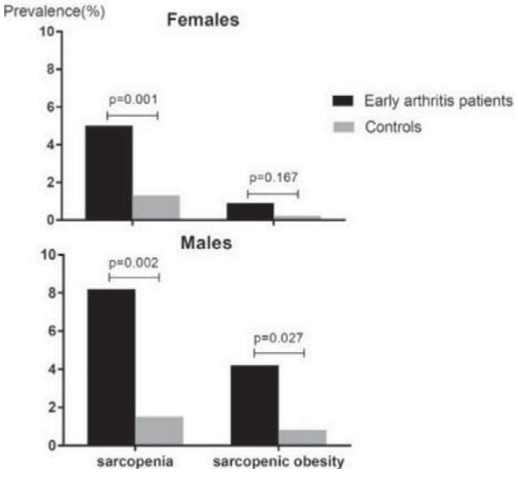
SAT0127 UNFAVORABLE BODY COMPOSITION ALREADY AT THE ONSET OF CLINICAL ARTHRITIS

S.A. Turk[1], D. van Schaardenburg[1,2], M. Boers[3], S. de Boer[1], C. Fokker[1], W.F. Lems[1,3], M.T. Nurmohamed[1,3]. *[1]Amsterdam Rheumatology and immunology Center| Reade; [2]Amsterdam Rheumatology and immunology Center| Academic Medical Center; [3]Amsterdam Rheumatology and immunology Center| VU University Medical Center, Amsterdam, Netherlands*



Background: Rheumatoid arthritis is associated with an increased cardiovascular (CV) risk. There is mounting evidence that inflammation is involved in the pathogenesis thereof (1). An unfavorable body composition is, independently, associated with an increased CV risk, and often present in established arthritis patients. This unfavorable composition is a loss of muscle mass (sarcopenia), in the presence of a stable or even increased (abdominal) fat mass (sarcopenic obesity) (2).
Objectives: Currently it is unknown when this unfavorable body composition develops. Therefore, we compared body composition in DMARD-naïve early arthritis patients with non-arthritis controls and explored the association with disease activity and traditional CV risk factors.
Methods: A total of 317 consecutive early arthritis patients and 1268 age, gender and ethnicity matched non-arthritis controls (3) had a Dual-energy X-ray absorptiometry scan to assess lean (muscle) mass index (LMI), fat mass index (FMI), fat mass distribution (arms and legs versus trunk) and android to gynoid fat mass ratio. For the obesity definition, the cut offs of Gallaher et al. were applied. For the sarcopenia definition, cut offs based on the control group were applied (mean minus two times SD). In addition, a disease activity score, erythrocyte sedimentation rate, lipid profile (total cholesterol, HDL, LDL and triglycerides) and blood pressure assessments were done.
Results: Early arthritis patients (84% fulfilling the 2010 ACR/EULAR criteria) had a significantly lower mean LMI ($p<0.01$) compared with controls. Female patients had a higher mean FMI ($p<0.01$) and more fat was distributed to the trunk in patients (females $p<0.01$, males $p=0.07$) (table). The prevalence of an unfavorable body composition (i.e. sarcopenia and sarcopenic obesity) was higher than in controls, for females 5.0% versus 1.3%, OR: 4.2, $p<0.01$ and for males 8.2% versus 1.5%, OR: 5.7, $p<0.01$ (figure). A higher FMI, more android fat and more fat distributed to the trunk were associated with higher blood pressure and lipid levels (and lower HDL levels). There was no clear relationship between body composition parameters and disease activity.

Table 1. Body composition of early arthritis patients and non-arthritis controls

	Arthritis females	Control females	Arthritis males	Control males
Fat mass index (mean, SD)	27.6 (5.3)	26.6 (4.6)*	26.8 (4.4)	27.4 (3.6)
% of fat distributed to the trunk (mean, SD)	52.2 (6.3)	49.4 (6.5)*	58.8 (6.4)	57.6 (5.6)
Android to gynoid fat mass ratio (mean, SD)	0.5 (0.2)	0.5 (0.2)	0.7 (0.2)	0.8 (0.2)*
Lean mass index (mean, SD)	6.6 (0.9)	6.7 (0.8)*	8.0 (1.1)	8.6 (1.0)*
Obese (n,%)	99 (45.2)	334 (38.4)	50 (52.1)	222 (57.7)
Sarcopenic (n,%)	11 (5.0)	11 (1.3)*	8 (8.2)	6 (1.5)*
Sarcopenic obesity (n,%)	2 (0.9)	2 (0.2)	4 (4.2)	3 (0.8)*

n = number, SD = standard deviation, % == percentages *p-value <0.05 between arthritis and non-arthritis controls.

Figure. Prevalence of sarcopenia and sarcopenic obesity in early arthritis patients compared with non-arthritis controls.

Conclusions: Patients at the clinical onset of arthritis more often have an unfavorable body composition (sarcopenia and sarcopenic obesity) than non-arthritis controls. An unfavorable body composition was associated with higher blood pressure and lipid levels (and lower HDL levels).

SAT0128 CLINICAL FEATURES AND EVOLUTION OF PULMONARY FUNCTION IN A SINGLE-CENTER COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS RELATED INTERSTITIAL LUNG DISEASE

S.C. Rodriguez-García, R.A. Castellanos-Moreira, M.V. Hernandez-Miguel, J. Ramirez, A. Cuervo, J. Cañete, R. Sanmarti-Sala. *Rheumatology, Hospital Clinic Barcelona, Barcelona, Spain*

Background: Interstitial lung disease (ILD) is an extra-articular manifestation of Rheumatoid Arthritis (RA), has been related with a poor prognosis. However, there is a lack of clinical data regarding its evolution with different treatment approaches.
Objectives: Our aim was to assess clinical features and evolution of ILD in a cohort of RA patients from a tertiary hospital
Methods: Single-centre retrospective observational study including all patients diagnosed with ILD with a previous or posterior diagnosis of RA evaluated from January 2007 to December 2016 in the Rheumatology Department of a university hospital.
Variables analysed: age, sex, smoking status, duration of RA, presence and titers of ACPA (antiCCP2) and rheumatoid factor (RF), presence of erosions, use of glucocorticoids (GC), synthetic and biological DMARDs before and after ILD diagnosis and presence of other extra-articular manifestations.
We also analysed: duration of ILD, HRCT (High Resolution Computed Tomography) patterns and pulmonary function tests (PFT) at baseline and during follow-up to assess the evolution of the disease. The PFT results were evaluated according to the American Thoracic Society/European Respiratory Society definitions (1).
Results: Twenty-one patients (18 women) were included, mean age 68. 4±11.9, mean RA duration 12.3±8.2 years. 9.5% were current smokers and 33.3% former smokers. 61.9% were ACPA + (52.4% with high basal titers, median ACPA titers: 698) and 81% RF+ (47.6% with high basal titers). 71.4% had erosions and 5 patients (23.8%) had extra-articular manifestations, mainly rheumatoid nodules.
RA diagnosis was made after that of ILD in 4 patients; mean elapsed time 1.56±1.26 years. In the other 17 patients, the mean duration of RA until ILD diagnosis was 11.2±7.2 years.
Currently 17 subjects (85%) receive GC; 4 (19%) in monotherapy and 11 (57.9%) synthetic DMARDs (5 methotrexate, 3 leflunomide (LEF), 1 hydroxychloroquine (HCQ) and 2 with double therapy (HCQ/AZA and HCQ/LEF)).
Four patients are currently treated with biological therapy (2 abatacept (ABA), 1 rituximab and 1 etanercept (ETN)), all of them in monotherapy.
Five patients received TNFi prior to ILD diagnosis (3 ETN, 1 infliximab and 1 adalimumab). Biological therapy was withdrawn in 3 cases and switched to ABA in the two remaining ones.
The median duration of EPID was 2.5 (range 0.7–11.9) years. HRCT patterns were: non-specific interstitial pneumonia (NSIP) 52.9%, usual interstitial pneumonia (UIP) 17.6%, cryptogenic organized pneumonia (COP)11. 8%, and other patterns 17.7%.
14 patients had baseline and follow-up PFT: 9 (64.3%) remained stable; 3 (21.4%) improved and 2 (14.3%) worsened (1 had received previous ETN). There was a trend for worsening of PFT in patients with UIP pattern.
No patient died from ILD during this period
Conclusions: In our RA-ILD cohort, NSIP was the most common HRCT pattern and PFT remained stable in most patients during follow-up. Five patients (23.8%) had received TNFi prior to ILD diagnosis and only one of them showed worsening of PFT during ETN treatment, with clinical improvement after withdrawal.

SAT0129 EXPLORATION OF COMORBIDITY INDICES IN AN ETHNIC RHEUMATOID ARTHRITIS SUBSET

S. Dowell[1], G. Kerr[2], C. Swearingen[3], M. Quinones[1], J. Berrian[1], S. Hochberg[1] on behalf of EMRAC Working Group. *[1]Rheumatology, Howard University Hospital; [2]Rheumatology, Washington VAMC, Washington; [3]NYU, New York, United States*

Background: Comorbidity is common in ethnic patients with rheumatoid arthritis (RA) and often impact choice of DMARD therapy and clinical outcomes. In addition to simple summation of comorbidities, composite indices have been proffered as better predictors of poor clinical outcomes in patients with rheumatoid arthritis[1]. However, their applicability in ethnic RA subsets is unknown.
Objectives: To compare composite to mean comorbidity indices in ethnic subsets with rheumatoid arthritis.
Methods: Patients enrolled in the Ethnic Minority RA Consortium (EMRAC), with at least 6 months of followup data were analyzed. At enrollment, sociodemographic data and RA disease status, rheumatic disease comorbidity index (RCDI)[1] and comorbidity count (COUNT)[1] were analyzed amongst ethnic subsets. Spearman correlation was estimated between RCDI and COUNT while Poisson regression

was used to model the differences in the comorbidity indices between race groups.

Results: 453 EMRAC subjects were analyzed; 342 (81.4%) were female, average age was 58.9 (± 15.1) years, average duration 13.3 (±11.1) years and average follow-up length 2.1 (±1.4) years. Individual comorbid frequencies as well as comorbid indices are summarized in Table 1. Spearman correlation between overall RDCI and COUNT was 0.90 (95% CI [0.88, 0.91], P<0.001). Hispanics, however, had significantly lower comorbidity indices scores than other race groups (RDCI Hispanic vs White P=0.003, Hispanic vs Black P=0.004, Hispanic vs Other P=0.038; COUNT Hispanic vs White P=0.012, Hispanic vs Black P=0.004, Hispanic vs Other P=0.151).

Table 1. Clinical Characteristics of EMRAC study cohort

	White	Black	Hispanic	Other	Total
N	102	195	85	71	453
Hypertension [N (%)]	36 (35.3%)	79 (40.5%)	24 (28.2%)	31 (43.7%)	170 (37.5%)
Coronary Artery Disease [N (%)]	12 (11.8%)	14 (7.2%)	3 (5.9%)	2 (2.8%)	31 (6.8%)
Other Heart Disease [N (%)]	11 (10.8%)	6 (3.1%)	2 (2.4%)	2 (2.8%)	21 (4.6%)
Fracture [N (%)]	11 (10.8%)	8 (4.1%)	2 (2.4%)	2 (2.8%)	23 (5.1%)
Psychiatric Disease [N (%)]	5 (4.9%)	10 (5.1%)	1 (1.2%)	0 (0.0%)	16 (3.5%)
Diabetes [N (%)]	11 (10.8%)	33 (16.9%)	9 (10.6%)	8 (11.3%)	61 (13.5%)
Cancer [N (%)]	9 (8.8%)	8 (4.1%)	5 (5.9%)	3 (4.2%)	25 (5.5%)
Stomach [N (%)]	8 (7.8%)	9 (4.6%)	8 (9.4%)	7 (9.9%)	32 (7.1%)
Stroke [N (%)]	4 (3.9%)	6 (3.1%)	2 (2.4%)	2 (2.8%)	14 (3.1%)
Hyperlipidemia [N (%)]	19 (18.6%)	29 (14.9%)	9 (10.6%)	12 (16.9%)	69 (15.2%)
Chronic Bronchitis [N (%)]	10 (9.8%)	17 (8.7%)	5 (5.9%)	5 (7.0%)	37 (8.2%)
Pulmonary Fibrosis [N (%)]	2 (2.0%)	5 (2.6%)	4 (4.7%)	0 (0.0%)	11 (2.4%)
Kidney Disease [N (%)]	3 (2.9%)	5 (2.6%)	0 (0.0%)	2 (2.8%)	10 (2.2%)
RAPID3	13.1 (6.8)	12.5 (7.4)	14.8 (6.9)	13.7 (7.2)	13.3 (7.1)
Enrollment					
RDCI	1.8 (2.1)	1.7 (2.0)	1.2 (1.7)	1.6 (1.8)	1.6 (1.9)
COUNT	1.0 (1.3)	1.0 (1.3)	0.7 (0.9)	0.9 (1.1)	0.9 (1.2)

Mean (SD) reported unless otherwise noted.

Conclusions: In an ethnic RA subset, the RCDI and COUNT correlated well across ethnic groups. The comorbidity indices were not associated with RA disease activity at enrollment as assessed by the RAPID3. Hispanics had lower RCDI and COUNT scores compared to other race groups but also presented at a younger age which could account for this difference. More studies are needed to determine the predictive value of these indices in determining poor outcomes and mortality in this ethnic subset.

SAT0130 EVALUATION OF THE FACTORS RELATED WITH RISK OF FALLING AND FEAR OF FALLING IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Unsal Delialioglu[1], G. Kilinc Kamaci[1], S. Ozel[1], F. Yurdakul[2], H. Bodur[2]. *[1]Ankara Physical Therapy and Rehabilitation Training and Research Hospital; [2]Ankara Numune Training and Research Hospital, Ankara, Turkey*

Background: People with rheumatoid arthritis (RA) have an increased risk of falls (1,2). The identification of predictive and potentially modifiable risk factors is essential for the development of effective falls prevention strategies (3).

Objectives: The aim of the study is to determine the relationship between falling risk and falling fear with balance, lower extremity muscle strength, functional status, disease activity and pain in patients with Rheumatoid Arthritis (RA)

Methods: A total of 124 patients (92 females, 32 males) who were diagnosed with RA according to the American College of Rheumatology (ACR) diagnostic criteria were included in the study. The fear of falling was assessed by the Fall Efficacy Scale (FES-I) and the shortened form (Short FES-I). Disease activity was assessed using the Disease Activity Score-28 (DAS28), the functional status was assessed with Health Assessment Questionnaire (HAQ). While lower extremity muscule strenght was determined using Chair Stand Test, Four Balance Test was used to determine the balance. The pain intensity was determined using 10 cm Visual Analogue Scale-Pain (VAS-pain).

Results: The mean age of the patients is 54.75±10.96 years, the mean duration of illness is 14.10±10.99 years. A statistically significant relationship was found between FES-I, Short FES-I scores and HAQ (respectively r:0,776, p:0,000; r:0,783, p:0,000), VAS rest (r:0.397, p:0,000; r:0,405, p:0,000), VAS motion (r:0.542, p:0,000; r:0,519, p:0,000), DAS28 values (r:0.216, r:0.181; r:0,260, p:0,004). There was a significant negative correlation between FES-I, Short FES-I scores and Chair Stand Test (respectively r:-0.644, p:0,000; r:-0.652, p:0,00), Four Balance Test (r:-0.597, p:0,000; r:-0.611, p:0,00). There was a statistically significant correlation between the number of falls in the last year and age, duration of illness, HAQ, DAS28, VAS scores (p<0,05)

Conclusions: The risk of falling and fear of falling is associated with balance, lower extremity muscle strength, disease activity, functional status, and pain in patients with RA. Therefore; the risk of falling and fear of falling should be determined and necessary measures must be taken in patients with RA.

SAT0131 MEDIAN NERVE THICKNESS RELATED TO RENAL IMPAIRMENT IN RHEUMATOID ARTHRITIS

S. Hannawi[1], I. AlSalmi[2]. *[1]Rheumatology, Ministry of Health and Prevention of UAE, Dubai, United Arab Emirates; [2]Nephrology, Royal Hospital, Muscat, Oman*

Background: Autoimmune processes, contribute to the burden of kidney disease. The reported kidney disease prevalence in patients with rheumatoid arthritis (RA) ranges from 5%>50% based on studies of different designs. Historically, patients with RA-associated renal amyloidosis had higher mortality rates relative to the general population. The occurrence of haematuria, proteinuria, or CKD has been reported to be associated with a 3- to 4-fold increased risk of death. Subclinical decreased kidney function has been identified as an independent risk factor for cardiovascular (CV) events with increase mortality in patients with RA. On the other hand, both rheumatoid arthritis and renal impairment have been reported to be associated with increase prevalence of carpal tunnel syndrome.

Objectives: To establish the median nerve thickness (measured by ultrasound) in RA and its relation to renal function.

Methods: 120 RA patients were recruited through a specialized rheumatology clinic. The US measurements were performed by the same person. Patients were sitting with their forearm resting in a supinated position on a small table. The US probe (an 8–16 MHz linear array transducer) was held as lightly as possible to avoid disturbing the anatomy of the nerve. The median nerve was examined at the entrance of the carpal tunnel, between the pisiform bone and the tubercle of the scaphoid bone, where the distal volar crease is an external pisiform landmark. A continuous trace was made just within the hyperechogenic boundary of the nerve. The cross-sectional area of the median nerve was calculated directly by the software of the US equipment. Each median nerve was measured three times, and the mean value was used for further analyses. Modification of Diet in Renal Disease (MDRD) equation used to estimate the Glomerualr Filatration Rate (GFR). The average of the right and the left areas of the median nerve were used when exploring bivariate correlations to the renal variables (Pearson's correlation coefficients). All statistics were performed using STATA programe.

Results: the average median nerve thickness was 9.79±2.6 mm^2 (Range 1.5 -22.25). The average GFR was 122±20 ml/min (59.6–286). Thickness of the median nerve was positively associated with the age of the participants (p=0.03, CI: 0.00, 0.08), body mass index (p=0.04, CI: 0.00, 0.21), uric acid level (p=0.033, CI: 0.00, 0.01), and urine microalbumin (p=0.04, CI 0.00, 0.01). GFR showed no significant relation the thickness of the median nerve.

Conclusions: RA patients without symptoms or clinical signs have a median nerve thickness that is positively correlated to the level of microalbumin and uric acid. Whether sosnographic examination of the median nerve would be helpful in predicting who is going to have a deteriorated renal function need to be explored in a larger study.

SAT0132 THE RHEUMATOID ARTHRITIS FLARE QUESTIONNAIRE (RA-FQ): RESULTS OF RASCH ANALYSIS AND FEEDBACK ON REAL-WORLD APPLICATIONS FROM INTERNATIONAL RA PATIENTS AND CLINICIANS

S.J. Bartlett[1,2], S.P. Barbic[3], V.P. Bykerk[4], B. Fautrel[5], F. Guillemin[6], A. den Broeder[7], R. Alten[8], R. Christensen[9], E. Choy[10], D. Furst[11], S. Hewlett[12], A. Leong[13], L. March[14], T. Woodworth[11], B.I.O. Clifton[2] on behalf of CATCH, STPR, & DRESS Investigators. *[1]McGill University, Montreal, Canada; [2]Johns Hopkins, Baltimore, United States; [3]University of British Columbia, Vancouver, Canada; [4]HSS, New York, United States; [5]Pierre & Marie Curie Universite, Paris;*

[6]Universite de Lorraine, Nancy, France; [7]Maartens Kliniek, Nijmegen, Netherlands; [8]Schlosspark Klinik, Berlin, Germany; [9]Parker Institute, Copenhagen, Denmark; [10]Cardiff University, Cardiff, United Kingdom; [11]UCLA, Los Angeles, United States; [12]University of the West of England, Bristol, United Kingdom; [13]Healthy Motivation, Santa Barbara, United States; [14]University of Sydney, Sydney, Australia

Background: Disease flares in RA are common. The RA Flare Questionnaire (RA-FQ) can be used to identify and quantify flares in rheumatoid arthritis (RA).
Objectives: To further explore the psychometric properties RA-FQ, we used Rasch analysis and reviewed results with RA patients research partners (PRPs) and clinicians to gain additional insight into the interpretability, meaningfulness, and utility of results.
Methods: People with RA in observational trials in Canada (CATCH; n=896) and France (STPR; n=138), and an RCT in the Netherlands (n=178) completed the RA-FQ. RUMM2030 was used to evaluate unidimensionality, targeting of items to people, reliability, response options, redundancy, local dependence, and response bias by sex, across age categories, and by country/language. ROC curves were used to identify sensitivity and specificity across potential threshold values to identify flares in different contexts of use. We reviewed results with RA patients research partners (PRPs) to gain additional insight into the interpretability, meaningfulness, and utility of results. Ten PRPs first completed the questionnaire then reviewed individual and group findings to provide feedback. RA clinicians provided feedback on utility and relevance of proposed cut points to identify flares.
Results: Rasch results supported the simple summation of items for a total score ranging from 0–50. Each item had ordered thresholds and acceptable fit. Reliability, was high (PSI =.91). Items and people covered a continuum ranging from -3.2 to +3.4 logits, and items were well-targeted to respondents. Overall model fit was excellent (χ^2 =31.6, df=45; p=0.935). There was little evidence of differential item functioning by sex, age, or country/language. Items suggest flare symptoms and impacts increased together showing a consistent story of how individuals experience worsening RA disease activity. Among PRPs, scores ranged from 10 to 41. There was unanimous agreement from the patients that the story depicted and individual results obtained were easily understood, meaningful, and very reflective of their current state. Many patients noted that beyond clinical trials, the RA-FQ could also enhance communication between doctors and patients at routine visits. Several noted potential applicability in monitoring day-to-day status and with self management. Thresholds for clinically important worsening to identify flare varied by setting, patient population, and context of use.

Conclusions: Taken together, results from classical and Rasch analyses support for the robust psychometric properties of the RA-FQ. The 5-item measure is easy to complete and simple to score. Feedback from RA PRPs and clinicians increase confidence in the relevance, meaningfulness, and easy interpretation of RA-FQ results for clinicians, researchers, and patients.

SAT0133 SUDOMOTOR DYSFUNCTION IN RHEUMATOID ARTHRITIS PATIENTS IN THE ABSENCE OF TRADITIONAL CARDIOVASCULAR RISK

T. Syngle[1], S. Kaur[2], I. Verma[3], A. Syngle[4]. *[1]#547, Sector 16D, Chandigarh, India, Healing Touch Foundation, Chandigarh, India; [2]Cardio-Rheuma & Healing Touch City Clinic, Chandigarh; [3]Maharishi Markandeshwar College of Pharmacy, M.M University, mullana; [4]Cardio-Rheuma & Healing Touch City Clinic and Fortis Multi Specialty Hospital, Chandigarh, India*

Background: Rheumatoid arthritis (RA) is an autoimmune chronic inflammatory disease associated with cardiovascular autonomic neuropathy. Cardiovascular autonomic neuropathy is a significant risk predictor for sudden cardiac death in rheumatoid arthritis.[1] Sudomotor dysfunction reflects small fibre neuropathy, cardiovascular autonomic neuropathy and peripheral sympathetic autonomic neuropathy.[2] However, sudomotor dysfunction and its relationship with inflammatory measures remain unexplored in RA patients in the absence of traditional cardiovascular (CV) risk factors.
Objectives: The aim of present study was to assess the sudomotor function and its association with disease specific measures: ESR, CRP and DAS-28 in RA patients with no apparent conventional cardiovascular risk factor.
Methods: In this cross-sectional study, 60 RA patients fulfilling 2010 Rheumatoid Arthritis Classification Criteria[3] and 40 age and sex-matched healthy controls were recruited. Sudomotor function was assessed using Sudoscan (Impeto Medical, Paris, France) through measurement of electrochemical skin conductance of hands and feet.[2] Sudoscan investigates the sweat gland activity and used as a surrogate to study the damage of sympathetic sudomotor nerves in neuropathy. It is an indirect assessment tool of sudomotor function. Inflammatory measures such as ESR and CRP and DAS-28 (disease activity score in 28 joints) were determined.
Results: Rheumatoid arthritis patients had significantly impaired sudomotor function (56.90±12.95 vs. 76.15±8.45 μs, p<0.00, Figure 1A), elevated ESR (31.30±12.34 vs. 16.72±4.46, p<0.001) and CRP (10.55±3.81 vs. 3.81±1.03, p=0.002) as compared to healthy controls, respectively. The mean disease duration of RA patients was 9.15±5.76 and they had high disease activity (mean DAS-28, 4.60±1.72). Sudomotor function was found to be inversely correlated with ESR (r =0.42, p=0.001, Figure 1B), CRP (r =0.60, p<0.001, Figure 1C) and DAS-28 (r =0.38, p=0.003, Figure 1D).

Fig. 1A. Comparison between sudomotor function RA patients and healthy controls

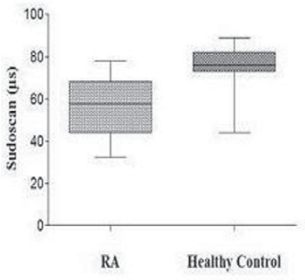

Fig. 1B. Inverse correlation between sudomotor function and ESR

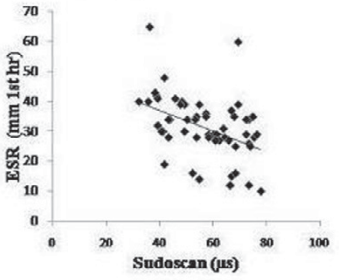

Fig. 1C. Inverse correlation between sudomotor function and CRP

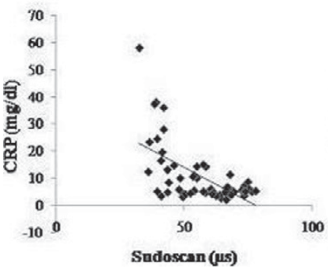

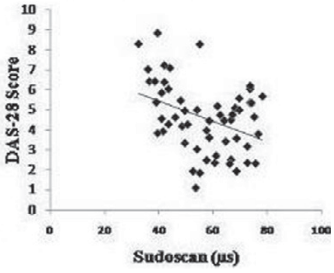

Fig. 1D. Inverse correlation between sudomotor function and DAS-28 score

Conclusions: Cardiovascular autonomic neuropathy occurs in RA in the absence of traditional CV risk factors. Sudomotor dysfunction is significantly associated with increased level of ESR, CRP and disease activity suggesting that increased inflammation may cause sudomotor dysfunction.

SAT0134 DAILY MONITORING OF ARTERIAL STIFFNESS IN WOMEN WITH RHEUMATOID ARTHRITIS

T.A. Romanova, N.M. Nikitina, A.P. Rebrov. *Hospital Therapy Department, State Medical University of Saratov, Saratov, Russian Federation*

Background: Patients with rheumatoid arthritis (RA) have an increased risk of cardiovascular (CV) disease. Monitoring of arterial stiffness could be used as an additional tool of cardiovascular risk assessment.
Objectives: of the study is to evaluate the main parameters daily monitoring of arterial stiffness (DMAS) in women with rheumatoid arthritis with or without arterial hypertension (AH).
Methods: DMAS was measured in 63 women with RA (ACR 1987 and/or EULAR/ACR 2010 criteria). The first group involved 39 RA female patients with AH (mean age – 58.3±6.08 years; median of RA duration - 8 [4; 14] years, median of DAS 28- 5.08 [4.04; 5.85]), the second group included 24 women with RA without AH (mean age 55±7.15 years; duration of RA is 10 [3; 17] years, mean DAS 28 – 5.25 [4.6; 5.7]).
30 women with AH without RA and other joint diseases and 22 healthy females were involved as a controls. Persons with and without RA were comparable

inconventional cardiovascular risk factors. Exclusion criteria were smoking, diabetes mellitus, symptomatic AH, cardiovascular diseases (except AH).
DMAS was measured by using the BPlab with technology VASOTENSE (Russian).An index of arterial stiffness (ASI), a daily index of arterial stiffness (AASI), an aortic pulse wave velocity (PWVao), augmentation index (AIx) were measured. All indexes were estimated at day and night hours.
Statistics was performed with STATISTICA 7.0 (StatSoft, USA).
Results: Hypertensive RA patients and AH patients without RA had comparable DMAS parameters (ASI, PWVao, AIx). The AASI index was higher in RA patients without AH versus controls (0.48±0.2 and 0.29±0.17, respectively, p=0.00001) and the AASI index was higher in hypertensive RA patients versus AH patients (0.5±0.2 and 0.38±0.15, respectively, p=0.01). AASI >0.07 revealed at RA patients more often than in controls: at 13.15% of hypertensive RA patients and at 16.6% of RA patients without AH, respectively, $p<0.05$. The increase of PWVao observed at RA patients frequently than in controls ($p<0.05$).
Daily index ASI100 was higher in RA patients without AH than in healthy controls (121 [109.5; 139] mmHg vs. 107 [103; 115] mmHg, p=0.014).
The increased of AIx75 was registered in 25% of RA patients without AH and in 9.09% of controls (p=0.08). PWVao and average Aix75 correlates with ESR (r =0.38 and r =0.36, respectively, $p<0.05$) in RA patients with AH; AASI correlates with level C-reactive protein (r=0.36, $p<0.05$).
ASI and AASI in RA patients with AH correlates with age (Spearmen's r =0.41 and r =0.36, respectively, $p<0.05$), systolic blood pressure (r =0.76 and r =0.65, respectively, $p<0.05$); pulse blood pressure (r=0.77 and r =0.43, respectively, $p<0,05$).
Conclusions: Arterial stiffness, according to daily monitoring, in RA patients is higher than in hypertensive patients without RA and healthy controls. Arterial stiffness in patients with RA and AH is higher than in patients with RA without AH or AH without RA. Age, systolic blood pressure, pulse blood pressure, high levels of ESR and C-reactive protein associated with increased arterial stiffness in RA patients.

SAT0135 CARDIOVASCULAR RISK IN RHEUMATOID ARTHRITIS PATIENTS FROM SOUTHERN BRAZIL AND ITS ASSOCIATION WITH SERUM LEVELS AND GENOTYPIC VARIATION OF MANNOSE BINDING LECTIN

B. Stadler[1], T.A.F.G. Dos Santos[1], T. Skare[1], R. Nisihara[1,2], R. Petisco[3], I. Goeldner[2], S. Utiyama[4], I.J.T. Messias-Reason[2]. *[1]Rheumatology Unit, Hospital Universitário Evangelico de Curitiba; [2]Department of Medical Pathology, Federal University of Paraná; [3]Evangelic School of Medicine; [4]Department of Clinical Analysis, Federal University of Paraná, Curitiba, Brazil*

Background: The binding lectin mannose (MBL) is a serum protein of collectin family that appears to be involved in the inflammatory process and in the genesis of atherosclerotic disease.
Objectives: To study the association of serum levels of MBL and its genotypic variation with carotid arteries intimal thickness (IMT) in rheumatoid arthritis (RA) patients from Southern Brazil.
Methods: Serum level, MBL genotyping and IMT were studied in 90 RA patients along with their demographic, clinical and laboratory profile. MBL levels were measured in 90 healthy controls.
Results: There was significant difference between mean serum levels of MBL in patients with RA and controls (528 ng/mL vs 937.5 ng/mL, p=0.05, respectively). The median IMT in RA patients was 0.59 mm (0.51 to 0.85 mm). There was no correlation between levels of MBL with disease activity measured by DAS-28 (disease activity score-28), erythrocyte sedimentation rate (ESR), autoantibodies presence or IMT (p=NS). A negative correlation was found between MBL levels with CRP levels (p=0.02). The mutation vat codon 54 (variant B) and HYPA haplotype were the most frequent (67.5% and 31.7%, respectively) in the RA sample. Dominant genotypes (A/A) are associated with lower IMT when compared with heterozygotes (A/O; p=0.04) and homozygous recessive (O/O; p=0.05). Also dominant genotypes had lower CRP when compared with heterozygous (p=0.04) or with recessive genotypes (p=0.05).

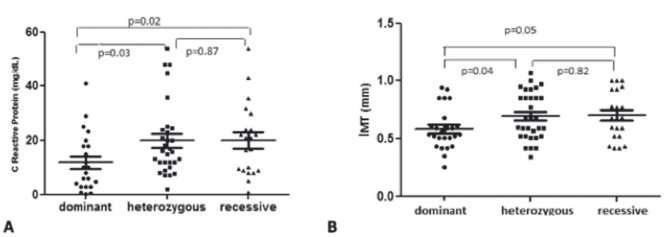

FIGURE 1: MBL GENOTYPING, C REACTIVE PROTEIN (CRP) AND CAROTID INTIMA MEDIA THICKNESS (IMT)

Conclusions: RA patients had lower MBL levels than controls. MBL serum levels are negatively associated with CRP; low producers of MBL had increased thickness of the IMT than high producers.

SAT0136 ASSOCIATION OF GENOTYPES FOR BCL1 POLYMORPHISM IN THE GLUCOCORTICOID RECEPTOR GENE WITH ISCHEMIC HEART DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS

V.S.S.U. Kmyta, O. Savchenko, L. Prystupa. *Internal Medicine Department, 4682, Sumy, Ukraine*

Objectives: The objective is to study association of genotypes for Bcl1 polymorphism in the glucocorticoid receptor (GR) gene with ischemic heart disease (IHD) in patients with rheumatoid arthritis (RA).
Methods: 161 subjects with rheumatoid arthritis aged 40 years and older were examined by means of instrumental, clinical and laboratory examinations. Rheumatoid arthritis was diagnosed according to ACR/EULAR Classification Criteria (2010). The IHD diagnosis was verified by means of AHA/ACC guidelines (2012). BCL1 polymorphism in exon 2 was identified using polymerase chain reaction with subsequent analysis of restriction fragment length polymorphism by Fleury I. et al. (venous blood was used as the material for the study). Statistical analysis was performed using SPSS–17 program.
Results: It was revealed that 76 (47.2%) patients had isolated RA (group I), while 85 (52.8%) individuals had RA with concomitant IHD (group II). In group I, there were 29 (38.2%) patients with C/C genotype, 39 (51.3%) – with C/G genotype, and 8 (10.5%) – with G/G genotype. The distribution in group I was as following: 16 were homozygous for the C allele (18.8%), 40 were heterozygous (47.1%) and 29 were homozygous for the G allele (34.1%) (χ^2=15.23; p=0.02). It was established that the risk of ischemic heart disease was 6.57 times higher in homozygotes for the G allele (OR=6.57; 95% CI=2.44−17.73; p=0.001) as compared with homozygotes for the C allele.
Conclusions: It was established that G/G genotype prevailed in RA patients with ischemic heart disease, while C/C genotype prevailed in patients with isolated RA. The risk of IHD development in patients with RA was associated with G/G genotype for Bcl1 polymorphism in the GR gene.

SAT0137 BONE MINERAL DENSITY MEASUREMENT INTERVALS FOR SEROPOSITIVE RHEUMATOID ARTHRITIS PATIENTS NOT TREATED FOR OSTEOPOROSIS

W. Park, K.-H. Jung, S.-R. Kwon, M.-J. Lim, S.-G. Park, M.-J. Jo. *In-Ha University Hospital, Incheon, Korea, Republic Of*

Background: Osteoporosis occurs more frequently in rheumatoid arthritis (RA) patients than in healthy individuals. However the appropriate interval for the bone mineral density (BMD) measurement in RA patients is not well established.
Objectives: This study investigated the effective BMD measurement interval and the risk factors associated with the development of osteoporosis for RA patients.
Methods: A retrospective study was performed on 511 RA patients aged more than 40 years old who had undergone BMD (DXA, GE LUNAR PRODIGY ADVANCE) testing more than once and who had normal BMD or osteopenia at the baseline BMD test and no history of any fracture of the spine or femur. The subjects were categorized into four subgroups: normal BMD (T-score > -1), mild (-1 ≥ T-score > -1.5), moderate (-1.5 ≥ T-score > -2), and advanced (-2 ≥ T-score > -2.5) osteopenia. The BMD testing interval was defined as the estimated time for 10% of the RA patients to make the transition into osteoporosis without osteoporotic fracture or the administration of any osteoporosis drug.
Results: The observation period was 2,214 patient-years, with an average of 4.3 years. The estimated BMD testing interval was more than 10 years for normal, 4.3 years for mild, 2.5 years for moderate, and 1.5 years for advanced osteopenia in each of the RA patient groups.
Conclusions: Our study indicated that in normal or osteopenic RA groups, a baseline BMD T-score is the most important factor in estimating the interval in which osteoporosis is predicted to occur. In addition, we recommend that the BMD measuring interval should be greater than 10 years in normal BMD RA

Table 1. Interval between baseline BMD testing and the development of osteoporosis

Baseline BMD	Mean interval to develop osteoporosis (year)		Mean interval to develop osteoporosis in 10% of each group (year)	
	Lumbar spine	Femur neck	Lumbar spine	Femur neck
Normal	9.4 (9.29–9.49)[a]	9.4 (9.25–9.53)[a]	>10	>10
Mild osteopenia	9.2 (8.58–9.71)[a]	9.1 (8.94–9.22)[a]	4.3	>10
Moderate osteopenia	7.9 (6.94–8.76)[a]	9.4 (8.93–9.87)[a]	2.5	7.5
Advanced osteopenia	5.4 (4.61–6.21)[a]	8.6 (7.68–9.50)[a]	1.5	2.2

BMD, bone mineral density. [a]Mean (95% confidence interval).

patients, 4 years in mild, 2 years in moderate, and 1 year in advanced osteopenic RA patients on the basis of L-spine BMD.

SAT0138 OPTIMIZING TARGETED THERAPY: CAN PROMS FILL THE GAP BETWEEN PATIENTS- AND PHYSICIAN- PERCEIVED REMISSION IN RHEUMATOID ARTHRITIS

Y. El Miedany[1], M. El Gaafary[2], N. El Arousi[3], S.S. Youssef[3], D. Palmer[4].
[1]Rheumatology, Darent Valley Hospital, Dartford, United Kingdom; [2]Community and Public health; [3]Rheumatology and Rehabilitation, Ain Shams University, Cairo, Egypt; [4]Rheumatology, North Middlesex University Hospital, London, United Kingdom

Objectives: 1. To compare the patient perspective on remission in RA in comparison to the rheumatologist perceived remission perspectives.
2. To determine the value of Patient Reported outcomes in identifying specific symptoms and aspects of disease able to define remission in RA from the patient perspective.
Methods: RA patients diagnosed according to ACR/EULAR criteria were treated according to treat-to-target regime with regular disease activity monitoring (every 1–3months). Remission was measured in two ways: 1) patient perceived remission using the question "Would you say that, at this moment, your disease activity is as good as gone? (yes/no)"; and 2) Physician perceived remission was defined as a physician global assessment ≤1 on a 0–10 VAS, phrased: "How active do you think the rheumatoid arthritis of your patient is today?" The study included 188 RA patients (76 males, 112 females; mean age 52.4±11 years) and 87 rheumatologists (30 males, 57 females; mean age 48.7±11.7 years). All participants were asked to complete a questionnaire which was composed of all domains identified in relation to the disease remission. 10 cm visual analogue scale (scored 0–10) was used to illustrate the importance of each factor in an individual opinion. The list included joint pain, functional ability, quality of life, absence of morning stiffness, absence of fatigue, normal laboratory tests, no comorbidity risk, radiologic remission, Disease Activity score and ability to work. In addition, patients were asked to complete a copy of the PROMs [1]. One-way analysis of variance was used for the comparison of independent variables. Spearman correlation coefficient was used to assess the correlation between variables.
Results: There were no significant differences in questionnaire answers in relation to patients' demographics and present disease activity. Regarding the patient perceived remission, the top 4 were: pain (76%), functional ability (71%), quality of life (69%) and fatigue (43%). Regarding the physician perceived remission, the following factors were rated more relevant by rheumatologists than the patients ($p<0.001$): low disease activity score (88%), radiologic remission and progression of erosions (76%), lab measures (ESR/CRP) (57%) followed by difficulties in performing paid work (49%).
Functional ability was scored significantly higher in patients >65 as compared with patients <65 years of age (9.6 vs 8.1 on VAS, p=0.03). In contrast the patient's cohort <65 years of age, rated quality of life at a higher level (9.7) than those below 65 (8.4). Functional ability was scored higher in patients with longer-standing disease as compared to patients with shorter disease duration ($p<0.05$). PROMs enabled the patient and the treating physician identify the aspects of relevance necessary for optimal clinical management.
Conclusions: Different factors are important for rheumatologists and RA patients regarding disease remission. Treatment satisfaction is determined not only by disease activity indices but also by other patient-oriented factors. PROMs could optimise targeted therapy as it can play a significant role in identifying disease activity parameters relevant to both the treating rheumatologist as well as the patient.

SAT0139 ASSESSING ENTHESITIS BY ULTRASONOGRAPHY IN PATIENTS WITH SERONEGATIVE RHEUMATOID ARTHRITIS

Z. Erturk[1], T. Özsoy[2], I. Yağcı[2], Y. Yalçınkaya[1], Ü. Gazel[1], P. Atagündüz[1], H. Direskeneli[1], N. İnanç[1]. *[1]Rheumatology; [2]Physical Therapy and Rehabilitation, Marmara University, Istanbul, Turkey*

Background: In patients with seronegative rheumatoid arthritis (RA) there is a difficulty to make the differential diagnosis with the spondyloarthropathies.
Objectives: To assess the presence of enthesitis in patients with seronegative rheumatoid arthritis in comparison with the healthy controls, patients with seropositive rheumatoid arthritis and ankylosing spondylitis.
Methods: In this cross-sectional study, seronegative and seropositive rheumatoid arthritis patients, who fulfilled the 2010 ACR/EULAR criteria, patients with ankylosing spondylitis and healthy controls have been assessed by grey scale and power doppler ultrasonography for the presence of enthesopathy at the achilles, plantar fascia, proximal patella, distal patella, quadriceps, tibialis anterior, triceps, common flexor and extensor tendons. Clinical assessment of the patient groups included demographic findings, health assessment questionnaire and disease activity score.
Results: In our study, we recruited age and sex matched 27 seronegative RA, 17 healthy controls, 20 seropositive RA and 12 ankylosing spondylitis patients. We evaluated and analysed both right and left sides of the enthesis regions separately which have been indicated in the methods section. The mean DAS28, mean ESR and mean CRP of the patients with seronegative RA were 3.6±1.28, 32.2±21.2 and 12.37±27.77 respectively (Table 1).
Median of Madrid sonographic enthesitis index (MASEI) was 5 in patients with seronegative RA. 4 patients have severe scores. There were significant differences between seronegative RA and healthy controls (3, p=0.014) but no differences has been observed between seronegative RA with seropositive RA (6) and anklosing spondylitis (7) in MASEI scores.
In comparison, hypoechogenicity of quadriceps tendon (16 (29.6%) vs 1 (2.5%), p=0.001), bone erosion at the quadriceps tendon attachment (9 (16.6%) vs 0, p=0.007), hypoechogenicity of triseps (13 (24%) vs 7 (17.5%), p=0.049) have been observed more frequently in patients with seronegative RA than seropositive RA. Significantly higher number of patients with bone erosion at the distal patella (10 (41.6%) v 3 (5.5%), p= <0.001), enthesophyte of achilles tendon (7 (29.1%) vs 2 (3.7%), p=0.001) have been detected enthesophyte of proximal patella (7 (29.1%) vs 0, p≤0.001) in patients with ankylosing spondylitis than seronegative RA.

Table 1

	Seronegative RA	Healthy controls	Seropositive RA	Ankylosing spondylitis
Age, years	51,85±11,49	44,42±7,6	52,05±11,26	41,75±5,1
Women, n (%)	48 (88,9)	34 (100)	36 (90)	20 (83)
RA duration, year	9,8±6,75		11,25±9,1	
RF titre (median)	10,77±3,21		345,88±405,32	12,1±3,23
Anti-CCP titre, median	3,99±4,13		326, 81±286, 2	4,32±3,7
DAS28, median	3,6±1,28		3,73±1,45	
ESR, median	32,2±21,2	23,3±11,8	41,63±28,07	19,83±9,38
CRP, median	12,37±27,77	3,14±3,87	14,34±19,97	6,61±5,6

Conclusions: We observed that enthesis involvement was not seldom in patients with seronegative RA. Furthermore there were also similar frequency of entesis involvement in seropositive patients with RA. The value of enthesis sites evaluationfor the differential diagnosis of patients with seronegative RA should be further investigated and the assessment of enthesis sites in seronegative and seropositive RA patients can be important to detect active and chronic changes at the enthesis region.

Rheumatoid arthritis - anti-TNF therapy

SAT0140 EFFECT OF OBESITY IN RESPONSE TO BIOLOGICS IN RHEUMATOID ARTHRITIS

A. Khan[1], S. Sukumaran[2], M. Kanitkar[1], A.-S. Zafar[2], S. Shah[2], S. Adnan[2].
[1]Department of Rheumatology, Queen Elizabeth Queen Mother Hospital, Margate; [2]Department of Rheumatology, William Harvey Hospital, Ashford, United Kingdom

Background: Obesity epidemic has impacted practically every area of health including care of patients with RA. Adipose tissue is an active organ that produces pro-inflammatory molecules. A significant treatment challenge remains is the standard dose of RA medications may not attain same concentrations at sites of inflammation in obese vs non-obese patients thus making them less effective.
Objectives: The study aim was to determine whether obesity represents a risk factor for a poor remission in RA requiring biologic therapies. Obesity may be associated with more severe and refractory inflammation through increased levels of inflammatory adipocytokines leptin, resistin or visfatin or decreased levels of the anti-inflammatory adipocytokine adiponectin. We retrospectively analysed 178 patients diagnosed with RA at East Kent University Hospitals.
Methods: Data analysed for age, sex, disease duration, prior DMARD, positivity RF and anti-CCP antibodies and response to biologics DAS28 score pre-treatment and at 6 months were analysed.Main aim was to analyse any difference between obese and non-obese patients in terms of their response to treatment. Obese patients were defined with a BMI of 30 or above.
Results: See Table 1.

Table 1. Demographics and Baseline Characteristics

Variable	Category	Non-Obese (n=95)	Obese (n=83)	P-value
Sex	Female	61 (64%)	66 (80%)	**0.02**
	Male	34 (36%)	17 (20%)	
Age		53±12	50±13	0.08
Duration disease		8 [6, 11]	12 [7, 14]	**<0.001**
Rheumatoid factor	Negative	20 (21%)	60 (72%)	**<0.001**
	RF	12 (13%)	8 (10%)	
	CCP	17 (18%)	0 (0%)	
	RF/CCP	46 (48%)	15 (18%)	
CRP		35 [10, 51]	24 [7, 40]	**0.02**
ESR		37 [14, 59]	28 [17, 45]	0.57
MTX		15.5±9.2	13.5±9.6	0.15
Administration	Infusion	4 (4%)	5 (6%)	0.74
	Subcutaneous	91 (96%)	78 (94%)	
DAS pre-treatment		5.6±0.7	5.4±0.8	0.06

Results suggested that there were significant differences between two groups for sex, duration of disease, RF and CRP. There was also some evidence of difference between groups in terms of their age and pre-treatment DAS28 score but these differences were only of borderline statistical significance. There was smaller proportion of males in the obese group with 20% male compared to 36% of non-obese patients. Obese patients had on average a longer disease duration with a median of 12 years compared to a median of 8 years for the non-obese group. The RF status also varied between groups with a much higher proportion of patients in the negative category for the obese group. CRP values were significantly lower in the obese group with a median of 24 compared to 35 in the non-obese group.

Table 2. EULAR response between obese and non-obese patients

EULAR response	Non-Obese N (%)	Obese N (%)	P-value
No response	9 (9%)	32 (39%)	<0.001
Moderate response	40 (42%)	36 (43%)	
Good response	46 (48%)	15 (18%)	<0.001
	Non-Obese (n=95), Mean ± SD	Obese (n=83), Mean ± SD	
DAS28 post-treatment	3.2±1.0	4.2±1.3	
DAS28 reduction	2.4±1.3	1.1±1.3	

Non-obese had the best response with 48% good response compared to18% of the non-obese group with post treatment mean DAS28 score of 3.2 and mean reduction of 2.4.

Conclusions: Obesity is important factor that impacts treatment and outcome in RA. Future clinical studies to elucidate the pharmacokinetics of specific biologic agents in relation to BMI should provide further clinical guidance.

SAT0141 OPTIMAL CIRCULATING ADALIMUMAB LEVELS RANGE ASSOCIATED WITH GOOD CLINICAL RESPONSE IN RHEUMATOID ARTHRITIS PATIENTS

A. Jochems[1], A. Martinez-Feito[1], C. Plasencia[1], B. Hernández-Breijo[1], A. Mezcúa[2], A. Villalba[1], I. Monjo[1], P. Nozal[2], A. Balsa[1], M.D. Pascual-Salcedo[1]. *[1]Immuno-Rheumatology Research Group; [2]Immunology Unit, University Hospital la Paz, Madrid, Spain*

Background: TNF inhibitors have become an important part of healthcare worldwide for inflammatory diseases such as RA[1]. Many publications show that responding patients have higher Adalimumab (Ada) serum trough levels (ATL) than non-responders. These factors are influenced by age, weight, gender or pharmacokinetics, which in turn depend on immunogenicity. Concomitant use of immunomodulators such as methotrexate (MTX) reduces immunogenicity and enhances therapy benefits[1,3].Increasing drug dosage in patients with less response is the standard practice, while lowering dosage is advisable in patients achieving remission. Many recent publications[2] assess serum trough levels that reflect optimal response and which could be used as benchmark for guidance to implement the Therapeutic Drug Monitoring.

Objectives: To establish an optimal Ada serum trough level (ATL) range in RA patients associated with good clinical response.

Methods: A prospective observational study with 40 RA patients under Ada treatment recruited in the Rheumatology Unit of Universitary Hospital La Paz was conducted. Demographic data, ATL and clinical activity of patients treated with 40 mg/kg every other week from 4 months up to 12 years of treatment were collected. A total of 206 samples were analyzed [χ=5 (3–13) samples/patient]. Disease activity was assessed using the DAS28 index and clinical improvement with $\triangle$DAS28. ATL were measured with a capture ELISA[3] [correlation with Promonitor (Derio, Vizcaya, Spain) k=1, r=0.91; and with Sanquin (Amsterdam, The Netherlands) k=1, r=0.86] and statistical analysis were performed with GraphPadPrism 5.0 software.

Results: Demographic data of our cohort were: mean age (±SD) 56.75±16.06, with 82.5% of females and 45% of patients treated with concomitant MTX. Sixty-five and 72% of patients were RF and ACPA positive, respectively. ATL were similar in patients treated with concomitant MTX (χ=3.82±2.42 μg/ml) or Ada monotherapy (χ=3.54±2.43 μg/ml) p=0.81.

Consistent with previous studies[1,2], low-disease activity patients (DAS28$\leq$3.2) presented higher Ada circulating levels than patients with high-disease activity [3.7 μg/ml (IQR 2.97–5.48) vs. 1.71 μg/ml (IQR 0.23–4.51), p=0.01]. The median of Ada levels excluding the values (n=6) that showed immunogenicity was 3.42 μg/ml (IQR 1.55–5.03) where 3.50 μg/ml represented the most frequent value (15% of patients). Lack of clinical improvement ($\triangle$DAS$<$1.2) was linked to drug levels below percentile 25 (p=0.04) whilst Ada levels above percentile 75 did not ensure more clinical improvement (p=0.7) than the values around the median.

Conclusions: ATL correlate with the disease activity and with the clinical improvement. The optimal range associated with good therapeutic response after the standard dose is *1.5–5 μg/ml*. Higher circulating drug levels do not entail better response, which indicates they could be unnecessary. The knowledge of the optimal drug ranges can guide the Personalized Drug Therapy in order to maximise effectiveness and minimise costs.

SAT0142 PREDICTORS OF INADEQUATE RESPONSE AND RAPID RADIOGRAPHIC PROGRESSION IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS RECEIVING METHOTREXATE: A POST HOC ANALYSIS OF 2 RANDOMIZED, CONTROLLED TRIALS OF ADALIMUMAB

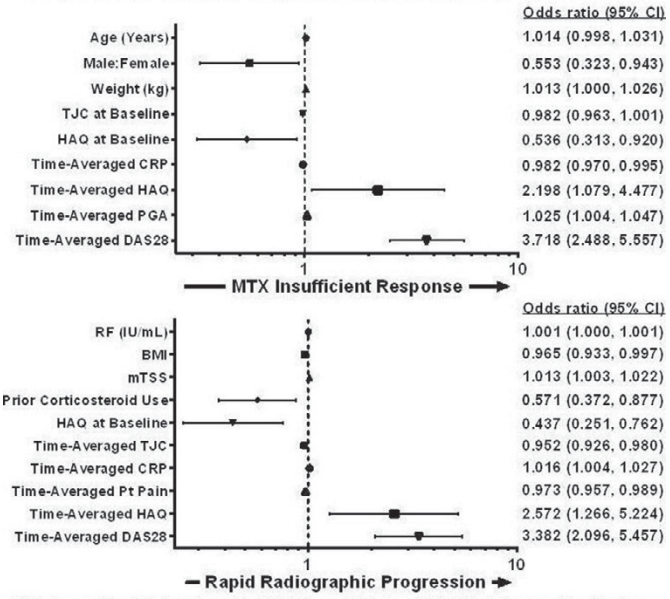
A. Kavanaugh[1], R.F. van Vollenhoven[2], B.A. Wolfe[3], S. Florentinus[3], S. Chen[3], J.L. Subotícki[3], J.S. Smolen[4]. *[1]Division of Rheumatology, Allergy, and Immunology, University of California, San Diego, la Jolla, United States; [2]Amsterdam Rheumatology and Immunology Center ARC, Amsterdam, Netherlands; [3]AbbVie Inc., North Chicago, United States; [4]Medical University of Vienna, Vienna, Austria*

Background: Methotrexate (MTX) is recommended as first-line therapy in patients (pts) with rheumatoid arthritis (RA).[1] However, information is limited regarding factors that may predict a poor response to MTX.

Objectives: To identify predictors of MTX insufficient response (IR) and rapid radiographic progression (RRP) among pts with early RA receiving 6 months (mos) of MTX therapy.

Methods: In OPTIMA, pts with RA $<$1 year were randomized to receive either adalimumab (ADA) 40 mg every other wk (EOW) + MTX weekly (wkly) or placebo (PBO) EOW + MTX wkly for 26 wks. In PREMIER, pts with RA $<$3 years were randomized to receive ADA 40 mg EOW + MTX wkly, ADA 40 mg EOW + PBO wkly, or PBO EOW + MTX wkly for 2 years. This post hoc analysis compared MTX-IR pts, defined as not reaching stable low disease activity at wks 22 and 26 in OPTIMA and wks 20 and 24 in PREMIER, with pts who responded to initial MTX monotherapy. Comparisons were also made between pts who did and did not have RRP, assessed by an increase in modified Total Sharp Score (mTSS) of $>$1.5 from baseline (BL) to 6 mos. In pts with available data, backward logistic regression was used to identify potential predictors of MTX-IR and RRP. Candidate predictors included BL demographics, time-averaged disease parameters for 3 time intervals (through 4 wks, 8 wks, and 12 wks of MTX exposure), and BL disease characteristics for the 12-wk interval. Time-averaged variables were calculated as area under the curve standardized for length of time interval.

Results: This analysis included 525 MTX-IR and 162 MTX responders. Mean disease duration at BL was 6 mo for both groups. The mean Disease Activity Score 28 (C-reactive protein; DAS28[CRP]) was 6.2 vs 5.6, Health Assessment Questionnaire Disability Index (HAQ-DI) was 1.6 vs 1.3, and mTSS was 15.5 vs 12.2 for MTX-IR vs MTX responders, respectively. 171 pts experienced RRP, while 499 pts had no RRP; the mean disease duration at BL was 6 mo for both groups. The mean DAS28(CRP) was 6.4 vs 6.0 and HAQ-DI was 1.6 vs 1.5 for pts experiencing RRP vs pts who did not experience RRP, respectively. Mean mTSS at BL was higher for pts who experienced RRP (20.7) vs those who did not (12.4). Predictors of MTX-IR and RRP at 6 mos are shown in the Figure. Time-averaged HAQ-DI and DAS28(CRP) through 12 wks were the strongest predictors of both MTX-IR and RRP. Additionally, early clinical response (time-averaged DAS28[CRP]) at both 4 and 8 wks was predictive of both MTX-IR and RRP; however, time-averaged HAQ-DI was not predictive until wk 12.



Conclusions: In the OPTIMA and PREMIER trials, post-BL measures of RA activity appeared to be the strongest predictors of subsequent MTX-IR and of RRP. Pts who are likely to progress on MTX or have RRP may be good candidates for switching to earlier step-up therapy to reduce the likelihood of permanent bone damage.

SAT0143 COMPARISON OF TREATMENT WITH GOLIMUMAB AND CERTOLIZUMAB-PEGOL IN ARTHRITIS- RESULTS FROM THE SOUTH SWEDISH ARTHRITIS TREATMENT GROUP (SSATG) REGISTER

C. Roseman, E. Lindqvist, P. Geborek, M. Crnkic Kapetanovic. *Section of Rheumatology, Lund University, Department of Clinical Sciences Lund, Skåne University Hospital, Lund, Sweden*

Background: "Head to head" studies comparing the efficacy and tolerability of different TNF inhibitors are scarce, in particular the comparison between certolizumab pegol and golimumab.
Objectives: To compare the efficaciousness, drug survival and tolerability of certolizumab-pegol and golimumab in adult patients with establish arthritis (RA, JIA, SpA or unspecified polyarthritis) starting these treatments between February 2010 and December 2013 at out-patient unit at the Skåne University Hospital, Department of Rheumatology Lund/Malmö and two associated private rheumatology units.
Methods: All patients starting treatment with biologics were consecutively included in the South Swedish Arthritis Treatment Group (SSATG) register and regularly followed up according the standard protocol including: SJC/TJC, CRP, ESR, physicians global assessment of disease activity, patients' assessment of disease activity and pain (VAS global and VAS pain) and HAQ. Last follow up date was October 17th 2016. Kaplan-Meier survival analysis was used to estimate the drug survival. Possible predictors of drug survival were analysed using Cox regression model.
Results: In total, 352 patients (71% women, mean age 51 years, mean disease duration 12 years, started these treatments during study period. Of these, 168 received golimumab and 184 certulizumab-pegol. Mean treatment time was 31 months (range 0–77). Percentage of patients with RA, SpA, JIA and unspecified arthritis were 58,4%, 16,4%, 5,7%, and 19,5% respectively. Certolizumab-pegol was more used in RA (67% vs 49%) and JIA (8% vs 2%) while golimumab was more frequent among patients with SpA (21% and 12%) or PsA (23% and 10, respectively). Only 7% of golimumab and 10% of certulizumab-pegol patients received these drugs as first biologic treatment and approximately 50% of patients received these drugs as $\geq$3. biological treatment.
In golimumab treated patients mean DAS28 decreased from 4,3 (baseline) to 3,3 (3 months); 2,8 (6 months) and 2,7 (12 months) but levelled off at 36 months follow up. Corresponding mean DAS28 levels in certulizumab-pegol treated patients were 4,6 (baseline); 3,2 (3 months); 2,8 (6 months) and 2,6 (12 months). The similar pattern was seen in changes in HAQ and CDAI over the study time. There were no statistically significant differences in DAS, HAQ or CDAI between treatments at any follow up visit. At the end of follow up 64 (38%) of golimumab and 60 (32%) of certulizumab-pegol patients remained on their treatment. No significant difference in drug survival was seen between the treatments (Figure). Patients with spondylartropathy had significantly better survival on golimumab compared to RA patients (p=0,005)whicih remained after adjustment for age, gender, CRP, number of previous biologics and concomitnt methotrexate at baseline.

Conclusions: Spondylarthropathy including psoriatic arthritis was associated with better drug survival on golimunab compared to certolizumab pegol. No other significant differences in efficacy, tolerability or drug survival were seen between golimumab and certolizumab pegol in patients with established arthritis in daily clinical practice. Approximately one third of patients starting these treatments remained on treatment after 3 years.

SAT0144 TUMOR NECROSIS FACTOR-ALPHA INHIBITORS AND PSYCHIATRIC SIDE EFFECTS: RESULTS FROM THE FRENCH PHARMACOVIGILANCE DATABASE

C.M. Yelnik[1], L. Gaboriau[2], N. Petitpain[3], H. Théophile[4], C. Scalbert[5], E. Delaporte[5], S. Gautier[2], M. Lambert[1]. *[1]Internal Medicine Department, University of Lille, UFR Medicine, Universitary Hospital Center of Lille; [2]Regional Pharmacovigilance center of Hauts-de-France, Lille; [3]Regional Pharmacovigilance center of Lorraine, Nancy; [4]Universitary Hospital Center of Bordeaux, Regional pharmacovigilance center of Bordeaux, Bordeaux; [5]Dermatology department, University of Lille, UFR Medicine, Universitary Hospital Center of Lille, Lille, France*

Background: Although Tumor Necosis Factor alpha (TNF-α) is a major proinflammatory cytokine in the brain, potential psychiatric side effects of TNF-α inhibitors have been little investigated. Manic and psychotic disorders are not recognized as TNF-α inhibitors' side effects even though few reports of such complications have been reported.
Objectives: This study reports cases with psychiatric symptoms (in the spectrum of psychotic and manic disorders) that occur during treatment with tumor necrosis factor alpha (TNF-α) inhibitors and aims to evaluate the role of these agents as causative factors.
Methods: We searched the French Pharmocovigilance Database for consecutive cases of positive psychiatric side effects reported during treatment with TNF-α inhibitors. Major psychiatric symptoms were defined, according to DSM-V, as mania and psychosis, and minor psychiatric symptoms as psychomotor agitation, euphoria, hallucinations, personality distortion, and increased libido. Each case had one major symptom or at least one minor symptom.
Results: Among 7912 consecutive cases of side effects registered in the database for TNF-α inhibitors, 184 reported psychiatric symptoms, and of these, 71 met inclusion criteria, whereas 113 met an exclusion criterion. Depression was the most frequent cause for exclusion. TNF-α inhibitors were the only medication suspected in 56 cases (79%). The time between beginning TNF-α inhibitors and onset of symptoms varied from hours to months with a median time of 49 days (IQR=156); initial symptoms mostly worsened under treatment. TNF-α inhibitors were withdrawn in 42 (61%) cases. The improvement of symptoms was significantly associated with treatment withdrawal (78% versus 22%, *p=0.01*). Relapses occurred after rechallenge of TNF-α inhibitors in three of four patients.
Conclusions: We report the first cohort of 71 cases with psychiatric symptoms in the spectrum of manic and psychotic disorders during treatment with TNF-α inhibitors. Our experience suggests that anti-TNFα therapy may cause manic or psychotic side effects.
Disclosure of Interest: None declared

Table 1. Description of psychiatric symptoms registered in the database for TNF-α inhibitors

Characteristics	Patients (Total = 71)
Major psychiatric symptoms:	11 (15%)
– Manic episode	8 (11%)
– Acute psychosis	3 (4%)
Minor psychiatric symptoms:	60 (85%)
– Anxiety/Nervousness	10 (14%)/6 (8%)
– Insomnia or decreased need for sleep	31 (44%)
– Psychomotor agitation/Aggressiveness	6 (8%)/8 (11%)
– Hallucinations	7 (10%)
– Libido exacerbation	2 (3%)
– Euphoria, grandiosity	4 (6%)
– Derealization, depersonalization	3 (4%)
Psychiatric side effect improved:	45 (63%)
– TNF-α Inhibitors withdrawn	32 (45%)
– TNF-α Inhibitors not withdrawn	9 (13%)
– Missing data	4 (6%)
Psychiatric side effect did not improved:	16 (22%)
– TNF-α Inhibitors withdrawn	8 (11%)
– TNF-α Inhibitors not withdrawn	4 (6%)
– Missing data	3 (4%)
Missing data improved/not improved	10 (14%)

SAT0145 INFLUENCE OF BODY MASS INDEX (BMI) ON THE DISEASE INFLAMMATORY ACTIVITY AND TREATMENT REPONSE IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Villalba Yllan[1], V. Navarro Compan[1], C. Plasencia Rodriguez[1], D. Peiteado Lopez[1], G. Bonilla Hernan[1], L. Nuño Nuño[1], A. Martinez Feito[2], D. Pascual-Salcedo[2], C. Diego[2], A. Balsa Criado[1]. *[1]Rheumatology; [2]Immunology, Hospital Universitario la Paz, Madrid, Spain*

Background: The use of biological therapy (BT) in rheumatoid arthritis (RA) has supposes a very important change in the disease's treatment and prognosis. Drugs like Anti-TNFα have proven unquestionable effectiveness. However, the lack or loss of such effectiveness over time raises the dilemma of what factors may influence it. There are studies that suggest the influence of BMI on the efficacy of these drugs and therefore on the control of the disease.
Objectives: To determine the influence of BMI on disease activity and response to treatment with infliximab (ifx) in patients with RA.
Methods: A retrospective observational study of a population of 76 patients with RA who received infliximab treatment, in a standard guideline of 3 mg/kg, in our service between 2000 and 2016 inclusive. The BMI was classified for some sub-studies in four categories: low (<18.5), normal (=18.5- <25), overweight (=25- <30) and obesity (=30). Disease activity was determined by DAS28 at three times: at baseline, at 6 months and at the year of infliximab treatment; Response to treatment was assessed by deltaDAS28 and EULAR response at 6 months and 1 year of treatment. The EULAR response was classified into two categories: "yes" (DeltaDAS28>1.2, or>0.6 and DAS28 <5.1) and "no" (DeltaDAS28 <.6, or <5.1). First, activity and response rates to treatment were compared in these four groups over the three periods. A regression analysis was then performed for BMI and both activity and response to treatment.
Results: Characteristics of the 76 patients included in the study when initiating IFX therapy were: 66 (86.8%) were women, median (range) age 54 (21–83) years, 77,% RF+, 81% ACPA+, disease duration 10,8 (1,0–39,0) years, 59% with concomitant methotrexate and 55% with other DMARDs. Median (range) BMI was 25,5 (16,7–40,2) kg/m^2. According to BMI, patients with underweight, normal, overweight and obesity were 0 (0,0%), 41 (53,9%), 22 (28,9%) and 13 (17,2%), respectively. The association between BMI and disease activity (median DAS28 (p25-p75)) is shown in Table 1:

Table 1

	Normal	Overweight	Obesity
DAS28 bas	5,63 (4–84–6,30)	5,44 (4,45–6,73)	6,25 (4,42–7,07)
DAS28 6m	3,90 (2,89–5-12)	3,97 (3,32–5,43)	4,80 (3,35–5,72)
DAS28 1y	3,91 (2,89–5,01)	3,69 (2,97–5,29)	4,48 (2,70–5,87)

The association between BMI and treatment response (median deltaDAS28 (p25-p75) and EULAR response (%)) is shown in Table 2:

Table 2

	Normal	Overweight	Obesity	*p*
ΔDAS28				
ΔDAS28 0–6m	1,72 (0,84–2,77)	1,39 (0,38–2,49)	0,77 (0,40–1,59)	*0,2*
ΔDAS28 0–1y	1,56 (0,81–2,74)	1,77 (,092–2,92)	1,20 (0,73–1,90)	*0,2*
EULAR response 6m	70,7	68,2	30,8	*0,065*
EULAR response 1y	61,0	54,5	61,5	*0,065*

In the longitudinal analysis, a trending but not statistically significant relationship between adjusted BMI and DAS28 was observed at six month and at one year of treatment onset: β: 0,051; 95% CI (-0,06 to 0,109) and β: 0,037; 95% CI (-0,022 to 0,097)

Conclusions: BMI seems to influence, in a non significantly manner, in disease activity and in treatment response in RA treated with infliximab. Obesity BMI values are associated with increased activity and a lower response to this treatment than lower BMI values.
Disclosure of Interest: None declared

SAT0146 RANDOMISED DOUBLE-BLIND STUDY SHOWS COMPARABLE LONG-TERM EFFICACY AND SAFETY BETWEEN RITUXIMAB BIOSIMILAR CT-P10 AND INNOVATOR RITUXIMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS: 48-WEEK RESULTS

C.-H. Suh[1], E. Chalouhi El Khouri[2], P. Miranda[3], F. F Cons Molina[4], P. Shesternya[5], F. Medina-Rodriguez[6], P. Wiland[7], S. Jeka[8], J. Chavez-Corrales[9], T. Linde[10], P. Hrycaj[11], I. Hospodarskyy[12], M. Abello-Banfi[13], J. Jaworski[14], M. Piotrowski[15], W. Park[16], S.C. Shim[17], S.J. Lee[18], S.Y. Lee[18], D.H. Yoo[19]. *[1]Ajou University School of Medicine, Suwon, Korea, Republic Of; [2]Clinica Internacional, Lima, Peru; [3]Centro de Estudios Reumatológicos, Santiago, Chile; [4]Centro de Investigacion en Artritis y Osteoporosis, Mexicali, Mexico; [5]KrasSMU, Krasnoyarsk, Russian Federation; [6]Biologics Especializados SA, Mexico City, Mexico; [7]Medical University, Wroclaw; [8]2nd University Hospital, CM UMK, Bydgoszcz, Poland; [9]Clinica San Borja, Lima, Peru; [10]Rheumatology Medical Center, Halle/Saale, Germany; [11]Poznañ University of Medical Sciences, Poznañ, Poland; [12]Ternopil Medical University, Ternopil, Ukraine; [13]Centro Integral de Reumatologia del Caribe, Barranquilla, Colombia; [14]Reumatika - Centrum Reumatologii, Warszawa; [15]Medical University of Lublin, Lublin, Poland; [16]IN-HA University, School of Medicine, Incheon; [17]Chungnam National University Hospital, Daejeon; [18]Celltrion, Inc., Incheon; [19]Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Republic Of*

Background: In phase 1 trials (NCT01534884 and NCT01873443), pharmacokinetic equivalence of CT-P10, biosimilar of rituximab, to innovator rituximab (RTX) was demonstrated. In the phase 3 study, equivalence of PK and efficacy up to week 24 were achieved between CT-P10 and RTX (US and EU sourced)[1,2].
Objectives: To investigate the long-term efficacy, pharmacodynamics, immunogenicity and safety of CT-P10 up to week 48.
Methods: Patients with rheumatoid arthritis were randomly assigned to CT-P10, US-RTX or EU-RTX, in combination with MTX. The patients received 2 treatment courses at Week 0 and 24, each consisting of 2 infusions of 1000mg study drug at 2-week interval.
Results: A total of 372 patients were randomised, and 330 patients completed the 2nd course treatment. DAS28 scores through Week 48 were comparable between CT-P10 and US/EU-RTX (Figure), as well as the proportion of ACR responses at Week 48 between the CT-P10 and combined rituximab groups; 81.3% and 79.8% for ACR 20, 55.4% and 53.9% for ACR50, and 31.7% and 33.7% for ACR 70, respectively.

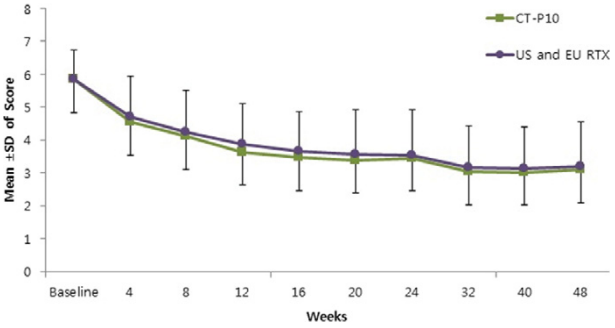

Figure 1. Efficacy Results – DAS28.

B-cell depletion was comparable from after the 1st infusion and up to Week 48. Number (%) of patients with positive anti-drug antibodies in the CT-P10, US-RTX, and EU-RTX was 7 (4.9), 13 (9.4), and 5 (8.6), respectively at Week 48.
The safety profile was also similar across groups (Table).

Table 1. Summary of Safety Profile [n (%)]

	CT-P10 (N=161)	US-RTX (N=151)	EU-RTX (N=60)	Reference Products (US-RTX + EU-RTX) (N=211)
AE	122 (75.8)	96 (63.6)	37 (61.7)	133 (63.0)
Serious Adverse Event	13 (8.1)	14 (9.3)	2 (3.3)	16 (7.6)
Infection	61 (37.9)	53 (35.1)	17 (28.3)	70 (33.2)
Serious infection	2 (1.2)	3 (2.0)	0	3 (1.4)
Infusion related reaction (IRR)*	33 (20.5)	12 (7.9)	13 (21.7)	25 (11.8)
Malignancy	0	2 (1.3)	1 (1.7)	3 (1.4)
Progressive multifocal leukoencephalopathy	0	0	0	0

*None of IRR were serious or led to study drug discontinuation.

Conclusions: This phase 3 randomised controlled trial demonstrated the comparability of CT-P10 with two rituximab in terms of efficacy, pharmacodynamics, immunogenicity and safety for 1 year.

SAT0147 SERUM LEVELS OF THE ANTI-TNF BIOLOGICS CORRELATE WITH CLINICAL EFFICACY IN PATIENTS WITH INFLAMMATORY ARTHRITIS

C.C. Mok[1], B. Fong[1], L.Y. Ho[1], C.H. To[2]. [1]*Medicine, Tuen Mun Hospital;* [2]*Medicine, Pok Oi Hospital, HK, Hong Kong*

Objectives: To study the correlation between levels of the anti-TNF biologics and clinical efficacy in patients with inflammatory arthritis

Methods: Adult patients who fulfilled the criteria for rheumatoid arthritis (RA), spondyloarthritis (SpA) and psoriatic arthritis (PSA) and were commenced on standard doses of the anti-TNF biologics were recruited. Serum samples saved at baseline, month 6 and 12 were assayed for the trough levels of the biologics (± anti-drug antibodies) retrospectively. Patients were followed longitudinally and efficacy analyses were conducted at 3-month intervals without the knowledge of the drug levels. Biologics would be discontinued from 6 months onwards according to protocol-based improvement criteria for each disease. Clinical efficacy of the anti-TNF biologics was compared among patients with different levels of the drug by statistical methods.

Results: 112 patients were studied (58 RA, age 51.2±10.9 years, disease duration 72.9±67 months; 41 SpA, age 39.1±9.9 years, disease duration 74.3±81.6 months; 13 PSA, age 53.5±10.7 years, disease duration 44.3±35.4 years). The number of patients treated with infliximab (IFX), adalimumab (ADM), golimumab (GLM) and etanercept was 3, 31, 36 and 42, respectively. At month 12, neutralizing antibodies against IFX, ADM and GLM were present in 2 (67%), 14 (45%) and 1 (3%) of the patients, respectively. In ADM users, the drug level was significantly lower in those with antibodies than those without (1.81±2.63 vs 8.02±4.14 ug/ml; $p<0.001$). Antibody titer against ADM correlated negatively with the levels of ADM (Rho -0.72; $p<0.001$). Patients were stratified arbitrarily into 3 groups for each biologic according to the trough levels of the drugs. Low drug concentrations were defined as levels $\leq$1.30 ug/ml, 0.05 ug/ml and 0.60 ug/ml in ADM, ETN and GLM users, respectively. In patients with RA/PSA (N=71), patients with the lowest anti-TNF drug level group (N=30) had a non-significant trend of less improvement in DAS28, CDAI scores at month 12 when compared to others (N=41). However, significantly more patients withdrew treatment due to inefficacy at month 12 in this group compared to others (67% vs 7.3%, $p<0.001$). In patients with SpA (N=41), patients with lowest anti-TNF drug levels stratum (N=9) had significantly less improvement in ASDAS compared with others at month 12 (N=32) (-0.57±0.63 vs -1.93±1.28; p=0.003). The proportion of patients who achieved an ASAS20 response was also significantly lower in this group of patients (33% vs 75%; p=0.04). In all the 112 patients studied, the cumulative withdrawal rate of the anti-TNF biologics at month 12 (by Kaplan-Meier's analysis) was significantly higher in those with low drug levels when compared to others (26.1% vs 54.6%; $p<0.001$ by log rank test).

Conclusions: The presence of neutralizing antibodies to the anti-TNF monoclonals is associated with lower trough levels of the drugs. Trough level of the anti-TNF biologics is useful for optimizing the clinical efficacy of the drugs in patients with inflammatory arthritis.

SAT0148 RABBIT RISK SCORE FOR SERIOUS INFECTIONS IN A ROMANIAN COHORT OF RHEUMATOID ATHRITIS TREATED WITH BIOLOGICS

C. Ancuta[1,2], C. Pomirleanu[1,2], R. Maxim[2], L. Petrariu[2], G. Strugariu[2], E. Ancuta[3], R. Chirieac[4]. [1]*University of Medicine and Pharmacy Grigore T Popa Iasi;* [2]*Rheumatology 2, Clinical Rehabilitation Hospital;* [3]*Research Dept., Elena Doamna Clinical Hospital;* [4]*Sanocare Medical & Research Center, IASI, Romania*

Background: The risk of infections, especially severe infections (SI), remains of particular interest in rheumatoid arthritis (RA), both defective immune response and therapeutic immunosuppression being responsible.

The RABBIT Risk Score (RRS), an instrument developed and validated for RA in the German Biologics Register RABBIT and replicated in other RA settings (British Register), allows the estimation of SI occurring during 12 months according to patient characteristics, based on data from similar risk profiles.

Objectives: To evaluate the RSS reliability in a Romanian RA cohort under different biologics, considering the agreement between observed and expected rates of SI at 12 months.

Methods: Longitudinal study on 272 consecutive RA with moderate-to-severe active disease, starting their biologic according to local guidelines, enrolled between 2008 and 2016 in a single academic center.

Along with disease activity and therapeutic response, baseline RRS (http://www.biologika-register.de/en/home/risk-score/) was applied for each case, based on multiple risk factors for infections including age, functional status, chronic lung and renal comorbidities, previous SI, number of treatment failures, current biologic (TNF or non-TNF inhibitors), mean corticosteroid dose.

The predictive value of RRS was considered by comparing the number and rate of expected versus reported SI in the first year of biologics (ROC curve, $p<0.05$), assessing the number of adverse events per year and per 100 patient-years, cases with at least one infection.

Statistical analysis (univariate, multivariate) was stratified according to different predictors of infection, patients being classified in two groups based on their recruitment before (2008–2012) and after (2013 up to date) implementation of national biologic register RRBR.

Results: The performance of RSS was previously established in a pilot study on 181 RA. Currently, the RSS was considered in 144 RA recruited to the first group and 128 to the second. The prescription pattern significantly changed ($p<0.05$) for patients enrolled in last years: RA were more likely to receive earlier bDMARD, for lower activity and functional status; moreover, lower corticosteroids (dose, duration) and fewer synthetic DMARDs before starting biologics were reported ($p<0.05$).

24.63% RA developed SI (a total of 67 episodes, 1.47% fatal outcomes). Irrespective of RA settings and scenarios, history of biologics, specific drug administered (TNF or non-TNF), RRS indicated an outstanding agreement between the observed and expected SI rates ($p>0.05$).

In addition, the rate of SI was lower in RA recruited after 2013 ($p<0.05$), while RRS has better predictive significance in the second cohort ($p<0.05$).

Conclusions: The RABBIT Risk Score is a consistent tool, able to predict serious infections in Romanian RA receiving biological therapy (TNF and non-TNF drugs), optimizing the selection of appropriate medication based of individual infectious risk profile in routine practice.

SAT0149 COMPARATIVE EFFECTIVENESS OF TOFACITINIB, BIOLOGIC DRUGS AND TRADITIONAL DISEASE-MODIFYING ANTIRHEUMATIC DRUGS IN RHEUMATOID ARTHRITIS

C.S. Moura[1], M.A. Machado[1], H. Behlouli[1], J.R. Curtis[2], M. Abrahamowicz[1], S. Bernatsky[1]. [1]*Division of Clinical Epidemiology, McGill University, Montreal, Canada;* [2]*Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, United States*

Background: Most rheumatoid arthritis (RA) patients initiate therapy with methotrexate (MTX), but only 1/3 will have low disease activity with this agent alone. Several therapeutic options are available for patients with MTX-resistant RA, including new Janus kinase (JAK) inhibitors (eg.: tofacitinib).

Objectives: To compare the effectiveness of traditional disease-modifying antirheumatic drugs (DMARDs), biologic DMARDs and tofacitinib for RA patients with inadequate response to MTX.

Methods: We used MarketScan® databases (2011–2014) to study adult RA individuals previously treated with methotrexate (oral or SQ) and newly prescribed one of the medications under study. The date of first filled prescription or infusion drug was defined as the cohort entry and a 12-month pre-period was used to exclude prior users of biologics or tofacitinib. We required subjects to be continuously enrolled in the medical and pharmacy plan 12 months before and after the cohort entry. Effectiveness was access through an algorithm previously validated[1], based on the following criteria: 1) non-adherence; 2) switching/adding a new biologic or tofacitinib; 3) switching/adding a new DMARD; 4) increasing of the dose of the starting therapy; 5) use of glucocorticoid joint injections; and 6) increasing the dose of oral glucocorticoid. A patient's therapy was defined as not effective if at least one of the criterion occurred during the first year of follow-up.

Results: 16,305 RA patients were included; 2,879 began therapy with DMARD, 13,345 with biologics and 81 with tofacitinib. Among all patients, 77.5% were female and the mean age was 56.2 years (standard deviation 12.6). Table 1 shows the proportion of patients that meet the individual criterion and that achieved effectiveness at the end of one-year follow-up.

Conclusions: Similar rates of therapy effectiveness were observed among groups, although the rates for the individual criteria differed. Fewer patients initiating biologic agents were non-adherent compared to DMARD and tofacitinib therapy, but switch/adding and injections tended to be higher in this group.

Table 1. Proportion and 95% confidence interval (CI) of patients who achieved therapy effectiveness and the individual criteria

Effectiveness criteria	DMARD		Biologics		Tofacitinib	
	%	95% CI	%	95% CI	%	95% CI
Non-adherence	75.1	73.5; 76.7	54.5	53.6; 55.3	69.1	59.1; 79.2
Switch/add biologic or tofacitinib	16.1	14.8; 17.5	34.6	33.8; 35.4	18.5	10.1; 27.0
Switch/add DMARD	13.0	11.7; 14.2	16.6	16.0; 17.3	16.0	8.1; 24.0
Increase in dose or frequency	8.6	7.6;9.7	6.9	6.5; 7.3	0	0
Glucocorticoid joint injection	7.8	6.9; 8.9	14.0	13.4; 14.6	9.6	3.4; 16.4
Increase in dose of oral glucocorticoid	19.0	17.6;20.5	17.6	17.0;18.2	22.2	13.2;31.3
Effective therapy (none of the criteria)	15.5	14.2; 16.8	17.9	17.2; 18.5	14.8	7.1; 22.6

SAT0150 PROSPECTIVE, INTERVENTION, MULTICENTER STUDY OF UTILITY OF BIOLOGIC DRUG MONITORING WITH RESPECT TO THE EFFICACY AND COST OF ADALIMUMAB TAPERING IN PATIENTS WITH RHEUMATIC DISEASES: PRELIMINARY RESULTS OF INGEBIO STUDY

E. Ucar[1], Í. Gorostiza[2], C. Gómez[1], C.E. Pérez[1], J.R. De Dios[3], B. Alvárez[3], A. Ruibal[3], C. Stoye[3], M. Vasques[3], J. Belzunegui[4], A. Escobar[2], Z. Trancho[2], A. Ruiz del Agua[5], A. Martínez[5], C. Jorquera[2], D. Nagore[5]. *[1]Rheumatology; [2]Research Unit, Basurto University Hospital, Bilbao; [3]Rheumatology, Hospital Univeristario Araba, Vitoria; [4]Rheumatology, Donostia University Hospital, San Sebastian; [5]R&D, Progenika-Grifols, Derio, Spain*

Background: Adalimumab (ADL) tapering based on clinical assessment is a usual practice especially in patients who have achieved clinical remission.
Objectives: To analyze how personalized management guided by biological drug monitoring (BDM) in rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS) patients impacts the annual direct costs to the Health System and the quality-adjusted life year with respect to conventional practice in Spain. To evaluate the effectiveness of BDM in the reduction of the number of days with high disease activity compared with conventional practice.
Methods: In a pragmatic, non-randomized, non-inferiority clinical study, adult patients treated with ADL (40 mg sc) who remained clinically stable for at least 6 months were recruited in 3 sites. Patients were grouped in Control (CG) and Intervention groups (IG) according to the site. ADL frequency was adjusted based on physician criteria. Patients are assessed at 8 timepoints (8 visits) for up to 18 months. Trough ADL and anti-ADL antibodies levels are measured with Promonitor-ADL and Promonitor-ANTI-ADL (Progenika, SA). BDM data were released only to the IG, and blinded to the CG (managed according to clinical assessment only). Physicians in the IG were not obliged to follow any therapeutic algorithm based on BDM results but could use tests to alter doses based on their judgement. Endpoints include DAS28, BASDAI, BASFI and HAQ-DI scores at every timepoint. Cost-effectiveness will be evaluated according to associated costs and QALY.
Results: A total of 169 patients were recruited (disease, N IG, N CG, %) (RA, 30, 33, 37.3%; PsA, 33, 21, 32%; and AS, 46, 6, 30.8%). Median disease duration was 117, 98.5 and 101.5 months for RA, PsA and AS, respectively. At baseline, 10 (16.7%) and 29 (26.6%) patients had low disease activity, 50 (83.3%) and 80 (73.4%) patients were in remission, and median trough ADL levels were 5,5 and 5,3 mg/L in the CG and IG, respectively. Mean follow-up (FU) was 505 and 499 days in the CG and IG, respectively. ADL doses were tapered in 22/60 (36,7%) and 39/109 (35,8%) patients in the CG and IG, respectively. Patients were in remission an average of 329 vs 344 days in the CG and IG, respectively. The number of flares in the CG and IG was 53 and 69, respectively. The rate of flares per patient-year of FU is 0,639 vs 0,463 in the CG and IG, respectively (difference of -0,176; CI95%: -0,379 to 0,0289). The risk of flare is 27,5% lower in the IG (IRR=0,7252; CI95%: 0,4997 to 1,0578). Quality of life (EQ-5D-5L) was significantly better in the IG at visits 2 (p=0,001) and 3 (p=0,035); EQ-5D-5L was higher (although not statistically significant) in the IG in the remaining visits. Average cost of ADL per patient-year was 11.898,60€ vs 11.240,81€ (-657.78€) in the CG and IG, respectively.
Conclusions: Preliminary results show that rheumatic patients have better quality of life, lower risk of flares and incur in lower treatment costs if patient management is complemented with BDM data.

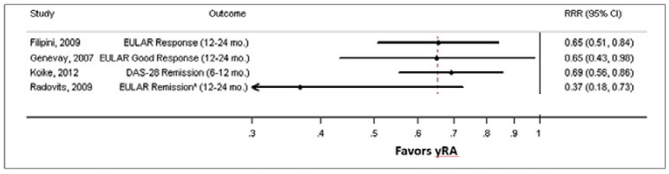
SAT0151 EFFICACY AND SAFETY OF BIOLOGIC THERAPY IN ELDERLY RHEUMATOID ARTHRITIS PATIENTS COMPARED TO YOUNG - A SYSTEMATIC REVIEW

D. Dalal[1], J. Duran[2], T. Brar[1], R. Alqadi[3], C. Halladay[4], A. Lakhani[1], J. Rudolph[4]. *[1]Medicine, Brown University School of Medicine, Providence, United States; [2]Medicine, Pontificia UniversidadCatolica de Chile, Santiago, Chile; [3]Medicine, Roger William Medical Center; [4]Medicine, VA Medical Center, Providence, United States*

Background: Rheumatoid arthritis (RA) patients are disproportionately older (33% >60 years). With improved biologic therapy for RA, there is a need to understand the efficacy and safety of biologic therapies in older RA (oRA) patients.
Objectives: To systematically review published literature to summarize the available evidence of efficacy and safety of biologic agents in oRA compared to young RA (yRA) patients.
Methods: A search in EMBASE, MedLine, Toxline, clinicaltrials.gov and Cochrane database was performed to identify clinical trials (RCT) and observational (OBS) studies of >6 months comparing the efficacy and safety of biologic agents in oRA relative to yRA. The biologics of interest were all anti-TNF agents, abatacept (ABA), tocilizumab (TCZ), rituximab (RTX) and tofacitinib (TOF). English language studies conducted in adult RA that reported age-associated outcomes were included. Studies assessing juveniles, inflammatory arthritis or not reporting older age outcomes were excluded. Safety outcomes included infections, adverse drug reactions (ADR), and malignancy. 2 independent rheumatologists reviewed abstracts, full text articles, and abstracted data from included articles. Conflicts were resolved by a 3rd reviewer. Abstracted data was summarized and evaluated for use within a meta-analysis
Results: Of 5353 abstracts, 187 were identified for full text review and 32 articles were included in this review. Articles were focused on efficacy (n=9), safety (n=15), or both (n=8). Most articles (n=22; 69%) focused on anti-TNF agents, then TCZ (n=4), ABA (n=2), TOF (n=2), RTX (n=1) and all biologics (n=1). Most studies were OBS studies (n=28, 88%) and fewer (n=4) were post-hoc analyses of RCT. In total, 99947 unique patients were identified, of which ~24% were older. Most studies used valid definitions of RA and outcomes; only 25% of the studies have <20% loss to follow up. There was heterogeneity in reporting outcomes and time of follow up.
Out of the 12 efficacy studies focusing on anti-TNF agents, 9 (75%) showed a reduced efficacy in oRA on DAS28, HAQ, CDAI, SDAI, EULAR or ACR response scales relative to yRA. Studies focusing on TCZ (n=2) and RTX (n=1) also showed a reduced efficacy in oRA. OBS studies in ABA (n=2) showed comparable efficacy in oRA and yRA. Meta-analysis was limited by heterogeneity.
Safety was the focus of anti-TNF (n=15), TCZ (n=3), 2 on TOF (n=2), 1 on ABA (n=1), RTX and all biologics (n=1) studies. Among these 23 safety studies, 74% (n=17) demonstrated worse safety outcomes in oRA. like in oRA. Of studies focusing on infection in anti-TNF agents, 82% (9 of 11) reported increased risk in oRA. Among the anti-TNF studies, 2 out of the 4 (50%) measured more ADR in oRA. A meta analysis of 4 studies reporting infectious outcomes in anti-TNF agents at >1 year found a pooled risk estimate was 1.59 (95% CI 1.45–1.76).

Figure 1: Forest plot of studies of anti-TNF agents measuring risk ratio of efficacy on EULAR or DAS28 response scale



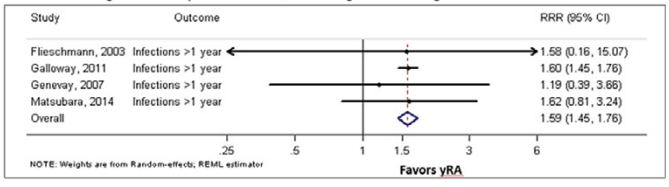


Figure 2: Forest plot of studies of anti-TNF agents measuring risk ratio of infections

Conclusions: There is heterogeneity within the literature of biological agents in RA, particularly when age is considered. Given the anticipated population increase in the oRA, there is an urgent need for analysis of these medications in oRA patients for both safety and efficacy.

SAT0152 REAL-LIFE INFLIXIMAB AND ADALIMUMAB TROUGH LEVEL AND ANTI-DRUG ANTIBODY MEASUREMENTS IN RHEUMATOLOGY: THE FINNISH EXPERIENCE

D. Ho[1], S. Valtanen[2], M. Havana[2], L. Kröger[3], K. Eklund[4], S. Jokiranta[1,2].
[1]Research Programs Unit, Immunobiology, University of Helsinki; [2]United Medix Laboratories Ltd, Helsinki; [3]Pediatric Rheumatology, Kuopio University Hospital, Kuopio; [4]Rheumatology, Helsinki University and Helsinki University Hospital, Helsinki, Finland

Background: Therapeutic drug monitoring of TNF inhibitors (TNFi) may optimize clinical benefits while at the same time reducing financial costs and risk of adverse events[1,2]. Monitoring the TNFi trough levels (TLs) and the anti-drug antibodies (ADAbs) can provide relevant information to make rational adjustments to therapy if indicated.
Objectives: To identify distributions and trends in infliximab (IFX) and adalimumab (ADL) TLs and ADAbs from clinically requested, real-life samples from Finnish patients with rheumatoid arthritis (RA), spondyloarthropathies (SpA), or juvenile idiopathic arthritis (JIA).
Methods: Samples for TL and ADAbs were taken on a clinical basis in daily practice from four university hospitals and 15 central hospitals in Finland and sent for analysis to United Medix Laboratories. Samples were collected and analyzed from January 2012 to February 2016. TL measurements were performed by enzyme-linked immunosorbent assay (either at Sanquin laboratories, Amsterdam, The Netherlands, or in Helsinki, Finland using Promonitor ELISA, Progenika Biopharma). TLs from 2–10 μg/ml (IFX) or 5–10 μg/ml (ADL) were considered as general target ranges. ADAb measurements were performed by radioimmunoassay (Sanquin). 1762 TL (1241 patients), 1598 ADAb (1203 patients), and 860 combined TL and ADAb samples (718 patients) were analyzed. Statistical analyses were performed by SPSS (IBM, Armonk, NY). $p<0.05$ was considered statistically significant.
Results: The highest proportions of samples with very low TLs (<0.1 μg/ml) were seen in IFX-treated RA patients (14.5%) and ADL-treated SpA patients (12.6%). The proportion of all samples in the general target range was 51.3% (IFX) and 33.4% (ADL). A greater proportion of ADL RA and SpA samples had possibly supratherapeutic (>10 μg/ml) TLs (RA: ADL, 22.9% vs IFX, 10.4%, $p<0.01$ and SpA: ADL, 21.4% vs IFX, 15.0%, p=0.05). A greater proportion of ADL JIA samples had TLs >10 μg/ml (ADL, 54.5% vs IFX, 36.3%, $p<0.01$). Proportions of samples with ADAbs (>12 AU/ml) ranged from 18.0% (IFX RA) to 28.6% (ADL SpA). A greater proportion of ADL samples with TLs of 2–5 μg/ml and detectable ADAbs (>12 AU/ml) (RA: ADL, 3.3% vs IFX, 0%; SpA: ADL, 5.6% vs IFX, 0%; JIA: ADL, 3.4% vs IFX, 0.9%) was observed.
Conclusions: IFX RA and ADL SpA samples had the highest proportions of very low TLs. Compared to IFX, greater proportions of ADL samples (all indications, particularly JIA) had TLs >10μg/ml. Proportions of samples with ADAbs >12 AU/ml ranged from 18.0% to 28.6%. Compared to IFX, a greater proportion of ADL samples with possibly therapeutic TLs had detectable ADAbs.

SAT0153 EFFECTIVENESS OF LOW AND HIGH DOSE METHOTREXATE IN COMBINATION WITH ADALIMUMAB IN A REAL WORLD SETTING: RESULTS FROM THE CORRONA RHEUMATOID ARTHRITIS REGISTRY

D. Pappas[1,2], J. Griffith[3], C.A. Schlacher[3], Y. Shan[2], C. Karki[2], J.M. Kremer[4].
[1]Columbia University, New York; [2]Corrona, LLC, Southborough; [3]AbbVie, Inc., Abbott Park; [4]Albany School of Medicine, Albany, United States

Background: Combination therapy of methotrexate (MTX) with biologics results in superior outcomes vs. monotherapy. Recent clinical trials have shown that lower MTX doses may be sufficient in patients with rheumatoid arthritis (RA) to achieve similar clinical and patient reported outcomes (PROs)[1,2].
Objectives: To evaluate whether high MTX dose in combination with adalimumab (ADA) results in improved clinical and PROs compared with low MTX dose.
Methods: Adult RA subjects naïve to other monoclonal antibodies, initiating standard dose ADA (40mg q2w) in combination with oral MTX (low dose: ≤12.5 mgs and high dose: ≥15 mgs) during 2003–2016 and had a 6 month follow-up visit were included. The primary outcomes were mean change in clinical disease activity index (CDAI), and PROs (mHAQ, pain, fatigue, morning stiffness) from baseline to 6 months. Secondary outcomes included achievement of remission (CDAI≤2.8)/low disease activity (CDAI≤10). Outcomes were evaluated adjusting for covariates that differed at baseline using mixed model linear regression. Persistency of ADA between the two groups was examined using Kaplan-Meier survival analysis.
Results: A total of 519 patients were included: N=101 and N=418 initiated ADA with low and high dose MTX respectively. Patients on high dose MTX were significantly younger (53.3 vs 59.7 years), with lower disease duration of RA (8.8 vs 11.2 years) compared to low dose MTX group. Patients in the high dose group also had higher disease activity (mean CDAI: 20.8 vs 15.4) and more likely to be biologic-naïve (71.3% vs 55.4%), compared to the low dose group (all $p<0.05$). Unadjusted and adjusted analyses found no sufficient evidence that patients on high dose MTX had a better improvement in the outcomes selected (table). Persistency of ADA did not differ between the two groups.

Table: Outcomes at 6 months among ADA plus low (≤12 mg) vs. high dose (≥15 mg) combination MTX therapy

	ADA + ≤12.5 mg (low dose)	ADA + ≥15 mg (high dose)	Unadjusted†	Adjusted†*
6 month outcomes	**Mean (SD)**	**Mean (SD)**	**β (95% CI)**	**β (95% CI)**
Change in CDAI	-5.1 (13.1)	-8.0 (14.2)	-2.65 (-5.68, 0.38)	2.70 (0.27, 5.12)
Change in mHAQ	-0.04 (0.30)	-0.09 (0.43)	-0.05 (-0.14, 0.04)	0.03 (-0.06, 0.13)
Change in pain	-3.3 (26.9)	-9.0 (28.1)	-5.59 (-11.65, 0.46)	2.25 (-3.21, 7.72)
Change in fatigue	1.8 (23.3)	-3 (27.6)	-4.81 (-12.54, 2.92)	-1.99 (-9.96, 5.98)
	Response rate n (%)	**Response rate n (%)**	**Odds Ratio† (95% CI)**	**Odds Ratio†* (95% CI)**
Achievement of Remission (CDAI≤2.8)	7 (11.7%)	47 (15.1%)	1.17 (0.47, 2.88)	0.92 (0.36, 2.4)
Achievement of LDA (CDAI≤10)	28 (46.7%)	135 (43.3%)	0.841 (0.47, 1.49)	0.63 (0.31, 1.26)

mHAQ: modified Health Assessment Questionnaire; LDA: Low Disease Activity; † Compared with low dose MTX group as a reference; *Adjusted for age, duration of RA, work status, insurance status, prior biologic count, MTX continuation, baseline CDAI and patient pain.

Conclusions: In this real world study, improvements in PROs and achievement of LDA/remission at 6 months were similar in the groups initiating ADA in combination with either low dose or high dose MTX.

SAT0154 EFFECTIVENESS AND SAFETY OF CT-P13 IN PATIENTS WITH RHEUMATOID ARTHRITIS, ANKYLOSING SPONDYLITIS, PSORIATIC ARTHRITIS AND PLAQUE PSORIASIS: OBSERVATIONAL STUDY IN REPUBLIC OF KOREA

D.-W. Kim[1], T.-H. Kim[2], S.R. Kwon[3], E.Y. Lee[4], C.-N. Son[5], Y.S. Kim[6], S.H. Kim[7], Y.-B. Park[8], J.-W. Hur[9], H.-S. Lee[10], S.J. Lee[11], S.H. Lee[11]. *[1]Inje University Busan Paik Hospital, Busan; [2]Hanyang University Hospital for Rheumatic Diseases, Seoul; [3]Inha University Hospital, Incheon; [4]Seoul National University College of Medicine, Seoul; [5]Keimyung University Dongsan Medical Center, Daegu; [6]Chosun University Hospital, Gwangju; [7]Gwangmyeong Saeum Hospital, Gyeonggi-do; [8]Yonsei University Severance Hospital; [9]Eulji University Seoul Hospital, Seoul; [10]Hanyang University Guri Hospital, Gyeonggi-do; [11]Celltrion, Inc., Incheon, Korea, Republic Of*

Background: CT-P13 is approved as a biosimilar of innovator infliximab for marketing in 79 countries around the world. After approval, observational study has been conducted in Republic of Korea in patients with Rheumatoid Arthritis (RA), Ankylosing Spondylitis (AS), Psoriatic Arthritis (PsA) and Plaque Psoriasis (PS).
Objectives: To evaluate the effectiveness and safety of CT-P13 under routine care in Republic of Korea.
Methods: This observational study included both biologic naïve patients (Naïve group) and patients who switched from other anti-tumor necrosis factor (TNF)s to CT-P13 (Switch group). Effectiveness were evaluated based on remission (DAS28≤2.6 in RA, BASDAI<3 in AS and absence of swollen and tender joint counts in PsA), and response (BASDAI 20/50/70 in AS and PASI 50/75 in PS). Adverse events (AEs) were collected over 6 month period.
Results: Total 940 patients (400 with RA, 531 with AS, 3 with PsA and 6 with PS) were registered and 338 (36.0%) patients (108 with RA, 228 with AS, 2 with PS) who switched to CT-P13 were included.
The proportion of patients achieving remission was similar between Naïve and Switch groups in both RA and AS during post-baseline visits (Table 1). In RA, the proportion of patients achieving each disease activity category by DAS28 was similar between Naïve and Switch groups (Figure 1). The proportion of patients

who achieved BASDAI 20/50/70 response gradually increased from week 6 to week 24 or 30 in Naïve group with AS (Figure 1).
Fifty percent of naïve patients with PsA achieved clinical remission. The proportions of both PASI 50 and 75 responses were 50% at Week 22 in Naïve group and were 100% and 50% in Switch group, respectively during post-baseline visits in PS patients.
Throughout this study, treatment-emergent adverse events (TEAE) and treatment-emergent serious adverse events (TESAE) were reported as Table 2. Only 11% of patients experienced infection.

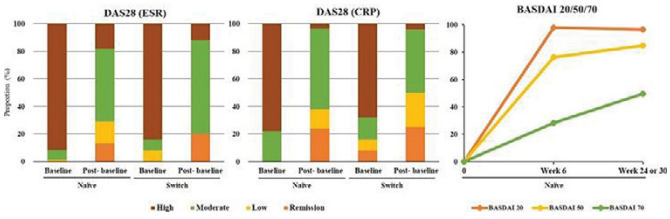

Table 1. Clinical remission in RA and AS

		Naïve		Switch	
		Baseline	Post-baseline	Baseline	Post-baseline
RA	DAS28 (ESR)	0/181 (0.0%)	24/182 (13.1%)	0/25 (0.0%)	5/25 (20.0%)
	DAS28 (CRP)	0/180 (0.0%)	43/179 (24.0%)	2/25 (8.0%)	6/24 (25.0%)
AS	BASDAI	2/292 (0.7%)	199/292 (68.2%)	112/209 (53.6%)	150/210 (71.4%)

Table 2. Summary of safety results

n/N (%)	RA	AS	PsA	PS
TEAE	198/400 (49.5)	183/531 (34.5)	1/3 (33.3)	3/6 (50.0)
TEAE related with CT-P13	73/400 (18.3)	64/531 (12.1)	0/3 (0.0)	2/6 (33.3)
TESAE	52/400 (13.0)	14/531 (2.6)	0/3 (0.0)	1/6 (16.7)
TESAE related with CT-P13	15/400 (3.8)	6/531 (1.1)	0/3 (0.0)	0/6 (0.0)
Infusion-related reactions	28/400 (7.0)	11/531 (2.1)	0/3 (0.0)	0/6 (0.0)

Figure 1. Clinical response of RA and AS

Conclusions: CT-P13 is efficacious and well-tolerated in RA/AS/PsA/PS patients. Efficacy and safety results in patients treated with CT-P13 were clinically consistent to historical data [1,2,3]. Especially, Switch group results showed that CT-P13 provides a useful alternative to other anti-TNFs.

SAT0155 ADALIMUMAB IN COMBINATION WITH NON-METHOTREXATE CONVENTIONAL SYNTHETIC DISEASE MODIFYING RHEUMATIC DRUGS IN A CLINICAL TRIAL SETTING

E.C. Keystone[1], J. Suboticki[2], J. Griffith[2], Y. Zhang[2], J.M. Kremer[3]. *[1]Mount Sinai Hospital, University of Toronto, Toronto, Canada; [2]AbbVie, Inc., North Chicago; [3]Albany School of Medicine, Albany, United States*

Background: Biologics in combination with methotrexate (MTX) are associated with improved outcomes versus monotherapy. However, few data exist regarding the use of non-MTX conventional synthetic disease modifying rheumatic drugs (csDMARDs) with biologics.
Objectives: To assess the effectiveness and safety of adalimumab (ADA) in combination with MTX and non-MTX csDMARDs through 6 months.
Methods: This post hoc analysis used data from the 24-week (wk) placebo-controlled trial of ADA (STAR), assessing safety and efficacy of ADA+csDMARDs in patients (pts) with moderate to severe RA.[1] For those pts receiving 1 csDMARD, pts were subgrouped according to csDMARD. The most frequently used csDMARDs assessed were MTX, sulfasalazine (SSZ), hydroxychloroquine (HCQ), and leflunomide (LEF). Nineteen pts who received parenteral gold in combination with ADA were excluded from this analysis. Baseline demographics and disease characteristics were summarized across csDMARD groups. 20/50/70% improvement in American College of Rheumatology (ACR) response criteria were assessed for each subgroup. Other clinical and functional endpoints were assessed using ANCOVA within subgroups as the least square (LS) means of the mean change from baseline to wk 24. Adverse events (AEs) were monitored throughout.
Results: Of the 290 pts randomized to receive ADA, 237 (82%) received ≥1 csDMARD [174 (60%) and 63 (22%) received ADA in combination with 1 and ≥2 csDMARDs, respectively]. Of the 63 pts who received ≥2 csDMARDs in combination with ADA, 55 (87%) received concomitant MTX therapy. Similarly, most of the pts receiving ADA in combination with a single csDMARD received MTX [114 (66%)], while 60 pts received ADA in combination with a single non-MTX csDMARD. Pts receiving non-MTX csDMARDs were slightly younger, on average, than those receiving MTX (mean age: 51.4 vs 56.4 years), but demonstrated slightly higher mean HAQ-DI (1.37 vs 1.26) and CRP (2.4 vs 1.3) at baseline. Following 6 months of combination therapy, pts receiving ADA+MTX experienced numerically better clinical and functional outcomes to pts receiving ADA+non-MTX csDMARDs (Table). The lower response in the non-MTX DMARD group appeared to be driven by pts receiving LEF, who tended to experience lower levels of response in combination with ADA. Overall, frequencies of AEs were similar between combination therapy with MTX and non-MTX csDMARDs (~90% in both groups). Serious AEs were observed in 10% of pts receiving non-MTX csDMARDs and 5% of pts receiving MTX. A total of 42% in the non-MTX csDMARD and 60% in the MTX group experienced infections during the course of the study. There were 3 serious infections, all occurring in the MTX group.

Table. Week 24 Clinical and Functional Outcomes Among Patients Receiving Adalimumab in Combination With a Single csDMARD

		ADA+non-MTX csDMARD n=60			
Variable	ADA+MTX n=114	Pooled n=60	LEF n=25	SSZ n=12	HCQ n=23
ACR20	69 (61)	27 (45)	8 (32)	7 (58)	12 (52)
ACR 50	40 (35)	14 (23)	3 (12)	4 (33)	7 (30)
ACR70	22 (19)	7 (12)	0 (0)	3 (25)	4 (17)
DAS28(CRP)	-1.912[a]	-1.923[b]	-1.516[c]	-1.979[d]	-2.206[e]
SDAI	-22.60[a]	-22.21[b]	-18.41[c]	-23.80[d]	-24.61[e]
CDAI	-21.90[f]	-20.95[g]	-18.05[c]	-23.79[d]	-22.02[h]
HAQ-DI	-0.509[f]	-0.435[i]	-0.251[e]	-0.595[d]	-0.524[h]

Discrete variables are summarized as n (%).
All continuous variables are within group LS means in mean change from baseline to week 24 using ANCOVA, with csDMARD subgroup as a factor and baseline value as covariate, with the exception of the pooled group, which is mean change from baseline.
[a]n=105; [b]n=52; [c]n=20; [d]n=11; [e]n=21 ; [f]n=106; [g]n=53; [h]n=22; [i]n=54.
csDMARDs, conventional synthetic disease-modifying antirheumatic drugs; ADA, adalimumab; MTX, methotrexate; LEF, leflunomide; SSZ, sulfasalazine; HCQ, hydroxychloroquine; ACR, American College of Rheumatology; DAS28(CRP), 28-joint disease activity score based on C-reactive protein; SDAI, simplified disease activity index; CDAI, composite disease activity index; HAQ-DI, health assessment questionnaire disability index.

Conclusions: MTX administered in combination with biologics, like ADA, leads to superior outcomes vs monotherapy. For pts who can't tolerate MTX, non-MTX csDMARDs, specifically HCQ and SSZ but not LEF, may be good alternatives, as outcomes were largely comparable with those of pts receiving MTX when combined with ADA. The limited sample size examined in this analysis should be confirmed in a larger pt population.

SAT0156 EXPOSITION TO BIOLOGICAL THERAPY DURING PREGNANCY: A SINGLE-CENTRE STUDY OF PREGNANCY OUTCOME IN MOTHERS WITH RHEUMATIC DISEASES

E. De Stefani[1], M. Padovan[1], A. Bortoluzzi[1], R. Capucci[2], M. Govoni[1]. *[1]Department of Medical Sciences, Section of Rheumatology, University of Ferrara and Azienda Ospedaliero-Universitaria di Ferrara; [2]Department of Obstetrics and Gynecology, Azienda Ospedaliero Universitaria S.Anna, Ferrara, Italy*

Background: Biologic DMARDs fall within the FDA category B or C. However many case series and registry data are available about women exposed during pregnancy.
Objectives: to extend information on this topic by the contribution of a tertiary single centre case series
Methods: Data were collected from a single-centre cohort of outpatients followed between 2006 and 2016. Women with rheumatic diseases (RD) exposed to biological (BE) agent during pregnancy or in the 3 months before conception were included. Outcomes in the BE group were compared with an age-matched group of pregnant women with RD non-exposed to biological agent (NE). Demographic and clinical data,obstetric outcome and neonatal complications were recorded.
Results: 34 pregnancies in 28 patients were included: 14 Rheumatoid Arthritis (RA), 6 ankylosing spondylitis (AS), 2 Psoriatic arthritis (PsA), 4 Undifferentiated spondyloarthritis (uSpA), 1 Dermatomyositis (DM), 1 Adult Onset Still's disease

(AOSD); all were exposed to a biologic agent: 16 Etanercept (ETA), 7 Adalimumab (ADA), 4 Infliximab (IFX), 1 Certolizumab (CTZ), 5 Rituximab (RTX), 1 Anakinra (ANK). Median age was 34 yrs (range 24–50). All patients treated with TNFi and ANK withdrew therapy in early pregnancy (<10 weeks gestational age). 2 RA patients had 2 pregnancies each, during ETA treatment. A RA woman became pregnant 4 times during RTX therapy. 10 patients were also on csDMARDs therapy at the time of conceptions: 7 Hydroxycloroquine (HCQ),1 HCQ + Sulphasalazine (SSZ), 1 Cyclosporine A (CYA), which was continued, and 1 with Methotrexate which was immediately withdrawn. 1 RA patient started SSZ from the 24th week. 15 patients (7 RA, 2 PsA, 2 AS, 2 uSpA, 1 DM) started or increased oral and/or intra-articular steroids because of disease flare. A control group of 45 pregnancies observed in 42 patients not exposed to biologics was selected="selected" (19 RA, 12 uSpA, 3 Juvenile Idiopatic Arthritis (JIA), 5 PsA, 1 AS, 1 DM, 1 AOSD), median age 35 (range 22–42). 18 patients were treated with csDMARDs during pregnancy (8 HCQ; 4 SSZ; 2 CYA+HCQ; 4 SSZ+HCQ). No other drugs were taken at the time of conception, apart from low dose of steroids in 24 cases; in 1 case intra-articular steroids were given because of disease flare.

Pregnancy outcomes are summarized in tab.1: therapeutic abortions were performed for an extrauterine pregnancy occurred twice in the patient with RA who became pregnant 4 times during RTX treatment, after the 5th and the 6th retreatment. After the 4th retreatment she had an early spontaneous abortion. Previously, she delivered 2 healthy children after exposure to ETA and 3 treatment cycles of RTX. No serious perinatal complication occurred, excluding very preterm baby delivery at 28th weeks, who needed neonatal intensive care. No congenital malformations were observed. Klinefelter syndrome was diagnosed in 1 case.

Tab. 1: Pregnancy outcomes of women with RD exposed to biological (BE) compared with pregnant women with RD non-exposed to biological agent (NE).

	BE group (34)	NE group (45)	p
Live births	29 (85,3%)	43 (95,5%)	ns
Spontaneous abortion	2 (5,9%)	2 (4,4%)	ns
Therapeutic abortion	2 (5,9%)	0	ns
Voluntary interruption of pregnancy	1 (2,9%)	0	ns
Pre-term delivery	5 (14,7%)	6 (13,3%)	ns
Preterm rupture of membrane	3 (8,8%)	4 (8,9%)	ns
Intra-uterine growth restriction	1 (2,9%)	1 (2,2%)	ns
Average birth weight	2875 g (720-4234)	3140 (1880-4200)	ns
Low birth weight (<2500 g)	6 (17,6%)	5 (11,1%)	ns

Conclusions: In our case series no significant differences did occur in pregnancy outcome between BE and NE group, according to the most recent data published in literature. Additional data from larger numbers of pregnacy exposed to biological agents are required.

SAT0157 MYCOBACTERIUM TUBERCULOSIS SPECIFIC RESPONSES FROM CD8+ AND CD4+ T CELLS IN PATIENTS WITH LATENT AND ACTIVE FORM OF TUBERCULOSIS

E. Zanova[1], D. Kozakova[1], M. Polanova[2], I. Solovic[2], I. Rybar[3]. *[1]National Institute of Rheumatic Diseases, Piešťany; [2]National Institute of Tuberculosis, Pulmonary Diseases and Thorax Surgery, Vysne Hagy; [3]Slovak Health University, Bratislava, Slovakia*

Background: Testing the presence of latent or active tuberculosis using IGRA tests is necessary part of the diagnostic screening at risk individuals. QuantiFERON-TB Gold Plus (QFT-Plus) is a test for cell-mediated immune (CMI) responses to peptide antigens that simulate mycobacterial proteins. Peptide antigens in TB1 tube elicit CMI responses from CD4+ T-helper lymphocytes, in TB2 tube from CD8+ T-cytotoxic lymphocytes. Test is based on the ability of effector T lymphocytes to produce the cytokine interferon gamma (IFN-γ).

Objectives: To compare and evaluate levels of IFN-γ produced by CD4+ and CD8+ cells in TB1 and TB2 tubes.

Methods: It was studied 33 subjects with latent form of tuberculosis (LTBI) and 33 subjects with active TB. QFT-Plus was used to detect in vitro responses to peptide antigens associated with *Mycobacterium tuberculosis* infection (ELISA, QIAGEN). Results were obtained by calculation of INF-γ levels in Mitogen, TB antigen (TB1, TB2) and Negative control tubes using QFT analysis software.

Results: QFT-Plus positive results were observed in both groups of people. Increased levels of IFN-γ produced by CD4+ cells (TB1) has been detected in 21 subjects with LTBI (63,64%) and in all 33 subjects with active TB (100,0%). Increased levels of IFN-γ produced by CD8+ cells (TB2) has been detected in 27 people with LTBI (81,82%) and in all 33 people with active TB (100,0%). Joint increase levels of IFN-γ in the tubes TB1 and TB2 was observed in 16 individuals with LTBI (48,48%) and in all 33 individuals with active TB (100,0%). In the group of patients with a negative QFT-Plus it was not observed increased levels of IFN in tubes TB1 and TB2.

Conclusions: Our findings confirm specific CD4+ and CD8+ T cell response to mycobacterial protein antigens in individuals with LTBI and also in active TB subjects, in which INF-γ was frequently found. The immunological response represented by CD4+ and CD8+ T cells was not detected in subjects with QFT-Plus negative.

Giovanni di Dio, Firenze; [9]Clinica Reumatologica, Università Politecnica delle Marche, Ancona; [10]U.O.Reumatologia, ASL Taranto-PP.OO.SS. Annunziata Taranto e Valle d'Itria, Taranto; [11]Department of Clinical Sciences and Community Health, Division of Rheumatology, University of Milan and Gaetano Pini Institute, Milano, Italy*

Background: The strategy for the choice of the second biologic agent after the failure of the first TNF inhibitor (TNFi) is still an unclear aspect in the treatment of both rheumatoid arthritis (RA) and psoriatic arthritis (PsA). Switching between structurally different TNFis (from etanercept [ETN] to monoclonal antibody [mAb] or vice versa) has been proposed as a more effective procedure than switching among different mAbs, but to date no study has been specifically focused on exploring this topic.

Objectives: To evaluate the comparative 2-year retention rate and the 12-month efficacy of adalimumab (ADA) as second biologic agent in etanercept (ETN) non-responder RA and PsA patients in a multicentre retrospective study.

Methods: All RA and PsA patients from 11 Italian Rheumatology Units treated with ADA after a first-course ETN failure and with at least 12-month follow-up were retrospectively collected in a multicentre registry. Data analysis was limited to the period from January 2002 to May 2016. Two-year ADA retention rate was calculated by Kaplan-Meier method. 12-month ADA response was defined as achievement of disease activity score 28 calculated by using erythrosedimentation (DAS28-ESR) <2.6 (remission) or >2.6 and <3.2 (low disease activity, LDA). Sub-analyses according to reason for ETN discontinuation and concomitant methotrexate in RA and PsA patients have been performed.

Results: The study population (219 patients) included 117 RA (female 85.5%, mean [± standard deviation, SD] age 53.2±13.5 years, mean [±SD] disease duration 10.1±7.7; positive rheumatoid factor 70.2%; positive anti-citrullinated peptide antibodies [ACPA] 59.6%; mean [±SD] baseline DAS28-ESR 4.97±1.3; MTX users 64.9%) and 102 PsA (female 63.7%; mean [±SD] age 51.7±10.6; mean [±SD] disease duration 7.1±5.1; mean [±SD] baseline DAS28-ESR 4.4±1.1; MTX users 50%). The 2-year retention rate was 48.2% in RA and 56.5% in PsA patients, irrespective of reason for ETN discontinuation. Similarly, concomitant MTX was not associated with an increased drug survival in both RA (p=0.09) and PsA (p=0.969) subgroup. 12-month clinical remission and LDA were achieved respectively in 27.3% and 23.9% RA patients, and 27.4% and 23.5% PsA patients.

Conclusions: In our large real-life cohort, the use of ADA in primary and secondary ETN failures was highly effective in both RA and PsA patients, with more than 50% of ADA treated patients achieving remission or LDA. Reasons for ETN discontinuation were not associated with different ADA clinical response, as well as concomitant MTX.

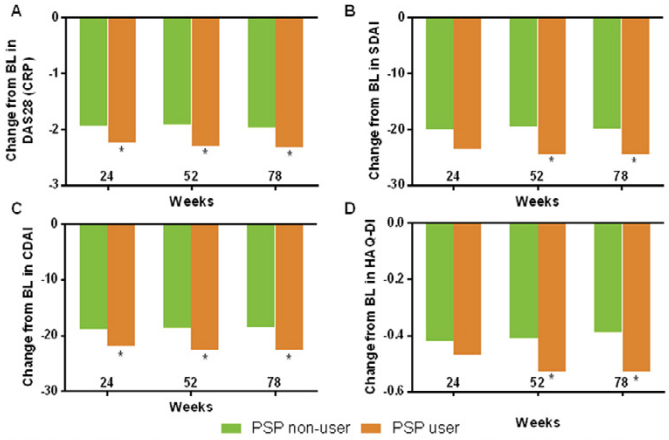
SAT0159 IMPACT OF PARTICIPATION IN THE ADALIMUMAB PATIENT SUPPORT PROGRAM ON FUNCTIONAL AND CLINICAL OUTCOMES AMONG PATIENTS WITH RHEUMATOID ARTHRITIS: PASSION STUDY

F. Van den Bosch[1], A. Ostor[2], S. Wassenberg[3], J.K. Anderson[4], N. Chen[4], C. Wang[4], V. Garg[4], J. Kalabic[5]. *[1]Ghent University Hospital, Ghent, Belgium; [2]Addenbrooke's Hospital, Cambridge, United Kingdom; [3]Rheumazentrum, Ratingen, Germany; [4]AbbVie Inc., North Chicago, United States; [5]AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany*

Background: Patients (pt) with Rheumatoid arthritis (RA) who are treated with adalimumab (ADA) are offered a Patient Support Program (PSP) with variety of services. To date, no prospective study has been conducted to analyze the acceptance and the impact of these PSPs on treatment effectiveness and pt satisfaction.



Objectives: The purpose of this study was to examine the effectiveness of ADA on rheumatoid arthritis (RA) treatment course in the context of PSP participation.

Methods: PASSION (NCT01383421) was a 78-week (wk) post-marketing observational study of pts with RA receiving ADA in routine clinical care. Pts from the EU, Israel, Mexico, Puerto Rico, and Australia with an insufficient response to ≥1 disease-modifying antirheumatic drug (DMARD) newly initiating ADA (1 prior

biologic DMARD was allowed) were enrolled. The primary endpoint was the % of pts achieving the minimal clinically important difference (MCID; improvement of ≥0.22 compared to baseline [BL]) in the Health Assessment Questionnaire Disability Index (HAQ-DI) at wk 78. Non-responder imputation (NRI) was used to account for the missing values. Secondary clinical parameters included % of pts achieving MCID in HAQ-DI at wks 24 and 52 and changes in the 28-joint DAS based on CRP (DAS28(CRP)), Simplified Disease Activity Index (SDAI), and Clinical Disease Activity Index (CDAI) at wks 24, 52, and 78 vs BL. Pts were categorized based on their participation in the PSP: ever (PSP users) vs never (PSP non-users) and outcomes were compared after adjusting for corresponding BL values.

Results: Overall, the primary endpoint, percentage of pts achieving the MCID for HAQ-DI, was achieved by 72.1% (as observed) and 42.8% (NRI) of pts at week 78 with the percentage of pts achieving the MCID for HAQ-DI significantly higher in PSP users vs PSP non-users (48.1% vs 37.8% [NRI]; $P<0.001$). From 1,025 pts, 48.7% pts were PSP users (BL: mean age, 54.3 years (y); % female, 77.1%; mean RA duration, 7.8 y; mean HAQ-DI, 1.5; mean DAS28(CRP), 5.3; mean SDAI, 35.6; mean CDAI, 33.3; 17.8% pts had received prior biologic DMARD. Significant changes ($P\leq0.05$) from BL to wk 78 were observed for pts using the PSP vs PSP non-users in HAQ-DI (0.53 vs 0.39), DAS28(CRP) (−2.33 vs −1.97), SDAI (−24.5 vs −19.8), and CDAI (−22.66 vs −18.55) scores (Figure). Study discontinuation rates were significantly ($P<0.001$) lower among PSP-users vs PSP non- users (25.5% vs 41.6%). Reasons for discontinuations are listed in the Table.

Figure: Changes from baseline in DAS28 (CRP) (A), SDAI (B), CDAI (C), and HAQ-DI (D) over time between PSP users and PSP non-users.

*significantly different between PSP users and PSP non-users ($P<0.05$). Data represented by LOCF imputation for intent-to-treat population. Results are adjusted for BL DAS28(CRP), SDAI, CDAI, and HAQ-DI. LOCF=Last Observation Carried Forward

Table: All reasons for study discontinuation by PSP utilization category

Subject Disposition	All Patients N=1025	PSP user N=499	PSP non-user N=526
Discontinued (%)* **	**346 (33.8)**	**127 (25.5)**	**219 (41.9)**
Adverse event	52 (5.1)	22 (4.4)	30 (5.7)
Withdrew consent	37 (3.6)	13 (2.6)	24 (4.6)
Lost to follow-up	46 (4.5)	17 (3.4)	29 (5.5)
Serious adverse events	24 (2.3)	10 (2.0)	14 (2.7)
Lack of efficacy	168 (16.4)	66 (13.2)	102 (19.4)
Other	51 (5.0)	16 (3.2)	35 (6.7)

***Statistically significant at $P<0.001$

Conclusions: The final study results showed that, in pts with moderate to severe RA who initiated ADA, significantly better improvement in functional and clinical outcomes was achieved in the PSP users vs the PSP non-users. Improvements were achieved at early timepoints and continued to increase throughout the study.

SAT0160 IMMUNOGENICITY OF BIOSIMILARS FOR THE TREATMENT OF INFLAMMATORY RHEUMATIC DISEASES: A REVIEW FROM CONFIRMATORY CLINICAL TRIALS

F. Araújo [1,2], J. Gonçalves [3], J.E. Fonseca [4,5]. *[1] Rheumatology, Hospital de Sant'Ana, SCML, Cascais; [2] Institute of Microbiology, Faculdade de Medicina da Universidade de Lisboa, Lisboa; [3] iMed-Research Institute of Medicines, Faculdade de Farmácia da Universidade de Lisboa; [4] Rheumatology, Hospital de Santa Maria, Lisbon Academic Medical Centre, Lisbon; [5] Rheumatology Research Unit, Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisboa, Portugal*

Background: The assessment of immunogenicity is mandatory during the comparability exercise of biosimilar candidate drugs, as even small structural differences can potentially elicit antidrug antibodies (ADA) and affect efficacy and safety.

Objectives: To review the incidence of ADA and neutralizing ADA (nADA) in confirmatory clinical trials of biosimilar drugs approved for the treatment of inflammatory rheumatic conditions in the European and North-American markets; to review the type of assays used for this purpose; to compare the incidence of ADA with historical data from reference biotechnological drugs.

Methods: We performed a literature search in the Medline database and hand searched EULAR and ACR meeting abstracts to identify phase I and III confirmatory clinical trials of biosimilar drugs for the treatment of rheumatic conditions approved in the European and North-American markets. Open-label extensions involving biological switch were not included. All outcomes regarding immunogenicity were extracted (ADA, nADA and type of immunogenicity assays).

Results: We screened 255 articles by title and abstract and 7 publications fulfilled our inclusion criteria. Three meeting abstracts were also included. Six studies assessed infliximab biosimilars (CT-P13 and SB2), three studies assessed etanercept biosimilars (SB4 and GP2015) and one study assessed an adalimumab biosimilar (ABP 501). All but two concerned phase III trials and seven were performed on rheumatoid arthritis patients. All biosimilars had comparable immunogenicity profiles in respect to their reference drugs, except for the etanercept biosimilar SB4, which presented significantly less ADA when compared to reference etanercept (0.7% vs 13.1% at 24 weeks and 1.0% vs 13.2% at 52 weeks, $p<0.001$ for both). As expected, infliximab had the highest incidence of ADA; the proportion of ADA in studies of infliximab and adalimumab was higher when compared to historical data. Only 4 studies reported nADA, which were highest in the infliximab biosimilar CT-P13 54-week study in ankylosing spondylitis patients. Electrochemiluminescence immunoassay was the preferred method to measure ADA. Table 1 summarizes the main findings in the included studies.

Table 1. Immunogenicity of biosimilars approved for the treatment of inflammatory rheumatic diseases. ADA: antidrug antibody, NA: not available, nADA: neutralizing antidrug antibody. *The EGALITY study presented a four-arm design in which two arms were continuously treated with either reference etanercept or GP2015 and the other two arms were systematically switched. The results presented in this table concern the groups continuously treated with reference etanercept or GP2015

Study population		Reference drug ADA (%)	Reference drug nADA (%)	Biosimilar ADA	Biosimilar nADA (%)	ADA/nADA assay
Rheumatoid arthritis	**CT-P13 (infliximab)**

Conclusions: Currently approved biosimilars for the treatment of rheumatic diseases have comparable immunogenicity profiles in respect to their reference drugs. The discrepancy in ADA between SB4 and reference etanercept did not correlate with efficacy or safety and did not preclude biosimilarity, according to the regulatory agencies. The higher proportion of ADA compared to historical data may be explained by the greater sensitivity of current immunogenicity assays, such as electrochemiluminescence.

SAT0161 PRELIMINARY REAL WORLD DATA ON SWITCHING PATTERNS BETWEEN ETANERCEPT, ITS RECENTLY MARKETED BIOSIMILAR COUNTERPART AND ITS COMPETITOR ADALIMUMAB, USING SWEDISH PRESCRIPTION REGISTRY

R. Alten[1], P. Neregård[2], H. Jones[3], E. Singh[3], C. Curiale[4], T. Meng[5], L. Lucchese[6], C. Miglio[6], J. Young[7], G.J. Bergman[7]. [1]*Schlosspark-Klinik, Berlin, Germany;* [2]*Pfizer, Stockholm, Sweden;* [3]*Pfizer, Collegeville, United States;* [4]*Pfizer, Rome, Italy;* [5]*Pfizer, Berlin, Germany;* [6]*QuintilesIMS, London, United Kingdom;* [7]*QuintilesIMS, Solna, Sweden*

Background: The increasing availability of biologic treatments over the past 10 years has revolutionized the management of chronic inflammatory autoimmune diseases such as rheumatic diseases. In April 2016, the first etanercept biosimilar (EtnBS) was launched in Sweden, which may represent a cheaper option to its innovator counterpart and other anti-TNF agents.
Objectives: The objective of this study was to describe the position of etanercept innovator (EtnI) within the Swedish biologic market for rheumatic diseases, before and after the launch of its biosimilar. The study also provides early real-world data on the market penetration of EtnBS by evaluating switching dynamics to and from this drug since the date of launch.
Methods: The overall biologic market share across all type of rheumatic diseases was monthly tracked over the last year of available data in the Swedish Prescription Registry (100% coverage). The proportion of patients receiving a rheumatologists' prescription for any biologic in each month, from November 2015 to October 2016, was recorded. In addition, switching dynamics of patients initiating EtnBS treatment between April 2016 and October 2016 were studied. The proportion of patients receiving no biologic treatment (naïve) and of those on treatment with EtnI, adalimumab and other biologic agents in the 12 months prior to initiate EtnBS was reported. Further, the proportion of patients who switched from EtnBS back to EtnI or adalimumab and the mean time to this second switch were also evaluated.
Results: EtnI and adalimumab dominate the biologic market for rheumatic diseases in Sweden, holding the 40% and 28% of market share, respectively, up to April 2016. However, in the 6 months after EtnBS was launched, the share of EtnI decreased constantly, dropping to 31% in October 2016 (Figure 1). Since April 2016, we identified in total 2,439 patients receiving first prescription of EtnBS by a rheumatologist. Of these, 977 (40.1%) were naïve to biologic, 1,179 (48.3%) had prior treatment with EtnI, 107 (4.4%) with adalimumab, 176 (7.2%) with other biologics. Among the patients who changed to EtnBS from prior EtnI, the 7% switched back to EtnI after an average time of 43 days. Similarly, of those who were on previous adalimumab treatment, 6% switched back to adalimumab after, on average, 57 days.

Conclusions: Many patients changed from EtnI to its biosimilar treatment since its launch in Sweden. However, this study showed that 7% of these patients switch back to their original treatment after short time. Despite the change from a brand biologic to the biosimilar is very likely made for economic reasons, the reasons for switching back to the innovator are not clear and may imply patients' preference or clinical reasons. Interestingly, the same pattern is observed for patients changing from adalimumab to EtnBS. Longer-term studies are required to confirm these early observations and investigate the reasons for switching back.

SAT0162 SWITCHING FROM ETANERCEPT TO CHS-0214: A ONE YEAR, RANDOMIZED, DOUBLE-BLIND STUDY IN PATIENTS WITH RHEUMATOID ARTHRITIS

J. O'Dell[1], A. Kivitz[2], T. Takeuchi[3], Y. Tanaka[4], I. Louw[5], T. Tiabut[6], S. Nakashima[7], J. Hodge[8], H. Tang[8], B. Finck[8] on behalf of The RApsody Study Group. [1]*University of Nebraska Medical Center, Omaha, NE;* [2]*Altoona Center for Clinical Research, Duncansville, PA, United States;* [3]*Keio University School of Medicine, Tokyo;* [4]*School of Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan;*[5]*Panorama Medical Center, Cape Town, South Africa;* [6]*City Clinical Hospital No. 1 of Minsk, Minsk, Belarus;* [7]*Daiichi-Sankyo, Tokyo, Japan;* [8]*Coherus BioSciences, Redwood City, United States*

Background: CHS-0214 is in development as a proposed biosimilar of etanercept for the treatment of rheumatoid arthritis (RA) and other auto-immune diseases.
Objectives: Equivalence of CHS-0214 to etanercept was demonstrated at 24 weeks in a global confirmatory, safety and efficacy study in patients with RA. This update provides efficacy results at 48 weeks and safety results over 52 weeks (or over 48 weeks for subjects who continued to the open-label safety extension study).
Methods: Patients had moderate/severe RA and an inadequate response to methotrexate (MTX). Patients were randomized to CHS-0214 or etanercept (commercial European-sourced) at 50 mg SC QW for 24 weeks (Part 1). Patients achieving ACR20 at Week 24 with no safety concerns then received CHS-0214 50 mg SC QW open-label for 24 weeks (Part 2). Patients continued their stable dose of MTX throughout the study.
Results: At Week 24, the response rates were 91.0% vs. 90.6% for ACR20, 67.6% vs. 63.7% for ACR50, and 38.3% vs. 37.9% for ACR70, in the CHS-0214 group (n=256) vs. etanercept group (n=256), respectively. At Week 48, the response rates were 93.8% vs. 92.7% for ACR20, 75.0% vs. 73.6% for ACR50, and 49.6% vs. 51.4% for ACR70, in patients who received CHS-0214 for 48 weeks (n=224) vs. patients who received etanercept for 24 weeks and then switched to CHS-0214 for 24 weeks (n=220), respectively. Thus, response rates were maintained both in patients who were switched at Week 24 from etanercept to CHS-0214 and in patients who received CHS-0214 for 48 weeks.
Over the 52-week study, adverse events (AE) were reported in 74.4% of patients who received CHS-0214 for 48 weeks and 76.6% who received etanercept for 24 weeks and were switched to CHS-0214 for 24 weeks. The majority of adverse events were mild or moderate in severity. No deaths were reported. Serious AEs were reported in 4.6% and 7.5% of patients, and serious AEs related to study drug per the investigator were reported in 0.9% and 1.9% of patients in the CHS-0214 and etanercept/CHS-0214 groups. Binding anti-drug antibodies (ADA) occurred in 1.3% and 4.7% of patients receiving CHS-0214 and etanercept during Part 1. In Part 2, treatment-emergent binding ADA occurred in 1.4% of patients receiving CHS-0214 and 0.7% of patients who switched from etanercept to CHS-0214.
Conclusions: This randomized, double-blind, active-control, global study demonstrated equivalence of CHS-0214 to etanercept based on the primary endpoint (ACR20 at Week 24) and maintenance of the efficacy response through Week 48. CHS-0214 was well tolerated and effective in patients with rheumatoid arthritis with no clinically meaningful differences to etanercept with regard to safety and immunogenicity. Over the 52-week study, no clinically meaningful differences in safety, immunogenicity, or efficacy were observed in patients who were switched from etanercept to CHS-0214 in comparison with those who only received CHS-0214.

SAT0163 SYSTEMATIC SWITCH FROM INNOVATOR INFLIXIMAB TO BIOSIMILAR INFLIXIMAB IN INFLAMMATORY RHEUMATIC DISEASES IN DAILY CLINICAL PRACTICE: THE EXPERIENCE OF COCHIN HOSPITAL, PARIS, FRANCE

J. Avouac[1], A. Molto[1], V. Abitbol[2], A. Salcion[1], L. Gutermann[3], O. Conort[3], F. Chast[3], C. Le Jeunne[4], C. Goulvestre[3], S. Chaussade[2], A. Kahan[1], C. Roux[1], Y. Allanore[1], M. Dougados[1]. [1]*Rheumatology;* [2]*Gastroenterology;* [3]*Paris Descartes University, Cochin Hospital, Paris, France;* [4]*Internal Medicine, Paris Descartes University, Cochin Hospital, Paris, France*

Background: Biosimilars of originator biologic therapeutics are going to change medical practices. In October 2015, the medical community of Cochin Hospital decided to systematically propose the switch from innovator infliximab to biosimilar infliximab to all treated patients.
Objectives: To investigate efficacy and safety of switching treatment from innovator infliximab to biosimilar infliximab.
Methods: This is a usual care study conducted in patients aged >18 years who agreed to switch to biosimilar infliximab, and who received at least 3 infusions of innovator infliximab prior to the switch.
The primary outcome of the study was the retention rate of biosimilar infliximab at the time of the third infusion. Secondary outcomes included the factors associated with biosimilar discontinuation, the change between baseline and the last visit (July 2016) in DAS28-CRP (rheumatoid arthritis, RA), BASDAI/ASDAS (axial

spondyloarthritis, axSPA) and infliximab trough levels, and the occurrence of adverse events.
Results: 260 patients fulfilled the inclusion criteria: 182 patients followed-up in Rheumatology (131 with axSPA, 31 with RA, and 20 with other inflammatory rheumatic diseases), 64 in Gastroenterology and 14 in Internal Medicine.
The retention rate at the time of the third biosimilar infusion was 82% (149/182 patients), which was lower than the rate observed in patients with inflammatory bowel diseases or uveitis followed-up in Gastroenterology and Internal Medicine, respectively (71/78 patients, 91%).
Between baseline and the last visit (mean follow-up: 34±4.5 weeks), 48/182 (26%) patients, including 36 patients with axSPA, discontinued biosimilar infliximab, mainly due to experienced inefficacy (n=47). No clinical or biological factors were associated with biosimilar discontinuation.
One infusion reaction led to treatment discontinuation. No serious adverse events occurred. 43 patients restarted innovator infliximab, 2 patients switched to etanercept, 1 to abatacept and 2 maintained biological-free.
In RA patients, the mean DAS28-CRP remained stable from baseline to the last visit: 3.38±1.16 to 3.08±1.08 (p=0.217). In axSpA patients, the mean BASDAI increased from 2.94±2.20 to 3.18±2.21 (p=0.046) and the mean ASDAS increased from 1.79±0.90 to 1.99±1.08 (p=0.022). In RA and axSPA, mean CRP levels at baseline (5.95±6.06 and 5.98±11.14 mg/l respectively) and the last visit (6.52±11.32 and 5.03±8.26 mg/l respectively) were not statistically different (p=0.289 and p=0.271, respectively).
Mean infliximab trough levels were similar in patients with RA (3.70±5.36 vs. 3.21±4.35 μg/ml, p=0.551) and AxSPA (5.88±5.82 vs. 5.70±5.42 μg/ml, p=0.617) during follow-up.
Conclusions: In the majority of patients, innovator infliximab can be switched to biosimilar infliximab without changes in efficacy and safety during 34 weeks follow-up. However, 26% of patients discontinued biosimilar infliximab, mainly those with AxSPA due to a subjective increase in BASDAI or ASDAS scores, possibly explained by suggestion or attribution effects rather than pharmacological differences.

