[1], M.J. Santos[1], M. Moll[1], D. Nemcova[1], C. Battagliotti[1], J. Brunner[1], D. Eleftheriou[1], L. Harel[1], T. Kallinich[1], K. Minden[2], S. Nielsen[1], K. Torok[1], Y. Uziel[1], A. Stevens[1], C. Pilkington[1], N. Helmus[1]. *[1]Hamburg Center for Pediatric Rheumatology, Hamburg; [2]DRFZ, Berlin, Germany*

Background: Juvenile systemic sclerosis (jSSc) is an orphan autoimmune disease. It was rarely looked at the differences between the clinical presentations of patients at different paediatric age groups. The juvenile scleroderma inception cohort (www.juvenile-scleroderma.com) is a prospective standardized register for patients with jSSc.
Objectives: Comparison of clinical characteristics of patients with different age range at the time of inclusion in the registry.
Methods: Patients with jSSc were included worldwide to the juvenile scleroderma inception cohort. We compared the demographics and clinical characteristics of

the patients at different age ranges. We created 3 cohorts with different age ranges at onset of disease. Patents aged less than 5 years (Group1), 5–10 years (Group2) and over 10 years (Group3) at the time of diagnosis of the first non-Raynaud involvement of jSSc.
Results: Up till now 88 patients were enrolled,14 patients (15%) in Group1, 22 (25%) in Group2 and 52 (59%) in Group3. Diffuse subtype occurred in 71% in Group1, in 82% in Group2 and in 65% in Group3. Most patients were Caucasian. Disease duration at time of inclusion into the cohort was 3.9 years in Group1, 4.9 years in Group2 and 2.2 years in Group3. ANA positivity was 57% in Group1, 77% in Group2 and 86% in Group3. Anti-scl 70 was around 30% in all groups. Anti-Centromere positivity was 7 to 10%. Mean modified skin score was 12.4 in Group1, 16.5 in Group2 and 15.9 in Group3. Raynaud Phenomenon occurred in 85 to 95% of the patients. History of active or inactive ulceration occurred in 57% in Group1, 62% in Group2 and 43% in Group3. Decreased FVC under 80% occurred in 43% in Group1, 32% in Group2 and 30% in Group3. Pulmonary hypertension occurred in 7% in Group1 and in 10% in Group3. No renal hypertension was observed. Urinary sedimentary changes occurred in 7% in Group1 and in 10% in Group3. Gastrointestinal involvement occurred in 21% in Group1, 45% in Group2 and 27% in Group3. Musculoskeletal involvement occurred in 58 to 64%. Patient global disease activity (VAS 0–100) was 42.8 to 47.9. Patient global disease damage (VAS 0–100) was 39.6- to 45.0. Physician global disease activity (VAS 0–100) was 35.4–40.0. Physician global disease damage (VAS 0–100) was 37.1 in Group1, 41.3 in Group2 and 27.7 in Group3.
Conclusions: It seems to be that patients, with onset of the disease in younger age have more severe disease as patients with disease onset after the age of 10 years. We need more patients in our cohort to gain more sufficient data to prove our preliminary observation.

AB0958 PROPOSAL FOR A JUVENILE SYSTEMIC SCLEROSIS RESPONSE INDEX (JSSCRI): RESULT OF THE CONSENSUS MEETING IN HAMBURG. GERMANY 11TH OF DECEMBER 2016

I. Foeldvari[1], D.F. Furst[2], J. Anton[3], E. Baildem[4], M. Blakley[5], T. Constantin[6], P. Costa Reis[7], M. Curran[8], M. Cutolo[9], C. Denton[10], K. Fligelstone[11], B. Hinrichs[12], F. Ingegnoli[13], A. Kienast[1], D. Němcova[14], C. Pain[4], C. Pilkington[15], V. Smith[16], D. Khanna[17]. *[1]Hamburg Center for Pediatric and Adolescent Rheumatology, Am Schön Klinik Eilbek, Hamburg, Germany; [2]UCLA, Los Angeles, United States; [3]Sant Joan de Déu Hospital, Barcelona, Spain; [4]Alder Hey Children's Foundation NHS Trust, Liverpool, United Kingdom; [5]Indiana University, Indianapolis, United States; [6]Semmelweis University, Budapest, Hungary; [7]Hospital de Santa Maria, Lisbon, Portugal; [8]Northwestern University, Chicago, United States; [9]University of Genova, Genova, Italy; [10]Royal Free Hospital; [11]FESCA, London, United Kingdom; [12]Practice Buchholz, AMS, Hamburg, Germany; [13]University of Milan, Milano, Italy; [14]Department of Pediatrics and Adolescent Medicine Charles University, Prague, Czech Republic; [15]GOSH, London, United Kingdom; [16]GU(H), Ghent, Belgium; [17]Univ Michigan, Michigan, United States*

Background: Juvenile Systemic Sclerosis (jSSc) is an orphan disease. There is increasing interest in testing novel therapies in the management of fibrotic diseases. Therefore, it is very important to develop a Response Index for jSSc (JSScRI) to distinguish effective therapies from placebo. In 2014 at the 1st JSScRI Consensus Meeting in Hamburg, following two rounds of a Delphi process, a proposal for domains and items for a JSScRI were made. In 2016, the 2nd JSScRI Consensus Meeting was held in Hamburg, Germany.
Objectives: To conduct a Nominal Group Technique (NGT) and select potential core data set items that could change as outcome measures) that will be incorporated in the development of a JSScRI.
Methods: Before the 2nd JSScRI Consensus Meeting, the items from the 1st JSScRI Consensus Meeting (2014) were scored via Email, in a Delphi by the participants of the current meeting. Participants included 14 experts in adult and juvenile SSc and a patient partner. During the subsequent face to face NGT meeting, moderated by DEF, and the items were scored anonymously by the participants after a nominal group discussion. The domains and items were scored regarding their importance for 1 year clinical trial from 1 (not relevant at all) to 9 (most relevant). A priori, it was agreed by the participants that the goal of the NGT was to exclude items that: 1. Are not feasible and 2. do not represent a changeable outcome measure even though they may represent the impact of disease on quality of life, vocational or recreational activity. Items with a median score of <4 in which greater than 1/3 of participants scored 1–3 [despite the item having a median score >3] were excluded.

Table 1. Assessment of the Activity of the Musculoskeletal domain

	Whole Group	1–3	4–6	7–9
1) Swollen joints	7	0	1	12
2) Limited range	7.5	1	1	10
3a) MMT	8	0	1	11
3b) CMAS	7	4	1	7
4) Presence of tendon friction rub	7	1	2	10
5a) CK	8	1	1	11
5b) Aldolase	7	3	3	7

Results: Seventy-one items in 13 domains were scored. Six items were not scored as they were felt to not represent an outcome measure or were non-feasible and six items received a median score less then 4.
Table 1 provides an example of the musculoskeletal domain with the median scores for different outcome measures.
Conclusions: In a rigorous, NGT consensus meeting, some item reduction for the JSScRI was achieved. Items will be tested in a prospective way in the patients of the inception cohort of juvenile SSc (www.juvenile-scleroderma.com).

AB0959 EVALUATE THE CARDIOVASCULAR RISK THROUGH CAROTID INTIMA-MEDIA THICKNESS IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS IN THE YOUNG ADULT AGE

J.J. Bethencourt, L. Expósito, S. Bustabad. *Rheumatology, Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain*

Background: The relationship between inflammation and atherosclerosis has been demonstrated, so it is important to identify early markers of the disease. Ultrasound carotid intima-media thickness (CIMT) measurement is a non-invasive, consistent, validated technique used as a marker to identify subclinical arteriosclerotic disease.
The long-term risk of cardiovascular disease in young adult patients with juvenile idiopathic arthritis (JIA) is unclear and there are no risk management guidelines for these patients.
Objectives: To assess whether there is an increase in CIMT in the young adult with a history of JIA and to relate CIMT with classic cardiovascular risk factors in these patients.
Methods: Observational and cross-sectional study. Follow-up patients from transitional care between 18 and 36 years old, with JIA diagnosis by ILAR classification. Filiations data, anthropometric variables and activity disease scores were collected.
We performed, prior informed consent, CIMT measurement by radiofrequency with Esaote MyLab 70XVG. Three measurements were performed on each carotid artery, according to the protocol of the American Society of Echocardiography.
Results: Of the 20 patients, 17 (85%) women and 3 (15%) men. Subtype distribution was 8 (40%) oligoarticular, 1 of them ANA negative; 8 (40%) polyarticular being 4 seropositive and 4 seronegative; 1 systemic (5%); 2 (10%) psoriatic arthropathy and 1 (5%) HLA B27 positive arthritis. 66.7% are with disease modifying drugs (26.7% synthetic and 40% biological), while 33.3% do not have specific treatment.
The main variables studied are described in the attached table (Table 1).
In two previous independent studies conducted by Falaschi and Huang, CIMT was found to be 0.54±0.03 mm and 0.54±0.06 mm in 26 and 38 patients, respectively. From these results a mean and standard deviation of 0.54±0.05 mm were obtained. Using this last result as a control group, we compared it with the results of our series (0.466±0.068), with a significant difference ($p<0.001$).
In the statistical analysis, using the Rho Spearman, a significant correlation of the CIMT with the time of evolution of the disease in years ($r=0.579$) and systolic blood pressure ($r=0.621$) was observed at the level of 0.01 and with C Reactive Proteine ($r=0.524$) and BMI ($r=0.471$) at the 0.05 level.

	N	Minimum	Maximum	Media	Typical deviation
Age	20	18	36	24,75	5,350
Diagnosis age	20	1	16	9,70	5,048
Evolution time (years)	20	5	27	15,00	6,720
BMI (Kg/cm^2)	19	15,5	38,5	24,505	6,4347
Abdominal perimeter	20	58	126	81,33	19,392
Waist-hip index	20	44	135	90,40	26,009
Systolic blood pressure	20	96	130	114,05	7,258
Diastolic blood pressure	20	60	99	73,80	12,271
Left CIMT	20	394	634	464,15	54,788
Right CIMT	20	337	600	467,45	80,275
HAQ	17	,00	2,25	,3529	,59986
VAS pain (mm)	18	0	8	3,17	2,618
CRP (mg/L)	17	,3	57,7	9,419	14,6040
DAS28	16	,97	3,97	1,8856	,88204

Conclusions: The carotid intima-media thickness of patients with JIA were lower than the controls previously described in the literature, so we will complement this study with our population controls.
In addition to classic cardiovascular risk factors such as systolic blood pressure and BMI, there is correlation with the evolution time in years of the disease and CRP, so that in transitional care programs we must the activity of the disease and insist on identification, control and follow-up of the classics factors associated with cardiovascular risk.

AB0960 GROWTH AND SEXUAL MATURATION IN GIRLS WITH JUVENILE IDIOPATHIC ARTHRITIS

L.M. Gonçalves[1], S.H. Machado[2], R.M. Xavier[3], P.J.C. Maróstica[4], P. Lora[5], L. Trindade[5]. *[1]student, PUCRS; [2]Rheumatology service, HCPA; [3]Rheumatology service, UFRGS; [4]Pediatrics service, UFRGS/Hcpa; [5]Unisinos, Porto Alegre, Brazil*

Background: Juvenile idiopathic arthritis (JIA) is a heterogeneous group of diseases with onset before the age of 16 years and joint inflammation as a main feature. Longitudinal growth is one of the main physical changes in childhood and adolescence. The etiology of delayed growth in children with JIA is multifactorial and strongly associated with prolonged inflammatory activity.
Objectives: To evaluate growth, sexual maturation, and the difference between final and expected height in girls with JIA and no glucocorticoid treatment for at least six months, as compared to a group of healthy girls.
Methods: This cross-sectional study involved 44 girls with JIA, diagnosed according to International League of Associations for Rheumatology (ILAR) criteria, and 59 healthy controls, aged between eight and 18 (incomplete) years with no comorbid chronic diseases. Demographic data were collected from all participants, and disease and treatment variables were compiled for the patient group. Anthropometric measurements were converted into z-scores based on WHO standards. Sexual maturation was classified according to Tanner stages.
Results: BMI and height z-scores were lower in girls with JIA as compared to control participants. These values differed significantly in Tanner stage II. Three (6.8%) girls with JIA had height-for-age z-scores <-2 (short stature). Girls with polyarticular JIA and higher cumulative glucocorticoid doses were significantly more likely to present with short stature. The percentage of prepubertal girls in the JIA group was significantly higher than that observed in the control group, (p=0.012). Age of menarche, adult height, and the difference between actual and expected height did not differ between groups.

Table 1. Comparison of pre- and postmenarcheal growth parameters between groups

Variables	Patients (n=44) Mean ± SD	Control participants (n=59) Mean ± SD	*p*
Menarche – n (%)	17 (38.6)	37 (62.7)	0.026
Age of menarche (years)	12.2±1.51	11.5±1.24	0,066
Menarche >2 years – n (%)	13/17 (76.5)	22/37 (59.5)	0.363
Δ Target height (father/mother)	-3.15±7.87 (n=8)	1.31±5.44 (n=16)	0.117
Nutritional data			
BMI z-score	-0.10±1.29	0.92±1.19	0.007
Height/age z-score	-0.14±1.24	0.27±1.17	0.253
Bone age z-score	-1.53±4.29	-1.42±2.17	0.928

Conclusions: These findings suggest that even six months after the suspension of glucocorticoid treatment, children with more severe forms of JIA and exposure to higher doses of glucocorticoids are still susceptible to growth impairment and delayed puberty.

AB0961 A COHORT OF PATIENTS WITH AUTOINFLAMATORY DISEASES FOLLOWED-UP IN A UNIT OF PAEDIATRIC AND TRANSITIONAL RHEUMATOLOGY: A DESCRIPTIVE STUDY

A. Boteanu, M. Llop Vilatella[1,1], M.A. Terán Tinedo, M.Á. Blázquez Cañamero, W.A. Sifuentes Giraldo, M. Vázquez Díaz, M.L. Gámir Gámir. *Rheumatology, Hospital Universitario Ramón y Cajal, Madrid, Spain*

Background: The autoinflammatory diseases (AD) are uncommon, most of them are presented as episodes of recurrent fever and may be accompanied by other inflammatory symptoms. This group of diseases includes polygenic entities (without a single known genetic mutation) such as Behçet's disease (BD), systemic-onset juvenile idiopathic arthritis (soJIA), Chronic recurrent multifocal osteomyelitis (CRMO) and PFAPA syndrome. On the other hand, we found the entities that present with specific monogenic mutations, such as Familial Mediterranean Fever (FMF), TNF receptor-associated periodic syndrome (TRAPS), hyper-IgD syndrome and periodic fever (HIDS), cryopyrinopathies (FCAS, MWS, CINCA), Blau's syndrome and PAPA. A group of patients who can not be classified into a specific diagnosis are clustered as recurrent fever without known genetic anomaly (RFW).
Objectives: To describe and compare the clinical features of monogenic and polygenic AD and RFW seen in a paediatric and transitional rheumatology unit of a Spanish tertiary care hospital.
Methods: We performed a retrospective study including 39 patients with AD followed-up in our center.
Results: The distribution of diagnoses was: soJIA 19 patients (48.72%), BD 5 (12.82%), PFAPA 6 (15.38%), CRMO 3 (7.69%), RFW 4 (10.26%), HIDS 1 (2.56%) and CINCA 1 (2.56%). Patients came from different regions of Spain, being 22 of them boys (56.41%) and 17 girls (43.59%). The genetic study was performed in 12 patients, being positive in 7 (17.95%). Mean age at onset of symptoms was 5±5.65 years in monogenic diseases, 7.96±4.84 years in polygenic disorders and 9.5±5.91 years RFW. Delay in diagnosis in monogenic diseases was higher than in polygenic diseases (67±69.29 months vs. 24.03±30.33 months, respectively). The clinical manifestations more frequently found were fever, followed by joint involvement, being more common in monogenic diseases than in polygenic disorders (table). Haemoglobin levels were lower in monogenic than in polygenic diseases 9.95 g/dL ± 0.63 vs. 11.69 g/dL ± 2, ESR and CRP was higher in monogenic diseases 106 mm/h ± 68.5 and 80.5 mg/L ± 84.14 vs. 56.1 mm/h ± 33.78 and 57.95 mg/L ± 57.95, unlike ferritin that was more elevated in polygenic disease 896 μg/dL ± 1788.34 than in monogenic diseases 183 μg/dL ± 195.7. During his follow up 84.62% of patients received corticosteroids, 51.8% methotrexate and 46.15% biological therapy.

	Monogenic	Polygenic	Recurrent fever
Fever	100%	81.25%	100%
Joint involvement	100%	62.5%	75%
Rash	100%	59.38%	0%
Lymphoadenopathy	50%	46.88%	25%
Splenomegaly	100%	12.5%	0%
Abdominal involvement	30%	21.88%	25%

Conclusions: soJIAs was the most frequent AD in our center. All the patients had a similar gender distribution. Delay in diagnosis was greater in monogenic diseases compared with polygenic disorders. Fever and joint involvement were the more common clinical manifestations, especially in monogenic diseases. Ferritin levels were higher in polygenic diseases, whereas CRP and ESR which were higher in monogenic diseases. During the follow-up most patients required treatment with corticosteroids and approximately half of them required biological therapy.

AB0962 CLINICAL AND LABORATORY CHARACTERISTICS OF NON-BACTERIAL OSTEOMYELITIS: DATA ANALYSIS OF 91 PATIENTS

M.M. Kostik[1], O. Kopchak[1,2], A. Mushkin[3]. *[1]Saint-Petersburg State Pediatric Medical University, Saint-Petersburg; [2]Kirov's regional children's hospital, Kirov; [3]Federal State Budget Institute "Science research Institute of Phthisiopulmonology", Saint-Petersburg, Russian Federation*

Background: Non-bacterial Osteomyelitis (NBO) is a sterile inflammatory bone disorder of unknown etiology. It typically affects children and most commonly presents with bone pain and/or swelling.
Objectives: The aim of study is to evaluate clinical and laboratory features of non-bacterial osteomyelitis in children.
Methods: Our retrospective – prospective study was included 91 patients with NBO. A routine blood test (WBC, platelets, ESR, C-reactive protein (CRP) and hemoglobin levels), a radiological examination and a bone biopsy with evaluation bacteriological and morphological data were performed in all patients.
Results: The mean age of onset NBO was 7.3 years (2.5; 10.6). We did not reveal any gender peculiarities in our study. Family history of immune-mediated diseases is found in 5/75 (6.7%) in prospective group. Concomitant immune-mediated diseases were noted in 62/89 (68.1%). Diagnostic delay was 6.3 (2.0; 17.8)

months. The radiological examination was performed in the following ratio: X-rays - 91 (100.0%), CT - 79 (86.8%), MRI - 66 (72.5), including MRI "whole body" with 15 pts, bone scintigraphy - 54 (59.3%). Monofocal form was registered in 1/3 cases. 2/3 cases was presented as a typical multifocal process with predominant involvement femur - 37 (40.7%), bone of foot - 36 (39.6%), tibia - 33 (36.3%), spine – 29 (31.9%). The number of foci is 3.0 (1.0; 6.0). We did not revealed any significant differences in quantity of WBC, platelets, hemoglobin level, ESR, CRP). Evidence confirming NBO was a negative bone biopsy in 100.0% cases. However, morphological data were as non-specific, as granulomatous inflammation.

Conclusions: NBO is determined as a primarily chronic multifocal process without specific clinical and laboratory peculiarities, associated with immune-mediated diseases. Diagnose must be established on morphological and bacteriological data bone biopsy.

AB0963 LIPID ABNORMALITIES IN CHILDREN AND ADOLESCENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

L.F. Bogmat, N.S. Shevchenko, I.N. Bessonova, V.V. Nikonova. *Department of Cardiorheumatology, Institute of Children and Adolescents Health Care, Kharkiv, Ukraine*

Background: Systemic lupus erythematosus is an autoimmune disease that leads to the progressive destruction of the vital organs and systems, promotes early disability, premature mortality. The main reasons for the latest adult population of patients have complications of atherosclerotic vascular lesions stuch as the myocardial infarction and the stroke. The greatest effectiveness of preventive measures of the progression of atherosclerotic process and its associated cardiovascular complications determine the maximum early to start immediately after diagnosis in childhood and adolescence.

Objectives: To evaluate the lipid spectrum of the blood of children and adolescent patients with SLE.

Methods: It was been examined 26 persons 7–18 years with systemic lupus erythematosus, mostly female (88.46%), which were determined by the concentration of total cholesterol (total cholesterol), HDL cholesterol (HDL cholesterol), low density lipoprotein cholesterol (LDL), triglycerides (TG), calculated coefficient of the atherogenicity (CA = (total cholesterol - HDL cholesterol)/HDL cholesterol). Distribution groups conducted depending on the duration of the disease: the first consisted of 10 patients (38.46%) with a term of 1–3 years of the disease, the second - 16 people (61,54%) with duration of more than 3 years. The control group consisted of 10 healthy peers.

Results: Average lipid spectrum of the blood of patients did not exceed the reference values and had no statistical differences in the patients allocated to groups. However, in comparison with the control group the children with SLE had significant differences that reflect the peculiarities of formation of their metabolic disorders. Thus, total cholesterol and TG levels in both the first and the second groups were significantly higher than the control value and accounted for (5,02±0,26) mmol /L (5,24±0,26) mmol/L vs (3,39±0,20) mmol/L ($p<0$, 05) and (1,64±0,54) mmol/L (1,45±0,19) mmol/L vs (0,72±0,08) mg /L ($p<0.05$), respectively. Similar changes had occurred with parameters of LDL cholesterol, which significantly increased among patients with disease duration of 1–3 years ((3,08±0,26) mmol/L vs (1,73±0,03) mg/dL in the control group; $p<0.05$) and reached biggest values in patients with SLE over the course of 3 years ((3,57±0,82) mmol/l, $p<0.05$). In parallel, the concentration of HDL cholesterol patients of the second group decreased ((1,38±0,06) mmol/L vs (1,51±0,08) mg/dL healthy subjects, $p<0.1$), the consequence was significant increase in their spacecraft ((2,79±0,69) conv. units. against (1,24±0,17) conv. units. in comparison group, $p<0.05$).

In addition, patients with SLE found a direct correlation of total cholesterol blood of disease activity, confirmed a direct correlation ($r = 0,632$; $p<0.05$).

Conclusions: Thus, changes of blood lipid profile in the SLE patients occur in the early stages of the disease in childhood and adolescence, have the atherogenic focus, which compounded with increasing the duration and disease activity.

AB0964 SOME PECULARITIES OF THE COURSE OF JUVENILE IDIOPATHIC ARTHRITIS IN PATIENTS TREATED WITH TOCILIZUMAB

O.A. Oshlyanska, A.G. Artsymovych. *Connective Tissue Disorders in Children, State Institute of Pediatrics, Obstetrics and Gynecology, Academy of Medical Sciences of Ukraine, Kyiv, Ukraine*

Background: The introduction of biological therapy drugs contributes to changing the natural course of the disease in cases of severe JIA.

Objectives: To clarify impact of tocilizumab on the course of JIA.

Methods: Of 117 children with JIA being under observation for the last five years 35% receive biologic therapy (3 etanercept, 21 adalimumab, 11 tocilizumab) during 1–5 years. Retrospective analysis of the data from clinical, laboratory and instrumental studies in the dynamics of the TCZ treatment of patients with JIA was made.

Results: Among children treated with TCZ 63,6% were sJIA cases, 63,6% were female. Age of onset 6,1±4,7y (6m–10,5y), all had acute onset, hyperthermia, severe pain syndrome, exudative arthritis in all pJIA cases and half of sJIA cases. ESR 39,7±11,2 mm/h, CRP 53,8±16,1 mg/L, all patients had anemia, leukocytosis and were seronegative for RF and anti-CCP, 3 of pJIA patients revealed ANA (1:1200–2400), IL-6 19,78±6,7 pg/ml. Before biological therapy has begun, SJIA courses were continuously relapsing in all cases with 4,7±2,1 exacerbations per y; during the 1st y of illness 8 cases run with coxitis, 7-cervical spine involvement, 9-wrists damage. All patients received CS therapy before initiating TCZ, 45,4% of them with pulse therapy, all marked by the inability to minimize the CS dose, all received 2–4 DMARDs in high doses. 2 patients received adalimumab before TCZ treatment. Elapsed time from the onset to biological agent prescription was 5,37±5,1 years. At the start of biological therapy JADAS was 19,6±5,7, stunted growth -1,88±0,3 σ, according to densitometry, osteoporosis took place in every case (Z=-2,7±1,1). After 6 month JADAS was 1,8±1,1, ESR and CRP normalized, IL-6 rate remained high in 36% cases. After 1 year the severity of osteoporosis decreased (Z = -1,17±0,8), bone deficiency depended on duration of TCZ exposure (r = -0,72) and on the elapsed time from onset of JIA before the start of biological therapy (r = -0,84). The mean increase in height was 7.73 cm/patient-year (+1±0,8 σ). Stunted growth depended on the duration of the TCZ course (r=-0,81) and the elapsed time from the onset of the disease to the start of biological therapy (r=-0,72). After 1 y of TCZ all children had normal weight and BMI for age (19,89±1,9). After 1–5 ys of treatment JADI was evaluated 2,1±2,9 (0–7), the degree of joint damage didn't depend on the duration of the biological therapy (r=0,24) and correlated with the time elapsed from the onset of the disease before treatment (r =0,59). During the treatment, exacerbations were marked only in 1 case, adverse events in 3 cases (skin infections, leukopenia). TCZ therapy allowed to completely discontinue CS in 63,6% cases, minimize them to 4 mg/day in others, DMARDs are discontinued in 9% cases.

Conclusions: Administration of TCZ is rather effective towards the drug induced remission even in long-time JIA process, but the least joint damage, osteoporosis and stunted growth can be obtained with earlier tocilizumab prescription. Reclassification of patients according to specific clinical and immunological features leads to optimization of the selection of targeted therapy.

References:

[1] While identifying in onset of JIA polyarticular destruction and systemic features (hyperthermia, anemia, leukocytosis, high laboratory activity and severity of osteoporosis) one should consider the feasibility of early administration of tocilizumab.

AB0965 EVALUATION OF BONE MINERAL DENSITY IN CHILDREN WITH CHRONIC RECURRENT MULTIFOCAL OSTEOMYELITIS AT DIAGNOSIS

Ö. Sert[1], E. Çomak[2], G. Kaya Aksoy[2], A. Gemici[2], M. Koyun[2], S. Akman[2]. *[1]Pediatrics; [2]Department of Pediatric Nephrology and Rheumatology, Akdeniz University School of Medicine, Antalya, Turkey*

Background: Chronic recurrent multifocal osteomyelitis (CRMO) is a rare autoinflammatory disorder that has sterile bone inflammation as a main phenotypic feature. Diagnosis of CRMO is based on typical clinical and radiologic findings and presence of some inflammatory markers. Plain radiographs, technetium bone scan and MRI may be used for diagnosis of children with suspected CRMO. Despite data for other imaging methods in chidren with CRMO, little information is available regarding the bone mineral density.

Objectives: The aim of the study was to evaluate bone mineral density (BMD) findings in children with CRMO at time of diagnosis.

Methods: The medical records of children with CRMO were reviewed retrospectively. Children who met Bristol diagnostic criteria were included in the study. Clinical and laboratory findings, bone scan and MRI features were analyzed. Bone mineral density was measured by DEXA technique at femoral neck and lumbar spine regions; a Z-score< -2 was considered as osteoporosis.

Results: A total of 6 patients, one girl and 5 boys, with a median age of 10 years (4 – 14 years) and a median follow-up period of 38.5 months (3 – 72 months) were included in the study. MRI and whole body technetium bone scan were performed at 6 and 4 children, respectively and detected at least two lesions MRI or bone scans. Osteoporosis was detected in 5 patients at diagnosis. Bone mineral density Z-scores were median -2.9 [-4.9±(-2,4)] and -2.9 [-4,1 – (-1,8)] at femoral neck and lumbar spine, respectively.

Conclusions: Osteoporosis is common in children with CRMO, it may be related with disease spectrum. Evaluation of bone mineral density abnormalities at time of diagnosis and during therapy may be a part of primary care in children with CRMO.

AB0966 THE CLINICAL OBSERVATION OF IMMUNOADSORPTION IN TREATMENT OF CHILDREN WITH REFRACTORY AUTOIMMUNE DISEASES

P. Zeng[1], H. Zeng[2]. [1]*Department of Pediatric Allergy, Immunology and Rheumatolog, Guangzhou Women and Children's Medical Center, Guangzhou;* [2]*Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children's Medical Center, Gungzhou, China*

Objectives: Explore the clinical efficacy and safety of the immunoadsorption assisted treatment of children with refractory autoimmune diseases.
Methods: Use HA280 type resin perfusion machine for four times of whole blood immunoadsorption treatment for one case of a 4-year-old child combined with severe dermatomyositis and pulmonary infection, one case of 9-year-old child with severe allergic purpura combined with gastrointestinal bleeding, intestinal perforation, after intestinal tract partial hepatectomy, one case of 11-year-old child with systemic juvenile idiopathic arthritis combined with head and facial cellulites and macrophage activation syndrome. Observe the improvement of its clinical manifestations, serum immunoglobulin, complement, liver and kidney function, myocardial enzymes, autoantibodies.
Results: The children's signs and symptoms improved significantly after treatment of whole blood immunoadsorption, the sensitivity of the adrenal cortex hormones increased, liver and kidney function, myocardial enzymes improved, the levels of serum IGG descended, complement (C3, C4) rose, anti-cyclic citrullinated peptide (CCP) was negative.
Conclusions: The whole blood perfusion immunity adsorption treatment is able to to reduce blood plasma IGG, improvement complement C3 and C4 level, eliminates anti-CCP immune body in vivo, reduce the cardiac muscle zymogram and the liver enzyme in a short time, increase sensitivity to the adrenal cortex hormone, alleviate immunological disease's symptom in active stage, have the affirmative function to make the baby pass the dangerous period safely. The child whole blood fills the class immunity adsorption not to present the untoward effect. No untoward effect happened.

AB0967 CLINICAL, LABORATORY PROFILES AND LONG-TERM OUTCOME OF JUVENILE CUTANEOUS PAN: A SINGLE CENTER EXPERIENCE

R.A. Castellanos-Moreira[1], J.M. Mosquera[1], S.C. Rodriguez-Garcia[1], J. Calzada[1], A. Vicente[2], E. Iglesias[1], R. Bou[1], J. Anton[1]. [1]*Rheumatology;* [2]*Dermatology, Hospital Sant Joan de Déu, Barcelona, Spain*

Background: Cutaneous polyarteritis nodosa (cPAN) is an immune complex-mediated rare disease that affects small and medium sized vessels in the dermis and subcutaneous tissue.
The clinical course is characterized by periodic exacerbations and remissions that may persist for many years. Most patients respond to NSAIDs and glucocorticoids (GC), whereas some may require DMARDs and/or immunomodulatory therapy.
Objectives: To describe the diferrent clinical patterns, laboratory findings and long term outcomes of juvenile cPAN in a tertiary care hospital.
Methods: Retrospective observational study, including all patients diagnosed with cPAN between 2002–2016. Diagnosis relied on clinical features confirmed by histological study. Recorded data included clinical features, laboratory results and long-term outcomes.
Results: 10 children were included (7 female), mean age at onset was 9.9 years (r:4.1–16.3). Delay from symptoms onset to biopsy confirmed diagnosis was 2±2.3 months; 4 patients underwent a second biopsy due to inconclusive results in the first performed.
Clinical features included cutaneous (100%) and osteomuscular involvement (50%), fever (40%), neuropathy (10%) and weight loss (10%). Reported cutaneous symptoms were 8 patients with nodules, 4 livedo, 4 purpura, 1 ulcer and 1 necrosis. Most lesions were localized in the lower limbs (8), even though it was also reported in upper limbs (3) and trunk (3). Most cases exhibited raised CRP, ESR and leukocyte count with a mean of 26.4±47.9 (mg/L), 27.7±29.7 (mm/h), and 8.6±5.3 (x 10^9/L) respectively.
As first line therapy, all patients received GC and 6 NSAIDs. 8 were given a DMARD such as HCQ or MTX. Due to persistent activity or relapse, rescue treatment with pulse-GC (20%), MMF (10%) or IVIG (20%) was instituted. Only 1 patient received penicillin prophylaxis due to relapses associated with streptococcal infection.
Mean follow-up was 3.9 years (r: 1.1–10.4). 4 patients had a monophasic disease, six suffered ≥2 relapses. At last follow-up 9 patients were on remission, even though 3 were off-therapy. No complications were reported.
Conclusions: Clinical and laboratory findings in our series was similar to previous reports. However, our patients presented a greater number of relapses and DMARDs requirement.

AB0968 HYPOVITAMINOSIS D IN JUVENILE IDIOPATHIC ARTHRITIS: PREVALENCE AND RELATED FACTORS

R. Galindo Zavala[1], L. Martín Pedraz[2], E. Núñez Cuadros[3], G. Díaz-Cordovés Rego[4], A.L. Urda Cardona[2]. [1]*Paediatric Rheumatology;* [2]*Paediatrics;* [3]*Universitary Regional Malaga Hospital, Malaga, Spain;* [4]*Rheumatology, Universitary Regional Malaga Hospital, Malaga, Spain*

Background: 25hydroxy-vitamin D not only plays a key role in calcium homeostasis, but also has antiinflammatory and immunomodulatory properties. Hypovitaminosis D prevalence in children suffering from Juvenile Idiopathic Arthritis (JIA) ranges from 6% to 30% according to different publications.
Objectives: Evaluate hypovitaminosis D prevalence in JIA pediatric patients in Spain and assess involved factors.
Methods: Observational cross-sectional study in JIA Spanish patients from 4 to 15 years, monitored by a Pediatric Rheumatology Unit. Monoarticular forms and patients with other chronic diseases or receiving different treatments from those indicated for JIA were excluded.
Anthropometric, clinical and treatment data were recorded. Bone metabolism parameters and validated diet (KIDMED) and exercise (PAQ-C/PAQ-A) questionnaires were obtained.
Hypovitaminosis D was defined as 25hydroxy-vitamin D plasma levels lower than 30 ng/ml
Results: 76 children participated. Their characteristics are included in table 1.
The population's prevalence estimation of hypovytaminosis D in children with JIA was 16 - 35% (CI 95%).
We found no relationship between 25 hydroxy-vitamin D levels and sex, JIA subtype neither duration or dose of systemic glucocorticoids.
In bivariate analysis we found direct association between hypovitaminosis D and Body Mass Index percentile (BMIp) (p=0,05), received dose of prednisone (p=0,03) and clinical activity duration (p=0,04); and an inverse relationship with physical activity level (p=0,04).
In multivariate analysis, relationship between hypovitaminosis D and BMIp (B 0,024; p 0,016) and with disease activity (B 0,015; p 0,01) were maintained. Moreover, we found an inverse association with biological disease-modifiying antirheumatic drugs (B-4,69; p 0,048), specifically with anti-tumoral necrosis factor α (antiTNFα) (B -4,7; p 0,042)

PATIENTS' CHARACTERITICS (N=76)		
Gender (Male), n (%)		23 (30,3)
Age (years), median (IR)		10,83 (8,52-13,54)
25OH-Vitamin D (ng/mL), mean (+/-SD)		34,04 ng/mL (8,90ng/mL)
DISEASE CHARACTERISTICS (N=76)		
JIA subtype, n (%)	Systemic	9 (11,8)
	Persistent oligoarticular	35 (46,1)
	Extended oligoarticular	12 (15,8)
	Positive RF polyarticular	1 (1,3)
	Negative RF Polyarticular	19 (25,0)
Duration disease (years), median (IR)		6,55 (3,29-9,45)
Inflammatory activity duration (days), median (IR)		385,0(246,75-761,25)
RECEIVED TREATMENTS (N=76)*		
Systemic GC, n (%)		61 (80,2)
GC treatment duration (days), median (IR) *(n=84)		125,00 (66,00-179,00)
Mean GC dose (mg/kg/day), median (IR)		0,276 (0,169-0,457)
Synthetic DMARDs treatment, n (%)		39 (51,3)
Biological DMARDs treatment,, n (%)		21(27,6)
Biological DMARDs treatment subtype, n(%)	Anti-TNFα	15 (19,7)
	Anti-IL1	4 (5,2)
	Anti-IL6	2 (2,6)

JIA: Juvenile idiopathic arthritis; RF: Rheumatic factor; GC: glucocorticoids; DMARD: Disease-modifying antirheumatic drug; Anti- TNFα: anti- tumoral necrosis factor α;Anti-IL1: anti-interleukin 1; Anti-IL6: anti-interleukin 6

Conclusions: Hypovitaminosis D prevalence in our population is similar to previously described.
JIA patients with higher BMIp have more hypovitaminosis D, as it has been reported in other inflammatory diseases.
A direct relationship exists between inflammatory activity and vitamin D, but we need more studies to asses if one is cause or consecuence of the other.
Patients treated with antiTNF have better plasma levels of 25 hydroxy-vitamin D, this can be explained because these drugs may increase 25 hydroxy-vitamin D

levels or due to a better response to antiTNF of those patient with higher plasma levels of 25 hydroxy-vitamin D.

AB0969 IMPACT OF JUVENILE IDIOPATHIC ARTHRITIS ON SCHOOLING

S. Rahmouni, A. Fazaa, K. Ouenniche, S. Kassab, S. Chekili, K. Ben Abdelghani, A. Laater. *Rheumatology Department, Mongi SLim hospital, marsa, Tunisia*

Background: Juvenile idiopathic arthritis (JIA) is the most common chronic rheumatic disease in children and is one of the major causes of morbidity and physical disability.Due to frequent absences,children with chronic health impairments are also often confronted with educational difficulties.
Objectives: The aims of this study were to assess the impact of JIA on children's schooling and to determine the factors that influence their school level.
Methods: This is a cross-sectional study including patients with JIA (ILAR criteria).A detailed questionnaire was completed for each participant by interviewing them or their parents as well as by information obtained from their medical records.Collected data included age,sex,subtype of JIA,disease duration,level of disability according to the Childhood Heath Assessment Questionnaire (CHAQ),visual analog scale for patient's overall assessment of disease activity,duration of morning stiffness, joint counts,erythrocyte sedimentation rate,C-Reactive Protein,Disease Activity Score (DAS28).Medications used for JIA treatment were also documented.
Data on the school performance of patients and their siblings were obtained using telephone interviews (educational level, absenteeism, school delay by repetition, drop-out).
The comparison of quantitative variables was performed with the Mann-Whitney test and the comparison of qualitative ones was performed with the Chi square test. The significance level was set at 0.05.
Results: A total of 38 patients with JIA were included, 23 female and 15 male, with a mean age of 26 years [12–51] and a mean disease duration of 237 months [5–496].The average age of the onset of the disease was 7.4 years [1.5–16].
The most common subtype was rheumatoid factor-positive polyarthritis (n=16) followed by systematic (n=7), oligoarticular (n=6), rheumatoid factor-negative polyarthritis (n=5) and Enthesitis-related arthritis (n=4). The mean DAS28 was 2.63 [0.76 - 5.55] and the median CHAQ was 0.528 [0–3].Twenty-seven of the children were receiving corticosteroid. Disease-modifying anti-rheumatic drugs were used by 34 of the 38 patients: methotrexate (n=23), sulfasalazine (n=8),leflunomide (n=7),biotherapies (n=14). Twenty patients had complications:*Hip arthritis (n=15),* growth stunting (n=12), uveitis (n=4). Joint replacement was required in 9 cases.
Four patients were illiterate,12 had dropped out of school,21 reported repeated absences due to illness.A year of schooling was repeated by 61.7% of patients.Ten out of 32 patients over the age of 20 had an university level.Almost 80% of patients were exempted of physical education.
There were no significant associations between the school-related problems,the socio-demographic characteristics and the various parameters of clinical and biological activity studied.School failure was similar among patients and their siblings (p=0.05).
Conclusions: Our study suggested that JIA negatively affects schooling of children.More studies with a larger sample are needed to identify the variables associated with school failure in order to ensure the proper management of these patients and to increase their academic performance.