SAT0164 ASSOCIATION BETWEEN FLARE AND RADIOGRAPHIC PROGRESSION IN PATIENTS WITH RHEUMATOID ARTHRITIS

J.S. Smolen[1], H. Jones[2], E. Mahgoub[2], R. Pedersen[2], L. Marshall[2]. *[1]Medical University of Vienna, Vienna, Austria; [2]Pfizer, Collegeville, United States*

Background: Biologic therapy has improved RA management, enabling some patients to achieve remission. Many clinicians decrease the biologic dose for patients in low disease activity (LDA) or remission. However, it is unclear which patients may flare and if flare contributes to radiographic progression.
Objectives: To assess whether patients who flared had a higher incidence of radiographic progression, and to compare patients with and without flares.
Methods: PRESERVE (ClinicalTrials.gov: NCT00565409) was a 2-period trial in patients with moderate RA despite MTX. Period 1 was open-label, single treatment induction with etanercept (ETN) 50mg+MTX weekly (QW) for 36 wks. Patients in LDA or remission (disease activity score for 28 joints [DAS28] $\leq$3.2) during wks 12 to 36 continued to Period 2, the randomized, double-blind phase to evaluate maintenance of LDA/remission. Patients were randomized to ETN 50mg+MTX QW, ETN 25mg+MTX QW, or placebo+MTX QW to wk 88. This post hoc analysis evaluated flare and radiographic progression at wk 88. Flare was defined 2 ways: 1) loss of LDA with/without DAS28 change of 0.6; and 2) relapse (DAS28$>$5.1 or DAS28$>$3.2 at $\geq$2 time points). Radiographic progression was evaluated according to 4 levels of stringency: 1) minimally clinically important difference (modified total Sharp score [mTSS] change $\geq$5); 2) smallest detectable difference (mTSS change $\geq$2.3); 3) mTSS change $\geq$0.5; and 4) mTSS change $>$0. Baseline (BL) characteristics were compared for patients with vs without flare, defined as loss of LDA and DAS28 change of 0.6. Analysis of covariance and chi-square test compared continuous and categorical outcomes, respectively.
Results: Age, race, BMI, and disease duration did not differ significantly for flare vs non-flare, total N=531. BL DAS28 was higher for flare vs non-flare: mean (SD) 4.37 (0.45) vs 4.27 (0.45), p=0.046. Other BL disease characteristics were similar between groups. With flare defined as relapse, significantly more flare than non-flare patients showed all 4 degrees of radiographic progression (table). With flare defined as LDA loss with/without DAS28 change of 0.6, radiographic progression did not differ significantly between groups, but numerically more patients with flare progressed. This was the trend for all treatments; the numbers were too small to analyze. Numerically more placebo patients progressed, regardless of flare status or progression category (data not shown).

Table. Radiographic progression at week 88

Outcome	Flare Patients	Non-flare Patients	P-value*
Flare defined as loss of LDA and DAS28 change of 0.6			
mTSS $>$0	43/271 (15.9)	31/260 (11.9)	0.2109
mTSS $\geq$0.5	38/271 (14.0)	24/260 (9.2)	0.1045
mTSS $\geq$2.3	20/271 (7.4)	10/260 (3.8)	0.0914
mTSS $\geq$5.0	9/271 (3.3)	2/260 (0.8)	0.0633
Flare defined as loss of LDA			
mTSS $>$0	44/280 (15.7)	30/251 (12.0)	0.2586
mTSS $\geq$0.5	39/280 (13.9)	23/251 (9.2)	0.1043
mTSS $\geq$2.3	20/280 (7.1)	10/251 (4.0)	0.1338
mTSS $\geq$5.0	9/280 (3.2)	2/251 (0.8)	0.0670
Flare defined as relapse			
mTSS $>$0	35/181 (19.3)	39/350 (11.1)	0.0119
mTSS $\geq$0.5	31/181 (17.1)	31/350 (8.9)	0.0065
mTSS $\geq$2.3	19/181 (10.5)	11/350 (3.1)	0.0011
mTSS $\geq$5.0	9/181 (5.0)	2/350 (0.6)	0.0015

*Fisher's exact test. Overall treatment group. Values are n/N (%).

Conclusions: Using relapse as a rigorous definition of flare, radiographic progression occurs in significantly more flare than non-flare patients, demonstrating that it is a consequence of flare following biologic withdrawal.

SAT0165 REAL-WORLD UTILIZATION OF CONCOMITANT MEDICATIONS IN PATIENTS INITIATING ETANERCEPT: A RETROSPECTIVE COHORT STUDY OF CANADIAN CLAIMS-LEVEL DATA

M. Khraishi[1], Y. Zhang[2], J. Ivanovic[2], B. Millson[2], M.-J. Brabant[2], E. Singh[3], J. Woolcott[4], H. Jones[3]. *[1]Faculty of Medicine, Memorial University of Newfoundland, St. Johns; [2]Health Access & Outcomes, QuintilesIMS, Kanata, Canada; [3]Inflammation and Immunology, Global Medical Affairs, Pfizer Inc., Collegeville, United States; [4]Health Economics and Outcomes Research, Pfizer Inc., Kirkland, Canada*

Background: Methotrexate (MTX) and prednisone (pred) are immune suppressants frequently used to treat immune-mediated inflammatory diseases (IMIDs). Etanercept is a soluble TNF receptor (humanized protein) indicated for the treatment of IMIDs, including rheumatoid arthritis (RA), psoriatic arthritis (PsA), psoriasis (PsO), and ankylosing spondylitis (AS). Limited information exists on how MTX or pred use changes in patients who initiate etanercept in real-world settings.
Objectives: To evaluate whether initiation of etanercept impacts use of co-therapy with MTX or pred in Canadian patients with IMIDs.
Methods: A retrospective cohort study was conducted using claims-level data from QuintilesIMS Private Drug Plan database, Ontario Public Drug Plan database, and Quebec Public Drug Plan database. Bio-naïve patients initiating etanercept between 07/2013 and 06/2015, were identified and their claims made for MTX or pred were analyzed. Patients' utilization of MTX or pred was calculated as average weekly dose in mg, and then compared in the 6-months pre versus 12-months post initiation of etanercept using a paired t-test. Differences in the presence of concomitant medications pre and post-etanercept were also examined using a paired t-test.
Results: The study captured 3,745 etanercept patients (61% female, 77% aged between 18 and 65, 84% rheumatic diseases, and 15% PsO) across Canada in the selection period. Of selected patients, 33% used MTX (n=1,244) and 14% (n=523) used pred pre and post initiation of etanercept. In concomitant MTX patients, the average weekly dose dispensed was 25.2mg in the 6 months prior to initiation of etanercept, and 25.0mg in the 12 months following the first claim of etanercept (p=0.7493). In concomitant prednisone patients, the average weekly dose dispensed reduced from 123mg pre-etanercept to 108mg post-etanercept initiation (p=0.2316). 19% of patients stopped MTX (n=287) use post-etanercept initiation, compared to 36% who stopped pred use (n=289).
Conclusions: In this real-world setting, approximately 1/5 of patients stopped or reduced co-therapy of MTX; and 1/3 of patients stopped or reduced co-therapy of pred following initiation of etanercept; however, those patients who remained on co-therapy showed non-significant changes in their average consumption. Further research is needed to understand the impact on overall patient outcomes and safety.

SAT0166 MARKERS OF RESPONSE TO INFLIXIMAB IN RHEUMATOID ARTHRITIS – THE PLACE OF ANTINUCLEAR ANTIBODY AND NUCLEASE SERUM ACTIVITY

M. Volkava[1], A. Kundzer[1], I. Generalov[2], D. Petrovich[1]. *[1]Cardiology and Rheumatology, BelMAPGE, Minsk; [2]Clinical Microbiology, VSMU, Vitebsk, Belarus*

Background: It is important to study new potential markers of response to treatment in rheumatoid arthritis (RA), because up to 40% patients don't achieve

remission even using biological therapy. DNAse activity of the blood serum and antinuclear antibody may be useful in this context. Changes of serum DNase activity in the RA treatment by biological agents previously have been not investigated.

Objectives: The aim of this work is to study the dynamics clinical and laboratory parameters, DNAse serum activity and ANA during the RA treatment by infliximab (INF) and assess the prognostic potential of them in prediction of response to INF.

Methods: 24 RA patients were involved in the study. All patients fulfilled the EULAR/ACR 2010 RA criteria. 22/24 patients received 6 infusions of INF at a dose of 3 mg/kg according to standard protocol: at 0th, 2th, 6th and then every 8 week. 2/24 patient received 4 infusions of INF. All patients received synthetic DMARDs therapy by metotrexate (10–17,5 mg weekly), 18/24 patients received glucocorticoids (methylprednisolone 4–8 mg daily) and non-steroidal anti-inflammatory drugs. Prior to treatment by INF patients did not receive any biological agents. All patients had high disease activity before INF treatment (DAS28<5,1).

ANA determination was performed by indirect immunofluorescence on Hep-2 cells using digital system AKLIDES. ANA was measured in serum samples before 1st INF administration, at 22–30 weeks after the 1st INF administration.

To determine the DNAse activity of serum the method of rivanol clot was used. DNase activity was measured in serum samples before 1st INF administration, at 6 weeks after the 1st INF administration, at 30 week of treatment.

Results: At week 30, ACR70 improvement reached 5/22 of the patients, ACR50 - 10/22 of the patients, ACR20 – 4/24 of patients.

At 30 weeks of treatment by INF 2/22 of patients achieved remission (SDAI<3,3), 10/22 - a low disease activity (3,3 <SDAI ≤11).

13/24 patients were ANA-positive before INF treatment, 12/22 - after 24 weeks of treatment.

Levels of serum DNase activity did not differ before and during the INF treatment (p>0,05).

For assessment prognostic value of laboratory signs for INF response prediction logistic regression was used. Prognostic model, which included changes in ANA (Δ ANA) and DNAse serum activity level (Δ DNAse serum activity), anti-CCP- and RF-negativity was better (p=0,02) (area under ROC-curve =1,0; 95% CI 0,844–1,00 p=0,0001) than the model, which included only anti-CCP- and RF-negativity (area under ROC-curve =0,795; 95% CI 0,597–0,924, p=0,0141).

Conclusions: The study confirmed the efficacy of RA treatment by INF for anti-CCP and RF negative patients. DNAse serum activity and ANA may be used as additional prognostic biomarker of INF response. For the assessment DNAse activity as marker of response to therapy is needed futher investigations with more number of patients.

SAT0167 CAN INFLIXIMAB EFFICACY BE PREDICTED BASED ON BLOOD CONCENTRATION AT THE FOURTH DOSE?

M. Sato[1], M. Takemura[2], T. Tani[1], T. Ohashi[1]. *[1]Rheumatology, Ohashi and Tani Orthopedics, Gifu; [2]Advanced Diagnostic System Research Laboratory, Fujita Health University Graduate School of Health Sciences, Toyoake, Japan*

Background: Biological drugs exhibit excellent efficacy and continuity in the treatment of rheumatoid arthritis (RA) and play an important role in RA treatment. Blood concentration is an important factor in the efficacy of biological drugs, particularly antibody drugs. Infliximab (IFX) is an antibody drug against TNF-α and is reported to require a blood concentration of ≥1 μg/mL to be effective.

Objectives: To investigate whether clinical efficacy can be predicted based on blood concentrations at the fourth dose of IFX in patients with RA.

Methods: This study included 56 patients with RA who were treated with IFX. Patients included 13 men and 43 women aged from 26 to 81 years (mean, 60.3 years). The IFX concentration was measured immediately before administering the fourth IFX dose (8 weeks after administering the third dose). We then investigated the relationship between subsequent IFX efficacy and IFX concentration immediately before the fourth dose of IFX in these patients with RA. Concentrations were measured in stored frozen serum by using the ELISA method.

Results: The IFX concentration immediately before the fourth dose was ≥1 μg/mL in 32 patients (≥1 μg/mL group) and <1 μg/mL in 24 patients (<1 μg/mL group). At the fourth dose, IFX was effective in 30 patients (93.8%) in the ≥1 μg/mL group, at a mean concentration of 5.18 μg/mL, while the mean concentration was 5.69 μg/mL for the remaining 2 non-responders. IFX was also effective in 21 patients (87.5%) in the <1 μg/mL group but did not elicit any response in the other 3 patients. At this point, all 5 non-responsive patients were primary non-responders. Of all 51 responders, 58.8% were in the ≥1 μg/mL group and 41.2% were in the <1 μg/mL group. Based on the data, we observed no relationship between efficacy and IFX concentration. After 1 year of IFX treatment, 36 of the 56 patients were responsive and 20 were non-responsive. In the 2 groups, 26 responsive patients (63.9%) and 9 non-responsive patients (45.0%) had an IFX concentration of ≥1 μg/mL immediately before the fourth dose.

Conclusions: At the fourth dose, many of the patients with an IFX concentration of <1 μg/mL were also responsive to the treatment, so future efficacy was difficult to predict based on IFX concentration. In other words, during clinical evaluation, measurement of IFX concentrations is not necessary in responsive patients. However, IFX concentrations should be measured in non-responsive patients or patients with a diminished response. If the concentration is <1 μg/mL, IFX efficacy should be restored by increasing the dose or shortening the administration interval.

SAT0168 DISCONTINUATION OF FIRST BIOLOGIC THERAPY IN RHEUMATOID ARTHRITIS: MAIN CAUSES AND CORRELATION BETWEEN SECONDARY INEFFICACY AND DEVELOPMENT OF IMMUNOGENICITY

P. Bogas[1], C. Plasencia[1], D. Pascual-Salcedo[2], G. Bonilla[1], E. Moral[1], C. Tornero[1], L. Nuño[1], A. Villalba[1], D. Peiteado[1], A. Martinez[2], B. Hernandez[2], A. Balsa[1]. *[1]Rheumatology; [2]Immunology, Hospital Universitario la Paz, Madrid, Spain*

Background: Biologic therapy has been a major change in Rheumatoid Arthritis (RA) prognosis, but around 40% of patients (pts) fail to respond. Part of this treatment failure can be explained by the development of anti-drug antibodies (ADA), but the ADA-associated secondary inefficacies rate is currently unclear

Objectives: To assess in our AR cohort treated with Adalimumab (Ada), Infliximab (Ifx), etanercept (Etn), certolizumab (Czp), Tocilizumab (Tcz) and Abatacept (Abt) as 1st biologic agent, the frequency of drug suspension as well as the main causes for discontinuation and the secondary inefficacy rate associated with the development of immunogenicity

Methods: From the RA cohort that initiated their 1st biologic agent at Hospital La Paz between 2005 and 2016, only those who had suspended those drugs were included, and causes for suspension were collected. Clinical activity was measured by DAS28 and Delta-DAS28 at 6 months of treatment to classify discontinuation by primary or secondary inefficacy. Drug levels (DL) and/or ADA were also measured by ELISA at 6 months since initiating the biologic agent in 43 pts and at drug discontinuation in 59 pts. Primary inefficacy was defined as DAS28>3.2 and delta-DAS28 <1.2 at 6 months with DL present. Secondary inefficacy was defined both as DAS28>3.2 plus delta-DAS28 <1.2 at 6 months with ADA+ and Delta-DAS28>1.2 or DAS28 <3.2 at 6 months with subsequent loss of efficacy. Statistical analysis was performed using SPSS version 20.0

Results: From the 246 pts who started their first biologic therapy, 144 (58%) pts who had definitively discontinued were included. [Ifx (n 35, 24%), Ada (n 40, 28%), Etn (n 30, 21%), Czp (n 23, 16%), Tcz (n 10, 7%) y Abt (n 6, 4%)]. 116 (80,6%) were women. The mean age was 56.3±14.7 years. The mean time of biologic was 2.23±1.96 years. From the global cohort, 18 (12.5%) drop out the treatment due to primary inefficacy, 41 (28.5%) to secondary inefficacy, 57 (39.6%) to adverse effects (AE), 11 (7.6%) to remission and 17 (11.8%) to other causes (surgery, pregnancy, etc.). 12.5% pts who discontinued due to AE or other causes had also a primary or secondary inefficacy; by including those pts in these last causes for suspension, a total of 20 pts (14%) failed due to primary inefficacy and 57 pts (39.6%) to secondary inefficacy. The most frequent AEs were: infections (35%), cutaneous AEs (psoriasis, rash, etc. (10.5%), infusion reactions (9%) and neoplasia (9%). Of the 59 pts who had DL/ADA measured at drug discontinuation, 42.4% were ADA +. Within the group that failed due to secondary inefficacy and had DL/ADA determined, 50% were ADA+; nevertheless this rate was smaller in suspensions due to other causes. Likewise, in the ADA+ pts, 73% suspended due to secondary inefficacy

Demographic Characteristics	
Age (years)	64±15,4
Sex (Female)	116 (80,6%)
Smokers	25 (17,6%)
BMC	27,79±8,87
Disease duration	16,7±8,04
RF +	117 (81,3%)
Anti-CCP +	119 (85,6%)
Duration of treatment (years)	2,23±1,96
Basal DMARDs	127 (89%)
Basal Methotrexate	82 (57,3%)
Basal Leflunomide	57 (39,6%)
Basal Salazopyrine	13 (9,1%)
Basal CPR	15,14±19,4
Basal ESR	34,2±23,4
Basal DAS	5,24±1,32

Conclusions: In our RA cohort, adverse effects were the main cause for discontinuation, with infections at 1st place. The 2nd cause conditioning interruption was the secondary inefficacy, in which 50% of our pts were ADA+ at drug

discontinuation. These data suggest that the development of ADA is a frequent cause of secondary inefficacy in our RA pts

SAT0169 MAINTENANCE AND IMPROVEMENT IN CLINICAL EFFICACY BETWEEN WEEK 12 AND 24 IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH SB4 OR REFERENCE ETANERCEPT

P. Emery[1], J. Vencovsky[2], E. Keystone[3], J. Ghil[4], S.Y. Cheong[4], E.E. Hong[4]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; [2]Institute of Rheumatology, Prague, Czech Republic; [3]Mount Sinai Hospital, Toronto, Canada; [4]Samsung Bioepis Co., Ltd., Incheon, Korea, Republic Of*

Background: SB4 is approved by the European Commission as a biosimilar of the reference etanercept (ETN).
Objectives: To evaluate the maintenance and improvement in clinical efficacy between week 12 and 24 in patients with rheumatoid arthritis (RA) treated with SB4 or ETN from a post-hoc analysis of phase III results.
Methods: Patients with RA were randomised to receive 50 mg/week of either SB4 or ETN with background methotrexate. American College of Rheumatology (ACR) and European League Against Rheumatism (EULAR) responses were compared at week 12 and week 24. At week 12, patients with available assessment results were categorised as ACR responders or ACR non-responders and EULAR responders (patients with moderate or good EULAR response) or EULAR non-responders. The same was assessed for week 24 and patients with missing data at week 24 were regarded as non-responders.
Results: A total of 551 patients (283 patients from SB4 and 268 patients from ETN) completed 24 weeks of the study. In both treatment groups, efficacy was well maintained between week 12 and week 24. Among patients who were ACR20, 50, or 70 responders at week 12, 90.8% vs. 91.4%, 80.5% vs. 80.6%, and 74.5 vs. 77.5% of patients from SB4 and ETN, respectively, maintained their responses at week 24. Likewise, EULAR response was maintained by 93.1% vs. 92.6% of patients who had a good or moderate response at week 12. (Table).
The improvement in ACR responses between week 12 and 24 was comparable between SB4 and ETN group (Table). In SB4 and ETN, respectively, 42.1% vs. 50.5% of 12-week ACR20 non-responders became ACR20 responders at week 24. Similarly, 20.9% vs. 21.9% of 12-week ACR50 non-responders became ACR50 responders and 13.0% vs. 11.4% of 12-week ACR70 non-responders became ACR70 responders. The improvement in EULAR responses was also comparable between SB4 and ETN. 43.2% vs. 52.2% of 12-week EULAR non-responders in SB4 and ETN, respectively, became EULAR responders at week 24.

Table. Maintenance and improvement of efficacy between week 12 and week 24

		Week 24 responders	
		SB4 50 mg n/n' (%)	ETN 50 mg n/n' (%)
ACR20	Responder at week 12	179/196 (91.3%)	162/175 (92.6%)
	Non-responder at week 12	41/97 (42.3%)	51/105 (48.6%)
ACR50	Responder at week 12	91/114 (79.8%)	75/93 (80.6%)
	Non-responder at week 12	37/179 (20.7%)	41/187 (21.9%)
ACR70	Responder at week 12	38/51 (74.5%)	31/40 (77.5%)
	Non-responder at week 12	31/242 (12.8%)	28/240 (11.7%)
EULAR response*	Responder at week 12	231/246 (93.9%)	215/231 (93.1%)
	Non-responder at week 12	19/46 (41.3%)	24/49 (49.0%)

n, number of responders; n', number of responders or non-responders at week 12
*Patients with moderate or good EULAR response were regarded as responders.

Conclusions: Efficacy of SB4 and ETN was well maintained and the maintenance rate was comparable between week 12 and week 24. In addition, a similar and considerable proportion of patients in SB4 and ETN who did not achieve a clinical response at week 12 reached clinical response at week 24. These results suggest that etanercept non-responders at week 12 may benefit from continuing treatment up to 24 weeks.

SAT0170 B-CELL PHENOTYPE AND IGD-CD27- MEMORY B CELLS ARE AFFECTED BY TNF-INHIBITORS AND TOCILIZUMAB TREATMENT IN RHEUMATOID ARTHRITIS

R.A. Moura[1], C. Quaresma[1], A.R. Vieira[1], M.J. Gonçalves[1,2], J. Polido-Pereira[1,2], V.C. Romão[1,2], N. Martins[2], H. Canhão[1,2], J.E. Fonseca[1,2]. *[1]Rheumatology Research Unit, Instituto de Medicina Molecular; [2]Rheumatology Department, Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria, Lisbon, Portugal*

Background: The use of TNF-inhibitors and/or the IL-6 receptor antagonist, tocilizumab, in rheumatoid arthritis (RA) have pleiotropic effects that also involve circulating B-cells.
Objectives: The main goal of this study was to assess the effect of TNF-inhibitors and tocilizumab on B-cell phenotype and gene expression in RA.
Methods: Blood samples were collected from untreated early RA (ERA) patients (<1 year of disease duration), established RA patients under methotrexate treatment, established RA patients before and after treatment with TNF-inhibitors and tocilizumab, and healthy donors. B-cell subpopulations were characterized by flow cytometry and B-cell gene expression was analyzed by real-time PCR on isolated B-cells. Serum levels of BAFF, CXCL13 and sCD23 were determined by ELISA.
Results: The frequency of total CD19+ B-cells in circulation was similar between controls and all RA groups, irrespective of treatment, but double negative (DN) IgD-CD27- memory B-cells were significantly increased in ERA and established RA when compared to controls. Treatment with TNF-inhibitors and tocilizumab restored the frequency of IgD-CD27- B-cells to normal levels, but did not affect other B-cell subpopulations. TACI, CD95, CD5, HLA-DR and TLR9 expression on B-cells significantly increased after treatment with either TNF-inhibitors and/ or tocilizumab, but no significant changes were observed in BAFF-R, BCMA, CD69, CD86, CXCR5, CD23, CD38 and IgM expression on B-cells when comparing baseline with post-treatment follow-ups. Alterations in B-cell gene expression of BAFF-R, TACI, TLR9, FcγRIIB, BCL-2, BLIMP-1 and β2M were found in ERA and established RA patients, but no significant differences were observed after TNF-inhibitors and tocilizumab treatment when comparing baseline and follow-ups. Serum levels of CXCL13, sCD23 and BAFF were not significantly affected by treatment with TNF-inhibitors and tocilizumab.
Conclusions: In RA, treatment with either TNF-inhibitors or tocilizumab affects B-cell phenotype and the frequency of memory B-cell subpopulations in peripheral blood, particularly DN (IgD-CD27-) B-cells, but not B-cell gene expression or serum levels of CXCL13, sCD23 and BAFF, when comparing baseline with post-treatment follow up. Overall, our results may suggest that TNF-inhibitors and tocilizumab inhibit B-cell trafficking towards inflammatory sites, thus supporting activated B-cell recirculation from tissues through blood and lymphatic systems.

SAT0171 ABP 501 BIOSMILAR TO ADALIMUMAB: FINAL SAFETY, IMMUNOGENICITY, AND EFFICACY RESULTS FROM AN OPEN-LABEL EXTENSION STUDY

S. Cohen[1], J.L. Pablos[2], H. Wang[3], G.A. Müller[4], A. Kivitz[5], A. Matsumoto[6], E. Krishnan[3]. *[1]Metroplex Clinical Research Center, Dallas, United States; [2]Instituto de Investigación Hospital, Madrid, Spain; [3]Amgen, Thousand Oaks, United States; [4]Abteilung für Nephrologie und Rheumatologie, Göttingen, Germany; [5]Altoona Center for Clinical Research, Duncansville; [6]Arthritis and Rheumatism Associates, Wheaton, United States*

Background: ABP 501 has been approved by the US FDA as the first biosimilar to the fully human recombinant monoclonal antibody, adalimumab. Totality of evidence to date suggests that ABP 501 is highly similar to adalimumab. Subjects receiving either ABP 501 or adalimumab in the active-controlled, comparative, pivotal phase 3 study in rheumatoid arthritis (parent study) continued on to this open-label extension (OLE) study if they had completed the final week 26 visit of that study.
Objectives: To describe the safety, immunogenicity, and efficacy outcomes of ABP 501 in the OLE study.
Methods: Subjects who completed the parent study were screened and were included if they met the eligibility requirements. All subjects included in the OLE were treated with ABP 501 40 mg subcutaneously every other week for 68 weeks followed by disease assessments at week 70 and the follow-up safety assessment at week 72 (or early termination). Data were summarized descriptively and no inferential analyses were performed.
Results: Of the 467 subjects enrolled in the OLE study, 466 were treated with ABP 501. Of these, 237 transitioned from the adalimumab arm of the parent study; 412/467 completed the study. Demographics and disease characteristics were balanced between subjects who transitioned from adalimumab and those who continued on ABP 501 from the parent study. Overall, the incidence of treatment-emergent adverse events (TEAEs) was 63.7% (297/466) and that of grade ≥3 TEAEs was 9.0% (42/466); incidence of TEAEs leading to discontinuation of investigational product was 3.6% (17/466). TEAEs with incidence ≥5% were nasopharyngitis (9.2%), upper respiratory tract infection (8.6%), bronchitis (6.4%), rheumatoid arthritis (6.2%), hypertension (4.7%), and pharyngitis (4.1%). The incidence of serious adverse events was 9.9% (46/466). Most common

TEAEs of interest were infections (40.8%), liver enzyme elevations (5.4%), and hypersensitivity (4.3%).
Overall, 18.2% (85/466) of subjects developed binding antidrug antibodies (ADAs) and 6.9% (32/466) developed neutralizing ADAs in the OLE study. The rates of ADA formation were similar between subjects who transitioned from adalimumab and those who continued on ABP 501.
The ACR20 response rate (using the parent study baseline) was 73.3% (340/464) at the OLE study baseline, 77.6% (361/465) at week 4, 74.2% (336/453) at week 24, 77.6% (337/434) at week 48, and 78.8% (327/415) at week 70. The overall mean DAS28-CRP change from parent study baseline was −2.25 (n=440) at the OLE study baseline, −2.36 (n=463) at week 4, −2.41 (n=450) at week 24, −2.55 at week 48 (n=433), and –2.60 at week 70 (n=412).
Conclusions: In this OLE study of ABP 501, efficacy documented in the parent study was maintained with no new safety findings. Long-term safety, immunogenicity, and efficacy results were similar between subjects who transitioned from adalimumab and those who continued on ABP 501 from the parent study.

SAT0172 ECONOMIC OUTCOMES, TREATMENT PATTERNS, AND ADVERSE EVENTS AND REACTIONS FOR PATIENTS PRESCRIBED INFLIXIMAB OR CT-P13 IN THE TURKISH POPULATION

K. Phillips[1], T. Juday[2], Q. Zhang[3], A. Keshishian[3]. *[1]Vanderbilt University Medical Center, Nashville; [2]AbbVie Inc., North Chicago; [3]STATinMED Research, Ann Arbor, United States*

Background: CT-P13, a biosimilar drug product to infliximab, was approved and marketed in July 2014 in Turkey. There is little information on the costs, treatment discontinuation and adverse events and reactions between patients who switched from infliximab to CT-P13 and patients who continued infliximab.
Objectives: The study objective was to evaluate health care costs, treatment discontinuation, and adverse events and reactions between patients who switched from infliximab to CT-P13 and patients who continued infliximab in the Turkish population.
Methods: Adult patients with ≥1 claim for infliximab or CT-P13 were identified in a Turkish healthcare administrative database representing 80% of the Turkish population during the identification period (16 July 2014–31 Aug 2015). Patients were required to continuously use infliximab for ≥6 months with no hospitalizations. Eligible patients either continued on infliximab (index date: date of first infliximab prescription), or switched from infliximab to CT-P13 (index date: switch date). Patients were excluded if they had ≥1 condition with an indication for infliximab during the baseline period. Patients who switched to CT-P13 were 1:10 matched to patients who continued infliximab based on the length of infliximab use prior to the index date. Demographics and clinical characteristics were measured 12 months pre-index date. Generalized linear models were used to compare adjusted health care costs, Cox regression was used to evaluate the adjusted risk of discontinuation, and Poisson regression was used to evaluate the adjusted risk of adverse events and reactions.
Results: The study included 1,524 patients, of whom 1,388 were continuous infliximab users and 136 switched to CT-P13. Ankylosing spondylitis and rheumatoid arthritis were the most common conditions indicated for infliximab and CT-P13; however, patients were much less likely to be switched to CT-P13 for other conditions. After adjusting for demographics and clinical characteristics, patients who switched to CT-P13 had higher outpatient ([Turkish lira] TL 269 vs TL 181; p=0.005), inpatient (TL 64 vs TL 29; p=0.313), and pharmacy costs (TL 1,473 vs TL 1,329; p=0.371), which resulted in significantly higher total health care costs (TL 2,009 vs TL 1,640; p=0.046) compared to patients who continued infliximab. Additionally, patients who switched to CT-P13 were more likely to discontinue treatment (13.2 vs 1.52 per 1000 person-years) compared to those who continued infliximab. Of patients who discontinued CT-P13, 79% switched back to infliximab. After adjusting for baseline characteristics, patients who switched to CT-P13 were significantly more likely to discontinue treatment compared to those who continued infliximab (HR=5.53; 95% CI: 4.01–7.63). There was no difference in the adjusted incidence rate ratio (IRR) between the cohorts for adverse events (IRR=0.67; 95% CI: 0.19–2.30) and reactions (IRR=0.84; 95% CI: 0.55–1.27).
Conclusions: Patients who switched to CT-P13 had significantly higher health care costs and were also more likely to discontinue treatment compared to those who continued infliximab. However, there was no difference in the rate of adverse events and reactions.

SAT0173 SWITCHING FROM REFERENCE PRODUCT ETANERCEPT TO THE BIOSIMILAR SB4 IN A REAL-LIFE SETTING: FOLLOW-UP OF 147 PATIENTS

V. Sigurdardottir[1,2], T. Husmark[1], A. Svärd[1,2]. *[1]Reumatologkliniken, Falu lasarett; [2]Centre of Clinical Research Dalarna, Falun, Sweden*

Background: The etanercept biosimilar SB4 was introduced in Sweden in early 2016. SB4 has been shown in a randomized controlled trial to be equivalent to its etanercept reference product (ERP) in terms of efficacy and safety in subjects with active rheumatoid arthritis (RA) (1). In light of this, and the fact that biosimilars offer considerable cost savings, all patients being treated with ERP at our clinic were switched to treatment with SB4 in april 2016.
Objectives: To describe the clinical experiences of switching patients on treatment with ERP to SB4 at our clinic.
Methods: All patients using ERP 50 mg at our clinic were identified using the Swedish Rheumatology Quality Register (SRQ). The patients were issued prescriptions for SB4 50 mg and were sent a letter encouraging them to switch to SB4 when they ran out of ERP. The process of switching was started 21st. However, the actual date of starting treatment with SB4 might have been 0–90 days from April 20th for individual patients, as prescriptions are written in 3 month increments.
Patients were followed up clinically and in the SRQ as planned at the last visit before switching.
For RA and psoriatic arthritis (PsA) patients DAS28 values from the last visit preceding the switch and the last visit after the switch registered up to January 2017 were collected from the SRQ. The paired T-test was used to compare mean DAS28 before and after switching.
Results: Before the switch, 147 patients were on treatment with ERP. Indications for treatment were RA (N=76), PsA (N=28), other spondyloarthritis (N=13), ankylosing spondylitis (N=12), unspecified arthritis (N=10) and juvenile arthritis (N=8).
At the end of January 2017, 126 patients (86%) were still on SB4.
Since the switch, 9 patients have requested to be switched back to ERP, 2 made the request before initiating therapy with SB4. No objective evidence for lack of efficacy was seen in these 9 patients. Seven patients have stopped treatment with SB4 because of inactive disease. Five patients have been switched to a non-etanercept biologic because of lack of efficacy, these patients also had lack of efficacy when on ERP.
The 76 RA patients had a mean disease duration of 17 years and had been on ERP for a mean duration of 4.7 years. As of January 2017, 60 of the RA patients have been on a follow-up visit and 54 of these had available DAS28 data from both the last visit before and after switching. For the RA patients DAS28 was 2.80 before and 2.79 after switching, p=0.960. Complete DAS28 data was available for 23 of the 28 PsA patients, mean DAS28 was 2.54 before switching and 2.06 after, p=0.161. The mean duration since switching at follow-up was 22 weeks for the RA and PsA patients.
Conclusions: Switching from the etanercept reference product to the biosimilar SB4 was acceptable to most of our patients. Low mean disease activity has been maintained in the RA and PsA group after the switch.

SAT0174 USE OF A 8-WEEK OBSERVATIONAL PERIOD FOR PREDICTING REMISSION AND LOW DISEASE ACTIVITY AT 52 WEEKS IN RA PATIENTS TREATED WITH CERTOLIZUMAB PEGOL – A MULTICENTER STUDY

Y. Kanayama[1], A. Kaneko[2], N. Takahashi[3], T. Kato[4], M. Hayashi[5], Y. Hattori[2], N. Asai[3], N. Ishiguro[3], T. Kojima[3] on behalf of TBCR study group. *[1]Orthopedic Surgery and Rheumatology, Toyota Kosei Hospital, Toyota; [2]Orthopedic Surgery and Rheumatology, Nagoya Medial Center; [3]Orthopedic Surgery, Nagoya University Graduate school of Medicine, Nagoya; [4]Orthopedic Surgery, Kato clinic, Okazaki; [5]Orthopedic Surgery and Rheumatology, Nagano Red Cross Hospital, Nagano, Japan*

Background: Certolizumab pegol (CZP) is a polyethylene glycol (PEG)ylated Fc-free new anti-TNF α agent. However few data still reported clinical efficacy of CZP treatment in the routine practice.
Objectives: This study aimed to provide clinical evidence of an adequate observational period for predicting remission and low disease activity (LDA) achievement at 52 weeks in RA patients treated with Certolizumab pegol (CZP).
Methods: Patients with a diagnosis of RA according to the 2010 ACR/EULAR criteria who had been prescribed CZP from Tsurumai Biologics Communication Registry (TBCR) between May 2013 and October 2015 were enrolled.The final study cohort of 98 Japanese RA patients. We reviewed the methods about the improvement of DAS28-ESR and SDAI which was an index of disease activity of RA using Wilcoxon signed-rank test and the rate of remission and LDA patients at

Week4, 8, 12, 24 and 52 by LOCF method. Also we used ROC analysis in order to determine the optimal period to achieve remission for the DAS-ESR and SDAI at Week52.

Results: The group of patients included 16 males and 82 females. The mean age was 59.5±14.7 years old; the disease duration was 9.4±8.8 years; the patients of receiving methotrexate (MTX) was 73 cases (74%); the MTX dose was 11.2±3.6 mg/week and b-DMARD naïve patients was 57 cases (61%). Clinical findings related to RA were as follows: mean tender joint count, 5.2±4.7; swollen joint count, 5.0±4.0; patient's and physician's global assessment of disease activity, 48.9±27.4 and 42.3±23.2mm; CRP, 1.9±2.2 mg/dL; ESR, 47.4±34.0 mm/h; MMP3, 233±186 ng/ml; the rate of rheumatoid factor positive patients was 78%; DAS28 (ESR), 4.84±1.36; and SDAI, 21.2±11.3. The mean DAS-ESR improved to 3.54±1.35, 3.31±1.46, 3.37±1.47 and 3.31±1.43 at Week 4, 12, 24 and 52 ($p<0.001$, $p<0.001$, $p<0.001$, $p<0.001$) and the mean SDAI improved to 11.4±9.0, 9.7±9.0, 9.8±9.1 and 9.4±9.1 at Week 4, 12, 24 and 52 ($p<0.001$, $p<0.001$, $p<0.001$, $p<0.001$) significantly (Fig.1). At Week 4, 12, 24 and 52 the rate of patients who achieved remission were each 28.8, 37.2, 32.9, 33.7% and 11.7, 29.3, 30.5, 28.8% in DAS-ESR and SDAI criteria (Fig.2). Also at Week 4, 12, 24 and 52 the rate of patients who achieved low disease activity (LDA) were each 46.6, 53.2, 51.2, 55.8% and 58.8, 64.1, 65.9, 71.3% in DAS-ESR and SDAI criteria. Areas under the receiver operating characteristic curves for the DAS28-ESR and SDAI at each time point for remision achievement at 52 weeks were each 0.578 and 0.702 at baseline, 0.755 and 0.822 at week4, 0.821 (cut-off index 2.73, odds ratio 16.7, sensitivity 0.75, specificity, 0.85) and 0.856 (cut-off index 5.30, odds ratio 29.6, sensitivity 0.86, specificity, 0.82) at week8, and 0.820 and 0.809 at week12.

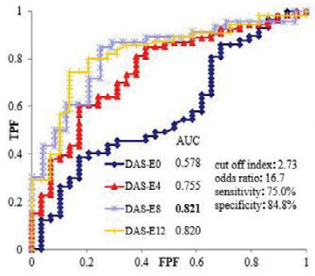

Figure 1 : ROC curves of the DAS28-ESR at each time point for predicting the achievement of remission at week 52 after starting CZP treatment

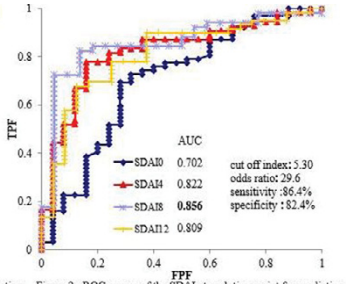

Figure 2 : ROC curves of the SDAI at each time point for predicting the achievement of remission at week 52 after starting CZP treatment

Conclusions: The new TNF-antagonist therapy of CZP was effective early and rapidly in patients with active Japanese RA. This study suggested that eight weeks is an adequate optimal period to judge whether the achieved remission or not at Week 52.

SAT0175 A DESCRIPTIVE ANALYSIS OF REAL-WORLD TREATMENT PATTERNS IN A TURKISH RHEUMATOLOGY POPULATION THAT CONTINUED INNOVATOR INFLIXIMAB (REMICADE) THERAPY OR SWITCHED TO BIOSIMILAR INFLIXIMAB

Y. Yazici[1], L. Xie[2], A. Ogbomo[2], D. Parenti[3], K. Goyal[3], A. Teeple[3], L. Ellis[3], I. Simsek[4]. *[1]New York University Hospital for Joint Diseases, New York; [2]STATinMED Research Inc, Ann Arbor; [3]Janssen Scientific Affairs, LLC, Horsham, United States; [4]Guven Hospital, Ankara, Turkey*

Objectives: This study examined treatment patterns in a rheumatology patient (pt) population initially prescribed innovator infliximab (IFX) that either switched to biosimilar infliximab (CT-P13) or continued on IFX following availability of CT-P13 in the Turkish healthcare system.

Methods: Adult pts with ≥1 diagnosis code (ICD-10-CM M05.X; M06.X) for rheumatoid arthritis (RA) and a prescription for IFX were identified in a national Turkish health care database during the study period (01DEC2010–01DEC2015). Eligible pts were those who continued on IFX (Continuers cohort; CC) or switched from IFX to CT-P13 (Switchers cohort; SC) during the identification period; had continuous medical/pharmacy benefit enrollment ≥12 months before and ≥6 months after the index date (date of switch for SC and a random IFX prescription date for CC); had a prescription claim for IFX within 16 weeks of the index date during the baseline period. Demographics, concomitant disease, medications, and treatment patterns (dose, refill interval, discontinuation, and switch) were summarized. A confirmed discontinuation was defined as a switch to another biologic medication or the absence of an index biologic claim for ≥120 days without censoring. Patient weight was unavailable in the dataset.

Results: Key results are shown in the Table. A total of 3018 pts met study criteria. The majority (95%; n=2870; CC) continued on IFX and had a mean age of 44 years; 46% were female and mean follow up of 12 months. A total of 148 pts (5%) switched to CT-P13 (SC) and had mean age of 44 years; 51% female and mean follow up of 9 months. Approximately 40% of pts in each cohort had a concomitant diagnosis for ankylosing spondylitis (AS; Table). Other concomitant diseases and medications appeared balanced between cohorts. In the CC, pts had an average of 4.7 infusions at a mean dose of 4.4 vials approximately every 10 weeks. In the SC, pts had an average of 2.6 infusions at a mean dose of 3.6 vials approximately every 10 weeks. Therapy discontinuation occurred in 38% in the CC; average time to any discontinuation or censoring of IFX was 256 days (Table). In the SC, CT-P13 discontinuation was observed in 82%; average time to any discontinuation or censoring of CT-P13 was 124 days; 74% of SC switched to another biologic with 94% of these returning to IFX.

	Switchers Cohort (N=148)		Continuers Cohort (N=2870)	
	N/Mean	%/SD	N/Mean	%/SD
Age (Mean) (years)	44	13	44	12
Gender				
Female	75	51%	1,332	46 %
Average Length of Follow up Period (in Months)	9	2	12	3
Concomitant Disease During Baseline Period				
Ankylosing Spondylitis	73	49%	1,214	42%
Psoriatic Arthritis or Psoriasis	19	13%	582	20%
Crohn's Disease	6	4%	191	7%
Ulcerative Colitis	8	5%	157	5%
Concomitant RA-Medications During Follow-Up Period				
Methotrexate	31	21%	652	23%
Sulfasalazine	21	14%	340	12%
Dosing Characteristics				
Average # of doses within follow up period	2.6	1.6	4.7	2.4
Mean # of weeks between doses	10.1	5.1	9.9	3.8
Mean # of days between 1st and 2nd dose	75	48	70	34
Mean # of days between 2nd and 3rd dose	72	38	70	29
Mean # of days between 3rd and 4th dose	65	31	67	26
Mean # of vials per Infusion	3.6	1.6	4.4	1.9
Switching				
# and % of patients with ≥1 switch	110	74%	471	16%
% of Primary Switches from CT-P13 to IFX	103	94%	NA	NA
Discontinuation				
# of Patients Confirmed to Have Discontinued	121	82%	1,089	38%
Time to confirmed discontinuation (days)	94	58	126	91
Time to any discontinuation or censoring (days):	124	87	256	138

Conclusions: This study shows switching from IFX to CT-P13 was infrequent. However, in those switching to CT-P13, a high percentage (82%) of CT-P13 discontinuation was observed and the majority returned to IFX. Further studies are needed to understand the reasons for these observations.

[1]Joint Rheumatology Program, University of Athens, Athens; [2]University of Ioannina, Ioannina; [3]University of Crete, Heraklion; [4]KAT Hospital, Athens; [5]University of Thessaly, Larissa; [6]Sismanoglio Hospital, Athens; [7]Aristotle University, Thessaloniki; [8]401 General Military Hospital; [9]NIMTS Hospital; [10]Private practice, Athens; [11]Agios Andreas Hospital, Patras; [12]Rheumatology Unit, Naval Hospital; [13]Hygeia Hospital, Athens, Greece

Background: There are limited literature data regarding the characteristics of rheumatoid arthritis (RA) patients treated with biologic DMARD (bDMARD) monotherapy.
Objectives: To evaluate the disease and treatment characteristics of RA patients treated with bDMARD monotherapy.
Methods: Multicenter, cross-sectional RA epidemiological study in Greece (06/2015–05/2016, ERE RA Study Group). Demographics, disease characteristics, treatment and co-morbidity data were collected via a web-based platform
Results: 1036 RA patients treated with bDMARDs were identified during the one year recruitment period (female: 82%, mean age: 61.5±13 years, mean disease duration: 12.5±8.9 years, mean DAS28-ESR: 3.4±3.3). Among them, 26% (n=273) were receiving bDMARDs as monotherapy and 8% (n=23) of them had never tried conventional synthetic DMARDs (csDMARDs) before; The latter group (n=23) compared to the csDMARD-exposed (92%, n=250) group, had more often co-morbidities [cardiovascular disease (22% vs. 8%, p=0.029), chronic hepatitis (13% vs. 3%, p=0.02), hypertension (57% vs. 38%, p=0.08), COPD (13% vs. 4.4%, p=0.07)] or were active smokers (41% vs. 14%, p=0.001). csDMARD discontinuation was mainly due to adverse events (AEs, 58%) followed by inadequate response (IR, 44%). Compared to the cs- and b-DMARD combination therapy group, monotherapy treated patients were more frequently seropositive (64% vs. 57%, p=0.003), had lower DAS28-ESR (3.2 vs 3.5, p=0.009) and were more likely to have discontinued csDMARDs for AEs (58% vs. 21%, $p<0.001$) or IR (44% vs. 27%, $p<0.001$). Tocilizumab (22.3% vs. 12.7%, $p<0.001$) and rituximab (19.8% vs. 13.5%, p=0.013) were utilized more often, whereas adalimumab less often (8.8% vs. 14.8%, p=0.012) as monotherapy compared to as part of combination therapy.
Conclusions: In our large RA cohort, one out of four bDMARD treated patients, were receiving bDMARDs as monotherapy. Co-morbidities rather than RA characteristics influence the initial decision for bDMARD monotherapy whereas among those starting combination cs- and b-DMARD therapy, the majority discontinue csDMARDs due to AEs.

SAT0177 SAFETY EVENTS ARE SIMILAR WITH ABATACEPT VS PLACEBO TREATMENT IN RA: RESULTS FROM INTEGRATED DATA ANALYSIS FROM NINE CLINICAL TRIALS

B. Soule[1], M. Hochberg[2], D. Fleming[1], A. Torbeyns[1], T. Simon[1], S. Banerjee[1], M. Boers[3]. *[1]Bristol-Myers Squibb, Princeton; [2]University of Maryland, Baltimore, United States; [3]VU University Medical Center, Amsterdam, Netherlands*

Background: Abatacept is a selective co-stimulation modulator that consists of the extracellular domain of human cytotoxic T lymphocyte-associated antigen-4 linked to the modified Fc portion of human immunoglobulin and was approved initially for the treatment of RA in 2005. The integrated safety database for abatacept in adult RA comprises data from short- and long-term periods of 16 open-label and double-blind RA clinical trials, and combines studies of both IV and SC abatacept involving 7044 total patients. Of these, data from the 9 double-blind, placebo-controlled studies involving 4138 total patients were included in this analysis. The most recent overall safety analysis was performed in 2012 and reported IV and SC results separately.
Objectives: To provide an update of the overall abatacept safety profile based on data analysis from both IV and SC trials.
Methods: This evaluation included all patients with RA enrolled in 9 key double-blind, placebo-controlled clinical trials of IV and/or SC abatacept. The safety analysis includes all serious adverse events (SAEs), as well as AEs of interest including infections, malignancies and autoimmune diseases.
Results: In total, 2653 patients were exposed to abatacept and 1485 received placebo. During the double-blind, controlled period, the mean (SD) duration of exposure was 10.3 (3.5) months for the placebo group and 10.8 (3.3) months for the abatacept group for a total exposure of 2357 and 1254 patient years, respectively (Table 1). The proportion of patients as well as incidence rates for death, SAEs, infections, malignancy and autoimmune diseases were similar between those treated with abatacept and placebo (Table 2).
Conclusions: In a large RA clinical trial database, safety events including deaths, serious infections, opportunistic infections, malignancies and autoimmune diseases occurred at similar frequencies and rates in the abatacept and placebo treatment groups.

SAT0178 PULMONARY INVOLVEMENT IN RHEUMATOID ARTHRITIS TREATED WITH BIOLOGIC

E. Guerrero[1], M.L. García[1], E. Galindez[1], E. Ruíz[1], I. Torre[1], L. Estopiñan[1], O. Fernández[1], A. Inchaurbe[1], C. Perez[1], J. Blanco[1], I. Calvo[1], O. Ibarguengoitia[1], N. Rivera[1], I. Gorostiza[2] on behalf of Rheumatology Service. *[1]Rheumatology Service; [2]Research Unit, Basurto Hospital, Bilbao, Spain*

Background: Use of biologic therapy (BT) has been determinant in Rheumatoid Arthritis' (RA) change of management and outcomes improvement for the last decade. Classic extraarticular manifestations are now uncommon, except for the pulmonary involvement, which can occur due to different causes and can complicate our patients' treatment and prognosis.
Objectives: The aim of this study is to evaluate the presence of pulmonary complication in RA patients under BT in our hospital, and assess its severity and the modifications required.
Methods: Review of clinical records of 208 RA patients receiving BT in the last 5 years (January 2012 to December 2016). 23 cases of preexisting lung disease for other causes have been excluded and finally 26 patients have been finally included. Demographic data, characteristics of RA, types of pulmonary involvement, evolution and changes in treatment have been collected. Statistical analysis were performed using SPSS v22.
Results: 73.1% are women, mean aged 59 years (31–80); 53.8% never smokers. They suffer from long term RA (median 176.92 months, SD 199.34); only 2 patientes have been recently diagnosed (less than a year). They are mainly seropositive (85% RF positive) with positive CCP antibodies in 69.2%, and with erosive disease in 70%. 25% have other extraarticular manifestations (3 rheumatoid nodules, 4 cardiac involvement).
Half of the patients were in remission or low activity (DAS 28) at the time of pulmonary disease diagnosis, and the median of CRP was 0.52 mg/dL (SD 1.72). 90% had received Methotrexate and almost half of them Leflunomide; 30% had been treated with BT (50% TNF alpha inhibitors).
Intersticial lung disease (ILD) was the most frequent pulmonary involvement (57.7%) and non-specific interstitial pheumonia (NSIP) the most prevalent pattern (>60%). We also found obstructive pulmonary disease (11.5%) and vascular involvement (7.7%). 40% of the patients had a normal radiograph (all of them a pathological CT).
Treatment was modified in 53.8% of the cases (synthetic DMARD was kept in 68% and BT in 64%).
The average time of evolution of pulmonary involvement is 37.85 months (1–156). 80% of the patients kept stable or improved from their arthritis and also from respiratory disease. Only one received a lung trasplant and another one died.
We haven't found an association between different types of pulmonary involvement and the different variables analyzed in the study. We didn't show significant differences in prognosis related to pulmonary disease distinct patterns; up to 80% of patients with ILD stabilize or improve.
Conclusions: Prevalence of pulmonary disease in our experience in RA patients under BT is similar to prevalence in other observational studies (10–20%), because diagnosis here is due to casual detection in a routine chest X-ray or for clinical suspicion for respiratory symptoms (cough, dyspnea, ...). The evolution has been good perhaps for the high prevalence of NSIP, which requires less therapeutic intervention. Protocols for systematic search of lung disease in RA patients seem essential for its proper diagnosis, and there is a need for further research in pathogenesis and management of this complication.

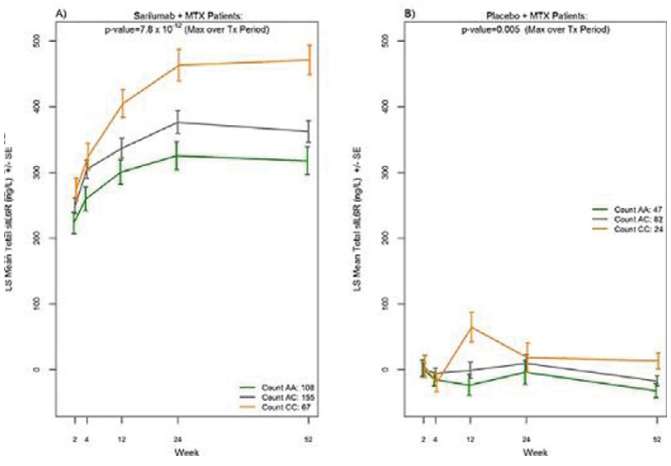
SAT0179 THE ASP358ALA VARIANT IN THE IL6R GENE IS SIGNIFICANTLY ASSOCIATED WITH DIFFERENCES IN SOLUBLE IL-6R PROTEIN LEVELS BUT NOT WITH DIFFERENCES IN SARILUMAB RESPONSE IN RHEUMATOID ARTHRITIS (RA) PATIENTS

A. Damask[1], A. Boyapati[1], J.D. Hamilton[1], S. Hamon[1], C. Paccard[2], J. Parrino[1], J. van Adelsberg[1], N.M. Graham[1], J. Penn[1], A. Lopez[1], J. Reid[1], J. Overton[1], A. Baras[1], A.R. Shuldiner[1], C. Paulding[1]. *[1]Regeneron Pharmaceuticals, Inc, Tarrytown, United States; [2]Sanofi R&D, Chilly-Mazarin, France*



Background: Sarilumab is a human mAb that blocks IL-6 from binding to both membrane-bound and soluble IL-6Rα (sIL-6R). A missense variant in the *IL6R* gene, Asp358Ala (rs2228145), falls within a proteolytic cleavage site and individuals with an alanine at this position have increased sIL-6R in circulation.[1] In addition, this variant has been associated with several diseases including RA.[2]
Objectives: To determine the impact of the Asp358Ala variant on sIL-6R concentrations and response of RA patients to sarilumab.
Methods: DNA was collected from patients enrolled in the MOBILITY study (NCT01061736) that evaluated the efficacy and safety of sarilumab + methotrexate (MTX) in RA patients with inadequate response to MTX. The pharmacogenetic analysis was conducted on 599 Caucasian patients (396 sarilumab 150 or 200 mg q2w + MTX, 203 placebo + MTX).
Results: Concentrations of sIL-6R were strongly associated with the Asp358Ala genotypes at baseline (p=4.2 × 10^{-11}). The difference in sIL-6R concentrations between genotype groups continued to increase in sarilumab-treated patients through the end of treatment, particularly for the CC genotype (Figure; p=7.8 × 10^{-12}). There was a modest association for change in sIL-6R in placebo + MTX–treated patients (p=0.0052). Variation in Asp358Ala was not associated with sarilumab efficacy, including mTSS at week 52 and ACR scores (Table).

Table 1. Efficacy Endpoints[1] and sIL-6R Levels by Asp358Ala Genotypes in Sarilumab-Treated Patients[2]

Genotype	sIL-6R	mTSS[3]	ACR20	ACR50	ACR70	MCR[4]	SJC[5]	TJC[6]
AA (n=129)	317.7 (21.0)	1.4 (0.5)	59	40	22	13	-10.9 (0.8)	-16.5 (1.2)
AC (n=190)	362.3 (16.4)	0.7 (0.3)	65	43	22	12	-11.1 (0.6)	-18.3 (1.0)
CC (n=77)	470.8 (22.8)	0.9 (0.5)	75	48	31	17	-11.6 (1.0)	-19.1 (1.5)
p value	7.8×10^{-12}	0.89	0.06	0.67	0.57	0.71	0.25	0.20

[1]sIL-6R, mTSS, SJC, TJC show LS mean (SE). Wk 24 ACR20, ACR50, ACR70, and MCR show % achieving endpoint. [2]150 or 200 mg q2w doses combined. [3]van der Heijde modified total Sharp score at wk 52. [4]Major clinical response is defined as achieving and maintaining ACR70 for ≥24 consecutive weeks during the 52-wk period. [5]Swollen joint count. [6]Tender joint count.

Figure 1. Total sIL-6R by Asp358Ala genotype in patients treated with A) Sarilumab + MTX and B) Placebo + MTX

Conclusions: The Asp358Ala variant in the *IL6R* gene is significantly associated with differences in sIL-6R levels at baseline and after sarilumab treatment. The differences across genotypes may be due to increases in sIL-6R production. Importantly, this variant was not associated with differences in sarilumab treatment response. These data suggest that the sarilumab doses used for this clinical study saturate both the membrane and soluble forms of IL-6R and effectively block IL-6 signaling. Sarilumab provides therapeutic benefit for RA patients irrespective of their Asp358Ala genotype status.

SAT0180 EFFICACY AND SAFETY OF SARILUMAB 200 MG Q2W ADMINISTERED AS COMBINATION THERAPY OR MONOTHERAPY IN DIFFERENT PATIENT POPULATIONS WITH ACTIVE RA

M.C. Genovese[1], R. Fleischmann[2], H. van Hoogstraten[3], E.K. Mangan[4], S. Jayawardena[3], G.R. Burmester[5]. *[1]Stanford University Medical Center, Palo Alto; [2]Metroplex Clinical Research Center, University of Texas Southwestern Medical Center, Dallas; [3]Sanofi Genzyme, Bridgewater; [4]Regeneron Pharmaceuticals, Inc, Tarrytown, United States; [5]Charité - University Medicine Berlin, Free University and Humboldt University of Berlin, Berlin, Germany*

Background: Sarilumab, a human mAb blocking the IL-6Rα, was evaluated in 3 pivotal clinical trials.
Objectives: To assess efficacy and safety of sarilumab 200 mg q2w + csDMARDs or as monotherapy (MONARCH) in adults with active RA and inadequate response or intolerance to MTX (MOBILITY/MONARCH) or TNFi (TARGET).
Methods: MOBILITY (NCT01061736) was a 52-wk study; TARGET (NCT01709578) and MONARCH (NCT02332590) were 24-wk studies. Patients were randomized to placebo (Pbo) or SC sarilumab 150 or 200 mg q2w + MTX (MOBILITY) or csDMARDs (TARGET). MONARCH patients were randomized to SC monotherapy with adalimumab 40 mg q2w or sarilumab 200 mg q2w. Efficacy endpoints assessed in all 3 studies will be presented.
Results: Within studies, baseline demographic and disease characteristics were similar among treatment groups. Sarilumab 200 mg q2w improved ACR responses, HAQ-DI, DAS28-CRP, and CDAI (Table). Treatment response with sarilumab + csDMARDs was similar in MTX-IR and TNF-IR patients and with sarilumab monotherapy. Incidence of TEAEs and SAEs with sarilumab was more frequent vs Pbo (MOBILITY, TARGET) and similar to adalimumab (MONARCH). The most common TEAEs included infections, neutropenia, and injection site reactions and occurred more often with sarilumab vs Pbo (MOBILITY, TARGET). In MONARCH, rates of infection were similar with sarilumab and adalimumab,

Abstract SAT0180 – Table 1. Sarilumab Efficacy in 3 Phase 3 Studies

	MOBILITY		TARGET		MONARCH	
	Pbo + MTX (N=398)	Sarilumab 00 mg q2w + MTX (N=399)	Pbo + csDMARDs (N=181)	Sarilumab 200 mg q2w + csDMARDs (N=184)	Adalimumab 40mg q2w (N=185)	Sarilumab 200 mg q2w (N=184)

although neutropenia was more frequent with sarilumab. Safety of sarilumab was generally comparable in monotherapy and combination studies; monotherapy was associated with fewer ALT elevations >3 × ULN compared with combination therapy: MONARCH, 3%; MOBILITY, 8%; TARGET, 4%.
Conclusions: Sarilumab 200 mg q2w + csDMARDs significantly reduced disease activity and improved physical function to a similar extent regardless of population (MTX-IR or TNF-IR) and as monotherapy. Safety profile of sarilumab was generally comparable across all 3 trials, with monotherapy resulting in fewer ALT elevations.

SAT0181 LOW DOSE INTERLEUKIN-2 COMBINED WITH TOCILIZUMAB SELECTIVELY INCREASES REGULATORY T CELLS HELPING REFRACTORY RHEUMATOID ARTHRITIS PATIENTS ACHIEVE REMISSION MORE RAPIDLY

Z. Sheng-Xiao[1], M. Xiao-Wen[2], L. Xiao-Qing[1], M. Miao[1], W. Xiao-Yan[1], N. Hong-Qing[2], W. Cai-Hong[2], L. Xiao-Feng[1]. *[1]Rheumatology; [2]The Second Hospital of Shanxi Medical University, Taiyuan, China*

Background: Rheumatoid arthritis (RA) is a prevalent chronic autoimmune inflammatory disease. Its pathogenesis is closely associated with a failure of endogenous immune tolerance that caused by the imbalance of pro-inflammatory T helper 17 (Th17) cells and anti-inflammatory regulatory T (Treg) cells. Low-dose Interleukin-2 (IL-2) has been showed to induce both Th17 and Treg cells' expansion and activation while IL-6 antagonist Tocilizumab suppresses the differentiation of Th17, which is expected to control the development of RA.
Objectives: To study the influence of the combination of IL-2 and Tocilizumab on T cells subgroups and its clinical efficacy and safety on refractory RA.
Methods: Total 50 RA patients with low Treg cells, who had been treated with glucocorticoids and DMARDs for over 6 months, were divided into three groups randomly. Patients in non-IL-2 group (n=15) were still given conventional glucocorticoids and DMARDs. Patients in IL-2 group (n=26) were not only given those treatments, but injected subcutaneously human IL-2 (aldesleukin) at 50 WIU per day for a 5 day course. Patients in IL-2 and Tocilizumab group (n=9) were not only received the treatment like IL-2 group, but also treated with Tocilizumab at the dosage of 160mg during the day 1 and day 3. The demographic features, clinical manifestations and laboratory indicators were compared before and after the treatment.
Results: There was no difference among all groups in gender, age and course of the disease (p >0.05). The ratios of Th1/Th2 and Th17/Treg were significant correlated with ESR, the number of tender or swollen joints and DAS28-ESR (p<0.05) in all three groups of patients. After treatment, the number of Th17 cells and Treg cells was significantly increased in IL-2 group (p<0.01). In IL-2/Tocilizumab group after the treatment, the number of Treg cells were also significantly increased (p<0.05), but not the Th17 cells (p>0.05), leading to a quickly decrease in their ratio (p<0.05). Before the treatment, there was no difference in clinical manifestations among all three groups (p>0.05), but compared with non-IL-2 group, there was a significantly decrease in the number of tender joints (p<0.01) or swollen joints (p<0.05) and DAS28-ESR (p<0.01) in IL-2 group and IL-2/Tocilizumab group after the treatment. Patients in IL-2/Tocilizumab group had better clinical manifestations' remission although no significant difference compared with IL-2 group (p>0.05). There was no difference in blood routine, liver and renal functions both before and after the treatment among all groups (p>0.05).
Conclusions: IL-2 can effectively increase the level of Treg cells as well as that of Th17 to some degree; while IL-2 combined with Tocilizumab only effectively expand Treg cell number without Th17 increasing, thereby quickly recovers the balance of Th17 and Treg cells. This combination selectively stimulate Treg Cells leading to induce autoimmune tolerance, and seems to help RA patients achieve remission in a rapid way without over-treatment and evaluated side effect, though the long term benefits of this therapy are required to further study in more patients.

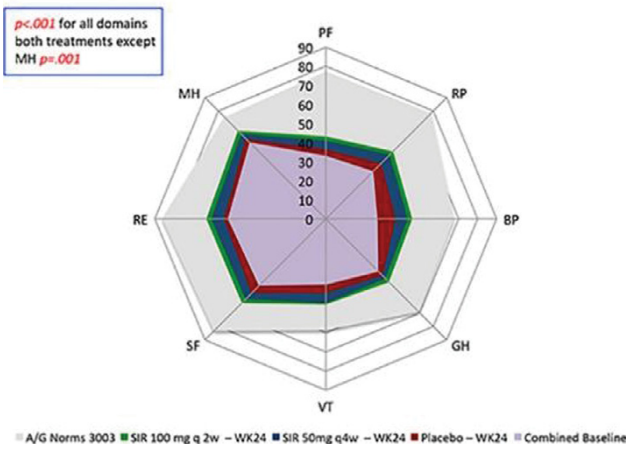
SAT0182 SIRUKUMAB LEADS TO SIGNIFICANT AND CLINICALLY MEANINGFUL IMPROVEMENTS IN HEALTH-RELATED QUALITY OF LIFE THAT MEET OR EXCEED NORMATIVE VALUES IN PATIENTS WITH RHEUMATOID ARTHRITIS REFRACTORY TO TNF INHIBITORS IN POST HOC ANALYSES OF A PHASE 3 TRIAL

V. Strand[1], R. Ganguly[2], N. Li[3], K. McQuarrie[3]. *[1]Stanford University, Palo Alto, CA; [2]GlaxoSmithKline, Collegeville, PA; [3]Janssen Research & Development, LLC, Spring House, PA, United States*



Background: Patients (pts) with rheumatoid arthritis (RA) experience reduced health-related quality of life (HRQoL). Sirukumab (SIR) is an anti–interleukin-6 (IL-6) monoclonal antibody.
Objectives: These post hoc analyses evaluated improvements over time in HRQoL relative to an age/gender-matched normative population in RA pts with inadequate responses to tumor necrosis factor inhibitors (TNF-IR) from the phase 3 SIRROUND-T trial.
Methods: 878 pts received SIR 50mg every 4 weeks (q4w), SIR 100mg every 2 weeks (q2w), or placebo (pbo) q2w. Health-related physical/emotional well-being were measured at baseline (BL) and Wk 24 by the 36-item Short Form Questionnaire (SF-36), fatigue by Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue (FACIT-F), and physical function by Health Assessment Questionnaire-Disability Index (HAQ-DI).
Results: SF-36 physical and mental component summary (PCS and MCS) mean scores at BL for pbo, SIR 50mg q4w, and 100mg q2w indicated substantial impairment (PCS: 33.2, 31.8, and 32.4; MCS: 41.9, 41.2, and 42.1). Significantly greater improvements from BL were reported at Wk 24 with SIR 50mg q4w and 100mg q2w vs pbo in PCS (4.8 and 5.1 vs 1.7) and MCS (3.9 and 4.0 vs 1.1) mean scores (all P<0.001), exceeding the minimum clinically important difference (MCID) of 2.5. Significantly greater least squares mean changes in the 8 SF-36 domain raw scores were reported with both doses of SIR vs pbo at Wk 24; all were >MCID of 5.0 (Table; Figure). More pts receiving SIR 50mg q4w or 100mg q2w reported SF-36 domain scores ≥normative values (ranges: 11–34% and 13–42%) vs pbo (range: 6–29%). For pbo, SIR 50mg q4w, and SIR 100mg q2w, BL FACIT-F scores were 26.0, 24.2, and 25.2; clinically meaningful improvements ≥MCID (4 points) were reported by 54.3 and 51.4% of pts receiving SIR 50mg q4w and 100mg q2w vs 33.7% with pbo (P<0.001). Numerically greater percentages of pts reported scores ≥normative values with both doses of SIR vs pbo (27 and 28% vs 16%). BL HAQ-DI scores were 1.57, 1.65, and 1.61 with pbo, SIR 50mg q4w, and 100mg q2w. Clinically meaningful improvements (change of ≤-0.22) were reported by significantly higher proportions of pts receiving SIR 50mg q4w (52.2%) or 100mg q2w (54.8%) vs pbo (37.4%; P<0.001). Numerically more pts reported HAQ-DI scores ≥normative values with SIR 50mg q4w and 100mg q2w vs pbo (13 and 16% vs 9%).

Table 1. Improvements in SF-36 Domain Scores at Wk 24 (all P<0.001)

Domain	LSM change SIR 50mg q4w	LSM change SIR 100mg q2w	LSM change pbo
Physical function	9.38	10.75	0.47
Role-physical	12.85	13.52	5.03
Bodily pain	17.66	17.51	7.46
General health	6.81	7.76	1.57
Vitality	10.10	9.68	4.14
Social function	12.40	11.75	3.68
Role-emotional	9.29	9.86	0.42
Mental health	6.73	7.96	2.10

LSM, least squares mean.

Figure. SF-36 domains at Wk 24 for SIR 50mg q4w and SIR 100mg q2w

Conclusions: In TNF-IR RA pts, SIR treatment resulted in greater and clinically meaningful improvements in HRQoL vs pbo that met or exceeded population normative values, with similar results for SIR 50mg q4w and 100mg q2w.

SAT0183 CLINICAL REMISSION IN SUBJECTS WITH RHEUMATOID ARTHRITIS TREATED WITH SUBCUTANEOUS TOCILIZUMAB AS MONOTHERAPY OR IN COMBINATION WITH METHOTREXATE OR OTHER SYNTHETIC DMARDS: A REAL-WORLD CLINICAL TRIAL (TOSPACE)

R. Sanmarti[1], E. Martín Mola[2], J.E. Fonseca[3], D.J. Veale[4], A. Escudero[5], C. González[6] on behalf of ToSpace Study group. *[1]Hospital Clinic, Barcelona; [2]Hospital la Paz, Madrid, Spain; [3]Hospital de Santa Maria, Lisboa, Portugal; [4]St.Vincent's University Hospital, Dublin, Ireland; [5]Hospital Reina Sofía, Córdoba; [6]Hospital Gregorio Marañón, Madrid, Spain*

Background: Subcutaneous tocilizumab (TCZ-SC) has demonstrated non-inferiority to TCZ-IV and superiority to placebo
Objectives: The primary objective of this study was to assess the 24-week efficacy and safety of subcutaneous (SC) tocilizumab (TCZ) 162 mg weekly (qw) as monotherapy or in combination with methotrexate (MTX) or other synthetic (s) DMARDs in patients with active rheumatoid arthritis (RA) in the real world setting
Methods: This multinational (Spain, Ireland, Portugal), multicenter, phase IIIb study. Subjects ≥18 years of age with active RA (DAS 28-ESR >3.2) who have had inadequate response or intolerance to sDMARDs or to a first anti-TNF drug. The study comprised a phase 1 with open-label design in which patients received TCZ-SC 162 mg qw (+/- oral/SC MTX or other sDMARDs) for 24-weeks and the main outcome was the percentage of patients achieving sustained clinical remission (DAS 28-ESR <2.6) at Week 20 and Week 24 (primary outcome of the study); and a phase 2 where patients achieving sustained clinical remission during the phase 1 were randomized to receive TCZ-SC 162 mg qw or TCZ-SC 162 mg q2w (+/- oral/SC MTX or other sDMARDs) for an additional 24 weeks; the main outcome of the phase 2 was the percentage of patients who maintained the remission at week 48 (i.e. DAS 28-ESR<2.6)
Results: 401 patients were included in the phase 1, 74 patients received TCZ-SC monotherapy and 327 patients received TCZ-SC in combination with oral/SC MTX or other sDMARDs. Sustained clinical remission rates were comparable between the mono- and combination-therapy groups at 24 week (48.4% vs. 52.9%, p=0.523). Of the 179 patients who achieved sustained clinical remission during the phase 1, 89 were randomly assigned to receive TCZ-SC 162 mg qw and 90 to receive TCZ-SC 162 mg q2w. At the end of phase 2, the percentage of patients who maintained the remission at week 48 was 91.5% with TCZ-SC qw and 73.9% with TCZ-SC q2w (p=0.002). Main efficacy outcomes for both phases of the study are presented in the table. Rates of serious adverse events (AEs) and rates of AEs leading to drug discontinuation were similar in patients treated with mono or combination therapy, and in patients treated with TCZ-SC qw or TCZ-SC q2w.

Phase 1 – Outcome	TCZ-SC monotherapy N=74	TCZ-SC Combination N=327	p-value
Sustained clinical remission, %	48.4	52.9	0.523
ACR20, %	79.7	83.3	0.495
ACR50, %	59.4	58.7	0.923
ACR70, %	40.6	37.7	0.666
ACR90, %	23.4	16.7	0.207
HAQ-DI (baseline/24 weeks), mean	1.49/0.85	1.36/0.82	NS
Phase 2 – Outcome	**TCZ-SC 162 mg qw N=89**	**TCZ-SC 162 mg q2w N=90**	**p-value**
Clinical remission, %	91.5	73.9	0.002
ACR20, %	96.4	88.8	0.056
ACR50, %	88.1	79.8	0.766
ACR70, %	71.4	65.2	0.377
ACR90, %	45.2	32.6	0.088
Mean change in DAS28	-0.02	0.35	0.037

Conclusions: In the real world setting, treatment with TCZ-SC 162 mg weekly in patients with active RA is associated with rate of sustained clinical remission of approximately 50% regardless it is administered as monotherapy or in combination with a sDMARD. The proportion of patients who remained in clinical remission at week 48 was significantly higher with TCZ-SC qw than with TCZ-SC q2w. The safety profile of TCZ-SC was consistent with previous studies of TCZ-SC and TCZ-IV

SAT0184 THERAPEUTIC DRUG MONITORING ON RHEUMATOID ARTHRITIS PATIENTS WITH REDUCED DOSES OF INTRAVENOUS TOCILIZUMAB

V. Ruiz-Esquide[1], C. Bastida[2], M. Pascal[2], J. Yagüe[3], D. Soy[2], R. Sanmartí[1]. *[1]Rheumatology; [2]Pharmacy; [3]Immunology, Hospital Clínic de Barcelona, Barcelona, Spain*

Background: Tocilizumab (TCZ) is an effective treatment for rheumatoid arthritis (RA). Literature suggests there is great variability in intravenous (iv) TCZ serum concentrations among individuals. Moreover, optimal drug dosage does not seem to be clear since Regulatory Agencies (FDA and EMA) approved the drug with a different initial posology. Empirical dose de-escalation strategies are being fostered in patients with disease remission.
Objectives: The purpose of the study was to examine TCZ serum concentrations at the different prescribed doses in RA. Secondary objectives were to evaluate the relationship between drug serum concentrations and laboratory parameters of disease activity.
Methods: Prospective, observational, single-center study conducted in a university tertiary hospital. Enrolled RA patients received iv TCZ at a dose range from 4 to 8 mg/kg every 28 days. Demographic characteristics and clinical laboratory data were obtained at study entry. Blood samples for drug concentration testing were collected from the third TCZ dose onwards, just before TZC infusion and, when possible, once a week until the next drug administration.
Results: 35 patients (88.6% women, 80% Caucasian) were included. Mean age ±SD was 54.1±12.3 and the median [range] of disease duration was 11.1 [2.9–48.5] years. Median treatment duration with iv TCZ was 36.5 [3–68] months. 54% of patients received the standard dose of 8mg/kg whereas the rest received reduced doses (23% were on 6mg/kg and 23% on 4mg/kg) due to persistent remission/low disease activity. 20 patients (57.1%) were being treated with low steroid dose and 24 (68.6%) were on concomitant DMARD, mainly methotrexate. Regarding drug concentration testing, a total of 109 samples were obtained. 19 patients participated to multiple drug sampling between two drug administrations and in the 17 remaining patients, a pre-dose sample was drawn. Mean TCZ concentrations are displayed in table 1 and showed in figure 1. No significant differences were observed in median pre-dose TCZ concentration values (54 samples) between patients on 8 and 6 mg/kg whereas significant lower drug levels were observed in those taking 4 mg/kg.
According to inflammatory parameters, mean C-reactive protein (CRP) concentration was significantly lower in those patients with trough TCZ concentrations >1μg/mL compared to those <1μg/mL (0.066mg/dL vs 0.689mg/dL, respectively; p<0.001). This difference was not observed with calprotectin serum concentrations (2.260μg/mL vs 2.143μg/mL).

Table 1. Mean (±sd) iv TCZ serum concentrations at different prescribed doses within time

Time (days)	TCZ 8 mg/kg	TCZ 6 mg/kg	TCZ 4 mg/kg
Pre-infusion (Ctrough)	8.9±6.1	5.7±9.1	0.8±1.2
T7	84.8±33.9	48.8±18.6	26.1±6.4
T14	46.4±19.8	31±11.4	15.2±5.6
T21	21.6±9.5	19.7±10.5	7.1±4.4
T28 (Ctrough)	10.6±7.3	10.3±10.8	1.3±2.3

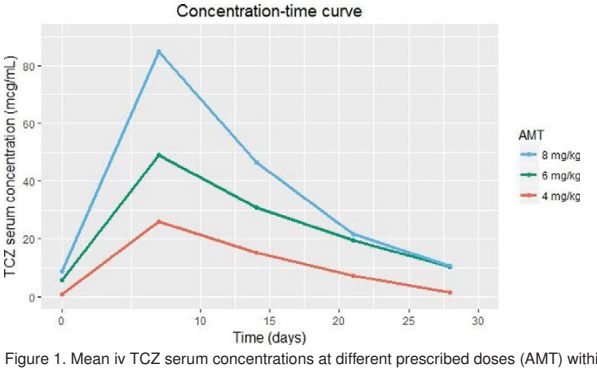

Figure 1. Mean iv TCZ serum concentrations at different prescribed doses (AMT) within time.

Conclusions: Trough TCZ serum concentrations do not differ between patients on an 8 and 6 mg/kg regimen. Therefore, according to the pharmacokinetics observed in our study, a maintenance dose of iv TCZ 6mg/kg would be appropriate for most RA patients. Although CRP levels are significantly higher in patients with trough iv TCZ concentrations <1μg/mL, serum calprotectin did not show the same tendency.

SAT0185 **BIO-HOLIDAY THERAPY WITH A TIGHT CONTROL STRATEGY IN RHEUMATOID ARTHRITIS PATIENTS WITH CLINICAL DISEASE ACTIVITY INDEX REMISSION ENABLES MAINTENANCE OF BONE METABOLISM STATUS**

E. Torikai, M. Suzuki, Y. Matsuyama. *Orthopaedic Surgery, Hamamatsu University School of Medicine, Hamamatsu, Japan*

Background: The cost of Bio therapy has become a major problem in health economics and is unaffordable for some patients. Thus, it is important to consider whether we should discontinue or extend the interval of Bio. At EULAR 2016, we reported that maintaining disease activity, radiographic progression, and physical function via Bio-holiday therapy in rheumatoid arthritis (RA) patients with clinical disease activity index (CDAI) remission under a tight control strategy is possible. Osteoporosis is another issue for RA patients. RA patients generally develop osteoporosis more frequently than healthy individuals because of increased bone resorption and inhibited bone formation.
Objectives: To investigate bone metabolism markers and bone mass index of RA patients with CDAI remission who underwent Bio-holiday therapy.
Methods: Sixty-four RA patients with CDAI remission were included and were classified into two groups. Bio-holiday group (group H) comprised 34 patients [golimumab (GLM) and tocilizumab (TCZ), 18 and 16 patients, respectively] and in which patients were taken off Bio if they achieved CDAI remission. Patients visited our clinic at least once every 2 months and were treated with Bio within 3 months after falling out of CDAI remission. They could be taken off Bio again when they reached CDAI remission. The Bio group (group C) comprised 30 patients (GLM and TCZ, 16 and 14 patients, respectively). The mean ages of groups H and C were 52.9 and 55.6 years, respectively, and the mean disease durations were 3.98 and 4.13 years, respectively. There were no statistical differences between the backgrounds of the two groups. We compared the change in bone metabolism makers [urine type I collagen cross-linked N-telopeptide (NTX), serum tartrate-resistant acid phosphatase 5b (TRACP5b), serum bone-specific alkaline phosphatase (BAP), and serum osteocalcin (OC)] and bone mineral density (BMD) of lumber spine (L-spine) and femoral neck (FN) between both groups for 2 years.
Results: The mean withdrawal periods were 12.1 and 8.8 months with GLM and TCZ, respectively. Three and four patients dropped out because of financial constraints in the in the groups H and C, respectively. One patient in each group dropped out because of RA flare-up. No patients in either group discontinued their therapy because of adverse events. Besides one patient who dropped out because of RA flare-up, all remaining patients in the group H were able to achieve CDAI remission without delay. There were no statistical differences in CDAI throughout the study period (Fig.1). There were no statistical differences in any of the bone metabolism makers throughout the study period (Table.1) and BMD of L-spine (Fig. 2(a)) and FN (Fig. 2(b)) at baseline and last evaluation.

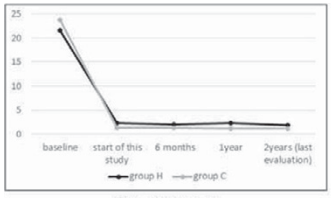

Fig.1 CDAI score

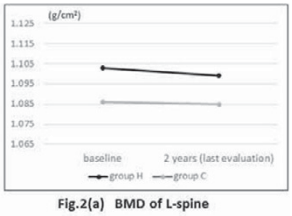

Fig.2(a) BMD of L-spine

[group H]	Start of this study	1 year	2 years
NTX(nmolBCE/mmolCr)	42.6± 24.7	44.3± 27.3	42.1± 26.6
TRCP5b (mU/dL)	355± 170	347± 156	364± 183
BAP (μg/L)	15.5± 6.1	16.5± 6.3	15.9± 6.0
OC (ng/mL)	11.9± 6.5	10.8± 6.2	11.3± 6.6
[group C]	Start of this study	1 year	2 years
NTX (nmolBCE/mmolCr)	40.3± 25.1	44.1± 28.4	43.5± 28.0
TRCP5b (mU/dL)	349± 169	352± 176	358± 165
BAP (μg/L)	15.9± 5.9	16.2± 6.1	16.4± 6.3
OC (ng/mL)	10.6± 5.9	10.9± 5.8	10.8± 6.2

Table.1 bone metabolism makers

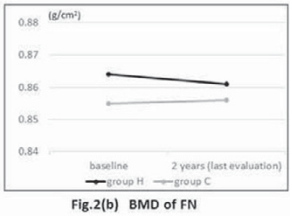

Fig.2(b) BMD of FN

Conclusions: We conclude that maintaining disease activity bone metabolism status via Bio-holiday therapy for RA patients with CDAI remission under a tight control strategy is possible. Given that the flare-up rate in RA patients with deep remission is not high, it is not difficult to resume Bio therapy and gain CDAI remission. Furthermore, this treatment is financially durable. Therefore, we recommend Bio-holiday therapy.

SAT0186 **EFFECTS OF DENOSUMAB, A SUBCUTANEOUS RANKL INHIBITOR, ON THE PROGRESSION OF STRUCTURAL DAMAGE IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH CSDMARDS: RESULTS FROM THE 12-MONTH DOUBLE BLIND PHASE 3, DESIRABLE STUDY**

T. Takeuchi[1], Y. Tanaka[2], S. Soen[3], H. Yamanaka[4], T. Yoneda[5], S. Tanaka[6], T. Nitta[7], N. Okubo[7], H.K. Genant[8], D. van der Heijde[9]. *[1]Keio University School of Medicine, Tokyo; [2]University of Occupational and Environmental Health, Kitakyushu; [3]Kindai University Nara Hospital, Ikoma; [4]Institute of Rheumatology Tokyo Women's Medical University, Tokyo, Japan; [5]Indiana University School of Medicine, Indianapolis, United States; [6]The University of Tokyo; [7]Daiichi Sankyo Co. Ltd, Tokyo, Japan; [8]University of California, San Francisco, United States; [9]Leiden University Medical Center, Leiden, Netherlands*

Background: Denosumab is a fully human monoclonal antibody (IgG_2 subclass) that inhibits bone resorption by inhibiting RANKL, a key mediator of osteoclast formation, function, and survival.
Objectives: To evaluate the effect of denosumab 60 mg every 6 months (Q6M) or every 3 months (Q3M) on the progression of joint damage in Japanese patients with RA on csDMARD background treatment.
Methods: DESIRABLE is a 12-month randomized, double-blind, placebo-controlled, parallel-group study in patients with RA receiving csDMARD treatment. Subjects fulfilling the 1987 ACR criteria or 2010 ACR-EULAR criteria were randomized (1:1:1) to denosumab 60 mg Q6M, denosumab 60 mg Q3M, or placebo. The primary endpoint is the change from baseline to 12 months in the van der Heijde modified total Sharp score (mTSS). Radiographs of hands and feet at baseline, 6 months and 12 months were scored with blinded time order by 2 readers independently. Average score of the 2 readers is used for the analysis. Comparisons of each denosumab group with placebo for the change from baseline were performed using van Elteren stratified rank test adjusting for baseline glucocorticoid use. Missing scores were imputed using linear extrapolation/interpolation.
Results: Among 679 patients randomized, 667 (placebo, n=223; Q6M, n=222; Q3M, n=222) received at least one dose of study drug, and 60 (placebo n=15; Q6M, n=23; Q3M, n=22) were discontinued during the study. Demographic and baseline characteristics were similar across the groups (Table 1). Mean change from baseline in mTSS and erosion score (ES) at 12 months was significantly lower with both denosumab 60 mg Q6M and Q3M compared with placebo, with no obvious evidence of an effect on joint space narrowing (JSN) score for denosumab. (Table 2).
Consistently, the percent of nonprogressors (ie, mTSS change $\leq$0.5) at 12 months was significantly greater with denosumab 60 mg Q6M (75.6%, p=0.010) and Q3M (78.1%, p=0.001) compared with placebo (64.2%).
Incidence of adverse events (AEs), serious AEs, and AEs leading to discontinuation of study drug were similar across treatment groups. No events of osteonecrosis of the jaw or atypical femoral fracture were observed.

Table 1. Baseline demographics and characteristics

Characteristic	Placebo N = 218	Denosumab 60 mg Q6M N = 217	Denosumab 60 mg Q3M N = 219
Female	167 (76.6)	168 (77.4)	154 (70.3)
Age (years)	55.8 ± 11.7	58.1 ± 12.3	58.2 ± 12.0
Disease duration (years)	2.1 ± 1.3	2.2 ± 1.3	2.2 ± 1.3
Rheumatoid factor positive	137 (62.8)	140 (64.5)	128 (58.4)
MTX use	190 (87.2)	176 (81.1)	189 (86.3)
Glucocorticoid use	69 (31.7)	73 (33.6)	68 (31.1)
DAS28-CRP	3.4 ± 1.0	3.6 ± 1.1	3.5 ± 1.0
mTSS	13.1 ± 21.4	15.9 ± 22.2	15.2 ± 19.0

Data presented are Mean ± SD or n (%).

Table 2. Change from baseline in mTSS, ES and JSN at 12 months

Characteristic	Placebo N = 218	Denosumab 60 mg Q6M N = 217	Denosumab 60 mg Q3M N = 219
mTSS	1.49 ± 3.76	0.99 ± 3.77 (p = 0.024)	0.72 ± 2.32 (p = 0.006)
Erosion score	0.98 ± 2.48	0.51 ± 2.15 (p = 0.010)	0.22 ± 0.95 (p < 0.001)
JSN score	0.51 ± 1.72	0.48 ± 2.08 (p = 0.257)	0.50 ± 1.76 (p = 0.533)

Data presented are Mean ± SD

Conclusions: Denosumab inhibited the progression of joint destruction significantly more than placebo and was generally well tolerated in Japanese patients with RA on csDMARDs. Denosumab has potential to be a new therapeutic option to inhibit structural progression for patients with RA.

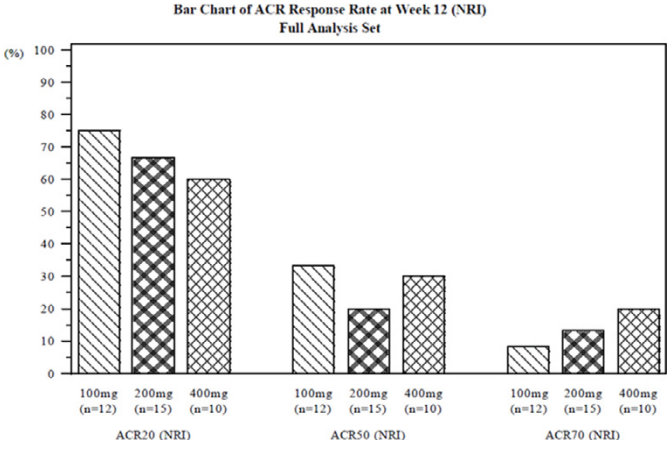
SAT0187 SAFETY, PHARMACOKINETICS AND EFFICACY OF E6011, AN ANTI-FRACTALKINE MONOCLONAL ANTIBODY, IN A FIRST-IN-PATIENT PHASE 1/2 STUDY IN RHEUMATOID ARTHRITIS; ADDTIONAL DATA OF 400 MG COHORT

Y. Tanaka[1], T. Takeuchi[2], H. Umehara[3], T. Nanki[4], N. Yasuda[5], F. Tago[6], Y. Kitahara[6], M. Kawakubo[6], S. Hojo[6], T. Kawano[5], T. Imai[5]. *[1]University of Occupational and Environmental Health, Japan, Kitakyushu; [2]Keio University, Tokyo; [3]Division of Rheumatology and Immunology, Nagahama City Hospital, Shiga; [4]School of Medicine, Faculty of Medicine, Toho University, Tokyo; [5]KAN Research Institute, Inc., Kobe; [6]EISAI Co. Ltd., Tokyo, Japan*

Background: Fractalkine (CX3CL1, designated as FKN hereafter) is the sole member of the CX3C-chemokine which leads to dual actions, chemotaxis and cell adhesion for leukocytes expressing the cognate receptor, CX3CR1, during their migration. Accumulating evidence is telling that FKN-CX3CR1 axis plays a pivotal role in leukocyte/lymphocyte accumulation in inflamed tissues in RA[1]. Last year, we presented an interim report (up to 200 mg cohort) of Phase 1/2 study of E6011, a novel humanized anti-FKN monoclonal antibody, for active Japanese RA patients[2].



Objectives: To evaluate safety, pharmacokinetics and efficacy of E6011 with the dosage up to 400 mg in a Phase 1/2, open-label, multiple ascending dose study in RA patients (NCT02196558).

Methods: Active RA patients with inadequate response (IR) to MTX or TNF inhibitors (TNFi) were received 7 consecutive doses (subcutaneous) of E6011 at week 0, 1, 2 and thereafter every 2 weeks up to week 10. The safety, pharmacokinetics and efficacy up to week 12 were evaluated.

Results: Twelve, 15 and 10 subjects were enrolled in the cohort of 100, 200 and 400 mg dosage, respectively, in total 37 subjects received repeated subcutaneous (SC) administrations of E6011. As a result, repeated dose of E6011 was found safe and well tolerated. The incidence of adverse event (AE), treatment-related AE and serious AE were 56.8%, 29.7% and 5.4%, respectively. AEs occurring in ≥2 subjects were nasopharyngitis, Injection site erythema, headache and oropharyngeal pain, among which there were no severe AEs, serious infections and deaths. No significant differences were observed in the incidence or severity of AEs across the cohorts.

After starting multiple SC injection of E6011, serum E6011 concentration reached steady-state at week 2, and its level was maintained up to week 12 in all cohorts. Clinical outcome was also available in the study in which response rates of ACR20, 50 and 70 at week 12 calculated using the non-responder imputation (NRI) were 75.0%, 33.3%, 8.3% in 100 mg cohort, 66.7%, 20.0%, 13.3% in 200 mg cohort and 60.0%, 30.0%, 20.0% in 400 mg cohort, respectively. The percentage of patients categorized "good response" with the EULAR response criteria at week 12 (NRI) were 16.7% in 100 mg cohort, 20% in 200 mg cohort and 40% in 400 mg cohort.

Conclusions: E6011 was safe and well tolerated, and the study demonstrated a promising efficacy of E6011 in active RA patients with MTX- or TNFi-IR. The results obtained suggest that a novel approach to target FKN/CX3CR1 interaction will be clinically beneficial for RA, and support to conduct phase 2 clinical trials in which the efficacy and safety should be confirmed in a placebo controled double-blind manner.

SAT0188 FIRST-LINE TREATMENT PATTERNS OF PATIENTS WITH RHEUMATOID ARTHRITIS WHO ARE ANTI-CYCLIC CITRULLINATED PEPTIDE ANTIBODY POSITIVE VERSUS NEGATIVE

K. Price[1], Y. Doleh[1], M. Eaddy[2], A. Ogbonnaya[2], H.-C. Shih[2], H. Ahmad[1], L. Lamerato[3], A. Szymialis[1]. *[1]Bristol-Myers Squibb, Princeton; [2]Xcenda, LLC, Palm Harbor; [3]Henry Ford Health System, Detroit, United States*

Background: Patients with RA who are at a higher risk for progressive and destructive arthritis could be identified using anti-cyclic citrullinated peptide (anti-CCP) levels.[1] Treatment guidelines recommend the use of non-biologic DMARDs as initial treatment in RA; but, if warranted, biologic (b)DMARDs could be considered in early treatment of RA.[2] Real-world data describing treatment patterns based on anti-CCP designations are limited.

Objectives: This study evaluated treatment patterns of patients with RA who are anti-CCP positive (+) or negative (–).

Methods: This retrospective study was based on electronic medical record (EMR) data with a supplemental chart review from a large integrated delivery system. Patients newly diagnosed with RA (International Classification of Diseases, Ninth Revision, Clinical Modification diagnosis code 714.0x) were identified between 1 January 2009 and 31 December 2014. The first RA diagnosis date was designated as the index date. Patients were required to have 12 months of continuous activity in the EMR (6 months pre- and 6 months post-index). Based on the baseline anti-CCP test results, patients were categorized as anti-CCP+ (≥7.0 U) or anti-CCP– (<7.0 U). First-line therapy (time to treatment initiation, treatment regimen, treatment changes and response to treatment) was evaluated in the post-index period. Response to treatment was determined based on physicians' notes.

Results: Overall, 217 anti-CCP+ and 191 anti-CCP– patients with RA were included in this study. A higher proportion of anti-CCP+ (153, 70.5%) than anti-CCP– patients (44, 23.0%; p<0.0001) initiated treatment, generally within 1 month after diagnosis (anti-CCP+, mean [SD]: 31.1 [42.1] days and anti-CCP–, 28.1 [37.4] days; p=0.6538). MTX was most commonly used as first-line therapy. More anti-CCP+ than anti-CCP– patients received MTX (73.2 vs 56.8%; p=0.0374), while more anti-CCP– than anti-CCP+ patients received hydroxychloroquine (31.8 vs 13.1%; p=0.0037). Only three anti-CCP+ and no anti-CCP– patients were treated with a bDMARD. Response to treatment was similar between the cohorts (p=0.2444); 22.9% of anti-CCP+ and 18.2% of anti-CCP– patients had a complete response to the first-line therapy, and 33.3% of anti-CCP+ and 25.0% of anti-CCP– patients had a partial response to the first-line therapy. Treatment change, however, significantly differed between the two cohorts (p=0.0058); 11.1 and 9.1% of patients discontinued, 9.8 and 9.1% of patients switched, and 3.9 and 9.1% of patients augmented in the anti-CCP+ and anti-CCP– cohorts, respectively. Treatment changes occurred approximately 3 months after treatment initiation (anti-CCP+, 82.0 [49.7] days and anti-CCP–, 83.8 [52.7] days; p=0.9178).

Conclusions: After diagnosis of RA, patients who are anti-CCP+ were more likely to start therapy, indicating that physicians were more aggressive in treating this cohort. Patients were treated according to guidelines with non-biologic DMARDs, predominantly MTX. Patterns of treatment change differed between the cohorts; however, treatment response was similar with a complete response rate of 20%.

SAT0189 FACTORS INFLUENCING THE PRESCRIPTION OF TOCILIZUMAB ALONE OR IN COMBINATION WITH DMARDS IN RHEUMATOID ARTHRITIS PATIENTS IN A REAL LIFE SETTING. POOLED ANALYSIS OF 3 OBSERVATIONAL STUDIES

A. Saraux[1], A. Cantagrel[2], B. Combe[3], R.-M. Flipo[4], I. Idier[5], C. Baffie[6], J. Tebib[7]. *[1]Rheumatology, University Hospital, Brest; [2]Rheumatology, University Hospital, Toulouse; [3]Rheumatology, University Hospital, Montpellier; [4]Rheumatology, University Hospital, Lille; [5]Medical, Chugai Pharma France, Paris la Defense; [6]Statistics, Roche SAS, Boulogne; [7]Rheumatology, University Hospital, Lyon, France*

Background: Tocilizumab (TCZ) as monotherapy (Mono) is nowadays a standard treatment in rheumatoid arthritis (RA) for patients in whom methotrexate (MTX) is inappropriate[1].
Objectives: To describe factors influencing the use of TCZ in Mono or in combination with DMARDs (Combo) in real-life practice in RA patients (pts).
Methods: *Analysis:* pooled data of 3 prospective, multicentre, observational studies (PEPS n=610, Spare-1 n=307, Act-solo n=577). *Patients:* RA pts requiring TCZ treatment according to their physician. *Treatment:* TCZ as prescribed in real life. *Endpoint:* Evaluation of factors influencing the use of TCZ in Mono or in Combo. *Data collected:* demographic characteristics, past medical history, RA characteristics and history including previous RA treatments, TCZ treatment strategy (Mono or Combo). *Statistical analysis:* Pts fulfilling inclusion and non-inclusion criteria and with ≥1 TCZ infusion were analyzed. 1- descriptive analysis 2- Univariate and multivariate analysis to determine factors influencing the use of TCZ in Mono. Variables with more than 20% of missing data were excluded from the multivariate model.
Results: 1494 pts (3 studies) were analysed at inclusion. Pts' characteristics: 56% of the pts were >55 years old, 79.6% female, mean RA duration 11.1±9.3 years, 83.0% positive for rheumatoid factors and/or ACPA, 77.3% with erosive disease on X-rays, mean ESR 29.9±23.1mm, mean CRP 19.9±26.2 mg/l mean DAS 28-ESR 5.21±1.22, mean HAQ-DI 1.56±0.68, and mean pain VAS 61.5±23.2. Past RA treatment included csDMARDs in 98.5% and biologics in 77.8% (median=2 [1–6]). TCZ was initiated as Mono in 36.4% of pts and in Combo in 63.6%, with MTX in 83.3% of Combo pts (mean dose 15.7±4.4mg/week). Corticosteroids were used in 74% of pts (mean dose 10±7mg/day). Variables associated with a TCZ prescription in Mono were age (≥65 years), number of previous bDMARD, use/dose of steroids, ESR/CRP values, VAS global activity (physician and pt), pain VAS and HAQ-DI. In the multivariate analysis, variables associated with a TCZ prescription in Mono were age ≥65 years (OR=1.71 [1.30 - 2.24], p<0.001), number of previous bDMARD (1 bDMARD, OR=1.35 [0.94 - 1.92], 2 bDMARD OR=1.82 [1.28 - 2.60], ≥2 bDMARD, OR=1.19 [0.82 - 1.71] p=0.006), higher pain VAS (OR=1.09 [1.04 - 1.15], p=0.001), higher ESR value (OR=1.07 [1.02 - 1.12], p=0.013).
Conclusions: This pooled analysis suggests that physicians preferably prescribe TCZ alone in older patients, heavily treated before, with higher inflammatory markers and higher pain VAS. This use might be explained by physicians' reluctance to prescribe the association in frailer patients and complementary data on comorbidity factors will be analysed to support this hypothesis.

SAT0190 ESTIMATE OF CLINICAL AND ANTIDESTRUCTIVE EFFECTS OF RITUXIMAB IN RHEUMATOID ARTHRITIS

A.V. Pivanova, G. Lukina, Y. Sigidin, A. Smirnov, K. Kuzikyants, A. Kuznetsova. *Nasonova Research Institute of Rheumatology, MOSCOW, RUSSIA, Moscow, Russian Federation*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by synovial hyperplasia, mononuclear cell infiltration, bone erosion and joint destruction. Antirheumatic treatment plays a important role in controlling the inflammation of rheumatoid arthritis and in minimizing joint damage. Rituximab - it is a chimeric monoclonal antibody that targets the CD20 molecule expressed on the surface of B cells. It has been successfully used to treat rheumatoid arthritis, and it is worth noting that his antidestructive effect sometimes does not meet the clinical.
Objectives: to assess clinical and antidestructive effect of Rituximab (RTX) in patients with rheumatoid arthritis (RA).
Methods: 108 patients (pts) with RA, most of them were middle-age women with high disease activity (mean DAS28 6,1±1,04, RF-positive 77%, ACCP-positive 83%) treated with RTX (1000 mgx2 or 500 mgx2). Clinical effect was evaluated by EULAR criteria; radiological progression by SVH method.
Results: 104 patients were treated by RTX (500 x2 or 1000 x2), had good response: after 48 week of treatment clinical improvement was achieved in 65% pts, good and moderate response by EULAR criteria in 23% and 42% pts accordingly. Noteworthy, after 12 months of treatment RTX radiological progression was absent in 50% pts with high disease activity.
Conclusions: RTX treatment slowed joint damage without clinical improvement. Clinical and antidestructive results did not always coincide which suggests different mechanisms of clinical and antidestructive effects of anti-B-cell therapy
Disclosure of Interest: None declared

Background: Disease modifying antirheumatic drugs (DMARDs) such as methotrexate (MTX), leflunomide (LFN) or antiTNFα have been implicated in development/exacerbation of Interstitial lung disease (ILD)of rheumatoid arthritis (RA). Several radiological patterns of ILD have been described: i) usual interstitial pneumonia (UIP), ii) nonspecific interstitial pneumonia (NSIP), iii) obliterating bronchitis (OB), and iv) Organized pneumonia (OP)
Objectives: To assess the response to Abatacept (ABA) in these patterns of ILD
Methods: Multicenter study of RA-ILD treated with ABA. ILD was diagnosed by high-resolution CT scan (HRCT) and classified in radiological patterns (Travis et al). We consider 3 subgroups: a) UIP, b) NSIP and c) "other" (OB, OP or mixed). ABA was used at iv or sc standard dose. We assessed: a) Dyspnea (Medical Research Council-modified scale; significant variations≥1); B) Respiratory function tests; significant changes≥10% in forced vital capacity (FVC) and DLCO≤10%, c) HRCT, d) DAS28. A comparative study was performed for the quantitative (U-Mann-Whitney) and qualitative variables (Fisher test) between the baseline and 3, 6 and 12 months.
Results: We included 63 patients (27 women/36 men), mean age; 63.1±9.6 years. At ABA onset the RA had a median evolution of 6.8 [2–13.6] years and the ILD of 1 [0.3–3.03]. RA was seropositive in 85.7%. The diagnosis of ILD was confirmed by biopsy (n=18). The ILD was related to DMARDs: MTX (4), etanercept (3), adalimumab (3), certolizumab (2), Infliximab (1). ABA was used in monotherapy (26) or combined with other DMARDs (37); LFN (15), Cyclosporin (1), sulfasalazine (4), MTX (6), hydroxychloroquine (10), azathioprine (4), chloroquine (1). Table 1 shows the evolution in the available cases. A significant improvement in dyspnea and HRCT was observed in the NIU type. DLCO remained stable in most patients regardless of the radiological pattern. The activity of RA (DAS28) also improved.

Table 1

SAT0192 SARILUMAB SUPPRESSES THROMBOSIS-RELATED GENE EXPRESSION IN CIRCULATING BLOOD CELLS IN MTX-IR AND TNF-IR PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS

C. Paccard[1], J. Msihid[1], A. Brisacier[1], A. Damask[2], C. Paulding[2], M. Zilberstein[3], A. Boyapati[2]. *[1]Sanofi R&D, Chilly-Mazarin, France; [2]Regeneron Pharmaceuticals, Inc, Tarrytown; [3]Sanofi R&D, Bridgewater, United States*

Background: Bone and joint damage due to chronic inflammation in the synovium of patients with RA is mediated by IL-6 and other cytokines. IL-6 mediates effects inside the joint and systemically and is blocked by sarilumab, a human mAb blocking the IL-6R?. Safety and efficacy of SC sarilumab (150 or 200 mg q2w) was evaluated in combination with MTX in patients with RA and inadequate response (IR) to MTX (MOBILITY; NCT01061736) or csDMARDs in patients with RA and IR or intolerance to ≥1 TNFi (TARGET; NCT01709578).

Objectives: To compare gene expression patterns in circulating blood cells after treatment with sarilumab vs placebo in patients from MOBILITY and TARGET.

Methods: Total RNA was isolated from whole blood collected at baseline (predose) and wk 2 posttreatment in patients from MOBILITY (placebo, n=58; sarilumab 150 mg q2w, n=60; sarilumab 200 mg q2w, n=46) and TARGET (placebo, n=19; sarilumab 150 mg q2w, n=27; sarilumab 200 mg q2w, n=16). Gene expression data were generated using microarray analyses (Agilent 8 × 60k platform). Data were processed using the limma package (R Bioconductor). Background correction and quantile normalization were performed and probes with low expression were filtered; 48,109 probes were analyzed. Effect of sarilumab vs placebo on gene expression was assessed in each study using linear mixed models. *P* values were adjusted using the Benjamini-Hochberg procedure to control false discovery rate (FDR; 5% threshold).

Results: After *P* value adjustment to control FDR at 5%, 2 genes implicated in thrombosis and atherosclerosis (thrombomodulin [THBD] and platelet endothelial cell adhesion molecule 1 [PECAM-1]) were downregulated after treatment with sarilumab 200 mg q2w vs placebo in both studies (Table). These genes decreased with a fold-change (FC) ≤0.8 in both studies ($P<0.001$). An additional gene associated with coagulation, von Willebrand factor (vWF), was significantly decreased in MTX-IR but not TNF-IR patients. Numerical decreases in gene expression between sarilumab 150 mg q2w and placebo did not reach significance.

Table 1. Select Genes Regulated by Sarilumab 200 mg q2w at Week 2

	MOBILITY Sarilumab 200 mg q2w + MTX		TARGET Sarilumab 200 mg q2w + csDMARDs	
Gene	*P* value	Fold reduction[a]	*P* value	Fold reduction[a]
THBD	6.3×10^{-7}	0.67	3.9×10^{-6}	0.58
PECAM-1	1.6×10^{-9}	0.78	2.1×10^{-4}	0.78
vWF	1.3×10^{-10}	0.58	0.55	0.91

[a]Fold reduction vs placebo.

Conclusions: In patients with active RA, sarilumab may decrease thrombosis-related gene expression in circulating immune cells. Additional analysis of the serum levels of thrombosis risk proteins is needed to test the hypothesis that sarilumab treatment decreases levels of thrombosis risk factors.

SAT0193 RA PATIENTS WITH INFLAMMATORY ANEMIA BENEFIT FROM INCREASED HEMOGLOBIN AND DECREASED FATIGUE UNDER TOCILIZUMAB THERAPY

C. Specker[1], H. Kellner[2], P. Kästner[3], C. Volberg[4], V. Braunewell[5], I. Schwarze[6], M. Aringer[7], M. Sieburg[8], M.W. Hofmann[9], J.P. Flacke[10], H.-P. Tony[11], G. Fliedner[12]. *[1]Kliniken Essen Süd, Essen; [2]Schwerpunktpraxis für Rheumatologie und Gastroenterologie, München; [3]MVZ Ambulantes Rheumazentrum Erfurt, Erfurt; [4]Rheumazentrum Neuss, Neuss; [5]Schwerpunktpraxis Rheumatologie, Mönchengladbach; [6]Praxis für Internistische Rheumatologie, Leipzig; [7]Medizinische Klinik III, Rheumatologie, Technischen Universität Dresden, Dresden; [8]Rheumatologische Gemeinschaftspraxis, Magdeburg; [9]Rheumatologie, Chugai Pharma Europe Ltd., Frankfurt; [10]Rheumatologie, Roche Pharma AG, Grenzach-Wyhlen; [11]Rheumatologie/Immunologie der Medizinischen Klinik und Poliklinik II, Universitaetsklinikum Wuerzburg, Wuerzburg; [12]Rheumapraxis, Osnabrueck, Germany*

Background: According to WHO definition approximately 15% of all patients with rheumatoid arthritis (RA) suffer from anemia (hemoglobin <13 g/dl for men and <12 g/dl for women). Interleukin 6 (IL-6) takes an active part in the pathogenesis of this inflammatory anemia.

Objectives: The 6th interim analysis of the non-interventional ICHIBAN study (NCT01194401) evaluated the occurrence of inflammatory anemia, characterized the patient population with anemia, and observed the response during intravenous Tocilizumab therapy (TCZ i.v.). Patients were subgrouped according to their anemic/non-anemic status at baseline.

Methods: Since 2010 the ICHIBAN study collects clinical data of the routine use of TCZ i.v. in RA patients. The observation period for each patient is up to two years. At the due date of the current interim analysis (Dec 10, 2015) 2999 patients were enrolled. 902 patients have completed the maximal 104 weeks observation period (Group W104).

Results: At baseline, the proportion of patients with anemia (acc. to WHO definition) was 21.4% (men) and 22.0% (women) in the group W104.

On comparison, RA patients with anemia showed, amongst others, increased inflammation parameters, a higher disease activity and higher rates of comorbidities. Already after 4 weeks with TCZ i.v. the proportion of patients with anemia improved to 12.1% (men) and 12.7% (women). After 104 weeks therapy the proportion of patients with anemia reduced further to 7.4% (men) and 8.4% (women). The relevant response parameters and laboratory values are shown in Table 1.

Despite the higher disease activity at baseline for anemic patients, the benefit was comparable for patients with and without anemia. DAS28-ESR values decreased on average by 2.9 (women) and 3.1 (men) in RA patients with anemia and by 2.7 (women) and 2.8 (men) in RA patients without, resulting in similar disease scores at the end of the observational period.

The effectiveness of TCZ i.v. was also confirmed by patient reported outcomes (PROs) via visual analogue scales (VAS). In particular, a reduction of the intensity of pain (>50%) and a reduction of fatigue (>38%) was observed (Table 1).

Table 1 Treatment response to TCZ in anemic patients (at baseline)

		Week 0 (Baseline)	Last visit with TCZ
% Anemia	male	21.4% (46/215)	7.4% (16/215)
	female	22.0% (151/687)	8.4% (58/687)

CRP [mg/l]	male	42.1 (27.3, 71.2)	7.3 (1.5, 25.4)
Median (Q1, Q3)	female	30.0 (11.1, 61.0)	3.1 (1.0, 11.9)
ESR [mm/h]	male	46.5 (30.0, 68.0)	4.5 (2.0, 13.0)
Median (Q1, Q3)	female	42.0 (28.0, 74.0)	8.0 (4.0, 16.0)
DAS28-ESR			
Change from baseline	male		-3.1 ± 2.1
Mean ± SD	female		-2.9 ± 1.5
% Remission (< 2.6)	male	0.0% (0/46)	52.2% (24/46)
	female	0.0% (0/151)	45.0% (68/151)
Visual analogue scales			
Fatigue	male	62.0 (40.0, 79.0)	30.0 (10.0, 52.0)
Median (Q1, Q3)	female	65.0 (35.0, 85.0)	40.0 (15.0, 63.0)
Intensity of pain	male	70.0 (45.0, 83.0)	32.0 (10.0, 61.0)
Median (Q1, Q3)	female	65.0 (43.0, 86.0)	30.0 (12.0, 56.0)
Sleep disturbances	male	48.0 (19.0, 67.0)	12.0 (5.0, 50.0)
Median (Q1, Q3)	female	52.0 (21.0, 80.0)	38.0 (12.0, 66.0)

(CRP = C-Reactive Protein; ESR = Erythrocyte Sedimentation Rate; Q1, Q3 = 1st / 3rd quartile; SD = standard deviation)

Conclusions: At start of therapy, approximately one out of five patients documented in ICHIBAN showed anemia according to the WHO definition. During TCZ i.v. therapy a noticeable decrease in the rate of anemia and improved hemoglobin values were observed. These effects can already be seen after four weeks of treatment and continue up to the end of this study (i.e. 2 years). Despite the higher burden of disease at baseline in RA patients with anemia, TCZ i.v. therapy resulted in good clinical response rates and PROs.

SAT0194 SIRUKUMAB INTEGRATED SAFETY IN RHEUMATOID ARTHRITIS PATIENTS: ANALYSIS OF THE SIRROUND PHASE 3 DATA

D. Aletaha[1], C. Thorne[2], M. Schiff[3], M. Harigai[4], R. Rao[5], N. Goldstein[6], B. Cheng[6], C. Cohen[7], B. Hsu[6], K. Brown[7]. *[1]Medical University of Vienna, Vienna, Austria; [2]University of Toronto and Southlake Regional Health Centre, Newmarket, ON, Canada; [3]University of Colorado School of Medicine, Denver, CO, United States; [4]Tokyo Women's Medical University, Tokyo, Japan; [5]GSK Medicines Research Centre, Hertfordshire, United Kingdom; [6]Janssen Research & Development, LLC, Spring House, PA; [7]GlaxoSmithKline, Collegeville, PA, United States*

Background: Sirukumab (SIR), a human monoclonal antibody that selectively binds the IL-6 cytokine, is in development for the treatment of rheumatoid arthritis (RA). Efficacy of SIR was shown in several phase 3 trials in RA patients (pts; SIRROUND program).

Objectives: To analyze safety data from completed/ongoing studies in the SIRROUND program.

Methods: Safety comparisons included SIR 50mg q4w and 100mg q2w doses vs placebo (pbo) in the pbo-controlled period (Wk 0–18) of 2 phase 3 studies. A long-term comparison of the safety of SIR 50mg q4w and 100mg q2w for the entire program was also performed.

Results: In phase 3 studies, 2926 pts received SIR for up to 3.4y (median duration, 1.46y). During Wk 0–18, there were more adverse events (AEs), AEs leading to discontinuation, and serious AEs (SAEs) with SIR vs pbo, with cumulative rates of SAEs remaining constant over time (Table). In general, no dose effect with SIR was observed in the 18-wk or long-term analysis. Mortality rates were similar across treatment groups through 18 wks and remained stable in long-term analysis. Serious infections were more frequent in SIR-treated pts vs pbo during Wk 0–18, with similar rates through long-term analysis. Rates of gastrointestinal (GI) perforations and malignancies were low and similar across groups during the 18-wk and long-term analysis; major adverse cardiovascular event (MACE) rates were similar through 18 wks and numerically higher with SIR 50mg q4w vs 100mg q2w in long-term analysis.

Conclusions: SIR is well tolerated in pts with moderately to severely active RA. Overall, no dose relationship was observed between SIR 50mg q4w and 100mg q2w for types or frequencies of AEs.

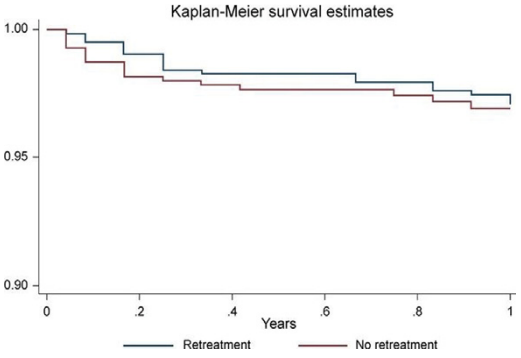
but recent registry data point to better responses and retention if a drug with a different mode of action is prescribed.
Objectives: Assess the long-term retention of rituximab (RTX) and TNFi following first biologic (b)DMARD inadequate response in RHUMADATA® registry patients (pts) with RA.
Methods: Data from RHUMADATA® pts with RA prescribed either RTX or TNFi as the second bDMARD after 1 January 2006 were analysed. Pts were followed until treatment discontinuation or 9 January 2017 cut-off. Pt characteristics were compared using descriptive statistics, bDMARD discontinuation rates using Kaplan-Meier methods, and proportional hazard models were used to identify predictors of treatment discontinuation.
Results: Data for 53 and 194 pts prescribed RTX or a TNFi, respectively, as second-line treatment were extracted. No clinically significant differences in baseline characteristics were noted between treatment groups. Most pts were women (74.9%), average age (SD) was 45.2 (12.9) years at diagnosis and disease duration 10.5 (8.7) years. Most pts were stopping an anti-TNF agent: 100% of those who were switched to RTX and 83% of those who were prescribed a second anti-TNF. Overall, 77.3% of pts stopped their first bDMARD after >6 months of treatment (secondary failure). Significant differences in retention between RTX and TNFi groups (log-rank p≤.0001) were observed (Table, Figure). Results remained unchanged for pts treated with TNFi only in first line, and primary/secondary failure of the first bDMARD did not affect sustainability of the second agent. Lack of efficacy (54.4%) and AEs (16.5%) were the most commonly cited reasons for treatment discontinuation.



Conclusions: Rituximab has better sustainability over a second line TNFi in RA patients having failed one prior bDMARD.

SAT0196 REPEATED RITUXIMAB INFUSIONS FOR THE THERAPY OF RHEUMATOID ARTHRITIS IS NOT ASSOCIATED WITH INCREASED RATES OF SERIOUS INFECTIONS

D.A. Pappas[1,2], G.W. Reed[2,3], S. Zlotnick[4], J. Best[4], R. Magner[3], G. Persuitte[2], J. Greenberg[2,5]. *[1]Columbia University, New York, NY; [2]Corrona, LLC, Southborough, MA; [3]University of Massachusetts Medical School, Worcester, MA; [4]Genentech, Inc., South San Francisco, CA; [5]New York University School of Medicine, New York, NY, United States*

Background: Extended observations in clinical trials have not demonstrated an increased risk of serious infection events (SIE) in patients with rheumatoid arthritis (RA) treated with rituximab.[1] However, continuous surveillance using large-scale observational data is of importance.
Objectives: To evaluate the rate of SIEs among patients with RA who received only an initial rituximab infusion vs those retreated with ≥1 rituximab infusion during the first year of therapy, and also to describe characteristics of rituximab-treated patients who experienced an SIE vs those who did not.
Methods: Patients with RA enrolled in the Corrona registry and treated with rituximab were followed until their most recent Corrona registry visit, first SIE, switch to another biologic or targeted synthetic disease-modifying antirheumatic drug, or 12 months after the most recent infusion with no further retreatment – whichever occurred first. The rate of SIEs was estimated in the overall population as well as in patients retreated with ≥1 infusion every 12 months after rituximab initiation and in those who did not receive a repeat infusion in the first 12 months. Patient characteristics were compared between those who experienced an SIE and those who did not.
Results: A total of 1361 patients with 1821 patient-years (PY) of follow-up were included; there were 59 SIEs for a rate of 3.24 SIE/100 PYs. 637 patients (46.8%) received ≥1 rituximab retreatment during the first 12 months and 724 (53.2%) received only the initial infusion. In the retreatment population there were 40 SIEs per 1312.8 PY for a rate (95% CI) of 3.05/100 PY (2.18–4.15), and in the no retreatment population there were 19 SIEs per 508.71 PY for a rate (95% CI) of 3.73/100 PY (2.25–5.83). The Kaplan-Meier curve depicting the occurrence of SIEs in the 2 cohorts during the first year of follow-up is shown (Figure). In the 59 patients (4.3%) who experienced an SIE, the mean (SD) number of rituximab infusions was 1.88 (1.18), compared with 2.07 (1.70) in the 1302 patients (95.7%) who did not experience an SIE. Patients who experienced an SIE vs those who did not were older (mean age [SD]: 62.9 [9.9] vs 58.1 [12.55] years), had longer disease duration (19.1 [13.1] vs 13.6 [10.4] years), were more frequently diabetic (16.9% vs 8.3%) and more frequently had cardiovascular disease (25.4% vs 12.8%), prior history of SIEs (18.6% vs 5.8%) and pulmonary disease (10.2% vs 4.8%). There were no differences in other clinical, demographic and medication history characteristics; steroid therapy was similar between the groups.

Conclusions: Retreatment with rituximab infusions was not associated with a higher rate of SIEs in this study. Patients who experienced an SIE had a higher prevalence of risk factors for infections.

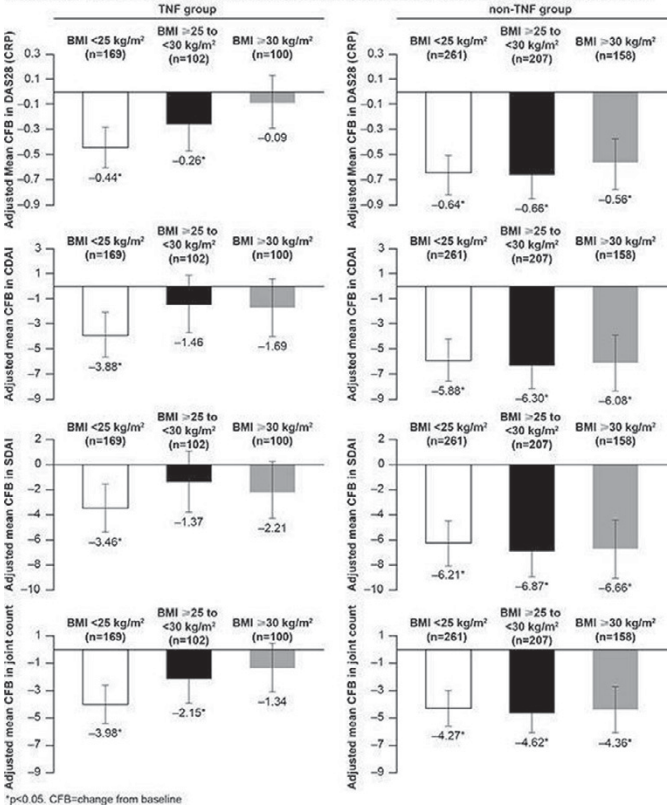
SAT0197 TREATMENT OUTCOMES WITH ANTI-TNF AND NON-ANTI-TNF DISEASE-MODIFYING THERAPY BY BASELINE BODY MASS INDEX



E. Alemao[1], Z. Guo[1], C. Iannaccone[2], M. Frits[2], M. Weinblatt[2], N. Shadick[2]. *[1]Bristol-Myers Squibb, Princeton; [2]Brigham and Women's Hospital, Boston, United States*

Background: Recent studies have indicated that being overweight or obese could reduce the effect of anti-TNF treatment in patients (pts) with RA.[1,2] Other data show that certain biologic (b)DMARDs, such as abatacept, work independently of BMI.[3,4] Additional data on the role of BMI on treatment outcomes in clinical practice settings is required to inform clinical practice.
Objectives: To evaluate the impact of BMI on outcomes of disease activity in pts with RA treated with TNF and non-TNF agents (conventional or other bDMARDs).
Methods: Pts enrolled in a tertiary care centre RA registry, established in 2003, were analysed. The registry mostly comprises pts with established RA who were evaluated semi-annually for multiple clinical patient-reported outcomes and resource utilization parameters, and annually for composite disease activity measures such as DAS28 (CRP), CDAI and SDAI. The current analysis is based on pts enrolled in the RA registry with BMI values at time of enrolment. Pts were classified into groups based on BMI: normal (BMI <25 kg/m^2), overweight (BMI ≥25 to <30 kg/m^2) and obese (BMI ≥30 kg/m^2). Outcomes evaluated included change from baseline in DAS28 (CRP), CDAI, SDAI and joint counts at 12 months

from treatment exposure. Treatments were categorized into TNF and non-TNF, which included conventional DMARDs and other non-TNF biologics. Multivariate linear regression analyses were used to evaluate impact of BMI on treatment outcomes controlling for baseline covariates of age, sex, disease duration, co-morbidities, baseline disease activity and serostatus. Separate models were run for the TNF and non-TNF groups.

Results: A total of 997 (78%) pts in the registry had baseline BMI values and were included in the analysis. Around 37% (n=371) had TNF exposure and were included in the TNF cohort; the remainder (63%; n=626) were included in the non-TNF cohort. Proportions of pts in the normal, overweight and obese groups for the TNF cohort were 45.5% (n=169), 27.5% (n=102) and 27.0% (n=100), respectively. For the non-TNF cohort, these were 41.7% (n=261), 33.1% (n=207) and 25.2% (n=158), respectively. In both cohorts, pts with normal BMIs were younger vs the overweight and obese BMI groups. However, obese BMI pts had higher disease activity measures at baseline (mean [SD] CDAI: 22.8 [17.8] for TNF and 24.9 [17.3] for non-TNF) vs the normal BMI pts (17.5 [15.9] for TNF and 19.9 [16.7] for non-TNF) and overweight BMI pts (20.9 [16.5] for TNF and 20.5 [15.0] for non-TNF). Adjusted mean change from baseline in disease activity in the TNF cohort was significantly reduced across all disease activity measures for the normal BMI group ($p<0.05$), but not for the overweight and obese groups (Fig). There were significant reductions in disease activity measures for all BMI groups (all $p<0.05$) in the non-TNF cohort (Fig).

Figure. Association between BMI and Treatment Outcomes DAS28 (CRP), CDAI, SDAI and Joint Count

*p<0.05. CFB=change from baseline

Conclusions: Independent of BMI, non-anti-TNF therapy demonstrated similar outcomes in pts with RA. However, obese and overweight pts with RA (vs normal weight) had less improvement in disease activity (as measured by DAS28 [CRP]) with anti-TNF therapy.

SAT0198 TOCILIZUMAB FOR THE MANAGEMENT OF RHEUMATOID ARTHRITIS: DISCONTINUATION DUE TO INEFFICACY AND TOXICITY – EXPERIENCE FROM A LARGE TEACHING HOSPITAL

E. Byrne, P. Mark, S. Khalid, K.-P. Kuet, R. Kilding, K. Graves, J. Maxwell, M. Akil. *Rheumatology, Sheffield Teaching Hospitals, Sheffield, United Kingdom*

Background: Tocilizumab (TCZ) is a humanised anti interleukin-6 receptor antibody licensed for use for the treatment of moderate to severe Rheumatoid Arthritis (RA) as monotherapy or in combination with methotrexate (MTX).

Objectives: To describe the use of TCZ for RA in a large UK teaching centre and examine reasons for treatment discontinuation.

Methods: A retrospective case note review of all adult patients receiving TCZ either alone or in combination with DMARDS, for the treatment of RA between April 2009 and January 2017 in Sheffield, UK.

Results: 132 patients received TCZ for RA. 71% were female. 61% were CCP positive. Mean disease duration was 15.6 years (range 1.5–43). 46 (34.6%) received TCZ as monotherapy, 55 (42.1%) in combination with MTX and 31 (23.3%) other DMARDS. 23% of patients received concomitant oral prednisolone. Median duration of TCZ treatment was 27 months across the whole cohort, and 19 months in those who discontinued treatment.

Overall 44 (33%) patients discontinued TCZ; 5 due to primary and 10 secondary inefficacy, 27 patients due to adverse events (8 recurrent infection, 5 abnormal LFT, 4 malignancy, 3 rash, 7 other including 1 death whilst on treatment). A logistic regression model, including gender, smoking status, disease duration, DMARD use, steroid treatment and number of prior biologics was constructed to examine association with treatment discontinuation. Of these factors, disease duration ($p=0.05$) and number of previous biologics ($p=0.09$) were weakly associated with persistence of TCZ and in particular there was no association of concomitant DMARD or steroid treatment with discontinuation either due to lack of efficacy or adverse events. Table 1 demonstrates the proportion of patients stopping treatment, and treatment duration according to previous biologic treatment received. We have not seen any cases of infusion reaction, diverticular perforation or reactivation of tuberculosis.

Table 1. Proportion of Patients Continuing TCZ and Treatment Duration According to Previous Biologic Treatment

		Previous Biologics Received			
		0	1	2	3 or more
Continued	N (%)	15 (83%)	31 (66%)	24 (51%)	12 (60%)
	Treatment Duration (Mths)*	46	27	26	58
Discontinued	N (%)	3 (17%)	16 (34%)	23 (49%)	8 (40%)
	Treatment Duration (Mths)	4.5	14	24	18
	Lack of Efficacy/Toxicity	2/1	7/9	9/14	3/5

*To date.

Conclusions: Our real world data on the use of TCZ in the treatment of adult patients with RA is consistent with clinical trial data for efficacy and safety and is similar to other biological drugs used in the treatment of RA. We have seen a relatively low rate of withdrawal due to primary and secondary treatment failure.

SAT0199 SUBCUTANEOUS TOCILIZUMAB MONOTHERAPY OR COMBINED WITH A CSDMARD IN PATIENTS WITH RHEUMATOID ARTHRITIS: TOZURA, A POOLED ANALYSIS OF PHASE IV STUDIES IN 22 COUNTRIES

E. Choy[1], R. Caporali[2], R. Xavier[3], B. Fautrel[4], R. Sanmarti[5], C. Bernasconi[6], A. Pethö-Schramm[6]. *[1]Cardiff University, Cardiff, United Kingdom; [2]University of Pavia, Pavia, Italy; [3]Universidade Federal do Rio Grande do Sul Porto Alegre, Rio Grande do Sul, Brazil; [4]Pierre and Marie Curie University, Paris, France; [5]Universitat de Barcelona, Barcelona, Spain; [6]F. Hoffmann-La Roche AG, Basel, Switzerland*

Background: Tocilizumab administered subcutaneously (TCZ-SC) has been approved for the treatment of rheumatoid arthritis (RA) both as mono- and combination therapy.

Objectives: To evaluate the efficacy and safety of TCZ-SC 162 mg once weekly (qw) as monotherapy or in combination with conventional synthetic DMARDs (csDMARDs) over 24 weeks in adult patients (pts) with moderate to severe RA.

Methods: TOZURA is a multinational, open-label, single-arm umbrella program comprising 7 single-country and 4 regional multicountry protocols (total 22 countries). Pts enrolled were inadequate responders to DMARD, and previous biologic DMARDs were allowed in 8 of 11 protocols. Pts received TCZ-SC 162 mg qw for 24 weeks administered at the investigator's discretion as monotherapy or in combination with a csDMARD. Stable oral NSAIDs and corticosteroids (CS), ≤10 mg/day prednisone or equivalent, were allowed. Efficacy and safety were evaluated at weeks 1, 2, 4 and every 4 weeks for 24 weeks (plus 8 weeks for safety). Propensity score-based matching was used for between-group tests.

Results: Of 1804 pts treated, 353 (19.6%) received monotherapy (mono) and 1451 (80.4%) combination therapy (combo); 349 pts (19.3%) had received a prior biologic DMARD. Background characteristics: 81.6% female; mean age, 54.1

years; mean RA duration, 7.7 years; and 82.7% seropositive –similar between treatment groups. Baseline CS was less frequent in the mono vs combo group (41.1% vs 51.2%); however, the mean prednisone equivalent daily dose was similar (6.6 vs 6.5 mg/day, respectively). Pts who continued TCZ to week 24 based on Kaplan-Meier estimates (95% CI) were 79.3% (74.7%>83.2%) for mono and 85.6% (83.7%>87.3%) for combo. DAS28 scores decreased comparably from baseline to week 24 in both groups (mean change: mono −3.40 and combo −3.46), with no significant difference between groups (P =0.61). Results were similar for the Clinical Disease Activity Index (CDAI, mean change by week 24: −23.5 and −23.8, with no significant difference between groups: P=0.42). The proportion of pts who achieved DAS28 or CDAI-based remission, low disease activity or ACR20/50/70/90 responses was similar between groups (Figure 1). In all, 18.2% of pts withdrew; 6.4% did so for safety reasons (mono 9.1%, combo 5.8%). AE rates were similar between groups (Table). Serious AE (SAE) rates were 14.6/100 PY (mono: 22.8/100 PY, combo: 12.8/100 PY). Serious infection and infestation rates were 3.6/100 PY (mono: 4.0/100 PY, combo: 3.5/100 PY) – similar between groups. Six deaths occurred (0.64/100 PY), 1 in the monotherapy group (0.57/100 PY) and 5 in the combination (0.65/100 PY) group.

Figure 1: DAS28 and CDAI Disease Activity and ACR Responses*

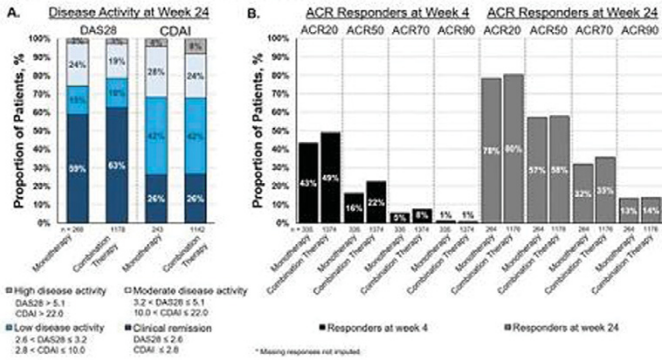

Table: Summary of Relevant Adverse Events

		Total Population (N = 1804; 943.3 PY)	Monotherapy (n = 353; 175.7 PY)	Combination Therapy (n = 1451; 767.6 PY)
Adverse events	Total patients with ≥ 1 AE, n (%)	1508 (83.6%)	282 (79.9%)	1226 (84.5%)
	Rate of AEs per 100 PY	622.4	622.1	622.5
Serious adverse events	Total patients with ≥ 1 SAE, n (%)	105 (5.8%)	29 (8.2%)	76 (5.2%)
	Rate of SAEs per 100 PY	14.6	22.8	12.8
Serious infections and infestations	Total patients with ≥ 1 SAE, n (%)	27 (1.5%)	6 (1.7%)	21 (1.4%)
	Rate of SAEs per 100 PY	3.6	4.0	3.5
Withdrawals due to insufficient therapeutic response	Total patients with ≥ 1 reason, n (%)	40 (2.2%)	9 (2.5%)	31 (2.1%)
Withdrawals due to safety reasons*	Patients, n (%)	116 (6.4%)	32 (9.1%)	84 (5.8%)
Deaths	Number of deaths, n (%)	6 (0.3%)	1 (0.3%)†	5 (0.3%)‡
	Rate of deaths per 100 PY	0.64	0.57	0.65

AE, adverse events; SAE, serious adverse events; PY, patient-year.
* Deaths, anaphylaxis and hypersensitivity reactions not included.
† Coronary artery disease.
‡ Myocardial infarction, pneumonia, pulmonary fibrosis, sepsis, septic shock.
Note: TOZURA trial numbers: NCT01995201, NCT02046603, NCT02011334, NCT02031471, NCT02001987, NCT01941095, NCT01941940, NCT02046616, NCT01988012, NCT01987479, NCT01951170.

Conclusions: TCZ-SC demonstrated convincing and comparable efficacy as mono- and combination therapy in pts with RA as was previously observed with TCZ-IV. The safety profile of TCZ-SC is consistent with the known safety profile of TCZ as monotherapy and in combination with csDMARDs.

SAT0200 BIOLOGIC THERAPY RETENTION IN RHEUMATOID ARTHRITIS (RA) PATIENTS (PTS) ACCORDING TO THE MOSCOW ARTHRITIS REGISTRY (MAR)

G. Lukina[1], E. Koltsova[2], E. Schmidt[3], E. Zhilyaev[4]. *[1]V.A. Nasonova Research Institute of Rheumatology, Moscow Clinical Scientific Center; [2]Research Institute of the Organization of health and healthcare management; [3]City Clinical Hospital 1 named after N.I. Pirogov; [4]Russian Medical Academy of continuing professional education, CJSC "European Medical Center", Moscow, Russian Federation*

Background: The use of biologics significantly improved results of the therapy of RA pts who did not achieve the target disease activity level on traditional DMARDS treatment. However the biologic therapy is in many cases withdrawn due to inefficacy or side effects (seldom because of sustained remission). Retention on treatment is a good integral index of efficacy and safety of biologics used in the real clinical practice.

Objectives: To assess the treatment survival of various biologics in RA pts in the real clinical practice.

Methods: Patients from MAR with RA receiving biologics were enrolled. Cases with missed results were excluded. A Cox proportional hazards regression model was used to determinethe predictors of the treatment discontinuation risk. Comparison of biologics retention rates for different biologicswas performed by means of Kaplan-Meier survival curves. Bonferroniadjustment was applied because of multiplicity of comparisons.

Results: 306 RA pts (mean age 54,5 years, mean age of disease onset 39,6 years, 86,5% women, 18% smokers, RF-positive 83,7%) were included in the study and 394 treatment courses (263 retrospective and 131 prospective) were analyzed. It was shown that significant independent predictors of discontinuation risk were: the biologic drug, the sequence number of the biologic drug in the patient and the age of RA onset. Risk of withdrawal was minimal by the use of the first biologic and increased by administration of the next ones. It also increased in pts with late onset of RA. Mass body index, age of the patient and the dose of methotrexate did not show significant correlations. Abatacept (ABA) demonstrated significant superiority over adalimumab (ADA) ($p<0.001$), infliximab (INF) ($p<0.001$), rituximab (RTM) (p=0.004) and etanercept (ETA) (p=0.035) when they was used as the first biologic drug. The treatment survival of tocilizumab was significantly higher compared to INF (p=0.02). As a second-line biological therapy ADA was maintained significantly longer than the INF (p=0.048).

Conclusions: Results of the real clinical practice trial show the significant differences in the retention rates of some biologics. It is reasonable to take these differences into consideration by the planning of the biologic treatment of RA pts.

SAT0201 ABATACEPT BUT NOT TNF INHIBITORS BLOCK AUTOANTIBODY-MEDIATED CYTOKINE PRODUCTION BY MONOCYTES

A. Bozec[1], Y. Luo[2], C. Engdahl[1], C. Figueiredo[3], H. Bang[4], G. Schett[1]. *[1]University of Erlangen-Nuremberg, Erlangen, Germany; [2]University of Chengdu, Chengdu, China; [3]Universidade de São Paulo, Sao Paulo, Brazil; [4]Orgentec Inc., Mainz, Germany*

Background: The anti-inflammatory effect of abatacept (CTLA4-Ig) is most pronounced in patients with high-titer autoantibodies (including anti-citrullinated protein antibodies, ACPA, and rheumatoid factor, RF) even exceeding the effect of TNF inhibitors (TNFi)[1]. Considering that autoantibodies trigger inflammatory cytokine production by monocytes[2] and that abatacept bind to monocytes influencing their functional state[3] we hypothesized that abatacept, in contrast to TNFi, may effectively inhibit the production of several different cytokines by ACPA-or RF-challenged monocytes.

Objectives: (i) To test whether abatacept inhibits the production of TNFa, IL-1b, IL-6 and IL-8 by monocytes exposed to ACPA or RF, (ii) to compare these effects of abatacept with those of TNFi and (iii) to investigate whether the effect of abatacept on cytokine production is based on IDO induction in monocytes.

Methods: CD68+ monocytes were isolated from peripheral blood and stimulated with MCSF for 24 hours before exposing them to random IgG alone (negative control), 10mg/mL purified anti-citrullinated vimentin antibodies (ACPA), 10mg/mL RF or LPS (positive control) in cell culture plates coated with citrullinated vimentin (to allow ACPA immune complex formation). ACPA and RF stimulation was done in the presence or absence of abatacept or TNF-antibody (adalimumab) with or without IDO inhibitor 1-MT. Supernatants were analyzed for four key pro-inflammatory cytokines TNFa, IL-1b, IL-6 and IL-8 by cytokine array (R&D Proteome Profiler) after 24h.

Results: Exposure to ACPA or RF dramatically induced the production of TNFa (20 fold and 27-fold, respectively) IL-1b (each 4-fold), IL-6 (12-fold and 11-fold, respectively) IL-8 (43-fold and 30-fold, respectively) in human monocytes. Abatacept significantly inhibited this up-regulation of inflammatory cytokine production with TNFa reduced by 79%, IL-1b by 74%, IL-6 by 88% and IL-8 by 83%. In contrast, TNFi did not influence autoantibody-induced production of IL-1b, IL-6 and IL-8. Inhibition of IDO by 1-MT reversed the effect of abatacept and unlocked cytokine production in the presence of ACPA and RF.

Conclusions: These data show that abatacept interferes with autoantibody mediated cytokine production by induction of IDO. The fact that several different

effector cytokines are inhibited simultaneously may explain the strong anti-inflammatory effect of abatacept in RA patients with high-titer ACPA and RF.

SAT0202 EFFICACY AND SAFETY OF SARILUMAB MONOTHERAPY VERSUS ADALIMUMAB MONOTHERAPY IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS IN THE PHASE 3 MONARCH STUDY, INCLUDING SUBPOPULATIONS

G.R. Burmester[1], Y. Lin[2], E.K. Mangan[3], H. van Hoogstraten[2], T. Kimura[3], J.I. Vargas[4], E.B. Lee[5]. *[1]Charité - University Medicine Berlin, Free University and Humboldt University Berlin, Berlin, Germany; [2]Sanofi Genzyme, Bridgewater; [3]Regeneron Pharmaceuticals, Inc, Tarrytown, United States; [4]Quantum Research, Puerto Varas, Chile; [5]Seoul National University College of Medicine, Seoul, Korea, Republic Of*

Background: Efficacy and safety of sarilumab + csDMARDs in RA patients have been demonstrated.
Objectives: To compare sarilumab monotherapy with adalimumab monotherapy in the ITT population of adults with active RA from MONARCH (NCT02332590) and across predefined subgroups.
Methods: Adults (N=369) intolerant of, inappropriate for, or inadequate responders (IR) to MTX (per investigator judgment) received SC sarilumab 200 mg q2w or adalimumab 40 mg q2w monotherapy. The primary endpoint was change from baseline in DAS28-ESR at wk 24. Consistency of treatment response (sarilumab vs adalimumab) for this endpoint was assessed in prespecified subpopulations.
Results: At wk 24, sarilumab was superior to adalimumab in change from baseline (BL) in DAS28-ESR (-3.3 vs -2.2; $P<0.0001$). Sarilumab-treated patients achieved significantly higher rates of ACR20 response (71.7% vs 58.4%; $P=0.0074$) and greater improvement in HAQ-DI (-0.6 vs -0.4; $P=0.0037$) and CDAI (-28.9 vs -25.2; nominal $P=0.0013$) vs adalimumab-treated patients. Extent of treatment effect with sarilumab vs adalimumab in change from baseline in DAS28-ESR at wk 24 was generally consistent ($P>0.05$) across subgroups; significant treatment-by-subgroup interactions were observed for body mass index ($P=0.047$) and baseline CRP ($P=0.006$) (Figure). The magnitude of treatment effect for DAS28-ESR was greater in patients with lower BMI and higher baseline CRP. Treatment effect was generally similar for other efficacy endpoints assessed, including ACR20, HAQ-DI, and CDAI. Clinical and functional responses in RF+/ACPA+, RF+/ACPA-, RF-/ACPA+, and RF-/ACPA- patients were similar to overall study results. Incidence of AEs was similar in both groups, including incidences of infections and serious infections. The most common AEs were neutropenia and injection site erythema (sarilumab) and headache and worsening of RA (adalimumab).