AB0970 CLINICAL AND IMMUNOLOGICAL CHARACTERISTICS IN CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS TREATED WITH RITUXIMAB

S. Garrote, A. Alia Jimenez, A. Boteanu, M.A. Blazquez, M.L. Gamir. *Rheumatology, Ramon y Cajal Hospital, Madrid, Spain*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease that is more severe in pediatric population than in adults. Biological therapy with anti-CD20 (rituximab) is an option in patient that do not respond to conventional therapy.
Objectives: The aim of this study is to determine the clinical and immunological response in 9 patients with childhood-onset systemic lupus erythematosus (cSLE) that received treatment with rituximab in a third level hospital
Methods: This is a retrospective observational study. 9 patients treated with Rituximab between November 2007 and October 2016 were included and their medical records were reviewed. The response to treatment at 6 months and one year after the first infusion of Rituximab were assessed. Patients with overlap syndromes were excluded. All patients fulfilled four or more of the 1982 revised American College of Rheumatology criteria for the diagnosis of SLE (<16 years).
Results: Nine pediatric patients with SLE treated with rituximab were included, all of them were female. The age at diagnosis of SLE was a mean of 15,22 years. The mean time duration of disease was 87,55months (5–255m). 7 patients were caucasians. Rituximab was indicated in 6 patients with class IV of lupus nephritis (LN) 1/9 with class III LN, 1/9 with severe cutaneous lupus, and with severe hematological manifestations in 1 case (haemolytic anemia). In addition, 6/9 patients had mucocutaneous and articular manifestations. The disease activity of all patients was assessed using SELENA-SLEDAI index pre rituximab infusion, the mean was
17,11 (8–33). All patients had low level of complement C3 and C4 and 8/9 increased anti-DNA. In 8/9 patients Rituximab was used as a rescue treatment and in a single case as a first line.
3/6 patients with renal involvement were previously treated with cyclophosphamide (CF) iv and mycophenolate, 2/6 CF. In case of cutaneous involvement the previous treatment was methotrexate, azathioprine (AZA) and dapsone and in case of hemolytic anemia was AZA.
The treatment protocol was 1 gram x 2 (1 cycle) in 7/9 patients, 375mg/m^2 x 4 in 1/9 cases and 600mg monthly for 5 months in the case of hemolytic anemia. Five patients received more than 1 cycle. After the administration of Rituximab, the SELENA-SLEDAI activity index was 4.5 points. At 6 months a complete response was obtained in the case of hematological and cutaneous manifestations, in 2 cases of lupus nephritis (proteinuria <0.5 g/day) and partial response was obtained in 2 cases. Data were not analyzed in 2 patients (death and less than 6 months of the first dose of rituximab). Patients with partial response and lack of response achieved complete response at 12 months. 2/9 patients had side effects (Rituximab pneumonitis in 1 case and infections in 2 cases). Mortality was 11.11% (1/9 patients, per infection and lupus activity, SLEDAI pre rituximab =33)
Conclusions: In our study, although it consisted of few patients, it was objected that Rituximab therapy in patients with cSLE is effective, reduces lupus activity index, especially in cases of renal, cutaneous and hematologic involvement, that don't respond to conventional therapy. It may be consider in the future as an effective alternative treatment at first line treatment.

AB0971 CHARACTERISATION OF THE PATIENTS AT THE TIME OF THE TRANSITION INTO THE ADULT RHEUMATOLOGY. 63% OF THE PATIENTS ARE IN REMISSION AT THE TIME OF THE TRANSITION

S. Tatsis[1], I. Foeldvari[2]. [1]*Department of Rheumatology, Marienkrankenhaus;* [2]*Hamburg Center for Pediatric and Adolescent Rheumatology, Am Schön Klinik Eilbek, Hamburg, Germany*

Background: The issue of transition from pediatric to adult rheumatology service is an emerging important topic. In 2012 a transition clinic was established according to the "Berliner Transitionsprogramm" [1] in cooperation of the Hamburger Zentrum für Kinder-und Jugendrheumatologie and the Rheumatology Unit of the Marien Hospital in Hamburg. The Berliner programm suggests three visits of the patient in transitionprocess, in the presence of the pedriatic and an adult rheumatologist together, and the fourth visit conducted by the adult rheumatologist alone. We present the characteristics of the patients at the time of the 4th visit.
Objectives: To characterize the patient population at the time of enrollment into the adult service in the frame of our transition programm.
Methods: We collected patient data starting 8/2012 to 11/2016. We summarized the patient population, who succesfully transitioned from pediatric to adult rheumatologic service, concerning diagnosis, sex, age at the time of diagnosis, disease duration at the time of transition, JADAS, HAQ, VAS globular assessment, VAS pain, medication and disease activity.
Results: 73 patients were transitioned. 65% of them female. Mean age at diagnosis of the patients was 12.5 years. Mean disease duration at time of transition ws 10.8 years. The mean JADAS Score was 3.18 and the mean HAQ Score was 0.136. The patients global activity score was, on a VAS of 0 to 100, 14.03 and the global pain score, on a VAS of 0 to 100, 12.33. 39.7% of the patients received synthetic DMARDS and 34% biologic DMARDS: Only 1 patient received steroids. 24.6% of the patients were off medication. 63% of the patients were in remission, 61% of them on medication and 39% off medication in remission.
Conclusions: In this monocenter cohort 63% of patients were in remission, and with the mean JADAS Score of 3.18 most of them have low disease activity under the current treatment. The mean HAQ Score with 0.136 reflects a score, which is expected in healthy controls. But 75.4% of the patients needed medication to

achieve this good condition. The amount of patients on medication emphasize the need of the structured transition.

AB0972 CHILDHOOD ONSET STROKE AND VASCULITIS ASSOCIATED WITH DEFICIENCY OF ADENOSINE DEAMINASE 2 (DADA2)

V. Paisal[1], E. Al-Abadi[1], T. Southwood[1], E. Wassmer[2]. [1]*Paediatric Rheumatology;* [2]*Paediatric Neurology, Birmingham Children's Hospital, Birmingham, United Kingdom*

Background: The deficiency of Adenosine Deaminase 2 (DADA2) is a rare autosomal recessive condition resulting from mutations in CECR1 (Cat Eye Syndrome Chromosome Region 1) gene, mapped to chromosome 22q11.1. It is a type of autoinflammatory disease, mainly characterised by early-onset polyarteritis, haemorrhagic, ischemic strokes and hypogammaglobulinemia (1). We report a case of 7-year boy presenting with haemorrhagic stroke and vasculitis responding to immunosuppression with Anti-TNF drug.

Objectives: A 7 year boy presented to the emergency department with reduced consciousness, headaches and nose bleeds. Initial imaging showed an intraparenchymal haemorrhage requiring frontal craniotomy and evacuation of the haematoma. This acute presentation was preceded by a history of recurrent fevers, weight loss, testicular pain, erythema nodosum and tender lymph nodes.

Methods: The laboratory findings revealed anaemia, ESR of up to 61mm/h, C-reactive protein 100, normal immunoglobulins, positive Anti nuclear antibody (ANA), mildly raised antibodies to double stranded DNA (dsDNA) and Proteinase 3 antibody. Skin biopsy confirmed panniculitis. CT imaging and angiography of the head at the time of acute presentation showed intraparenchymal haemorrhage and aneurysm of the left middle cerebral artery. Further CT angiography of the whole body revealed renal and liver microaneurysms. A provisional diagnosis of Polyarteris nodosa was made and started on steroids and cyclophosphamide. He had further genetic testing, showing mutation in CECR1, leading to Adenosine deaminase 2 deficiency. Patient responded to cyclophosphamide induction regime, which was followed by Etanercept.

Results: We report a case of ADA2 deficiency presenting initially with features of an autoinflammatory disorder, complicated by acute stroke secondary to haemorrhage. Our patient exhibited most of the clinical symptoms previously reported in ADA2 deficiency, including its association with polyarteritis nodosa (2). Although, he did not exhibit hypogammaglobulinaemia (3) which has been reported, interestingly, he was positive for markers of autoimmunity (ANA, ANCA) (4). It has been reported that treatment with anti-TNF and IL-6 (5) could lead to improvement, and our patients initial response to cyclophosphamide was excellent, followed by continued treatment with Etanercept.

Conclusions: Screening for adenosine deaminase 2 deficiency should be considered in all children presenting with neurological symptoms and features of vasculitis.

AB0973 ANTIPHOSPHOLIPID ANTIBODIES IN CHILDREN WITH SYSTEMIC LUPUS ERYTHMATOSUS AND JUVENILE IDIOPATHIC ARTHRITIS

W. Gouda[1], A. Mohamed[2]. [1]*Rheumatology, Aswan University, Aswan;* [2]*Pediatrics, Mansoura Univeristy, Mansoura, Egypt*

Background: Antiphospholipid antibodies (aPL) are a family of autoantibodies that present in a small percentage of the population but occur more commonly in patients with Antiphospholipid syndrome (APS) and Systemic lupus erythematosus (SLE).

Objectives: We aimed to determine of the level of anti-β2-glycoprotein I (anti-β2GPI) (IgG and IgM) isotypes and anticardiolipin antibodies (aCL) as inflammatory markers in children with SLE and Juvenile Idiopathic Arthritis (JIA) and figure out their relation to the clinical manifestations and activity of the disease.

Methods: This prospective study included one hundred twenty children, sixty five having SLE and fifty five having JIA, their ages range between 4.5 – 16 years (37 males and 83 females).In addition, twenty apparently healthy children of comparable age, sex and nutritional status were used as a control group. All patients and normal controls were subjected to full clinical and laboratory investigations included aCL and anti-β2GPI level (IgG and IgM) measured by a standardized ELISA.

Results: IgG isotype of anti-β2GPI was found to be positive in 27.7% and 14.5% for SLE and JIA groups respectively. However IgM isotype of anti-β2GPI was found to be positive in 24.6% and 7.25% for SLE and JIA groups respectively. The mean levels of both IgG and IgM isotypes of anti-β2GPI were found to be significantly increased in comparison to controls ($P<0.001$) in both SLE and JIA groups. IgG isotype of aCL was found to be positive in 23.1% and 18.2% for SLE and JIA groups respectively. However IgM isotype of aCL was found to be positive in 18.5% and 18.2% for SLE and JIA groups respectively. A significant positive correlation was found between IgM and IgG isotypes of anti-β2GPI and with their corresponding class of aCL in both SLE and JIA groups. A significant positive correlation was found between the elevation of anti-β2GPI (IgG) and thrombocytopenia together with neuropsychiatric disease in SLE. While in JIA elevation of anti-β2GPI was found to be correlated only with elevation of aCL irrespective to clinical or laboratory data.

Conclusions: The study reported a higher prevalence of aPL in children with SLE and JIA. Elevated levels of anti-β2GPI (IgG) correlated with thrombocytopenia together with neuropsychiatric disease in SLE.

AB0974 ETANERCEPT TREATMENT FOR A PATIENT WITH REFRACTORY MACROPHAGE ACTIVATION SYNDROME IN JUVENILE SYSTEMIC LUPUS ERYTHEMATOUS

Y. Ramirez, T. Díaz, R. Maldonado, E. Faugier, A.V. Villarreal, N. Acevedo on behalf of Pediatric Rheumatology. *Hospital Infantil de México Federico Gómez, Mexico City, Mexico*

Background: Macrophage activation syndrome (MAS) is a serious, potentially fatal complication of childhood systemic inflammatory disorders, and it is most frequent in Systemic Juvenile Idiopthic Arthritis, for instance, it is increasingly reported in other pediatric rheumatic diseases as lupus erythematosus and Kawasaki disease.

Objectives: To describe clinical case report of a 16 year old girl with Juvenil Systemic Lupus Erythematosus and Macrophage Activation Syndrome refractory.

Methods: A 16-year-old woman with recent diagnosis of Systemic Lupus Erythematosus in November 2015. At admission with continuos fever lasting 2 months, with initial laboratory studies with Triglycerides 395 mg/dl, Ferritin 3.300 ug/l, soluble receptor IL-2 2.838 U/ml, fibrinogen 166 mg/dl, Hemophagocytos in bone marrow, presence of persistent cytopenias. Initial management with methylprednisolone 30 mg/kg/day (3 days) without clinical response was initiated. Management is added to Cyclosporin A (10 mg/kg/day), reporting subtherapeutic serum levels despite high doses without clinical response and improvement of laboratory controls. During the hospital stay complete 13 weeks of treatment with Etposide (180 mg/dose), with ferritin levels in 4,180 ug/l, triglycerides 438, Fibrinogen 455 mg/dl, WBC 5,000 ul^{-1} (3,400 neutrophils, lymphocytes 1,050), platelet count 78 x 103 ml^{-1}, hemoglobin 7.2 g/dl. After three months of treatment, she was given with Etanercept 0.4mg/kg/dose, 2 times a day. Currently in week 3 of treatment with WBC 6,500 ml^{-1}, hemoglobin 9.7 g/dl, platelet count 140 x $103ml^{-1}$ and ferritin 4,270 ng/ml. The patient remains disease with costicosteroid, cyclosporine, and etanercept, without adverse events.

Results: Patient treated with Etanercept during 5 weeks, presenting clinical response for MAS.

Conclusions: A general therapeutic protocol for MAS is not available: first line treatment is usually represented by parenteral administration of high dose corticosteroids. Mild forms are reported to respond to steroids alone in association with supportive medicaments. Steroid-resistant cases or the most severe forms of MAS require the addition of cyclosporine A, other therapeutic regimens have been studied such as high-dose intravenous immunoglobulins, antithymocyte globulins, etanercept, etoposide and plasmapheresis

AB0975 **INCIDENCE OF INFECTIONS WITH BIOLOGICAL THERAPIES IN PARAGUAYAN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS: BIOBADAGUAY (BIOLOGICAL THERAPIES ADVERSE EVENTS PARAGUAYAN-URUGUAYAN REGISTER)**

Z. Morel[1,2], P. De Abreu[3], I. Acosta[3], G. Avila[4], S. Cabrera[4] on behalf of BIOBADAGUAY Group. *[1]Cátedra de Pediatría, Universidad Nacional de Asunción; [2]Pediatría, Hospital Central del IPS; [3]Sociedad Paraguaya de Reumatología; [4]Hospital Central del IPS, Asunción, Paraguay*

Background: Biological Therapies (BT) are important in the therapeutic arsenal of rheumatic diseases; however there is an increased risk of infections with their use.
Objectives: To determine the frequency and type of infections in Paraguayan patients with Juvenile Idiopathic Arthritis (JIA), included in the BIOBADAGUAY Register.
Methods: A prospective observational study of patients with JIA treated with BT, included in the BIOBADAGUAY Register. Patients at the onset of BT were included. The change and/or discontinuation of BT and the occurrence of adverse events (AEs) were recorded. Infectious events as affected organ, type, severity, outcome and need of temporary or permanent suspension of the biological agent were analyzed.
Results: 59 patients with JIA and 69 BT were identified between May 2012 and December 2016. Female: 63% (37), Men: 37% (22). The mean age was 10 (3–18) years old. Mean disease progression of 2.8 (0.2–12) years from the diagnosis to BT beginning. JIA subtypes: poliarticular negative RF (27%), oligoarticular (27%: extended 22% and persistent 5%), enthesitis related arthritis (21%), systemic (12%), poliarticular positive RF (7%), psoriatic (3%), other (indeterminate) (3%). Biologic treatments: Adalimumab (ADM) 41 (59%), Etanercept (ETN) 19 (28%), Tolicizumab (TCZ) 9 (13%). There were 83 AEs of all treatments, 80 (96%) no serious and 3 (4%) severe with 1 death. Infections and infestations 54 (65%) of AEs were recorded. Of all TB infections: the 94% (51) were not serious and the 63% (34) required temporal discontinuation. Most infectious recovered without sequelae, except one death due to pneumonia (Table 1).

Type	Number AA	Agent	Suspension	Complete recovered
Respiratory Infection	33	18 ADM	21 Temporal	Yes
Infection		9 ETN		
		6 TCZ		
	1	1 TCZ	Yes	No (Death)
Pulmonary Tuberculosis	1	1 ETN	1 Temporal	Yes
Dengue	3	2 ADM	3 Temporal	Yes
		1 ETN		
Infectious Diarrea	3	1 ADM	3 Temporal	Yes
		1 TCZ		
		1 TCZ		
Urinary Infection	2	1 ETN	2 Temporal	Yes
		1 ADM		
Chickenpox	1	1 ADM	Temporal	Yes
Herpes	2	2 ADM	No	Yes
Toxoplasmosis	1	1 ADM	1 Temporal	Yes
Vulvovaginitis	1	1 ADM	No	Yes
Skin Infection	5	1 ADM	2 Temporal	Yes
		3 ETN		
		1 TCZ		
Scabies	1	1 TCZ	No	Yes
Total	54	28 ADM	34 Temporal	
		16 ETN		
		10 TCZ		

Conclusions: 1) Infections and infestations (65%) were the AEs more frequently observed. 2) Of al Infections, respiratory tract iwere the most frequently observed. 3) Most of the infections were not serious and recovered without sequela. 4) The most frequently agent involved in infectious events was ADM (52% of all infections); even so it is most frequently administered agent. 5) Increased number of patients, greater diversity of treatment as well as a longer data to corroborate the observation period is required.

Other orphan diseases

AB0976 **REMISSION OF MULTICENTRIC RETICULOHISTIOCYTOSIS WITH COMBINATION TOCILIZUMAB AND ZOLEDRONATE**

A. Gough[1], B. Barber[2], H. Evennett[3], S. Hern[4], M. Lloyd[1]. *[1]Rheumatology; [2]Radiology; [3]Dermatology, Frimley Park Hospital, Frimley; [4]Dermatology, Spire Clare Park Hospital, Crondall, United Kingdom*

Background: Multicentric reticulohistiocytosis (MRH) is a rare non-Langerhans cell histiocytosis. It can affect any organ but predominantly skin and joints. Joint involvement usually precedes skin involvement and can be very destructive. Early diagnosis and treatment is therefore important but can be difficult.We describe a woman with MRH and severe erosive joint disease who responded to combination tocilizumab and zoledronate.
Objectives: A 43 yr old woman presented in 2012 with a 3 mth history of rash on her face, chest and ears and fingers, and arthralgia affecting shoulders, wrists, fingers and knees. On examination she had diffuse hand swelling, right knee effusion and erythematous eruption affecting her face, chest and ears with papules on the sides of her fingers.
Investigations: normal FBC, CRP, U+Es, LFTs. ESR 12 mm/hr. ANA +ve at 1:1280 (finely speckled). Ro +ve; ENA including Jo-1, ANCA and dsDNA antibodies -ve, C3/4, Igs all normal/-ve. Hand XR: periarticular DIP erosions. Skin biopsy: large multinucleate cells with abundant cytoplasm staining positive with CD68 (histiocytic marker); CD1a negative (Langerhans cell marker), consistent with MRH. PET-CT body: incidental finding of thymic remnant.
Methods: Initial Rx:prednisolone 20 mg od + HCQ 200mg bd with initial good response of joint and skin symptoms, but recurrence of symptoms on reducing steroid dose. Nov 2012: MTX up to 20mg /week added. Stopped after 4 mths because of a linear rise in P3NP levels to 11.2. Fibroscan showed slightly raised stiffness of 7.4kPa. AZA 75mg od introduced in Feb 2013, then etanercept 50mg weekly. This led to good control of symptoms for approximately 4 mths on single agent therapy. March 2014: relapse of joint and skin symptoms. June 2014: tocilizumab 8mg/kg iv 4 weekly started. After 5 infusions, her skin cleared for the first time. December 2014: relapse of joint and skin symptoms. Tocilizumab was adjusted to 650mg per mth from 620mg in view of slight weight gain. Annual iv zoledronate 5mg was started. She has had no further joint or skin exacerbations. July 2015: prednisolone was down to 1mg daily and stopped completely by May 2016. From July 2015 there appears to have been no progression in DIP joint erosions, and possibly some healing of the DIP changes. She has remained off any steroids.
Results: Picture shows X ray hands July 2015

Conclusions: The pathogenesis of MRH is poorly understood. The overexpression of cytokines including TNFα, IL-1 and IL-6 in inflammatory lesions gives a number of logical drug options, including tocilizumab. The observation that mononuclear cells in both skin nodules and synovium in MRH exhibit some properties of osteoclasts might explain the mechanism behind reported success using bisphosphonates. To our knowledge, this is only the second case to report success with using tocilizumab in the treatment of MRH and the first to report on concomitant treatment with a bisphosphonate. No adverse effects have been observed throughout treatment, and remission appears to be sustained. Without withdrawing treatment we cannot know if the remission is natural or drug induced, though the relatively short timescale suggests a drug effect.

AB0977 **DETERMINATION OF A CUT-POINT BETWEEN LOW/HIGH ANTI RNP ANTIBODIES TITRES, IN PATIENTS WITH MIXED CONNECTIVE TISSUE DISEASE**

D.A. Botello Corzo[1], C. Bouroncle Alaluna[1], C. De la Puente Bujidos[1], A. Boteanu[1], G. Roy Ariño[2]. *[1]Rheumatology; [2]Immunology, Hospital Ramón y Cajal, Madrid, Spain*

Background: Sharp described Mixed Connective Tissue Disease (MCTD) in 1972[1]. MCTD is characterised by the presence of Raynaud phenomenon, puffy hands, synovitis, acrosclerosis, myositis and positive anti-ribonucleoprotein (RNP) antibodies. Classification criteria for MCTD except for Kasukawa's criteria demand the presence of high titres of anti-RNP antibodies (measured by hemagglutination). As a result, the cut-point between low and high anti-RNP titres must be well defined. In best of our knowledge, this cut-point have not been established for modern laboratory techniques.
Objectives: Determinate a cut-point between low/high anti-RNP titles measured by ELISA, for the diagnosis of Mixed Connective Tissue disease. Describe the clinical and immunological characteristics of patients with positive titres of anti-RNP antibodies.
Methods: It was a Retrospective cohort study of patients with positive anti-RNP antibodies (>10) measured by ELISA. We had identified all patients with positive antiRNP antibodies titres in the last five years, using our laboratory base date. Clinical histories were reviewed, we recollected clinical and paraclinical data. We performed descriptive analysis and ROC curves for diagnostic tests with STATA software.
Results: We detected 75 patients with positive antiRNP antibodies, we obtained 65 clinical records. 89,23% (58) of patients were women and 10,77% (7) men.

The mean age at diagnosis was 45,01 years (SD 16,71 ± years), The median of tracing was seven yeas (P25 de four years/P75 de 14 years). The mean initial antiRNP titre was 239,33 the median was 144 (P25 58/P75 400). The initial diagnosis were Mixed Connective Tissue Disease 6,25% (4), Undifferentiated Connective Tissue Disease 31,25% (20), systemic erythematosus lupus 45,31% (29) and Others 14,06% (9). MCTD diagnosis was made in 29,69% (19) of patients at the end of follow-up. Patients with MCTD as final diagnosis presented in their first visit Raynaud phenomenon 73,68% (14), puffy hands 31,58% (5), acrosclerosis 10,56% (2), myositis 21,05% (4), Arthralgias 68,42% (13), arthritis 57,89% (11), Pulmonary arterial hypertension 5,26% and Interstitial lung disease 10,53% (2). The initial RNP titre was evaluated using the number of times over the laboratory cut point. The area under the ROC curve for the initial RNP was 0,70. Looking for the highest specificity with and adequate sensitivity, we selected the cut-point with highest LR +. The selected cut-point was ≥24,4 times the laboratory cut-point, with s specificity of 77,78 and a sensitivity of 57,89.

Conclusions: The cut-point for low/high RNP titres measured by ELISA in our cohort of patients with MCTD as a final diagnosis was ≥24,4 times the laboratory cut-point.

AB0978 ASSOCIATION OF INFLAMMATORY ARTHRITIS WITH VOGT-KOYANAGI-HARADA SYNDROME (VKHS)

D. Ramos-Bello [1], G. Aguilera Barragán-Pickens [1], A.J. Pedro-Martínez [1], G. Martínez-Flores [1], T.A. Luna-Zúñiga [1], A.N. Rangel-Botello [1], P.L.R. Hernández-Briano [2], M.G. Rangel-Charqueño [2], E. Santillán-Guerrero [1], C. Abud-Mendoza [1]. *[1] Unidad regional de Reumatología y Osteoporosis; [2] Departamento de Oftalmología, Hospital Central "Dr. Ignacio Morones Prieto" y Facultad de Medicina de la Uaslp, SLP, Mexico*

Background: VKHS is a rare cause of granulomatous uveitis leading to significant visual loss in patients who develop it, usually accompanied with extraocular manifestations that include meningismus, vitiligo, poliosis, and hearing loss. In our country is responsible for 13% to 27% of all uveitis, affecting mainly young women.

Objectives: To describe the presence of inflammatory arthritis in patients with VKHS at a third level hospital.

Methods: A cross-sectional study of 4 patients with established VKHS that fulfilled the 2001 revised diagnostic criteria for Vogt-Koyanagi-Harada disease (1) was rolled out. Ultrasonography was performed to all patients by a trained rheumatologist in carpal, metacarpophalangeal (MCP) and proximal interphalangeal (PIP) joints evaluating presence of power Doppler (PD) signal, bone erosions, and cartilage changes.

Results: We included 3 women and 1 man, mean age was 34.7±10.3 years, and they all had characteristics of complete VKHS. Mean disease duration (since first manifestation of ocular symptoms) was 5.2±3.5 months. One patient had synovitis on physical examination. Out of the 4 patients with PD signal, 4 had involvement of both wrist, MCP and PIP joints consistent with polyarthritis pattern, and bone erosions were detected in one patient (Table)

Table. Characteristics of patients with VKHS and inflammatory arthritis

	Sex	Age	Complete VKHS	Serous retinal detachment	PD in carpal joints	Number of MCP joints with PD	Number of PIP joints with PD	Number of erosions	ESR/CRP elevation	Reumatoid Factor/ACCP
Patient 1	F	21	Yes	Yes	Yes	4	3	0	Yes	No
Patient 2	F	36	Yes	Yes	Yes	7	3	0	Yes	No
Patient 3	M	36	Yes	Yes	Yes	6	4	0	Yes	No
Patient 4	F	46	Yes	Yes	Yes	7	1	2	Yes	No

VKHS: Vogt-Koyanagi-Harada syndrome; PD: power Doppler signal; MCP: metacarpophalangeal joint; PIP: proximal interphalangeal joints, ESR: erythrocyte sedimentation rate; CRP: C reactive protein; ACCP: anti-cyclic citrullinated peptide

Conclusions: The presence of inflammatory arthritis in patients with VKHS has only been described in one case (2). Despite the exceptionality, we propose that polyarthritis and probably erosive arthritis can represent part of the spectrum of the disease, processes that share some features of the genetic susceptibility with rheumatoid arthritis as HLA-DR4, CTLA-4 and STAT4.

AB0979 EOSINOPHILIC FASCITIS: CLINICAL EXPERIENCE IN A SERIES OF 21 PATIENTS

J.C. Quevedo [1], R. Lopez [1], M. Garcia-Bustuinduy [2], C. Rodriguez-Lozano [1], B. Rodriguez-Lozano [3], S. Bustabad [3], E. Trujillo [3]. *[1] Servicio de Reumatologia, Hospital Universitario de Gran Canaria Doctor Negrin, Las Palmas; [2] Servicio de Dermatologia; [3] Servicio de Reumatologia, Hospital Universitario de Canarias, la Laguna, Spain*

Background: The Eosinophilic fascitis (EF) is a uncommon sclerodermiforme síndrome with unknown etiology and poorly understood pathogenesis and natural evolution. The published series are short, with a total of 280 cases described in the literature from 1974.

There is neither clinical tests nor consensus on the EF treatment.

Objectives: To describe a series of 21 patients with EF.

Methods: Multicentric, retrospective Case Series Study.

We reviewed 21 patients diagnosed of EF (cutaneous induration+consistent biopsy) between January 1998 to January 2015. A total of 13 males and 8 females.

Results: The mean age at diagnosis was 41 years 8range between 28 and 66).

Trigger factor was suspected in 8 patients (intense exercise in 7).

The zones of cutaneous affectation were fundamentally the upper and low extremities.

The hyperesonophilia was present in 100% of the patients. The average of the % more high of hyperesosinophilia was 21.2% (range 4–45.4%).

11 patients presented artralgias and 5 patients presented arthritis (4 polyarticular/1 oligoarticular).

The MRI was used for diagnosis and/or follow-up in 8 patients, especially in the diagnosed ones in the last 5 years.

The average initial dose of prednisone was 40 mg/día, the average maximum dose of prednisone was 40 mg/dia and the mean steroid treatment duration was 22 months (range 9–47 months). Other immunomodulatory agents were: methotrexate 11, hydroxychloroquine 2, azatioprina 2 and D penicillamine 1.

5 years after follow-up, the evolution was the complete resolution in 13 patients and the partial improvement in 6.

Other clinical and analytical manifestations (N=21).	YES, n (%)	NO, n (%)
Hypergammaglobulinemia	13 (63)	8 (37)
Elevated ESR	4 (16)	17 (84)
Elevated CRP	8 (37)	13 (63)
Elevated CK	0	21 (100)
Systemic symptoms	7 (32)	14 (68)
Visceral affectation	3 (11)	18 (89)
Autoimmune thyroid	2 (5)	19 (95)
Peripheral neuropathy	4 (16)	17 (84)

Conclusions: In our series, the EF prevails in males, in the decade of the 40 and in the majority one did not find trigger factor. There was presence of arthritis in a significant percentage of patients. In the last years the use of the RMN has been added to the diagnosis and to the follow-up. Though there are no clinical tests that support it the use of the metotrexato has been generalized as adjuvant treatment to the steroids.

AB0980 EPIDEMIOLOGICAL PROFILE OF THE PULMONARY DISEASES IN MIXED CONNECTIVE TISSUE DISEASE: ABOUT 55 CASES

R. Amri [1], I. Mejri [1], H. Sahli [2], A. Mahfoudhi [1], I. Ben Ahmed [1], R. Jazi [1]. *[1] Internal Departement; [2] Rheumatology Departement, Mohamed Taher Maamouri University Hospital, nabeul, Tunisia*

Background: Mixed connective tissue disease (MCTD) are a systematic autoimmune disease that the aetiopathogeny remains misunderstood. This disease is often associated with systemic involvement which sometimes is very serious, such as pulmonary diseases.

Objectives: To describe the characteristics of the pulmonary diseases among a sample of MCTD.

Methods: We conducted a retrospective study including patient's cases diagnosed with a MCTD between the period of 10 years in the departement of internal medicine. The demographic, clinical, treated in the immunological, biological and radiological data were collected then analysed.

Results: In total we had 55 patients. 87% of them were female. The mean age of the sample was 50, 64±15 years. Major types of MCTD were: Rheumatoid polyarthritis (45.5%), sarcoidosis (18.2%), scleroderma (12.7%), and the lupus erythematosus (10. 9%). These causes were diagnosed after a mean delay of 686, 18 days. A lung disease was found in 50.9% of the cases. It was either present without symptoms in 52.8% of the cases or revealed by dyspnoea (22.6%), a cough (18.9%)or hemoptysie isolated or associated to thoracic pains (1.9% each).The most frequent type of respiratory diseases were adenopathies (26.9%). Pleurisy, fibrosis, and interstitial lung diseases were described among 11.5% of the cases. Bronchiectasis, Lung arterial high blood pressure, pleural nodules, bronchi dilatation were reported in 7.7%. In only 3.8% we had patients with cancer and emphysema. Chest radiographs were normal in 65.5% of the

cases but we discovered interstitial lung diseases (12.7%), pleurisy (7.3%), pleural nodule and mediastinal enlargement (3.6%) and pneumopathy (1.8%). The same appearences were described in the CT scann normal in 18.5% but in different proportions: adenopathies (25.9%), interstitial lung abnormalities (14.8%), fibrosis (11.1%), bronchiectasis (7,4%) and bronchi dilatation, pleurisy, nodule and mediastinal enlargement (3.7%). Respiratory functional exploration were normal in 69.2% obstructive lung disease and restrictive pulmonary disease were found within 11.5% of the patients.
Conclusions: Improvement of the knowledge of these diseases will improve the care before the appearance of complications.

AB0981 CLINICAL FEATURES OF 28 CASES OF LIMB RESTRICTED VASCULITIS AND FASCIITIS

H. Mukoyama, K. Nishimura, R. Saito, Y. Nakamura, T. Nagamoto, T. Yokota. *Department of Endocrinology and Rheumatology, Kurashiki Central Hospital, Kurashiki, Okayama, Japan*

Background: We sometimes experience the cases with fever and muscle pain of lower limbs without any other specific features. There are sporadic case reports of eosinophilic fasciitis and limb restricted vasculitis. However, few reports compare and discuss such cases.
Objectives: To describe the clinical features, MRI findings, histopathology, diagnosis and response to treatment of these cases.
Methods: We retrospectively analyzed the clinical features of 28 patients who were admitted to our hospital because of fever and muscle pain of lower limbs from 2004 to 2016.
Results: Among the 28 patients, 17 were vasculitis syndrome; eleven were limb restricted small vessel vasculitis (LrSvv), six were microscopic polyangiitis (MPA). Seven were fasciitis; three were eosinophilic fasciitis, three were diffuse fasciitis without eosinophilia and one was tuberculous fasciitis. One was relapsing polychondritis, one was Behçet's disease and the other two were myalgia without specific diagnosis. In our study, average age was 57.5±19.9 years old and older than in previously reported cases of limb ristricted vasculitis[1,2]. Sixteen were female, twelve were male. Abnormal MRI findings in non-infectious fasciitis and vasculitis syndrome were bilateral. Tuberculous fasciitis showed specifically abnormal intensity and fluid collection in unilateral thigh. Unilateral lesion and fluid collection may indicate infectious disease and bilateral lesion may indicate autoimmune or autoinflammatory diseases. MRI of vasculitis syndrome and fasciitis showed hyperintense T2-weighted signals in muscles of either legs, or thighs, or both. (n=3), MPA (n=1) and fasciitis (n=3). On MRI scan, abnormal fascial signal intensity was seen in all the patients with fasciitis and 6 (40%) with vasculitis syndrome. It was difficult to differentiate between vasculitis and fasciitis by MRI findings. Muscle biopsy was performed in 25 patients. In most cases, we performed en bloc biopsy, including muscle, fascia, skin and subcutaneous tissue. MRI was useful to determine the location of biopsy. All patients were treated with glucocorticoids. Immunosuppressive agents (azathioprine, n=10; methotrexate, n=5; cyclophosphamide, n=1; tacrolimus, n=1) were added in 15 patients and anti-tuberculous drugs in one. None of the 11 patients with LrSvv showed positive blood tests of anti-neutrophil cytoplasmic antibody or developed any other organ involvement during follow-up period (median 96 months; range 3–125). They responded well to glucocorticoid therapy (oral prednisolone 0.5–0.6mg/kg/day or intravenous methylprednisolone at doses of 1g/day). Recurrence rate of LrSvv patients was 0%, although that of MPA patients was 50% (n=3). In four patients with LrSvv, treatment was ceased and they achieved drug-free remission. There were no apparent differences between the patients who achieved drug-free remission and who didn't.
Conclusions: MRI and muscle biopsy were useful for diagnosis of disease with fever and muscle pain of lower limbs.

AB0982 ANALYSIS OF THE TREATMENT EFFICACY FOR RETROPERITONEAL FIBROSIS - A CASE SERIES. SUSPICION OF ERDHEIM-CHESTER DISEASE IN A PATIENT WITH AN INITIAL DIAGNOSIS OF RETROPERITONEAL FIBROSIS, REFRACTORY TO STANDARD TREATMENT

J. Koblowski[1], A. Juszkiewicz[1], M. Kania-Pudło[2], W. Tlustochowicz[1]. *[1]Internal Medicine and Rheumatology; [2]Radiology, Military Institute of Medicine, Warsaw, Poland*

Background: Retroperitoneal fibrosis (RPF) is a rare disorder characterized by the development of fibrotic tissue in the retroperitoneum involving the abdominal aorta, iliac arteries and ureters. Erdheim-Chester disease (ECD) is a rare, non-Langerhans histiocytosis. Symptoms of ECD often resemble retroperitoneal fibrosis.
Objectives: Evaluation of standard treatment efficacy in 13 consecutive RPF patients. Revision of the diagnosis in patients unresponsive to standard therapy.
Methods: A retrospective analysis of 13 consecutive RPF patients (10 males and 3 females) treated in our department since 2008 was performed. All patients were treated with tapered dose of steroids combined with an immunosuppressive agent (cyclophosphamide in 4, azathioprine in 9, methotrexate in 6, hydroxychloroquine in 5 patients). Urologic interventions were undertaken as necessary.
Results: The treatment was effective in 10 patients: reduction of the retroperitoneal mass in computed tomography (CT) and normalization of the laboratory tests, including markers of inflammation and creatinine concentration. No improvement was found in 3 patients. However, in a further diagnostic work-up the diagnosis of RPF was maintained only in one of these 3 patients. In the second pateint an ANCA-asssotiated vasculitus was ultimately diagnosed. The third patient was treated with a combination of steroids and cyclophosphamide without any radiological improvement. However, the revision of CTs revealed the presence of changes typical of Erdheim-Chester disease.
Conclusions: The standard treatment (based on a combination of steroids and immunosuppressive drugs) is efficient in most partients with RPF. In refractory cases an alternative diagnosis, such as systemic vasculitis or Erdheim-Chester disease, should be taken into account.

AB0983 MEFV MUTATIONS IN ARMENIAN PATIENTS WITH SYSTEMIC AUTOIMMUNE DISEASES

K. Ginosyan, A. Beglaryan[1,1], V. Vardanyan. *Internal Medicine, Yerevan State Medical University, Yerevan, Armenia*

Background: The systemic diseases of connective tissue have autoimmune mechanism in development. While autoimmunity involves adaptive immune activation, autoinflammation involves innate immune activation. The prototype of autoinflammatory diseases is familial Mediterranean fever (FMF), which is the global medical problem for Armenian ethnos on the whole, affecting 1–2% of population.
Objectives: The aim of this study was investigation of MEFV mutations and their possible influence on the systemic diseases in Armenian patients.
Methods: We have examined 183 patients with FMF. All patients with FMF fulfilled Tel-Hashomer FMF diagnostic criteria. Molecular-genetic detection of 12 MEFV mutations common for Armenians carried out in Medical Genetic Centre of Armenia. In 49 patients one of autoimmune systemic diseases was diagnosed: in 24 patients- seronegative spondyloarthropathy (SNSA), in 23 - systemic lupus erythematosus (SLE), 1 patient developed Sjogren's disease and 1- systemic sclerosis.
Results: In the SNSA group from 24 patients 16 were male, 8 were female, the mean age of patients was 35,4±12,2.The mean age at the beginning of the disease was 14,91±12,6. In all cases the symptoms of FMF were preceded symptoms of arthritis. Unilateral sacroiliitis was revealed in 6 patients, bilateral sacroiliitis-in 18 patients. The limitation of lumbar motion was assessed by Schober's test. 7 patients with Schober's test 1–2 cm had bilateral sacroiliits grade III-IV and fulfilled the modified New York criteria for ankylosing spondylitis. HLA B-27 was examined in 7 patients. In 5 cases it was negative, and in 2 cases –positive. MEFV gene analyses were carried out in 21 cases: 7 patients had one heterozygote mutations: 6-M694,1-M680I; 5 patients -M694V/M694V, 9 patients had compound heterozygote mutations: 5- M694V/V726A, 3 - M694V/E148Q, 1 - M680I/E148Q. So, the prevalent mutation was M694V.
In SLE group from 23 patients female were 21 (91.3%), male – 2 (8.7%). Mean age of patients was 37.4±2.5 years. The beginning of FMF was earlier than SLE. The activity of SLE estimated by SLEDAI index was significant lower than in SLE without FMF. SLE co-occurring with FMF had mild duration than classic lupus according to both clinical and laboratory findings including serological markers of SLE -ANA, anti-dsDNA. The prevalent mutation was M694V - 44.6%; V726A composed 21.7%, M680I-9.8%. Most common variations with M694V were followings:M694V/M694V,M694V/V726A,M694V/N.
Conclusions: A remarkable overlap was highlighted between FMF and SLE: both diseases have such common features as arthralgia, myalgia, arthritis, fever, skin involvement, serositis and renal involvement. It is likely, that the moderation in disease phenotype and peculiar disease characteristics observed in patients with both SLE and FMF are related to MEFV. MEFV mutations appear to modify SLE phenotype. Sacroilitis may be seen more frequently in FMF patients than expected. On the other hand, FMF must be kept in mind if patients not responding to the usual therapeutic interventions for sacroiliitis.

AB0984 TOCILIZUMAB MONOTHERAPY FOR POLYMYALGIA RHEUMATICA ~ RESULTS OF 52-WEEK TREATMENT OF A PROSPECTIVE, SINGLE-CENTER, OPEN, SINGLE-ARM TRIAL

K. Amano, K. Chino, Y. Okada, A. Shibata, A. Okuyama, T. Kurasawa, H. Takei, T. Kondo. *Rheumatology and clinical immunology, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan*

Background: Polymyalgia rheumatic (PMR) is a chronic inflammatory rheumatic disease in the elderly people. Glucocorticoid (GC) is still definitely a mainstay for the treatment of PMR, but long-term GC therapy is a major risk factor of osteoporotic fractures, diabetes, hyperlipidemia, cardio-cerebral vascular events, glaucoma, etc. So GC-free treatment strategies for PMR are necessary for some patients with PMR. IL-6 is involved in the pathogenesis of PMR and quite a few case reports have already shown the efficacy of tocilizumab (TCZ) in PMR patients and some of them received TCZ monotherapy without GC.
Objectives: To assess the efficacy and safety of TCZ monotherapy for PMR
Methods: Thirteen PMR patients (male 3, female 10) who had been diagnosed by 2012 ACR/EULAR classification criteria from Jan 2013 to Feb 2015 were enrolled in our study (IRB application No. 638, UMIN registration No. 000008812) after obtaining the written informed consent. TCZ (8 mg/kg) was administered biweekly for the first 2 months (5 infusions) and every 4 weeks thereafter for 40 weeks (total 48 weeks). ESR, CRP, patient's global health assessed by visual analog scale (VAS), PMR activity score were evaluated every 4 week prospectively and were evaluated at week 52. Remission was defined as PMR activity score less than 1.5.
Results: Baseline patients' characteristics revealed various kinds of comorbidities in 11 patients; hypertension in 7, hyperlipidemia in 5, diabetes mellitus in 3, osteoporotic vertebral fractures in 2, history of angina pectoris in 1, history of brain infarction in 1, history of hematemesis due to NSAID ulcer in 1 and glaucoma in one patient. Nine patients could complete this 52-week trial and could achieve remission at week 52. Two patients discontinued TCZ because of no response at week 6 (No.1) and week 16 (No. 8) respectively. One patient (No.2), who were in clinical remission of PMR, dropped out from this study due to pemphigoid at week 50 and received GC therapy. Patient No. 12 abandoned TCZ at week 12 because of lung infiltrates although she was treated successfully with TCZ monotherapy, and she had been in remission without any treatment until week 52. The other 3 drop-out patients could obtain remission with GC therapy at week 52. There were no serious adverse events during 52-week treatment period.
Conclusions: TCZ mono-therapy was effective in most (9 out of 13) PMR patients although response was not so rapid as compared to GC. TCZ mono-therapy may be a good alternative therapy instead of GC for elderly patients with various comorbidities.

AB0985 METHOTREXATE AS INDUCTION OF REMISSION THERAPY FOR LOCALIZED MANIFESTATIONS OF IGG4-RELATED DISEASE

L. Rovati[1], E. Della-Torre[1], M. Lanzillotta[1], E. Bozzalla Cassione[1], E. Bozzolo[1], C. Canevari[2], M. Falconi[3,4], L. Dagna[1,4]. *[1]Unit of Immunology, Rheumatology, Allergy and Rare Diseases; [2]Unit of Nuclear Medicine; [3]Pancreatic Surgery Unit, San Raffaele Scientific Institute; [4]Università Vita-Salute San Raffaele, Milan, Italy*

Background: Medium to high dose glucocorticoids represents the treatment of choice for inducing remission in IgG4-related disease (IgG4-RD) patients[1]. However, clinicians might prefer alternative equally effective drugs in clinical settings where long-term corticosteroids treatment is contraindicated, such as diabetes or osteoporosis. We recently reported the efficacy of methotrexate in maintaining glucocorticoids induced IgG4-RD remission[2].
Objectives: To evaluate the efficacy of methotrexate as induction of remission therapy in selected cases of mild and localized IgG4-RD complicated by clinical scenarios that might advise against corticosteroids treatment.
Methods: Five patients with active untreated IgG4-RD were started on oral or subcutaneous methotrexate (up to 15–20 mg/week). Efficacy of methotrexate in inducing remission was assessed at 6 months by 18F-FDG PET/CT scan and by measuring the IgG4-RD Responder Index (RI)[3] and circulating plasmablasts[4]. Partial response (PR) corresponded to an improvement of the IgG4-RD RI >2 points. Complete response (CR) corresponded to an IgG4-RD RI score <3.
Results: All patients were males with a mean age of 67 years (range 53–78). Two had pancreatic involvement; one had lymph node enlargement; one had pancreatic and lymph node involvement; one had pancreatic, aortic, submandibular gland and lymph node involvement. Patients with pancreatic involvement presented with increased serum amylases or abdominal discomfort; none had obstructive jaundice; all had overt diabetes. The mean IgG4-RD RI, serum IgG4 concentration and plasmablasts counts at baseline were 8 (6–15), 483 mg/dL (136–983) and 3336/mL (330–9330 /mL), respectively. All patients had increased 18F-FDG uptake on PET/CT scan within the affected organs. After 6 months of methotrexate, Patients 1, 2, and 3 were on CR with improved or normalized PET/CT findings, serum IgG4 and plasmablasts levels. Patient 5 achieved PR, showing improved 18F-FDG-PET/CT findings, normal plasmablasts level, but stable serum IgG4 concentration; after 10 months of methotrexate, persistence of disease activity prompted the introduction of glucocorticoids. Methotrexate was stopped in Patient 4 after 5 months because of nausea and vomiting; at 6 months he showed persistently increased plasmablasts count and 18F-FDG uptake on PET/CT, thus requiring a rescue therapy with glucocorticoids. (Table 1)

	Patient #1 (M, 78) Type 1 AIP, aortic, submandibular gland, lymph node involvement		Patient #2 (M, 67) Type 1 AIP		Patient #3 (M, 70) Type 1 AIP, lymph node involvement	
	Pre-Treatment	6 months (MTX 20 mg/week)	Pre-Treatment	6 months (MTX 15 mg/week)	Pre-Treatment	6 months (MTX 15 mg/week)
IgG4-RD RI	15	2 (CR)	6	2 (CR)	9	1 (CR)
IgG4 (mg/dL)	498	313	586	324	221	157
PBs/mL	2520	250	940	470	3560	130
18F-FDG-PET/CT	Increased FDG activity in all affected organs except pancreas	Decreased FDG activity in submandibular glands; negative in all the other organs	Increased FDG activity in pancreatic head and tail	Partial reduction in pancreatic FDG activity	Increased FDG activity in pancreas and hilar lymph nodes	Negative in all the involved organs

	Patient #4 (M, 61) Type 1 AIP		Patient #5 (M, 53) Lymph node involvement	
	Pre-Treatment	6 months (MTX 15 mg/week)	Pre-Treatment	6 months (MTX 20 mg/week)
IgG4-RD RI	6	NA	6	3 (PR)
IgG4 (mg/dL)	136	NA	973	819
PBs/mL	330	880	9330	0
18F-FDG-PET/CT	Increased FDG activity in pancreatic head and body	Markedly increased FDG activity in pancreatic head and body	Increased nodal FDG activity	Decreased nodal FDG activity, but not dimensional reduction of the lymph nodes

Abbreviations: M, male; AIP, autoimmune pancreatitis; MTX, methotrexate; PDN, prednisone; IgG4-RD RI, IgG4-related disease responder index; PBs, plasmablasts; 18F-FDG, fluorodeoxyglucose; PET/CT, positron emission tomography/CT scan; CR, complete response; PR, partial response; NA, not available.

Conclusions: In localized forms of IgG4-RD with mild manifestations, methotrexate represents a promising alternative strategy for inducing disease remission, especially in the presence of contraindications to glucocorticoids.

AB0986 FAMILY MEDITERRANEAN FEVER GENE MUTATIONS: A POORLY STUDIED CAUSE OF INTERMITTENT HYDRARTROSIS

M. Espinosa Malpartida[1], C. Barbadillo Mateos[1], C. Ramos Giraldez[1], B.J. Flores Robles[1], E. González Vioque[2], C. Merino Argumanez[1], M. Jimenez Palop[1], J. Sanz Sanz[1], H. Godoy Tundidor[1], J. Campos Esteban[1], J.L. Andreu Sanchez[1], L.F. Villa Alcazar[1], J. Mulero Mendoza[1]. *[1]Rheumatology; [2]Biochemistry, Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain*

Background: Familial Mediterranean Fever (FMF) is an inherited autoinflammatory disorder caused by *mutations in the MEFV gene* encoding pyrine, characterized by recurrent episodes of fever and serositis. Some patients with FMF present *incomplete penetrance* of the disease and may manifest only as *intermittent arthritis*.
Objectives: Characterization of *musculoskeletal clinical manifestations* in patients with mutations of the MEFV gene in our hospital.
Methods: We retrospectively reviewed clinical records of patients with mutations detected in the Family Mediterranean Fever MEFV gene in our hospital from January 1, 2008 to October 1, 2016. We collected parameters such as age at diagnosis, age of onset Of the symptoms, sex, affected joints, other extra-articular manifestations and type of MEFV gene mutation.

Abstract AB0986 – Table 1

Patient	Sex	Diagnostic age	Onset age	Arthritis	Location	Other musculoskeletal manifestations	Extra-articular manifestations	MEFV Mutation	Homo/ Heterocytosis
1	M	47	40	Yes	Knee	No	No	p Glu148Gln	Heterocytosis
2	M	14	13	Yes	Knee	No	No	R202Q	Homocytosis
3	M	22	22	No		No	Lymphocytic myocarditis	p Glu148Gln	Heterocytosis
4	M	52	47	No		Arthralgias	Abdominal pain. Pleuritis	R202Q	Heterocytosis
5	M	39	20	Yes	PIPs	Arthralgias	Abdominal pain	R202Q	Heterocytosis
6	M	61	54	No		Tendinopathy	Recurrent pericarditis	R202Q	Homocytosis
7	M	17	16	No		No	Abdominal pain	R202Q	Heterocytosis

Results: Seven patients with MEFV gene mutations were reviewed, all of them were women, ranging in age from 14 to 61 years old. Two of them had *recurrent knee monoarthritis*, one had a history of *arthritis* in the hands and erratic *arthralgias*, one had erratic arthralgias and two had no musculoskeletal manifestations. The 2 patients with intermittent hydrartrosis responded satisfactorily to *colchicine*, but not the other patients with other musculoskeletal manifestations.
Conclusions: *Genetic testing* of the common *mutations of the MEFV gene* should be considered in patients with *recurrent episodes of monoarthritis* without justifying cause (palindromic rheumatism, intermittent hydrartrosis, etc.)

AB0987 THE RELATIONSHIP BETWEEN ANTI-INTERLEUKIN-1 THERAPIES AND MEFV GENE MUTATIONS IN FAMILIAL MEDITERRANEAN FEVER PATIENTS: A SINGLE CENTER EXPERIENCE

M.E. Derin[1], S. Gültekin[2], M. Şahin[3], A. Şahin[1]. *[1]Rheumatology - Internal Medicine; [2]Internal Medicine; [3]Biochemistry, Cumhuriyet University Medical Faculty, Sivas, Turkey*

Background: Familial Mediterranean fever (FMF) is an autoinflammatory disease characterizing recurrent self-limiting attacks of inflammation mainly placed in serosal surfaces of the body with fever (1). Colchicine is an important weapon of the humanity in FMF treatment yet. However, the puzzle of inflammation was solved, and so, inflammasome complex and interleukin-1 were discovered. Eventually, new era started with anti-interleukin-1 agents in colchicine resistant and/or intolerant FMF patients (2).
Objectives: The aim of this study is to evaluate the effectiveness of anti-interleukin-1 (anti-IL-1) agents on the characteristics of attacks, the adverse effects associated with anti-IL-1 treatment, and relation between therapy and MEFV gene mutations in 23 FMF patients with resistant and/or intolerant to colchicine.
Methods: Between January 2015 and December 2016, twenty-three-FMF patients that following-up at Cumhuriyet University Medical Faculty Rheumatology-Internal Medicine Department were included in to the study. Anakinra (69,6%), and canacinumab (30,4%)] were used in 23 FMF patients. 20 cases were resistant to colchicine, 3 were intolerant to colchicine.
Results: The median age of the patients was 28 years,(18–54) and the median age at diagnosis was 20 years (3–50). Of the FMF patients, nine (39.1%) were female and fourteen (60.9%) were male. The distribution of MEFV gene mutation frequencies in the FMF patients was no mutation in one (4,3.%) patient, M694V heterozygous in nine (39,1%), M694V homozygous in 7 (30,4%), E148Q heterozygous in one (4,3%), and compound heterozygous mutation in 3. (13%) patients. 16 patients used anakinra (100mg/day) for 6 mounths (median) and 7 used canacinumab (150mg/2 months) for 3 mounths (median). Four of 7 patiens were resistant to anakinra. After a median follow up 6 months overall clinical response [no attack (18 patients) or decreased frequency of attacks (5 patients)] was %100. In an FMF patient with no mutation, his brother and mother had FMF with no mutations on MEFV gene. We achieved good clinical and laboratory responses in the patient by canacinumab.
Conclusions: Anti-IL-1 agents can be got involved in a new place safely and effectively in FMF patients along with colchicine. In addition, whole gene analysis should be done in refractory FMF patients with no mutations in order to could investigate new mutations, epigenetic mechanisms or other unexplained reasons.

AB0988 BEHÇET'S DISEASE IN A DEFINED AREA OF NORTHWESTERN SPAIN

M. Estévez, A. Argibay, R. Lorenzo, M. Freire, J. Fernandez-Martín, B. Gimena, C. Vázquez-Triñanes, A. Rivera. *Systemic Autoimmune diseases and Thrombosis Unit, University Hospital Complex of Vigo, Vigo, Spain*

Background: Behçet's disease (BD) is a multisystemic inflammatory chronic disease. There is a wide variation in the clinical features of BD among geographical groups.
Objectives: To determine the demographic and clinical characteristics of BD in a defined area of northwestern Spain (Vigo).
Methods: Patients with BD (International Criteria BD) and seen in the University Hospital of Vigo in Spain, from 1994 to 2016, were retrospectively enrolled. Demographic, clinical, treatment and evolution data were recorded and analyzed using SPSS 22.0.
Results: Our patients were 26 male and 25 female. The mean age at the onset of the disease was 33±11.95 years (11–62). Oral and genital ulcers were seen in 100% and 84.3% respectively and skin lesions in 88.2%. Ocular involvement occurred in 35.3%, neurological disease in 39.2% and gastrointestinal involvement in 29.4% (the area worst affected was colon and small bowel). Vascular disease was present in 33.3%. See table 1. Pathergy test was performed in 18 patients (35.29%) and 10 (55.5%) were positives. HLA B51 was studied in only 13 patients (25.5%) and 8 (61.5%) were positives. 62.7% of patients had no cardiovascular risk factors (CVRF), 27.4% were smokers, 7.8% were hypertensive and 3.9% were hyperlipidemic and diabetic respectively. CVRF were not related to thrombotic events ($p>0.05$). In regard to gender influence, only pseudofolliculitis was significantly more frequent in men ($p<0.001$). There was a trend for increased prevalence of ocular disease and elevated erythrocyte sedimentation rate/serum C-reactive protein in men, and anemia in women, which, however, did not reach statistical significance. Treatment consisted of corticosteroids (92.2%), colchicine (68.6.%) and another immunosuppressive agent (35.3%). During the disease course 78.4% of the patients had an outbreak, 45.1% initiated or changed to immunosuppressive agent and 19.6% used biological drugs. Most of our patients (92.1%) were admitted to hospital and these constitute an evident bias. Two patients died during the followup period, but only one in relation of BD (upper gastrointestinal bleeding and seizures).
Conclusions: Our series has some particular aspects especially the high frequency of gastrointestinal lesions and neurologic involvement. CVRF do not seem to play a role in the development of thrombotic events. Our results confirm the ethnic and geographic variation of BD expression.

Abstract AB0988 – Table 1. Clinical manifestation of our BD patients

Skin lesions 41/55 (88.2%)	Ocular disease 18/51 (35.3%)	Neurologic disease 20/51 (39.2%)	Vascular disease 17/51 (33.3%)	Gastrointestinal involvement 15/51 (29.4%)
Pseudofolliculitis 58.8%	Uveitis 23.5%	Aseptic meningitis 11.7%	Venous thrombosis 21.6%	Pain 11.7%
Erythema nodosum 39.2%	Retinal vasculitis 5.9%	Seizures 7.8%	Arterial thrombosis 7.8%	Bleeding 9.8%
Leukocytoclastic vasculitis 5.9%	Episcleritis 3.9%	Cerebral venous thrombosis 5.9%	Mixed thrombosis 2%	Diarrhea 5.9%
	Vascular occlusion 2%	White matter lesions 5.9%	Aneurysm 2%	Fever 2%
		Stroke 3.9%		
		Paresthesias 3.9%		
		Others 5.9%		

AB0989 RHEUMATOLOGIC COMPLICATIONS OF THALASSEMIA: SHOULD RHEUMATOLOGISTS JOIN THE MANAGEMENT TEAM?

M.H.A. Noureldine[1], A.T. Taher[2], A.A. Haydar[3], A. Berjawi[2], M.A. Khamashta[4,5], I. Uthman[2]. *[1]Department of Neurosurgery, Lebanese American University; [2]Department of Internal Medicine, American University of Beirut; [3]Gilbert and Rose-Marie Chagoury School of Medicine, Lebanese American University, Beirut, Lebanon; [4]Lupus Research Unit, St Thomas Hospital, London, United Kingdom; [5]Department of Rheumatology, Dubai Hospital, Dubai, United Arab Emirates*

Background: Beta-thalassemia major is accompanied by progressive multiple organ systems involvement due to the disease pathophysiology as well as iron overload from blood transfusions on a regular basis. Rheumatologists are not frequently involved in the multidisciplinary management of the disease, in which rheumatologic complications are relatively common.

Objectives: To highlight the rheumatologic complications of beta-thalassemia, which include musculoskeletal manifestations such as arthritis and arthropathies, joint effusions, osteoporosis, bone fractures, and arthralgias as well as connective tissue diseases such as pseuoxanthoma elasticum (PXE).
Methods: We searched the literature through GoogleScholar and PubMed for all publications reporting on rheumatologic manifestations in beta-thalassemia. The following keywords were used: thalassemia, rheumatoid arthritis, osteoarthritis, iron-overload, septic arthritis, deferiprone-related arthropathy, crystal arthritis, effusions, osteoporosis, fractures, bone marrow hyperplasia, scoliosis, aseptic necrosis, arthralgia, myalgia, and pseudoxanthoma elasticum. All reports published between 1970 and 2016 were included.
Results: Arthralgia and low back pain are among the most common musculoskeletal manifestations of thalassemia. Many studies are reporting an increased rate of RA in hemoglobinopathies such as thalassemia, the association of which may be attributed to genetic factors. Arthritis may develop secondary to iron deposition in the synovial tissue or due to iron chelators such as deferiprone, which may provoke a self-limited arthritis due to synovial destruction sustained by free radicals production during iron interchange. Several studies reported increased incidence (16%>30%) of arthropathy in beta-thalassemia patients on deferiprone therapy. Multiple etiologies contribute to osteoarthritis in thalassemia patients such as bone marrow expansion, iron deposition within the joint, and hypoparathyroidism. Only few cases of Salmonella enteriditis septic arthritis were described in thalassemia patients. The associations between osteoporosis and hypogonadism, diabetes, and vitamin D and calcium deficiency were found significant. Skin lesions of PXE were reported in up to 16% in beta-thalassemics.
Conclusions: The pathophysiology of thalassemia and subsequent blood transfusions affect almost every organ system. Rheumatologic manifestations ranging from musculoskeletal complications to connective tissue diseases are common among thalassemia patients. Rheumatologists are highly encouraged to be involved in the multidisciplinary approach for the management of beta-thalassemia.

AB0990 PERI-ARTERITIS AS A NOVEL PARANEOPLASTIC PRESENTATION OF MYELODYSPLASTIC SYNDROME: A CASE SERIES AND REVIEW OF THE LITERATURE

N. Droz, C. Gota. *Rheumatology, Cleveland Clinic Foundation, Cleveland, United States*

Background: Myelodysplastic syndromes (MDS) are characterized by ineffective and dysplastic hematopoiesis resulting in peripheral blood cytopenias with varying risk for progression to acute myelogenous leukemia (AML)[1].
Autoimmune manifestations have been well described in association with MDS[2]. Peri-arteritis has rarely been reported.
Objectives: Here, we present a novel association of MDS with peri-arteritis.
Methods: Three patients within our institution and one in the literature were identified. Patients were diagnosed with MDS according to 2008 World Health Organization classification with concomitant occurrence of peri-arteritis on imaging[3].
Results: See Table 1.
Conclusions: Autoimmune manifestations associated with MDS occur in 7–25% of patients. The most commonly reported conditions include vasculitis, inflammatory arthritis and connective tissue disease. There is a paucity of literature describing peri-arteritis associated with MDS[2]. Review of the literature revealed only one other case of peri-arteritis associated with MDS outside of those identified at our facility[4].
With this case series, we report peri-arteritis as a novel presentation of MDS. Peri-vascular inflammation may mimic idiopathic retroperitoneal fibrosis, however, persistent cytopenias, lack of response to immunosuppressive therapy and persistence of elevated inflammatory markers should prompt the physician to evaluate for an underlying diagnosis of MDS.

AB0991 PREVALENCE OF FIBROMYALGIA AND DEPRESSION IN PATIENTS WITH AUTOIMMUNE /INFLAMMATORY SYNDROME INDUCED BY ADJUVANTS COMPARED TO PATIENTS WITH SYSTEMIC SCLEROSIS

O. Vera-Lastra, P. Blas Hernadez, A. Sánchez-Rodríguez, L.J. Jara. *Internal Medicine, Hospital Especialidades CMN la Raza. Instituto Mexicano Seguro Social, Mexico City, Mexico*

Background: Autoimmune/inflammatory syndrome induced by adjuvants (ASIA) has been associated with previous exposure to various agents such as mineral oil, silicone and vaccines, which act as adjuvants eliciting chronic stimulation of the immune system and manifestation of autoimmune diseases. There is little information about fibromyalgia (FM), depression and the deterioration of the quality of life in ASIA patients.
Objectives: To determine the prevalence of FM, depression and both in ASIA patients associated to mineral oil versus systemic sclerosis (SSc) patients.
Methods: A comparative cross-sectional study was performed in patients with ASIA according to Shoenfeld's criteria associated to injection of mineral oil with cosmetic purposes. The prevalence of fibromyalgia according to criteria of ACR, depression by Beck questionnaire and quality of life with FS-36 in patients with ASIA versus patients with systemic sclerosis matched by age were evaluated.
Results: There were 100 women, 50 ASIA patients (mean age 49±9.7 years) compared to 50 SSc patients (mean age 49±10 years). Of patients with ASIA, 40 patients had non-specific rheumatic disease and 10 met ACR criteria for SSc in 4 patients, SLE 3 and overlap syndrome 1 (SLE plus SSc) and rheumatoid arthritis 2. In ASIA vs. SSc we found depression in 72% vs 46% respectively, $p<0.005$, fibromyalgia in 66 vs 48%, $p<0.008$ and fibromyalgia plus depression in 56% vs. 28, $p<0.005$. Patients with ASIA had a worse quality of life than SSc by SF36 and the most affected parameter was the emotional one.
Conclusions: ASIA patients associated to injection of mineral oild had higher prevalence of depression, fibromyalgia and greater deterioration of quality of life compared to SSc patients. There is a possible link between ASIA, depression and FM.

Abstract AB0990 – Table 1

Patient	1	2	3	4[4]
Age	67	37	67	70
Sex	Female	Female	Female	Male
MDS type	CMML-1	MDS with multi-lineage dysplasia; progression to AML	MDS Unclassifiable	MDS with multi-lineage dysplasia
Presenting Symptoms	Hydronephrosis, abdominal pain, weight loss	Serositis, dyspnea, fevers, rash	Rapidly evolving peri-arteritis, adominal pain	Organizing pneumonia, fever, arthralgias
Bone Marrow Biopsy	Hypercellular, features of CMML-1	Normocellular, multilineage dysplasia, 4%blasts, 20q deletion	Hypercellular, granulocytic hyperplasia, 2% blasts	Normocellular, multilineage dysplasia
ANCA and ANA	Negative	Negative	Negative	Negative
ESR (0–15mm/hr)	21	76	57	
CRP (<0.9mg/dL)	5.4	31.2	4.9	9
Radiographic extent of peri-arteritis	Infra-renal abdominal aorta and common iliac arteries	Thoracic aorta and branch vessels	Carotid arteries, thoracic and abdominal aorta, femoral vessels	Internal carotid artery
Treatment	Corticosteroids	Corticosteroids, anakinra, methotrexate, IVIG	Corticosteroids	Corticosteroids
Clinical Course	Ureteral stenting and nephrostomy tube placement improved symptoms. Inflammatory markers remained elevated despite treatment.	Multiple treatment modalities failed to improve symptoms or inflammatory markers. MDS transformed to AML requiring stem cell transplant. Her disease was then quiescent.	Despite treatment, disease was complicated by aortic dissection which was managed non-operatively. Azacitidine was initiated but she died of infectious complications.	Epipharyngeal mass improved with corticosteroids. Disease course was complicated by infection.

AB0992 A DIFFICULT DISTINCTION – ERDHEIM-CHESTER DISEASE MIMICKING IGG4-RELATED DISEASE

P. Korsten[1], C.O. Sahlmann[2], S. Hakroush[3]. *[1]Department of Nephrology and Rheumatology; [2]Department of Nuclear Medicine; [3]Institute of Pathology, University Medical Center Göttingen, Göttingen, Germany*

Background: Rheumatologists are often confronted with systematic and rare diseases. Even among the rare diseases, clinical features may overlap, but treatment options for different diseases may differ.
Objectives: To illustrate the diagnostic challenges the clinician is confronted with when facing rare and systemic diseases in clinical practice with a case report where clinical features were overlapping.
Methods: A 64-year-old woman was presented to our institution after suffering from two ischemic strokes. Cerebral imaging was suggestive of large-vessel vasculitis. Additionally, imaging also revealed a left-sided retro-orbital mass. Her past medical history was notable for retroperitoneal fibrosis with ureteral obstruction requiring percutaneous drainage six months before presentation and placement of a cardiac pacemaker several years ago. Treatment with high-dose prednisone had been initiated but showed no clinical or laboratory improvement.
Results: Clinical examination revealed mild persistent facial hemiparesis and difficulty with ambulation. Mild exophthalmos was present on her left side. On palpation, there were palpable axillary masses bilaterally. Otherwise, her physical examination was normal. Laboratory analysis revealed elevated soluble interleukin-2 receptor levels at 2800 IU/mL (N: 230–770 IU/mL) and mildly increased C-reactive protein at 10 mg/L (N: <5 mg/L). Autoantibodies, including rheumatoid factor, IgG4, ANCA, ANA, and ENA were all within normal range. Plasma cells were normal on flow cytometric analysis. A PET-CT was performed which revealed signs of alveolitis, retroperitoneal fibrosis, axillary masses with strong tracer uptake (figure 1) as well as tracer uptake of the left femur and periaortic sheathing. We performed a biopsy of the left-sided axillary mass. Histopathologic analysis showed Touton giant cells and septal fibrosis. Staining was negative for CD1a and S100 but positive for CD68. Molecular pathologic analysis revealed the presence of the BRAFV600E mutation, findings that are consistent with the diagnosis of Erdheim-Chester disease. We initiated treatment with the BRAF-inhibitor vemurafenib and will follow the patient closely. Staining for IgG4 was negative.

Conclusions: Erdheim-Chester disease (ECD) and IgG4-related disease are very rare disorders and can present with similar clinical findings, such as retroperitoneal fibrosis, alveolitis or lymph node enlargement. About 500 cases of ECD worldwide have been reported. ECD is a non-Langerhans cell histiocytosis with a reported five-year survival rate of about 68%. Roughly 50% of patients show a BRAF mutation. Various treatment options have been reported and are recommended by the recently published consensus guidelines (1). These include interferon-alpha, vemurafenib and also TNF-alpha inhibitors, such as infliximab, but also interleukin-antagonists, such as anakinra (IL-1) or tocilizumab (IL-6). Rheumatologists have to consider non-Langerhans cell histiocytoses in the differential of systemic diseases because the distinction can be difficult and imaging, as well as meticulous histopathologic analyses, are necessary to correctly diagnose these patients because treatment differs.

AB0993 ELDERLY - ONSET SARCOIDOSIS: A SINGLE CENTER COMPARATIVE STUDY

S. Kobak[1], F. Sever[2], H. Semiz[3], M. Orman[4]. *[1]Rheumatology, Istinye University Faculty of Medicine, LIV Hospital, Istanbul; [2]Chest Diseases, Medicalpark Hospital; [3]Internal Medicine; [4]Statistics, Ege University Faculty of Medicine, Izmir, Turkey*

Background: Sarcoidosis is a chronic granulomatous inflamatory disease characterized with non-caseified granuloma formation. It is rarely affects patients older than 65 years old.
Objectives: The purpose of this study is to compare and evaluate the demografic, clinical and laboratory features of elderly-onset (EOS) and young-onset sarcoidosis (YOS) patients.
Methods: One hundred and thirty one patients diagnosed with sarcoidosis according to clinical, radiologic and histopathological evaluation were included in this study.The patients with initial symptoms started after age 65 were accepted as EOS. Demografic, clinic, radiologic, and laboratory data and the medication which the patients recieved were recorded and retrospectively evaluated.
Results: Twenty (15.3%)of 131 patients were diagnosed as EOS, and 111 (84.7%) patients were evaluated as YOS. Fifteen of 20 EOS patients were female and 5 of them were male. Average duration of the disease was determined as 38.4months for YOS and 22.5months for EOS (p=0.556).Delay of the diagnosis was 12months for YOS while it was 3months for EOS (p=0.001).Higher rates of fatique, comorbid diseases and more Hydroxychloroquine (HQ) use were detected in EOS patients comparing to YOS (p=0.010, p=0.003 and p=0.039 respectively).There was obviously more disease modifying anti-rheumatic drugs (DMARDs) use by YOS group but statistical difference wasn't significant. The 3-year survival rate after diagnosis of sarcoidosis was %95 in the EOS group, compared with %100 in the YOS group.
Conclusions: In this study we showed that YOS and EOS patients may be presented with different clinical, and laboratory features. EOS patients are characterized with higher rates of fatique and comorbid diseases, less inflammatory sign and delayed diagnosis, and less DMARDs usage.

AB0994 ANTI TNF-ALPHA THERAPY WOULD BE LIFESAVING IN DEFICIENCY OF ADENOSINE DEAMINASE-2

S. Sahin[1], A. Adrovic[1], K. Barut[1], S. Ugurlu[2], E.T. Turanli[3], H. Ozdogan[2], O. Kasapcopur[1]. *[1]Department of Pediatric Rheumatology; [2]Department of Rheumatology, Istanbul University, Cerrahpasa Medical Faculty; [3]Department of Molecular Biology and Genetics, Istanbul Technical University, Faculty of Science and Letters, Istanbul, Turkey*

Background: Deficiency of adenosine deaminase-2 (DADA2) is a rare form of autoinflammatory disorder with limited reported cases.
Objectives: In this study, we have characterized the clinico-immunological, radiological and genetic characteristics of eight childhood-onset DADA2 patients. We aimed to compare these features between surviving and deceased patients.
Methods: Demographic features, clinical characteristics, imaging findings, mutations and pharmacological treatments compared between surviving and deceased DADA2 patients.
Results: Eight patients from seven families were enrolled. While five of them were still surviving, three of them had died due to various reasons. Median age of the patients at disease onset and diagnosis were 7 years (range 0.5–13 years) and 14 years (range 5–27years), respectively. The main clinical manifestations were cutaneous manifestations (7/8), recurrent low-grade fever (6/8), neurological involvement (6/8) and gastrointestinal involvement (5/8). All patients had increased acute phase reactants at presentation and also during flares. Until the diagnosis of DADA2, five patients have been followed-up with the diagnosis of PAN; two patients both with PAN and FMF, and one patient with CAPS and vasculitis.

Abstract AB0994 – Table 1. Clinical features and imaging results of DADA2 patients

Age at disease onset	7	0.5	1	9	7	7	1.5	13
Previous diagnosis	PAN	PAN	PAN	PAN	PAN-FMF	PAN-FMF	CAPS, Vasculitis	PAN
GIS involvement	Yes	Yes	No	Yes	Yes	Yes	No	No
Cutaneous findings	Yes	Yes	Yes	Yes	Yes	Yes	Yes	No
Neurologic involvement	Yes	Yes	Yes	Yes	No	No	Yes	Yes
Neuroimaging findings	Ischemic stroke	Hemorrhagic stroke	Periventricular leucomalasia	Normal	Normal	Cerebral atrophy	İschemic stroke	İschemic stroke
CECR1	p.Gly47Arg	p.Gly47Arg	p.Gly47Arg	p.Gly47Val and p.Trp264Ser	p.Gly47Arg	p.Gly47Arg	p.Gly47Arg and p.Arg306Ter	p.Gly47Arg

Demographic, clinical, neurological features and genetic mutations did not differ in surviving and deceased DADA2 patients. Deceased and surviving subjects differed in terms of medication usage after the diagnosis of DADA2. Anti-TNF alpha treatment has been initiated in 5 surviving patients soon after the diagnosis of DADA2. However, unfortunately three patients who have died, were able to use either a few doses of anti-TNF alpha treatment or none; one patient due to reluctance of patient and two patients due to establishment of a definite diagnosis with genetic analysis after the patients had died.

Conclusions: Although this study includes limited number of patient, to our knowledge this study for the first time compares the phenotypic, genotypic and medication differences between surviving and deceased DADA2 patients. Anti-TNF alpha treatment seems to be very efficient and lifesaving in DADA2 patients.

AB0995 CLINICAL, THERAPEUTIC, AND GENETIC ANALYSES IN A PATIENT WITH PAPA SYNDROME COMPLICATED WITH INFLAMMATORY BOWEL DISEASE

T. Koga[1], Y. Hidaka[1], K. Fujimoto[1], S. Kaieda[1], K. Mitsuyama[2], K. Iwamoto[3], K. Fujita[4], R. Nishikomori[5], T. Hoshino[1], H. Ida[1]. *[1]Division of Rheumatology, Department of Medicine, Kurume University School of Medicine; [2]Division of Gastroenterology, Department of Medicine, Kurume University School of Medicine, Kurume University School of Medicine; [3]Coloproctology Center, Kurume Hospital, Kurume, Fukuoka; [4]Department of Pathology, Tenri Hospital, Tenri, Nara; [5]Department of Pediatrics, Kyoto University Graduate School of Medicine, Kyoto, Japan*

Background: PAPA syndrome is an autoinflammatory disease linked to mutations in the *PSTPIP1* gene [1]. These mutations produce a hyper-phosphorylated PSTPIP1 protein and alter its participation in the activation of the "inflammasome" [2]. PAPA syndrome is characterized by pyogenic arthritis with pyoderma gangrenosum and acne, and ususally treated with corticosteroids. Reports from the literature suggest that patients with poorly controlled PAPA syndrome may benefit from IL-1 blockade [2]; however, we cannot use these biologics for PAPA syndrome in our country.

Objectives: To elucidate the pathogenesis of PAPA syndrome, we examined the clinical status and complications before and after treatment and also analyzed the *PSTPIP1* gene.

Methods: We herein report a 25-year-old Japanese male who suffered from recurrent arthritis in his knee and ankle joints, pyoderma gangrenosum, and acne. He had experienced melena and multiple colonic ulcers had been detected by colonfiberscopy. His ulcerations resembled ulcers associated with Crohn's disease. A histological examination was then performed for the synovium of this knee joints, skin lesions of pyoderma gangrenosum, and the colon. The genomic DNA of *PSTPIP1* were analysed in both the patient and his family. We also examined the serum level of IL-1, IL-6, and TNF-α before and after treatment of biologics (adalimumab and infliximab) in this patient.