Conclusions: Sarilumab monotherapy demonstrated superiority to adalimumab monotherapy in the ITT population in change from baseline in DAS28-ESR. The extent of treatment effect with sarilumab vs adalimumab was generally consistent across subpopulations. Overall incidences of AEs and serious AEs and rates of infection and serious infection were similar between groups.

SAT0203 SIGNIFICANCE OF EXTENSION OF TOCILIZUMAB INFUSION INTERVALS FROM 4 WEEKS TO 6 WEEKS IN RA PATIENTS WHO HAD SHOWN GOOD RESPONSE TO 4 WEEK INTERVALS

H. Uda[1], K. Shigematsu[2], O. Saiki[1,3]. *[1]Rheumatology; [2]Orthopedics, Higashiosaka City Medical Center, Higashiosaka; [3]Internal Medicine, Shiraishi Hospital, Imabari, Japan*

Background: A period of 4 weeks (w) has been recommended as tocilizumab (TCZ, 8mg/kg) infusions. However, we found that 5 or 6w intervals were also effective in more than 90% of RA patients with low disease activity (LDA) at 4w intervals (1).
Objectives: We conducted the study to investigate the significance of extension of intervals from 4w to 6w. We compared, in the same patients, the clinical features such as diseases activity, major and minor side reactions between at 4w and at 6w. Moreover, we also considered the mechanisms.
Methods: This was a retrospective observational study. Among RA patients who had shown LDA with TCZ infusions at 4w intervals, the patients who could extend the intervals from 4w to 6w with LDA for more than 2 years without changing the doses of oral medicines were enrolled. In the same patients, we compared the events of serious and common side reactions between at 4w and 6w intervals. We examined the course of the levels of total cholesterol (TCHO), triglyceride (TG), and platelet (PLT) counts. We also examined the levels of serum trough TCZ and IL-6.
Results: Among 120 patients who maintained LDA at 4w intervals, more than 60% of patients maintained LDA at 6w intervals. When we compared the disease activity of 6w-responders between at 4w and 6w-intervals, all parameters reflecting the disease activities such as CRP and DAS28CRP score at 6w intervals were elevated significantly, but were still within LDA. At 4w intervals, serious adverse events were occurred as much as 11 cases during 2 years. At 6w intervals, however, they were decreased to 3 cases only in the same period. The common adverse events such as general fatigue, nausea, and dizziness occurred frequently at 4w intervals in most of the patients. At 6w intervals, these common adverse events were decreased significantly. At 4w intervals, the levels of TCHO and TG were elevated significantly. At 5w and 6w intervals, however, they were decreased accordingly. At 6w intervals, they were within normal limits. In most of patients, the levels of PLT counts were decreased significantly at 4w intervals. At 5w and 6w intervals, however, they were increased gradually. When TCZ were infused at 4w intervals, the serum trough TCZ levels were around 10 μg/mL. In contrast, they became undetectable when extended to 5w, and it is obvious that the trough TCZ levels of 6w were lower than 5w. The levels of IL-6 were significantly high at 4w-intervals, but the levels of IL-6 were decreased to less than 10 pg/mL at 5w-intervals.
Conclusions: The present study provide evidence that more than half of RA patients who showed good response to TCZ infusions at 4w could extend the intervals to 6w. By extension of intervals to 6w, major and minor side reactions were reduced significantly, and the levels of TG, TCHO and PLT were also normalized with sustaining LDA, suggesting that the dose of TCZ (8mg/kg) at 4w intervals might be excessive in some patients. Taken together, we should be careful for deciding the intervals of TCZ infusion in each patient.

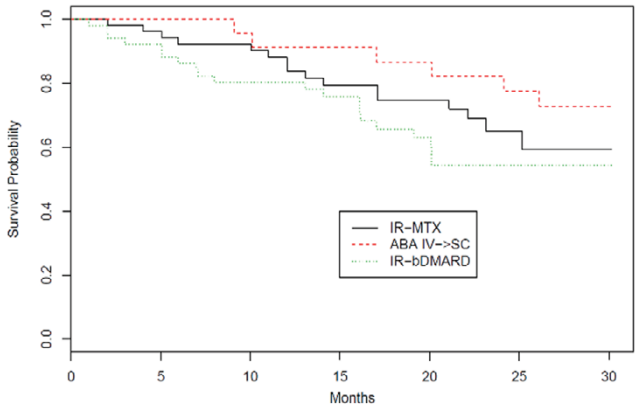
SAT0204 ABATACEPT SURVIVAL IN RHEUMATOID ARTHRITIS PATIENTS AT 2 YEARS IS 59%; ITS USE AS A 2ND LINE BIOLOGIC AGENT AND LOWER BASELINE HAQ PREDICT BETTER SURVIVAL IN CLINICAL PRACTICE: A PROSPECTIVE, OBSERVATIONAL SINGLE CENTER STUDY

I.D. Flouri[1,1], A. Repa[1], N. Avgoustidis[1], N. Kougas[1], A. Fanouriakis[1], I. Papalopoulos[1], C. Adamichou[1], P. Kyfonidou[1], E. Kampouraki[1], M. Terizaki[1], D.T. Boumpas[2], G. Bertsias[1], P. Sidiropoulos[1]. *[1]Rheumatology, Clinical Immunology and Allergy, Faculty of Medicine-University of Crete, Heraklion-Crete; [2]4th Internal Medicine Department, Attikon University Hospital, Athens, Greece*



Background: Long-term prospective observational studies are complementary to controlled clinical trials to explore effectiveness and safety of biological therapies in clinical practice.
Objectives: To study abatacept survival, reasons of discontinuation and clinical responses in everyday clinical practice of patients with rheumatoid arthritis (RA).
Methods: Prospective, observational single center study at the Rheumatology Clinic, University Hospital of Heraklion, Crete. At baseline, patient demographics, co-morbidities and disease characteristics are being recorded, while during follow-up, discontinuations, disease activity and adverse events are collected. For this analysis, all patients who received Abatacept intravenously from 6/2007 till 6/2016 were included. Kaplan-Meier curves and Cox regression analysis were used to determine drug survival and predictors thereof. Linear regression was used to compare DAS difference at 12 months between different lines of bDMARD therapy.
Results: A total of 224 patients (women: 87%, seropositive: 34%) were included. Median (IQR) age was 63 (56–70) years, disease duration 7.4 (4–13.4) years and baseline DAS28 5.9 (5.2–6.5). Abatacept was the 1st bDMARD in 59 (26%), 2nd in 71 (32%) and ≥3rd in 94 (42%) patients. During follow-up [total: 508 patient-years, median (IQR): 1.7 (0.7–3.3) years], 54% patients discontinued therapy (87% for treatment failure, 10% for adverse events). Two-year treatment persistence was 59%. In multivariable regression analysis, predictors of longer Abatacept survival were lower baseline HAQ [HR (95% CI) for unit increase =2.29 (1.5–3.48), p<0.001], longer disease duration [HR (95% CI) for ≥8 vs.<8 years=0.51 (0.30–0.88), p=0.016], Abatacept as 2nd vs 1st or ≥3rd bDMARD [HR =0.52 (0.30–0.91), p=0.022] and a more recent year of therapy start [HR=0.39 (0.16–0.95), p=0.022].
DAS28<3.2 and remission at 6 (12) months were achieved by 12% (18%) and 5% (7%) of patients respectively. DAS28 difference at 12 months was greater in patients who received Abatacept as the ≤2nd than those on ≥3rd bDMARD (p=0.009).
A total of 312 adverse events were registered, of which 65 were serious (SAE). Incidence of total (serious) adverse events was 61 (13) /100 patients/year. SAE included 5 cases of cancer, 10 cardiovascular events and 24 infections, mainly of the respiratory tract.
Conclusions: In the present study, Abatacept survival at 2 years was 59%. The majority of patients discontinued therapy due to inadequate response. Use as a 2nd line biologic agent and lower baseline HAQ predicted better survival. Improvement in DAS was higher when Abatacept was used as the ≤2nd bDMARD. Rates of remission or low disease activity in clinical practice are rather low, while the safety profile was excellent.

SAT0205 LONG-TERM DRUG SURVIVAL AND CAUSES OF DISCONTINUATION OF SUBCUTANEOUS ABATACEPT IN RHEUMATOID ARTHRITIS: 32-MONTH RESULTS FROM A PROSPECTIVE COHORT STUDY

J.C. Sarmiento-Monroy[1,2], N. Molano-Gonzàlez[2], M. Rodríguez-Jiménez[2], R.D. Mantilla[1,2]. *[1]Rheumatology, Center of Dermatology and Rheumatology (FUNINDERMA); [2]Center for Autoimmune Diseases Research (CREA), Universidad del Rosario, Bogotá D.C., Colombia*

Background: Survival time or time to discontinuation of medication is a surrogate of the long-term impact on the course of disease in real life. It reflects clinical effectiveness in the absence of significant adverse events [1]. Treatment discontinuation can result from loss of efficacy or safety concerns, but prognostic factors for patient retention have not been explored thoroughly despite data for abatacept and other biologics being available from national registries [2].
Objectives: To assess drug survival of subcutaneous (SC) abatacept among patients with rheumatoid arthritis (RA) according to treatment background.
Methods: This was a prospective study in which well-characterized patients with RA (by 1987 ACR criteria) were assessed from April 2014 to December 2016. Each patient was evaluated by a rheumatologist in a single rheumatology outpatient private center in Bogotá, Colombia. Patients were stratified by treatment background: (n=54) biologic-naïve, (n=24) switched from IV to SC abatacept administration, and (n=51) inadequate response to at least 1 biologic disease-modifying antirheumatic drug. The Mantel-Haenszel test was used to test if there were any differences in the survival curves among groups. The test was performed by the survdiff function of the "survival" R package [3].
Results: A total of 129 patients were included. Baseline characteristics of patients were as follows: female gender 86%, mean age 52±13 years, median disease duration 10 (IQR 11) years, Rheumatoid Factor positive 94%, Anti-Cyclic Citrullinated Peptide Antibodies 89%, and erosive phenotype 35%. At baseline, mean DAS28 and RAPID3 were 5.4±1.3 and 16.6±6.8, respectively. SC abatacept monotherapy was reported in 27%. Demographics and disease characteristics were similar in all groups, except for baseline DAS28 and RAPID3 in switch group (p<0.0001). According to the Mantel-Haenszel test (Fig.1), there were not significant differences between survival curves (p=0.158). Forty-three patients (33%) discontinued treatment. The most frequent reasons for drug suspension were loss of efficacy in 25%, insurance-related problems (i.e., access to medication/specialist) and adverse drug reactions in 16%. Other causes include lack of efficacy, surgeries (i.e., articular replacement), patient preference, and pregnancy.

Figure 1. Subcutaneous abatacept survival by treatment background.

IR-MTX: inadequate response to methotrexate (biologic-naïve); ABA IV→SC: switched from intravenous to subcutaneous abatacept administration (125mg-wk); IR-bDMARD: inadequate response to biologic Disease-Modifying AntiRheumatic Drugs.

Conclusions: Our results disclose a similar drug survival of SC abatacept regardless of treatment background. Patients switching from IV to SC formulation of abatacept had lower activity and functional impairment at baseline, and survival tends to be higher through follow-up. The insurance-related limitations is a reality in Latin American countries, and could have a negatively impact on survival time of several drugs.

SAT0206 RETENTION OF TOCILIZUMAB AS MONOTHERAPY VERSUS TNF INHIBITORS WITH CONVENTIONAL SYNTHETIC DMARDS IN RHEUMATOID ARTHRITIS PATIENTS WITH INADEQUATE RESPONSE TO TNF INHIBITORS: A STUDY FROM THE TOCERRA COLLABORATION

K. Lauper[1,2], D.C. Nordström[3], K. Pavelka[4], V. Hernandez[5], M.J. Santos[6], Z. Rotar[7], F. Iannone[8], C. Codreanu[9], G. Lukina[10], S.L. Gale[11], K. Sarsour[11], A. Pethoe-Schramm[12], D.S. Courvoisier[1], C. Gabay[1,2]. *[1]Univ Hosp of Geneva, Geneva; [2]SCQM Registry, Zurich, Switzerland; [3]ROB-FIN Helsinki Univ Central Hosp, Helsinki, Finland; [4]Charles Univ, Prague, Czech Republic; [5]Rheumatology Department, Hospital Clinic Barcelona, Barcelona, Spain; [6]Rheumatology Unit, Hospital Garcia de Orta, Almada, Portugal; [7]BioRx.si, Univ Med Center, Ljubljana, Slovenia; [8]GISEA, Univ Hospital of Bari, Bari, Italy; [9]Univ of Medicine and Pharmacy, Bucharest, Romania; [10]ARBITER, Inst of Rheumatology, Moscow, Russian Federation; [11]Genentech, South San Francisco, CA, United States; [12]F. Hoffmann-La Roche, Basel, Switzerland*

Background: Tocilizumab (TCZ) as monotherapy has been shown to be more efficacious than the TNF inhibitor (TNFi) adalimumab as monotherapy in patients with rheumatoid arthritis (RA). However, effectiveness data comparing TCZ as monotherapy versus TNF inhibitors in combination with csDMARDs are limited.
Objectives: To examine retention of TCZ administered alone (TCZ mono) versus TNFi in combination with csDMARDs (TNFi combo) in patients with RA who had an inadequate response to ≥1 TNFi (TNFi-IR).
Methods: Patients with RA who were TNFi-IR and treated with TCZ mono or TNFi combo with baseline (BL) data, not immediately lost to follow-up and started treatment after TCZ was available across 9 European registries in TOCERRA from 2009 to 2016 were included. The hazard for TCZ discontinuation was modeled using a country-stratified Cox proportional hazards model, adjusting for

age, gender, disease duration, seropositivity, HAQ and CDAI at BL, number of previous csDMARD and biologic DMARD (bDMARD), glucocorticosteroid and calendar year of treatment initiation. Missing data on covariates were imputed using multiple imputation with chained equations.
Results: A total of 4748 patients were eligible, including 585 who received TCZ mono and 4163 who received TNFi combo. Patients who received TCZ mono were older with a longer disease duration, more previous bDMARDs and less glucocorticosteroids at baseline (Table 1) compared with patients who received TNFi combo. The crude median retention for TCZ mono was 1.82 years (95% CI: 1.59–2.09) and 1.54 years (95% CI: 1.43–1.64) for TNFi combo, (P=0.65). Causes of discontinuation differed between TCZ mono and TNFi combo (P<0.001): TCZ mono stopped more frequently for ineffectiveness (25.7% vs. 13.8%) and TNFi combo stopped more frequently for safety issues (18.3% vs. 12.8%). In a country-stratified, covariate-adjusted analysis, we found that hazards of discontinuation were significantly lower among patients who received TCZ mono (HR: 0.71, P<0.001). More previous treatment with bDMARDs and a greater HAQ and CDAI at BL were significantly associated with greater risk of discontinuation.

Table 1. Baseline characteristics.

	TCZ mono (N = 585)	TNFi combo (N = 4163)	*P*
Age, yr, median [IQR]	57.8 [44.2-65.5], n = 585	54.3 [44.2-61.7], n = 4161	< 0.001
Female gender, N (%)	485 (82.9%), n = 585	3333 (80.1%), n = 4161	0.12
Disease duration, yr, median [IQR]	9.7 [4.5-16.7], n = 569	7.8 [3.3-14.3], n = 3575	< 0.001
Seropositivity (RF and/or ACPA), N (%)	445 (83.6%), n = 532	2573 (81.0%), n = 3175	0.17
N previous bDMARDs, N (%)			< 0.001
1	250 (42.7%)	2882 (69.2%)	
2	206 (35.2%)	526 (12.6%)	
≥ 3	129 (22.1%)	755 (18.1%)	
Glucocorticosteroids, N (%)	193 (33.0%), n = 585	2487 (59.7%), n = 4163	< 0.001
Concomitant csDMARD, N (%)			--
MTX	--	1766 (42.4%)	
MTX + other	--	1291 (31.0%)	
Other	--	1106 (26.6%)	
CDAI, mean (SD)	23.2 (16.1), n = 322	21.9 (14.7), n = 3021	0.25
HAQ, mean (SD)	1.4 (0.7), n = 226	1.1 (0.7), n = 2429	< 0.001

Conclusions: In routine care across 9 European countries, TCZ mono retention is better than TNFi combo in patients with RA who were TNFi-IR.

SAT0207 LONG-TERM EFFECT OF BIOLOGICAL THERAPIES ON BONE MINERAL DENSITY (BMD) FOR RA PATIENTS COMPARED TO PATIENTS TREATED BY SYNTHETIC DMARD OVER AN 8-YEAR FOLLOW-UP

L. Bustamente[1], V. Breuil[2], R. Fabre[3], L. Euller-Ziegler[2], C. Pradier[3], C. Roux[1]. *[1]Rheumatology, University Nice, Sofia Antipolis, Nice; [2]Rheumatology; [3]Santé publique, University Nice, Sofia Antipolis, Nice Cedex 1, France*

Background: Secondary osteoporosis is a comorbidity of Rheumatoid Arthritis (RA). Previous studies have suggested that biological therapies may reduce the rate of generalized bone loss in RA. Most of them focus on the short-term effect of Tumor Necrosis factor alpha (TNFα) inhibitors while the long-term effect of biological therapies is rarely studied.
Objectives: Our primary aim was to analyze the long-term effect of biological therapies on bone mineral density (BMD) for RA patients compared to patients treated by synthetic DMARD over an 8-year follow-up.
Methods: Patients were selected from a prospective, observational cohort of RA patients meeting the ACR/EULAR 2010 settings in Nice University Hospital between 2001 and 2016. BMD was assessed before the introduction of the biological therapy and during the follow-up. Two groups were studied: patients treated by biological therapies (TNFα inhibitors, Tocilizumab, Abatacept, Rituximab or Anakinra) and patients treated by synthetic DMARD only. Demographic, disease and treatment data were collected at each visit and BMD of the lumbar spine, femoral neck and total hip were assessed using dual energy X-ray absorptiometry (DXA) at baseline and after 1, 2, 3, 5 and 8 years.
Results: A total of 181 patients with active RA starting a biological therapy were included versus 131 patients treated by synthetic DMARD. In both groups, the BMD of the lumbar spine, femoral neck and total hip remained stable after a 2-year follow-up (respectively -0.37%, p=0.66 versus +0.02%, p=0.83, -3.70%, p=0.77 versus -5.35%, p=0.74 and -3.31%, p=0.45 versus -4.84%, p=0.16), while a significant bone loss was found between initial measurement and 3, 5 and 8 -year-follow-up at femoral neck and total hip level. There was no significant difference between patients whether treated by biological or non-biological DMARD neither over the 0–1-year period nor over the 0–2, 0–3, 0–5 and 0–8-periods. Bone loss in patients treated by Tocilizumab were statistically lower at femoral neck level compared with TNFα inhibitors (p=0.02), Abatacept (p=0.02) and Rituximab (p=0.02), but also at total hip level, in comparison with TNF α inhibitors (p=0.05) and Abatacept (p=0.05).
Conclusions: This study is the first to assess the effects of biological RA therapies as compared to synthetic DMARD ones. It highlights the protective effect of both biological and non-biological DMARD on bone loss during the first two years of treatment with no significant difference between them. Our results suggest that the effects of RA treatments depend on the inflammatory and disease activity which must be monitored clearly. Tocilizumab seems to be more effective than the other biological therapies, but further studies are necessary to confirm or infirm this tendency.

SAT0208 CYCLING VERSUS SWAPPING IN PATIENTS WITH RHEUMATOID ARTHRITIS WITH AN INADEQUATE RESPONSE TO AT LEAST ONE TUMOR NECROSIS FACTOR ALPHA INHIBITOR: A SYSTEMATIC REVIEW AND META-ANALYSIS OF OBSERVATIONAL STUDIES

M.A. Lopez-Olivo[1], A. Matusevich[2], M.E. Suarez-Almazor[1]. *[1]General Internal Medicine, The University of Texas, MD Anderson Cancer Center; [2]School of Public Health, The University of Texas, Health Science Center at Houston, Houston, United States*

Background: In patients with rheumatoid arthritis (RA) who do not respond or lose response, opinions are divided on whether it is better to try an alternative TNFi (cycling) or switch to a therapy with a different mode of action (swapping).
Objectives: To compare the efficacy and safety of the cycling versus the swapping strategies.
Methods: We searched 4 electronic databases, sources of gray literature, and bibliographic references of relevant articles for observational studies evaluating the efficacy and safety of targeted therapies in adult RA patients who failed to respond to at least one TNFi. Studies were excluded if they were single-arm or had insufficient data to evaluate the outcomes of interest. Two independent reviewers selected studies, extracted data and evaluated study quality using the Newcastle-Ottawa Scale (NOS). Our primary outcome measure was change in Disease Activity Score of 28 joints (DAS28). We also evaluated the modified American College of Rheumatology 20%, 50% and 70% response criteria (mACR which excludes acute phase reactants) and total serious adverse events. All analyses were based on the random-effects model.
Results: Of 33,716 citations, 24 observational studies (n=10,074 patients) representing 14 countries, met the inclusion criteria. Eight were conference abstracts. Most publications (13 of 24) were based on registries. Most studies had a NOS score equal to or greater than 7 (out of 9) with comparability being the weakest domain. The mean age of patients was 48.7–62.8 years, the majority were females (78%) with a disease duration of 6–17.3 years and a baseline disability score 0.6–2.0. Sixteen studies evaluated cycling versus swapping directly of which 13 were suitable for analysis. Most compared TNFi to rituximab (10 of 13) with two studies investigating tocilizumab or abatacept and one comparing non-TNFi as a group. Other comparisons reported were: (i) cycling vs. conventional disease modifying antirheumatic drugs (cDMARDs), (ii) swapping vs. cDMARDs, (iii) cycling vs. another cycling alternative, (iv) swapping vs. another swapping alternative, (v) swapping monotherapy vs. swapping combined with cDMARDs, and (vi) combination of TNFi and non-TNFi vs. TNFi alone. At 12 and 24 weeks, DAS28 score improved significantly in those swapping compared to those cycling (mean difference (MD) 0.89, 95% confidence interval (CI) 0.05 to 1.74 and MD 0.34 95% CI: 0.2, 0.48; respectively). Similar results were observed for the mACR50 favoring the swapping strategy at 24 weeks (OR =1.45 95% CI: 1.06, 1.98). At 52 weeks no difference was observed. No statistically significant differences were observed between groups in the odds of achieving DAS28 remission, mACR20 or mACR70, or experiencing a serious adverse event.
Conclusions: Current evidence from observational studies shows greater improvements with the swapping strategy compared with the cycling strategy in terms of efficacy for RA patients failing their first TNFi. No differences were observed regarding safety. Data were not available for anakinra, certolizumab pegol, golimumab, or tofacitinib.

SAT0209 OBSERVATIONAL STUDY ON THE EFFECTS OF IL-6 INHIBITOR THERAPY ON MYOSTATIN IN PATIENTS WITH RHEUMATOID ARTHRITIS

M.J. Chapman[1], R.P. Narayanan[2], A. Cross[3], R. Moots[3], J. Wilding[2], N. Goodson[3]. *[1]Department of Rheumatology, Aintree University Hospital; [2]Department of Obesity and Endocrinology; [3]Institute of Ageing and Chronic Disease, University of Liverpool, Liverpool, United Kingdom*

Background: Rheumatoid cachexia (RC), a phenotype of increased adiposity, reduced lean mass and insulin resistance can occur in rheumatoid arthritis (RA). It is most prevalent in those with high disease activity and is associated with increased cardiovascular morbidity and mortality. Tocilizumab (TCZ), a monoclonal anti-IL-6 antibody, successfully reduces disease activity in RA. It has also been associated with improved insulin sensitivity, increased lean mass and hyperlipidaemia. The serum concentration of myostatin, a myokine released by skeletal muscle, is increased in most disease states associated with cachexia. Moreover, its knockout and inhibition increase lean mass. However, its role in RA has not been fully elucidated.
Objectives: To investigate the effect of tocilizumab treatment on serum myostatin in patients with RA.
Methods: 19 patients with RA (16 female, 3 male) mean age 49.6yrs, mean DAS28 6.1, median disease duration 10yrs (range 0 to 30), mean BMI 27.4, received 13 IV infusions of TCZ 8mg/kg every four weeks as part of a 52 week, single-centre, open-label study (ACT-NEUT [1]). 8 had previously been exposed to a biological agent, 4 were on regular steroids, and all patients received concurrent methotrexate. Serum myostatin was measured at 0, 1, 3 and 6months of treatment using ELISA. BMI, serum lipid profile, CRP, ESR and DAS28 were measured at each visit (0, 1, 3 and 6months). Data were analysed using STATA 14. Change between 0, 3 and 6months was analysed using Wilcoxon signed rank test, statistical significance was confirmed using mixed model analysis adjusting for BMI, age and gender. Linear regression with adjustment for age, BMI and gender assessed correlation at baseline.
Results: DAS28, CRP and ESR all significantly decreased with TCZ treatment. A significant increase in BMI (25.5 (IQR 21.6–31.7) vs 26.0 (IQR 21.4–32.5) p=0.0052) between baseline and 6months and serum triglycerides between baseline and 3 months (1.3 (IQR 1.3–2.2) vs 1.6 (IQR 1.3–2.6) p=0.028) was seen with TCZ. Baseline serum myostatin concentrations were negatively correlated with baseline DAS28 (r^2=0.39 p=0.038). Treatment with tocilizumab for 6months resulted in a significant increase in serum myostatin from baseline (2.7ng/mL (IQR 2.0–3.1) vs 3.3ng/mL (IQR 3.0–5.0) p<0.001) [Fig. 1]. Moreover, a significant association was seen between baseline myostatin and change in cholesterol at 3 months (r^2=0.51 p=0.029), when adjusting for baseline cholesterol, age, gender, BMI and change in BMI.

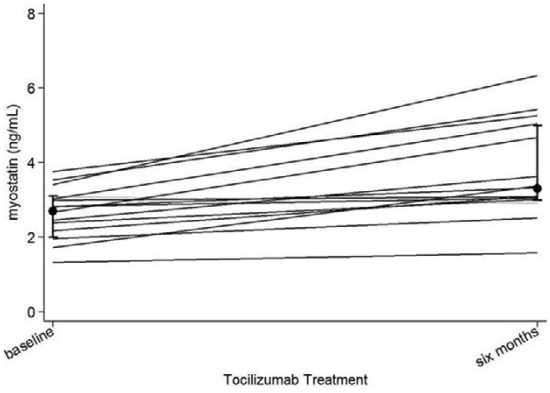

Fig 1. Serum myostatin levels significantly increase after six months of tocilizumab in patients with rheumatoid arthritis. Values shown are actual serum values for individual patients (n=19 at baseline n=15 at 6months). Black lines represent increasing serum values, grey lines decreasing values with treatment. Circles represent median±IQR. Change evaluated by Wilcoxon signed rank test p<0.001

Conclusions: We have demonstrated a significant correlation between myostatin and DAS28 and a significant change in myostatin with tocilizumab treatment. It is possible that IL-6 blockade results in a rise in myostatin. This might attenuate any improvement in muscle wasting. Future studies should measure body composition and muscle function to help understand the changes we have observed.

SAT0210 IMPROVEMENT OF DISEASE ACTIVITY IN A 5-YEAR COHORT OF RHEUMATOID ARTHRITIS PATIENTS TREATED UNDER TREAT TO TARGET RECOMMENDATIONS RECEIVING BIOLOGICAL THERAPY

P. Santos-Moreno[1], D. Gomez[1], E. Castillo[1], R. Giraldo[1], G. Ballesteros[1], L. Villarreal[2], J. Bello[3], D. Buitrago-Garcia[3]. *[1]Rheumatology; [2]Psychology and processes; [3]Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia*

Background: Treat to Target (T2T) strategy becomes from the need to develop therapeutic targets and tools to achieve defined outcomes in rheumatoid arthritis (RA), this strategy has become recognized as a standard of good practice embodying the principle that rapid attainment of remission, or low disease activity, can halt joint damage and maintain good quality of life. However, there is no direct comparison between biologics in cohorts of patients with long-standing RA using T2T approach in real-life settings, which could have implications in treatment decisions and health economics.
Objectives: The aim of this study was to describe global change in Disease Activity Score 28 (DAS28) using T2T strategy for a 5 year period in patients with biological therapy in a large cohort of patients from a Colombian specialized in RA center with multidisciplinary approach.
Methods: A descriptive dynamic cohort study was performed. Records of patients using biological DMARD treatment (Anti-TNF and others) from specialized in RA center were reviewed; those patients were followed-up under T2T standards. Clinical follow-up was according to DAS28 as follows: every 3–5 weeks (DAS28 >5.1), every 7–9 weeks (DAS28 ≥3.1 and ≤5.1), and every 11–13 weeks (DAS28 <3.1). Therapy had to be adjusted with DAS28 >3.2 unless patient's conditions don't permit it. We divided patients in three groups: low disease activity (LDA), moderate disease activity (MDA) and severe disease activity (SDA) patients. Descriptive epidemiology was done, percentages and averages were calculated; the median of each variable was analyzed using t-Student assuming normality for DAS28 distribution and the level activity disease was analyzed using Pearson's statistics.
Results: During 60 month period we included 695 patients with biological therapy, 85% were female and 15% male. Mean age was 58 years ± 11. At beginning mean DAS28 was 4.1±1.1 and 20% of patients were in SDA, and 55% in MDA. At the end of 5 year period mean DAS was 3.2±0.89 and only 7% of patients were in SDA and 33% in MDA. The median was analyzed using t-Student assuming normality for DAS28 distribution. It showed statistical significant improvement (p<0.00).

ACTIVITY LEVEL	TIME 0 n(%)	2011-2012 n(%)	2013-2014(%)	2015-2016(%)
REM	-	50 (7)	166 (24)	217 (31)
LDA	178(26)	236 (34)	181(26)	198(28)
MDA	382 (55)	361(52)	278 (40)	234(74)
SDA	135 (19)	98(14)	70(10)	46(7)

Conclusions: There was a global improvement of DAS28 in a cohort of RA patients receiving biological therapy followed and treated under recommendations of T2T approach demonstrating that with the strategies mentioned above it is possible to obtain a good control of the activity of the disease.

SAT0211 REAL WORLD DATA OF RITUXIMAB EFFECTIVENESS IN RHEUMATOID ARTHRITIS: DIFFERENCES BETWEEN BIOLOGIC-NAIVE PATIENTS AND PREVIOUSLY EXPOSED TO BIOLOGICS

R.M. Ferreira, R. Fonseca, D.R. Gonçalves, F. Aguiar, T.M. Rocha, A. Bernardo, S. Pimenta, M. Bernardes, L. Costa. *São João Hospital Centre, Porto, Portugal*

Background: Rituximab is only approved for rheumatoid arthritis (RA) treatment in patients with an incomplete response or intolerance to others DMARDs, including TNF alfa inhibitors. It represents a significant advance in RA biologics arsenal due to its safety and efficacy profiles.
Objectives: To evaluate the effectiveness of rituximab in RA patients and to compare the response between first-line rituximab patients and those previously exposed to other biologics.
Methods: An observational retrospective study was conducted, including all the consecutive patients with diagnosis of RA under rituximab, followed at our Rheumatology department until December 2016. Demographic and clinical data were obtained by consulting the national database (Reuma.pt). DAS28 variations and EULAR response were measured at 6, 12 and 18 months. Parametric and non parametric tests were used for statistics (SPSS 20.0).
Results: We included 63 RA patients (81% of women), with a mean (SD) age of 61 (10) years and a mean disease duration of 19 (10) years; 86% rheumatoid factor positive and 87% anti- citrullinated peptide antibody (ACPA) positive. Bone erosions and extra-articular manifestations were present in 85,7% and 58,7% of the patients, respectively. At baseline, the mean DAS28 was 5.79 (65% and 29% of patients with severe and moderate disease activity, respectively, and 6% in clinical remission). Thirty patients were treated with rituximab as first-line therapy and 33 patients were previously exposed to other biologics. Combination therapy

with methotrexate (MTX) was observed in 48% and with others classic DMARDs in 30%, while 22,3% received rituximab monotherapy. First-line rituximab option was justified by lung involvement in 21%, past malignancy in 13%, recurrent infections in 5%, congestive cardiac failure in 3%, vascular involvement in 3% and untreated latent tuberculosis in 3%. In the group previously exposed to biologics, 13% switched therapy due to ineffectiveness and 87% due to adverse events. No significant differences were found between the 2 groups in terms of age, gender, concomitant use of MTX and baseline DAS28. The group previously exposed to biologics had a longer disease duration (mean 23 vs 15 years, p=0.001) and fewer patients with ACPA seropositivity (79% vs 97%, p=0.035). There was a significant reduction of DAS28 at 6, 12 and 18 months ($p<0.001$ for all). Fifty six percent of the patients achieved a EULAR response at 6 months, 46% at 12 months and 59% at 18 months. DAS28 variation at 6 months differed significantly between groups, with a better clinical response in naive biological patients comparing to those previously exposed to biologics (median 1.173 vs 0.477; p=0.038). There were no differences in terms of DAS28 variation at 12 and 18 months (p=0.642 and p=0.135, respectively) and in EULAR responses at 6, 12 and 18 months between the groups (p=0.289, p=0.523 and p=1.000, respectively).

Conclusions: Our study confirms the effectiveness of rituximab in RA patients and suggests a higher magnitude of response in naive biological patients at 6 months of RTX therapy. These findings put in perspective an extension of rituximab as a first-line biologic for RA treatment.

SAT0212 SARILUMAB DOSE REDUCTION IN AN OPEN-LABEL EXTENSION STUDY IN RA PATIENTS WITH INADEQUATE RESPONSE TO TNF INHIBITORS

R. Fleischmann[1], P. Hrycaj[2], H. van Hoogstraten[3], E.K. Mangan[4], Y. Lin[3], S. Jayawardena[3], G.R. Burmester[5]. *[1]Metroplex Clinical Research Center, University of Texas Southwestern Medical Center, Dallas, United States; [2]Department of Rheumatology and Clinical Immunology, Poznań University of Medical Sciences, Poznań, Poland; [3]Sanofi Genzyme, Bridgewater; [4]Regeneron Pharmaceuticals, Inc, Tarrytown, United States; [5]Charité - University Medicine Berlin, Free University and Humboldt University Berlin, Berlin, Germany*

Background: Sarilumab is a human mAb blocking the IL-6Rα. In the phase 3 TARGET study (NCT01709578), sarilumab (150 or 200 mg SC q2w) + csDMARDs demonstrated efficacy in adults with active, moderate-to-severe RA and inadequate response or intolerance to ≥1 TNFi. Infections, neutropenia, injection site reactions, increased lipids, and increased transaminases were among the most common TEAEs. EXTEND (NCT01146652) is an open-label extension study evaluating long-term safety and efficacy of sarilumab in patients from the sarilumab clinical development program.

Objectives: To examine the effects of dose reduction of sarilumab 200 mg q2w to 150 mg q2w in patients from TARGET that occurred in EXTEND primarily for protocol-specified laboratory abnormalities.

Methods: Patients were switched to or initiated on sarilumab 200 mg q2w after enrolling in EXTEND. Per protocol, investigators could reduce the sarilumab dose from 200 mg q2w to 150 mg q2w for ANC ≥0.5 to 1.0 Giga/L, platelet count ≥50 to 100 Giga/L, or ALT ≥3 to 5×ULN. Dose reductions were also performed at the investigator's discretion. Efficacy data from EXTEND were analyzed before and 24 weeks after dose reduction.

Results: As of the July 2016 interim analysis (N=452), dose reduction from sarilumab 200 mg q2w to 150 mg q2w had occurred in 14.6% of patients (n=66) from TARGET. The most common reasons for dose reduction were decreased ANC (8.8%; n=40) and increased ALT (3.3%; n=15). At the time of analysis, 80.3% of patients (n=53) whose dose was reduced were continuing treatment, with a median treatment duration of 1.6 years after dose reduction. Improvements in ANC and ALT were observed over the 6 months after dose reduction (Table 1). Efficacy was maintained 24 weeks after dose reduction (Table 2).

Table 1. ANC and ALT After Dose Reduction[a]

	Before dose reduction n (%)	6 months after dose reduction n (%)
ANC		
≥0.5 to <1.0 Giga/L	25/40 (62.5)	5/39 (12.8)
<0.5 Giga/L	0	0
ALT		
>3 to ≤5×ULN	13/15 (86.7)	1/13 (7.7)
>5 to ≤10×ULN	1/15 (6.7)	0

[a]Denominator represents patients who dose reduced because of decreased ANC or increased ALT who had ANC/ALT measured within specified time point.

Table 2. Efficacy After Dose Reduction

	Before dose reduction (N=60)	6 months after dose reduction (N=53)
ACR20 response rate, n (%)	49 (81.7)	43 (81.1)
ΔHAQ-DI, mean (SD)	-0.7 (0.6)	-0.8 (0.7)
ΔDAS28-CRP, mean (SD)	-3.0 (1.2)	-3.0 (1.3)
ΔCDAI, mean (SD)	-28.4 (12.5)	-28.6 (14.6)

Conclusions: In patients from TARGET whose sarilumab dose was reduced from 200 mg q2w to 150 mg q2w during EXTEND, there was an improvement in laboratory abnormalities and continuation of treatment for the majority of patients. Improvements in signs and symptoms of RA and physical function were maintained after dose reduction.

SAT0213 LOW DOSE IL-2 RESTORES DECREASED ABSOLUTE NUMBER OF REGULATORY T CELLS AND IMBALANCE BETWEEN TH17 AND REGULATORY T CELLS IN PATIENTS WITH RHEUMATOID ARTHRITIS

R. Jia[1], X. Li[1], C. Wang[1], C. Gao[2]. *[1]The Department of Rheumatology, the Second Hospital of Shanxi Medical University, Taiyuan, China; [2]Pathology, Joint Program in Transfusion Medicine, Brigham and Women's Hospital/Children's Hospital Boston, Harvard Medical School, Boston, United States*

Background: A therapeutic revolution in the past decade is still a considerable unmet need in the treatment of rheumatoid arthritis (RA). On the other hand, dysfunction of regulatory T cells (Tregs) has been considered to be a pivotal cause of RA and correction of this dysfunction to be a potential RA therapy[1]. However, abnormalities of Tregs in patients with RA were reported controversially in previous studies[2], in which only proportion was measured and Tregs were defined using different protein markers.

Objectives: In this study, we measured both absolute numbers and proportions of CD4+CD25+Foxp3+ Tregs in peripheral blood of RA patients and investigated the effects of low-dose recombinant human IL-2 (rhIL-2) on Tregs and CD4+ effector T cell subsets in patients with RA.

Methods: Both absolute numbers and proportions of Treg and Th17 cells in peripheral blood, defined as the CD4+CD25+FOXp3+T or CD4+IL-17 + T cell population, were examined by flow cytometry in 342 patients with RA with different 28-joint Disease Activities (DAS28), including 75 who had never received disease-modifying antirheumatic drugs (DMARD) and 151 who were receiving or had received DMARD. Among these patients, 112 consented at enrollment to receive rhIL-2 treatment. Before and after treatment, the Th17 and Treg cells in peripheral blood were analyzed by flow cytometry.

Results: The absolute count of Treg cells in patients with RA was significantly low compared with that of healthy controls ($P<0.05$), but the absolute count of Th17 cell was no different between RA and healthy controls. After the course of rhIL-2 treatment, there was a significant increase in the absolute count of Th17 and Treg cells in the CD4+ T cell population ($P<0.01$), but Th17/Treg was significantly low after the treatment.

Conclusions: The data suggest that, besides propotion, the decrease of Treg cell number, defined as the CD4+CD25+FOXp3+population, may contribute to the pathogenesis of RA. Over the treatment of rhIL-2, there was a more significant increase in the absolute count of Treg cells than that of Th17, and consequently restore the balance of Th17/Treg.

SAT0214 AN ANALYSIS OF INCREASING SPACING TIME FOR THE INTRAVENOUS ADMINISTRATION OF TOCILIZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Ito[1], D. Kobayashi[1], C. Takai[1], Y. Nomura[1], A. Abe[1], H. Otani[1], H. Ishikawa[1], A. Murasawa[1], I. Narita[2], K. Nakazono[1]. *[1]Niigata Rheumatic Center, Shibata; [2]Division of Clinical Nephrology and Rheumatology Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan*

Background: Although the biological disease-modifying antirheumatic drugs (bDMARDs) are the most effective treatment for rheumatoid arthritis (RA), the costs are much higher than those of conventional synthetic DMARDs. A number

of studies on discontinuation, dose reduction and/or spacing of bDMARDs have been performed, but there have been few reports on increased spacing time between tocilizumab (TCZ) administrations so far.
Objectives: To analyze the efficacy of spacing of the intravenous (IV) administration of TCZ in patients with RA.
Methods: 63 patients (11 M, 52 F) who were administered IV TCZ for more than 1 year were enrolled. Eleven patients had shifted to subcutaneous injection and the data at the last IV infusion were analyzed.
Results: Mean age was 57.4 years old (30–78), mean body weight was 55.5kg (37–85.5), mean duration of illness was 10.7yrs (0–32), The number of the bDMARDs previously administered were 0.9 (0–3), and duration of TCZ treatment was 46.9 months (13–83). The intervals between administrations were 4 weeks: 28.6%, 5 weeks: 38.1%, 6 weeks: 17.5%, 7 weeks: 6.0%, 8 weeks: 7.9%, and 10 weeks: 1.6%. Tender joint count, swollen joint count, erythrocyte sedimentation rate (ESR), C-reactive protein, matrix metalloproteinase-3 (MMP-3), patient's visual analogue scale (VAS), doctor's VAS, disease activity score (DAS) 28-ESR, simplified disease activity index (SDAI), clinical DAI (CDAI) were significantly improved. All of patients remission rates were 90.5% for DAS28-ESR, 44.4% for CDAI, and 42.9% for SDAI. Patients with prednisolone (PSL) decreased from 50 to 38 (p=0.031), at doses of 5.3 (2–10) to 2.7 (0.5–5) mg/day (p<0.0001). Patients with methotrexate (MTX) decreased from 46 to 32 patients (p=0.017), at doses of 8.1 (2–18) to 6.6 (2–14) mg/weeks (p<0.0001). There were no changes in the usage of other csDMARDs. The remission rates of the patients with increased spacing (n=45) were 75.6% for DAS28-ESR, 28.9% for CDAI, and 35.6% for SDAI. In 45 patients with increased spacing, both PSL and MTX were significantly reduced even after spacing (2.9: 0.5–5.5 to 2.6: 1–7.0) mg/day, and (6.45: 2–10 to 5.2: 2 -12) mg/ weeks, respectively (p=0.0013, p=0.0085). At the introduction of TCZ, there was no difference in the serum levels of MMP-3 in patients with increased spacing and without spacing 274.8 (24–1310) ng/ml vs 283.3 (32–626) ng/ml p=0.692). Serum revels of MMP-3 at the first time of increased spacing were significantly lower in the patients with increased spacing than those at the final point of patients without spacing 72.0 (22.2–236.0) ng/ml vs 165.8 (35.8 -619.0) ng/ml, p=0.000752. The number of patients with normal levels of MMP-3 among the patients with increased spacing were 25/45 (55.6%) with significantly higher levels for those patients who had no spacing 3 /18 (16.7%, p=0.00567).
Conclusions: TCZ treatment was associated with significantly reduced disease activity and reduced use of PSL and MTX. Increased spacing between administrations was used in 71.4% of the patients. TCZ was able to reduce PSL and MTX even after spacing. MMP-3 might be a useful marker to decide the spacing period. TCZ is the most inexpensive bDMARD in Japan, but with increased spacing, it is possible to reduce the cost even further with acceptable control of RA symptoms.

SAT0215 CHARACTERISTICS OF PATIENTS WITH ANKYLOSING SPONDYLITIS, RHEUMATOID AND PSORIATIC ARTHRITIS IN TREATMENT WITH BIOLOGICS IN VERONA'S COHORT: RESULTS FROM VENETO'S REGION BIOLOGICS REGISTER

S. Troplini, O. Viapiana, E. Fracassi, A. Carletto, L. Idolazzi, G. Orsolini, A. Giollo, M. Rossini. *Rheumatology Unit, University of Verona, Verona, Italy*

Background: Since 2013, in Veneto's Region, data registration is mandatory for all patients affected by Rheumatoid arthritis (RA), Psoriatic Arthritis (PA), Ankylosing Spondylitis (AS) in treatment with biologic agents. The biologic DMARDs currently marketed in Italy are: anti-TNF (originator and biosimilar infliximab, etanercept, adalimumab, certolizumab and golimumab), anti-IL6 (tocilizumab), anti-CD20 (rituximab), CTLA-4 like (abatacept) and anti IL-12/23 (ustekinumab).
Objectives: The aim of this study was first to describe the characteristics of patients with RA, PA, AS under biologics and then, to extract and analyze real-life data regarding rheumatic treatments in Verona's cohort.
Methods: The study has been carried out on behalf of Regione del Veneto, Giunta regionale- Ricerca Sanitaria Finalizzata-Venezia-Italy. Data used for analysis were retrieved from Veneto's Region Biologics Register (VRBR). VRBR provides that core variables such as onset and type of disease, anthropometric characteristics (age, sex, body weight, height) are registered at the beginning. Furthermore, prior and concomitant rheumatic treatment (conventional and biologic DMARDs, corticosteroids, NSAIDs), disease activity indicators (DAS 28-PCR, ASDAS-PCR, pain-NRS), prognostic factors (positivity for rheumatoid factor and/ or anti-citrulline antibodies in AR, presence of radiological erosions) were assembled at baseline, every 6 months and at the time of biologic's switch or swap.
Results: A total of 983 patients under biologics were examined; 543 (55,2%) with AR, 272 (27,7%) with AP and 168 (17,1%). Between these, 262 (27,2%) patients were naïve to biologics, 128 with AR, 84 with AP, 50 with SA. Mean duration of disease was of 15,3, 10,7 and 12,6 years respectively for RA, PA and AS. Radiological erosions were present in 73% of RA-patients and the percentage was higher in those with positivity for rheumatoid factor and/ or anti-citrulline antibodies (84,4% versus 56,2%). More than half of the patients in this cohort were treated at least with one biologic agent; anti-TNFs were the main biologic used (RA:54,8%, PA:92,7%, AS: 100%) followed by Abatacept (25,4%), tocilizumab (12,3%) and rituximab (5,9%) in patients with RA. Methotrexate (MTX) was the prevalent associated c-DMARDs (41,8% in RA and 34,2% in PA) with mean dose of 11,9 mg/week in RA and 12,1 mg/week in PA. The optimal dose of methotrexate was not achieved prevalently because of drug intolerance.
Conclusions: Profile of both conventional and biological DMARDs looks very different according to the type of rheumatic disease. The first data show an underuse of MTX in patients with RA and PA under biologics with a low mean dosage due to intolerance. Next step is to evaluate long-term outcomes in clinical practice.

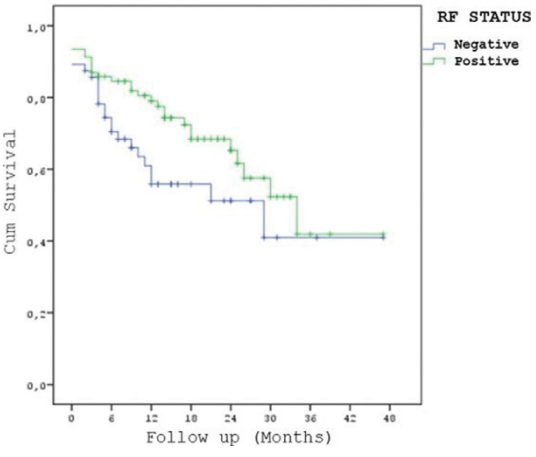
SAT0216 ABATACEPT EXPERIENCE IN BIOLOGIC NAIVE RHEUMATOID ARTHRITIS PATIENTS: HUR-BIO REAL LIFE RESULTS



A. Sari, B. Armagan, L. Kilic, A. Erden, O. Karadag, A. Akdogan, S. Apras Bilgen, S. Kiraz, U. Kalyoncu, I. Ertenli. *Rheumatology, Hacettepe University School of Medicine, Ankara, Turkey*

Background: Abatacept (ABA), a T lymphocyte blocker, is one of the treatment options in rheumatoid arthritis (RA) patients who are resistant to initial therapy with non-biologic disease modifying drugs (DMARDs).
Objectives: Aim of this study was to evaluate the effectiveness, safety and drug survival rates of ABA in RA patients registered in HUR-BIO (Hacettepe University Rheumatology Biologic Registry) database.
Methods: HUR-BIO is a prospective,single center database of biological treatments including 1229 RA patients by August 2016. In total, 247 of patients had received ABA and in 175 (71%) of them ABA was the first biological agent. In this analysis, 158 patients were evaluated due to lack of first follow-up visit in 17 patients. Demographics, clinical and serological data were evaluated. DAS-28 and HAQ-DI scores before ABA and last follow-up visit were also assesed. Kaplan-Meier analysis was used to estimate drug survival rates.
Results: Among 175 (82% female) patients, mean age was 53.6±11.3 and mean disease duration was 10.3±7.3. Seropositivity for RF and/or ACPA was present in 74.8% of patients. Table 1 represents DAS-28 scores of patients before ABA and last follow-up visit. Mean duration from ABA initation to first and last follow-up visit was 4.5±3.1 and 15.1±10.2 months, respectively. Female gender was found as a risk factor in terms of remaining of DAS-28 above 3.2 at first control [OR 5,63 (%95 CI 1,72–18,41)]. In first follow-up visit, improvement in DAS-28 score of ≥1,2 from baseline was more frequent in ACPA positive patients (48/62 (77.4%) vs 17/33 (51.5%), p=0.01). HAQ score of >1.0 was observed in 57.8%, 36.3%and 26.1% of patients at baseline, first follow-up visit and last follow-up visit, respectively. ABA had been cessated in 60 (38.0%) patients during follow-up. The reason for ABA withdrawal was primary unresponsiveness in 22 (36.6%) patients and infection in 2 (3.3%) patients. Drug survival for ABA was shown in Figure 1. Log-rank between RF positive and negative patients was found as 0.067.

Table 1. DAS-28 scores at first and last follow-up visits

	First control visit (n=136)	Last control visit (n=136)
Follow up duration, mean (SD)	4.5 (3.1)	12,3 (10.9)
DAS-28 >5.1,n (%)	11 (8.2)	16 (11.8)
DAS-28=3.2–5.1,n (%)	56 (41.8)	46 (33.8)
DAS-28=2.6–3.2,n (%)	23 (17.2)	23 (16.9)
DAS-28 <2.6,n (%)	44 (32.8)	51 (37.5)
Remission or low disease activity among patients with at least one follow-up visit, n (%)	67 (50.0)	74 (54.4)
Remission or low disease activity among all patients, n (%) (The worst scenario)	67/158 (42.4)	74/158 (46.8)

Figure 1. ABA survival rates in RF positive and negative patients

Conclusions: In our database, 70% of RA patients received ABA were biologic naive. Remission or low-disease activity was achieved approximately 50% of patients in first follow-up visit with an average of 4.5 months after begining of the treatment. Functional improvement was observed in two thirds of patients.

Death or life threatening side effects were not seen during follow-up. ABA is an acceptable treatment option in DMARD resistant biologic naive RA patients.

SAT0217 EARLY PATIENT-REPORTED OUTCOMES AND CLINICAL OUTCOMES WITH ABT-494 IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS WHO ARE INADEQUATE RESPONDERS TO METHOTREXATE OR TUMOR NECROSIS FACTOR INHIBITORS: POST-HOC ANALYSIS OF PHASE 2 RANDOMIZED CONTROLLED TRIALS

V. Strand[1], N. Tundia[2], I.H. Song[2], S. Meerwein[2], J. Lin[2], N. Chen[2], A. Friedman[2]. *[1]Stanford University, Palo Alto; [2]AbbVie Inc., North Chicago, United States*

Background: Janus kinase (JAK) inhibitors are being evaluated for treatment of active rheumatoid arthritis (RA). Understanding their onset of action on patient reported outcomes (PROs) and clinical endpoints in RA patients (pts) is limited.
Objectives: To assess onset of benefit with ABT-494, a selective JAK1 inhibitor vs placebo (PBO) in RA pts with active disease ≥3 months in 2 randomized controlled trials (RCTs) evaluating safety and efficacy of ABT-494. M13–537 (NCT02066389) included pts who were inadequate responders to methotrexate (MTX-IR) and M13–550 (NCT01960855) to tumor necrosis factor inhibitors (TNF-IR).
Methods: Data were analyzed separately for each RCT in pts who received 6mg or 12mg bid ABT-494 or PBO. Analyses included cumulative assessment of PROs such as patient global assessment of disease activity (PtGA), pain Visual Analogue Scale (VAS) and Health Assessment Questionnaire Disability Index (HAQ-DI) in terms of Routine Assessment of Patient Index Data 3 (RAPID3) scores, and clinical outcomes such as DAS28 (CRP) and CDAI. To assess onset and maintenance of effect, the number of pts whose improvements met or exceeded minimal important differences (MID) RAPID3: reduction ≥3.6; DAS28: reduction ≥1.2; CDAI: reduction ≥11.0 and were calculated at weeks 2 and 12. Additionally, Kaplan-Meier (KM) analysis estimated mean time to achievement of RAPID3, DAS28 and CDAI MID. Non-responder imputation accounted for missing data.
Results: In M13–537 (N=150 pts) and M13–550 (N=166 pts) RCTs, significantly more pts in ABT-494 12mg groups reported improvements ≥MID in RAPID3 vs PBO at Wk 2: 68% vs 30% and 73% vs 38%, respectively (Table). In M13–537, significantly more pts receiving ABT-494 6mg BID vs PBO (54% vs 30%) had improvements ≥MID in RAPID3. These responses were sustained throughout both trials in pts receiving 12mg ABT-494 (M13–537: 80%; M13–550: 71%). Significantly more pts achieved and maintained changes ≥MID in DAS28 in both RCTs and in CDAI in M13–550. Based on KM analyses, in M13–537, estimated mean time (±SE) to achievement of RAPID3 MID was shorter for both ABT-494 doses vs PBO (12mg: 3.9±0.5 weeks; 6mg: 3.9±0.4 weeks; PBO 6.0±0.6 weeks). Similarly, estimated mean time to these responses was shorter with both ABT-494 doses vs PBO (12mg: 3.6±0.4 weeks; 6mg: 4.9±0.6 weeks; PBO: 6.6±0.6 weeks) in M13–550, although it was underestimated due to censoring.

Table. Number of patients reporting clinically meaningful improvements over study period.

	M13-537			M13-550		
n (%)	ABT-494 6mg N=50	ABT-494 12mg N=50	PBO N=50	ABT-494 6mg N=55	ABT-494 12mg N=55	PBO N=56
RAPID3: ≥MID						
Week 2	27 (54)[a]	34 (68)[b]	15 (30)	25 (45)	40 (73)[b]	21 (38)
Week 12	32 (64)	40 (80)[b]	24 (48)	35 (64)[a]	39 (71)[b]	23 (41)
DAS28: ≥MID						
Week 2	26 (52)[a]	27 (54)[b]	9 (18)	27 (49)[a]	36 (65)[b]	14 (25)
Week 12	37 (74)[a]	44 (88)[b]	22 (44)	32 (58)	38 (69)[b]	23 (41)

SAT0218 EFFECT OF TOCILIZUMAB IN DMARD-NAÏVE EARLY RHEUMATOID ARTHRITIS PATIENTS ON HEALTH-RELATED QUALITY OF LIFE: RESULTS OF THE U-ACT-EARLY TRIAL

X.M. Teitsma[1], J.W. Jacobs[2], P.M. Welsing[2], A. Pethö-Schramm[3], M.E. Borm[4], J.M. van Laar[1], F.P. Lafeber[1], J.W. Bijlsma[1]. *[1]Rheumatology and Clinical Immunology; [2]UMC Utrecht, Utrecht, Netherlands; [3]F. Hoffmann-La Roche, Basel, Switzerland; [4]Roche Nederland B.V., Woerden, Netherlands*

Background: Tocilizumab (TCZ), a humanized interleukin-6 receptor inhibitor, has been shown effective in suppressing symptoms of rheumatoid arthritis (RA). In U-Act-Early, a significantly greater proportion of patients with early RA who initiated TCZ (84%) or TCZ plus MTX therapy (86%) achieved sustained remission (Disease Activity Score assessing 28 joints (DAS28) <2.6 with ≤4 swollen joints for ≥24 weeks), when compared to those initiating MTX (44%).[1]
Objectives: To determine the effect of treat-to-target TCZ therapy, with or without MTX, on health-related quality of life (HRQoL) in disease modifying anti-rheumatic drugs (DMARD)-naïve patients with early RA.
Methods: Patients (n=317) were randomized to initiate TZC, TCZ+MTX or MTX therapy and treated according to a step-up strategy. TCZ was given (8 mg/kg) every 4 weeks and MTX (oral) was started at 10 mg/week and increased with steps of 5 mg steps 4 weekly up to 30 mg/week (or maximum tolerable dose) until remission. If after 20 weeks remission was not achieved, hydroxychloroquine was added and discontinued 12 weeks thereafter if the target still was not achieved. Patients who originally initiated monotherapy then switched to TCZ+MTX therapy and those already on this combination therapy switched to a tumour necrosis factor inhibitor. To evaluate the effect of TCZ on HRQoL, we used the 36-item Short-Form (SF-36), which can be summarized into a physical (PCS) and mental (MCS) component score. HRQoL was measured at baseline and after 12, 24, 52, and 104 weeks. A linear mixed effect model with a random intercept was used to evaluate differences between treatment strategies over time with visit (time), strategy, baseline SF-36 score, baseline DAS28 level (i.e., DAS28 <5.1 or ≥5.1) and centre as fixed effects. The proportions of patients exceeding the minimum clinically important differences (MCID, ≥2.5-point increase from baseline) were tested for significance using the two-sided Pearson's chi-squared test.
Results: We found significantly greater improvements over time in the SF-36 PCS in patients initiating treatment with TCZ (TCZ *vs* MTX; p=0.041, TCZ+MTX *vs* MTX; p=0.011, Fig. 1). For the SF-36 MCS, no significant differences over time were noted between the treatment arms (p≥0.11). A significantly higher proportion of patients initiating treatment with TCZ (76%; p=0.016, 89%; p=0.030) or TCZ+MTX (73%; p=0.049, 89%; p=0.027) achieved MCID in the SF-36 PCS at week 12 and week 52, when compared to those initiating treatment with MTX (59% and 73%, respectively). Although the proportions of patients achieving MCID in the SF-36 MCS were numerically higher in the TCZ arms, no significant differences were found (p≥0.06).

Fig. 1: Mean (SE) change from baseline in SF-36 PCS (**A**) and SF-36 MCS (**B**).

Conclusions: Initiation of TCZ, with or without MTX, at start of therapy resulted in statistically significant and clinically relevant improvements in the HRQoL when compared to initiation of MTX alone and may be considered as a valuable treatment strategy in DMARD-naïve patients with early RA.

SAT0219 EFFICACY AND SAFETY OF ATACICEPT IN PATIENTS WITH HIGH DISEASE ACTIVITY IN A 24-WEEK, RANDOMIZED, PLACEBO-CONTROLLED, PHASE IIB STUDY (ADDRESS II)

J.T. Merrill[1], D.J. Wallace[2], A. Kao[3], C. Vazquez Mateo[3], P.A. Fraser[3], P. Chang[3], D. Isenberg[4]. *[1]Oklahoma Medical Research Foundation, Oklahoma City; [2]Cedars-Sinai Medical Center, University of California Los Angeles, Los Angeles; [3]EMD Serono Research & Development Institute, Inc. (a business of Merck KGaA, Darmstadt, Germany), Billerica, United States; [4]University College London, London, United Kingdom*

Background: Atacicept targets B-cell stimulating factors BLyS and APRIL, and has shown evidence of clinical response in SLE.
Objectives: Exploration of atacicept efficacy and safety in a pre-defined subpopulation of SLE patients with high disease activity (HDA, SLEDAI-2K $\geq$10 at Screening) in the phase IIb ADDRESS II study (NCT01972568).
Methods: Autoantibody positive patients on standard of care therapy were randomized 1:1:1 to double-blind weekly SC injections of atacicept 75 or 150 mg or placebo (PBO) for 24 weeks. Analyses of the HDA subpopulation are now reported.
Results: 52% of the ITT population had HDA (n=158: 52 PBO; 55 atacicept 75 mg; 51 atacicept 150 mg). 92% were female, 67% were white, and baseline characteristics were balanced between groups. At week 24 (Table 1; Figure 1), the proportion of SLE Responder Index (SRI)-4 ($p<0.05$) and SRI-6 ($p<0.005$) responses was greater with atacicept 150 mg vs PBO. BICLA response rate was higher with both doses ($p<0.05$). More patients achieved SLEDAI-2K $\leq$2 with atacicept 150 mg vs PBO ($p<0.01$). Time to severe and moderate-severe flare was significantly reduced at both atacicept doses vs PBO ($p<0.05$). Patients in the quartile with the largest decline in serum IgG had the highest SRI-6 response rates (Table 2). Treatment-emergent adverse event (TEAE) rates were similar between groups (PBO 71.2%; 75 mg 78.2%; 150 mg 74.5%). Serious/severe infections were not increased with atacicept 150 mg (PBO 9.6%; 75 mg 10.9%; 150 mg 0%). There were no patient deaths.
Conclusions: In SLE patients with HDA, Atacicept 150 mg demonstrated significant clinical responses and an acceptable safety profile.

SAT0220 EFFECTS OF TYPE I INTERFERON INHIBITION ON BLOOD LEUKOCYTE SUBSETS IN PATIENTS TREATED IN A PHASE IIB CLINICAL STUDY OF ANIFROLUMAB IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

W. White, K.A. Casey, M.A. Smith, L. Wang, D. Sinbaldi, M.A. Sanjuan, G. Illei. *MedImmune LLC, Gaithersburg, United States*

Background: A Phase IIb randomized controlled study (NCT01753193) was conducted with anifrolumab, a fully human, anti-interferon (IFN)–α receptor (IFNAR) specific antibody in adults with moderate to severe SLE. Anifrolumab binds to subunit 1 of the IFNAR and inhibits the activity of all type I IFNs. A complete blood count analysis demonstrated that anifrolumab reversed leukopenia. However, the types of peripheral immune cells affected following treatment have not been reported.
Objectives: To better understand how changes in the immune cell repertoire may be associated with SLE severity, type I IFN test status (high vs. low), and treatment with anifrolumab, we performed flow cytometry to assess peripheral blood cell types: dendritic cells (myeloid and plasmacytoid), B cells (naïve, memory, and plasma cells), neutrophils, and T cells (CD4, CD8, naïve, memory, central memory, and effector).
Methods: Patients were randomized 1:1:1 to anifrolumab 300 mg, or 1,000 mg, or placebo (PBO) every 4 weeks for 48 weeks. Peripheral blood was collected from a subset of patients (91 total) on Days 1 (prior to first dose), 85, 141, 169, 253, 337, and 365. Patients were approximately evenly distributed between treatment arms. Baseline absolute immune cell numbers were compared over treatment course in the context of SLE Disease Activity Index (SLEDAI)–2K scores, type I IFN test, and therapy response. Statistics were calculated using the Student's *t*-test; p-values $\leq$0.05 were considered statistically significant.
Results: At baseline, several blood cell types were lower for patients with SLEDAI $\geq$10, including naïve B cells, and memory T and B cells. In IFN-high patients, neutrophils, memory T cells, and plasmacytoid dendritic cells (pDCs) were significantly decreased. Anifrolumab led to significant increases in absolute numbers of T-cell subsets in the blood of IFN-high patients. In contrast, no significant changes were observed for IFN-low patients. Observed increases were within normal reference ranges. The alterations did not appear to be secondary to tapering of oral corticosteroids, as these cell types were not significantly different in PBO groups, regardless of tapering. Patients with $\geq$6-point SLEDAI reductions following anifrolumab demonstrated significant increases in total CD4 and CD8 T cells, and nonsignificant decreases in memory B cells. Significant increases in pDCs were also evident. Anifrolumab did not cause significant differences in other cell types measured.
Conclusions: Memory T cell numbers, among other cell types, were significantly reduced in patients with SLEDAI $\geq$10 and those classified as IFN high at baseline. This suggests that, for patients with more severe disease, type I IFN may be involved in cell migration into the peripheral tissues from the blood. Consistent with this, we found that neutralization of type I IFN with anifrolumab promoted immigration and/or prevented emigration of potentially pathologic immune cells between the tissues and the blood. These data suggest that some effects observed following anifrolumab treatment might be a result of altering the migration patterns of T and other immune cells, which may partially explain its biological activity.

SAT0221 SIX-MONTH PROTEINURIA MEASUREMENT PREDICTS RENAL RESPONSE AT 18 MONTHS IN LUPUS NEPHRITIS: ANALYSIS OF TWO PHASE III RANDOMIZED CLINICAL TRIALS

M.D. Cascino[1,2], T. Schindler[3], L.M. Gomez Mendez[2], P. Brunetta[1], L. Dragone[1], M. Dall'Era[2], J. Garg[1]. *[1]Genentech, Inc., South San Francisco; [2]University of California – San Francisco, San Francisco, United States; [3]F. Hoffmann-La Roche, Basel, Switzerland*

Background: Early identification of patients with lupus nephritis (LN) likely to achieve complete renal response (CRR) may expedite the evaluation of new therapies and guide clinical care. Prior analyses have shown that early improvement in proteinuria is associated with subsequent renal response.[1,2] Several ongoing LN trials including NOBILITY, an assessment of the efficacy of the anti-CD20 monoclonal antibody obinutuzumab in combination with standard of care immunosuppression, will evaluate proteinuric response at 6 months as a key secondary endpoint.[3] Whether short-term response accurately predicts future CRR, however, is uncertain.
Objectives: To assess the predictive value of early measurements of the level of proteinuria and to identify proteinuria cutoffs that best identify patients who will achieve CRR at 18 months.
Methods: LUNAR and BELONG were multicenter, double-blinded studies that in total randomized 522 patients with ISN/RPS class III or class IV LN to blinded investigational infusions or placebo in combination with standard of care immunosuppression.[4,5] CRR was assessed at 18 months and defined for this analysis as achievement of urine protein to creatinine ratio (UPCR) <0.5 with normal serum creatinine that was not increased from baseline by $>25\%$. Bootstrapping was used to generate nonparametric receiver operating characteristic (ROC) curves and estimate area under the curve (AUC). The Youden index was used to identify UPCR cutoff values that maximize sensitivity and specificity. Positive predictive value (PPV) and negative predictive value (NPV) were calculated.
Results: ROC curves were constructed for proteinuria measurements at baseline and 3, 6, 9, and 12 months after randomization (Figure 1). AUC increased from baseline to month 3 (0.64 vs. 0.80, $P<0.001$) and from month 3 to month 6 (0.80 vs. 0.84, $P<0.01$) but did not increase beyond month 6 ($P>0.05$ for each pairwise comparison). Achievement of 6-month UPCR <1 was 83.8% sensitive and 71.0% specific for CRR at 18 months and had PPV and NPV of 64.9% and 87.2%, respectively. Evaluation of lower 6-month UPCR cutoff values yielded improvements in specificity and PPV but marked decreases in sensitivity and NPV. In multivariate analysis, the addition of 6-month serum creatinine and percent change in UPCR from baseline did not result in meaningful increases in AUC compared with 6-month proteinuria measurement alone.

Figure: Receiver operating characteristic curves for CRR at 18 months

Conclusions: Level of proteinuria at 6 months alone was predictive of CRR at 18 months in aggregated data from two phase III LN clinical trials. After 6 months of treatment, UPCR <1 had high sensitivity and NPV for CRR at 18 months. This cutoff might be used to prospectively identify patients who are unlikely to achieve complete response within 18 months on the initial therapy for LN. The impact of these findings on guiding treatment decisions outside the setting of randomized clinical trials requires further investigation.

Franchimont[4]. *[1]Northwell Health, Great Neck; [2]Hospital of the University of Pennsylvania and the Veteran's Administration Medical Center, Philadelphia; [3]Brigham and Women's Hospital, Harvard Medical School, Boston; [4]Biogen, Cambridge, United States; [5]Biogen, Zug, Switzerland*

Background: Type I interferons (IFN-I) are central to the pathogenesis of systemic lupus erythematosus (SLE). BDCA2 is a plasmacytoid dendritic cell (pDC)-specific receptor that, upon engagement, inhibits the production of IFN-I and other inflammatory mediators. Targeting BDCA2, therefore, represents an attractive therapeutic strategy for inhibiting pDC-driven inflammation that is such a key feature of SLE pathogenesis. BIIB059, an investigational anti-BDCA2 humanized monoclonal antibody, has been shown to engage BDCA2, and this interaction leads to BDCA2 internalization and the consequent in vitro inhibition of TLR-induced IFN-I production by pDCs (Pellerin 2015).
Objectives: This first-in-patient study aimed to assess safety, tolerability, pharmacokinetic (PK) and pharmacodynamic (PD) effects and clinical activity of BIIB059 in adult SLE patients with active cutaneous lupus (CLE) following administration of a single BIIB059 dose.
Methods: A Phase 1b randomized, double-blinded, placebo controlled, multicenter clinical trial was conducted in 12 adult SLE subjects (meeting 1997 ACR criteria) with active cutaneous manifestations (including acute, sub-acute and/or chronic cutaneous forms of cutaneous lupus erythematosus (CLE)). Subjects received a single IV administration of either BIIB059 20mg/kg (n=8) or placebo (n=4). A panel of IFN-responsive genes (IRG) was assessed from whole blood by qPCR at baseline and several post-dose time points. Skin biopsies from active lesions were obtained and evaluated at baseline and week 4 for IFN-regulated proteins, including MxA and IFITM3 using quantitative immunohistochemistry. CLE disease activity was assessed using the Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI), and safety data, including adverse events (AEs) and laboratory tests, were also collected.
Results: Most SLE subjects had high IRG signatures in the blood. Skin biopsies demonstrated features of inflammation consistent with active CLE, including elevated expression of MxA and other IFN-regulated proteins. A single dose of BIIB059 decreased the expression of IRG in blood and MxA and IFITM3 proteins in the skin in most patients. CD45+ cells were reduced in skin biopsies of BIIB059-treated patients. The reduction in inflammatory cells as well as MxA and IFITM3 expression at week 4 correlated with improvement in CLASI activity score at multiple timepoints post-dose. BIIB059 was generally well tolerated with no discontinuations due to AEs. The incidence of AEs was similar between BIIB059- and placebo-treated SLE subjects, and most AEs were mild or moderate in severity.
Conclusions: A single dose of BIIB059 resulted in inhibition of the IRG in peripheral blood and MxA and IFITM3 expression in lesional skin of SLE subjects, consistent with BIIB059's proposed mechanism of action. The clinical and biomarker data together confirm the role of human pDCs in the pathogenesis of SLE, and support further development of BIB059 in SLE.

Outcome at 52 weeks				*Odds ratio SC/IV (95% credibility interval)*				
HDA criteria		1				2		
SRI response		0.90 (0.53, 1.52)				0.88 (0.58, 1.33)		
4-point reduction in SELENA-SLEDAI		0.99 (0.58, 1.68)				0.95 (0.63, 1.43)		
Rate of severe flares		0.69 (0.37, 1.28)				0.89 (0.53, 1.50)		

patients with active, autoantibody-positive systemic lupus erythematosus (SLE) who are receiving standard SLE therapy has been demonstrated. To date, no direct comparison of intravenous (IV) BEL vs subcutaneous (SC) BEL has been performed, hence the importance of an indirect treatment comparison (ITC).

Objectives: To indirectly compare the clinical effectiveness of BEL IV and SC formulations in patients with SLE high disease activity (HDA) via an ITC.

Methods: Three BEL IV Phase lll randomised controlled trials (RCTs; HDA/BLISS-52, 327/577; HDA/BLISS-76, 265/548; HDA/North East Asia study [BEL113750], 427/677) and one BEL SC RCT (HDA/BEL112341; 356/836) were compared via a Bayesian ITC (BEL207255). We evaluated the relative efficacy of the formulations in patients meeting three measures of HDA at baseline (1. BLISS-52 and BLISS-76, C3 <0.9 g/L or C4 <0.16 g/L; BEL112341 and BEL113750, C3 <0.9 g/L or C4 <0.10 g/L; and 2. anti-dsDNA positive [≥30 IU/mL] or 3. Safety of Estrogen in Lupus Erythematosus National Assessment-SLE Disease Activity Index [SELENA-SLEDAI] scores ≥10). Analyses were conducted in patients meeting Criteria 1: low C3/C4 and high anti-dsDNA; and Criteria 2: low C3/C4 and high anti-dsDNA or SELENA-SLEDAI ≥10 or low C3/C4. The primary endpoint was SLE Responder Index (SRI) response (≥4-point reduction in SELENA-SLEDAI, no worsening in Physician's Global Assessment, no new 1A/2B British Isles Lupus Assessment Group domain scores) at Week 52. Secondary endpoints included ≥4-point reduction in SELENA-SLEDAI and SLE Flare Index rate. Safety endpoints were not assessed.

Results: Baseline characteristics were relatively similar between RCTs and a fixed effects model binomial distribution with logit link was used for all efficacy endpoints (Table). In this indirect comparison, no differences were identified between BEL IV and BEL SC for the efficacy endpoints.

Conclusions: In this indirect comparison, BEL IV and BEL SC were similar for SRI response, ≥4-point reduction in SELENA-SLEDAI, or rate of severe flare at Week 52 in patients with SLE. Outcomes were consistent irrespective of the criteria applied.

SAT0224 THE ROLE OF INTENSIVE IMMUNOSUPPRESSIVE THERAPY IN THE MANAGEMENT OF SLE-ASSOCIATED PULMONARY ARTERIAL HYPERTENSION: A SINGLE-CENTER COHORT STUDY

Q. Wang [1], J. Zhao [1], J. Qian [2], Z. Tian [3], M. Li [1], X. Zeng [1]. *[1]Rheumatology; [2]Internal Medicine; [3]Cardiology, Peking Union Medical College Hospital, Beijing, China*

Background: Autoimmune and inflammatory mechanisms could play a significant role in the pathogenesis of pulmonary arterial hypertension (PAH), especially in patients with systemic lupus erythematosus (SLE). The effect of immunosuppressive therapy in the treatment of SLE-associated PAH (SLE-PAH) has not been fully investigated in a large cohort previously.

Objectives: We aimed to review the clinical outcomes in patients with SLE-PAH cohort treated with intensive immunosuppressive therapy with or without PAH-targeted therapy.

Methods: In this single-center cohort study, 126 patients with SLE-PAH were consecutively enrolled between May 2006 through December 2015. All patients were performed right heart catheriazation to confirm the diagnosis of PAH, and all received intensive immunosuppressive therapy including combination of high-dose glucocorticosteroids and immunosuppressants, such as cyclophosphamide, mycophenolate and calcineurin inhibitors. Baseline demographics, clinical features, laboratory findings, hemodynamic measurements and treatment were analyzed. Kaplan-Meier curves and Cox proportional hazards regression analysis were used to evaluate the role of intensive immunosuppressive therapy.

Results: Of the 126 SLE-PAH patients, eighty-two (65.1%) patients received PAH-targeted therapy at baseline. Demographic and clinical characteristics were shown in Table 1. Survival analysis indicated that responders had a better survival than nonresponders in both with and without PAH-targeted therapy groupPatients with a shorter SLE disease duration (p=0.009) and better baseline pulmonary hemodynamics (mean pulmonary arterial pressure, pulmonary vascular resistance and Cardiac index, p<0.001) were more likely to benefit from immunosuppressive therapy (Table 1).

SAT0225 CEREBLON MODULATOR CC-220 DECREASES NAÏVE AND MEMORY B CELLS AND PLASMACYTOID DENDRITIC CELLS IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) PATIENTS: EXPOSURE-RESPONSE RESULTS FROM A PHASE 2A PROOF OF CONCEPT STUDY

A. Gaudy [1], Y. Ye [1], S. Korish [1], D. Hough [1], M. Weiswasser [1], S. Choi [1], R. Furie [2], V. Werth [3], P. Schafer [1]. *[1]Celgene Corporation, Summit, NJ; [2]Northwell Health, Great Neck, NY; [3]University of Pennsylvania and the VA Medical Center, Philadelphia, PA, United States*

Background: CC-220 is a cereblon E3 ligase modulatory compound currently in development for the treatment of Systemic Lupus Erythematosus as well as other autoimmune conditions and multiple myeloma. As a high affinity ligand for cereblon, CC-220 administration results in significant reductions in ikaros (IKZF1) and aiolos (IKZF3), transcription factors which are genetically linked to SLE risk, and are overexpressed in the peripheral blood of SLE patients compared to healthy controls.

Objectives: To describe the pharmacokinetics (PK), pharmacodynamics (PD), and the PK-PD relationship of CC-220 in subjects with SLE.

Methods: CC-220-SLE-001 is a randomized, double-blinded, placebo-controlled,

phase 2a dose escalation study to investigate the safety, PK, PD, and efficacy of CC-220 in patients with SLE. Forty-two (42) adult SLE subjects fulfilling SLE ACR criteria, having a history of SLE for ≥6 months and a baseline Safety of Estrogens in Lupus Erythematosus National Assessment–Systemic Lupus Erythematosus Disease Activity Index (SELENA-SLEDAI) score ≥4 were randomized to placebo or 1 of 4 escalating doses of CC-220 (0.3 mg QOD, 0.3 mg QD, 0.6/0.3 mg alternating QD, or 0.6 mg QD).

Results: CC-220 concentration-time profiles demonstrated dose proportionality between cohorts, with moderate accumulation in the non-alternating dose cohort. CC-220 significantly reduced total CD20+ B cells by as much as 96%, immature B cells by as much as 91.2%, switched memory B cells by as much as 81.4%, BAFFR+ B cells by as much as 67.5%, and plasmacytoid dendritic cells (pDCs) by as much as 86.5% (Day 85 median percent change from baseline). Whereas reductions in B cells were observed, CD4+ as well as CD8+ T cells increased, and the rise in T cells paralleled the observed increase in plasma cells in those subjects who received the highest dose (0.6 mg). An exposure-response analysis demonstrated decreasing B cells, pDCs and neutrophils with increased exposure to CC-220.

Conclusions: It was determined that 0.3 mg QD to 0.6/0.3 mg alternating QD reduced concentrations of B cells and pDC's while avoiding neutropenia. These findings, in combination with the PK, safety, and exploratory efficacy data, support continued development of CC-220 in SLE.

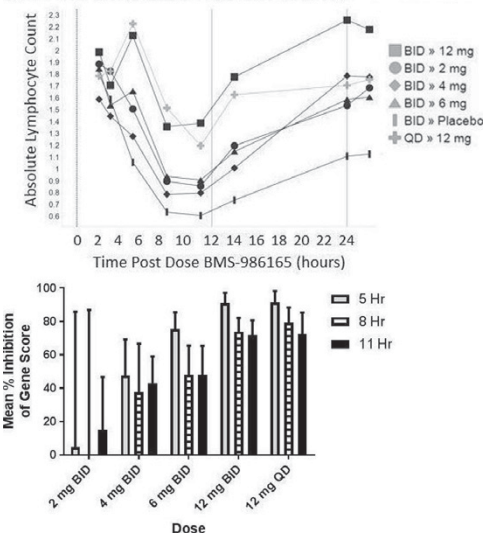
SAT0226 A FIRST-IN-HUMAN, STUDY OF BMS-986165, A SELECTIVE, POTENT, ALLOSTERIC SMALL MOLECULE INHIBITOR OF TYROSINE KINASE 2

I. Catlett[1], U. Aras[2], Y. Liu[3], D. Bei[2], I. Girgis[2], B. Murthy[2], M. Honczarenko[1], S. Rose[1]. *[1]Innovative Clinical Development; [2]Clinical Pharmacology; [3]Global Biometric Sciences, Bristol-Myers Squibb, Princeton, United States*



Background: Tyrosine kinase 2 (Tyk2) is a member of the JAK family that phosphorylates STAT proteins downstream of the IL-12, IL-23 and the Type I interferon receptor. Tyk2 genetic variants have been linked to multiple autoimmune diseases,[1] with a deactivating coding variant conferring significant protection against multiple immune-mediated disorders including systemic lupus erythematosus (SLE).[2] Selective pharmacologic inhibition of Tyk2 has proven daunting, given the high degree of similarity among JAK catalytic domains. Using a novel approach, we have developed BMS-986165, a highly selective and potent small molecule inhibitor, which blocks receptor-mediated Tyk2 activation by stabilizing the regulatory pseudokinase domain of the protein. Lupus-like disease is strongly inhibited in NZB/W mice treated with BMS-986165. Together, these data establish Tyk2 as a highly promising therapeutic target for SLE.

Objectives: We report the first evidence of safety, pharmacokinetics (PK), target engagement (TE), and pharmacodynamic activity (PD) of BMS-986165, a novel inhibitor of Tyk2.

Methods: Safety, PK, TE, and PD were assessed in a randomized, double-blind, single and multiple ascending dose study of 108 (83 active: 25 placebo) healthy participants (NCT02534636). Target engagement was assessed by an ex vivo assay, IL-12 and IL-18 induced IFNγ production. Roferon-A was administered to assess in vivo pharmacodynamic effects of BMS-986165 on physiological manifestations of IFN exposure and on IFN-regulated gene (IRG) expression.

Results: BMS-986165 was safe and overall well-tolerated. There were no serious adverse events and the frequency of non-serious adverse events were similar in the active (75%) and placebo (76%) groups. The most frequently reported adverse events by preferred term were headache (23% active versus 28% placebo), nausea (12% active versus 8% placebo), rash (12% active versus 8% placebo), and upper respiratory tract infection (11% active versus 12% placebo). After oral administration, BMS-986165 was rapidly absorbed and exhibited an apparent elimination half-life of 8–15 hours. Modest accumulation (1.4x-1.9x) was observed after multiple dosing. BMS-986165 inhibited IL-12/IL-18-induced IFNγ production in *ex vivo* assays in a dose and concentration dependent manner. Following an *in vivo* challenge with a clinical dose of Interferon-alfa-2A, BMS-986165 demonstrated dose-dependent inhibition of lymphocyte count decreases and expression of 53 IRGs in blood (Figure 1).

Figure 1: *In vivo* pharmacodynamic challenge

Conclusions: BMS-986165 is a safe and potent Tyk2 inhibitor with clear evidence of *ex vivo* and *in vivo* biologic activity in healthy participants, and the potential for once daily dosing. Overall, Inhibition of IL-12/23 and type I IFN pathways support further testing of BMS-986165 in diseases such as lupus and psoriasis. A Phase 2 study in patients with moderate-to-severe psoriasis is ongoing (NCT02931838).

SAT0227 HEALTH CARE UTILIZATION AND COSTS OF SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) IN THE UNITED STATES: SYSTEMATIC REVIEW

E. Hammond[1], I.B. Murimi[2], D.H. Lin[2], H. Kan[2], J. Tierce[2], X. Wang[1], H. Nab[3], B. Desta[1], G.C. Alexander[2]. *[1]AstraZeneca, Gaithersburg, MD; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States; [3]AstraZeneca, Cambridge, United Kingdom*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease that affects as many as 518 persons per 100,000 people in the United States and Europe.

However, much of our current knowledge on SLE health care utilization and costs is based on analyses conducted prior to 2011, after which important treatment innovations (e.g., belimumab and, to some extent, rituximab) and health care marketplace changes occurred in the United States.

Objectives: The objectives of this systematic review were to summarize the patterns of health care utilization for patients with SLE and to characterize the direct and indirect costs of SLE by disease severity in the United States.

Methods: We conducted a systematic literature review of adult patients with SLE in the United States by searching PubMed and Embase for relevant articles written in English and published during January 2000–April 2016. We examined health care utilization measures including emergency department (ED) visits, hospitalizations, outpatient visits, medication use, and adherence. We restricted the analysis to observational studies, excluding case reports and commentaries. All monetary costs were converted to US 2016 $.

Results: In total, 4,700 articles were screened, 388 articles were retained for full-text review, and 38 articles were selected for inclusion in this report. Across these 38 studies, mean patient ED utilization rates were 0.9–2.1 visits/year. Mean hospitalization rates were 0.4–2.6 inpatient stays/year, with 5–6 days/stay on average. Patients averaged 10–19 total physician visits/year. More than 90% of patients with SLE had ≥1 visit to a primary care provider annually. In addition, 51–71% visited rheumatologists, and 6–7% visited nephrologists. Health care resource use with respect to ED visits, hospitalization rates, inpatient length of stay, and ambulatory care was greater for patients with lupus nephritis than for patients with SLE without nephritis. Mean annual direct costs from various studies ranged between $15,171–88,445 for patients with SLE regardless of the presence of nephritis. Nearly all studies indicated that mean direct medical costs were greater for patients with moderate or severe disease ($22,300–83,000) than those with mild disease ($8,900–15,000). Mean annual pharmacy costs ranged between $1,572–13,138, accounting for 19–23% of total direct costs, and medical costs ranged between $21,290–82,854. On average, 12–49% of patients were unemployed, and the mean number of sick days/month was 2.3 days. The range of estimates of mean total direct costs for patients with SLE overall were often

larger when derived from commercial claims ($21,600–55,400) than from public payers (Medicare and Medicaid, $16,000–23,000).
Conclusions: Our findings suggest that patients with SLE, especially those with moderate or severe disease, use considerably more health care services and incur greater direct and indirect costs relative to those with mild disease. Thus, SLE remains a significant driver of health care resource utilization and costs.

SAT0228 APOPTOTIC EFFECT OF BLYS ON ENDOTHELIAL CELLS AND ENDOTHELIAL PROGENITOR CELLS IS MEDIATED BY BLYS RECEPTROS AND IS REVERTED BY BELIMUMAB

F.R. Spinelli, C. Barbati, F. Ceccarelli, T. Colasanti, F. Morello, L. Massaro, V. Orefice, C. Alessandri, F. Conti, G. Valesini. *Dipartimento di Medicina Interna e Specialità Mediche - Reumatologia, Sapienza Università di Roma, Rome, Italy*

Background: Circulating endothelial progenitor cells (EPCs) are surrogate markers of endothelial function. Several studies demonstrated a reduction and functional impairment of EPCs in patients with Systemic Lupus Erythematosus (SLE), partially accounting for endothelial dysfunction. In murine models of atherosclerosis, treatment with a B Lymphocyte Stimulator (BLyS) inhibitor slowed the progression and reduced the size of atherosclerotic plaque. Belimumab (BLM) is a human anti-BLyS monoclonal antibody approved for the treatment of SLE.
Objectives: We aimed at evaluating the effect of BLyS inhibition on EPCs and endothelial cells both *ex vivo* – in SLE patients receiving BLM– and *in vitro*. Moreover we investigated the expression of receptors for BLyS on EPC and mature endothelial cell surface.
Methods: We enrolled consecutive patients with SLE who were due to start BLM, without known cardiovascular disease and age and sex-matched healthy subjects. Peripheral blood mononuclear cells (PBMC) were isolated by Ficoll density-gradient centrifugation. Cells were incubated with anti-CD34 and anti-VEGF-R2/KDR monoclonal antibodies; acquisition was performed by flow cytometry: EPCs were defined as CD34/KDR double-positive cells. Recovered EPC isolated from healthy donors' PBMC were plated on dishes coated with human fibronectin. Apoptosis was investigated after 6, 12 and 24 hours of incubation with BLyS at different concentrations – 5, 20 and 100 ng/ml – and re-evaluated after 6 hours of co-incubation with BLM at 173 and 300 μg/ml. The same experiments were repeated with the human endothelial cell line EA.hy926. Finally, EPCs and EA.hy926 were incubated with monoclonal antibodies anti-B Activating Factor-Receptor (BAFF-R), B-cell maturation antigen (BCMA) and transmembrane activator and calcium modulator and cyclophilin ligand (CAML) interactor (TACI) and analysed by flow cytometry; the results were expressed as mean fluorescence intensity (MFI).
Results: We treated with BLM 10 female patients (mean age 45.6±10.2 yrs, mean disease duration 17.8±10.8 yrs) with active disease (mean baseline SLEDAI 8.4±2.6). Number of EPCs was significantly lower in SLE patients than in NHS (p=0.005). After 4 weeks of BLM, mean EPC number increased from 0.013±0.016 to 0.021±0.016 (p=0.012 vs baseline; p=n.s. vs NHS). At week 12, EPC number did not significantly differ compared to week 4 nor to baseline.
In vitro studies demonstrated that 20 ng/ml of BLyS induced apoptosis of EPC after 6 hours of incubation; this effect was reverted by the addiction of BLM. Similarly, after 6 hours of incubation with 20 ng/ml of BLyS we detected an increase in EA.hy926 apoptosis that was reverted by co-incubation BLM. Both EPCs and EA.hy926 expressed on their surface BAFF-R (MFI =3.8 and 1.5, respectively) and BCMA (MFI =1.25 and 1.15, respectively); EPCs also expressed TACI (MFI =1.4).
Conclusions: The results of this study demonstrated that the reduction of EPCs number detected in SLE patients was restored by BLM. *In vitro* results support a direct pro-apoptotic effect of BLyS that was reverted by the addition of BLM both in EPCs and EA.hy926 culture. The apoptotic effect of BLyS seems to be mediated by the three receptors (BAFF-R, BCMA and TACI) that are expressed on EPCs and mature endothelial cells surface.

SAT0229 THE USE OF ANTIMALARIAL DRUGS DURING PREGNANCY CAN PREVENT THE DEVELOPMENT OF PREECLAMPSIA IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

M.A. Saavedra[1], D. Miranda-Hernández[1], A. Lara-Mejía[1], A. Sánchez[1], C.V. Cruz-Reyes[1], U. Angeles[2], L.J. Jara[3]. *[1]Rheumatology; [2]Epidemiology Direction; [3]Education and Research Direction, Hospital de Especialidades, Cmn la Raza, IMSS, México, Mexico*

Background: The antimalarial drugs decrease the risk of lupus activity during gestation, but the beneficial effect on other maternal-fetal complications is controversial.
Objectives: To analyze the beneficial effect of antimalarial drugs on maternal-fetal complications in pregnant women with systemic lupus erythematosus (SLE).
Methods: A prospective cohort of pregnant women with SLE (ACR 1997) from January 2009 to June 2015 was studied. The patients were assessed every 4 to 6 weeks and postpartum both, by a rheumatologist and a gynecologist. Clinical, biochemical, and immunological characteristics, along with maternal and fetal complications were registered. For analysis, the patients were allocated to one of two groups: pregnancies exposed to antimalarial drugs in comparison to those not exposed. A logistic regression analysis including variables such as smoking, obesity, infections, first pregnancy, age, SLE flare, drugs (prednisone, antimalarials, aspirin, and azathioprine), anti-DNA antibodies, anticardiolipin antibodies, and antiphospholipid syndrome was performed.
Results: We studied 197 lupus pregnancies, 154 expose to antimalarial drugs and 47 unexposed. We found no differences between groups in age, years of evolution of SLE, first pregnancy, childhood-onset SLE, lupus nephritis, and use of prednisone, aspirin and azathioprine. The rate of most maternal and fetal complications was also similar in both groups (Table). A lower incidence of preeclampsia was observed in patients exposed to antimalarial drugs compared to those not exposed (9% vs 23%, p=0.01). Additionally, 2 maternal deaths in patients not exposed to antimalarial drugs. The logistic regression analysis showed that the use of antimalarial drugs during pregnancy is a protective factor for the development of preeclampsia (RR 0.1, 95% CI 0.05–0.58, p=0.004); on the other hand, active SLE before pregnancy (RR 4.8, 95% CI 1.3–17.8, p=0.01) and lupus nephritis (RR 2.9, 95% CI 0.9–8.8, p=0.05) were associated factors with the development of preeclampsia.

Table 1. Maternal and fetal outcomes

	Antimalarial drugs (n=154)	No antimalarial drugs (n=43)	P value
Maternal complications	74 (48.0)	18 (41.8)	0.47
Preeclampsia	14 (9.0)	10 (23.2)	0.01
PROM	15 (9.7)	1 (2.3)	0.12
Cesarean section	99 (64.2)	29 (67.4)	0.53
Maternal death	0 (0)	2 (4.6)	0.007
SLE flare	60 (38.9)	8 (18.6)	0.01
Renal flare	23 (14.9)	5 (11.6)	0.58
Infection	21 (13.6)	5 (11.6)	0.73
Fetal complications a	71 (46.1)	22 (51.1)	0.56 b
Live births a	137 (88.9)	38 (88.3)	0.98 b
Prematurity a	40 (25.9)	13 (30.2)	0.58 b
Miscarriage a	13 (8.4)	5 (11.6)	0.52 b
Stillbirth a	4 (2.5)	0 (0)	0.28 b
Weeks' gestation c	35.1±5.9	35.0±6.3	0.89 d
Birth weight (g) c	2,534±651	2,444±827	0.5 d
Apgar score 1 c	7.4±1.6	7.2±1.6	0.41 d
Apgar score 2 c	8.6±1.4	8.3±1.3	0.37 d

[a]Results expressed in mean (SD). [b]Student's t-test. [c]Results expressed in numbers and percentages. [d]Chi-square test.

Conclusions: Our study suggests that the use of antimalarial drugs during pregnancy can prevent the development of preeclampsia in women with SLE.

SAT0230 NEW ORAL ANICOAGULANTS IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME

M.A. Satybaldyeva, N. Seredavkina, L. Kashnikova, E. Nasonov, T. Reshetnyak. *Nasonova Research Institute of Rheumatology, MOSCOW, RUSSIA, Moscow, Russian Federation*

Background: Antiphospholipid syndrome (APS) is an acquired thrombophilia characterized by reccurent venous and arterial thrombosis, obstetric pathology (fetal loss), and synthesis of antiphospholipid antibodies. Warfarin is a "golden" standard of APS therapy. However it has number of disadvantages. Dabigatran etexilate is a direct thrombin inhibitor and its main differences from warfarin are fixed dose, no need of regular INR monitoring,less elimination half-life.
Objectives: To evaluate efficacy and safety of dabigatran etexilate in patients with APS.
Methods: 38 patients (pts) (F:26, M:12) with primary and secondary APS, 37,2±9,9 years old. 24 pts with primary APS, 14 pts with secondary APS: 13 had systemic lupus erythematosus (SLE) + APS, 1 rheumathoid arthritis (RA) + APS. The diagnosis of APS was established due to international APS criteria (Sydney), SLE – SLICC 2012, RA - ACR/EULAR 2010. The majority number of pts (n=28) received warfarin, others – sulodexide (n=1), low molecular heparin (n=1), had no anticoagulant therapy (n=3), 5 pts received dabigatran etexilate before inclusion to trial. The control of coagulogram was done 3 times: before inclusion to trial, in 24 weeks and in 48 weeks after inclusion. Trial assays were performed in the laboratory in V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation. APPT and thrombin time tests were done with the automated coagulometer Coalysys Plus C (Behnk Electronic, Germany); thrombin time test was done with STA-thrombin reagent (Diagnostica Stago, France), APPT with STA-Cephascreen reagent (Diagnostica Stago, France). Lupus anticoagulant was assessed by the dilute Russell's viper venom time, using Siemens Healthcare (Germany) LA1 (screening) and LA2 (confirmation). IgG or IgM antibodies against cardiolipin and β2 glycoprotein I (β2GPI) were measured with automated enzyme-immunoassay analyzer Alegria with Anti-Cardiolipin IgG/IgM and Anti-beta-2-Glycoprotein I IgG/IgM reagents (Orgentec Diagnostika GmbH, Germany).

Triple positivity was defined as positive antibodies against cardiolipin and β2GPI and a positive test for lupus anticoagulant.
Results: 32 pts had high or medium level of aPL (anticardiolipin antibodies IgG,IgM, anti-β2glycoprotein antibodies IgG,IgM), 6 had low or normal level of aPL. 12 pts were triple positive. APPT and thrombin time before inclusion to trial were 44,2 [36,5;53,5] and 16,1 [14,9;17,0], on 24 week after dabigatran etexilate start 51,0 [40,5;65,7] and 163,5 [108,7;240,0] and on 48 week 58,7 [45,6;63,2] and 194,1 [152,6;255,2] respectively.1 patient was excluded due to non-compliance. During follow-up period from 1,5 to 12 (10,6±3,2) months 7 pts (22,6%, 20,7 per 100 patient-years) experienced reccurent thrombosis including superficial vein thrombosis (n=2; 6,5%, 5,9 per 100 patient-years), thrombosis of paranephric veins (n=1; 3,2%, 2,9 per 100 patient-years), acute cerebrovascular disorders (n=4; 12,9%, 11,8 per 100 patient-years). All pts with reccurent thrombosis had high or medium level of aPL; 2/7 were triple positive, both had acute cerebrovascular disorders. 5 pts (16,1%, 14,8 per 100 patient-years) experienced bleeding: 2 hemorrhoidal bleedings, 1 uterine bleeding, 2 nasal bleedings. There was no case of severe bleeding.
Conclusions: Dabigatran etexilate could be used in patients with APS in the case of warfarin non-effectiveness. These findings need to be confirmed in larger studies.

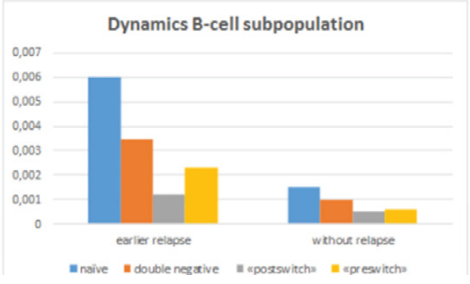
SAT0231 SAFETY OF SUBCUTANEOUS BELIMUMAB IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A 6-MONTH OPEN-LABEL EXTENSION STUDY

A. Doria[1], W. Stohl[2], A. Schwarting[3], M. Scheinberg[4], A. Hammer[5], C. Kleoudis[6], J. Groark[5], N.L. Fox[7], D. Roth[5], D. Bass[5], D. Gordon[5].
[1]University of Padua, Padua, Italy; [2]University of Southern California, Los Angeles, United States; [3]ACURA Kliniken, Bad Kreuznach, Germany; [4]Hospital Abreu Sodré, São Paulo, Brazil; [5]GSK, Philadelphia; [6]GSK, Research Triangle Park; [7]GSK (former employee), Rockville, United States

Background: Intravenous belimumab (BEL) 10 mg/kg is approved in adult patients with active, autoantibody-positive systemic lupus erythematosus (SLE), on standard SLE therapy (SoC). A Phase III, double-blind (DB), study of subcutaneous (SC) BEL 200 mg weekly plus SoC showed efficacy and safety in patients with SLE.
Objectives: The ongoing safety and efficacy of BEL 200 mg SC weekly were assessed in a 6-month open-label extension (OLE) study.
Methods: Patients with SLE who completed BLISS-SC (BEL112341; NCT01484496), a Phase III, randomised (2:1), DB, placebo (PBO)-controlled, 52-week trial of BEL 200 mg SC, were eligible to enter a 6-month OLE; the outcomes are reported here. Patients were maintained on weekly BEL (BEL group) or switched from PBO to BEL (PBO to BEL group). Baseline differed according to study treatment (Day 0 of the DB phase for BEL; Week 52 of the DB phase for PBO to BEL). The primary focus was safety, evaluated by adverse event (AE) reporting, laboratory tests and immunogenicity. OLE AEs were those occurring on or after the first OL dose. Efficacy evaluations were conducted, at reduced frequency, as per the DB phase[1].
Results: Overall, 677 patients completed the DB phase, 662 entered the OLE; 625 completed. Mean baseline Safety of Estrogens in Lupus Erythematosus National Assessment-Systemic Lupus Erythematosus Disease Activity Index scores were 10.4 (BEL group) and 5.8 (PBO to BEL group, implying better SoC in the DB phase); Systemic Lupus International Collaborating Clinics/ACR Damage Index scores were similar (0.7 and 0.6, respectively). Most OLE AEs were mild/moderate in severity. Despite differences in BEL exposure (BEL: 1 year [DB]; 6-month OLE, and PBO to BEL: 6-month OLE), OLE AE rates were similar (table). Infections and infestations were the most frequent AEs (190/662, 28.7%; drug-related, 55/662, 8.3%; serious AEs [SAEs]; 17/662, 2.6%). AEs of depression/suicide/self-injury (12/662, 1.8%), infections of special interest (17/662, 2.6%), post-injection systemic reactions (21/662, 3.2%) and local injection site reactions (4/662, 0.6%), were low. Two deaths occurred (metabolic acidosis; pneumonia and acute respiratory failure); unrelated to study drug. The percentage of patients worsening (≥2 grade) from baseline was low for all clinical laboratory parameters. Three patients had anti-BEL immune responses during the OLE or follow-up; this resolved on subsequent testing. Efficacy was maintained across the OLE.

Patients, n (%)	PBO to BEL 200 mg SC (n=206)	BEL 200 mg SC (n=456)	Total (N=662)
AE	106 (51.5)	220 (48.2)	326 (49.2)
Treatment-related AE	26 (12.6)	58 (12.7)	84 (12.7)
SAE	14 (6.8)	25 (5.5)	39 (5.9)
Severe AE	9 (4.4)	17 (3.7)	26 (3.9)
AE leading to study drug discontinuation	5 (2.4)	12 (2.6)	17 (2.6)
Death	1 (0.5)	1 (0.2)	2 (0.3)



Conclusions: No new differences in safety and efficacy of BEL 200 mg SC plus SoC were seen in this 6-month OLE study compared with the DB phase.

SAT0232 B-CELL SUBPOPULATION DYNAMICS IN SLE PATIENTS FOLLOWING RITUXIMAB THERAPY

A.A. Mesnyankina, E.N. Aleksandrova, S.K. Soloviev, E.V. Suponitskaya, A.P. Aleksankin, A.A. Novikov, E.A. Aseeva, E.L. Nasonov. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Objectives: To study B-cell subpopulation dynamics in SLE patients following Rituximab (RTX) therapy.
Methods: The study included 31 SLE pts (3m/28f) with high (SLEDAI2K≥10–28 pts.) and moderate (SLEDAI2K<10–3 pts.) disease activity; out of them 12 pts with SLE nephritis, 5 pts with neurolupus and 8 with vasculitis. RTX was administered to pts who failed to respond to glucocorticoids (GCs) and cytostatics (CTs). B-cells subpopulations were assessed before RTX administration (Mo0), and at Mo3 and Mo6 of RTX therapy. RTX was administered at 500 to 2000 mg doses depending on disease activity. The absolute counts of CD19+ B-cells, the total population of memory B-cells (CD19+CD27+), "preswitch" (CD19+IgD+CD27+) and "postswitch" (CD19+IgD-CD27+) memory B-cells, "naive" (CD19+IgD+CD27-), plasma cells (CD19+CD38+) and double negative B-cells (CD19+CD27-IgD) were measured. All B cell subsets were analyzed with multicolor flow cytometry using a panel of monoclonal antibodies to B-lymphocytes' surface membrane markers.
Results: Following initiation of RTX SLE clinical and lab activity indices have decreased in all 31 pts by Mo3 and Mo6 of follow up (SLEDAI-2K Mo0–Me 15 [12;18], Mo3-Me 6 [4;10], Mo6–Me 4 [2;8]), as well as absolute count CD19+ B-cell population (Mo0–Me 0,119x10^9/l [0,05;0,26], Mo3–Me 0x10^9/l [0;0,003], Mo6-Me 0,004x10^9/l [0;0,02]). B-cell repopulation by Mo6 in 15 out of 31 pts without signs of relapse and 4 pts with earlier relapse SLE was dependent on "naïve" B-cells (Me 0,0015x10^9/l [0,0002;0,01] vs Me 0,006x10^9/l [0,0033;0,008]), double negative (Me 0,001x10^9/l [0,0002;0,002] vs Me 0,0035x10^9/l [0,0018;0,005]) "postswitch" (Me 0,0005x10^9/l [0,00008;0,003] vs Me 0,0012x10^9/l [0,0003;0,0035]) and "preswitch" memory B-cells (Me 0,0006x10^9/l [0,00007;0,001] vs Me 0,0023x10^9/l [0,0005;0,005]).

Figure: dynamics of lymphocyte subpopulations in patients with early relapse and without relapse SLE/

Conclusions: Decrease in clinical and lab SLE activity was documented in all 31 pts by Mo3 after one course of RTX therapy. In 4 pts with earlier relapse SLE at Mo6 B-cell was found repopulation and significant increase "naïve" B-cells, double negative, "postswitch" and "preswitch" memory B-cells compared with the group without relapse.

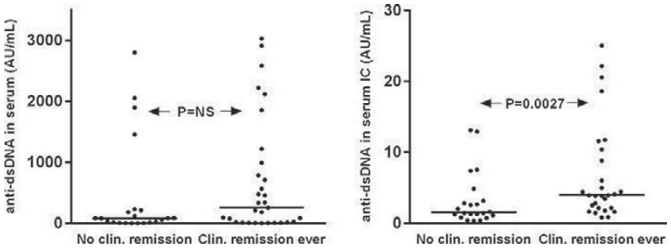
SAT0233 HIGH ANTI-DSDNA CONTENT IN SLE IMMUNE COMPLEXES IS ASSOCIATED WITH CLINICAL REMISSION FOLLOWING BELIMUMAB TREATMENT

A. Sohrabian[1], I. Parodis[2], N. Carlströmer-Berthén[1], C. Sjöwall[3], A. Jönsen[4], A. Zickert[2], M. Frodlund[3], A. Bengtsson[4], I. Gunnarsson[2], J. Rönnelid[1].
[1]Department of immunology, Genetics and Pathology, Uppsala University, Uppsala; [2]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm; [3]Rheumatology/AIR, Department of Clinical and Experimental Medicine, Linköping University, Linköping; [4]Section of Rheumatology, Department of Clinical Sciences Lund, Lund University, Lund, Sweden

Background: Systemic lupus erythematosus (SLE) is considered driven by

immune complexes (IC), and autoantibodies are supposed to participate in IC formation. Thus, the fraction of autoantibodies participating in IC formation merits interest as a diagnostic and/or prognostic marker. We have developed a technique to quantify autoantibody content in IC (Sohrabian et al. Ann Rheum Dis 2015;74(Suppl 1):A74).

Objectives: To evaluate quantification of autoantibodies in IC as a measure of disease activity and prognosis for response in belimumab-treated SLE patients.



Methods: Fifty-five SLE cases classified according to the ACR criteria were treated with belimumab and followed for one year. High disease activity was defined as SLE Disease Activity Index 2000 (SLEDAI-2K) $\geq$10, or as low levels of complement factors C3 and/or C4. Treatment responses were recorded using the SLE Responder Index (SRI), or as a value 0 for modified SLEDAI-2K with suppression of autoantibody and complement data (clinical remission). Low disease activity was also recorded as Lupus Low Disease Activity State (LLDAS). Response data were recorded at 3, 6 and 12 months.

IC were purified from sera by binding to C1q-coated beads, and thereafter eluted. Autoantibody levels were determined in unmodified serum and in solubilised IC with addressable laser bead immunoassay (FIDIS Connective, Theradiag, Paris) for autoantibodies against dsDNA, histones, ribosomal P antigen, proliferating cell nuclear antigen (PCNA), SSA/Ro60, SSA/Ro52, SSB, Sm, U1RNP and the Sm/RNP complex. Autoantibody levels in serum and in IC were compared with Mann-Whitney's U test between patients with high and low disease activity at baseline and between patients with and without treatment response during the follow-up period.

Results: Antibodies against dsDNA, SSA/Ro60 and Sm/RNP were found in 65%, 54% and 43%, other antibodies with lower percentages. Low complement levels were associated with high serum anti-dsDNA (p=0.003) and anti-ribosomal P antigen (p=0.008) levels, whereas high SLEDAI-2K associated with high anti-dsDNA (p=0.02) and anti-Sm/RNP (p=0.047) levels. Serum levels of antibodies against SSA/Ro60, SSB and SSA/Ro52 were lower in patients attaining LLDAS after 6 months (p=0.02, 0.051 [trend] and 0.04, respectively); these associations were stronger for corresponding IC fractions (p=0.01, 0.005, and 0.002, respectively).

Baseline levels of anti-dsDNA and anti-histones in IC associated with clinical remission ever during the follow-up period (p=0.003 and p=0.05). Low levels of anti-Sm and anti-Sm/RNP in serum but not in IC associated with clinical remission at month 6 (p=0.02 and 0.04 respectively), and for Sm/RNP also at month 3 (p=0.04).

Serum levels of all antibodies except SSA/Ro52 declined during the first 6 months, most prominently for dsDNA, histones ribosomal P, PCNA and Sm/RNP ($p<0.0001$ for all). Levels of antibodies in IC declined only for dsDNA (p=0.048).

Conclusions: Autoantibody levels in serum and in IC show different associations to disease activity and to treatment response. High baseline anti-dsDNA levels in IC were most strongly associated with clinical remission, and decreased during belimumab treatment. Belimumab effect might primarily relate to autoantibodies in IC.

SAT0234 PROSPECTIVE SINGLE CENTRE STUDY OF EFFECTIVENESS OF UPFRONT RITUXIMAB AND MYCOPHENOLATE WITH MINIMUM STEROID IN SLE

B.G. Dharmanand. *Rheumatology, Sakra World Hospital, Sy No.52/2 & 52/3, Devarabeesanahalli, Oppsite Intel, Varthur Hobli, Bengaluru, Karnataka 560103, Bangalore, India*

Background: Treatment options for SLE have significant morbidity and mortality. Side effects from corticosteroid usage limit patient adherence and treatment efficacy. B cell depletion appears to target a critical pathophysiological pathway in SLE. Trails with rituximab have shown mixed results. Rituxilup study demonstrated efficacy and steroid sparing action of rituximab and mycophenolate (1)

Objectives: We aim to analyse our experience of using rituximab and mycophenolate upfront on presentation with minimum oral steroids.

Methods: 12 patients with SLE, seen between Jan 2015 to march 2016, were included in the study. All patients completed 6 months of follow-up. Patients were treated with 2 doses of rituximab (1 g) and methyl prednisolone (500 mg) on days 1 and 15, and maintenance treatment of mycophenolate mofetil (2000mg) and low dose prednisolone ($<$7.5 mg) which was tapered off.

Results: 10 were females and 2 males. Mean age of the patients is 24.5. 9 had lupus nephritis, 1 mesenteric vasculitis, 1 CNS vasculitis and 1 severe cutaneous vasculitis with pancytopenia. Average SLEDAI improved from 14 to 4. 6/9 LN attained complete renal remission and 2 partial remission. one patient died due to infection and renal disease 15 days after infusion. 2 vasculitis and one NPSLE patient improved completely. Two patients had infection requiring hospitalization with in 8 weeks of infusion and one patient had severe bradycardia during the infusion and received only 1000mg rituximab. Steroid was stopped by 6 months in 6 patients and in the dose was below 5 mg in rest.

Conclusions: Early Rituximab and mycophenolate is an effective option for treating severe lupus and has steroid sparing property.

SAT0235 BIIB059, A MONOCLONAL ANTIBODY TARGETING BCDA2 SHOWS SAFETY, TOLERABILITY, PHARMACOKINETICS, PHARMACODYNAMICS IN HEALTHY VOLUNTEER SUBJECTS

D. Martin[1], L. Stevenson[1], P. Prasad[1], K. Smirnakis[1], A. Kao[1], D. Rabah[1], W. Wang[1], C. Barbey[2], C. Musselli[1], N. Franchimont[1]. *[1]Biogen, Cambridge, United States; [2]Biogen, Zug, Switzerland*

Background: Type I interferons (IFN-I) are central to the pathogenesis of systemic lupus erythematosus (SLE). BDCA2 is a plasmacytoid dendritic cell (pDC)-specific receptor that, upon engagement, inhibits the production of IFN-I and other inflammatory mediators. Targeting BDCA2 therefore represents an attractive therapeutic strategy for inhibiting pDC-derived IFN-I and may be an effective therapy for the treatment of SLE. BIIB059, an investigational anti-BDCA2 humanized monoclonal antibody, has been shown to engage BDCA2, and this interaction leads to BDCA2 internalization and the consequent in vitro inhibition of TLR-induced IFN-I by pDCs (Pellerin 2015).

Objectives: This study is a first-in-human study that aimed to assess safety, tolerability, PK and PD of BIIB059 in HV subjects following administration of single ascending doses of BIIB059.

Methods: A randomized, double-blinded, placebo controlled, single ascending dose-escalation was conducted in adult HV. Subjects received a single administration of either BIIB059 or placebo. BIIB059 was administered IV at 0.05, 0.3, 1, 3, 10 or 20mg/kg or SC at 50mg at ratio of 2:1 or 3:1. Blood samples were obtained before and after dose administration up to week 16. Target modulation of BDCA2 and serum BDCA2 concentration were measured using flow cytometry, and an enzyme-linked immunosorbent assay (ELISA), respectively, and anti-drug antibodies (ADA) were measured using a bridging ELISA.

Results: 54 HV (38 BIIB059; 16 placebo) were assigned to cohort 1–7. BIIB059 demonstrated non-linear PK consistent with target mediated drug disposition. Bioavailability of SC administration was $\sim$50%. Treatment with BIIB059 led to rapid and complete down-modulation of BDCA2 on the surface of pDCs at all dose levels. Time to reappearance of BDCA2 on pDC cell surface correlated with circulating levels of BIIB059, establishing an in vivo pharmacokinetic/pharmacodynamics (PK/PD) relationship. Single dose administration of BIIB059 was well tolerated across all dose levels. All AEs were mild to moderate in severity with no serious AEs. There were no clinically significant changes in laboratory assessments, physical examinations, or electrocardiogram (ECG) values. Anti-drug antibodies were detected at low levels in a small number of BIIB059-treated subjects. Responses were largely transient and demonstrated no impact on BIIB059 exposure or association with any safety event.

Conclusions: The first-in-human study in HV demonstrated acceptable safety/tolerability and PK profile in healthy subjects and supports further multiple-dose studies with BIIB059. BIIB059 treatment showed dose dependent target engagement and internalization of BDCA2 establishing a PK/PD correlation *in vivo* on circulating pDC. These data support further evaluation of clinical efficacy and safety of BIIB059 as a potential novel therapy in SLE patients.

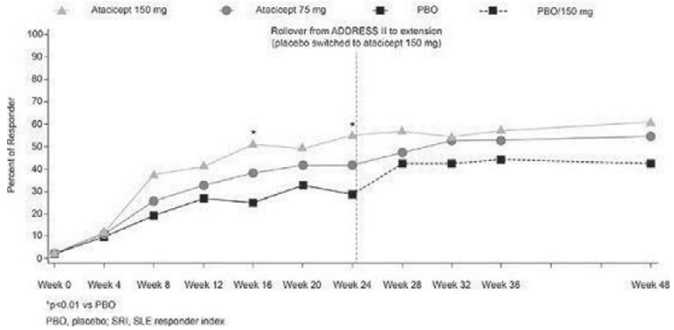
SAT0236 SAFETY AND DISEASE ACTIVITY CHANGES IN AN EXTENSION OF A PHASE IIB STUDY OF ATACICEPT IN PATIENTS WITH SLE (ADDRESS II)

D.J. Wallace[1], D. Isenberg[2], S. Wax[3], A. Kao[3], P. Chang[3], P.A. Fraser[3], J.T. Merrill[4]. *[1]Cedars-Sinai Medical Center, University of California Los Angeles, Los Angeles, United States; [2]University College London, London, United Kingdom; [3]EMD Serono Research & Development Institute, Inc. (a business of Merck KGaA, Darmstadt, Germany), Billerica; [4]Oklahoma Medical Research Foundation, Oklahoma City, United States*



Background: We previously reported results of the 24-week phase IIb ADDRESS II study of atacicept, which demonstrated clinical response in patients with autoantibody-positive SLE, particularly those with high disease activity (HDA; SLEDAI 2K ≥10 at screening).
Objectives: This extension study of ADDRESS II evaluated safety and disease activity in patients with SLE given continued atacicept treatment to week 48 (NCT01972568).
Methods: Atacicept was given as weekly subcutaneous injection to completers of ADDRESS II on average for an additional ≥24 weeks (i.e. ≥48 weeks total from Day 1 of ADDRESS II). Patients already receiving atacicept continued on the same dose (75 mg or 150 mg); those receiving placebo (PBO) switched to atacicept 150 mg (PBO/150 mg).
Results: Of 262 patients completing ADDRESS II, 253 (95%) entered the extension (PBO/150 mg n=83; 75 mg n=82; 150 mg n=88). Demographics were balanced between groups, and most patients were female (91.3%) and white (70%). All three treatment groups had similar rates of treatment-emergent adverse events (TEAEs), TEAEs leading to treatment discontinuation, serious TEAEs, and serious/severe infection (Table 1). Two deaths occurred in the 150 mg arm, considered unrelated to treatment (reported events of stroke and abdominal pain with hematemesis). In the ITT population (n=253), SLE responder index (SRI)-4 rates were maintained between weeks 24 and 48 in the original atacicept groups (75 mg 56.9 vs 55.9%; 150 mg 53.8 vs 56.7%) and moderately increased in the PBO/150 mg group (44.0 vs 48.0%). This improvement was greater for SRI-6 in the HDA subpopulation (PBO/150 mg 28.8% at week 24 vs 42.3% at week 48; 75 mg 41.8 vs 54.5%; 150 mg 54.9 vs 60.8%; Figure 1). The proportion of HDA patients achieving SLEDAI scores ≤2 was also maintained in the atacicept groups (75 mg 20.0 vs 21.8%; 150 mg 37.3 vs 39.2%) and increased in the PBO/150 mg group (13.5 vs 19.2%). In the ITT and HDA populations, most flares occurred before week 24, with reduced risk of severe (BILAG A) and moderate/severe (BILAG A/2B) flares afterwards. Some increase in complement C3 and C4, and decrease in anti-dsDNA antibodies occurred after week 24. Serum IgG decreased moderately, without severe hypogammaglobulinemia (IgG <3 g/L) in any patients.

Table 1. Summary of adverse events

Adverse events, n (%)	PBO/150 mg* (n=83)	Atacicept 75 mg (n=82)	Atacicept 150 mg (n=88)
Any TEAEs	62 (74.7)	63 (76.8)	65 (73.9)
TEAEs leading to treatment discontinuation	6 (7.0)	4 (4.9)	5 (5.7)
Infections and infestations	27 (32.5)	35 (42.7)	43 (48.9)
Herpes zoster	1 (1.2)	0	1 (1.2)
Influenza	1 (1.2)	1 (1.2)	2 (2.3)
Serious TEAEs	15 (18.1)	10 (12.2)	10 (11.4)
Serious/severe infections	4 (4.8)	4 (4.9)	5 (5.7)
Death	0	0	2 (2.3%)†

PBO, placebo; TEAE, treatment-emergent adverse event. *Patients receiving PBO in ADDRESS II who switched to atacicept 150 mg. †Due to 1) stroke and 2) hematemesis.

Figure 1. SRI-6 response rates over time up to week 48 in the HDA population

Conclusions: There were no new safety signals with atacicept between week 24 and 48, and clinical responses achieved during the first 24 weeks were maintained.

SAT0237 BONE MARROW AS A TARGET ORGAN OF SYSTEMIC LUPUS ERYTHEMATOSUS: ANALYSIS OF CASES WITH AUTOIMMUNE MYELOFIBROSIS

D. Üsküdar Cansu[1], H. Üsküdar Teke[2], S. Işıksoy[3], C. Korkmaz[1]. *[1]Eskişehir Osmangazi University, School of Medicine, Rheumatology; [2]Eskişehir Osmangazi University, School of Medicine, Hematology; [3]Eskişehir Osmangazi University, School of Medicine, Pathology, Eskişehir, Turkey*

Background: Cytopenia in the course of systemic lupus erythematosus (SLE) may be due to multiple factors. One of these factors can be SLE-associated autoimmune myelofibrosis (AIMF). However, the frequency of SLE-associated AIMF is not well known and the role of clinical and laboratory parameters in the development of AIMF is not clear.
Objectives: Our aim was to identify the frequency of SLE-associated AIMF and compared SLE-associated AIMF group with non-AIMF group in terms of clinical findings and morphological properties of the bone marrow (BM) in cytopenic SLE patients.
Methods: We retrospectively analyzed 224 SLE patients' files who met 1997 revised Classification criteria for SLE. BM aspirates and trephine biopsies were re-examinded. Patients were divided into two groups according to whether they had myelofibrosis or not (AIMF and non-AIMF groups). Concurrent SLE organ involvements, and drugs given pre- and post-AIMF were recorded. BM cellularity, the presence of fibrosis (reticulin or collagen) and grade of fibrosis, the presence of dysplasia, and lymphoid infiltration were recorded.
Results: 45 (20%) of 224 SLE patients were found to experienced BM biopsy due to cytopenia. Four patients were excluded from analyses (2 drug-induced cytopenia, 1 lymphoma, 1 insufficient BM biopsy samples). While AIMF was detected in 29 (70.7%) of the 41 patients, 12 patients did not have AIMF. All patients with AIMF had reticulin fibrosis, 2 patients (6.9%) had also collagen fibrosis. Between the AIMF and non-AIMF groups, no differences were identified in terms of erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), SLEDAI, BM cellularity, or BM dysplastic changes (p=0.989, p=0.387, p=0.788, p=0.672, and p=0.494, respectively). In the AIMF group, 27 patients responded to immunosuppressive therapy and corticosteroids, but 2 patients were unresponsive. The response time was longer for the AIMF group compared to the non-AIMF group (3.3±3.1 months vs 1.7±1.2 months, p=0.091). Correlation analysis revealed that higher the grade of BM fibrosis, longer the response time (r=0.471, p=0.002).
Conclusions: AIMF may be underestimated in SLE patients. AIMF as an additional factor for cytopenia in SLE patients may lead to delayed response to appropriate therapy, which was dependent on the presence of high grade fibrosis.

SAT0238 GLUCOCORTICOID WITHDRAWAL IN AN INCEPTION COHORT OF LUPUS NEPHRITIS PATIENTS

S. Wautier, F. Tamirou, S. Nieuwland-Husson, F.A. Houssiau. *Rheumatology Department, Cliniques Universitaires Saint-Luc, Bruxelles, Belgium*

Background: Few studies have addressed glucocorticoid (GC) withdrawal in lupus nephritis (LN). Yet, this remains a pivotal issue due to GC-induced side effects on the one hand, and to the risk of relapse on the other hand.
Objectives: We reviewed the data of the Louvain Lupus Nephritis Inception Cohort (LOULUNIC) i): to determine the percentage of patients able to permanently or transiently stop GC; ii): to compare their baseline and follow-up characteristics to patients who never stopped; and iii): to assess the consequences of GC withdrawal.
Methods: Ninety patients with new-onset biopsy-proven LN were included. All were under the care of the same senior physician (FAH) during follow-up. Clinical, pathological and biological data were extracted from our data base. The SLICC/ACR-DI was assessed at last visit. Unpaired t-tests, Mann-Whitney tests and ANOVA were used, as appropriate.
Results: Out of 90 patients with incident LN, 43 (48%) ever stopped GC (group E), of which 32 permanently (group P). Median time to stop GC was 37 months. 47 patients (52%) never stopped GC (group N).
At *baseline*, serum creatinine, uP/C ratio, ISN/RPS classes, activity and chronicity indices did not differ between groups, nor did the mean initial dose of methylprednisolone (MP) (N: 28 mg/d; E: 32 mg/d; P: 31 mg/d), the use of IV MP pulses (82

and 77% in N and E groups, respectively) and of IV cyclophosphamide (81 and 77%, respectively).
During the *first year*, mean (SD) uP/C decreased statistically more in group E compared to group N (p=0.028 by ANOVA), with striking differences at month 3 (N: 1.73±1.87; E: 0.96±1.34; p=0.038 by unpaired t-test). This difference at month 3 was also noticed for group P patients (0.85±0.76; p=0.02 by unpaired t-test). Interestingly, the mean MP dose at month 3 was statistically higher in group E (19±8) and P (20±9) compared to group N (15±6) (p=0.005 by unpaired t-test).
At *last follow-up*, serum creatinine was statistically lower in E and P patients compared to N patients. Eight of the 11 patients from the T group suffered form a renal relapse, justifying restart of GC, after a median time of 30 months. Importantly, SLICC/ACR-DI was significantly lower in E and P patients, compared to N patients (p=0.0068 and 0.0027, respectively).
Conclusions: In half of LN patients, complete GC withdrawal is achievable and in one third it can be maintained long term. As expected, patients able to stop GC display less damage at last followup. Patients who were able to stop GC decreased their proteinuria much more promptly during the first year of treatment. Interestingly, they received more GC within the first 3 months of therapy, thereby suggesting that a higher dose of GC during the first 3 months of treatment might be associated with a higher probability of later GC withdrawal.

SAT0239 LATE-ONSET NEUTROPENIA FOLLOWING RITUXIMAB TREATMENT IN SYSTEMIC LUPUS ERYTHEMATOSUS – A ROLE OF THE BAFF/APRIL PATHWAY

I. Parodis, F. Söder, F. Faustini, F. Wermeling, R.F. van Vollenhoven, E. Svenungsson, I. Gunnarsson. *Department of Medicine, Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden*

Background: Rituximab-mediated late-onset neutropenia (LON) has been studied in various diseases, but data from systemic lupus erythematosus (SLE) are limited.
Objectives: To study the prevalence and contributing factors for LON following treatment with rituximab in patients with SLE, including B cell related cytokines and growth factors of the myeloid lineage.
Methods: Patients from the Karolinska SLE cohort treated with rituximab (n=107) were enrolled in this observational study. Rituximab was given according to the lymphoma course (weekly for four weeks), the arthritis course (at week 0 and 2), or as a single infusion, with or without concomitant pulses of cyclophosphamide. LON was defined as an absolute neutrophil count $<$1,500 cells/μL, occurring four weeks to two years after initiation of rituximab treatment, provided that other apparent causes were excluded. Neutropenia occurring later than two years after treatment initiation but during sustained B cell depletion were also considered LON. B lymphocyte stimulator (BLyS/BAFF), a proliferation-inducing ligand (APRIL), interleukin 6 (IL-6), granulocyte colony stimulating factor (G-CSF) and granulocyte-macrophage colony stimulating factor (GM-CSF) were measured by ELISA prior to treatment (n=70) and either at the incidence of LON in patients who developed LON or after approximately the same median time following rituximab treatment in patients who did not develop LON (n=52).
Results: Thirty-four of 107 patients developed LON after a median time of 222 days (IQR: 105–355 days). BLyS levels increased from baseline (median: 0.62 ng/mL; IQR: 0.42–1.07 ng/mL) through the post-treatment measurement, both in patients who developed LON (median: 1.73 ng/mL; IQR: 1.03–2.13 ng/mL; P=0.005) and patients who did not (median: 1.03; IQR: 0.67–1.56 ng/mL; P$<$0.001), but the increase was greater in patients who developed LON, resulting in significantly higher post-treatment BLyS levels (P=0.029). BLyS levels did not differ between the two groups at baseline (P=0.745). We observed a numerical increase in APRIL levels from baseline (median: 1.29 ng/mL; IQR: 0.85–2.3 ng/mL) through the post-treatment measurement in patients who developed LON (median: 2.39; IQR: 1.08–5.16 ng/mL; P=0.074) and a numerical decrease in patients who did not (median: 1.11 ng/mL; IQR: 0.77–1.64 ng/mL; P=0.064), resulting in significantly higher post-treatment APRIL levels in the LON group (P=0.032), from being similar at baseline (P=0.125). We found no difference in levels of G-CSF, GM-CSF or IL-6 between patients who developed LON and patients who did not, either at baseline or at the post-treatment measurement. Higher prednisone dose administered concomitantly to rituximab (P=0.003) and younger age (P=0.001) were found to be associated with the development of LON, whereas neither the use nor the doses of cyclophosphamide were found to have any impact.
Conclusions: The prevalence of rituximab-mediated LON within the SLE patients of the current study (31.8%) was higher compared to previous reports on patients with lymphoma (3–27%), ANCA-associated vasculitis (11.9%) and rheumatoid arthritis (3%). Our results imply a role of the BAFF/APRIL pathway in the immunologic mechanisms underlying this phenomenon and demonstrate that LON following rituximab treatment is a common complication in SLE patients.

SAT0240 PHASE 3 TRIAL RESULTS WITH BLISIBIMOD, A SELECTIVE INHIBITOR OF B-CELL ACTIVATING FACTOR, IN SUBJECTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

J. Merrill[1], R.S. Martin[2], W.R. Shanahan[2], M. Scheinberg[3], K. Kalunian[4], D. Wofsy[5]. *[1]OMRF, Oklahoma; [2]ANTHERA, Hayward, United States; [3]Hospital Abreu Sodré, Sao Paolo, Brazil; [4]UCSD, San Diego; [5]UCSF, San Francisco, United States*

Background: Targeted, biologic inhibitors of B-cell Activating Factor (BAFF) have been evaluated in Phase 3 trials in over 5000 patients with SLE. Post hoc analyses of these studies identify lower placebo response and greater treatment effect using more stringent endpoints in patients entering with higher disease activity, greater corticosteroid doses, and/or anti-double-stranded DNA (dsDNA) and low complement C3 or C4[1,2].
Objectives: The Phase 3 CHABLIS-SC1 trial evaluated blisibimod, an inhibitor of B-cell activating factor (BAFF), in a "responder population" identified from prior studies with this drug class.
Methods: 442 SLE patients with anti-nuclear antibodies or anti-dsDNA, SELENA-SLEDAI score $\geq$10 on standard of care medications were randomized to receive weekly subcutaneous blisibimod (200 mg) or placebo. Corticosteroid taper was encouraged from Week 8 with the goal to reach $\leq$7.5 mg prednisone/day. The primary endpoint at Week 52 was the SLE Responder Index-6 (SRI-6): $\geq$6-point improvement in SELENA-SLEDAI, no new BILAG 1A or 2B domain scores, and $<$0.3-point increase in Physician's Global Assessment.
Results: This study did not meet its primary endpoint at Week 52. Response rates to blisibimod were equivalent to past trials of BAFF inhibitors, but the placebo response was greater. A slightly higher proportion of subjects on blisibimod met the SRI-6 and SRI-4 criteria at most timepoints and more blisibimod-treated subjects achieved corticosteroid taper to prednisone $\leq$7.5 mg/day from Week 40 through Week 52 (p=0.04 at Week 44). Reductions in peripheral B cell lineages, anti-dsDNA, anti-phospholipid antibodies, and serum immunoglobulins, and increases in complement C3 and C4 were observed with blisibimod (see Table).
Blisibimod was well-tolerated. The most common adverse events were upper respiratory tract infection (10.6% vs 14.3% on placebo), urinary tract infection (6.9% vs 10.7%), injection site erythema (7.8% vs 2.0%), injection site reaction (7.3% vs 2.6%), and diarrhea (7.3% vs 2.6%).

Table of Results

	Blisibimod (N=245)	Placebo (N=197)
Disease characteristics at baseline		
SELENA-SLEDAI mean score	13.4	13.5
Low C3/C4 & anti-dsDNA, %	62.4	61.7
Proteinuria $\geq$0.5 g/g, %	32.7	27.9
Mean prednisone dose, mg	15.6	15.6
Oral immunosuppressant use, %	42.4	41.6
Antimalarial use, %	61.2	62.2
Results at Week 52 (*p$<$0.05, **p$<$0.01)		
SRI-6 (primary), %	46.9	42.3
SRI-4, %	56.7	52.0
Taper to $\leq$7.5 mg prednisone/day, %	23.3	16.9
Total B cell change from baseline, counts	-3.30**	-1.58
Anti-dsDNA change from baseline, IU	-134.8	-75.5
C3 and C4 change from baseline, mg/dL	0.11**, 0.03**	0.03, -0.002
Anticardiolipin IgG % change from baseline	-12.7*	9.3

Conclusions: With a deliberate focus on a "responder population" for whom lower placebo rates were observed in previous trials, much higher placebo response rates were observed in the CHABLIS-SC1 trial. Modest benefits of blisibimod were observed on serological effects and corticosteroid tapering.

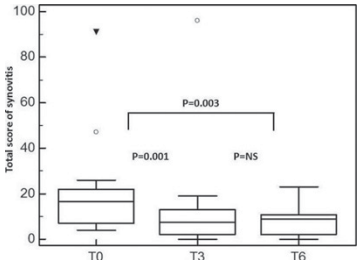
SAT0241 EARLY RESPONSE TO BELIMUMAB IN SLE-RELATED JOINT INVOLVEMENT EVALUATED BY ULTRASONOGRAPHIC ASSESSMENT

L. Massaro, F. Ceccarelli, F.R. Spinelli, F. Morello, C. Perricone, F. Miranda, S. Truglia, V. Orefice, I.M. Rutigliano, C. Alessandri, G. Valesini, F. Conti. *Medicina Interna e Specilità Mediche, Reumatologia, Sapienza Università di Roma, Roma, Italy*



Background: Belimumab (BLM), a fully human monoclonal antibody directed against B lymphocyte stimulator (BLyS), is currently the only biological drug

approved for the treatment of active Systemic Lupus erythematosus (SLE) patients not responding to standard of care. Data from RCTs and observational studies have demonstrated its efficacy, especially in patients with joint involvement. Focusing on this specific manifestation, the response has been also demonstrated by using Disease Activity Score on 28 joints (DAS28) (1). No data are available about the response to BLM in terms of synovitis, assessed by ultrasonography (US).

Objectives: In the present 6-months longitudinal study, we evaluated the response to BLM in SLE patients treated for joint involvement, by using clinimetric indices and US assessment.

Methods: SLE patients starting BLM in the period between August 2013 and December 2016 were prospectively examined. The present analysis was restricted to patients requiring BLM for joint involvement. A complete physical examination and US assessment were performed at baseline (T0) and after 3 (T3) and 6 months (T6). At each time, we assessed the global disease activity by Systemic Lupus Erythematosus Disease Activity Index-2000 (SLEDAI-2K) and the joint involvement activity by DAS28. US evaluation of 12 joints (I-V metacarpophalangeal, I-V proximal interphalangeal, wrist and knee bilateral) was performed to identify inflammatory features (synovial effusion and hypertrophy, power Doppler) according to the OMERACT definitions. These elementary lesions were scored according to a semi-quantitative scale (0=absent, 1=mild, 2=moderate and 3=severe) and a total score, corresponding to the patient's inflammatory status (0–216) was obtained by their sum.

Results: Moving from 35 SLE patients starting BLM, 14 (14 female; mean age±SD 48.4±8.6 years; mean disease duration±SD 255.4±124.2 months) were treated for prevalent joint involvement. At baseline, the mean DAS28±SD was 4.5±1.1, the mean SLEDAI-2K±SD was 6.1±1.5 and the mean daily prednisone±SD was 7.8±3.5 mg. After 3 months of treatment we observed a significant reduction in mean DAS28 (3.1±0.8 *vs* 4.5±1.1, P=0.007) and in mean SLEDAI-2K (3.5±2.1 *vs* 6.1±1.5, P=0.003) compared to baseline. The mean daily prednisone significantly decreased at T6 (4.7±1.4 *vs* 7.8±3.5 mg, P=0.03) while the rest of the therapy remained stable for 6 months. Of note, the mean total US score significantly decreased at T3 compared to T0 (13.7±24.4 *vs* 22.2±22.6, P=0.001). This result was maintained in 12 patients (85.7%) after 6 months with a statistically significant difference compared to T0 (7.9±6.6 *vs* 22.2±22.6, P=0.003) (Figure 1).

Conclusions: The results of the present study demonstrated the efficacy of BLM in SLE-related joint involvement, evaluated by SLEDAI-2K and DAS28, confirming previous data reported in the scientific literature. For the first time, we demonstrated an early response to BLM as proved by the reduction of the total US synovitis score after 3 months, reflecting the improvement of the joint inflammatory status.

SAT0242 MEASURES OF PERIPHERAL BLOOD B-CELL DEPLETION PREDICT RENAL RESPONSE IN PATIENTS WITH LUPUS NEPHRITIS TREATED WITH RITUXIMAB

L.M. Gomez Mendez[1], M.D. Cascino[2], J. Garg[2], P. Brunetta[2], M. Dall'Era[1], L. Dragone[2]. *[1]UCSF; [2]Genentech, San Francisco, United States*

Background: LUNAR, a randomized controlled trial, investigated the addition of rituximab (RTX) to standard of care for the treatment of lupus nephritis (LN). While this study did not meet its primary endpoint, there was an increase in partial renal response associated with RTX. Subsequent observational studies have suggested that there is variability in the degree of peripheral blood B-cell depletion in patients with SLE following treatment with RTX and that greater B-cell depletion may result in increased therapeutic efficacy.

Objectives: To assess the relationship between parameters of B-cell depletion and measures of renal response in patients treated with RTX.

Methods: We analyzed data from the LUNAR trial (registry number NCT00282347) who were treated with RTX and for whom complete CD19 measurements and renal endpoints were available (n=70). We developed several parameters to assess the degree, duration and rate of depletion of CD19 counts from randomization through day 364. Complete renal response (CRR) was defined as urine protein to creatinine ratio (UPCR) <0.5, normal serum creatinine or, if normal at baseline, not increased by ≥15%, and inactive urinary sediment. Spearman's correlation was used to identify associations between baseline characteristics and measures of B-cell depletion. The association between measures of B-cell depletion and CRR (at weeks 52 and 78) was examined using logistic regression adjusted for baseline UPCR. Separately, analyses were stratified by baseline anti-double stranded DNA antibody titer status (anti-dsDNA).

Results: Baseline UPCR correlated with the degree of B-cell depletion following RTX treatment by several measures (time spent at CD19 =0 cells/ml [r = -0.32]; CD19 nadir [r =0.33]; percent change from baseline to nadir [r =0.3]). Measures of B-cell depletion were associated with CRR and percent change in UPCR at week 78 (Table 1). Achievement of a nadir of CD19 =0 cells/ml had an odds ratio (OR) =5.18 (95% CI: 1.03–26.1); patients who spent greater than the median percent of time at CD19 =0 cells/ml had OR =3.3 (95% CI: 1.14–9.62) for CRR at week 78. In subgroup analyses, associations between these measures of peripheral blood B-cell depletion and renal response were strongest among patients with high baseline anti-dsDNA titer. No measures of B-cell depletion were associated with CRR at week 52.

Table 1. Adjusted multivariate measures of B-cell depletion and their associations with complete renal response and percent change from baseline UPCR.