Results: 1) A histological analysis revealed that a large number of neutrophils had accumulated in the skin lesions; however, very few neutrophils were detected in the pathological lesions of the knee joints and colon. 2) According to a gene analysis, we detected a novel heterozygous mutation (E101G) in the *PSTPIP1* gene; however, his healthy father also had the same mutation, thus suggesting that this mutation of *PSTPIP1* might not be related to his phenotype. We are searching for other affected genes besides the *PSTPIP1* gene for PAPA syndrome in this case. 3) After treatment of biologics (infliximab), the clinical symptoms, such as arthritis and multiple colonic ulcers were considerably improved and the serum level of IL-6 and TNF-α were decreased in this patient.

Conclusions: We herein reported a Japanese PAPA syndrome patient who was complicated with inflammatory bowel disease and had a good response to biologics. A genetic analysis suggested that this particular phenotype might not have been affected by a mutation of the *PSTPIP1* gene.

AB0996 FREQUENCY OF HLA-B*51 AND THE ASSOCIATION WITH CLINICAL MANIFESTATIONS IN ARMENIAN PATIENTS WITH BEHÇET DISEASE

V.N. Mukuchyan, A. Haroyan. *Erebuni Medical Center, Yerevan, Armenia*

Background: Behçet disease (BD) is a system inflammatory disease mostly characterized by oral and genital ulcers and variable manifestations affecting other organs, mainly skin and eye. The HLA class I molecule HLA-B*51 allele is strongly associated with BD in many different ethnic groups and appears to be a significant risk factor for BD in the ancient Silk Route areas in contrast with Western and Northern Europe and U.S.[1–4]

Objectives: Our purpose was to show the frequency of presence of HLA-B*51 allele in Armenian patients with BD and estimate any correlation with common symptoms of disease depended on presence of HLA-B*51.

Methods: Forty-seven patients of Armenian origin (28 males 59.6% and 19 females 40.4%) fulfilling the International Criteria for BD (ICBD) with mean age 29.7±11.3 years; disease duration – 5.3±12.4 years were enrolled. We observed the clinical manifestations of BD of both HLA-B*51 carriers and non-carriers.

Results: HLA-B*51 was detected in 38 (80.8%) patients, of whom 25 male and 13 female (65.8% and 34.2%, respectively). Arthritis, erythema nodosum and genital ulcers were significantly more common in HLA-B*51-positive patients (83.3%, 83.3% and 80.6% respectively) than in HLA-B*51-negative ones (16.7%, p=0.032, 16.7% p=0.032 and 19.4% p=0.023 respectively).

Conclusions: In this ever first estimation of HLA-B*51 gene frequency in patients with BD in Armenia, our results indicated that the frequency of HLA-B*51 allele in BD is 80.8% which is higher than elsewhere (in Japan 58.9%, Iran 61.9%, Turkey 75%, Saudi Arabia 76.9% Greece 78.9%)[5]. Furthermore, this investigation revealed HLA-B*51 carriage much more often in male than in female BD patients. In addition HLA-B*51 carriers are in significant higher risk of development of arthritis, erythema nodosum and genital ulcers.

AB0997 ULTRASONOGRAPHIC EVALUATION OF ANTERIOR KNEE PAIN IN YOUNG ADULTS

A.A. Negm, M. Khairy, A. Hasseb, K. Abbas. *Rheumatology, Al-Azhar University, Cairo, Egypt*

Objectives: The Primary outcome of the present work is to detect type and frequency of Ultrasonographic changes in patients with anterior knee pain. Secondary outcome is to determine the role of MSUS in early detection of causes of anterior knee pain (AKP).

Methods: Sixty patients with AKP and 20 sex and age matched healthy control were included in this study obtained from the outpatient of Physical Medicine and Rheumatology Department of El Hussein and Bab El-Sharia university hospitals. Inclusion criteria: age between 20–40. Exclusion criteria: Trauma, Crystal induced arthritis, connective tissue diseases (RA, SLE, SpA), chronic liver or kidney disease and previous surgery. Full medical history and clinical examination as well as WOMAC, knee Conventional Radiography and Musculoskeletal Ultrasonography (MSUS) were done to all patients. Bilateral MSUS examination of the following common sites: Insertion of quadriceps tendon, Ligamentum patellae and Anterior aspect of the knee from medial to lateral. According to EULAR guide lines for musculoskeletal ultrasonography.

Results: The mean duration of knee pain in patients group was 11.42±9.134 months. ESR, CRP and WOMAC were higher in patients group ($p<0.01$). MSUS showed significantly more frequent Supra-patellar and Infra-patellar bursitis in patients than control group (p=0.000). patients had higher frequency of cartilage clarity loss (p=0.039) as well as lower cartilage thickness than control, 2.28±0.258 vs 2.73±0.261 mm respectively (P=0.000, 95% CI: 0.31 to 0.58)

Conclusions: The degree of Knee pain, measured by WOMAC, is positively correlated with inflammatory biomarkers (ESR and CRP) in patients with Anterior knee pain. MSUS revealed a positive correlation between Femoral Articular Cartilage thickness and the periarticular tendon- thickness, namely Patellar origin, patellar insertion and Quadriceps insertion. Interestingly, our data present an evidence of the negative impact of the duration of knee pain over Femoral Articular Cartilage thickness as well as Patellar origin thickness. (FAC thickness get worse with longer duration of pain)

AB0998 DIAGNOSTIC VALUE OF 14-3-3 (ETA) IN RHEUMATOID ARTHRITIS

A. Novikov, E. Aleksandrova, M. Cherkasova, T. Popkova, E. Luchihina, D. Novikova, D. Karateev. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Protein 14-3-3η (eta) involved in the upregulation of inflammatory and joint damage factors [1]. 14-3-3η is the candidate biomarker of rheumatoid arthritis (RA) [2].
Objectives: To evaluate the clinical utility of 14-3-3η for diagnosis of RA.
Methods: We studied 44 patients (pts) with RA, 5 man and 39 women, median (25–75 percentile) of age 45 (33–59) years; disease duration is 10 (5–20) months, DAS28 5,2 (4,4–6,2); 5 pts with systemic lupus erythematosus, 4 – ankylosing spondylitis, 5 – OVERLAP, 4 with psoriatic arthritis and 20 healthy individuals. 14-3-3η, anti-cyclic citrullinated peptide autoantibody (anti-CCP) was measured in serum by commercial enzyme-linked immunosorbent assays, IgM rheumatoid factor (IgM RF) measured – by immunonephelometry.
Results: The diagnostic sensitivity of 14-3-3η for RA (cut off 0,19 ng/ml) is 70,5%, specificity – 83,7%; positive likelihood ratio – 4,33, negative likelihood ratio – 0,35; positive predictive value – 81,6%, negative predictive value – 73,5%; AUC – 0,78 (CI 0,68–0,88). Concomitant presence of 14-3-3η and IgM RF, anti-CCP was determined in 68%, 73% of the patients with RA respectively. 14–3-3η had correlation with IgM RF ($r=0,7$, $p<0,05$).
Conclusions: Serum 14-3-3η are helpful for the diagnosis of RA.

AB0999 FINNISH COHORT OF PATIENTS WITH RAYNAUD'S PHENOMENON-NAILFOLD VIDEOKAPILLAROSKOPY FINDINGS AND AUTOANTIBODY VALUES

A. Häme[1], K.-L. Vidqvist[2], P. Parmanne[1], A. Puhakka[3], T. Hasan[4], H. Mäkinen[2], J. Panelius[4], R. Peltomaa[1], M. Perovaara[2], R. Luosujärvi[1]. *[1]Rheumatology, Helsinki University Hospital, Helsinki; [2]Rheumatology, Tampere University Hospital, Tampere; [3]Actelion Pharmaceuticals, Espoo; [4]Dermatology, Helsinki University Hospital, Helsinki, Finland*

Background: Raynaud'n phenomenon (RP) is very common all around the world, especially in cold climates (from 3 to 22%) (1). Nailfold capillaroscopy and autoantibodies have a pivotal role in diagnosing of different diseases in the context of RP (2).This is a first study of patients with RP in Finnish tertiary care hospitals.
Objectives: Aim is to investigate nailfold videokapillaroskopy (NVC) findings and autoantibody-values in patients with Raynaud's phenomenon first time in Finnish prospective multicenter study cohort.
Methods: We enrolled consecutive 160 patients with Raynaud's phenomenon who underwent NVC 9/2012–4/2013. Nailfold capillaries of II-V fingers of both hands were examined by using an optical probe videokapillaroskope mounted with x200 magnification lens. Images where analyzed with Videocapt software (DS Medigroup, Milan, Italy). NVC findings were classified with qualitative scoring, and early, active and late patterns were classified as"scleroderma pattern". Serum levels of antinuclear antibodies (ANA), antitopoisomerase I antibodies (anti-Scl-70) and anticentromere antibodies (ACA) were analyzed. Clinical and epidemiological features were reviewed.
Results: The mean age of the patients was 50, 4 years (±14, 8 SD), range 19–81 years, and 79, 4% were female. 15, 6% of patients were smokers and 3 had diabetes. Reasons for performing of NVC can be divided into three categories: (i) assessment of disease activity in previously diagnosed scleroderma (n=26), (ii) differential diagnosis of Raynaud's phenomenon (n=98), and (iii) assessment of Raynaud's phenomenon in other rheumatic diseases (n=36).
In group ii mean age was 48, 6 years (±14, 6 SD), 77, 6% were female and 17,3% were smokers. In this group 26, 5% (n=26) were diagnosed with scleroderma or there was strong suspicion of scleroderma at the first consultation of this study, 52% (n=51) were diagnosed with primary Raynaud's phenomenon and 21, 5% (n=21) were diagnosed with some other rheumatic disease (MCTD (n=2), Sjögren's syndrome (n=3), SLE (n=4), UCTD (n=8) and rheumatic arthritis (n=4)). Among those patients who was diagnosed with scleroderma, only 4% (n=1) had normal NVC pattern, 76,0% had scleroderma pattern (n=19) and 20,0% (n=5) had other non-specific changes. 19,2% (n=5) had low titers of ANA, 7,7% (n=2) had medium titers of ANA and 76,0% (n=19) had high titers of ANA. 69, 2% (n=18) had anticentromere antibodies (ACA) and 3, 8% (n=1) had antitopoisomerase I antibodies (anti-Scl-70). Those patients who had positive ACA or anti-Scl-70 also had a NVC scleroderma-pattern.
Conclusions: The main reason for NVC in this cohort was differential diagnosis of Raynaud's phenomenon, and in most patients in diagnostic group primary Raynaud's phenomenon was diagnosed. NVC is useful method for differential diagnosis of Raynaud's phenomenon.

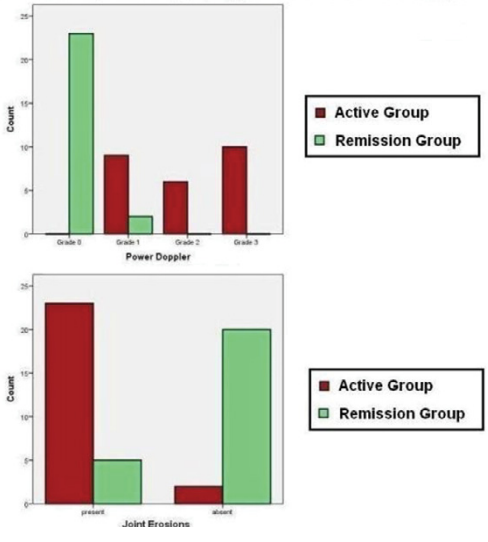
AB1000 EVALUATION OF NEUROPATHIC FOOT AND ANKLE PAIN IN RHEUMATOID ARTHRITIS PATIENTS: ELECTROPHYIOLOGICAL AND ULTRASOUND STUDIES

A.E.-S.I. El-Hewala[1], S.G. Soliman[2], A.A.E.-A. Labeeb[2], A.A. Zytoon[3], A.T. Elshanawany[2]. *[1]Rheumatology and Rehabilitation, Zagazig University, Sharqeya; [2]Rheumatology and Rehabilitation; [3]Radiodiagnosis, Menoufia University, Menoufia, Egypt*



Background: The majority of rheumatoid arthritis (RA) patients develop symptoms related to their foot or ankle.[1] Extraarticular manifestations occur in 10–20% of patients. Symptoms of neuropathy may be overlooked or overestimated in case of severe joint disease, restriction, pain and deformities.[2]
Objectives: This study aimed to evaluate neuropathic foot and ankle pain in RA patients using electrophysiology and musculoskeletal ultrasound (MSUS) to address the association between these findings and disease activity.
Methods: Fifty patients fulfilling the 2010 ACR/EULAR classification criteria and having neuropathic foot and/or ankle pain, were recruited. According to DAS28 system, patients were divided into two equal groups (25 patients each); active and remission. Twenty five healthy subjects were included as controls. Routine tibial and peroneal nerve conduction studies, as well as electromyography of tibialis anterior and abductor hallucis muscles, were performed.[3,4] MSUS assessment of the ankle joint and extra-articular portion of the foot was also performed.[5]
Results: Thirty nine (78%) patients showed the electrophysiological findings of foot neuropathy, irrespective of the disease activity level. In total, 48% of the patients had demyelinating mononeuropathies (entrapment neuropathies), whereas the other 30% had symmetrical axonal neuropathies (Table 1).

Table 1. Electrophysiological Findings (n=50)

	N (%)
Posterior tibial entrapment at ankle	10 (20%)
Peroneal entrapment at fibular neck	6 (12%)
Combined entrapments of posterior tibial nerve at ankle & peroneal nerve at fibular neck	8 (16%)
Pure sensory axonal neuropathy	12 (24%)
Sensorimotor axonal neuropathy	3 (6%)

Ultrasound diagnosis of posterior tibial entrapment at the ankle was encountered in 20 (40%) patients. In addition, a positive power Doppler (PD) signal and

Figure (1): Distribution of power Doppler signals and erosions among patients (n=50)

erosions of the ankle joint were prevalent among the active group in comparison with patients in remission ($p \leq 0.001$), as shown in figure (1).
Conclusions: Peripheral nerve affection is common in the rheumatoid foot, irrespective of the disease activity level. The most common foot neuropathies are; posterior tibial entrapment at the ankle, peroneal entrapment at the fibular neck and pure sensory axonal neuropathy. MSUS is valuable for diagnosis of posterior tibial entrapment at the ankle. In addition, a positive PD signal and erosions of the ankle joint are associated with disease activity.

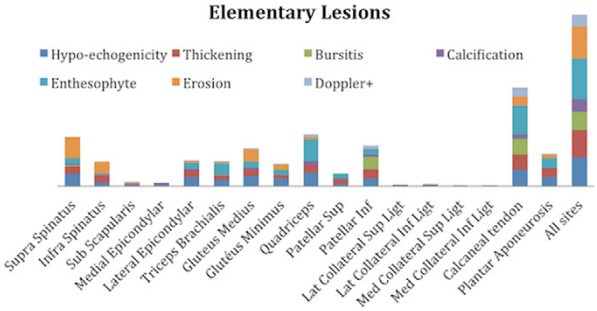
AB1001 CLINICAL VERSUS ULTRASOUND EVALUATION OF PERIPHERAL ENTHESITES IN A COHORT OF SPONDYLOARTHRITIS

A. Haddouche, S. Haid, S. Bencheikh, S. Slimani, A. Abdessemed, N. Brahimi, A. Ladjouze. *Medicine, University of Algiers 1, Algiers, Algeria*

Objectives: Clinical versus ultrasound evaluation of peripheral enthesites in a cohort of spondyloarthritis
Methods: A monocenter prospective study of all SpAs ≥18 years meting the ASAS criteria for SpA followed in a rheumatology center over a period from January 2015 to April 2016. Demographic, clinical, lab and ultrasound characteristics were noted. Fifteen entheseal sites were investigated bilaterally: insertions of supra-spinatus, sub-scapular, medial and lateral epicondylar tendons, triceps brachialis, gluteus medius, quadriceps proximal and distal insertion (patellar ligament, medial and lateral collateral ligament), Achilles tendon, plantar aponeurosis. These sites were assessed clinically and with US during the same visit and then results were compared between the clinical and the US examination.
Results: A total of 208 patients were included, mainly men (63.5%). The mean age was 40.2±11.7 years and the mean duration of the SpA was 11.8±8.7 years. Axial radiographic SpA was the most frequent phenotype (69.2%) and ankylosing spondylarthritis was the most frequent sub-group (57.7%). At examination, 88.9% had an active disease (ASDAS-ESR and/or ASDAS-CRP>1.3) and 64.4% of SpAs were taking NSAID. Clinical examination and US revealed at least one abnormal enthesis in 55.3% and 86.1%, respectively. Overall, 6240 entheses were examined, 44.2% were considered abnormal by clinical examination and 83.2% by US. The US abnormalities were entesophytes (69.5%), erosions (54.8%), hypochogenicity (49%), thickening (46.4%), bursitis (30.5%), calcifications (20.9%) and finally Doppler signal near the cortical bone in 20% of the examined entheses. The evidence of entheseal abnormalities by clinical examination has a poor likehood ratio (LR) for the presence of any US abnormality (LR + =1.4, LR- =0.8), for the acute US abnormalities (LR + =1.25, LR-=0,8), for the chronic US abnormalities (LR + =1.3, LR =0.8) as well as for the presence of the Doppler signal (LR + =1.1, LR- =0.9) at all sites.
Conclusions: US is useful to detect structural and inflammatory abnormalities of the enthesis in the SpA and can complete physical examination in order to better evaluate enthesitis.
Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.1978

AB1002 CLINICAL AND ULTRASOUND PREVALENCE OF PERIPHERAL ENTHESITIS IN AN ALGERIAN COHORT OF SPONDYLOARTHRITIS



A. Haddouche, S. Haid, S. Bencheikh, S. Slimani, A. Abdessemed, N. Brahimi, A. Ladjouze. *Medicine, University of Algiers 2, Algiers, Algeria*

Background: Algerian Spondyloarthritis (SpA) is characterized by a high prevalence and more severe axial and articular lesions compared to the caucasian population, What about enthesitis involvement?
Objectives: To estimate the global and site-specific clinical and ultrasound prevalence of peripheral enthesitis in an Algerian cohort of SpA
Methods: AA monocenter prospective study of all SpA ≥18 years meting the ASA criteria for SpA followed in a rheumatology center at EHS Ben Aknoun over a period from January 2015 to April 2016 Demographic, clinical, lab and ultrasound characteristics were noted. Fifteen enthesic sites were investigated: insertions of supra-spinatus, sub-scapular, medial and lateral epicondylar tendons, triceps brachialis, gluteus medius, quadriceps proximal and distal insertion (patellar ligament, medial and lateral collateral ligament), Achilles tendon, plantar aponeurosis. These sites were assessed clinically and ultrasonographically during the same consultation to determine the global and site-specific clinical and ultrasound prevalence of peripheral enthesitis. Elementary ultrasonographic lesions were noted. The comparison between clinical and ultrasound prevalence was performed using the Mac Nemar test using the SPSS software.
Results: A total of 208 patients were included, mainly men (63.5%). The mean age was 40.2±11.7 years. The mean duration of the SpA was 11.8±8.7 years. Axial radiographic SpA was the most frequent phenotype (69.2%) and ankylosing spondylarthritis was the most frequent sub-group (57.7%). At examination, 88.9% had an active disease (ASDAS-vs and/or ASDAS-crp>1.3) and 64.4% of SpAs were taking NSAID 6240 entheses were assessed clinically and 7072 entheses examined with ultrasound

Table 1. The global and site-specific clinical and ultrasound prevalence of peripheral enthesitis

	Clinical%	Ultrasound%	P
Calcaneal tendon	13,9	68,8	<0,001
Quadricipital	9,9	49	<0,001
Supra Spinatus	17,8	45,7	<0,001
Gluteus Medius	11,3	34,6	<0,001
Patellar Inf	8,9	32,5	<0,001
Plantar Aponeurosis	14,7	32,2	<0,001
Triceps Brachialis	10,3	26,7	<0,001
Lateral Epicondylar	23,8	24,5	NS
Infra Spinatus	–	24	–
Gluteal Minimus	–	22,6	–
Patellar Sup	10,6	14,9	NS
Sub Scapularis	18,5	5	<0,001
Medial Epicondylar	12,7	3,8	<0,001
Inf Collateral Lat Ligt	6,5	2,6	0,009
Sup Collateral Lat Ligt	5,8	1,9	0,007
Collateral Med Sup Ligt	5,8	0,7	<0,001
Collateral Med Inf Ligt	5	0,5	<0,001
All sites	44,2	83,2	<0,001

Figure 1 summarizes the prevalence of elementary ultrasound lesions per site.

Conclusions: In this cohort and as expected, ultrasound (with at least one elementary lesion) was superior to clinical examination for the detection of peripheral enthesitis (83.2 vs. 44.2%, P<0.001). Interesting sites to explore according to the prevalence and to the presence of a Doppler signal (<2mm/cortical) would be insertions of the calcaneal, quadricipital, patellar, gluteal, plantar aponeurosis and triceps brachialis tendons.

AB1003 MEDIAN AND ULNAR NERVE CROSS-SECTIONAL AREA IN CARPAL TUNNEL SYNDROME WITH EXTRATERRITORIAL SPREAD OF SENSORY SYMPTOMS

B. Mansiz Kaplan[1], M. Akdeniz Leblebicier[2], I. Yagci[3]. *[1]Department of Physical Medicine and Rehabilitation, University of Health Sciences, Ankara Training and Research Hospital, Ankara; [2]Department of Physical Medicine and Rehabilitation, Gumushane State Hospital, Gumushane; [3]Department of Physical Medicine and Rehabilitation, School of Medicine, Marmara University, Training and Research Hospital, Istanbul, Turkey*

Objectives: To evaluate the relationship between extramedian spreading of sensorial symptoms and median and ulnar nerve cross-sectional area in patient with carpal tunnel syndrome (CTS), to compare the ultrasonographic and electrophysiological findings in patients with CTS whose sensorial symptoms are extramedian spreading or median distribution only.
Methods: Patients with CTS were divided into two groups as with and without extramedian symptoms and were assessed clinically, electrophysiologically and ultrasonographically by three blind investigators. In electrophysiological tests, median and ulnar nerve conduction studies were performed. Nerve cross-sectional areas were measured at hamatum hook, psiform bone, radio-ulnar joint, one-third distal part of forearm, and medial epicondyle for median nerve; radio-ulnar joint, psiform bone, one-third distal part of forearm, and medial epicondyle for ulnar nerve by ultrasonography.

Results: The study was completed with 61 patients (108 hands). Extramedian symptoms were present in 31 patients (54 hands). Finger grip strength was lower, pain values evaluated with visual analogue scale were higher in these patients ($p<0.05$). There was no statistically significant difference in electrophysiological and ultrasonographic parameters between two groups.
Conclusions: These results suggest that extramedian spread in CTS patients is more related to central and peripheral sensitization than peripheral causes.

AB1004 NOMENCLATURE ON MEDICAL, DIAGNOSTIC, AND THERAPEUTIC PROCEDURES IN RHEUMATOLOGY

B. Yoldi[1], M.A. Martin[2], C. Plana[3], A. Gómez[4], M. Valero[5], J.L. Andreu[6], J.V. Moreno[7]. *[1]Rheumatolgy, Hospital Universitari Dexeus, Barcelona; [2]Sociedad Española de Reumatología, Madrid; [3]Rheumatology, Hospital Clínic Provincial, Barcelona; [4]Rheumatology, Hospital Parc Taulí, Sabadell; [5]Rheumatology, HM Hospitales; [6]Rheumatology, Hospital Universitario Puerta del Hierro, Madrid; [7]Rheumatology, Hospital Vall d'Hebron, Barcelona, Spain*

Background: One of the missions of the Spanish Society of Rheumatology (SER) is to provide professionals involved with the necessary tools to ensure a better care for patients suffering from a rheumatic disease. Up to now, there is no benchmark that quantifies the complexity of medical acts in this specialty. Therefore, there is a need to adopt a physician activity scale that would allow assessment of their professional activity and skills regarding patient care.
Objectives: To compile a nomeclature of medical, diagnostic, and therapeutic procedures in the field of rheumatology; and to establish a hierarchical classification system according to a complexity index.
Methods: A list of care, diagnostic, and therapeutic acts was compiled based on the nomenclature created by Drs Fernandez and Olive. The hierarchical classification system was based on the construction of a complexity index which was calculated by two factors: time of completion and degree of complexity of each act. Time of completion was stated according to the document "Standards of Process Time and Patient Care Quality" by Dr Alonso. The degree of complexity of each rheumatologic act was agreed thanks to a panel of experts using a Delphi technique in two rounds. Subsequently, it was validated against a questionnaire which was sent to the 1144 partners of SER via its web.
Results: The total of included acts was 54. The results obtained with the Delphi method tended to show a consensus of opinion (media $\sigma 2$ - $\sigma 1$=0.75–1.43=-0.68, media IQR2 – IQR1=0.8–1.9=-1.1). Furthermore, a validation of these results was carried out through a massive survey among the partners of SER. The survey results showed a high degree of agreement (at least 70.0 per cent of the partners agreed or strongly agreed with the complexity of each act).
The degree of complexity in successive visits was 100. In the query section for consultations, the highest scores were obtained by first visit to hospitalized patient (366) and home visit (369). Regarding diagnostic techniques, the highest scores were obtained with biopsies: bone (465), sural nerve (416), and synovial (380). Also worth mentionioning the scores obtained by ultrasound scan (204), capillarioscopy (113) and densitometry (112). Regarding therapeutic techniques, intra-articular injection under sedation in children obtained a score of 388; while intra-articular injection with ultrasound control obtained a score of 163. The clinical report of disability was agreed to have a score of 323, and the expert report obtained a score of 370.
Conclusions: This work has made it possible to create a nomenclature of 54 acts in Rheumatology where biopsies (bone, sural nerve, synovial), visits to hospitalized patients, home visits, infiltration under sedation in children, and expert reports are identified as the most complex acts. Musculoskeletal ultrasound is considered twice as complex as a successive visit, capillaroscopy, or bone densitometry. These results will make it possible to improve patient care and establish a solid and agreed foundation to negotiate the provision of public and private services.

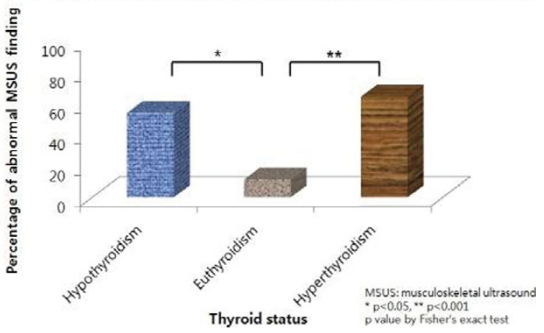
AB1005 HYPOTHYROID AND HYPERTHYROID STATUS WAS STRONGLY ASSOCIATED WITH MUSCULOSKELETAL ULTRASONOGRAPHIC ABNORMALITIES WITH ARTHRALGIA

B.Y. Kim[1], S.S. Kim[2], J.R. Choi[3], H.-S. Kim[1]. *[1]Department of Internal Medicine, Soonchunhyang University college of Medicine, Seoul; [2]Department of Internal Medicine, Gangneung Asan Medical Center, Gangneung; [3]Department of Internal Medicine, Pohang Saint Mary's Hospital, Pohang, Korea, Republic Of*



Background: Thyroid dysfunction can cause musculoskeletal symptoms and sign. Ultrasonography is a useful tool for the evaluation of synovitis and is more accurate than clinical examination.
Objectives: The purpose of the study was to determine whether musculoskeletal ultrasonographic (MSUS) abnormalities were observed according to the state of thyroid disease.
Methods: Patients with thyroid disease were categorized as euthyroid, hypothyroid, or hyperthyroid status according to thyroid hormone levels and evaluated the association with MSUS abnormalities. In addition, the association of the presence of thyroid autoantibodies with MSUS abnormalities was also studied. In MSUS, an experienced rheumatologist examined the presence of synovial fluid, synovial hypertrophy, and grade of power doppler in the knee joint.
Results:

Table 1. Patient characteristics

	Patients (n=109)
Age – mean ± SD (years)	58.2±13.0
Sex – n (%)	
Male	13 (11.9)
Female	96 (88.1)
Thyroid diseases duration – median (range), (years)	4 (0–13)
Distribution of thyroid diseases - n (%)	
Euthyroid status	61 (56)
Hypothyroid status	11 (10.1)
Hyperthyroid status	37 (33.9)
Positive thyroid autoantibodies – n (%)	68 (62.4)
Taking thyroid medication – n (%)	100 (91.7)
Patient's Knee VAS (100mm) – median (range)	10 (0–80)
MSUS finding – n (%)	
Normal	72 (66.1)
Abnormal	37 (33.9)

109 consecutive patients who visited the endocrinology outpatient clinic and had thyroid disease with normal or abnormal thyroid function tests participated in the study. MSUS abnormalities were statistically significantly higher in hyperthyroid or hypothyroid status than in euthyroid status ($p<0.001$). However, there was no statistically significant difference between hypothyroid status and hyperthyroid status. The presence of MSUS abnormalities with abnormal thyroid function was corrected according to the presence of radiological Knee osteoarthritis. Both hypothyroid and hyperthyroid status was still associated with MSUS abnormalities regardless of knee osteoarthritis. Visual analogue scale for knee pain was higher in patients with MSUS abnormalities ($p<0.001$). But, there was no statistically difference of MGUS abnormalities with presence of thyroid autoantibodies.

Figure 1. It shows frequency of Abnormal MSUS finding according to thyroid status

Conclusions: Both hypothyroid and hyperthyroid status was significantly associated with MSUS abnormalities with knee arthralgia. MSUS is a useful tool to detect clinically early joint abnormalities. We suggest that patients with diagnosed thyroid dysfunction and who remain uncontrolled, should assess the MSUS examination in patients with arthralgia. Moreover a thyroid function test for unexplained arthritis maybe warranted.

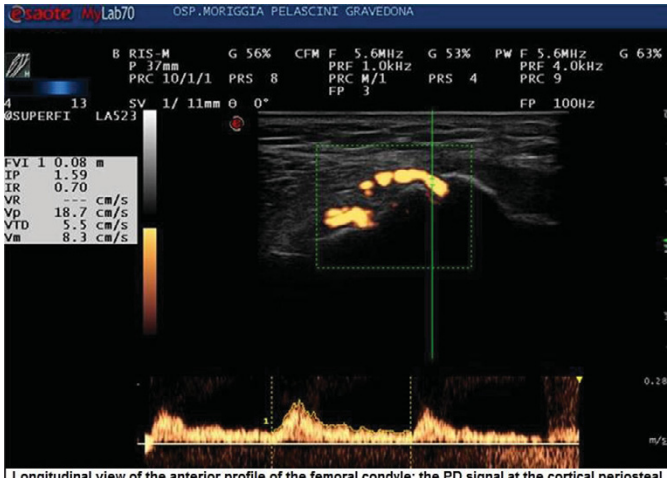
AB1006 POWER-DOPPLER TECHNIQUE IN PAGET'S DISEASE OF BONE: A NEW MONITORING TOOL OF THERAPEUTIC RESPONSE. STUDY ON 43 PATIENTS

C. Artusi[1], C. Mastaglio[2], C. Arnoldi[2], V. Galbiati[2], P.L. Meroni[1]. *[1]Chair and Division of Rheumatology, Gaetano Pini Institute, University of Milan, Milan; [2]Unit of Rheumatology, Ospedale Moriggia-Pelascini, Gravedona (CO), Italy*

Background: To date the evaluation of the disease activity and the monitoring of the therapeutic response of patients affected by Paget's disease of bone is based only on clinical and hematological data. However, in clinical practice the management of these patients is still challenging. Previous angiographic

and histological studies have revealed that the accelerated bone turnover is associated with an increased blood flow and hypervascularity, suggesting a role of high-resolution sonography with power-Doppler (PD) and color- Doppler (CD) in Paget's disease. Our preliminary data demonstrated that this technique shows not only the alterations of the pagetic bone profile, but also the hypervascularization of the osteoperiosteal-layer, both at the diagnosis and during follow-up.



Objectives: To validate the PD technique as a useful tool not only for the diagnosis of Paget's disease of bone but also for the evaluation of the disease activity and for the monitoring of the therapeutic response.

Methods: Forty-three consecutive patients affected by Paget's disease of bone and treated with neridronate were followed up over the last ten years. Patients were classified in eight clinical patterns defined by the presence of bone alkaline phosphatase elevation over the normal range (BAP+), bone pagetic pain as visual analogue scale ≥30 (VAS+) and PD alterations of osteoperiosteal vascularization (PD+). Data were analyzed by Fisher exact test (two tails) to assess the associations between BAP+, VAS+ and PD+ at different times during follow up: before the start of the therapy, after the first, the second and the third neridronate cycle of therapy, and at the end of all cycles.

Results: At any time BAP+ and VAS+ were not associated. A trend of association between VAS+ and PD+ could be observed only after the first neridronate cycle. In contrast, the association between BAP+ and PD+ was statistically significant before the therapy, at the end of all cycles of therapy and after the second one, but not after the first one.

Table 1. Associations between BAP elevation over the normal range, VAS and PD alterations of osteoperiosteal vascularization, p<0.05

	BAP+/VAS+		BAP+/PD+		VAS+/PD+	
	n	P value	n	P value	n	P value
Before therapy	40	1.000	35	0.0063	35	0.5620
After first therapy cycle	40	0.6225	35	0.6176	35	0.0751
After second therapy cycle	22	0.4701	21	0.0263	21	1.000
After third therapy cycle	9	1.000	9	1.000	9	1.000
At the end of all therapy cycles	40	1.000	35	0.0290	35	1.000

Longitudinal view of the anterior profile of the femoral condyle: the PD signal at the cortical periosteal layer shows a systolic peak and a continuous diastolic flow with low-resistance index.

Conclusions: The lack of association between VAS+ and PD+ or BAP+ may be due to the difficulty of the patients in identifying and quantifying the pagetic pain, and suggests the weakness of the clinical criteria in defining the disease activity. Otherwise, PD technique proves to be a fast, reliable and not expensive tool, which is also very useful for monitoring/achieving better control of Paget's disease of bone.

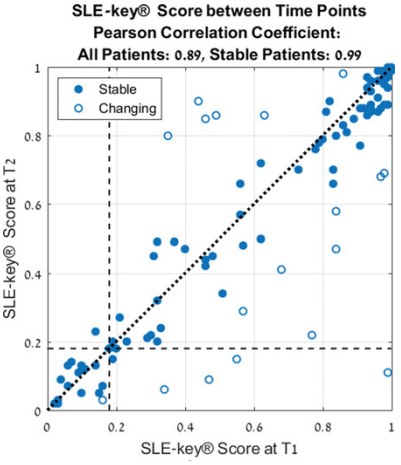
AB1007 THE SLE-KEY® TEST DETECTS AN SLE SEROLOGIC SIGNATURE THAT PERSISTS OVER TIME AND IS INDEPENDENT OF DISEASE ACTIVITY



C. Putterman[1], M. Petri[2], R. Caricchio[3], P. Safer[4], K. Jakobi[4], R. Sorek[4], I. Gluzman[4], S. Wallace[5], I.R. Cohen[6]. *[1]Division of Rheumatology, Albert Einstein School of Medicine, NY; [2]Division of Rheumatology, Johns Hopkins University School of Medicine, MD; [3]Temple Lupus Clinic, Temple University, Philadelphia, PA, United States; [4]ImmunArray LTD, Rehovot, Israel; [5]ImmunArray Inc, VA, United States; [6]Weizmann Institute of Science, Rehovot, Israel*

Background: We previously described the SLE-key® RuleOut test[1,2] to rule out the presence of systemic lupus erythematosus (SLE) with 94% sensitivity, 75% specificity, and 93% negative predictive value. We also reported that the SLE-key® signature appeared to be independent of disease activity or duration[3] suggesting[4] that that the SLE-key® signature might persist over time in the same subject.

Objectives: Here we report that the SLE-key® signature remains stable over time in paired samples drawn from most individual subjects, regardless of disease activity.

Methods: We determined the SLE-key® RuleOut scores for 113 paired serum samples submitted by clinics specializing in SLE. SLEDAI scores at the time of the blood draw ranged from 0 to 22. The mean SLEDAI difference within the pairs was 2.7±6.3. Samples were collected from subjects with a T1-T2 time difference that ranged from 0 to 11.5 years (mean =2±2.6 years).

Results: The SLE-Key® RuleOut test identifies an SLE-specific signature based on a profile of autoantibodies to a combination of nucleic acids (complex ssDNA and a defined oligonucleotide) and protein biomarkers. Patients with an SLE-key® score of >0.18 are considered not ruled out for a diagnosis of SLE. In 84% of paired samples, patients' SLE-key® scores remained essentially the same (Figure 1, closed circles). The scores for these subjects were stable, persistent, and independent of SLEDAI score or time between sampling. Significant changes in the SLE-key® scores of 18/113 patient pairs (open circles) appear to be independent of time between blood draws and change in SLEDAI score. In 7 cases there was a change in Rule Out status of the patients. In 3 cases, both scores were close to the 0.18 threshold and the change was deemed not significant. In 4 cases, patients' status changed from RuledOut to Not Ruled Out, but with no correlation to change in SLEDAI score or time between sampling dates. Records of patients with changing SLE-key® scores are being studied to determine the reasons and the clinical implications of the change.

Conclusions: The SLE-key® RuleOut test detects a serologic signature which remains stable between sampling dates and over a long period of time after diagnosis in 84% of subjects. Subjects who were ruled out at T1 were generally ruled out at T2. Patients not ruled out at T1 remained not ruled out at T2. The clinical implications of a changing SLE-key® RuleOut score in the remaining 16% of patients may be meaningful, and are currently being carefully investigated.

AB1008 DISTRIBUTIONS OF ANTIBODIES IN SLE PATIENTS IN DIFFERENT ETHNIC GROUPS IN XINJIANG

C. Xiaomei, W. Lijun. *Department of Rheumatology and Immunology, People's Hospital of Xinjiang Uyghur Autonomous Region, urumqi, China*

Objectives: The aim of this study was to explore distributions of antibodies in SLE patients in different ethnic groups in xinjiang.

Methods: Data were obtained from 670 patients with SLE from Department of Rheumatology and immunology in our hospital between January 2012 and October 2016.All patients fulfilled the 1997 ACR SLE classification criteria. Data about their gender, age, ethnic groups and result of antibodies test were collected.
Results: Totally 670 completed data were collected.there are 438 (65.37%) of these patients (68.22%) were Han population,136 (20.29%)were Uighur, 43 (6.42%) were Kazakh, 30 (4.48%) were hui people and 23 were other minorities live in xinjiang. The titer of ANA was higher in minorities than Han population (Z=-3.516, P<0.01). As compared with Han population, the positive rate of anti-Smith antibaodies and anti-SSA antibodies in SLE patients, significantly higher than han population (χ^2=5.902, P<0.017; χ^2=42.787, P<0.001, respectively). However, there are no significant different of the positive rate ofanti-SSA antibodies, anti-Scl-70 antibodies, anti-Jo-1 antibodies,anti-ds-DNA antibodies between Han population and minorities.
Conclusions: Distributions of antibodies in SLE patients were different between Han population and minorities.the positive rate of anti-Smith antibaodies and anti-SSA antibodies in SLE patients were significantly higher than han population.