	OR of Complete Renal Response (95% CI)		Percent change in UPCR (95% CI)	
	Week 52	Week 78	Week 52	Week 78
CD19 reaches 0 cells/μl at any time point	2.12 (0.49, 9.07)	5.18 (1.03, 26.08)	-18.9% (−42.7, 4.88)	−31.8% (−70.7, 7.01)
Above median percent of time at 0 cells/μl	1.23 (0.41, 3.67)	3.32 (1.14, 9.62)	−11.28% (−31, 8.5)	−39.5% (−68.2, −10.8)
Area under the curve for all B cell measurements in one year	0.78 (0.38, 1.59)	1.88 (0.90, 3.94)	-1.87% (−15.4, 11.6)	1.15% (−19.6, 22.6)
For every 30 of days spent at 0 cells/μl	1.11 (0.89, 1.38)	1.16 (0.95, 1.45)	−2.7% (−6.9, 1.38)	−6.18% (−12.3, 0.06)
Percent of visits at 0 cells/μl	1.01 (0.98, 1.05)	1.03 (1.00, 1.06)	−0.45% (-1.06, 0.15)	−1.05% (-1.93, −0.17)
Every increment of 30 days to nadir	1.06 (0.9, 1.25)	0.92 (0.78, 1.08)	-0.72% (−3.81, 2.34)	1.05% (−3.6, 5.7)
Percent change in CD19 from baseline to nadir	0.74 (0.36, 1.53)	0.56 (0.25, 1.28)	0.01% (−11.4, 11.4)	23% (−0.84, 46.9)
CD19 nadir	0.49 (0.12, 1.94)	0.22 (0.04, 1.12)	19.5% (−2.33, 41.4)	28.4% (−7.06, 63.8)

OR, odds ratio; UPCR, urine protein to creatinine ratio.

Conclusions: Baseline UPCR was inversely correlated with the degree of peripheral B-cell depletion. B-cell depletion measures were associated with increased odds of achieving CRR and decreased UPCR at week 78 and these associations were strongest among patients with high baseline anti-dsDNA titer. These data support the exploration of high-sensitivity B-cell measurements in future studies of B-cell depleting treatments in LN and suggest that longer duration of follow up may better demonstrate efficacy with B-cell depleting agents.

SAT0243 EXPOSURE-RESPONSE (E-R) ANALYSIS FOR SELECTION OF OPTIMAL DOSAGE REGIMEN OF ANIFROLUMAB IN PATIENTS (PTS) WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

L.C. Santiago[1], B. Wang[1], P. Brohawn[2], L. Wang[2], G. Illei[2], L. Roskos[2]. *[1]MedImmune LLC, Mountain View; [2]MedImmune LLC, Gaithersburg, United States*

Background: Anifrolumab is a fully human IgG_1 monoclonal antibody directed against subunit 1 of the type I interferon–α receptor (IFNAR1). It is in development for treatment of SLE.

Objectives: To support dosage selection for pivotal anifrolumab studies, using an E−R model.

Methods: In the Phase IIb MUSE study (NCT01438489),[1] adult pts with moderate to severe SLE, who had inadequate responses to standard-of-care (SOC) medications, were randomized 1:1:1 to intravenous anifrolumab 300 or 1,000 mg or placebo every 4 weeks (Q4W), in addition to SOC medications, for 48 weeks. Pts were stratified by type I interferon gene signature (IFNGS) test status (high or low) using a validated 4-gene expression assay, oral corticosteroid dosage (<10 or ≥10 mg/day of prednisone or equivalent), and SLE disease activity index−2K score (<10 or ≥10) at screening. A mechanistic target-mediated drug disposition model[2] was used to describe the pharmacokinetics (PK) of anifrolumab. The dichotomous efficacy endpoint, SLE responder index [SRI (4)], was modeled using logistic regression. A dropout hazard function was used to describe voluntary withdrawals during treatment. Clinical simulations were conducted to assess dosing scenarios in virtual SLE pts.

Results: There was no PK difference between type I IFNGS test–high or –low pts (mean [standard deviation] C_{trough} (Day 169): 17.0 [11.5] μg/mL and 23.3 [16.0] μg/mL, respectively). SRI (4) modeling demonstrated no anifrolumab treatment effect in type I IFNGS test–low pts compared with placebo; interpretation of this

result may be limited by small sample size. In type I IFNGS test–high pts, a log-linear logistic model was used to describe the treatment effect of anifrolumab. Pt dropouts were more likely in nonresponders. Clinical simulations demonstrated dosages <300 mg would result in inadequate PK exposure and suboptimal efficacy in some pts with SLE. In contrast, simulations indicated minimal efficacy improvement for dosages >300 mg, consistent with the Phase IIb MUSE study outcomes.

Conclusions: Based on E–R analyses and overall risk assessment, a 300 mg Q4W, intravenous dosage regimen is recommended for pivotal anifrolumab studies in pts with SLE.

SAT0244 A LONG-TERM FOLLOW-UP STUDY OF ALLOGENEIC MESENCHYMAL STEM CELLS TRANSPLANTATION IN PATIENTS WITH DRUG-RESISTANT SYSTEMIC LUPUS ERYTHEMATOSUS

D. Wang [1], L. Sun [2]. [1] *Department of Rheumatology and Immunology;* [2] *Department of Rheumatology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

Background: Allogeneic mesenchymal stem cells (MSC) transplantation showed therapeutic effect in active and refractory systemic lupus erythematosus (SLE).

Objectives: To determine the long-term safety and efficacy of allogeneic MSC transplantation (allo-MSCT) in severe SLE patients refractory to previous therapies.

Methods: All consecutive SLE patients who received at least one allo-MSCT were analyzed. SLEDAI score of more than or equal to 8 or with at least one BILAG grade A or at least two BILAG grade B manifestations. All the patients were refractory to corticosteroid and/or immunosuppressive drugs treatment. Allogeneic bone marrow and/or umbilical cord derived MSCs were infused intravenously, with one million cells per kilogram of bodyweight for each infusion. The primary end point was 5-year overall survival. Secondary end points included complete clinical remission, partial clinical remission and relapse.

Results: Eighty-one patients were enrolled and underwent allo-MSCT. Thirteen patients died within 5 years post-MSCT and the 5-year overall survival rate was 84% (68/81). At 5-year follow-up, 22 patients (22/68, 32%) were in complete clinical remission and another 6 patients (6/68, 9%) were in partial clinical remission, and the 5-year disease remission was 41% (28/68). In total, 37 patients had achieved clinical remission (27 in complete remission and 10 in partial remission) at the 5 years visit and then 9 patients subsequently relapsed. The 5-year overall rate of relapse was 24% (9/37). SLEDAI scores, levels of serum albumin and complement C3, peripheral white blood cell and platelet numbers, as well as proteinuria levels continued to improve during the follow-up.

Conclusions: Allogeneic MSCT is safe and resulted in long-term clinical remission in severe and drug-resistant SLE patients.

SAT0245 SERUM IFN GAMA MAY PREDICT THERAPEUTIC EFFECT OF MESENCHYMAL STEM CELLS TRANSPLANTATION IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

D. Wang, L. Sun. *Department of Rheumatology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

Background: Umbilical cord (UC) derived mesenchymal stem cells (MSCs) show immunoregulatory properties on various immune cells and display clinical effect on lots of autoimmune disease like systemic lupus erythematosus (SLE).

Objectives: The aim of this study is to investigate the effect of SLE environment on UC MSCs and to observe the possible serum biomarker to predict the therapeutic effect.

Methods: UC MSCs were co-cultured with peripheral blood mononuclear cells (PBMC) from active lupus patients at a ratio of 1:4. The proliferation, apoptosis and surface markers of UC MSCs were observed. UC MSCs functional molecules were assessed by real-time PCR and the signaling pathways were analyzed by western blot. Different recombinant cytokines were used to stimulate UC MSCs *in vitro* and the functional factors were determined by real-time PCR. In the last, twenty-six patients with SLE, refractory to conventional therapies, were given UC MSCs transplantation. The clinical effect was followed-up for one year to classify responder and non-responder groups, and baseline serum cytokines were analyzed by ELISA.

Results: The co-culture of lupus patients PBMC had no effect on UC MSCs surface markers and apoptosis, but promoted MSCs proliferation. Lupus PBMC were more prone to stimulate UC MSCs to secret VEGF as well as CXCL-12, compared to PBMC from normal controls. Furthermore, lupus PBMC activated Akt, IκB and Stat5 signaling pathways in UC MSCs but not affect Erk1/2 and Smad1/5/8 pathways. When stimulated by different cytokines, we found that interferon γ (IFN-γ) was still the most important cytokine to induce IDO1 as well as IDO2 productions in UC MSCs; both had dose-dependent manners. Moreover, our clinical study showed that baseline higher levels IFN-γ might predict a good response to MSCs transplantation in active lupus patients.

Conclusions: Baseline IFN-γ levels may predict clinical response to MSCs therapy for active lupus patients, which will help us to choose appropriate patient for clinical transplantation.

SAT0246 EXPLORER STUDY: RITUXIMAB USE IN SYSTEMIC LUPUS ERYTHEMATOSUS, A NEW LOOK ON OLD DATA

M. Scherlinger, C. Carcaud, M.E. Truchetet, P. Dufau, L. Couzy, J. Seneschal, T. Barnetche, E. Lazaro, C. Richez. *Fhu Acronym, CHU de Bordeaux, Bordeaux, France*

Background: Even if randomized trials EXPLORER and LUNAR failed to prove the superiority of rituximab versus placebo in patients with systemic lupus erythematosus, several encouraging indications as refractory lupus nephritis and new clinical trials renewed interest for this molecule.

We hypothetized that SLE response criteria used in EXPLORER were not sensible enough to show rituximab efficacy and that new response criteria could show a significant difference.

Objectives: Our objective was to reanalyze EXPLORER trial's raw data using the newly described SLE response criteria.

Methods: We proceeded to a pre-specified re-analyze of EXPLORER trial's raw data. The patients included in EXPLORER study had active SLE disease defined by a British Isles Lupus Assessment Group (BILAG) score A or 2 BILAG B despite immunosuppressive regimen. Renal and neurological SLE were excluded. Patients were randomized through a 2/1 ratio to receive either two 1gr rituximab infusions (day 0 and 15) repeated at month 6 or a placebo. Standard SLE treatment and other immunosuppressant were continued. Patients received in a stratified manner prednisone ranging from 0.5 to 1.0 mg/kg depending on disease severity at inclusion. The original efficacy criterion was a composite clinical score using BILAG at week 52.

In our new analysis, rituximab efficacy was assessed at week 52 using 4 criteria: SRI-4 (Systemic lupus erythematosus Responder Index) with and without a concomitant oral prednisone (OP) tapering objective of <10mg at month 6 (SRI-4 with and without OP tapering), Lupus Low Disease Activity Score (LLDAS) and BILAG-based Combined Lupus Assessment (BICLA).

Results: Data from all 257 patients were available. There was 234 women (91%) with a mean age of 40,3 years among which 177 (69%) received hydroxychloroquine.

At week 52, SRI-4 response rate was 27,2% in the rituximab group vs 22,7% in the placebo group (p=0.43); SRI-4 with OP tapering was 16% in the rituximab group vs 13.6% in the placebo group (p=0.62); LLDAS was 16% in the rituximab group vs 12.5% in the placebo group (p=0.46) and BICLA was 15.4% in the rituximab group vs 15.9% in the placebo group (p=0.91).

Subgroup analyses demonstrated a trend for better efficacy of rituximab compared to placebo in the subgroup of patients co-treated with methotrexate: SRI-4 of 30.6% in the rituximab group vs 12% in the placebo group (n=74, p=0.08). This trend was not found in the subgroup co-treated with azathioprine: SRI-4 of 26.7% in the rituximab group vs 30.6% in the placebo group (p=0.68), nor in the subgroup co-treated with mycophenolic acid: SRI-4 of 23.1% in the rituximab group vs 21.6% in the placebo group (p=0.86). In the subgroup of patients with a BILAG A/B in hematological system or vasculitis at baseline, there was a significantly higher SRI-4 response rate with rituximab: 28,6% vs 5,3% in the hematological group (n=61, p=0,047) and 39,3% vs 0% in the vasculitis group (n=38, p=0,037). Cumulative dose of steroids at week 52 were not statistically different: 4223mg in the rituximab group vs 4390mg in the placebo group (p=0,65).

Conclusions: Our study confirms the results from the original EXPLORER study. These results might be partly related to the study's design, notably the high daily oral prednisone used. Our work suggests efficacy in subgroups with vasculitis and hematological involvement.

SAT0247 EFFICACY AND SAFETY OF MODIFIED-RELEASE PREDNISONE IN MANAGING MODERATE ACTIVITY SYSTEMIC LUPUS ERYTHEMATOUS DURING PREGNANCY: AN IMPLEMENTED CASE-CONTROL STUDY

M. Meroni[1,2], V. Ramoni[3], M. Limonta[2], M. Cutolo[1]. *[1]Research Laboratory and Academic Division of Clinical Rheumatology, Internal Medicine Dept., University of Genova, Genova; [2]Rheumatology Unit, ASST Papa Giovanni XXIII, Bergamo; [3]Division of Rheumatology, IRCCS San Matteo Hospital Foundation, University of Pavia, Pavia, Italy*

Background: Systemic lupus erythematosus (SLE) primarily affects women of childbearing age. Despite the overall favorable outcome, pregnancy represents a challenge for both patients and clinicians. Since the complications rate is linked to the disease activity, the achievement of remission is recommended before pregnancy. Prednisone represents a cornerstone in SLE management and is safely used, at low doses (<7.5 mg daily), during pregnancy. Modified-release prednisone (MRP) optimize corticosteroid treatment strategy in rheumatic diseases, thanks to its capability of respect the physiological cortisol circadian secretion. MRP has been approved from FDA in SLE treatment, but no data are available regarding its administration during pregnancy.
Objectives: We aimed to investigate whether this drug is safe and effective as the immediate release prednisone (IRP) in SLE pregnant patients.
Methods: We retrospectively evaluated 9 female patients, fulfilling the ACR criteria for SLE, consulting our Centers in a 4-years observational range. All of them, thanks to a stable disease (not requiring treatment regimen modifications within 12 months), experienced a successful pregnancy during the observation. All the cases were taking low-dose MRP (5 to 7.5 mg/daily) as a baseline treatment, from at least 6 months. They were matched to 9 controls, defined as SLE patients with the same age and duration of disease, taking the same prednisone dose, from at least 6 months, in the IR formulation. Overall pregnancy outcome features; SLE disease activity (calculated at least once during pregnancy, SLEPDAI) and at baseline/post-partum (SLEDAI) score; patient's global assessment (VAS) at baseline, during pregnancy and in postpartum (mm); need of treatment changes throughout pregnancy and at postpartum (%) were assessed. Homogeneity tests, percentages and scores comparison were run out by non-parametric statistical analysis.
Results: Mean MRP age group was 26±7; disease duration, 4±8 years; IR one, respectively, 28±6 and 3±9 (both, p=ns). SLEDAI at baseline was 1±0.1 among MPR and 1±0.3 among IR women; SLEPDAI, 1±0.9 and 2±0.2 (both, p=ns). No major perinatal complications were detected. Preterm births, cesarean section rates, newborns weight and APGAR scores did not differ between the two subpopulations (all, p=ns). SLEDAI assessed at postpartum was 2.8±0.6 in MRP subjects and 3.4±0.4 in IR (p<0.05). Patients VAS (MRP *vs* IR) was 3±0.4 and 2±09 at baseline (p=ns); 2±0.6 and 4±0.7 during pregnancy (p<0.05) and 3±0.3 and 4±0.9 at postpartum (p<0.05). Regarding treatment regimen changes (add-on strategy), the observed rates involved 1/9 (MRP) and 5/9 (IR) women during the observational gap (pregnancy+postpartum) (p<0.001). Results synthesis is reported in Table I.

	Cases MRP	P value	Controls IRP
Age (years±months)	26±52	ns	28±43
Disease duration (years±months)	4±8	ns	3±9
PDN dose baseline (mg)	5±2.5	ns	5±2.5
SLEDAI baseline	1±0.1	ns	1±0.3
VAS baseline (mm)	20±6	ns	21±5
PDN dose pregnancy (mg)	5±2.5	p<0.05	7.5±2.5
SLEPDAI	1±0.9	p<0.05	3±0.2
VAS pregnancy (mm)	41±8	p<0.05	23±7
Gestation (weeks±days)	38±5	ns	37±6
Child weight (g)	3230±420	ns	3120±390
APGAR	9±1	ns	9±0
PDN dose postpartum (mg)	2.5±2.5	p<0.05	5±2.5
PDN need to change (%)	11	p<0.001	56
SLEDAI postpartum	2.8±0.6	p<0.05	3.4±0.4
VAS postpartum (mm)	50±4	p<0.05	71±6

Conclusions: Activity (SLEDAI) score was significantly higher at postpartum and treatment had to be increased in IR patients, in comparison to the MRP, to manage SLE. VAS, conversely, was significantly higher among IR, both during pregnancy and postpartum. No major perinatal side effects were observed during the study; minor and expected complications rates did not differ between the two subpopulations. Despite the limited number of subjects, MRP treatment seems to be as safe, but more effective, in comparison to the standard IR one, during pregnancy of SLE-affected women.

DOI: 10.1136/annrheumdis-2017-eular.3135

SAT0248 BASELINE CLASI-DAMAGE IS A MAJOR PREDICTOR OF SKIN RESPONSE TO BELIMUMAB IN A MULTICENTRIC COHORT OF SLE PATIENTS

M. Gatto[1], L. Iaccarino[1], L. Andreoli[2], F. Conti[3], R. De Angelis[4], S. De Vita[5], L. Emmi[6], R. Gerli[7], M. Govoni[8], M. Mosca[9], C. Salvarani[10], A. Tincani[2], A. Doria[1]. *[1]Unit of Rheumatology, University of Padova, Padova; [2]Rheumatology and Clinical Immunology Unit, Spedali Civili and University of Brescia, Brescia; [3]University LA Sapienza, Rome; [4]Rheumatology Unit, Univerisity of Marche, Iesi; [5]University of Udine, Udine; [6]AOU Careggi, Florence; [7]Rheumatology Unit, University of Perugia, Perugia; [8]Unit of Rheumatology, University of Ferrara, Ferrara; [9]Unit of Rheumatology, University of Pisa, Pisa; [10]Rheumatology Unit, Arcispedale S Maria Nuova - IRCCS, Reggio Emilia, Italy*

Background: Belimumab is used to treat several systemic lupus erythematosus (SLE) manifestations and predictors of response are advisable in clinical practice.
Objectives: To explore the effects of belimumab treatment on skin involvement in SLE patients in a real-life setting.
Methods: SLE patients treated with belimumab (10 mg/kg day 0, 14, 28 and then every 28 days), as add-on therapy in 11 Italian cohorts were prospectively followed-up for 24 months. Skin involvement was measured by the CLASIa score (Cutaneous Cutaneous LE Disease Area and Severity Index Activity) at baseline and every six months until month 24. Damage was measured by CLASI-Damage (CLASId). Response was defined as CLASIa <2 at measured timepoints.
The following variables were tested to determine baseline predictors of response at 12, 18 and 24 months: gender, age, disease duration, SLE activity index 2000 (SLEDAI-2K) ≥10, prednisone dose >7.5 mg/day, baseline CLASIa and CLASId, concomitant immunesuppressants (yes/no) and number of previous immunesuppressants. Statistical analysis was performed with SPSS 22.0 software.
Results: 188 patients were studied, among whom 48 (25.5%) had skin involvement as the leading feature for belimumab therapy. Mean follow-up period was 17.5±10.96 months. Thirty-eight patients completed a 6-month follow-up; 27 completed a 12-month follow-up; 19 completed a 18-month follow-up and 15 completed a 24-month follow-up. Fourteen patients discontinued due to adverse events (7/14, 50%), lack of efficacy (4/14, 28.5%) or other causes (3/14, 21.4%). CLASIa, daily prednisone dosage and SLEDAI-2K significantly decreased during the follow-up (p<0.001). CLASIa<2 was achieved by 25/38 patients (65.7%) at 6 months, 19/27 (70%) at 12 months, 11/19 (58%) at 18 months and 10/15 (67%) at 24 months. A lower baseline CLASIa was associated with CLASIa response at 18 and 24 months (responders vs. non-responders: 3.4±2.4 vs. 9.5±5.6; 3.5±2.5 vs. 11.2±6.5; p<0.005 for both), while a lower baseline CLASId was associated with CLASIa response at each timepoint (responders vs. non-responders: at 12 months: 0.6±0.9 vs. 2.4±2.5; at 18 months: 0.5±0.8 vs. 2.5±2.3; at 24 months: 0.6±0.8 vs. 3.25±2.7; p=0.01 for all). Multivariate analysis was only performed at 12 months due to low patient number at 24 months. CLASId was the only independent negative predictor of response (OR 0.52, p=0.05). Notably, CLASId remained stable during the follow-up.
Conclusions: Belimumab use in cutaneous involvement is associated with reduced activity in skin lesions and hindrance of skin damage. Early use of belimumab before damage is established is likely to be associated with a better response.

SAT0249 SAFETY, PHARMACOKINETICS, PHARMACODYNAMICS AND INHIBITION OF T-CELL DEPENDENT ANTIBODY RESPONSE (TDAR) WITH MEDI4920, A NOVEL, ENGINEERED CD40 LIGAND (CD40L) ANTAGONIST: RESULTS OF A FIRST-TIME-IN-HUMAN STUDY

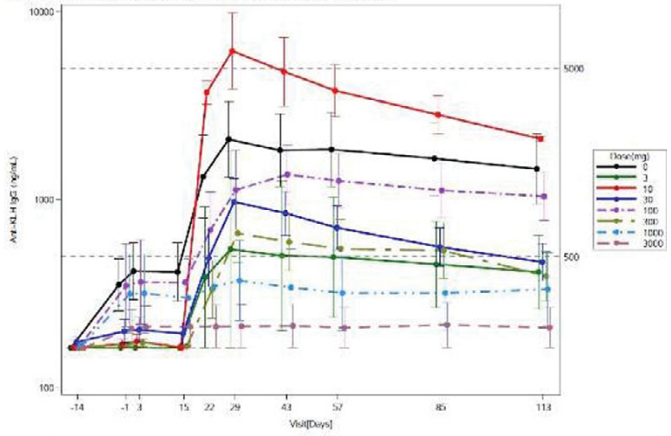
M.G. Albulescu[1], M. Gunsior[2], J. Li[3], J. Bush[4], A. Godwood[1], R. Miday[2], E. Grant[5], D. Howe[1], R. Faggioni[3], L. Roskos[2]. *[1]MedImmune, Cambridge, United Kingdom; [2]MedImmune, Gaithersburg; [3]MedImmune, Mountain View, United States; [4]Covance Clinical Research Unit Ltd, Leeds, United Kingdom; [5]Gilead Sciences Inc, Foster City, United States*

Background: The CD40/CD40L pathway is involved in the T-cell-dependent activation of B cells, which subsequently produce autoantibodies and inflammatory mediators that contribute to autoimmune disease pathology. MEDI4920 is an engineered fusion protein and antagonist of CD40L that lacks the fragment crystallisable (Fc) domain thought to be involved in thromboembolic events (TEs) previously reported with anti-CD40L agents containing an Fc domain.
Objectives: The primary objective of this Phase I, randomised, double-blind, placebo-controlled, single-ascending dose study was to evaluate the safety and tolerability of MEDI4920 in healthy subjects. Secondary objectives were to characterize T-cell-dependent antibody response (TDAR) to keyhole limpet hemocyanin (KLH) neoantigen, pharmacokinetics (PK), and anti-drug antibodies (ADAs) to MEDI4920.
Methods: Fifty-six healthy adult male subjects, aged 19–49 years, received a single intravenous dose of either MEDI4920 (3, 10, 30, 100, 300, 1000 or 3000 mg) or placebo. TDAR inhibition was analysed by measuring serum concentrations of

IgG and IgM antibodies to KLH over time. A dose–response model was generated for TDAR inhibition. Blood samples were collected to evaluate PK, total soluble CD40L (sCD40L) and ADA concentrations.

Results: No deaths, TEs, severe or serious hypersensitivity reactions or infections or infusion-related reactions were observed in the study. One serious adverse event (fractured tibia) was reported in the placebo arm. MEDI4920 showed inhibition of the TDAR IgG response after the second administration of KLH on Day 15 at higher doses (≥300 mg; Figure 1A). An E_{max} model adequately characterised the TDAR dose–response at Day 43 ($p<0.001$; ED_{50}=491 mg), with the 3000 mg dose showing 86% inhibition of the TDAR (95% CI: 68–94%; Figure 1B). MEDI4920 exhibited linear PK. MEDI4920 produced a dose-dependent increase in total sCD40L concentrations. A high ADA incidence (90%) was observed in dose cohorts ≤100 mg; however, ADA incidence (29%) and ADA titres decreased with ≥300 mg doses of MEDI4920. ADA-high subjects had reduced MEDI4920 and total sCD40L concentrations compared with ADA-negative subjects or those with low ADA titres. ADA incidence did not correlate with any clinical events.

Figure 1A: Plot of mean anti-KLH IgG concentrations over time



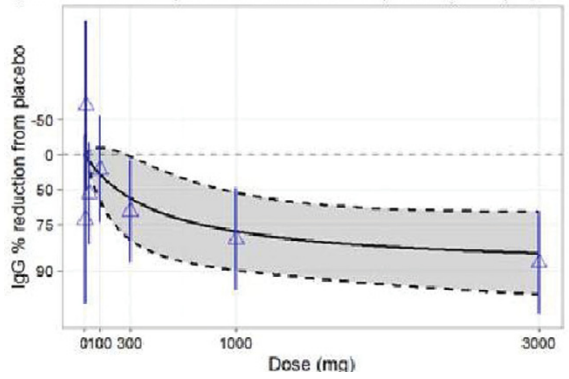


Figure 1B: Plot of dose–response model for TDAR inhibition (anti-KLH IgG at Day 43)

Conclusions: MEDI4920 demonstrated an acceptable safety and tolerability profile, and dose-dependent inhibition of TDAR. The dose-dependent increase in total sCD40L concentrations indicates binding of MEDI4920 to sCD40L and target engagement. The decreases in ADA incidence and ADA titres correlate with increasing MEDI4920 dose, consistent with the immunosuppressive mechanism of action of this molecule. These results support further exploration of MEDI4920 administration in subjects with autoimmune diseases where the CD40/CD40L pathway is activated.

SAT0250 BODY MASS INDEX IS INVERSELY ASSOCIATED WITH RESPONSE TO RITUXIMAB IN LUPUS NEPHRITIS: ANALYSIS OF THE LUNAR TRIAL

M.D. Cascino[1,2], L.M. Gomez Mendez[1], J. Garg[2], L. Dragone[2], M. Dall'Era[1], P. Brunetta[2]. [1]*University of California – San Francisco, San Francisco;* [2]*Genentech, Inc., South San Francisco, United States*

Background: Increased body mass index (BMI) has been associated with poor functional capacity and systemic inflammation in lupus,[1] alterations in rituximab (RTX) pharmacokinetics,[2] and failure to achieve trial endpoints among patients treated with RTX for ANCA-associated vasculitis.[3] Although RTX is not approved for the treatment of lupus nephritis (LN), current EULAR/ERA-EDTA guidelines include RTX for use in refractory cases.[4] The effect of BMI on outcomes of patients treated with RTX for LN is unknown.

Objectives: To assess the association between pre-treatment BMI and renal response using data from the LUNAR trial.

Methods: LUNAR randomized 144 patients with ISN/RPS class III or IV LN to RTX (2 doses of 1000 mg at baseline and month 6) or placebo in combination with mycophenolate and a steroid taper.[5] BMI was measured at the screening visit. Complete renal response (CRR) was defined as achievement of UPCR <0.5, normal serum creatinine not increased from baseline by >15%, and inactive urinary sediment at week 52. Alternative definitions of response and achievement of CRR at week 78 were also considered. Logistic regression was used to model interactions and to calculate odds ratios (OR) and 95% CI. Peripheral $CD19^+$ B cell measurements were examined.

Results: We identified qualitative interactions between BMI and treatment for CRR and alternative response measures. In unadjusted analysis, each 5 kg/m^2 increase in pre-treatment BMI was associated with OR =0.47 (95% CI 0.24–0.92) in the RTX group and OR =1.44 (95% CI 0.93–2.23) in the placebo group for achievement of CRR (*P* value for interaction =0.006). The results of analysis adjusted for baseline UPCR and serum creatinine are presented in the Table. A sensitivity analysis identified consistent associations between BMI and response in the RTX group only. Among patients in the RTX group, increased BMI was associated with increased time to peripheral $CD19^+$ count <5 cells/μL (Figure).

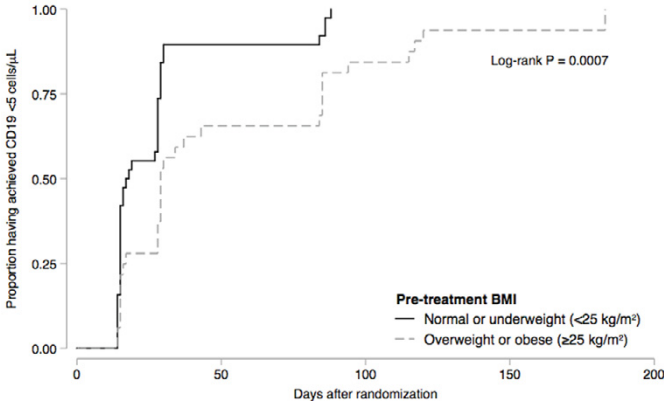

Table 1

	Adjusted OR (95% CI) per 5 kg/m^2 increase in pre-treatment BMI		*P* value for interaction
Response measure	Rituximab (n=72)	Placebo (n=72)	
CRR	0.48* (0.23–0.97)	1.60* (1.01–2.55)	0.005
Overall renal response	0.78 (0.51–1.19)	1.42 (0.94–2.16)	0.045
UPCR <0.5	0.61* (0.38–0.97)	1.37 (0.91–2.07)	0.010
UPCR <0.7	0.58* (0.37–0.92)	1.33 (0.87–2.02)	0.010
CRR at week 78	0.53* (0.29–0.99)	1.58 (0.99–2.52)	0.006

*P <0.05.

All endpoints were measured at week 52 except where specified.

Figure. Kaplan-Meier estimates: Time to peripheral $CD19^+$ count <5 cells/μL

Conclusions: In this exploratory analysis of the LUNAR trial, BMI was inversely associated with renal response among patients treated with RTX. We did not observe this same relationship between BMI and response among patients in the placebo group, and in fact found evidence of a positive correlation between BMI and one measure of response in this group. Among patients treated with RTX, BMI was associated with time to B cell depletion, generating the hypothesis that the observed differences in response are mediated by differences in the timing and/or degree of B cell depletion. These findings warrant additional analyses to better understand the relationships between patient characteristics, pharmacokinetics, B cell depletion, and treatment response in the LN population.

SAT0251 PREDICTING AND MANAGING PRIMARY AND SECONDARY NON-RESPONSE TO RITUXIMAB USING B-CELL BIOMARKERS IN SYSTEMIC LUPUS ERYTHEMATOSUS

M.Y. Md Yusof[1,2], D. Shaw[1], Y.M. El-Sherbiny[1,2], A.C. Rawstron[3], P. Emery[1,2], E.M. Vital[1,2]. *[1]Rheumatology, Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]NIHR Leeds Musculoskeletal Biomedical Research Unit; [3]Haematological Malignancy Diagnostic Service, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

Background: Rituximab (RTX) is the most commonly used biologic for the treatment of SLE. However, there is are no clinically applicable predictors of response, which is of particular importance in this heterogeneous disease with other biologics being restricted to certain subgroups.
Objectives: To assess factors associated with primary and secondary non-response to RTX in SLE in order to develop more targeted and effective B-cell therapy.
Methods: A prospective observational study was conducted in 125 SLE patients treated with RTX in Leeds for over 12 years. A major clinical response was defined as improvement of all active BILAG-2004 domains to grade C/better and no A/B flare. Partial responders were defined by 1 persistent BILAG B. B-cell subsets were measured using highly sensitive flow cytometry. Predictors of response were analysed using logistic regression analysis.
Results: 117 patients had evaluable data. In cycle 1 (C1), 96/117 (82%) achieved BILAG response [major=50%,partial=32%]. In MVA, younger age & B-cell depletion at 6 weeks increased the odds of major response (Table 1). Complete depletion was predicted by normal complement & lower pre-RTX plasmablasts. 77 (with data on 72) C1 responders were retreated on clinical relapse. Of these, 61/72 (85%) responded in C2. Of 11 C2 non-responders, 9 met secondary non-depletion non response (2NDNR) criteria, as defined by *infusion reaction & defective depletion (*incidence=12%) and tested positive for anti-RTX antibodies. Lack of concomitant immunosuppressant & higher pre-RTX plasmablasts predicted 2NDNR.
Conclusions: B-cell subsets should be monitored in the routine care of SLE patients receiving RTX and should aim to achieve complete depletion. About 1 in 8 SLE patients lose depletion on repeat cycles and this is associated with anti-RTX antibodies. Clinical trials using more intensive RTX treatment regimens in those predicted not to completely deplete, or alternatively use of humanised anti-CD20mAbs are likely to increase clinical response rates to B-cell depleting agents.

SAT0252 THE NUMBER OF TREG CELLS IN PERIPHERAL BLOOD IN PSS PATIENTS IS DECREASED AND LOW DOSE IL-2 CAN PROMOTE ITS PROLIFERATION

M. Miao[1], Z. Hao[1], Y. Guo[1], X. Zhang[2], S. Zhang[1], X. Wu[2], D. Xu[1], C. Gao[3], X. Li[2]. *[1]The Second Hospital of Shanxi Medical University; [2]Department of Rheumatology, the Second Hospital of Shanxi Medical University, Taiyuan, China; [3]Department of Pathology, Joint Program in Transfusion Medicine, Brigham and Women's Hospital/Children's Hospital Boston, Boston, United States*

Background: PSS is a kind of autoimmune disease without clear pathogenesis. Treg cell plays an important role in autoimmune disease. However, opinions about change of amount of Treg cells in peripheral blood in autoimmune disease are various. Besides, the researches mainly focus on RA and SLE but not PSS.
Objectives: To explore the change of the number of Th17 and Treg (CD4+CD25+Foxp3+T cells) cells in peripheral blood in PSS and the effects of low dose IL-2 therapy on the balance of Treg and Th17 cells.
Methods: One hundred and ninety two PSS patients in our department, and 30 healthy controls were put in the research. The amount of Th17 cells and Treg cells were calculated by flow cytometry. Eighty eight in 192 were given low-dose IL-2 (50 WIU/day for 5 days) by hypodermic injection combined with standard therapy which includes glucocorticoid, immune-suppressants, biological agents or combination of them, while others (12 in 69) were given standard therapy only. The amount of these cells were calculated again after therapy.
Results: There was significant decrease in the absolute number of Treg cells and significant increase of the ratio of Th17/Treg cells in PSS patients when compared with healthy controls. There was no significant difference in absolute number of Th17 cells between PSS patients and healthy controls. Further, the number of Treg cells were negatively relative to ESSDAI. Traditional DMARDs had no obvious impact on Treg and Th17 cells. The amount of Treg cells significantly increased after the treatment of IL-2 by 1 week. But there was no significant improvement in clinical manifestations in the short time when comparing combinational treatment of IL-2 and classical drugs with classical therapy. No obvious adverse reactions were observed.

Table 1. Absolute number and percentage of CD4+T subsets in peripheral blood in PSS patients and Healthy controls.

Study Participants	Health	PSS	Untreated PSS
Th17	6.44 (5.10, 8.55)	7.09 (4.05, 11.48)	6.08 (4.30, 12.60)
Treg	36.20 (27.82, 47.02)	28.24 (15.89, 41.36)*	27.30 (17.43, 39.87)*
Th17%	0.96 (0.67, 1.33)	1.26 (0.77, 1.95)*	1.26 (0.86, 1.92)^
Treg%	4.80 (4.19, 6.37)	4.64 (3.10, 6.44)	4.70 (2.52, 6.91)
Th17/Treg	0.18 (0.14, 0.29)	0.27 (0.15, 0.43)*	0.28 (0.15, 0.47)^

Median (range, cells/μl). ^P<0.1, *p<0.05, **p<0.01, ***p<0.0001 vs Healthy controls.

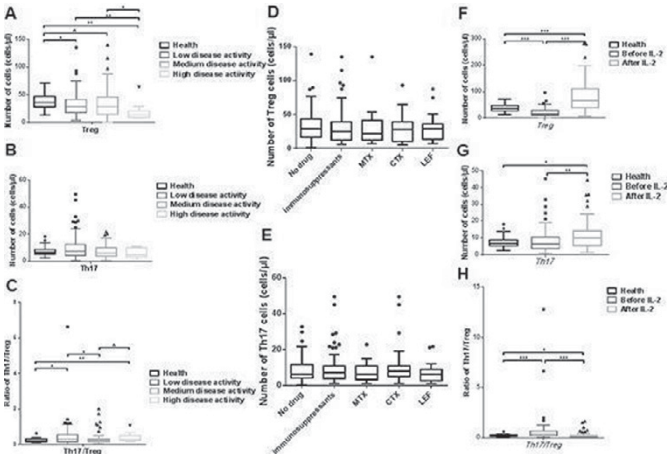

Figure 1

Conclusions: The number of CD4+CD25+Foxp3+T cells in peripheral blood was decreased obviously and was inversely related to ESSDAI. While there was no significant difference of Th17 cells between PSS patients and healthy controls. And there was no correlation between the number of Th17 cells and ESSDAI. So the imbalance of Th17/Treg is due to the decrease of Treg cells not increase of Th17 cell which indicates that the pathogenesis of PSS maybe mainly because of shortage of autoimmune tolerance. Low dose IL-2 therapy can effectively promote proliferation of Treg cells by which low dose IL-2 may induce and restore autoimmune tolerance to benefit disease control.

SAT0253 EFFICACY AND SAFETY OF LEFLUNOMIDE THERAPY IN LUPUS NEPHRITIS:A META-ANALYSIS

Q. Ren[1], H. Zeng[2]. [1]*Department of Pediatric Allergy, Immunology and Rheumatolog;* [2]*Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children's Medical Center, Guangzhou, China*

Objectives: To evaluate the efficacy and safety of leflunomide in treating lupus nephritis (LN).
Methods: According to the requirements of meta-analysis, a literature search about efficacy and safety of leflunomide therapy in LN was performed among Cochrane clinical controlled trials database, PubMed, BMJ-Clinical Evidence, CNKI, VIP and Wanfang data from the establishment of the database till December 2010.All included RCTs were graded in term of randomization, allocation concealment and blinding and non-RCTs were graded in term of grouping method, blinding, withdrawal and loss of follow-up, baseline comparability, diagnostic criteria and bias control. RevMan 5.0 software was used for meta-analysis.
Results: A total of 828 literatures were included. Five RCTs and 2 non-RCTs were enrolled for meta-analysis.Leflunomide group was treated with leflunomide and glucocorticoid, while control group was given cyclophosphamide and glucocorticoid or placebo. The 24 h urine protein, SCr and SLEDAI scores of leflunomide group were significantly lower than that of cyclophosphamide group. There was no significant difference in C3,positive rate of anti-ds DNA between leflunomide group and cyclophosphamide group. There was no significant difference in infection, herpes zoster,hypertension, palpitations, leukopenia, alopecial, elevation in ALT, memoxenia, rashes, or the incidence of gastrointestinal reactions between the two groups.
Conclusions: Based on the current evidence, the efficacy and safety of leflunomide for treatment of LN are close to cyclophosphamide. Further evidence from RCT studies is needed to elucidate the efficacy and safety of leflunomide for LN.

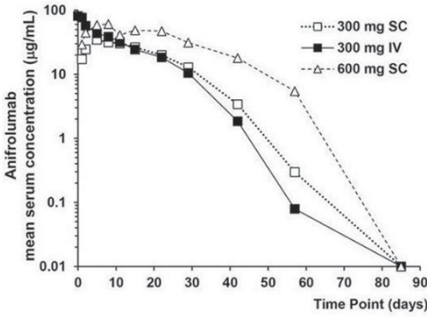
SAT0254 SAFETY, TOLERABILITY, AND PHARMACOKINETICS OF SUBCUTANEOUS AND INTRAVENOUS ANIFROLUMAB IN HEALTHY VOLUNTEERS

R. Tummala[1], T. Rouse[2], A. Berglind[2], L. Santiago[3]. [1]*AstraZeneca, Gaithersburg, MD, United States;* [2]*AstraZeneca, Gothenburg, Sweden;* [3]*MedImmune, Mountain View, CA, United States*



Background: Anifrolumab is a fully human anti–interferon-α receptor monoclonal antibody in Phase III development for systemic lupus erythematosus (SLE). In Phase IIb trials, intravenous (IV) anifrolumab (300 mg every 4 weeks) significantly decreased SLE disease activity with safety and tolerability comparable to placebo.[1]
Objectives: The primary objective of this Phase I, double-blind, randomized, controlled study (NCT02601625) was to characterize the pharmacokinetics (PK), safety, and tolerability of anifrolumab administered subcutaneously (SC) and intravenously to healthy volunteers.
Methods: Thirty male and female adults were assigned to three sequential treatment cohorts of equal size (anifrolumab 300 mg SC injection; anifrolumab 300 mg IV; anifrolumab 600 mg SC by infusion). Individuals were randomized within each cohort to receive a single dose of either anifrolumab (n=6/cohort) or placebo (PBO) (n=4/cohort). Serial blood samples were collected up to Day 85. Serum anifrolumab concentrations were analyzed with a validated assay. PK parameters were estimated by noncompartmental analysis. Immunogenicity of anifrolumab was assessed by measuring serum anti-drug antibodies (ADAs).
Results: Anifrolumab serum concentration-time profiles and primary PK parameters in healthy volunteers are presented in the figure and table, respectively. Anifrolumab serum concentrations were below the limit of detection in all individuals by 85 days post dose. Maximum serum concentrations in the SC cohorts occurred after 4 to 7 days. Exposure to SC anifrolumab increased approximately dose proportionally from 300 mg to 600 mg based on AUC. At the 300-mg dose, anifrolumab exposure after SC administration reached approximately 86% of the IV administration exposure. SC administration of anifrolumab 300 mg and PBO elicited minimal injection-site reactions. Transient injection-site induration occurred in five of six individuals in the anifrolumab 600-mg group and two of four in the PBO group. Transient, mild to moderate injection-site induration and pruritus occurred simultaneously in two of six individuals in the anifrolumab 600-mg group, but not those in the PBO group. Adverse events were reported by 50% (n=9) of anifrolumab-treated and 33% (n=4) of PBO-treated individuals. No serious adverse events were observed. ADAs were detected in only one individual in the anifrolumab 300-mg IV group at the Day-85 assessment.

Anifrolumab Serum PK Parameters

	Anifrolumab		
	300 mg SC (N=6)	300 mg IV (N=6)	600 mg SC (N=6)
C_{max} (μg/mL)			
Mean ± SD	36.2±11.6	82.4±13.2	63.9±20.5
CV (%)	32.1	16.0	32.0
AUC (day.μg/mL)			
Mean ± SD	785±331	907±175	1,828±680[a]
CV (%)	42.1	19.3	37.2
t_{max} (day)			
Median	4.13	0.03	7.00
Minimum–maximum	4.02–7.00	0.03?1.03	3.96?8.95

[a]N=5 because 1 individual was lost to follow-up at 1 month post dose. AUC = area under serum concentration-time curve from time zero extrapolated to infinity; C_{max} = observed maximum serum concentration; CV = coefficient of variation; t_{max} = time to reach maximum serum concentration.

Serum Concentration–Time Profiles

Mean data below limits of detection are plotted as 1/2 of the lower limits of quantification (0.02 μg/mL).

Conclusions: Exposure of anifrolumab 300 mg SC was approximately 86% of IV administration, with single SC administrations of anifrolumab being generally well-tolerated in healthy volunteers.

SAT0255 A RANDOMIZED, PLACEBO-CONTROLLED, DOUBLE-BLIND, ASCENDING-DOSE, SAFETY STUDY OF CC-220 IN SUBJECTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

V.P. Werth[1], R. Furie[2], S. Korish[3], M. Weiswasser[3], A. Azaryan[3], P.H. Schafer[3], N. Delev[3], S. Choi[3], D. Hough[3]. [1]*University of Pennsylvania School of Medicine, Philadelphia;* [2]*Northwell Health, Great Neck;* [3]*Celgene Corporation, Summit, United States*

Background: CC-220 is a CUL4CRBN E3 ubiquitin ligase modulator that binds to cereblon and leads to potent and deep reduction of the transcription factors Ikaros (IKZF1) and Aiolos (IKZF3), which are overexpressed in the peripheral blood of Systemic Lupus Erythematosus (SLE) subjects. This study evaluated the safety, and tolerability of CC-220 in subjects with SLE. Exploratory efficacy assessments were included.
Methods: Subjects with history of SLE ≥6 months and a baseline of hybrid SELENA-SLEDAI (hSS) score ≥4 were randomized to 1 of 4 escalating doses of CC-220 or matching placebo (PBO). The 4 active treatments were CC-220 0.3 mg QOD, 0.3 mg QD, 0.3 mg alternating with 0.6 mg QD, and 0.6 mg QD; subjects were randomized 4:1 active to PBO in each group for 12 weeks of treatment, followed by 12 weeks of observational follow-up and/or long-term extension. Stable doses of corticosteroids (≤10 mg prednisone or equivalent daily), non-steroidal anti-inflammatory drugs, and antimalarials were permitted. Safety assessments included clinical evaluation of adverse events (AEs), laboratory parameters, electrocardiograms, physical examinations, and overall tolerability. Exploratory efficacy assessments included hSS, Cutaneous Lupus Area and Severity Index (CLASI) skin scores, Physician Global Assessment (PGA), swollen joint counts (SJC), and tender joint counts (TJC).
Results: A total of 42 adult subjects were randomized; 39 subjects were female (93%); Mean age was 47.2 years; 64% were White and 31% were Black or African-American. Mean SLE duration was 9.4 years, with a mean baseline hSS score of 6.6, CLASI activity score of 9.8, and PGA score of 1.3. Seventy-nine percent of subjects completed the study; 9 of 42 subjects discontinued, of which 6 subjects discontinued due to an adverse event (AE): 1 in the placebo group and 5 in the 2 highest CC-220 groups combined. No discontinuations were due to lack of efficacy. Four subjects had serious AEs (highest CC-220 doses: n=2 [pneumonia]; PBO: n=2). Three subjects had neutropenia (grade 3: n=2; grade 1: n=1); 2 subjects in the highest CC-220 dose group had dermatitis, and 1 subject in the 0.3 mg QD and 1 in the 0.6 mg QD dose groups had urticaria. Mean reductions in the CLASI activity score at day 85 ranged from 4.3 to 7.8 in the CC-220 treatment groups compared to an increase of 0.4 in the placebo group. More subjects receiving CC-220 had a ≥4-point reduction in hSS score vs PBO by Day 85 (22.2%>50.0% vs 12.5%).
Conclusions: CC-220 was generally well tolerated in this SLE population over 12 weeks of treatment, with neutropenia and dermatitis observed at the highest doses studied. Treatment with CC-220 resulted in a trend toward greater improvement

in multiple measures of SLE disease activity compared with PBO. These results support further development of CC-220 in SLE patient population.

SAT0256 MULTI-TARGET THERAPY WITH MIZORIBINE, TACROLIMUS, AND PREDNISOLONE IN LUPUS NEPHRITIS: ANALYSIS OF 47 CASES

R. Kawato, R. Rokutanda, M. Kishimoto, M. Okada. *Immune-rheumatology center, St.luke hospital, Tokyo, Japan*

Background: Mizoribine (MZB), an inosine monophosphate dehydrogenase inhibitor, is an effective glucocorticoid-sparing agent for gromerulonephritis and variety of rheumatic diseases. However, its clinical usefulness as multi-target therapy in patients of lupus nephritis has been unclear.
Objectives: To evaluate efficacy of multi-target therapy with MZB, tacrolimus (TAC) and prednisolone (PSL) for lupus nephritis.
Methods: We extracted all the cases with lupus nephritis treated with PSL, MZB, and TAC during period from 2008/1 to 2016/10. Retrospective medical chart review was performed to collect following data; baseline patient characteristics, dose of PSL, serum creatinine, urine protein, compliment, anti-DNA ab, remission rates, and safety profiles. We define complete remission as urine protein $<$0.5 g/gCre and normal serum creatinine, partial remission as urine protein decreasing more than 50% at baseline, and $<$3g/day, and normal serum creatinine or increasing within 15%. Patents' records were followed from the beginning of multi-target treatment to 12 months after.
Results: 43 cases (female; n=37, male; n=6, mean age; 37.4 years old) were included for analysis. Of 30 cases who underwent renal biopsy, 10 cases were classified as class IV nephritis, and 7 cases were classified as class III nephritis. Mean urine protein (g/gCr) at baseline, at 3 months, and at 6 months are 1.9, 0.4, and 0.4, respectively. Mean dose of steroid was 32.8 mg/day at baseline, 9.8 mg/day at 3 months, and 8.7 mg/day at 6 month. 79.1% of the patients achieved complete remission at 3 months, and the remission rate was more than 80% at 6 months and later. As for adverse events, 14 cases had some Infection, 3 out of 14 needed antibiotics treatment. Four cases had renal impairment after starting TAC, all of them recovered after stopping or decreasing dose of TAC.
Conclusions: Multi-target therapy with MZB, TAC and PSL showed good remission rate, and few severe adverse events. We need the further evaluation of long-term efficacy of the therapy.

SAT0257 "AIMING FOR THE BULLSEYE": RETINAL TOXICITY SCREENING FOR HYDROXYCHLOROQUINE THERAPY – ARE WE HITTING THE TARGET?

S. Gubbins, J. Steen, A. Gorman, S. Khan, A. Mohammad, K. O'Rourke. *Rheumatology, Midlands Regional Hospital Tullamore, Tullamore, Ireland*

Background: Hydroxychloroquine (HCQ) is commonly used to treat a variety of rheumatological and inflammatory conditions such as RA, SLE and Sjogrens. Retinal toxicity is a well known complication of HCQ therapy. Initially, the incidence of retinal toxicity was believed to be quite minimal1. However, subsequent large epidemiological studies have highlighted its much greater prevalence-up to 7.5% in certain populations2,3. Furthermore, the visual toxicity is typically permanent with possible progression up to years after drug cessation and with no current treatment4. Detection at an early stage has been shown to be crucial in preserving central vision and foveal architecture5. As a result ophthalmological screening is an essential consideration for any patient on HCQ therapy.
In view of the updated scientific data available on toxicity prevalence and the benefits of screening, the American Academy of Ophthalmology (AAO) have updated their screening recommendations for 20166. This includes baseline fundus examination to rule out pre-existing maculopathy and annual screening after 5 years of treatment.
Objectives: To investigate compliance with the AAO Recommendation on Screening for Chloroquine and Hydroxychloroquine Retinopathy (2016)6 in a regional rheumatology centre.
Methods: A retrospective analysis was undertaken of the electronic patient records of 161 patients with a diagnosis of connective tissue disease at a single regional centre assessing level of antimalarial usage, adherence to screening guidelines and level of documented toxicity.
Results: Of our cohort, 91 (56%) were on regular HCQ. Of these, 12 had received routine ophthalmology screening and 4 developed documented ocular toxicity. 15 suffered non-ophthalmic toxicity requiring therapy cessation. 46 had been on therapy greater than 5 years and of these 9 (21.5%) had been screened.
Conclusions: Our analysis revealed significant deficiencies in routine screening and demonstrated a high level of toxicity in patients who were routinely screened. This indicates that there may be a significant number of patients with toxicity that is not being picked up and reinforces the importance of screening. We would recommend a more streamlined referral pathway for rheumatology patients on HCQ and hypothesise that this would lead to greater and earlier pick-up of ocular toxicity in this population, ultimately reducing morbidity in this population.

SAT0258 SYNERGETIC B-CELL IMMUNOMODULATION WITH RITUXIMAB AND BELIMUMAB IS CLINICALLY EFFECTIVE IN SEVERE AND REFRACTORY SYSTEMIC LUPUS ERYTHEMATOSUS – THE SYNBIOSE PROOF-OF-CONCEPT STUDY

T. Kraaij[1], S.W. Kamerling[1], E. de Rooij[1], P.L. van Daele[2], I. Bajema[3], O.W. Bredewold[1], T.W. Huizinga[4], T.J. Rabelink[1], C. van Kooten[1], Y.K. Teng[1]. *[1]Nephrology, LUMC, Leiden; [2]Immunology, Erasmus MC, Rotterdam; [3]Pathology; [4]Rheumatology, LUMC, Leiden, Netherlands*

Background: The pathogenesis of systemic lupus erythematosus (SLE) is characterized by B-cell hyperactivity leading to autoreactive plasma cells (PCs) that produce pathogenic autoantibodies and contribute to onset and maintenance of SLE. Therefore, novel treatment strategies in SLE are aimed at targeting autoreactive PCs. Rituximab (RTX) is used as off-label treatment in SLE and depletes CD20+ B-cells effectively, but is unable to deplete CD20- PCs. Belimumab (BLM), an anti-BAFF (B-cell activating factor) antibody, demonstrated efficacy in SLE as add-on therapy and resulted in reduction of B-cells and PCs.
Objectives: Because RTX+BLM has potential to target autoreactive PCs, we designed an open-label, proof-of-concept study to assess the clinical efficacy and safety of RTX+BLM in severe, refractory SLE patients.
Methods: A phase 2 proof-of-concept study, the SynBioSe study, was set up to treat severe, serologically active and refractory SLE patients with RTX following BLM. The following endpoints were assessed at 24 weeks: a) clinical efficacy by SLEDAI; b) immunological effects on B-cells and PCs by high sensitivity flow cytometry, immunoglobulins and autoantibody levels, and c) safety parameters.
Results: The study included 11 severe, refractory SLE patients of which 10 had lupus nephritis and 1 patient had neuropsychiatric lupus with a median SLEDAI of 18 [range 8–29]. Treatment with RTX+BLM led to clinically significant improvement to a median SLEDAI score of 2 [0–13] (p=0.002). Low disease activity (SLEDAI $<$4) was achieved in 80%. Clinical response was achieved while tapering steroids from a median dose of 60 [0–60] to 7.5 mg [0–12.5] and concomitant mycophenolate (MMF) was tapered to zero in all patients. With respect to safety, 23 adverse events (AEs) were reported of which none were serious AEs, 8 mild infections and 2 hypogammaglobulinemia. Complement usage was restored in all patients with a median increase in C3 of 33% [range 8–133] and in C4 levels of 39% [9–266]. RTX+BLM led to reduction of anti-dsDNA antibodies, from median 120 IU/ml [18–505] to 35 IU/ml [10–374] (p=0.012). CD19+ B-cells were depleted throughout the complete follow up (from median $206*10^6$ cells/L [range $21*10^6$-$511x10^6$] at screening to $5x10^6$ [0–$24x10^6$] at 24 weeks, p=0.004), including transitional B-cells (from median $1.3x10^3$ cells/L [1–$1.3x10^4$] at screening to 98.5 [0–$3.4x10^3$] at 24 weeks, p=NS). Importantly, total immunoglobulin levels only declined temporarily. The latter was further corroborated by transient reductions in CD3-CD38brCD27brCD20- PCs from median $1.6x10^6$ cells/L [$5.6x10^3$–$1.1x10^7$] to $1.5x10^5$ cells/L [$5.3x10^4$–$1.3x10^7$] at 12 weeks (p=NS). At 24 weeks, these PCs were restored to baseline levels ($1.4x10^6$ cells/L [$9.2x10^4$–$3x10^7$]).
Conclusions: This is the first study to demonstrate that RTX+BLM effectively reduced disease activity in severe, refractory SLE without raising major safety issues, while reducing other immunosuppressant drugs. Autoreactive PCs were specifically targeted by RTX+BLM. Therefore, combination therapy of RTX+BLM is a promising strategy in severe SLE.

SAT0259 HIGH PLASMA CONCENTRATION OF MYCOPHENOLATE ACID IN EARLY PHASE OF INDUCTION THERAPY PREDICTS GOOD RENAL OUTCOME IN LUPUS NEPHRITIS CLASS III OR IV

T. Kiyokawa, H. Hanaoka, H. Iida, K. Ishimori, Y. Takakuwa, T. Okazaki, S. Ozaki.
Division of Rheumatology and Allergology, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan

Background: Mychophenolate mofetil (MMF) is recommended as initial induction treatment for most cases of lupus nephritis (LN) class III-IV. Although the association between area under the concentration-versus-time curve (AUC) of myochophenolate acid (MPA) and therapeutic efficacy has been well shown in renal transplantation, it has been poorly investigated in LN. Furthermore, MMF interacts with multiple factors and its concentration may be decreased by high prednisolone (PSL) dose, low serum albumin level and low creatinine clearance. Since these factors dramatically change in induction phase of LN, the plasma concentration of MPA may also change by fixed dose of MMF administration. Here, we measured AUC_{0-12} of MPA at different phases of induction treatment, early and middle, and prospectively investigated which concentration predicted future renal response in LN class III-IV.
Objectives: To investigate the relationship between the plasma concentration of MPA in early or middle phase of induction therapy and future renal response.
Methods: We prospectively enrolled patients with biopsy proven LN class III or IV who hospitalized from Apr to Oct 2016. As induction therapy, PSL was started at dose of 1mg/kg/day and tapered to 10mg/day by 12 weeks. Fixed dose of MMF at 2,000mg/day was continuously introduced. We measured 2 points of MPA plasma concentration depending on the phase of induction therapy, at early (week 2) and middle (week 12). We evaluated the association between these concentration and complete renal response (CR) rate at week 12.
Results: Six patients were enrolled. AUC_{0-12} between the early and the middle phase was not correlated (R^2=0.17, p=0.7), but that of the early phase tended to be lower (47.4±25.6 vs 58.9±19.1 mgh/L). All the patients with high AUC_{0-12} (over 40mgh/L) at the early phase achieved CR at week 12 (Figure 1). But we could not find any association between AUC_{0-12} at middle phase and CR rate at week 12.

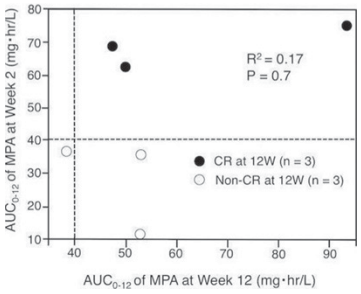

Figure 1

Conclusions: High AUC_{0-12} of MPA at the early phase of induction therapy might predict good renal response.

SAT0260 OVARIAN FUNCTION PRESERVATION WITH GONADOTROPIN-RELEASING HORMONE ANALOGUES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS TREATED WITH CYCLOPHOSPHAMIDE

V.A. Pacucci[1], F. Ceccarelli[1], G. Perrone[2], I. Zannini[2], M. Candelieri[2], I. Leccese[1], C. Perricone[1], F. Miranda[1], S. Truglia[1], F.R. Spinelli[1], C. Alessandri[1], G. Valesini[1], F. Conti[1]. *[1]Lupus Clinic, Rheumatology, Dipartimento di Medicina Interna e Specialità Mediche; [2]Gynecology, Dipartimento di Scienze Ginecologico-Ostetriche e Scienze Urologiche, Policlinico Umberto I Sapienza University of Rome, rome, Italy*

Background: The fertility in childbearing Systemic Lupus Erythematosus (SLE) patients can be impaired due to several conditions. In particular, treatment with alkylating agents, as cyclophosphamide (CYC), could determine menstrual irregularities and premature ovarian failure (POF). Gonadotropin-releasing hormone analogues (GnRH-a) is one of the preventive strategy suggested by the recently published EULAR recommendations (1). They are characterized by good safety profile and effectiveness in reducing POF rate in patients with malignancies and autoimmune diseases. So far, only few studies have been published focusing on the use of GnRH-a to prevent POF in SLE women receiving CYC treatment.
Objectives: In the present case-control study, we aimed at evaluating the efficacy of GnRH-a on the ovarian function preservation in SLE patients treated with CYC.
Methods: We enrolled consecutive SLE patients, fulfilled the 1997 ACR revised criteria treated with CYC in the period between 2005 and 2012, receiving GnRH-a (GnRH-a+). As control, SLE patients treated with CYC not receiving GnRH-a (GnRH-a-) were assessed. Clinical and laboratory data were collected in a standardized, computerized and electronically filled form. Ovarian function was assessed by the evaluation of FSH and estradiol level (E2). GnRH-a (triptorelin 3.75 mg/monthly intramuscularly) was prescribed. SLE patients treated with CYC were followed after the treatment every six months during the first year and then annually.
Results: Thirty-tree SLE patients treated by CYC were evaluated in the present analysis: 75.7% of patients were treated for lupus nephritis. Among [FC1] these, 18 GnRH-a+ (mean±SD age 29.3±7.6 years; mean±SD disease duration 7.2±4.2 years) and 15 GnRH-a- (mean±SD age 31.0±10.5 years; mean±SD disease duration 6.3±7.4 years). The mean±SD SLEDAI-2K score in GnRH-a+ patients was 10.1±3.7, in GnRH-a- patients 8.3±3.3 (p=NS). Moreover, no differences were identified concerning the duration of CYC treatment (GnRH-a+: 6.1±2.8 months *versus* GnRH-a- 6.1±2.2 months, p=NS) and follow-up (GnRH-a+: 8.11±2.2 years versus GnRH-a- 9.3±7.2 years, p=NS). The prevalence of POF was significantly higher in GnRH-a- (5 patients, 33.3%) in comparison with GnRH-a+ (2 patients, 11.1%, P=0.0002). A significantly higher mean age at the time of CYC treatment was observed in patients developing POF (37.7±5.9 years) in comparison with those not developing this complication (28.0±8.5 years, p=0.008). Moreover, the use of GnRH-a seems to be protective also in terms of menstrual cycle regularity: the cycle remained regular during treatment in 83.3% of GnRH-a+ and only in 33.3% of GnRH-a- (p=0.003). During the follow-up, 3 patients in the GnRH-a+ group underwent pregnancy, with a good outcome.
Conclusions: The results of the present study showed the protective role of GnRH-a for the preservation of ovarian function in SLE patients treated by CYC. Furthermore, the age resulted the only risk factor associated with POF development.

SAT0261 REFRACTORY SYSTEMIC LUPUS ERYTHEMATOSUS IS MAINLY ASSOCIATED WITH THE DECREASED NUMBER OF REGULATORY T CELLS AND LOW-DOSE IL-2 COMBINED WITH RAPAMYCIN CAN EFFICIENTLY RECOVERY THE BALANCE OF TH17/REGULATORY T CELLS

X. Jing[1], X. Liu[1], J. Wang[1], Y. Qiao[1], Z. Liang[1], M. Hao[1], J. Chen[1], C. Gao[2], X. Li[1]. *[1]Department of Rheumatology, The Second Hospital of Shanxi Medical University, Taiyuan, China; [2]Department of Pathology, Joint Program in Transfusion Medicine, Brigham and Women's Hospital/Children's Hospital Boston, Harvard Medical School, Boston, United States*

Background: Refractory system lupus erythematosus (SLE) still relies on aggressive treatment with high-dose glucocorticoids and immunosuppressive agents,but a significant proportion of patients persist with activity or relapse and show serious side-effects by the treatment.However, the imbalance of Th17 cells and regulatory T (Treg) cells in peripheral blood of patients with SLE may be an important factor in the pathogenesis of SLE.Because low-dose IL-2 can selectively enhance Treg function while avoiding the activation of effector T cells and rapamycin can promote the proliferation of Treg cells[1–2],the combination of the low-dose IL-2 and rapamycin has been considered to treat refractory SLE for the purpose of remission.
Objectives: To observe the effect of low-dose IL-2 combined with rapamycin on the balance of Th17/Treg cells in patients with refractory SLE.
Methods: Eighty-two refractory SLE patients (80 women and 2 men),with a mean duration of 72.41±37.52 months and mean age of 36.22±12.48 years, were enrolled.They are in line with the standard of ACR in 1997,who are treated with glucocorticoid and immunosuppressant for more than one year, but the subjects continues to rise to a peak.After the eligible patients are given IL-2 and rapamycin in combination therapy with conventional therapy at 0, 6, 12, 24 week respectively after medication.The clinical symptoms, blood routine, urine routine, ESR, Th17 cells, Treg cells, Th17/Treg cells and the dosage of corticosteroids and immunosuppressant are registered one by one.
Results: At 24 week after treatment,28.9% patients with refractory SLE were relieved.Low-dose IL-2 combined with rapamycin leaded to an increase in the absolute counts of Treg cells in refractory SLE patients,from a median of 12.98 cells/ul (at week 0) to 22.1 cells/ul (at week 24) (P=0.002).The ratio of Th17/Treg cells shows a reduction from a median of 0.44 at week 0 to 0.29 at week 24 (P=0.029).No significant difference was observed in the absolute counts of Th17 after combined treatment.At week 24, the mean dosage of prednisone which refractory SLE patients were receiving decreased from 17.20 mg/d to 8.87 mg/d.And the categories of DMARDs use were also reduced ($P<0.05$).
Conclusions: Our results suggest that refractory SLE is major associated with the decreased number of Treg but not that of Th17.The Th17 and Treg cells in the peripheral blood of patients with refractory SLE tends to balance due to the significantly increase the number of Treg cells after low-dose IL-2 combined with rapamycin treatment.Low-dose IL-2 combined with rapamycin treatment can reduce the dosage of glucocorticoid and DMARDs.

SLE, Sjögren's and APS - clinical aspects (other than treatment)

SAT0262 BCL2-ASSOCIATED ATHANOGENE 3 PROTEIN IS ASSOCIATED WITH B-CELL HYPERACTIVITY INCLUDING LYMPHOMA IN PRIMARY SJÖGREN'S SYNDROME

A. Alunno[1], F. Carubbi[2,3], A. Falco[4], O. Bistoni[1], V. Valentini[1], G. Cafaro[1], R. Giacomelli[2], M. Pascale[4], R. Gerli[1]. *[1]Department of Medicine, Rheumatology Unit, University of Perugia, Perugia; [2]Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila; [3]Department of Medicine, ASL 1 Avezzano-L'Aquila-Sulmona, L'Aquila; [4]Department of Pharmacy, University of Salerno, Salerno, Italy*

Background: Bcl2-associated athanogene 3 (BAG-3) is a co-chaperone protein that interacts with the ATPase domain on heat-shock protein 70. BAG-3 is involved is several biologic processes including apoptosis, cytoskeleton organization and autophagy and, therefore, it has been extensively investigated in the field of tumorigenesis (1). In particular, BAG-3 expression is constitutive in human primary tumors including leukemias and lymphomas and it is induced in different normal cell types, including leukocytes, by a variety of stimuli. BAG-3 is able to induce and maintain cell proliferation, resistance to therapy and cell motility, namely metastatization. On this basis, a role of BAG-3 in chronic inflammatory diseases may be postulated, but data on this topic are not available.
Objectives: The purpose of our study was to investigate the expression of BAG-3 in primary Sjogren's syndrome (pSS) and the relationship with clinical and serological features.
Methods: BAG-3 concentration was assessed in the serum of 103 patients with pSS according to the 2002 American-European classification criteria and in 40 sex and age matched healthy donors (HD). Clinical and serological records were collected and statistical analysis was performed with SPSS 21.0.
Results: Twenty-six pSS patients were positive for BAG-3 (BAG-3+), with serum levels ranging from 32.1 to 950 pg/ml. When setting the cut-off value according to the highest value found in HD (300 pg/ml), we identified 13 pSS patients displaying a peculiar clinical serological phenotype. In detail, in this subgroup of pSS patients the prevalence of purpura, low C4, both anti-Ro and anti-La autontibodies, rheumatoid factor and lymphoma was higher, when compared to pSS patients with BAG-3 levels $<$300 pg/ml or BAG-3- (all $p<0.05$). Furthermore, they displayed less frequently sicca symptoms such as xerostomia and xerophtalmia (both $p<0.05$). Binary logistic regression analysis revealed that pSS patients with BAG-3 levels $>$300 pg/ml had on odds ratio (OR) of 12 (95% CI 1.9–86, p=0.009) for lymphoma and this association was independent of the presence of purpura, a well know marker of lymphoma in pSS. When including low complement, another feature associated with lymphoma, in the multivariable analysis, both low C4 and BAG-3 levels $>$300 pg/ml resulted independently associated to lymphoma (OR=24 and 12.4 respectively).
Conclusions: Our study assessed for the first time serum BAG-3 levels in a large cohort of pSS patients. The results showed that the highest levels of BAG-3 identify a peculiar clinical and serological pSS phenotype, as consequence of a B-cell hyperactivity. Since it is known that BAG-3 is an anti-apoptotic protein playing a pivotal role in cell survival, and that B-cell hyperactivity in pSS is the consequence of coordinated and integrated actions of several stimuli and appropriate cytokines, our results may suggest that BAG-3 overexpression is involved in B-cell proliferation and activity, as well as in oligoclonal and monoclonal expansion in pSS.

SAT0263 NEOPLASIA IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN SPAIN: RELESSER REGISTRY DATA

A. Urruticoechea-Arana[1], I. Rua-Figueroa[2], M.A. Martín-Martínez[3], F. Alonso[4], J. López-Longo[5], M. Galindo-Izquierdo[6], A. Olivé[7], J. Calvo[8], A. Fernández-Nebro[9], J.M. Pego-Reigosa[10] on behalf of Group of relesSER. *[1]Rheumatology, Can Misses Hospital, Ibiza; [2]Rheumatology, Doctor Negrín Hospital, Las Palmas de GC; [3]Rheumatology, Research Unit of the Spanish Society of Rheumatology; [4]Research Unit, Spanish Society of Rheumatology; [5]Rheumatology, Gregorio Marañón Hospital; [6]Research Unit, 12 de Octubre Hospital; [7]Rheumatology, Germans Trias and Pujol hospital, Madrid; [8]Rheumatology, Araba Hospital, Vitoria; [9]Rheumatology, Regional of Málaga Hospital, Málaga; [10]Rheumatology, Meixoeiro of Vigo. "Institute of Sanitary Research South Galicia (IISGS)", Vigo, Spain*

Background: There is limited evidence on the risk of neoplasia in autoimmune diseases such as systemic lupus erythematosus.
Objectives: The objective of this study is to analyze the incidence of cancer in the Spanish population with SLE and the factors associated in its development: RelesSER Registry Data.
Methods: We calculated the incidence density of malignant neoplasms, the standardized incidence ratio and the average time to develop the first neoplasm after diagnosis of SLE in patients of the SLE registry of the Spanish Rheumatology Society (RelesSER) fulfilling ACR97 criteria. We carried out a bivariate analysis of the associated factors to neoplasms and multivariate by logistic regression.
Results: A total of 3607 patients (90.4% female) were included. We registered 140 neoplasms in women (4.3%) and 14 in men (4%) ($p<0.821$). Incidence density 7.3/1000 patient-years (95% CI:4.85–10.98) (7.39 in patient-years women and 6.93 in men) without significant differences. After stratification by gender and age, cancer appeared in 3.2% of the women aged under 45 versus 3.8% of the men; 4.1% of women aged 45–65 years versus 5.9% of men and a 5.3% of women 65 and older versus 2.5% of men the same age. The standardized incidence ratio (SIR) was 2.16; 1.51 in men and 2.38 in women, highest for women under 65 years old. The SIR for $>$65 years was 0.98; 0.59 in men and 1.55 in women.
The average time until de development of the first malignant neoplasm was 10 years (RI:5.75–17.00), being lower in women [9.5 (RI: 5.00–17.0) years] than in men [12.5 (8.75–17.5)] and in patients under 45 years versus over 45 years [8.0 (RI: 5.00–16.00)].
Malignant neoplasms were the cause of death in 10% of the patients (15/154), predominantly hematological and breast cancers, both at 19% followed by lung cancer in 14.3%.
Factors associated to malignant neoplasms in the bivariate analysis are shown in (table 1). No immunosuppressive therapy was associated with the development of neoplasms. In the multivariate model, adjusted for age and time of disease duration, age was the only significant variable (OR:1.030; 95% CI: 1.003–1.059; p=0.029) with a trend for ACE inhibitors use (OR:1.866; 95% CI: 0.808–4.306; p=0.144), SLEDAI (last visit) (OR: 0.904; 95% CI: 0.806–1.015; p=0.089, SLICC/ACR DI) (without neoplasias) (OR: 1.160; 95% CI: 0.961- 1.401; p=0.123), and duration of the disease in months (OR: 1.003; 95% CI: 1.000–1.006; p=0.068).

Table 1

	Cáncer	Control	*p*
Gender, men %	4	96	0.821
Gender, women %	4.3	95.7	0.821
Mean age at first criterion, years (DS)	38.35 (16.01)	32.72(14.29)	<0.001
Diagnostic age SLE, years (DS)	40.37 (15.68)	34.75 (14.46)	<0.001
Age at last evaluation, years, mean (DS)	57.74 (14.38)	46.17 (14.58)	<0.001
Disease duration (months), mean (DS)	208.71 (102.95)	140.1 (99.69)	<0.001
Follow-up in Rheumatology (months), mean (DS)	170. 1 (90.75)	118.12 (86.90)	<0.001
Sjogren´s syndrome, %	20.5	14.1	0.029
SLEDAI, median [p25-p75]	1.00 [0.00-3.25]	2.0 [0.00-4.00]	0.026
KATZ, median [p25-p75]	3 [2-4]	2 [1-3]	0.001
SLICC*, median [p25-p75]	1.00 [0.00-3.00]	0.00 [0.00-1.00]	<0.001
CHARLSON*, median [p25-p75]	3 [2.00-4.00]	1 [1.00-3.00]	<0.001
Time on antimalarals (months) median [p25-p75]	78.00 (27.75-136.50)	60.00 (24.00-119.00)	0.099

Conclusions: The incidence of neoplasia in Spanish women with SLE is higher than expected for age and gender. Malignant neoplasms were the cause of death in 10% of the patients, predominating hematological and breast cancers followed by lung cancer.

SAT0264 VALVULOPATHY AND PULMONARY HYPERTENSION IN A SERIES OF PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME

A. Robles, M.J. Núñez, E. Rodríguez-Castellano, C. Busca, J.J. Ríos, A. Noblejas, F. Arnalich, E. Martínez. *Internal Medicine, Hospital Universitario la Paz, Madrid, Spain*

Objectives: To evaluate the prevalence of cardiac valvular involvement and

pulmonary arterial hypertension (PAH) and predictive risk factors in a cohort of patients with antiphospholipid antibodies.
Methods: We included 232 patients from our cohort who underwent an echocardiogram. A total of 84 (36%) patients with primary antiphospholipid syndrome (PFS), 47 (20%) with APS secondary to systemic lupus erythematosus (SLE), 47 (20%) patients with antiphospholipid antibodies 23%) with SLE without AAF.
The determinations of AAF and lupus anticoagulant were performed according to the indications of the international thrombosis society.
Statistical analysis was performed with SPSS 18; using the Chi square test and the Fisher exact test.
Results: In patients with AAF, the echocardiogram was pathological in 88 patients (52%) (p=0.023). Valvular affectation was evidenced in 64 (38%) (p=0.005) and PAH in 16 (p = ns). Seventeen patients (35%), SAF (48%), SAFS (26%), AIF silent (14%) and 9 patients in the non-AAF group (12%) presented with valvular affectation (p=0.002). PAH presented 19 patients, 9 with SAFP (47%), 6 in the SAFS group (32%), 1 in the silent AAF group (5%) and 3 in the non-AAF group (16%) (p=). Both PAH and valvular involvement were asymptomatic in most cases, although two patients required valvular replacement. The most frequently affected valve in all groups was mitral valve (84%), except in patients with PAH where the most prevalent valvular pathology was tricuspid insufficiency. Patients with valvulopathy and APS had a higher prevalence of total thrombosis than SAF without valvulopathy (p=0.05). Patients with valvulopathy also significantly increased stroke and thrombocytopenia (p=0.04). Patients with valvulopathy had lupus anticoagulant more frequently (p=0.04), with no difference for the rest of AAF.
Conclusions: Subclinical valvular involvement is very common in patients with AAF. Every patient with AAA should be given an echocardiogram in the initial protocol of their study in order to rule out both significant valvulopathy and PAH that can modify the management of the condition.

SAT0265 CLINICAL CHARACTERISTICS OF SYSTEMIC LUPUS ERYTHREMATOSUS IN AN EGYPTIAN POPULATION: A RETROSPECTIVE COHORT

B. Medhat[1], T. El Hadidi[2], K. El Hadidi[1], A. Yousri[1], D. Hassan[1], F. Talaat[1], L. Maged[1], M. Shabaan[3], M. Eissa[1], N. Hamdy El Gobashy[1], N. Sobhy[1], N. Abd El Baki[1], R. El Refai[1], S. Ghoneim[1], W. AbdRahman[1]. *[1]Rheumatology and Rehabilitation, Faculty of Medicine-Cairo University; [2]Rheumatology and Rehabilitation, Armed forced hospital; [3]Rheumatology and Rehabilitation, Helwan hospital, Cairo, Egypt*

Background: Systemic lupus erythrematosus (SLE) is an autoimmune disease with a myriad of manifestations, that could vary among different ethnic and racial groups.
Objectives: To study the prevalence of various manifestations of SLE in an Egyptian population.
Methods: Information in this study was derived from the medical records of SLE patients who followed up in a private clinic in Cairo from January 1980 to June 2016.
Results: This descriptive retrospective case series included 1109 juvenile (19.4%) and adult (80.6%) patients, of which 114 (10.3%) were males and 995 were females (89.7%). Age of onset showed a mean of 26±11.19 years, and the mean of disease duration was 48.78±58.46 months (median: 26 years). The most common manifestations were synovitis (76.7%), malar rash (48.5%), leukopenia (45.7%), and photosensitivity (45.6%). At least one of the antiphospholipid antibodies was present in 41.8% of the patients tested for APL (636 patients). However thromboembolic manifestations and/or recurrent fetal loss occured in 11.5% of the patients. Neuropsychiatric manifestations were evident only in 6.4% of the patients, with seizures being the most common neuropsychiatric manifestation, present in 4% of the patients. 33.1% of the patients had nephritis, which followed the onset of the disease by a mean duration of 20±21.3 months (median=12 months). There were gender differences in the disease characteristics. Cutaneous vasculitis, nephritis, and hypocomplementemia were statistically higher in males (p=0.012, p=0.01, and p=0.041 respectively). Whereas, synovitis, and alopecia were statistically higher in females (p=0.012 and p=0.006 respectively). Patients with juvenile onset had a statisticaly higher frequency of nephritis (0=0.01), seizures (p=0.012) haemolytic anemia (p=0.001), and hypocomplementinemia (p=0.02).
Conclusions: Synovitis and malar rash were the most common manifestations in our study. Secondary antiphospholipid was present in 11.5% of the patients. Male patients and juvenile patients showed a tendency towards a more severe disease.

SAT0266 EFFECT OF THE METABOLIC SYNDROME ON ORGAN DAMAGE AND MORTALITY IN CHINESE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A LONGITUDINAL ANALYSIS

C.C. Mok, S.M. Tse, L.Y. Ho. *Medicine, Tuen Mun Hospital, HK, Hong Kong*

Objectives: To study the effect of the metabolic syndrome (MetS) on organ damage and mortality in patients with SLE.
Methods: Consecutive patients who fulfilled ≥4 ACR criteria for SLE and were assessed for the presence of the MetS between 2010 and 2011 were included. Those patients who did not have MetS assessment or succumbed before 2010 were excluded. The MetS was defined by the updated joint consensus criteria, using the Asian criteria for central obesity, when ≥3 of the following components were present: (1) Increased waist circumference to ≥90cm in men or ≥80cm in women; (2) Elevated blood pressure to ≥130/85mmHg or requiring drug therapy; (3) Elevated serum triglyceride level to ≥1.7mmol/L; (4) Reduced serum high density lipoprotein (HDL)-cholesterol to ≤1.0mmol/L in men and ≤1.3mmol/L in women; and (5) Elevated fasting glucose level to ≥5.6mmol/L. Longitudinal data regarding new organ damage, vascular events and mortality on follow-up were retrieved from our cohort database. The association of the MetS with new organ damage and mortality was studied by logistic regression analyses.
Results: 577 SLE patients were studied (93% women; age at entry 41.2±13.4 years; SLE duration 9.3±7.2 years). The mean follow-up time of the patients since entry was 66.3±1.8 months. The mean body mass index (BMI) of the patients was 22.3±3.9kg/m^2 (11% >27kg/m^2). A total of 85 (14.7%) patients qualified the MetS (28% fulfilling waist; 20% fulfilling blood pressure; 25% fulfilling triglyceride; 33% fulfilling HDL and 9.2% fulfilling glucose criteria). New organ damage and vascular (coronary, cerebrovascular and peripheral vascular) events developed in 128 (22%) and 23 (4.0%) patients, respectively. The most common new arterial events were stroke (50%), acute coronary syndrome (33%) and peripheral vascular disease (17%). Thirty-nine (6.8%) patients died (infection 36%; vascular causes 18%; cancer 15%; lung fibrosis 8%; suicide 3%). Patients with the MetS (N=85), when compared to those without (N=492), had significantly higher SDI accrual at their last clinic visits (0.70±1.0 vs 0.26±0.6; p<0.001). Regarding individual systems, the increase in SDI scores in the ocular, renal, cardiovascular, musculoskeletal and endocrine (new diabetes mellitus) systems were significantly higher in the MetS group of patients. New vascular events (11% vs 2.8%; p=0.001), all-cause mortality (14% vs 5.5%; p=0.003), death due to vascular complications (7.1% vs 0.2%; p<0.001) were significantly more common in patients with MetS than those without. Logistic regression revealed that the MetS was significantly associated with new damage in the ocular (OR 2.77 [1.05–7.34]; p=0.04, renal (OR 4.72 [1.86–12.0]; p=0.001), cardiovascular (OR 3.66 [1.03–12.9]; p=0.04] and endocrine system (OR 41.9 [4.93–357]; p=0.001), adjusted for age, sex, SLE duration and the antiphospholipid antibodies (IgG-anticardiolipin or the lupus anticoagulant). The presence of the MetS increased the risk of new vascular events (OR 2.94 [1.18–7.31]; p=0.02), all-cause mortality (OR 1.60 [0.73–3.47]; p=0.24) and vascular mortality (OR 30.3 [3.42–268]; p=0.002) after adjustment for the same covariates.
Conclusions: In this 5-year longitudinal study, the MetS is significantly associated with new organ damage, vascular events and mortality in patients with SLE.

SAT0267 SERUM 25-HYDROXYVITAMIN D3 LEVELS AND FLARES OF SYSTEMIC LUPUS ERYTHEMATOSUS: A LONGITUDINAL COHORT ANALYSIS

C.C. Mok[1], R. Singh[2], L.Y. Ho[1], P. Jannetto[2]. *[1]Medicine, Tuen Mun Hospital, HK, Hong Kong; [2]Laboratory Medicine and Pathology, Mayo Clinic, Rochester, United States*

Objectives: To study the relationship between serum 25-hydroxyvitamin D3 levels and flares of systemic lupus erythematosus (SLE) in a longitudinal cohort of Chinese patients.
Methods: Patients who fulfilled ≥4 of the ACR criteria for SLE were recruited from our rheumatology out-patient clinics in November 2011. Blood was taken at 10 AM and was assayed for the serum levels of 25-hydroxyvitamin D3 by liquid chromatography tandem mass spectrometry (LC-MS/MS). Patients were stratified according to the 25-hydroxyvitamin D3 levels; group 1 (<15ng/ml, deficiency); group 2 (15–30ng/ml, insufficiency); and group 3 (>30ng/ml, adequate); and were followed longitudinally every 2–4 months for serial assessment of disease activity (by SELENA-SLEDAI) and the occurrence of mild/moderate or severe SLE flares (by SELENA flare instrument). Comparison was made among these groups in the baseline and mean summated SLEDAI over time (area under the curve), and the annual incidence of mild/moderate and severe flares by the one-way ANOVA test.
Results: 276 SLE patients were studied (94% women; age 41.0±13.8 years; SLE duration 8.7±6.6 years). 25 (9.1%) patients had eGFR ≤60ml/min. The proportion of patients with 25-hydroxyvitamin D3 levels of <15, 15–30, >30ng/ml was 26%, 54% and 20%, respectively. Patients with vitamin D deficiency (group 1) were significantly younger, had lower body mass index (BMI) but higher baseline eGFR and SLEDAI scores when compared with the other groups. No significant differences in the clinical manifestations were observed among the three groups of patients except for lower prevalence of facial rash in group 3 (p=0.02). After a mean follow-up of 32.5±5.5 months, 153 mild flares and 91 severe flares developed in our patients. The mean summated SLEDAI score over time was: 3.2±2.0 (group 1); 2.4±1.9 (group 2); and 2.7±2.1 (group 3), respectively (p=0.02). The annual incidence of mild/moderate and severe flares was: 0.26±0.39 and 0.20±0.45 (group 1); 0.20±0.33 and 0.09±0.22 (group 2); and 0.20±0.32 and 0.14±0.46 (group 3), respectively (p=NS in all). In a subgroup of 73 patients who did not have clinical or serological SLE activity at baseline (SLEDAI=0), a similar

but non-significant trend of higher annual rates of mild/moderate and severe flares over time was also observed in patients with vitamin D deficiency. At the last visit, 27 (10%) patients had new damage scores; 5 patients had new vascular events; and 4 patients had new onset diabetes mellitus. There were no significant differences among the three groups of patients with regard to the incidence of new damage or vascular events over time.

Conclusions: Vitamin D insufficiency and deficiency was frequent in our cohort of SLE patients. Patients with vitamin D deficiency were associated with higher baseline and mean disease activity scores, as well as a tendency of more severe lupus flares over time.

SAT0268 CLINICAL PRESENTATION OF NASAL INVOLVEMENT IN PRIMARY SJÖGREN'S SYNDROME: A MULTIDISCIPLINARY TEAM APPROACH TO A NEGLECTED AND DISABLING CONDITION

C. Baldini[1], V. Seccia[2], E. Elefante[1], M. Scarano[2], L. Cristofani[2], F. Ferro[1], N. Luciano[1], M. Mosca[1]. *[1]Clinical and Experimental Medicine, Rheumatology Unit, University of Pisa; [2]Otorhinolaryngology Unit, University of Pisa, Pisa, Italy*

Background: Dry nose is reported quite frequently by patients affected by primary Sjögren's syndrome (pSS) in daily practice. However, a clear definition of nasal involvement in pSS is not available.

Objectives: a) to explore clinical presentation of nasal involvement in pSS analyzing key symptoms, objective findings at the inspection of the external and inner nose and nasal cytology b) to investigate any associations/correlation between nasal involvement and other clinical-serological disease manifestations c) to assess the overall impact of nasal involvement on patients reported outcomes (PROs).

Methods: Consecutive pSS patients (AECG 2002) were seen by a team of rheumatologists and ENT specialists. In addition to a standard rheumatologic evaluation, all the patients underwent a complete ENT evaluation. Nasal symptoms (i.e dry nose, nasal stuffiness, crusting, hyposmia) were collected by an "ad hoc questionnaire" and scored by the patients on visual analogique scales. Inspection of the external and inner nose, endoscopy of the nasal cavity and nasal cytology were performed as well. Allergy testing were also carried out when indicated. The following tools were used to assess PROs: ESSPRI, SF-36 and SNOT-22.

Results: Forty-six pSS patients were included in the study [M:F =45:1; median age (IQR):64 (53–70); median disease duration (IQR): 66 months (24–120)]. Nasal symptoms ranged from: dryness in the nose (56.5%), crusting 10/46 (21.7%), nasal stuffiness 20/46 (45.5%) and hyposmia 7/46 (15.2%). Thirteen patients did not present signs of nasal involvement, whereas 21 patients (45.7%) presented rhinitis sicca (RS), 6 (13%) allergic rhinitis (AR), 4 (8.7%) chronic rhinosinusitis (CRS) and 2 (4.3%) non-allergic rhinitis (NAR). Patients with nasal involvement were more frequently seronegative (p=0.04) and presented significantly higher SNOT-22 scores (p=0.008) when compared to patients without nasal involvement; no additional demographic or clinical differences between the two groups. Allergy testing were more frequently positive in patients with RS and AR. Nasal cytology showed that the rates of the cells (eosinophils and neutrophils) in patients without nasal involvement were negligible whereas they were significantly increasead in pSS patients with RS and AR. The SNOT-22 (r=-.433, p=0.02) and the scores assigned to the VAS of nasal dryness (r=-.755, p=0.003) and crusting (r=-.794, p=0.001) strongly correlated with SF-36 questionnaire. SNOT-22 also correlated with the ESSPRI (r=.399, p=0.04), whereas we did not find a correlation between VAS scores assigned to nasal dryness and VAS scores of oral and ocular dryness. PROs related to nasal symptoms were significantly influenced by a concomitant diagnosis of fibromyalgia.

Conclusions: Rhinitis sicca was the most common clinical presentation of nasal involvement in pSS patients, especially in seronegative patients. Apparently, nasal symptoms correlated weakly with ocular and oral dryness. PROs exploring nasal symptoms revealed that nasal involvement impact significantly on patients quality of life.

SAT0269 RDW LEVELS ARE ASSOCIATED WITH DAMAGE ACCRUAL IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

C. Reategui-Sokolova[1], M. Ugarte-Gil[1], R. Gamboa-Cárdenas[1], F. Zevallos[1], J. Cucho-Venegas[1], J. Alfaro-Lozano[1], M. Medina[1], Z. Rodríguez-Bellido[1], C. Pastor-Asurza[1], G. Alarcón[2], R. Perich-Campos[1]. *[1]Rheumatology, Hospital Guillermo Almenara Irigoyen, Lima, Peru; [2]School of Medicine, The University of Alabama, Birmingham, United States*

Background: Systemic Lupus Erythematosus (SLE) patients show higher Red blood cells Distribution Width (RDW) regardless of anaemia status[1]. RDW has been found to positively correlate with serum IgM, CRP, ESR, and SLE Disease Activity Index 2000 (SLEDAI-2K), and glucocorticoid treatment decreased both SLEDAI-2K and RDW[2].

Objectives: To determine whether RDW levels in SLE are associated with damage accrual.

Methods: This cross-sectional study was conducted in 276 SLE patients, 257 females and 19 males. Evaluations included interview, medical records review, physical examination and laboratory tests. Disease activity was measured with the SLEDAI. Damage accrual was ascertained with the SLICC/ACR damage index (SDI). Univariable and multivariable Poisson regression models were performed to determine if RDW levels were associated with damage accrual. These models were stratified by tertiles of RDW. The multivariable model was adjusted for variables known to be associated with this outcome [age at diagnosis, gender, socioeconomic status, ethnicity, tobacco use, disease duration, SLEDAI, anemia, antimalarials and immunosuppressive drugs use, average daily dose and time of exposure to prednisone (PDN)].

Results: The patients mean (SD) age at diagnosis was 34.38 (13.33) years; nearly all patients were mestizo. Disease duration was 7.04 (6.16) years. The SLEDAI was 5.24 (4.67) and the SDI 0.92 (1.28). The average daily dose of PDN was 6.90 (6.07) mg/d and the time of exposure to PDN was 6.58 (9.59) years. RDW levels were 14.57 (1.52)%. Hemoglobin levels were 12.4 (1.7) g/dl. We divided the RDW levels into tertiles with cut points in 13.8 and 14.0; the highest tertiles were associated with disease damage; with a Rate Ratio (RR) 1.57 (1.07–2.28; p: 0.020 for the highest tertile, and 1.67 (1.15–2.42; p: 0.007) for the medium tertile.

Conclusions: Higher RDW levels are associated with damage accrual in SLE patients independent of other well-known risk factors for such occurrence.

SAT0270 ULTRASONOGRAPHY OF MAJOR SALIVARY GLANDS IN JUVENILE SJÖGREN'S SYNDROME – PRELIMINARY FINDINGS IN A MULTI-CENTER STUDY

D.S. Hammenfors[1], V. Valim[2], B. Bica[3], S.G. Pasoto[4], V. Lilleby[5], J.C. Nieto-González[6], C.A. Silva[7], E. Mossel[8], R.M. Pereira[9], H. Bootsma[10], J.G. Brun[11], R. Jonsson[12], M.V. Jonsson[13]. *[1]Department of Rheumatology, Haukeland university hospital, Bergen, Norway; [2]Department of Rheumatology/Medical Clinic, Federal University of Espírito Santo, Vitoria; [3]Department of Rheumatology, Federal University of Rio de Janeiro, Rio de Janeiro; [4]Sjögren's syndrome outpatient/Hospital das Clinicas HCFMUSP, University of São Paulo, São Paulo, Brazil; [5]Department of Rheumatology, Oslo University Hospital, Oslo, Norway; [6]Department of Rheumatology, Hospital General Universitario Gregorio Marañón, Madrid, Spain; [7]Department of Pediatric Rheumatology, Federal University of São Paulo, São Paulo, Brazil; [8]Department of Rheumatology and Clinical Immunology, University Medical Center Groningen, Groningen, Netherlands; [9]Rheumatology Division - School of Medicine, University of São Paulo, São Paulo, Brazil; [10]Department of Rheumatology and Clinical Immunology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands; [11]Department of Clinical Science – Section for Rheumatology; [12]Broegelmann Research Laboratory, Department of Clinical Science; [13]Department of Clinical Dentistry – Section for Oral and Maxillofacial Radiology, University of Bergen, Bergen, Norway*

Background: Juvenile Sjögren's syndrome (jSS) is a rare, poorly defined and possibly underdiagnosed condition. There is little information on the use of major salivary gland ultrasonography (SGUS) in this patient-group.

Objectives: To characterize symptoms and clinical findings of jSS and to investigate SGUS as a diagnostic tool.

Methods: Sixty-four patients were recruited from Brazil (n=40), Norway (n=11), the Netherlands (n=8) and Spain (n=5). All patients had disease onset at the age of 18 or younger. Clinical examination and sialometry was performed in 60/64 patients. Additional clinical information was obtained from the medical records and through patient interview. SGUS of the parotid and submandibular glands was performed in all patients using linear high-frequency transducers (6–15 MHz), by an expert in SGUS. Glandular homogeneity and presence of hypoechogenic areas were evaluated and glands characterized as normal or SS-like.

Results: The female:male ratio was 6:1. Mean age at diagnosis was 12.1 years (range 4–18), with first symptoms occurring at 10.3 years (range 1–17). Time from onset of symptoms until diagnosis was 1.6 years (range -2–8 years). Subjective oral and ocular symptoms were reported in 70% and 64% patients, respectively. Reduced secretion of tears was detected in 41% patients, and hyposalivation in 31% patients. Minor salivary gland lip biopsy had been performed and focus score determined in 34 patients; 28 biopsies (82%) had focus score $\geq$1. Serologically, 92% were positive for ANA, 73% were anti-Ro/SSA+, 38% were anti-La/SSB+, and 41% were RF+. Salivary gland enlargement had been experienced by 53% of the patients; one patient had also experienced lacrimal gland enlargement. Systemic manifestations at some time-point, was registered in 66% of the patients. Systemic treatment at inclusion was registered in 67% of the patients; previous systemic treatment was registered in 83%. Diagnostic criteria for primary Sjögren's syndrome (pSS) was fulfilled by 34/64 patients (53%) and 39/64 patients (61%),

AECG criteria and ACR/EULAR criteria, respectively. SGUS revealed SS-like changes in 37/64 patients (59%); interestingly, SS-like findings were observed in 22/23 patients in the European cohort, compared to 15/40 patients in the Brazilian cohort.

Conclusions: Common symptoms and findings in jSS include dry mouth, systemic manifestations and salivary gland enlargement, followed by reduced tear secretion and hyposalivation.

SAT0271 IS THERE A NEED TO INCLUDE SEROLOGICAL PATTERN TO PREDICT DAMAGE IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME: DIAPS APPLICATION

D. Mazilu[1], D. Potarniche[2], I. Saulescu[1], A. Borangiu[1], L. Groseanu[1], C. Constantinescu[1], V. Vlad[2], D. Opris[3], A. Balanescu[1], D. Predeteanu[1], R. Ionescu[1]. *[1]"Sfanta Maria" Clinical Hospital, "Carol Davila" University of Medicine; [2]"Sfanta Maria" Clinical Hospital; [3]"Sfanta Maria" Clinical Hospital, "Carol Davila" Univeristy of Medicine, Bucharest, Romania*

Background: Antiphospholipid syndrome (APS) is an autoimmune disease defined as the presence of antiphospholipid antibodies (aPL), at least a clinical thrombotic event and is associated with an important risk of organ damage. The new index proposed, Damage Index in patients with Thrombotic Antiphospholipid Syndrome (DIAPS) may be an useful tool to estimate cumulative damage in patients with primary and secondary APS. It includes 38 clinical items expanded to show the complexity of clinical manifestations in APS patients.

Objectives: The aim of this study is to analyze the serological pattern as potential predictive factor for an increased DIAPS.

Methods: All consecutive patients known with APS according to the Sapporo and/or Sydney classification criteria were included in our monocentric cohort. Data on medical history, clinical manifestations, aPL profile and medication were collected. DIAPS score was used to measure damage in each patient. The relationship between aPL profile and DIAPS score was analysed.

Results: Seventy six patients with APS were included: 11 patients with primary APS, 65 patients with secondary APS. Their mean disease duration was 9.59±7.39years. The most frequent clinical manifestation from DIAPS was the peripheral vascular (deep vein thrombosis, intermittent claudication, tissue loss, vascular venous insufficiency) found in 61.8% of patients, followed by the neuropsychiatric manifestations (46.1%). The mean DIAPS score in our cohort was 4.25±3.51, not significantly different between patients with primary vs secondary APS (4.72 vs 4.16, p=0.629). Lupus anticoagulant (LA) was found in 25 patiens (32.9%), anti cardiolipin antibodies (aCL) in 49 patients (64.5%) and antibodies to β2-glycoprotein I (β2GPI) in 23 patients (30.3%). There were 36 patients known with a single positive aPL (47.4%), 27 patients (35.5%)with 2 positive aPL and only 2 patients with triple positivity. There were no significant differences regarding antibody profile between patients with primary and secondary APS. Higher values of DIAPS were seen in patients with β2GPI (p=0.042) and with positivity for 2 aPL (p=0.003). DIAPS value correlated to the presence of β 2GPI (p=0.042, R=0.233) and to positivity for two aPL (p=0.003, R=0.341).

Conclusions: Our study suggests that double positivity for aPL, especially the presence of β2GPI confers an increased value of DIAPS in patients with primary and secondary APS.

SAT0272 LACK OF ASSOCIATION OF GLUCOCORTICOID EXPOSURE AND METABOLIC SYNDROME IN SLE

D. Apostolopoulos, A. Hoi, E. Morand. *Monash Health, Melbourne, Australia*

Background: The Metabolic Syndrome (MetS) is a disorder of energy utilisation and storage, associated with an increased risk of cardiovascular (CV) disease. MetS may contribute to the increased CV disease in SLE, but the prevalence, cause, and impact of MetS in SLE is poorly understood, as are the effects of glucocorticoid (GC) exposure.

Objectives: To characterise the prevalence of the features of MetS in a well-characterised cohort of SLE patients, and determine the effect of GC use on these parameters.

Methods: SLE patients studied as part of a single centre prospective longitudinal cohort. Disease activity (SLEDAI-2K), treatment and laboratory details were recorded at each visit. Other investigation results were collected from institution databases. MetS defined as ≥3 criteria[1]: BMI >30kg/m^2; triglycerides>1.7mmol/L; HDL-cholesterol <1.3mmol/L; blood pressure >130/85mmHg or treatment for hypertension; fasting glucose >5.6mmol/L or treatment for hyperglycaemia. Continuous variables were described as median (IQR), and compared using Kruskal-Wallis tests. Categorical variables were described as frequency and compared using Chi-squared tests.

Results:

	Total (289)	GC exposed (211)	GC not –exposed (78)	p-value
BMI >30kg/m^2	50 (17%)	33 (24%)	17 (22%)	0.22
éTriglycerides	80 (28%)	69 (33%)	11 (14%)	0.002
êHDL-cholesterol	95 (33%)	73 (35%)	22 (28%)	0.33
é Fasting glucose	32 (11%)	24 (11%)	8 (10%)	1.00
Hypertension	137 (47%)	110 (52%)	27 (35%)	0.01
Metabolic Syndrome	*49 (17%)*	*36 (17%)*	*13 (17%)*	*1.00*

289 patients were included (87% female; 51% Caucasian, 29% Asian), and median age at enrolment of 37.7y. Median follow-up was 3.43y (med 15 visits). Time adjusted-mean SLEDAI (AMS) over the study period was 3.67. 81% (211) patients received GC (time-adjusted mean 4.25mg prednisolone/d) and AMS was significantly higher in GC-exposed patients (4.19 vs 1.97 [EM1], p<0.01). MetS criteria were met by 49 (17%) of patients (Table 1). Hypertriglyceridaemia and hypertension were significantly more frequent in GC-treated patients, but the prevalence of obesity and other MetS domains, or MetS overall, were not. There were significantly more patients with MetS score =0 in the GC-exposed subset (43/78 vs 76/211 p<0.01).

The prevalence of obesity of 17% is lower than in the general population. There was no significant change in BMI across the period of observation and surprisingly, no association between GC exposure and change in BMI.

Conclusions: The prevalence of MetS in SLE was lower than previously reported in other, smaller, lupus cohorts [2,3]. This study suggests GC exposure was associated with hypertriglyceridaemia and hypertension in SLE. Potential negative effects of active disease on MetS domains require further investigation.

SAT0273 FACTORS RELATED TO ALEXITHYMIA IN SYSTEMIC LUPUS ERYTHEMATOSUS

D.P.E. Margiotta, F. Basta, M. Vadacca, G. Dolcini, M. Lo Vullo, A. Rigon, A. Afeltra. *Unit of Allergology, Immunology and Rheumatology, Università Campus Bio-Medico di Roma, Rome, Italy, Rome, Italy*

Background: Several evidences described a considerable prevalence of alexithymia among patients with chronic diseases, such as systemic autoimmune diseases. In patients affected by Systemic Lupus Erythematosus (SLE), alexithymia seems to be related to mood disorders and personality.

Objectives: In this study we evaluated alexithymia in relation to HR-QoL (Health related Quality of Life) and to factor associated to HR-QoL, such as mood disorders, fatigue, work ability, sleep quality and physical activity.

Methods: We consecutively enrolled SLE patients and healthy controls in a cross sectional study with a retrospective design. We wvaluated alexithymia by the Toronto Alexithymia Scale 20 (TAS-20). AHR-QoL was expressed by MOS-SF-36. Mood disorders was assessed by BDI and HAM-H. Fatigue was evaluated by Facit-Fatigue. Physical activity was quantified using International Physical Activity Questionnaire (IPAQ) and the sleep quality using the Pittsburgh Sleep Quality Index (PSQI). Work ability was assessed by Work Productivity and Activity Impairment (WPAI). Cognitive impairment was defined according to MOCA screening test.

Results: Fifty-two SLE patients and 50 age-matched healthy subjects were enrolled in the study. Mean TAS-20 score was significantly higher in SLE compared to controls (p<0.01). Alexithymic patients presented increased values of BDI score and HAM-H score (p<0.01 and p<0.05) and reduced Facit-Fatigue score (p<0.05). We found increased values of Work missed due to health problems and Activity impairment in alexithymic SLE subjects (p<0.05). SF-36 summary components PCS and MCS and SF-36 individual components did not significantly differ between alexithymic and non-alexithymic SLE. A greater proportion of alexithymic SLE patients presented fibromyalgia (p<0.05), low scholastic education (p<0.01), cognitive impairment according to MOCA test (p<0.01) and mild-to-severe depression according to BDI (p<0.01). We did not find differences among alexithymic and non alexithymic in MeS, obesity and physical inactivity prevalence. TAS-20 values positively correlated with BDI score (p<0.001), HAM-H score (p<0.01) and activity impairment score (p<0.01) and negatively with Facit-Fatigue score (p<0.01). In multiple linear regression,

predictors of TAS-20 values were to be fibromyalgic and to have mild-to-severe depression according to BDI. In multiple logistic regression, alexithymia was significantly associated to BDI score (OR 1.2, 95% CI 1.0–1.4) and inversely associated to cognitive impairment (OR 0.1, 95% CI 0.02–0.8).
Conclusions: SLE patients frequently present alexithymic tract. Alexithymia seems to be associated neither to disease feature, to disease course (activity and damage) and to SLE therapy, nor to HR-QoL expressed by SF-36. Nevertheless, alexithymia could be tightly related to QoL-associated factors as depression and fibromyalgia

SAT0274 URINARY VITAMIN D-BINDING PROTEIN AS A BIOMARKER FOR LUPUS NEPHRITIS

D.J. Go[1,2], J.Y. Lee[2], M.J. Kang[2], I.A. Choi[3], E.Y. Lee[1], E.B. Lee[1], E. Yi[2], Y.W. Song[1,2]. *[1]Department of Internal Medicine, Seoul National University Hospital; [2]Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, and College of Medicine, Medical Research Institute, Seoul National University, Seoul; [3]Department of Internal Medicine, Chungbuk National University Hospital, Cheongju, Korea, Republic Of*

Background: Lupus nephritis (LN) is a major complication of systemic lupus erythematosus (SLE). However, conventional biomarkers for assessing renal disease activity are imperfect in predicting clinical outcomes associated with LN.
Objectives: The aim of this study is to identify urinary protein biomarkers that reliably reflect the disease activity or predict clinical outcomes.
Methods: A quantitative proteomic analysis, using liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS), was performed to identify protein biomarker candidates that can differentiate between SLE patients with and without LN. Selected biomarker candidates were further verified using urine samples from a larger cohort of SLE patients (n=121) by enzyme-linked immunosorbent assay (ELISA) to investigate their predictive values for LN activity measure. Furthermore, association between urinary level of selected panel of potential biomarkers and prognosis of LN was assessed with a 4-year follow-up study of renal outcomes.
Results: From proteomic assay, vitamin D binding protein (VDBP), transthyretin (TTR), retinol binding protein 4 (RBP4) and prostaglandin D synthase (PTGDS) were selected as candidates for quantification. These proteins were significantly elevated in SLE patients with LN, especially in patients with active LN (n=21). Among them, VDBP well correlated with severity of proteinuria (rho =0.661, $P<0.001$) and renal SLE disease activity index (renal SLEDAI) (rho =0.520, $P<0.001$). In the 4-year follow-up, VDBP was a significant risk factor (hazard ratio 9.627, 95% CI 1.698 to 54.571, P=0.011) for the development of proteinuric flare (randum urine protein/creatinine ratio >1.0) in SLE patients without proteinuria (random urine protein/creatinine ratio <0.5) (n=100) after adjustments of multiple confounders.
Conclusions: Urinary VDBP correlated with proteinuria and renal SLEDAI, and predicted the development of proteinuria.

SAT0275 COMPARISON OF CLINICAL AND SEROLOGICAL DIFFERENCES ACCORDING TO THE AUTOANTIBODY CLUSTER IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS FROM THE KOREAN LUPUS NETWORK (KORNET) REGISTRY

D.-J. Park, J.-H. Kang, J.-E. Kim, K.-E. Lee, S.-S. Lee. *Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic Of*

Objectives: Individual autoantibodies are associated with the clinical features in patients with systemic lupus erythematosus (SLE). However, few studies have investigated differences in disease presentation based on autoantibody profiles in Asian patients with SLE. This study evaluated autoantibody clusters and compared the clinical and serological presentation and clinical outcome in Korean SLE patients.
Methods: The Korean Lupus Network (KORNET) is a nationwide multicenter, hospital-based registry, set up to prospectively assess outcomes in Korean SLE patients. Of the 505 SLE patients enrolled in the KORNET registry from July 2014 to November 2015, the study group comprised 339 consecutive female SLE patients. Seven autoantibodies (anti-dsDNA, anti-Sm, anti-RNP, anti-Ro, anti-La, lupus anticoagulant (LAC), and anti-cardiolipin antibody [aCL]) were selected for cluster analysis using the K-means cluster analysis procedure.
Results: Three distinct autoantibody clusters were identified: cluster 1, anti-dsDNA and anti-Ro; cluster 2, anti-RNP; and cluster 3, anti-RNP, anti-Ro, and anti-La. Compared with patients in clusters 2 (n=99) and 3 (n=85), patients in cluster 1 (n=155) had a shorter symptom duration before SLE diagnosis and higher incidence of biopsy-proven lupus nephritis. Patients in cluster 3 had a higher incidence of discoid rash, central nervous system involvement, lupus pancreatitis, pulmonary arterial hypertension, Raynaud's phenomenon, and premature gonadal failure. In addition, patients in cluster 3 had the lowest proportion of mean prednisolone >7.5 mg/day in the medication history.
Conclusions: Autoantibody clusters were associated with the clinical features in women with SLE. Clustering autoantibodies could be a valuable approach for differentiating between various clinical subsets of SLE, and may help to guide prediction of the subsequent clinical course and organ damage in these patients.

SAT0276 EYE TOXICITY IN PATIENTS WITH SYSTEMIC LUPUS ERITHEMATOSUS TREATED WITH ANTIMALARICS IN DOMINICAN REPUBLIC

E. Rodríguez-Bautista[1], Y. Cruz-Rojas[1], I. Mercedes-Núñez[1], E. Tejada-Reyes[1], N. Abreu-Arbaje[2], M. Arbaje-Khoury[2], V. Rosario[1], R. Munoz-Louis[1], R. Peña-Blanco[3], T. Valdez-Lorie[3], R. Alba-Fériz[1]. *[1]Rheumatology, Hospital Docente Padre Billini; [2]Ophthalmology, Centro de Oftalmología y Glaucoma; [3]Rheumatology, Hospital Docente Universitario Francisco Moscoso Puello, Santo Domingo, Dominican Republic*

Background: Antimalarics are derivatives of quinine indicated in the treatment of autoimmune inflammatory diseases. The mechanism of antimalarial toxicity is unclear. It is hypothesized that toxicity is a result of drug binding to retinal pigmentary epithelium, damaging photoreceptors resulting in vision loss. Early retinal toxicity is asymptomatic with subtle alterations in foveal pigmentation generally not evident at routine ophthalmologic examination, progressively producing classic "bull's-eye" maculopathy, manifested as a decrease in central, color and night vision, and central scotoma. To prevent the sequelae of antimalarial use, sensitive tools are used to detect toxic maculopathy such as: campimetry, optical coherence tomography (OCT) and eye fundus.
Objectives: To evaluate ocular toxicity in patients with systemic lupus erythematosus treated with antimalarics.
Methods: Multicenter cross-sectional study, two rheumatology departments clinical records were analyzed from January 2016 to January 2017, with diagnosis of systemic lupus erythematosus according to ACR 1997 criteria, with $\geq$4 years using antimalarial drugs. 298 patients were identified, 93 of them fulfilled inclusion criteria, and were evaluated by two retinologists performing OCT on each patient. Accumulated antimalarial doses were calculated and all variables were analyzed with SPSS software V.22.
Results: 97.8% were females, the mean age was 37.4±13 years, 78.5% of the patients used 4mg/kg of chloroquine (CQ) versus 21.5% took 6mg/kg of hydroxychloroquine (HCQ), the mean use duration was 5.1±2 years, 19.4% of patients had retinal pigment epithelium (RPE) changes suggesting maculopathy, of which, 15% used CQ versus 4.35% with HCQ, 54.50% using CQ had a cumulative dose of 365 grams, 10.75% with HCQ had cumulative doses of 292 grams, and the mean for the cumulative dose of both antimalarials was 485 grams.
Conclusions: Previous studies have shown that the antimalarial toxicity rate are between 7.5%>13.1%, in our population we observed that our patients had a higher toxicity rate associated with the use of CQ compared to HCQ, and no association was found relevant with other variables. We understand that both, patients and physicians who manage this drug, should be educated about the need to maintain an adequate ophthalmologic control, due to the progression of retinopathy from 1 to 3 years after discontinuation of treatment. It is necessary to carry out prospective studies with a greater number of patients.

SAT0277 COGNITIVE DYSFUNCTION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN DOMINICAN REPUBLIC

E. Tejada-Reyes[1], I. Mercedes-Nuñez[1], Y. Cruz-Rojas[1], E. Rodríguez–Bautista[1], K. Polanco-Soriano[2], M. Perdomo-Ramirez[2], V. Rosario[1], R. Muñoz-Louis[1], R. Peña-Blanco[3], T. Valdez-Lorie[3], R. Alba-Fériz[1]. *[1]Rheumatology; [2]Psychology, Hospital Docente Padre Billini; [3]Rheumatology, Hospital Docente Universitario Dr. Francisco E. Moscoso Puello, Santo Domingo, Dominican Republic*

Background: Cognitive dysfunction (CD) is a deficit of cognitive faculties including attention, memory, language, executive function and visuospatial processing. CD is the most frequent neuropsychiatric manifestation of SLE (55–80%) 1 and this is 3 times higher in patients with Systemic Lupus Erythematosus (SLE) than in healthy subjects.2 This is not routinely evaluated because it requires a lot of time. Brief and simple questionnaires are needed to identify CD.
A study carried out by D'Amico et al. evaluated 21 SLE patients and all of them had CD.3 Pedraza et al. analyzed the MMSE score and Montreal Cognitive

Assessment (MOCA) and concluded that MOCA performs much better than MMSE for cognitive impairment correct diagnosis.4

Objectives: To determine the prevalence of CD in SLE patients and compare MMSE and MOCA diagnosis effectiveness.

Methods: All patients with at least 18 years old that met ACR/EULAR 2012 SLE classification criteria were included. Patients with associated comorbidity, not SLE related, that could alter cognitive functions, were excluded. 55 patients that fulfilled the inclusion criteria were admitted to Hospital Docente Padre Billini's rheumatology department from March to April 2016. After obtaining written consent, the psychology department applied both tests, MMSE and MOCA. A standardized form registered demographic variables. Data was analyzed using Microsoft Excel 2013.

Results: 94.5% of the patients were women, 53% were between 31–45 years old, 52.7% were mulatto ethnic, 34.5% had at least a high school degree, 27.2% were diagnosed 1 year before enrollment, 60% had a low activity score using SLEDAI (<4), hypertension was the most common comorbidity with a 38.1%, 90.9% were taking corticoids, 80% were on antimalarial drugs (6 abandoned treatment, 2 by eye involvement, 1 allergic reaction, 2 were diagnosed with SLE the interview day), the most frequent neuropsychiatric symptom ever presented was convulsion (7.2%). Using MMSE 25.4% of the patients showed CD, however after adjusting the results according to the educational level, the percentage increased to 41.8%. MOCA classified that 67.2% of the patients had CD, of which 13 patients were MMSS positive, and finally, 22 classified after the score adjustment.

Conclusions: MOCA is more effective than MMSE to detect CD. Nonetheless the MMSE should be considered as an option for patients with low levels of education.

SAT0278 INCREASED FREQUENCY OF NAILFOLD VIDEOCAPILLAROSCOPY ABNORMALITIES IN PRIMARY ANTIPHOSPOLIPID (PAPS) PATIENTS

E. Martin-Nares, G. Hernandez-Molina, P. Bermudez-Bermejo, V. Zamora-Legoff, T.S. Rodriguez-Reyna. *Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico*

Background: Primary antiphospholipid syndrome (PAPS) is characterized by venous and arterial thrombosis, obstetric morbidity and the presence of antiphospholipid antibodies. The utility of nailfold videocapillaroscopy in conditions such as scleroderma (SSc) and primary Raynaud's phenomenon is well known. Whether patients with PAPS have specific findings in nailfold videocapillaroscopy is not well stablished.

Objectives: To evaluate findings on nailfold videocapillaroscopy in patients with PAPS and their association with clinical and serological features.

Methods: We prospectively included 26 PAPS patients according to the modified Sidney criteria and the Alarcón-Segovia criteria for haematologic antiphospholipid syndrome, who regularly attend a tertiary referral center in Mexico City, and 15 healthy controls. We performed nailfold videocapillaroscopy according to the Cutolo technique (Optilia 200x) and obtained: capillary morphology, nonspecific abnormalities (tortuosity, crossed and dilated capillaries, capillary haemorrhages, neo-angiogenesis) and mean vascular density on 32 images per patient. We collected demographic, clinical (thrombosis, obstetric morbidity, non-criteria manifestations and comorbidities), serological (anticardiolipin antibodies, anti-β2 glycoprotein 1 antibodies and lupus anticoagulant) and treatment information. Analysis was performed used SSPS v.22, Chi square test was used to compare frequencies and Student's t test was used to compare means.

Results: PAPS patients had higher frequency of at least 1 abnormal finding on videocapillaroscopy (77% vs 12%, p<0.009, OR=23, 95% CI=4–132), higher frequency of enlarged capillaries (69% vs 0%, p=0.0001, OR=33, 95% CI=3.8–295), lower frequency of "perfect normal" pattern (11.5% vs 56%, p=0.004, OR=0.1, 95% CI=0.02–0.48) than controls, and 8 patients (31%) showed changes compatible with the "early" SSc Cutolo pattern (<4 dilated capillaries/mm, <4 haemorrhages/mm, preserved architecture and no avascular areas). In PAPS patients, capillary haemorrhages were associated to neurologic manifestations (75% vs 14%, p=0.02, OR=19, 95% CI=1.4–248) and to comorbidity with hypertension (75% vs 14%, p=0.02, OR=19, 95% CI=1.4–248).

Conclusions: PAPS patients frequently show at least one abnormality on videocapillaroscopy. The most frequent abnormalities are enlarged capillaries, microhaemorrhages and the presence of an "atypical normal" pattern. Capillary haemorrages are frequently found in patients with neurologic involvement of PAPS. The coexistence of hypertension or other comorbidities may contribute to the development of capillary abnormalities in PAPS patients.

SAT0279 ANTI-RO52 KDA AND ANTI-RO60 KDA ANALYSIS IN SYSTEMIC LUPUS ERYTHEMATOUS PATIENTS TO DETECT ANTI-RO FALSE-NEGATIVES

E. Grau Garcia[1], I. Chalmeta Verdejo[1], E. Labrador Sánchez[1], M. Fernandez Matilla[2], F.M. Ortiz-Sanjuan[1], C.M. Feced Olmos[1], N. Fernandez-Llanio[2], K. Arévalo Ruales[1], R. Negueroles Albuixech[1], J. Ivorra Cortes[1], J.J. Fragio Gil[1], I. Martínez Cordellat[1], R. González Mazarío[1], L. Gonzalez Puig[1], C. Alcañiz Escandell[1], C. Nájera Herranz[1], I. Cánovas Olmos[1], E. Vicens Bernabeu[1], J.E. Oller Rodriguez[1], J.A. Castellano Cuesta[2], V. Fornés Ferrer[3], D. Hervás Marín[3], D. Gimenez Romero[4], J.A. Román Ivorra[1]. *[1]Rheumatology Department, HUP la Fe; [2]Rheumatology Section, Hospital Arnau de Vilanova; [3]Biostatistics Unit, IIS la Fe; [4]Physical-Chemistry Department, UV, Valencia, Spain*

Background: Systemic lupus erythematous (SLE) is an autoimmune disease characterized by immune system disruption with autoantibodies production. One of the upregulated autoantibodies is the specific to the Ro antigen, a ribonucleoprotein associated to a small RNA, constituted by the 52KDa and 60 KDa polypeptides, whose epitopes are mainly conformational. The routine detection method for anti-Ro is an enzyme immunoassay, however, is possible to obtain false-negatives for anti-Ro and this could be avoided by analyzing both subunits separately.

Objectives: To identify false-negatives for anti-Ro by analyzing both 52KDa and 60 KDa subunits separately, as well as to characterize if there are clinical or molecular differences in this subgroup of patients compared to anti-Ro negative cases.

Methods: A cross-sectional, observational study of patients diagnosed of SLE according to SLICC 2012 criteria was performed. In these patients a complete blood-test was made, and clinical data by personal interview was collected. INF1A, Anti-Ro, anti-Ro52KDa and anti-Ro60KDa levels where measured by colorimetric methods. Biostatistical analysis was performed with R 3.3.2.

Results: We selected 69 SLE patients with negative results for anti-Ro (2.34±4.17 U/mL) out of 142 total SLE patients. A total of 51 patients were negative for both anti-Ro subunits and 18 cases presented positive results (up to 20 pg/mL) for at least one of them. The subgroup of patients that exhibit simultaneously high levels of anti-Ro52KDa and anti-Ro60KDa have higher clinical activity compared to negative anti-Ro cases (75% of active patients against 41.2% in anti-Ro negative patients). However, no differences in the accumulated damage evaluated by SLICC score between negative anti-Ro cases and patients with at least one positive subunit were observed. We analyze serum levels of INF1A cytokine in the four groups of patients, and anti-Ro and subunits negative cases showed significant lower INF1A levels than the other patients (8.26±14.87 pg/mL and 26.62±40.71 pg/mL respectively; P=0.04). In addition, patients with high levels of anti-Ro52KDa subunit are those with the highest INF1A levels (anti-Ro 52+/anti-Ro60- 23.5±47.6pg/mL of INF1A; anti-Ro 52+/anti-Ro60+ 36.4±37.9pg/mL of INF1A).

Conclusions: In our anti-Ro seronegative patients, a 26% of false-negative cases were detected. These cases with high levels of almost one anti-Ro subunit showed significantly higher levels of INF1A in contrast to negative cases, supporting the fact that they are indeed a different group from the negative cases. Moreover, the high INF1A levels could be the reason of the observed differences in the clinical activity measured by SLEDAI score in both groups.

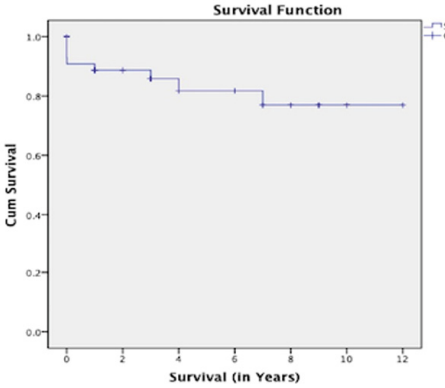
SAT0280 A TEN-YEAR SURVIVAL ANALYSIS OF FILIPINO PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AT THE NATIONAL KIDNEY AND TRANSPLANT INSTITUTE (PHILIPPINES)

E.M.L. Yap, C.C. Bermudez. *Internal Medicine, National Kidney and Transplant Institute, Quezon City, Philippines*



Background: Systemic lupus erythematosus (SLE) is increasingly being diagnosed in our country. Despite the increasing number of patients, there are no studies describing their clinical profile at the time of diagnosis at the National Kidney and Transplant Institute (NKTI). This study aims to describe patients' initial clinical presentations, outcomes, and their survival rate within ten years.

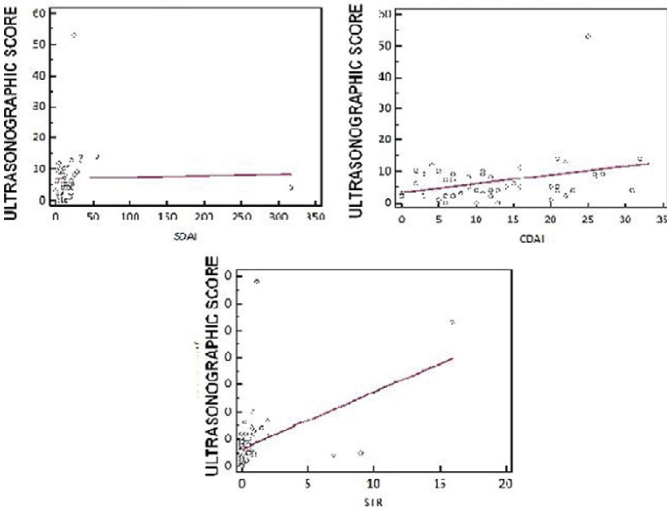
Objectives: To determine the ten-year survival rate and presenting clinical manifestations of Filipino patients first diagnosed with SLE at the National Kidney and Transplant Institute (NKTI)

Methods: This is a retrospective cohort study using chart review of patients first diagnosed with SLE in 2004 followed up in the next ten years.

Results: Eighty-five patients were first diagnosed with SLE wherein their average age was 28.10 years old ±12.03, 34.12% had hypertension, and 74.12% with renal involvement. The patients' cumulative 10-year survival was 75% with average survival time of 9.84 years. Moreover, biopsy- proven lupus nephritis had significantly longer survival time (mean=10.57 years, p=0.006) while those with cardiopulmonary manifestations had shorter survival (mean=0.71 years, p=0.030) as well as those on hemodialysis (mean=8.82 years, p=0.040). Lastly, eleven patients (12.94%) expired during the study period with active diseases and infections as the common causes of mortality.

Figure 1. Kaplan-Meier Curve showing the survival of patients with SLE from 2004 to 2014 ***(Mean=9.842, Median=8.625)***

Interval in years	Estimated Cumulative Survival Rate
1	87%
2	87%
3	84%
4	80%
5	80%
6	80%
7	75%
8	75%
9	75%
10	75%



Conclusions: The 10-year survival rate of patients with systemic lupus erythematosus was 75% which was comparable to the findings from several countries. Although renal involvement was the most common initial manifestation, it did not significantly affect survival similar to prominent studies.

SAT0281 JOINT ACTIVITY INDICES CORRELATES WITH ULTRASONOGRAPHIC SCORE IN SLE PATIENTS WITH MUSCULO-SKELETAL INVOLVEMENT

E. Cipriano, F. Ceccarelli, C. Perricone, L. Massaro, G. Capalbo, F. Natalucci, F.R. Spinelli, F. Miranda, S. Truglia, C. Alessandri, G. Valesini, F. Conti. *Medicina Interna e Specialità Mediche, Sapienza Università di Roma, Roma, Italy*

Background: Joint involvement represents one of the most frequent manifestations in Systemic Lupus Erythematosus (SLE) patients (incidence 69–95%), with different degrees of severity. Currently, there are no validated indices to evaluate joint involvement in SLE. Musculo-skeletal ultrasonography (US) has been widely applied in patients affected by different arthropathies. US-detected synovitis reflects the inflammatory state at the joint level, as demonstrated by the correlation with histological modifications. Furthermore, US-synovitis significantly correlated with disease activity indices, such as DAS28.
Objectives: In the present study, we aimed at assessing a correlation between the composite indices DAS28 (Disease Activity Score 28), CDAI (Clinical Disease Activity Index), SDAI (Simplified Disease Activity Index), STR (Swollen to Tender Ratio) and the US-detected synovitis in a cohort of SLE patients with joint involvement.
Methods: One hundred seven patients (M/F 7/100, mean age ±SD 48.4±13.8 years, mean disease duration ±SD 156.0±129.6 months) with at least one tender joint were enrolled. We registered the number of swollen and tender joint count (0–28) and the patient's/physician's disease activity on visual analogue scale (0–100). DAS28-ESR, CDAI, SDAI and STR were calculated. The US evaluation of 12 joints (I-V metacarpophalangeal, I-V proximal interphalangeal, wrist and knee bilateral) was performed to identify inflammatory features (synovial effusion, synovial hypertrophy and power Doppler) according with OMERACT definitions. These elementary lesions were scored according to a semi-quantitative scale (0 = absent, 1 = mild, 2 = moderate and 3 = severe). The sum of the semi-quantitative scores allows obtaining a total score of the patient's inflammatory state (0–216).
Results: As reported in Figure 1, by using the Spearman analysis, a positive correlation between US-score and SDAI (r=0.33, P=0.02), CDAI (r=0.29, P=0.03) and STR (r=0.42, P=0.0005) was identified. In particular, SLE patients with high disease activity according with STR value (>1) showed a higher US score (16.3±19.3) in comparison with moderate (7.7±4.5, P=NS) or low disease activity (7.1±7.9, P=0.02). Moreover, US score resulted significantly lower in patients with DAS28 remission compared to those with an active disease (4.5±4.4 *versus* 7.05±5.1, P=0.03; Mann-Whitney test).
Conclusions: We analyzed a large SLE cohort with articular involvement identifying a significant correlation between US scoreand the composite indices CDAI, SDAI and STR. Furthermore, US-score may be able to discriminate DAS28-remission patients. Taken together, these results suggest the ability of composite indices in detecting the joint activity in SLE patients and the possibility

Figure 1: correlation between US score and SDA, CDAI, STR

to use them in clinical practice to assess this frequent and potentially disabling manifestation.

SAT0282 AUTOIMMUNITY AND PREGNANCY: EVIDENCE FROM AN OBSERVATIONAL STUDY

F. Del Porto[1], S. Ferrero[2], M. Proietta[3], N. Cifani[3], M. Catoni[1], F.M. Ubaldi[2], L. Rienzi[2], L. Ferri[1], R. Di Rosa[3]. *[1]SApienza University; [2]Genera Valle Giulia, Roma; [3]SApienza University, Rome, Italy*

Background: Obstetrical APS is defined by positive aPLs and a history of one or more unexplained deaths of morphologically normal fetus at or beyond the 10th week of gestation (WG) or one or more consecutive spontaneous abortions before the 10th WG. Also one or more premature birth before 34 WG because of eclampsia, severe pre-eclampsia, or recognized features of placental insufficiency represent one of the diagnostic criteria (1). Infertility is defined as the inability of a couple practicing frequent intercourse and not using contraception to conceive a child after 12 months. Autoimmune diseases are not inclued among major causes of infertility, despite defective embryonic implantation could be considered an aspect of recurrent fetal losses in patients with positive antiphospholipid antibodies, due to their capabilities to reduce trophoblast prolipheration and growth (2).
Objectives: The aim of our study was to evaluate the prevalence of aPLs and pregnancy outcome in a population of women undergoing in vitro fertilization.
Methods: from December 2012 to December 2016, we selected 75 consecutive patients undergoing in vitro fertilization and evidence positive autoantibodies. Each of them was evaluated for genetic, anatomic, hormonal and infective causes of infertility. Moreover antinuclear antibodies (ANA), anticardiolipin antibodies (aCL), anti-β2-glycoprotein I (GP1), lupus anticoagulant (LA) and extractable nuclear antigens (ENA) profile were assessed.
Results: patients mean age was 41.38±4.87 years, ranging from 31 to 53 years. Prevalence of aPLs in our population was 68%. All women showed at least twice positive aPLs. aCL IgM and LA were the main antibody populations observed. ANA were positive in 50% of women, whereas SSA or SSB were positive in 4.17%. In 22.9% of patients a systemic autoimmune disease was newly diagnosed, mainly systemic lupus erythematosus. All patients with hystory of recurrent miscarriages and positive aPL were treated with subcutaneous low weight heparin plus daily oral acetylsalicylic acid (ASA 100 mg) (3). Full term pregnancy was obtained in 45.8% of patients.
Conclusions: Prevalence of aPLs in the general population is 1–5%, whereas in our selected series positive aPLs were detected in 68% of the patients, suggesting that prevalence of aPLs may be increased in infertile patients (4). Moreover, a systemic autoimmune disease was newly diagnosed in 22.9% of patients suggesting that paucisimptomatic disease can be underestimated. Finally we would suggest that treating autoimmune co-morbidities ameliorates implantation rates in women undergoing in vitro fertilization (5).

SAT0283 ANTIBODIES TO CARBAMYLATED VIMENTIN IN PATIENTS WITH SYSTEMC LUPUS ERYTHEMATOSUS ARE ASSOCIATED WITH RENAL INVOLVENMENT

F.R. Spinelli, S. Truglia, T. Colasanti, A. Pecani, F. Ceccarelli, F. Miranda, R. Mancini, C. Perricone, M. Pendolino, C. Alessandri, G. Valesini, F. Conti.
Dipartimento di Medicina Interna e Specialità Mediche - Reumatologia, Sapienza Università di Roma, Rome, Italy

Background: Vimentin is a cytoskeleton protein of the intermediate filaments family, expressed by mesenchymal cells including vascular endothelial cells and renal tubular cells. Vimentin has been recently proposed as a target of the in situ immune response in lupus nephritis. Antibodies to vimentin have been described in 10–53% of patients with Systemic Lupus Erythematosus (SLE) and account for a fibrous pattern of cytoplasmic immunofluorescence. Post-translational modifications increase the immunogenicity of vimentin, as demonstrated by the detection of anti-modified vimentin antibodies in patients with rheumatoid arthritis. Carbamylation is a non-enzymatic post-translational modification consisting in the addition of a cyanate group on lysine and arginine residues; since carbamylation is time dependent, structural proteins with a slow turnover are more likely to be carbamylated. The role of carbamylated vimentin as an antigenic target in SLE has not been yet evaluated.
Objectives: Aims of the study were to assess the prevalence of anti-carbamylated vimentin in a cohort of SLE patients and to evaluate the possible associations with clinical and serological feature of the disease.
Methods: Patients with SLE classified according to 1987 ACR criteria were enrolled. Clinical features, autoantibodies profile and disease activity – as measured by SLE Disease Activity Index 2000 (SLEDAI 2K) - were collected. Sera obtained from each patient were tested for anti-carbamylated vimentin by a home-made enzyme-linked immunoassay. Data were expressed as mean±standard deviation or median (interquartile range) when appropriate. To investigate difference in anti-carbamylated vimentin prevalence and anti-carbamylated vimentin serum levels Mann-Whitney and Chi square test were applied. P value <0.05 was considered statistically significant.
Results: We enrolled 109 SLE patients (102F:7M, mean age 39.4±12.6 years, mean disease duration 10.5±9.5 years, mean SLEDAI 2K 5±5.5).
Overall, 30 out of 109 patients (27.5%) were positive for anti-carbamylated vimentin. According to the clinical features, the prevalence of anti-carbamylated vimentin was significantly higher in patients with lupus nephritis (18/44) compared to those without renal involvement (12/66) (41.8% vs 18.2%, p=0.006); moreover, anti-carbamylated vimentin serum levels were significantly higher in patients with lupus nephritis [2561 (1783) OD] compared to those without [1970 (1123) OD; p=0.0178]. We didn't find any difference in prevalence or titre of anti-carbamylated vimentin according to presence/absence of other clinical manifestations (musculoskeletal, muco-cutaneous, hematologic, neuropsychiatric) or serology (low complement, anti-dsDNA). Moreover, we did not find any correlation between anti-carbamylated vimentin serum levels and SLEDAI 2K.
Conclusions: Higher prevalence and serum levels of anti-carbamylated vimentin antibodies in patients with lupus nephritis confirm the role of vimentin as a target of the immune response in patients with glomerulonephritis and suggest their possible role as a biomarker of kidney involvement in SLE patients.

SAT0284 ASSOCIATION OF PATHOGENIC AND REGULATORY B-CELL SUBSETS WITH CLINICAL AND HISTOLOGICAL FEATURES IN PRIMARY SJÖGREN'S SYNDROME

F. Carubbi[1,2], A. Alunno[3], P. Cipriani[1], P. Di Benedetto[1], V. Liakouli[1], P. Ruscitti[1], O. Berardicurti[1], S. Di Bartolomeo[1], R. Gerli[3], R. Giacomelli[1].
[1]Department of Biotechnological and Applied Clinical Science, Rheumatology Unit, School of Medicine, University of L'Aquila; [2]Department of Medicine, ASL1 Avezzano-Sulmona-L'Aquila, L'Aquila; [3]Department of Medicine, Rheumatology Unit, University of Perugia, Perugia, Italy

Background: Several data pointed out that B-cells play a central role in the development, maintenance and progression of primary Sjögren's syndrome (pSS). B-lymphocyte hyperactivity, salivary gland (SG) infiltration, and the development of B-cell follicles containing germinal center (GC)-like structures, represent hallmarks of the disease. On this basis, B-cell depleting therapy with anti-CD20 monoclonal antibody rituximab (RTX) has been employed in pSS showing promising results. However, currently available data do not allow to draw definitive conclusion on its efficacy.
Objectives: Aim of the study was to assess mature and regulatory B cell subsets in patients with pSS and explore possible associations with clinical and histological features and their possible modulation by RTX treatment.
Methods: We evaluated by flow cytometry peripheral blood (PB) B-cell subsets (mature B cells: Bm1, Bm2, Bm2', Bm3, Bm4, early(e)Bm5, Bm5; IL-10-producing B-cells), in 17 pSS patients and in 10 healthy donors (HD). Nine pSS patients received a course of RTX (1000 mg at days 1 and 15) and PB B-cell subsets were also evaluated after 3 (T3) and 6 (T6) months and compared to baseline values (T0).
Results: We confirmed that the percentage of Bm1, eBm5 and Bm5 was lower and that of Bm2, Bm2' and Bm3+Bm4 was higher in pSS patients compared to HD (all $p<0.05$). When we divided patients according to the ESSDAI score (<5 or ≥ 5) or to SG-GC (presence/absence), we observed for the first time that the percentage of Bm2' cells, also called GC founders, was higher in patients with ESSDAI≥ 5 ($p=0.02$) compared to those with lower ESSDAI score and in pSS patients with GC ($p=0.02$) compared to those without GC. Although we observed a reduction of all B-cells subsets at T3 and T6 after RTX treatment, the proportion of Bm1, Bm3+Bm4, eBm5 and Bm5 persisted lower and the percentage of Bm2 and Bm2' persisted higher in pSS patients ($p<0.05$) compared to HD. No differences regarding IL-10-producing B-cells was obeserved between pSS patients and HD. However, the percentage of IL-10-producing B-cells was higher in patients with ESSDAI≥ 5 compared to patients with ESSDAI<5 ($p=0.02$).
Conclusions: We demonstrated for the first time that a subset of circulating mature B-cells, Bm2', also called GC founders, is strongly associated with higher disease activity and with the presence of SG-GC. Moreover, a higher ESSDAI is associated with higher percentage of circulating IL-10-producing B-cells. Pathogenic B-cell hyperactivity is a hallmark of pSS, however B-cells are also a source of inhibitory cytokines such as IL-10 and TGF-beta and the increase of IL-10 producing B cells that we observed in active pSS patients may suggest an ongoing compensatory mechanism to counteract chronic inflammation. Therefore, the design of novel B cell targeted therapies should ensure that only pathogenic B cells are depleted and regulatory B cell subsets are not hampered while, ideally, potentiated.

SAT0285 THE PHYSICAL PERFORMANCE OF SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITH LOW DISEASE ACTIVITY: COULD THE CARDIOPULMONARY EXERCISE TESTING REFINE ITS ASSESSMENT?

G. Gusetu[1], A. Mociran[2], C. Pamfil[3], L. Damian[2], D. Pop[1], D. Zdrenghea[1], S. Rednic[3]. *[1]Cardiology, University of Medicine and Pharmacy; [2]Rheumatology, County Emergency Hospital; [3]Rheumatology, University of Medicine and Pharmacy, Cluj-Napoca, Romania*

Background: Even during remission, the systemic lupus erythematosus (SLE) patients have reduced exercise performance and this contributes to impairment of their quality of life[1]. Several causes as depression and deconditioning, arthritis, anemia, cardiovascular and respiratory involvement are widely accepted; however the weight of each factor is less known in particular individuals.
Objectives: Our study aimed to assess through cardiopulmonary exercise testing (CPX) the exercise performance of a SLE cohort and to establish its main determinants.
Methods: Thirty-one SLE patients with low disease activity underwent a CPX on cycle ergometer; the main metabolic parameters and standard 12-leads ECG were recorded; before exercise testing, a cardiac Doppler ultrasound was performed. The patient's characteristics, cumulative organ damage and laboratory data were retrieved by medical chart review. The control group consisted of 25 age and sex-matched healthy, non-trained individuals.
Results: Within the study group, 28 (90.3%) were female, the mean age was 42.7±10.6 years and disease median duration 7.9 years. The aerobic performance was decreased by 16.2% (17.6 vs 21.36 ml/kg/min, p=0.022); the main disease characteristics which correlated with maximum oxygen uptake (VO2Mx) were anemia (p=0.035), renal involvement (p=0.05) and antiphospholipid syndrome (APS) (p=0.042) but not disease duration, cumulative damage or the immunological tests (hypocomplementemia, anti-Ro, anti-Sm, anti-dsDNA, AAN or APL antibodies).
One quarter of patients did not reach the ventilatory anaerobic threshold (VAT, expressed as a percentage of calculated VO2Mx), mainly due to musculoskeletal pain (5 patients), dyspnea (2 patients with history of pulmonary embolism) and sudden rise in blood pressure (1 patient). Among the rest of them (23 patients, 74%), the VAT was at the lower limit of normal range (41.03% vs 54.0% for controls, p=0.014) corresponding to a "training reserve" of 31%. Of particular importance from this point of view were the criteria for test termination: dyspnea in 4 patients (1 with anemia, 1 with pulmonary fibrosis and 2 by hyperventilation proved by mean VE/VCO2 =41.5), fatigue (9 patients) and arthralgia (7 patients). Notably, among patients with established diagnosis of mild pulmonary fibrosis, COPD, ischemic or valvular heart disease, not dyspnea but arthralgia or fatigue was the reason for test termination, even if the VO2Mx was lower than recorded in the rest of the group (15.8 vs 19.2 ml/kg/min, p=0.037).
Conclusions: The exercise aerobic capacity of SLE patients is diminished and correlates with anemia, renal involvement and with hystory of pulmonary embolism. Surprisingly, even in patients with mild cardiovascular or respiratory involvement, the decreasing of exercise performance is limited mainly from musculoskeletal symptoms and from deconditioning.

SAT0286 INCIDENCE AND MORTALITY OF PRIMARY SJÖGREN'S SYNDROME: TIME TRENDS OVER A 40-YEAR PERIOD IN A POPULATION-BASED COHORT IN THE UNITED STATES

G. Maciel[1,2], C. Crowson[3], E. Matteson[1], D. Cornec[4,5]. *[1]Rheumatology, Mayo Clinic, Rochester Minnesota, United States; [2]Hospital Maciel, Montevideo, Uruguay; [3]Division of Biomedical Statistics and Informatics, Department of Health Sciences Research; [4]Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester Minnesota, United States; [5]Rheumatology, CHRU Brest, Brest, France*

Background:
Few studies have reported the incidence of primary Sjögren's syndrome (pSS) in well-defined populations worldwide, and none of them covered a period of time long-enough to analyze potential time trends in incidence rates. Whether pSS is associated with a higher mortality rate compared to the general population is also unclear from previously published studies.
Objectives: To estimate the incidence and mortality rates of pSS among residents of Olmsted County, Minnesota, and their evolution over time.
Methods: All medical records of patients with a diagnosis or suspicion of SS in Olmsted County, MN, from January 1, 2006 to December 31, 2015 were reviewed to identify incident cases of pSS (defined according to physician diagnosis). All patients with doubtful cases and all patients with an associated systemic autoimmune disease were excluded. These cases were combined with a previous 1976–2005 incident cohort from the same population (reference). Incidence rates were age and sex adjusted to the US white 2010 population. Survival rates were compared with the expected rates in the general population of Minnesota.
Results: With 61 incident cases of pSS diagnosed in Olmsted County in 2006–2015, the total cohort included 172 patients with incident pSS in 1976–2015. Of the 172 patients, 151 (88%) were women and 161 (94%) were white, with a mean (SD) age at diagnosis of 58.3 (16.7) years. The average age- and sex- adjusted annual incidence for 2006–2015 was 5.9 per 100,000 population (95% CI 4.4–7.4), and overall incidence for the entire period was 5.8 (95% CI: 4.9–6.6) per 100,000. Incidence was 2 to 7 times higher in females compared to males in the different age classes (5.9 times higher on average), and increased progressively with age, culminating at 19.6 per 100,000 in females aged 65–74 years, with a slight decline thereafter to 15.9 per 100,000 among females aged 75 years and older. The incidence increased with calendar time over the 40-year period (p=0.005, figure). There was no apparent seasonality in the incidence of pSS, with similar number of cases diagnosed during all four seasons. There was no difference in mortality in the pSS cohort compared to expected (standardized mortality ratio 1.15, 95% CI 0.86–1.50).

Conclusions: The average annual incidence of pSS in this population based-cohort was 5.8/100,000, with a progressive increase over the 40 years of the study. Overall survival of pSS patients was not different from the general population.

SAT0287 TH1, TH2 AND TH17 LYMPHOID SUBPOPULATIONS IN PRIMARY ANTIPHOSPHOLIPID SYNDROME

G. Medina[1], O.I. Florez-Durante[2], L. Montiel Cervantes[3], R. Molina-Aguilar[3], E. Reyes-Maldonado[2], L.J. Jara[4]. *[1]Clinical Research Unit, Instituto Mexicano del Seguro Social, Hospital de Especialidades Centro Médico la Raza; [2]Escuela Nacional de Ciencias Biológicas, Instituto Politécnico Nacional; [3]Hematology Laboratory; [4]Direction of Education and Research, Instituto Mexicano del Seguro Social, Hospital de Especialidades Centro Médico la Raza, Mexico City, Mexico*

Background: Primary antiphospholipid antibody syndrome (PAPS) is characterized by thrombosis at different levels and maternal fetal complications in the presence of antiphospholipid antibodies (aPL). Lymphoid subpopulations and cellular immune responses have not been fully studied.
Objectives: To analyze the lymphoid subpopulations, Th1, Th2 and Th17 immune response in patients with PAPS and long term evolution.
Methods: Patients with PAPS,>18 years of age, of both sexes and a group of healthy blood donors matched for age and sex were included. All patients were receiving oral anticoagulants (Coumadin type). No patient had a recent episode of thrombosis or other manifestation of APS at the time of the study. Peripheral blood was obtained and lymphoid subpopulations were determined by flow cytometry in order to identified with specific immunological markers for Treg cells: CD4+/CD25+/FoxP3+ and CD8+/CD25+/FoxP3+. The dendritic cells analyzed were: Type 1: Lin1- HLA-DR+/CD11c+; Type 2: Lin-HLA-DR+/CD123+; B lymphocytes with antiCD19-APC; Monocytes with anti-CD14-PE; NK: CD3-/CD16+56+ and NKT: CD3+/CD16+56+ lymphocytes. Th1 cells were identified by IFN-g$^+$ positivity; Th2: positivity for IL-4+; Th17: positivity for IL-17+. Parametric statistics and Mann-Whitney U-test were used.
Results:

	PAPS (cells/μL)	Healthy controls (cells/μL)	p
Total leukocytes	5655	7000	<0.05*
Lymphocites	1800	2085	NS
Total CD3	1033	1338	NS
Total CD4	701	775	NS
Total CD8	258	441	<0.05*
Monocytes	213	219	NS
B lymphocites	41	86	NS
NK	118	177	NS
NKT	33	45	NS
iNKT	9	20	<0.005**
Tγδ Lymphocites	34	45	NS
LTreg 4 Lymphocites	23	13	NS
Treg 8 Lymphocytes	26	13	NS
DC1	2	4	<0.005**
DC2	1	5	<0.0005***

A total of 39 patients with PAPS were included, age: 51.9±12.8, evolution time: 12.8±8.9 years and 35 healthy controls. In patients with PAPS there was a decrease in the total CD8 count ($p<0.05$) in iNKT ($p<0.005$), DC1 ($p<0.005$) and DC2 ($p<0.0005$) cells compared to the control group (Table 1).We found significant decrease in Th1, Th2 and Th17 cytokines basal and after activation compared to healthy controls.
Conclusions: This study shows profound alterations in innate and adaptive immunity in patients with long-term PAPS, characterized by a decrease in certain lymphocyte subpopulations, with consequent functional alteration. These abnormalities can become new therapeutic targets in order to restore immune imbalance. Our findings may explain in part, the development of thrombosis and other complications, despite treatment with oral anticoagulants in PAPS patients with long term disease evolution.

SAT0288 QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC LUPUS ERIYTHEMATOSUS

G. Voicu[1], L. Groseanu[1], M. Abobului[1], V. Vlad[1], F. Berghea[1], D. Predeteanu[1], V. Bojinca[2], I. Saulescu[2], A. Borangiu[2], S. Daia[2], D. Mazilu[2], A. Balanescu[2], C. Constantinescu[2], D. Opris[2], R. Ionescu[2]. *[1]Rheumatolgy; [2]internal medicine and Rheumatolgy, Sfanta Maria Clinic Hospital, Bucharest, Romania*

Background: The Quality of life (QoL) in patients with SLE is deeply affected by multiple factors including psychological and physical factors, the functional status and the general perception over health.
Objectives: Evaluation of Quality of life and the perceptions over the disease in patients with SLE.functional status and the general perception over health.
Methods: This is a 10 month prospective, cross-sectional study performed on 52 patients hospitalized diagnosed with SLE according to SLICC 2012 criteria. There were evaluated demographic data, organs manifestations, disease activity scores (SLEDAI, SLICC) and treatment. To evaluate the QoL several questionnaires were performed: Health Assessment Questionnaire (HAQ), EuroQol five dimensions questionnaire (EQ5d), Illness Perception Questionnaire and SF-36.
Results: All patients were women with the mean age 49 years with a mean durations of illness 136 month (14). The mean SLEDAI – 5,52 (5,37) and SLICC – 2,25 (1,71).
The mean HAQ value was 0,83 (0,81). The HAQ score doesn't correlate with SLICC (p=0,461) and with SLEDAI (p=0,172), but it was correlated with the neuropsychiatric manifestations. So the psychiatric affectation influences performing the usually daily activities (p=0,005).
When assessing Illness Perception Questionnaire, patients considered their life seriously affected by pain, mean value 6,3 (2,6), 72% consider the illness will be

present for the rest of their lives, 90% appreciate that treatment is improving the QoL mean 9,3 (1,3), 68% consider to have many severe symptoms, more than 80% patients consider themselves preoccupied for their illness, more than 70% are emotionally affected by their illness and 48% consider stress being the main determinant factor of their illness.
Questionnaire EQ-5d: 10% must stay in bed due to the disease, 8,33% can not wash or dress themselves, 12,5% are unable to perform usual daily activities, 62% experience pain or a moderate uncomfortable state and 65% are worried and or depressed. Cardio-vascular manifestations are correlated with diminished mobility (p=0,002) leading to deficiency in self care (p=0,002)also correlated with renal (p=0,034) and psychiatric (p=0,022) manifestations. Psychiatric manifestations also affect usual daily activities (p=0,05). Age is correlated with pain and uncomfortable state (p=0,004) but the responses to this item of EQ5D are not correlated with organ affectation, biological modification or disease activity scores. The presence of cutaneous manifestations is correlated with anxiety and depression (p=0,02).
Based on SF36 when calculating the mean value on each category was observed all the 8 categories affected - smallest values at physical role (37,32) and general health (34,21), less influenced part being the social function (51,32).None of this items of SF 36 is correlated with SLICC or SLEDAI.
Conclusions: SLEDAI as well as SLICC or specific organ involvement give no indications over the patients QoL, which must be assessed by performing HAQ and SF 36.

SAT0289 CARDIOVASCULAR RISK STATUS MODIFICATION IN SLE PATIENTS BY MEANS OF CAROTID ULTRASOUND EXAMINATION

H. Sánchez-Pérez, B. Tejera-Segura, I. Ferraz-Amaro. *Rheumatology, Hospital Universitario de Canarias, la Laguna, Spain*

Background: Systemic lupus erythematosus (SLE) is associated with a higher cardiovascular risk (CVR), at least doubled when compared with the general population, as well as an increased prevalence of atherosclerosis,which occurs prematurely and independently of traditional CVR factors. The presence of atheromatous plaques documented with carotid ultrasound (US) examination implies a change in the patient's CVR category to "very high risk",according to the "European Guidelines on cardiovascular disease prevention in clinical practice, 2016". General guidelines do not take into account the specific increase in CVR risk that it's present in patients with autoimmune diseases.
Objectives: To examine if the use of carotid US leads to a more accurate CVR classification in SLE patients, and in that way to a better CVR management.
Methods: Cross-sectional study that emcompassed 102 SLE patients currently being followed in our Rheumatology Department. Demographic variables, the presence of CVR factors and previous/current CV events, disease duration and drug use were analysed; lipid profile was assessed using blood tests, as well as carotid intima media thickness and the presence of carotid plaques using US scan. The current CVR status was calculated using the SCORE classification (low risk $<$1%, moderate risk $<$5%, high risk $<$10% and very high risk $>$10%).
Results: 95% of our patients were women,mean age was 51.6+/- years,median disease duration was 16 years (IQR 9–28). 35.29% of patients presented with at least one CVR factor before the SLE diagnosis,and 61.76% at the time of the research (19.60% current smokers, 39.21% high blood pressure (HBP),33.33% dyslipidemia, 7.84% type II diabetes. A CV event was diagnosed in 11.76% of our patients throughout their SLE disease. According to the SCORE classification,55 of them had a low CVR (53.92%),26 moderate CVR (25.49%),6 high CVR (5.88%) and 15 of them very highCVR (14.70%). Carotid plaques were found in 28 patients (27.45%): 23 of them had never had a CV event (22.54%),21.42% of them were current smokers,64.28% had HBP,53.57% dyslipidemia and 17.86% type II diabetes. After adjustment of the SCORE classification with the presence of carotid plaques,16.36% of patients from the "low CVR" category would be re-classified has having "very high CVR", as well as 30.76% from the "moderate CVR" category and 50% from the "high CVR" category. Of note,8 patients within the "very high CVR" category also presented carotid plaques. Out of this patients with atheroma plaque,13 were not using statins,and in 2 of them it would have been mandatory in order to achieve the LDL $<$70mg/dl target. In 2 of the 15 patients that were indeed under statins this target was not achieved. 60.71% of the atheromatous patients were under hydroxicloroquine use and 17.64% of them used steroids as a regular basis (33.33% of them within the medium range dose)
Conclusions: More than half of our SLE patients presented with at least 1 CVR factor. Around 15% of patients were categorised as "very high CVR" according to the SCORE classification.The presence of carotid plaque was found in 27.45% of our patients,and 82% of them hadn't suffered any CV event. The use of carotid US examination allowed us to re-classify 20 patients (19.60%)in the "very high risk" category according to the SCORE classification. The need for a change in CVR management (ie., change in statin regime)was demonstrated in 4 of this 20 "re-classified" patients.

DOI: 10.1136/annrheumdis-2017-eular.6632

SAT0290 OSTEONECROSIS IS THE MOST COMMON ORGAN DAMAGE AND IS ASSOCIATED WITH CUMULATIVE STEROID DOSAGE AS WELL AS LUPUS NEPHRITIS ITSELF IN PATIENTS WITH SLE

H.H. Kwon[1], S. Won[2], Y.B. Joo[3], M.J. Kim[1], H.Y. Kim[1], G.Y. Ahn[1], S.-C. Bae[1]. *[1]Hanyang University Hospital for Rheumatic Diseases; [2]Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul; [3]St Vincent's Hospital, Suwon, Korea, Republic Of*

Background: In patients with SLE, musculoskeletal system is common organ system involved cumulatively over time. Osteonecrosis (ON) is common in musculoskeletal damage accrual and often disabling. Steroid use has been a risk factor in the development of ON, but SLE itself has also been suggested to have a role. It is important to understand factors related to the development of ON.
Objectives: We investigated the overall profile of organ damage accrual, particularly musculoskeletal damage and focused on factors associated with ON in a single Asian cohort.
Methods: Patients with SLE who met American College of Rheumatology (ACR) criteria were enrolled and followed from 1998 to 2014 in the Hanyang BAE Lupus cohort. Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI) was measured annually. ON was confirmed by X-ray, bone scan or MRI. Patients with ON was compared to controls without ON from the same cohort for clinical, laboratory, and therapeutic factors. Univariate logistic regression followed by multivariate logistic regression were used to determine risk factors for ON.
Results: We recruited 1,219 SLE patients. The most common type of organ damage was musculoskeletal (205 patients, 16.8%). ON was the most common subtype (133 patients, 10.9%) of the musculoskeletal damage. The mean time from diagnosis of SLE to development of ON was 4.97±4.15 (0.17∼20.25) years. One hundred twenty-six patients were eligible for identifying distribution of ON. Overall, 291 joints were affected by ON and mean number of ON joint per patients with ON was 2.3±1.23 (1∼9). The percentage of $>$2 joint involvement was 24.6%. The hip (femoral head) was the most frequently involved joint (65.6%), followed by the knee (distal femur, proximal tibia, proximal fibula, patella: 20.6%), shoulder (humeral head: 5.2%) and ankle (distal tibia, distal fibula, talus: 5.2%).
In univariate analysis, age at diagnosis, follow up duration, accumulative number of ACR criteria, serositis, renal disorder & neurologic disorder (based on ACR criteria), cyclophosphamide & mycophenolate use, and cumulative steroid dosage were significantly associated with ON. In multivariate analysis, renal disorder (p=0.0109), and cumulative steroid usage (p=0.0131) were significantly associated with ON.
To evaluate the effect of cumulative steroid usage on ON, age, sex and disease duration matched ON cases and controls (1:4, a total of 665 patients) were selected from the same cohort. Total cumulative steroid dosage was divided into 4 groups by grams ($>$0 & $\leq$5g, $>$5g & $\leq$10g, $>$10g & $\leq$20g, and $>$20g). More than 10g group of cumulative steroid use was significantly associated with ON. And then we stratified 530 patients according to biopsy proven lupus nephritis (class III to V) and cumulative steroid dose (10g cut-off), and tested by Chi-square test and logistic regression. ON was significantly higher in the group with lupus nephritis within $>$10g group of total cumulative steroid.

Table 1. Total cumulative steroid dose as risk factor for ON

Total cumulative steroid dose(g)	OR (95% CI)	p-value
>0 & ≤5	1.00	
>5 & ≤10	2.00 (0.91-4.39)	0.0844
>10 & ≤20	2.34 (1.19-4.58)	0.0133
>20	2.96 (1.60-5.47)	0.0005

Table 2-1. Association between Osteonecrosis and lupus nephritis based on total cumulative steroid 10g

Total cumulative steroid dose >10g (371 patients)				
	Total	ON(+)	ON(-)	p-value
Lupus nephritis(+)	196	58(29.59)	138(70.41)	0.0018
Lupus nephritis(-)	175	27(15.43)	148(51.75)	

Table 2-2. Association between Osteonecrosis and lupus nephritis based on total cumulative steroid 10g

	OR (95% CI)	p-value
Steroid dose≤10 & Lupus nephritis(-)	1.00	
Steroid dose>10 & Lupus nephritis(-)	1.58 (0.81-3.10)	0.1826
Steroid dose≤10 & Lupus nephritis(+)	2.48 (1.02-5.99)	0.0441
Steroid dose>10 & Lupus nephritis(+)	3.64 (1.97-6.75)	<0.0001

Conclusions: ON was the most frequent damage in lupus patients. We confirmed again cumulative steroid dosage as a risk factor for the development of ON. In addition, lupus nephritis itself was suggested as an independent risk factor for ON.

SAT0291 NON-REPORTING OF SYSTEMIC LUPUS ERYTHEMATOSUS IN DEATH CERTIFICATES OF LUPUS PATIENTS: ITS EXTENT AND PREDICTORS

I. Padjen[1,2], M. Erceg[3], M. Cerovec[1,2], M. Mayer[1,2], R. Stevanović[3], B. Anić[1,2]. *[1]Department of Internal Medicine, Division of Clinical Immunology and Rheumatology, University Hospital Centre Zagreb; [2]University of Zagreb, School of Medicine; [3]Croatian Institute of Public Health, Zagreb, Croatia*

Background: Systemic lupus erythematosus (SLE) is frequently not reported in death certificates of lupus patients, despite its known role as an underlying and/or immediate cause of death. Possible reasons may be insufficient access to patients' medical records at time of death (including details on their medical history) and/or physicians' unawareness of the contribution of SLE to death.
Objectives: We aimed to analyze the extent and predictors of non-reporting of SLE in death certificates of 90 deceased SLE patients regularly followed-up in a routine academic setting at our Department.
Methods: We retrospectively observed 90 SLE patients (68 females) deceased within the 2002–2011 period. All patients were ≥18 years of age and Croatian residents at the time of death, fulfilling ≥4 classification criteria of the American College of Rheumatology (ACR). We identified patients with SLE listed as a cause of death in the death certificate. An extensive set of variables was compared between patients with and without SLE reported in the certificate: demographics, ACR criteria at time of death and damage according to the Systemic Lupus Erythematosus International Collaborating Clinics (SLICC)/ACR index and its components at the time of death. We also compared the proportion of in-hospital deaths and autopsies performed. Frequencies were compared using the χ^2 and Fisher's exact test, and continuous variables using the t-test and Mann-Whitney U test. Variables associated with reporting of SLE in the death certificate in the univariate analysis were included in a multivariate logistic regression model.
Results: SLE was reported in death certificates of 41/90 (46%) patients. Patients with SLE not reported in their death certificates were older at death (62±14 vs. 53±15 years) and diagnosis (53±14 vs 42±18 years) and had a longer time from their last visit at our Department to death (0.80±1.00 vs. 0.34±0.66 years), compared to patients with SLE listed in the death certificate ($p<0.05$). They also had a lower proportion of renal disorder (20/49 vs. 29/41), cardiovascular and pulmonary damage (18/49 vs. 28/41 and 7/49 vs. 13/41, respectively), and died less frequently in hospital (28/49 vs. 35/41) and due to infections (4/49 vs. 26/41) ($p<0.05$). Conversely, these patients had a higher frequency of malignancy as a feature of damage (17/49 vs. 6/41) and a cause of death (14/49 vs. 1/41) ($p<0.05$). Only patients without SLE listed in their death certificate accrued gastrointestinal damage (7/49 vs. 0/41, p=0.015), hence this type of damage could not be included in the multivariate logistic model. In the multivariate model, the presence of infection as a cause of death was the single variable related to (non-)reporting of SLE (OR 0.053; 95% CI 0.012–0.237) (Table 1).

Table 1. Predictors of non-reporting of SLE in death certificates (OR: odds ratio; CI: confidence interval)

Variable	OR	95% CI	p
Age at diagnosis (years)	1.050	0.961-1.148	0.280
Age at death (years)	0.996	0.906-1.096	0.938
Time from last visit to death (years)	1.122	0.496-2.542	0.782
Renal disorder (yes/no)	0.434	0.126-1.499	0.187
Pulmonary damage (yes/no)	0.536	0.119-2.406	0.416
Cardiovascular damage (yes/no)	0.412	0.102-1.666	0.214
Malignancy (feature of damage) (yes/no)	2.934	0.597-14.423	0.185
Infection as cause of death (yes/no)	0.053	0.012-0.237	<0.001
In-hospital death (yes/no)	1.012	0.223-4.592	0.987

Conclusions: Non-reporting of SLE in death certificates of lupus patients may be an obstacle towards assessing the true extent of SLE-related mortality, calling into question the reliability of vital statistics data extracted only from death certificates. Infections as causes of death and gastrointestinal damage may influence reporting of SLE in death certificates.

SAT0292 LONG-TERM PROGNOSIS AND PREDICTING FACTORS OF CHINESE PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME

J. Zhao, Y. Sun, P. Zhang, Q. Wang, M. Li, X. Zeng. *Peking Union Medical College Hospital, Beijing, China*

Background: Antiphospholipid syndrome (APS) is an acquired autoimmune prothrombotic condition characterized by persistent circulating antiphospholipid antibodies (APL). The pathogenic mechanisms that lead to clinical manifestations associated with APL are only partially understood. And to date, long-term anticoagulation has been the only treatment shown to reduce vascular complications.
Objectives: The aims of the present study were to assess and identify the prognostic factors of the long-term outcomes and mortality of antiphospholipid syndrome (APS) in Chinese patients.
Methods: Records of 160 patients with APS admitted to Peking Union Medical College Hospital in Beijing between 2005 and 2015 were investigated. Demographic characteristics, cumulative clinical and laboratory features, autoantibody profiles were retrieved from the database. Survival rates were studied by Kaplan-Meier method, and COX proportional hazard model was adopted to perform the analysis of predicting factors for mortality.
Results: The entire cohort consisted of 110 (68.8%) female and 50 (31.3%) male patients. Mean (SD) age at study entry was 36.5±14.9 years. The most prevalent thrombotic risk factors were hypertension, dyslipidemia, and smoking, present in 5–15% of the total cohort. In total, 50.6% of the patients had primary APS, 45.9% had APS associated with SLE, 2.0% APS associated with other connective tissue diseases. The most prevalent immunological features at baseline were LA (71.3%), aCL (55.0%), and β2GPI (49.4%). No significant statistical differences were found in the clinical presentation of the APS according to the presence or absence of any of these antibodies. During the 10-year period, 16 (10.0%) patients (8 female and 8 male) died. The overall 1, 3, and 5-year survival rate was 92.6%, 89.1% and 87.1%, respectively. The most common causes of death were severe thrombotic events, including pulmonary embolism, strokes and myocardial infarction (43.8% of total deaths), infections (18.8%). COX proportional hazard model show thrombocytopenia is the independent prognostic factor of mortality (HR 8.228, 95% CI 1.866–36.282).

Table 1. Baseline characteristics of APS patients

Clinical characteristics	Prevalence	Thrombotic event	
		No (N=51)	Yes (N=109)
Female, n/%	110 (68.8%)	42 (82.4%)	68 (62.4%)
Age, year, mean+SD	36.5±14.9	34.2±14.9	37.4±14.9
Thrombotic events			
Arterial thrombosis	59 (36.9%)	–	59 (54.1%)
Venous thrombosis	72 (45.0%)	–	72 (66.1%)
Coexist of arterial and venous thrombosis	22 (13.8)	–	22 (20.2%)
Systemic autoimmune diseases	79 (49.4%)	33 (64.7%)	46 (42.2%)
Thrombophylic risk factors			
Smoking	8 (5.0%)	2 (3.9%)	5 (5.5%)
Dyslipidemia	20 (12.5%)	6 (11.8%)	14 (12.8%)
HTN (systolic>140)	24 (15.0%)	7 (13.7%)	17 (15.6%)
ACL	88 (55.0%)	32 (62.7%)	56 (51.4%)
β2GP1	79 (49.4%)	31 (60.8%)	48 (44.0%)
Lupus anticoagulants	114 (71.3%)	39 (76.5%)	75 (68.8%)
Tri-positive	41 (25.6%)	21 (41.2%)	20 (18.3%)
Thrombocytopenia	71 (44.4%)	23 (45.1%)	48 (44.0%)
Hypocomplementaemia	59 (36.9%)	25 (49.0%)	34 (31.2%)

Conclusions: patients with APS develop significant morbidity and mortality despite current treatment. More attention should be devoted to APS patients with thrombocytopenia.

SAT0293 PNEUMOCOCCAL INFECTION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

J. Schurder, T. Goulenok, R. Jouenne, A. Dossier, D. van Gysel, T. Papo, K. Sacre. *Paris-7 University, APHP, Bichat Hospital, Paris, France*

Background: A 5-fold increase in the risk of death is due to infection in systemic lupus erythematosus (SLE) patients when compared to age- and sex-matched controls Pneumococcal infection (PI) has been reported to be more frequent and severe in SLE
Objectives: Our study aimed to analyze the risk factors associated with the occurrence and severity of PI in SLE patients
Methods: Medical records of all SLE patients and all patients admitted with PI in the Department of Internal Medicine (Bichat Hospital, Paris, France) from January 2005 to December 2014 were retrospectively reviewed. Clinical characteristics associated with PI occurrence and severity were analyzed, both in SLE and non SLE patients.
Results: One hundred and ninety SLE patients (42.2+14.9 years; 87.4% females) were hospitalized over a 10-year period. PI was the reason for admission in 6 (3.2%) patients, including 5 cases of invasive infection. With a follow-up of 2112.8

years for the total cohort, incidence of invasive PI in SLE was of 236/100.000 patient-years. As compared to the incidence in general French population, invasive PI was 26 times more frequent in SLE patients. PI occurred at a younger age (43.5+14.9 versus 65.3+18.7 years, p=0.009) and was more severe, with a higher frequency of invasive infection (p<0.001) and higher need for ICU admission (p=0.015) in SLE as compared to non SLE patients. Of note, unusual PI sites, including pneumococcal endocarditis (n=1), arthritis (n=1) and peritonitis (n=1) were observed in SLE patients only. Risk factors associated with PI in SLE patients were a serum gammaglobulin level <5g/L (p=0.003) and a past history of lupus nephritis (p=0.047), only. Steroids (p<0.001) and immunosuppressive drugs (p=0.027) were associated with infection severity.

Conclusions: Pneumococcal infections occur at a younger age, are more frequent and severe in SLE patients. Hypogammaglobulinemia and lupus nephritis increased the risk for PI, whereas steroids and immunosuppressive drugs were associated with infection severity only. Our study shows that SLE patients have an increased risk for invasive PI and points to the need for vaccination against *streptococcus pneumoniae* in SLE.

SAT0294 COMPARISON OF CLINICAL CARE BETWEEN CHINESE AND AMERICAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

J. Dong[1], H. Ma[1], W.N. Roberts[2], L. Wang[1], F. Khan[3], K.A. Lyn Shue[2], L. Zhao[1], L. Pan[1]. *[1]Rheumatology and Clinical Immunology, Affiliated Hospital of Qingdao University, Qingdao, China; [2]Rheumatology; [3]Internal Medicine, University of Louisville, Louisville, KY, United States*

Background: In addition to gender and ethnicity, modifiable variables like geography, socioeconomic status, health system structure, education, and physician expertise may influence outcomes in systemic lupus erythematosus (SLE).

Objectives: To compare characteristics of and treatment options for subsets of Chinese and American patients with SLE to elucidate factors that contribute to disease activity and damage.

Methods: Chart review of 77 Chinese (Qingdao) and 48 Midwestern American (Louisville, Kentucky) patients meeting American College of Rheumatology (ACR) criteria for a diagnosis of SLE followed up for four years were analyzed retrospectively. Organ damage was assessed using the Systemic Lupus International Collaborating Clinics (SLICC)/ACR Damage Index (SDI), and disease activity was assessed using the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI). Statistics were parametric exploratory tests of significance and multiple regression analyses in this hypothesis-generating effort.

Results: The interval between the time of onset and diagnosis was 44 months shorter in the Chinese arm (p=0.001), and Chinese patients followed up at six times greater frequency than American patients (p<0.001). Despite the lack of formal matching, the two cohorts featured similar disease activity according to the SLEDAI. Based on the SDI, rates of organ damage were higher in the American group. Chinese patients received more steroids, cyclophosphamide, hydroxychloroquine, intravenous immune globulin, and cyclosporine than the Louisville group, while the Louisville patients received more mycophenolate mofetil and azathioprine (p=0.001).

Table 1

Variable	Qingdao (*n*=77), mean ± SD	Louisville (*n*=48), mean ± SD	*p*-value
Onset age (years)	30.24±11.95	30.21±12.21	0.989
Age at diagnosis (years)	30.89±11.92	34.5±12.99	0.114
Duration between SLE onset and diagnosis (months)	7.94±18.46	52.30±89.90	0.001
Clinic visits per year	10.93±7.09	3.02±1.91	<0.001
Interval between the last two times of follow up (months)	1.89±1.31	12.32±28.32	0.014
Disease duration (years)	5.97±5.72	5.22±5.53	0.466
SLEDAI	5.81±4.32	4.63±4.77	0.156
SDI	0.44±0.64	1.23±1.057	<0.001

Table 2

Medication	Qingdao (*n*=77)	Louisville (*n*=48)	*p*-value
Prednisone	77 (100%)	29 (60.42%)	<0.0001
Cyclophosphamide	34 (44.16%)	6 (12.50%)	<0.0001
Hydroxychloroquine	72 (93.51%)	32 (66.67%)	<0.0001
Methotrexate	9 (11.69%)	3 (6.25%)	0.489
Mycophenolate mofetil	10 (12.99%)	18 (37.50%)	0.001
Azathioprine	2 (2.60%)	5 (10.42%)	0.147
Intravenous immune globulin	12 (15.58%)	1 (2.08%)	0.035
Cyclosporine	17 (22.08%)	1 (2.08%)	0.005

Conclusions: The establishment of follow-up and treatment of SLE differs in specific, identifiable ways between these subsets of Chinese and midwestern American patients. Greater access to and increased frequency of follow-up appears associated with a lesser degree of organ damage, supporting the treat-to-target concept as applied to SLE. Complete, controlled trials in both settings are necessary, and further detailed comparison of larger cohorts may inform conclusions about the likelihood of generalizability of trial results from one setting to another.

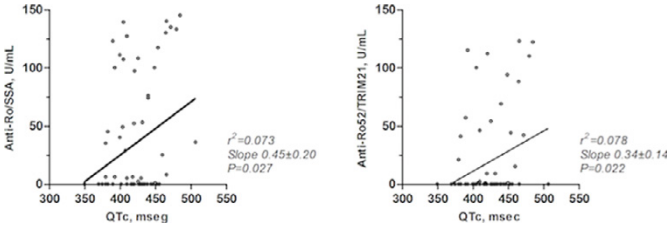
SAT0295 ANTI-RO52/TRIM21 ANTIBODIES ARE ASSOCIATED WITH QT INTERVAL PROLONGATION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS



L.F. Perez, L.H. Silveira, L. Amezcua, O. Estevez, M. Moreno. *Reumatologia, Instituto Nacional de Cardiologia Ignacio Chavez, Mexico City, Mexico*

Background: Long QT syndrome (LQTS) is characterized by an abnormal QT corrected (QTc) interval prolongation that is associated with increased risk of sudden death. Studies have associated LQTS with several rheumatic conditions, and evidence points towards a link between the degree of systemic inflammation and the duration of QTc interval. Moreover, recent evidence suggests that anti-Ro antibodies may play a role in the QTc prolongation by mechanisms not fully understood, thus constituting a novel autoimmune-mediated LQTS.

Objectives: This study was aimed to assess whether QTc interval prolongation is associated with the presence of anti-Ro antibodies in SLE, particularly with reactivities against Ro52/TRIM21 antigens.

Methods: Consecutive patients fulfilling the 1997 ACR criteria for SLE were included. Patients with history of ischemic heart disease, with implantable pacemakers, and those taking drugs that potentially could affect QT interval (except for antimalarials) were excluded. Patients underwent a resting 12-lead electrocardiogram recording to measure QT interval corrected by BazzetÕs formula. A QTc interval duration greater than 460 msec in women and 440 msec in men was set to be abnormal. Serum anti-Ro and anti-Ro52/TRIM21 antibody levels were measured by ELISA. Data were expressed as frequencies and means (± standard deviation), and differences were tested by YatesÕ continuity corrected chi square or Mann-Whitney tests, while linear regressions were performed to assess linearity between autoantibody levels and QTc duration. The GraphPad Prism 4.02 software was used for calculations.

Results: Sixty-six patients with mean age of 39±13 years (57 female gender) were included. A QTc prolongation was found in 10 patients (15%), with mean QTc interval of 470±18 msec as compared to 414±23 msec in those with no LQTS. Main clinical and demographic characteristics were similar for both groups, except for a lesser use of antimalarials and higher serum creatinine levels in patients with LQTS. Disease activity was similar between groups.Anti-Ro antibody levels were significantly higher in patients with prolonged QT interval (75±66 U/mL versus 29±44 U/mL; P=0.005); similarly, anti-Ro52/TRIM21 levels were higher in those with LQTS (50±55 U/mL versus 14±30 U/mL; P=0.01). Notably, a linear association (see the Figure) between the QTc intervals and levels of anti-Ro antibodies (r2=0.073; P=0.02) and anti-Ro52/TRIM21antibodies (r2=0.078; P=0.02) was observed.

Conclusions: Our results strengthen the hypothesis that a specific autoantibody-mediated LQTS occur in SLE patients positive to anti-Ro antibodies. This interference in the ventricular repolarization appears to be associated with increased levels of antibodies against Ro52/TRIM21 antigens, and supports the realization of an electrocardiogram as part of the routinely evaluation in SLE patient with circulating anti-Ro antibodies.

SAT0296 RELATIONSHIP BETWEEN DISEASE ACTIVITY INDEX SCORES AND SUBJECTIVE ASSESSMENTS IN EARLY SYSTEMIC LUPUS ERYTHEMATOSUS

M. Garabajiu[1], V. Sadovici-Bobeica[1], L. Mazur-Nicorici[1], M. Cebanu[1], V. Salaru[2], M. Mazur[1]. *[1]Rheumatology; [2]Family Medicine, State University of Medicine and Pharmacy "Nicolae Testemitanu", Chisinau, Moldova, Republic of*

Objectives: To evaluate the disease activity in patients with early systemic lupus erythematosus (early SLE) and to compare it to patient's and physician's global assessment.

Methods: Cross-sectional study including 41 early SLE patients that fulfilled SLICC classification criteria, 2012. The early disease was defined one with the duration 2 years from the diagnosis. The disease activity was assessed by SLEDAI-2K and SLAM. Global indices were appreciated by patient and physician global assessments (PGA and MDGA), rated by 0–100 numeric score. We correlated disease activity indices with global assessments by Pearson coefficient.

Results: There were 41 SLE patients integrated in the study, female:male ratio 9,25:1, mean age (SD) 39 (12.35) years (range 20–67 years), disease duration (SD) was 9.92 (9.18) month (range 1–24). The mean disease activity by SLEDAI was 11.2±7.84 (range 2–34) and SLAM – 8.83±4.41 (range 3–22) points, both indices denoted high disease activity level. Mean PGA values were 48.93 (19.13) (range 10–80), and mean MDGA values 45 (19.04) (range 10–80). Also, PGA and MDGA didn't correlate with SLEDAI (r=0,25, p>0,05; r=0,27, p>0,05), while a statistically significant correlation was determined with SLAM index (r=0,85, p<0.001; r=0,46, p=0.002). A subclass analysis of SLAM components showed that cortical dysfunction (depression, psychosis) and the presence of headache correlated with PGA (r=0,36, p<0,05; r=0,4, p<0,05), so we can establish that the difference in correlation between SLAM and SLEDAI with PGA and MDGA is explained by a more accurate disease assessment by SLAM, including also subjective complaints that influences the global patient's status.
Conclusions: The use of SLAM for disease activity assessment in early SLE patients is more sensible than SLEDAI and its results correlates with PGA and MDGA.

SAT0297 SLE PATIENTS WITH SECONDARY SJÖGREN'S SYNDROME ARE CHARACTERIZED BY TYPICAL AUTOANTIBODIES AND A PRO-INFLAMMATORY STATE

M. Kvarnström[1], G. Ruacho[2], J.T. Gustafsson[3], A. Zickert[3], V. Oke[3], J. Rönnelid[4], K. Elvin[5], I. Gunnarsson[3], E. Svenungsson[3]. *[1]Dep. of Medicine, Unit of Experimental Rheumatology, Karolinska Institutet, Karolinska Uniververity Hospital, Stockholm; [2]Centre for Clinical Research Sörmland, Uppsala Univerity, Sörmland; [3]Dep. of Medicine, Unit of Rheumatology, Karolinska Institutet, Karolinska Uniververity Hospital, Stockholm; [4]Department of Immunology, Genetics and Pathology, Uppsala Univerity, Uppsala; [5]Unit of Clinical Immunology, Department of Clinical Immunology and Transfusion Medicine, Karolinska Institutet, Karolinska Uniververity Hospital, Stockholm, Sweden*

Background: Sjögren's syndrome occurs in isolation (primary Sjögren's syndrome, pSS), but it is also often secondary (sSS) to, and sometimes difficult to delineate from, other rheumatic diseases, in particular from systemic lupus erythematosus (SLE). Consequently there is a need to investigate similarities and differences between SLE patients with (SLE-sSS) and without sSS (SLE-noSS).
Objectives: To investigate the occurrence of sSS in a large cohort of SLE patients and to explore clinical and laboratory characteristics associated with SLE-sSS as compared to SLE-noSS and controls.
Methods: We included 504 consecutive SLE patients and 322 population controls, individually matched for age and gender to the first patients. All patients fulfilled the 1982 revised ACR criteria for SLE. SLE-sSS was defined according to the American-European consensus criteria (AECC). Accordingly, subjective and objective quantifications of sicca symptoms were recorded on all subjects. All underwent a thorough clinical investigation. SLE-associated autoantibodies, (ANA screening by BioPlex 2200 system, Bio-Rad) and Rheumatoid factor (RF, Phadia Immunocap 250) were determined with standardized methods for all subjects, Routine laboratory workup and a panel of cytokines (MSD 30-plex cytokine assays, performed on samples from 433 consecutive SLE patients and 319 controls) were measured on fasting blood samples.

Immunoglobulins, autoantibodies and pro-inflammatory cytokines in SLE-SS, SLE-noSS and population controls

	Controls N=322 median (IQR) or N(%)	SLE-SS N= 117 median (IQR) or N(%)	SLE-noSS N=387 median (IQR) or N(%)	p-value SLE-SS vs. SLE-noSS
IgA total g/L	2.1 (1.5-2.8)	2.9 (1.8-4.3)	2.7 (1.9-3.6)	0.38

IL-6 pg/mL	0.5 (0.4-0.7)	1.5 (0.8-3.0)	1.1 (0.6-2.0)	0.009
MCP-4 pg/mL	55.8 (40.8-80.5)	94.9 (66.9-131.3)	74.7 (52.4-120.0)	0.019
MIP-1 β pg/mL	43.7 (33.4-56.4)	81.1 ((54.8-123.6)	68.9 (50.3-105.1)	0.021
IL12/IL-23p40 pg/mL	131.2 (99.8-179.5)	211.3 (141.4-363.8)	177.1 (119.6274.5)	0.032
IP-10 pg/mL	351.9 (259.2 -476.4)	808 (536-1911)	726 (440-1471)	0.036

Results: SLE-sSS, as defined by AECC, occurred in 23% of the SLE patients. Compared to SLE-noSS the SLE-sSS group was older, both at inclusion (55 vs 43yrs, p<0.0001) and at disease onset (40 vs. 32 yrs p<0.0001), and with a greater number of females (96 vs. 83%, p=0.0007), higher occurrence of leucopenia (57 vs. 45%, p=0.02) and peripheral neuropathy (15 vs 7%, p=0.01). Nephritis was less common in SLE-sSS (32 vs 43%, p=0.03). Higher levels of total IgG, positivity for anti-SSA/Ro52, anti-SSA/Ro60, anti-SSB antibodies, RF IgM and RF IgA further characterized the SLE-sSS group. 20/30 investigated cytokines were detectable, of these 19/20 were higher in SLE than in controls. 6/20 cytokines (TNF-a, IL-6, MCP-4, MIP-1β, IL12/IL-23p40 and IP-10) were upregulated in SLE-sSS vs. SLE-noSS (see table for figures).
Conclusions: Through strictly applying the AECC criteria we report that the frequency of SLE-sSS increases with age and affects roughly ¼ of SLE patients. Nephritis was less common while leucopenia and peripheral neuropathy were more common among SLE-sSS patients. In addition to excess of well-known SS-associated autoantibodies we report higher levels of six pro-inflammatory cytokines in SLE-sSS as compared to SLE-noSS. These findings demonstrate that, though often regarded as a milder version of SLE, patients with SLE-sSS are characterized by a state of chronic systemic inflammation.

SAT0298 INFLUENCE OF AGE ONSET IN CLINICAL AND BIOLOGICAL SPECTRUM OF SYSTEMIC LUPUS ERYTHEMATOSUS

M. Kechida[1], N. Lorenzo[2], I. Ben Chaaben[1], R. Klii[1], S. Hammami[1], I. Khochtali[1]. *[1]Internal Medicine and Endocrinology Department, Fattouma Bourguiba Hospital, Monastir, Tunisia; [2]Internal Medicine and cancerology Department, Saint-Cyr Hospital, Lyon, France*

Background: Systemic lupus erythematosus (SLE) is a multi systemic auto immune disease which can affect patients at any age.
Objectives: We aimed to study influence of age onset in clinical and biological spectrum of SLE
Methods: medical records of 89 patients diagnosed as SLE according to the ACR criteria of 1997, between January 2004 and December 2016, were retrospectively analyzed. Patients were divided into 3 groups according to the age of onset: Juvenile onset patients (group 1) (G1) (≤16 years), Adult onset patients (group 2) (G2) (>16 and <50 years), Late onset patients (group 3) (G3) (≥50 years). Clinical and biological comparative study was conducted between the 3 groups. Data were analyzed by chi-square test and potentially associated factors were tested by binary logistic regression.
Results: among the patients 11.2% are in G1, 75.3% in G2 and 13.5% in G3. Prevalence of SLE was higher in female than male (F/M=9/1) but predominance of women was lower in G1 (F/M=4/1) compared to G2 (F/M=10/1) and G3 (F/M=11/1). Patients in G3 had more hypertension (41.7%) compared to G2 (6%) (p=0.5) and G1 (0%) (p=0.04). Vespertilio erythema was less frequently found in G3 (33.3%) compared to G2 (64.2%) (p=0.045) and G1 (80%) (p=0.04). Anti Sm antibodies were more frequent in G1 (87.5%) compared to G2 (38.5%) (p=0.009) and G3 (18.2%) (p=0.003). Multivariate analysis showed that hypertension is significantly associated to late onset lupus (OR=29, 95% IC= [2.77 – 320], p=0.05) and anti Sm antibody is more frequent in juvenile onset patients (OR=12, 95% IC= [1.4- 117], p=0.024).
Conclusions: according to our study, prevalence of lupus is higher in female regardless of age onset. Late onset lupus is associated to a high frequency of co morbidity while anti Sm antibody seems to be a hallmark of juvenile onset.

SAT0299 ATYPICAL ANTIBODIES IN PATIENTS WITH PRIMARY SJOGREN'S SYNDROME

M. Fernandez Castro[1], J.L. Andreu[2], C. Sanchez-Piedra[3], V. Martínez Taboada[4], A. Olive[5], J. Rosas[6] on behalf of SJOGRENSER group, part of the Spanish Society of Rheumatology Systemic Autoimmune Diseases Study Group (EASSER). *[1]Rheumatology, Hospital Infanta Sofía; [2]Rheumatology, Hospital Puerta de Hierro Majadahonda; [3]Research unit, Spanish Society of Rheumatology, Madrid; [4]Rheumatology, Hospital Marque's de Valdecilla, Santander; [5]Rheumatology, Hospital Hospital Germans Trias i Pujol, Barcelona; [6]Rheumatology, Hospital Hospital Marina Baixa, Alicante, Spain*

Background: One of the main features of primary Sjögren's syndrome (pSS) is

the polyclonal activation of B cells, leading to the synthesis of a large variety of autoantibodies.
Objectives: The aim of this study is to describe the prevalence of atypical autoantibodies in patients with pSS from the SjogrenSER registry.
Methods: SjogrenSER registry is a multicenter transversal study of pSS patients fulfilling European/American consensus criteria 2002. Patients were included by randomization from thirty-three Rheumatology Spanish departments. Data were collected by reviewing clinical records and interviewing the patients. Informed consent was obtained and local ethics committees approved the study. Variables were analysed by descriptive statistical methods, using means, medians, and rates. Chi-square was used to establish the statistical associations, being considered a $p<0,05$ as significant.
Results: Four hundred and thirty-seven patients were included. Ninety-five percent of them were women. The median age of the cohort was 58 years. Twenty-three patients had AntiDNA (5.26%), 10 patients AntiSm (2.29%), 23 patients AntiRNP (5.26%) and 26 patients antiphospholipid antibodies (5.95%). Regarding AntiDNA+ patients, there were minimal non-significant differences in age at diagnosis and age at onset of symptoms compared to AntiDNA- patients (47 vs 50.5 years and 43.5 vs 46.5 years, respectively). The association with some systemic manifestation was only observed with joint involvement, which was significantly more frequent in AntiDNA+ patients (56.5% vs 34.2%, p=0.031). Regarding AntiSm+ patients, a significant negative association with AntiDNA antibodies was observed, being 70% of patients AntiDNA-; we also found a significant positive association with AntiRo and AntiLa, being 100% and 68% of patients AntiRo+ and AntiLa+ respectively. A significant negative association with lymphopenia was observed (no AntiSm+ patient had lymphopenia). AntiRNP+ patients showed a significant negative association with AntiDNA antibodies, being 80% of patients AntiDNA-, and a significant positive association with AntiRo, being 96% patients AntiRo+. A significant positive association was also observed with decreased C4 compared to AntiRNP- patients (28% vs 13.38%, p=0.025). Regarding patients with antiphospholipid antibodies, a significant negative association was observed with antiDNA antibodies, being 93% of patients AntiDNA-. A significant positive association with some systemic manifestation was only observed with the presence of anemia (44% vs 17.7%). A significant positive association with decreased C3 and C4 was also observed, compared with the AntiRNP- patients (C3 20% vs 13.67% and C4 33% vs 12.67%).
Conclusions: More than 5% of pSS patients had antibodies characteristic of other autoimmune diseases. These atypical autoantibodies were significantly related to some pSS characteristic: antiSm, antiRNP and antiphospholipid antibodies were significantly related to the presence of antiRo, antiDNA antibodies were significantly related to joint involvement, antiphospholipid antibodies were significantly related to anemia, and antiRNP and antiphospholipid antibodies were significantly related to hypocomplementemia.

SAT0300 HIGH PROPORTIONS OF DEMENTIA AMONG SLE PATIENTS: A BIG DATA ANALYSIS

O. Gendelman[1,2], S. Tiosano[1,2], D. Comaneshter[3], A. Cohen[3,4], Y. Shoenfeld[1,2], H. Amital[1,2]. *[1]Internal Medicine 'B', Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Ramat-Gan; [2]Sackler School of Medicine, Tel-Aviv University; [3]Chief physician's office, Clalit Health Services, Tel-Aviv; [4]Siaal Research Center for Family Medicine and Primary Care, Faculty of Health Sciences, Ben Gurion University of the Negev, Beer Sheva, Israel*

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease affecting wide range of systems including the peripheral and central nervous system[1]. Cognitive impairment leading to dementia is one of the harmful central nervous system manifestations of SLE[2].
Objectives: The aim of this study was to investigate the association of SLE and dementia.
Methods: A cross-sectional study was performed utilizing Clalit Health Care database, the largest HMO in Israel with more than 4.4 million enrollees. SLE patients were compared in a 1:5 ratio to age and sex matched controls. Chi-square and *t* tests were used for univariate analysis, and a logistic regression model was used for multivariate analysis.
Results: The study included 4886 SLE patients and 24,430 age and sex frequency matched controls without SLE. The proportion of dementia was higher among SLE patients compared to controls (1.56% and 0.51% respectively; $p<0.001$).
This finding was consistent across all age groups by univariate analysis.
In a multivariate logistic regression analysis, SLE was significantly associated with dementia (OR =2.039, 95% CI =1.110–2.039).
Conclusions: SLE is significantly associated with dementia. This finding should give rise to search for SLE in patients with an ambiguous cause for dementia, especially those with an early onset cognitive decline.

SAT0301 SERUM AUTOANTIBODY PROFILING OF PRIMARY SJÖGREN'S SYNDROME PATIENTS REVEALS NOVEL BIOMARKERS ASSOCIATED WITH THE DISEASE, DISEASE ACTIVITY, AND CLINICAL RESPONSE TO VAY736

P. Budde[1], J. Doucet[2], H.-D. Zucht[1], R. Kazma[2], P. Maguire[2], A. Avrameas[2], M.-A. Valentin[2], S. Oliver[3], P. Schulz-Knappe[1], A. Vitaliti[2]. *[1]Medical Research, Protagen, Dortmund, Germany; [2]Translational Medicine/Biomarker Development; [3]Translational Medicine, Novartis Institutes for Biomedical Research, Basel, Switzerland*

Background: Overexpression of B cell activating factor (BAFF) in salivary glands contributes to the pathogenesis of primary Sjögren's syndrome (pSS) by promoting autoantibody (AAB) production. Treatment of pSS patients with VAY736, an anti-BAFF receptor mAb, appears promising and was associated with a depletion of circulating B cells and a positive therapeutic effect [1]. In addition to the classical anti-SS-A/Ro and anti-SS-B/La, a broader set of AABs may reflect B cell disturbances in pSS and could serve as markers during clinical development of novel pSS therapeutics.
Objectives: In this study, we explored novel AABs in pSS patients and healthy controls (HCs) and we tested their associations with the disease, disease activity, and clinical response to VAY736.
Methods: Reactivity of AABs to 1,596 antigens was measured in serum samples from 27 pSS patients from a placebo-controlled trial at baseline and post-treatment week 12 and from 50 age and gender-matched HCs. Patients were treated at baseline with a single dose of VAY736 at 10 mg/kg (n=12), 3 mg/kg (n=6), or placebo (n=9). First, to identify AABs associated with pSS, 3 different methods compared AAB levels at baseline between pSS patients and HCs: Wilcoxon rank sum test, significance analysis of microarrays, and comparison of the 90th quantiles between groups. Second, to identify AABs associated with pSS activity, Pearson correlation of AABs with EULAR Sjögren's Syndrome Disease Activity Index, secondary outcomes, and salivary and serum BAFF were tested, using baseline and week 12 levels as well as relative changes. Third, VAY736 treatment-specific changes in AAB levels were investigated using linear mixed-effects models adjusting for dosage, age, and gender effects.
Results: Of 1,596 antigens, 36 were statistically different between pSS patients and HCs for at least one of the 3 tests, including the known SS-A/Ro and SS-B/La (significant for all 3 tests) as well as novel antigens. SS-A/Ro and SS-B/La AABs were not associated with disease activity or response to treatment. However, 48 AABs were significantly correlated with pSS activity combining all treatment arms, and 12 AABs had baseline values that correlated with change in pSS activity upon VAY736 treatment (unadjusted $p<0.05$). Interestingly, 51 serum AABs correlated with BAFF saliva levels ($|r|>0.55$), but not with BAFF serum levels. The genes encoding novel antigens are involved in apoptotic, anti-viral, metabolic, inflammatory, blood coagulation and B-cell processes, suggesting a possible link to the disease pathology.
Finally, there was no reduction in AABs levels in response to VAY736, possibly because the 12 weeks post-treatment analysis was too short to identify large effects.
Conclusions: In conclusion, we identified new AABs in pSS patients that have the potential to serve as markers of diagnosis, pSS activity, or as predictors of clinical outcome measures. Further large-scale studies are needed to confirm the value of these markers.

Objectives: Baseline characterization of European patients diagnosed with primary Sjögren syndrome (SS) according to the 2002 AE criteria.
Methods: The Big Data Sjögren Project was formed in 2014 to take a "high-definition" picture of the main features of primary SS by merging international SS databases. International experts of the EULAR-SS Task Force were invited to participate. By January 2017, the database included 9302 consecutive patients recruited from 21 countries of the 5 continents.
Results: A total of 6586 (71%) patients were included from European countries. In comparison with non-European countries, European patients had a higher mean age (54 v 51yrs, p<0.001), higher frequency of men (7% v 5%, p=0.001), dry eyes (94% vs 88%, p<0.001), dry mouth (94% vs 91%, p<0.001), and lower frequency of abnormal ocular (84 vs 86%, p=0.049) and oral (75 vs 81%, p<0.001) tests. Immunologically, European patients had a lower frequency of anti-Ro/La antibodies (69 vs 78%, p<0.001) and a higher frequency of RF (50 vs 47%, p=0.01), low C4 (14 vs 9%, p<0.001) and cryoglobulins (8% vs 3%, p<0.001). Logistic regression identified as independent variables older age (OR 1.02), male gender (OR 2.62), abnormal oral tests (OR 0.26), anti-Ro/La antibodies (OR 0.69), RF (OR 1.76), low C4 (OR 1.97) and cryoglobulins (OR 3.85).
Conclusions: European patients are diagnosed at older age, are more frequently men, and presented a lower frequency of anti-Ro/La antibodies and a higher frequency of immunological markers related to mixed cryoglobulinemia.

SAT0303 CLINICAL DIFFERENCES BETWEEN DEFINITE AND PROBABLE ANTIPHOSPHOLIPID (APS) PATIENTS: SHOULD THEY BE TREATED THE SAME?

F. Signorelli, G. Balbi, R.A. Levy. *Rheumatology, Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil*

Background: The management of patients with recurrent thromboses/pregnancy morbidity and transient detection of antiphospholipids antibodies (aPL) can be a medical challenge. Although these patients are commonly seen in practice, there are no specific guidelines for the treatment in this situations.
Objectives: To investigate the clinical differences between definite and probable APS patients.
Methods: We performed a cross-sectional study in a group of 90 outpatients seen in our department. Seventy-seven of them met the Sydney classficiation criteria for definte APS, and thirteen had thrombosis or gestational morbidity, but no definite serological criteria for the diagnosis of APS. Clinical and serological features were collected during visits and by chart review, and the two groups were compared. Transient aPL was defined as only one detection of aPL (lupus anticoagulant, anticardiolipin IgM/IgG and/or anti-beta-2-glycoprotein 1 IgM/IgG) after 2 or more assays, at least 12 weeks apart.
Results: Demographic and clinical characteristics are shown in Table 1. In a bivariate analysis, there was no difference between groups regarding the criteria and non-criteria manifestations of APS, except for the presence of livedo (p=0.033). In a multivariate regression analysis, the model was adjusted to age, sex, and variables with p<0.10 in the bivariate analysis (age, sex, race, livedo, Raynaud's phenomenon). No difference between groups was found after the analysis.
Conclusions: This study suggests patients with transient detection of aPL have the same clinical characteristics of patients with definite APS, including thrombotic features, pregnancy morbidity, and non-criteria manifestations. In this context, our data suggests that both groups should be treated according to the current treatment guidelines for APS.

SAT0304 STIMULATORY AND INHIBITORY KILLER IMMUNOGLOBULIN-LIKE RECEPTORS ON NATURAL KILLER T (NKT) CELLS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE): RELATION TO DISEASE ACTIVITY

S.I. Nasef [1], A.M. Asker [2], H.H. Omar [2], H.M. Hassoba [2]. *[1] Physical Medicine, Rheumatology and Rehabilitation; [2] Clinical Pathology, Faculty of Medicine, Suez Canal University, Ismailia, Egypt*

Background: Natural killer T (NKT) cells are a unique subgroup of T cells that represents a bridge between innate and adaptive immunity. The functions of NKT-cells are regulated by the balance between activating and inhibitory Killer cell immunoglobulin-like receptors (KIRs). Systemic lupus erythematosus (SLE) patients showed aberrant expression of KIRs on NKT-cells. Whether the expression pattern of KIRs on NKT-cells is associated with disease activity in SLE is still unknown.
Objectives: Assessment of expression of stimulatory and inhibitory KIRs on NKT-cells in SLE patients and its relation to disease activity.
Methods: We recruited 40 SLE patients and 20 age and gender matched healthy controls. According to SLE disease activity index (SLEDAI), patients were divided into two groups; active SLE (n=20) and inactive SLE (n=20). SLE was active when SLEDAI was ≥4. Immuno-phenotyping by flow cytometry was done using markers for NKT-cells (CD3 and CD56), stimulatory KIRs (KIR2DL4, CD158D) and inhibitory KIRs (KIR3DL1, CD158E1). Absolute counts and percentage of NKT cells expressing CD158D and CD158E1 together with their mean fluorescence intensity (MFI) were measured. The histogram of CD158 expression was used to assess KIRs on NKT cells.
Flow cytometry charts of lymphocytes and NKT cells in SLE patients (active and inactive) and controls are shown in (Figure 1).
Laboratory work included ANA, anti-dsDNA, Anti-smith, C3, C4, CRP and ESR.
Results: Mean age of patients was 29.9±10.8 years. Females constituted 95% (n=38) of patients. Mean disease duration was 4.4±4.5 years. Mean SLEDAI was 11.75±7.43.
NKT-cells absolute number (cell/mm^3) was significantly decreased in SLE patients (89±135) compared to controls (287±133), (*P*=0.001). Likewise, the absolute number of NKT-cells (cell/mm^3) was significantly lower in active SLE patients (65.2±57.8) compared to inactive ones (114.5±181.1), (*P*=0.001).

The expression of inhibitory KIRs was significantly lower in SLE patients (2.83±2.8%) compared to controls (5.54±2.01%) *(P*=0.001) While, stimulatory KIRs were significantly higher in SLE patients (3.2±3.7%) than controls (1.02±0.5%), (*P*=0.001). Active SLE patients showed significantly increased expression of stimulatory KIRs (5.29±4.29%) than inactive patients (1.13±0.89%), (*P*=0.004). However, inhibitory KIRs were significantly decreased in active (1.28±1.32%) than inactive SLE patients (4.38±3.05%), (*p*=0.003).
Expression of stimulatory KIRs correlated positively with ESR (*r*=0.3, *P*=0.04) and negatively with C4 (*r*=-0.4, *P*=0.01). In contrast, inhibitory KIRs correlated negatively with ESR (*r*=-0.5, *P*=0.003) and positively with C4 (*r*=0.4, *P*=0.02).
Using Receiver operating characteristic (ROC) curve analysis, expression of inhibitory KIRs on NKT-cells predicted disease activity at a cut-off value of ≤1.7% with 80% sensitivity and 80% specificity *(P*=0.001). While, expression of stimulatory KIRs on NKT-cells predicted active disease at a cut-off value of >1.4%, sensitivity (85%), and specificity (80%) *(P*=0.001*)*.
Conclusions: SLE activity is associated with an increased expression of stimulatory KIRs as well as a decreased expression of inhibitory KIRs on NKT cells. This may play a role in the pathogenesis of flares and acceleration of disease activity in SLE and could be a therapeutic target for SLE patients.

SAT0305 HISTOLOGY OF MINOR SALIVARY GLANDS IN PATIENTS WITH SJÖGREN'S SYNDROME, ASSOCIATION WITH CLINICAL AND LABORATORY ASPECTS

S. Colafrancesco[1], F. Arienzo[1], B. Cerbelli[2], A. Gattamelata[1], A. Minniti[1], G. Picarelli[1], C. Giordano[2], G. D'Amati[2], R. Priori[1], G. Valesini[1]. *[1]Dipartimento di medicina interna e specialità mediche; [2]Dipartimento di radiologia, Oncologia e Scienze Radiologiche, Sapienza University of Rome, Rome, Italy*

Background: Minor salivary gland (MSG) biopsy represents an useful tool not only for the diagnosis of primary Sjogren's Syndrome (pSS) but also to evaluate patients prognosis. Recognition of germinal centers (GCs) by hematoxilin eosin (HE) and/or IHC staining for follicular dendritic cells (FDC) detection is mandatory, representing a risk factor for lymphoma development. Focus score (FS) is one of the main instrument to quantify MSG impairment, nonetheless quality information regarding the type of infiltrate such as the entity, structure and localization, are lacking.
Objectives: Aim of this study is to find any association of specific histological features of MSG from patients with pSS with the principal clinical and laboratory features. Moreover, to investigate the utility of histological parameters, other than FS or GCs, for characterizing patients.
Methods: Patients with pSS were enrolled in our SS clinic, and clinical/laboratory data (table) referring to the time of MSG biopsy, gathered on a dedicated database. MSG, removed for diagnostic purposes, were preserved as paraffin embedded tissue, then cut and sequentially stained by H&E and IHC [polyclonal rabbit anti-CD3 (lymphocytes T); monoclonal mouse anti-CD20 (lymphocytes B); monoclonal mouse anti-CD21 (FDC)]. Images were collected by Zeiss Axio Scan and analysed (ZEN software) as follows: FS calculation, mean foci area, percentage of infiltration, presence of segregated foci (SF) (specifically, clear evidence of T and B cells area by CD3-CD20 double staining), GCs and lymphoepithelial lesions (LELs) detection.
Results: 53 MSG from patients with pSS were collected and analysed. Patients clinical and laboratory data are reported in table. FS positively correlated with the percentage of infiltration (p<0.001) as well as with the presence of SF (p=0.005), GCs (p=0.02) and LELs (P=0.005). Mean foci area and percentage of infiltration correlated with SF (p=0.0002 and p<0.001, respectively), GCs (p=0.0004 and p<0.001, respectively) and LELs (both p<0.001). SF correlated with GCs and LEL (p<0.001). Anti nuclear antibodies (ANA) were associated with the presence of SF (p=0.029, OR=5.7 CI=1.1–28.8) while gland swelling was associated with the presence of GCs (p=0.043, OR=4, CI=1.1–15).

Clinical features	Number (%)
Sex (M/F)	4/49
Mean age at diagnosis (mean±SD, years)	54.9±12.1
Xerophtalmia	47/53 (88.6)
Xerostomia	47/53 (88.6)
Salivary gland swelling	16/53 (30.1)
Arthritis	8/53 (15)
Lymphoma	0/53 (0)
Purpura	2/53 (3.7)
PNS and/or CNS involvement	1/53 (1.8)
Pancreatitis	1/53 (1.8)
Laboratory features	
ANA	39/53 (73.6)
Anti-Ro/SSA	17/53 (32.1)
Anti-La/SSB	14/53 (26.4)
Hypergammaglobulinaemia	18/53 (33.9)
Rheumatoid factor	10/53 (19)
Leukopenia	8/53 (15)
Hypocomplementemia	6/53 (11.3)
Monoclonal component	8/53 (15)
Cryoglobulinaemia	2/53 (3.7)

Conclusions: The FS was associated with the presence of GCs and LELs, as well as with more organized infiltrates characterized by segregation in T and B areas (SF), thus representing an useful tool which mirrors the risk of lymphoma. From our study, the qualitative characteristics of the biopsy, including SF, percentage of infiltration or the mean foci area, appear to be strictly linked. Moreover, their association with the presence of GCs and LELs supports the importance to consider also these features during histological examination. The lack of correlation between histological parameters and clinical/laboratory features might reveal a weaker connection between histological findings and specific SS phenotypes except for the relationship between glandular swelling and GCs which confirms how this clinical aspect should be considered as a risk factor for lymphoma development.

SAT0306 ASSOCIATION BETWEEN QUALITY OF SLEEP, QUALITY OF LIFE AND DISEASE ACTIVITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

S. Monov[1], D. Monova[2], M. Ivanova[3]. *[1]Department of Rheumatology, Medical University - Sofia; [2]Department of Internal Diseases, Medical University - Sofia, Medical Institute; [3]Department of Internal Diseases, Medical Institute, Sofia, Bulgaria*

Background: Systemic Lupus Erythematosus (SLE) patients are known to have sleep disturbances. Quality of sleep may affect quality of life, but this association has not been systematically evaluated.
Objectives: The aim of this study was to examine the association of quality of sleep, quality of life and SLE disease activity in patients diagnosed with SLE.
Methods: 132 SLE patients with a confirmed diagnosis of SLE according to the ACR classification criteria were enrolled in this study. The patients completed the following questionnaires: the Pittsburgh Sleep Quality Index (PSQI), the 12 item Short Form Health Survey (SF-12), the Lupus Patient-Reported Outcome tool (LupusPRO), SLE Quality of Life Questionnaire (SLE - QoL). Clinical information, including the SLE Disease Activity Index (SLEDAI), was obtained from medical records. Student's t-test, ANOVA, Pearson correlation measured were used in statistical analysis.
Results: The majority of the participants (84,4%) had sleep disturbances (PSQI >5). Total PSQI score was weakly associated with all of the SF-12 subcategories and showed weak to moderate associations with the LupusPRO subcategories (r <0,05), except for "medication" (r <0,20). "Sleep duration" was not associated with any of the SF-12 or LupusPRO subcategories. "Sleep efficiency" was weakly associated with "physical health", "physical function", and "pain" in the SF-12 and LupusPRO. "Sleep quality" and "sleep disturbances" were weakly associated with "pain" and the "emotional" and "mental" subcategories in the SF-12 and LupusPRO. SLE - QoL was significantly higher in patients with good sleep.
Conclusions: We found that quality of sleep, especially "sleep efficiency", was poor for the majority of patients with SLE. Quality of sleep was associated with various aspects of quality of life, especially pain, vitality, and emotional health. Management of pain and emotional health may be important for improving quality of sleep in SLE patients.

SAT0307 RECURRENCE RATE OF THROMBOSIS FOR PATIENTS WITH ANTI-PHOSPHOLIPID ANTIBODIES INITIALLY AND DISAPPEARED LATER AFTER THROMBOSIS

S.M. Kim[1], J. Kim[2], Y. Kim[3], S.W. Kang[2], S.-C. Shim[2], S.-J. Yoo[3]. *[1]Internal Medicine, Chungbuk National University Hospital, Cheong-ju; [2]Internal Medicine, School of Medicine Chungnam National University; [3]Internal Medicine, Chungnam National University Hospital, Daejeon, Korea, Republic Of*

Background: In case of anti-phospholipid syndrome, anticoagulants are recommended. However, there were no data about recurrence rate for thrombosis in patients with anti-phospholipid antibodies (APS) initially which disappeared later.
Objectives: We compared recurrence rate of thrombosis between negative conversion group and control group.
Methods: We reviewed the medical records of patients diagnosed with thrombosis such as cerebral infarct, myocardial infarct, deep vein thrombosis, or thrombosis of other vessels at a tertiary medical center from 2000 to October 2016. Of these, 14 patients whose APA status was converted from positive to negative after more than 12 weeks were enrolled as negative conversion group. Forty-six patients without APA were matched with the ratio of 1:3∼1:4 according to age, sex, thrombosis type (arterial or venous) and therapeutic agents as control group.
Results: There was no difference between negative conversion group and control group in smoking status, presence of diabetes or hypertension, duration from the thrombosis to last visits or to recurrence, the proportion of patients taking glucocorticoids. There was no difference in the overall recurrence of thrombosis between two groups [negative conversion group, 3/14 (21%) vs. control group,

6/46 (13%), p=0.423]. In the negative conversion group, the number of patients diagnosed with SLE was significantly higher than the control group [SLE, 3/14 (21%) vs. 1/46 (2%), p=0.036]. However, thrombosis had recurred in one out of three patients with SLE.
Conclusions: The cumulative incidence of thrombotic events was not significantly different between negative conversion group and control group.

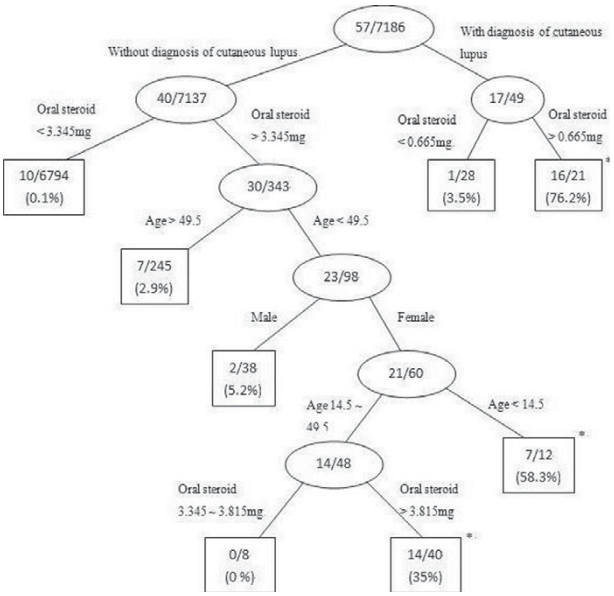
SAT0308 CLINICAL, BIOLOGICAL AND IMMUNOLOGICAL FEATURES OF SJÖGREN SYNDROME: A STUDY OF 270 TUNISIAN PATIENTS



T. Ben Salem, I. Naceur, M. Lamloum, I. Ben Ghorbel, M.H. Houman. *Internal Medicine, Rabta university hospital, Tunis, Tunisia*

Background: Sjögren syndrome (SS) is a chronic autoimmune disease characterized by a sicca syndrome and a wild spectrum of extra-glandular manifestations.
Objectives: The aim of this study was to describe clinical, biological and immunological characteristics of patients with SS and to compare them in primary and associated SS.
Methods: We conducted a monocentric, retrospective study over a period of 15 years. Patients who fulfilled the American European Consensus Group criteria for Sjögren syndrome were enrolled.
Results: SS was diagnosed in 270 patients. The sex-ratio female/male was 10.73. The mean age at disease onset was 45 years +/- 13 years (range 15–74 years) and at diagnosis was 47 years +/- 13 years (range 15–76) with a mean delay of 3 years (range 0–25 years). Sicca syndrome revealed the disease in most cases; both ocular and buccal dryness (n=48), xerophtalmia (n=21), xerostomia (n=21) or parotid gland swelling (n=17). SS was also revealed by joint involvement (n=39), neurological manifestations (n=26) or interstitial lung disease (n=14). SS was systematically screened in 27 patients with another autoimmune disease and was found in 3 mothers who had a child with congenital atrio-ventricular bloc. Patients complained of xerophtalmia and xerostomia in respectively 95.2% and 95% of cases. Minor salivary biopsy was positive in 92.6% of cases. Parotid gland swelling was noted in 40 cases. Arthralgia and arthritis were respectively noted 77% and 18% of cases whereas myalgia and myositis were found in 11% and 5% of patients. Patients had pulmonary involvements in 27% of cases. Peripheral and central nervous system involvements were confirmed in 22% and 13% of cases and 12 patients presented with psychiatric disorders. Raynaud's phenomenon and purpura were noted in 48 and 17 patients. Biological data showed lymphopenia (n=115), anemia (n=83), thrombocytopenia (n=25) and hypergammaglobulinemia (n=151). Antinuclear antibodies were positive in 210 cases; anti-SSA and anti-SSB were present in respectively 57% and 37% of patients. SS was primary in 155 patients and was associated to another autoimmune disease in 113 patients; systemic lupus erythematosus (n=48), rheumatoid arthritis (n=20), systemic sclerosis (n=19), autoimmune liver disease (n=13) and auto-immune thyroiditis (n=9). Arthralgia (91.2% vs 66.2; $p<0.0001$), arthritis (35.7% vs 5.2%; $p<0.0001$), myalgia (17% vs 7.1%; p=0.012) and Raynaud's phenomenon (33.3% vs 7.7%; $p\leq0.0001$) were significantly less frequent in primary SS. Lymphopenia (61.1% vs 32.9%; $p<0.0001$), anemia (48.6% vs 19.5%; $p<0.0001$), inflammatory syndrome (35.8% vs 17.9; p=0.002) and ANA (92% vs 70.9%; $p<0.0001$) were significantly more frequent in associated SS. Corticosteroids and immunosuppressive therapy were used in respectively 141 and 90 patients because of severe complications. Only 3 case of lymphoma were observed and 3 patients died. The mean duration of follow up was 50 months.
Conclusions: Sicca syndrome is the major symptom of SS but extra-glandular manifestations are less frequent and can be serious causing disability specially neurologic and pulmonary involvements. Some manifestations are significantly more frequent in patients with associated autoimmune diseases like joint involvements, Raynaud's phenomenon, anemia and lymphopenia. These manifestations are mainly related to SLE, rheumatoid arthritis and systemic sclerosis.

SAT0309 CAN WE FORESEE SLE IN ITP PATIENTS? TO DISTINGUISH ITP PATIENTS WITH HIGH RISK OF SLE BY A NATIONWIDE COHORT STUDY-BASED DECISION TREE

T.-H. Li[1], Y.-S. Chang[2], C.-Y. Tsai[3]. *[1]Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Chiayi Branch, Taichung Veteran General Hospital, Chiayi City; [2]Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taipei Hospital, Ministry of Health and Welfare, New Taipei City; [3]Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Taipei Veteran General Hospital, Taipei City, Taiwan, Province of China*

Background: Immune thrombocytopenic purpura (ITP) is an autoimmune-associated thrombocytopenia which is occasionally the initial presentation of systemic lupus erythematosus (SLE), and thus periodical following up has been suggested. Whereas long-term surveillance on all ITP patients would be time and cost-consuming, and thus to distinguish those with high probability of SLE development among ITP patients should be more practical.
Objectives: To distinguish ITP patients with high risk of SLE development by a decision tree model.
Methods: We enrolled ITP patients without previous SLE diagnosis from the National Health Insurance research database between 1997 and 2012 and identified those certificated with catastrophic illness of SLE during follow up, by which the diagnosis was reconfirmed by another rheumatologists. We also analyzed the symptoms and comorbidities as well as the dose of average oral steroid to derive the decision trees, which classified the ITP patients with different probability of development of SLE.
Results: A total of 10,265 ITP patients were enrolled, among whom 80 patients developed SLE while following-up. The whole ITP patients were allocated to training group (7,186 patients including 57 with SLE) and testing group (3,079 patients including 23 with SLE); the former was used for derivation of the decision-tree based model and the latter for validation of the previously mentioned model, and provided high sensitivity (78.2%), specificity (99.2%) and negative prediction value (99.8%, Fig.). To reduce the complexity, we also pruned our decision tree to propose less-complicated models.

Conclusions: We derived classification decision tree suitable for various clinical scenarios of ITP patients, among whom those with high probability of development of SLE would be distinguished.

SAT0310 ULTRASONOGRAPHIC SCORING OF THE MAJOR SALIVARY GLANDS IN SJOGREN'S SYNDROME: A COMPARATIVE STUDY WITH DISEASE ACTIVITY INDEXES

N. İnanç[1], Y. Yalçınkaya[1], G. Mumcu[2], Z. Ertürk[1], A.U. Unal[1], P. Atagündüz[1], H. Direskeneli[1]. *[1]Department of Internal Medicine, Division of Rheumatology, Marmara University, School of Medicine; [2]Marmara University, Faculty of Dentistry, Istanbul, Turkey*

Background: Sjogren's syndrome (SjS) is characterised by chronic autoimmune inflammation primarily affects the salivary and lacrimal glands. Recently, ultrasonography (USG) of major salivary glands (SG-USG) has been used to evaluate salivary glands in primary and secondary SjS.
Objectives: We aimed to investigate the association between the ultrasonographic scoring of major salivary glands and disease activity indexes in patientswith primary SjS.
Methods: Forty-two primary SjS patients fulfilling ACR-EULAR classification criteria (2002) were included. Disease activity indexes (Sjögren's Syndrome Patients Reported Index (ESSPRI), Visual Analogue Scale (VAS), EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI)] were recorded. Major salivary glands (bilateral parotis and submandibular glands) were scored according to two different scoring system [Hocevar A. (0–48) ve Milic VD. (0–12)].
Results: Demographics, clinical characteristics, disease activity indexes and SG-USG scores were summarised in table 1 and table 2.

Table 1. Demographics and Clinical Characteristics of SjS patients (n=42)

Age (year)	54±11
Gender (F/M)	41/1
Duration of follow-up (month)	55±51
Siccasymptoms	39 (93%)
Arthralgia/arthritis	37 (88%)
Parotitis	9 (21%)
RaynaudPhenomenon	5 (12%)
Leucocytoclasticvasculitis	5 (12%)
Peripheralneuropathy	2 (5%)
Interstitiallungdisease	2 (5%)
Lymphadenopathy	6 (14%)
ANA	34 (81%)
Anti-Ro/La	19 (45%)

Tablo-2: Disease Activity Indexes and SG-USG Scores of SjS Patients

	n=42
ESSPRI-total	15,4±5,4
-dryness	5,7±2,2
-fatigue	5,2±2,6
-pain	5,4±2,6
VAS	55±20
ESSDAI-total	1±1
Hocevar-USG Score	20±10
Milic-USG Score	6±3

Twenty-four (57%) and25 (60%) patients had the cut-offvalues of ≥17 (Hocevar) and ≥6 (Milic USG).The patients with the scores of ≥17 (Hocevar)were found to have higher scores of ESSPRI-total (18±5 vs 14±5, p=0,01). Hocevar and Milic USG scores were shown to be higher in anti-Ro(+) SjS patients (25±10vs14±7and7±3vs4±2, p=0,01).USG scores were not found to be associated with the scores of ESSDAI, VAS and ESSPRI items.

Conclusions: Hocevar scoring system of major salivary glands was found to be related to patient reported activity in SjS. USG scores were associated with anti-Ro positivity. Evaluation of SG-USG might promote the diagnosis and follow-up of the SjS patients.

SAT0311 PROLONGED EXPOSURE TO ANTIPHOSPHOLIPID ANTIBODIES IS ASSOCIATED WITH ENDOTHELIAL DYSFUNCTION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Y.-J. Park[1], I.-W. Baek[2], K.-J. Kim[1], W.-U. Kim[3], C.-S. Cho[4]. *[1]Division of Rheumatology, St. Vincent Hospital, The Catholic University of Korea, Suwon; [2]Division of Rheumatolgy, Yeouido St. Mary's Hospital, The Catholic University of Korea; [3]Division of Rheumatology, Seoul St. Mary's Hospital, The Catholic University of Korea; [4]Division of Rheumatology, Yeouido St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of*

Background: Antiphospholipid syndrome has been shown to be associated with increased cardiovascular mortality, but the role of antiphospholipid antibodies (aPL) on endothelial dysfunction remains elusive.

Objectives: We investigated the association between endothelial dysfunction and aPL in systemic lupus erythematosus (SLE) patients.

Methods: 188 SLE patients and 62 controls were enrolled. Endothelial function was measured by flow-mediated dilatation (FMD). Cardiovascular risk factors were assessed and quarterly measurement of anti-cardiolipin (aCL) and anti-β_2 glycoprotein I Ab were used to calculate time-integrated values throughout disease duration. Circulating endothelial progenitor cell (EPC), defined by CD34+/KDR+ mononuclear cells, was quantified by flow cytometry.

Results: Median FMD was significantly lower in SLE patient than in controls (6.9 versus 9.3%, $P<0.001$). In univariate analysis, older age, hypertension, thrombocytopenia, and persistent positive lupus anticoagulant (LAC) were associated with decreased FMD in SLE patients ($P=0.021$, $P=0.011$, $P=0.004$, and $P=0.028$). Time-integrated aCL value (TI-aCL), but not a single value, was correlated with decreased FMD ($P=0.001$). Multivariate analysis showed that hypertension and TI-aCL were independent factors for decreased FMD ($P=0.027$, $P=0.008$); addition of positive LAC increased the adjusted probability of decreased FMD ($P=0.023$). FMD was correlated with EPC number ($\gamma=0.342$, $P=0.005$) and TI-aCL was also an independent factor of reduced EPC after multiple adjustment ($P=0.019$). The predicted probability of endothelial dysfunction at median EPC level was higher in group with high TI-aCL than in group with low TI-aCL ($P=0.004$).

Conclusions: Cumulative burden of aPL was closely associated with endothelial dysfunction in SLE patients, which was mediated in part by reduction of EPC.

SAT0312 MICRORNA-125B AS A POTENTIAL FIBROTIC AND APOPTOTIC REGULATOR IN SYSTEMIC SCLEROSIS

A. Kozlova[1], E. Pachera[1], F. Renoux[1], M. Rudnik[1], B. Maurer[1], A. Jüngel[1], J.H. Distler[2], G. Kania[1], O. Distler[1]. *[1]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; [2]Department of Internal Medicine 3, Friedrich-Alexander University Erlangen-Nuremberg, Erlangen-Nuremberg, Germany*

Background: MicroRNAs (miRs) are a class of small, noncoding RNAs that regulate many biological processes. Some microRNAs are involved in skin fibrosis.

Objectives: To analyze the differential expression, regulation and the pathophysiological role of miR-125b in systemic sclerosis (SSc).

Methods: For screening a low density array was run on pooled RNA from fibroblasts derived from 3 SSc patients vs. 3 healthy controls (HC). For further validation we performed qPCR on RNA derived from cultured fibroblasts, whole skin biopsies as well as on paraffin fixed dermis and epidermis. Next, fibroblasts were stimulated with pro-inflammatory and/or pro-fibrotic cytokines such as TGFβ, IL-1β, -4, -13, -17A, TNFα and PDGF. In order to identify downstream effects of miR-125b, knockdown with anti-miR-125b (or scrambled controls) in HC fibroblasts was performed. RNA was isolated from healthy fibroblasts (n=4) after knockdown and was proceeded to deep sequencing using Illumina HiSeq2000. Sequencing data were validated using qPCR on HC as well as SSc fibroblasts. Apoptosis was assessed by Caspase-Glo 3/7 assay and immunofluorescence of cleaved caspase 3 on cultured fibroblasts.

Results: Screening identified miR-125b as one of the candidate miRs differentially expressed in SSc. MiR-125b was confirmed by qPCR in primary dermal fibroblasts (SSc =11, HC =8), where it was downregulated by 47% (median expression 53%, $Q_{1,3}$ 33%, 70%; $p<0.01$). MiR-125b expression appeared to be independent from main cytokines operative in SSc. Additionally, the expression of miR-125b was assessed in skin biopsies of both SSc patients (n=4) and HC (n=5). In SSc, miR-125b was downregulated by 35% (median expression 65%, $Q_{1,3}$ 61%, 78%; $p<0.05$). To localize its expression in the skin, we separately analyzed miR-125b expression in dermis and epidermis of paraffin fixed skin. In both cases, expression of miR-125b was downregulated.

RNA sequencing identified >3500 differentially expressed genes with $p<0.05$. More than half of the differently expressed genes with at least 15% change were predicted targets of miR-125b by TargetScan and MiRWalk, indicating successful functional inhibition of miR-125b. Gene ontology revealed extracellular matrix organization and apoptosis regulation as the two main clusters of differentially expressed genes. Among them, BAK1, BMF and BBC3 are participants of the BCL2 apoptosis pathway and predicted targets of miR-125b. Consistent with the sequencing results, qPCR showed that knockdown of miR-125b upregulates these genes 24, 48 and 72 hours after transfection ($p<0.05$ for each). That was confirmed also on protein level by Western blot. Accordingly, miR-125b knockdown resulted in a higher rate of apoptosis (mean±SD: 60% ± 29%, $p<0.01$) compared to scrambled controls, measured by Caspase-Glo 3/7 assay.

Moreover, miR-125b knockdown reduced TGFβ-induced αSMA expression both on RNA and protein levels, suggesting that miR-125b might play an additional role in the cytoskeletal reorganization of fibroblasts during fibrosis.

Conclusions: MiR-125b is differentially expressed in SSc skin and primary dermal fibroblasts. MiR-125b downregulation increases apoptosis, inhibits cytoskeletal reorganization and therefore might become a potential anti-fibrotic therapeutic strategy.

Cipriani[1]. *[1]Department of Applied Clinical Sciences and Biotechnology, Rheumatology Unit, School of Medicine; [2]Department of Applied Clinical Sciences and Biotechnology, University of L'aquila, L'Aquila, Italy*

Background: The microvascular damage is a pivotal event in the pathogenesis of Systemic Sclerosis (SSc) and, after injury, both endothelial cells (ECs) and pericytes might trans-differentiate toward myofibroblast, responsible of fibrosis. Platelet-derived growth factor B (PDGFB) and transforming growth factorβ (TGFβ) play a key role in SSc pathogenesis. PDGFB is a potent mitogen for myofibroblasts, while TGFβ stimulate myofibroblast activation, including alpha smooth muscle actin (αSMA) expression. A key regulator of PDGFB and TGFβ signaling may be the CD248, a trans-membrane receptor required for proliferation and migration of pericytes and fibroblasts. It has been showed that, in an animal model of kidney fibrosis, the genetic deletion of CD248 modulates the response of renal pericytes to injury, by reducing the differentiation of myofibroblasts. The expression of CD248 is required for TGFβ-induced αSMA expression in pericytes and CD248 enhances the PDGFB pathway, mediating the proliferation and migration of perivascular cells.
Objectives: The aim of this work was to evaluate the expression of CD248, in SSc skin biopsies and its possible role in perivascular stromal cells proliferation, responsible to myofibroblast trans-differentiation, during SSc.
Methods: After ethical approval, skin biopsies and bone marrow mesenchymal stem cells (MSCs) were collected from 20 diffuse SSc patients and 10 healthy control (HC). CD248 expression was investigated in the skin, and in isolated MSCs treated with TGFβ or PDGFB, by immunofluorescence, qRT-PCR and western. Furthermore, we silenced CD248 in SSc-MSCs, to confirm the role of this molecule in TGFβ- or PDGFB-signaling modulation.
Results: CD248 expression in SSc skin was significantly higher when compared with HC skin. In particular, an increased expression of CD248 was found in ECs, stromal fibroblast and perivascular like stromal cells, co-expressing CD90, a marker of un-differentiated MSCs. Furthermore, in both, HC- and SSc-MSCs, TGFβ treatment induced a significant reduction of CD248 mRNA expression, in parallel with a significant increase of αSMA and a decrease of proliferation (ki67), when compared with untreated- (UT-) cells. Interestingly, the ability of TGFβ to inhibit CD248 expression in HC-MSCs was significantly higher than SSc-MSCs, suggesting that local environment in SSc patients affect TGFβ ability to suppress CD248 expression in SSc-MSCs. After treatment with PDGFB in both SSc- and HC-MSCs, CD248 expression was not affected, while significant reduction of αSMA and an increased expression of Ki67 was observed compared with UT-cells. After silencing of CD248 in SSc-MSCs, both TGFβ and PDGFB signaling were inhibited.
Conclusions: CD248 over-expression may play an important role in tissue fibrosis by modulating the pericytes to myofibroblast trans-differentiation, via regulation of both PDGFB and TGFβ signaling, during SSc.

SAT0314 **A NOVEL HIGHLY SELECTIVE 5-HYDROXYTRYPTAMINE 2B (5-HT2B) RECEPTOR ANTAGONIST AMELIORATING FIBROSIS IN PRECLINICAL MODELS OF SYSTEMIC SCLEROSIS**

C. Wenglén, L. Pettersson, H. Arozenius, G. Ekström. *ANAMAR, Lund, Sweden*

Background: Microvascular injury is one of the first pathological events in systemic sclerosis, and precedes the fibrosis. A consequence of vascular damage is the exposure of subendothelial connective tissue that causes activation of platelets and local serotonin (5-hydroxytryptamine, 5-HT) release. Binding of 5-HT to 5-HT_{2B} receptors on *e.g.* fibroblasts results in increased myofibroblast differentiation and release of excessive amounts of matrix proteins subsequently leading to fibrosis. Thus, pharmacologic inhibition of 5-HT_{2B} receptor signalling may represent a new treatment opportunity for systemic sclerosis.
Objectives: The objective of the present study was to evaluate a novel highly selective 5-HT_{2B} receptor antagonist for its ability to reduce the production of matrix proteins in human dermal fibroblasts and to ameliorate fibrosis in the tight-skin-1 model of systemic sclerosis.
Methods: Dermal fibroblasts isolated from patients with systemic sclerosis were cultured with different concentrations of the 5-HT_{2B} receptor antagonist AM1125 with or without 1 μM 5-HT. Anti-fibrotic effects were evaluated by measuring matrix production, myofibroblast differentiation and TGF-β production. The tight-skin-1 model was used to evaluate anti-fibrotic effects *in vivo* using a therapeutic treatment approach. AM1125 was administered at 10 and 50 mg/kg orally, b.i.d. from week 5 to week 10. Hypodermal thickening, myofibroblast counts and collagen production (hydroxyproline) were evaluated at the end of the treatment period.
Results: *In vitro* the 5-HT_{2B} receptor antagonist AM1125 dose-dependently reduced TGF-β, PAI, nuclear SMAD2/3 and collagens in human dermal fibroblasts. In addition, stress fiber formation and α-SMA mRNA were reduced indicating decreased myofibroblast differentiation. Therapeutic treatment with AM1125 at 50 mg/kg reduced hypodermal thickness ($p<0.001$), myofibroblast counts ($p<0.05$) and hydroxyproline content ($p<0.01$) in the tight-skin-1 model. In addition, the lower dose (10 mg/kg) reduced hypodermal thickness ($p<0.001$).
Conclusions: The results demonstrate that the 5-HT_{2B} receptor antagonist AM1125 prevents pro-fibrotic events in human dermal fibroblasts and attenuates dermal fibrosis using a therapeutic treatment approach in the tight-skin-1 model. Thus, 5-HT_{2B} receptor antagonists, exemplified by the novel compound AM1125, could represent a new treatment opportunity for systemic sclerosis.

SAT0315 **IMATINIB-LOADED TARGETED GOLD NANOPARTICLES AMELIORATE EXPERIMENTAL LUNG FIBROSIS INDUCED BY BLEOMYCIN**

V. Codullo[1], S. Breda[1], F. Meloni[1], E. Cova[1], S. Inghilleri[1], M. Colombo[2], D. Prosperi[2], M. Malatesta[3], L. Calderan[3], C. Montecucco[1], J. Distler[4]. *[1]IRCCS policlinico San Matteo Foundation, Pavia; [2]University of Milan - Bicocca, Milan; [3]University of Verona, Verona, Italy; [4]Department of Internal Medicine 3, University of Erlangen-Nuremberg, Erlangen, Germany*

Background: Systemic Sclerosis (SSc) is an autoimmune disorder frequently affected by an interstitial lung involvement (ILD) that significantly deteriorates long term outcomes. In previous experiments we proved that specifically engineered gold-nanoparticles (GNP) loaded with imatinib and targeted with an anti CD44 Ab (GNP-HCim) significantly inhibited proliferation and induced apoptosis of fibroblast-like cells derived from ILD-SSc patients [1]. *In vitro*, GNP-HCim showed higher efficacy compared to the drug alone.
Objectives: To demonstrate in vivo the efficacy of GNP-HCim in ameliorating bleomycin-induced lung fibrosis
Methods: Eight-week-old C57BL6 male mice (n=8/group) were assigned to either: (1) controls receiving intratracheal aereosolization of saline solution and unloaded functionalised GNP (GNP-HC); (2) mice treated with intratracheal instillation of bleomycin (50 uL) on day 0 and GNP-HC; (3) mice treated with bleomycin on day 0 plus GNP-HCim; (4) mice treated with bleomycin plus intraperitoneal (i.p.) Imatinib (50 mg/kg, once daily). GNP-HC or GNP-HCim were administered by intratracheal instillation on day 10–15–20–25 and 3 h before culling. All mice were sacrificed on day 28. Lung specimens were analysed by electron microscopy, immunohistochemistry and immunofluorescence (IF). Data were evaluated by 2 blind observers and analysed with GraphPrism software for statistics.
Results: The administration of imatinib i.p or via GNP-HC reduced pathologic changes of the lungs as evaluated by the Lung Injury score and the Ashcroft score ($p<0.05$ for both). Collagen quantification by Picro Sirius Red revealed a significantly reduced staining only in the GNP-HCim group (p=0.0135 vs controls). IF revealed a significant reduction in αSMA+ myofibroblast counts when mice were inhaled with GNP-HCim (14.36±1.69/hpf) or injected i.p with imatinib (7.64±1.17/hpf) as compared to the controls (24.01±3.58/hpf, p=0.003 and p=0.0013 respectively). IF also showed significantly reduced counts of CD45+ (15.21±1.87/hpf vs 29±2.247/hpf in controls, p=0.0006) and CD44+ cells in groups treated with GNP-HCim (18.61±1.495) or imatinib i.p. (13.57±0.864), versus controls (28.56±2.854, p=0.0111 and p=0.0004 respectively). In imatinib i.p. and GNP-HCim-treated groups there was a significant reduction of phosphorylated c-Abl and PDGF-R, two downstream targets of imatinib, to levels comparable to group 1 controls with respect to the bleomycin group ($p<0.05$ for both). Finally, electron microscopy revealed accumulation of GNP-HCim and GNP in alveolar macrophages.
Conclusions: In the experimental model of bleomycin-induced lung fibrosis imatinib delivered to lungs through inhalation of anti CD44 targeted GNP was as effective as imatinib administered by i.p. route. These data favour the use of GNP in the development of new therapeutic approaches to SSc-ILD, which might be associated to a lower toxicity and side effects of systemic treatment.

Background: Pulmonary arterial hypertension (PAH) is a rare disease whose etiopathogenesis is poorly understood, and existing treatments are neither curative nor sufficient for stopping disease progression [1]. PAH is one of the major complications of connective tissue diseases, and 7–15% of patients with systemic sclerosis (SSc) develop PAH [2]. Mice deficient for the leukocytic receptor P-selectin glycoprotein ligand-1 (*PSGL-1*$^{-/-}$) spontaneously develop a SSc-like autoimmune syndrome with ageing [3].
Objectives: To check whether *PSGL*$^{-/-}$ mice may develop PAH and which mechanisms might be implicated in the initiation and progression of the disease.
Methods: Vascular remodeling was assessed by immunohistochemistry on lung sections of WT and *PSGL-1*$^{-/-}$ C57BL/6 mice. Doppler pulse echochardiography was used to evaluate pulmonary artery flow acceleration time/ ejection time (TPV/ET) ratio. Isolated pulmonary artery rings were incubated with KCL, serotonin or acetylcholine and responses were registrated with a wire myograph coupled to an isometric force transducer. Angiotensin II lung concentration was quantified by ELISA. ACE, ACE2, AT1R and AT2R expression was evaluated by western blot. Expression levels of the NO-sensing probe DAR-4M AM and IFN-γ were measured by flow cytometry.
Results: *PSGL-1*$^{-/-}$ mice presented vascular remodeling of distal lung blood vessels. Aged *PSGL-1*$^{-/-}$ females showed reduced flow TPV/ET ratio in the pulmonary artery and RV remodeling, indicating PAH. Moreover, pulmonary arterial rings from aged *PSGL-1*$^{-/-}$ females presented increased vasoconstriction response to KCL and reduced vasodilation response to acetylcholine. Importantly, NO production by lung EC was reduced in aged *PSGL-1*$^{-/-}$ females. Expression of AT2R was reduced in lungs of *PSGL-1*$^{-/-}$ females from a young age. With ageing, the levels of angiotensin II and the percentages of IFN-γ-producing interstitial macrophages, T and B lymphocytes were increased in PSGL-1$^{-/-}$ females.
Conclusions: Together, these studies implicate leukocyte-endothelium interactions for the maintenance of vascular homeostasis and protection against PAH in PSGL-1 deficient female mice.

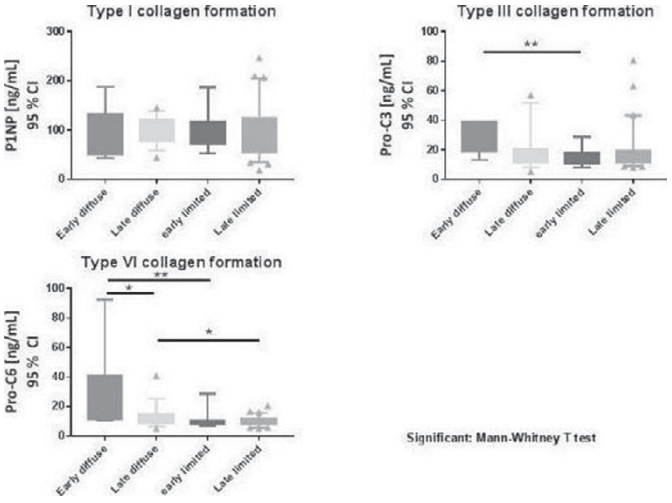
SAT0317 TYPE VI COLLAGEN FORMATION: A NEW OBJECTIVE BLOOD-BASED MARKER REFLECTING FIBROSIS OF THE SKIN IN SYSTEMIC SCLEROSIS



P. Juhl[1], L. Iversen[2], T. Karlsmark[2], M. Karsdal[1], A.-C. Bay-Jensen[1], M. Mogensen[2], A.S. Siebuhr[2]. *[1]Nordic Bioscience, Herlev; [2]Department of dermatology, Bispebjerg Hospital, Copenhagen, Denmark*

Background: Systemic sclerosis (SSc) is characterized by fibrosis of the skin. The dermis of the skin is rich in type I and III collagen, but other collagens as type VI collagen are present in the skin and play a key role in the organization of type I and III collagen. There is a lack of objective disease activity markers in SSc for frequent assessment of patients. The only measurement of disease activity currently is the subjective modified Rodnan skin score (mRSS).
Objectives: The objective is to examine blood-based markers of type I, III, and VI collagen formation as surrogates of disease activity and fibrosis in SSc.
Methods: SSc patients fulfilling the ACR criteria (n=121) were included. The study included both limited SSc (lSSc, n=79) and diffuse SSc (dSSc, n=42) (approval number H-B-2008–131). Markers of type I, III and VI collagen formation (P1NP, PRO-C3 and PRO-C6, respectively) were measured in serum by ELISA. Difference in the markers between groups were tested by Mann-Whitney T test and correlations were assessed by multiple linear regression adjusting for age, gender and BMI. Discriminative power of the markers was analyzed by ROC AUC on tertiles of mRSS.
Results: There were no significant difference in gender, BMI or disease duration between lSSc and dSSc. The mean age of the population was 57.4 (SD 11.6) years, 84% were female, mean disease duration was 11.7 (SD 8.9) years and mean mRSS was 11.2 (SD 8.6).
PRO-C3 and PRO-C6 were significantly higher early (<4 years) dSSc compared to early lSSc patients (both p=0.006). PRO-C6 was significantly elevated in early dSSc compared to late dSSc (p=0.04) and increased in late dSSc compared to late lSSc (p=0.02; Figure). Both PRO-C3 and PRO-C6 correlated with mRSS when adjusted for age, gender, and BMI with R-partial of 0.36 (p=0.0001) and 0.29 (p=0.002), respectively.
Both PRO-C3, and PRO-C6 could separate the patient group having the highest tertile of mRSS from the rest with an AUC (95% CI) of 0.73 (0.62–0.82), and 0.74 (0.63–0.83), respectively. Together, PRO-C3 and PRO-C6 could separate the groups with an AUC (95% CI) of 0.77 (0.67–0.86) (Table 1).
PRO-C3 and PRO-C6 performed equally well for identification of patients with the highest skin score (highest tertile vs. the middle and lower tertile) with a relative risk of 2.3 (1.4–3.8) (Table 2). The risk of being in the highest tertile of mRSS compared to the lowest were significantly higher with a high PRO-C6 (relative risk 2.6, 95% CI: 1.3–5.2) compared to PRO-C3 (relative risk: 2.2, 95% CI: 1.2–3.8) (Table 2).

Table 1

Skin (highest vs lowest tertile)	AUC (95% CI)	P-value
P1NP	0.56 (0.44–0.67)	
PRO-C3	0.73 (0.62–0.82)	<0.0001
PRO-C6	0.74 (0.63–0.83)	<0.0001
PRO-C3, PRO-C6	0.77 (0.67–0.86)	<0.0001

Analyzed by ROC curve.

Conclusions: Markers reflecting fibrosis (measures of type III and VI collagen formation) could be novel objective, and potentially predictive, biomarkers of disease activity and severity.

OR: odds ratio, RR: relative risk.

mortality. Epigenetic changes might play important roles in mediating chronic fibroblast activation. Trimethylation of H3 at lysine residue K27 (H3K27me3) is a repressive epigenetic mark that was recently identified as an important negative regulator of fibroblast activation [1]. Jumonji domain containing protein 3 (JMJD3) mediates H3K27me3–demethylation. JMJD3 inhibitors are being tested as therapeutic strategies in malignant diseases.

Objectives: The aim of this study was to characterize the role of JMJD3 in fibrotic disease and to explore JMJD3 as a potential drug target in SSc.

Methods: Expression analyses of JMJD3 were performed using qPCR, IF and Western blot. siRNA mediated knockdown and the pharmacologic H3K27me3-demethylase inhibitor GSKJ4 were used to target JMJD3. *In vivo,* we analyzed the effects of GSKJ4 in bleomycin-induced dermal fibrosis and in Topoisomerase-I-induced (TopoI) fibrosis. H3K27me3 levels at the Fra2 promotor were analyzed by CHIP.

Results: We observed increased expression of JMJD3 in SSc skin compared to healthy controls. Fibroblast-specific overexpression of JMJD3 was also reflected in experimental fibrosis models. TGFβ upregulated JMJD3. Inhibition of JMJD3 increased H3K27me3 *in vitro* and *in vivo*. Inhibition of JMJD3 reverted the activated fibroblast phenotype in SSc fibroblasts and decreased the expression of contractile fibers and of α-smooth muscle actin. In addition, JMJD3 inhibition reduced the basal and TGFβ induced collagen secretion of SSc fibroblasts. JMJD3 regulated the TGFβ induced expression of Fra2. GSKJ4 reverted the TGFβ induced reduction of H3K27me3 at the Fra2 promotor. Moreover, the anti-fibrotic effects of JMJD3 inhibition were evened in Fra2 knockout fibroblasts. Overexpression of Fra2 in JMJD3-knockdown fibroblasts restored the profibrotic effect of JMJD3. *In vivo*, inhibition of JMJD3 ameliorated fibrosis in bleomycin- and TopoI- induced experimental fibrosis and reduced dermal thickening, hydroxyproline content and myofibroblast differentiation.

Conclusions: We present first evidence that JMJD3 contributes to the activated phenotype of SSc fibroblasts. TGFβ upregulated JMJD3. Inhibition of JMJD3 prevented the aberrant activation of fibroblasts *in vitro* and ameliorated dermal fibrosis in several mouse models *in vivo*. The profibrotic effects of JMJD3 might be mediated by reducing the H3K27me3 at the Fra2 promotor and consecutive overexpression of Fra2.

SAT0319 MULTIPARAMETRIC DETECTION OF AUTOANTIBODIES TO INVESTIGATE RELATIONSHIPS BETWEEN SEROLOGICAL AND CLINICAL SUBSETS OF SYSTEMIC SCLEROSIS PATIENTS

P. Budde[1], H.-D. Zucht[1], D.S. Wirtz[1], K. Marquart[1], M. Schneider[2], P. Schulz-Knappe[1], N. Hunzelmann[3]. *[1]Protagen Ag, Dortmund; [2]Rheumatology & Hiller-Forschungszentrum, Heinrich-Heine-University, Düsseldorf; [3]Dermatology, University of Cologne, Cologne, Germany*

Background: Systemic sclerosis (SSc) is a largely heterogeneous autoimmune disease, with patients exhibiting an extensive range of clinical presentations and various disease course. The most widely used classification divides SSc into two major subsets diffuse cutaneous (dcSSc) and limited (lcSSc) SSc by the extent and severity of skin fibrosis. However, not all patients fit into these subsets. This has created great interest to examine disease heterogeneity at the molecular level to uncover unrecognized SSc subtypes that may differ with regard to clinical manifestations, prognosis or therapy response.

Objectives: In large-scale "omics"-type autoantibody (AAB) profiling studies we have recently identified novel SSc-associated autoantigens. Here, we describe the development of a 20 marker multiplexed AAB assay to facilitate the discovery and validation of AAB-based patient subgroups.

Methods: A Luminex bead-based AAB assay was designed by combining 8 connective tissue disease (anti-centromere, anti-Scl70, U1-snRNP, SSB, Ro52, Ro60, SmB, anti-ribosomal P) antigens with 12 novel antigens (including BICD2, JMJD3/KDM6B, and PPP1R2). Novel AAB targets were previously detected in SSc patients with a p-value <0.05 (Mann-Whitney-U-test) and frequency$>15\%$. AAB reactivity was analysed in 92 SSc patients (dcSSc: n=32, lcSSc: n=50, SSc overlap: n=9). The mean modified Rodnan skin score (MRSS), mean disease duration (month), and mean age (years) of the SSc cohort was 10.51, 162.5 and 56.94, respectively. To analyze the individual-level patient similarity of AAB reactivity, the total number of AABs reactive in each patient was calculated and referenced to the number of all available antigens in percent. Patient's demographics and clinical data were dichotomized into patients with mRSS higher or lower than the mean value. Hierarchical cluster analysis was performed to investigate the relationship between AAB patient signatures and clinical and demographic features.

Results: Based on their AAB reactivity pattern, the SSc sample cohort can be decomposed into four apparent clusters and additional fine-level clusters. LcSSc patients were spread over three clusters, each with clearly distinct AAB profile. Compared to dcSSc patients, lcSSc patients were more heterogeneous in their AAB profile. The percentage of lcSSc patients in clusters 1–3 was 70%, 90% and 53%, respectively. Patients in cluster 2 had an extended AAB repertoire that is anti-centromere, KDM6B, SSA, BICD2 and PPP1R2. 63% of all patients in cluster 4 were dcSSc and anti-Scl70 positive, who were most afflicted of the disease. AAB signatures of patients were mapped against dichotomized demographic and clinical features. Moving from cluster 1 to 4 the number of patients with shorter disease duration, lower age, higher mRSS and higher frequency of lung involvement increased.

Conclusions: The multiplexed analysis of AABs in SSc enables defining an AAB reactivity score and patient clusters. This might support to subclassify SSc beyond lcSSc and dSSc.

SAT0320 SSC- IGG EFFECTS ARE MEDIATED THROUGH DISTINCT PATHWAYS IN THP-1 CELLS

G. Eleftheriadis[1], M. Wannick[1], C. Sadik[1], G. Riemekasten[2]. *[1]Institute of Experimental Dermatology; [2]Department of Rheumatology, University of Lübeck, Lübeck, Germany*

Background: Peripheral blood mononuclear cells (PBMCs) are thought to play a key role in the pathogenesis and progress of systemic scleroderma (SSc) with patients displaying distinct shifts in count, receptor expression profile and cytokine secretion patterns. SSc-IgG with elevated anti-AT_1R (angiotensin II type 1 receptor)/ET_AR (endothelin-1 type A receptor) -AAb (autoantibody) titers have been correlated to disease severity and progression[1]. It remains poorly understood through which pathways SSc- IgG mediates its effects.

Objectives: In this study we sought to analyze the expression patterns of THP-1 cells (a monocytic cell line) after SSc-IgG application and their reversibility through application of numerous pharmacological inhibitors.

Methods: Transcription of IL-8- and CCL-18 in THP-1-cells after SSc-IgG and normal IgG stimulation was quantified by qPCR. Stimulations of THP-1 cells with total IgG of phenotypically different groups of SSc patients as well as ET-1 and AT-2 were carried out. In addition, stimulation with pharmacological inhibitors was conducted in a dose-dependent-manner. The results were quantified by IL-8- and CCL18-ELISA of the supernatants.

Results: Expression of IL-8 and CCL-18 is induced by SSc-IgG treatment in comparison to normal IgG which does not follow this trend. IL-8 secretion of THP-1 cells upon SSc-IgG stimulation is mediated through specific autoantibody effects and transduced through NF-κB, ERK-, and AP-1 pathways. CCL-18 secretion of THP-1 cells upon SSc-IgG stimulation is not mediated through aforementioned pathways.

Conclusions: A stable cell culture system able to reproduce previous PBMC data on IL-8 and CCL-18 induction upon SSc-IgG-treatment could be established and insight was gained regarding key pathways which are involved in the transduction leading to IL-8 secretion. The effects of specific surface receptor expression profiles on transduction remain to be elucidated.

SAT0321 MKP-1 AS A PROTECTIVE FACTOR AND NOVEL DRUG TARGET IN SCLERODERMA: MKP-1 DEFICIENT MICE DEVELOP MORE SEVERE DERMAL FIBROSIS IN A WIDELY USED EXPERIMENTAL MODEL OF SCLERODERMA

M. Scotece, M. Hämäläinen, T. Leppänen, E. Moilanen. *The Immunopharmacology Research Group, Faculty of Medicine and Life Sciences, University of Tampere and Tampere University Hospital, Tampere, Finland*

Background: Scleroderma is a chronic connective tissue disease of unknown aetiology. In early stages, vascular injury and inflammation lead to fibrosis, resulting in irreversible damage in various organs. Inflammation is believed to be necessary in order to activate fibroblasts to over-produce extracellular matrix components. At the present, there is no effective standard treatment to reverse or slow down the progression of scleroderma but one of the feasible approaches is to target key inflammatory pathways that are involved in the pathogenesis of the disease.

MKP-1 (Mitogen-Activated Protein Kinase Phosphatase-1) is a nuclear phosphatase present in most cell types and tissues. Studies with MKP-1 deficient mice have undoubtedly shown that MKP-1 is an important regulator of innate and adaptive immune responses to limit and suppress inflammation (1) but its role in fibrosing diseases has not been studied.

Objectives: In the present study, we aimed to investigate the potential protective role of MKP-1 in the pathogenesis of scleroderma by using MKP-1 deficient mice and a widely studied experimental model of scleroderma.

Methods: We used bleomycin-induced dermal fibrosis in the mouse as an experimental model of scleroderma (2). Wild type (WT) and MKP-1 deficient mice were injected subcutaneously with bleomycin every other day for 28 days. Dermal

thickness and collagen accumulation were determined by histological analyses. The expression of several inflammatory and pro-fibrotic mediators were measured by quantitative RT-PCR.
Results: We found that bleomycin-induced dermal thickness and lipodystrophy were increased in MKP-1 deficient mice. Collagen accumulation in the dermis and mRNA expression of collagens 1A1 and 3A1 were enhanced in the skin from MKP-1 deficient mice as compared to the skin from WT animals. Affected skin from MKP-1 deficient mice presented increased expression of factors related to inflammation and fibrosis, namely IL-6, TGF-β1, fibronectin-1 and YKL-40 as well as chemokines MCP-1, MIP-1α and MIP-2.
Conclusions: This study demonstrates, for the first time, that MKP-1 deficient mice develop more severe bleomycin-induced dermal fibrosis than their WT counterparts, indicating that MKP-1 regulates the inflammatory and fibrotic processes typical for experimentally-induced scleroderma. These findings suggest that compounds which enhance expression/activity of MKP-1 have potential as novel drugs for the stage-specific modulation of the pathogenesis of scleroderma.

SAT0322 ADAM-17 IS EXPRESSED IN THE INFLAMMATORY MYOPATHY, AND IS INVOLVED WITH INTERSTITIAL LUNG DISEASE (ILD)

A. Nishimi, T. Isozaki, S. Nishimi, S. Ishii, T. Tokunaga, H. Furuya, K. Wakabayashi, T. Kasama. *Division of Rheumatology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan*

Background: A disintegrin and metalloprotesase (ADAM) family is protease that is thought to have an important role in tissue destruction and inflammatory reaction. ADAMs are also involved in the amputation from the cell surface of inflammatory cytokines. ADAM-17 is one of the ADAM family, and is first described as the protease responsible for tumor necrosis factor (TNF)-α shedding. The implication of ADAM-17 substrates in immunoregulation has made this enzyme an efficient therapeutic target in the treatment of a number of pathological conditions including airway inflammation and arthritis.
Objectives: The function of ADAM-17 in myositis is unclear. Therefore, we clarify the expression of ADAM-17 in inflammatory myopathy and the role of inflammation in interstitial lung diseases (ILD).
Methods: The serum were collected from the patients who were diagnosed with inflammatory myopathy in Showa University Hospital from 2003 to 2015. Twenty-six patients were diagnosed with polymyositis (PM), 34 patients were diagnosed with dermatomyositis (DM), and 10 patients were diagnosed clinically amyopathic dermatomyositis (CADM). Clinical manifestations and clinical data were also collected. The levels of ADAM-17 in the serum samples were measured using enzyme-linked immunosorbent assay (ELISA). ADAM-17 expression was determined in muscle tissues from DM using immunohistological staining. To determine that the role of lung fibrosis in inflammatory myopathy with ILD, we used human lung fibroblasts (HLF). ADAM-17 expression on HLF was also demonstrated by immunohistrogical staining. ADAM-17 expression in interleukine (IL)-6 and IL-6 receptor (IL-6R) stimulated HLF was performed by ELISA.
Results: ADAM-17 in inflammatory myopathy was significantly higher than in healthy control (n=19) (mean ± SEM; 1048±312 pg/ml and 36±18 pg/ml, respectively, $p<0.05$). ADAM-17 in corticosteroid and/or immunosuppressant treatment patient serum was also significantly decreased compared with in pre treatment patient serum (1465±562 pg/ml and 1059±503 pg/ml, respectively, $p<0.01$). In addition, ADAM-17 in inflammatory myopathy with ILD patients (n=46) was significantly higher than in non-ILD patients (n=24) (1379±454 pg/ml and 413±226 pg/ml, respectively, $p<0.05$), while ADAM-15 did not have the differences between ILD and non-ILD group. Finally, we found the expression of ADAM-17 in muscle biopsy tissue. Hence, ADAM-17 on HLF was expressed by immunohistochemistry. ADAM-17 in IL-6 and IL-6R stimulated HLF was significantly higher compared with non-stimulated HLF (48±6 pg/ml and 0±0 pg/ml, respectively, $p<0.05$).
Conclusions: ADAM-17 is expressed in inflammatory myopathies especially with ILD and expressed on HLF, suggesting that ADAM-17 may play the role in lung fibrosis. ADAM-17 may be a potential target in inflammatory myopathies with ILD.

SAT0323 THE ENDOTHELIAL-TO-MESENCHYMAL TRANSITION (ENDOMT) IN SCLERODERMA CAN BE PREVENTED BY THE USE OF DUAL ENDOTHELIN RECEPTOR ANTAGONISTS BOSENTAN AND MACITENTAN

C. Corallo[1], M. Cutolo[2], S. Soldano[2], A. Montella[1], C. Chirico[1], R. Nuti[1], N. Giordano[1]. *[1]Medicine, Surgery and Neurosciences, University of Siena, Siena; [2]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, Institute for Research and Health Care (IRCCS), University of Genoa, Genoa, Italy*

Background: Systemic sclerosis (SSc) is characterized by early vascular abnormalities and subsequent fibroblast activation and differentiation into myofibroblasts, leading to fibrosis. Recently, endothelial-to-mesenchymal transition (EndoMT), a complex biological process in which endothelial cells lose their specific markers and acquire a mesenchymal or myofibroblastic phenotype, has been reported in SSc.
Objectives: The goal of the study was to evaluate the potential of endothelin-1 (ET-1) dual receptor antagonists bosentan (BOS) and macitentan (MAC) to antagonize EndoMT *in vitro*.
Methods: 20 patients with limited SSc were enrolled and underwent double skin biopsy (affected and nonaffected skin). Fibroblasts and microvascular endothelial cells (MVECs) were isolated from biopsies. Mono- or coculture of MVECs (isolated from nonaffected skin) with fibroblasts (isolated from affected skin and stimulated with ET-1 and transforming growth factor beta [TGF-β]) were performed. In cocultures, the MVEC layer was left undisturbed or was preincubated with either BOS or MAC. After 48 h of coculture, MVECs were analyzed for their capillary formation ability and for messenger RNA and protein expression of different vascular (CD31, vascular endothelial growth factor-A [VEGF-A], VEGF-A165b) and profibrotic (alpha-smooth muscle actin [α-SMA], collagen type I [Col I], TGF-β) molecules.
Results: MVECs showed a reduced capillary formation ability when cocultured with SSc fibroblasts with respect to mono cultures. CD31 and VEGF-A resulted in downregulation, while VEGF-A165b, the antiangiogenic isoform, resulted in upregulation. At the same time, mesenchymal markers α-SMA, Col I, and TGF-β resulted in overexpression in MVECs. Capillary formation ability was restored when MVECs were preincubated with BOS or MAC, also reducing the expression of mesenchymal markers and restoring CD31 expression as well as the imbalance between VEGF-A and VEGF-A165b.
Conclusions: BOS and MAC seem able to antagonize EndoMT phenomenon in MVECs *in vitro*. Blocking EndoMT is important for two reasons: first, because capillary formation ability in MVECs can be restored; second, because the endothelium-derived fibrotic development in SSc can be counteracted.

SAT0324 INCREASED FREQUENCIES OF CIRCULATING CXCL10-, CXCL8- AND CCL4-PRODUCING MONOCYTES AND SIGLEC-3-EXPRESSING MYELOID DENDRITIC CELLS IN SYSTEMIC SCLEROSIS PATIENTS

T. Carvalheiro[1,2,3], S. Horta[1,4], J.A. van Roon[2,3], M. Santiago[5], M.J. Salvador[5], T.R. Radstake[2,3], H. Trindade[1], J.A. da Silva[5,6], A. Paiva[1,7]. *[1]Blood and Transplantation Center of Coimbra, Portuguese Institute of Blood and Transplantation, Coimbra, Portugal; [2]Department of Rheumatology & Clinical Immunology; [3]Laboratory of Translational Immunology, University Medical Center Utrecht, Utrecht, Netherlands; [4]Department of Chemistry, University of Aveiro, Aveiro; [5]Department of Rheumatology, Coimbra University Hospital Center; [6]Faculty of Medicine, University of Coimbra; [7]Flow Cytometry Unit, Clinical Pathology Service, Coimbra University Hospital Center, Coimbra, Portugal*

Background: Systemic sclerosis (SSc) is an inflammatory and fibrotic disease characterized by vascular dysfunction, excessive extracellular matrix deposition and immune dysregulation. Recent observations suggest that monocytes and dendritic cells (DCs) might be involved in SSc; including cell recruitment, trafficking, activation and an enhanced pro-fibrotic phenotype. Hence these cells might be important contributors to the disease pathogenesis. However, detailed analysis of circulating monocytes and DCs in SSc in relationship to disease activity has not been performed so far.
Objectives: To investigate the *ex vivo* pro-inflammatory properties of classical and non-classical monocytes as well as myeloid dendritic cells (mDCs) in SSc patients in relationship to disease activity.
Methods: This study enrolled 43 SSc patients, 30 classified as limited cutaneous SSc (lcSSc) and 13 as diffuse cutaneous (dcSSc). The healthy control group (HC) included 20 age- and gender- matched individuals. The Spontaneous production of CXCL10, CCL4, CXCL4 and IL-6 was intracellularly evaluated in classical and non-classical monocytes and Siglec-3-expressing mDCs from peripheral blood using flow cytometry. In addition, the production of these cytokines was determined upon toll like receptor 4 (TLR4) plus Interferon-γ (IFN-γ) *in vitro* stimulation.
Results: The frequency of non-classical monocytes spontaneously producing CXCL10 was increased in both lcSSc and dcSSC subsets of SSc patients ($p<0.05$) and CCL4 was augmented in the dcSSc patient subset ($p<0.05$). The proportion of CCL4 producing- mDCs were also elevated in dcSSc patients ($p<0.01$) and the percentage of mDCS producing CXCL10 only in lcSSc patients ($p<0.05$ compared to HC, but $p<0.01$ comparing to dcSSc). Upon *in vitro* stimulation the frequency of non-classical monocytes expressing CXCL8 was

increased in both patient groups ($p<0.01$) and mDCs expressing CXCL8 only in lcSSc ($p<0.01$). SSc patients characterized by the presence or history of lung fibrosis, displayed a higher frequency of non-classical monocytes expressing CCL4 and CXCL10 in dcSSc patients as compared to those without this clinical manifestation ($p<0.01$ and $p<0.05$ respectively). Strikingly, the percentage of classical monocytes producing CXCL8 was augmented upon *in vitro* stimulation in lcSSc patients with lung fibrosis as compared to those without ($p<0.01$). No differences were found in the percentage of IL-6 producing cells.

Conclusions: These data point towards a role of activated non-classical monocytes and mDCs producing enhanced levels of proinflammatory cytokines in SSc, potentially contributing to lung fibrosis.

SAT0325 NAILFOLD CAPILLAROSCOPIC CHANGES IN PATIENTS WITH IDIOPATHIC AND SYSTEMIC SCLEROSIS-RELATED PULMONARY ARTERIAL IPERTENSION

A. Corrado[1], M. Correale[2], N. Mansueto[1], A. Mele[1], A. Carriero[1], R. Colia[1], M. Di Biase[3], F.P. Cantatore[1]. *[1]Department of Medical and Surgical Sciences - Rheumatology Clinic; [2]Department of Medical and Surgical Sciences - Cardiology Clinic; [3]Department of Medical and Surgical Sciences - Cardiology Clinic, University of Foggia, Foggia, Italy*

Background: Pulmonary arterial hypertension (PAH) represents one of the main clinical expression of the vascular changes in Systemic Sclerosis (SSc). Many clinical and experimental evidences suggest that lung microvascular changes play a role in the pathogenesis of idiopathic PAH (IPAH) also.

Objectives: The aim of this study is to investigate the presence of capillaroscopic abnormalities in patients with idiopathic PAH and to evaluate the differences in capillary naifold changes between patients with IPAH and SSc patients with and without PAH.

Methods: 37 subjects with SSc (of whom 17 with PAH), 21 subjects with IPAH and 20 healthy subjects were recruited. PAH was diagnosed by right heart chateterization. Periungual capillaroscopy was performed in all recruited subjects, considering the following parameters: loops length and width, capillary density, microhemorrhages, avascular areas, neoangiogenesis. To define the pattern of capillary changes in IPAH and healthy subjects a semiquantitative scoring (normal, minor abnormalities, major abnormalities) was used, whereas in SSc subjects the capillary changes were defined as early, active and late pattern.

Results: In all SSc subjects a capillaroscopic scleroderma pattern was found. Particularly, comparing SSc-PAH vs SSc-nonPAH we found an early pattern in 26,7% vs 50%, an active pattern in 66,6% vs 33,3% and a late pattern in a 6,6 vs 16,7% of subjects. None of IPAH subject presented a capillaroscopic scleroderma pattern, but interestingly in 36,4% of minor or major capillaroscopic changes were found. Analysing the single capillarocopic parameters, capillary density was lower in SSc subjects compared to the other groups; in SSc-PAH was lower than in SSc-nonPAH; in IPAH capillary density was lower compared to healthy control. Capillary width was higher in SSc patients compared to healthy and IPAH subjects, being higher in SSc-PAH compared to SSc-nonPAH. The number of megacapillaries, bushy capillaries and microhemorrages was significantly higher in patients with SSc-PAH compared to SSc-nonPAH patients. Interestingly, compared to healthy controls, the IPAH subjects presented a significantly lower capillary density and a significantly higher mean capillary width. Further, IPAH subjects presented a significant increase of number of microhemorrages and ectasic capillaries compared to healthy controls.

Conclusions: Microcirculation alterations, and particularly the reduction of capillary density and the increase od capillary width appears to be more severe in SSc subjects with PAH compared to SSc subjects without PAH. Capillaroscopic changes can be present in IPAH subjects also. These data support the hypothesis that in SSc peripheral microcirculation changes can be related to the entity of pulmonary microcirculation changes and that an altered vascular lung remodelling could play a role in IPAH also.

SAT0326 THE ASSCOCIATION OF SERUM TYPE 1 INTERFERON ACTIVITY AND AUTOANTIBODIES IN INFLAMMATORY MYOSITIS

A. Maruyama, N. Ono, M. Sakai, Y. Sadanaga, S. Koarada, Y. Tada. *Rheumatology, Saga universitiy, Saga, Japan*

Background: Recent reports had shown that most of clinically amyopathic dermatomyositis (CADM), which showed poor prognosis, was positive for anti-Melanoma differentiation-associated gene 5 (MDA5) antibody (Ab). It had been shown that patients not only with lupus but with dermatomyositis (DM) also showed increased type 1 interferon (IFN) signature. MDA5 acts as a cytosolic RNA sensor, which drives type 1 IFN production. These facts suggested that type 1 IFN might have some roles in anti-MDA5 Ab positive patients.

Objectives: We evaluated the association of serum type 1 IFN signature and autoantibodies in patients with inflammatory myositis, in particular anti-MDA5 Ab positive patients and anti-aminoacyl-tRNA synthetases (ARS) Ab positive patients.

Methods: Sera from 33 inflammatory myositis patients (13 DM, 10 PM and 10 CADM) were studied for type 1 IFN activity, using a functional reporter cell assay. Briefly WISH cells were incubated with serum containing media for 6 hours. Serum IFN signature scores of the incubated cells were evaluated by the sums of gene expressions of Mx1, IFIT3, IFI44L and IFI44 by real time PCR (Reference). Anti-MDA5 Ab and Anti-ARS Ab were measured by ELISA. We divided these patients into three groups, anti-MDA5 Ab positive group (MDA5 group), anti-ARS Ab positive group (ARS group) and double negative group (DN group). We included double positive patients into MDA5 group. The presence of interstitial lung disease (ILD) and the prognosis were also investigated.

Results: MDA5 group had 12 patients (8 CADM and 4 DM), ARS group had 8 patients (4 DM, 1 CADM and 3 PM), and DN group had 13 patients (5 DM, 1 CADM and 7 PM). 9 of MDA5 group, 5 of ARS group, and 1 of DN group were complicated with ILD. Serum IFN signature scores of MDA5 group were significant higher than those of ARS group and DN group (12.43 1.406, 2.407, p=0.0005). The most of ARS group showed low serum IFN signature activities. The overall survivals of ARS group were fairer than MDA5 group, but not significantly. The deceased cases of MDA5 group showed especially high serum IFN signature activities.

Conclusions: We characterized two major groups in inflammatory myositis patients. ARS group was characterized by low IFN signature with the susceptibility to DM and ILD. MDA5 group was characterized by high serum IFN signature with the high susceptibility to CADM. Our results suggest that these two entities may have different onset mechanisms, leading to different outcomes.

SAT0327 NUTRITIONAL STATUS IN PATIENTS WITH SYSTEMIC SCLEROSIS

A. Wojteczek[1], M. Ziętkiewicz[1], S. Małgorzewicz[2], Z. Zdrojewski[1]. *[1]Department of Internal Medicine, Connective Tissue Diseases and Geriatrics; [2]Department of Clinical Nutrition, Medical University of Gdańsk, Gdańsk, Poland*

Background: Systemic sclerosis (SSc) is a chronic connective tissue disease characterized by involvement of multiple organs. Many clinical aspects, such as gastrointestinal involvement, mood disturbances, functional status, and inflammation, may lead to disease-related malnutrition [1]. The connection between inadequate nutritional status and systemic sclerosis is still not well established. It is important to identify the symptoms of malnutrition, because it is known as a predictor of poor clinical outcome [2].

Objectives: To assess nutritional status in patients with systemic sclerosis.

Methods: The study involved fifty-two patients with SSc (44 women and 8 men, mean age 54,3±11,7 year) who were diagnosed according to ACR/EULAR criteria. The assessment of nutritional status was determined by subjective global assessment (SGA), body mass index (BMI) and level of serum albumin. Appetite was assessed by simplified nutritional appetite questionnaire (SNAQ). In all patients hand grip strength and triceps skinfold were established. The C-reactive protein (CRP), lipid profile, and level of haemoglobin/lymphocytes were measured in serum.

Results: Inadequate nutritional status was diagnosed in 14 patients (26,9%) with SSc. According to SGA 11 (21,15%) patients had signs of mild malnutrition, while 41 (78,85%) were well-nourished. Considering BMI, 1 patient (1,92%) was underweight, 24 (46,15%) were eutrophic, 21 (40,38%) overweight and 6 (11,54%) obese. Significantly lower BMI had patients with inadequate nutritional status (23,17±4,47 vs. 25,98±3,34; p=0,009). Low level of serum albumin was detected in 5 patients (9,6%) with SSc. Level of serum albumin and appetite were significantly decreased in patients with inadequate nutritional status (p=0,009; p=0,003). No statistical differences were noticed in hand grip strength, triceps skinfold, lipid profile, levels of CRP and haemoglobin/lymphocytes.

Conclusions: Malnutrition in systemic sclerosis is still underestimated clinical issue. This study provides useful data about nutritional status of patients with

systemic sclerosis. Altered level of albumin and decreased appetite may lead to worsening in nutritional status. Assessment of nutritional status in this group of patients should be performed regularly, because it can be potentially modified.

SAT0328 AN OPEN-LABEL STUDY OF AMBRISENTAN WITH ANTI-FIBROTIC AGENT COMBINATION THERAPY IN THE TREATMENT OF DIFFUSE SYSTEMIC SCLEROSIS

A. Schorpion[1], M. Shenin[2], R. Neubauer[1], C.T. Derk[1]. *[1]Division of Rheumatology, Hospital of the University of Pennsylvania; [2]Division of Rheumatology, Thomas Jefferson University Hospital, Philadelphia, United States*

Background: Systemic sclerosis (SSc) is marked by immune dysregulation, inappropriate fibrosis and a vasculopathy for which there is currently no universally accepted disease modifying regimen. Ambrisentan, a selective type A endothelin receptor antagonist (ERA) has known benefits in the treatment of the vasculopathy related to pulmonary arterial hypertension and has been postulated to have anti-fibrotic effects. The additive effect of an ERA in combination with an anti-fibrotic agent has not previously been studied in SSc.
Objectives: To determine the safety and efficacy of ambrisentan in combination with an anti-fibrotic agent in early diffuse cutaneous systemic sclerosis (dcSSc).
Methods: Patients already on anti-fibrotic therapy for early dcSSc with onset of skin sclerosis less than 48 months before study entry were placed on ambrisentan 5mg daily for 12 months in an open-label study. Laboratory and clinical parameters to assess safety, as well as severity and progression of SSc were obtained at specified intervals. The primary outcome measure was the modified Rodnan skin score (mRSS), and secondary outcomes were the Medsger severity score, the Short Form Health Survey (SF)-36 questionnaire, pulmonary function tests (PFTs), and 2D echocardiograms (echo).
Results: A total of 15 patients were recruited who were on anti-fibrotic therapy upon entry of the study, most commonly mycophenolate (14 patients) and 1 patient on methotrexate. Of the patients entering the study, 10 patients (66.7%) completed 12 months of treatment with the study drug. Using intention-to-treat analysis, the mRSS improved significantly with a mean difference in mRSS of -8 from study entry to study end (p=0.000167). Among study completers (n=10), there was a trend for improvement in all but one category of the SF-36 while only the physical health component was of statistical significance (p=0.025). The median Medsger severity scores remained unchanged except for a change in median skin score. No statistically significant change was observed in PFTs and in mean estimated pulmonary arterial pressure by echo for those patients in whom data was obtained at baseline and at 12 months (n=12 and n=5, respectively). The most common adverse events included peripheral edema and dizziness. Two patients withdrew from the study due to intolerance of the study drug. Serious adverse events (SAE's) occurred in 4 study subjects and included scleroderma renal crisis (n=1), upper gastrointestinal bleeding (n=1) and infections (n=2). None of the SAEs were deemed to be related to the study drug.
Conclusions: In this prospective open-label study of ambrisentan and anti-fibrotic combination therapy in early dcSSc, we observed significant improvements in the mRSS and patient-perceived physical health status on the SF-36. There was no observed change in peripheral vascular involvement and no consistent trend in PFTs. Combination ambrisentan and anti-fibrotic therapy appears relatively safe in this 12-month study. Larger, controlled trials are needed to further investigate the safety and efficacy of combination therapy.

SAT0329 INTRAVENOUS CYCLOPHOSPHAMIDE ACCORDING TO THE EURO-LUPUS NEPHRITIS PROTOCOL FOR PROGRESSIVE INTERSTITIAL LUNG DISEASE IN PATIENTS WITH POLYMYOSITIS/DERMATOMYOSITIS

A. Notarnicola[1], M. Dastmalchi[1], S. Nyren[2], K. Gunnarsson[1], L. Dani[1], I.E. Lundberg[1]. *[1]Department of Medicine, Rheumatology Unit, Karolinska University Hospital and Karolinska Institutet; [2]Department of Molecular Medicine and Surgery (MMK), K1, Diagnostic Radiology, Karolinska University Hospital and Karolinska Institutet, Solna, Stockholm, Sweden*

Background: Interstitial lung disease (ILD) affects 30–70% of patients with Polymyositis (PM) and Dermatomyositis (DM) and is one of the major contributors of morbidity and mortality.
Objectives: To study the efficacy and the safety of intravenous cyclophosphamide (IVCYC) according to the Euro-Lupus nephritis protocol for ILD in PM/DM patients.
Methods: Twelve patients with PM/DM (mean age 54± SD 8), who received, 500 mg IVCYC every other week, up to 12 times, according to the treating physician, as first line treatment, were retrospectively studied. Six patients had anti-Jo1, 4 anti-PL7, 1 anti-PL12, and 1 anti-MDA5 auto-antibodies. The median (IQR) disease duration before IVCYC was 4 (10,8) months. High doses of prednisolone were given for the first month and then gradually tapered. Response to treatment after a median (IQR) follow-up of 5 (2,8) months was based on pulmonary function tests (PFT) and HRCT). The extent of pure ground-glass opacity (pGGO), pulmonary fibrosis (PF), honeycomb cysts (HCs) and emphysema was scored (0=0%, 1=1–5%, 2=6–15%, 3=16–20%, 4=21–25%, 5=26–50%, 6=51–75%, 7= >75%) in the upper, middle and lower lung zones before and after therapy. The total score for each finding was calculated as the sum of the scores of the 3 zones (1).
Results: The mean IVCYC total amount was 4.75 ± SD 1.4 gr. Before IVCYC, the median (IQR) values of forced vital capacity (FVC)%, forced expiratory volume in 1 second (FEV1)%, vital capacity (VC)%, total lung capacity (TLC)% and diffusion capacity of the lung for carbon monoxide (DLCO)% were 67 (26), 60 (14), 63 (11), 63 (12) and 57 (25), respectively. After therapy, the median (IQR) values became 74 (29), 80 (18), 80 (24), 77 (19) and 68 (27), respectively. The difference between baseline and follow-up TLC%, FVC% (fig.1) and VC% median values was statistically significant ($p<0,05$). FVC% and TLC% improved >10% in 6 and 5 patients, respectively; DLCO% improved >15% in 3 patients. Before IVCYC, the median (IQR) scores of pGGO and PF were 12,5 (9) and 12 (7), respectively. After IVCYC, they decreased (7 (6) and 9 (12), respectively). In the group of anti-Jo-1 positive patients, the difference was close to the statistically significant (from 13,5 (10) to 7,5 (15), p=0,06 and from 9,5 (10) to 4,5 (16), p=0,07, respectively). The median (IQR) pGCO scores of anti-Jo-1 negative patients improved (from 11,5 (11) to 8,50 (17)), while the median (IQR) PF scores were unchanged (from 13,5 (4) to 14 (10)). At baseline and follow up, the median scores of HCs and emphysema were 0. No statistically significant correlations were found between PFT values and HRCT scores. The difference of PF extent was negatively correlated with the disease duration before the first IVCYC (r=-0,56, p=0,056, fig 1). No adverse events or drug toxicity were observed.
Conclusions: After IVCYC according to the Euro-Lupus nephritis protocol PFT and HRCT findings improved in PM/DM patients with ILD without any adverse events or drug toxicity. Longitudinal controlled studies are needed to confirm the efficacy and the safety of this treatment protocol.

SAT0330 LOWER PREVALENCE BUT COMPARABLE CLINICAL CHARACTERISTICS AND PROGNOSIS OF SYSTEMIC SCLEROSIS IN CRETE-GREECE AS COMPARED TO OTHER EUROPEAN COUNTRIES: A SINGLE CENTER EXPERIENCE

A. Repa, I. Gergianaki, G. Spyrou, N. Kougkas, A. Kountouri, N. Avgoustidis, G. Bertsias, P. Sidiropoulos. *Rheumatology, University of Crete, Heraklion Crete, Greece*

Background: Systemic Sclerosis (SSc) is a rare, multisystemic connective tissue disease with significant morbidity. Prevalence and incidence of SSc varies worldwide (0.7–265 cases per 100,000/y[1,2] and 0.06–12.2 cases per 100,000/y[1] respectively). Mortality in SSc patients remains 3.5 times higher than the general population[3]. We sought to generate updated data on the epidemiology and burden of SSc in the Greek population.
Objectives: To study the prevalence and incidence of SSc, describe the clinical characteristics and assess mortality and main causes of death in Crete (Greece) over a 5-year period (2010–2015).
Methods: We conducted a cohort Study in defined geographic area (6,5% of Greek population). We reviewed demographics, clinical features, autoantibodies status and the causes of death from the Scleroderma cohort followed at the Rheumatology clinic of the University Hospital, Heraklion. The cause of death was categorized as related or not to scleroderma. Incidence and prevalence were estimated including patients living permanently in Crete who fulfilled SSc 2013 ACR/EULAR Classification Criteria for Scleroderma.
Results: 72 patients (88% women, mean±SD age at diagnosis 48.5±16.7 years [range 15–87]) were identified, corresponding to a crude point prevalence of $13.8/10^5$ (CI 95% 11–17/10^5) (December 2015). The Incidence rate was estimated at $0.05/10^5$ per year (period 2010–2015). Diffuse SSc (dSSc) was present in 27.7%, limited SSc (lSSc) in 72.2%, while an overlap syndrome in 19.4% (9.7% with systemic lupus erythematosus). Frequencies of anti-Scl70 and anti-cectromere antibodies were 59.7% and 9.7%, respectively. Arthritis was present in 69.5%, lung involvement in 61% (9.7% pulmonary arterial hypertension [PAH]), whereas only a single patient developed renal crisis. 8.3% developed cancer. Case fatality rate during 2010–2015 was 9.7% (CI 95% 7.4–11.9) with an average (±SD) age of death at 65.2 (± 17.6) years. Mortality cases were related to SSc in 30.7%. The main cause of death was sepsis (30.8%) followed by PAH and cardiac arrest (15.4% each). Male gender ($p<0.001$) and presence of PAH (p=0.001) were related to mortality. Mean disease duration until death was 5.3

(±3.2) years in cases of SSc-related death, as compared to 18.3 (±11.0) years in deaths not related to SSc.
Conclusions: SSc prevalence (13,8/10^5) in Crete is consistent with previous (2002) Greek studies (15,4/10^5)[4] albeit lower compared to other European countries and USA[5]. Despite its rarity, the disease has significant burden. The SSc-related mortality occurs early in the disease course. Early recognition and treatment may decrease disease burden and improve the outcomes.