AB1009 MRI CONTRIBUTES TO ACCURATE DIAGNOSIS OF NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS IN PATIENTS WITH SERUM NEGATIVE HLA-B27

C.-C. Lu[1,2], G.-S. Huang[3], H.-C. Chen[1], T.S.-H. Lee[4], F.-C. Liu[1], S.-Y. Kao[1], S.-J. Chu[1], T.-Y. Ho[1], C.-H. Chen[5], S.-Y. Lyu[6]. *[1]Division of Rheumatology, Department of Internal Medicine, Tri-Service General Hopsital, National Defense Medical Center, Taipei City, Taiwan, Province of China; [2]Department of Pathology, University of Washington, Seattle, United States; [3]Department of Radiology, Tri-Service General Hopsital, National Defense Medical Center; [4]Department of Health Promotion and Health Education, National Taiwan Normal University, Taipei City; [5]Division of Rheumatology, Department of Internal Medicine, Taipei Tzu Chi Hospital, New Taipei City; [6]Division of Radiology, Taoyuan General Hospital, Ministry of Health and Welfare, Taoyuan City, Taiwan, Province of China*

Background: Based on ASAS axial spondyloarthritis (SpA) criteria, the presence of structural changes of sacroiliac (SI) joints such as sclerosis, bone erosion, joint space widening or ankyloses dose not meet the definition of active sacroiliitis on magnetic resonance imaging (MRI), if there is no bone marrow edema (BME). However only less than half Asian patients with SpA were characterized by BME. Neither serum inflammatory markers such as c reactive protein (CRP) nor erythrocyte sedimentation rate (ESR) is able to be useful as diagnostic markers in the early phase of SpA. HLA-B27 is associated with early diagnosis of SpA and axial inflammation of SI joints on MRI. Nonetheless, HLA-B27 is not associated with structural lesions of SI joints. All factors contribute to difficult defining early Asian SpA patients in the absence of serum HLA-B27 and active imaging inflammation.
Objectives: The aim of this study is to evaluate the prevalence of structure changes of SI joints on MRI in Taiwanese SpA patients in the absence of serum HLA-B27.
Methods: Thirty-three patients with inflammatory back pain and morning stiffness (disease duration more than 3 months) and high disease activity (BASDAI$\geq$4) who had to be either serum HLA-B27 positive (10 patients) with $\geq$1 SpA-feature or HLA-B27 negative with $\geq$2 SpA-features (22 patients) were included in this prospective study. All patients did not meet the definition for a positive radiograph according to the modified New York criteria. MRI was performed with multiple sequence (Coronal and axial T1-weighted spin echo, coronal and axial short-tau inversion recovery). SI joints were evaluated for the prevalence of subchondral BME and structure changes (sclerosis, bone erosion, joint space widening and ankylosis). All patients were tested for X-rays of the pelvis and serum levels of ESR and CRP. Correlation analysis was performed among the different collected variables.
Results: Subchondral BME was only present in 8 of 23 patients with SpA in the absence of serum HLA-B27 (34.8%), while 7 of 10 (70%) HLA-B27 serum positive SpA patients had active BME on MRI. Structural changes of SI joints, including sclerosis, bone erosion and joint space widening were identified in 8 (80%), 10 (100%) and 5 (50%) SpA patients with positive serum HLA-B27, respectively. Nevertheless, these structural changes of SI joints on MRI were more common in HLA-B27 serum negative patients, as 15 (65.2%), 20 (87.0%) and 7 (30.4%) of 23 serum negative patients, respectively.
Conclusions: MRI contributes to detect structural changes of SI joints for patients with nonradiographic axial SpA in the absence of serum HLA-B27.

AB1010 ULTRASOUND MORPHOSTRUCTURAL PATTERN OF THE TIBIOFIBULAR JOINT. PRELIMINARY RESULTS

C. Hernández-Díaz[1], L. Ventura-Rios[1], M. Maldonado[2], G. Sanchez-Bringas[3]. *[1]Laboratorio de Ultrasonido Musculoesquelético y Articular, Instituto Nacional de Rehabilitación, Mexico City, Mexico; [2]Reumatologa, Cuzco, Peru; [3]Departamento de Embriologia, Facultad de Medicina, UNAM, Mexico City, Mexico*

Background: The anatomy of the proximal tibiofibular (TF) joint is directly related to its ability to withstand stress applied in either a longitudinal or axial fashion. It is traditionally evaluated by CT scan, however, in certain conditions, it could be evaluated by ultrasound (US) conveniently; so far US has not been using to evaluate the TF joint. US is an innocuous, accessible and cheap image technique, that has demonstrated its utility for evaluating joints in several pathologic conditions, and might have an important role in the early diagnosis of inflammatory, degenerative or even tumoral lesions at the level of the TF joint; there are no studies that have evaluated the morpho- structural pattern of the TF joint.
Objectives: To describe the morphostructural pattern of the tibiofibular joint in healthy subjects.
Methods: Subjects older than 18 yrs old, with no history of past/present lesion of the knee, without any joint or neurovascular disease were included. A short questionnaire related to physical activity applied, and clinical evaluation to discard instability performed. US of both knees in extension done, using an Esaote ® MyLab 70 ultrasound equipment with a 7.5 - 12 MHz linear transducer. Descriptive statistics done
Results: Thirty-six patients (27 women, 75%) included, mean age 41.2±8.9 years, mean weight 71±12.46 kg, mean height 1.61±0.09 ms and BMI 71.07±12.40. 69% of the subjects practice mild exercise activities. By US mean distance between tibia and fibula were 3.2±1.17 cm; the mean thickness of the ligaments (superior and inferior) was 3.2±0.99 cm and 3.2±0.89 respectively, and in the superior e inferior fibular ligaments were 3.2±0.99 cm and 3.2±0.89 cm respectively. Ligaments were hyperechoic in 61.1%, a well-defined border was seen only in 48.6%. Inside of joints a hypoechoic tissue was observed
Conclusions: These preliminary results suggest that US can be a useful tool for evaluating the tibiofibular joint.

AB1011 RELIABILITY OF SONOGRAPHIC PERITENON EXTENSOR TENDON INFLAMMATION PATTERN IN PSORIATIC ARTHRITIS

C. Macía[1], H.B. Hammer[2], S. Falcao[3], J. Medina[4], M. Gutierrez[5], E. De Miguel[6]. *[1]Rheumatology, Hospital Universitario Severo Ochoa, Madrid, Spain; [2]Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; [3]Rheumatology, Chronic Diseases Study Center (CEDOC), NOVA Medical School, UNL, Lisboa, Portugal; [4]Rheumatology, Hospital Clínico Universitario, Valladolid, Spain; [5]Rheumatology, Division of Musculoskeletal and Rheumatic Disorders. Instituto Nacional de Rehabilitación, Mexico City, Mexico; [6]Rheumatology, Hospital Universitario la Paz, Madrid, Spain*

Background: Preliminary results demonstrate that the peritenon inflammation of the extensor digitorum tendon (PTI) is a specific ultrasound (US) pattern of Psoriatic Arthritis (PsA) at metacarpophalangeal joint (MCPj) level. It was suggested as a pattern playing a key role in the differential diagnosis between Rheumatoid Arthritis and PsA [(1,2)].
Objectives: In spite of PTI's clinical impact, there are no data regarding the reliability of US PTI evaluation. The present study addressed this topic by testing the reliability of US on evaluation of PTI.
Methods: 27 consecutive non selected PsA patients with clinical involvement of at least one 2nd to 5th MCPj were included. A rheumatologist trained in PTI assessments obtained the US images exploring the dorsal aspect of MCPj from 2nd to 5th of both hands using a MyLab 70 XVG machine, Esaote, Genova, Italy, with a greyscale (GS) 13 MHz probe and a 7.1 MHz power Doppler (PD) frequency, PRF 750 Hz and a 60 Gain. 3–5 seconds videos of each MCPj were obtained in transversal and longitudinal views for further reliability analysis. In the inter-reader reliability analysis, performed by five readers from five different hospitals and four countries, it was scored as present or absent 1) PTI (defined as an hypoechoic swelling of the soft tissue surrounding the extensor tendon at MCPj level with or without PD) and 2) intra-articular synovitis (IAS, OMERACT definition), both in PD and GS. The consensus of true US results for every joint and lesion was achieved when at least three readers had the same opinion. Cohen's Kappa test was used for statistical analysis.
Results: Clinical MCPj involvement was present in 60 (27.7%) of the 216 joints whereas US detected IAS and/or PTI in 75 (34.7%). US showed GS PTI in 41 (19%) and PD in 38 (17.6%) of the joints, while GS IAS was found in 63 (29.2%) with PD activity in 41 (19%) of the joints. The inter-reader reliability is shown in the Table. Intra-reader reliability results expressed as mean Kappa were 0.826 for PTI PD, 0.784 for PTI GS, 0.743 for IAS PD and 0.637 for IAS GS.
Conclusions: US examination of MCPj shows that PTI is near as frequent as IAS in PsA with reliability of its scoring at least as good as for joint synovitis. This opens the possibility of introducing US scoring of PTI, which may be of importance for the diagnosis and follow-up of PsA patients.

AB1012 CLINICAL UTILITY OF ANTIHISTONE ANTIBODIES: A DESCRIPTIVE STUDY

D. Boveda-Ruiz[1], B. Vilas-Pio[2], M. Freire-Dapena[2], R. Lorenzo-Castro[2], A. Soto-Peleteiro[2], S. Mirete-Bachiller[3], A. Rivera-Gallego[2]. *[1]Internal Medicine, Hospital Clínico Universitario de Valladolid (SACYL), Valladolid; [2]Internal Medicine; [3]Immunology, Complexo Hospitalario Universitario de Vigo, Vigo, Spain*

Background: Antihistone antibodies (AHA) have been linked to Drug-Induced Lupus Erythematosus (DILE) for decades[1]. However, for some authors this relationship is not so clear and sugest that the presence of these autoantibodies is related to other autoimmune diseases more frequently[2,3,4].
Objectives: The main objetive of this work was to study the association of AHA with different autoimmune entities (including DILE) and secondarily, look into which clinical manifestations and which autoantibodies are more frequently related to AHA.
Methods: We performed a descriptive study. A database was constituted using all patients with AHA+ in any blood analysis between years 2000 and 2016 in the University Hospital Complex of Vigo. The variables of the study were: presence of autoimmune disease, clinical manifestations and related autoantibodies.
Results:

Variable	Men	Women	All	% Total
Age	50	45	46	
Gender	15	58	73	100
SLE	8	27	35	48
DILE	0	0	0	0
Scleroderma	0	4	4	5
Sjögren	1	8	9	12
Rheumatoid Arthritis	0	3	3	4
No diagnosis	5	19	24	33
Malar rash	1	11	12	16
Photosensitivity	2	11	13	18
Oral ulcers	1	10	11	15
Arthritis	6	31	37	51
Lupic nephropathy	4	13	17	23
Raynaud	1	11	12	16
Hematological abnormalities	5	20	25	34
AntiRo+	4	12	16	22
AntiLa+	2	5	7	10
AntiSm+	3	8	11	15
AntiDNAds+	3	25	28	38

None of the 73 patients AHA+ developed DILE while almost the 50% of them suffer any other autoimmune disease. We found a high percentage of AHA+ patients with lupus erythematous complications such as arthritis and hematological abnormalities. AntiDNAds antibody was the more frequent coexpressed autoantibody.
Conclusions:
- AHA detection is not useful as DILE screening.
- AHA+ sugest the presence of other autoimmune disease rather than DILE.
- AHA+ may be related to lupus erythematous systemic complications.

AB1013 DEVELOPMENT AND VALIDATION OF A FLOURESCENCE OPTICAL IMAGING RHEUMATOID ARTHRITIS SCORING SYSTEM FOR SYNOVITIS IN THE WRIST AND HAND

D. Glinatsi[1], M. Østergaard[1,2], L. Terslev[3], S. Ohrndorf[4], M. Ammitsbøll-Danielsen[3]. *[1]Copenhagen Center for Arthritis research, COPECARE, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup; [2]Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copehangen; [3]Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Denmark; [4]Department of Rheumatology and Clinical Immunology, Charité – University Medicine, Berlin, Germany*

Background: Fluorescence optical imaging (FOI) has been suggested as an imaging modality for assessment of inflammation (i.e. synovitis) in the hands, and has in several studies been compared to US and MRI, using different, but not validated scoring systems.
Objectives: To develop and validate a semi-quantitative FOI RA scoring system for synovitis in the wrist and hand.
Methods: 46 RA patients, eligible for induction or intensification of disease modifying anti-rheumatic drug and with ≥1 clinically swollen joint in the hand were included. FOI image-sets of both wrists and hands were obtained at baseline, and after 3 and 6 months' follow-up using a Xiralite system unit (nanoPET Pharma GmbH, Berlin, Germany). The patients received a bolus of i.v. indocyanine green (ICG) pulsion (1mg/kg body weight) 10 seconds after starting the examination, which obtained 1 image/second over 6 minutes. The image-sets were anonymized and randomized and were assessed for synovitis at the wrist, 1st-5th metacarpophalangeal, 1st interphalangeal and 2nd-4th proximal interphalangeal joint levels in both hands by two readers blinded to patient data but not chronology. 23 image-sets were re-anonymized and re-read for intra-reader agreement analysis. The scoring system for synovitis was based on the assumption that inflamed tissue would demonstrate a more rapid enhancement than surrounding tissues. For each joint, the images were assessed sequentially from start of the injection of ICG-pulsion to peak enhancement. At the peak enhancement, the color index was adjusted in order to increase the discrepancy between colors. Synovitis was defined as a sharply marginated enhancement with clear delineation from surrounding tissues and correct anatomical location lasting ≥3 seconds. The thickness of the pathology fulfilling these criteria was compared to the width of the joint in the transverse plane at the 3rd second of enhancement and the following semi quantitative scoring system (0–3) was applied: grade 0: no enhancement, grade 1: <1/3, grade 2: ≥1/3 but ?2/3, grade 3: ≥2/3 of joint thickness (range 0–66). Descriptive statistics and the Wilcoxon signed-rank test were used to assess change in score over time. Intra-/inter-reader for status and change scores were assessed using single measure intra-class correlation coefficients (ICC) and smallest detectable change (SDC, change scores only). Responsiveness was assessed using standardized response mean (SRM).
Results: Median (IQR) total synovitis score at baseline was 9.5 (4.0;16.5) and improved with -5.0 (-10.0;-1.0) and -8.0 (-13.5;-3.0) at 3 and 6 months' follow up, respectively ($p<0.01$). Intra- and inter-reader ICCs were good to very good for total scores (Table 1). The SDCs were generally low and for the inter-reader SDCs, 56% and 60% of the patients had a change >SDC between baseline and 3 and 6 months, respectively. The mean SRM for total change scores at 3 at 6 months' follow-up were moderate to good (0.7 and 0.8).

Table 1

	ICC Baseline	ICC 3 months' follow-up	ICC 6 months' follow-up	ICC Change, baseline to 3 months	ICC Change, baseline to 6 months	SDC Change, baseline to 3 months	SDC Change, baseline to 6 months

Total scores	0.95	0.97	0.90	0.90	0.90	6.2	6.5
Wrist	0.92	0.88	0.81	0.78	0.80	1.6	1.6
MCP joints	0.96	0.96	0.92	0.92	0.89	3.3	3.4
PIP joints	0.94	0.95	0.80	0.88	0.90	3.8	3.9
	Inter-reader agreement						
Total scores	0.88	0.84	0.60	0.81	0.70	4.8	6.2
Wrist	0.76	0.72	0.58	0.67	0.65	1.1	1.3
MCP joints	0.86	0.80	0.76	0.81	0.66	3.1	3.7
PIP joints	0.91	0.82	0.39	0.79	0.71	2.6	3.6

Intra-and inter-reader intra-class correlation coefficients (ICC) were interpreted as follows: good: ICC≥0.60, very good: ICC≥0.80. Abbreviations: SDC: smallest detectable change, MCP: metacarpophalangeal, PIP: proximal interphalangeal.

Conclusions: The novel FOI RA synovitis scoring system showed high reliability and moderate to good responsiveness in the wrist and hand. Future studies should focus on assessing the sensitivity and specificity of the FOI synovitis score with ultrasound and magnetic resonance imaging as gold standard.

AB1014 SAFETY OF OUTPATIENT PERCUTANEOUS NATIVE RENAL BIOPSY IN PATIENTS WITH SYSTEMIC AUTOIMMUNE DISEASES: RESULTS FROM A MONOCENTRIC COHORT

D. Roccatello, S. Sciascia, D. Rossi, C. Naretto, M. Bazzan, L. Solfietti, M. Radin, S. Baldovino, E. Menegatti. *Department of Rare and Immunologic Diseases, G. Bosco Hospital and University of Turin, TOrino, Italy*

Background: Renal involvement is common in patients with systemic autoimmune conditions, mainly systemic lupus erythematosus (SLE) and vasculitis, including cryoglobulinemia. Despite the advances in percutaneous kidney biopsy (PKB) techniques and overall improved safety of the procedure, clinically significant bleeding complications do occur.
Objectives: to investigate the safety of performing percutaneous native kidney biopsy (PKB) as an outpatient procedure (implying an observation period of 6 hrs) compared to the traditional inpatient policy in patients with systemic autoimmune conditions.
Methods: Group I, in whom PKB was performed in the outpatient department (2012–2016) and followed by 6 hours' observation period and then by regular outpatient visits and group II, in whom PKB was performed and followed by at least 1-day hospital admission. Group II included retrospectively retrieved patients who underwent PKB in our Institution between January 2000 and November 2012 as in patient procedure. All biopsies were performed by a single nephrologist following a structured protocol.
Results: A total of 81 biopsies (group I and group II) were included in this study, 44 (54%) of patients were female and the mean age was 49.9±17.6 years. Twenty-six per cent of biopsies were performed for the diagnostic workup of nephrotic range proteinuria, 21% for rapidly progressive renal insufficiency, and the remaining 53% for non-nephrotic proteinuria and/or hematuria. No patient suffered for a major complication and only 3 (3.7%) patients (one with cryoglobulinemic vasculitis and 2 with ANCA associated vasculits) developed a minor complication, including gross hematuria in one case and sub-capsular perinephric hematoma on sonography not requiring intervention in 2 patients
Conclusions: The lack of major complications and the very limited rate of minor bleeding support that outpatient biopsy could be a valuable, safe, and perhaps cost-effective method of obtaining diagnostic renal tissue in the majority of patients with systemic autoimmune diseases.

AB1015 AUTOMATED SQUEEZE TEST (GAENSLEN'S COMPRESSION MANEUVER) IN RHEUMATOID ARTHRITIS PATIENTS. EXPLORATORY STUDY

D. Vega-Morales, J.A. Esquivel-Valerio, A.C. Arana-Guajardo, M.A. Garza-Elizondo. *Rheumatology Service, Hospital Universitario Dr. José Eleuterio González, Monterrey, Mexico*

Background: The squeeze test (a.k.a Gaenslen's Compression Maneuver) consists on the compression of the metacarpal-phalangeal (MCP) joints to elicit pain in a patient with active synovitis. The squeeze test has three main purposes: Screening of inflammatory arthritis, as a predictor of rheumatoid arthritis in arthralgia patients, and as a quick and practical evaluation of the presence/absence of synovitis in patients already diagnosed with RA. The force and the way to perform the squeeze test had been evaluated in rheumatologists on a biomechanical device, with conflicting results. We developed a biomechanical device to perform the squeeze test.
Objectives: Our aim is to determine the force whether the automated squeeze test discriminate patients with active RA from inactive ones. And the force that differentiates a healthy patient from a RA patient.
Methods: Observational study in RA (ACR/EULAR 2010) patients and healthy persons. We perform 3-squeeze test on the device in the MCP joints and record the force enough to elicit pain. And then compare them with the joint counts by the clinician
Results: Two hundred MCP joints from 50 hands were tested. From 25 RA patients with a mean age of 54.6 years (SD 11.22), with a mean disease latency of 1.2 years (SD 2.7). The total swollen joint count was 16 (7 right joints + 9 left joints) and 70 total tender joint count (30 right joints and 40 left joints). The median of force that caused pain in the RA patient's right hand was 3.07 kg (IQR 2.4) and the left hand was 2.78 kg (IQR 3.8). The cut-off for the force to detect a tender right hand joint was 1,020 grams with a sensitivity of 100% and specificity of 10%; for a swollen right hand joint was 1,400 with a sensitivity of 100% and specificity of 28.6%. For a tender left hand joint was 1620 grams with a sensitivity 70% and specificity of 6.7%; and for a swollen left joint was 1990 grams with a sensitivity of 100% and specificity of 27.3%.
In the second phase, 560 MCP joints of 140 hands from 70 healthy volunteers were compressed. The median force to elicit pain in the right hand was 4.2 kg (IQR 9.5) vs. 3.07 kg (IQR 8.7) from RA patients (p=0.003). And for left hand 4.6 kg (IQR 9.7) vs. 2.78 kg (IQR 9.2) from RA (p=0.014).
Conclusions: It is necessary to continue the exploration of the maneuver in different clinical settings. Validate the strength in patients with different arthropathies, activity levels and different clinical stages (screening, activity, prediction) and also with imaging methods for evidence of inflammation (US, MRI)

AB1016 ANTI-DFS70, A TOOL IN USUAL CLINICAL PRACTICE: A CASE SERIES

D. Ybáñez-García [1], E. Valls-Pascual [1], C. Vergara-Dangond [1], M. Aguilar-Zamora [1], L. Montolio-Chiva [1], Á. Martínez-Ferrer [1], J.M. López-Ortega [2], J.J. Alegre-Sancho [1]. *[1]Rheumatology; [2]Clinical Analysis Laboratory Service, Hospital Universitario Dr. Peset, Valencia, Spain*

Background: The presence of anti-nuclear antibodies (ANA) has been considered a characteristic of systemic autoimmune diseases (SAD). Patients are frequently referred for study because they have ANA and are followed because of the possibility to develop SAD. Approximately, 20% of healthy individuals with ANA detected by indirect immunofluorescence (IFI), especially at low titers, have a dense, fine speckled pattern (DFS) that frequently corresponds to the presence of anti-DFS70 antibodies. The importance of this antibody is due to its low prevalence in subjects with ASD (<1%) compared to its presence in 33.1% of healthy subjects with ANA.
Objectives: To describe the usefulness of Anti-DFS70 in a series of patients presenting ANA.
Methods: We collected prospectively throughout the year 2016 all the patients referred to a tertiary hospital for ANA study and in whom the presence of anti-DFS70 antibodies was confirmed. All patients underwent a thorough medical history, physical examination, and relevant follow-up tests were performed according to the clinical presentation. The IFI was performed in a Menarini Zenit-Up/GSight system, as well as ANA screening in Hep-2000 (Fluorescent IgG ANA-Ro Test System-immunoconcepts) and the detection of anti-DFS70 antibodies by immunoblot (ANA + DFS70 Dot Blot-Alphadia).
Results: We collected in a period of 12 months a total of 7 patients with anti-DFS70 antibodies. Most of them (6/7) were referred because of non-specific symptoms such as arthralgia, fatigue, thrush, edema, ... and the presence of ANA. The findings are detailed in Table 1.

Abstract AB1016 – Table 1

Case	1	2	3	4	5	6	7
Symptoms	Polyarthralgias Arthritis 4th interphalangeal joint	General pain Dry eye and dry mouth	Polyarthralgias Back pain Inflammatory markers +	Arthromyalgias Fatigue Fever Anti-TNF-a	Polyarthralgias Back pain Fatigue, oral aphthosis	Hand pain and deformity of 2nd PIPs	Left foot edema
Gender	♀	♀	♀	♂	♀	♀	♀

Schirmer/Ss	NP	N	NP	NP	NP	NP	NP
CRP/ESR	N	N	21/17	N	N	N	N
Comorbidities	Type 2 DM	Graves Basedow	Hand angioedema	PsA	Graves Basedow	Dyslipidemia	No
RX /MRI	CPPD	Degeneration of left TMC and dorsal spine	L4-L5, L5-S1 Retrolistesis			Mild degenerative signs in PIP and TMCs	Synovial fluid in talo-navicular and tarsal joints
Axial/joint	Degenerative axial and joint signs		C5-C6-C7 Protrusions				
Diagnosis	OA CPPD	OA	OA Discopathy	PsA	Fibromyalgia Chronic fatigue	OA	Resolved foot arthritis

NP: not performed, N: normal, OA: osteoarthritis, PsA: psoriatic arthritis, CPPD: chondrocalcinosis.

Conclusions: Anti-DFS70 is a valuable biomarker, with a very low prevalence in SAD, which gives it a role as a negative predictive marker of developing SAD when it is appears alone. Its detection in serum with a dense fine speckled pattern ANA (IFI) should be part of the protocol of the immunology laboratory. It is a cost-effective determination, as demonstrated in a recent study, by avoiding the costs associated with the follow-up of these patients. In our case, its finding allowed us to reassure the patient and avoid the accomplishment of further complementary tests, as well as an unnecessary monitoring.

AB1017 THE DEFEAT OF THE HIP JOINT IN ANKYLOSING SPONDYLITIS BY MAGNETIC RESONANCE IMAGING

E. Agafonova[1,1], T. Dubinina, A. Dyomina, O. Rumiantceva, D. Rumiantceva, M. Podryadnova, A. Starkova, S. Krasnenko, M. Urumova, S. Erdes. *Laboratory seronegative spondyloarthritis, Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: According to the carried out epidemiological studies in Russia of patients with ankylosing spondylitis (AS) defeat of the hip joints was impairment in 46% of cases, but was the reason for the replacement in 7% of cases. i
Objectives: To compare the clinical manifestations of hip arthritis (coxitis) with the results of magnetic resonance imaging (MRI) of the hip joints (HJ) in patients with ankylosing spondylitis (AS).
Methods: Examined 117 patients (mean age 31,7±12.7 y meeting modified N-Y criteria), with complaints of pain in the hip joints. The average age of onset of disease was 26.3±20.3 years, HLA-B27 identified in 93% of patients. The median duration of AS – 57 [2–384] months. BASDAI 5,7±3,1. Diagnosis of hip septic arthritis were made based on clinical signs - the presence of pain in hips and/or restriction of movements in HJ at the time of patient admission to the clinic. In addition to clinical and radiographic examination all patients were performed MRI modes T1 and STIR.
Results: The Median duration of clinical manifestations of coxitis by the time of the study was 60 months. [25‰; 75‰], evaluation of pain in HJ for numeric rating scaler (NRS) – 4 [2; 8]. According to MRI identified the following inflammatory changes (IC): synovitis-71 (83%) patients, bone marrow edema (BME)- 44 (31,6%) patients (BME acetabulum 36%, BME heads 63%), a combination of synovitis and BME were 7 patients (9%). Depending on radiological stage (estimated by BASRI hip), patients were divided into two groups (table 1).
Results:

Table 1

Parameters	Group (1) BASRI hip 0-I (n=48)	Group (2) BASRI hip II-IV (n=60)	P
Gender (w/m), n	20/28	33/36	0,04*
AS duration,mo, Me [25‰, 75‰]	43 [19;80]	102 [24;120]	0,006*
BASDAI, Me [25‰, 75‰]	4,1 [2,6; 5,5]	5,6 [4,2; 6,7]	0,003*
BASFI, Me [25‰, 75‰]	2,8 [2,0; 3,8]	3,3 [2,0; 5,4]	0,2*
HLA-B27, n (%)	96 (91%)	84 (91%)	0,7*
ASDAS (CRP) Me [25‰, 75‰]	2,8 [2,0; 3,8]	3,5 [2,6; 3,8]	0,002*
ESR, mm/h, Me [25‰, 75‰]	10 [5; 25]	25 [8; 35]	0,001*
CRP, mg/mL, Me [25‰, 75‰]	10,5 [3,8; 28,5]	23,0 [4,9; 43,5]	0,06*
NRS, Me [25‰, 75‰]	5 [3;6]	6 [4;7]	0,01*
MRI Synovitis n (%)	44 (92%)	27 (45%)	0,003*
Osteitis n (%)	6 (12,5%)	38 (64%)	0,0001*

Conclusions: MRI allows to clarify the cause of the pain and limitations of movement in HJ with AS, determine the patient has inflammatory changes, including in the absence of radiographic changes in these joints. Patients with severe radiological change (BASRI II-IV), have a greater duration of the disease, severe functional abnormalities in the BASFI index. With increasing radiological stage (BASRI hip II-IV) increased the detection rate of osteitis by MRI. Further research to clarify the relationship of clinical manifestations of coxitis (pain level) from MRI data.

AB1018 DETECTION OF ANTI-DFS70 ANTIBODIES BY INDIRECT IMMUNOFLUORESCENCE (IIF) ON NOVEL HEP-2/DFS70-KO SUBSTRATE FOR DISCRIMINATING ANTINUCLEAR ANTIBODIES (ANA) – POSITIVE HEALTHY INDIVIDUALS (HI) AND PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

E. Aleksandrova, Z. Verizhnikova, A. Novikov, T. Panafidina, T. Popkova. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Autoantibodies against intracellular antigens are a serological hallmark of ANA-associated systemic autoimmune rheumatic diseases (AARD) such as SLE. IIF on HEp-2 cells for ANA remains the "gold standard" but it has very low positive predictive value. Up to 20% of serum samples from HI have been reported to have a positive ANA IIF test, the majority of them due to the presence of anti-dense fine speckled 70 (anti-DFS70) antibodies. Monospecific anti-DFS70 antibodies represent a biomarker that can be used to discriminate AARD patients (pts) from HI in ANA IIF positive subjects. Recognition of the DFS70 ANA IIF pattern can be challenging. The DFS-KO Hep-2 cells inhibit anti-DFS70 antibodies reactions, providing clear differentiation of the DFS pattern from classical ANA patterns.
Objectives: To evaluate the utility of a novel HEp-2/DFS70-KO IIF substrate for the detection of anti-DFS70 antibodies in HI and SLE pts.
Methods: We studied 45 HI (36 F/9 M; age 50.4 [24.0–72.0] years, median [interquartile range 25–75%]) and 12 pts with SLE (ACR criteria, 1997) (10 F/2M, age 38.9 [17.0–65.0] years; disease duration 100.3 [4.0–432.0] months; SLEDAI 2K score 11.7 [2–30]; SLICC damage index score 1.28 [0–4]). Serum samples were tested for classical ANA and anti-DFS70 antibodies by IIF technique with a mixture of standard HEp-2 cells and DFS70-KO HEp-2 cells ("Trinity Biotech", Bray, Ireland) as a substrate. Fluorescence titers $\geq$1: 160 were considered as positive for ANA patterns.
Results: ANA were present in 7/45 (15.6%) of HI and in 12/12 (100%) of SLE pts. All SLE pts and 3/45 (6.7%) of HI showed classic ANA patterns (homogeneous, speckled, and mixed) in the absence of DFS70 pattern. 4/45 (8.9%) of HI had classic ANA negative/anti-DFS70 antibodies positive IIF results. Isolated anti-DFS70 antibodies were found in 57% of ANA IIF positive HI. Among HI classic ANA and anti-DFS70 antibodies were detected in the low- to medium-titer range (1:160–1:320). The frequency of anti-DFS70 antibodies did not correlated with age.
Conclusions: The detection of isolated anti-DFS70 antibodies may be regarded as an exclusion criterion for the diagnosis of SLE. The testing for anti-DFS70 antibodies in a single step by HEp-2/DFS70-KO IIF method should be included into a modified ANA diagnostic algorithm. Additional investigations are required to evaluate the clinical relevance of anti-DFS70 autoantibodies.

AB1019 ASSOCIATION OF INFLAMMATORY DISEASES – A CURRENT TOPIC FOR THE PRACTITIONER

A. Cardoneanu[1,2], A. Burlui[1,2], C. Cijevschi Prelipcean[3], E. Rezus[1,2]. *[1]Rheumatology, University of Medicine and Pharmacy "Gr.T.Popa"; [2]Rheumatology Clinic, Rehabilitation Hospital; [3]Gastroenterology, University of Medicine and Pharmacy "Gr.T.Popa", iasi, Romania*

Background: Autoimmune, infectious, traumatic or neoplastic inflammation represents a warning for the practitioner. Numerous clinical specialties face daily with the presence of inflammation. The efforts of medical staff aim to establish the pathogenesis, the expansion and to find the most effective ways of treatment.
Objectives: Our study objective is to highlight the correlations between Spondylarthropathies (SpA) and intestinal manifestations, the link between the antigen HLA B27 and joint and intestinal inflammatory changes and also the relationship between the presence of sacroiliitis and bowel disorders.
Methods: The study included 42 patients (28 men, 14 women). Of the 42 patients, 31 were diagnosed with ankylosing spondylitis (AS) (according to modified New York criteria), 8 with psoriatic arthritis (PsA) (using CASPAR diagnosis criteria) and 3 patients had had reactive arthritis (ReA) (according to ASAS criteria). All subjects enrolled in the study were screened for the presence of the antigen HLA-B27. Sacroiliitis was highlighted through pelvis X-ray centered on the SI joints. All patients diagnosed with AS presented radiological sacroiliitis, only 5 cases in the group of PsA and 1 patient diagnosed with ReA. To investigate the presence of intestinal inflammation, a colonoscopy with biopsy was performed to all subjects included in the study. Among patients with AS, 5 of them had inflammatory changes suggestive of Crohn's disease (CD) and 2 for ulcerative colitis (UC). Subclinical intestinal inflammation was evidenced in 15 cases: 12 of SA group and 3 of PsA group. We also highlighted 7 cases of irritable bowel syndrome: 1 patient with PsA and 6 patients with SA.
Results: After the statistical analysis of the collected data, the following statistically significant correlations were found ($p<0.05$): radiological sacroiliitis correlated with AS and PsA; the antigen HLA-B27 is in close relation with all 3 forms of spondylarthritis; subclinical intestinal inflammation was positively correlated with AS and PsA. No associations were found between the presence of intestinal inflammation and sacroiliitis.
Conclusions: This study points the link between intestinal and joint inflammation, primarily due to a common pathogenic mechanisms. A careful monitoring and a close collaboration between gastroenterologists and rheumatologists contributes to an optimal management of these patients.

AB1020 MULTIFREQUENCY BIOIMPEDANCE COMBINED WITH ACOUSTIC MYOGRAPHY – A NON-INVASIVE PAIN-FREE ASSESSMENT OF MUSCLE USE

E.M. Bartels, J. Kvistgaard Olsen, H. Bliddal, L.E. Kristensen, B. Danneskiold-Samsøe. *The Parker Institute, Department of Rheumatology, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Frederiksberg, Denmark*

Background: Musculoskeletal diseases may involve muscle function, which often deteriorates due to a combination of pain and lack of exercise. Possible correction of this by training, or at least achievement of optimal efficiency of involved muscles with therapy, taking age and affecting disease into account, is an area which needs easily applicable and non-invasive pain-free assessment methods capable of monitoring daily living tasks outside a strict laboratory setting. Multi-frequency bioimpedance (mfBIA), assessing muscle health prior to exercise, in combination with Acoustic Myography (AMG), which allows real-time tests while e.g. walking or bicycling, may be such a method.
Objectives: To validate AMG combined with mfBIA for muscle-use assessment during a series of daily activity movements and exercise with the aim of introducing the method in the clinic.
Methods: 10 healthy subjects aged 25–68 years were assessed with mfBIA (Impedimed, Brisbane, Australia) prior to and following exercise of m. gastrocnemius during walking, stair climbing and descending, and cycling with increasing load. AMG was recorded with a CURO unit (MyoDynamik ApS, Frederiksberg, Denmark), and data handling was carried out with the software belonging to the devices. The mfBIA parameters considered were resistance (R), internal (Ri) and external (Re) resistance and centre frequency (fc), and the AMG parameters were Efficiency (E) – synchronization of motoric units, Temporal summation (T) – how frequently do you use a particular muscle fibre, and Spatial summation (S) – how many fibres in use at a given time, all given as Median; Min,Max.
Results: The mfBIA data, showing the health state of the muscle, showed changes in R, Ri, Re and fc as expected for a healthy muscle as an effect of exercise. The AMG data showed good reproducibility with repeated measurements. Walking on flat ground was less synchronized (E 2; 1,4) as were walking up (E 4; 1,6) and down stairs (E 3; 1,6), than cycling (E 8.5; 5,9). With increasing load during cycling, E decreased with the higher demand to E 5.5 range 1–7. The T-score was similar around 7 for all types of walking, while overall decreasing with increasing load during cycling from 6.5 to 5.5. The S-score was low during the three types of walk, indicating use of many fibres (S around 3), which is in line with the low E-score. For cycling the S-score decreased slightly with increasing load, from 8 to 7.5.
Conclusions: The combined method of mf-BIA and AMG shows good reproducibility. This method has the potential to assess training possibilities in patients with musculoskeletal diseases by testing directly on muscles during the movements of daily function. The method is applicable in real life settings outside the laboratory.

AB1021 VIDEOCAPILLAROSCOPIC FINDINGS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS WITH OR WITHOUT JACCOUD'S ARTHROPATHY

C. Lins[1], E.P.D. Fonseca[2], D.L.D.S. Ribeiro[2], W.G.D. Santos[2], G. Rosa[2], V. Machicado[2], A.L. Pedreira[2], A.P.M.D. Souza[2], C. Baleeiro[2], L.G.D.S. Ferreira[2], I.S.D. Oliveira[3], J.P.C.G.D. Silva[3], A.M. Atta[3], M.B. Santiago[2]. *[1]EBMSP - Escola Bahiana de Medicina e Saude Publica; [2]EBMSP - Escola Bahiana de Medicina e Saude Publica; [3]HUPES - Hospital Universitario Edgard Santos, Salvador, Bahia, Brazil*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease that can present, as other collagen vascular disorders, changes in blood vessels. It can be evaluated by a non-invasive technique called periungual nailfold videocapillaroscopy (VCP). This technique is helpful in the diagnosis of systemic sclerosis (SSc), being part of the new classification criteria, and identifies individuals with Raynaud's phenomenon who are at a higher risk for developing SSc.
Objectives: This study aims to describe the videocapillaroscopic profile of a series of SLE patients and investigate if the VCP pattern is different among those with Jaccoud's arthropathy (JA) compared to the patients without this complication.
Methods: The patients were submitted to VCP, clinical evaluation, and laboratory tests. The capillaroscopic patterns were defined as minor, major and scleroderma (SD). The presence of capillaroscopic findings such as elongated capillaries, increased tortuosity, ectasia, prominent venous plexus, neoangiogenesis, hemorrhage and megacapillaries was also observed.
Results: In a population of 113 female patients with SLE (67 without JA and 46 with JA), at least one alteration was observed in VCP in 89.40% of patients, and the "nonspecific changes" were the most prevalent. Minor changes were seen in 39 (58.2%) and 26 (56.5%) patients, and major changes were seen in 21 (31.3%) and 11 (23.9%) patients without and with JA, respectively. The SD patterns were observed in 02 (3.0%) and 03 (6.5%) patients without and with JA, respectively ($p>0.05$).
Conclusions: The majority of patients of SLE present changes in the VCP exam, but such a tool does not allow distinguish those with or without JA.