SAT0331 AMINAPHTONE INCREASES SKIN BLOOD PERFUSION AND IMPROVES CLINICAL SYMPTOMS IN PATIENTS WITH BOTH PRIMARY AND SECONDARY RAYNAUD'S PHENOMENON: AN OPEN SIX MONTH PILOT STUDY

B. Ruaro, S. Paolino, C. Pizzorni, E. Alessandri, E. Gotelli, M. Cutolo, A. Sulli.
Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS AOU San Martino, Genoa, Italy

Background: Aminaphtone (1,4-Dihydroxy-3-methyl-2-naphthyl-4-aminobenzoate) is a vasoactive drug that was recently demonstrated to improve the symptoms of Raynaud's phenomenon (RP) and to down-regulate endothelin-1 production by endothelial cells (1–3).
Objectives: To evaluate skin blood perfusion and clinical symptom changes during aminaphtone treatment in patients with both primary and secondary RP, during a six-month follow-up.
Methods: Forty-six patients with active RP were enrolled during routine clinical assessment in November 2015 (11 primary RP, mean age 49±19SD years, mean RP duration 6±3 years; 35 secondary RP to systemic sclerosis, mean age 61±17 years, mean RP duration 11±9 years), after informed consent. Aminaphtone was administered 75 mg twice daily (off label) in addition to current treatments (the patients were on a stable drug regimen for at least two months before, which remained unmodified during the follow-up). Blood perfusion was measured by Laser Speckle Contrast Analysis (LASCA) and values recorded as perfusion units (PU) (4), at the level of fingertips, periungual areas, dorsum and palm of hands, and face, at baseline (T0), after one (T1), four (T4), twelve (T12) and twenty-four (T24) weeks of treatment. Raynaud's condition score (RCS) and both frequency and duration of Raynaud's attacks were assessed at the same time. Forty-six patients with RP (9 primary RP and 37 secondary RP to systemic sclerosis) not treated with aminaphtone were also enrolled as a control group and evaluated at T0 and T24.
Results: A progressive statistically significant increase of blood perfusion was observed from T0 to T12 in all skin areas analyzed (median PU at T0, T1, T4, T12, T24 respectively: fingertips 55, 88, 101, 107, 98 periungual areas 44, 88, 91, 92, 92; dorsum of hands 38, 61, 71, 75, 75; palm of hands 56, 85, 89, 94, 82; whole face 127, 138, 144, 159, 129; $p<0.001$ for all areas). From T12 to T24 was not observed any further increase of blood perfusion. A progressive statistically significant decrease of RCS (median at T0, T1, T4, T12, T24: 7, 6, 4, 4, 4; $p<0.0001$), frequency of Raynaud attacks/day (median: 2, 2, 1, 1, 1; $p<0.0001$) and Raynaud duration (median: 20, 20, 10, 4, 4 minutes; $p<0.0001$) was also recorded from T0 to T12. The results were similar in both primary and secondary RP patients (p=0.40). Aminaphtone administration had to be stopped in 2 patients due to headache, and one patient was lost during follow-up. Any statistically significant variation of blood perfusion was not observed in the control group (median PU at T0 and T24 respectively: fingertips 70, 71; periungual areas 68, 70; dorsum of hands 57, 57; palm of hands 59, 59; whole face 132, 130; p=n.s. for all areas).
Conclusions: This study demonstrates that aminaphtone treatment seems able to increase skin blood perfusion and to improve RP symptoms, even in patients affected by systemic sclerosis. These preliminary results should be further confirmed by a randomized clinical trial, also to assess the role that aminaphtone plays in the treatment/prevention of disease clinical complications.

SAT0332 HEPATOBILIARY INVOLVEMENT IN SYSTEMIC SCLEROSIS AND THE CUTANEOUS SUBSETS. CHARACTERISTICS AND SURVIVAL OF PATIENTS FROM THE SPANISH RESCLE REGISTRY

B. Marí Alfonso[1], C. Tolosa-Vilella[2], L. Morera-Morales[2], A. Marín-Ballvé[3], J. Chamorro Fernández[4], X. Pla Salas[5], B. Madroñero-Vuelta:[6], C. Simeón Aznar[7] on behalf of RESCLE Investigators of the Autoimmune Diseases Study Group (GEAS). *[1]Internal Medicine, Corporació Sanitària Parc Tauli; [2]Internal Medicine, Corporació Sanitària Parc Tauli. Sabadell. Barcelona, Sabadell; [3]Internal Medicine, Hospital Clínico Universitario Lozano Blesa, Zaragoza; [4]Internal Medicine, Complejo Asistencial Universitario de Salamanca, Salamanca; [5]Internal Medicine, Consorci Hospitalari de Vic, Barcelona; [6]Internal Medicine, Hospital General San Jorge, Huesca; [7]Internal Medicine, Hospital Universitario Vall d'Hebron, Barcelona, Spain*

Background: Hepatobiliary involvement (HBI) has been associated to systemic sclerosis (SSc). However, it is not considered as characteristic clinical manifestation of that autoimmune disease
Objectives: To assess the prevalence and causes of HBI in SSc and to investigate the clinical characteristics and prognosis of SSc patients with HBI (SSc-HBI) and without HBI (SSc-non HBI).
Methods: Up to January 2015, 1572 SSc patients were collected in the Registro de ESCLErodermia (RESCLE) and causes of hepatobiliary disturbances were recorded. We investigated the HBI related characteristics and survival from the entire cohort and according to the following cutaneous subsets: dcSSc, lcSSc, and SSc sine scleroderma (ssSSc).
Results: Out of 1572, 118 (7.5%) patients had HBI, and primary biliary cholangitis (PBC) was largely the main cause (n=67, 4.3%), followed by autoimmune hepatitis (n=19, 1.2%), and anti-mitochondrial negative PBC (n=6, 0.4%). Other causes of HBI were: secondary liver diseases (n=11, 0.7%), SSc-related HBI (n=7, 0.4%), nodular regenerative hyperplasia (n=3, 0.2%), liver cirrhosis (n=3, 0.2%), and unknown origin (n=2, 0.1%). In multivariate analysis, HBI was independently associated to lesser risk of dcSSc (5.1% vs 24.4%, OR: 0.18, p=0.005%), and higher frequency of calcinosis (26% vs 18%, OR: 1.80; p=0.028), left ventricular diastolic dysfunction (46% vs 27%, OR: 1.73; p=0.027), sicca syndrome (51% vs 29%, OR: 2.03; p=0.003), and anti-centromere antibodies (ACA, 73% vs 44%, OR: 1.86; p=0.023). According to the cutaneous subsets, HBI was associated: (1) in lcSSc subset, to longer time from SSc onset to diagnosis (10.8±12.5 vs 7.2±9.3, OR: 1.03; p=0.012), sicca syndrome (54% vs 33%, OR: 1.96; $p<0.001$), and ACA (80% vs 56%, OR: 2.64; $p<0.001$); and (2) in ssSSc subset, to sicca syndrome (44% vs 19%, OR: 3.43; p=0.018). No associations were found in dcSSc subset. HBI was the cause of death in 2.3% patients. Kaplan–Meier cumulative survival for the SSc cohort and the cutaneous subsets, according to the presence or absence of HBI showed no differences.
Conclusions: The prevalence of HBI in SSc was 7.5%. Primary autoimmune liver diseases accounted for 77% of all conditions. PBC was the main cause of HBI reaching 4.6% of the overall SSc cohort. Patients with HBI were rarely classified as dcSSc subset and the elapsed time from the first SSc symptom to SSc diagnosis was longer. Calcinosis cutis, diastolic dysfunction, sicca syndrome, and the presence of ACA were all independently associated to HBI. In lcSSc subset, HBI was associated to sicca syndrome and ACA but in ssSSc only sicca syndrome was more prevalent. HBI was the cause of death in 2.3%

SAT0333 PREVALENCE OF SARCOPENIA IN PATIENTS WITH SYSTEMIC SCLEROSIS ACCORDING TO THE REVISED CRITERIA OF THE EUROPEAN WORKING GROUP ON SARCOPENIA IN OLDER PEOPLE

C. March[1], E. Siegert[1], E. Preis[1], A. Makowka[1], F. Buttgereit[1], G. Riemekasten[2], K. Norman[3]. *[1]Department of Rheumatology and Clinical Immunology, Charité-Universitätsmedizin Berlin, Berlin; [2]Department of Rheumatology, University of Luebeck, Luebeck; [3]Research Group on Geriatrics, Charité-Universitätsmedizin Berlin, Berlin, Germany*

Background: Systemic Sclerosis (SSc) is a chronic inflammatory connective tissue disease that is often associated with gastrointestinal involvement and myopathy. Sarcopenia is defined as age-associated loss of muscle mass, strength and function with profound impact on functionality as well as on mortality (1). "Secondary sarcopenia" has now been described in the context of severe and chronic disease such as malignant disease or inflammatory disorders (2) and been linked to poor clinical outcome.
Objectives: Analysis of the prevalence of sarcopenia in patients with SSc with respect to clinical characteristics, quality of life and severity of physical impairment.
Methods: 129 patients were included. Sarcopenia was defined according to the

criteria of the European Working Group on Sarcopenia in Older People (3) using appendicular lean mass assessed by bioelectric impedance analysis and grip strength - stratifying both by body mass index. We also used the 2016 formula by Scafoglieri et.al to calculate appendicular lean mass (4). This approach is different from previous studies because we combined the new formula with established cut-off values, which incorporate a functional parameter. Muscle function was assessed by hand grip, knee extension strength and peak expiratory flow. Impairment and quality of life were evaluated using the Scleroderma Health Assessment Questionnaire (SHAQ) and Short-Form 36 Health Survey (SF-36®). Clinical data were assessed according to standardised procedures.

Results: The prevalence of sarcopenia in our study group was 27.1%.There were no significant differences between patients with and without sarcopenia regarding age (p=0.838) and disease duration (p=0.832). There were significant differences regarding grip strength (p<0.001), knee extension strength (p=0.003), peak flow (p=0.042), SF-36® Physical Function (p=0.009) and the number of immunosuppressive (p=0.048) and other drugs taken (p=0.037). See Table 1.

Table 1 Comparing analysis between two patient groups (Sarcopenia/ No Sarcopenia)

Variable	Sarcopenia, n = 35	No Sarcopenia, n = 94	p
Women	32 (91.4)	85 (90.4)	0.862
Age (years)	59.5 ± 14.8	59.0 ± 13.5	0.838
Disease duration (years)	8.6 ± 6.0	8.9 ± 6.9	0.832
Body Mass Index (kg/m²)	20.6 ± 2.7	25.5 ± 5.2	< 0.001
Hand grip strength (kgF)	10.3 ± 6.1	18.7 ± 8.0	< 0.001
Knee extension strength (kgF)	13.6 ± 7.2	22.3 ± 16.3	0.003
Peak flow (l/min)	305.8 ± 102.0	348.3 ± 101.9	0.042
SF-36® Physical Health SUM	40.5 ± 18.1	48.5 ± 19.6	0.043
SF-36® Physical Function	41.7 ± 27.1	54.3 ± 27.4	0.026
SHAQ score	0.66 ± 0.12	0.64 ± 0.07	0.010
IPAQ (level of activity – high)	5 (14.3)	28 (29.8)	0.073
Number of medication	6.2 ± 3.8	4.8 ± 3.2	0.037
Number of immunosuppressive medication	1.4 ± 1.1	1.0 ± 1.0	0.048

Data are given in mean ± SD or n (%)
SSc – Systemic Sclerosis; SF-36® - Short Form 36; SHAQ – Scleroderma Health Assessment Questionnaire; IPAQ – International Physical Activity Questionnaire; CRP – C-reactive protein

Conclusions: There is a high prevalence of sarcopenia in patients with SSc even among younger patients. Sarcopenic patients have a significant increase in physical impairment and a decreased quality of life regarding their physical health. Taking a higher number of immunosuppressive or other drugs was identified as a risk factor for sarcopenia. This could be due to severe organ involvement being a confounder or an indication for the immunological component in the pathophysiology of secondary sarcopenia. This suggests that sarcopenia might be linked to severe disease or multimorbiditiy in SSc patients.

SAT0334 CORRELATING MULIPLEX PLASMA CYTOKINE ANALYSIS WITH RIGHT HEART CATHETERISATION FINDINGS IN SCLERODERMA ASSOCIATED PULMONARY ARTERIAL HYPERTENSION

C.H. Ho[1], S. Nihtyanova[2], B. Ahmed Abdi[2], G. Coghlan[3], C. Denton[2], B. Schreiber[4], V.H. Ong[2]. *[1]Department of Medicine, Queen Elizabeth Hospital, Kowloon, Hong Kong; [2]Centre for Rheumatology and Connective Tissue Diseases, University College London Medical School, Royal Free Hospital; [3]Department of Cardiology; [4]Department of Rheumatology, Royal Free Hospital, London, United Kingdom*

Background: Right heart catheterisation (RHC) is an important test for the diagnosis and subclassification of pulmonary hypertension (PH), one of the serious manifestations of systemic sclerosis (SSc). It provides haemodynamic information for diagnosis and management. Routine RHC in SSc cases with suspected PH permits blood sampling to explore plasma levels of key cytokines that may be markers of mediators of pulmonary arterial hypertension (PAH) pathogenesis.

Objectives: This is an exploratory study to assess for associations between plasma cytokine levels and haemodynamic assessment from RHC in SSc patients.

Methods: SSc patients undergoing routine RHC were recruited. Indications for referral included suspected PH, or those on treatment for established PH for assessment of response to therapy. Blood samples were collected during RHC in consented patients. Demographic and clinical data were obtained. Haemodynamic data from RHC including mean right atrial pressure (mRAP), mean pulmonary arterial pressure (mPAP), pulmonary capillary wedge pressure (PCWP), pulmonary vascular resistance (PVR), cardiac output (CO) and cardiac index (CI) were recorded. Plasma samples were analysed using a bead-based multiplex platform for IL1b, IL4, IL6, IL10, IL17A, IL17F, IL21, IL22, IL23, IL25, IL31, IL33, IFNg, sCD40L and TNFa (Bio-Rad Pro Assays). Plasma from a small group of healthy controls were also analysed for comparison. For analytes found to be below the lower limit of detection of the assays, they were assumed to be equal to the lower limit of the detection as per the assay's protocol.

Results: 32 SSc patients were recruited. Their mean age was 59.4-year-old, and 31 of them (97%) were female. Most (n=29, 91%) had limited cutaneous SSc. The commonest antibody was anti-centromere antibody (n=16, 55%), followed by anti-U3RNP antibody (n=4, 14%). None of these patients had significant pulmonary fibrosis (≥20% involvement on HRCT thorax scan). PAH, defined as mPAP ≥25mmHg & PCWP ≤15mmHg, was diagnosed at RHC in 26 patients (81%).

Among the proteins tested, only the level of sCD40L was significantly different among the three groups, namely SSc with PH, SSc without PH and healthy controls (p=0.008). sCD40L was also the only biomarker which was significant higher among patients with SSc (with and without PH) than healthy controls (p=0.0284).

Interestingly, there was a weak negative correlation between sCD40L and mPAP (correlation coefficient=-0.35, p=0.0486). There was a moderately strong positive correlation between mRAP and IL4 (correlation coefficient=0.57, p=0.0006) and IL10 (correlation coefficient=0.51, p=0.0028). We found no evidence for association between any of the biomarkers and cardiac output, cardiac index, PCWP or PVR.

Conclusions: Our data suggest that some individual plasma proteins may correlate with specific RHC haemodynamic parameters. Future studies will extend these findings and explore whether combining multiple analytes may give stronger non-invasive prediction of relevant haemodynamic variables and could be used in detection or monitoring of PAH in SSc.

SAT0335 SERUM KYNURENINE/TRYPTOPHAN (KYN/TRP) RATIO AND NEOPTERIN (NEO) LEVELS ARE RAISED IN SYSTEMIC SCLEROSIS (SSC) AND ASSOCIATE WITH SPECIFIC CLINICAL AND AETIO-PATHOGENETIC FEATURES

C. Campochiaro[1], S.D. Lytton[2], B. Ahmed Abdi[1], V.H. Ong[1], C.P. Denton[1]. *[1]Centre for Rheumatology and Connective Tissue Diseases, Royal Free Hospital and UCL Division of Medicine, London, United Kingdom; [2]SeraDiaLogistics Benediktenwandstr 7, 81545, München, Germany*

Background: The enzymes IDO degrades Trp into Kyn and is induced by IFN-gamma/IL-1. Neo is produced by monocytes/macrophages after IFN-gamma stimulation through the enzyme GTPCH and is a biomarker for monitoring immune activation in several diseases [1]. The activity of GTPCH is induced in parallel to IDO and the Kyn/Trp ratio has been suggested to be a direct measure of IDO activity [2].

Objectives: To assess serum level of Kyn, Trp, Neo and Kyn/Trp ratio in SSc and potential associations with specific disease features.

Methods: 60 SSc pts and 10 healthy controls (HC) were recruited and serum levels of Kyn, Trp and Neo were measured. Kyn/Trp ratio was calculated. The results were then correlated with specific disease features: disease duration, limited or diffuse disease, autoantibody profile (anti-RNA pol III (ARA), anti-topoisomerase (ATA) and anti-centromere (ACA)), inflammatory markers, Hb level, concurrent modified Rodnan skin score (mRSS), peak mRSS, pulmonary fibrosis (PF), pulmonary arterial hypertension (PAH), history of scleroderma renal crisis (SRC), GI involvement, vasculopathy, environmental exposure, oncology history, smoking status, immunosuppressive treatment, NT-proBNP and urate levels. Non-parametric statistical tests were used.

Results: Kyn/Trp ratio was higher in SSc compared to HC (mean 49.97±32.77 [41.50 – 58.43] vs 22.5±6.3 [13.5 – 32.5] μmol/mmol, p<0.05) and, more specifically, dcSSc showed higher ratio compared to lcSSc that had higher ratio than HC (mean 56.58±39.62 [43.18 – 69.99] vs 40.05±13.93 [34.16 – 45.93] vs 22.5±6.3 [17.99 – 27.01] μmol/mmol respectively, p<0.05). Moreover,

ARA+SSc had a significantly higher ratio compared to ATA+ and ACA+pts (mean 61.24±41.40 [45.78 – 76.70] vs 39.62±17.99 [29.66 – 49.58] and 37.77±10.20 [32.12 – 43.42] μmol/mmol respectively, $p<0.05$). Kyn/Trp ratio was significantly correlated with SRC ($p<0.05$). We found a direct correlation with mRSS (r=0.269, $p<0.05$), peak mRSS (r=0.276), urate level (r=0.376), CRP (r=0.285) and ESR (r=0.320). Conversely, Neo levels, although significantly higher in SSc compared to HC (mean 12.63±9.30 [10.21 – 15.06] vs 7.11±3.31 [4.74 – 9.48] nmol/L, $p<0.05$), were not significantly different in diffuse compared to limited SSc, but were higher in ARA+ compared to ACA+ and ATA+ patients (mean 14.93±11.52 [10.54 – 19.31] vs 10.81±4.95 [8.07 – 13.56] vs 10.02±6.83 [6.24 – 13.80] respectively, $p<0.05$). Neo levels significantly correlated with PAH. A direct correlation (p=0.05) was found with CRP (r=0.471) and ESR (r=0.430).

Conclusions: These data suggest that Kyn/Trp ratio and Neo levels may reflect aetio-pathogenetic mechanisms in SSc and be elevated in the subgroup of dcSSc that are ARA+, or those manifesting SSc complications associated with ARA+. A specific IFN-gamma signature could be thought to be responsible for the higher levels found in patients although larger studies are required.

SAT0336 MALNUTRITION AND SARCOPENIA IN A LARGE COHORT OF PATIENTS WITH SYSTEMIC SCLEROSIS

C. Caimmi[1], P. Caramaschi[1], A. Venturini[1], E. Bertoldo[1], M. Ferrari[2], M. Rossini[1]. *[1]Rheumatology Unit; [2]Internal Medicine, University of Verona, Verona, Italy*

Background: Systemic sclerosis (SSc) is an autoimmune disease that may affect gastrointestinal tract, leading to malabsorption and malnutrition. Previous studies defined this complication with no widely accepted criteria. No thorough evaluations of sarcopenia are available.

Methods: 141 SSc consecutive outpatients have been enrolled. A thorough history, blood samples and body composition by densitometry were collected. Malnutrition was defined accordingly to recently published and widely accepted ESPEN criteria (1); sarcopenia was diagnosed in patients with a reduced skeletal muscle index (2).

Results: The table summarizes cohort's characteristics. Malnutrition was diagnosed in 9.2% (CI95%: 4.4–14.0%). Malnourished patients were more often treated with steroids (p=0.039), had worse gastrointestinal symptoms accordingly to UCLA questionnaire (p=0.007), lower physical activity accordingly to International physical activity questionnaire (p=0.028), longer disease duration (p=0.019), worse predicted DLCO/VA and FVC (p=0.009, respectively) and worse disease severity accordingly to Medsger severity score (DSS) ($p<0.001$ for total, p=0.001 for lung and $p<0.001$ for gastrointestinal tract). In multivariate analysis only FVC (p=0.006) and disease severity (p=0.003), in particular lung involvement as defined by DSS (p=0.013), were confirmed to be worse in malnourished patients. Z-scores were significantly lower in malnourished patients at lumbar site p=0.033), even after correcting for possible confounders. Sarcopenia was diagnosed in 20.7% (CI95% 14.0–27.4%); 11/29 sarcopenic patients were also malnourished and 6/29 were cachectic (i.e. sarcopenia + systemic inflammation). Sarcopenic patients had worse DLCO/VA (p=0.003) and lung (p=0.005) involvement accordingly to DSS than non-sarcopenic ones; cachectic had even lower value (p=0.016 for both). Sarcopenic patients had also longer disease duration (p=0.033).

Table 1. Patients' characteristics

Age	63 (13)
Sex (female)§	119 (84.4)
Diffuse disease subset§	44 (31.2)
Disease duration (year)	13.3 (7.2)
Interstitial lung disease§	39 (27.7)
Pulmonary arterial hypertension§	12 (8.5)
Active disease accordingly to Valentini§	27 (19.1)
FVC predicted (%)	103 (23)
DLCO/VA predicted (%)	75 (21)
mRSS*	8 (7)
Medsger severity score*	5 (3)
Erythrocyte sedimentation rate (mm/h)	26 (16)
C-reactive protein (mg/l)*	3 (0)
Endothelin receptor antagonists§	16 (11.3)
Prostanoids (any)§	130 (92.2)
Steroids§	23 (16.3)
Immunosuppressive treatment§	35 (24.8)

*Expressed as media (IQR); §Expressed as absolute valute (%).

Conclusions: Malnutrition defined with widely accepted diagnostic criteria was found to be lower than previously reported (3–7) using screening tool or non-validated criteria. Sarcopenia was found to be somewhat common, although no previous study on comparable cohorts are available. Lung involvement and function was shown to be significantly linked with nutritional status and may not be explained only by muscle weakness given the absence of correlation between muscle weakness and FVC but only with DLCO/VA.

SAT0337 IMPACT OF ORGAN INVOLVEMENT ON PATIENT-REPORTED OUTCOMES IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

D. Huscher[1], K. Albrecht[1], J. Richter[2], J. Henes[3], T. Alexander[4], A. Zink[1,4]. *[1]Epidemiology, German Rheumatism Research Centre, Berlin; [2]Policlinic & Hiller Research Unit for Rheumatology, Medical Faculty, Heinrich-Heine-University Duesseldorf, University Clinic, Duesseldorf; [3]Department of Rheumatology and Clinical Immunology, Eberhard Karls-University of Tuebingen, Tuebingen; [4]Department of Rheumatology and Clinical Immunology, Charité University Hospital, Berlin, Germany*

Background: Idiopathic inflammatory myopathies (IIM) are associated with considerable morbidity, primarily related to severe muscle weakness and visceral involvement, resulting in disability and impaired quality of life[1]. Results from the OMERACT Myositis Special Interest Group indicate that there is insufficient knowledge on patient-reported outcomes (PROs) in IIM[2].

Objectives: To analyse the association between organ involvement and PROs in IIM patients, taking the presence of autoantibodies into account.

Methods: Data of IIM patients, recorded in the National Database of the German collaborative arthritis centres between 2007 and 2014, were analysed. Physician-reported data on myositis disease phenotypes, organ involvement and antibody status were linked with PROs on functional status (FFbH, range 0–100, 100 indicating full capability), and numerical rating scales (0–10) for pain, fatigue, general health, physical and emotional well-being and coping. Multivariable linear regression analysis was used to investigate the impact of phenotype, organ involvement and autoantibodies on PROs, adjusted for sex, age and disease duration.

Results: A total of 142 IIM patients - 60 polymyositis (PM), 46 dermatomyositis (DM), 15 antisynthetase syndrome (ASS), 12 overlap (OL), 9 others - with mean disease duration of 7.4 years were included. 85% showed muscular, 36% skin involvement, 22% arthritis, 28% interstitial lung disease, 17% dysphagia and 9% cardiomyopathy. Visceral (lung, cardiac or gastrointestinal) manifestation was present in 46% (PM), 54% (DM), 100% (ASS), and 80% (overlap). While moderate to severe (4–10) fatigue was predominately reported in overlap (64%) and ASS (70%), pain was more frequent in overlap (55%) and emotional discomfort was reported most frequently in ASS (57%). For all PROs, worse outcomes were documented in patients with visceral manifestation. Myositis-specific autoantibodies, predominantly Anti-Jo1, were present in 63% of the patients, and were associated with more frequent visceral manifestation (73% vs. 46%), especially interstitial lung disease (50% vs. 15%), and arthritis (32% vs. 13%), but less skin involvement (26% vs. 49%). DM and PM subtypes showed almost identical coefficients for fatigue, physical well-being, general health and coping, while PM was associated with higher emotional strain. Pulmonary hypertension had a severe impact on pain, functional status and daily activities. Cardiomyopathy was associated with impaired general health, arthritis with poorer scores for coping, physical and emotional well-being.

Conclusions: IIM patients with distinct subtypes differ considerably regarding the frequency of organ involvement and self-reported dimensions of disease burden. Anti-Jo1 positivity is associated with higher visceral organ involvement and arthritic manifestations and may therefore also indicate a higher patient-reported disease burden.

SAT0338 SURVIVAL IN A TURKISH INFLAMMATORY MYOSITIS COHORT: A SINGLE-CENTRE STUDY

E. Er Gülbezer, F. Yargucu Zihni, G. Karabulut, G. Keser, Y. Kabasakal. *Rheumatology, Ege University Medical Faculty Internal Medicine, Izmir, Turkey*

Background: Inflammatory myositis is an uncommon group of diseases that

can be associated with significant morbidity and mortality related to systemic involvement or treatment-related complications.
Objectives: This study aimed to describe the clinical features and survival of patients with inflammatory myositis in our centre.
Methods: We performed a single-centre, retrospective study on patients with inflammatory myositis (polymyositis [PM], dermatomyositis [DM], or Anti-Jo1 syndrome) seen from 2000 to 2014, noting their demographic data, clinical features and outcome until December 2016. The primary outcome assessed was all-cause mortality. Cumulative mortality rates were estimated using the Kaplan-Meier test; the Log Rank (Mantle-Cox) test was used to compare subgroup differences in survival.
Results: Seventy-four patients (19 PM, 28 DM, 27 Anti-Jo1 syndrome) were available for the study. Median age at diagnosis was 47 years (min 17, max 75) and median follow-up time was 93 months (min 4, max 311). Sixty-one patients (82, 4%) were female and 13 (17, 6%) were male. Malignancy was found in 4 patients (2 invasive ductal adenocancer of breast, 1 over cancer and 1 non-small cell lung cancer) and they were all female DM patients. Nineteen patients (25,7%) died at the end of the follow-up.
The 19 patients with PM consisted of 15 female and 6 male, with a median age at diagnosis of 45 years (min 22, max 74) and median follow-up time of 88 months (min 5, max 204). The 28 patients with DM consisted of 24 female and 4 male, with a median age at diagnosis of 52 years (min 17, max 75) and median follow-up time of 80 months (min 4, max 288). The 27 patients with Anti-Jo1 syndrome consisted of 22 female and 5 male, with a median age at diagnosis of 50 years (min 22, max 63) and median follow-up time of 117 months (min 5, max 311).
Overall survival rates of the whole group were 91%, 83%, and 76% for 1, 5, and 10 years, respectively. The survival rates at 1, 5 and 10 years from the diagnosis were respectively 88%, 82%, %82 for PM, %88, 80%, %80 for DM and 96%, 88%, 74,5% for Anti-Jo1 syndrome. But there was no significant difference between the survival rates of the diagnose groups (p=0,734). Also there wasn't a significant difference between the survival rates of sex and age groups (p=0,503), (p=0,112). But the survival rates were significantly lower in patients with the time from diagnose less than 8 years (p=0,000).

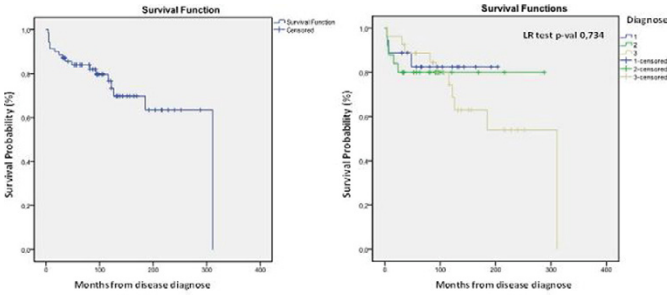

Figure 1. Survival probability of all patients with inflammatory myositis (Graph A) and according to the diagnose* (Graph B).
*1, Polymyositis; 2, Dermatomyositis; 3, Anti-Jo1 syndrome

Conclusions: Our study involved 74 patients followed up for a median of 7, 7 years and is one of the largest cohorts of patients with inflammatory myositis in Turkey. Survival was quite similar with the literature. Usually mortality has been expected in the first years after the diagnosis.

SAT0339 LUNG TRANSPLANTATION IN PATIENTS WITH INTERSTITIAL LUNG DISEASE ASSOCIATED WITH ANTISYNTHETASE AND ANTI-MDA5 SYNDROMES. EXPERIENCE FROM A REFERENCE SPANISH HOSPITAL

E. Trallero-Araguás[1], C. Berastegui[2], M. López-Corbeto[1], I. Bello[3], A. Román[2], A. Selva-O'Callaghan[4]. *[1]Rheumatology Unit; [2]Pneumology Department; [3]Thoracic Surgery Department; [4]Internal Medicine Department, Hospital Vall d'Hebron, Barcelona, Spain*

Background: Interstitial lung disease (ILD) is the most characteristic feature and prognosis determinant of patients with antisynthetase (AS) and anti-MDA5 syndromes. Despite immunosuppressive treatment, ILD sometimes progresses to an end-stage lung disease, for which lung transplantation (LT) is the only therapeutic option. There is scarce data about post-LT outcome in this group of patients.
Objectives: To describe clinical characteristics and post-LT outcome of patients with ILD associated to AS and anti-MDA5 syndromes included in the LT program of the Vall d'Hebron Hospital of Barcelona.
Methods: We performed a review of patient records listed in the LT program.
Results: From 1990 to 2016 ten patients (5 women) with ILD related to AS or anti-MDA5 syndromes were included in the LT program (3% of patients with ILD accepted for LT). Nine patients (2 anti-MDA5, 4 anti-Jo1, 2 anti-PL12 and 1 anti-PL7) received LT while 1 patient (anti-Jo1) was still in list at the end of this study. Median age (range) of disease diagnosis was 39 years (25–55). Six patients had clinical myopathy [2 dermatomyositis (DM) and 4 polymyositis] whereas 1 patient was diagnosed with amyopathic DM. Four patients had associated pulmonary hypertension. Time between disease diagnosis and patient inclusion in LT list was higher in anti-Jo1 patients [median (range) 8.8 years (8.3–17.6)] than in the rest of the cohort [anti-MDA5 <1 year; antiPL12 0.7 and 3.9 years; anti-PL7 1.3 years] ($p<0.05$). Four patients underwent bilateral LT and 5 unilateral LT. Three patients received an urgent LT (2 anti-MDA5 and 1 anti-Jo1). Six patients presented an histologic pattern of UIP and 3 of NSIP. Early complications (<45 days) included: primary graft disfunction in 3 patients; phrenic paresis in 2 patients and infection in 6 patients. One patient suffered an acute rejection (AR). Six patients presented late complications (>45 days): one patient developed an acute cellular rejection (ACR) and an autoantibody mediated rejection 8 and 10 months from LT respectively; 4 patients suffered chronic lung allograft dysfunction (CLAD), 2 of whom are still alive; Infection was diagnosed in 6 patients. One patient developed a squamous skin carcinoma. No flare of myopathic or lung disease was observed after LT in any case. Four patients (44%) died: 2 of an acute respiratory failure in the immediate postoperatory period (1 caused by suture dehiscence and 1 by refractory ACR); 1 of an invasive aspergillosis, 17 months after LT; and 1 of CLAD after 54 months. Median follow-up (range) of the rest of the cohort was 35 months (8–70). All patients who survived more than 45 days recovered an optimal functional capacity for daily activities with no request for long-term oxygen therapy.
Conclusions: LT should be considered a valid option to treat patients with end-stage or severe and rapidly progressive ILD associated to AS and anti-MDA5 syndromes. An early remission to LT referral centers for evaluation should be considered especially in non-Jo1 patients. No relapse of myositis or ILD was observed after LT. Mortality could not be attributed to the primary disease.

SAT0340 SUBCLINICAL CARDIOVASCULAR DISEASE IN SCLERODERMA: A STUDY WITH CARDIOVASCULAR RISK CHARTS, CT CORONARY CALCIUM SCORE AND CAROTID ULTRASONOGRAPHY

I. Sanz Pérez[1], F. Martínez Valle[1], A. Guillén del Castillo[1], N. Pizzi[2], A. Roque Pérez[3], H. Cuéllar Calàbria[3], A. Fernández Codina[1], E. Callejas Moragas[1], V. Fonollosa Pla[1], C.P. Simeón Aznar[1]. *[1]Internal Medicine; [2]Nuclear cardiology; [3]Radiology, Hospital Universitari Vall d'Hebron, Barcelona, Spain*

Background: Recently published population-based cohort studies had shown a high prevalence of cardiovascular (CV) disease in Systemic Sclerosis (SSc) patients.
Objectives: The aim of this study is to compare three different methods to measure CV risk in patients with scleroderma.
Methods: We conducted a cross-sectional study in a single center that included 43 SSc patients without CV events. We used both CV risk assessment charts SCORE for populations with low CV risk and REGICOR algorithm adjusted to Spanish subjects. Coronary Compute Tomography (CT) with coronary arterial calcium score (CACscore) was performed considering several cut-off points as predictors of CV risk. Carotid doppler ultrasound was performed to measure the Carotid Intima Media Thickness (CIMT) and for the detection of cholesterol plaques, according to Mannheim consensus criteria.
Results: Risk factors and SSc related features are described in table 1. None of the patients were catalogued as high risk according to SCORE chart (>5%). According to REGICOR chart, 17 patients (39,5%) were catalogued as intermediate risk and none as high risk. Twenty-two patients (51,2%) had carotid plaques (CP) and the CACscore of these patients was 283.4. In patients without CP CACscore was 53,2 ($p<0.05$).
Based on the presence of CP we performed ROC curve with CACscore. The AUC was 0.778. The best cut off point was 28 with a sensibility of 71% and a specifity of 82%. Kappa's coefficient was 0.54. Twenty patients (46.5%) had CACscore>28. Compared to patients with CACscore<28 statistical significance was found on CIMTmax (0.93 vs 0.80mm; $p<0.01$), presence of CP (79% vs 25%, $p<0.01$) and number of CP (2.55 vs 0.43, $p<0.01$). There was no statistical significance on CIMTm (0.71 vs 0.64mm p: 0.11).

Female	37 (82%)
Age	59 (33–83)
Disease duration	19 (3–57)
Limited cutaneous SSc	32 (74,4%)
Diffuse cutaneous SSc	10 (23,3%)
Sine Scleroderma SSc	1 (2,3%)
Arterial Hypertension	26 (60,5%)
Diabetes mellitus	5 (11,6%)
Statin treatment	22 (51,2%)
Smokers	5 (11.6%)
Digital ulcers	24 (55,8%)
Pulmonary Hypertension*	6 (14%)
Interstitial lung disease	20 (46.5%)
Altered conduction in Electrocardiogram	15 (34,9%)
Left Ventricular diastolic dysfunction**	32 (74,4%)
Left ventricular systolic dysfunction**	3 (7%)

*Mean pulmonary artery pressure >25 mm Hg at right heart catheterization. **Measured by echocardiography.

If the presence of CP or CAC score>28 were considered as subclinical atheromatosis disease (SAD), a total of 26 patients (60.5%) were diagnosed. We performed multivariate regression analysis, CIMTm, CIMTmax, low High Density Lipid (HDL), high erythrocyte sedimentation rate (ESR) and age were independent factors for the presence of SAD.
Conclusions: SSc patients often have SAD which is misdiagnosed by CV risk charts. Plaque detection by carotid ultrasonography and CT CACscore are useful to detect SAD. The optimal cut-off point of CACscore in this study is 28. SAD detection would be indicated in elderly, patients with low HDL or high ESR. The measure of CIMT could be useful in some cases.

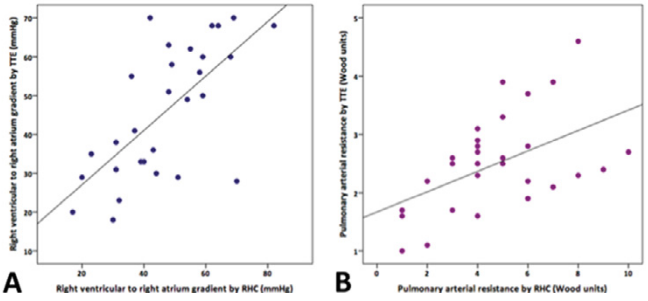
SAT0341 PILOT STUDY: HOME MANAGEMENT OF ILOPROST IN THE MICROPUMP/24 HOURS, IN PATIENTS SUFFERING FROM SCLERODERMA, FOLLOWED FOR 12 MONTHS

G. Pistone, R. Daita, C. Arcuri, N. Catalano, S. Liuzza, C. Rinollo, G. D'Aguanno, A. Allotta, M. Lo Monaco, R. Mallaci Bocchio, G. Natoli, S. Corrao.
AZ.OSP.ARNAS Civico, PALERMO, Italy



Background: evaluate the effectiveness on Raynaud's phenomenon and on digital ulcers, safety and side effects, during intravenous infusion of iloprost therapy in patients with diffuse and limited scleroderma
Objectives: the effectiveness of the therapy was assessed at 0 and 12 months, on the basis of daily number of episodes of Raynaud's phenomenon, evaluation of digital ulcers changes of the vascular nail bed to capillaroscopio, evaluation of pulmonary hypertension.
Security according to the appearance of adverse events.
Methods: They were enrolled consecutively, for a period of 12 months, 12 patients, 9 women and 2 men, 9 suffering from diffuse scleroderma (positive Scl70) and 3 suffering from limited scleroderma (positive anticentromere), middle age 52,91 years, mean age of disease 7,8 years, 11 non-smoking. They were subjected to infusion of iloprost 1/2 vial diluted in 25 cc of saline solution to 0,6 ml/h, in micropump Infonde for 24 consecutive hours, for 4 days a month for 12 months, 10 patients with peripheral lines and 2 with central venous access.
Results: of 12 patients with the Raynaud's phenomenon, there was a reduction in the daily number in 4 patients, unchanged in 8 patients. Digital ulcers disappeared in 6 patients, they were unchanged in 5 patients, improved although present in 1 patient. In 7 patients capillaroscopic framework remained unchanged, in 5 patients improved capillary density. 10 patients had no pulmonary hypertension, 2 patients had pulmonary hypertension, no change in the two groups at T0 and T 12. None of the patients experienced side effects during the infusion.
Conclusions: the cyclical infusion therapy iloprost prevented the onset of ulcers in patients at T0 not presented or the appearance of new ulcers; it has contributed to the reduction in the daily number of Raynaud's phenomenon and also allowed to reach the same effective dose of a vial of iloprost to dilute in 50 cc of saline solution, allowing the patient to perform at home therapy with greater compliance. In terms of safety none of the patients experienced side effects or adverse effects
Disclosure of Interest: None declared

SAT0342 TRANSTHORACIC ECHOCARDIOGRAPHY TO QUANTIFY PULMONARY VASCULAR RESISTANCE IN PATIENTS WITH SYSTEMIC SCLEROSIS

S. Billet[1], T. Chollet[1], P. Fournier[1], L. Tetu[2], G. Prévot[2], M. Galinier[1], D. Carrié[1], O. Lairez[1], G. Pugnet[3]. *[1]Service de Cardiologie, CHU Rangueil; [2]Service de Pneumologie, CHU Larrey; [3]Service de Médecine Interne, CHU Toulouse Purpan, Toulouse, France*

Background: One of the major causes of systemic sclerosis (SSc)-related death is pulmonary arterial hypertension, which develops in 12–15% of patients with SSc and accounts for 30–40% of deaths. Consequently, monitoring of pulmonary arterial pressure (PAP) and resistances is essential in patients with SSc. Abbas formula performed by transthoracic echocardiography (TTE) was reported as a good tool to quantify pulmonary vascular resistances (PVR).
Objectives: Explore the accuracy of TTE and Abbas formula to quantify PVR in patients with SSc.
Methods: All consecutive patients with SSc, diagnosed according to the 2013 ACR/EULAR criteria, or the LeRoy and Medsger criteria for diffuse or limited subsets classification, had within 24H a Doppler echocardiographic examination and right-heart catheterization were performed. The ratio of peak tricuspid regurgitant velocity (TRV, *ms*) to the right ventricular outflow tract time-velocity integral (TVI_{RVOT}, *cm*) obtained by Doppler echocardiography (TRV/TVI_{RVOT}) was then correlated with invasive PVR measurements using regression analysis. An equation was modeled to calculate PVR in Wood units (WU) using echocardiography, and the results were compared with invasive PVR measurements [1].
Results: Thirty-three consecutive patients were included, 13 (39.4%) were male and the mean age was 64.6±12.1 years. Most were classified as limited cutaneous SSc (lcSSc; n=29, 87.9%). All patients tested positive for antinuclear antibodies, 18 (21.2%) for anti-scleroderma-70, 7 (54.5%) for anticentromere antibodies and 2 (6.1%) for anti-RNA polymerase III antibodies. Mean and systolic PAP were 31±9 and 53±16 mmHg respectively. There was a good correlation between right ventricle to right atrium gradient pressure assessed by TTE and RHC (R=0.620, P<0.001). RVP assessed by Abbas formula (2.6±1.0 wood units) were well correlated with RVP assessed by RHC (4.8±2.3; R=0.446, P=0.013).

Figure. Correlations between right ventricular to right atrium gradient and pulmonary arterial resistances assessed by transthoracic echocardiography and right heart catheterization

Conclusions: Doppler echocardiography using Abbas formula may provide a reliable, noninvasive method to determine PVR in SSc patients.

SAT0343 SCREENING OF PULMONARY ARTERIAL HYPERTENSION IN PATIENTS WITH SYSTEMIC SCLEROSIS USING DETECT ALGORITHM – VALIDATION IN THE COHORT OF JAPANESE SINGLE CENTER

H. Yasuoka[1], Y. Shirai[2], Y. Tamura[3], T. Takeuchi[1], M. Kuwana[2]. *[1]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine; [2]Departmenrt of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine; [3]International University of Health and Welfare Mita Hospital, Tokyo, Japan*

Background: Pulmonary arterial hypertension (PAH) complicated with systemic sclerosis (SSc) has the worst prognosis in PAH associated with other connective tissue diseases (1) and is one of leading cause of death in patients with SSc (2). To improve prognosis in SSc patients, earlier detection and diagnosis of PAH by annual screening is recommended even in asymptomatic patients (3). To effectively detect PAH in patients with SSc at earlier phase, DETECT algorithm is reported as a good tool to identify candidates who need right heart catheterization (RHC), with high sensitivity (4). However, its usefulness has not been validated in Japanese cohorts.
Objectives: To validate the effectiveness of DETECT algorithm in the Japanese single center cohort.
Methods: Patients with SSc who visited Keio University Hospital between 2005 and 2016 were included in the study. Patients over 18 years old, disease duration more than 3 years, and DLCO predicted less than 60% were selected and clinical information was retrospectively collected from records. The sensitivity, specificity, and negative and positive predictive values of the algorithm based on the result of RHC evaluation were calculated in a cohort of PAH patients and non-PAH patients, in whom RHC data were available. Validation with patients with data minimally-required for algorithm were also examined.
Results: Three hundred four cases were visited our hospital during from 2005 to 2016. Patients who fulfilled criteria and had data minimally-required for algorithm were 126 cases. Of 126 patients, 50 were examined RHC evaluation and patients diagnosed as pulmonary hypertension were 26 (21%) and 21 (15%) were PAH. When a cohort of PAH patients and non-PAH patients with RHC data was applied to DETECT algorithm, referral rate to RHC evaluation was 78%, missed diagnosis of PAH was 0%. Sensitivity/specificity for detecting PAH patients were 100%/42%, and positive/negative predictive values were 60%/100%, respectively. Evaluation of 126 patients with data minimally-required for algorithm was also examined. Referral rate to RHC evaluation was 43%, missed diagnosis of PAH was 0%, and sensitivity/specificity and positive/negative predictive values for detecting PAH patients were 100%/72%, 43%/100%, respectively. However, there was a patient who was initially excluded at Step 1, but developed PAH one year later.
Conclusions: The DETECT algorithm was reassured as a good tool to effectively screening tool for PAH in SSc patients. However, we have to keep in mind that unnecessity of RHC referral judged by this algorithm does not guarantee the patient to be free from future development of PAH.

SAT0344 DISEASE RELATED MALNUTRITION IN SYSTEMIC SCLEROSIS AND ASSOCIATED FACTORS: A CROSS-SECTIONAL STUDY

I. Türk[1], N. Cuzdan Coskun[2], V. Ciftci[3], D. Arslan Taş[1], M.C. Doğan[4], I. Unal[5]. *[1]Department of Internal Medicine, Division of Rheumatology; [2]Department of Physical Medicine and Rehabilitation, Division of Rheumatology; [3]Faculty of Dentistry, Department of Pediatric Dentistry; [4]Department of Pediatric Dentistry; [5]Department of Biostatistics, Çukurova University, Adana, Turkey*

Background: The risk of malnutrition increases in patients with systemic sclerosis (SSc) which has a negative prognostic effect. Additionally malnutrition is a significant cause of morbidity and mortality.
Objectives: The aim of this study was to evaluate the associations between malnutrition and clinical features of the disease, depression in SSc patients.
Methods: Concomitant SSc patients followed in our outpatient and inpatient clinics were enrolled in the study. Skin involvement was assessed with modified Rodnan skin score (mRSS), joint/tendon involvement with finger-tip to palm distance (FTP). İnterstitial lung disease (ILD) and heart involvement were evaluated with clinical and radiological methods. Patients were questioned for dysphagia and gastroesofageal reflux as an indicator of esophageal involvement, early satiety and vomiting as gastric involvement, and diarrhea, constipation and bloating as bowel involvement.[1] Interincisal distance measurement was used to assess the maximal mouth opening capacity. Malnutrition risk was assessed by the Malnutrition universal screening tool (MUST). The Beck Depression Inventory (BDI) was used for measuring the severity of depression. sWe examined associations between malnutrition risk and clinical features of the disease, depression in SSc patients.
Results: Ninety eight SSc patients with 69 diffuse and 29 limited type of the disease were enrolled in the study. 84.7% of the patients were female and the mean age was 52.67±11.28 years. According to MUST scores 61.2% of patients have low, 15.3% medium and 23.5% high risk for malnutrition. We found no difference between the malnutrition risk among genders (p=0.065). mRSS and FTP were significantly different between malnutrition risk groups (p=0.005, 0.050 respectively). Malnutrition risk was higher with patients with ILD than the patients without ILD (p=0.044). Malnutrition risk was higher with patients with bowel involvement than the patients without bowel involvement. (p=0.021).
Interincisal distance was significantly different between malnutrition risk groups (p=0.003). 78.7% of SSc patients have BDI scores $\geq$10, 54.3% of SSc patients have BDI scores $\geq$17. BDI scores were significantly different between malnutrition risk groups ($p<0.001$). Factors affecting malnutrition risk were evaluated with logistic regression analysis. Interincisal distance and bowel involvement were found to be the most relevant factors for malnutrition risk. SSc patients with bowel involvement have 2.519-fold increased risk of malnutrition compared to patients without bowel involvement (95% CI 1.039–6.105). Every 1 mm decrement in interincisal distance was associated with 1.101 fold increase in malnutrititon risk of SSc patients (95% CI 1.032–1.176).
Conclusions: Malnutrition is common in SSc patients. Malnutrition risk is associated with skin, tendon/joint involvement, DU count, ILD, bowel involvement, microstomia and depression severity.

SAT0345 THE IMPACT OF GASTROINTESTINAL INVOLVEMENT IN HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC SCLEROSIS

J. Caetano[1], J. Branco[2], S. Oliveira[1], J. Delgado Alves[1,3]. *[1]Systemic Autoimmune Diseases Unit, Department of Medicine IV; [2]Department of Gastroenterology, Fernando Fonseca Hospital, Amadora; [3]CEDOC, NOVA Medical School, Lisbon, Portugal*

Background: Apart from skin involvement, the gastrointestinal (GI) system is the second most commonly involved organ in systemic sclerosis (SSc), affecting over 80% of the patients. Although rarely being a direct cause of death, it is associated to a high morbidity and to a significant impairment in health-related quality of life (HRQoL). Few data are published considering the influence of GI manifestations in the quality of life of SSc patients.
Objectives: The purpose of this study is to characterize the impact of GI involvement in HRQoL in SSc, and to compare it with that in patients with inflammatory bowel disease (IBD).
Methods: 29 consecutive SSc patients with GI involvement were selected from a cohort of 44 SSc patients, followed in a single referral centre and classified according to 2013 ACR/EULAR criteria. Comparative analysis was made with 24 consecutive patients with IBD without arthritis (14 Crohn's disease; 10 - ulcerative colitis). Health Assessment Questionnaire (HAQ-DI) and Short Form 36 (SF36), physical component summary (PCS) and mental component summary (MCS) scales, were used to assess HRQoL in both groups. The UCLA Scleroderma Clinical Trial Consortium Gastrointestinal Tract 2.0 (UCLA SCTG GIT 2.0) was performed in SSc patients to assess the severity of GI involvement. Clinical data were obtained by medical records review. T-test and Fisher's exact test were used to compare binary variables. Pearson's correlation was used for continuous variables.
Results: The most common GI segments involved in SSc patients were the esophagus in 90%, the stomach in 60% and the bowel in 48%, while the anorectum was involved in a smaller percentage (10.3%). The mean UCLA SCTG GIT 2.0 score was 0.64±0.51, compatible with a moderate severity, with higher scores obtained for reflux, distention and emotional wellbeing. The mean HAQ-DI score was 1.13±0.57 (0-best health), and the mean PCS and MCS scores were 35.2±9.4 and 35.3±11.4 (100-best health), respectively. These scores were significantly worse than in SSc patients without GI involvement (HAQ-DI - p=0.001; PCS - p=0.04 and MCS - p=0.005). There was a significant correlation between higher UCLA SCTG GIT 2.0 scores and worse quality of life evaluated by HAQ-DI (r=0.42, p=0.03), but the same correlation was not found for the SF36 components. Comparing with IBD patients, SSc patients with GI involvement had worse life quality, with statistical significantly higher HAQ-DI ($p<0.001$) and lower PCS ($p<0.001$) and MCS (p=0.01) scores.
Conclusions: GI involvement in SSc significantly impaired patient's quality of life. The impact of GI involvement in HRQoL of SSc patients was more severe than in IBD patients. Although physical components were relevant, with esophagus being most frequently involved, mental components associated with GI involvement significantly compromised HRQoL in SSc. Therefore, the assessment of SSc patients using clinical severity measure tools, similar to UCLA SCTG GIT 2.0 score, is crucial for a better characterization of the disease and to an optimized clinical approach.

SAT0346 SYSTEMIC SCLEROSIS'S EARLY STAGES AND ITS SIGNIFICANCE IN DAILY PRACTICE

J.P. Abreu, I. Almeida, A. Marinho, C. Vasconcelos. *Unidade de Imunologia Clínica, Centro Hospitalar do Porto, Porto, Portugal*

Background: Systemic Sclerosis (SSc) is an autoimmune disease, characterized by skin and internal organs fibrosis. Its clinical manifestations are heterogeneous, hence, the definitive diagnosis of SSc rely on scores, such as American College of Rheumatology (ACR) for SSc. Leroy and Medsger, proposed the potential criteria for the classification of early stages of SSc, due to the insufficient sensitivity previous methods. Lately EUSTAR proposed the concept of Very Early SSc, defined by the presence of 3 red flag – RF, Puffy Fingers and ANA; if 2 of these are present, capilaroscopy and specific antibody must be accessed; if one of the last positive, further search for Systemic involvement must be taken in account.
Objectives: We propose to: analyse a group of patients that had been diagnosed with early stages of SSc; study the presence of systemic involvement (at the time of diagnosis and throughout the follow-up), and the possible predictors for progression to definitive SSc.
Methods: The patients were selected by consulting the clinical data from patients followed in our hospital with diagnose of early stages of SSc. Very Early SSc criteria were used to define early stage SSc. The data concerning red flags, capilaroscopy, specific auto-antibodies, systemic involvement (Gastrointestinal, Pulmonary, Cardiac, Kidney, Muscoloskeletal).
Results: We obtained a sample of 70 patients, 65 being female subjects (92,9%), with mean age of diagnosis 47,9 years (SD 13,6). 16 patients (22,9%) were classified as Pre-scleroderma at the admission, 16 as Early SSc (22,9%), 15 (21,4%) as Very Early SSc, 16 (22,9%) as possible SSc, 6 (8,6%) as Limited SSc (despite not scoring to ACR criteria) and 1 (1,4%) as Sin Scleroderma SSc. 63 patients (90%) had RP, 15 (21,4%) had puffy fingers, 63 (90%) ANA positivity – 11 patients (15,7%) had 1 red flag, 45 (64,3%) had 2 red flags and 13 (18,6%) had 3 red flags.
54 patients (78.3%) were positive to specific SSc autoantibodies; 47 patients (71.2%) had capiloroscopy compatible with SSc in different stages (17.1% Early, 12,9% Active, 4,3% Late and 32,9% compatible). 54 patients (77,1%) scored for Very Early SSc.
At the moment of the diagnosis, 56 patient (81,2%) had systemic involvement.
34 patients (48,6%) scored to the definitive diagnosis by ACR 2013 criteria, after 2,56 years in mean (SD 2.51) of first diagnosis.
No correlation was found in what concerns to predictors of progression to SSc or systemic involvement.
Conclusions: This study shed a light on the importance of the recognition of SSc's early stages, since a significant part of these patients have systemic involvement at the moment of diagnosis, yet not scoring to ACR 2013 criteria. Almost half of the patients scored to definite diagnosis of SSc at the moment of the last appointment. The importance of these findings rely on the possibility to identify systemic involvement and address it in time to prevent/delay further disease progression.

SAT0347 DISEASE MODIFYING EFFECT OF ILOPROST IN PATIENTS WITH SYSTEMIC SCLEROSIS AND POSSIBLE ROLE OF CXCL4 CHEMOKINE

K. Stefanantoni[1], I. Sciarra[1], M. Vasile[1], R. Palazzo[2], L. Frasca[2], G. Valesini[1], V. Riccieri[1]. *[1]Dipartimento di Medicina Interna e Specialità Mediche, Sapienza Università di Roma; [2]National center for research and pre-clinical and clinical evaluation of drugs- Immune-mediated diseases UNIT, Istituto Superiore di Sanità (Nat. Inst. of Health), Rome, Italy*

Background: Iloprost is a synthetic prostaglandine used for vascular manifestation of Systemic Sclerosis (SSc), in particular it is indicated for active digital ulcers (DU) and severe Raynaud Phenomenon (RP) (1). It acts on several receptors such as IP and EP receptors and PPRs. Iloprost is also involved in the regulation of gene expression, fibrosis and inflammation (2,3,4). CXCL4 o Platelet Factor 4, is a 70KDa CXC-chemokine synthesized in megakaryocytes and plasmacytoid dendritic cells, released after platelet activation. In SSc, it seems to be higher in patients with early diffuse SSc and it correlates with mRSS and presence of PAH (5).
Objectives: To evaluate the effect of Iloprost on vascular manifestations, on disease activity and on serum levels of CXCL4 at baseline (T0) and after 1 month (T1), 3 months (T3) and 6 months (T6) of therapy.
Methods: 30 patients (M/F =1/29; mean age =58.2 yrs; mean disease duration =12.8 yrs) with established SSc according to ACR criteria, were enrolled. At T0, T1, T3 and T6 treatment with Iloprost at standard dosage we determined RP VAS, number of DU, European Scleroderma Study Group Activity Index (EScSGAI) and serum levels of CXCL4, measured using commercially available immunoassay kit (Human CXCL4/PF4 R&D SYSTEMS®). All patients underwent to a complete clinical, instrumental and laboratory evaluation.
Results: Regarding RP VAS, we found a statistically significant increase (p=0.04) at T3, corresponding to the colder winter period, while it decreased, although not significantly at T1 and at T6, where this reduction was significant compared to T3 values (p=0.0008). Considering the number of active DU, we have highlighted the same trend of the RP VAS. EScSGAI values showed a statistically significant reduction (p=0.03) comparing T3 to T6. Regarding CXCL4, we found significantly higher levels in SSc patients respect to a group of healthy controls (HC) (p=0.047). No significant difference was found in serum levels of CXCL4 at T0, T1,T3 and T6. Evaluating patients with higher levels of CXCL4 at baseline, respect to the average of HC values (CXCL4>25,000 pg/ml) (11/30 patients), we found that 7 subjects had a significant improvement in disease activity at T6 evaluated by EScSGAI (p=0.015). In these patients we also detected a significant reduction in T3 CXCL4 values (p=0.043) persisting and at T6, although not reaching statistical significance. Moreover higher basal levels of CXCL4 in patients with disease duration less of 60 months (p=0.05) and in patients with pericardial effusion (p=0.037) were detected. Besides we found significantly lower levels of CXCL4 in patients with DU history (p=0.049) and esophageal involvement (p=0.008).
Conclusions: Our study confirms the efficacy of Iloprost on vascular manifestation of SSc and also highlights its effect on the disease activity. Moreover this drug seems to influence, in a subgroup of patients, concentrations of CXCL4, an important chemokine involved in SSc pathogenesis that deserves further investigations.

SAT0348 ASSOCIATION OF VITAMIN D DEFICIENCY WITH REDUCED IL10-PRODUCING REGULATORY B CELLS IN SYSTEMIC SCLEROSIS

A. Mavropoulos, C. Liaskos, A. Gkoutzourelas, C.G. Katsiari, D.P. Bogdanos, L.I. Sakkas. *Rheumatology and Clinical Immunology, University of Thessaly, School of Health Sciences, LARISSA, Greece*

Background: IL-10-producing regulatory B cells (Bregs), also known as B10 cells, are decreased and functionally impaired in patients with systemic sclerosis (SSc), particularly in those with SSc-associated interstitial lung disease (1). As serum 25-OH-vitamin D (vitD) levels are associated with clinical aspects in patients with SSc (2), we investigated whether there is any link between vitD levels and Breg levels.
Objectives: To assess whether or not vitD deficiency in SSc is associated with the percentages of circulating IL-10-producing Breg cells.
Methods: PBMCs and serum samples were isolated from 55 patients with systemic sclerosis. Serum VitD levels were measured using a commercially available sandwich ELISA kit. Phenotypic analysis of CD19, CD24, CD27, CD38 and intracellular expression of cytoplasmic IL-10 following bacterial CpG (ODN2006) and PMA/ionomycin stimulation was examined by flow cytometry using specific fluorochrome-conjugated monoclonal antibodies (BD Biosciences).
Results: Systemic sclerosis patients were divided into two groups (vitD deficient or not) based on a serum concentration cut off value of 20 ng/ml. The mean vitD levels in the deficient group were 14.11±3.6 ng/ml (n=17) whereas the mean vitD levels in the non-deficient group were 37.5±12.9 ng/ml (n=38). IL-10-producing B cells (B10 cells) were significantly decreased in vitD deficient patients compared to those with medium/high levels (p=0.02). CD19+CD27+ (memory) B cells were also significantly reduced in patients with VitD deficiency (p=0.004). In addition the ratio of naïve/memory B cells was significantly higher in VitD deficient patients (p<0.05). Within the memory B cell fraction, the CD19+CD27+CD24hi cells also known as phenotypic memory Bregs, were mostly decreased (p=0.001). There was no significant association between CD19+CD38hiCD24hi (transitional) Bregs and VitD levels.
Conclusions: Our data suggest that vitamin D deficiency may account for reduced B10 cells in systemic sclerosis

SAT0349 EVALUATION OF STANDARD SWALLOWING FUNCTION IN ASSESSING ASPIRATION RISK FOR PATIENTS WITH SYSTEMIC SCLEROSIS

L. Yan, P. Yunfeng, Y. Mengru. *Department of Rheumatology, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Background: Swallowing dysfunction is a common symptom of systemic sclerosis, which usually induce aspiration pneumonia to aggravate lung progress. It is necessary to screen swallowing disorders effectively at an early stage.
Objectives: To investigate the value of standard swallowing function assessment (SSA) in aspiration screening for inpatients with Systemic sclerosis.
Methods: SSA and Video fluoroscopic swallowing study (VFSS) were performed in 120 inpatients with Systemic sclerosis from March 2014 to September 2016.The sensitivity, specificity, positive predictive value and negative predictive value of SSA in the diagnosis of aspiration in patients were calculated by taking VFSS examination as the gold standard. The incidence of pneumonia in SSA-positive and SSA-negative patients were compared.
Results: The diagnostic sensitivity of SSA was 81.2%, the specificity was 75%, the positive predictive value was 68.6% and the negative predictive value was 90.3%. The incidence of pneumonia in SSA positive patients was higher than that in SSA negative patients (54.1% vs 28.3%) (P<0.01).
Conclusions: SSA is a valuable screening tool for the evaluation of aspiration risk in patients with Systemic sclerosis.

SAT0350 DOES A SYSTEMIC SCLEROSIS PATIENT'S CLINICAL PHENOTYPE DEMONSTRATE HIS AUTOANTIBODY STATUS?

M. Boonstra[1], J.A. Bakker[2], M.K. Ninaber[3], N. Ajmone Marsan[4], T.W. Huizinga[1], J.K. de Vries-Bouwstra[1]. *[1]Rheumatology; [2]Clinical Chemistry and Laboratory Medicine; [3]Pulmonology; [4]Cardiology, LUMC, Leiden, Netherlands*

Background: Although antibody status has shown to improve clinical subsetting in Systemic sclerosis (SSc), it is far from perfect. For optimal clinical subsetting as well as for evaluating the possible pathogenic role of SSc specific antibodies, it is relevant to know to what extent clinical SSc phenotypes are determined by presence of these antibodies.
Objectives: To evaluate 1. if clinical relevant subsets of SSc patients are distinguishable using only clinical data, 2. how SSc specific autoantibodies are distributed among these subsets, and 3. whether adding antibody status to cluster analyses improves recognition of SSc subsets.
Methods: Using data from SSc patients of the Combined Care In Systemic Sclerosis (CCIS) cohort, Leiden University Medical Center, hierarchical clustering based on Ward Method was performed on the first obtained factor of principal component analysis of 7 organ systems (skin;lung;heart;kidney;muscle;vascular;gastro-

intestinal) and time since non-Raynaud phenomenon. Clinical characteristics and prevalence of auto-antibodies within clusters was evaluated. We assessed whether adding autoantibody status as additional factor improved clinical subsetting.

Results: Of 407 SSc patients included, 371 patients (91%) fulfilled ACR/EULAR 2013 criteria. Prevalence of anti-centromere (ACA) was 37%, anti-topoisomerase (ATA) 24%, anti-RNAPIII 5%, anti-fibrillarin 4%, anti-Pm/Scl 5%. Cluster analysis identified clinically recognisable clusters of SSc patients based on absence of skin involvement (cluster 1), peripheral vascular involvement (cluster 2), fibrotic complications (cluster 4), and severe vascular complications (pulmonary arterial hypertension [PH], renal crises; cluster 5). Except for cluster 4, where ATA was dominant, in all clusters ACA was the most prevalent auto-antibody. No cluster associated with any of the more rare SSc specific auto-antibodies. Adding of auto-antibodies resulted in increased clinical overlap, with a frequency of PH between 6 – 8% and a frequency of digital ulcers between 24 – 39% in clusters 2,4 and 5.

Table 1. Clustering of SSc patients based on clinics

	Cluster 1 (n=66)	Cluster 2 (n=50)	Cluster 3 (n=129)	Cluster 4 (n=81)	Cluster 5 (n=81)
Age in years, mean (SD)	53 (14)	54 (14)	54 (14)	53 (16)	62 (12.4)
Female, % (n)	90 (60)	86 (43)	85 (110)	72 (58)	74 (60)
Time since non-Raynaud, median (range)	3 (-3–14)	10 (-3–44)	2 (0–20)	3 (0–27)	13 (0–46)
dcSSc, % (n)	0 (0)	2 (1)	17 (22)	65 (53)	25 (20)
Mean mRSS (SD)	0 (0)	4 (3)	4 (3)	14 (11)	4 (6)
PAH, % (n)	3 (2)	4 (2)	0 (0)	5 (4)	20 (16)
DLCO, %predicted, mean (SD)	70 (18)	66 (16)	70 (15)	64 (16)	54 (18)
History of renal crisis, % (n)	0 (0)	0 (0)	0 (0)	3 (2)	17 (14)
Digital ulcers, % (n)	15 (10)	98 (49)	4 (5)	28 (23)	6 (5)
Anti-topisomerase, % (n)	5 (3)	15 (7)	22 (28)	48 (37)	24 (19)
Anti-centromere, % (n)	62 (39)	48 (23)	41 (53)	8 (6)	30 (24)

Conclusions: Based on clinical data alone, relevant subgroups in SSc can be distinguished. Adding antibody status to cluster analyses increases overlap of clinical features between subgroups. These findings show that solely presence of SSc specific antibodies is of limited clinical relevance. For optimal risk stratification more complex serological findings as antibody titers might be additive.

SAT0351 DIFFERENCES AMONG PATIENTS WITH INTERSTITIAL LUNG DISEASE ACCORDING TO THEIR SYSTEMIC SCLEROSIS SUBCLASSIFICATION

M. Laffont[1], I. Catellvi[2], D. Castillo[3], M. Millan[2], C. Diaz-Torné[2], P. Moya[2], B.P. Magallares[2], A. Laiz[2], H.S. Park[2], J.M. De Llobet[2], J. Casademont[2].
[1]Reumatologia, Hospital Jose Maria Ramos Mejia, Ciudad Autónoma de Buenos Aires, Argentina; [2]Reumatologia; [3]Neumonologia, Hospital Universitario de la Santa Creu I Sant Pau, Barcelona, Spain

Background: Systemic Sclerosis (SSc) has been widely studied from a purely global standpoint, but only a few trials have analysed patients with interstitial lung disease (SSc-ILD) as well.

Objectives: 1. Describe the clinical features of a cohort of patients with SSc and SSc-ILD. 2. Determine whether there are disparities among different types of SSc-ILD and their progression in patients with either limited (lcSSc) or diffuse involvement (dcSSc). 3. Ascertain whether there are disparities among different types of SSc-ILD and their progression according to the SSc-specific autoantibody (AAb).

Methods: Retrospective study of a cohort of patients with ILD-SSc controlled during an SSc consultation. The following variables were collected: sex, age, SSc and ILD progress in years, type of SSc and ILD, smoking, digital ulcers (DU), pulmonary hypertension, digestive disorders, cancer, SSc treatment, corticosteroid doses and lastly, lung function tests upon diagnosis, at treatment onset, and 24 months later. Additionally, a record was kept on the types of AAb present in every SSc. Qualitative and quantitative variables were compared in relation to the clinical and immunological sub-classification. Chi-square and Student's T Tests were performed. A p-value$\leq$0.05 was considered significant.

Results: out of 266 patients with SSc, data from 47 patients with ILD-SSc were gathered; 89.4% were female, with an age range of 66.09±15.1 years old, and 9.85±10.2 and 4.38±9.24 years of progression of their SSc and ILD respectively. 33 out of 47 sustained lcSSc, and both Scl-70/ATA (29.8%) and ACA (26.1%) were the most frequently found AAb. Non-specific interstitial pneumonia (NSIP) was the most common ILD radiological pattern (76.6%). Most patients with SSc underwent treatment (51.1%), 24% with mycophenolate mofetil (MMF); 36.2% of the patients had been concomitantly administrated corticosteroids with a mean prednisone dose of 15.73±10.3 mg/d.

Upon comparing patients with lcSSc and dcSSc, prevalence of DU was higher in those with dcSSc (p<0.01), MMF was less frequently used (p<0.02), rituximab was more usually employed (p<0.03), and they presented worse values of FEV1/FVC ratio after 24 months of treatment (p<0.03). No differences were observed as to either type of ILD or progression. However, when variables were analysed regarding AAb in SSc, patients with ACA presented both fewer DU (p<0.02) and NSIP pattern (p<0.02), and more frequent compromise of the small airway (p<0.01), they were younger and thus, they had had shorter progression of the disease. ILD diagnosis was made significantly earlier in those patients with RNA polymerase, and later in those with anti-U1RNP. No AAb was observed associated with neoplasia. Considering the types of ILD, patients with NSIP pattern were younger (p0.054) and presented worse spirometric values.

%DLCO 24 months after diagnosis of ILD	61.31± 17.47	63± 18.74	58.45±15.68	Ns	Ns	Ns	Ns	Ns

Conclusions: In terms of ILD-SSc patient stratification, sub-classification by AAb appears to be more specific than the clinical sub-classification. ACA is related to less frequency of NSIP pattern. Unlike what has been described for SSc from a global point of view, in patients with ILD-SSc no association between AAb and neoplasia could be established.

SAT0352 MORTALITY IN IDIOPATHIC INFLAMMATORY MYOPATHY-RESULTS FROM A SWEDISH NATIONWIDE POPULATION-BASED COHORT STUDY

C. Dobloug[1], J. Svensson[2], I. Lundberg[2], M. Holmqvist[2]. *[1]Oslo University Hospital, Oslo, Norway; [2]Karolinska Institutet, Stockholm, Sweden*

Background: Little is known about mortality in idiopathic inflammatory myopathies (IIM) compared to the general population, especially the risk development since diagnosis. In a recently published study, the 5-, and 10-year mortality was lower for IIM than previously reported, suggesting improved outcomes in recent years.

Objectives: To assess the mortality following IIM diagnosis in a nationwide population-based cohort of IIM patients diagnosed 2002–2011 compared to the general population.

Methods: We used nationwide fully covering health care registers to identify all individuals who were treated by a rheumatologist, neurologist, or dermatologist for IIM and who had a listing of IIM at $\geq$two visits within 1–12 months between 2002 and 2011, general population comparators, and death during follow up. We calculated mortality rates with 95% confidence intervals (CI) and compared the mortality in IIM to that in the general population using Cox proportional hazards models adjusted for age, sex, year of diagnosis, and residential area.

Results: During a median follow up of 4 years, 228 (31%) of the 733 IIM patients and during a median follow up of 6 years, 888 (12%) of the 7,340 general population comparators died. This corresponded to a crude mortality of 61/1,000 person-years in IIM, and 20/1,000 person-years in the comparators. The cumulative mortality at 1 year after diagnosis was 10% in IIM and 1% in the general population, at 5 years it was 24% in IIM and 7% in general population, and at 10 years the proportion was 31% and 12%. The overall hazard ratio (HR) (95% CI) of death comparing the NPR cohort and its comparator, was 3.5 (3.0–4.0). When restricting the outcome to cardiovascular disease-, cancer-, infection-, or pulmonary disease- specific death we noted increased mortality from all outcomes in IIM compared to the risk in the general population. When we stratified on time since diagnosis we noted an increased absolute and relative risk of death in the first year of diagnosis in particular for pulmonary disease and cancer, whereas cardiovascular mortality was a major cause of death also after 10 years after IIM diagnosis (table).

Conclusions: IIM patients are still at increased risk of death. The highest mortality

Abstract SAT0352 – Table 1. Hazard ratio (HR) and 95% confidence intervals (CI) comparing the mortality in idiopathic inflammatory myopathy (IIM) patients identified in the National Patient register between 2002 and 2011 and in an individually matched general population comparator. Overall mortality and stratified by underlying cause of death and time since IIM diagnosis

	IIM duration categories HR (95% CI) Deaths per 1,000 person years IIM patients/comparators			
	<1 year	1–<5 years	5–10 years	>10 years
Overall	10.3 (7.5–14.2) 110.8/ 11.6	3.2 (2.5–4.0) 51.2/19.6	2.6 (1.8–3.6) 48.2/24.7	2.4 (0.6–9.2) 42.1/27.7
Cardiovascular disease	5.3 (2.8–9.9) 21.9/4.4	2.3 (1.6–3.5) 14.9/8.0	2.4 (1.4–4.2) 16.7/10.0	6.49 (1.1–40.0) 28.1/13.4
Cancer	12.4 (7.4–20.8) 46.7/4.2	3.2 (2.1–4.8) 15.4/5.5	3.1 (1.6–6.0) 12.8/5.6	1.5 (0.1–14.9) 14.0/6.7
Pulmonary disease	22.49 (4.2–119.7) 7.3/0.1	5.2 (2.5–10.8) 6.1/0.3	2.4 (0.7–8.5) 3.0/1.0	- -

was noted within a year of diagnosis due to pulmonary disease, cancer and cardiovascular disease which calls for extra vigilance with respect to comorbidities during the first year of IIM diagnosis.

SAT0353 SMALL AIRWAYS INVOLVEMENT IN SCLERODERMA PATIENTS: RESULTS OF A CASE-CONTROL STUDY

M. Bonifazi[1], M. Mattioli[2], P. Fraticelli[3], C. Fischetti[2], L. Paolini[1], S. Gasparini[1], A. Gabrielli[2]. *[1]Pulmonary Diseases Unit, Department of Internal Medicine, Azienda Ospedaliero-Universitaria "Ospedali Riuniti"; [2]Department of Biomedical Sciences and Public Health, Università Politecnica delle Marche, Ancona; [3]Clinica Medica, Department of Internal Medicine, Azienda Ospedaliero-Universitaria "Ospedali Riuniti", Ancona, Italy*

Background: Interstitial lung disease (ILD) and pulmonary hypertension are the leading cause of morbidity and mortality in systemic sclerosis (SSc). Although a ventilatory obstructive pattern, due to large airways impairment, has been rarely observed in SSc, a potential involvement of smaller airways (SA) has been suggested in previous reports. Recently, impulse oscillometry (IOS), a non-invasive forced oscillation technique, has been advocated as a valuable diagnostic tool for a sensitive assessment of SA.

Objectives: The main objectives of the present study was to investigate the prevalence of SA dysfunction by IOS in SSc patients compared to healthy controls, and to evaluate the correlation between SA dysfunction and selected radiological and clinical disease-related features.

Methods: Consecutive SSc patients were included in the present study according to eligibility criteria; controls were health volunteers. Both cases and controls underwent IOS measurements; cases also underwent pulmonary function tests and St. George's respiratory questionnaire. Radiological features were assessed on the latest chest high resolution computed tomography (HRTC) scan available in the twelve months before study enrolment, evaluating for both SA signs of disease and ILD. A SA involvement at IOS was defined as R5-R20 $\geq$0.07 kPa/L/sec. Odds ratios and 95% confidence intervals for the IOS value was computed using multiple logistic regression models. Correlation between SA dysfunction and selected parameters were assessed using Pearson's correlation coefficient.

Results: 92 cases (M/F 14/78, mean age 57.06) and 84 controls (M/F 15/69, mean age 54.28) were included in the present study. The R5-R20$\geq$0.07 kpa/L/sec was found in 20.65% of cases and in 3.57% of controls. The OR was 7.027 (95% CI 1.99–24.72, p<0.01). This value did not significantly change after the adjustment for confounding variables (OR a* 7.091). Correlations between R5–20 $\geq$0,07 kPa/L/s and selected parameters showed a significant inverse association with vital capacity (FVC) and forced expiratory volume in first second (FEV1) and a direct correlation with pulmonary artery systolic pressure estimated. With reference to cutaneous subtype a SA dysfunction was more prevalent in the limited form compared to the diffuse, respectively in 23% and 12%. Radiologic HRCT assessment of SA pathological features and ILD extent were provided for 77 patients: 19 (24.7%) presented at least one sign of SA disease. An underlying ILD was detected in 40 patients, characterized by NSIP pattern in 37.

Conclusions: A significant involvement of SA was found in a substantial proportion of SSc patients, compared to healthy controls. Moreover, this seemed to be associated with a more severe functional obstructive and restrictive impairment, and with higher PAPs values. Therefore, our findings suggests that SA may be a potential, less known, target of disease, and further studies are needed to assess prognostic and therapeutic implications of this pathologic feature.

SAT0354 NAILFOLD VIDEOCAPILLAROSCOPY AND RAYNAUD'S PHENOMENON IN A COHORT OF MESTIZO LATIN AMERICAN PATIENTS: A PRELIMINARY OBSERVATIONAL STUDY

C.J. Velásquez-Franco[1], A. Facio-Lince García[2], A.L. Zapata-Castellanos[1], L.M. Rodríguez-Padilla[2], M.A. Mesa-Navas[1] on behalf of Clinical Immunology and Rheumatology Group. Universidad Pontificia Bolivariana. *[1]Rheumatology, Clinica Universitaria Bolivariana. Universidad Pontificia Bolivariana; [2]School of Health Sciences. Universidad Pontificia Bolivariana, Medellin, Colombia*

Background: The prevalence of Raynaud's phenomenon (RP) has been reported between 3–22%. When associated with systemic autoimmune diseases (SAD), especially systemic sclerosis (SSc), it is the sentinel event of irreversible organic damage. Nailfold videocapillaroscopy (NVC) is a non-invasive and safe procedure that allows *in vivo* observation of the microcirculation. Between 15–20% of patients who have RP with videocapillaroscopic alterations and certain autoantibodies will develop a SAD over two years. In addition, 90% of individuals with SSc and 85% with mixed connective tissue disease (MCTD) had RP as the first symptom.

Objectives: To evaluate the role of NVC in the differential diagnosis of RP, as well as in the early detection of SAD, in a cohort of Colombian patients.

Methods: A prospective, longitudinal, analytical study was conducted in subjects with RP, over 18-year-old, not active smokers, without previous connective tissue disease, secondary causes or aggravating factors. Optilia NVC with OptiPix software was used (Optilia Instruments; Sollentuna, Sweden). Qualitative variables are described by means, as well as absolute and relative frequencies; quantitative variables, according to the distribution of data, were reported by means or median, with standard deviation (SD) and interquartile range (IQR), respectively. We are reporting the baseline characteristics of these individuals.

Results: Fifty-eight individuals were included; 91.4% were female. The mean age was 40.9 years (SD: 14.1). RP was biphasic in 63.6% of the patients, with a median of 30 episodes per month (IQR: 8–30). In 41 subjects (available data), antinuclear antibodies were positive; the most common patterns were: speckled (41.5%) and centromere (26.8%). The median of erythrosedimentation rate (ESR) was 9 (IQR 4–13). Ten individuals (19.2%) were diagnosed with SAD in the first NVC: Seven patients with limited SSc, two with MCTD, and one with diffuse SSc. The patterns observed in the individuals with SSc were: early (n=3), active (n=3), late (n=2), and minor and unspecific abnormalities in subjects with MCTD (one each). The most frequent NCV alterations in subjects with SAD were: megacapillaries (n=10), microhemorrhages (n=10), avascular zones (n=8), neovascularization (n=6), and capilar disorganization (n=6). In these subjects, the mean capillary diameter was 76.7±33.9 mm; the median of capillary number per mm was 7 (IQR: 6–8).

Conclusions: The frequency of systemic autoimmune disease was similar to the published reports in the literature. We highlight the following aspects: 1) The normal erythrosedimentation rate in subjects with a rheumatologic diagnosis, a particular finding when compared to previous data; 2) The important percentage of subjects with a specific diagnosis in the first nailfold capillaroscopy; one possible explanation could be a underdiagnosed disorder; this fact could be possibly demonstrated by the large capillary diameter found.

SAT0355 NEUROPATHIC PAIN: IS IT AN UNDERESTIMATED SYMPTOM IN SYSTEMIC SCLEROSIS?

N. Cuzdan Coskun[1], I. Turk[2], T. Sarpel[1], E. Erken[2], Z.N. Alparslan[3]. *[1]Department of Physical Therapy and Rehabilitation, Division of Rheumatology; [2]Department of Internal Medicine, Division of Rheumatology; [3]Department of Biostatistics, Cukurova University Faculty of Medicine, Adana, Turkey*

Background: Pain is one of the most common symptoms in SSc patients, yet not considered in the assessment of disease severity. Former studies have shown that pain has a neuropathic component; however there is still lack of evidence about its distribution in the body regions and the direct effect of neuropathic pain on the quality of life (QoL).

Objectives: We aimed to investigate the frequency of neuropathic pain syndrome (NPS) and to evaluate its interference with the quality of life in SSc patients.

Methods: Diffuse and Limited SSc patients diagnosed by *American College of Rheumatology* 2013 criteria were included in the study. Pain was evaluated with *Visual Analogue Scale* (VAS); painful body regions and pain intensity with *Brief Pain Inventory* (BPI); presence of neuropathic pain with *The Leeds Assessment of Neuropathic Symptoms and Signs* (LANNS) questionnaire; disease activity with *Medsger Disease Severity Scale* and QoL with *Short-form 36* (SF36). Multiple regression analysis was used to assess the associations of NPS with sociodemographic and clinical factors.

Results: One hundred twenty patients were included in the study (mean age 53.64±11.44 years, female/male 83.3%>16.7%). Total pain frequency was found 69.2% and NPS was 35.9% in the whole patient group. Mean VAS in the

group of patients with and without NPS were 5.44±2.03, 3.45±1.82; respectively ($P<0.001$). Pain was most frequently seen in wrist-hand (50.6%) and ankle-foot (43.4%) regions; albeit, NPS rates were highest in face (94.4%), lower leg (87.5%) and gluteal (78.6%) regions. SF 36 scores were lower in patients with NPS than the patients without NPS but the difference has not reached to a statistically significant level ($P>0.05$). The most associated factors with NPS were Medsger Disease Severity Score for muscle and drug consumption of the patient.
Conclusions: According to our results, high frequency of NPS is seen in SSc patients, and NPS is associated with low QoL. The highest rates of NPS presence were seen in face, gluteal and lower leg regions of the body. Differential diagnosis of NPS is important to consider right treatment options and accurate management of pain in all rheumatologic diseases including SSc.

SAT0356 VIDEOFLUOROSCOPY SWALLOW STUDY IN PATIENTS WITH SYSTEMIC SCLEROSIS. CORRELATION WITH CLINICAL PATTERNS

P. Fraticelli[1], C. Fischetti[2], A.M. Pisani[3], S. Barchiesi[2], G. Romanelli[2], A. Gabrielli[1,2]. *[1]Clinica medica, Department of internal medicine, Ospedali Riuniti; [2]Department of Clinical and Molecular Sciences, Università Politecnica delle Marche; [3]Department of Radiology, Ospedali Riuniti, Ancona, Italy*

Background: Systemic Sclerosis (SSc) is a chronic autoimmune disease characterized by proliferative vascular lesions and progressive fibrosis of skin and internal organs, including the gastrointestinal tract. Gastrointestinal involvement is a very frequent complication, reported in up to 90% of SSc patients in both limited (lSSc) and diffuse (dSSc) cutaneous forms, and it is one of the earliest events.
Objectives: To evaluate the correlation between radiological items analyzed by videofluoroscopy swallow study and clinical patterns of patients SSc.
Methods: 55 patients (M/F: 6/49; median age 56y; median disease 6y, lSSc /dSSc:36/19; anti-Scl70+:21/55, ACA+:18/55, only ANA+:16/55), with a diagnosis of SSc and a history of dysphagia underwent a dynamic and morphological study of the oral, pharyngeal and esophageal phases of swallowing with videofluoroscopy. The oral and pharyngeal esophageal phases were performed in the upright position, while the esophageal phase was performed in the prone-oblique position, after administration of contrast material either in bolus form or diluted. Data were analyzed by radiologist with experience in videofluoroscopy for the evaluation of 17 videofluoroscopy items, of which, 4 concerning the oral, 4 the pharyngeal and 9 the esophageal phase, respectively. Results were expressed in a binary system. Then the main relevant videofluoroscopy findings were correlated with the principal scleroderma pattern of disease: lSSc vs dSSc; disease duration (more than 2 years) and subset of autoantibodies.
Results: Radiological study of swallowing disorders showed for oral phase: inadequate velar elevation in 4%, leakage in 15%, drooling in none (0%) and stasis of bolus in mouth in 4% of the patients. As for pharyngeal phase: stasis of bolus on pharyngeal in 49%, penetration in the laryngeal aditus in 53%, post-swallowing aspiration in 22%, abnormal upper esophageal sphincter behavior in 13% of the cases. Concerning esophageal phase: inadequate primary peristalsis in 53%, abnormal secondary peristalsis in 29%, non-peristaltic contractions in 40%, defects of clearance in 69%, abnormal lower esophageal sphincter behavior in 76%, hiatal hernia in 80%, esophageal reflux in 56%, esophagitis in 82% of the patients, nobody presented esophageal luminal stenosis. When we analyzed the swallowing disorders in different conditions we found that these are prevalent in patients with more than 2 year of disease, although may be found also early. Conversely, we have not found a significant prevalence between the lSSc or the dSSc, or a particular correlation with different patterns of autoantibodies.

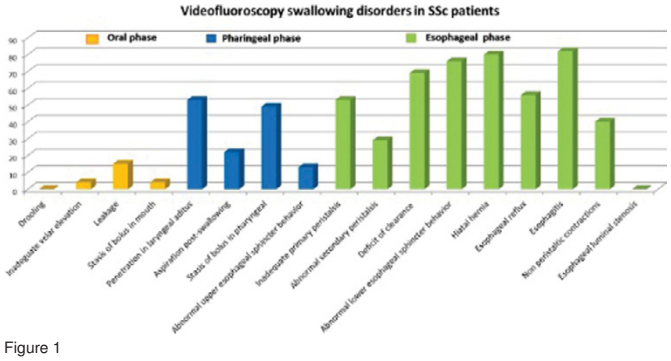

Figure 1

Conclusions: Our study demonstrated relevant abnormalities in swallowing functions in high number of patients with SSc. Pharyngeal and esophageal phases are the most affected, also early. Swallowing disorders increase with disease progression and involve similarly the limited or the diffuse SSc. An early and detailed diagnosis, supported by a semi-quantitative analysis with the use of videofluoroscopy scores, may be useful to guide the appropriate therapeutic approach, either rehabilitative or pharmacological, and finally, to improve the patient's quality of life. Extensive studies are necessary to confirm and transfer our data into clinical practice.

SAT0357 FEATURES ASSOCIATED WITH MODERATE TO HIGH RISK OF MALNUTRITION IN A COHORT OF PATIENTS WITH SYSTEMIC SCLEROSIS

P.M. Marcaida[1], D. Vanesa[1], V. Martire[1], F. Melo[1], A. Secco[1], M. Mamani[1], S. Scarafia[1], M. Lazaro[2], A. Cusa[2], F. Cusa[3], V. Caputo[4], J. Sarano[5], M. Molina[6], A. Nitsche[7], M. Gaona[8], C. Pena[9], M. Garcia[9], S. Gordon[10], N. Muñoz Cantos[8], S. Montoya[8]. *[1]Rheumatology, Rivadavia Hospital; [2]Rheumatology; [3]Nutrition, IARI; [4]Rheumatology, Military Hospital; [5]Rheumatology, Lanari Institute; [6]Rheumatology, Central Hospital of San Isidro; [7]Rheumatology, Diagnostic system-CM; [8]Rheumatology, Ramos Mejia Hospital, Buenos Aires; [9]Rheumatology, HIGA, la plata; [10]Rheumatology, HIGA, Mar del plata, Argentina*

Background: It is estimated that about 28% of Systemic Sclerosis (SS) patients have moderate to high risk of malnutrition.
Objectives: to evaluate differences between SS patients with moderate to high risk of malnutrition and those with low risk.
Methods: cross-sectional, observational, multicentric study. We included patients with SS according to ACR-EULAR 2013 classification criteria. Patients were classified in groups depending on whether they were in low or moderate-high risk of malnutrition, according to the screening method for detection of adult malnutrition (MUST). Were evaluated: disease duration, disease subtype (limited or diffuse), presence of microstomia, xerostomia, active or past digital ulcers, amputations, arthritis, Rodnan Score, gastroesophageal and bowel involvement, anxiety and depression, and hands functionality by Duruöz Index. Continuous variables were described as median (IQR) or mean (SD) and percentages for categorical variables. Mann Whitney or t-test was used for continuous variables, and Fisher exact test or chi squared for categorical variables. A $p<0.05$ was considered significant. A multivariate analysis was made taking MUST as a dependent variable.
Results: 116 patients were included. Thirty percent were at moderate to high risk of malnutrition. These patients experienced significantly higher frequency of diffuse SS (49% vs 21%, p=0,003), bowel involvement (49% vs 27%. p=0,02), gastroesophageal involvement (74% vs 48%, p=0,009), higher cutaneous involvement (*median* 12 vs 6, p=<0,01), microstomia (40% vs 15%, p=0,003), worst hand functionality (*median:* 11 vs 3, p=0,02), and moderate-severe depression (37% vs 16%, p=0,012). Also, men experienced a higher moderate-high risk of malnutrition (20% vs 6%, p=0,02). In the multivariate analysis, the male sex (OR 4.55, 95% CI 1.11–20, p=0.03), the Rodnan score >9 (OR 3.13, 95% CI, 95% CI, p=0,01), and gastroesophageal involvement (OR 2.87, 95% CI 1.07–7.73, p=0.03), were independently and statistically significant.
Conclusions: These results highlight the importance of assessing the nutritional status of our SS patients.

SAT0358 DECREASED BODY FAT, LEAN BODY MASS AND BONE MINERAL DENSITY IN PATIENTS WITH SYSTEMIC SCLEROSIS ARE ASSOCIATED WITH DISEASE ACTIVITY AND PHYSICAL ACTIVITY

S. Oreska[1], M. Spiritovic[1,2], P. Cesak[2], M. Cesak[2], H. Storkanova[1], K. Kubinova[1], M. Klein[1], L. Vernerova[1], O. Ruzickova[1], H. Mann[1], K. Pavelka[1], L. Senolt[1], J. Vencovsky[1], R. Becvar[1], M. Tomcik[1]. *[1]Department of Rheumatology, 1st Medical Faculty, Charles University, Institute of Rheumatology; [2]Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic*

Background: Systemic sclerosis (SSc) is characterized by fibrosis of the skin and visceral organs, especially digestive tract, and musculoskeletal involvement, which limit mobility/self-sufficiency of patients, and can have a negative impact on body composition.
Objectives: To assess body composition and physical activity of SSc patients and healthy controls (HC).
Methods: 59 patients with SSc (50 females, 9 males; mean age 52.1; disease duration 6.7 years; limited cutaneous (lcSSc,36)/diffuse cutaneous (dcSSc,23)) and 36 age-/sex-matched HC (30 females, 6 males, mean age 51.4) without rheumatic/tumor diseases or manifest cardiovascular event were included. SSc patients fulfilled EULAR/ACR 2013 criteria. Anthropometric parameters and body composition were assessed (by densitometry-iDXA Lunar, and by bioelectric impedance-BIA-2000-M), and physical activity was evaluated using Human Activity Profile (HAP) questionnaire. Routine biochemistry analysis was performed after 8 hours of fasting. Disease activity was evaluated by EUSTAR SSc activity score. Data are presented as mean±SD.
Results: Compared to HC, patients with SSc had significantly lower body-mass index (BMI: 26.4±3.3 vs. 22.4±4.3 kg/m^2, p<0.0001) and body fat % assessed by both iDXA (BF%: 37.2±6.6 vs. 32.6±8.2%, p=0.0014) and BIA (BF%: 31.1±6.4 vs.

24.6±7.8%, p<0.0001), and a trend to decreased visceral fat weight (0.9±0.9 vs. 0.5±0.5kg, p=0.0670). Compared to HC, SSc patients demonstrated significantly decreased lean body mass assessed by both iDXA (LBM: 46.6±7.5 vs. 40.9±6.8kg, p=0.0003) and BIA (LBM: 53.2±8.7 vs. 47.7±7.0kg, p=0.0017), and increased ECM/BCM ratio (extracellular mass/body cell mass: 1.03±0.1 vs. 1.29±0.4, p<0.0001), which reflects worse muscle predispositions for physical exercise, aerobic fitness/performance, and usually increases with deteriorating nutritional status. Compared to HC, SSc patients had significantly lower bone mineral density (BMD: 1.16±0.10 vs. 1.05±0.11g/cm^2, p<0.0001), and were currently able to perform less energetically demanding physical activities according to HAP score (84.7±6.6 vs. 64.1±17.2, p<0.0001). Disease activity negatively correlated with BF% (r=-0.324, p=0.014), and physical activity (HAP) positively correlated with BMD (r=0.276, p=0.034) and negatively with ECM/BCM (r=-0.625, p<0.0001).

Conclusions: Compared to healthy age-/sex-matched individuals we found significant negative changes in body composition of our SSc patients, which are associated with their disease activity and physical activity, and could reflect their nutritional status, and gastrointestinal and musculoskeletal involvement.

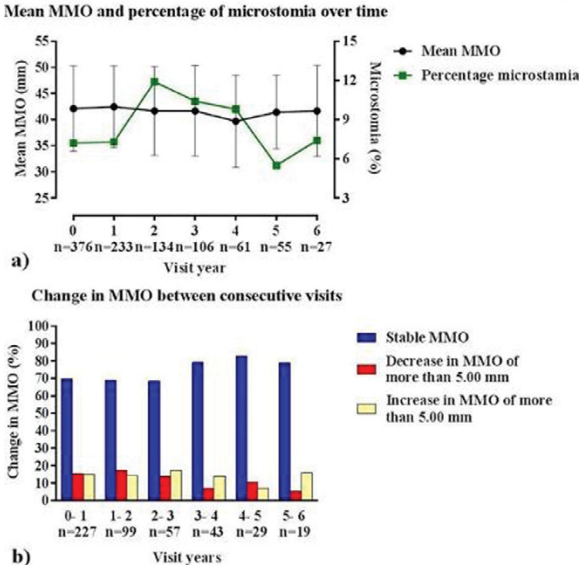
SAT0359 THE COURSE OF MOUTH OPENING AND ITS RELATIONSHIP WITH DISEASE CHARACTERISTICS, GLOBAL FUNCTIONING, HEALTH-RELATED QUALITY OF LIFE AND MOUTH HANDICAP IN PATIENTS WITH SYSTEMIC SCLEROSIS

S.J.H. Khidir[1], M. Boonstra[1], G.W.M. Boerrigter[2], E.M. Voogt-van der Harst[2], S.A. Bergstra[1], M.K. Ninaber[3], N. Ajmone Marsan[4], T.W.J. Huizinga[1], J.K. de Vries-Bouwstra[1]. *[1]Rheumatology; [2]Physiotherapy; [3]Pulmonology; [4]Cardiology, Leiden University Medical Center, Leiden, Netherlands*

Background: Systemic sclerosis (SSc) is a fibrotic disease which can lead to reduced maximal mouth opening (MMO). Previous cross-sectional research showed that reduced MMO in SSc correlated with higher disease severity and lower oral quality of life. Interpretation of interventions that possibly influence MMO is difficult, as the natural history of MMO in SSc is not well described.



Objectives: To evaluate in SSc 1) the course of MMO 2) disease characteristics predictive for decreasing MMO and 3) the relationship between the course of MMO and global functioning, health-related quality of life (HRQoL) and mouth handicap.

Methods: SSc patients from the Leiden Combined Care In Systemic Sclerosis (CCIS) cohort, Leiden University Medical Center were included if at least one MMO measurement was available. Annual clinical assessment includes MMO measurement, global functioning (HAQ), HRQoL (Short Form-36; SF-36), mouth handicap (Mouth Handicap in Systemic Sclerosis scale; MHISS). We assessed mean MMO, prevalence of microstomia (MMO<30.00 mm) and decreasing MMO (decline >5.00 mm/year) over time. Predictors for decreasing MMO were assessed by a linear mixed model (LMM), including baseline clinical parameters reflecting 7 domains (peripheral vasculopathy, skin, heart, gastrointestinal, lung, renal, musculoskeletal). Additionally, MMO over time was correlated with baseline HAQ, SF-36 and MHISS in separate LMMs adjusted for gender, Body Mass Index, age and disease characteristics correlated significantly (p<0.05) with the course of MMO.

Table 1. Multivariate mixed model to determine the association between Maximal Mouth Opening (MMO) and baseline disease characteristics in SSc patients

	β	*p*-value	95% Confidence Interval	
			Lower limit	Upper limit
Non cutaneous SSc (3)			ref	
Limited SSc (2)	-2.2	**0.036**	-4.2	-0.2
Diffuse SSc (1)	-4.1	**0.004**	-6.9	-1.4
Gastrointestinal involvement	-2.6	**0.001**	-4.1	-1.1
Pulmonary involvement	-1.8	**0.032**	-3.4	-0.2
Peripheral vasculopathy	-2.3	**0.003**	-3.8	-0.8

Figure 1 Mean Maximal Mouth Opening (MMO), percentage of microstomia and change in MMO over time in SSc patients

Results: 382 patients were included with mean age 54±14 years, 83% female and 25% diffuse cutaneous SSc. Mean MMO during 6 years of follow-up ranged from 39.4 to 42.5 mm. The annual mean percentage of patients with microstomia was 9%, range 6 to 12% (Figure 1a). A decrease in MMO between two consecutive annual measurements was observed in 5 to 17% of patients, mean 12% (Figure 1b). More extended cutaneous involvement, peripheral vasculopathy, pulmonary and gastrointestinal involvement at baseline were predictive for decreasing MMO over time (Table 1). Baseline HAQ (β=-1.6, 95% CI=-2.7 to -0.6), SF-36 physical component (β=0.1, 95% CI=0.0 to 0.1) and MHISS (β=-0.2, 95% CI=-0.2 to -0.1) correlated with longitudinal MMO.

Conclusions: Over time, MMO is relatively stable in the majority of SSc patients. Microstomia is seen in 9% and important decrease of MMO in 12% and is associated with more severe organ involvement. Even though this concerns only a small subgroup of SSc patients, a significant association with global functioning and HRQoL was demonstrated, underlining the need for treatment strategies improving MMO.

SAT0360 MYOSITIS-SPECIFIC AND MYOSITIS-ASSOCIATED AUTOANTIBODIES IN PATIENT WITH DERMATOMYOSITIS / POLYMYOSITIS; COMPARISON BETWEEN LINE BLOT AND ENZYME-IMMUNOASSAY ASSAYS

S. Nakashima, T. Kameda, M. Izumikawa, H. Shimada, H. Ozaki, R. Wakiya, A. Kondou, N. Kadowaki, H. Dobashi. *Department of Internal medicine, Division of Hematology, Rheumatology and Respiratory Medicine, Kagawa University, Kagawa, Japan*

Background: MESACUP^{TM} test (enzyme-immunoassay assays; TIF1γ, MDA5, Jo-1, EJ, PL-7, PL-12, and KS; MBL) (MESA) is used for a diagnosis of idiopathic inflammatory myopathies (IIMs) in Japan. On the other hand, EUROLINE myositis Profile 3 (line blot; EUROIMMUN) (EURO) can analyze plural Myositis-specific autoantibodies (MSA: Mi-2, Jo-1, SRP, PL-7, PL-12, EJ, OJ) and Myositis-associated autoantibodies (MAA; Ku, PM-Scl) at the same time, which is used commercially in Western countries. However, the difference between utility of MESA and that of EURO haven't be disclosed.

Objectives: To clarify difference between utility of EURO and MESA, and extract the problem of respective examination.

Methods: We enrolled 58 patients diagnosed DM/PM in our facility. Polymyositis (PM) and dermatomyositis (DM) were diagnosed according to Bohan and Peter's criteria.[1)] The MAA and MSA were analyzed using MESA and EURO. In case of MESA (+), MSA (anti-Jo1, anti-PL7, anti-PL12, anti-KS) were identified by specific ELISA. When those results were different, we analyzed by immunoprecipitation. And we analyzed the association between each autoantibody and clinical features.

Results: MSA and MAA were detected in 43/58 (74%) (anti-PL7: 12, anti-Jo1: 7, anti-EJ: 3, anti-PL12: 1, anti-OJ: 0, anti-Ro52: 27, anti-PM-Scl75: 7, anti-Ku: 6, anti-PM-Scl100: 1) by EURO. On the other hand, MSA and MAA were detected in 30/58 (52%) (anti-PL7: 9, anti-Jo1: 7, anti-EJ: 4, TIF1γ: 4, MDA5: 3, U1RNP: 3) by MESA. Five patients were MESA (-) and EURO (-). In the case of ARS positive patient, Two of EURO (-) patients was positive in MESA, respectively Jo1 and EJ. Three of MESA (-) patients was positive in EURO. Although MESA(-) and EURO(+) patients had plural MSA and MAA (PL7+Jo1, PL7+PL12, PL7+Ku), MSA and MAA weren't detected by immunoprecipitation in MESA(-) and EURO(+) patients. Two of patients that detected plural MSA or MAA had rapid progressive ILD.

(Association between clinical manifestations and MSA, MAA)

All patients with anti-ARS (anti-Jo-1, anti-PL-7, anti-PL-12 and anti-EJ) had ILD. In addition, anti-ARS were associated with arthritis and mechanic's hands. Anti-Mi-2 positive patients didn't have ILD. Patients detected anti-PM-Scl75, anti-PM-Scl100, anti-Ku were almost overlap syndrome. All of Anti-SRP positive patients was PM.

Conclusions: EURO is a convenient and reliable method useful for detection of MSA and MAA. It was suggested the patients whom plural antibodies were detected by EURO have unique clinical course in others.

SAT0361 CHEST COMPUTED TOMOGRAPHY AS AN ALTERNATIVE TO HIGH RESOLUTION MANOMETRY FOR THE DIAGNOSIS OF SCLERODERMA ESOPHAGUS

S. Panopoulos, V.K. Bournia, G. Karamanolis, K. Denaxas, A. Zorbala, P.P. Sfikakis. *First Department of Propedeutic Internal Medicine and Joint Academic Rheumatology Program, National and Kapodistrian University, Medical School, Athens, Greece*

Background: Severe esophageal disease in patients with systemic sclerosis (SSc), referred as scleroderma esophagus, is characterized by ineffective or absent peristalsis along with hypotensive esophagogastric junction (hEGJ). The associations between scleroderma esophagus and different clinical and laboratory manifestations of SSc are still controversial.
Objectives: To assess associations between scleroderma esophagus, diagnosed by high resolution manometry (HRM), and other manifestations of disease.
Methods: Fifty-four consecutive SSc patients (49 women, mean age 50.6±11.6 years) with esophageal symptoms underwent clinical interview, medical records review and HRM. HRMs were analyzed according to the Chicago Classification in order to provide esophageal motility diagnosis; EGJ <9 mmHg was considered hypotensive. Demographic characteristics, patient-reported symptoms, SSc subtypes, pulmonary fibrosis, cutaneous ulcers, and anti-Scl-70 positivity were compared between SSc patients with or without scleroderma esophagus. Comparison was also performed in chest computed tomography (CT) findings of esophageal lumen in 26 patients with available data. Esophageal dilatation was deemed present when the diameter was >9 mm.
Results: Absent contractility was present in 37 (68.5%) patients; among these patients hEGJP was found in 32, thus 32/54 (59.2%) patients had classic scleroderma esophagus. There were no associations with gender, age, esophageal symptoms, skin involvement extent, anti-Scl-70, pulmonary fibrosis and cutaneous ulcers. Notably, esophageal dilation on chest CT was more frequent in patients with scleroderma esophagus compared to those without (77% *vs.* 8%, p=0.04, respectively).

Table 1. Associations between scleroderma esophagus and various SSc manifestations

	Scleroderma esophagus (n=32)	No scleroderma esophagus (n=22)	p
Age (yrs)	52. 5±11.9	52. 5±11.9	
Sex (F, %)	28 (87.5)	21 (98.4)	0.362
Diffuse SSc (n, %)	12 (55.5)	14 (43.8)	0.646
Pulmonary fibrosis (n,%)	25 (78.1)	15 (68.1)	0.750
Cutaneous ulcers (n, %)	19 (59.4)	12 (54.5)	0.854
Anti-Scl-70 (n, %)	23 (71.9)	12 (54.5)	0.540
CT coronal diameters >9 cm (n, %)*	10 (76.9)	1 (7.7%)	0.045
Presence of symptoms (%)			
– dysphagia	18 (56.3)	13 (39.1)	0.914
– heartburn	25 (78.1)	21 (95.4)	0.620
– regurgitation	28 (87.5)	19 (86.4)	0.126
– chest pain	13 (56.3)	7 (31.8)	0.653

*Data available in 26 SSc patients (13 with and 13 without scleroderma esophagus).

Conclusions: Scleroderma esophagus diagnosed by HRM was present in less than 2/3 of symptomatic patients with SSc and associated only with esophageal dilation (>9mm) in CT. Although further studies are needed, esophageal dilation on chest CT may be a non-invasive alternative for evaluation of SSc patients with esophageal symptoms.

SAT0362 RISK FACTORS AND OUTCOME OF THAI PATIENTS WITH SCLERODERMA RENAL CRISIS (SRC): A DISEASE DURATION-MATCHED CASE CONTROL STUDY

S. Wangkaew[1], S. Lertthanaphok[1], S. Puntana[1], K. Noppakun[2]. [1]*Rheumatology;* [2]*Nephrology, Chiang Mai University, Chiang Mai, Thailand*

Background: Data regarding the prevalence, risk factors and outcome of scleroderma renal crisis (SRC) in Asian patients with systemic sclerosis (SSc) are limited.
Objectives: To determine the prevalence, risk factors and outcome of SRC in Thai SSc patients.
Methods: Medical records of all SSc patients, fulfilling the 1980 American College of Rheumatology classification criteria for SSc, seen at the Division of Rheumatology, Maharaj Nakorn Chiang Mai Hospital, Thailand, from January 1990 and December 2015 were retrospectively reviewed. Patients younger than 18 years old or overlapping with rheumatoid arthritis, systemic lupus erythematosus or mixed connective tissue disease were excluded. Cases of SRC were identified based on the international Scleroderma Renal Crisis Study criteria[1]. Controls were selected from consecutive SSc patients without SRC from our database that was ranked closest to the cases based on hospital number, and matched for disease duration from the first non-Raynaud's phenomenon, by±1 year. The ratio for SRC patients to control patients was 1:4.
Results: Of 608 SSc patients seen during the study period, 19 SRC were identified resulting of the SRC prevalence of 3.13% and there were 76 matched controls. Of the 19 cases, mean±SD age and median (IQR1, 3) disease duration was 56.2±13.8 years and 9 (5.0, 16.0) months, respectively. Seventeen patients (89.5%) had dcSSc. There were 12 (63.2%) patients with hypertensive renal crisis (HRC) and 7 (16.8%) patients with normotensive renal crisis (NRC). Univariate conditional logistic regression analyses showed that current myositis (Odd ratio [OR]21.75, 95% CI 2.65– 178.71,p=0.004), cardiac involvement (OR5.68, 95% CI2.03 – 15.84,p=0.001), age >60 years (OR2.82,95% CI 1.01 – 7.94,p=0.049), WBC>10,000 cell/mm^3 (OR2.69,95% CI 0.99 – 7.26,p=0.050), serum albumin<3.0 mg/dl (OR11.08,95% CI 3.02 – 40.66,p<0.001), and current prednisolone used≥15 mg/day (OR19.36,95% CI 2.29 – 163.66,p=0.007) were associated with SRC. Digital gangrene tended to show an association with SRC in the univariate analysis (OR8.00,95% CI0.72 – 88.22,p=0.090). Variables with p<0.15 in univariate conditional logistic regression analysis were included in the multivariate conditional logistic regression analysis. When multivariate conditional logistic regression analysis was performed, digital gangrene (adjusted odd ratio [AOR]31.41,95% CI 1.16 – 852.23,p=0.041), current prednisolone use≥15 mg/day (AOR31.22, 95% CI 1.59 – 613.85,p=0.024), serum albumin <3 mg/dl (AOR7.97, 95% CI 1.49 – 42.56,p=0.015) and cardiac involvement (AOR 6.62,95% CI1.08 – 40.63,p=0.041) were confirmed to be independent risk factors for SRC. During a median (IQR 1, 3) follow-up of 1 (0, 2) months, 15 (78.9%) patients required hemodialysis, including 9 of 12 (75.0%) patients with HRC and 6 of 7 (85.7%) with NRC. Twelve (63.2%) patients received ACEI, including 9 of 12 (75.0%) patients with HRC and 3 of 7 (42.9%) patients with NRC. Ten (52.6%) patients died, including 5 of 12 patients (41.7%) with HRC and 5 of 7 (71.4%) patients with NRC.
Conclusions: SRC was an uncommon complication in Thai patients with SSc, but associated with high mortality. Digital gangrene, current prednisolone used≥15 mg/day, serum albumin<3 mg/dl and cardiac involvement were independent risk factors of SRC.

SAT0363 INTERSTITIAL LUNG DISEASE IN IDIOPATHIC INFLAMMATORY MYOPATHIES: A REPORT FROM THE REMICAM REGISTRY

T. Cobo-Ibáñez[1], F.J. López-Longo[2], B. Joven[3], V. Maldonado[4], I. Llorente[5], C. Barbadillo[6], A. Gómez Gómez[7], L. Barrio Nogal[8], R. Almodóvar[9], L. Lojo[10], L. Ruiz[11], M.J. García de Yébenes[12], L. Nuño[13] on behalf of REMICAM. [1]*H. Infanta Sofía, Universidad Europea;* [2]*H. Gregorio Marañón;* [3]*H. Doce de Octubre;* [4]*H. Ramón y Cajal;* [5]*H. la Princesa;* [6]*H. Puerta de Hierro;* [7]*H. HM Sanchinarro;* [8]*H. Príncipe de Asturias;* [9]*H. Fundación Alcorcón;* [10]*H. Infanta Leonor;* [11]*H. Niño Jesús;* [12]*Instituto de Salud Musculoesquelética;* [13]*H. la Paz, Madrid, Spain*

Background: Interstitial lung disease (ILD) in idiopathic inflammatory myopathies (IIM) may appear at any time in evolution and is associated with a worse prognosis.
Objectives: To investigate sociodemographics data and clinical characteristics of patients with IIM and ILD from the REMICAM registry.
Methods: A multicenter retrospective study (1980–2014) was performed. Patients were classified as polymiosytis (PM), dermatomyositis (DM), IIM with anti-synthetase antibodies (AB) and overlap syndrome. In addition, ILD was classified according to HRCT pattern: usual interstitial pneumonia (IP), non specific IP, organizing pneumonia, and acute IP. We compared sociodemographic data, clinical characteristics, AB and treatments of patients with and without ILD, patients with ILD according to subgroup of myositis or ILD.
Results: 478 patients were included, of whom 129 (27%) had ILD. Patients with ILD had a higher age at diagnosis, ESR and CRP and worse initial respiratory function. They were characterized by increased frequency of arthritis, systemic and cardiac manifestations, Raynaud, cardiovascular disease, pulmonary hypertension, ischemic ulcers, sclerodactyly and anti-synthetase AB (p<0.001). The differences among patients with ILD were: less arthritis in PM, greater frequency of Raynaud and sclerodactyly in overlap and antisynthetase syndrome, more anti-RNP AB in the overlap syndrome, more anti-synthetase and anti-Ro AB in the antisynthetase syndrome, and a higher prevalence of cutaneous signs and mechanical hands in DM (p<0.001). There were no differences according to the type of ILD or treatments.
Conclusions: We found some clinical manifestations and AB that may help for detection of patients with IIM associated to ILD, as well as clinical manifestations to better differentiate myositis subtypes in patients with ILD.

SAT0364 HISTORY OF DIGITAL ULCERS IN PATIENTS WITH SYSTEMIC SCLEROSIS IS ASSOCIATED WITH PERIPHERAL VASCULOPATHY AS ASSESSED BY VIDEOCAPILLAROSCOPY AND 22-MHZ POWER DOPPLER ULTRASONOGRAPHY

T. Schioppo[1,2], A. Orenti[1,3], P. Boracchi[1,3], O. De Lucia[2], A. Murgo[2], P.L. Meroni[1,2], F. Ingegnoli[1,2] on behalf of OPERA study group. [1]*Università degli Studi di Milano;* [2]*ASST Pini-CTO;* [3]*Lab of Medical Statistics, Epidemiology and Biometry GA Maccacaro, Milan, Italy*

Background: Vasculopathy is considered a primary pathogenic event in systemic

sclerosis (SSc) and it substantially contributes to prominent features of the disease such as digital ulcers (DUs). History of DUs (HDUs) has been shown to correlate with disease severity, new cardiovascular events, new DUs and overall poor prognosis [1]. Microvascular abnormalities as assessed by nailfold videocapillaroscopy (NVC) and power Doppler ultrasound (PDUS) have been demonstrated to be predictive of new DUs occurrence [2,3].

Objectives: To study the severity of microvascular involvement at the 3rd and 4th finger of the dominant hand in patients with SSc with or without HDUs as assessed by NVC and 22-MHz PDUS.

Methods: 100 SSc consecutive patients fulfilling the 2013 EULAR classification criteria were enrolled. PDUS was performed at the 3rd and 4th finger of the dominant hand after exclusion of ulnar artery occlusion (UAO). In case of UAO non-dominant hand was examined. Ultrasound investigation was performed with Esaote MyLab 70 XVG by means of linear array transducer (10–22 MHz). Power Doppler settings were standardized (Doppler frequency 14.3 MHz, Gain 55%, PRF 750 Hz). PDUS measurements included sagittal scan of nailbed and fingertip qualitatively graded from 1 (no signal) to 4 (marked hyperemia) [4], and resistivity index (RI) of ulnar and radial proper digital arteries. Capillary density (number/mm) was calculated by NVC with magnification 200X performed on two images of the same digits examined by PDUS.

Results: 100 SSc patients, 87 (87%) women, 86 (86%) limited cutaneous SSc, median age 62.2 years old, median disease duration 8 years were evaluated. 7 (7%) patients had UAO. 33 (33%) had HDUs among them 23 had experienced more than one DUs and 2 had active DUs at the moment of evaluation. Semiquantitative perfusion score of sagittal scan of nailbed and fingertip were not significantly associated with the presence of HDU. RI and capillary density were significantly different in the two groups as shown in the table below:

	Presence of HDUs	Absence of HDUs	Mean difference (95% CI)
Capillary density	3.023	3.884	-0.862 (-1.390, -0.333)
RI	0.740	0.792	-0.052 (-0.090, -0.014)

Conclusions: A significant lower RI of ulnar and radial proper digital arteries reported in patient with HDUs is novel. By contrast PDUS grading of nailfold and fingertip were not significantly different in patients with or without HDUs. The finding of a significant lower capillary number assed by NVC in patients with HDUs is consistent with previous results [2]. Adequately longitudinal studies exploring the predictive value of PDUS parameters are required to fully ascertain its role in SSc.

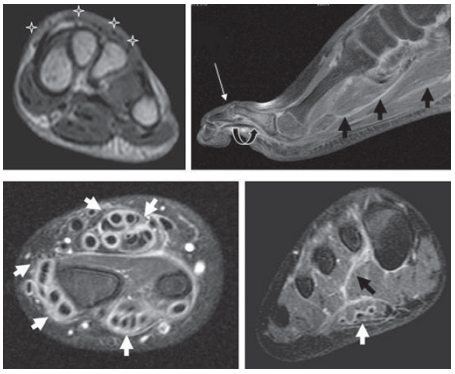
SAT0365 MUSCULOSKELETAL US AND MRI FINDINGS IN JUVENILE SCLERODERMA



M. Tsinti, V. Dermentzoglou, E. Tsitsami. *Pediatric Rheumatology Unit, 1st Department of Pediatrics, University of Athens, Children's Hospital "Aghia Sofia", Athens, Greece*

Background: Musculoskeletal (MS) involvement and clinically evident arthritis occurs in up to 65% of patients with Juvenile Systemic or localized Scleroderma (JSc). It may be the first manifestation preceding even the onset of Raynaud or skin manifestations; patients presenting with arthritis, tenosynovitis or enthesistis may suffer from Sc. On the other hand clinical examination often underestimates MS involvement in Sc. US and MRI can help distinguish arthritis with effusion from dry tenosynovitis of Sc, define whether loss of range of motion (LOM) derives only from skin thickening or from bone and joint involvement and monitor disease progression.

Objectives: To describe the spectrum of MRI and US features in juvenile scleroderma with musculoskeletal involvement.

Methods: We describe MRI and color Doppler MSUS findings of clinically affected (with arthritis and/or LOM and/or overlying skin with edema or sclerosis) lower or upper extremities from 4 males and 2 females;2 with systemic sc (ssc), 2 with linear scleroderma, 1 with generalized morphea, 1 with mixed morphea (median age 8,5 years, range 7–10,5; median time from symptom onset to MRI 11 months, range 2–24). MRI sequences;T1, fluid-sensitive, and T1-FS contrast-enhanced. Comparisons were made to uninvolved areas of the extremity, and the contralateral extremity. Findings guiding diagnosis and evaluation of disease extent are depicted in the Figure.

Results: Thickening of the dermis and infiltration of the subcutaneous fat with increase in signal intensity on fluid sensitive sequences and contrast-enhanced T1w images and hypointense signal lesions on unenhanced T1w images (asterisks) was apparent in 4 patients. In 2 male patients with generalized scleroderma, clinical LOM of fingers and wrists preceded skin sclerosis by 2 months. Joint and tendon sheath synovitis, indicated by initial MSUS, was detected in fluid sensitive and T1w enhanced images (white arrows). The combination of tendon-sheath synovitis and muscular fascia thickening and enhancement (black arrows), and contractures (thin white arrow) very characteristic of scleroderma, helped identify sclerodermatous musculoskeletal involvement in the absence of skin induration. Focal bone marrow edema depicted as high signal intensity in fluid sensitive sequences (curved arrow) was found in 2 cases; 1 with generalized morphea without apparent overlying skin sclerodermatous lesion, 1 with linear scleroderma with atrophic lesions in all overlying structures

Conclusions: Musculoskeletal imaging features of juvenile scleroderma involving the skin, fascia, musculature and bones reflect pathomorphologic changes of this rare disorder and enable a complete assessment of the disease extent, including depth of infiltration and disease activity.In the described cases implementation of MSUS and MRI in Juvenile scleroderma led to earlier definition of the diagnosis and assisted the evaluation of disease extension.

SAT0366 SMOKING BEHAVIOUR AND THE PROGRESSION OF ORGAN MANIFESTATIONS IN SYSTEMIC SCLEROSIS: A LONGITUDINAL EUROPEAN SCLERODERMA TRIALS AND RESEARCH GROUP STUDY

V.K. Jaeger[1], G. Valentini[2], E. Hachulla[3], L. Czirják[4], E. Siegert[5], O. Distler[6], L.M. Bambara[7], E. Rosato[8], Y. Allanore[9], M. Matucci-Cerinic[10], P. Airó[11], U. Walker[1] on behalf of EUSTAR co-authors. *[1]University Hospital Basel, Basel, Switzerland; [2]Second University of Naples, Naples, Italy; [3]Université de Lille, Lille, France; [4]University of Pécs, Pécs, Hungary; [5]University Hospital Charité, Berlin, Germany; [6]University Hospital Zurich, Zurich, Switzerland; [7]University of Verona, Verona; [8]Sapienza University of Rome, Rome, Italy; [9]Paris Descartes University, Paris, France; [10]University of Florence, Florence; [11]Spedali Civili, Brescia, Italy*

Background: Systemic sclerosis (SSc) is a rare, multisystem autoimmune disorder. It is characterised by generalized microangiopathy, in which hypoxia and oxidative stress have been implicated in its pathogenesis. Tobacco inhalation increases free radicals and strongly promotes vascular damage. So far, data available with regards to a role of tobacco exposure with SSc severity and progression are scarce.

Objectives: We aimed to assess the effects of smoking on the speed of worsening of organ manifestations, namely lung involvement (forced vital capacity, FVC; forced expiratory volume, FEV1/FVC ratio; diffusing capacity for carbon monoxide corrected for alveolar volume, DLCO/VA), skin involvement (modified Rodnan skin score; mRSS), and digital ulcers (DU) in the European scleroderma trials and research (EUSTAR) database.

Methods: Adult SSc patients from the EUSTAR cohort with a follow-up visit 12±4 months after their baseline visit and available data on their smoking habits were included.

The associations of smoking behaviour (never smokers *vs* ex-smokers *vs* current smokers) with the disease manifestations at follow up were assessed after adjusting for potentially confounding covariates using multivariable linear or logistic regression analyses.

Missing data were imputed using multiple imputations.

Results: Of the 3,023 patients included (mean age 57 years, SD 13; 85% female), 66% stated that they never smoked, 23% were ex-smokers and 11% were current smokers. On average, ex-smokers had smoked for 19.5 years (SD 12) while current smokers smoked for 29.1 years (SD 13). Ex-smokers had smoked on average 17.3 pack-years (SD 20) and current smokers 29.3 pack-years (SD 36). The mean time since smoking cessation in ex-smokers was 15.8 years (SD13).

The FEV1/FVC ratio changed from 96.3 (SD 14) at baseline to 96.2 (SD 13) at follow up. Taking into account the effect of age, sex, autoantibody status, disease duration and SSc subset as well as the baseline values of the outcome, the FEV1/FVC ratio decreased faster in currently smoking SSc patients than in never smokers (β=-2.8, p=0.001). Similarly, the DLCO/VA diminished faster in current

smokers (β=-3.7, p=0.006) while on average the DLCO/VA decreased from 78.1 (SD 18) to 76.5 (SD 17). Changes in FVC were however not associated with smoking behaviour (p=0.13).
The mRSS changed between baseline and follow-up from an average of 7.6 (SD 7) to 7.3 (SD 7); on average, in smokers the mRSS improved faster than in never smokers (β=-0.65, p=0.015). The presence of DUs at follow-up was not associated with current smoking (p=0.9).
Having previously smoked was not significantly associated with the progression of any of the assessed outcomes.
Conclusions: Although the adverse effects of smoking on bronchial airways that is known in the general population could be replicated in the SSc population, the lack of a measurable adverse effect of smoking on SSc organ manifestations argues against a major role of tobacco associated free radicals and vasoconstriction in the pathogenesis of SSc vasculopathy and fibrosis.

SAT0367 CAPILLAROSCOPY PATTERNS AMONG SYSTEMIC SCLEROSIS PATIENTS WITH GASTROINTESTINAL INVOLVEMENT AND MALNUTRITION EVALUATED BY SELF-REPORTED QUESTIONNAIRES

Y. Yalçınkaya, Z. Ertürk, A.U. ÜNal, S. Kaymaz, P. Atagündüz, H. Direskeneli, N. Inanç. *Department of Internal Medicine, Division of Rheumatology, Marmara University, School of Medicine, Istanbul, Turkey*

Background: Gastrointestinal system (GI) is commonly involved in systemic sclerosis (SSc) beginning after early stages of disease.
Objectives: We aimed to investigate capillaroscopic findings among the SSc patients with GI involvement and malnutrition.
Methods: GI involvement was evaluated by UCLA SCTC GIT 2.0 questionnaire (Khanna D.) (7 multi-item; reflux, distension, soilage, diarrhea, social functioning, emotional wellbeing and constipation) in SSc patients ACR/EULAR classification criteria (2013). To report the nutrition status of the patients “malnutrition universal screening tool (MUST)” (sum of the scores of body mass index, weight loss in last 3–6 months and acute disease effect) scores were calculated. Simultaneously, nail fold video-capillaroscopy (NVC) was performed in all paatients to deterimine ealy, active late scleroderma patterns (Cutalo et al.).
Results: In 58 SSc patients (51 female); the mean age, duration of Raynaud’s, non-Raynaud symptom (year) and follow-up (month) were 46±13, 54±50, 10±9 and 7±7, respectively. Limited cutaneous form, positive ANA and anti-Scl70, telangiectases, dysphagia, digital ulcers, lung disease were found in 40 (71%), 48 (83%) and 21 (36%), 45 (78%), 39 (67%), 33 (57%), 23 (40%) in patients, respectively. Of the NVC patterns, early was found in 16 (28%), active was in 11 (19%), late was in 28 (48%) and normal in 3 (5%). The scores of disease activity, severity and GI were shown to be higher in patients with late NVC pattern (table-1). Of the patients with MUST score of >0 (n=10), 9 had late and 1 had early NVC pattern.

Table 1. The scores of disease activity and severity and UCLA SCTC GIT 2.0 in SSc patients

	NVC (early)	NVC (active)	NVC (late)	p
Modified Rodnan skin score	4,3±5,1	8,3±6,9	*12,3±7,5*	P=0,001*
Telangiectasia score (Shah)	2,3±2,4	4,6±1,9	*6±3,5*	P<0,001*
Disease activty score (Valentini)	0,9±0,9	1,1±1,2	*1,9±1,2*	P=0,014*
Disease severity score (Medsger)	3,4±2	4,6±3	*6,5±2,6*	P=0,001*
UCLA SCTC GIT 2.0	0,063±0,111	0,259±0,288	*0,353±0,327*	P=0,002*
Reflux	0,263±0,415	0,500±0,509	*0,874±0,667*	P=0,002*
Distension	0,118±0,357	0,296±0,498	0,564±0,881	NS
Soilage	0±0	0±0	0,107±0,315	NS
Diarrhea	0±0	0,500±0,741	0,268±0,552	NS
Social functioning	0±0	0,105±0,237	0,184±0,406	NS
Emotional wellbeing	0,011±0,050	0,211±0,372	0,118±0,308	NS
Constipation	0,184±0,380	0,159±0,322	0,259±0,469	NS

*Bonferroni, NS = not significant.

Conclusions: This SSc cohort predominantly had limited cutanous disease and vascular manifestations. In patients with late scleroderma pattern, severity of GI was higher similar to disease activity and severity. Undernutrition was frequently seen in patients with late pattern. NVC might be useful to predict the severity of GI and malnutrition and allow to direct the patients to required procedures earlier.

SAT0368 THE PREVALENCE OF OSTEOMYELITIS IN INFECTED DIGITAL ULCERS IN SYSTEMIC SCLEROSIS PATIENTS

Y. Braun-Moscovici [1], Z. Keidar [2], M. Braun [3], D. Markovits [1], K. Toledano [1], Y. Tavor [1], F. Sabbah [1], A. Rozin [1], K. Dolnikov [1], A. Balbir-Gurman [1]. *[1] Rheumatology Department, Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion; [2] Department of Nuclear Medicine, Rambam Health Care Campus Rappaport Faculty of Medicine Technion, Haifa; [3] Liver Institute, Beilinson Hospital Petach-Tikva, Sackler School of Medicine, Tel Aviv University, Petach-Tikva, Israel*

Background: Skin ulcers, particularly digital ulcers occur in at least 50% of systemic sclerosis (SSc) patients (pts) and cause significant morbidity. They are often complicated by local infection which can lead to contiguous osteomyelitis.
Objectives: Our aims were to evaluate the accuracy of clinical diagnosis of osteomyelitis and to assess whether there are clinical parameters that may improve the precision of the clinical diagnosis.
Methods: We retrospectively analyzed the clinical data of consecutive SSc patients hospitalized for skin ulcers in a tertiary referral center for SSc. Our cohort is part of the EUSTAR cohort. The patients were evaluated by rheumathologists skilled in managing SSc skin lesions. All the patients with infected ulcers and suspected for contiguous involvement of underlying bone had bone scans. All the positive scans were followed with 99m-Technetium-Tc-labeled white blood cells (WBC) scintigraphy, in order to differentiate true osteomyelitis from acro-osteolysis or soft tissue infection. We collected demographic data, disease type, extent and severity, routine lab data (CBC, C-reactive protein -CRP, erythrocyte sedimentation rate (ESR), alkaline phosphatase (ALKP), albumin) and wound culture. Each hospitalization was considered a separate event. Statistical analysis: descriptive, student’s T test, Mann-Whitney test.
Results: During the years 2003–2016, 220 SSc pts with skin/digital ulcers were hospitalized in our department for ilomedin treatment (993 hospitalizations). Most of the pts were hospitalized several times due to recurrent ulcers. Tc bone scan was performed in 39 pts (59 admissions) with infected ulcers (32 females, mean (SD) age 48 (15), disease duration 9 (6.6) years, 25 with diffuse SSc, skin score (MRSS) 9.9 (8)). Osteomyelitis was confirmed in 18 pts on 23 occasions. Osteomyelitis occurred twice in 5 pts in different locations. No statistically significant differences were found between the group with positive scans and the group with negative scans regarding demographic, clinical and lab data. 9 pts had 25 admissions for infected ulcers, osteomyelitis was confirmed in 14 of the admissions. No statistically significant differences were found for CBC ESR CRP ALKP between the osteomyelitis events and superficial infected ulcer admissions in these pts. The causative infectious agents were similar between the 2 groups. Positive bone and WBC scans confirmed osteomyelitis in 39% of clinical suspected cases. WBC scans confirmed osteomyelitis in 75% or the patients with positive Tc bone scans.
Conclusions: The prevalence of osteomyelitis among our SSc pts admitted for digital ulcers was 10%. The prevalence of confirmed osteomyelitis by scintigraphy in clinically highly suspected cases was 39%. Even when contiguous osteomyelitis was suspected by highly skilled rheumathologists, bone scan ruled out the diagnosis in 61% of the cases, thus avoiding unnecessary prolonged antibiotic therapy. No clinical predictors to rule osteomyelitis in or out could be identified.

SAT0369 HETEROGENEITY IN THE UNDERLINING PATHOGENESIS IN PATIENTS WITH CONNECTIVE TISSUE DISEASE-ASSOCIATED BORDERLINE MEAN PULMONARY ARTERIAL PRESSURE AND ITS DISTINCTIVE HEMODYNAMIC CHARACTERISTICS FROM THOSE WITH NORMAL PULMONARY ARTERIAL PRESSURE

Y. Yamasaki [1], Y. Asari [1], K. Tsuchida [1], K. Suzuki [2], Y.J. Akashi [2], T. Okazaki [2], S. Ozaki [1], H. Yamada [3]. *[1] Rheumatology and Allergology; [2] Cardiology, St. Marianna University School of Medicine, Kawasaki; [3] Medical Center for Rheumatic diseases, Seirei Yokohama Hospital, Yokohama, Japan*

Background: Borderline mean pulmonary artery pressure (PAP) (21–24 mmHg) may comprise a transition phase from normal pulmonary hemodynamic condition to pulmonary arterial hypertension (PAH), which is one of the fatal complications in connective tissue diseases (CTD) [1]. The accumulated evidence is not enough to conclude that treatment for PAH in this stage may be associated with improving clinical outcomes. On the other hand, CTD-associated PH is caused by various cardiopulmonary comorbidities. It is possible that borderline mean PAP, like overt PH, is caused not only by pulmonary vasculopathy but also by cardiac and pulmonary complications [2].
Objectives: To clarify whether patients with borderline mean PAP associated with CTD have distinctive hemodynamic characteristics from those with normal mean PAP and its underlining pathogenesis is heterogeneous as those with manifest PH.
Methods: We retrospectively investigated 76 CTD patients who underwent right heart catheterization from 2008 through 2016. Of the 76 patients, 25 (33%) and 16 (21%) had manifest PH and borderline mean PAP, respectively. The rest of the 35 patients had normal mean PAP. Systemic sclerosis was the most common

CTD among the enrolled patients (61%), followed by MCTD (16%). Hemodynamic characteristics and findings after exercise echocardiography in patients having normal mean PAP, borderline mean PAP, and PH were compared. We also determined the validity of therapeutic intervention.

Results: The values of tricuspid regurgitation pressure gradient (TRPG) were comparable between patients with borderline (31.1±7.8 mmHg) and normal mean PAP (28.3±6.9 mmHg) (P=0.1572) but its value became significantly higher in patients with borderline mean PAP (39.1±8.0 mmHg) than in those with normal mean PAP (32.8±7.4 mmHg) after exercise echocardiography (P=0.0391). Pulmonary arterial wedge pressure was significantly elevated in patients with borderline mean PAP (12±3 mmHg) compared with that in normal mean PAP (7±3 mmHg) ($P<0.0001$) and its value was comparable to those with overt PH, suggesting the heterogeneity on the cause of borderline mean PAP among CTD patients. The clinical course of 10 patients with borderline mean PAP was studied. Five were treated for precapillary disease, 3 for postcapillary disease, and 2 for interstitial lung disease (ILD). Normalization of mean PAP was seen in 3/4 and 3/3 of the patients treated for precapillary and postcapillary disease, respectively. Deterioration of TRPG was seen in one patient after receiving pulmonary vasodilators. One with severe ILD developed PH.

Conclusions: The pathogenesis of borderline mean PAP, clearly distinctive from normal mean PAP, was heterogeneous as that of manifest PH in CTD patients. Though the clinical course may be altered with appropriate therapeutic intervention, repeated assessment is needed.

SAT0370 EVALUATIONS OF EXERTION DYSPNEA IN PATIENTS WITH CONNECTIVE TISSUE DISEASE (CTD) BY CPET (CARDIOPULMONARY EXERCISE TESTING) FOR EARLY DETECTING ASSOCIATED PULMONARY HYPERTENSION (APAH)

Y. Nobuhara, Y. Kamei, Y. Fujikawa, T. Nakazawa. *Rheumatology, Osaka saiseikai nakatsu hospital, Osaka, Japan*

Background: Patients with CTD often complain of exertion dyspnea, due to lung diseases, heart diseases, musculoskeletal disorders and/or APAH. Although imaging and physiological tests could reveal pathophysiology, some of them remain unknown. Especially APAH is rarely diagnosed in WHO functional class I or II, because pulmonary vasculopathy (PV) cannot be detected until two-thirds of pulmonary blood vessels deteriorated, [1] with cardiac ultrasonography (UCG) or right heart catheterization (RHC) at rest. Pathophysiological considerations suggest that the haemodynamic/metabolic impairment in APAH may be observed during exercise before the disease becomes evident at rest.[2–3] We evaluated exertion dyspnea of unknown to find out early APAH with CPET.

Objectives: We performed CPET in patients who complained of exertion dyspnea and tried to detect early PV.

Methods: From June 13th in 2015 to October 28th in 2016, we performed CPET and evaluate their clinical state in 28 patients, 17–80 years 2 males/26 females, 5 mixed connective tissue disease (MCTD), 15 SSc, 3 SLE, 2 Sjögren's syndrome, 3 dermatomyositis. They underwent UCG, pulmonary function testing (PFT), 6-minutes walk test, and nailfold capillaroscopy by Cutolo's method.[4]

Results: Twenty cases presented decreased peak VO2. VE/VCO_2 ratio, which represent increased ventilation-perfusion mismatch, elevated in 12 cases. 8 cases, with decreased peak VO2 but normal VE/VCO_2, were regarded that muscle weakness mainly induced exertion dyspnea, and advised exercise. Twelve cases with decreased peak VO2 and elevated VE/VCO_2 were estimated to have APAH or/and interstitial lung disease (ILD). Seven of them underwent RHC and 1 case diagnosed as definite APAH, and another 1 case as post capillary PH.

A 34 years MCTD woman without ILD showed an active capillaroscopic pattern, her peak VO2 decreased (13.9ml/kg/min.) and nadir VE/VCO_2 elevated (39). Although her mean PAP was normal, we suspected she had early PV and administered PDE5 inhibitor to her and her dyspnea had gone soon and CPET parameters improved.

CPET was also useful for early detections of therapeutic gains in APAH. A SSc woman, diagnosed as APAH by RHC, was performed CPET only 9 days after administration of PDE5 inhibitor. Her peak VO2 elavated (13.3 to 15.4 ml/kg/min.) and nadir VE/VCO_2 decreased (43.4 to 38.9) promptly.

Thirteen patients showed an early capillaroscopic pattern, 7 an active pattern and 3 a late pattern. Median values of minimum VE/VCO_2 ratio significantly differed ($p<0.05$) in the three capillaroscopic groups, being progressively worse from early to late capillaroscopic pattern.

Conclusions: We performed CPET in every patient safely. Although more research is required, CPET may provide valuable information notably in APAH patients.

SAT0371 BONE FRACTURE RISK ASSESSMENT IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES: RESEMBLANCES TO RHEUMATOID ARTHRITIS

Z. Griger, A. Vincze, K. Szabó, J. Gaál, K. Dankó. *Division of Clinical Immunology, Department of Internal Medicine, University of Debrecen, Debrecen, Hungary*

Background: Idiopathic inflammatory myopathies are chronic, heterogeneous systemic autoimmune diseases with symmetrical proximal muscle weakness. During the disease course, osteoporosis and bone fractures are more common compared to the healthy population, which can be explained by the chronic inflammation, immobilization, spontaneous falls and steroid treatment, and affect crucially the patients' quality of life. Recently, a WHO fracture risk calculation tool, FRAX score is available, to measure the 10-year probability of osteoporotic fractures. It takes into account relevant clinical risk factors, such as rheumatoid arthritis, however myositis does not exist among the risk factors.

Objectives: Estimation the effect of myositis and myositis related bone mineral densities on bone fracture risk calculated by FRAX tool.

Methods: FRAX score was determined in 71 patients with idiopathic inflammatory myopathies and results were compared with the data from 50 age, sex and BMI matched patients with rheumatoid arthritis. Moreover, osteoporosis related biomarkers, disease related fractures and bone mineral densities were determined using DXA examinations. Statistical analysis was performed with IBM SPSS 20.0 software.

Results: There were no significant differences between the demographical data, biomarkers (Ca, Vitamin D, parathormone level) of the two groups. Disease duration and cumulative steroid dose were higher in the myositis group. Results of the FRAX score without BMD were significantly lower in the patients with myositis, in both fracture risk: major osteoporotic (8,61±6,36%, vs. 15,59±12,66%; p: 0,002) and femur neck (2,66±3,24%, vs. 6,34±9,018; p: 0.003). T score results of the DXA examination were not significantly different between the two populations (Lumbar1–4: -0,9±1,43 vs.-0,829±1,38; p:0,829; Femoral neck: -1,4±1,08 vs. -1,02±1,08; p: 0,93), but the presence of osteopenia (60% vs. 39,5%) and osteoporosis (13,5% vs. 7%) were more frequent in the myositis group (p: 0,045). Disease related fracture was associated with disease duration in the myositis group and with antibody (RF, ACPA) presence in the RA group. FRAX score with BMD results showed no significant differences between the two populations (Major osteoporotic: 9,44±6,72 vs. 13,25±9,43; p: 0,053; Hip: 2,77±3,01 vs. 3,57±5,08; p: 0,811).

Conclusions: As far as we know, this is the first study which examine the fracture risk using FRAX score in patients with idiopathic inflammatory myopathies. According to our data, we can conclude that existence of myositis might indicate similar, independent risk factor in fracture probability, like rheumatoid arthritis. Evaluation of fracture risk should be done with DXA result in patients with IIM, otherwise risk could be underestimated. An exact value of the "myositis related risk" could be determined by a 10-year prospective study.