AB1022 THE RECALL SURVEY: THE RELATIONSHIP BETWEEN ULTRASOUND SYNOVITIS AND BONE EROSION IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Filippucci[1], C. Bonali[2], P. Macchioni[3], A. Iagnocco[4], A. Delle Sedie[5], S. Tropea[6], O. Epis[7], M. Canzoni[8]. *[1]Clinica Reumatologica, Università Politecnica delle Marche, Ancona; [2]Rheumatology Unit, Ospedale San Paolo, Bari; [3]Rheumatology Unit, Reggio Emilia Hospital, Reggio Emilia; [4]Academic Rheumatology Unit, Università degli Studi di Torino, Torino; [5]Rheumatology Unit, Università di Pisa, Pisa; [6]ASP7, Busacca Hospital, Ragusa; [7]Rheumatology Unit, Ospedale Niguarda Milano, Milano; [8]Local Health Unit (ASL) Rome-1, Rome, Italy*

Background: Ultrasound (US) has shown to be a sensitive imaging tool for the detection of subclinical signs of synovitis in patients (pts) with rheumatoid arthritis (RA); further studies are still required to delineate the impact of US findings in the management of RA pts in daily clinical practice.
Objectives: To investigate the relationship between US findings indicative of joint inflammation and US bone erosions at joint level in pts with RA.
Methods: In 2015 an educational event focused on the added value of US in RA pts was held in 22 rheumatology centers in Italy. In every center, the local rheumatologists provided RA pts to be examined by US. Pts signed an informed consent and a brief history of them was collected by the local rheumatologists (previous and current therapy, DAS28, HAQ score). Bilateral US examinations of wrists, metacarpophalangeal (MCP) and metatarsophalangeal (MTP) joints were performed by rheumatologists expert in US, to assess synovitis (joint effusion, synovial proliferation, and power Doppler (PD) signal), and bone erosions, using a Logiq E R7, General Electrics, with a 4.2–13 MHz linear probe. All US findings were scored using a 4 degree semiquantitative scoring system.
Results: In 465 RA pts, a total of 10.230 joints were scanned. Of these joints, 3.969 (39%) showed joint effusion and/or synovial proliferation and 1.784 (17%) were found positive for PD signal. The most frequently involved joints were the wrists followed by the second MCP joints and first MTP joints. In 749 joints US detected at least one bone erosion. The most frequently eroded joints were the wrists, the second and fifth MCP joints and the first and fifth MTP joints. A total of 226 RA pts showed at least one bone erosions and in 181 (80%) of these pts the eroded joints were found positive for PD signal.
Conclusions: A high prevalence of PD signal was found in the joints found eroded by US. This is the first study providing such an evidence using a portable US equipment.

AB1023 QUANTIFERON®-TB GOLD IN-TUBE ASSAY CAN BE USED FOR LATENT TUBERCULOSIS SCREENING BEFORE BIOLOGICAL DRUG TREATMENT IN A BCG VACCINATED COUNTRY: HUR-BIO SINGLE CENTER REAL LIFE RESULTS

E. Şeyhoğlu[1], O.A. Uyaroğlu[1], A. Erden[2], L. Kılıç[2], B. Armağan[2], A. Sarı[2], M. Baykal[2], S. Ak[2], Ö. Karadağ[2], A. Akdoğan[2], S. Apraş Bilgen[2], S. Kiraz[2], I. Ertenli[2], U. Kalyoncu[2]. *[1]Department of Internal Medicine; [2]Division of Rheumatology, Department of Internal Medicine, Hacettepe University School of Medicine, Ankara, Turkey*

Background: Patients treated with biologic agents have increased risk of

developing active tuberculosis (TB). It is essential to screen patients for latent TB before starting a biologic drug. Population is vaccinated with BCG in Turkey and BCG vaccination decreases the specifity of tuberculin skin test. QuantiFERON-TB Gold In-Tube Assay (QFT) is an another good option to screen latent TB.
Objectives: The objective of this study was to assess reliability of QFT test for latent TB before biological treatment.
Methods: Hacettepe University Rheumatology Biologic Registry (HUR-BIO) is a single center biological registry since 2005. Between Nov 2011 and July 2015, 1347 patients were assessed by QFT for latent TB. All consecutive patients were evaluated by a standard questionnaire between July 2015 and October 2016. This questionnaire included demographic characteristics, medical and treatment history, symptoms of active TB. 671 patients were assessed by the physicians. TB status of other 676 patients were checked from Turkish national tuberculosis registery records. It's an obligatory disposition for physicians to inform health ministery about TB cases and all TB patients must be recorded in those regitry. The mean TB incidance per year was calculated for every anti-TNF agents and non-TNF biological agents.
Results: Total 1347 (58.1% female) patients were recruited to study. Mean age was 42±12 years. Diagnosis were followed; RA 436 (32.4%), SpA 844 (62.5%), others 67 (5.1%). Total biological drug exposure was 2329 patient-years; adalimumab (660 years), etanercept (630 years), infliximab (426 years), golimumab (283 years), certolizumab (78 years), and total anti-TNF duration (2071 years). Non-TNFi exposure was 258 patient-years. Positive and indeterminate QFT results were found in 267 (19.8%) and 20 (1.5%) patients, respectively and those patients were prescribed INH prophylaxis. In addition, INH was prescribed to 37 (2.7%) patients according to chest X-Ray and physician decision. Pulmonary TB found in 3 of 1347 (0.22%) patients. TB was developed 38, 28 and 21 months after TNFi. The mean TB incidance per year was 128.8/100.000 for all biological drugs. The mean TB incidance per year according to QFT positive and negative patients were 181.8/100.000 vs 112.4/100.000.
Conclusions: According to QFT screening for latent TB, INH was started almost 20% of patients. However, if we used TST for latent TB test in BCG vaccinated countries, INH would started almost 70–80% of patients. Therefore QFT was a good tool for latent TB screening in BCG vaccinated countries. Consequently, QFT test seems acceptable to determinate latent TB during biological drug usage. In addition, TB incidance has increased almost 7 times of our national TB incidance.

AB1024 ULTRASOUND IN GIANT CELL ARTERITIS: CUT-OFF AND PITFALLS IN THE HALO SIGN

E. De Miguel[1], L.M. Beltran[2], I. Monjo[1], F. Deodati[2], W.A. Schmidt[3], J. García-Puig[2]. *[1]Rheumatology; [2]Internal Medicine, Hospital Universitario la Paz, Madrid, Spain; [3]Rheumatology, Immanuel Krankenhaus, Berlin, Germany*

Background: At the age of presentation of Giant Cell Arteritis (GCA) atherosclerosis is common. The ultrasonographic (US) appearance of athermanous plaque is usually easily differentiated from the hypoechoic halo of GCA. However, the US appearance of the increased of the intima-media-thickness (IMT) in an atherosclerotic carotid artery may have similar image appearance as the halo sign. We hypothesize that atherosclerosis could produce an increase of temporal artery (TA) IMT and cause false-positives halo sign.
Objectives: The aim of this study was to explore the better cut-off in the IMT of TA to minimise the number of false-positive GCA diagnosis caused by atherosclerosis.
Methods: Consecutive non selected patients, ≥50 years-old with high vascular risk according to European Guidelines on cardiovascular disease prevention, and without signs or symptoms of GCA, were included.
Ultrasonography of carotid artery: Carotid US examinations were performed on a Mylab Seven (Esaote Medical Systems, Italy) with a 4–13 MHz linear-array. The system employed dedicated software radiofrequency-tracking technology to obtain IMT (QIMT®).
Ultrasonography of temporal superficial artery: A color Doppler ultrasound (CDU) and grey scale measure of the IMT/halo sign in both TA and its branches was performed by a second experienced sonographer. A Mylab Twice equipment (Esaote, Geneve, Italy) was used, with a 22 MHz frequency for grey scale and a 12.5 MHz for CDU (color gain of 51, PRF of 2 kHz). The sonographer was blind to the clinical and carotid ultrasound IMT data.
Results: Forty patients were studied, 28 men (70%), with a mean age of 70,6±6,9 years. Three patients were active smokers and 27 ex-smokers. Arterial hypertension was present in 39 (97.5%), dyslipidaemia in 34 (85%) and diabetes in 19 (47.5%). The mean erythrocyte sedimentation rate was 13.6±11.0. The table shows that an IMT >0.30 mm (halo sign) was seen in at least 1 TA branch of 18 patients (45%) with 33 TA branches affected (20.6%). An IMT cut-off >0.34 mm, was present in 4 patients (10%). When at least two affected branches with this measure were required to make the US diagnosis (criteria recommended to improve specificity) only one patient (2.5%) produced a false-positive halo sign.
Conclusions: To the best of our knowledge, this is the first communication indicating that atherosclerosis is a potential cause of false-positive halo sign. We propose a cut-off of AT IMT >0.34 mm in at least two branches to minimise the number of false positives in GCA diagnosis.

AB1025 THE SUPERB MICROVASCULAR IMAGING IS MORE SENSITIVE THAN CONVENTIONAL POWER DOPPLER IMAGING IN DETECTION OF ACTIVE SYNOVITIS IN RHEUMATOID ARTHRITIS PATIENTS

G.Y. Lee[1], S. Kim[1], S.T. Choi[2], J.-S. Song[2]. *[1]Radiology; [2]Internal Medicine, CHUng-Ang University College of Medicine, Seoul, Korea, Republic Of*

Background: Precise evaluation of synovial inflammation and bony deformity is very important for the management of rheumatoid arthritis (RA). One of the most popular used methods to detect synovial inflammation and bony erosion is ultrasonography. Previous literatures revealed that US using power Doppler imaging (PDI) could detect more sensitive synovial inflammation than conventional radiography. However, there are still some limitations in ultrasonography. The superb microvascular imaging (SMI) is a new software technology introduced by Toshiba, which can detect a vascularity more sensitively without artifacts.
Objectives: In this prospective study, we evaluated the clinical usefulness of the SMI compared to PDI for the detection of active synovitis in patients with RA.
Methods: This prospective observational study includes 56 patients with RA (42 females; mean age,), from June 2015 to October 2016. The mean age of RA patients was 53.2±17.6 years, and 42 patients were female (75.0%). All the included patients underwent ultrasound about both wrists and hands (total 22 joints; wrist joints, metacarpophalangeal joints, and proximal interphalangeal joints). All the ultrasound examinations were performed at the volar side of the wrists and hands using both conventional PDI and SMI which use Aplio TM 500 Ultrasound (Toshiba Medical Systems Corporation). Their results were scored for each joint from grade 0 to grade 3 according to the vascularity (grade 0, no vascularity; grade 1, single vessel; grade 2, vascular flow less than 50% in field of view; grade 3, equal to 50% or more). The sum of grades for 22 joints was compared between PDI (PDI-sum) and SMI (SMI-sum). The correlation between the sum of grades values and inflammatory laboratory parameters including the erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and disease activity score 28 (DAS28) were also evaluated.
Results: The mean values of ESR, CRP and DAS28 were 27.13±18.06 mm/hr, 6.78±9.14 mg/L, and 2.71±1.11 respectively. The positive rates of rheumatoid factor and anti-cyclic citrullinated antibody were 73.2% and 75.0%, respectively. The sum of grades for 22 joints was significantly higher in SMI-sum compared to PDI-sum (10.27±6.20 vs. 5.80±3.79, $p<0.001$). The SMI-sum was highly correlated with the PDI-sum score ($\gamma=0.800$, $p<0.001$). The SMI-sum showed positive correlation with DAS28, tender joint count, swollen joint count, visual analogue pain scale, and CRP level ($\gamma=0.486$, $p<0.001$; $\gamma=0.385$, $p=0.003$; $\gamma=0.467$, $p<0.001$; $\gamma=0.547$,$p<0.001$; $\gamma=0.351$, $p=0.008$, respectively). The number of clinical remission (DAS28 score below 2.6) was 28 (50.0%). The SMI-sum was significantly higher than PDI-sum in patients with clinical remission (7.96±5.39 vs. 4.64±3.03, $p<0.001$). All of the patients with clinical remission showed active synovitis at more than one joint in SMI.
Conclusions: SMI showed a more sensitive vascularity in RA patients than PDI. We could detect active synovitis through SMI in the RA patients with clinical remission. SMI could be a useful technology for the evaluation of synovitis in RA patients, especially for the detection of clinically subtle, but active synovitis in RA patients with remission.

AB1026 AN ANA SCREENING ASSAY (ELIA® CTD SCREEN) CONTAINING MULTIPLE ANTIGENS INCREASES THE SENSITIVITY AND SPECIFICITY OF ANA TESTING BY INDIRECT IMMUNOFLUORESCENCE

G. Steiner[1], T. Perkmann[2], T. Horn[3], H.P. Kiener[1]. [1]*Internal Medicine III-Rheumatology;* [2]*Laboratory Medicine, Medical University Vienna;* [3]*Phadia Austria GmbH, Thermo Fisher Scientific, Vienna, Austria*

Background: Antinuclear antibodies (ANA) are the serological hallmark of connective tissue diseases (CTD) and indirect immunofluorescence (IIF) on Hep-2 cells is still considered the gold standard for ANA screening. While this method is sensitive it lacks specificity. Moreover, low-titer ANA subspecificities may escape detection by IIF.
Objectives: To investigate the usefulness of an ANA screening assay containing most of the diagnostically relevant antigens for CTD diagnostics.
Methods: Sera from 265 consecutive patients presenting with symptoms characteristic of connective tissue diseases (but without a clear diagnosis yet) were analysed by IIF and the EliA® CTD Screen (Thermo Fisher Scientific) containing the following antigens: dsDNA, U1-snRNP, Sm, Ro60, Ro52, La, Rib-P, topoisomerase I (Scl-70), centromere B, RNA polymerase III, fibrillarin, Jo-1, Mi-2, Pm/Scl. All positive sera were further analyzed by monospecific assays (Thermo Fisher Scientific).
Results: Among the 265 patients, 90 were positive by IIF and 78 by CTD Screen; 61 sera were positive in both systems, 17 only in the CTD Screen and 29 only in IIF. In all double positive patients at least one diagnostically relevant antibody was detected, with anti-Ro and anti-dsDNA antibodies being most frequently detected. Importantly, antibodies were also detected in 15 of the 17 patients who were exclusively positive in the CTD Screen: 7 patients had anti-dsDNA, 4 anti-Ro, 1 anti-La, 2 anti-U1snRNP, and 1 patient had anti-Jo-1 antibodies. In contrast, among the 29 sera exclusively positive by IIF only two contained a diagnostically relevant antibody. Clinical evaluation revealed that 16 out of the 17 CTD Screen pos/IIF negative patients presented with at least 1 clinical sign commonly associated with systemic rheumatic disease (sicca syndrome, 12 patients; arthritis/arthralgias, 13 patients; microangiopathy, 2 patients; myositis, 2 patients; leukocytopenia, 2 patients; Raynaud's phenomenon, 5 patients; pericarditis, 1 patient; thromboembolic events, 2 patients). These patients may be at higher risk for developing a CTD, or, alternatively, may be at an early stage of a CTD in which a definite diagnosis is not yet to be made. The combination of distinct autoantibodies with clinical signs of systemic rheumatic disease, however, warrants a careful follow up in these patients.
Conclusions: ANA screening assays containing multiple antigens such as the EliA® CTD Screen seem to be helpful diagnostic tools that should be used in addition to IIF for detection of disease-associated autoantibodies enabling the physician to substantially improve diagnostics of connective tissue diseases.

AB1027 THE UTILITY OF LIP BIOPSY IN PATIENTS DIAGNOSED OF IPAF (INTERSTITIAL PNEUMONIA WITH AUTOIMMUNE FEATURES)

H.S. Park[1], P. Millan[2], D. Castillo[2], M. Millan[1], P. Moya[1], B. Magallares[1], A. Laiz[1], C. Diaz[1], J.M. De Llobet[1], I. Castellvi[1]. [1]*Rheumatology;* [2]*Pneumology, Hospital Universitari de la Santa Creu i Sant Pau, Barcelona, Spain*

Background: The European Respiratory Society/American Thoracic Society Task Force has defined a classification criteria for interstitial pneumonia with features of autoimmunity that does not accord to a specific systemic disease. This criteria combines clinical, serological and radiological domains. The clinical criteria does not include dry syndrome eventhough the serological criteria does include antiRo and antiLa antibodies. It is known that some patients with dry syndrome with antibodies negativity undertake lip biopsy to confirm Sjögren Syndrome (SS). Therefore lip biopsy could be useful to IPAF if SS is suspected.
Objectives: Determine the utility of lip biopsy in patients with interstitial pneumonia that present symptoms suggestive of an autoimmune disease.
Methods: Retrospective study of patients attended between june of 2010 and june of 2016 in a tertiary referral hospital was done. We included 23 Pneumology patients diagnosed of IPAF that were referred to Rheumatology clinic to rule out underlying connective disease. All patients had a complete immunologic study, two pulmonary function test including diffusion capacity of CO and a lip biopsy to confirm SS. The results of the lip biopsy was analysed with different variables.
Epidemiologic data, blood test, pulmonary function test and pattern of ILD by high definition CT or lung biopsy were analysed. Changes in therapeutic decisions and pulmonary function test a year after the lip biopsy were also registered. To compare qualitative variables we used Chi Square test or Fisher exact test when necessary. The statistical significance was set up to p-value inferior to 0.05.
Results: 16 of 23 patients with ILD met classification criteria of IPAF (69.6%). 12 were women (52.2%) with a median age of 77 (from 54 to 87 years). The findings of our group is summarised in table 1.
9 lip biopsies confirmed SS (39.1%) and 7 changed treatment according to result (30.4%). No variables such as sex, smoking, previous lung disease, dry syndrome or Schirmer test showed relation with lip biopsy result. Previous treatment with corticosteroids did not seem to influence the results of lip biopsy eventhough it was not statistically significant (p-value 0.059). No relation with antinuclear antibody or acute phase reactants was observed either. Lip biopsy was most useful to diagnose SS for those with Usual Interstitial Pattern ($p<0.02$) among other patterns of ILD.

Variable	Number (percentage %)
Sex	Women 12 (52.2), Men 11 (47.8%)
Exposition to toxic	3 (13%)
Dry syndrome	19 (82.6%)
Altered Schirmer test	11 (55%)
Antinuclear antibody (>1/160)	12 (52.2%)
Anti La/Ro52/Ro60	0 (0)
Rheumatoid Factor	6 (26.1%)
Previous corticosteroid therapy	7 (30.4%)
Diagnostic lip biopsy	9 (39.1%)
IPAF criteria	16 (69.6%)
ILD pattern	UIP 4 (17.4%), NSIP 13 (56.5%), LIP 1 (4.3%)

Conclusions: Lip biopsy is a complementary examination to consider for IPAF. In our group the results were significant for UIP. Corticosteroid therapy did not seem influential to the results of lip biopsy eventhough it was not statistically significant. In 39.1% SS was diagnosed and in 30.4% treatment was changed according to results.

AB1028 PREVALENCE AND DISTRIBUTION OF SESAMOID BONES IN THE HAND DETERMINED USING DIGITAL TOMOSYNTHESIS

H.H. Kwon[1], B.S. Koo[2], Y. Song[3], Y.-K. Sung[1], S. Lee[3], J.-B. Jun[1]. [1]*Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases;* [2]*Department of Internal Medicine, Inje University Seoul Paik Hospital, Inje University College of Medicine;* [3]*Department of Radiology, Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Republic Of*

Background: Sesamoid bones are round or oval-shaped bones that are embedded in tendons. The prevalence and distribution of sesamoids in the hand varies between different populations. Conventional radiography (CR) is generally used to identify the sesamoid bones. However, there was no study using digital tomosynthesis (DTS).
Objectives: The aim of this study was to identify the prevalence and distribution of sesamoid bones in the hand using DTS in comparison to previous studies.
Methods: Using CR and DTS, hand images (81 left and 100 right) taken at a tertiary hospital were retrospectively reviewed. The sesamoid bones were identified in the distal interphalangeal (DIP), interphalangeal (IP), and metacarpophalangeal (MCP) of the thumb (I), index (II), long (III), ring (IV), and small (V) fingers. Differences in number of sesamoid bones detected on CR and DTS were analyzed.
Results: Sesamoid bones were observed in MCP I (100%), MCP II (46%), MCP III (2%), MCP IV (2%), MCP V (53%), and IP (53%) on CR. Using DTS, sesamoid bones were found more often in MCP I (100%), MCP II (54%), MCP III (2%), MCP IV (1%), MCP V (59%), and IP (75%). Differences in the mean number of sesamoid bones detected on CR and DTS were statistically significant. Sesamoid bones in DIP joints were frequently observed on DTS, but rarely found on CR.
Conclusions: Most sesamoid bones in the hand were detected in MCP I, II, V, and IP joints, and were more often detected on DTS than CR. DTS is a reliable tool to evaluate bony structures in the hand.

AB1029 ULTRASOUND NAIL ASSESSMENT IN PSORIATIC ARTHRITIS AND PSORIASIS COMPARED WITH HEALTHY CONTROLS

I. Janta[1], O. Baniandres Rodriguez[2], L. Valor[1], J. Martinez Barrio[1], J.G. Ovalles[1], J.C. Nieto Gonzalez[1], C. Gonzalez[1], J. Lopez Longo[1], I. Monteagudo[1], E. Naredo[1,3]. [1]*Rheumatologist;* [2]*Dermatology, Hospital General Universitario Gregorio Marañón;* [3]*Rheumatology, Joint and Bone Research Unit, Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain*

Background: Assessment of nail involvement is currently made by clinical assessment using nail psoriasis severity index (NAPSI). Whilst clinical assessment can detect superficial nail changes, the matrix and the extensor tendon region are not accessible for clinical assessment.
Musculoskeletal (MS) ultrasound (US) is playing an important role in the evaluation of psoriatic arthritis (PsA) patients. Recently, MSUS has been more used in the evaluation of nail involvement in psoriasis (Pso) and PsA patients.
Objectives: The primary objective of this observational, cross-sectional study was to assess the MSUS morphological and vascular abnormalities in nail in PsA and Pso patients compared with healthy controls. The secondary objective was to compare MSUS and clinical assessment of the nail in PsA and Pso patients.
Methods: We included patients with PsA (diagnosed according to CASPAR criteria) and patients with Pso without joint involvement (diagnosed by an experienced dermatologist according to clinical findings) and healthy controls.

Clinical evaluation consisted in the evaluation of the NAPSI and PASI scores. The MSUS evaluation consisted in the evaluation of 10 hand nails. In B-mode (BM) we evaluated the followings: thickness of the nail bed from the distal phalanx bone surface to the ventral plate (PB) according to Worstman X et al.; thickness of the nail from dorsal to ventral plate (IP); dorsal and ventral plate morphology, echogenicity and integrity. Additionally, we performed a color Doppler (CD) evaluation for the presence of CD signal at the nail bed and matrix level. A score for BM and different scores for CD were calculated for each nail and sums of all nails for BM and CD scores were calculated for each patient.

Results: We evaluated 60 patients with PsA, 23 with Pso and 20 controls. 52.4% were female. The mean age (SD; range) was 50.2 (13.6; 23–83). The age was higher in patients (Pso and PsA) than in controls ($p<0.001$). Patients with PsA were more treated with DMARD (81.7%) while patients with Pso were more treated with topics (73.9%) than DMARDs (13%), ($p<0.001$). The majority of the patients (96%) had a PASI score less than 12. The NAPSI was higher in Pso patients than in PsA patients ($p<0.001$); for all controls the NAPSI was 0.

US measurements of IP and PB were significantly higher in patients than in controls in the majority of the nail ($p<0.045$). Total US score for BM was significantly higher in patients than in controls ($p<0.001$). There were no significant differences for the majority of CD scores between patients and controls.

Overall we found weak to moderate positive correlations between NAPSI and US scores for BM, both for matrix and bed. For most of the nails we found no correlation between NAPSI and CDUS scores; for the rest of the nails the correlation was weak, both positive and negative.

References:

[1] The MSUS measurements and scores showed to be higher in patients with PsA and Pso compared with controls, while CD scores showed no differences.

AB1030 IDENTIFICATION OF VERTEBRAL FRACTURES IN FRACTURE LIASION SERVICES ACROSS THE UNITED KINGDOM

J. Sayer, S. Stephenson. *Service Development, National Osteoporosis Society, Bath, United Kingdom*

Background: Fracture Liaison Services (FLS) can prevent secondary fracture through systematic identification of low trauma fractures using dedicated case finding, with assessment and treatment of osteoporosis where necessary. Services are now being measured for quality against *Clinical Standards for Fracture Liaison Services* published by the National Osteoporosis Society in 2015.[1] The first standard asserts that all patients over 50 years with a newly reported vertebral fracture will be systematically and proactively identified.

Objectives: To evaluate provision for systematic identification of newly reported vertebral fractures in patients aged over 50 at Fracture Liaison Services (FLS) across the UK.

Methods: A gap analysis tool was used to measure service provision against standard one of the *Clinical Standards for Fracture Liaison Services*, relating to the systematic and proactive identification of vertebral fractures. Data was collected at 78 sites in the UK.

Results: 63% (49) of sites had *no* systematic process in place to identify vertebral fractures. Only 10% (8) sites identified *all* newly reported vertebral fractures. 27% (21) had procedures in place to identify *some* vertebral fractures, i.e. those within certain cohorts. There was considerable disparity across the UK. Sites in Scotland were significantly more likely to have comprehensive processes in place (38%, 6/16) than in the rest of the UK (3%, 2/62).

Conclusions: Systematic identification of vertebral fractures poses a particular challenge to services due to a number of factors. Vertebral fractures are difficult to identify as they tend not to present or be admitted in acute settings where FLS are primarily based. In addition, services require support from Radiology, including a commitment to avoid ambiguous terminology when reporting vertebral fractures. Furthermore, as a category, vertebral fractures fall between departments (Rheumatology, Orthopaedic, Fracture Clinic, A&E, Spinal services) making systematic identification even more challenging. In the Fracture Liaison Service Database Facilities Audit (May 2016), the most frequently cited barrier to the identification of vertebral fractures was lack of a patient pathway.[2] Gap analysis shows a paucity of provision in the identification of vertebral fractures. This is the key driver for work underway in the NOS to develop a patient pathway for vertebral fractures, in conjunction with clinical experts, to promote best practice and best patient care.

AB1031 ANTI-DRUG ANTIBODIES: ASSAY PERFORMANCE IN PATIENTS TREATED WITH ANTI-TNF BIODRUGS

B. Hock[1], J.L. O'donnell[2], J. Liu[2], P. Keating[2], M. Spellerberg[2], L. Stamp[3], M. Barclay[3]. *[1]Haematolgy Research Group, University of Otago; [2]Immunology Section, Canterbury Health Labs; [3]Medicine, University of Otago, Christchurch, New Zealand*

Background: Minimum biodrug concentrations of ~7mg/l are predictive of disease remission[1]. Very low/absent biodrug concentrations associate with loss of benefit which may be due to ADA[2] however the clinical utility of ADA is assay dependant. In rheumatoid arthritis the combination of low/absent drug concentration and the presence of ADA appears to have the greatest utility[3]. Canterbury Health Laboratories, New Zealand (CHL) has developed a competitive binding ELISA to detect neutralising antibodies whereas most commercial assays utilise a bridging methodology

Objectives: Compare performance of a competitive binding assay with two commercial bridging assays in the detection of ADA to anti-TNFα biodrugs in serum samples with low/absent biodrug concentration

Methods: Serum samples referred for anti TNF biodrug concentrations found to have very low/undetectable concentrations (<1mg/l) were tested for ADA using the competitive-bind assay and two bridging assays (TANI Medikal and GRIFOLS)

Results: Over a 22 month period (Jan 2014 – Oct 2016), 67% (331/497) of referred samples had biodrug concentrations below 7mg/l and 15% (n=79) had low/undetectable biodrug concentrations (adalimumab n=36 or infliximab n=43). ADAs were detected in 53% (42/79) of this latter group. The competitive binding assay detected ADAs in all samples testing positive for ADA by binding assay. In addition a further 8 samples were positive for ADA by the competitive assay: 53% (42/79) positive for ADA by the competitive assay and 33% positive by one or other of the commercial assays

Conclusions: The competitive binding ELISA was more sensitive in detecting biodrug ADAs in serum samples with very low/undetectable biodrug concentrations

AB1032 COMPARISON OF DIFFERENT TECHNIQUES FOR DETECTING ANTI-DFS70 ANTIBODIES

J.M. López-Ortega[1], Á. Sánchez-Herrero[1], N. Estañ-Capell[1], D. Ybáñez-García[2], E. Valls-Pascual[2], C. Vergara-Dangond[2], M. Aguilar-Zamora[2], L. Montolio-Chiva[2], À. Martínez-Ferrer[2], J.J. Alegre-Sancho[2]. *[1]Laboratory; [2]Rheumatology, Hospital Universitario Doctor Peset, Valencia, Spain*

Background: Antinuclear antibodies (ANA) positivity with a dense fine speckled (DFS) pattern by indirect immunofluorescence (IIF), as per the definition of the International Consensus on ANA Patterns (ICAP), is not uncommon and is linked to the presence of anti-DFS70 antibodies. These antibodies, in the absence of others, are very valuable as biomarkers of exclusion of a systemic autoimmune disease (SAD).

Objectives: To evaluate anti-DFS70 antibody detection by two different laboratory techniques and its relation with different IIF patterns, including DFS pattern.

Methods: During three months, the serum of patients with positive ANA was consecutively collected. Three groups of patients were established according to their IIF pattern: a first group (D) with a DFS pattern as per ICAP; a second group (M) with other speckled with positive mitosis patterns; and a third group (C), as a control, with well defined homgeneous and speckled patterns.

In order to perform a preliminary analysis, 10 serum samples were randomly selected from each group. In each serum sample, an ANA screening by IIF on Hep-2000 cells (Fluorescent IgG ANA-Ro Test System – Immunoconcepts) using an AP-16 Elite/Zenit-Up/GSight system from Menarini, and an anti-DFS70 antibodies detection by two different laboratory techniques (IIF on Hep-2 cells [Hep-2/DFS70 Knock-out - Immco Diagnostics] and inmunoblot [ANA+DFS70 Dot Blot – Alphadia]) were performed. Simultaneously, antibodies against extractable nuclear antigens (ENA), nucleosomes (NUS) and histones (HIS) were tested.

Results: In group D, positivity for anti-DFS70 antibodies was confirmed in 7/10 cases, all of them being negative for other ANA. In group M, 2/10 serum samples were positive for anti-DFS70 and 2/10 were positive for anti- NUS antibodies, none of them being positive for anti-ENA. In group C, no sample was positive for anti-DFS70 antibodies, while all of them showed positivity for antibodies against ENA, NUS and HIS.

The detection of anti-DFS70 was found to be equal by the two methods in 8 of the 9 positive cases, being both negative in the others. In no case the presence of anti-DFS70 was associated with a diagnosis of SAD.

Conclusions: Both IIF and immunoblot are suitable methods for detecting anti-DFS70 antibodies. We propose to determine anti-DFS70 and to perform an ENA screening in case of finding a DFS pattern of ANA by IIF, and to investigate anti-DFS70 in other speckled patterns with positive mitosis if no other specificities have been previously found.

AB1033 THE EXPRESSION OF IMMUNOGLOBULIN G AND IMMUNOGLOBULIN G4 IN LYMPHOMA

J. Li[1], Z. Zhang[2]. *[1]Rheumatology department, Shanxi Dayi Hospital, Shanxi; [2]Rheumatology department, Peking University First Hospital, Beijing, China*

Background: Although IgG4-related disease has been gradually recognized, its relationship with malignant diseases, especially lymphoma has been an eternal topic.
Objectives: To explore the expression of IgG4 positive cells in lymphoma.
Methods: Surgical excision specimens with definite diagnosis of lymphoma from January to December, 2013 were collected. Hematoxylin-eosin staining and immunohistochemical staining of IgG and IgG4 were then evaluated on dense lymphoplasmacytic infiltration, storiform fibrosis and obliterative phlebitis. For the quantification of IgG and IgG4 positive cells, the areas with the highest density of positive cells were evaluated. Three high-powered fields (hpf) in each section were analyzed, and the average number of positive cells per hpf was calculated.
Results: 16 patients with lymphoma were selected in our study. There were 9 males and 7 females with an average age of 51 years old. The pathologic type included 13 cases of non-Hodgkin lymphoma and 3 cases of Hodgkin lymphoma. Sub types of Non-Hodgkin lymphoma contained 8 cases of diffuse large B cell lymphoma, 2 cases of small B cell lymphoma, 1 case of mucosa accociated lymphoid tissue marginal zone B cell lymphoma (MALToma), follicular lymphoma, peripheral T-cell lymphoma and hepatosplenic T-cell lymphoma. The 16 specimens all manifested as dense lymphocytic infiltration, accompanied by atypical lymphocytes. Proliferation of fibrous tissue was only seen in one specimen. 14 cases were IgG positive with the highest cell count from 20–350/hpf. IgG can be expressed in both cytoplasm and cytomembrane. 2 cases of IgG4 positive were Hodgkin lymphoma and the highest cell counts were 11 and 12/hpf respectively.
Conclusions: IgG4 positive cell, fibrosis and obliterative phlebitis seldom appear in lymphoma. Added specific tumor signature molecules, it may not be difficult to distinguish lymphoma from IgG4-related disease.

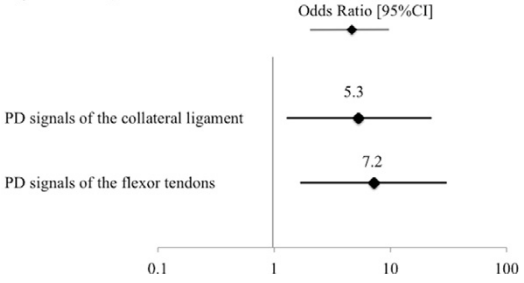
AB1034 SCORING SYSTEMS OF MUSCLE MRI IN IDIOPATHIC INFLAMMATORY MYOPATHIES

K. Kubinova, H. Mann, J. Vencovsky. *Institute of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic*



Background: MRI is a widely used radiological method for assessing muscle involvement in idiopathic inflammatory myopathies (IIM). There is still no universally accepted and validated scoring protocol for the quantification of pathological changes in muscles.
Objectives: To identify MRI scoring systems used in previous studies. To summarize the most frequently evaluated MRI features and to suggest parameters for a unified scoring system, that has to be validated in the future.
Methods: A detailed literature search was conducted in the standard medical databases. Information regarding individual MRI scoring systems were obtained from the methodological explanations and their parameters were compared.
Results: We identified different scoring systems with a large variability of assessed localizations and parameters (Table 1). Muscle oedema as a sign of active muscle inflammation was evaluated in all studies. There were some studies using modified Mercuri score for evaluation of the fatty infiltration as a marker of chronic muscle damage or the Goutallier grading (1, 2), developed originally for the assessment of inherited neuromuscular disorders or structural changes in orthopedics. Perifascicular oedema or soft-tissue oedema were also assessed in some cases. There was no concordance between evaluated muscle groups.
Conclusions: MRI plays a significant role in the evaluation of pathological changes in IIM. This search demonstrated, that there is no widely used, standardized method for assessment of a MRI finding. According to our results, a future concept of MRI scoring system should include evaluation of muscle oedema, fatty infiltration and possibly also the presence of perifascicular (-fascial) and subcutaneous tissue inflammation. Muscle groups most convenient for evaluation have to be determined as well.

AB1035 EXAMINATION OF ULTRASOUND FINDINGS IN UNDIFFERENTIATED SPONDYLOARTHRITIS PATIENTS WITH DACTYLITIS

K. Fujikawa[1], Y. Endo[1], A. Mizokami[1], M. Mine[2], A. Kawakami[3]. *[1]Rheumatology, Japan Community Healthcare Organization, Isahaya General Hospital; [2]Rheumatology, Suga Orthopedic Hospital, Isahaya; [3]Immunology and Rheumatology, Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan*

Objectives: To evaluate the ultrasound findings in undifferentiated spondyloarthritis (uSpA) patients with or without dactylitis.
Methods: Between April 2014 and December 2016, sixty-six patients with uSpA diagnosed at our center were consecutively enrolled. The diagnosis of uSpA was made by the Japan College of Rheumatology (JCR)-certified rheumatologists and dactylitis was defined as sausage-digit appearance. Ultrasound, clinical and laboratory findings at diagnosis in patients with dactylitis (dactylitis group; n=30) were compared to those without dactylitis (non-dactylitis group; n=36). Grey scale (GS) and power Doppler (PD) signals of the wrist and finger joints, PD signal of extensor and flexor tendon sheaths, and PD signals of the collateral ligament of the fingers in both hands were assessed by ultrasound. Ultrasound assessment was made by JCR-registered sonographers.
Results: There were no significant differences in clinical and laboratory findings, including inflammatory back pain, arthritis of the lower limbs, tenderness of the entheses, radiographic/MRI changes of sacroiliac joint and HLA-B27 allele frequency, between two groups. In ultrasound findings, the dactylitis group had significantly more PD signals of the flexor tendon sheaths (83% vs. 22%, $p<0.0001$), the collateral ligament (83% vs. 25%, $p<0.0001$), and the MCP joint (30% vs. 3%, $p<0.01$) as compared with the non-dactylitis group. In logistic

Figure 1. Logistic regression analysis of ultrasound findings for the contribution of diagnosis of dactylitis

Abstract AB1034 – Table 1. Muscle MRI scoring systems

Author	Muscle oedema	Fatty infiltration	Sequences	Muscle groups	Other aspects
Pipitone 2016	1 = present, 0 = absent	–	STIR	17 bilat.	–
Andersson 2015	1 = present, 0 = absent	0 - 4 Goutallier gr.	T1W, STIR	thigh, NS	–
Malattia 2014	0 = no abnormalities, 1 = mild-moderate <50%, 2 = high degree >50%	–	STIR	42 (whole body MRI)	perifascicular + subcutaneous tissue inflammation
Zheng 2014	0–5 scale from normal to moderate intrafascicular global oedema	0–5 modif. Mercuri score	T1W, STIR	12, thigh muscles bilat.	–
Davis 2011	0 = absent, 1 = mild, 2 = moderate, 3 = severe	–	STIR	4, thigh bilat.	soft-tissue + perifascicular oedema
Studynkova 2007	VAS 0–10	–	STIR	thigh muscles, NS	muscle oedema extent + total MRI affection

STIR = short-tau inversion recovery, NS = not specified, T1W = T1 weighted sequences, VAS = visual analogue scale.

regression analysis, the PD signals of the flexor tendons and collateral ligament were independent contributors to a diagnosis of dactylitis (Figure 1).
Conclusions: Development of active inflammation of enthesis organ determined by ultrasound is supposed to associate importantly with the judgment as dactylitis in patients with uSpA.