SAT0372 CLINICAL AND SEROLOGICAL ASSOCIATIONS OF AUTOANTIBODIES TO BICD2 AS A NOVEL MARKER FOR SYSTEMIC SCLEROSIS

M. Mahler[1], C. Bentow[1], J. Milo[1], M. Hudson[2], H.-D. Zucht[3], P. Budde[3], D. Wirtz[3], J. Schulte-Pelkum[3], M. Choi[4], M. Fritzler[4]. *[1]Research and Development, Inova Diagnostics, San Diego, CA., United States; [2]Department of Medicine, McGill University, Quebec, Canada; [3]Protagen, Dortmund, Germany; [4]Cumming School of Medicine, University of Calgary, Calgary, Canada*

Background: Anti-nuclear antibodies (ANA), which are present in approximately 90% of systemic sclerosis (SSc) patient's sera, play an important role in establishing the diagnosis and predicting prognosis of SSc. Recently, a novel autoantibody has been described in SSc patients targeting Cytoskeleton-Like Bicaudal D Protein Homolog 2 (BICD2).

Objectives: The aim of this study was to assess the prevalence and titers of anti-BICD2 antibodies in SSc and controls and to study the clinical associations of this new antibody.

Methods: A total of 502 samples from SSc patients enrolled in the Canadian Scleroderma Research Group (CSRG) cohort were included in this study. Clinical associations were assessed either as anti-BICD2 antibody positivity

with and without other autoantibodies present using 451 SSc patients with complete dataset. Autoantibodies to several scleroderma-related autoantibodies were detected using commercial or research use only kits (Inova Diagnostics, San Diego, USA). P-values below 0.05 were considered significant.

Results: The sensitivity and specificity of anti-BICD2 antibodies were determined as 22.1% and 99.0%, respectively. Receiver operating characteristic (ROC) analysis showed an area under the curve of 0.79 (95% CI 0.75–0.84). The likelihood (LR) and odds ratios (OR) were 17.7 (LR+), 0.8 (LR-) and 20.4 (OR). The prevalence of these autoantibodies was equally distributed between limited and diffuse form of SSc (22.8% and 24.0%). When SSc patients without the classification criteria markers anti-Scl-70, anti-Centromere and anti-RNA Pol III (n=184) were compared with controls, similar performance was obtained as seen in the entire cohort. Results are summarized in table 1 below.

Table 1

Performance Characteristic	Entire SSc cohort (n=502)	Anti-Scl-70, anti-Centromere and anti-RNA Pol III negative (n=184)
Sensitivity	22.1%	13.6%
Specificity	99.0%	99.0%
AUC	0.79 (95% CI 0.75–0.84)	0.78 (95% CI 0.72–0.84)
LR+	28.1	15.6
LR-	0.21	0.13
OR	133.1	123.7

Several statistically relevant clinical associations were found for anti-BICD2 as summarized in table 2 below.

Conclusions: Our data confirm the presence of anti-BICD2 antibodies in SSc patients that may help to differentiate SSc from other systemic autoimmune rheumatic diseases and to stratify SSc patients into more defined subforms of the disease.

SAT0373 EVALUATION OF AMERICAN COLLEGE OF RHEUMATOLOGY PROVISIONAL COMPOSITE RESPONSE (CRISS) INDEX IN THE FASSCINATE TRIAL

D. Khanna[1], V. Berrocal[1], C. Denton[2], A. Jaheris[3], H. Spotwood[4], C. Lin[3], J. Siegel[3], D. Furst[5]. *[1]Univ Michigan, Ann Arbor, United States; [2]UCL, London, United Kingdom; [3]Genentech, San Francisco, United States; [4]Roche, Welwyn Garden, United Kingdom; [5]UCLA, Los Angeles, United States*

Background: Treatment with tocilizumab (TCZ) in early systemic sclerosis (SSc; FaSScinate trial) resulted in consistent, but not statistically significant, improvements in skin sclerosis (mRSS) at wks 24 and 48[1]. The CRISS index has been proposed as a composite index for trials in SSc[2]. CRISS is a 2-step process that assigns a probability of improvement for each subject ranging from 0.0 [no improvement] to 1.0 [marked improvement]. Step 1 assesses clinically meaningful decline in cardio-pulmonary-renal involvement and assigns a probability of 0.0. For remaining subjects, 5 variables are used to calculate probability of improvement. These are: FVC%, mRSS, patient (PT GA) and physician globals (MD GA), and HAQ-DI.

Objectives: To assess the performance of CRISS index in the FaSScinate trial.

Methods: In FaSScinate, pts ≥18 y with active SSc were randomized 1:1 to TCZ or placebo (PLA) for 48 wks. Step 1 CRISS was captured using review of serious adverse event data. Non-parametric Wilcoxon test was used to assess significant differences between the CRISS scores in both arms. Analyses were carried out for subject who had complete data at baseline and 24 weeks and at baseline and 48 weeks.

Results: 87 pts (43 TCZ, 44 PBO) were enrolled. Baseline characteristics were similar between arms. 4 subjects in the PBO group and none in TCZ met the pre-defined definition of worsening in Step 1 and were given a score of 0.0. For remaining subjects, we calculated probability score for each subject. Using CRISS as a continuous measure, the median score was statistically significant and favored TCZ compared to PBO at wks 24 and 48 (p=0.04 and 0.01; Table). Table also presents the individual components of Step 2 where only FVC% was statistically significant favoring TCZ at wk 48.

Table 1. Comparison of TCZ and PBO using CRISS index and individual variables at 24 and 48 weeks

	TCZ	PBO**	P value
CRISS, median [IQR] at 24 week	0.23 [0.003; 0.95], N=33	0.008 [0.00; 0.10], N=36	0.04*
CRISS, median [IQR] at 48 week	0.31 [0.008; 0.99], N=27	0.001 [0.00; 0.18], N=35	0.01*
MRSS, mean change at 24 week	-4.2, N=33	-2.1, N=34	0.24
MRSS, mean change at 48 week	-5.9, N=27	-3.2, N=31	0.35
FVC% predicted, mean change at 24 week	-0.78, N=33	-4.4, N=34	0.08
FVC% predicted, mean change at 48 week	-1.6, N=27	-5.1, N=31	0.02
PT GA, mean change at 24 week	-0.41, N=33	-0.10, N=34	0.64
PT GA, mean change at 48 week	-0.69, N=27	-0.45, N=31	0.72
MD GA, mean change at 24 week	-0.94, N=33	-0.80, N=34	0.76
MDGA, mean change at 48 week	-1.81, N=27	-0.73, N=31	0.07
HAQ-DI, mean change at 24 week	0.09, N=33	0.06, N=34	0.76
HAQ-DI, mean change at 48 week	0.00, N=27	0.16, N=31	0.10

*Using Wilcoxon test as CRISS data is not normally distributed. **There are 4 subjects in the PBO who met step 1 and were given a score of 0.0.

Conclusions: In this post-hoc analysis, CRISS index was able to discriminate TCZ from PBO, supporting its validity in an independent cohort.

hampered research efforts, resulting in remarkably limited therapeutic evidence. The EuroMyositis Registry was created to pool resources and expertise across the international IIM research community.

Objectives: To describe the phenotypic characteristics of different IIM subtypes. Associations with malignancy, interstitial lung disease (ILD), cardiac involvement and dysphagia were assessed.

Methods: Pooled data from the EuroMyositis Registry (from Belgium, China, Czech Republic, Hungary, Italy, Mexico, Norway, Sweden, Switzerland, UK, Vietnam) were obtained. Associations were assessed using logistic regression and multinomial logistic regression with polymyositis (PM) as the reference group.

Results: Data regarding 3,196 patients were analysed. The UK was the largest contributor (n=1,307). The most common diagnoses were dermatomyositis (34%), PM (32%) and connective tissue disease (CTD)-overlap myositis (15%). In those with anti-synthetase syndrome (7%), 85% had muscle weakness, 86% ILD and 58% arthritis. Overall, 43% had a myositis specific antibody, most commonly anti-Jo1 autoantibodies (20%). Glucocorticoid usage was noted in 98%. Most commonly used disease modifying agents were methotrexate (71%) and azathioprine (50%).

Malignancy occurred in 9% and was associated with a diagnosis of dermatomyositis (Relative Risk Ratio [RRR] 1.68, 95% CI 1.09–2.56, p=0.018). Cardiac involvement occurred in 9%, most commonly in those with CTD-overlap myositis (13%), and was associated with a higher Health Assessment Questionnaire disability index (1 versus 0.75, OR 1.40, 95% CI 1.03–1.91, p=0.031). Dysphagia occurred in 39% and was associated with a diagnosis of CTD-overlap myositis (RRR 2.25, 95% CI 1.61–3.15, p<0.001).

Conclusions: This large international cohort demonstrates the heterogeneity of IIM and the burden of associated malignancy, ILD, cardiac and gastrointestinal involvement. The EuroMyositis Registry facilitates international collaborative research outputs, underlining the benefits of harmonised data collection methodology between centres.

SAT0375 METABOLOMICS OF SERA REVEALS POTENTIAL BIOMARKERS OF SKIN FIBROSIS IN SYSTEMIC SCLEROSIS THAT CORRELATE WITH PRO-FIBROTIC GENE EXPRESSION IN SKIN BIOPSIES

S. Ahmed[1], M.K. Rai[1], D. Dubey[2], A. Rawat[2], D.P. Misra[1], D. Kumar[2], V. Agarwal[1]. *[1]Clinical Immunology, Sanjay Gandhi Post Graduate Institute of Medical Sciences; [2]Centre for BioMedical Research, Lucknow, India*

Background: There is an unmet need for biomarkers in Systemic Sclerosis (SSc). Despite its shortcomings, the modified Rodnan skin score (mRSS) has remained the standard disease assessment tool for SSc. Expression of certain genes, cartilage oligomeric matrix protein (*COMP*), thrombospondin-1 (*THS1*), interferon-induced 44 (*IFI44*) and sialoadhesin (*SIG1*), and, more recently, Tenascin-C (*TNSC*), have been shown to correlate with skin fibrosis. However, assessment of the expression of these genes requires a skin biopsy. Hence, we used an open-ended approach to identify a serum-based biomarker of SSc.

Objectives: To identify small molecules in serum that correlate with mRSS and profibrotic genes that are upregulated in skin of SSc patients

Methods: We obtained serum and skin biopsies from 25 consenting adult patients with SSc and serum from 25 age- and sex-similar controls. mRNA levels of five genes: *COMP*, *THS1*, *IFI44*, *SIG1*, and *TNSC* were estimated as fold-change relative to Glyceraldehyde 3-phosphate dehydrogenase (*GAPDH*), a housekeeping gene. H^1NMR (Nuclear Magnetic Resonance) based metabolomics studies were performed on the sera using standard protocols. Principal component analysis (PCoA) and Partial Least Squares Discriminant Analysis (PLSDA) were used to delineate metabolites that were different between patients and healthy controls. Then spearman correlations (ρ) of these metabolites with mRSS and the fold-expression of the five pro-fibrotic genes were estimated.

Results: H^1NMR based metabolomics identified 126 peaks that were different between patients and controls. Out of these, the levels of glycine had the best correlation with pro-fibrotic gene expression (ρ=0.5, p<0.05 for *IFI44*; ρ=0.44, p<0.05 for *TNSC*). Choline inversely correlated with *SIG1* (ρ=-0.41; p=0.05) while Glycerophosphocholine correlated with mRSS (ρ=0.50, p<0.05).

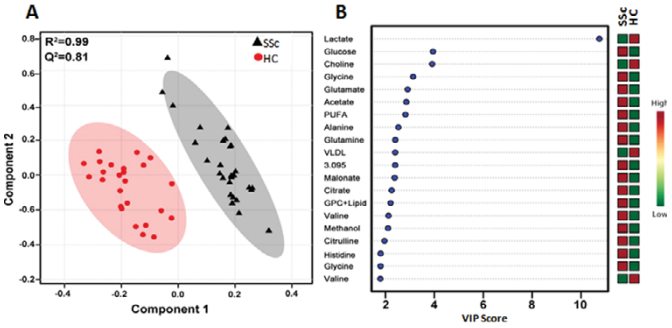

Figure 1: H^1-NMR Metabolomics data (A) PCoA plot showing metabolomics can clearly distinguish between patients of systemic sclerosis and healthy controls (B) Plot showing 20 representative metabolites that were significantly different between patients and controls; SSc: Systemic Sclerosis, HC: Healthy Controls, PUFA: Poly Unsaturated Fatty Acids; VLDL: Very Low Density Lipoproteins, GPC: Glycerophosphocholine, VIP: Variable Importance in Projection Score

Conclusions: H^1NMR based metabolomics identified glycine, choline and their metabolites as potential biomarkers for skin fibrosis in SSc. These findings require validation in a larger cohort.

SAT0376 ANTI-NT5C1A AUTOANTIBODIES ARE FREQUENT IN JUVENILE MYOSITIS AND ASSOCIATED WITH INCREASED ILLNESS SEVERITY

R. Yeker[1], I. Pinal-Fernandez[1], T. Kishi[2], I.N. Targoff[3], F.W. Miller[2], L.G. Rider[2], A. Mammen[1]. *[1]Muscle Disease Unit, National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS)/National Institutes of Health (NIH); [2]Environmental Autoimmunity Group, National Institute of Environmental Health Sciences (NIEHS)/National Institutes of Health (NIH), Bethesda; [3]University of Oklahoma Health Sciences Center, Oklahoma City, United States*

Background: Autoantibodies (Abs) against 5'-Nucleotidase, Cytosolic 1A (NT5C1A) have been portrayed as a potential diagnostic aide in distinguishing inclusion body myositis (IBM) and polymyositis (PM) in adults. However, 4–21% of dermatomyositis (DM) patients also have Abs to NT5C1A.

Objectives: The prevalence and clinical features of anti-NT5C1A Abs in juvenile-onset myositis (IIM) patients is unknown, so we sought to examine this in a large cohort.

Methods: We screened 384 juvenile IIM patients meeting probable or definite Bohan and Peter criteria for anti-NT5C1A Abs by immunoblotting for the full length NT5C1A protein in transfected and non-transfected lysates. Clinical characteristics and HLA typing were compared between juvenile IIM patients who were anti-NT5C1A positive (Ab+) and those who were anti-NT5C1A negative (Ab-).

Results: In this cohort, 29% (103) of juvenile DM, 15% (3) of juvenile PM, and 37% (15) of juvenile overlap myositis patients tested positive for anti-NT5C1A Abs. Compared with anti-NT5C1A Ab- patients, anti-NT5C1A Ab+ juvenile IIM patients showed a similar distribution of race, gender, and association with myositis-specific Abs. However, NT5C1A Ab was associated with anti-p155/140 Abs (p=0.05). The only observed clinical difference was an increased frequency of V- or shawl-sign rashes ever present (44% vs. 26%, p=0.002). Disease severity was increased in anti-NT5C1A Ab+ patients, based on more frequent hospitalizations (p=0.02), more medications used (p<0.001), and more treatment trials per year (p<0.001). Additionally, pulse steroids (p<0.001) and intravenous immunoglobulin therapy (p=0.008) were prescribed more frequently in anti-NT5C1A Ab+ than Ab- patients. The HLA alleles DRB1*07 (20% vs. 9%, p<0.05) and DQA1*0201 (21% vs. 7%, p<0.01) were present more frequently in anti-NT5C1A Ab- compared to Ab+ patients.

Conclusions: Anti-NT5C1A Abs are commonly present in juvenile DM and juvenile overlap myositis patients, and are present more frequently in patients with anti-p155/140 Abs, but are also seen in association with other myositis specific Abs. Consistent with data in adult IIM patients, anti-NT5C1A Abs have few distinguishing clinical features in juvenile myositis, but are associated with increased illness severity marked by increased hospitalizations and receipt of additional therapy.

SAT0377 RELIABILITY OF A NEW AUTOMATED SYSTEM FOR ABSOLUTE CAPILLARY NUMBER COUNTING (AUTOCAPI) ON SYSTEMIC SCLEROSIS NAILFOLD VIDEOCAPILLAROSCOPIC IMAGES

M. Cutolo[1], K. Melsens[2], A.C. Trombetta[1], C. Pizzorni[1], E. Deschepper[3], A. Sulli[1], V. Smith[4]. *[1]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, Genoa, Italy; [2]Department of Internal Medicine, Faculty of Medicine and Health Sciences; [3]Department of Public Health, Biostatistics Unit; [4]Department of Internal Medicine, Faculty of Medicine and Health Sciences; Department of Rheumatology, Ghent University Hospital, Ghent University, Ghent, Belgium*

Background: Nailfold capillary density is a useful measure in systemic sclerosis (SSc) classification and evaluation. Its manual detection may be time-consuming, hampering its use in largescale investigations. We evaluated a new automated system to assess the absolute nailfold capillary number.
Objectives: To attest the instrumental reliability of automatic counting in SSc patients using nailfold video capillaroscopy (NVC) images.
Methods: 75 NVC random images, from SSc patients, were blindly analyzed by four raters (2 less and 2 more experienced; raters: 1,2,3,4) from two European centers. Each rater was asked to define the region of interest (ROI) on the NVC images and to manually count the number of capillaries, according to the following instructions: upper bound placed on top of the longest capillary head and lower bound placed on half of the length of that longest capillary (figure 1); if the common branch of an abnormal shape (neoangiogenesis) is in ROI it is counted as being one; if the common branch is out of ROI it is counted as separate capillaries; if the capillary is on the edge of the vertical line of ROI, it is only counted when the head of the capillary is half in ROI; if the capillary head is on the edge of lower bound, it is counted as soon as the "head" part is in the ROI; all "heads" in the ROI are counted (not only distal row). The dedicated automated system (AUTOCAPI-ds medica, IT) also counted the number of capillaries in the same ROI (figure 1). Reliability between the manual and automatic counting was investigated per rater through intraclass correlation coefficient (ICC) and reported with 95% confidence interval (CI). External validation was obtained by multi-rating of the same set of images. Average difference between automated and manual counting per rater was calculated.
Results: The ICC (95% CI) of manual versus automatic counting in ROI was 0.77 (0.61–0.86) for rater 1 ($p<0.0001$), 0.81 (0.71–0.88) for rater 2 ($p<0.0001$), 0.65 (0.50–0.76) for rater 3 ($p<0.0001$) and 0.81 (0.71–0.87) for rater 4 ($p<0.0001$). The average difference was -0.69 for rater 1, 0.04 for rater 2, -0.03 for rater 3 and 0.16 for rater 4.

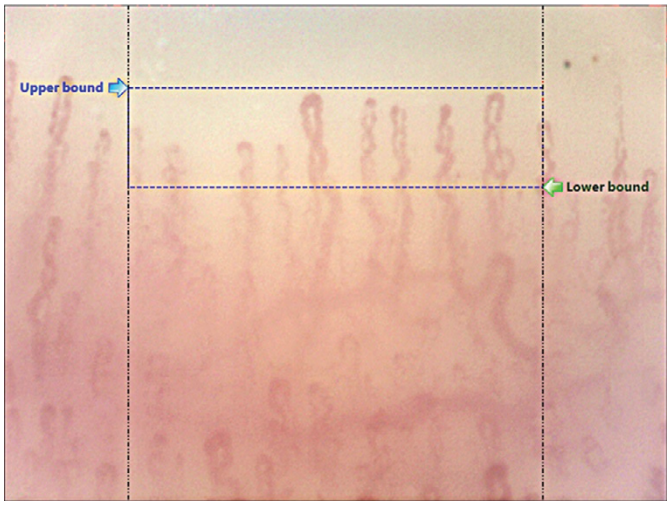

Figure 1. In the picture captured by the operator (normal subject), two vertical bars, with a distance of 1 mm appears automatically in the middle of the picture, together with two horizontal bars (upper bound and lower bound) to be placed manually (see text) in order to define the ROI.

Conclusions: This is a first study to attest the reliability of a new automated system to calculate the absolute number of capillaries in a ROI arising from SSc NVC images. High performance of the new automated counting system was confirmed in pathological conditions (SSc).

SAT0378 BONE MARROW OEDEMA AND SYNOVITIS ON MRI OF THE HAND ARE ASSOCIATE WITH DIGITAL ULCERS, ACTIVE DISEASE AND IMPAIRED FUNCTIONAL CAPACITY IN SYSTEMIC SCLEROSIS

B. Stamenkovic[1,2], S. Stojanovic[1,2], J. Nedovic[2], V. Zivkovic[1,2], S. Milenkovic[2], J. Jovanovic[2], N. Damjanov[3], A. Stankovic[1,2]. *[1]Medical School; [2]Rheumatology, Institute Niska Banja, Nis; [3]Rheumatology, Institute for Rheumatology, Belgrade, Serbia*

Background: Hand inflammatory involvement is a major feature in patients with systemic sclerosis (SSc), responsible for major disability. Magnetic resonance imaging (MRI) can identify and characterize subclinical inflammation and joint damage on hand with much greater precision than clinical, radiographic and ultrasonography assessment in SSc.
Objectives: To determine the association of MR bone marrow oedema, synovitis and probability for the occurrence of listed inflammatory changes with clinical features and laboratory tests in SSc patients
Methods: 112 SSc patients were tested (mean age 54y). Contrast enhanced low field MRI of the wrist and MCP2–5 joints was performed to all the pts. MRI bone marrow oedema and synovitis were assessed and scored by OMERACT RAMRIS scoring system. Age, sex, SSc type, disease duration (date of first non Raynaud symptom), Raynaud phenomenon, articular or periarticular pain, joint swelling and contractures, digital ulceration, HAQ, acroosteolysis (by standard PA radiographs of hand and wrist) pulmonary arterial hypertension (PAP>40mmHg at rest on Doppler echocardiography), pulmonary fibrosis (by CT and pulmonary function tests) and laboratory tests (antibody profile, RF, CRP, Creatine phosphokinase) and disease activity (by Valentini index) were done.
Results: By multiple logistic regression analysis taking into account all clinical and laboratory variable, we found that MRI bone marrow oedema of the hand was associated and probability for the occurance of MRI bone marrow oedema was higher for the SSc pts with digital ulcers (OR=6.081;95%IP:1.295–28.550; $p<0.05$), HAQ>1.5 (OR=6.448; 95%IP: 1.714–24.257; $p<0.01$) and active disease (OR=3.377; 95%IP; 1.175–9.706; $p<0.05$).
MRI synovitis of the hand was associated and probability for the occurance of MRI synovitis was higher, also, for the SSc pts with digital ulcers (OR=5.128; 95%IP: 1.085–24.243; $p<0.05$), HAQ>1.5 (OR=9.067; 95%IP: 1.925–42.708; $p<0.01$) and active disease (OR=3.565; 95%IP: 1.181–10.764; $p<0.05$).
Conclusions: MRI bone marrow oedema and synovitis on the hand in SSc are associate with digital ulcers, impaired functional capacity and active disease. Monitoring and treatment of clinical features and organ involvement are essential in all the pts with SSc, especially those with proven bone marrow oedema and synovitis on MRI of the hand.

SAT0379 NAILFOLD CAPILLAROSCOPY FINDINGS IN PATIENTS WITH INFLAMMATORY MYOPATHY AND/OR SPECIFIC OR ASSOCIATED ANTIBODIES

A.M. Millan Arciniegas[1], M.A. Martinez[2], A. Baucells[2], C. Juarez[2], L. Martinez[2], H.S. Park[1], B. Magallares[1], A. Laiz[1], P. Moya[1], J.M. Llobet[1], C. Diaz Torne[1], I. Castellvi[1]. *[1]Rheumatology; [2]Immunology, Hospital de Sant Pau, Barcelona, Spain*

Background: Nailfold videocapillaroscopy (NVC) is an easy, fast and non-aggressive tool, useful in the study of autoimmune diseases. The use of NVC in Inflammatory Myopathy (IM) is not clearly established.
Objectives: 1. To evaluate capillaroscopic findings in patients with IM and/or with presence of specific or associated antibodies with this pathology. 2. To analyze possible relationships with clinical characteristics of the patients.
Methods: Retrospective review of a cohort of patients with IM and/or with presence of specific or associated antibodies, followed in Rheumatology Unit of a University Hospital.
Patients underwent a NVC at 200x, being evaluated for the presence of: loss of capillary density, enlarged and giant capillaries, ramified capillaries, haemorrhages, thrombosis, tortuous capillaries, avascular areas, disorganization of capillary architecture and subpapilar venous plexus. The following variables were also collected: sex, age, active smoking, muscle weakness, CK elevation at diagnosis, compatible muscle EMG and biopsy, skin findings, cardiac disease, dysphagia, lung disease, Raynaud's phenomenon, cancer history and overlap syndromes.
For the comparison of qualitative and/or quantitative variables Fisher's exact Test or T-test was performed when necessary.
Results: Twenty patients with at least one NVC (45% with 2), 65% female, with a mean age of 58 years ± 11.6 were evaluated. The characteristics of the patients are detailed in table 1.
65% of patients had some capillaroscopic alteration. The findings in NVC-1 and NVC-2 were: loss of capillary density 30% and 33%, tortuous capillaries 90% and 89%, enlarged capillaries 65% and 66.7% (giants 30% and 33%), ramifications 40% and 55.6%, disorganization 10% and 33%, haemorrhages 25% and 44%, thrombosis 20% and 0%, avascular areas 25% and 22%, visible venous plexus 40% and 55%.
The presence of dysphagia was associated with the presence of loss of capillary

density ($p<0.02$) and haemorrhages ($p<0.01$) in the initial NVC, as well as the presence of ramifications in the control NVC ($p<0, 05$).
It was observed that patients with normal capillary organization presented better value of FVC ($p<0.01$), TLC ($p<0.01$), and lower FEV1/FVC ratio ($p<0.02$), the latter finding also found in control NVC ($p<0.03$). As additional data, we found that patients with anti-Ku+ presented better values of FVC ($p<0.04$) and TLC ($p<0.05$), but although they all had normal capillary organization, the association of this antibody with NVC was not statistically significant. We also did not find a statistically significant relationship between the alterations in NVC and the presence of Raynaud's phenomenon, the other clinical variables, cancer history and the presence of overlap syndromes.

Table 1	PATIENTS
N	20
Age at diagnosis (years)	55 ± 11,7
Time of evolution (years)	2,9 ± 1,8
Active smoking	5 (25%)
Muscle weakness	7 (35%)
CK elevation at diagnosis	8 (40%)
EMG compatible with IM	5/8 (62.5%)
Muscle biopsy compatible with IM	7/8 (87,5%)
Skin findings	6 (30%)
Cardiac disease	1 (5%)
Disphagia	5 (25%)
Lung disease	7 (35%)
Concomitant cancer	1 (5%)
Raynaud's phenomenon present	11 (55%)
Overlap:	5 (25%)
-With Systemic Sclerosis	4/5 (80%)
-With Sjögren Syndrome	1/5 (20%)
Anti-Mi2	4 (20%)
Anti-Ku	5 (25%)
Anti-Jo1	2 (10%)
Anti-PL7	2 (10%)
Anti-Ro52	5 (25%)
Other Ab (SRP, PL12, PM/SCL, OJ, MDA5, TIF1G)	6 (30%)

Conclusions: Patients with capillary disorganization in NVC showed worse values of FVC, TLC and FEV1/FVC. We found a statistically significant association between esophageal disease and haemorrhages, loss of capillary density and ramifications. Prospective studies with larger sample sizes are required to define the usefulness of NVC in the diagnosis, prognosis and follow-up of these patients.

Jaeger[11], V. Lóránd[7], B. Maurer[9], S. Nihtyanova[8], G. Riemekasten[12], E. Siegert[13], G. Valentini[14], S. Vettori[14], U. Walker[15], U. Müller-Ladner[10], Y. Allanore[16], F. Del Galdo[3,4], M. Matucci-Cerinic[1] on behalf of DeSScipher Consortium and contributing EUSTAR centres. *[1]Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy; [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [3]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust; [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; [5]Department of Rheumatology and Immunology, Charité University Hospital and German Rheumatism Research Centre, Berlin, Germany; [6]Department of Rheumatology, University of Paris Descartes, Paris, France; [7]Department of Rheumatology and Immunology, University of Pécs, Pécs, Hungary; [8]Department of Rheumatology, University College London, Royal Free Hospital, London, United Kingdom; [9]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; [10]Department of Rheumatology and Clinical Immunology, Justus–Liebig University Giessen, Kerckhoff Clinic Bad Nauheim, Giessen/Bad Nauheim, Germany; [11]Department of Rheumatology, University of Basel, Basel, Switzerland; [12]University Schleswig-Holstein Lübeck, Lübeck; [13]Department of Rheumatology and Immunology, Charité University Hospital, Berlin, Germany; [14]Department of Rheumatology, Second University of Naples, Naples, Italy; [15]Department of Rheumatology, University of Basel, Basel, Switzerland; [16]Department of Rheumatology, University of Paris Descartes, Paris, France*

Background: A consensus on DU definition in SSc has been recently reached (1),while for their evaluation,classification and categorisation it is still missing.
Objectives: To identify in SSc a set of essential items for DU evaluation, to assess if the existing DU classification (2) was useful and feasible in clinical practice, and to investigate if the DU categorisation (3) was preferred to the simple division of DU in recurrent and not recurrent.
Methods: The DU Desscipher items that reached >60% of completion rate were administered to EUSTAR centres via online survey.These items were: DU distal to the proximal interphalangeal joints, recurrent DU, DU history, infection, gangrene, amputation, total number of DU, number of new DU, number of healed DU, number of DU defined as loss of tissue, number of DU due to calcinosis and number of DU due to digital pitting scars (DPS).Questions about feasibility and usefulness of the existing DU classification (DU due to DPS, to loss of tissue, derived from calcinosis and gangrene) (2) and newly proposed DU categorisation (episodic, recurrent and chronic) (3) were also administered.
Results: All Desscipher and 82/194 EUSTAR centres (42.3%) completed the questionnaire.Out of 27 items selected for the Desscipher study, those scored by>70% of participants as essential and feasible for DU evaluation in clinical practice were only the following: number of DU defined as a loss of tissue (level of agreement 91.1%), recurrent DU (84%) and number of new DU (74.4%).For 64.6% of the centres,the classification of DU was considered useful and feasible in clinical practice.Moreover, 80.3% of the centres preferred the categorization of DU in episodic,recurrent and chronic.
Conclusions: For clinical practice, EUSTAR centres identified only three essential items for DU evaluation and considered useful and feasible the proposed classification and categorisation of DU.The set of items needs to be further validated by Delphi voting in order to implement its use in clinical practice while further implementation of DU classification and categorisation is warranted.

SAT0381 CORRELATION BETWEEN THREE DIFFERENT METHODS TO ASSESS DERMAL THICKNESS IN SYSTEMIC SCLEROSIS PATIENTS WITH DIFFERENT PATTERNS OF NAILFOLD MICROANGIOPATHY

B. Ruaro, A. Sulli, E. Alessandri, S. Paolino, M. Ghio, A.C. Trombetta, C. Pizzorni, V. Tomatis, M. Cutolo. *Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS AOU San Martino, Genoa, Italy*

Background: Systemic sclerosis (SSc) is characterized by the increase of dermal thickness (DT) (1). The modified Rodnan skin score (mRss) is the validated method to evaluate the severity of skin impairment (2,3). Several studies have reported the capability of high frequency skin ultrasound (US) to reflect the overall severity of the skin damage in SSc patients (4–5). The plicometer skin test (PST) is another method to evaluated cutaneous involvement in SSc patients (6).
Objectives: The aim of this study was to identify possible correlations between US, mRss and PST to evaluate DT in SSc patients with different patterns of nailfold microangiopathy.
Methods: Sixty-three SSc patients (mean age 64±11SD years, mean disease duration 7±6 years, 43 lcSSc and 20 dcSSc) and 63 sex and age matched healthy subjects were enrolled after written informed consent. All subjects were assessed by mRss, US and PST to evaluate the DT in the seventeen skin areas of the body usually evaluated by mRss (zygoma, fingers, hands, dorsum of hands, forearms, arms, chest, abdomen, thighs, legs, feet) (1–6). Nailfold videocapillaroscopy (NVC) was used to assess the proper pattern of microangiopathy and to calculate the microangiopathy evolution score (MES) (7–8). Statistical evaluation was performed by non-parametric tests.
Results: As expected, the group of SSc patients had a statistically significant higher DT, as evaluated by the three methods, at level of all areas when compared to the control group ($p=0.0001$). All methods demonstrated a progressively higher DT in patients with "Early", vs. "Active" and vs "Late" pattern of nailfold microangiopathy ($p<0.005$), and a positive correlation was observed with MES ($r=0.71$ $p<0.001$). A positive correlation was observed in SSc patients between the three method to evaluate DT (PST vs mRss $r=0.98$, $p<0.0001$; PST vs US $r=0.53$, $p<0.0001$; US vs mRss $r=0.53$, $p<0.0001$).
Conclusions: This study demonstrates a relationship between different methods to assess DT (US, mRss and PST) in SSc patients and a relationship between skin damage and microangiopathy impairment.

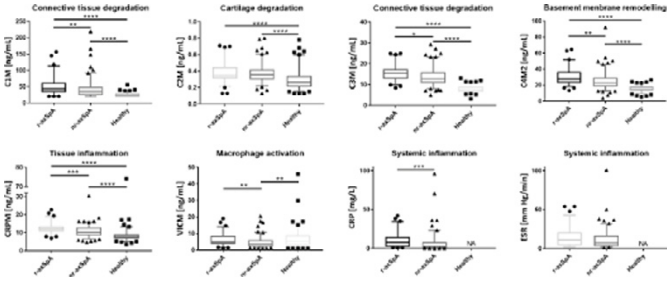
Spondyloarthritis - clinical aspects (other than treatment)

SAT0382 CHANGES IN VOLUMETRIC BONE MINERAL DENSITY AND BONE MICROARCHITECTURE IN PATIENTS WITH ANKYLOSING SPONDYLITIS. A FIVE-YEAR PROSPECTIVE STUDY USING HRPQCT

A. Deminger[1], E. Klingberg[1], M. Lorentzon[2], H. Carlsten[1], L.T. Jacobsson[1], H. Forsblad-d'Elia[1,3]. [1]*Department of Rheumatology and Inflammation Research, Sahlgrenska Academy at University of Gothenburg;* [2]*Geriatric Medicine, Institute of Medicine, Sahlgrenska Academy at University of Gothenburg and Sahlgrenska University Hospital, Göteborg;* [3]*Department of Public Health and Clinical Medicine, Rheumatology, Umeå University, Umeå, Sweden*

Background: Studies have demonstrated increased prevalence of osteoporosis in patients with ankylosing spondylitis (AS) in the hip and lumbar spine assessed by conventional DXA but the peripheral skeleton is less studied. The peripheral skeleton can be studied in detail by high-resolution peripheral quantitative computed tomography (HRpQCT) demonstrating data of the volumetric bone mineral density (vBMD) and bone microarchitecture. We have previously shown that patients with AS from Western Sweden had lower vBMD measured by HRpQCT in radius and tibia compared with healthy controls [1]. No prospective study in this matter has been published in AS.
Objectives: To investigate changes over 5 years in the peripheral vBMD and microarchitecture in patients with AS.
Methods: HRpQCT of ultra-distal radius and tibia was performed in male AS-patients (NY criteria) at baseline and at the five-year follow-up. The patients were also assessed with blood samples and questionnaires.
Results: Of the 69 patients included at baseline 57 (83%) patients were re-examined at the five-year follow-up. Baseline characteristics of the 57 patients [median (IQR)]: age 48 (35 to 61) years, symptom duration 21 (11 to 34) years, ESR 10 (5 to 17) mm/h, CRP 3 (1 to 7), $ASDAS_{CRP}$ 1.8 (1.3 to 2.8) and BASDAI 2.3 (1.2 to 4.2). 23% used TNF-inhibitors, 75% used NSAIDs and 2% bisphosphonates. All measurements at tibia had good quality and matched images had common regions $\geq$80%. The images of radius of 12 patients had to be excluded due to insufficient quality. At tibia, the total, cortical and trabecular vBMD decreased significantly. In the microarchitecture an increase in the trabecular separation was seen (Table). Changes in vBMD were negatively and significantly correlated; Spearman's correlation coefficient between -0.3 and -0.4, to Δ-values (difference between follow-up and baseline) for ESR, CRP (cortical vBMD), $ASDAS_{CRP}$ (total vBMD and cortical vBMD) and BASDAI (total vBMD). At radius, no significant change in vBMD was observed; however, less power for analyses of radius. An increase was seen in the cortical thickness and the trabecular number while the trabecular thickness decreased (Table). Changes in cortical vBMD was negatively and significantly correlated, r $\approx$ -0.3, to Δ-CRP and Δ-$ASDAS_{CRP}$.

Table.



Site		Baseline mean ± SD	Five-year follow-up mean ± SD	Difference mean% ± SD	p-value
Tibia	**Total vBMD, mg/cm³**	297.9 ± 55.5	292.8 ± 55.8	**-1.7 ± 3.9**	**0.002**
	Cortical vBMD, mg/cm³	842.7 ± 54.8	834.1 ± 62.5	**-1.1 ± 1.9**	**0.001**
	Trabecular vBMD, mg/cm³	184.8 ± 34.6	179.5 ±31.9	**-2.6 ± 4.8**	**0.001**
	Cortical thickness, mm	1.22 ± 0.32	1.21 ± 0.32	-1.0 ± 5.2	0.35
	Trabecular thickness, mm	0.08 ± 0.01	0.07 ± 0.01	-1.5 ± 7.3	0.26
	Trabecular number in 1/mm	2.06 ± 0.30	2.04 ± 0.32	-0.7 ± 6.7	0.19
	Trabecular separation, mm	0.42 ± 0.08	0.43 ± 0.08	**1.8 ± 6.9**	**0.027**
Radius	Total vBMD, mg/cm³	319.6 ± 64.9	320.7 ± 69.9	0.1 ±4.7	0.47
	Cortical vBMD, mg/cm³	854.4 ± 54.9	854.1 ± 59.5	-0.1 ±1.9	0.98
	Trabecular vBMD, mg/cm³	177.5 ± 40.5	173.6 ± 41.9	-2.3 ± 6.2	0.082
	Cortical thickness, mm	0.83 ± 0.21	0.85 ± 0.21	**2.5 ± 5.4**	**0.004**
	Trabecular thickness, mm	0.08 ± 0.02	0.07 ± 0.01	**-5.4 ± 10.5**	**0.001**
	Trabecular number in 1/mm	1.96 ± 0.24	2.01 ± 0.24	**4.2 ± 10.8**	**0.041**
	Trabecular separation, mm	0.44 ± 0.07	0.43 ± 0.06	-2.7 ± 10.1	0.080

Conclusions: Over five years, this group of male patients with AS decreased in the vBMD of tibia, both trabecular and cortical. Even though there were alterations in the microarchitecture, no significant change in vBMD of radius was seen. Increases in inflammatory markers and disease activity had a negative impact on the cortical vBMD. The differences in the development of vBMD and microarchitecture in loaded and unloaded skeleton as well as factors associated with the changes needs to be further investigated.

SAT0383 BIOMARKERS OF ECM DEGRADATION REFLECT DISEASE ACTIVITY IN RADIOGRAPHIC AND NON-RADIOGRAPHIC SPONDYLARTHRITIS

A.S. Siebuhr[1], A.-C.S. Bay-Jensen[1], K. Pavelka[2], S. Forejtova[2], K. Zegzulkova[2], M. Tomcik[2], M.A. Karsdal[1], M. Urbanova[2], K. Grobelna[2], J. Horinkova[2], J. Gatterova[2], M. Husakova[2]. [1]*Biomarkers and Research, Nordic Bioscience, Herlev, Denmark;* [2]*Institute of Rheumatology and Department of Rheumatology, Charles University, Praugh, Czech Republic*

Background: Axial spondyloarthritis (axSpA) comprises two groups - radiographic (r-axSpA) and non-radiographic (nr-axSpA) with varying disease activity, spine involvement and response to biological therapy. An objective biomarker of disease activity may be able to select patients, which will benefit from a given biological treatment.
Objectives: We investigated the association of extracellular matrix (ECM) degradation biomarkers in axSpA patients (r-axSpA and nr-axSpA) with disease activity.
Methods: AxSpA patients (n=193; 72 r-axSpA and 121 nr-axSpA) and 100 healthy controls were included in the study. Biomarkers of type I, II, III and IV degradation (C1M, C2M, C3M, C4M2), MMP-degraded CRP (CRPM) and MMP-degraded and citrullinated vimentin (VICM) were detected by ELISA in serum. Mann-Whitney t-test tested the difference in the biomarker levels between groups and multiple regression analysis investigated the association between biomarkers and clinical manifestations with adjustment for age, gender, BMI, disease duration and CRP. ROC AUC tested the biomarkers capacity to differentiate the patient groups.
Results: Patients with r-axSpA compared to nr-axSpA patients had higher radiographic status and longer disease duration ($p<0.001$), whereas nr-axSpA had more swollen joints (p=0.0093). They were alike in age, BMI and disease activity (ASDAS-CRP, BASDAI and HAQ). All tested biomarkers except VICM were elevated in the axSpA patients compared to healthy subjects (all $p<0.001$). VICM was lower in the axSpA group, particularly in nr-axSpA compared to healthy (p=0.036 and p=0.002 respectively). R-axSpA compared to nr-axSpA patients had higher level of C1M, C3M, C4M2, CRPM and VICM ($p<0.001$, =0.001, <0.001, <0.001 and =0.003), but not C2M (p=0.92). C1M correlated to ASDAS-CRP in both r-axSpA and nr-axSpA (r-partiel: 0.46 and 0.44) with adjustment for age, gender, BMI and disease duration, but the correlation was lost by adjustment for CRP. Also C3M and C4M2 correlated to ASDAS-CRP in both axSpA groups. C2M was in r-axSpA patients moderately correlated to ASDAS-CRP, but minimal after adjustment of CRP (r-partiel: 0.32 unadjusted and 0.18 adjusted). CRPM correlated to ASDAS-CRP with adjustment to CRP in r-axSpA (r-partiel: 0.27 unadjusted, 0.26 adjusted), but not in nr-axSpA (r-partiel: 0.19 unadjusted, 0.03 adjusted).
Especially, C3M and C4M2 could differentiate between healthy and the axSpA patients (AUC 0.95 and 0.89), but also C1M, C2M, CRPM had AUC of $\geq$0.72. VICM was the only biomarker to differ between r-axSpA (AUC 0.92 and nr-axSpA (AUC 0.51).

Conclusions: Biomarkers of ECM turnover, C3M and C4M2 in particular, were associated with r-axSpA and nr-axSpA and could define disease. The biomarkers of ECM degradation, especially C1M, may reflect the pathogenetic background of axSpA.

SAT0384 RISK OF MYOCARDIAL INFARCTION AND CEREBROVASCULAR ACCIDENT IN ANKYLOSING SPONDYLITIS: A GENERAL POPULATION-BASED STUDY

A.C.L. So[1], J. Chan[1], E.C. Sayre[2], J.A. Avina-Zubieta[1]. [1]*UBC Division of Rheumatology;* [2]*Arthritis Research Canada, Vancouver, Canada*

Background: There is conflicting data on the risk of myocardial infarction (MI) and cerebrovascular accidents (CVA) in patients with Ankylosing Spondylitis (AS).

Objectives: 1) To assess the future risk of newly recorded MI and CVA events among incident cases of AS compared to non-AS controls from the general population by utilizing physician billing, medication, and hospitalization data that covers the entire province of British Columbia (BC), Canada.
Methods: Our data includes all outpatient visits and hospitalizations (1990–2012) and all dispensed medications (1996–2012) for all BC residents. We conducted a retrospective matched cohort study of all patients >18 years of age satisfying the following criteria: 1) two ICD-9 or 10 codes (720.0 or M45) for AS at least two months apart and within a 2-year period by any physician or hospitalization; 2) all AS cases had at least a 7-year run-in period before the 1st ICD code for AS in order to consider the case as incident. Each AS patient was matched with up to 10 controls by birth year, sex, and entry cohort time. The outcomes were a newly recorded MI (ICD-9-CM: 410 or ICD-10-CM: I21) or CVA (ICD-9 codes: 433–434, ICD-10 codes: I63-I66) event from hospital or death certificates. We estimated relative risks (RRs), adjusting for age, sex, and entry cohort time as well as multivariable models adjusting for confounders including glucocorticoids and non-steroidal anti-inflammatory drugs using a Cox proportional hazard model.
Results: 7,190 individuals with newly diagnosed AS were identified (48.7% female, mean age of 45.8 yrs). 7,148 and 7,107 were free of previous CVA/MI, respectively. 80 developed CVA (incidence rate=1.8 per 1000 patient years) and 115 had MI (incidence rate=2.6 per 1,000 patient years) (Table 1). The age-, sex-, and entry-time-matched RR for CVA was 1.60 (95% CI, 1.25–2.03) and MI was 1.52 (95% CI, 1.24–1.85). When adjusted for cardiovascular risk factors (obesity, angina, COPD, hospitalizations in year before index date, Charlson's comorbidity index, oral glucocorticoids, cardiovascular drugs, anti-diabetic medication, HRT, contraceptives, fibrates, statins, NSAIDs, and Cox-2 inhibitors), the estimated RR was 1.34 (1.04–1.73) for CVA and 1.21 (0.98–1.49) for MI.

Table 1. Relative risk of incident CVA and MI according to AS status

	AS (N=7,148)	Non-AS (N=71,489)
CVA events, n	80	492
Incidence Rate of CVA/1000 Person-Years	1.81	1.13
Incidence Rate Ratio of CVA (95% CI)	1.60 (1.25–2.03)	1.0
Multivariable RR of CVA (95% CI)	**1.34 (1.04–1.73)**	1.0
	AS (N=7,107)	Non-AS (N=71,033)
MI events, n	115	748
Incidence Rate of MI/1000 Person-Years	2.62	1.73
Incidence Rate Ratio of MI (95% CI)	1.52 (1.24–1.85)	1.0
Multivariable RR of MI (95% CI)	**1.21 (0.98–1.49)**	1.0

Conclusions: This large population-based study demonstrates an increased risk of CVA, but not for MI. These findings support that increased monitoring for this potentially fatal outcome and its modifiable risk factors is warranted for AS patients.

SAT0385 SIMILARITIES AND DIFFERENCES BETWEEN PATIENTS FULFILLING NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS AND UNDIFFERENTIATED SPONDYLOARTHRITIS CRITERIA: RESULTS FROM THE ESPERANZA COHORT

A. Juan Mas[1], X. Juanola Roura[2], E. de Miguel Mendieta[3], E. Collantes Estévez[4], J.C. Quevedo Abeledo[5], E. Alonso Blanco-Morales[6], V. Navarro-Compán[3] on behalf of ESPeranza working group. *[1]Rheumatology, Hospital Son Llàtzer, Palma de Mallorca; [2]Hospital Bellvitge, Barcelona; [3]Hospital la Paz, IdiPaz, Madrid; [4]Hospital Reina Sofía, Córdoba; [5]Hospital Gran Canaria Dr. Negrín, Gran Canaria; [6]Hospital Juan Canalejo, A Coruña, Spain*

Background: Patients with spondyloarthritis (SpA) were classified in five subgroups: ankylosing spondylitis (AS), psoriatic arthritis, arthritis associated with inflammatory bowel disease, reactive arthritis and undifferentiated SpA (uSpA). ASAS criteria classify patients in peripheral SpA and axial SpA (axSpA), being the latest classified in two groups: classical AS and non-radiographic axSpA (nr-axSpa). Whether or not patients with nr-axSpA represent the same group of patients that used to be classified as uSpA remains unclear.
Objectives: To evaluate the similarities and differences between patients with predominant axial disease classified currently as nr-axSpA versus those traditionally classified as uSpA.
Methods: Baseline data from the ESPeranza program (a multicenter national initiative to early diagnose SpA between 2008 and 2011) was used. Inclusion criteria for this program were: age <45 years and inflammatory back pain plus ≥1 SpA features with symptoms duration between 3 and 24 months. Demographic, clinic, laboratory and image results were compared between two groups: 182 patients with nr-axSpA and 166 patients classified as uSpA. In order to get a deeper knowledge of the differences between nr-axSpA and uSpA, we also compared: i) 88 patients only classified as nr-axSpA, ii) 72 patients only classified as uSpA; iii) 94 patients fulfilling both criteria. Student-t test for continuous variables and Pearson Chi-square test for categorical variables were used.
Results: Compared to patients classified as uSpA patients with nr-axSpA were younger, had HLA-B27 positive more frequently and higher values of CRP. On the other hand, they had history of SpA less frequently and lower values for BASDAI, BASFI and ASQoL (table). No differences were observed for gender, work incapacity, dactilitis, enthesitis, Pt's and Phy's VAS, BASMI and BASRI.

Table 1. Results are presented in mean ± standard deviation for continuous variables and n (%) for categorical variables

	Both, nr-axSpA & undifferentiated SpA N (%) = 94	Only nr-axSpA N (%) = 88	Only undifferentiated SpA N (%) = 72	p value*
Age (years)	30.9±7.3	32.2±6.9	35.2±6.9	**<0.01**
Male	61 (64.9)	50 (56.8)	34 (47.2)	0.2
Family history	48 (51.1)	21 (23.9)	30 (41.7)	**<0.05**
HLA-B27	81 (86.2)	65 (73.9)	6 (8.3)	**<0.001**
Enthesitis	29 (30.9)	18 (20.5)	22 (30.6)	0.1
BASDAI	3.7±2.3	3.8±2.1	4.7±2.3	**<0.01**
BASFI	2.2±2.2	2.1±2.1	2.9±2.5	**<0.05**
ASQoL	5.9±4.7	5.2±4.5	7.4±5.2	**0.01**
CRP (mg/L)	10.7±14.3	9.8±16.5	5.1±9.1	**<0.05**

*p value for differences between nr-axSpA and undifferentiated SpA (Student-t test for continuous variables and Pearson Chi-square test for categorical variables).

Conclusions: Compared with patients traditionally classified as uSpA, patients who are currently classified as nr-axSpA are diagnosed earlier, are more frequently HLA-B27 carriers and have higher disease activity according to objective parameters. On the other hand, they report lower values for patient reported outcomes.

SAT0386 EXTREME PATIENT REPORTED OUTCOME (PRO) IN EARLY SPONDYLOARTHRITIS: A SURROGATE FOR FIBROMYALGIA? ITS IMPACT ON TNF-ALPHA BLOCKERS TREATMENT EFFECT?

B. Meghnathi[1], A. Etcheto[1], P. Claudepierre[2], M. Dougados[1], A. Moltó[1]. *[1]Paris Descartes University, Medicine Faculty; APHP, Rheumatology B Department, Cochin Hospital; [2]Paris XII University; Rheumatology Department, Hôpital Henri-Mondor, Paris, France*

Background: In case of a concomitant fibromyalgia (FM) with axial spondyloarthritis (axSpA), there is a risk of misclassifying a patient as active (e.g. BASDAI >4), and to falsely consider him as refractory to NSAIDs/ biologics, since FM patients often report higher level of pain and fatigue[1]. We hypothesized that not only are extreme patient reported outcome (PRO) potentially surrogate marker of FM in axSpA, but also that this extreme PRO may have an impact on the TNF-α blockers (TNFb) treatment effect
Objectives: A) To describe the prevalence of extreme PRO in an early axSpA cohort. B) To compare the phenotype of axSpA patients with and without extreme PRO. C) To assess the impact of extreme PRO on the TNFb efficacy.
Methods: This analysis was performed on the DESIR cohort which included 708 adult patients (>18 and <50 years) with inflammatory back pain suggestive of axSpA (according to the rheumatologist's conviction of ≥5/10) for >3 months but <3 years duration. All patients were biologic naïve at inclusion and were followed up every 6 months for the first 2 years. At baseline, data pertaining to demographics, BASDAI, history of depression, type of medications (antidepressants or muscle relaxants) used and concomitant diseases were collected. It is worth noting that no systematic assessment of the fulfilment of the ACR criteria for FM was performed in this study; thus, we created a "FM gold standard" according to the available data (i.e., presence of either Muscle relaxants/ Depression/ Anti-depressant drug treatment/ Fibromyalgia comorbidity reported in the CRF). BASDAI was the selected PRO for this study due to its widespread use in clinical practice. BASDAI was tested against this "FM gold standard": we plotted ROC curves to define the best cut-off to define an "extreme PRO" for BASDAI. Phenotype of patient's with/without extreme PRO scores was compared. Impact of extreme PRO score on TNFb efficacy was assessed by comparing the retention rate of the first TNFb by Cox analysis.
Results: ROC curves to define an "extreme PRO" determined a different cut-off for each BASDAI question (i.e. >6, >5, >1, >4, >5 and >3 for question 1 to 6, respectively), and the need of at least 4 out of these 6 cut-offs to fulfil the "extreme PRO" condition; giving us a prevalence of 42.9% (304 patients) of extreme PRO in DESIR. Phenotypically, this group with extreme PRO, consisted of older patients (34.6 (8.3) vs 33.1 (8.8)), had more females (184 (60.5%) vs 195 (48.8%)), reported less sacroiliitis [radiographic and MRI, (36 (12%) vs 76 (19.4%)) and (82 (27.6%) vs 148 (37.8%)), respectively], showed less HLA B27 positivity (160 (52.6%) vs 248 (62.2%)), had higher CRP values (102 (34.3%) vs 102 (26.5%)), and more arthritis/ enthesitis history (212 (69.7%) vs 190 (47.5%)/ 182 (59.9%) vs 166 (41.5%)). A lower retention rate was observed in the group of patients with "extreme PRO" (Figure 1)
Conclusions: Coexistence of extreme PRO might be considered as a surrogate marker for FM in axSpA patients. Moreover, it appears to have a negative impact on TNF-α blockers retention rate.

Background: During the development of recommendations and implementation aids of the GECOAx project, the importance of avoiding certain situations was highlighted.
Objectives: To recognize what prescriptions, risk assessments, or preventive strategies are wrong practices and should thus be avoided in clinical practice. To establish not to do recommendations in the management of the comorbidity of AxSpA.
Methods: A multidisciplinary group was selected [10 rheumatologists, 1 internist, 1 cardiologist, 1 gastroenterologist, 1 psychologist and 2 family physicians]. With the support of 3 methodologists, and after interactions aimed to edit a document for the management of comorbidity launched by the same panel, a list of Not to do recommendations was issued. In a discussion meeting, evidence was provided to support the recommendations, items without sufficient basis were removed, and the final list was produced.
Results: A summary list of Not to do recommendations (Table 1) was issued.

Table 1

– DO NOT prescribe NSAIDs to patients with high cardiovascular (CV) risk and particularly with hypertension.
– DO NOT prescribe NSAIDs to patients with CKD, heart failure or liver cirrhosis and, if necessary, exert caution.
– DO NOT use CV risk scores in patients who already suffered a CV event or those with multiple risk factors (smoking, obesity, sedentary lifestyle, DM, hypertension, dyslipidemia) or a family history of premature CV disease; All should be considered high CV risk.
– DO NOT base renal disease screening on a single glomerular filtration test and/or albuminuria (ALWAYS should be confirmed); serum creatinine should not be used as the only test to evaluate renal function.
– DO NOT administer biological therapy in case of active, serious and uncontrolled infection, sepsis or risk of sepsis or tuberculosis or without a previous screening of chronic HBV, HCV, HIV and TB.
– DO NOT repeat HBV vaccination unless HBV antibody levels are not achieved.
– DO NOT vaccinate a patient in therapy with biological agents or in immunosuppressive treatment with live viruses

Conclusions: These recommendations aim to avoid making common mistakes in clinical practice and to help better management of frequent comorbidity in patients with AxSpA.

SAT0388 ANALYSIS OF THE MUSCULOSKELETAL MANIFESTATIONS IN INFLAMMATORY BOWEL DISEASE PATIENTS AND ITS RELATIONSHIP WITH BIOLOGICAL TREATMENT

S. Mainero Mendoza[1,2], C.M. Feced Olmos[1], L. Gonzalez Puig[1], J. Ivorra Cortes[1], I. Martínez Cordellat[1], C. Nájera Herranz[1], R. Negueroles Albuixech[1], J.E. Oller Rodriguez[1], F.M. Ortiz-Sanjuan[1], E. Vicens Bernabeu[1], E. Grau Garcia[1], E. Labrador Sánchez[1], K. Arévalo Ruales[1], J.J. Fragio Gil[1], R. González Mazarío[1], C. Alcañiz Escandell[1], I. Cánovas Olmos[1], I. Chalmeta Verdejo[1], V. Fornés Ferrer[3], J.A. Román Ivorra[1,2]. *[1]Rheumatology Department, HUP la Fe; [2]Medical School, UCV; [3]Biostatistics Unit, IIS la Fe, Valencia, Spain*

Background: Crohn's disease (CD) and ulcerative colitis (UC) are the main entities of inflammatory bowel disease (IBD). Both present extraintestinal manifestations that do not always depend on the IBD activity. The most common manifestations involve the musculoskeletal system and they are included in the seronegative spondiloarthritis group. If there is active or known IBD, treatment of this is priority because it usually improves joint disease. However, joint disease can also have an independent course of the intestinal manifestations as in patients with IBD and ankylosing spondylitis (AS).
Objectives: To analyze the prevalence of extraintestinal manifestations in IBD patients and treatment provided.
Methods: Retrospective observational analysis of IBD patients that have been remitted to the rheumatology department of HUP La Fe with musculoskeletal manifestations. Demographic, clinical and treatment data of patient were collected. Biostatistical analysis with R (3.3.2.) was performed.
Results: We recruited 183 patients diagnosed with IBD (57.4% women), 117 with CD and 66 with UC, with a mean age at diagnosis of 37.03±14.02 years old. 29 of them have axial affection and 51 peripheral affection, and simultaneously in 22 cases. We observed no statistical differences in axial or peripheral affection according to the IBD diagnosis. 79 cases were on biological therapy, and these treatments were conducted by Rheumatology in the 44% of cases and by Digestive Department in the 66% of cases. We observed that patients with axial affection present higher probability that the treatment has been conducted by Rheumatology (P=0.007), and broken down axial affections AS diagnosis had the most probability to be conducted by Rheumatology (n=36 P=0.0102). Related to peripheral manifestations, uveitis diagnosis had the most probability to be conducted by Rheumatology (n=14 P=0.0337).
Conclusions: In our patient series with IBD and musculoskeletal manifestations, the most common were peripheral affection. Among patients with IBD and axial and/or peripheral manifestation, 44% were conducted by Rheumatology, and are cases with axial predominance, where IBD treatment does not improve musculoskeletal disease and a primary spondyloarthritis treatment is needed.

SAT0389 COMPARISON OF ANKYLOSING SPONDYLITIS AND NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS IN A MULTI-ETHNIC ASIAN POPULATION OF SINGAPORE

C. Hong[1], Y.H. Kwan[2], W. Fong[1]. *[1]Department of Rheumatology and Immunology, Singapore General Hospital; [2]Programme in Health Services and Systems Research, Duke-NUS Medical School, Singapore, Singapore*

Background: The relationship between non-radiographic axial spondyloarthritis (nr-axSpA) and ankylosing spondylitis (AS) is currently debated. Till date, there is no study exploring the differences between AS and nr-axSpA in Asia.
Objectives: The primary objective of this study was to compare clinical characteristics, disease activity, patient-reported outcomes and associated co-morbidities between patients with AS and nr-axSpA in a multiethnic Asian population of Singapore.
Methods: All patients fulfilled 2009 ASAS classification criteria for axial SpA. Of these, all AS patients fulfilled the modified New York criteria. AS and nr-axSpA patients were retrieved from the PREcision medicine in SPONdyloarthritis for Better Outcomes and Disease Remission (PRESPOND) registry in Singapore General Hospital. Patients were followed up over 2 years. Baseline characteristics, medications, disease activity, patient-reported outcomes and inflammatory markers prior and 6 months post treatment were recorded using standardized questionnaires.
Results: 262 AxSpA patients (82% Chinese, 79% males) were included. Current mean age (S.D.) was 41.7 (13.7) years, mean age of diagnosis was 31.7 (12.5) years, mean length of disease was 10.1 (8.3) years and body mass index was 24.7 (6.3) kg/m^2, which was similar between AS and nr-axSpA patients. AS patients were older [mean age 42.7 (13.5) vs 37.4 (13.8) years, p=0.02], had longer disease duration [mean disease duration 10.9 (8.7) vs 6.4 (4.8) years, p<0.01], more frequently HLA-B27 positive (82% vs 68%, p=0.03), associated with uveitis (33% vs 17%, p=0.03), and hypertensive (17% vs 0%, p<0.01) compared to nr-AxSpA respectively. nr-axSpA patients had higher BASDAI [mean BASDAI 4.2 (1.6) vs 3.5 (1.9), p=0.02], BAS-G [mean BAS-G 4.7 (1.7) vs 3.9 (2.1), p<0.01] and ASQOL [mean ASQOL 4.9 (4.8) vs 3.5 (4.1), p=0.04] scores

compared to AS patients respectively at baseline. Peripheral arthritis, enthesitis, dactylitis, psoriasis, inflammatory bowel disease, hyperlipidemia, cardiac disease, diabetes mellitus, patient global assessment, BASFI, HAQ and SF-36 physical component summary and mental component summary were similar in both groups at baseline. Mean BASDAI, BAS-G, patient global assessment, HAQ and SF-36 physical component summary and mental component summary scores were similar at 12 months between both groups, except for BASFI, which was higher in AS patients ($p<0.001$). Medications used were similar between AS and nr-AxSpA patients (81% of axial SpA patients were on NSAIDs, 31% on concomitant DMARDs and 14% on biologics). Mean erythrocyte sedimentation rate and C-reactive protein were similar between both groups at baseline and 12 months post treatment.

Conclusions: In our multi-ethnic Asian cohort, patients with AS are more likely to be HLA-B27 positive, have uveitis, hypertension, and poorer physical function despite therapy; whilst nr-axSpA patients have higher baseline disease activity scores and tend to experience poorer well-being and quality of life. Although both groups represent different aspects of the same disease, they respond similarly to treatment.

SAT0390 DIFFUSION WEIGHTED IMAGING (DWI) IS MORE USEFUL THAN SHORT TAU INVERSION RECOVERY (STIR) SEQUENCE IN DIAGNOSIS OF NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS (SPA) AND BOTH SEQUENCES ARE PARTICULARLY USEFUL IN EARLY DISEASE STAGE

C.W.S. Chan, H.Y. Chung. *Medicine, Queen Mary Hospital, Hong Kong, Hong Kong*

Background: Diffusion weighted imaging (DWI) is a new Magnetic Resonance Imaging (MRI) sequence proposed for spondyloarthritis (SpA) diagnosis. Whether it is more useful than the traditional short tau inversion recovery (STIR) sequence in disease diagnosis had not been evaluated.

Objectives: By comparing with traditional STIR sequence in a group of back pain patients newly referred to rheumatology clinics, we evaluated the usefulness of DWI in SpA diagnosis at different stages.

Methods: All new patients referred to the rheumatology clinics with persistant back pain were recruited. DWI and STIR MRI were performed. Conventional radiographs of the pelvis were assessed according to the modified New York criteria for ankylosing spondylitis. Bone marrow edema (BME) and active sacroiliitis according to the ASAS definition were evaluated in STIR and DWI by two independent observers.

Results: One hundred and thirty-three patients were recruited. Ninety patients (67.7%) had a clinical diagnosis of SpA. Average back pain duration was 8.5±8.9 years. The presence of Human Leukocyte Antigen (HLA) B27 was found in 42.9% of the study population. Inter-observer correlations were excellent (STIR 95.4%, $p<0.001$; DWI 69.5%, $p<0001$). DWI was found to be comparable to STIR in disease diagnosis (sensitivity DWI 34.1% vs STIR 34.3%; specificity DWI 85% vs STIR 93.8%) and when applied to the Assessment of SpondyloArthritis international Society (ASAS) criteria for axial SpA (sensitivity DWI 78.9% vs 79.5%; specificity DWI 75.0% vs 78.8%). DWI is better than STIR in non-radiographic axial SpA group (sensitivity DWI 37.8% vs STIR 33.8%; specificity DWI 85.3% vs STIR 95.6%). In the group with disease duration less than 3 years, the two images showed improved sensitivity (sensitivity DWI 34.5% vs STIR 41.4%; specificity DWI 84.6% vs STIR 88.5%).

Conclusions: DWI is useful in SpA diagnosis especially in non-radiographic axial SpA group. Both DWI and STIR are especially useful for early disease diagnosis.

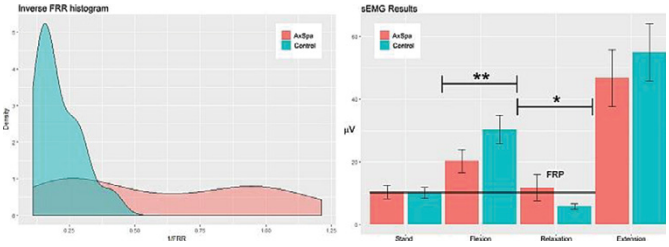
SAT0391 LUMBAR FLEXION/RELAXATION PHENOMENON IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS



C. Aranda-Valera[1], J.L. Garrido-Castro[2], A.M. Galisteo[1], J. Peña-Amaro[1], C. González-Navas[2], P. Font-Ugalde[2], E. Collantes-Estevez[2]. *[1]University of Cordoba; [2]Maimonides Institute for Biomedical Research of Cordoba, Cordoba, Spain*

Background: Surface electromyography (sEMG) has been used in several studies to assess muscle activity in patients with low back pain (LBP). It has also been analyzed the lumbar flexion-relaxation phenomenon (FRP) defined by reduced lumbar erector spinae (ES) muscle myoelectric activity during full trunk flexion in healthy individuals, through the flexion relaxation ratio (FRR). In LBP patients, this relaxation, compared to the peak reached at the flexion phase, is smaller and even non-existent. There are very few studies that analyze this effect in patients with Axial Spondyloarthritis (axSpA).

Objectives: To evaluate muscular activity at the erector spinae using sEMG in patients with axSpA to analyze FRP.

Methods: 39 subjects were included: 25 patients with axSpA (49.3±5.6 years, 75% men) and 14 healthy subjects (46.7±8.7 years, 71% men) as control group. Demographic data, conventional metrology, advanced metrology using motion capture (UCOTrack) and PRO questionnaires were collected. Electrodes were placed on left and right side, at L4-L5 level and separated 2cm from the spinous process, on the ES. Muscle activity values were obtained in 4 phases (standing, flexion, relaxation and extension). With the values of flexion and relaxation, the FRR index and its inverse 1/FRR were calculated. Student t tests were used for differences between groups.

Results: There were no significant differences between the right and left sides of the measurements at ES, so mean values were considered for the analysis. There were also no significant differences in age and gender between the control group and patients. Results obtained in each of the phases are shown in the graph. The FRP appeared in healthy individuals, but not in patients, as show the FRP line in the graph: in axSpA, sEMG values at the Flexion phase are above values at the stand phase, and in control group is the opposite, so there is a truelly relaxation. There were significant differences between patients and control group in flexion, relaxation, and in the FRR and 1/FRR ratios. 1/FRR presented better correlations with several parameters (age, lateral flexion, Schöber, BASMI, BASFI, UCOASMI, BASG, all with $p<0.01$), but not with activity indexes (BASDAI, ASDAS). Distribution of 1/FRR values and results of sEMG between group (** $p<0.01$, * $p<0.05$) are shown at the chart. The area under a ROC curve to discriminate healthy patients using 1/FRR was 0.85 (95% CI 0.72–0.96 $p<0.001$).

Conclusions: In our study, there were differences between healthy and patients with axSpA in the FRP, as in other studies with LBP patients. The 1/FRR index shown the best results in correlation with other parameters and it was where major differences between groups appeared. There was good correlation with the patient global score (BASG) and with the functional BASFI index, so assessment with sEMG could be an objective and quantitative test to evaluate the patient's functional status. It would be very interesting to analyze, in future studies, the sensitivity to change to treatments which would give us a good indicator to assess their effectiveness.

SAT0392 THE DIAGNOSTIC ACCURACY OF EXISTING GRADING CRITERIA OF SACROILIAC JOINT CT IN ANKYLOSING SPONDYLITIS

D. Gao, K. Li, Y. Wang, J. Zhu, J. Zhang, F. Huang. *Rheumatology, Chinese PLA General Hospital, Beijing, China*

Background: Imaging modalities are essential for the diagnosis of ankylosing spondylitis (AS) due to the absence of specific clinical manifestations. Sacroiliac Joint (SIJ) CT has been used to identify sacroiliitis for decades with a higher diagnostic accuracy than radiography in detecting structural changes, and not reducing the specificity like MRI. However, no well-accepted grading system for SIJ CT existed.

Objectives: We evaluated the diagnostic accuracy of existing grading criteria of sacroiliitis, aiming to provide references for future better reading of SIJ CT in AS.

Methods: A total of 2714 patients who had received CT scanning for any reasons with complete SIJ structures displaying between June 2012 and December 2015 were included. The CT scans were read by 2 rheumatologists together who had received professional training in radiology. Patients with sacroiliitis were selected and bilateral SIJs of each patient were evaluated separately by the 1984 modified New York (mNY) criteria, the criteria proposed by Lee (Lee criteria)[1] and the criteria from Innsbruck workshop report (Innsbruck criteria)[2], respectively. The grading differences among these criteria were analyzed.

Results: Amount to 509 patients were detected having sacroiliitis with an average age of 34 years and 64% of male. Among 1018 SIJs of these patients, 45 SIJs graded 1∼3 by mNY criteria were graded 0 by Lee criteria, indicating the better specificity of Lee criteria. Lee criteria was much more convenient and reliable than mNY criteria for its more explicit definitions. The SIJs with definite sacroiliitis estimated by mNY and Lee criteria were 79.37% and 82.91%, respectively, and simply divided into grade 3 or grade 4. Conversely, 85.27% SIJs were identified as definite sacroiliitis and classified into 5 grades, from grade IIB to grade IVB, by Innsbruck criteria, and the percentages of each grade were 8.94%, 26.82%, 20.92%, 10.12% and 18.47%, respectively, which means a higher discrimination capability than the other two criteria. Other than graded by the extent of lesions in mNY criteria or Lee criteria, the grading assessment by Innsbruck criteria was based on the lesion types, which was more consistent with the natural progression of sacroiliitis.

Abstract SAT0392 – Table 1. The existing grading criteria of SIJ CT

mNY criteria	Lee criteria	Innsbruck criteria
0 = Normal	0 = Normal	IA = SIJ>4 mm
1 = Suspicious for erosions or sclerosis	1 = Focal erosions seen on only one of either semi-coronal or axial images	IB = SIJ<2 mm
2 = Mildly abnormal with definite erosions or sclerosis, but without alteration in the joint width	2 = ≤25% erosions*, but without alteration in the joint width	IIA = Contour irregularities
3 = Moderately abnormal with erosions or sclerosis, joint space narrowing or widening and/or partial ankylosis	3 = ≥25% erosions*, joint space alteration and/or partial ankylosis	IIB = Erosion
4 = Complete ankylosis	4 = Complete ankylosis	IIIA = Subchondral sclerosis
		IIIB = Spur formation
		IVA = Transarticular bony bridges
		IVB = Ankylosis

*Extent of erosions; (%) = number of slices with erosions/total number of slices × 100.

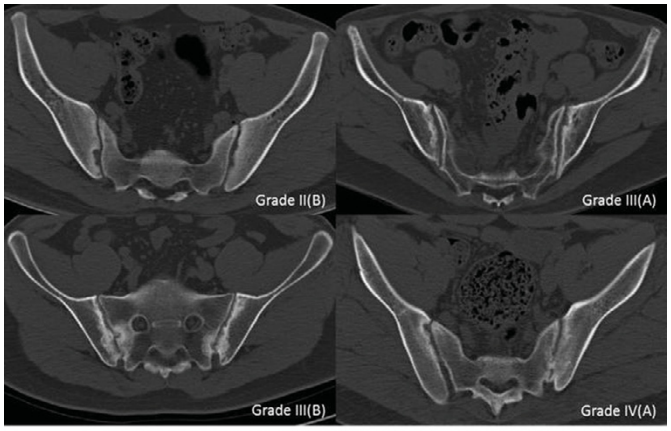

Figure 1 SIJ CT images graded 3 by mNY criteria or Lee criteria, while graded from II(B) to IV(A), respectively, by Innsbruck criteria.

Conclusions: Lee criteria has a better diagnostic specificity with a lower difficulty in the evaluation process, while Innsbruck criteria is a more detailed grading system, which has a higher consistency with the progression of sacroiliitis in AS.

SAT0393 PROTEIN FINGERPRINTING SCREENING SPECIFIC PROTEINS IN SERUM OF PATIENTS WITH ANKYLOSING SPONDYLITIS

D. Ma, L. Zhang. *Rheumatology Department, Shanxi DaYi Hospital, Shanxi Academy of Medical Sciences, Taiyuan, China*

Background: Ankylosing spondylitis (AS) is a chronic inflammatory rheumatic diseases which mainly affects the spine and sacroiliac joint. So far, the pathogenesis of AS remains elusive, making it difficult to improve early diagnosis and treatment. Proteomics is a new enabling technology to screen disease associated proteins which can be used in diagnostics or therapeutics.

Objectives:
The surface-enhanced laser desorption ionization/time of flight mass spectrometry (SELDI-TOF-MS) and protein chip screening specific biomarkers in serum of patients with ankylosing spondylitis (AS) are used to diagnose and assess the disease as well as to anticipate the program of disease.

Methods:
The serum samples of 69 AS patients, 10 rheumatoid arthritis (RA) and 12 healthy individuals were detected by SELDI-TOF-MS and weak cation exchange (WCX-2) chip. Then 69 AS patients were divided into several types such as the active and inactive stage of illness, axial arthritis involved and peripheral and axial arthritis involved, the positive and negative group of HLA-B27 to study differentially expressed proteins in the pathogenesis of AS by using Biomarker Wizard and Biomarker Pattern software of SELDI to screen the specific proteins and set up the diagnostic prediction models of disease.

Results: 1.The contents of 27 proteins between AS patients and healthy groups were significantly different. Of these proteins, 14 were up-regulated and 13 were down-regulated in patients with AS.The diagnostic model made up of 8085, 2640 and 2932 could be used to diagnose AS, which the sensitivity and specificity were 94.23% and 100% respectively.

2.The contents of 30 proteins were significantly different. Of these proteins, 14 were up-regulated and 16 were down-regulated in the active stage of AS. The diagnostic model made up of 3677, 3880, 2539, 3159 and 3242 could be used to determine the disease activity of AS, which the sensitivity and specificity were 98.11% and 100% respectively.

3.The contents of 3 proteins were significantly different. The protein of M/Z 8687 was up-regulated in the axial arthritis involved of AS, while the proteins of M/Z 4700, 18538 were down-regulated. The diagnostic model made up of the three proteins could be used to predict AS whether peripheral arthritis was involved or not, which the sensitivity and specificity were 80.00% and 82.35% respectively.

4.There were no different expressed proteins in serum between the positive and negative group of HLA-B27.

5.The contents of 23 proteins were significantly different. Of these proteins, 14 were up-regulated and 9 were down-regulated in the AS patient. The diagnostic model made up of 10259, 7972, 2048, 2154 and 2954 could be used to distinguish AS and RA, which the sensitivity and specificity were 100% and 100% respectively.

Conclusions:
The serum protein fingerprinting set up by SELDI-TOF-MS could screen new biomarkers in AS, which is expected to become a screening platform in diagnose and assessment of disease.

SAT0394 THE IMPAIRMENT OF HIP JOINTS IN PATIENTS WITH EARLY AXIAL SPONDYLOARTHRITIS (CORSAR COHORT) BASED ON THE RESULTS OF THE TWO-YEAR OBSERVATION

D. Rumiantceva[1], T. Dubinina[1], O. Rumyantseva[1], A. Demina[1], E. Agafonova[1], S. Erdes[1], S. Krasnenko[1], A. Smirnov[2]. *[1]Laboratory of spondyloarthritis; [2]Laboratory of radiology, Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation*

Background: Previous studies showed that the impairment of hip joints (HJ) - coxitis leads to a hip replacement and it is a frequent cause of early disability in patients (pts) with spondyloarthritis (SpA). Early detection of coxitis have a great clinical importance.

Objectives: To study the incidence and character of the impairment of HJ involvement in patients with early axial SpA (axSpA).

Methods: The study include 65 patients with axSpA (ASAS 2009) with disease duration <5 years and age at onset <45 years, mean age 28,5 (5,8) y., 32 (49,2%) males, 60 (92,2%) pts were HLAB27-positive, average disease duration was 24,1 (15,4) mo. The following evaluations were made: HJ pain (numerical rating scale – NRS - from 0 to 10), inter-malleolar distance (IMD), radiological HJ changes (BASRI-hip), ultrasound examination (US) and pts who had US evidence or/and clinical coxitis - MRI of hip joints. For 2 years pts taking NSAIDs at therapeutic doses. The dosages of NSAIDs accounted by the ASAS NSAID index.

Results: After 2 years follow-up reduce HJ functional limitations and pain in the

Table 1. Clinical characteristics of imparment HJ at baseline and after 2 years

	Baseline	After 2 years	P
Bilateral HJ pain, % pts	22 (33,8%)	17 (26,1%)	0,2
Pain in the right HJ, % pts	6 (9,2%)	5 (7,6%)	0,5
Pain in the left HJ, % pts	32 (49,2%)	8 (12,3%)	0,000003
HJ funcional limitations, % pts	13 (20,0%)	3 (4,6%)	0,007
Bilateral HJ funcional limitations, % pts	8 (12,3%)	3 (4,6%)	0,1
IMD, mean (s.d.)	110,8 (11,0)	110,8 (11,0)	1,0

Table 2. MRI symptoms of the impairment HJ and US symptoms of coxitis at baseline and after 2 years

	Baseline	After 2 years	P
MRI symptoms of the defeat HJ, % pts	22 (68,7%)	14 (43,7%)	0,08
Bilateral synovitis, % pts	17 (77,2%)	10 (71,4%)	0,5
One-side synovitis, % pts	4 (18,1%)	2 (14,2%)	0,5
Bilateral swelling of bone marrow in femoral head, % pts	1 (4,5%)	0	0,5
One-side swelling of bone marrow in femoral head, % pts	2 (9,0%)	0	0,2
Bilateral swelling of acetabular roof, % pts	2 (9,0%)	3 (21,4%)	0,3
One-side swelling of acetabular roof, % pts	0	1 (7,1%)	0,5
US symptoms* of coxitis, % pts	14 (21,5%)	11 (16,9%)	0,3
Bilateral US symptoms of coxitis, % pts	2 (14,2%)	4 (28,5%)	0,3
One-side US symptoms of coxitis, % pts	12 (85,7%)	7 (50,0%)	0,9

*The distance between the anterior joint capsule and the femoral neck, capsular-neck distance CND >7 mm.

left HJ (Table 1). There were no statistical differences between MRI symptoms of the impairment HJ and US symptoms of coxitis at baseline and after 2 years (Table 2).
Radiographic progression (BASRI-hip≥1 stage) after 2 years follow-up founded in 7 (31,8%) pts with MRI symptoms of the impairment HJ. There are radiographic progression from normal HJ to bilateral stage 1 in 5 (71,4%) pts, from bilateral stage 1 to bilateral stage 2 in 2 (28,6%) pts. Mean NSAID index in pts with radiographic progression (31,8%) amount 62,2%, while in pts without radiographic progression – 72,5% (p=0,2).
Conclusions: 1. In patients with early axial spondyloarthritis in two years of observation radiographic progression observed in 31,7% patients despite on regular intake of NSAIDs. 2. Further studies of the impairment HJ are required in patients with axial SpA.

SAT0395 SIMILARITIES AND DIFFERENCES BETWEEN NON-RADIOGRAPHIC AND RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS IN PROOF COHORT

D. Poddubnyy[1], R.D. Inman[2], J. Sieper[1], S. Akar[3], S. Muñoz-Fernández[4], M. Hojnik[5]. *[1]Charité Universitätsmedizin Berlin, Berlin, Germany; [2]Toronto Western Hospital, Toronto, Canada; [3]Izmir Katip Celebi University School of Medicine, Izmir, Turkey; [4]Hospital Universitario Infanta Sofía, Universidad Europea, Madrid, Spain; [5]AbbVie, Ljubljana, Slovenia*

Background: Previously, some differences between non-radiographic and radiographic axial spondyloarthritis (axSpA) – such as a higher prevalence of females and lower level of acute phase reactants in non-radiographic axSpA (nr-axSpA) – have been reported in national observational studies, mostly from Europe.
Objectives: To compare demographic and clinical characteristics of patients (pts) with nr-axSpA and radiographic axSpA (ankylosing spondylitis, AS) in a large multinational cohort of pts with recently diagnosed axSpA.
Methods: PROOF is a prospective observational study evaluating clinical and radiographic outcomes in axSpA pts in rheumatology clinical practice in 29 countries. Pts with axSpA fulfilling ASAS classification criteria were eligible if diagnosed ≤1 year prior to study enrolment. Investigator's confidence with the diagnosis of axSpA was ascertained on a numeric rating scale (NRS 0–10) at enrolment and end of follow-up. At baseline, demographic and clinical data related to the diagnosis, disease activity, quality of life and work productivity, as well as conventional radiographs of the sacroiliac joints were collected. Classification as nr-axSpA or AS was based on the results of the assessment of sacroiliac radiographs. Available radiographs were assessed first by a local reader and then by a central reader according to the grading system of the modified New York criteria. In the case of a disagreement in the classification (nr- axSpA or AS), the radiograph was evaluated by the 2nd central reader, who was blinded to the previous assessments and the final classification was made based on the decision of 2 out of 3 readers.
Results: Of the 2126 pts enrolled in PROOF, 1281 (60.3%) pts were classified as AS and 845 (39.7%) as nr-axSpA according to investigators. The confidence with the diagnosis of axSpA was 8.7±1.8. The final classification according to the central assessment of sacroiliac radiographs was confirmed in1583 pts included in this analysis. A total of 987 pts (62.3%) were classified as AS and 596 (37.7%) as nr-axSpA. AS pts expectedly had longer symptom duration, more frequently had elevated and higher CRP and were more often male and treated with TNF inhibitors (Table). In addition, HLA-B27 positivity was more frequent among AS pts, while pts with nr-axSpA had a significantly higher prevalence of enthesitis, psoriasis, and inflammatory bowel disease (IBD). The prevalence of other SpA features was comparable between the two subgroups of axSpA. Mostly, pt-reported outcomes reflecting burden of disease were comparable between the two subgroups, but BASDAI was significantly higher in the nr-axSpA subgroup (Table).
Conclusions: There were a few differences between nr-axSpA and AS pts in the PROOF cohort. The clinical constellation of female sex, low CRP, enthesitis, psoriasis, and IBD in nr-axSpA pts appears to reflect a phenotype less prone to structural damage in the sacroiliac joints. However, the clinical burden of disease was comparable between the two subgroups of axSpA.

SAT0396 INVESTIGATION OF IRON DEFICIENCY ANEMIA IN ANKYLOSING SPONDYLITIS PATIENTS

Y. Bulut[1,2,3], D. Arslan Tas[4], O. Goruroglu Ozturk[2], U. Karaogullarindan[3]. *[1]Cukurova University, Faculty of Medicine, ADANA, Turkey; [2]Biochemistry; [3]Internal Medicine; [4]Rheumatology-Immunology Department, Cukurova University, Faculty of Medicine, ADANA, Turkey*

Background: It is reported that subclinic intestinal inflammation may occur in Ankylosing spondylitis (AS) patients, besides, using NSAIDs cause peptic and duedenal ulcers. %50–60 of AS patients have asymptomatic ileal and colonic mucosal inflammation. It is reported that inflammatory bowel disease (IBD) is found in 5–10% of AS patients and 4–10% of IBD patients have concomittant findings with AS. These conditions may cause iron deficiency anemia (IDA).
Objectives: It is well known that chronic disease anemia is a frequent finding in AS patients. But there is no study in the literature about relationship between AS patients and IDA. In this particular study we aimed to asses frequency of IDA in AS patients and to investigate the etiologies of IDA.
Methods: Ninety four consecutive AS patients who meet 2012 ASAS/EULAR criteria, who were followed Çukurova University Romatology Clinic, were icluded. We investigated the etiologies of IDA in anemic patients. Twenty six AS patients were diagnosed as IDA. Twenty six patients without anemia were assigned as a control group. Hepcidin, soluble transferrin receptor1 (sTfR1) and anemia parameters were tested in both groups. Findings were anayzed with SPSS version 23.
Results: Twenty six of 94 AS patients were diagnosed as IDA (%27). Frequency of IDA in our AS patients was higher when compared to the IDA prevalence in the society (%1–2). Endoscopy and colonoscopy were performed for searching etiology of IDA. Mucosal inflammation was found in 62% of patients by endoscopy and 11% of patients by colonoscopy. One patient was diagnosed as Crohn's disease and one patient was diagnosed as Coeliac disease histopathologically. Hepcidin was found to be significantly lower in IDA patients ($p<0.01$). We found sTfR1 levels significantly higher in IDA patients ($p<0,01$). BASDAI (Bath Ankylosing Spondylitis Disease Activity Index) and sedimentation values were found to be higher in IDA patients statistically ($p<0.01$and $p=0.01$ respectively). Although we found C- reactive protein (CRP) values were higher when compared to the non- anemic patients; however it was not statistically significant ($p>0.05$).
Conclusions: We found higher frequency of IDA when compared to the normal

population. We found that AS was more active in patients who were diagnosed as IDA. We suggest that AS activitiy may cause mucosal inflammation and subsequently may result as IDA. Also we found that mucosal inflammation in AS patients is not related to NSAIDs because there was no difference about mucosal lesions between NSAID taking and non-NSAID taking group. No study was met in the literature concerning AS and IDA. Our findings should be supported by further studies.

SAT0397 RISK FACTORS FOR DEVELOPMENT AND PERSISTENCE OF CHRONIC WIDESPREAD PAIN, IN ANKYLOSING SPONDYLITIS AND UNDIFFERENTIATED SPONDYLOARTHRITIS

E. Mogard[1], E. Lindqvist[1], A. Bremander[2,3], S. Bergman[2,4]. *[1]Department of Clinical Sciences, Section of Rheumatology and Skåne University Hospital; [2]Department of Clinical Sciences, Section of Rheumatology, Lund University, Lund; [3]School of Business, Engineering and Science, Halmstad University, Halmstad; [4]Primary Health Care Unit, Department of Public Health and Community Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden*

Background: Chronic back pain is a prominent symptom in Spondyloarthritis (SpA), and an important contributor to diminished quality of life (1,2). Chronic pain can develop in intensity, become more spread, and progress to chronic widespread pain (2). Mechanisms for this are yet inconsistent (3), and in SpA, knowledge of progression to chronic widespread pain (CWP) is lacking.
Objectives: To study the development of CWP in patients with SpA, and to identify risk factors for development and persistence of CWP.
Methods: A cohort study with baseline and 2.5-year follow-up postal surveys. 644 patients (47% women) with ankylosing spondylitis (AS) and undifferentiated spondyloarthritis (SpA) answered both surveys, and were categorized as no chronic pain (NCP), chronic regional pain (CRP), and CWP. Logistic regression analyses, with CWP as the main outcome were performed. Due to multicollinearity, each risk factor candidate (disease duration, BMI, smoking, and different patient-reported outcome measures; PROMs) were analysed in separate logistic regression models together with a base model (age, sex, and SpA-subgroup).
Results: At follow-up, prevalence estimates for NCP, CRP and CWP were similar to those at baseline, but 38% of the patients had transitioned between the groups. A large group, 72% of the patients with initial CWP, also reported persistent CWP at follow-up (Figure). Risk factors (OR and 95% CI) for development of CWP from initial NCP/CRP were more pain regions (1.36; 1.20–1.53), pain intensity (1.35; 1.20–1.52), fatigue (1.25; 1.13–1.38), global health (1.35; 1.19–1.54), EQ-5D (0.05; 0.01 – 0.19), BASDAI (1.25; 1.07 – 1.45), BASFI (1.32; 1.16 – 1.50), ASES pain (0.97; 0.96 – 0.99), ASES symtom (0.98; 0.97 – 0.99), and HADb (1.10; 1.02 – 1.19). The risk factors for persistent CWP, compared to patients transitioning to NCP or CRP, were similar to those predicting development of CWP, but in addition, also higher age (1.02; 1.00–1.04), and female sex (1.82; 1.06–3.10), predicted the outcome.

Figur 1. Transition of patients to and from the pain groups (NCP, CRP, CWP) between 2009 and 2011. Pearson Chi-Square test p≤0.001.

Conclusions: The total prevalence of CWP did not change over the study-period, although a substantial transition between the pain-groups were found. More pain regions, higher pain intensity, fatigue and worse self-reported health predicted the development into CWP, and persistent CWP. Also, higher age and female sex were risk factors for persistent CWP in SpA. Special attention in patients who report increased pain and related symtoms is essential, to early identify the development of CWP in patients with SpA.

SAT0398 PREGNANCY OUTCOMES IN KOREAN WOMEN WITH ANKYLOSING SPONDYLITIS

E.H. Park[1], J.K. Jun[2], S.M. Lee[2], Y.W. Song[1], E.B. Lee[1]. *[1]Division of Rheumatology, Department of Internal Medicine; [2]Department of Obstetrics and Gynecology, Seoul National University College of Medicine, Seoul, Korea, Republic Of*

Background: Ankylosing spondylitis (AS) is a chronic, systemic, inflammatory disease that primarily affects the sacroiliac joints and spine. Despite overwhelming prevalence of AS in men, it can also occur in women. Since AS mainly affects the sacroiliac joints, a special attention should be paid to the normal labors and pregnancy outcomes in these female patients. However, very little is known about the impact of AS on pregnancy outcomes due to rare occurrence of the disease in women.
Objectives: To investigate the pregnancy outcomes in Korean female patients with AS.
Methods: All of the 27 deliveries from 20 AS female patients who had been cared at Seoul National University Hospital between February 1994 and June 2016 were retrospectively evaluated through medical record review. After matching each pregnancy of the AS women with the pregnancies of the control group on a 1 to 4 ratio based on maternal and gestational age, pregnancy outcomes of AS patients were compared with those of the control group. Pregnancy outcomes included cesarean section (CS) rate, preterm birth, low birth weight infant, fetal growth restriction (FGR), fetal malformations and preeclampsia. Each pregnancy was considered as a separate observation, and outcomes between the groups were compared by regression models estimated using Generalized Estimating Equations (GEEs) to account for the matched nature of the data. For zero events in either group in which GEE models do not converge, Fisher's exact test or Chi-square test were used.
Results: Caesarean section (CS) was performed in 44.4% of deliveries among women with AS compared with 20.4% in controls (p=0.002) (Table 1). The indications of CS included previous uterine surgery, breech position, placenta previa, placental abruption, fetal distress, and cephalopelvic disproportion (CPD), which were comparable between two groups. When excluding the cases of elective CS, 16 pregnant women with AS were tried for the vaginal delivery. Among them, 15 cases (93.8%) achieved successful vaginal deliveries, which was comparable to the successful vaginal delivery rate in controls (86/90 (95.6%), p=0.566). CS due to CPD was done in 1 case (8.3%) of AS women, while there was no case in the controls (p=0.353). Interestingly, the severity of sacroiliitis in AS patients did not show any association with CS (p=0.342). Women with AS had a higher frequency of LBW compared to the controls (22.2% vs 8.3%, p=0.024). However, there was no statistically significant difference in other adverse pregnancy outcomes, including preterm birth, FGR, fetal malformations, and pre-eclampsia.

Table 1. Overall pregnancy outcomes

Characteristics	Pregnancies with AS (n=27)	Pregnancies without AS (n=108)	*p*-value[1)]
Caesarian section delivery, n (%)	12(44.4)	22(20.4)	0.002
Fetal loss, n (%)	0(0.0)	0(0.0)	-
Maternal death, n (%)	0(0.0)	0(0.0)	-
Preeclampsia, n (%)	0(0.0)	4(3.7)	0.583*
Twin pregnancy, n (%)	5(18.5)	8(7.4)	0.016
Fetal malformation, n (%)	1(3.7)	1(0.9)	0.329
Transfusion, n (%)	1(3.7)	2(1.9)	0.577
Hospital stay, days, mean (SD)	4.1(2.9)	5.1(7.9)	0.283
Sex of child, female, n (%)**	17(53.1)	63(54.8)	0.883
Neonatal weight, g, mean (SD)**	2960.3(523.8)	3065.3(509.4)	0.370
1 min Apgar Score <4, n (%) **	1(3.1)	7(6.1)	> 0.999
5 min Apgar Score <7, n (%) **	1(3.1)	4(3.5)	> 0.999

1) P-value: calculated from regression models estimated using GEEs to account for the matched nature of the data
* P-value: calculated from Fisher's exact test because of zero events in either group in which GEE models do not converge
** Analyzed by neonates and information of twins reflected, pregnancies with AS, n=32; pregnancies without AS, n=115

Conclusions: Although pregnant women with AS are concerned about CPD during their labors due to the involvement of the sacroiliac joints, vaginal deliveries

can be tried in patients with AS. The obstetric and perinatal outcomes in women with AS were also comparable to normal pregnant women.

SAT0399 HEADACHE AS A CLINICAL COMPLAINT AT INITIAL PRESENTATION AND DURING THE DISEASE COURSE IN PATIENTS WITH SPONDYLOARTHRITIS INDICATES CONCOMITANT / SECONDARY FIBROMYALGIA

E. Roussou, M. Karela, A. Georgiou. *Rheumatology, Barking, Havering and Redbridge University Hospitals NHS Trust, London, United Kingdom*

Objectives: To evaluate the symptom of headache as being able to clinically distinguish associated secondary fibromyalgia in patients with spondyloarthropathies (SpA). To compare the incidence of MSK complaints (related to SpA) in patients with headache to those that did not. To assess headache during the SpA disease course.
Methods: Registry data from 776 patients seen in clinic with SpA were analysed with reference to headache as symptom at presentation. The data of those patients presented with headache were compared with data of those patients who did not report headache with regards to demographics and disease characteristics. In addition, other MSK complaints, fatigue and pain during disease course were also analysed.
Results: From a total of 776 patients (m: f=265:508) age 48.3 (SD +14.1), 13 were excluded as no answer was recorded. 117/ 763 patients (15.08%) representing 28 males and 89 females (23.9% vs 76.1% ratio 1:3.1) reported headache at disease onset.
During the disease course, 13 patients out of the initial 117 did not record an answer to the question and were excluded. From remaining 104 patients, 95 patients (91.3%) continued to describe headache as a symptom.
From those not reporting headache as initial symptom, (n=659) 148 did not record an answer and were excluded. From the remaining 511 patients, 194 (37.9%) reported headache during the disease course.
On the data obtained from these 2 sub-groups, comparison took place using paired sample t-test.
Table shows demographics and disease characteristics as well as differences between the 2 SpA sub-groups. Those presenting with headache describe worse disease, more fatigue and a greater percentage describe pain at pressure points and MSK system.

	Headache at presentation (n=117)	No headache at presentation (n=656)	Statistical significance (p)	CI
Age (mean ± SD)	47.7 (13.16)	48.3 (14.3)	0.1	-5.757 to 0.912
Gender (M:F) ratio	28:89 (1:3.1)	219:419 (1:1.9)	0.3	-0.025 to 0.077
Disease duration (y) (mean ± SD)	11.4 (12.1)	10.9 (10.8)	0.4	-1.905 to 4.470
Delay in diagnosis (y) (mean ± SD)	6.43 (8.9)	6.3 (8.1)	0.7	-3.151 to 2.151
ESR (mean ± SD) mmHg	15.5 (14.8)	18.2 (18)	0.07	-11.064 to 0.582
CRP (mean ± SD) mg/dL	10.4 (36)	8.2 (9.8)	0.4	-6.106 to 12.536
BASDAI score (mean ± SD)	7.31 (3.7)	6.06 (2.08)	<0.005	0.783 to 2.624
BASFI score (mean ± SD)	5.6 (2.7)	5.04 (2.7)	0.09	-0.143 to 1.626
Buttock pain (%)	31.6	12.8	0.001	0.083 to 0.293
Back pain (%)	82.9	58.8	<0.005	0.125 to 0.337
Neck pain (%)	72.6	24.4	<0.005	0.340 to 0.583
Knee pain (%)	63.2	30.6	<0.005	0.284 to 0.520
Shoulder (%)	70.9	23	<0.005	0.312 to 0.559
Foot (%)	57.2	22	<0.005	0.279 to 0.524
Hip (%)	55.5	19.9	<0.005	0.217 to 0.467
Eye (%)	23	4.3	<0.005	0.102 to 0.274
Fatigue	77/116 (66.4%)	340/608 (55.9%)	0.018	0.029 to 0.299
Pain with pressure	71/117 (61.2%)	257/807 (42.4%)	0.000	0.122 to 0.378
Headache as co-morbidity	95 (109) 87.2%	195/509 (38.3%)	0.000	0.808 to 0.935

Conclusions: Headache can clinically represent secondary FM among SpA patients. A proportion of patients (representing 15%) report headache at presentation. The majority of those patients (>90%) continue to describe headache during the disease course. From those patients who did not have headache at presentation, 38% report headache during the disease course. Patients describing headache at presentation have more MSK complaints at presentation.

SAT0400 IS WHIPLASH INJURY A TRIGGERING OR EXACERBATING FACTOR FOR AXIAL SPONDYLOARTHRITIS?

F. Urano, S. Ono, R. Hara, M. Yasumura, T. Muramatsu, S. Suzuki. *Arthritis and Lupus Center, J a Nagano Koseiren Shinonoi General Hospital, Nagano City, Japan*

Background: Axial spondyloarthritis (AxSpA) can be triggered by infection and environmental factors, and some cases involve trauma. Whiplash injury in a traffic accident may lead to exacerbation of symptoms of AxSpA.
Objectives: The aims of this study are to survey the prevalence of trauma before or after onset of AxSpA and to examine the prevalences of neck trauma and other trauma in patients with a history of AxSpA.
Methods: The patients completed a questionnaire, and clinical presentation, inflammatory markers (ESR, CRP), radiographs, MRI of sacroiliac joints, Bath ankylosing spondylitis disease activity index (BASDAI), Bath ankylosing spondylitis functional index (BASFI), and Bath ankylosing spondylitis metrology index (BASMI) were assessed. Onset of symptoms was evaluated using European criteria for spondyloarthritis and patients were asked about mechanical stress (spinal trauma, extremity trauma, and internal organ injury). Patients with rheumatoid arthritis (RA) were included as controls and underwent the same evaluation. Patients with neck trauma were divided into four groups based on a short (<3 years) (group A) or long (≥3 years) (group B) period between disappearance of trauma symptoms and onset of inflammatory back pain (IBP); continuous IBP after trauma (group C); and a gradual change from minor symptoms to severe IBP after trauma (group D).
Results: The subjects were 124 patients with AxSpA and 102 with RA. Trauma occurred at a significantly higher rate in patients with AxSpA than in those with RA (66 (53.2%) vs. 12 (11.8%), p<0.0001). Neck trauma was also significantly more frequent in patients with AxSpA (63 (53.2%) vs. 9 (8.8%), P<0.0001) (Table 1). There were no significant differences in clinical background between patients with AxSpA with and without trauma (Table 2). Regarding the period from neck trauma to onset of IBP in patients with AxSpA, there were 4 (6.3%), 22 (34.9%), 14 (22.2%), and 23 (36.5%) cases in groups A, B, C and D, respectively.

Table 1. Prevalence of items related to mechanical stress in patients with axial spondyloarthritis (AxSpA) and rheumatoid arthritis (RA)

Item	AxSpA n (%) (95%CI)	RA n (%) (95%CI)	P value
Cases (male/female)	124 (46/78)	102 (15/87)

BASMI	2.62±1.58 (2.24-3.00)	2.48±1.69 (2.05-2.91)	ns

SD: standard deviation, CI: confidence interval, ns: not significant (P>0.05)

Conclusions: The remarkable finding in this study is that half of patients with AxSpA had a history of whiplash injury. These results suggest that trauma may influence the course of AxSpA through the immunological system or hypothalamic-pituitary-adrenal axis.

SAT0401 PREVALENCE OF ULTRASONOGRAPHIC LOWER AND UPPER ENTHESITIS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

G. Cuomo [1], M. Zappia [2], M. Verde [1], D. Sgambato [2], M. Romano [2]. *[1] Dipartimento Assistenziale Integrato di Medicina Interna, UOC Medicina Interna - Università degli Studi della Campania - Luigi Vanvitelli; [2] Dipartimento di internistica Clinica e Sperimentale, Università degli studi della Campania - Luigi vanvitelli, Napoli, Italy*

Background: Spondyloarthritis (SpA) occurs in up to 20% of patients with inflammatory bowel disease (IBD) [1]. Symptomatic enthesitis is a characteristic feature of SpA and represents an early sign of SpA [2]. The prevalence of enthesitis in patients with IBD is not known.
Objectives: This study was designed to evaluate whether patients with IBD showed an increased prevalence of entheseal involvement, even in the absence of clinical symptoms.
Methods: Thirty-five IBD patients (25 M and 10 F, median age 41 yrs), 25 with Crohn's disease (CD) and 10 with ulcerative colitis (UC), all with moderate intestinal activity, and 22 (13 M and 12 F, median age 44 yrs) control subjects with irritable bowel syndrome underwent a thorough clinical evaluation followed by entheses ultrasonography of upper limb (brachial triceps) and lower limb (quadriceps, proximal and distal rotuleus, Achilles tendon and plantar fascia). The Madrid sonographic entheses index (MASEI) was used to score entheses abnormalities [thickness, enthesophytosis, bursitis, erosions with and without power doppler (PD)]. Correlation between IBD features (type, duration and

activity), age, sex and MASEI score was assessed with nonlinear Spearman's rho. Significance of differences was assessed by chi-square test. The level of statistical significance of differences was set at p

Results: All of 35 patients with IBD presented at least one entheses alteration with a mean MASEI of 5.43 (thickness 57.1%, enthesophytosis 42.8%, bursitis 0%, erosions 0%, PD abnormalities 14.2%) vs 3 patients of control group (enthesophytosis 14%) (p

Conclusions: 1) IBD patients showed a significantly higher prevalence of early entheses involvement, even in the absence of clinical symptoms; 2) the entity of entheses alteration as assessed by MASEI did not correlate with type, duration and activity of IBD; 3) age was the only variable which significantly correlated with ultrasonographic entheses involvement.; 4) we speculate that IBD patients should undergo ultrasonography evaluation of entheses and, if any alteration, be followed up for early detection of SpA.

SAT0402 FREQUENCY AND HLA PHENOTYPE OF REACTIVE ARTHRITIS, UVEITIS, AND CONJUNCTIVITIS IN JAPANESE PATIENTS WITH BLADDER CANCER FOLLOWING INTRAVESICAL BCG THERAPY: A 20-YEAR, TWO-CENTER RETROSPECTIVE STUDY

H. Nishikawa[1], Y. Taniguchi[1], K. Inoue[1], Y. Yoshinaga[2], Y. Terada[1]. *[1]Kochi Medical school, Nankoku; [2]Kurashiki Medical center, Kurashiki, Japan*

Background: Intravesical instillation of Bacillus Calmette-Guerin (iBCG) is used as an effective immunotherapy of bladder cancer. However it may have, as adverse event, a reactive arthritis (ReA) and the frequencies are known as about 0.5 to 1% in Western countries.

Objectives: To evaluate the frequencies and HLA phenotype of reactive arthritis (ReA), uveitis, conjunctivitis and other adverse events in Japanese patients with bladder cancer following iBCG therapy.

Methods: The clinical findings of Japanese patients who received iBCG (n=555 [250 and 305 in Kochi Medical School Hospital {KMSH} and Kurashiki Medical Center {KMC}, respectively]) for bladder cancer from March 1997 to February 2016 were retrospectively assessed, with specific attention to patients with ReA and conjunctivitis/uveitis. We also looked at human leukocyte antigen (HLA) phenotypes of patients with ReA.

Results: Patient age was 73±10 and 70±11 years and male/female ratio was 198/52 and 240/65 in KMSH and KMC, respectively. 91/555 (16.4%), 121/555 (21.8%), and 196/555 (35.3%) of all enrolled patients presented with fever, haematuria, and dysuria, respectively. Of the 555 cases, ReA, uveitis and conjunctivitis were revealed in 11/555 (2.0%), 4/555 (0.7%) and 33/555 (5.9%), respectively. The frequency and the protocol of iBCG therapy were stable over the 20 years. Notably, HLA-B27, -B35, -B39 and -B51 positivity was more frequent in ReA patients (9.1%, 36.3%, 36.3% and 63.6%, respectively) ($p<0.05$) than in healthy subjects without ReA (0.3%, 8.3%, 4.0% and 9.1%, respectively).

Conclusions: The 2.0% ReA frequency in iBCG-treated Japanese patients exceeds that in Western countries. HLA phenotype, especially HLA-B51 and -B39 alleles in addition to -B27, may be a risk factor in iBCG-induced ReA in Japanese patients.

SAT0403 ARTERIAL HYPERTENSION IN PATIENTS WITH ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS – RESULTS OF 10-YEARS FOLLOW-UP

I.Z. Gaydukova, A. Aparkina, E. Kchondkaryan, A. Rebrov. *Hospital Therapy, Saratov State Medical University, Saratov, Russian Federation*

Background: Spondyloarthritis (SpA) (ankylosing spondylitis (AS) and psoriatic arthritis (PsA)) are associated with increased cardiovascular risk [1]. Destabilization of arterial pressure in chronic inflammation and anti-inflammatory treatment could be one of the reasons of early cardiovascular events onset.

Objectives: The purpose of this work is evaluate the occurrence and risk of arterial hypertension (AH) onset in patients with AS and PsA.

Methods: 663 patients were involved in the study: AS patients fulfilled mNew-York criteria (1984), PsA patients fulfilled CASPAR criteria (2006). Study included cross-sectional analyze, where 159 AS and 85 PsA patients participated, and 10-year prospective follow-up part, included 278 AS patients, 109 PsA patients. 276 patients were excluded due to lose the follow-up. In follow-up part of the study were involved SpA patients without AH at baseline. 182 healthy volunteers participated in the study like controls, 32 of them lost the follow-up. New cases of AH were registered after 4 and 10 years.

Statistics was performed in SPSS17 and GraphPadPrizm. All the results were adjusted to cardiovascular risk factors.

Results: Characteristics of the patients and controls with 10-years follow-up are presented in table 1.

Table 1. Baseline characteristics of the patients, involved in the study

	AS, n=278	PsA, n=109	Controls, n=150
Age, years (M ± SD)	40.0±11.4	40.55±10.6	39.0±11.2
Gender, male, n (%)	212 (76.25)#@	41 (48.2)	84 (56)
Disease duration, years (M ± SD)	13.7±10.03	14.8±14.4	–
Obesity, n (%)	32 (11.5)	24 (28.2)	22 (14.7)
Smoking, n (%)	151 (54,31)#@	30 (35,2)	40 (26,7%)

AS, ankylosing spondylitis; PsA, psoriatic arthritis; "–", absence of data. #$p<0.001$ for the difference with controls. @$p<0.001$ for the difference with PsA.

100% of patients recieved NSAIDs, 10% - glucocorticoids (5–10 mg prednisolone), 68.8% of PsA patients recieved methotrexate (10–25 mg/week), 14.3 of AS patients - sulfasalazine (2.0–3.0 g/day).

Due to cross-sectional analyses was shown that AH occurred in 48.7 of AS and in 67.5% of PsA patients, respectively, p=0.03.

Numbers of new AH cases during follow-up are presented in table 2.

Table 2. New cases of arterial hypertension in ankylosing spondylitis, psoriatic arthritis and healthy controls after 4 and 10-years of follow-up

	AS, n=278		PsA, n=85		Controls, n=150	
	4 years	10 years	4 years	10 years	4 years	10 years
AH cases, n (%)	95.0 (34.1)	139.0 (50)*	59.0 (69.4)	61.0 (71.7)*	31.0 (36.5)	31.0 (36.5)

*$p<0.0001$ for the difference with controls.

The relative risk (RR) of AH onset in patients with AS compared to healthy individuals is 2.22 (95% confidential interval (CI) 1.59 - 3.1); RR in PsA patients is 3.08 (95% CI 2.19 - 4.03), difference between risk of AH development in PsA and AS is significant, $p<0.0001$. Median to new AH cases in AS and PsA is 10±2.57 years from the first SpA symptoms appearance.

Conclusions: AH is frequently presented in PsA patients than in AS. Risk of new AH onset in patients with AS and PsA is superior compared with the healthy individuals. The number of new cases of hypertension increases with time, and in 10 years from diagnosis half of PsA/AS patients without cardiovascular disease will be in the risk of hypertension.

SAT0404 RELATIONSHIP OF SCLEROSTIN AND DICKKOPF-1 SERUM LEVELS WITH DISEASE ACTIVITY AND INFLAMMATORY MRI LESIONS IN PATIENTS WITH SPONDYLOARTHRITIS

I. Shynkaruk[1], O. Iaremenko[1], D. Fedkov[1], K. Iaremenko[2]. *[1]Bogomolets National Medical University; [2]Olexandrivska Kyiv City Hospital, Kyiv, Ukraine*

Background: Dickkopf-1 (Dkk-1) and sclerostin (Scl) are likely to play important roles in the process of ankylosis in Spondyloarthritis (SpA) [1]. Their serum levels are associated with the formation of new syndesmophytes [2]. But the relationship between these biomarkers and disease activity including active inflammatory lesions in sacroiliac joints (SIJ) on magnetic resonance imaging (MRI) still not clear.

Objectives: To estimate the relationship between the Scl and Dkk-1serum levels and active inflammatory MRI lesionsin SIJ, disease activity and functional status in SpA patients (pts).

Methods: Serum levels of Scl and Dkk-1 (pmol/l; ELISA) were measured at baseline in 79 pts with SpA. Mean age of pts (63.3% male) was 37.5±11.3, mean disease duration – 10.7±9.44 yrs. Radiological sacroiliitis defined according to Kellgren grade was: 0 – 1.6%, I – 22%, II – 49.2%, III – 13.6% and IV – 13.6%. Active inflammatory lesions in SIJ were evaluated with Spondyloarthritis Research Consortium of Canada (SPARCC) MRI SIJ score (0–72, n=46). Disease activity was measured by Ankylosing Spondylitis Disease Activity Score (ASDAS) using C-reactive protein (CRP), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI, mm), CRP (mg/l) and erythrocyte sedimentation rate (ESR, mm/hr). Functional status estimated using Bath Ankylosing Spondylitis Functional Index (BASFI, mm). For correlation the Spearman correlation coefficient was calculated.

Results: Mean value (M±σ) of biomarkers in all SpA pts were: Scl – 19.2±11.63, Dkk-1 – 30.7±19.5. The mean value of indices and laboratory parameters in all SpA pts were: ASDAS-CRP – 3.01±1.09, BASDAI – 4.36±1.88, CRP – 20.3±33.0, ESR – 25.8±20.7, BASFI – 3.01±2.33. SPARCC score was 24.6±10.9.

Scl level was significantly higher in pts with lower activity by SPARCC score (23.1±12.7) vs higher activity (16.6±7.63), p=0.043, in pts with moderate disease activity by ASDAS-CRP (22.3±15.6) vs very high disease activity (14.6±9.89), p=0.031, and in women (23.1±12.6) vs men (16.9±10.5), p=0.014. Its level didn't depend on CRP, ESR, BASDAI, BASFI and HLA B27 positivity.

Scl showed significantly negative correlation with BASDAI (r=-0.381, p=0.041) only in women.

There was no difference in Dkk-1 serum level depending on the gender, disease activity (by ASDAS-CRP), functional status, the presence of HLA B27 and inflammatory changes in SIJ (with quartile distribution). But the correlation analysis showed significant relationship of Dkk-1 with CRP (r=0.243, p=0.031) and SPARCC MRI SIJ score (r=0.351, p=0.017). The strength of the correlation between Dkk-1 and CRP was slightly higher in HLA B27 positive pts (90%; r=0.334, p=0.018).

In SpA pts with lower activity by SPARCC score significant correlation between Dkk-1 and inflammatory lesions in SIJ (r=0.400, p=0.043) and a negative correlation between Dkk-1 and BASDAI (r=-0.513, p=0.017) were found.
There was no correlation between Scl and Dkk-1 levels among all pts and different subgroups.
Conclusions: Scl level is significantly higher in pts with lower disease activity by SPARCC MRI SIJ score and ASDAS-CRP. Dkk-1 significantly positively correlates with disease activity due to CRP level and SPARCC score, but not to BASDAI.

SAT0405 CLINICAL, BIOLOGICAL AND GENETIC FACTORS, PREDICTORS OF TREATMENT NONRESPONSE TO TNF INHIBITORS (TNFI), IN ANKYLOSING SPONDYLITIS (AS) AND PSORIATIC ARTHRITIS (PSA)

J. Polo y La Borda, J. Campos, J. Sanz, J. Mulero, A. Sánchez. *Reumatología, Instituto de Investigación Biomédica, Hospital Universitario Puerta de Hierro Majadahonda, Madrid, Spain*

Background: TNF inhibitors (TNFi), are effective in controlling the activity of spondyloarthritis. But, there is a proportion of patients, who have to stop treatment due to its ineffectiveness or to the appearance of adverse events. In addition, these therapies imply high economic costs. To identify predictors of response, would help us to make decisions and to improve the risk/benefit ratio, in patients candidates who are candidates to initiate TNFi
Objectives: To determine clinical, biological and genetic predictors of nonresponse to treatment with TNFi in patients with AS and PsA.
Methods: We analyzed 118 patients [49 AS and 69 PsA (24 axial and peripheral involvement and 45 only peripheral)], under treatment or who were to start treatment with TNFi. Data were collected, prior to the start of the TNFi and at the last scheduled visit to the Rheumatology Service of the Hospital Puerta de Hierro, during the period 2013–2014. A clinical response was defined as the reduction ≥50% of the initial BASDAI, in patient with axial involvement, and if the final DAS 28 PCR was <2.6, in those patients with only peripheral involvement. A total of 73 men and 45 woman, mean age 53±11.2 years, and a median duration of illness of 15 years (IQR 10–23) were included. The baseline ESR and CRP were (10mm/hr IQR 5.0–27.0 and 2mg/l IQR 0.0–9.0) respectively. The mean and SD of BASDAI, DAS28 CPR and BASFI were (6.0±1.9, 3.0±0.6 and 5.4±2.5) respectively. A univariate analysis was performed using a Cox proportional hazard regression model which included: Smoker status, axial pain, peripheral arthritis, sacroiliitis, IBD, uveitis, psoriasis, HLA B27, VSG, PCR, BASDAI, BASFI, VGP, the number of TNFi and 45 single nucleotide polymorphism (SNPs) previously reported to be associated with response to TNFi. SNP genotyping was performed using de Sequenom MassARRAY plataform.Variables with a *P*-value <0.1 were included in a multivariate analysis. The discrimination capacity of the model was assessed using the Harrell C index. *P*-values <0.05 were considered statistically significant. Statistical analysis was performed with the SPSS v.17 software.
Results: The median duration of treatment was 62.9 months (IQR 40.7–96.5), the response to TNFi was 79.7% of patients, with mean and SD of BASDAI, BASFI and DAS 28 PCR (2.7±2.2, 4.2±2.8, 1.5±0.6) respectively. The factors that increased the non-response rate, were: the group of peripheral PsA versus AS (HR 2.94, *P*=0.023), VGP (HR 1.47, *P*<0.001), BASDAI (HR 1.80, *P*=0.001), BASFI (HR 1.52, *P*=0.001) and the number of TNFi used (*P*<0.001). There was a trend of significance (*P* <0.10) for females, with a 2.13-fold lower response rate than males *(P*=0.065). The SNPs associated were: rs4240847 of the *MAPKAPK2* gene (allele A, HR 1.63, *P*=0.019), rs11096957 of the *TLR-10* gene (T allele, HR 1.49, *P*=0.011), rs11541076 of the *IRAK-3* (allele T, HR 1.47, *P*=0.050), rs916344 of the *MAPK14* gene, in a recessive form,since CC alleles against CG or GG increased 10.12 times the non-response rate (HR 10,12; *P*=0.027) and rs11591741 of the *CHUK* gene (GG+GC/CC; HR 8.3, *P*=0.035).The mutivariable analysis is shown in the following table:

Table. Multivariate analysis and factors independently associated with the nonresponse rate

Variable	*P*-value	Hazard ratio	95% IC HR	
			Lower	Upper
Sex (Female/Male)	0,007	4,46	1,49	13,35
BASFI at the start of treatment	0.000	1,75	1,31	2,35
rs11591741 (GG/GC o CC)	0,022	3,83	1,21	12,12

Discriminatory capacity of the model, Harrell Index C 0.92

Conclusions: Female gender, basal BASFI elevated and SNP rs11591741 (GG) of *CHUCK* gene were identified as predictors of nonresponse to TNFi treatment in these patients.

SAT0406 PREVALENCE OF VERTEBRAL FRACTURES IN AXIAL SPONDYLOARTHRITIS. A SYSTEMATIC REVIEW OF OBSERVATIONAL STUDIES

J.C. Nieto-González [1], R. Cubero [2], S. Castañeda [3], J. Ramírez [4], L. Carmona [2]. *[1] Rheumatology, Hospital G.U. Gregorio Marañón; [2] Statistics, Instituto de Salud Musculoesquelética; [3] Rheumatology, Hospital la Princesa, Madrid; [4] Rheumatology, Hospital Clinic, Barcelona, Spain*

Background: Some studies have described a higher rate of osteoporosis in axial spondyloarthritis (AxSpA). However, there are still some doubts about whether vertebral fractures (VF) should be a concern in AxSpA patients
Objectives: To evaluate the prevalence and incidence of VF in AxSpA
Methods: A systematic review was performed in Medline, Embase and Cochrane Library databases limited to studies published from Jan/2006 to Dec/2015) in Spanish, Italian and English. Search strategy combined synomyms of AxSpA, fractures, plus a filter study type. We selected cross-sectional or longitudinal studies estimating the prevalence and/or incidence of VF in adult AxSpA patients
Results: The search retrieved 3944 references which after screening by title and abstract ended in 90 studies to study in depth. Finally, 12 estudies were included. The majority of the studies evaluated the VF prevalence, and only 2 studies evaluated the incidence of VF. Prevalence estimates depended on VF definitions, varying between 4.1% (clinically diagnosed VF) and 32.4% (morphometric fracture by Genant definition). Table 1 shows all studies included and their data
Conclusions: The published studies that focus on VF in AxSpA are very heterogeneous, but in general showed a slight increase in the VF prevalence. More studies are need focused on VF incidence in AxSpA
Acknowledgements: Funding: This Project was funded by Merck Sharp & Dohme Spain. Merck Sharp & Dohme did not influenced neither the development of the review nor the confection of the abstract.

SAT0407 RISE IN THE DIAGNOSIS OF NON-RADIOGRAPHIC FORM OF AXIAL SPONDYLOARTHRITIS IN NORTHERN ISRAEL OVER TIME

K. Zilber, S. Ginsberg, D. Rimar, M. Rozenbaum, N. Boulman, L. Kaly, A. Awisat, N. Jaries, I. Rosner, G. Slobodin. *Rheumatology, Bnai Zion Medical Center, Haifa, Israel*

Background: Approach to the diagnosis of axial spondyloarthrithis (axSpA) has changed in the last decade, with the aim of diagnosing the disease in its early form.
Objectives: The objective of this study was to explore change in the diagnostic pattern of axSpA in Northern Israel over the last 15 years.
Methods: Patients with the clinical diagnosis of axSpA from six rheumatology practices affiliated with the Rheumatology Unit of the Bnai Zion Medical Center in Haifa, Israel were recruited to the study. Ankylosing Spondylitis (AS) was diagnosed in the presence of sacroiliitis grade 2 or more on X-ray films; all other patients were considered as having non-radiographic axSpA. All patients were subdivided by time periods to 5 groups, and percentages of patients diagnosed in the non-radiographic stage of the disease, as well as patient demographic data were compared using exact Fisher test.
Results: One hundred twenty five patients were subdivided to 5 groups by periods of diagnoses (before 2000, 2001–2004, 2005–2008, 2009–2012, 2013–2016). Gradual increase in a proportion of patients diagnosed with non-radiographic axSpA was observed over years, with statistical significance achieved in 2013–2016 ($p<0.05$) (Fig.1). Patients' gender and age distribution did not differ significantly among the groups.

Conclusions: Progressive increase in the proportion of patients diagnosed with non-radiographic form of axSpA over years was observed in this study. This finding, made on the basis of real life data, reflects change in the diagnostic approach to spondyloarthritis during the last decades.

SAT0408 POSITIVE CORRELATION BETWEEN INFLAMMATION ON SACROILIAC JOINT MRI AND SERUM C-TERMINAL TELOPEPTIDE OF TYPE-I COLLAGEN IN ANKYLOSING SPONDYLITIS BUT NOT IN NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS

K.Y. Kang [1], Y.S. Hong [2], J.H. Ju [3], S.-H. Park [3]. *[1]Division of Rheumatology, Internal Medicine, Catholic University of Korea, seoul; [2]Catholic University of Korea, Incheon; [3]Catholic University of Korea, seoul, Korea, Republic Of*

Background: The MRI-determined inflammatory score was suggested as a more objective measure of disease activity than clinical activity scores in axial spondyloarthritis. It would be useful to identify the disease activity scores and/or laboratory biomarkers that objectively reflect inflammation on MRI.
Objectives: To identify the clinical disease activity scores and laboratory markers that best reflect magnetic resonance imaging (MRI)-determined sacroiliac joint (SIJ) inflammation in ankylosing spondylitis (AS) and non-radiographic axial spondyloarthritis (nr-axSpA).
Methods: This cross-sectional study included all consecutive patients who presented with axial spondyloarthritis in 2013–2015. All underwent SIJ MRI. The bone marrow edema in the inflammatory lesions on MRI was scored using the SPondyloArthritis Research Consortium of Canada (SPARCC) method. Bone-specific alkaline phosphatase (BALP), serum C-terminal telopeptide of type-I collagen (sCTX-I), and inflammatory markers were measured. Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score (ASDAS) were assessed. The correlations between the MRI-determined SIJ inflammation scores and disease activity scores and laboratory variables were evaluated.
Results: Of the 81 patients with axSpA, 45 had AS and 36 had nr-axSpA. The AS and nr-axSpA groups did not differ in terms of disease activity scores, physical functional index, or MRI-determined SIJ inflammation. Erythrocyte sedimentation rate, C-reactive protein, and ASDAS correlated with MRI inflammatory scores in nr-axSpA but not in AS. sCTX-I correlated with MRI-determined SIJ inflammatory scores in AS only. BASDAI and BALP levels did not associate with MRI inflammatory scores in either group. Multivariate analysis showed that sCTX-I associated independently with MRI inflammatory score in AS (β=17.047, p=0.038).
Conclusions: Inflammatory markers and ASDAS correlated with active sacroiliitis on MRI in nr-axSpA only. In AS, only sCTX-I correlated with active inflammation on SIJ MRI. sCTX-I may be useful as a marker of objective inflammation in AS.

SAT0409 IMPORTANCE OF ULTRASONOGRAPHY FOR THE DETECTION OF PERIPHERAL ENTHESITIS IN SPONDYLOARTHRITIS

L. Mani, K. Baccouche, S. Hmila, M. Bouhoula, B. Safaa, Z. Alaya, N. El Amri, H. Zeglaoui, E. Bouajina. *Rheumatology, Farhat Hached Hospital, Sousse, Tunisia*

Background: Peripheral enthesitis has been repeatedly described like the primary lesion in all forms of spondyloarthritis (SpA), and it may occur at any enthesis in SpA, though it is most common in the entheses of the lower limbs. Ultrasonography (US) has proved to be a highly sensitive and noninvasive tool, to assess the presence of enthesitis
Objectives: To estimate the prevalence and the US abnormalities of enthesitis in patients with SpA, compared to a control group.
Methods: We have consecutively included 40 patients with established SpA, including 30 patients with ankylosing spondylitis (AS), 8 patients with psoriatic arthritis (RP) and two patients with arthritis-associated with Crohn's disease. Control populations consisted of 20 patients with mechanical low back pain (MBP). Ultrasound (US) in B mode and power Doppler (PD) was performed at Achille tendon (AT) and plantar fascia (PF).
Results: The study sample included 40 control patients (4 male- 16 female) with a mean (SD) age of 51.05 (11.45) years (range 32–73) and mean duration of disease 8.40 (range 5–81) years.
SpA subtypes were: ankylosing spondylitis 30; psoriatic arthritis 8; arthritis-associated inflammatory bowel disease (AIBD) 2. 47.5% of entheses were tender at clinical examination. Axial form was found in 36 cases (90%) and peripheral form in 4 cases (10%).
In SpA patients, a total of 109/160 (68.12%) of the entheseal sites were abnormal compared with 27/80 (33.75%) in controls, which was statistically significantly fewer than in the SpA group for AT (p=0.000) and PF (p=0.023). Abnormal vascularization in the cortical bone insertion was found in 47 cases (29.375%) versus 4 cases in control group with a significant correlation. We also found a significant correlation for decreased echogenicity and bone erosions. No major variation in the proportion of abnormal entheses identified by US examination was observed between different forms of SpA.
US abnormalities were not correlated to the duration of the disease in patients with SpA, and there was no significant difference between US findings and either ESR, CRP, BASDAI score or BASFI score. We also, found no significant correlation between entheseal US abnormalities and the anti-TNF medications used among the SpA patients.
Conclusions: Ultrasonography can be useful for detecting subclinical enthesitis in SpA patient and the enthesis US score can be useful for improving the diagnostic of SpA.

SAT0410 HLA-B27 ROLE IN ANKYLOSING SPONDYLITIS PHENOTYPE: RESULTS FROM THE REGISPONSER DATABASE

M. Arevalo [1], P. Font [2], M. Moreno [1], D. Ruiz [2], M. Castro [2], P. Carreto [3], M. Larrosa [1], E. Collantes [2], J. Gratacós [1] on behalf of REGISPONSER group. *[1]Rheumatology, Parc Taulí Hospital Universitari. Institut d'Investigació i Innovació Parc Taulí I3PT. Universitat Autònoma de Barcelona. Sabadell, Spain, Sabadell; [2]Rheumatology, Hospital Universitario Reina Sofía/IMIBIC/Universidad de Córdoba., Córdoba; [3]Gerency MFyC de Valladolid East Area, Valladolid, Spain*

Objectives: To assess if there are different phenotypical patterns of Ankylosing Spondylitis (AS) patients depending on the positivity or negativity of HLAB27.
Methods: This is a multicentric, observational, transversal and descriptive study of AS patients from the spanish database REGISPONSER. We compared HLAB27 positive and HLAB27 negative patients regarding clinical and demographical data, disease activity and structural damage. In order to assess disease activity we used the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and acute phase reactants (VSG and PCR). Functional disability was measured by Bath Ankylosing Spondylitis Functional Index (BASFI), and structural damage by Bath Ankylosing Spondylitis Radiology Score (BASRI). For qualitative variables we used the Chi square test and for quantitative ones the t test. An univariate

and multivariate comparative analyisis was performed, in order to define which variables were related to the negativity or positivity of HLAB27.
Results: Data of 1235 AS pacients were analysed. Of them 1029 (83.3%) were HLAB27 positive and 206 (17.7%) HLAB27 negative. 924 (74.8%) were men. AS patients with HLAB27+ presented significantly more familiar history of spondyloarhritis (p=0.002), were younger (p=0.012) and had earlier disease onset and disease diagnosis (p<0.001), with a longer disease duration (p=0.037) and a trend to a higher percentage of uveitis compared to those with HLAB27-. On the other hand, AS patients with HLAB27- also presented significantly more peripheral arthritis (p=0.0022), dactylitis (p=0.001) and extraarticular manifestations (psoriasis, palmoplantar pustulosis, inflammatory bowel disease (IBD) and balanitis (p<0.001)) compared with those of HLAB27+. AS patients with HLAB27- also presented higher scores of BASDAI and BASFI (p=0.047 and p=0.005 respectively). The study didn't show differences between both groups of patients regarding sex distribution, axial manifestations, enthesitis nor radiological damage (assessed by BASRI). In the multivariate analysis, the family history of spondyloarthritis (OR 2.10, IC95% 1.27–3.49, p=0.004), the age at diagnosis (OR 0.97, IC95% 0.96–0.98, p<0.001), the presence of dactylitis (OR 0.16, IC95% 0.05–0.56, p=0.004), extraarticular manifestation specially IBD (OR 0.22, IC95% 0.12–0.40, p<0.001) and peripheral arthritis (OR 0.53, IC95% 0.32–0.89, p=0.016) were the variables independently associated with the presence of HLAB27.
Conclusions: The presence of HLAB27 in AS patients is associated to an earlier disease onset, a higher frequency of familiar history of spondyloarthritis, and a lower frequency of dactylitis, extraarticular manifestations and peripheral arthritis.

SAT0411 CORRELATION BETWEEN DISEASE ACTIVITY SCORES AND QUALITY OF LIFE IN SPONDYLOARTHRITIS

M. Linda, K. Baccouche, S. Lataoui, S. Belghali, Z. Alaya, N. El Amri, H. Zeglaoui, E. Bouajina. *Rheumatology, Farhat Hached Hospital, Sousse, Tunisia*

Background: Spondyloarthritis (SpA) is a group of chronic inflammatory rheumatism and it is known to be one of the leading causes of disability.
Objectives: This study aimed to investigate the quality of life and the psychological disorders (depression, anxiety and insomnia) in patients with SpA.
Methods: A total of 60 patients were included with the diagnosis of SpA meeting the Amor and New York modified criteria, in a prospective study. In a questionnaire, the characteristics of the disease and sociodemographic patient were collected. Also psychiatric assessment was done using the insomnia severity index score (ISI) and the Hospital Anxiety and Depression scale (HAD). In addition, patients answered to the Ankylosing Spondylitis Quality of Life (ASQoL) questionnaire and the SF-12.
Results: The sex-ratio (men/women) was 3.28 (46/14), the average age was 37.95 years (18–70). The average duration of disease progression was 11.5 years (1–30). The mean value of the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) was 5.11 and the Bath Ankylosing Spondylitis Functional Index (BASFI) was 5.22. Uveitis was reported in 11.7% of patients, osteoporosis in 35%, enthesitis in 36.7% and coxitis in 36.7%. 78.3% of patients received NSIAD and 30% were treated with biotheraby. On the psychological level, 25% of patients had an anxiety, 20% had depression. According to the ISI, 35% of patients had sub threshold insomnia, 20% had moderate insomnia and 10% had severe insomnia. The mean value of the ASQoL was 9 (0–16). The mean value of the physical health was 37.13 (19.34–60.41) and for the mental health was 41.65 (14.9–60.35). A significant positive correlation was found between the disease activity and the ASQoL (p=0.000), the physical health (p=0.000) and the mental health (p=0.002). Also, we found a significant positive correlation between the BASDAI and depression (p=0.01) and insomnia (p=0.001).
Conclusions: SpA is a chronic inflammatory disease that contributes to significant physical disability and decreased quality of life in a significant number of patients. The treatment of those patients must consider the improvement of quality of life, as part of a global approach.

SAT0412 ASSOCIATION BETWEEN SMOKING WITH SPINAL LEVEL OF STIFFNESS AND FUNCTIONAL LIMITATION IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: RESULTS FROM THE SPANISH ATLAS

M. Garrido-Cumbrera[1], J. Chacón-García[1], J. Gratacos-Masmitja[2], D. Galvez-Ruiz[1], V. Navarro-Compan[3], C. Blanch-Mur[4], E. Collantes-Estevez[5], P. Zarco-Montejo[6], O. Brace[1]. *[1]Universidad de Sevilla, Seville; [2]H. Parc Taulí, Sabadell; [3]H. la Paz, Madrid; [4]Novartis, Barcelona; [5]Universidad de Córdoba, Cordova; [6]H. Fundación Alarcón, Madrid, Spain*

Background: Smoking has been associated with greater disease activity and radiographic progression in patients with Axial Spondyloarthritis (ax-SpA). In addition, radiographic damage has been linked to greater functional limitation. However, clarification is still being sought as to whether or not this association exists.
Objectives: To investigate the association between smoking and both the area of spinal stiffness and functional limitation in patients with ax-SpA.
Methods: A sample of 680 patients diagnosed with ax-SpA was interviewed during 2016 as part of the Spanish Atlas, which aims to promote early referral and improve healthcare and the use of effective treatments in patients with ax-SpA. Tobacco consumption was recorded as: Smoker (62.4%), Occasional Smoker (8.9%) and Non-Smoker (28.7%). Spinal stiffness was assessed in the three different vertebral areas: cervical, dorsal and lumbar.
To determine de degree of functional limitation we used a composed index which includes the sum of the degree of limitation in the 18 daily activities well established (dressing, grooming, bathing, tying shoelaces, moving around the home, stairs, getting to/out of bed, toilet, shopping, preparing meals, eating, cleaning, walking, using public transportation, going to the doctor, driving, physical exercise, sexual relations) using an ordinal variable (0=none, 1=little, 2=some and 3=moderate). A descriptive analysis was used to compare the level of stiffness (chi-squared test) and the mean degree of limitation (Kruskal-Wallis test) in the different groups of smokers consumptions. Regression analysis was also used to assess the relation between smoking and degree of limitation (0–54).
Results: 53% were females, mean age 46 years and 77.1% were HLA-B27+. The percentage of patients with stiffness in the lumbar region was significantly higher in habitual/occasional smokers than in non-smokers (89.0%, 93.8%, 83.5% respectively; p<0.01) (Table). The mean degree of functional limitation increased with tobacco consumption, although this difference was not statistically significant (47.9±12.1 vs. 45.1±11.5 vs. 44.8±13.7 respectively; p=0.2). However, regression analysis showed a statistically significant correlation between smoking and functional limitation (r=0.096; p=0.02).

Relationship between tobacco consumption and spinal stiffness levels in patients with ax-SpA

	Smoker	Occasional smoker	Non smoker	*P*	χ^2
Cervical stiffness	84.2%	77.1%	73.1%	0.171	9.044
Dorsal stiffness	76.0%	76.6%	72.4%	0.408	6.141
Lumbar stiffness	89.0%	93.8%	83.5%	0.002	20.518

Source: Spanish Atlas.

Conclusions: Smoking in patients with ax SpA is associated to greater stiffness in the lumbar region, but is not related to stiffness in the cervical or dorsal regions. Additionally, smoking is associated to the degree of functional limitation in these patients.

SAT0413 INFECTIOUS PROFILE IN A TUBERCULOSIS-ENDEMIC POPULATION WITH SPONDYLOARTHROPATHIES

M.A. Alzate[1,1], F. Ramirez[2], F. Vargas[2], D. Hernandez-Parra[1], J.C. Salazar-Uribe[3], P. Ortiz-Salazar[1], R. Pineda[1] on behalf of Artmedica IPS, Medellin, Colombia. *[1]Clinical information group; [2]Rheumatology division, Artmedica IPS; [3]School of Statistics, Faculty of Sciences, National University of Colombia, Medellin, Colombia*

Background: Screening latent tuberculosis (TB) and other opportunistic infections in patients with spondyloarthropathies (SpA) with biologic or immunosuppression therapy is important in highly endemic population (1).
Objectives: To assess the prevalence of latent and active TB, hepatitis B, hepatitis C, HIV and Syphilis in a colombian cohort with SpA, as well as evaluate differences between treatments.
Methods: A cross-sectional study was conducted in 621 patients with SpAs, in whom TB, hepatitis B, hepatitis C, HIV and syphilis screening was analyzed based on type of diagnosis. Differences among immunomodulatory therapies were assessed. Statistical association was examined by means of Chi-square tests, Mann-Whitney test, and logistic regression analyses.
Results: The prevalence of latent and active TB in this cohort were 63,1%, and 2,9%, respectively. Significant differences were found in proportions of latent and active TB among types of SpAs, indicating a positive association with AS. A high

Table 1. Infectious profile in colombian patients with SpAs

	All N=621		AS N=340		PsA N=222		Und SpA N=59		p-value
	N	%	N	%	N	%	N	%	
Latent TB	251/398	63,1	156/244	63,9	76/126	60,3	19/28	67,9	0,009
Positive TST before immunotherapy	175/398	44	98/244	40,2	64/126	50,8	13/28	46,4	0,64
TST conversion during immunotherapy	76/398	19,1	59/244	24,2	13/126	10,3	4/28	14,3	<.0001
Active TB	18	2,9	12	3,5	4	1,8	2	3,4	0,03
Latent TB conversion to active TB	7	1,1	6	1,8	1	0,4	0	–	0,04
Active TB during immunotherapy	11	1,8	10	2,9	1	0,4	0	–	0,008

VDRL test	2/285	0,7	1/167	0,6	1/94	1,1	0/24	–	0,38
HIV	3/330	0,9	2/197	1	0/111	–	1/22	4,5	0,14

Ankylosing spondylitis (AS), psoriatic arthritis (PsA), undifferentiated spondyloarthritis (Und SpA), tuberculin skin test (TST).

proportion of TST conversion during immunotherapy was found. According to the immunomodulatory therapy, no differences were found among latent TB patients, active TB disease and no infection with the use of conventional DMARD therapy, but a positive association between latent TB and the use of biologic therapy was recognized. Low prevalences of opportunistic infections (i.e., Hepatitis B and C, syphilis and HIV) were found in this cohort, dispite the frequent use of biologic therapy.

Conclusions: In a TB-endemic population, higher prevalences of latent and active TB were found in patients with SpAs, when compared to the general population. Complete infectious screening is mandatory in patients under consideration of biologic agents, and close follow-up must be done to recognize TST conversion.

SAT0414 DIFFERENCES IN CLINICAL PRESENTATION BY GENDER IN COLOMBIAN PATIENTS WITH SPONDYLOARTHROPATHIES

M.A. Alzate[1], F. Vargas[2], F. Ramirez[2], D. Hernandez-Parra[1], J.C. Salazar-Uribe[3], P. Ortiz-Salazar[1], R. Pineda[1] on behalf of Artmedica IPS, Medellin, Colombia. *[1]Clinical information group; [2]Rheumatology division, Artmedica IPS; [3]School of Statistics, Faculty of Sciences, National University of Colombia, Medellin, Colombia*

Background: Spondyloarthropathies (SpAs) are a group of auto-inflammatory diseases, with overlapping symptoms, that include ankylosing spondylitis (AS), psoriatic arthritis (PsA), undifferentiated spondyloarthritis (Und SpA), enteropathic arthritis, and reactive arthritis (1). Historically, SpAs have been viewed as diseases that predominantly affected men (2).

Objectives: To analyze the influence of gender on disease patterns and therapeutic approach in a large cohort of Colombian patients with SpAs.

Methods: A cross-sectional study was conducted in 621 patients with SpAs, in whom clinical and therapeutic characteristics were analyzed based on gender. Statistical association was examined by means of Chi-square tests, Mann-Whitney test, and logistic regression analyses.

Results: The male-to-female ratio was 1,1:1 in this cohort. Younger age at diagnosis was found in males. AS was the most frequent disease (54,7%), followed by PsA (35,7%), and undifferentiated SpA (9,5%). The male gender was positively associated to the presence of AS (OR 2,29 95%IC 1,31–4,04), radiographic sacroilitis (OR 3,46 95%IC 1,82–6,56), HLAB27 positivity (OR 1,95 95%IC 1,31–2,91), low back pain (OR 1,85 95%IC 1,34–2,54) and axial involvement (OR 1,98 95%IC 1,42–2,77). According to the therapeutic profile, female gender was positively associated to the use of conventional DMARD therapy (i.e., methotrexate (p=0,03), leflunomide (p=0,0057), chloroquine (p=0,013)), while male patients were more associated to the use of biologic therapy.