AB1036 PREDICTIVE VALUE OF BASAL REACTANTS IN AN EARLY ARTHRITIS CLINIC. DOES ESR ELEVATION CRITERIA MAKE A DIFFERENCE?

L. Mayordomo[1], M.L. Velloso[1], P. González-Moreno[2], C. Gómez-Cano[1], A. Gutiérrez-Leonard[3], J.L. Marenco[1]. *[1]Rheumatology Department, Hospital Universitario Valme; [2]Rheumatology Department, HVM; [3]Physioterapy, HVR, Sevilla, Spain*

Background: The presence of high acute phase reactants may help the diagnosis and classification of patients with rheumatoid arthritis, specially in seronegative patients.
Objectives: Our objective was to establish if the presence of high basal reactants in early arthritis may help to establish the diagnosis of rheumatoid arthritis following criteria of ACR 1987 (which does not include positive reactants in diagnostic criteria). at 12 months of follow-up.
Methods: The presence of acute phase reactants at the baseline visit (elevated CRP and elevated ESR according to two different criteria) was studied in a population of 70 patients referred to the arthritis clinic with criteria for suspicion of early arthritis to meet at least one of the Following criteria: a) Swelling in 2 or more joints b) Pain in MCFs, MTFs and/or wrists c) Morning stiffness greater than 30 minutes (* SERAP study criteria), with <12 months of evolution of symptoms. None of the patients had previous diagnosis of rheumatoid arthritis or other inflammatory joint disease nor had previous treatment with steroids or DMARDs. The presence of high VSG (mm/h) was considered according to two criteria: a) ESR 1: VSG>20 or b) ESR 2 (criterion according to age and sex) (1): Age ≥50 years ESR>20 in men and ESR>30 in women; Age <50 years of age, ESR>15 mm/h in men and>20 in women.Statistics: Chi-square or Fisher test (for any value <5), Odds ratio (OR) calculation.
Results: 70 patientes, 45 women (64,3%), x age 51,57±16,08 y (18–85) were included, x disease duration 3,47 meses ± 2,59 (0,53–11.73), 48/70 (68,5%) RF and ACPA negative. 49 patients meet ACR 1987 criteria, but 5 were finally classified in non-RA group because they meet criteria of other inflammatory chronic articular conditions (eg. psoriatic arthritis RA-like). 45/70 patients had high baseline CRP (64.3%), ESR 1 38/70 (54.3%) and ESR 2 35/70 (50%). Basal CRP>5 showed statistically significant differences for RA diagnosis (ACR 1987 criteria) p=0.003, OR =4,64 (1.62–13,24) but basal positive ESR 1 criteria did not (p=0.122). Basal positive ESR2 showed significant differences for diagnosis of RA, with p=0.036, OR =2,78 (0,99–7,47). In the subgroup of seronegative patients, basal CRP could predict ACR 1987 RA diagnosis at 12 months follow-up p=0,019, OR 4,2 (1,23–14,36), but ESR (both ESR1 and ESR2) not (p=1,000). If the 5 patients ACR 1987 meeting criteria RA-like but diagnosed ot other inflammatory conditions were included, the results are similar but ESR2 reached a better confidence interval p=0.036, OR 3,63 (1,20–10,94).

RA ACR 1987 CRITERIA 44 PT		RA YES	P univariate	OR	IC 95 %
CRP	YES	34/45 (75,5%)	0,003	4,64	(1,62-13,24)
	NO	10/25 (40%)			
ESR1	YES	30/38 (78,9%)	0,122 NS	-	-
	NO	19/32 (59,4%)			
ESR2	YES	26/35 (74,3%)	0,048	2,78	(0,99-7,47)
	NO	18/35 (51,4%)			
CRP	YES	18/28 (64,3%)	0,019	4,2	(1,23-14,36)
seronegative	NO	6/20(30%)			

ACR 1987 CRITERIA (AR+AR-LIKE) 49 PT		RA YES	P univariate	OR	IC 95 %
CRP	YES	37/45 (82,2%)	0,006	5,01	(1,67-14,98)
	NO	12/25 (48%)			
ESR1	YES	30/38 (78,9%)	0,116 NS	-	-
	NO	19/32 (59,4%)			
ESR2	YES	29/35 (82,8%)	0,036	3,63	(1,20-10,94)
	NO	20/35 (57,1%)			

Conclusions: The presence of elevated basal CRP>5 may be used as a factor that helps to predict the diagnosis of rheumatoid arthritis according to ACR 1987 criteria for RA. The baseline elevated ESR according to the sex and age criterion could be useful as a predictor factor for the diagnosis of rheumatoid arthritis, while the VSG criterion>20 in all patients does not demonstrate differences in the study between the two groups with final diagnosis AR and non-RA. In seronegative patientes, only CRP demostrated predictive value but ESR not.

AB1037 INTEROBSERVER RELIABILITY OF KNEE OSTEOARTHRITIS LESIONS USING MUSCULOSKELETAL ULTRASOUND: DIFFERENCES BETWEEN STATIC VERSUS REAL TIME READING

M.J. Audisio[1], A.M. Bertoli[2], G.E. Py[1]. *[1]Reumatología, DHEG; [2]Reumatología, Instituto Strusberg, CORDOBA, Argentina*

Background: Musculoskeletal ultrasound (MSU) is an imaging technique proved to be valid in several musculoskeletal conditions. In osteoarthritis (OA) it allows the identification of inflammation and structural damage. However, MSU is an operator dependent method and its widespread use has been hampered by questions related to the reliability of both, image acquisition and image interpretation.
Objectives: The objective of this study was 1) to evaluate the interobserver reliability of knee OA according to the definitions used by the OMERACT reliability exercise of inflammatory and structural abnormalities in patients with knee osteoarthritis using ultrasound and 2) to compare the interobserver reliability on previous collected images (static reading, thereafter) versus after the acquisition and interpretation of images in real time (real time reading, thereafter).
Methods: A reliability exercise based on the reading of US images was conducted by two experienced rheumatologists in MSU. A set of 59 images of both, normal and OA knee lesions were collected for the static reading. A set of 20 knees were scanned by each rheumatologist for the real time reading. Dichotomous and semi-quantitative scoring (0–3) was performed for the presence of damage on the condrosynovial margin, osteochondral margin and matrix of the throchlear cartilage, osteophytes at the lateral and medial femoral condyle and proximal tibia, medial and lateral meniscal extrusion and Baker's cyst. Interobserver reliability was calculated by the Cohen's kappa coefficient.
Results: Interobserver reliability scores for the static reading were good for cartilage damage, meniscal extrusion and Baker's cyst, while they were excellent for the presence of osteophytes. The scores for the real time reading were poor to moderate for cartilage damage, osteophytes and Baker's cyst and good for meniscal extrusion. These results are shown in Table 1.

Table 1. Interobserver κ values for agreement of the static and real time reading of US abnormalities in knee osteoarthritis

Lesion	Static reading κ (SE)	Real time reading κ (SE)
Condrosynovial margin	0,588 (0,180)	0,588 (0,180)
Cartilage matrix	0,732 (0,118)	0,317 (0,143)
Osteochondral margin	0,658 (0,148)	0,251 (0,163)
Medial condyle osteophyte	0,538 (0,176)	0,412 (0,213)
Lateral condyle osteophyte	0,792 (0,194)	0,385 (0,228)
Medial tibial osteophyte	0,865 (0,129)	0,490 (0,96)
Lateral tibial osteophyte	0,744 (0,236)	0,432 (0,213)
Medial meniscal extrusion	0,673 (0,204)	0,704 (0,159)
Lateral meniscal extrusion	0,633 (0,234)	0,573 (0,185)
Baker's cyst	0,714 (0,256)	0,490 (0,960)

Conclusions: This exercise shows that the interobserver reliability of MSU for the detection of knee OA lesions is widely different depending on the type of reading (static versus real time). Although MSU seems to be reliable for the detection of knee OA lesions, caution needs to be taken in the interpretation of published data regarding the type of reading exercise performed.

AB1038 INFLUENCE OF AGE ON ENTHESIS IN TUNISIAN PEOPLE: AN ULTRASOUND STUDY

K. Ben Abdelghani[1], M. Chammakhi[1], A. Fazaa[1], S. Rejaibi[2], S. Kassab[1], S. Chekili[1], A. Laatar[1]. *[1]Rheumatology, Hopital Mongi Slim; [2]Epidemiology, Faculty of Medicine of Tunis, Tunis, Tunisia*

Background: By aging, many changes occur in the different components of the locomotor system, leading to a pathological situation such as osteoarthritis or remaining totally asymptomatic.
Objectives: The aim of the current study was to compare,via ultrasound, the entheseal changes in two groups of people having different ages by calculating a modified Madrid sonography enthesitis index.
Methods: The study was conducted in the rheumatology department of Mongi Slim hospital in Tunisia, between June 2015 and December 2016, including 17 healthy subjects. We indentified two groups: (G1) 9 persons aged >50 years [51–68] and (G2) 8 persons aged ≤50 years-old [37–50].
All the included persons underwent an enthesis ultrasound exploration (Esaote-MyLab 60 machine and a 13–18 MHz linear array transducer) by a rheumatogist

experimented in ultrasound. Five enthesis locations bilaterally (distal Achilles tendon, distal andproximal patellar ligaments, distal quadriceps, and brachial triceps tendons) in each person were explored.The following elemental lesions of enthesis were evaluated: thickness, presence of calcifications, erosions,enthesophyte, loss of fibrillar patternand power Doppler signal.
The calculated index was compared by Mann-Whitney U test between cases and controls. The significance level was set at 5%.
Results: In our study population, the median age was 51.8±2.3 years and the median body mass index was 30±1 kg/m^2. This last was similar between the two groups. All included subjects were female.
The total enthesitis index was higher in G1 (6.67±0.91)than G2 (3.50±0.73) with a statistically significant difference (p=0.01).
Considering each evaluated enthesis, the distal patellar ligament score was significantly higher in the G1 (1.67±0.55 vs 0.25±0.16 with p=0.03). For the other enthesis, there was no significantly difference between the 2 groups.
Conclusions: The distal patellar ligament enthesis changes shown in older persons may be the traduction of a silent-stage of knee osteoarthritis.

AB1039 RELATIONSHIPS BETWEEN SONOGRAPHIC AND ELECTROPHYSIOLOGICAL MEASURES IN PATIENTS WITH IDIOPATHIC CARPAL TUNNEL SYNDROME WAITING FOR SURGERY

M. Valls Roc[1], E. Junyent Vilanova[2], A. Grau Martin[3], O. Codina Guinó[1], M. Sala Gomez[1]. *[1]Rheumatology; [2]Traumatology; [3]Internal Medicine, HOSPITAL of FIGUERES, Girona, Spain*

Background: Sonography is a diagnostic tool with great development in diagnosing entrapment neuropathy. It's an easy, painless, fast, non-invasive technique and can explore how the nerve's morphology and pathologies are associated. An electroneurogram is used to assess the intensity of nerve involvement.
Objectives: To determine the relationship between the intensity of nerve involvement by electroneurogram and the measurement of the cross-sectional area (CSA) of the median nerve by sonography in patients with idiopathic carpal tunnel syndrome (CTS) waiting for surgery.
Methods: 56 wrists of 39 consecutive patients waiting for surgery were tested, however 5 were excluded because were found to have anatomic variants (4 bifid nerves, 2 median arteries) and 1 fybrolipoma. Therefore, the final sample was 51 wrists of 37 consecutive patients (11 male and 26 females), with a mean age of 59.2 years (26–85), all with electrophysiologically confirmed idiopathic CTS. Patients were classified by their electrophysiologic grade. The median nerve cross-sectional area at proximal and distal carpal tunnel was measured using high frequency ultrasound.
Relationships between CSA, the severity of the electrophysiologic grade and the duration of symptoms were analysed. Also, a median nerve morphological characteristics examination (hipoecogenicity, loss of fascicular structure, Power Doppler signal and anatomical variants) was undertaken.
A comparison between CSA and the severity of the electrophysiologic grade was made using an independent T test and the connection between CSA and the duration of symptoms was calculated using ANOVA test.
Results: Patients were classified by their electrophysiologic severity grade (8 mild, 13 moderate, 29 severe and 1 very severe). The mean ultrasound area of distal medial nerve was 8.7 mm^2 in mild-moderate and 9.2 mm^2 in severe-very severe cases (p=0.52). The average of proximal CSA was 11.6 mm^2 in mild-moderate and 14.1 mm^2 in severe-very severe cases with statistical signification differences (p=0.026). Relationship between CSA and symptom's duration wasn't identified. In 89.2% of the cases, hipoecogenicity and the loss of fascicular structure were observed but no cases were found to show positive Power Doppler signal.
Conclusions: The most valid and relevant parameter regarding the electroneurogram in the diagnosis of CTS is CSA at proximal carpal tunnel by sonography. A cross-sectional area measuring more than 9–10 mm^2 has been suggested to be pathologic and our study confirms these results. While the electroneurogram is the gold-standard method in the diagnosis of nerve involvement severity, a sonography could improve the diagnostic sensibility and give information about nerve's morphology and associated pathologies.

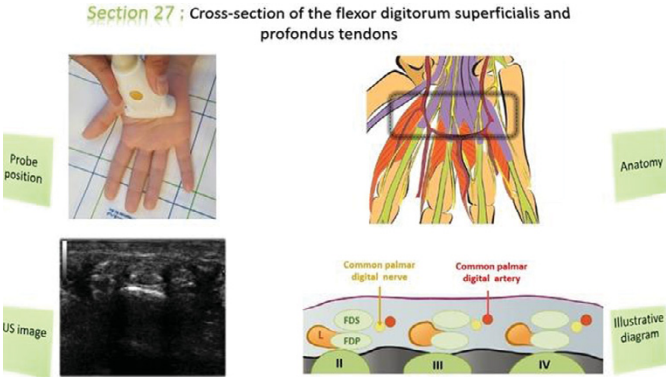
AB1040 CLINICAL UTILITY OF BONE SCINTIGRAPHY FOR INFLAMMATORY ARTHRITIS



M. Jiang, K. Le Marshall, K. Lim. *Department of Rheumatology, Western Health, Footscray, Australia*

Background: Bone scintigraphy is often used in the workup of patients with rheumatological disease, in particular for the investigation of inflammatory arthritis. It also has a role in the investigation of malignancy and fractures. As an imaging technique, it is very sensitive but not specific for inflammation. The most common technique used is triple phase scintigraphy, with the 2nd phase (blood pool phase) being the most useful for identifying inflammation.
Objectives: To evaluate the clinical utility of bone scintigraphy in the workup of patients with rheumatological disease, in particular for inflammatory arthritis.
Methods: This was a retrospective study of patients seen in the rheumatology outpatients between January 2011 and July 2014, who had bone scintigraphy as part of their workup. Their clinical record was reviewed to obtain pre- and post-test clinical diagnoses, bone scintigraphy reports and investigations (ESR/CRP, rheumatoid factor/CCP antibodies). For patients who had followup at one year we recorded their clinical diagnosis at this time.
Results: A total of 226 patients had bone scintigraphy, with a median age of 54 years. 63% were female.
The main indication for bone scintigraphy was to assess for inflammation in 194 patients. For this group, the most common pre-test diagnosis of inflammatory arthritis (41%), followed by degenerative arthritis (36%), unclear diagnosis (20%) and mixed inflammatory and degenerative arthritis (3%).
Overall, 49% (n=95) of patients had their diagnosis changed after bone scintigraphy.
The pre-test diagnosis was compared to bone scintigraphy findings with the highest confirmatory rate for degenerative arthritis (67%), followed by inflammatory arthritis (49%) and mixed arthritis (40%).
Bone scintigraphy findings were also compared to post test diagnosis with the highest confirmatory rate for degenerative arthritis (91%), followed by inflammatory arthritis (70%) and mixed arthritis (14%).
There was no significant association between patient factors (age, gender, ESR/CRP, RF/CCP) and having confirmatory or conflicting bone scintigraphy findings.
The post test diagnosis was compared to the diagnosis at one year, with the diagnosis being unchanged in 84% for inflammatory arthritis and 45% for degenerative arthritis.
Conclusions: This study showed that bone scintigraphy lead to a change in diagnosis in a large proportion of patients and was better at confirming degenerative arthritis or ruling out inflammatory arthritis.

AB1041 ULTRASONOGRAPHY OF NORMAL MUSCULOSKELETAL STRUCTURES IN 100 SECTIONS: A BOOKLET AND A CD-ROM

M.A. Mahdi, H. Rkain, M. Erraoui, S. Aktaou, L. Tahiri, R. Bahiri, F. Allali, N. Hajjaj-Hassouni. *Rheumatology, Faculty of Medicine and Pharmacy, University Mohamed V, Rabat, Morocco*

Objectives: To present a booklet and a CD-ROM with a mini-atlas including 100 sections illustrating the normal ultrasound musculoskeletal anatomy.
Methods: We performed an ultrasound examination of large and small joints of the medical staff not suffering from any musculoskeletal disorder. Ultrasound examination was performed using a high-frequency linear probe (Toshiba Xario®, frequency (8–14 MHz)) in B mode. Finally, for the sake of clarity of the presentation of this library, we presented each image accompanied with another showing the valid positioning of the probe and an annotated schema for each section made.
Results: We present in the form of CD-ROM and booklet a photo library of a mini-atlas.

The joints studied are:
- The wrist and hand
- The elbow
- The shoulder
- The ankle and foot
- The knee
- and the hip

100 sections were performed, we presented them together with images showing ther normal corresponding musculoskeletal anatomy, the valid positioning of the probe, and also an annotated schema corresponding to each section. We give here below the example of a section illustrating a cross-section of flexor digitorum superficialis and profondus tendons

Conclusions: We hope that we give to rheumatologists a simple tool to recall and standardize the practice of musculoskeletal ultrasound. We intend to enrich it, in the future, with the pathological images and interventional ultrasound videos.

AB1042 DYNAMIC CONTRAST-ENHANCED MAGNETIC RESONANCE IMAGING IN A RANDOMIZED PLACEBO-CONTROLLED RHEUMATOID ARTHRITIS TRIAL – IMPACT OF APPLYING JOINT COVERAGE QUALITY CRITERIA

M.B. Axelsen[1], H. Bliddal[2], L.T.H. Jacobssen[3], M.S. Hansen[4], A. Dudek[5], M. Rell-Bakalarska[6], M. Boesen[7], J. Stefanek[8], B. Sundman-Engberg[9], M. Østergaard[1]. *[1]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Centre of Head and Orthopedics, Rigshospitalet; [2]The Parker Institute, Hospital Frederiksberg-Bispebjerg, Copenhagen, Denmark; [3]Department of Rheumatology and Inflammation Research, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden; [4]Center for Rheumatology and Spine Diseases, Rigshospitalet, Gentofte, Denmark; [5]Centrum Medyczne MEDENS S.C., Wojewodztwo slaskie; [6]Rheumatology, Rheumatology, Poland, Poland; [7]Department of Radiology, The Parker Institute, Hospital Frederiksberg-Bispebjerg, Copenhagen, Denmark; [8]UCB Biosciences GmbH, Monheim, Germany; [9]UCB Pharma AB, Stockholm, Sweden*

Background: Dynamic contrast-enhanced MRI (DCE-MRI) has been proposed for evaluating treatment response in RA. In a 16-week anti-TNF trial, DCE-MRI measures of inflammation analyzed for regions of interest (ROIs) covering MCP joints 2–5 and PIP joints 2–5 detected improvements at week 16, but not at earlier time point[1].

Objectives: To investigate if solely analyzing joints fulfilling predefined MRI quality criteria for joint visualization would increase the responsiveness and discrimination between treatments of DCE-MRI.

Methods: Patients with active RA despite stable DMARD therapy for ≥12 weeks were randomized 2:1 to certolizumab pegol (CZP) or 2 weeks of placebo (PBO) followed by CZP (CZP+PBO). MRIs were obtained at weeks 0 (baseline), 1, 2, 4, 8 and 16. Only joints fulfilling MRI joint quality criteria (≥3MCP/≥2PIP joint slices including the distal and/or the proximal bone of the joint and part of the joint cavity) were included in analyses. ROIs covering each joint were analyzed for number of enhancing voxels (Nvoxel), initial rate of enhancement (IRE) and maximum enhancement (ME) using the DYNAMIKA software (Image Analysis, UK).

Results: For 38 (CZP: 26; PBO+CZP: 12) of the 40 randomized patients, ≥1 joint fulfilled the quality criteria at baseline. 31 MCP2, 28 MCP3, 23 MCP4, 7 MCP5, 29 PIP2, 29 PIP3, 28 PIP4 and 12 PIP5 joints were included. No individual joints showed significant changes over time or differences between groups. Analyses by joint group (MCP2–4 and PIP2–4) had few data available. Nvoxel and ME decreased numerically, but not significantly, for PIP2–4.

Conclusions: There were no statistically significant changes in DCE-MRI on joint level or joint group level or between groups. Applying strict joint coverage quality criteria compromises the statistical power of the DCE-MRI analyses underlining the importance of standardization of the method.

AB1043 RHEUMATOID FACTOR ISOTYPES – STILL AN USEFUL TOOL IN THE DIAGNOSIS OF RHEUMATOID ARTHRITIS?

M. Guerra[1], R. Vieira[1], A.P. Cruz[2], T. Videira[1], P. Pinto[1]. *[1]Department of Rheumatology; [2]Department of Clinical Pathology, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova de Gaia, Portugal*

Background: Rheumatoid factor (RF) and anti-citrullinated peptide antibodies (ACPA) are key serologic markers in the diagnosis of Rheumatoid Arthritis (RA) included in the 2010 ACR/EULAR diagnostic criteria. Determination by enzyme-linked immunosorbent assay (ELISA) allows RF isotypes' quantification (IgG, IgA and IgM), improving diagnostic accuracy [1,2].

Objectives: To assess the clinical value of RF-IgG/IgA/IgM (ELISA) in the diagnosis of RA, in comparison to RF-IgM (nephelometry).

Methods: A population of RA outpatients fulfilling the 2010 ACR/EULAR diagnostic criteria was cross-sectionally evaluated. Data on demographic and clinical characteristics was collected. RF-IgG / IgA / IgM (ELISA, Orgentec®), RF-IgM (nephelometry, Siemens®) and ACPA-IgG (ELiA, ThermoFisher®) were measured. Values three times or more above the upper limit of normal were considered high-positive (in agreement to 2010 ACR/EULAR diagnostic criteria).

Results: A total of 87 patients (70.1% female) were included, with a mean (SD) age of 57.3 (12.29) years. Median time of disease evolution was 6 years, ranging from 0 to 37 years. Erosions were present in 50.6% (N=44). RF-ELISA was positive (at least one isotype increased) in 85.1% (N=74); the most frequent isotype was IgM (70.1%;N=61) and the most frequent combination was IgG, IgA and IgM positivity (46.0%;N=40) (table1). FR-nephelometry and ACPA were positive in 58.6% (N=51) and 47.1% (N=41), respectively.

Comparing the two RF methods, 56.3% (N=49) were both RF-nephelometry and RF-ELISA positive; 28.7% (N=25) were RF-ELISA positive and RF-nephelometry negative, and only 2.3% (N=2) verified the opposite (p=0.001). As for RF high-positivity, 4.6% (N=4) of the 87 patients were only RF-nephelometry high-positive, 9.2% (N=8) only RF-ELISA high-positive and 34.5% (N=30) both high-positive ($p<0.001$).

In the RF-nephelometry negative population (N=36), ACPA and RF-ELISA were both positive in 11.1% (N=4). Only 8.3% (N=3) were solely ACPA positive and 58.3% (N=21) solely RF-ELISA positive, however without statistical significance.

Considering the ACPA negative population (N=46), 32.6% (N=15) were both RF

Table 1. Frequencies of RF-ELISA isotypes' profiles

Profile	n	%

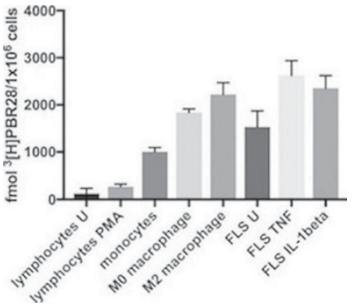
AB1044 EVALUATION OF A FLUOROENZYME IMMUNOASSAY (ELIA-CTD) IN THE SCREENING OF PATIENTS SUSPECTED FOR AUTOIMMUNE CONNECTIVE TISSUE DISEASES

M. Elkhalifa[1], R. Abdulhadi[1], H. Ramadan[1], S. Barrientos[1], S. Saleh[1], O. Alsaed[2], A.-W. Al-Allaf[2]. *[1]Laboratory Medicine and Pathology; [2]Medicine, Hamad Medical Corporation, Doha, Qatar*

Background: Detection of auto-antibodies directed against nuclear antigens (antinuclear antibodies or ANA) have important diagnostic and prognostic implications in connective tissue diseases (CTD). The conventional indirect immunofluorescence assay on HEp-2 cell line (ANA-IIF) is the most commonly used method to detect ANA. The ANA-IIF can be labor intensive and suffers from lack of specificity.
Objectives: To evaluate the utility of a new fluoroenzyme Immunoassay "EliA-CTD" as an alternative for screening patients suspected for autoimmune connective tissue diseases.
Methods: Sixteen Hundread (1600) consecutive patients' sera submitted for anti-nuclear antibodies were tested using the ANA-IIF (Diasorin S.P.A, Saluggia, Italy) and the new EliA-CTD screen (Phadia GmbH, Frieiburg, Germany). ANA testing was ordered by both primary and secondary care physicians. The EliA-CTD screening assay is a fluoroenzyme immunoassay which is performed on the Phadia-250 automated platform. The EliA–CTD assay contains ANA-targeted recombinant antigens including dsDNA, Sm-D, Rib-P, PCNA, U1-RNP (70, A, C), SS-A/Ro, SS-B/La, Centromere B, Scl-70, Fibrillarin, RNA Polymerase III, Jo-1, Mi-2, and PM-scl. The test results are expressed as ratio, with >1.0 considered positive. For ANA-IIF, the cut off for positive results was 1:40 or greater. Additionally, further testing for dsDNA and other extractable nuclear antigens (ENA) was undertaken on a subset of sera that were ANA-IIF+ or whenever there was discrepancy between the two methods.
Results: The overall agreement between the two methods was 84.2%. Three hundread and eight (308) out of 1600 (19.3%) samples tested positive by ANA-IIF positive as compared to 101/1600 (6.6%) for the EliA-CTD assay. Additional testing showed that 105 samples were positive for ENA including dsDNA. Of those, 101 were EliA-CTD positive and 81 were ANA-IIF positive. By incorporating the ENA results, the calculated sensitivity and specificity for the EliA-CTD were 97.1% and 99.7% respectively with positive and negative predictive values for the EliA-CTD assay of 96.1% and 99.8%, respectively. The corresponding sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) for the ANA-IIF assay at different dilutions is shown below:

Titer	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
≥1:40	77.7	84.8	26.0	98.2
≥1:80	60.3	95.3	32.4	98.4
≥1:160	57.4	97.4	41.3	98.4
≥1:320	46.5	98.7	48.8	98.5



Conclusions: The new automated EliA-CTD assay shows superior sensitivity and specificity compared to the conventional labor intensive ANA-IIF. The EliA-CTD can be used as an upfront screening tool for connective tissue diseases. Depending on the clinical details, any EliA-CTD positive results could be reflexly followed by additional testing including ANA-IIF testing to elucidate the titer and pattern.

AB1045 MACROPHAGE TARGETED POSITRON EMISSION TOMOGRAPHY (PET) FOR THE IMAGING OF INFLAMMATORY ARTHRITIS; AN IN VIVO AND IN VITRO INVESTIGATION OF TRANSLOCATOR PROTEIN (TSPO) TRACER UPTAKE

N. Narayan[1], H. Mandhair[1], C. Coello[2], A. Saleem[2], A. Sabokbar[1], P. Taylor[1]. *[1]Nuffield Dept of Orthopaedics, Rheumatology, Musculoskeletal Sciences, University of Oxford, Oxford; [2]Imanova Centre for Imaging Sciences, London, United Kingdom*

Background: TSPO targeted PET tracers are increasingly recognised as cellular imaging markers of macrophage infiltration, due to the high expression of TSPO on activated macrophages. Previous work demonstrated the ability of [^{11}C]PK11195 TSPO PET to detect subclinical inflammation in RA, and predict flare in both those with established RA and ACPA positive arthralgia. However, high background uptake of [^{11}C]PK11195 in bone, and inability of [^{11}C]PK11195 to detect lesions in AS has driven the investigation of newer TSPO tracers for the detection of inflammatory arthritis.
Objectives: Here, we present data confirming the ability of the TSPO tracer [^{11}C]PBR28 to detect and quantify synovitis in both RA and PsA, and in vitro work that assesses more fully what TSPO tracer accumulation in inflamed synovium actually reflects at a cellular level, especially considering TSPO is ubiquitously expressed.
Methods: 10 patients (5 with RA, 5 with PsA) with evidence of inflammation in one or both knees (as confirmed by clinical examination and US) and 4 healthy volunteers underwent PET/CT both knees using the TSPO tracer [^{11}C]PBR28. Arthritis patients underwent synovial biopsy of one knee within 7 days of scan. Healthy synovium was obtained from patients undergoing knee arthroscopy for ligamentous injury. Synovial tissue was stained for CD68, CD163 and TSPO. For in vitro work, human monocytes, lymphocytes and synovial FLS from RA patients were harvested, and macrophages differentiated from monocytes. RNA was extracted for PCR. Other cells underwent density centrifugation to extract the cytoplasmic cell fraction, and a radioligand binding assay with [^{3}H]PBR28 was undertaken, to assess tracer binding to TSPO in each cell type
Results: Tracer uptake correlated significantly with severity of inflammation on clinical examination and ultrasound, as did synovial sublining staining for CD68, TSPO and CD163 (see table 1). There was negligible staining for all stains in healthy control synovium. qPCR demonstrated highest TSPO mRNA in stimulated FLS (fold change 62.75±10.03) and M2 macrophages (60.69±2.38), with lymphocytes having the least TSPO expression. PBR28 saturation binding confirmed these findings at protein level (see graph 1).

Tissue marker	Clinical synovitis severity		
	1 (mild)	2 (moderate)	3 (severe)
TSPO	1.50±0.08	2.19±0.19	3.06±0.12
CD68	2.17±0.3	2.42±0.21	2.96±0.05
CD163	1.61±0.03	2.19±0.1	2.81±0.04

Conclusions: Our data demonstrates that the TSPO tracer PBR28 is capable of detecting and quantifying synovitis in RA and PsA. PBR28 tracer uptake correlates with macrophage marker staining, but not with fibroblast marker staining in our patient cohort. mRNA and protein data demonstrate, however, that there is a similar expression of TSPO in activated macrophages and activated FLS, hence TSPO tracer accumulation is as likely to represent FLS activation as it is macrophage activation.

AB1046 COULD SERUM TWEAK LEVEL BE AN INDICATOR OF SUBCLINICAL ATHEROSCLEROSIS IN RHEUMATOID ARTHRITIS?

M. Ucer[1], N. Yilmaz[2], B. Cengiz Elcioglu[3], T. Sahin[3], P. Gun Atak[4], S. Yavuz[2]. *[1]Internal Medicine; [2]Rheumatology; [3]Cardiology; [4]Biochemistry, Istanbul Bilim University, Istanbul, Turkey*

Background: TWEAK is a type 2 transmembrane glycoprotein of TNF family that has multiple functions such as angiogenesis, regulation of tissue production-

destruction, proinflammatory cytokine release. TWEAK and Fn14 receptor interaction has an important role in pathogenesis of atherosclerosis. Our aim was to evaluate subclinical atherosclerosis and its association with serum sTWEAK, Fn14 and CD163 levels in RA patients.
Methods: One hundred Rheumatoid Arthritis (RA), 50 Spondyloarthritis (SpA) patients and 50 healthy controls (HC) were included in the study. Serum soluble TWEAK, CD163 and Fn14 levels were measured by ELISA tecnique. Subclinical atherosclerosis was evaluated by echocardiography, which includes carotis intima media thickness (cIMT), aortic strain, stiffness and elasticity.
Results: In RA group 73 (73%) patients were using DMARD's and 27 (27%) were biological drugs, the mean DAS28 score was 3.49±1.31. At the end of the study, TWEAK levels were found significantly lower (RA; 942.4±305.9, AS; 1087.2±311.0 and HC; 1061.3±402.8 pg/ml, p=0.05), and Fn14 levels were significantly higher (RA; 509.4±861.4, AS; 163.5±249.0 and HC; 91.5±67.9 pg/ml, $p<0.01$) in RA patients compare to both groups. In addition Fn14 levels were higher in RA patients using biological drugs and seropositive subgroups (1042±1363 vs. 312±451 pg/ml, $p<0.01$ and 674±101 vs. 188±236 pg/ml, respectively, $p<0.01$). Fn14 levels were correlated with disease duration (r=0.38, $p<0.01$). CD163 levels were similar in all groups. Although there was not any difference in cIMT measurements among groups, aortic stiffness was increased (p=0.03), aortic strain and elasticity were decreased (p=0.03, p=0.02) in RA patients compare to healthy controls. Multivariate analysis showed cardiovascular parameters were only associated with age.
Conclusions: In this study we observed impaired aortic parameters showing subclinic atherosclerosis in RA patients. At the same time, decreased levels of serum sTWEAK and elevated levels of serum sFn14, were also shown in RA group. The difference in levels of serum soluble form of these biomarkers may be related to vascular damage in our RA patients who have low disease activity. However, further studies are needed to demonstrate association between atherosclerosis and these biomarkers in RA patients.

AB1047 CAN THE ACR/EULAR 2010 CLASSIFICATION CRITERIA BE USED AS DIAGNOSTIC TOOL FOR RHEUMATOID ARTHRITIS IN REAL LIFE?

N.F.L. Conijn[1], D. Lopes Barreto[1], T.M. Kuijper[1], M. van der Steen[2], J. van der Kooij[3], A.E.A.M. Weel[1], J.M.W. Hazes[4], M.R. KoK[1]. *[1]Rheumatology; [2]Business intelligence; [3]Planning and Control, Maasstad hospital; [4]Rheumatology, Erasmus Medical Center, Rotterdam, Netherlands*

Background: To date, due to the large variability in its clinical manifestations, early identification of rheumatoid arthritis (RA) relies on practice-based evidence. Moreover, this variation hampers the comparability and accurate stratification of the base population within and between RA trials. In 2010 the ACR/EULAR working group developed RA classification criteria that were primarily intended for research purposes. Despite its use in scientific settings, one can speculate on the effectiveness of these criteria when used in the routine clinical practice of diagnosing RA.
Objectives: In this study we aimed to investigate the degree of concordance between the diagnosis of RA in routine clinical practice and the ACR/EULAR 2010 classification criteria.
Methods: All patients who received a diagnosis of RA between 2010–2016 within our hospital were identified according to the financial diagnosis treatment combination (DTC) code, which corresponds to the ICD-10. Clinical and demographic data were extracted from our digital patient records of which 10% of the data were cross-checked by random selection. In retrospect we collected variables at time of RA diagnosis such as: number and type of swollen/painful joints, inflammatory markers, rheumatoid factor (RF), anti-citrullinated protein antibody (ACPA), disease duration and patients primary/secondary/tertiary diagnosis according to the rheumatologist. Additionally, all patients were classified according to the ACR/EULAR 2010 criteria for RA. The degree of concordance was determined by descriptive statistics.
Results: The database included 977 patients with a DTC RA of which 673 (69%) had RA according to the rheumatologist. From the patients who were clinically diagnosed with RA, 463 (69%) fulfilled the ACR/EULAR 2010 criteria (see figure 1), this is 47% of the total DTC RA patients. The majority of the population was female (72%) and the mean age was 59. A number of 161 (24%) patients were diagnosed with RA according to the rheumatologists, but did not fulfil the ACR criteria. These patients had less inflammation, were more often RF and/or ACPA negative, and had less involved joints. About 5% of the data were missing.
Conclusions: It can be concluded that the DTC codes are not the most reliable source of information in terms of the diagnosis. There is a discrepancy between the DTC code, the diagnosis according to the rheumatologist and the classification criteria. The degree of concordance between rheumatologist and the ACR criteria is comparable to the numbers described in literature. Since in our practice aspects of the ACR classification are used for diagnostic purposes, we will investigate factors that drive the specificity. Furthermore, reasons for the ICD-10/ DTC and final diagnostic mismatch is of great importance and will be studied as well. These factors will indicate opportunities on the use of the ACR/EULAR criteria in clinical practice.

DOI: 10.1136/annrheumdis-2017-eular.5790

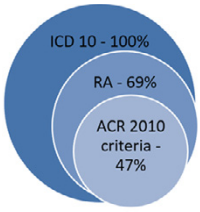

Fig. 1. Degree of concordance between RA identification and diagnosis, and classification criteria. RA refers to the diagnosis RA made by the rheumatologist. As some patients with RA may have been incorrectly classified by ICD 10, the circles are not completely overlapping.

AB1048 ULTRASOUND ASSESSMENT OF CARTILAGE THICKNESS IN PATIENTS WITH HAND OSTEOARTHRITIS

O. Balueva[1], A. Sarapulova[2], O. Teplyakova[2]. *[1]Ultrasound Diagnosis, Medical Association "New hospital"; [2]Urals State Medical University, Yekaterinburg, Russian Federation*

Background: The destruction of cartilage is one of the basic mechanisms of the progression of hand osteoarthritis (HOA). Radiographic study indicates the thickness of the cartilage indirectly based on the degree of joint space narrowing (JSN). At the same time, the ultrasound (US) method allows to measure it directly.
Objectives: To determine the thickness of the cartilage in the interphalangeal joints of patients with HOA and to correlate this rate with the degree of JSN, identified by radiologic imaging.c imaging.
Methods: 45 women at the age of 45 – 75 years were included in the research. All of them were diagnosed of HOA according to the criteria of American College of Rheumatology (ACR). For each patient 8 proximal interphalangeal joints (PIP) were surveyed. The conventional radiographs (CRs) of each hand were performed for all patient in the standard frontal projection and the radiological changes were assessed using Kallman's method. Next, US investigation was carried out. The thickness of the cartilage was measured in the central part of the 2–5 proximal phalanx heads of both hands in the dorsal longitudinal view in the static image in gray- scale with the flexion position no more than 90 degrees. The cartilage is defined as a thin hypoechoic smooth layer, paralleling the contours of the articular surface. The thickness of the cartilage was defined as the distance between the subchondral bone and the surface layer of cartilage, which was the border between the cartilage and the joint cavity. In the presence of synovitis measurement of joint cartilage was carried out before the border and hypertrophic synovial if they differed in the degree of intensity of the US signal. The measurement of cartilage thickness was carried out by a conventional line, which was an exact perpendicular to the surface of the subchondral bone and parallel to the direction of US waves. Measurement was not carried out if visualization of the surface layer of cartilage was not possible. The control group consisted of 45 women 45–75 years old without HOA, but with ultrasound investigation. Data were analyzed using Statistica 10.0 and are presented as mean (standard deviation), "odds ratio" coefficient (OR) and χ 2 Pearson's correlation coefficient.
Results: 360 joints of both hands were investigated with successful measurement of the cartilage thickness of 338 (94.7%) joints. The average value of the cartilage in all PIP was 0.31 (0.11) mm. The maximum thickness of the cartilage was obtained in the 2nd PIP joints - 0.34 (0.12) mm on the right hand and 0.36 (0.14) mm on the left hand. For the control group results were 0.38 (0.11) mm and 0.37 (0.13) mm respectively. We have found a reliable relationship between the degree of JSN and cartilage thickness with the OR 1.849 (95% confidence interval 1.198 – 2.855), $\chi 2 = 7.772$, p=0.0053.
Conclusions: US reduction of the cartilage thickness is a marker of cartilage loss which is correlated with the results of radiologic examination. This makes possible to use ultrasound as an alternative method of diagnosing HOA.

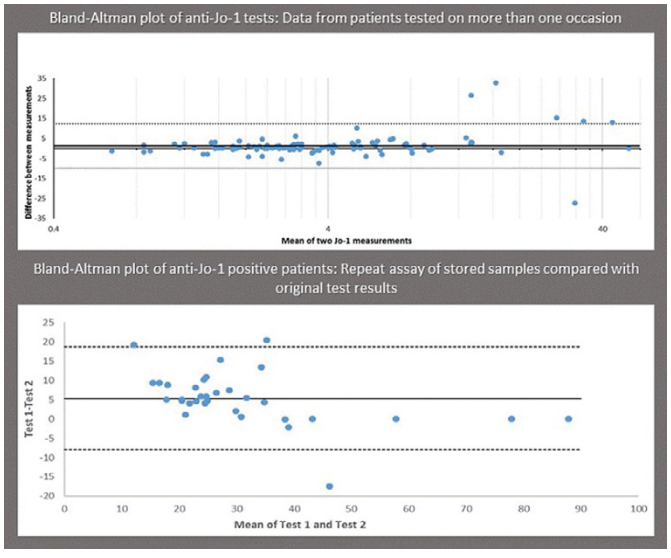
AB1049 CLINICAL UTILITY OF AUTOANTIBODIES AGAINST EXTRACTABLE NUCLEAR ANTIGENS IN ROUTINE CARE: FREQUENCY OF REPEATED TEST REQUESTS AND DIAGNOSTIC VALUE OF ANTI-JO-1 (ANTI-HISTIDYL-TRNA SYNTHETASE)

P. Jobanputra[1], F. Malik[2], E. Derrett-Smith[1], T. Plant[3], A. Richter[4]. *[1]Department of Rheumatology, Queen Elizabeth Hospital Birmingham, Birmingham; [2]Department of Rheumatology, Epsom & St. Helier University Hospitals NHS Trust, Carshalton; [3]Department of Immunology, University of Birmingham; [4]Department of Immunology, Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom*



Background: High-throughput high-sensitivity ELISAs for autoantibodies associated with CTD, such as extractable nuclear antigens (ENA), are used widely. Anti-Jo-1 (anti-histidyl-tRNA synthetase), one of this panel, is believed to confer a poor prognosis due to an association with interstitial lung disease (ILD) and myositis.

Objectives: To describe: the pattern of anti-ENA positive tests; frequency of repeated requests; stability and repeatability of anti-Jo-1 tests; clinical characteristics of anti-Jo-1 +ves compared with controls; and diagnostic value of anti-Jo-1 for ILD.
Methods: All anti-ENA test requests, from any hospital department, between Jan 2013 and Dec 2014 were identified. Serum samples are screened for ENA (Quanta Lite® ENA profile, Inova Diagnostics) and positive samples have specific ENA antibodies levels quantified. Data from anti-Jo-1 positive patients and controls was extracted from electronic records allowing a minimum of 12 months after first test.
Results:

	Jo-1 Positive (n=40)	Controls (n=80)	P value*
Age, mean years (range)	53 (19–86)	52 (17–87)	–
Sex (% female)	70%	79%	0.37
Dead	13%	4%	0.12
Current or previous malignancy	10%	10%	1.0
Raynauds	17.5%	6.3%	0.10
Inflammatory arthritis	20%	19%	1.0
Clinical myositis diagnosis	5%	1.3%	0.26
CPK >1000 units/liter	5%	1.3%	0.26
Interstitial lung disease	12.5%	6%	0.30
CT chest done during study period	17/40	20/80	0.06
ANA (≥1:100)	18/38 (47.4%)	22/79 (27.8%)	0.06
RF	8/25 (32%)	12/44 (27.3%)	0.78
CCP	0/19 (0%)	3/33 (9.1%)	0.54
Anti-dsDNA (Crithidia +ve)	7.5%	1.3%	0.11
Scl70	7.5%	0%	**
SSA/Ro	10%	0%	**
SSB/La	10%	0%	**
RNP	10%	0%	**

*Fisher's exact test, two tailed. **Statistical analyses were not done on these comparisons as by definition controls were negative for ENA antibodies.

4009 samples from 3581 patients were tested. The first sample tested, chronologically, was designated test of interest. 616 (17.2%) patients were anti-ENA screen +ve, and 40 (1.1%) anti-Jo-1 +ve (>20 AU/mL). Anti-ENA tests were done more than once for 350/3581 (9.8%) patients (428/4009 (10.7%) samples) and for 7/40 (17.5%) of anti-Jo-1 +ve patients. The median interval between 1st and 2nd requests: 124 days (IQR 233 days). The Table shows data for anti-Jo-1 patients and randomly selected ENA -ve controls. The frequency of ILD, myositis and Raynaud's was comparable. Sensitivity and specificity of Jo-1 for ILD, a key feature of "anti-synthetase syndrome", were 50% (CI 19–81%) and 68% (CI 59–77%) respectively. Positive predictive value 12.5% (CI 4 to 27%) and negative predictive value 93.8% (CI 86–98%). Of patients with the highest anti-Jo1 titres (≥40 AU/mL, 10/40 patients, 25%): 3 had ILD, 1 myositis and 2 had a malignancy (disseminated melanoma and CML). Bland-Altman plots show that anti-Jo-1 values remained stable when patients were re-tested at another time but re-testing available stored samples from +ve patients showed important variation (Figure).

Conclusions: Anti-Jo-1 is uncommon in a heterogenous hospital population and is only weakly predictive for ILD. When tested repeatedly levels remain stable over many months. Repeated testing for anti-ENA is common and potentially unnecessary. Controls over repeated requests could yield cost savings.

AB1050 COMPARATIVE STUDY BETWEEN ULTRASONOGRAPHIC ASSESSMENT AND CLINICAL EXAMINATION IN RHEUMATOID ARTHRITIS WITH OPTIMIZED BIOLOGICAL THERAPY AND NON BIOLOGICAL TREATMENT

R. Martínez[1], M. Fernández[1], E. Rubio[1], R. Menor Almagro[1], B. Hernández[2], J. Povedano[2]. *[1]Rheumatology, Hospital Universitario Virgen del Rocío; [2]Rheumatology, Hospital Universitario Virgen Macarena, Sevilla, Spain*

Background: In rheumatoid arthritis (RA), patients in low activity disease or clinical remission measured by disease activity indexs can present subclinical activity by ultrasound study. The ultrasonographic inflammation in examination of joints is an important predictive value of structural damage.
Objectives: The aim of our study was to describe subclinical ultrasonographics activity in patients with RA in low disease activity or clinical remission, with optimized biological therapy and non biological treatment.
Methods: Transversal and longitudinal study describing the ultrasonographic changes in gray scale and doppler in parallel with blind clinical evaluation. We included patients with RA according to ACR/EULAR classification criteria in low activity disease or remission measured by DAS28, under optimized biological therapy at least for 6 months and non biological treatment. They were sent by their usual clinician, making a random selection. They were evaluated in the same day by a rheumatologist and blind sonographer. VAS, VGP, VGM, HAQ, tender joints count, swollen joint count, CDAI, SDAI and DAS28 were evaluated. Regarding the ultrasound, were evaluated synovitis and doppler in 12 joints (wrists, second to fifth MCF and fifth bilateral MTF). The comparison between clinical examination and ultrasonography test was performed by the kappa index, with satisfactory value of >0,6.
Results: A total of 69 patients were included, 35 with optimized biological therapy and 34 non biological treatment. The median optimization time was 12 months. The baseline characteristics only offered stadistical significance in swollen joint count and average time of disease (table 1).
The concordance study between clinical joint exploration and ultrasonographic examination showed a higher kappa index in patients with optimized biological therapy: 0,52 in gray scale and 0,40 in doppler. In patients without biological therapy showed an index kappa =0.17 by the gray scale test, and kappa index =0.26 by doppler.

Table 1

Variable characteristics	Non biological treatment	Optimized biological therapy	p
Age: average ± DE (years)	53,8±10	54±11,7	0,834
Women (%)	73,5	65,7	0,498
Time of diseases progression: median (p25-p75) (months)	55 (34–116)	120 (84–139)	0,003
Rheumatoid factor + (%)	71,3	81,80%	0,544
Anti CCP + (%)	71,4	81,7	0,512
Metotrexate dose: average ± DE	9,0±1,3	8,1±1,4	0,658
Corticoids dose: average ± DE	1,7±0,4	1,5±0,4	0,856
HAQ: average ± DE	1,0±0,2	1,3±0,2	0,309
Tender joint count: median (p25-p75)	0 (0–1,5)	1 (0–2)	0,200
Swollen joint count: median (p25-p75)	0 (0–1)	1 (0–2)	0,013
CDAI: average ± DE	7,7±5,1	6,8±5	0,437
SDAI: average ± DE	10,0±5,6	10,0±6,5	0,588

Conclusions: Our results show the existing discrepancy between the clinical examination and ultrasonographic test in patients in low disease activity/remission by DAS28, even more with the use of doppler. In the comparison of both groups we observed an increase in the difference in those who did not receive biological therapy. In patients with optimized biological teraphy, with higher swollen joint count in physical examination, kappa index was near of normality in grayscale. The detection of subclinical joint damage is often undertreated, showing ultrasound as a noninvasive technique of great help reducing joint damage.

AB1051 ULTRASONOGRAPHY AND POWER DOPPLER ULTRASONOGRAPHY OF KNEE JOINT IN PATIENTS WITH HEPATITIS C VIRUS RELATED ARTHRITIS

R. Elgohary[1], A. Khalil[2], G. Ragab[3]. *[1]Internal Medicine, Rheumatology & Clinical Immunology subspecialty, Kasr Alainy; [2]New Kasr El-Aini Teaching Hospital; [3]Internal Medicine, Rheumatology & Clinical Immunology subspecialty, Kasr Alainy, Cairo, Egypt*

Background: HCV is a hepato-lymphotropic virus. Chronic arthritis is one of its extrahepatic manifestations[1]. The high frequency of rheumatoid factor (RF) positivity in HCV patients makes it difficult to differentiate between rheumatoid arthritis (RA) and HCV-related arthritis (HCVrA). An accurate and early diagnosis of HCVrA is important to avoid unnecessary immunosuppressive therapy[2]. Ultrasonography provides safe and quick access for the diagnosis of many rheumatic diseases.
Objectives: To illustrate ultrasonographic findings obtained in knee joints of patients with HCVrA & to compare these findings with those obtained from knee joints of RA patients.

Methods: Fifteen patients with HCVrA & 15 RA patients were subjected to: full history, clinical examination, Ultrasonography assessment using a Philips HDI 5000 system with 12–5 MHz Broadband Linear Transducer. Both knees were examined by one ultrasonographer who was blind to clinical data.
Results: In HCVrA, synovial hypertrophy was detected in 10% of knees (3/30) of which 66% (2 knees) exhibited Doppler signals, while in RA it was detected in 70% (21/30) of which 95% (20 knees) exhibited Doppler signals. Significant difference was found between the two groups ($p<0.01$). Knee effusion was detected in 80% (24/30), & 86% (26/30), of patients with HCVrA & RA respectively, no significant difference was found. Cartilage degeneration was detected in 76% (23/30) & 83% (25/30), of patients with HCVrA & RA respectively. Bone erosions were detected in 20% (6/30) in the RA group. It was not detected in HCVrA patients. In HCVrA, there was no correlation between the presence of synovial hypertrophy with respect to cartilage degeneration and knee effusion.
Conclusions: We found no specific ultrasonographic feature specific for HCV related knee arthritis, the knee effusion is a predominant feature and the hypertrophied synovium is not frequently found. No destructive lesions were found to be related to the disease itself; however this should be confirmed by histopathological assessment.

AB1052 QUALITATIVE SYSTEMATIC REVIEW: LACK OF CONSENSUS ON THE CLASSIFICATION CRITERIA FOR DIFFUSE IDIOPATHIC SKELETAL HYPEROSTOSIS

J.S. Kuperus[1], E.E. de Gendt[1], F.C. Oner[1], P.A. de Jong[2], S.C. Buckens[2], A.E. van der Merwe[3], G.J. Maat[4], E.A. Regan[5], D. Resnick[6], R. Mader[7], J.-J. Verlaan[1]. *[1]Orthopedics; [2]Radiology, University Medical Center Utrecht, Utrecht; [3]Anatomy, Academic Medical Center, Amsterdam; [4]Anatomy, Leiden University Medical Center, Leiden, Netherlands; [5]Medicine, National Jewish Health, Denver, Colorado; [6]Radiology, University of California San Diego, San Diego, California, United States; [7]Rheumatology, Ha'Emek Medical Center, Afula, Israel*

Background: Diffuse idiopathic skeletal hyperostosis (DISH) is a condition characterized by flowing ossifications of the spine with or without ossifications of entheses elsewhere in the body.[1,2] Studies on prevalence and pathogenesis of DISH use a variety of partially overlapping combinations of classification criteria, making meaningful comparisons across the literature difficult.[3,4]
Objectives: The aim of this study was to systematically summarize the criteria available to classify or diagnose DISH to aid in the development of a more uniform set of diagnostic and/or classification criteria.
Methods: A search was performed in Pubmed, Embase, Cochrane Library and Web of Science using the term DISH and its synonyms. Articles were included when two independent observers agreed that the articles proposed a new set of classification criteria for DISH. All retrieved articles were evaluated for methodological quality and the presented criteria were extracted. The criteria were placed into one of three groups being "descriptive studies", "sets of criteria for dichotomous diagnosis" or "sets of criteria with consecutive phases".
Results: A total of 24 articles met the inclusion criteria. Two articles were descriptive studies, 11 contained dichotomous classification criteria and 11 described a set of criteria with consecutive phases. In all articles spinal hyperostosis was required for the diagnosis of DISH. Peripheral, extraspinal manifestations were included as a (co-)requirement for the diagnosis DISH in five articles. Most discrepancies revolved around the threshold for the number of vertebral bodies affected and to defining different developmental phases of DISH. More than half of the retrieved articles described a dichotomous set of criteria and did not consider the progressive character of DISH.
Conclusions: In our systematic review we summarize the available different classification criteria for DISH and highlight the lack of consensus on the diagnosis of (early) DISH. Consensus criteria, including consecutive phases of new bone formation that characterize DISH can be developed based upon established diagnostic and/or classification criteria.

AB1053 A NOVEL METHOD FOR IDENTIFYING RADIOGRAPHIC BASELINE RISK OF OSTEOARTHRITIS USING AN ANISOTROPY-BASED TEXTURE ANALYSIS ALGORITHM: DATA FROM THE OSTEOARTHRITIS INITIATIVE

R. Ljuhar[1], T. Haftner[2], Z. Bertalan[1], D. Ljuhar[3], A. Fahrleitner-Pammer[4], H.-P. Dimai[4], S. Nehrer[2] on behalf of Osteoarthritis. *[1]ImageBiopsy Lab, Vienna; [2]Department for Health Sciences and Biomedicine, Danube University Krems, Krems; [3]Braincon Technlogies, Vienna; [4]Division of Endocrinology and Diabetology, Medical University Graz, Graz, Austria*

Background: Osteoarthritis (OA) is the most common form of arthritis and affects disproportionately the knee. Recent developments in imaging techniques showed that OA is not just a joint disease but also involves progressive changes in the subchondral/subarticular bone area of the tibia. On top of the accepted method of measuring the joint space width, assessments of the trabecular bone structure in selected regions of interest (ROI) in conventional X-rays may be offering an alternative method for quantifying the risk and progression of this disease.
Objectives: The accepted method for assessing OA - Joint space width (JSW) and Joint Space Area (JSA) measurements - have limited capabilities in regard to early identification and reproducible follow-ups of the disease. The objective of this abstract is to evaluate the trabecular bone structure as an area for early identification of OA risk, applying texture anisotropy algorithms and subsequently comparing the results to standard JSW and JSA measurements.
Methods: This study was performed using data from the Osteoarthritis Initiative. The image data set was restricted to female, Caucasian, right knee exams recorded with the same modality. Furthermore we selected exams which had a KL grade of 0 at the baseline exam and a deteriorating KL grade $\geq$2 at the 96 month follow up. 22 cases fulfilled these criteria and we selected 22 matching controls with no signs of OA at the 96 month follow up. The selected region of interest (ROI) for the analysis of the radiographic texture consisted of four ROIs in the subchondral tibia and one additional ROI in each femur condyle – in total 6 ROIs. For each individual ROI, the degree of texture anisotropy was calculated and compared between case/control. In addition, JSW & JSA were calculated in both groups using a proprietary software-based method (ImageBiopsy Lab, Vienna, Austria).
Results: Whereas the JSW and the JSA measurements did not yield any significant differences with respect to their mean values (Cohen's d =0.139 and 0.028), the calculated texture parameters showed that differences in values between cases and controls can be found in two of the subchondral ROIs (ROI1&2) with Cohens'd values of 0.625 and 0.831, respectively. With respect to selected patient, the differences in anisotropy results were significant using these texture parameters.
Conclusions: Our results indicate that using the selected radiographic texture parameters, an early identification of patients at risk for developing OA using conventional X-rays can be achieved. This may offer an additional method for quantifying the risk of baseline OA. This is supported by the Cohen's d values that are by definition relatively large (0.625 and 0.831). Ongoing research focuses on larger sample set validation and the use of such algorithms for additional applications, such as the early identification of fracture risk.

AB1054 QUANTITATIVE ULTRASOUND FOR ASSESSMENT OF DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: RELIABILITY AND CONSTRUCT VALIDITY

R.P. Goswami, A. Ghosh, D. Lahiri, P. Ghosh. *Department of Rheumatology, IPGMER, KOLKATA, INDIA, Institute of Post Graduate Medical Education and Research, Kolkata, India*

Background: Joint ultrasound is an integral part of assessment of patients with rheumatoid arthritis (RA). Semi-quantitative grading of ultrasound is subjective whereas quantitative ultrasound (QUS) may be more objective.
Objectives: To evaluate the reliability and construct validity of QUS of wrist joints in patients with RA.
Methods: We studied 95 patients with RA. Following parameters were studied: swollen and tender joint counts (SJC and TJC), patient and evaluator global assessment (PGA, EGA) and disease activity score (DAS28). Patients were classified as active disease and disease in remission as per expert clinician opinion. Colour Doppler ultrasound (CDUS) of wrists was done to obtain semiquantitative grading. Scans were processed in image analysis software (Photoshop CS4) to obtain the following: colour fraction of intrasynovial (IS) vascular signals (CF(IS) = pixel area of IS vascular signals/pixel area of entire IS area (area(IS)), CF(total) (pixel area of both IS and extrasynovial vascular signals/area (IS)) and number of IS (N(IS)) and extrasynovial (N(ES)) vascular signals. Images were stored and independently rated for both CDUS and QUS by two different raters blinded to each other's rating.
Results: Demographics of patients were: mean age 48±16.7 years, mean disease duration 24 months (range 4–600), mean DAS28 of 2.98±1.18 and 40% (38/95)

had active disease. CDUS findings were: synovial proliferation: grade 1: 27.4%, grade 2: 54.7%, grade 3: 11.6%; vascularity: grade 1: 41.1%, grade 2: 32.6% and grade 3: 9.5%. Summary findings of QUS were: CF(IS): 8.6±10.63 (median 4.4), CF(total): 9.9±11 (median 5.2), median N(IS): 3 (0–26) and mean N(ES): 1.2 (0–19). Cohen's kappa for synovial proliferation was 0.402 ($p<0.001$) and vascularity was 0.605 ($p<0.001$). Intraclass correlation (ICC(1,2)) for CF(IS) was 0.996 (95% confidence interval (CI): 0.994–0.997) and ICC(1,2) for CF(total) was 0.995 (95% CI: 0.993–0.997). CF(IS) was correlated with SJC (r=0.22, p=0.029), TJC (r=0.39, $p<0.001$), PGA (r=0.5, $p<0.001$), EGA (r=0.583, $p<0.001$) and DAS28 (r=0.47, $p<0.001$); correlations for CF (total) were: SJC (r=0.25, p=0.013), TJC (r=0.41, $p<0.001$), PGA (r=0.525, $p<0.001$), EGA (r=0.515, $p<0.001$) and DAS28 (r=0.5, $p<0.001$). Significant correlations were also observed for N(IS) with SJC (r=0.282, p=0.006), TJC (r=0.411, $p<0.001$), PGA (r=0.48, $p<0.001$), EGA (r=0.514, $p<0.001$) and DAS28 (r=0.467, $p<0.001$). Spearman rank correlations of CDUS vascularity were: SJC (r=0.26, p=0.01), TJC (r=0.292, p=0.004), PGA (r=0.26, p=0.012), EGA (r=0.168, p=0.103) and DAS28 (r=0.275, p=0.007). Spearman rank correlations of CF(IS), CF(total) and N(IS) with CDUS vascularity were 0.828, 0.864 and 0.689 respectively ($p<0.001$). Cut-off values for CF(IS), CF(total) and N(IS) for distinguishing active RA from RA in remission were 4.78 (AUC: 0.82, 95% CI: 0.73–0.9), 5.75 (AUC: 0.89, 95% CI: 0.69–0.88) and 2.5 (AUC: 0.77, 95% CI: 0.68–0.86) respectively. There were 40 patients with CDUS vascularity $\geq$2 among which 62.5% (25/40) had active disease. In this group only CF(total) >5.75 could distinguish between patients with active disease from disease in remission (100% (25/25) vs., 80% (12/25), p=0.046).

Conclusions: CF(IS) and CF(total) had excellent inter-rater reliability and construct validity. Simple quantitative cutoff values could distinguish between active RA from remission.

AB1055 LEUKOCYTE ESTERASE REAGENT STRIPS FOR RAPID DIAGNOSIS OF INFLAMMATORY SYNOVIAL FLUID

S. Rodríguez-Muguruza[1], S. Malumbres[2], A. Olive[3], O. Valero[4], S. Holgado[3], L. Mateo[3], M. Martínez-Morillo[3]. *[1]Rheumatology, Virgen de la Cinta Hospital, Tarragona, Spain; [2]Clinical Biochemistry Service, Germans Trias I Pujol Hospital, Barcelona, Belgium; [3]Rheumatology, Germans Trias I Pujol Hospital; [4]Department of Statistics, Automona de Barcelona University, Barcelona, Spain*

Background: The analysis of synovial fluid is an important tool for diagnosing joint disease. When synovial fluid is removed, the white cell count (WCC) decreases with time, and an inflammatory liquid could become a false non-inflammatory specimen. Reagent strip testing of urine is a valid tool for the diagnosis of urinary tract infection, via the detection of leukocyte esterase activity. It has been used for the analysis of others body fluids. Synovial fluid test at the site of arthrocentesis using reagent strips could have potential benefits as a screening tool.

Objectives: To evaluate the performance of leukocyte esterase reagent strips for diagnosis of inflammatory synovial fluid.

Methods: Prospective single center study. We analyzed synovial fluids samples collected from patients in a tertiary university Hospital (November 2015- December 2016). Synovial fluid samples were tested within 1 hour after collection. We analyzed: The presence of leukocyte esterase using the leukocyte esterase reagent strips test (originally designed for urine test, URI-Clip Test, Menarini Diagnostics). It was recorded semi quantitatively: negative, 1+ (>25 WBC/uL), 2+ (>75 WBC/uL) or 3 +(>500 WBC/uL) by comparison with a standard color chart found on the container's label. The WCC, formula, glucose level. The WCC was measured by manual leukocyte counting, using saline as diluents. Cultures were also collected. We consider + if leucocyte esterase pad was more or equal than 1+ positive. The cut-off for the WCC (>2000cells/mm^3) was used to differentiate between inflammatory and non-inflammatory specimens. We compared the WCC (reference standard diagnostic test) with the presence of leukocyte esterase using the leukocyte esterase reagent. Sensitivity (Se), specificity (Sp), PPV, NPV were determined. P-value smaller than 0.05 were considered significant.

Results: During the study period, 125 joint fluid specimens were analyzed: 56 (44.8%) mechanical and 69 (55.2%) inflammatory. Of the mechanical fluids 33 (58.9%) were negative by leukocyte esterase reagent and of the inflammatory fluids 67 (97.1%) were positive. The Se and Sp of leukocyte esterase reagent was 97.1% and 58.9% respectively. The PPV was 74.4% and NPV was 94.3%. The 2 false-negative results (negative by leukocyte esterase reagent but more than 2000 WBC/mm^3), showed a predominance of mononuclears (> =91%), the median WCC was 2 775/mm and median neutrophil percentage was 8.5%. For inflammatory fluids: semi-quantitative results (negative, 1+, 2+ and 3+) were significantly different regarding the main leukocyte, neutrophil and lymphocyte count (table).

	Negative	1+	2+	3+	p value
Total cell (cel/mm^3)	3025	18272.9	10553.5	56494.2	<0.0001
Leukocyte (cel/mm^3)	2775	12907.1	8528.8	30870.2	<0.0001
Lymphocyte (%)	91.5	50.4	21.61	6.4	<0.0001
Neutrophil (%)	8.5	49.6	83.7	91.7	<0.0001

Conclusions: Our results demonstrate that leukocyte esterase reagent strips are a rapid, cheap, and sensitive tool to identify inflammatory synovial fluid. Leukocyte esterase reagent strips had an excellent Se but a poor Sp, it could be used as a screening tool in primary care practice. A positive result may indicate an inflammatory process, then the patient should be referred to a rheumatologist.

AB1056 RADIOGRAPHIC ANALYSIS OF METATARSUS PRIMUS ELEVATUS IN PATIENTS WITH RHEUMATOID FOREFOOT DEFORMITIES

S. Mizuki, D. Hiraoka, K. Kushimoto, H. Yamasaki, K. Yoshida, K. Oryoji, K. Kamada, E. Yokota. *The Center for Rheumatology, Matsuyama Red Cross Hospital, Matsuyama, Ehime, Japan*

Background: Metatarsus primus elevatus involves dorsal elevation of the first metatarsal relative to the lesser metatarsals. The role of metatarsus primus elevatus in rheumatoid forefoot deformity is yet to be elucidated. We hypothesize that metatarsus primus elevatus can be attributed to a different pathomechanism than typical rheumatoid forefoot deformities such as hallux valgus, splay foot, and flat foot.

Objectives: To clarify the radiographic characteristics of metatarsus primus elevatus in patients with rheumatoid forefoot deformities.

Methods: We retrospectively reviewed standing anteroposterior and lateral radiographs of 51 feet (37 patients; mean age 65.7±7.1 years) before toeplasty due to metatarsalgia at our hospital. The elevation of the first metatarsal relative to the second metatarsal (MPE), the hallux valgus angle (HVA), the intermetatarsal angle (IMA), talar pitch, and calcaneal pitch were measured. For statistical analyses, the Mann-Whitney U test was used.

Results: Median MPE was 1.7 mm (interquartile range: 0.7–4.5 mm). We compared the group with MPE >5 mm (N=12 feet) to the group with MPE $\leq$5 mm (N=39 feet). The group with higher MPE was significantly younger (p=0.011). There was no significant difference in HVA between the two groups (p=0.068), although IMA was significantly smaller in the group with higher MPE (p=0.033). In the group with higher MPE, calcaneal pitch was greater ($p<0.001$) and talar pitch was smaller (p=0.016).

Conclusions: In patients with metatarsus primus elevatus, other rheumatoid forefoot deformities such as spray foot and flat foot were not observed. There was a wide range of hallux valgus severity. Metatarsus primus elevatus may be attributed to greater hindfoot calcaneal pitch.

AB1057 MULTIDISCIPLINARY APPROACH FOR DIAGNOSING CONNECTIVE TISSUE DISEASE-RELATED LUNG DISEASE: IS IT USEFUL FOR RHEUMATOLOGISTS?

S. Peña Montelongo[1], A. Monroy Calero[1], O. Acosta Fernández[2], S. García Hernández[3], L. Pérez Martín[2], A. Bonilla Arjona[4], H. Sánchez Pérez[1], S. Bustabad Reyes[1], B. Rodríguez-Lozano[1]. *[1]Rheumatology; [2]Pneumology; [3]Pathology; [4]Chest Section, Radiology, Hospital Universitario de Canarias, Tenerife, Spain*

Background: Many patients with idiopathic interstitial pneumonia (IP) have certain clinical, serological and/or pulmonary morphologic features suggesting an underlying autoimmune disease (AD), but without meeting established criteria for connective tissue disease (CTD), a situation labelled as "IP with autoimmune features" (IPAF)[1]. To identify an underlying aetiology is important because it may impact on treatment and prognosis, and could be optimised by multidisciplinary approach.

Objectives: 1.To identify prevalence of IPAF in routine practice. 2. To determine the value of lung biopsy to diagnose underlying AD.3. To describe the course of IPAF.

Methods: Observational, longitudinal retrospective study in a tertiary hospital specific outpatient clinic for IP patients with cough and dyspnea as dominant symptoms requiring co-evaluation by rheumatologists in 2010–2016. Variables included: clinical, serologic and morphological findings by High-Resolution Computed Tomography of lungs assessed by 2011 current guidelines[2] and open lung biopsy. Statistical analysis:SPSS 17.0.

Results: Of 410 patients evaluated for IP, 93 had rheumatologist assessment, 70 F (75.3%), mean age at diagnosis 62.6 years (SD12.13), of whose 48 had no previous diagnosis. Mean follow-up 3.54 (SD2.77)years in undiagnosed patients. The most frequent radiological patterns were: inconsistent with usual interstitial pneumonia (UIP) (67.7%), UIP (22.6%), Possible UIP (4.3%), others (4.3%). Lung biopsy was performed in 15 patients (16%),11 without previous diagnosis. Histopathology patterns: 8 non-specific interstitial pneumonia (NSIP) in whom final rheumathologic clinical diagnosis was IPAF in 6 and UCTD in 2; 1 UIP (Sjögren); 1 vasculitis (p-ANCA) and 1 lymphoid interstitial pneumonia (LIP) corresponding to IPAF. We found lymphoid aggregates in one patient diagnosed as a IPAF. Overall new diagnostics were: IPAF 43.8%, UCTD 4.2%, CTD 52.1%.14/93 (15%) patients died, of whom 6 had IPAF (43%).

Conclusions: 1. Of patients with IP referred for rheumatologist assessment, 31% has no established CTD, with IPAF as clinical diagnosis in 24.7% of overall patients. 2. Surgical lung biopsy allowed to diagnose AD in 23% of unlabelled

patients. 3. After a follow-up time of 3.5 years,43% of patients that died had been diagnosed as a IPAF.

AB1058 SENSITIVE DETECTION OF DYNAMIC CHANGES OF BONE EROSIONS IN INFLAMMATORY ARTHRITIS BY MUSCULOSKELETAL ULTRASOUND: A COMPARATIVE ANALYSIS WITH HIGH-RESOLUTION PERIPHERAL QUANTITATVE COMPUTED TOMOGRAPHY

S. Finzel[1,2], G. Schett[2], S. Kraus[3], R. Voll[1], M. Backhaus[4]. *[1]Department of Rheumatology and Clinical Immunology, University Medical Center Freiburg, Freiburg; [2]Department of Internal Medicine III, Rheumatology and Immunology, University Clinic of Erlangen, Erlangen, Germany; [3]Department of Internal Medicine, Kontonsspital Baden, Baden, Switzerland; [4]Department of Internal Medicine, Rheumatology and Clinical Immunology, Park-Klinik Weissensee, Academic Hospital of Charité, Berlin, Germany*

Background: Bone erosion is a hallmark of inflammatory joint diseases. Its meticulous detection is highly important for correct diagnosis and monitoring of therapy response. Earlier studies showed that musculoskeletal ultrasound (MSUS) has a higher sensitivity than conventional radiography with regards to detection of bone erosions (1) making MSUS more and more popular. The OMERACT ultrasound working group is currently standardizing and validating MSUS as an imaging outcome tool.
Objectives: To investigate the ability of MSUS to sensitively and specifically detect bone erosions in a longitudinal setting using HR-pQCT as a gold standard.
Methods: This is a sequel study to our 2011 cross-sectional comparative analysis on MSUS and HR-pQCT (2). 4/6 healthy individuals, 6/6 psoriatic arthritis patients and of 10/14 rheumatoid arthritis patients were available for follow-up and received an MSUS and an HR-pQCT scan of the clinically dominant hand. Bone erosions at the radial, palmar, and dorsal sites of the second metacarpophalangeal (MCP) joint, as well as the palmar and dorsal sites of the third and forth MCP joints were assessed for prevalence and severity in MSUS and by HR-pQCT. Afterwards, data were compared to the 2011-dataset. MSUS was graded as described earlier (2).
Results: Datasets without follow-up from the baseline cohort were eliminated. Sensitivity of MSUS in comparison to HR-pQCT regarding correct detection of erosions was 95% and specificity was 75%. %. For this analysis, grade 1 lesions were included. At follow-up sensitivity was 86% and specificity 79%. At follow-up, 36 MSUS-lesions were no longer detectable in MSUS; 21/36 were false-positive lesions at baseline. Only one false-positive lesion was detected at both time points. One new lesion was detected by MSUS and confirmed by HR-pQCT. Overall severity of bone erosions regressed in MSUS; these findings were confirmed by HR-pQCT (p=0.04).
Conclusions: This is the first study on change of bone erosions over time comparing MSUS and HR-pQCT. MSUS was confirmed being a sensitive imaging tool able to detect changes of erosions over time. Thus, it may be an adept tool to monitor treatment response in inflammatory joint diseases. Correct identification of bone erosions and differentiation from physiological vessel channels requires knowledge of predilection sites of erosions and physiological cortical breaks; this might aid to further increase the diagnostic value of MSUS.

AB1059 THE PREVALENCE OF DENSE FINE SPECKLED PATTERN IN ROUTINE SCREENING FOR SYSTEMIC AUTOIMMUNE DISEASES USING INDIRECT IMMUNOFLUORESCENCE-ANTINUCLEAR ANTIBODY TEST

S. Kim, Y.L. Jeon, M.H. Kim, W.I. Lee, S.Y. Kang. *Department of Laboratory Medicine, Kyung Hee University College of Medicine, Seoul, Korea, Republic Of*

Background: The nuclear dense fine speckled (DFS) pattern is one of the most commonly observed finding in indirect immunofluorescence-antinuclear antibody (IIF-ANA) assay on HEp-2 cells. Unlike other ANA, DFS pattern is not prevalent in ANA-associated rheumatic diseases (AARD). The antigen was initially named DFS70 (70kD protein) according to the IIF pattern and later known as the lens epithelium-derived growth factor p75 (LEDGF/p75). Autoantibodies showing a DFS pattern have been reported in interstitial cystitis, various chronic inflammatory conditions, autoimmune thyroiditis, atopic dermatitis, cancer, as well as in apparently healthy individuals. Among IIF-ANA tests referred to the laboratory from the Department of Dermatology, the most common IIF-ANA positive pattern is DFS.
Objectives: To compare the clinical significance of DFS pattern in dermatologic diseases (including alopecia) with other departments.
Methods: Between June and December 2016, IIF-ANA testing using HEp-2 cell line slide (Kallestad; Bio-Rad, USA) was performed on 4,130 samples referred as screening for systemic autoimmune diseases in Kyung Hee University Hospital. The identified patterns in IIF-ANA assays were analyzed according clinical department and diagnosis.
Results: The Department of Dermatology was the most requesting IIF-ANA assay (2579/4130, 62.4%) and the Department of Rheumatology and the remaining departments were 18.1% (749/4130) and 19.5% (802/4130), respectively. The prevalence of IIF-ANA positivity was 10.97% (453/4130) and those of the Department of Dermatology, the Department of Rheumatology, and the remaining departments were 8.5% (219/2579), 15.5% (116/749), and 14.7% (118/802), respectively. The DFS pattern was the most common IIF-ANA positive pattern (173/453, 38.2%) and the prevalence of DFS pattern in the Department of Dermatology, the Department of Rheumatology, and the remaining departments were 48.4% (106/219), 26.7% (31/116), and 30.5% (36/118), respectively.
Among 173 patients with ANA pattern of DFS, 168 patients were reviewed based on their medical chart. The most of patients were from Department of Dermatology and Rheumatology. 101 patients with positive DFS were from Department of Dermatology, the majority of 55 patients were diagnosed with alopecia. 31 patients of department of Rheumatology showed positive ANA pattern of DFS and a great part of patients were diagnosed with rheumatism.
Conclusions: According to previous studies, up to 20% of healthy individuals have been reported to have a positive IIF-ANA test and the DFS pattern has been reported in 33% of ANA positive healthy individuals, but not in ANA positive systemic autoimmune diseases. In this study the prevalence of DFS pattern of ANA positivity in patients with dermatologic diseases including alopecia was similar with prevalence reported in healthy individuals. The patients with alopecia appear to show higher prevalence of positive ANA pattern of DFS than other patients with dermatologic disorders. This study was performed with routinely IIF-ANA requested patients to screen for systemic autoimmune diseases. Therefore, further evaluations comparing healthy individuals and patient group with more various disease entities are needed to confirm our findings.

AB1060 MEASURING AGREEMENT IN THE ULTRASONOGRAPHIC EVALUATION OF DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS PATIENTS. A LATIN-AMERICAN MULTICENTER EXERCISE ASSESSING THE INFLUENCE OF SONOGRAPHER EXPERIENCE AND EXPERTISE

T. Cazenave[1], M.V. Martire[2], C. Waimann[3], M. Rosemffet[1]. *[1]Instituto de rehabilitación psicofísica, Buenos Aires; [2]Hospital Italiano de la Plata, la Plata; [3]Hospital Dr. Hector Cura, Olavarria, Argentina*

Background: Ultrasonography (US) is an important tool in rheumatology practice but it depends on sonographer's experience.
Objectives: To evaluate the reliability of US assessment among observers across Latin American using a web tool.