Table 1. General characteristics of patients with SpAs by gender

	All (N=621)		Male (N=328)		Female (N=293)		p-value
Age (mean)	49,4		48,6		50,2		0,15
Age at diagnosis (mean)	38,9		37,2		40,6		**0,0042**
Years of evolution (mean)	9,8		10,6		9,1		**0,02**
	N	%	N	%	N	%	
Age at onset <45 years	469	75,5	257	78,3	212	72,3	0,008
Diagnosis							
AS	340	54,7	208	63,4	132	45,1	
PsA	222	35,7	96	29,2	126	43	**<0.0001**
Und SpA	59	9,5	24	7,3	35	11,9	
Low back pain	342	55,1	204	62,2	138	47,1	**0,0002**
Arthritis	411	66,2	215	65,5	196	66,9	0,72

SAT0415 HIGH PREVALANCE OF HIP ARTHRITIS IN PATIENTS WITH ANKYLOSING SPONDYLITIS TREATED WITH TNF INHIBITORS

M. Konsta[1,2], M.T. Nurmohamed[2], A. Iliopoulos[1], J.C. van Denderen[2], I. Visman[2], P.P. Sfikakis[1], I.E. van der Horst-Bruinsma[2]. *[1]First Department of Propaedeutic Internal Medicine, Rheumatology Department, Joined Rheumatology Program, National and Kapodistrian University of Athens, Medical School, Athens, Greece; [2]Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands*

Background: Hip involvement is the most frequent extraspinal arthritic manifestation of Ankylosing Spondylitis (AS) and a common cause of disability. It is present in 24% to 36% of AS patients, leading to total hip replacement (THR) in 5%.

Objectives: To examine the prevalence of hip arthritis in patients with AS under TNF-inhibitor (TNFi) treatment, to identify predictors of its development and possible gender differences.

Methods: Consecutive TNFi-naïve AS patients (fulfilling the modified New York criteria) who were eligible for TNFi treatment were included. At baseline (before the start of TNFi), disease activity and function were recorded by BASDAI, ASDAS-CRP/ESR, BASFI and BASMI. Anteroposterior x-rays of the pelvis and lateral x-rays of cervical and lumbar spine were obtained at baseline and scored according to the BASRI-hip scoring system and mSASSS. Hip involvement was assessed both clinically (as pain, reduced range of motion and intermalleolar distance) and radiographically (BASRI-h score $\geq$2 was defined as definitive hip involvement). Mann-Whitney, two-sample t-test and logistic regression analysis were applied. The groups' averages were expressed as mean±SD, or median (IQR) according to the normality of data.

Results: 298 consecutive AS patients (214 men, age: 49±12years (mean±SD), disease duration: 23.8±11.8 years) were included. Definite hip involvement was detected in 113/298 (38%) patients. Bilateral THR and unilateral THR underwent 10/298 (3.4%) and 9/298 (3%) patients respectively. No gender difference in the prevalence of hip arthritis was observed (females: 26/84 (31%) vs. males 87/214 (40.8%). The patients with hip arthritis compared to those without had significantly higher disease activity scores (BASDAI (6.1±1.7 vs. 5.5±1.9, p=0.008), ASDAS-CRP (3.9±0.8 vs. 3.4±0.9, p=0.0001), CRP [16 (7.7–32) median (IQR) vs. 7 (2.9–22), p=0.0001], ESR [26 (10–42) vs. 15.5 (7–33), p=0.004], higher BASFI-scores (6.3±2.1vs. 4.8±2.3, p<0.0001), BASMI-scores (5.1±2.3vs. 3.4±2, p<0.0001) and reduced intermalleolar distance (89±23 vs. 104.8±19 cm, p<0.0001). AS patients with hip arthritis also had significantly higher mSASSS-scores [15 (3- 39) vs. 4 (0–16), p<0.0001] more often syndesmophytes [75/107 (70.1%) vs.75/181 (41.4%), p<0.0001] and peripheral arthritis [54/111 (48.7%) vs. 68/184 (37%), p=0.048). According to multivariate logistic regression analysis, independent risk factors for hip arthritis were: raised CRP (OR: 1.01 CI: 1.001–1.02), presence of syndesmophytes (OR: 2.6, CI: 1.45–4.8) and a high BASFI (OR: 1.33, CI: 1.1–1.5).

Conclusions: The prevalence of hip arthritis in AS is very high (1/3) and significantly related to high disease activity and a high mSASSscore. No gender difference in prevalence of hip arthritis was found. Considering the large impact on function, this manifestation might need more attention.

SAT0416 ANKYLOSING SPONDYLITIS DISEASE ACTIVITY SCORE (ASDAS) IS ASSOCIATED WITH NSAID USE OVER TIME

M.J. Carbo[1], S. Arends[1,2], F. Maas[1], E. Bouwer[1], R. Bos[2], H. Bootsma[1], E. van der Veer[3], F. Wink[2], A. Spoorenberg[1,2]. *[1]Rheumatology and Clinical Immunology, University Medical Center Groningen, Groningen; [2]Rheumatology, Medical Center Leeuwarden, Leeuwarden; [3]Laboratory Medicine, University Medical Center Groningen, Groningen, Netherlands*

Background: Non-steroidal anti-inflammatory drugs (NSAIDs) are the cornerstone of conventional treatment in ankylosing spondylitis (AS). In case of insufficient response, tumor necrosis factor-alpha (TNF-α) inhibitors are available. Still little is known about concomitant NSAID use.

Objectives: To investigate the longitudinal association between disease activity and NSAID use in established AS patients.

Methods: The present analysis is part of the GLAS cohort, an ongoing longitudinal observational axial spondyloarthritis (SpA) cohort study in daily clinical practice. During 52 weeks of follow-up, NSAID use was recorded prospectively. The ASAS-NSAID index was calculated using the dosage and frequency assessed retrospectively from clinical records. Disease activity was assessed using ASDAS, BASDAI, and serum CRP levels.

Generalized estimating equations (GEE) was used to evaluate NSAID use in relation to assessments of disease activity over time. NSAID use was analyzed using 4 parameters: NSAID use (yes/no), ASAS-NSAID index, low on demand use (index $\geq$10 versus <10), and high use (index $\geq$90 versus <90). Analyses were stratified for treatment regimen: patients starting TNF-α inhibitors and patients on conventional treatment.

Results: Of the 393 included AS patients, 67% were male, mean age was 44±13 years, median symptom duration 15 years (IQR 8–24), and 79% were

HLA-B27 positive. In total, 254 (66%) patients started TNF-α inhibitors and 139 (34%) patients received conventional treatment. Patient characteristics were comparable between both groups, except higher disease activity, more often peripheral arthritis, and worse physical functioning in patients starting TNF-α inhibitors. NSAID use and disease activity reduced significantly after starting TNF-α inhibitors and remained low and stable during follow-up. In the conventional treatment group, disease activity was low and NSAID remained stable at all visits. GEE analysis over time showed that NSAID use was significantly associated with disease activity (Table 1). In the TNF-α inhibitor group, a significant association of all NSAID parameters with ASDAS was found: NSAID use yes vs. no, ASAS-NSAID index, index ≥10 vs. <10, and index ≥90 vs. <90. Comparable results were found for BASDAI and CRP. The association between NSAID use and ASDAS remained significant in the 217 patients who used TNF-α inhibitors more than 80% of the follow-up time and when analyzing only 12 to 52 weeks of follow-up to exclude the initial effect of TNF-α inhibitors, although the regression coefficients were lower in these last analyses. In the conventional treatment group, a significant but less prominent association of NSAID parameters with ASDAS was found: NSAID use yes vs. no, index ≥10 vs. <10, and index ≥90 vs. <90. BASDAI was only significantly associated with on demand NSAID use. For CRP, no significant associations with NSAID use were found.

Table 1. Association between ASDAS and NSAID use over time in AS patients.

		B (95% CI)	P-value	Interval	n
TNF-α Inhibitors					
NSAID use Yes	Complete group	0.825 (0.664-0.985)	**<0.001**	1074	251
ASAS-NSAID index	Complete group	0.009 (0.007-0.012)	**<0.001**	1073	251
	TNF-α≥80%*	0.011 (0.009-0.013)	**<0.001**	953	214
	12-52 weeks**	0.005 (0.003-0.007)	**<0.001**	633	246
ASAS-NSAID index≥10	Complete group	0.831 (0.672-0.990)	**<0.001**	1073	251
ASAS-NSAID index≥90	Complete group	0.855 (0.682-1.028)	**<0.001**	1073	251
Conventional treatment					
NSAID use Yes	Complete group	0.250 (0.006-0.493)	**0.045**	315	131
ASAS-NSAID index	Complete group	0.002 (0.000-0.005)	0.059	314	131
ASAS-NSAID index≥10	Complete group	0.223 (0.022-0.425)	**0.030**	314	131
ASAS-NSAID index≥90	Complete group	0.269 (0.038-0.501)	**0.023**	314	131

*Subgroup analysis of patients who used TNF-α inhibitors ≥80% of the follow up time. ** Analysis for 12 to 52 weeks of follow-up (excluding baseline and 6 weeks).

Conclusions: In this observational cohort of established AS patients, NSAID use over time was significantly associated with ASDAS, which was most pronounced for patients treated with TNF-α inhibitors.

Acknowledgements: The GLAS cohort was supported by an unrestricted grant from Pfizer. Pfizer had no role in the design, conduct, interpretation, or publication of this study.

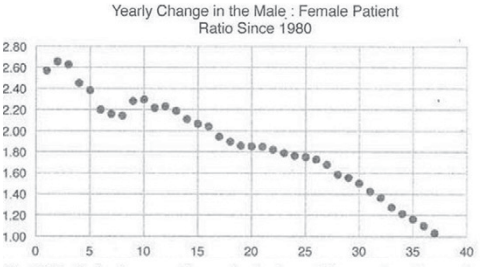
SAT0417 GRADUAL PROGRESSIVE CHANGE TO EQUAL PREVALENCE OF ANKYLOSING SPONDYLITIS AMONG MALES AND FEMALES IN SWITZERLAND: DATA FROM THE SWISS ANKYLOSING SPONDYLITIS SOCIETY (SVMB)



H. Baumberger[1], M.A. Khan[2]. *[1]PhD. First president of, Schweizerische Vereinigung Morbus Bechterew, Zurich, Switzerland; [2]Professor Emeritus of Medicine, Case Western Reserve University, Cleveland OH, United States*

Background: Classic ankylosing spondylitis (AS) with radiographic sacroiliitis has long been considered to be more common in men than women. But this difference has gradually decreased with increasing recognition of this condition in women so that the more recent data suggest a range of 2:1 to 1.2:1 ratio in favor of men [1].

Objectives: To document greater disease recognition in women during the last 30 years in Switzerland as reflected by AS patient membership in the Swiss Ankylosing Spondylitis Society (SVMB) since its foundation in 1978 [2].

Methods: We reviewed the Society's quarterly newsletters that have kept record since 1980 not only of the number of members, but also the percentage of males and females AS patients. We calculated yearly AS patient membership and also change in the male/female patient ratio (M:F).

Results: There has been a progressive decline in the M:F ratios since 1980 as shown in the Figure. There were 44 female forming 28% of the patient population, with a M:F ratio of 2.57 in 1980. At the end of 2016, there are 1731 females forming 49% of the total number of patients, and the M:F ratio is now 1.03.

The M:F ratio is shown on the vertical axis, and the number of years is shown on the horizontal axis.

Conclusions: AS is now being recognized as often in females as in males, as reflected in the membership of SVMB over the last 36 years. There can be various reasons for this observation, one of them being the availability of better imaging tools to recognize AS/axial spondyloarthritis (axSpA), especially among women whose disease is clinically and radiologically less pronounced and is therefore often overlooked [2]. For example, the use of MRI (for early detection of spinal inflammation) and the ASAS criteria have resulted in >50% females in a German cohort of patients with nonradiographic axSpA [3]. SVMB has played a major role in achieving greater disease recognition in Switzerland by increasing disease awareness and educating patients and their families, the general public, the governing bodies and the allied health professionals about AS, and by interacting closely with rheumatologists. Other possible factors influencing our data include: women outliving men, forming a little greater percentage of the general population, and possibly more likely to join patient self-help groups and societies, We did not investigate any gender difference in disease severity and clinical presentation. In conclusion, AS/axSpA almost equally afflicts men and women in Switzerland.

Objectives: To assess disease activity and quality of life in anxious and depressed SpA patients.
Methods: Observational, retrospective, cross-sectional study of SpA patients on bDMARDs, registered at Reuma.pt, Portuguese Rheumatology registry, with ≥1 clinical evaluation from November 2015 to July 2016. Demographic and clinical outcomes including: BASDAI, BASMI, BASFI, ASDAS, DAS 28–3V ESR in peripheral psoriatic arthritis, tender and swollen 44 joints count (TJC, SJC), patients' pain and global assessments, physician's global assessment, CRP, ESR, ASQoL, EQ-5D, FACIT-F for fatigue and HADS scale with 2 domains, HADS-A for anxiety and HADS-D for depression (a cutoff of 8 defining these symptoms), were collected. Statistics: Mann-Whitney test, $p<0.05$. SPSS® v.17.
Results: 160 patients were included, 41.9% were male, with mean: current age 50.7±11.9, age at diagnosis 36.9±11.96, at 1st bDMARD 46.2±11.8, time from diagnosis 18.5±10.3, years. The mean DAS 28–3V ESR was 3.2±1.4, BASDAI 2.98±2.2, ASDAS 2.4±1.2, BASFI 2.68±2.26, BASMI 3.36±1.7, patient's global assessment 28.8±24.1, physician's global assessment 14.5±15.2, ESR 18.8±18.1 mm/h, CRP 6.7±16.01 mg/L, ASQoL 6.2±5.6, FACIT-F 37.2±10.1 and EQ-5D 0.417±0.19. The mean HADS-A was 5.96±4.01 and HADS-D was 5.05±4.1 (HADS-A≥8 in 39.5% and HADS-D≥8 in 28.3% patients). Comparison of anxious vs non-anxious and depressive vs non-depressive groups appears on table 1.
Conclusions: These results suggest that anxious and depressed patients may have higher disease activity, more functional limitations and worse quality of life. These symptoms should not be underestimated, but instead, they should be controlled to achieve clinical improvement.

SAT0419 SIMILARITIES AND DIFFERENCES BETWEEN HLA B27 POSITIVE AND HLA B27 NEGATIVE SPONDYLOARTHRITIS: RESULTS FROM THE ESPERANZA COHORT

P. Serrano[1,2], V. Navarro-Compán[2], S. Rodríguez[3], M. Fernández[4], P. Zarco[5], E. de Miguel[2]. *[1]Universidad Autónoma; [2]Hospital la Paz, IdiPaz, Madrid; [3]Hospital Nuestra Señora de Valme, Sevilla; [4]Hospital Guadalajara, Guadalajara; [5]Hospital Fundación Alcorcón, Madrid, Spain*

Background: The diagnostic relevance of HLA B27 for spondyloarthritis (SpA) is well established and highlighted by its inclusion in the classification criteria. However, the clinical relevance of this gen on the disease manifestations is unclear.
Objectives: To investigate the influence of HLA B27 status on disease manifestations in patients with recent-onset SpA.

Table 1

Characteristic	Axial SpA			Peripheral SpA		
	HLA-B27+ N (%)=219 (75)	HLA-B27- N (%)=72 (25)	p value	HLA-B27+ N (%)=28 (33)	HLA-B27- N (%)=58 (67)	p value

Inflammatory back pain	83 (37.9)	29 (40.3)	0.7			
Family history	84 (38.4)	17 (23.6)	**<0.05**	10 (35.7)	21 (36.2)	0.9
APRs:						
– ESR (mmHg)	13.6±13.2	13.5±14.3	0.9	13.8±14.6	14.2±12.9	0.9
– CRP (mg/L)	11.3±15.3	9.4±14.9	0.4	19.5±48.0	11.0±18.8	0.2
SJC	0.3±1.5	0.2±0.8	0.8	1.6±3.0	1.3±2.0	0.6
VAS (0–10) physician	2.8±2.2	3.2±2.1	0.2	2.2±2.2	2.5±2.2	0.5
VAS (0–10) patient	4.0±2.7	4.6±2.6	0.2	2.9±2.6	3.3±2.4	0.6
BASDAI	3.7±2.3	4.2±2.2	0.2	2.6±1.7	3.9±2.4	0.02
BASFI	2.2±2.3	2.8±2.2	0.1	1.2±1.4	1.9±2.1	0.09
Temporary disability	19 (8.7)	7 (9.7)	0.7	5 (17.9)	13 (22.4)	0.7
ASQoL	5.5±4.7	7.0±4.8	**<0.05**	3.3±4.0	5.0±5.3	0.2

Methods: Baseline database from ESPeranza cohort (<45 years, symptoms duration 3–24 months and with inflammatory back pain or asymmetrical arthritis or spinal/joint pain plus ≥1 SpA features) was used. Inclusion period in the program was 2008–2011. For this study, 377 fulfilling the ASAS classification criteria for SpA were included. A descriptive analysis was used to compare demographic and clinical characteristics between HLA B27+ and HLA B27- patients for both subgroups, axial SpA and peripheral SpA. Chi- square test for qualitative variables and Student-t test for quantitative variables were employed to compare variables among groups.
Results: A total of 291 patients (75% B27+ and 25% B27-) were classified as axial SpA and 86 (33% B27+ and 67% B27-) as peripheral SpA. Results (mean –standard deviation- and relative frequencies) are presented in the table. In axial SpA, B27+ patients were younger, more frequently males and with a family history of SpA while B27- patients had more frequently psoriasis, IBD and poorer quality of life. In peripheral SpA, B27- had more frequently psoriasis and reported higher BASDAI.
Conclusions: In patients with SpA, HLA B27 status influences on the presentation of the disease. In axial SpA, the presence of B27 is associated with an earlier onset, male predominance and more frequency of family history of SpA. In peripheral SpA, the presence of B27 is linked with lower subjective parameters of disease activity. In both, axial and peripheral SpA, the absence of B27 is associated with psoriasis, IBD and poor quality of life.

SAT0420 RELATIONSHIP BETWEEN HEALTH-RELATED QUALITY OF LIFE WITH DISEASE ACTIVITY AND FUNCTIONAL STATUS, IN PATIENTS WITH ANKYLOSING SPONDYLITIS

P. Chiowchanwisawakit, V. Srinonprasert, W. Katchamart. *Faculty of Medicine, Siriraj Hospital, Mahidol University, Bangkok, Thailand*

Background: Ankylosing spondylitis (AS) is a chronic disease resulting in diminished quality of life (QoL). There was no study regarding QoL in Thai patients with AS.
Objectives: To identify factors associated with quality of life, measured by EuroQol 5-dimension, 5-level questionnaire (EQ-5D-5L), in patients with AS.
Methods: This was a cross-sectional study. Demographic data and outcomes related to health utility or HU [Thai version EQ-5D-5L], disease activity [BASDAI (0–10), ASDAS-ESR or CRP, number of tender (TJC) and swollen joint (SJC), and enthesitis], and functional status [BASFI (0–10) and HAQ (0–3)] were collected. The HU was calculated on the basis of responses to 5-domains using the Thai value set. Regression analysis was used to explore factors associated with each EQ-5D domain and HU. Multiple models using different outcome measures for disease activity and functional status were performed to identify the best predictive model.
Results: Among 119 AS patients, most (73%) were male with mean (SD) age of 40.4 (11.6) years. Most (52.9%) were married and 92 (77.3%) were employed. The median (IQR) disease duration, BASDAI, BASFI, and HAQ were 7.5 (11.8) years, 3.2 (3.7), 2.3 (4.2), and 0.4 (0.9), respectively. The mean (SD, range) EQ-5D and VAS were 0.75 (0.20, -0.24–1.00) and 68.8 (18.8, 10–100), respectively. In univariate analysis, higher disease activity, higher functional index score, and more severe peripheral joint involvement were significantly associated with lower HU and moderate to very severe problem in each EQ-5D domain compared with no to mild problem with $p<0.05$, except SJC which was not associated with mobility problem. Conversely, age, gender, marital status, and disease duration were not associated with any EQ-5D domains or HU. In multivariate regression analysis, disease activity and functional status were significantly associated with HU (Table 1), when adjusted for age. The best predictive model using BASDAI, CRP, and HAQ with adjusted for age correctly predicted 77.4% of the variance in HU, while using BASFI instead of HAQ in the same model yielded slightly lower predictive value of 70.7%.
Conclusions: Disease activity and functional status were significantly factors related to QoL and HU in patients with AS. To improve QoL, the aim of treatment should be achieve remission or at least low disease activity and improve or at least maintain function.

SAT0421 FAT MASS NEGATIVELY AFFECTS THE RESPONSE TO TNF ALPHA BLOCKERS IN ANKYLOSING SPONDYLITIS PATIENTS

S.E. Ibáñez Vodnizza[1,2], M.T. Nurmohamed[3,4], I.M. Visman[3], J.C. van Denderen[3], W.F. Lems[3,4], I.E. van der Horst-Bruinsma[4]. *[1]Rheumatology department, Clínica Alemana de Santiago; [2]Rheumatology department, Hospital Padre Hurtado, Santiago, Chile; [3]Amsterdam Rheumatology and immunology Center, Reade; [4]Amsterdam Rheumatology and immunology Center, VU University Medical Center, Amsterdam, Netherlands*

Background: Women with Ankylosing Spondylitis (AS) seem to be less responsive to TNF-α blockers and have a shorter drug survival. This might be explained by differences in body composition (BC), as women have higher total body fat (BF).
Objectives: Assess the relationship between gender, BC and response to TNF-α blocker treatment in a cohort of TNF-α blocker naïve AS patients.
Methods: AS patients (Modified New York criteria), ≥18 years old, who had a Dual-Energy X-ray Absorptiometry BC analysis before the start of TNF-α treatment and at least 6 months thereafter were included. Demographic information and the disease activity measures ASDAS CRP and BASDAI were reported. Fat Mass (FM) was reported as BF% (FM/Total body mass), and Fat Mass Index (FMI= FM kg/height m^2). Fat Free Mass (lean mass + bone mineral content) was reported as its index (FFMI kg/m^2). BF%, FMI, and FFMI percentiles, according to the reference population tables, stratified by age and gender, were also reported.
Results: Forty-one patients were included, 61% were men. Demographic characteristics were similar in men and women. The FFMI percentile was remarkably low in men, probably reflecting muscle wasting (figure 1). The percentiles increased in men and decreased in women after treatment. The clinically important improvement (CII) of ASDAS CRP was achieved by 52% of men and only 37.5% of women. The minimum CII for BASDAI was achieved by 64.7% of men, and only 35.7% of women that had a BASDAI ≥4 at baseline. After multivariate analysis we found a significant relationship between higher BF%, FMI or FMI percentile at baseline and a lower chance of achieving at least a CII of ASDAS CRP; the same relationship was found between FMI percentile at baseline and the minimum CII for BASDAI (table 1).

Table 1. Multivariate logistic regression analysis results[a]

Outcome	Variable	OR (95% CI)
Clinically important or major improvement of ASDAS CRP	Body Fat % at baseline	0.8 (0.7–0.98)
	Fat Mass Index at baseline	0.7 (0.4–0.99)
	FMI percentile[b] at baseline	0.9 (0.9–0.99)
BASDAI MCII[c]	FMI percentile[b] at baseline	0.95 (0.91–0.99)

[a]Controlled for gender, age, years with symptoms, days of follow up, use of DMARDs and NSAIDs and baseline outcome value. [b]Percentiles according to the reference population tables, stratified by age and gender. [c]Only for patients with a BASDAI ≥4 at baseline. CRP = C-reactive protein, ASDAS = Ankylosing Spondylitis Disease Activity Score, BASDAI = Bath Ankylosing Spondylitis Disease Activity Index, MCII = minimum clinically important improvement, FMI = Fat Mass Index.

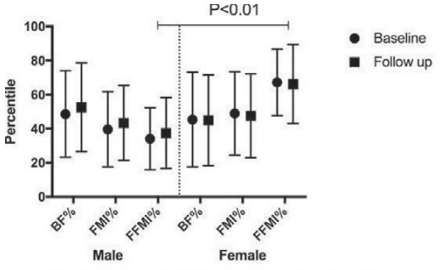

Figure 1. Body Fat % (BF%), Fat Mass Index (FMI) and Fat Free Mass Index (FFMI) percentiles according to reference population tables, stratified by gender. At baseline and follow-up the FFMI was significantly higher in female patients (*P* <0.001).

Conclusions: Higher body fat content at baseline is independently associated with a worse response to treatment with TNF-α blockers, measured by ASDAS-CRP and BASDAI change, and might contribute to the lower response to treatment rates in female patients. Also, there is a trend toward muscle mass recovery in male patients after treatment with TNF-α blockers.

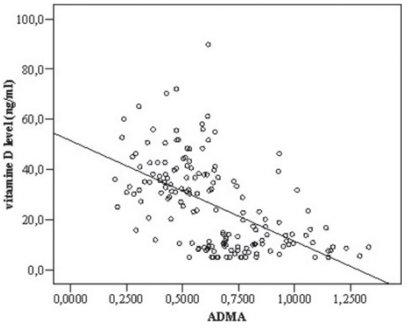
SAT0422 EFFECTS OF VITAMIN D REPLACEMENT ON THE DISEASE ACTIVITY AND INFLAMMATORY PARAMETERS SUCH AS IL-1, IL-6, TNF-α, ASYMMETRIC DIMETHYLARGININE (ADMA) AND ARGININE/ADMA RATIO IN ANKYLOSING SPONDYLITIS



S. Ergulu Esmen[1], S. Yılmaz[2], L. Kebapcılar[3], A. Ünlü[4], S.H. İpekci[3], S. Abusoglu[4]. *[1]Rheumatology, Internal Medicine, Konya Education and Research Hospital; [2]Rheumatology, Internal Medicine; [3]Endocrinology and Metabolic Diseases, Internal Medicine; [4]Biochemistry, Selcuk University, Konya, Turkey*

Background: Asymmetric dimethylarginine (ADMA) levels in AS patients were found to be higher than controls (1).The relationship between vitamin D level and disease activity was shown in AS (2). But the effects of vitamin D replacement on the disease acitivity, inflammatory parameters and ADMA pathway were not investigated in AS.
Objectives: To determine the effects of vitamin D replacement on the disease activity, inflammatory parameters and ADMA pathway in AS.
Methods: All AS patients with vitamin D level of <20 ng/ml who consecutively attended the outpatient rheumatology clinic were enrolled.C-reactive protein, erythrocyte sedimentation rate, Bath AS disease activity index (BASDAI), Bath AS Functional Index (BASFI) TNF-α, IL-1, IL-6, ADMA, symmetric dimethylarginine (SDMA), NG-monomethyl-L-arginine (LNMMA), arginine, arginine/ADMA ratio and citrulline levels were analyzed when vitamin D level was <20 ng/ml and ≥20 ng/ml, after replacement.
Results: The study population was represented by 82 patients, 48 women (58.5%), mean age 39 years old and mean disease duration 5.5 years. When vitamin D levels were increased to normal levels, levels of IL-1 (4.8±9.7 and 3.1±4.0 p<0.001), IL-6 (7.1±14.1 and 4.7±2.1 p=0.009), ADMA (0.8±0.2 and 0.4±0.1 p<0.001), SDMA (0.9±0.2 and 0.4±0.2 p<0.001), LNMM (0.08±0.02 and 0.06±0.02 p<0.001), arginine (385.8±106.4 and 269.2±79.0 p<0.001) and citrulline (91,1±34,3 and 75,3±23,5 p<0,001) were reduced. Levels of arginine/ADMA ratio was increased (498.7±136.5 and 576.7±170.7 p<0.001) (Table 1). Also BASDAI, BASFI and erythrocyte sedimentation rate were decreased but it was statistically meaningless. In pearson correlation analysis, ADMA, SDMA, LNMMA, arginine and citrulline were negatively correlated with vitamin D levels.Multiple regression analysis showed that SDMA, arginine and citrulline were significantly related with vitamin D levels. Negative correlation between ADMA and vitamin D levels was shown in Figure 1

Table 1

	Vit D <20 (ng/ml)	Vit D ≥20 (ng/ml)	P
TNF-α (pg/mL)*	19.04±14.39	19.36±8.18	0.041
IL-6 (pg/mL)*	7.17±14.19	4.75±2.15	0.009
IL-1 (pg/mL)*	4.86±9.70	3.17±4.05	<0.001
ADMA (μmol/L) **	0.80±0.21	0.49±0.16	<0.001
SDMA (μmol/L) **	0.93±0.26	0.49±0.20	<0.001
LNMMA (μmol/L) **	0.08±0.02	0.06±0.02	<0.001
Arginine (μmol/L)**	385.83±106.43	269.22±79.08	<0.001
Arginine/ADMA	498.72±136.51	576.74±170.76	<0.001
Citrulline (μmol/L)**	91.14±34.34	75.30±23.52	<0.001

*Wilcoxon sign test **paired samples t test.

Conclusions: Vitamin D replacement in AS with low vitamin D levels improves antioxidant status via ADMA pathway and shows anti-inflammatory effects on IL-1 and IL-6. In literature, there is no other study investigating the effects of increased vitamin D levels on disease activity, inflammatory parameters and ADMA pathway in AS.

SAT0423 INCREASED PREVALENCE OF EXTRA-ARTICULAR MANIFESTATIONS AMONG INDIVIDUALS WITH ANKYLOSING SPONDYLITIS IN CANADA: RESULTS FROM THE RHUMADATA® MULTICENTRE REGISTRY

S. Szabo[1], S. Chehab[2], L. Coupal[3], D. Choquette[3]. *[1]Broadstreet HEOR, Vancouver; [2]Novartis Pharmaceuticals Canada; [3]Institut de Recherche en Rhumatologie de Montréal, Montreal, Canada*

Background: Among populations with ankylosing spondylitis (AS), the frequency and severity of extra-articular manifestations (EAMs) vary widely; due to underlying geographic and genetic differences, individual characteristics, and the impact of treatment with anti-tumour necrosis factor [TNF] agents. The frequency of EAMs

among Canadians with AS has not previously been examined, using data from a large clinical registry.
Objectives: To estimate the prevalence of EAMs, including uveitis, inflammatory bowel disease (IBD), dactylitis, and enthesitis, in a population of Canadians undergoing active management for AS.
Methods: This retrospective study used RHUMADATA®, a multicentre registry developed by rheumatologists of the IRRM and *Centre d'ostéoporose et de rhumatologie de Québec* to evaluate the effectiveness and safety of rheumatologic therapies. Up to 15 years of real-world observational data on the broad set of patients treated in clinical practice are available. The proportion with EAMs was estimated according to type. The frequency of EAMs was compared according to age at cohort entry (≤40 vs >40 years), sex, AS severity (by BASDAI score), and status of treatment with anti-TNFs (anti-TNF-naive, anti-TNF treated [without switching], and anti-TNF treated [with switching]).
Results: The mean (SD) age at cohort entry was 36.0 (12.6) years, and 60.0% were male. Of the 944 patients, 268 (28.4%) were ever diagnosed with an EAM over a median of 9.66 (10.58) years of follow-up. Prevalence was 14.7% for uveitis, 5.8% for IBD, 4.3% for dactylitis, and 9.0% for enthesitis (Table). The proportion with EAMs was: slightly higher among females versus males (31.0% vs. 26.7%), among older versus younger patients (29.5% vs. 25.9%), among those with more severe disease (from 29.2% [mild AS] vs. 34.1% [severe AS]), and among anti-TNF treated patients (18.8% [anti-TNF-naïve] to 47.0% [treated with anti-TNFs, with switching]).

Table 1. EAMs among Canadian patients with AS from the Rhumadata dataset; overall, and according to levels of treatment status, key clinical, and demographic characteristics

	N	Uveitis		IBD		Dactylitis		Enthesitis		Any EAM	
		n	%	n	%	n	%	n	%	n	%
Overall											
N			14.7		5.8		4.3		9.0		28.4
Males	566	81	14.3	29	5.1	23	4.1	47	8.3	151	26.7
Females	378	58	15.3	26	6.9	18	4.8	38	10.1	117	31.0
≤40 years at cohort entry	651	111	17.1	37	5.7	29	4.5	58	8.9	192	29.5
>40 years at cohort entry	293	28	9.6	18	6.1	12	4.1	27	9.2	76	25.9
Missing AS severity	166	12	7.2	7	4.2	2	1.2	3	1.8	21	12.7
Mild AS (BASDAI <3.5)	271	47	17.3	16	5.9	12	4.4	21	7.7	79	29.2
Moderate AS (3.5 ≤ BASDAI <6.0)	252	44	17.5	12	4.8	13	5.2	26	10.3	81	32.1
Severe AS (BASDAI ≥6.0)	255	36	14.1	20	7.8	14	5.5	35	13.7	87	34.1
Anti-TNF naïve	490	47	9.6	18	3.7	11	2.2	25	5.1	92	18.8
Anti-TNF treated [no switching]	286	51	17.8	21	7.3	15	5.2	28	9.8	97	33.9
Anti-TNF treated [with switching]	168	41	24.4	16	9.5	15	8.9	32	19.0	79	47.0

Conclusions: EAMs are common among Canadians with AS, occurring in up to 28% over almost 10 years of follow-up, with uveitis occurring the most frequently (in almost 15% of the cohort). EAMs were most frequent among those with more severe disease (in 34%) and among those treated with anti-TNFs (in 20–50% of such patients). These estimates are useful for comparing to other geographic areas, where the risk factor distribution for AS and its sequelae would differ; and for use in economic models to evaluate the benefits and costs of new therapies.

SAT0424 AXIAL DISEASE IN PSORIATIC ARTHRITIS: BURDEN OF UNDERDIAGNOSED DISEASE AND RISK FACTORS IN REAL LIFE

S.Z. Aydin[1], U. Kalyoncu[2] on behalf of the PsART study group. *[1]University of Ottawa, Ottawa, Canada; [2]Hacettepe University, Ankara, Turkey*

Background: The frequency of axial disease in Psoriatic Arthritis (PsA) is around 24–78% with additional patients with subclinical disease who have spondylitic changes or sacroiliitis in the absence of clinical findings. Despite that most of the physicians do not perform routine imaging with the argument that subclinical disease has no effects on management decisions.
Objectives: We aimed to explore barriers for diagnosing axial disease in PsA and its implications in real life.
Methods: PsART (Psoriatic Arthritis Registry of Turkey) is a prospective, multicentre registry where PsA patients are consecutively recruited. Radiographs of the spine and sacroiliac joints were scored by one central reader, whenever available. Patients with axial disease according to the physician were compared with patients with imaging findings only and risk factors for being underdiagnosed were investigated.
Results: Among 1195 patients, 35% had axial disease according to the physician who were more frequently men (41.2% vs 32.2%; p=0.04), younger (44.4 (12.2) vs 47.9 (13); p<0.001), more frequently smokers (44.6% vs 34.1%; p<0.001), more on anti TNFs (37.1% vs 29.4%; p=0.01) and had more nail involvement (49.9% vs 43.2%; p=0.03). Within the IBP criteria, the ASAS criteria had the lowest sensitivity (59.7%) which was even lower in women (53.1%). Forty-nine (15.7%) patients were classified as having axial disease according to the rheumatologist despite not fulfilling any of the IBP criteria which was more frequent for women (21.1%) than men (8.2%, p=0.002). Among 71 patients that had syndesmophytes, 20 patients (28.2%) were not classified as having axial disease according to the physician. This was higher for women (15/42, 35.7%) then men (5/29, 17.2%).
There were 126 patients who had sacroiliitis fulfilling the ASAS criteria, despite not being categorized as having axial disease by the clinician. The risk of being underdiagnosed was higher for women (30.8% vs 18.4%; p=0.003). These patients had higher Leeds enthesitis scores, tender and swollen joint counts (table) and were less using anti-TNF medications (14.6% vs 38.7%; p<0.001). The PROs and the physician global assessment were similar, suggesting a similar disease activity state according to the patients and physicians in diagnosed and underdiagnosed groups.

Table 1. Comparison of outcomes in patients with axial disease according to the clinician and axial disease by imaging only

	Axial disease according to the Clinician (n=415)	Axial disease by imaging only (n=126)	p
Patient global assessment	47 (24.8)	49.2 (20.8)	0.4
Pain	46.4 (28.7)	50.1 (23.3)	0.3
Fatigue	47.1 (27.7)	51.9 (23.6)	0.1
BASDAI	4.5 (2.5)	3.9 (2.3)	0.08
BASFI	3.3 (2.5)	3.2 (2.4)	0.8
Physician's global assessment	38.7 (23.3)	41 (18.9)	0.2
Tender joint count	3.4 (4.7)	5.3 (6)	<0.001
Swollen joint count	1.3 (2.5)	2 (3)	<0.001
Leeds enthesitis index	0.3 (0.8)	0.4 (1)	0.05

Conclusions: Underdiagnosed axial disease is frequent in PsA, women having higher risk and IBP criteria being less sensitive in women. More complex patients (eg with higher enthesitis and peripheral arthritis) have a higher risk of being underdiagnosed. These patients are less frequently treated with biologic treatments, which could be the right treatment choice if were diagnosed. Axial disease needs to be ruled out using imaging modalities, even if back pain does not clinically suggest an inflammatory pattern.

SAT0425 SYMPTOMOLOGY, DISEASE STATUS, AND REMISSION RATES OF NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS AND ANKYLOSING SPONDYLITIS PATIENTS IN EUROPE

T.M. Hunter[1], D. Sandoval[1], S. Lobosco[2], R. Moon[2], J. Birt[1], G. Miligan[2]. *[1]Eli Lilly and Company, Indianapolis, United States; [2]Adelphi Real World, Bollington, United Kingdom*

Background: Axial Spondyloarthritis (axSpA) is a chronic inflammatory disease predominantly affecting the sacroiliac joints and spine. Ankylosing spondylitis (AS) and non-radiographic axSpA (nr-axSpA) have been considered to represent the same axial spondyloarthritis disorder, but are differentiated by the presence or absence of structural changes in the sacroiliac joints as determined by common imaging modalities.
Objectives: To better understand the symptoms and clinical characteristics of nr-axSpA patients and how they compare to ankylosing spondylitis patients in Europe.
Methods: Data drom the 2015 SpA Disease Specific Programme, a cross-sectional, multi-national survey of patients and rheumatologists conducted in France, Germany, Italy, Spain, and the UNited Kingdom were analyzed. Rheumatologists (n=299) completed forms containing patient demographics, clinical results and symptomology. Symptoms, disease activity, and disease status (defined as improving, stable, unstable, deteriorating) of AS and nr-axSpA patients were compared.
Results: A total of 3,033 patients (AS: 1,520; nr-axSpA: 1,513) were included in the analysis. A higher proportion of AS patients were male (72% vs. 53%), older (mean age=44.8 vs. 41.0), had a higher BMI and were employed when compared to nr-axSpA patients. Nr-axSpA patients' current disease status was less likely to be stable (p<0.0001) in comparison to AS patients. Nr-axSpA patients were also less likely to be in remission (p<0.0001). Nr-axSpA patients were reported as having higher pain level (p=0.0333) than AS patients. AS patients had more axSpA symptoms, such as spinal fusion and loss of movement, however nr-axSpA patients were more likely to have inflammatory back pain, enthesitis, persistent lower back pain, and nocturnal wakening.
Conclusions: Both nr-axSpA and AS appear to have many similar clinical characteristics with few distinct features between them. However, in spite of these similarities, nr-axSpA patients show less stability and a lower likelihood of remission when compared to AS patients. These findings may suggest that nr-axSpA is as burdensome as AS, and that both conditions may warrant similar treatment approaches from an early stage.

SAT0426 HIGH LEVELS OF EMPLOYMENT BUT PERSISTING WORK PLACE IMPAIRMENT IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS ON BIOLOGIC THERAPY

T.G. Nadin[1], D. Wallis[1], C. Holroyd[1], P. Clayton[1], R. Armstrong[1], C. Cooper[2], B. Davidson[1], N. Harvey[2], E. Dennison[2], R. Seth[1], K.E. Walker-Bone[2], S. Bennett[1], C.J. Edwards[1,3]. *[1]Rheumatology; [2]MRC Lifecourse Epidemiology Unit; [3]NIHR Wellcome Trust Clinical Research Facility, University Hospital Southampton, NHS Foundation Trust., Southampton, United Kingdom*

Background: Axial spondyloarthritis (axSpA) is associated with reduced work productivity. Biologic therapies have demonstrated a positive impact on work-related outcomes in clinical trials but real world data are limited.
Objectives: To investigate the prevalence and predictors of work impairment and disability in patients with axSpA attending a biologic therapy clinic.
Methods: Data were collected from a single-centre, prospective cohort of patients with axSpA treated with biologic therapy. Standardised outcome measures, including the Work Productivity and Activity Impairment (WPAI) Questionnaire for axSpA, are collected every 6 months. Data from the most recent clinic visit were analysed using IBM SPSS Statistics 24. Disease activity was compared between employed patients and those unemployed due to disability from axSpA. The effect of smoking status and gender on work related outcomes was analysed. The relationship between work-related outcomes and disease severity was investigated using Pearson's correlation. Significance was defined as $p<0.05$ with Bonferroni correction.
Results: Data were available for 165 patients (mean age 47.6 years, 75% male, 21% current smokers). Mean time since diagnosis was 15.4 years and mean duration of biologic therapy 4.7 years, with 19/165 (12%) on a reduced dose regimen. Mean BASDAI was 4.0, ASQoL 6.6, BAS-G 3.9 and spinal pain VAS 4.0. Employment data were provided by 144 patients of whom 99/144 (69%) were employed; 17/144 (12%) not working due to disability caused by SpA; 19/144 (13%) retired; 5/144 (4%) unemployed; 2/144 (1%) full-time education; and 2/144 (1%) full-time parents. Of the 144 patients in employment, 8 (6%) had missed hours of work in the week prior to the last clinic visit due to axial SpA (mean hours missed =13). There was no difference between males and females in (i) the proportion of patients employed or (ii) the proportion not working due to disability from SpA.
Mean impairment while working due to axial SpA was 23% and impairment of regular daily activities 35%. There was no significant difference in percentage work impairment between males and females. BASDAI was higher in patients unemployed due to SpA (7.1±1.6) compared to those who were employed (3.5±2.2, $p<0.001$). Higher levels of work impairment were observed in current smokers compared to previous smokers and never smokers ($p=0.003$). Positive correlations were found between individual WPAI domains and each of BASDAI, BAS-G, ASQoL and spinal pain VAS ($p<0.001$).
Conclusions: In this cohort of axial SpA patients on biologic therapy, the majority were employed and few reported missing time at work. As expected, disease activity was higher in patients unemployed due to disability compared to those who were currently in paid work. Gender did not appear to affect employment rates, disability rates or work impairment. Smoking was associated with increased work impairment. The impact of disease on employment should be considered in the clinic and strategies for enhancing work participation directed towards those patients most at risk.

SAT0427 ASAS HEALTH INDEX: VALIDITY AND RELIABILITY IN ARGENTINEAN PATIENTS WITH SPONDYLOARTHRITIS

V.M. Duarte[1], U. Kiltz[2], V. Navarro-Compán[3], N. Lloves[1], G. Crespo Amaya[1], L. Ferreyra[4], C. Orozco[5], E.E. Schneeberger[5], H. Maldonado Ficco[6], D. Baenas[7], F. Colombres[8], M. Mamani[1], J.A. Maldonado Cocco[9], E. Soriano[4]. *[1]Hospital B. Rivadavia, Buenos Aires, Argentina; [2]Rheumazentrum Ruhrgebiet, Herne, Germany; [3]Hospital la Paz, IdiPaz, Madrid, Spain; [4]Hospital Italiano de Buenos Aires; [5]Instituto de Rehabilitación Psicofísica (IREP), Buenos Aires; [6]Hospital San Antonio de Padúa, Río Cuarto; [7]Hospital Privado de Córdoba, Córdoba; [8]Hospital de Clínicas Dr. Avellaneda, Tucumán; [9]Consulting Profesor of Rheumatology, University of Buenos Aires, Buenos Aires, Argentina*

Objectives: The aim of the study was to translate and validate the ASAS Health Index (ASAS-HI) for Argentinean patients with spondyloarthritis.
Methods: Translation was done using a forward-backward procedure and qualitative interview were done with the translation. Patients fulfilling ASAS classification criteria for either axial (axSpA) or peripheral SpA (pSpA) were included to test psychometric properties. Test-retest reliability was assessed by intraclass correlation coefficient (ICC) in patients without treatment changes (stable disease state). In patients who required therapeutic modifications due to changes of disease activity, responsiveness was evaluated using a standardized response mean (SRM). Construct validity against other health outcomes was evaluated by Spearman correlation. Internal consistency (Cronbach-alfa) and discriminative ability between ASAS-HI and ASDAS were assessed.
Results: Translation into Argentinean Spanish was accepted with minor changes. Fifty two patients were recruited [65% male, mean (SD) age 39. 5 (12.5) years and median (IQR) disease duration 72 (45–138) months]. Most of the patients had axSpA diagnosis (AS: 26, nr-axSpA: 18) while the rest had pSpA (8). The total score of the ASAS-HI was 7.4 (SD: 4.4), BASDAI: 4.4 (SD: 2.7), BASFI: 4.0 (SD: 3.1), ASDAS-CRP: 2.4 (SD: 0.9). Test-retest reliability (n: 20) was good ICC: 0.88 (95%IC 0.76 to 0.98). Sensitivity to change was tested in 13 patients and SMR was -0.61 for those patients receiving TNF inhibitors (n: 11). Convergent validity ranged as hypothesized with Spearman correlations from low (age: 0.27) to good (pain: 0.65), (table 1). The ASAS-HI discriminated well between patients with different stages of disease activity and function irrespective of the measure applied (ASDAS, BASDAI and BASFI) (table 2). The internal consistency according to Cronbach's alfa was 0.81.

Table 1. Spearmen correlation coefficient

Characteristics	Spearmen correlation coefficient	
	ASAS-HI (0–17)	p value
Age	0.27	<0.05
Pain (0–10)	0.65	<0.001
Night spinal pain (0–10)	0.54	<0.001
ASDAS	0.51	<0.001
BASDAI (0–10)	0.60	<0.001
BASFI (0–10)	0.54	<0.001
SF-36 Total	0.46	<0.001

Table 2. ASDAS Status Groups

	ASDAS Status Groups			
	Inactive (n: 9)	Moderate (n: 9)	High (n: 29)	very high (n: 5)
ASAS-HI (0–17)	3.44 (± 3.9)	5.77 (± 4.79)	9. 06 (± 3.49)	10.05 (± 4.5)
BASFI (0–10)	0,53 (± 0,35)	1.41 (± 1.40)	5.5 (± 2.46)	6.46 (± 3.12)
BASDAI (0–10)	1.21 (± 0.49)	2.37 (± 1.7)	5.73 (± 1.91)	6.46 (± 3.38)

Conclusions: The Argentinean version of the ASAS-HI was comprehensive and reliable by patients with SpA. The ASAS-HI is a valid tool for assessing overall functioning and health in spondyloarthritis.

SAT0428 WHICH CRITERIA FOR INFLAMMATORY BACK PAIN IN SPONDYLOARTHRITIS ARE OPTIMAL? DATA FROM THE SCREENING FOR AXIAL SPONDYLOARTHRITIS IN PSORIASIS, IRITIS, AND COLITIS STUDY (SASPIC)

R. Carmona[1], J. Yeung[2], A. Masetto[3], L. Martin[4], S. Keeling[5], J. Chan[2], D. Mosher[6], O. Ziouzina[4], J. Paschke[7], A. Carapellucci[7], R.G. Lambert[8], W.P. Maksymowych[5,7]. *[1]St. Joseph's Healthcare Hamilton, Hamilton; [2]Medicine, University of British Columbia, Vancouver; [3]Medicine, Université de Sherbrooke, Sherbrooke; [4]Medicine, University of Calgary, Calgary; [5]Medicine, University of Alberta, Edmonton; [6]University of Calgary, Calgary; [7]CaRE Arthritis; [8]Radiology, University of Alberta, Edmonton, Canada*

Background: Criteria for inflammatory back pain (IBP) in spondyloarthritis (SpA) include the Calin, Berlin, and Assessments in SpA International Society (ASAS) criteria, although no studies have undertaken comparative validation to determine which are optimal versus the rheumatologist expert opinion gold standard assessment.
Objectives: We aimed to compare IBP criteria in unselected patients presenting with undiagnosed back pain to rheumatology practice.
Methods: The Screening for Axial Spondyloarthritis in Psoriasis, Iritis, and Colitis (SASPIC) Study is aimed at the development and validation of a triage strategy for detection of axial SpA in patients presenting with undiagnosed back pain. Consecutive patients $\leq$45 years of age with $\geq$3 months undiagnosed back pain with any one of psoriasis, acute anterior uveitis, or colitis diagnosed by the relevant specialist undergo routine clinical evaluation by a rheumatologist for axial SpA. The rheumatologist determines the presence or absence of IBP (defined as <5 or >5 on 0–10 scale, respectively) and axial SpA (yes/no) after the clinical evaluation and review of labs (B27, CRP) and imaging (x-ray, MRI). Clinical and laboratory data, radiographs and MRI scans are also assessed centrally for diagnosis of axial SpA (yes/no). We assessed sensitivity and specificity of each

of the IBP criteria for diagnosis of IBP according to the local rheumatologist, diagnosis of axial SpA by local rheumatologist, diagnosis of axial SpA by central assessment, and concordant diagnosis of axial SpA by both local and central assessment.

Results: We recruited 185 patients (48.6% male, mean age 27.6 years, mean back pain duration 7.0 years) with iritis (30.3%), psoriasis (17.3%), Crohn's (38.4%) and ulcerative colitis (18.9%). IBP and/or axial SpA were considered present in 65.2% and 47.3%, respectively, of all patients by the local rheumatologist. By central assessment axial SpA was considered present in 32.7% while amongst patients with a concordant diagnosis by both local and central assessment 37.2% were considered to have axial SpA. Sensitivity was comparatively high for all IBP criteria but specificity was poor. The Berlin criteria consistently performed best while the Calin criteria consistently performed worst (Table).

Gold standard	IBP criteria	Sensitivity (%)	Specificity (%)	LR+	LR–
IBP by local rheumatologist	ASAS	83.8	58.8	2.03	0.28
	Berlin	88.9	76.5	3.78	0.15
	Calin	94.0	37.3	1.50	0.16
Axial SpA by local rheumatologist	ASAS	82.9	44.9	1.50	0.38
	Berlin	84.3	51.3	1.73	0.31
	Calin	90.0	19.2	1.11	0.52
Axial SpA by central assessment	ASAS	80.0	37.5	1.28	0.53
	Berlin	80.0	38.9	1.31	0.51
	Calin	94.3	20.8	1.19	0.27
Axial SpA by central and local assessment	ASAS	86.2	44.9	1.56	0.31
	Berlin	86.2	51.0	1.76	0.27
	Calin	93.1	22.4	1.20	0.31

Conclusions: IBP criteria lack specificity for rheumatologist diagnosed IBP or axial SpA but the Berlin criteria have consistently better performance.

SAT0429 THE PERFORMANCE OF MAGNETIC RESONANCE IMAGING USING THE VIBE TECHNIQUE TO DETECT STRUCTURAL CHANGES IN PATIENTS WITH EARLY AXIAL SPONDYLOARTHRITIS IN COMPARISON TO CONVENTIONAL RADIOGRAPHY AND COMPUTED TOMOGRAPHY

X. Baraliakos[1], F. Hoffmann[1], X. Deng[2], Y. Wang[2], F. Huang[2], J. Braun[1]. *[1]Rheumazentrum Ruhrgebiet, Herne, Germany; [2]Department of Rheumatology, Chinese PLA General Hospital, Beijing, China*

Background: Magnetic resonance imaging (MRI) is the gold standard for detection of inflammation in the sacroiliac joints (SIJ) of patients (pts) with axial spondyloarthritis (axSpA), while for chronic, structural changes (erosions, sclerosis and ankylosis) conventional radiographs (CR) and computed tomography (CT) are often preferred. The 3D volumetric interpolated breath-hold sequence (VIBE) is an MRI technique, easy to acquire in daily practice, that can visualize cartilage especially well because of its good contrast to synovial tissue.

Objectives: To compare the ability of the VIBE technique to detect structural changes in comparison to CR and CT in SIJs of axSpA patients in relation to symptom duration and age.

Methods: Complete sets of MRI (T1 and VIBE techniques), CT and CR of SIJs of 109 AS patients were available. Two readers evaluated all images independently, blinded to demographic data and in separate sessions for each technique. The assessment of lesions was performed based on SIJ-quadrants (SQ) to score erosions, sclerosis and ankylosis (SIJ-halves). Lesions were counted as positive if both readers were in agreement. Comparisons between MRI techniques were performed by Wilcoxon-test. Linear regression analysis was used to evaluate the influence of age and disease duration on the occurrence of different structural lesions by modeling the differences in the number of lesions in different imaging techniques as dependent variable.

Results: The mean age ± standard deviation was 45.3±13.9 years (y), 55 pts (50.5%) were aged ≤45y, 67.9% male, 82.3% HLA-B27+, 58 pts (53.2%) had a disease duration ≤3y. Agreement for positive and negative findings between MRI and CT was generally high (>80% of SQs in all subgroups) and agreement between readers for all techniques and lesion types was excellent (ICC=0.979–0.997).

Overall, MRI detected significantly more SQ with erosions in pts ≤45y (n=134) and in pts with disease duration ≤3y (n=125) as compared to CT (n=91, p=0.002 and n=90, p=0.003, respectively) and in pts with age ≤45y (n=61, p<0.001) as compared to CR, while there were no differences between MRI and CT in pts. >45y or disease duration >3y. Linear regression analysis showed that MRI was superior in the detection of erosions in younger ages as compared to CT (B=0.032, p=0.001).

However, CT detected significantly more SIJ halves with ankylosis in all subgroups and more SQ with sclerosis in pts with disease duration ≤3y (n=64 vs. n=37, respectively, p=0.006), and it also detected more SQ with sclerosis in pts >45y (n=67 vs. n=38, p=0.001) and disease duration >3y (n=64 vs. n=40, p=0.003) as compared to MRI, while no differences were found in the assessment of ankylosis.

Conclusions: MRI in the T1 and VIBE technique is more sensitive in the detection of erosions as compared to CT and CR in axSpA pts with short disease duration and younger age. This is due to its ability to identify structural damage in the SIJ cartilage that has not yet extended to the underlying bone. These differences are not found in pts with longer disease duration or older age. This data suggests a more prominent role for MRI also for the early detection of structural changes in the SIJ of axSpA pts.

SAT0430 THE RELATIONSHIP BETWEEN EXOSOMAL MIRNA21-5P AND ANKYLOSING SPONDYLITIS

Y. Huang, T. Li, Z. Huang, W. Deng, S. Zheng, Z. Huang. *Guangdong No. 2 Provincial People's Hospital, Guangzhou, China*

Background: Ankylosing Spondylitis (AS) affects human health seriously, which is difficult to diagnose in the early stages. It is reported that MicroRNAs (miRNAs) may serve as novel biomarkers for AS. Exosome can function as vehicles to deliver miRNAs in body fluids including saliva and plasma. Our previous study shows that exosomal miRNA21–5P is higher expressed in AS patients, compared with healthy subjects. However, the relationship between exosomal miRNA21–5P and AS has yet to be determined.

Objectives: The aim of the present study is to explore the relationship between exosomal miRNA21–5P and AS.

Methods: AS patients who fulfilled the modified New York criteria were enrolled for this study. Healthy subjects were also enrolled as control group. BASDAI, BASFI, C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were evaluated. Quantitative reverse-transcription PCR (qRT-PCR) was used to confirm the expression of exosomal miRNA21-5P, and receiver-operator characteristic (ROC) curve was used to evaluate the diagnostic value of exosomal miRNA21-5P for AS. According to the cut off value, AS patients were divided into exosomal miRNA21–5P low value group (<cut off value) and exosomal miRNA21-5P high value group (≥cut off value), and the difference of AS patient's clinical characteristics between the two group were explored.

Results: Twenty healthy subjects and 38 AS patients were enrolled in the study. The qRT-PCR results indicated that the expression level of exsomal miRNA21-5P in AS patients was (2.041±0.975) times higher than that of healthy subjects. ROC curve analysis showed that exsomal miRNA21-5P had significant diagnostic value for AS with the AUC of 0.809 (CI95%: 0.691–0.921). In addition, the cut off value was 1.310, with the specifity of 80.0% and sensitivity of 76.32%. According to the cut off value of exsomal miRNA21–5P, AS patients were divided into the low exsomal miRNA21-5P group (<1.310) and the high exsomal miRNA21-5P group (≥1.310). Among the 38 AS patients, 12 cases were in the low exsomal miRNA21–5P group and 26 cases were in the high exsomal miRNA21-5P group. Comparations of the clinical characteristics of the two groups showed that BASDAI, BASFI, CRP and ESR were significantly increased in exsomal miRNA21-5P high value group.

Conclusions: Exsomal miRNA21-5P was significantly increased in AS patients, which may be used as a biomarker for AS.

SAT0431 THE RELATIONSHIP OF SEASONAL VARIATION, THE ONSET AND THE SYMPTOMS OF ANKYLOSING SPONDYLITIS MEASURED BY SELF-ADMINISTRATED QUESTIONNAIRES IN CHINESE PATIENTS

Y. Jiang, M. Yang, Z. Lin, Q. Wei, S. Cao, J. Gu. *Rheumatology, the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Background: Ankylosing spondylitis (AS) is a chronic inflammatory disease which mainly involves sacroiliac joints, resulting in pain, functionally limitation and even less life expectancy. Seasonal variation was found in rheumatoid arthritis and gout [1,2]. No reports had been focused on seasonal variation of AS onset or symptoms in AS patients.

Objectives: Our study was to investigate the relationship of seasonal variation and the onset and symptoms of AS in Chinese patients.

Methods: Adult AS patients diagnosed with the modified New York criteria for AS whose disease duration was over 2 years were enrolled from several provinces all over China. Participants were required to complete a set of questionnaires and examinations, including demographic and clinical information. Questions included "in which season(s) did you have the initial symptoms of AS", and "in which season(s) were the symptoms aggravated/improved". The Statistical Package for Social Sciences (SPSS) software version 21 was used for all data management and analysis.

Results: Of all the 859 AS patients, 75.1% were male patients. 47.8% were married. Mean age was 30.60±9.50 years. Mean disease duration was 7.43±6.92 years. 27.7% of the patients had an onset of the disease in summer, while the lowest incidence happened in autumn (12.5%, p<0.05). 29.6% of the patients could not recall the exact season. 29.5% of the patients' symptoms got worse in winter,

while only 2.6% of the patients felt worse in autumn, in comparison of 10.3% in spring and 6.0% in summer. 24.4% of the patients felt relieved in summer, while surprising, only 2.7% felt better in spring, with a lowest rate in the four season. However, 48.1% of the patients believed there were no seasonal differences.

Conclusions: More patients had an onset of AS in summer, compared to other seasons. More patients felt worse in winter and better in summer. Nearly half of AS patients considered that there were no seasonal differences in the deterioration or improvement of the symptoms.

SAT0432 CORRELATION BETWEEN THE SPINAL MRI FINDINGS AND NEW BONE FORMATION FACTOR (DKK-1)I N PATIENTS WITH SPONDYLOARTHRITIS

Z. Zhao, G. Wang, Y.Y. Wang, J.S. Yang, J. Zhu, F. Huang. *Rheumatology, Chinese PLA General Hospital, Beijing, China*

Background: Recent prospective data suggest that spinal inflammatory damage in patients with ankylosing spondylitis will eventually convert into fat. In these complex inflammatory lesions, bone formation and inflammation are not synchronized. The molecular basis responsible for new bone formation in SpA patients is still unclear. Serum level of dickkopf-1 (Dkk-1), the natural inhibitor of WNT protein, is a main factor in limiting new bone formation.

Objectives: In this study, we aimed to assess the correlation between the secreted protein Dkk-1 and abnormal findings on spinal MRI through a prospective study of SpA.

Methods: Thirty patients with active axial SpA (axSpA) who fulfilled the ASAS axSpA criteria were enrolled. All patients received an injection of recombinant human TNF receptor-antibody fusion protein (YISAIPU) at a dosage of 50 mg/week for 6 months. Patient report outcome measure questionnaires and physical examination, blood tests were completed according to the study protocol. All patients were scored for bone marrow edema and fat infiltration on spinal MRI imaging. The spinal MRI imaging of the patients before and after the treatment were blindly reviewed and scored using the SPARCC scoring system by two individuals who were familiar with the system.

Results: There are 28 male and two female patients (mean age: 31±5.5 yrs, range: 22–41; mean duration: 93.5±75.8; HLA-B27(+): 96.7% (29/30)). In patients who finished the 6 month anti-TNF treatment, the ESR, CRP, BASDAI, BASFI, BASMI and ASDAS-CRP were significantly decreased ($P<0.01$). Serum Dkk-1 concentration was also significantly decreased ($P<0.05$), as were the edema measurements of spinal bone marrow ($P<0.05$), but not with the before and after treatment differences in fat infiltration scores ($p>0.05$). (Table1). Correlation analysis found that serum Dkk-1 concentration before treatment was significantly correlated with spinal bone marrow edema scores ($P<0.01$). The differences in serum Dkk-1 levels significantly correlate with differences in spinal MRI bone marrow edema scores after treatment ($P<0.05$).(Figure 1 and 2).

Table 1. Clinical indexes, serum DKK-1 and spine imaging scores before and after treatment

	Before treatment	After treatment
ESR (mm/h)	23.78±22.27	5.03±4.63**
CRP (mg/dl)	2.59±2.90	0.40±0.52**
BASDIA	6.23±1.29	2.52±1.84**
BASFI	5.78±1.44	2.69±1.72**
BASMI	2.46±1.91	0.69±1.21**
ASDAS-CRP	3.77±0.83	1.58±0.74**
DKK-1 (ng/ml)	98.23±113.41	51.88±41.90*
Spine-BME	20.27±23.53	6.08±8.09**
Spine- FAT	10.08±10.38	13.81±15.34

*p<0.05; ** p<0.01.

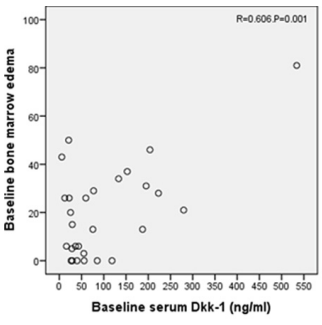

Figure 1. Serum Dkk-1 level is correlated with bone marrow edema at baseline

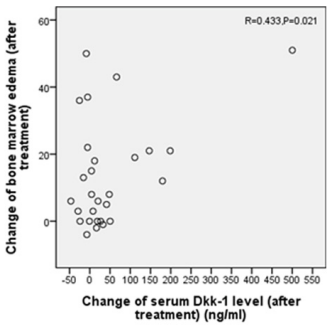

Figure 2. After treatment，the change of serum Dkk-1 level is correlated with change of bone marrow edema

Conclusions: Spinal marrow edema may have a role in predicting new bone formation in the spine, since the change of serum Dkk-1 level is correlated with change of spinal marrow edema. And Dkk-1 may participate in the molecular basis of the TNF inhibitor's blockade of new bone formation. Further research is needed on patients who have received long-term TNF antagonist treatment to find the time points when serum Dkk-1 level reaches a stabilized plateau. Increased knowledge in this area will be helpful when assessing a predictive marker for the timing of treatment withdrawal.

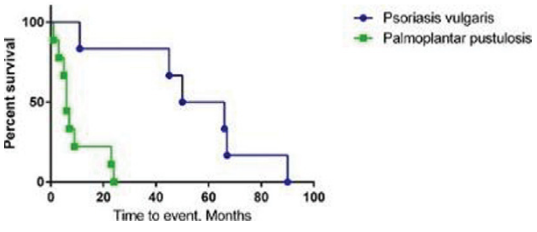
Psoriatic arthritis

SAT0433 ANTI-TNF TREATMENT IN RHEUMATOID ARTHRITIS AND ANKYLOSING SPONDYLITIS PATIENTS IS ASSOCIATED WITH A STRONG INCREASE OF PALMOPLANTAR PUSTULOSIS BUT NOT OF PSORIASIS VULGARIS

J. Ruwaard[1], E. van der Vlugt[1], M. Nurmohamed[1], T. Rispens[2], G.J. Wolbink[1,2]. *[1]Amsterdam Rheumatology and immunology Center | Reade; [2]Department of Immunopathology, Sanquin Research and Landsteiner Laboratory Academic Medical Centre, Amsterdam, Netherlands*

Background: The prevalence of paradoxical psoriasis developed with biological use is already studied. However, none of these studies discriminate between psoriasis vulgaris (PV) and palmoplantar pustulosis (PPP), while these might be different entities (1). The prevalence in general population is 2–4% for PV and 0.01–0.05% for PPP (1–3). Moreover, most reports in the literature imply only a role for anti-Tumor necrosis factors (anti-TNF), although, a few cases described paradoxical psoriasis in patients treated with biologicals other than anti-TNF.



Objectives: To study the prevalence and incidence density of paradoxical psoriasis and palmoplantar pustulosis in patients with rheumatoid arthritis (RA) and ankylosing spondylitis (AS) treated with biological therapy. Second to investigate differences between paradoxical psoriasis and palmoplantar pustulosis.

Methods: Data were collected from the observational cohorts of AS and RA patients. 1499 consecutive patients were included for calculating prevalence and incidence density. Incidence density is calculated per 1000 person years. For calculating differences, only biological naïve patients (n=830) were included. Kaplan Meier curve was used to show the difference in time in onset.

Results: In all, 13 cases of PPP and 16 cases of PV were observed in both the RA as AS cohorts. In AS patients 1.73% developed PPP and 1.38% PV. In RA patients respectively 0.66% and 0.99%.

The incidence density of PPP in RA was 2.1 (95% CI 0.7–3.6), for PV 3.2 (95% CI 1.4–5.0). In AS, 4.7 (95% CI 0.6–8.8) for PPP and 3.7 (95% CI 2.3–12.7) for PV. Although not statistically significant, PPP was more prevalent in adalimumab (0.94%) compared to etanercept (0.34%). In contrast, PV occurs in 0.53% in adalimumab and 0.92% in etanercept treated patients. PPP was only observed in anti-TNF, PV was also observed in 1 patient treated with tocilizumab and 1 with abatacept. A difference was observed in the time to event, with a median of 6 months (IQR 4–16 months) for PPP and 50 months (IQR 11–67 months) for PV; p=0.003 (figure 1). Discontinuation of biological treatment was indicated in 80% of the PPP patients and 18.2% PV patients.

Figure 1. Difference between patients who developed psoriasis vulgaris versus palmoplantar pustulosis on biological therapy.

Conclusions: Our findings show that biological therapy in patients with RA or AS is associated with a 13 to 35 fold increase in prevalence of PPP. While the prevalence of biological-associated PV is lower than the prevalence of PV in the general population. In this study PV and PPP are different from each other regarding prevalence, time to onset and consequences for biological treatment, and therefore should be considered as separate entities.

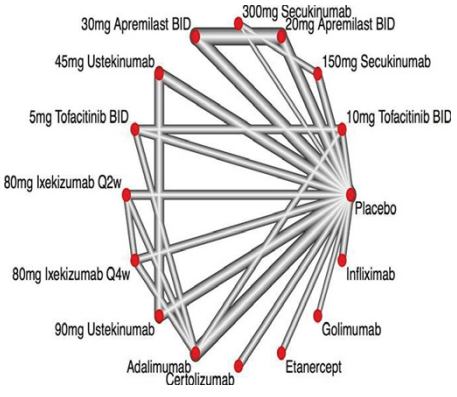
SAT0434 NETWORK META-ANALYSIS ON THE EFFICACY OF NOVEL THERAPEUTIC AGENTS IN PATIENTS WITH PSORIATIC ARTHRITIS



T.T. Cheung, M.F. Tsoi, Y. Fei, C.S. Lau, B.M.Y. Cheung. *Medicine, The University of Hong Kong, Hong Kong, Hong Kong*

Background: Novel therapeutic agents are more effective than DMARDs in the management of psoriatic arthritis. However, direct comparisons of efficacy between these novel therapeutic agents are lacking.
Objectives: This network meta-analysis aims to compare the relative efficacies between different novel therapeutic agents.
Methods: Literature searching was conducted in MEDLINE, EMBASE, Scopus, ISI Web of Science, Cochrane Library, Clinicaltrials.gov and recent rheumatology conference abstracts up to Nov 2016. 2 independent researchers analysed the articles. For inclusion, randomised, placebo-controlled trials must report the proportion of patients achieving ACR20, ACR50, ACR70 and PASI75 responses. The outcomes of this network meta-analysis were the proportion of patients achieving ACR20, ACR50, ACR70 and PASI75 responses with reference to placebo and etanercept.
Results were analysed using random effect model by R statistics (version 3.3.1) with statistical package netmeta (version 0.9–2). The heterogeneity of the study results was determined by the I^2 statistics.
Results: 18 trials were included into this study. In general, all novel therapeutic agents demonstrated superior efficacies than placebo. With reference to etanercept, apremilast and ustekinumab were associated with less proportions of patients achieving ACR20 response (odds ratio [95% confidence interval]: 20mg apremilast: 0.18 [0.07–0.48]; 30mg apremilast: 0.24 [0.09–0.62]; 45mg ustekinumab: 0.26 [0.09–0.73]; 90mg ustekinumab: 0.32 [0.11–0.90]).
Etanercept was not different from apremilast, ustekinumab, golimumab, adalimumab, ixekizumab, certolizumab, ixekizumab and secukinumab in terms of ACR20 and ACR50 responses.
Golimumab and infliximab were associated with greater proportions of patients achieving PASI75 response, though the difference did not reach statistical significance. (odds ratio [95% confidence interval]: golimumab: 3.51 [0.44–28.2]; infliximab: 5.97 [0.89–40.2]).

Table 1. Network meta-analysis on proportion of patients achieved ACR20 and PASI75 response with reference to etanercept

	ACR20 response	PASI75 response
10mg Tofacitinib BID	0.38 [0.12; 1.22]	0.68 [0.13; 3.54]
150mg Secukinumab	0.64 [0.22; 1.90]	0.49 [0.07; 3.19]
20mg Apremilast BID	0.18 [0.07; 0.49]	0.39 [0.08; 1.83]
300mg Secukinumab	0.77 [0.21; 2.80]	0.67 [0.10; 4.56]
30mg Apremilast BID	0.24 [0.09; 0.63]	0.48 [0.10; 2.22]
45mg Ustekinumab	0.26 [0.09; 0.75]	1.18 [0.15; 9.09]
5mg Tofacitinib BID	0.25 [0.08; 0.81]	0.64 [0.12; 3.29]
80mg Ixekizumab Q2w	0.40 [0.12; 1.27]	2.74 [0.49; 15.37]
80mg Ixekizumab Q4w	0.35 [0.11; 1.11]	1.73 [0.32; 9.31]
90mg Ustekinumab	0.32 [0.11; 0.92]	1.40 [0.18; 10.74]
Adalimumab	0.33 [0.13; 0.86]	0.77 [0.17; 3.50]
Certolizumab	0.42 [0.12; 1.39]	NA
Etanercept (reference)	1.00	1.00
Golimumab	0.93 [0.25; 3.40]	3.51 [0.44; 28.22]
Infliximab	0.74 [0.26; 2.12]	5.97 [0.89; 40.22]
Placebo	0.10 [0.04; 0.22]	0.09 [0.03; 0.35]

NA: not applicable.

Conclusions: Apremilast and ustekinumab were less efficacious than etanercept in terms of ACR20 response. All the novel therapeutic agents demonstrated comparable efficacies in terms of ACR50, ACR70 and PASI75 responses.

SAT0435 IL17 CORRELATES POSITIVELY WITH TGF-BETA 1 AND DKK1 AND INVERSELY WITH BMP2 AND 4 IN SYNOVIAL MEMBRANE OF PATIENTS WITH PSORIATIC ARTHRITIS

J. Pinto-Tasende, M. Fernandez-Moreno, M.E. Vazquez-Mosquera, J.C. Fernandez-Lopez, N. Oreiro-Villar, M. Bejerano-Herrería, B. Acasuso-Pardo de Vera, F.J. Blanco-García. *INIBIC-Rheumatology, Complejo Hospitalario Universitario A Coruña, A Coruña, Spain*

Background: Immune and non-immune cells contribute to the pathology of chronic arthritis and they can contribute to tissue remodeling and repair as well as disease pathogenesis. An important role for their products such as TGF-beta 1, IL17 or BMPs has been suggested in homeostatic and remodeling mechanisms in arthritis. BMP signaling could have an anti-inflammatory role in the control and maintenance of low levels of pro-inflammatory factors in healthy joints or the early stage of RA.
Objectives: to analyze and compare serum levels, gene expression and immunohistochemistry (IHC) in synovial membrane of inflammation and bone destruction/regeneration biomarkers in patients with psoriatic arthritis (PsA), undetermined seronegative arthritis (USA), Osteoarthritis of the knee (kOA) and ankylosing spondylitis (AS).
Methods: We recruited 45 consecutive patients with chronic knee arthritis referred for undergoing arthroscopies (17 PsA, 12 USA, 12 kOA, 4 AS). Synovial membrane was processed for IHC analysis and quantification of mRNA expression ratio by qRT-PCR. Serum levels of TGF-beta 1, IL6, IL17 and IL22, DKK1, Sclerostin, BMP2, BMP4, Wnt1 and Wnt5a were measured (ELISA). We analyzed and compared these data with the demographic, clinical, analytical and radiological characteristics of the patients. Data were analyzed using the SPSS version 17.0 software and statistical significance was defined as $P<0.05$.
Results: We obtained valid synovial membrane samples from 41 patients for IHC, RNA extraction and purification from 29 patients for analyze mRNA expression and serum from 38 patients for protein levels measurement. IL17 gene expression was higher in PsA patients (p=0.027) and correlated positively with DKK1 (r=0.424, p=0.022) and negatively with BMP2 (r=-0.396, p=0.033) and BMP4 (r=-0.472, p=0.010). IHC reactivity for TGF-beta 1 in synovial tissue was higher in patients with psoriatic arthritis (p 0.010) and correlated positively with IL17 (r=0.389, p=0.012) and DKK1 (r=0.388, p=0.012). Moreover, serum levels of TGF-beta 1 were significantly increased in PsA with erosions (p=0.044).
Conclusions: IL17 gene expression in synovial membrane from patients with psoriatic arthritis was higher than in seronegative undetermined arthritis, osteoarthritis and ankylosing spondylitis patients, correlating positively with DKK1 and negatively with bone morphogenetic proteins 2 and 4. In addition, TGF-beta in synovial tissue, necessary for the activation of Th17 cells, was higher in patients with psoriatic arthritis, in relation to IL17 and DKK1 increased. Serum TGF beta 1 levels were also higher in patients with erosive disease.

SAT0436 DURABILITY OF APREMILAST RESPONSE IN PATIENTS WITH PSORIATIC ARTHRITIS: LONG-TERM (208-WEEK) RESULTS FROM THE PALACE 1 TRIAL

A. Kavanaugh[1], D.D. Gladman[2], J.J. Gomez-Reino[3], S. Hall[4], E. Lespessailles[5], P.J. Mease[6], G. Schett[7], M. McIlraith[8], N. Delev[8], M. Paris[8], L. Teng[8], J. Wollenhaupt[9]. *[1]UCSD School of Medicine, la Jolla, United States; [2]Toronto Western Research Institute, Toronto, Canada; [3]Hospital Clínico Universitario, Santiago, Spain; [4]Monash University, CabriniHealth, Melbourne, Australia; [5]University of Orléans, Orléans, France; [6]Swedish Medical Center and University of Washington School of Medicine, Seattle, United States; [7]University of Erlangen-Nuremberg, Erlangen, Germany; [8]Celgene Corporation, Summit, United States; [9]Schön Klinik Hamburg Eilbek, Hamburg, Germany*

Background: Optimizing treatment choice in psoriatic arthritis (PsA) necessitates an understanding of the long-term effects of therapies across varied manifestations of this complex disease. Data from 4 years of apremilast (APR) treatment in PALACE 1 were used to examine disease control across markers of active inflammation, such as SJC, as well as improvements in patient (pt) functionality, as assessed using the HAQ-DI.
Objectives: Evaluate long-term outcomes with APR treatment after ≥1 DMARD or biologic in pts with active PsA.
Methods: Pts were randomized (1:1:1) to placebo (PBO), APR 30 mg BID (APR30), or APR 20 mg BID (APR20). The PBO-controlled phase continued to Wk 24, at which time all remaining PBO pts were re-randomized to APR30 or

APR20. Double-blind APR treatment continued to Wk 52; pts could continue APR for up to 4 additional years in an open-label extension.

Results: 504 pts were randomized and received ≥1 dose of study medication (PBO: n=168; APR30: n=168; APR20: n=168); 86.9% (225/259) of pts entering the third year completed 208 wks of APR treatment; overall, this is 44.6% (225/504) of pts randomized at baseline (BL). At Wk 52, 53.2% of APR30 pts achieved a modified ACR20 response (Table), regardless of when APR was started (BL, Wk 16, or Wk 24). At Wk 208, a sustained response rate was observed in APR30 pts, as shown by an ACR20 response rate of 67.5%. Marked improvements in SJC were seen throughout the study, with a mean percent decrease of −84.2% at Wk 208; TJC reductions were consistent (Table). Functionality is of paramount importance to pts; large improvements were seen in HAQ-DI score, with a mean change of −0.47. Pts also note fatigue as a disease- or treatment-related impairment; a mean improvement of 5.7 was seen in FACIT-F score at Wk 208 (Table), and the pt population reached a mean score of 35.7. In addition, long-term treatment led to the maintenance of the proportions meeting the minimal clinically important difference in HAQ-DI score change, achieving ACR50/ACR70 responses and reaching PASI-75 and PASI-50 responses (Table). No new safety concerns were identified with APR treatment up to 208 wks. During Wks >156 to ≤208, the only adverse event (AE) occurring in ≥5% of APR30-exposed pts was URTI (5.2%); most AEs were mild/moderate in severity. Among APR30-exposed pts, serious AEs occurred in 6.7% of pts in Wks >156 to ≤208, consistent with earlier data. Importantly, few discontinuations due to AEs occurred throughout the long-term treatment period.

Outcomes at Wk 52 and Wk 208		
	Wk 52	Wk 208
	APR30 n=193*	APR30 n=123*
ACR20, n/m§ (%)	101/190 (53.2)	83/123 (67.5)
ACR50, n/m§ (%)	49/191 (25.7)	56/122 (45.9)
ACR70, n/m§ (%)	27/191 (14.1)	35/123 (28.5)
Swollen joint count, mean % change	−50.5	−84.2
Tender joint count, mean % change	−45.1	−78.1
HAQ-DI (0-3), mean change	−0.31	−0.47
HAQ-DI MCID ≥0.30, n/m (%)	85/193 (44.0)	72/123 (58.5)
HAQ-DI MCID ≥0.35, n/m (%)	85/193 (44.0)	72/123 (58.5)
DAS-28 (CRP) <2.6, n/m (%)	41/189 (21.7)	57/122 (46.7)
DAS-28 (CRP), mean change	−1.26	−2.08
FACIT-F, mean change	3.8	5.7
PASI-75‡, n/m (%)	31/95 (32.6)	21/60 (35.0)
PASI-50‡, n/m (%)	52/95 (54.7)	37/60 (61.7)

Data as observed. *The n reflects the number of pts treated with APR30, regardless of when treatment started (BL, Wk 16, or Wk 24), and who had data available at the specific time point; actual number of pts available for each end point may vary. §Denominators vary slightly due to availability of sufficient data for each level of ACR response assessment. ‡Examined among pts with psoriasis involvement of the body surface area ≥3% at BL and data at the specific time point. APR30=apremilast 30 mg BID; ACR20/50/70=20%/50%/70% improvement in modified American College of Rheumatology response criteria; n/m=number of responders/number of pts with sufficient data for evaluation; HAQ-DI=Health Assessment Questionnaire-Disability Index; MCID=minimal clinically important difference; DAS-28=28-joint count Disease Activity Score; CRP=C-reactive protein; FACIT-F=Functional Assessment of Chronic Illness Therapy-Fatigue; PASI-75/50=≥75%/≥50% reduction from BL Psoriasis Area and Severity Index score; pts=patients; BL=baseline.

Conclusions: APR30 demonstrated sustained, clinically meaningful improvements in signs and symptoms of PsA, physical function, and associated psoriasis over 208 wks. APR30 continued to demonstrate a favorable safety profile and was generally well tolerated.

SAT0437 IXEKIZUMAB IMPROVES NAIL AND SKIN LESIONS IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS AND PRIOR TNF INADEQUATE RESPONSE

L.E. Kristensen[1], J.F. Merola[2,3], J. Dutz[4], D.H. Adams[5], L. Kerr[5], P. Rich[6].
[1]Copenhagen University Hospital, Bispebjerg and Frederiksberg, Denmark; [2]Brigham and Women's Hospital; [3]Harvard Medical School, Boston, United States; [4]The University of British Columbia, Vancouver, Canada; [5]Eli Lilly and Company, Indianapolis; [6]Oregon Health Science University, Portland, United States

Background: Ixekizumab (IXE), a high-affinity monoclonal antibody selectively targeting interleukin-17A, significantly improved fingernail psoriasis by Week (Wk) 12 vs placebo (PBO) in patients (pts) with moderate-to-severe plaque psoriasis[1]. Moreover, IXE had significantly reduced signs and symptoms of psoriatic arthritis (PsA) at Wk 24 in biologic disease-modifying antirheumatic drug (bDMARD)-naïve pts with active PsA[2].

Objectives: To evaluate the impact of IXE on nail and skin lesions in active PsA pts who have previously received bDMARD therapy.

Methods: In this phase 3, multicentre, double-blind, PBO-controlled, outpatient study, pts (aged ≥18 years) with active PsA and bDMARD-experience randomly (1:1:1) received PBO for 24 Wks, 80 mg IXE as one injection every 2 (IXE Q2W) or 4 Wks (IXE Q4W) after starting dose of 160 mg. At Wk 16, inadequate responders received rescue medication and PBO pts were re-randomised (1:1) to receive either IXE Q2W or IXE Q4W. The efficacy of IXE was assessed by Nail Psoriasis Severity Index (NAPSI) in pts with nail psoriasis at baseline (PBO, n=73; IXE Q4W, n=89; IXE Q2W, n=74), Psoriasis Area and Severity Index (PASI) 75/90/100 response rate at Wk24 in pts with baseline body surface area (BSA) ≥3 (PBO, n=67; IXE Q4W, n=68; IXE Q2W, n=68) and percentage of pts achieving static Physician Global Assessment (sPGA) of psoriasis score of 0 (cleared) or 1 (minimal) in pts with baseline sPGA≥3 (PBO, n=55; IXEQ4W, n=60; IXEQ2W, n=62). Missing data and inadequate responder data were imputed using the nonresponder imputation for categorical variables. For continuous variables, least squares mean (LSM) changes were calculated using mixed effects models for repeated measures, observed data from Wks 16 to 24 was excluded for inadequate responders.

Results: Overall the demographics and baseline characteristics were comparable between the treatment groups. The mean (SD) NAPSI total score at baseline was 19 (19), 20 (20), and 21 (22) in PBO, IXE Q4W and IXE Q2W, respectively. At Wk 24, the change in NAPSI total score from baseline was significantly greater with IXE Q4W (LSM±SE -10.2±2.04) and IXE Q2W (-10.8±2.12) vs PBO (0.5±2.13, p<.001 each). Similarly, the mean percentage improvement in NAPSI total score was significantly greater with IXE Q4W (LSM±SE 35.4±22.14, p<.001) and IXE Q2W (30.9±22.95, p=.001) vs PBO (-45.2±23.04). At Wk 24, significantly greater percentage of pts achieved a NAPSI score of 0 with IXEQ4W or IXEQ2W treatment vs PBO (Table). At Wk 24, the percentage of pts achieving PASI 75/90/100 response was significantly greater with IXE Q4W and IXE Q2W vs PBO (Table). Overall, the safety profile of IXE was aligned with the general study population.

Table: Percentage of patients with improvement in skin and nail lesions

Efficacy endpoints (%)	Placebo	IXE Q4W	IXE Q2W
PASI 75[a]	14.9	55.9*	60.3*
PASI 90[a]	11.9	44.1*	50.0*
PASI 100[a]	4.5	35.3*	27.9*
sPGA (0, 1)[b]	9.1	66.7*	75.8*
NAPSI (0)[c]	6.8	20.2**	29.7*

*p<.001; **p=.022; [a]Patients with baseline ≥3% BSA; [b]in patients with baseline sPGA ≥3; [c]Patients with baseline fingernail psoriasis

Conclusions: In the present study, ixekizumab led to significantly greater reduction and clearance of the nail and skin lesions in active PsA pts who had previously received bDMARD therapy compared to placebo.

SAT0438 PSORIATIC ARTHRITIS AND NODAL OSTEOARTHRITIS CAN BE DIFFERENTIATED USING HAND RADIOGRAPHS: A NOVEL METHOD

S. Bahadur[1], A. Zavareh[2], C. Hughes[3], R. Mandegaran[3], S. Subesinghe[3], B. Kirkham[3]. *[1]Rheumatology; [2]Radiology; [3]Guys and St Thomas Trust, London, United Kingdom*

Background: One of the difficulties of rheumatology practice is the differentiation of Psoriatic Arthritis (PsA) and Nodal Osteoarthritis (NOA) in some patients with distal interphalangeal joint involvement. MRI and ultrasound imaging, have recently been demonstrated as inconclusive in some cases (1,2). This differentiation is critical, as treatment for these debilitating conditions is completely different.
Objectives: To establish a scoring system of radiographic joint and soft tissue features to differentiate PsA from NOA.
Methods: We devised a scoring system for hand radiographs of interphalangeal joints, soft tissue and bone features, allocated major and minor weighting. The scoring system was then tested in a single blind analysis of hand radiographs from 48 patients with PsA, 50 with NOA and 1 with RA (incorrectly classified as PsA at study entry) seen between 2008 and 2016. Anonymised patient images were assessed by a Musculoskeletal (MSK) Radiologist, blind to clinical information. Radiological diagnosis was then compared with clinical diagnosis. We taught the method to 2 rheumatology and 1 radiology trainees over 1 hour, who then independently assessed the same radiographs.
Results: The MSK radiologist reported normal hand radiographs in 5 patient sets. Of the remaining 94 patient sets, the scoring system correctly allocated 100% of images into PsA, NOA or RA. Notably, 2 patients with NOA who subsequently developed PsA several years later, and 1 patient with seropositive RA, initially misclassified as PsA, were correctly identified by the MSK radiologist.
Trainees using the system also achieved good agreement, after removing radiographs assessed as normal; Rheumatology trainees: 88% and 67% correct; Radiology trainee: 70% correct.
Conclusions: This initial single-centre study shows our novel radiological scoring system is effective at differentiating patients with PsA from NOA. Radiographs provide an accurate, time-efficient (for both clinician and patient) and inexpensive test. We also show that trainees can learn this scoring system with moderate accuracy after a short educational programme. We are currently carrying out a detailed analysis of the scoring system to optimise accuracy and ease of use by non-radiologists.

SAT0439 INTEGRATED SAFETY SUMMARY OF TOFACITINIB IN PSORIATIC ARTHRITIS CLINICAL STUDIES

G. Burmester[1], O. FitzGerald[2], K. Winthrop[3], G. Williams[4], V.F. Azevedo[5], W.F.C. Rigby[6], K. Kanik[7], C. Wang[7], P. Biswas[8], T. Jones[9], S. Menon[7], N. Palmetto[8], R. Rojo[7]. *[1]Charité - University Medicine Berlin, Berlin, Germany; [2]Department of Rheumatology, St. Vincent's University Hospital, Dublin, Ireland; [3]Oregon Health and Science University, Portland, OR; [4]Williams Cancer Drug Consulting LLC, Wayne, NJ, United States; [5]Universidade Federal do Paraná, Curitiba, Brazil; [6]Geisel School of Medicine at Dartmouth, Lebanon, NH; [7]Pfizer Inc, Groton, CT; [8]Pfizer Inc, New York, NY; [9]Pfizer Inc, Collegeville, PA, United States*

Background: Tofacitinib is an oral Janus kinase inhibitor under investigation for psoriatic arthritis (PsA).
Objectives: To describe the safety profile of tofacitinib from integrated Phase (P)3 and long-term extension (LTE) studies.
Methods: Data were analysed for patients (pts) who received ≥1 dose of tofacitinib 5 or 10 mg BID or placebo (PBO), integrated across 2 P3 studies (OPAL Broaden [12 months; NCT01877668]; OPAL Beyond [6 months; NCT01882439]) and 1 LTE study (OPAL Balance [ongoing, database not locked; NCT01976364]). Common adverse events (AEs; occurring in ≥2% of tofacitinib pts in any group) were analysed in the PBO-controlled portion (Months 0–3) of the P3 studies (Cohort 1 [C1]). Serious AEs (SAEs) and discontinuations due to AEs were analysed over 12 months in pts randomised to tofacitinib 5 or 10 mg BID in P3 studies (Cohort 2a [C2a]); pts randomised to PBO were excluded from this analysis. Deaths and AEs of special interest (serious infections [SI], herpes zoster [HZ], opportunistic infections [OI] including HZ, major adverse cardiac events [MACE], malignancies, non-melanoma skin cancer [NMSC]) were evaluated in all tofacitinib-treated pts in the P3 and LTE studies (Cohort 3 [C3]). Incidence rates (IR; pts with events/100 pt-years [PY] and 95% confidence intervals) are reported. Laboratory results will be reported in future publications.
Results: C1 included 474 tofacitinib- and 236 PBO-treated pts; C2a included 474 tofacitinib-treated pts; and C3 included 783 tofacitinib-treated pts (exposure: 776 PY). Nasopharyngitis (5.9%) and headache (8.5%) were the most commonly reported AEs at Month 3 in pts receiving tofacitinib 5 and 10 mg BID, respectively (Table). In pts randomised to tofacitinib 5 or 10 mg BID, over 12 months (C2a), the IRs for SAEs were 7.92 (4.09, 13.84) and 8.11 (4.19, 14.17), respectively. Discontinuation due to AEs occurred in 11 (4.6%) and 11 (4.7%) pts randomised to tofacitinib 5 and 10 mg BID, respectively, with IRs of 7.16 (3.58, 12.82) and 7.31 (3.65, 13.08), respectively, over 12 months (C2a). Across all tofacitinib-treated pts in the P3 and LTE studies (C3), SIs occurred in 11 pts (1.4%; IR 1.40 [0.70, 2.50]). HZ was reported in 16 pts (2.0%; IR 2.05 [1.17, 3.33]) receiving tofacitinib. All 3 cases of multidermatomal HZ were adjudicated as OIs; these were the only OIs (0.4%; IR 0.38 [0.08, 1.11]). In C3, 2 deaths occurred (0.3%; IR 0.25 [0.03, 0.91]); all were considered unrelated to the study drug. MACE were reported in 3 pts (0.4%; IR 0.38 [0.08, 1.11]), malignancies (excluding NMSC) in 5 pts (0.6%; IR 0.63 [0.21, 1.48]) and NMSC in 4 pts (0.5%; IR 0.51 [0.14, 1.30]).

Table: Common adverse events (≥2% occurrence in any group, all causalities) at Month 3 in patients receiving tofacitinib 5 or 10 mg BID or placebo

Common Adverse Events, n (%)	Tofacitinib 5 mg BID (N=238)	Tofacitinib 10 mg BID (N=236)	Placebo (N=236)
Diarrhoea	8 (3.4)	9 (3.8)	1 (0.4)
Dyspepsia	5 (2.1)	2 (0.8)	2 (0.8)
Nausea	6 (2.5)	5 (2.1)	7 (3.0)
Fatigue	0	7 (3.0)	1 (0.4)
Bronchitis	6 (2.5)	4 (1.7)	0
Nasopharyngitis	14 (5.9)	13 (5.5)	6 (2.5)
Pharyngitis	1 (0.4)	7 (3.0)	3 (1.3)
Upper respiratory tract infection	12 (5.0)	11 (4.7)	11 (4.7)
Urinary tract infection	3 (1.3)	6 (2.5)	5 (2.1)
Headache	9 (3.8)	20 (8.5)	11 (4.7)
Dizziness	6 (2.5)	1 (0.4)	3 (1.3)
Acne	3 (1.3)	5 (2.1)	0
Hypertension	4 (1.7)	5 (2.1)	3 (1.3)

BID, twice daily; N, number of patients evaluable

Conclusions: Tofacitinib was well tolerated in pts with PsA, with a safety profile consistent to that seen in RA; no new risks were identified. Longer-term follow-up and larger pt populations will provide further information on the safety profile of tofacitinib in pts with PsA.

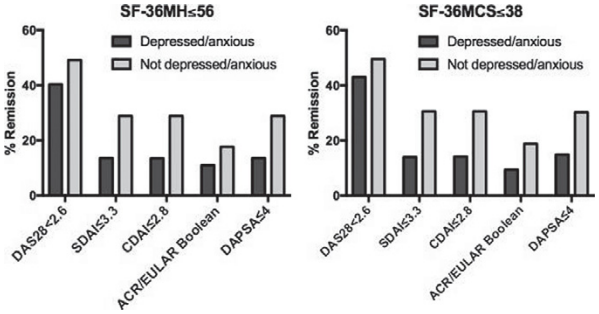
SAT0440 DO DEPRESSION AND ANXIETY INFLUENCE THE CHANCE OF REMISSION IN PATIENTS WITH PSORIATIC ARTHRITIS? REAL LIFE DATA FROM THE NOR-DMARD STUDY

B. Michelsen[1,2], E.K. Kristianslund[1], K.M. Fageli[1], E. Lie[1], H.B. Hammer[1], G. Haugeberg[2,3], T.K. Kvien[1]. *[1]Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo; [2]Dept. of Rheumatology, Hospital of Southern Norway Trust, Kristiansand; [3]Dept. of Rheumatology, Martina Hansens Hospital, Oslo, Norway*

Background: Depression and anxiety are frequent comorbidities in psoriatic arthritis (PsA). Still, the potential influence of depression/anxiety on achievement of remission remains unexplored.
Objectives: To investigate the predictive value of baseline depression/anxiety on the likelihood of achieving remission in PsA, as well as the associations between

Abstract SAT0440 – Table 1



Months	Odds ratio (95% CI) for remission in patients with vs. without baseline depression/anxiety according to SF-36MH≤56

3	0.61 (0.35–1.06), p=0.08	0.36 (0.17–0.76), p=0.007	0.48 (0.25–0.93), p=0.03	0.62 (0.29–1.30), p=0.20	0.37 (0.18–0.79), p=0.01
6	0.81 (0.44–1.51), p=0.51	0.38 (0.18–0.82), p=0.01	0.39 (0.19–0.81), p=0.01	0.61 (0.28–1.33), p=0.21	0.40 (0.19–0.84), p=0.02
Months	Odds ratio (95% CI) for remission in patients with vs. without baseline depression/anxiety according to SF-36MCS≤38				
	DAS28<2.6	SDAI≤3.3	CDAI≤2.8	ACR/EULAR Boolean	DAPSA≤4
3	0.68 (0.42–1.01), p=0.11	0.37 (0.20–0.69), p=0.002	0.45 (0.26–0.78), p=0.004	0.45 (0.23–0.88), p=0.02	0.42 (0.23–0.76), p=0.004
6	0.91 (0.54–1.56), p=0.74	0.42 (0.22–0.79), p=0.008	0.43 (0.24–0.78), p=0.005	0.51 (0.26–1.00), p=0.05	0.46 (0.25–0.86), p=0.02

baseline depression/anxiety and the components of the remission criteria at follow-up.

Methods: From the prospective multi-center observational NOR-DMARD study we included PsA patients starting first-time methotrexate/tumor necrosis factor inhibitors between year 2006 and 2012. The following criteria for depression/anxiety were assessed: 1) the Medical Outcomes Survey Short Form-36 (SF-36) Mental Health subscale (MH)≤56 and 2) SF-36 Mental Component Summary score (MCS)≤38.[1] The predictive value of baseline depression/anxiety on remission at 3 and 6 months was explored in prespecified logistic regression models adjusted for age, sex, disease duration and smoking, and the associations between baseline depression/anxiety and the components of the remission criteria at follow-up in prespecified multiple linear regression models adjusted for age, sex, disease duration and smoking.

Results: 805 PsA patients were included (mean (SD) age 48.0 (12.4) years, median (25th-75th percentile) disease duration 1.0 (0.07–6.8) years, 50.8% females, 28.6% current smokers). According to the SF-36MH≤56/SF-36MCS≤38 criteria 15.6/25.2% of the patients had depression/anxiety at baseline, respectively. Lower percentages of patients with vs. without baseline depression/anxiety achieved remission at 6 months (unadjusted analyses;figure). Patients with baseline depression/anxiety had consistently lower point estimates for achievement of remission at follow-up, but did not reach significance for all the analyses (adjusted analyses, table).

Baseline depression/anxiety was associated with increased patient's global assessment and joint pain at follow-up, but not with swollen joint count or levels of acute phase reactants.

Conclusions: Depression and anxiety may reduce likelihood of remission based on composite scores in PsA. These observations support a focus on depression and anxiety as comorbidities in a treat-to-target strategy and may also reflect that patient reported outcome measures are part of all these composite measures used to define remission.

SAT0441 COMPARISON OF DIFFERENT REMISSION TARGETS IN PATIENTS WITH PSORIATIC ARTHRITIS AND EVALUATION OF THEIR PROGNOSTIC VALUE

L.C. Coates[1], L. Aikman[2], A. Szumski[3], A. Chhabra[4]. *[1]University of Leeds, Leeds; [2]Pfizer, Walton Oaks, United Kingdom; [3]inVentiv Health, Princeton; [4]Pfizer, New York, United States*

Background: Psoriatic arthritis (PsA) is a complex form of arthritis that develops in people with psoriasis. There is no agreement on the optimal criteria to identify remission in patients with PsA and some of them may miss skin lesions.

Objectives: To investigate the merits of different potential remission definitions using data from the PRESTA study.[1]

Methods: Remission was investigated for disease activity index for PsA for 3 definitions: very low disease activity (VLDA), Disease Activity in PsA (DAPSA), and clinical (c)DAPSA. VLDA index was defined as 7/7 met criteria of the minimal disease activity (MDA) cut-off points: tender joint count (TJC) ≤1, swollen joint count (SJC) ≤1, psoriasis activity and severity index (PASI) ≤1, patient global visual analog scale (Pt VAS) ≤20mm, Pt pain VAS ≤15mm, health assessment questionnaire (HAQ) ≤0.5, tender entheseal points ≤1. DAPSA remission was defined as DAPSA ≤4 (TJC, SJC, physician global VAS [cm], Pt VAS [cm], C-reactive protein [CRP]) and cDAPSA remission was defined as cDAPSA ≤4 (DAPSA without CRP).

Results: At Week 24, the proportion of patients achieving remission was 9.6%, 31.0%, and 34.7% for VLDA, DAPSA, and cDAPSA remission, respectively. Discordance between VLDA and DAPSA or cDAPSA remission was 21.7% or 25.1%, respectively. Only 0.2% of the patients that achieved VLDA did not achieve DAPSA remission and 21.5% vice versa (Kappa coefficient 0.38) and 0.0% in the case of cDAPSA remission and 25.1% vice versa (Kappa coefficient 0.33). At the end of the study, residual levels of dactylitis and enthesitis appeared to be similar among all definitions (all ≤3.0%); however, patients achieving DAPSA and cDAPSA remission had higher proportions of patients with PASI >1 than patients achieving VLDA remission (PASI 2–9: VLDA 0.0% vs DAPSA 46.4% vs cDAPSA 47.2%; PASI ≥10: VLDA 0.0% vs DAPSA 5.8% vs cDAPSA 6.4%). Raised CRP values (upper limit of normal >8.99) were 7.8%, 4.8%, and 7.3% for VLDA, DAPSA, and cDAPSA, respectively.

Conclusions: VLDA remission is a more stringent target than DAPSA and cDAPSA remission, with the advantage of including a measurement for psoriasis. Therefore, VLDA is more useful than DAPSA or cDAPSA in assessing a remission state in patients with PsA and extended skin lesions. Measurement of CRP levels does not appear to provide further information on current disease activity level in these patients and exclusion of this laboratory marker should facilitate remission assessment in clinical practice.

SAT0442 FUNCTIONAL DISEASE STATUS AND HEALTHCARE COSTS IN PSORIATIC ARTHRITIS: A SIMILAR RELATIONSHIP TO THAT SEEN IN RHEUMATOID ARTHRITIS

A. Maguire[1], I. Handel[2], W. Tillett[3], F. Mughal[4], J. Morris[5], N. Hawkins[6], C. Cavill[3], E. Korendowych[3], N. McHugh[3]. *[1]Department of Psychology, University of Cambridge, Cambridge; [2]Royal (Dick) School of Veterinary Studies, University of Edinburgh, Edinburgh; [3]Royal National Hospital for Rheumatic Diseases NHS Foundation Trust, Bath; [4]Celgene Ltd, Uxbridge; [5]Cogentia Healthcare Consulting Ltd, Cambridge; [6]Health Economics and Health Technology Assessment, University of Glasgow, Glasgow, United Kingdom*

Background: The Health Assessment Questionnaire-Disability Index (HAQ-DI), an important, validated measure of functional status in patients with psoriatic arthritis (PsA), has been used as an intermediate variable in modelling of costs and quality-adjusted life-years. The relationship between HAQ-DI and costs has been well documented for rheumatoid arthritis (RA),[1,2] but less so for PsA. The HAQ-DI study data in PsA patients from the British Society for Rheumatology Biologics Registers was mapped to resource use data in the Health Improvement Network dataset.[3] A drawback of this approach relates to the HAQ-DI and resource use data being derived from separate patient cohorts.

Objectives: Estimate the HAQ-DI and cost relationship in PsA within a single cohort of patients.

Methods: Functional disease status, patient demographic, disease history and healthcare resource use data were extracted from a cohort of patients at the Royal National Hospital for Rheumatic Diseases. Resource data were available for primary and secondary care consultations, prescriptions, accident and emergency attendance, hospital admissions and tests, and collected for 6 months before and after HAQ-DI measurement. Medication costs were excluded from the modelling as it was not possible to specify which were PsA-related. Linear regression models were used to predict costs as a function of HAQ-DI and age at HAQ-DI

measurement. As cost data were not normally distributed, standard errors (SEs), 95% confidence intervals (CIs) and *P* values were estimated by bootstrap resampling (10,000 samples).

Results: Data were available for 95 PsA patients (female: n=43). Mean HAQ-DI score was 0.81 (SE 0.08); mean age at HAQ-DI measurement was 58.6 (SE 1.04). Mean total annual healthcare costs, excluding medication costs, were £ 1,588 (SE 172.3). Regression modelling indicated that a 1-point increase in HAQ-DI score was associated with an increase in total costs, excluding medications, of £ 547.49 (SE 222.7; 95% CI 191.7–1,103.8; *P*=0.004) (Table). Subgroup analyses suggested trends for higher cost increases within the lower HAQ-DI cutoff subgroup (HAQ-DI 0–1) and for those with greatest disease duration (>10 years). Costs associated with secondary care consultations seemed to be the primary factor in the association between HAQ-DI and total costs.

Estimated HAQ-DI Coefficient (£/Unit) From Regression of Costs on the HAQ-DI (Bootstrapped SE, 95% CI, and *P* Value)

Outcome	Estimate (SE)	95% CI	*P* Value
Tests	21.45 (14.18)	-7.93 – 47.5	0.130
Accident and emergency	15.67 (5.46)	6.46 – 28.89	0.002
Primary care consultation	69.98 (24.32)	20.97 – 115.90	0.004
Secondary care consultation	293.67 (48.26)	205.81 – 398.67	<0.001
Admitted care	162.25 (201.13)	-132.82 – 707.29	0.434
Total cost	547.49 (222.74)	191.69 – 1,103.82	0.004

Conclusions: Models incorporating total healthcare costs were highly significant; this association appears to be driven mainly by secondary care consultation costs. Costs in this study were similar to previous studies in RA populations. A study limitation was that only direct medical costs were considered, which may underestimate the true burden of PsA on healthcare systems and the wider society.

SAT0443 IDENTIFICATION OF PREDICTORS OF MINIMAL DISEASE ACTIVITY IN EARLY PSORIATIC ARTHRITIS

A. Zabotti[1], L. Idolazzi[2], L. Quartuccio[1], M. Sartori[1], A. Fassio[2], F. Zuliani[1], D. Gatti[2], M. Rossini[2], S. De Vita[1]. *[1]Department of Medical and Biological Sciences, Rheumatology Clinic, "Santa Maria della Misericordia" University Hospital, Udine, Italy, Udine; [2]Rheumatology Clinic, Aoui Verona Reumatologia, Verona, Italy*

Background: Psoriatic arthritis (PsA) is a systemic inflammatory disease with articular and extra-articular features, the disease activity ranges from mild mono-oligoarthritis to destructive polyarthritis. Hence, establishing the prognosis of a patient with PsA is important to better define the treatment strategy. Furthermore, minimal disease activity (MDA) is a validated composite outcome measure since it correlates well with long-term outcomes (e.g. development of joint damage)[1].

Objectives: The aim of this study was to identify the baseline clinical variables associated with MDA at 12th month of follow up in two cohorts of early PsA.

Methods: Consecutive PsA patients, attending the outpatient Early Arthritis Clinic in Udine or Verona in the last two years, were assessed. All the included patients had: I) CASPAR score ≥ 2[2] II) new diagnosis of PsA III) a complete clinical data and follow-up of at least 12 months. The GRAPPA recommendations on the management of PsA were followed. Statistical analysis included T- test, ANOVA and Pearson's test in order to find possible predictors of MDA.

Results: Eighty-one early PsA patients were included in the study. 47/81 (58.2%) reached MDA at 12th month of follow-up; 68/81 (83.9%) were in c-DMARDs while 11/81 (13.6%) were in b-DMARDs. Two variables at baseline were selected comparing the groups based on achievement of MDA. These were: 1) LEI, which was significantly lower at baseline in patients reaching MDA (0.43 *Vs* 0.86, p=0.001); and 2) a lower baseline CRP (1.2 mg/dl *vs* 2.8 mg/dl, p=0.008). Of note, neither the baseline disease activity evaluated with DAPSA nor the time to referral were selected by statistical analysis.

Conclusions: Baseline lower LEI score and lower CRP were identified as clinical predictors of MDA after 12 months of treatment in PsA. Therefore, patients with a more active enthesitis or higher inflammation may have a less responsive disease. This may be relevant to select proper treatments at baseline, and indirectly confirms that enthesitis is a key therapeutic target in PsA.

SAT0444 DETECTION OF PSORIATIC ARTHRITIS AT EARLY ONSET: A MULTI-PROTEOMIC APPROACH TO DEVELOPING A NEW BLOOD TEST

A.F. Mc Ardle[1], A. Szentpetery[2], S. De Rook[3], B. Hernandez[1], O. FitzGerald[4], S.R. Pennington[1]. *[1]School of Medicine and Medical Sciences, University College Dublin; [2]Rheumatology, St. Vincents University Hospital, Dublin 4, Ireland; [3]Wilhelmina Kinderziekenhuis, Hospital, Utrecht, Netherlands; [4]Rheumatology, St. Vincents University Hospitla, Dublin 4, Ireland*

Background: Psoriatic Arthritis (PsA) is an inflammatory arthritis (IA) frequently associated with psoriasis. Clinically, it is a complex heterogeneous disease and there are no diagnostic tests or criteria [1]. At first presentation, PsA may resemble other disease types - especially rheumatoid arthritis (RA). Making an accurate and early diagnosis is particularly important to ensure that individual patients receive effective and safe medication and so optimise long-term patient outcomes. Thus, it is widely acknowledged by physicians and patients alike that a new diagnostic test is needed to facilitate the early and specific diagnosis of PsA [2].

Objectives: To (i) identify and verify candidate biomarkers with the potential to segregate patients with PsA from those with RA; and (ii) explore the value of combining different proteomic discovery platforms.

Methods: Serum samples were obtained from a cohort of 64 patients (32 PsA and 32 RA) defined as early onset (<12 months) and DMARD naïve. Individual baseline samples were analysed with label free LC-MS/MS (n=64), the Luminex xMAP (n=62) and an aptamer based platform called SOMAscan (n=36). The random forest test was applied to each individual data set as well as to a combined-matched data set (n=36). To verify MS data, a multiple reaction monitoring (MRM) assay was developed for 54 of the most discriminatory proteins to be applied to both pooled (PsA n=9, RA n=9) and individual patient samples (n=64).

Results: In this study, it was possible to quantify 387, 48 and 1129 proteins from LC-MS/MS, Luminex and SOMAscan analysis, respectively. Proteins with the ability to segregate PsA patients from those with RA were identified by random forest analysis; LC-MS/MS (AUC 0.94), Luminex (AUC 0.69) and SOMAscan (AUC 0.73). The application of the random forest model to the (i) combined data and (ii) MRM data set is part of ongoing work.

Conclusions: To date, statistical analysis revealed LC-MS/MS identified proteins were the most discriminatory. An MRM assay has been developed to the top 54 LC-MS/MS proteins and this assay has been applied to the discovery cohort (data analysis ongoing). The assay will next be applied to additional evaluation cohorts that include patients with spondyloarthritis and psoriasis. Discriminatory proteins verified here represent candidates for inclusion in a blood based multi-analyte test that could ultimately be used in the diagnosis of PsA.

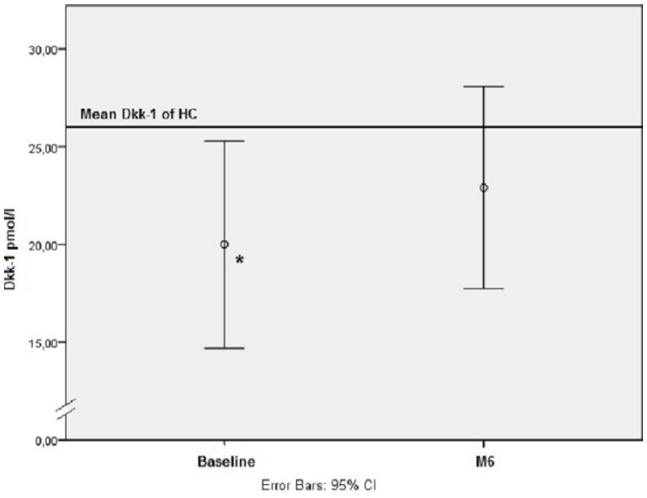
SAT0445 SHORT-TERM EFFECTS OF SECUKINUMAB ON BONE TURNOVER MARKERS AND WNT SIGNALING ANTAGONISTS IN PATIENTS WITH PSORIATIC ARTHRITIS

A. Fassio, L. Idolazzi, O. Viapiana, C. Benini, E. Vantaggiato, M. Rossini, D. Gatti. *Rheumatology, Aoui Verona Reumatologia, Verona, Italy*

Background: psoriatic arthritis (PsA) is a chronic inflammatory disease characterized also by increased levels of cells producing IL-17 [1], and these levels have been shown to correlate with measures of disease activity and structural damage and bone loss [2]. Secukinumab is a new monoclonal antibody licensed woth the treatment of PsA which selectively binds to and neutralizes interleukin-17 (IL-17). Currently, data about the effects on the activity of either bone-reabsorbing cells and bone-forming cells secondary to the inhibition of the IL-17 pathway are completely absent.

Objectives: the aim of our study was to explore the short-term effects of secukinumab on bone turnover markers (BTM) and Dkk-1 and sclerostin.



Methods: we enrolled 28 patients with PsA, classified with the CASPAR criteria and 43 healthy controls (HC). For the PsA group DAS28 was recorded and serum samples were stored at baseline and then at the first, the third and the sixth month of therapy. Intact N-propeptide of type I collagen (PINP) and C-terminal

telopeptide of type I collagen (CTX-I). Dickkopf-related-protein 1 (Dkk-1) and sclerostin were dosed too. For the HC group, a single blood sample was taken.
Results: Neither P1NP nor CTX showed any statistically significant variation. Baseline Dkk-1 for the PsA group was lower than HC. Both Dkk-1 and sclerostin demonstrated a significant increase at the sixth month. When the PsA groups was compared to HC, the difference between the levels of Dkk-1 lost significance at month six.

Table 1

	Healthy controls (N=43)			
Dkk-1 pmol/l	25,92±11,26†			
Sclerostin pmol/l	33,11±16,85			
	PsA patients (N=28)			
	Baseline values (Mean ± SD)	month 1	month 3	month 6
DAS28	3,97±1,30	3,78±1,21	3,57±1,58	3,41±1,55
P1NP ng/ml	43,5±14,5	-0,31±12,91	-0,81±11,97	0,96±14,87
CTX ng/ml	0,25±0,16	0,02±0,14	0,04±0,20	0,08±0,27
Dkk-1 pmol/l	20,0±13,64	-1,45±7,89	-1,38±9,49	2,90±7,45*
Sclerostin pmol/l	30,9±12,02	-0,76±8,39	3,09±7,54*	3,03±7,77*

*p<0,05 vs baseline, †p<0,05 vs Dkk-1 of the PsA group at baseline, month 1 and month 3.

Conclusions: our study demonstrated that the treatment with secukinumab has little influence on the levels of BTM within the first six months of treatment but a definite influence on some fine regulators of the bone cells activity such as the WNT inhibitors and it is able, in some way, to normalize the Dkk-1 levels in PsA patients. The clinical implications of this trend are currently unclear thought it might suggest an drug-induced inhibition of the over-proliferation of bone typical of the joint lesions of PsA. Further studies with greater numbers of patients are warranted to determine whether these preliminary results have clinical relevance.

SAT0446 IXEKIZUMAB IMPROVES PATIENT-REPORTED OUTCOMES IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS AND PREVIOUS INADEQUATE RESPONSE TO TUMOUR NECROSIS FACTOR-INHIBITORS

A. Kavanaugh[1], R. Vender[2], J. Birt[3], D.H. Adams[3], O. Benichou[3], C.-Y. Lin[3], P. Nash[4]. *[1]Univ of CA San Diego Health System, la Jolla, United States; [2]Dermatrials Research Inc., Hamilton, Canada; [3]Eli Lilly and Company, Indianapolis, United States; [4]University of Queensland, Brisbane, Australia*

Background: Ixekizumab (IXE), a monoclonal high affinity antibody that selectively targets interleukin-17A, was superior to placebo (PBO) in achieving clinical responses and improving health related quality of life (HRQoL) for psoriatic arthritis (PsA) patients who were biologic-naïve.[1] Herein, results are presented from a phase 3 trial (SPIRIT-P2; NCT02349295) with IXE in patients with active PsA and previous inadequate response to tumor necrosis factor-inhibitors (TNF-i).
Objectives: To explore the impact of IXE on patient reported HRQoL outcomes up to 24 weeks (wks) in patients with active PsA.
Methods: In this phase 3, multicentre, double-blind study, 363 adult patients with active PsA were randomly assigned in the ratio of 1:1:1 to subcutaneous administration of either 80-mg IXE every 4 wks (Q4W; N=122) or every 2 wks (Q2W; N=123) following a 160-mg starting dose at Wk 0 or PBO (N=118). All patients entering the study had an inadequate response to one or two TNF-i or were intolerant to TNF-i. At baseline and Wk 24, HRQoL was measured by the Short Form-36 Health Survey (SF-36) Physical Component Summary (PCS) and Mental Component Summary (MCS), European Quality of Life 5 Dimensions Visual Analog Scale (EQ-5D VAS), Work Productivity and Activity Impairment-Specific Health Problem (WPAI-SHP; absenteeism; presenteeism, work productivity, and activity impairment), the itch Numeric Rating Scale (NRS), and the Dermatology Life Quality Index (DLQI). Itch NRS, DLQI, and Psoriasis Area Severity Index (PASI) responses were assessed in patients with baseline psoriatic lesion involving ≥3% body surface area (BSA; N=203). Treatment comparisons were made by a mixed model for repeated measures for continuous data and by a logistic regression model for categorical data with missing values imputed by nonresponder imputation.
Results: Mean baseline (Wk 0) scores for HRQoL measures indicated impaired physical and mental function, quality of life, and work productivity (Table). At Wk 24, clinical efficacy was shown by 50.6% and 58.1% of IXE-treated patients achieving ACR20 and PASI75 responses, respectively. Patients receiving IXE (Q4W or Q2W) reported significantly greater improvements in SF-36 PCS and MCS, EQ-5D VAS, and WPAI-SHP (presenteeism, work productivity, and activity impairment) than patients treated with PBO (Table; p<.05). For PsA patients with co-morbid psoriasis (≥3% BSA), IXE treatment (Q4W or Q2W) resulted in significantly greater improvements in itch NRS and DLQI than PBO treatment (Table; p<.001). Finally, 51.5% of IXEQ4W patients and 50.0% of IXEQ2W patients reached a DLQI total score of 0 or 1 at Wk 24, which is significantly greater than patients treated with PBO (9.0%, p<.001).

Table: Summary of Patient-Reported Outcomes at Baseline and Week 24

		PBO N=118	IXEQ4W N=122	IXEQ2W N=123
SF-36 PCS[a]	Baseline	33.9 (9.0)	34.8 (8.8)	34.3 (9.1)
	Change from Baseline	3.3 (1.4)	8.9 (1.3)***	8.2 (1.2)***
SF-36 MCS[a]	Baseline	48.0 (13.1)	49.6 (11.3)	49.1 (11.5)
	Change from Baseline	0.9 (1.3)	3.6 (1.2)*	4.0 (1.2)**
EQ-5D VAS[a]	Baseline	53.6 (20.0)	53.9 (22.4)	53.9 (19.7)
	Change from Baseline	1.8 (3.4)	15.3 (3.2)***	12.8 (3.0)***
WPAI-SHP: Absenteeism[b]	Baseline	11.9 (28.1)	11.6 (26.6)	8.8 (23.2)
	Change from Baseline	4.5 (5.0)	3.7 (4.6)	9.4 (4.4)
WPAI-SHP: Presenteeism[b]	Baseline	40.4 (28.8)	45.0 (25.7)	36.9 (25.0)
	Change from Baseline	-7.2 (4.9)	-26.6 (4.3)***	-24.0 (4.1)***
WPAI-SHP: Work Productivity[b]	Baseline	41.5 (29.6)	46.9 (26.7)	38.8 (26.6)
	Change from Baseline	-4.5 (5.4)	-23.2 (4.7)***	-17.6 (4.6)*
WPAI-SHP: Activity Impairment[b]	Baseline	54.0 (25.8)	53.9 (24.9)	49.3 (26.5)
	Change from Baseline	-14.8 (4.1)	-30.2 (3.9)***	-26.2 (3.7)**
		N=67	N=68	N=68
Itch NRS[b,c]	Baseline	5.7 (2.8)	5.5 (2.5)	5.6 (3.0)
	Change from Baseline	-1.2 (0.5)	-3.4 (0.4)***	-3.5 (0.4)***
DLQI[b,c]	Baseline	9.6 (8.1)	9.1 (7.4)	9.2 (7.8)
	Change from Baseline	-3.1 (0.9)	-7.7 (0.8)***	-7.3 (0.8)***

Baseline values are mean (SD); Change from baseline values are least squares mean (SE).
[a]Increase in score represents improvement.
[b]Decrease in score represents improvement.
[c]Patients were from the intent-to-treat population with ≥3% BSA at baseline.
*p<.05;**p<.01;***p<.001; with respect to placebo control; p-values are from a repeated measures mixed model.

Conclusions: In patients with active PsA and previous inadequate response to TNF-i, IXE provided significant improvement through 24 wks in all joint and skin associated HRQoL outcomes, including physical and mental function, quality of life, work productivity, DLQI, and itch.

SAT0447 **PREVALENCE OF RADIOGRAPHIC SACROILIITIS IN PATIENTS WITH PSORIATIC ARTHRITIS AND THE CLINICAL, ANALYTICAL AND DEMOGRAPHIC FACTORS ASSOCIATED TO ITS APPEARANCE**

C. López-Medina[1,2], S. León-Idougourram[2], M.D. López-Montilla[1,2], L. Bautista-Aguilar[1,2], L. Ladehesa-Pineda[1,2], E. Collantes-Estévez[1,2]. *[1]Hospital Universitario Reina Sofía de Córdoba/ Imibic; [2]Universidad de Córdoba, Córdoba, Spain*

Background: To date, published studies suggest that a significant proportion of patients with Psoriatic Arthritis (PsA) present asymptomatic sacroiliitis; that is to say, an inflammatory back pain (IBP) absence. This fact could result in the underdiagnosis of axial involvement in these patients (1).
Objectives: To evaluate the prevalence of radiographic sacroiliitis in patients with PsA and to determine its association with clinical, analytical and demographic factors.
Methods: A cross-sectional, observational, and unicentre study in which clinical, analytical and demographic data from 359 patients belonging to a PsA monographic consultation were analyzed. All patients met the CASPAR criteria. The presence of sacroiliitis in the sacroiliac x-ray image was used as a dependent variable, formerly evaluated by a trained Rheumatologist. Likewise, independent variables related to arthropathy, cutaneous involvement and sociodemographic characteristics of the patients were used as well. A descriptive analysis and two logistic regressions (univariate and multivariate), were performed to associate radiographic sacroiliitis to different covariates.
Results: Out of the 359 patients, 214 (59.6%) were men with a mean time of PsA evolution of 10.05±11.6 years. The x-ray image performed showed sacroiliitis in 127 patients (35.4%). Univariate analysis showed that radiographic sacroiliitis is related ($p<0.05$) to gender (men), psoriasic paternal family history, IBP, positive HLA-B27 antigen and psoriatic cutaneous involvement greater than 25%. The multivariate analysis showed that radiographic sacroiliitis in these patients is predominantly associated to the presence of IBP, the positive HLA-B27 antigen and gender (men). However, sacroiliitis is not not associated to the onset age of PsA ($p>0.05$).

Univariate logistic regression

	Sacroiliitis n=127 (n%)	No Sacroiliitis n=232 (n%)	OR (CI 95%)	p-value
Sex (men)	94 (74.0)	120 (51.7)	2.6 (1.6–4.2)	<0.001
Psoriasis duration, mean (SD)	12.6 (9.2)	10.8 (0.2)	1.0 (0.9–1.0)	0.082
PsA duration, mean (SD)	5.5 (5.9)	4.5 (6.3)	1.0 (1.0–1.0)	0.041
Onset age of PsA ≤45 years	76 (59.8)	131 (56.6)	1.1 (0.7–1.7)	0.536
Family history of Psoriasis – None	70 (56.5)	150 (65.8)	Reference	
– Paternal	29 (23.4)	35 (15.4)	1.7 (1.0–3.1)	0.048
– Maternal	25 (20.2)	43 (18.9)	1.2 (0.7–2.2)	par 0.449
IBP	93 (73.2)	22 (9.5)	26.1 (14.9–47.0)	<0.001
HLA-B27 +	22 (17.5)	11 (4.8)	4.1 (1.9–9.0)	<0.001
Psoriasis extension – <10%	177 (76.6)	78 (61.9)	Reference	
– 10–25%	21 (16.7)	21 (16.7)	1.5 (0.8–2.8)	0.170
– >25%	23 (10.0)	27 (21.4)	2.6 (1.4–4.9)	0.002

Conclusions: The prevalence of radiographic sacroiliitis in our population is 35.4%, higher than in other series due to the fact that the sacroiliac x-ray images were performed on all patients, regardless of the clinic. The radiographic sacroiliitis in patients with PsA is related to the presence of IBP, HLA-B27 antigen and gender. However, the time of evolution of arthropathy and the onset age of PsA are not related to sacroiliac radiographic involvement.

SAT0448 **APREMILAST TREATMENT AND LONG-TERM (UP TO 156 WEEKS) IMPROVEMENTS IN DACTYLITIS AND ENTHESITIS IN PATIENTS WITH PSORIATIC ARTHRITIS: ANALYSIS OF A LARGE DATABASE OF THE PHASE III CLINICAL DEVELOPMENT PROGRAM**

D.D. Gladman[1], A. Kavanaugh[2], J.J. Gomez-Reino[3], J. Wollenhaupt[4], M. Cutolo[5], G. Schett[6], E. Lespessailles[7], M. McIlraith[8], C. Hu[8], C.J. Edwards[9], C.A. Birbara[10], P.J. Mease[11]. *[1]Toronto Western Hospital, Toronto, Canada; [2]University of California, San Diego, School of Medicine, la Jolla, United States; [3]Hospital Clínico Universitario, Santiago, Spain; [4]Schön Klinik Hamburg Eilbek, Hamburg, Germany; [5]University of Genova, Genova, Italy; [6]University of Erlangen-Nuremberg, Erlangen, Germany; [7]University of Orléans, Orléans, France; [8]Celgene Corporation, Summit, United States; [9]University Hospital Southampton, Southampton, United Kingdom; [10]University of Massachusetts Medical School, Worcester; [11]Swedish Medical Center and University of Washington School of Medicine, Seattle, United States*

Background: Dactylitis and enthesitis, hallmark features of psoriatic arthritis (PsA), may be difficult to manage. PALACE 1, 2, and 3 compared the efficacy and safety of apremilast (APR) with placebo (PBO) in patients (pts) with active PsA despite prior conventional DMARDs and/or biologics.
Objectives: Report the impact of long-term APR 30 mg BID (APR30) treatment on dactylitis and enthesitis in pts with active PsA.
Methods: Pts were randomized (1:1:1) to PBO, APR30, or APR 20 mg BID (APR20) stratified by baseline (BL) DMARD use (yes/no). After the 24-wk PBO-controlled phase, all pts received APR30 or APR20 and could enroll in long-term follow-up. Data for pts entering the study with pre-existing dactylitis or enthesitis were pooled across PALACE 1–3, as prespecified, to allow for robust analysis. Dactylitis count (number of digits [hands/feet] with dactylitis present [0=absence, 1=presence]; range: 0–20) was used to assess dactylitis improvement. Enthesitis was evaluated based on MASES (range: 0–13), indicating the number of painful entheses out of 13 enthesis sites. Wk 24 analyses used LOCF for missing values and data for early escape pts; Wks 52 and 156 used data as observed.
Results: Among pts with dactylitis (n=610) or enthesitis (n=915) at BL and ≥1 post-BL value, BL mean dactylitis counts ranged from 3.2 to 3.4 and MASES ranged from 4.4 to 4.8. At Wk 24, mean change in dactylitis count was −1.8 (APR30) vs −1.3 (PBO) (P=0.0097); more APR30 pts achieved a dactylitis count of 0 vs PBO pts (Table). Mean change in MASES was −1.3 (APR30) vs −0.9 (PBO) (P=0.0194); more APR30 pts achieved a MASES of 0 vs PBO pts. Significant effect on enthesitis was confirmed in the PSA-006 (ACTIVE) study of APR in pts with a maximum of 1 previous DMARD treatment, in which the Gladman Enthesitis Index was used, focusing on more peripheral sites of activity: significant effect for APR vs PBO was seen as early as Wk 2, and at Wk 24, mean changes were −1.5 vs −0.5 (P=0.0032, MMRM). Sustained improvements in dactylitis and enthesitis severity were seen in APR pts at Wk 156 in PALACE 1–3 (Table): for dactylitis, 79.6% achieved a count of 0 and the mean percent change was −83.6%; for MASES, 55.0% of APR pts achieved a score of 0 and the mean percent change was −65.2%.

	Wk 24		Wk 52	Wk 156

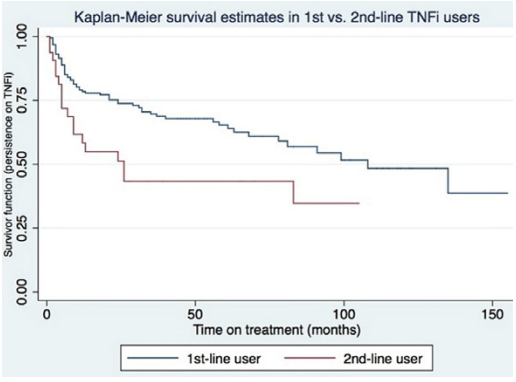
Median % change from BL	−21.1	−50.0‡	−66.7	−100.0
Pts achieving score of 0, %	22.5	27.5	37.7	55.0



The n at Wk 24 represents pts with a BL value >0. The n at Wk 52 and Wk 156 represents the number of pts taking APR, regardless of when treatment started (BL, Wk 16, or Wk 24), with a BL value >0 and a value at Wk 52 or Wk 156.
*Dactylitis count is the sum of all scores (0=absence of dactylitis; 1=presence of dactylitis) from each of the 20 digits. §MASES ranges from 0 to 13, with 0 indicating no pain at any assessed enthesis and 13 indicating pain at all assessed entheses. ‡P<0.05 vs PBO. ‖P<0.01 vs PBO.
PBO=placebo; APR30=apremilast 30 mg BID; BL=baseline; pts=patients; MASES=Maastricht Ankylosing Spondylitis Enthesitis Score.

Conclusions: The majority of pts (63%) in PALACE 1–3 had active enthesitis and 42% had dactylitis at BL. APR30 demonstrated early and long-term benefit (up to 156 wks) in treating dactylitis and enthesitis, including resolution of BL disease in many pts.

SAT0449 SEX, METABOLIC CO-MORBIDITIES AND LINE OF THERAPY PREDICT TNF-INHIBITOR THERAPY PERSISTENCE IN PSORIATIC ARTHRITIS: A RETROSPECTIVE COHORT STUDY

W. Ye[1], T. Guruparan[1], C. Stober[2], E.E.P. Htut[2], D.R. Jadon[2]. [1]*School of Clinical Medicine, University of Cambridge;* [2]*Department of Rheumatology, Cambridge University Hospitals, Cambridge, United Kingdom*

Background: Although tumour necrosis factor-alpha inhibitor (TNFi) therapy has proven efficacy in the management of psoriatic arthritis (PsA), relatively little is known about predictors of TNFi persistence. Such knowledge would assist the application of stratified medicine.
Objectives: To determine baseline clinical characteristics associated with TNFi persistence in patients receiving their first-line agent, and to compare TNFi persistence in first versus second-line users.
Methods: A retrospective cohort study was performed of all patients with PsA attending a single-centre between 2003–2016. Demographic, clinical and laboratory characteristics were compared with TNFi persistence, using Kaplan-Meier survival analysis and multivariable Cox proportional hazards models.
Results: A total of 188 PsA cases had used TNFi therapy as first-line over a period spanning 7,620 person months: 46% male; mean age at TNFi initiation 47.27 (SD 11.36) years; median disease duration at initiation 11 (IQR 7,16) years. Etanercept was used by 102 and adalimumab by 86. Concomitant DMARDs were used by 121/186 (65%) and 87/188 (46%) had metabolic co-morbidities (hypertension, dyslipidaemia, type-2 diabetes, obesity). TNFi therapy was terminated in 65/188 (35%) of cases (35% due to primary inefficacy, 22% secondary inefficacy, 43% adverse events), with a median duration of TNFi persistence of 26.5 (IQR 10.5, 62.0) months. Multivariable Cox proportional hazards modelling found the following parameters at TNFi initiation to be associated with shorter (poorer) TNFi persistence in first line users: female sex (hazard ratio, HR 2.57; 95% CI 1.26, 5.24; p=0.01); presence of metabolic co-morbidity (HR 2.65; 95% CI 1.24, 5.69; p=0.01); with a non-significant statistical trend towards younger age at TNFi initiation (HR 0.94; 95% CI 0.88, 1.00; p=0.06) and older age at PsA onset (HR 1.05; 95% CI 0.99, 1.12; p=0.08). Parameters not statistically associated with TNFi persistence included: choice of TNFi agent (adalimumab *vs.* etanercept), concomitant DMARD/methotrexate use, tender/swollen joint counts, patient global assessment (PGA) of disease activity, CRP, ESR and disease duration. Of 32 cases proceeding to a second TNFi (19 adalimumab, 13 etanercept), persistence was 14/32 (44%) over 954 person months. TNFi failure was two-fold more likely in second versus first-line users (HR 2.02; 95% CI 1.20, 3.42; p=0.009) [Figure 1], with no significant contribution from other co-variables.

Conclusions: Patients with PsA who are female and have metabolic co-morbidities appear to be more likely to fail first-line TNFi therapy. Contrary to observations in rheumatoid arthritis, and somewhat challenging the few studies in PsA, choice of TNFi agent (humanised monoclonal *vs.* chimeric), concomitant methotrexate use, acute-phase response and joint counts prior to TNFi initiation did not influence TNFi persistence. Although TNFi failure was more likely in second-line users, a significant proportion of PsA cases responded to second-line TNFi therapy, advocating this strategy in refractory cases.

SAT0450 SILENT AXIAL DISEASE IN THE RUSSIAN COHORT OF EARLY PERIFERAL PSORIATIC ARTHRITIS PATIENTS

E.E. Gubar, E.Y. Loginova, A.V. Smirnov, S.I. Glukhova, T.V. Korotaeva. *V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Axial involvement in early psoriatic arthritis (ePsA) patients (pts) is often asymptomatic, poorly diagnosed and has not been studied properly. Magnetic resonance imaging (MRI) of sacroiliac joints (SIJs) helps to better define spinal involvement in ePsA.
Objectives: to study the prevalence of axial involvement in peripheral ePsA pts.
Methods: 89 pts (M/F–42 /47) with peripheral ePsA according to CASPAR criteria were included; mean age 36.5±10.9 yrs, disease duration 12.1±10.1 mo., disease activity index (DAS) 5.2±2.8, C-RP 16.1 [6.6; 31.0] mg/l, ESR 22.5±19.2 mm/h. All patients were evaluated for the presence of inflammatory back pain (IBP) by ASAS criteria. In pts having IBP disease activity was also measured according to BASDAI. The examination included X-ray of sacroiliac joints (SIJs) (pelvic radiograph), HLA B27 antigen, MRI of SIJs was performed in 79 pts, both with and without IBP, on Signa Ovation 0,35T. Bone marrow edema on MRI (STIR), considered as active MRI sacroiliiitis (MRI-SI), was evaluated by an independent reader. Radiographic sacroiliitis (R-SI) was defined when 2 grade changes in at least one SIJ appear, and included definite radiographic SI (dR-SI) and "non-definite" radiographic SI (ndR-SI). dR-SI was determined according to New York criteria (unilateral grade≥3 or bilateral grade≥2). 2 grade changes in only one SIJ were qualified as ndR-SI.
Results: IBP was found in 58 out of 89 (65.1%) pts, 35 (60.3%) of them had short-term (episodic) IBP, and 23 (39.7%) pts had long-term IBP. MRI-SI was observed in 28 out of 79 (35.4%) pts. R-SI was determined in 42 out of 89 (47.2%) pts, while dR-SI was found in 27 out of 89 (30.3%) pts, the remaining 15 (16.9%) pts had ndR-SI. 34 (38. 2%) pts were HLA B27 positive. In pts having IBP disease activity according to BASDAI was 4.5±1.6. Correlation has been detected between MRI-SI and IBP: among the group of pts having MRI-SI IBP was observed in 92.9% cases while out of the group of patients without MRI-SI in 54.9% cases (p=0.0002). An association was found between MRI-SI and long-term IBP (p=0.003) as well as between MRI-SI and short-term IBP (p=0.006). Moderate correlation has been detected between the presence of dR-SI and IBP (p=0.038). It's worth noting that among the 26 pts having dR-SI, 5 (19.2%) pts never had IBP before. And among the 15 pts having ndR-SI, 6 (40.0%) pts never had IBP before. No association was found between the presence of MRI-SI/R-SI/dR-SI and HLA B27 status.
Conclusions: in the Russian cohort of early peripheral psoriatic arthritis pts, careful examination quite often revealed high prevalence of axial involvement: 65% of pts had IBP (moreover, more than half of them (60%) had short-term IBP), 35% of pts had MRI-SI, half of the pts had R-SI, one third of the pts had definite R-SI. A significant number of patients (40%) developed 2 grade changes in one SIJ without previous IBP. An association was found between IBP and SI revealed by any of the visualization methods used. No association has been detected between the presence of MRI-SI or R-SI and HLA B27 status. These data indicate that in peripheral ePsA pts axial involvement is often asymptomatic and is poorly diagnosed. Careful identification of IBP together with MRI of SIJs will help to better define spinal involvement.

SAT0451 THE ONE-YEAR RADIOGRAPHIC PROGRESSION AND MINIMAL DISEASE ACTIVITY IN EARLY PSORIATIC ARTHRITIS PATIENTS TREATED ACCORDING TO TREAT-TO-TARGET STRATEGY (RESULTS OF AN ONGOING OPEN-LABEL REMARCA STUDY)

E. Loginova, T. Korotaeva, A. Smirnov, A. Koltakova, D. Karateev. *V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Treat-to-target (T2T) strategy has benefit in early psoriatic arthritis (EPsA) treatment. Its influence on radiographic progression has limited data.
Objectives: to investigate radiographic outcomes and minimal disease activity (MDA) after 1-year of T2T strategy in patients with EPsA.
Methods: 40 (M-18/F-22) DMARD-naïve pts with active EPsA, according to the CASPAR criteria, mean age 38.4±11.1 yrs., PsA duration 11.9±10.6 months, psoriasis duration 73.8±84.6 months, median DAS 3.8 [3.2; 4.7] from the open-label REMARCA study were included. At baseline all pts were treated by Methotrexate (MTX) subcutaneous (s/c) 20–25 mg/week. Pts that still had medium or high activity after 3–6 months were treated by combination therapy MTX+ biologic therapy (BT) - anti-TNF or Ustekinumab (n=21). By the end of the study, 19 pts were treated by MTX-monotherapy. At baseline and after 1-yr. of treatment PsA activity index and digital radiographs of hands and feet were performed. All images were scored according to Sharp/van der Heijde (Sh.-v.d. H) method by a blinded musculoskeletal radiologist. Median total score (TS Sh.-v.d. H) = total erosion score (TES) + total narrowing score (TNS), the proportion of pts who reached MDA, M±SD, Me [Q75; Q50], W-test, U-test, (%) were calculated. All $p<0.05$ were considered to indicate statistical significance.
Results: At baseline, 23 out of 40 pts (57%) had erosion. By 1 yr., the number of pts with erosion increased up to 26 pts (65%). The median TS Sh.-v.d. H significantly increased from 91.5 [72–108.5] to 91.5 [73.5–111.5] (W-test, $p<0.01$), TES from 2 [0–4.5] to 2.5 [0–5] (W-test, $p<0.05$) and TNS from 85 [69–105] to 87 [71.5–107] (W-test, $p<0.01$). At 1 yr. of therapy there was no significant difference between the treatment groups in the value of TS Sh.-v.d. H (W-test $p>0.05$).
25 of pts (62.5%) had reached MDA by 1 yr. In pts who did not reach MDA (n=15) by 1 yr. TES was significantly higher at baseline compare to those who reached MDA: 3 [2–9] and 0 [0–3] accordingly (U-test, $p<0.05$). In the group of pts who did not reach MDA 1 yr. progression was significantly higher (table).
In 29 out of 40 pts (72.5%) there was no X-ray progression considering both erosion and joint space narrowing. 13 of them (45%) were treated by MTX and 16 pts (55%) by MTX+BT. Negative X-ray progression was found in 11 out of 40 pts (27.5%): 6 of them (54.5%) were treated by MTX and 5 pts (45.5%) by MTX+BT.

Table 1

Sh.-v. d.H score	MDA (n=25)		No MDA (n=15)	
	Baseline	After 1 yr.	Baseline	After 1 yr.
TES	0 [0–3]	1* [0–3]	3# [2–9]	5# [2–11]
TNS	88 [70–108]	88 [71–108]	84 [68–98]	84 [74–103]
TS Sh.-v.d. H.	89 [72–109]	89* [72–110]	93 [81–106]	93* [83–115]

#significant differences between groups (U-test, p<0.05). *- significant differences into group (W-test, p<0.05).

Conclusions: In the Russian cohort of active EPsA pts erosion was found in more than half of cases. Active EPsA pts treated according to T2T strategy during 1 year in 72.5% did not show any radiographic progression, only a quarter of pts (27.5%) had negative X-ray progression by the end of the study, regardless of the type of therapy. The pts who achieved MDA had less erosive progression.

SAT0452 INFLUENCE OF ANTIRHEUMATIC THERAPY ADMINISTERED IN ACCORDANCE WITH "TREAT TO TARGET" PRINCIPLES ON HEART RATE VARIABILITY AND CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH ACTIVE EARLY PSORIATIC ARTHRITIS

E. Markelova, D. Novikova, T. Korotaeva, E. Loginova, I. Kirillova, L. Denisov, D. Karateev. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Psoriatic arthritis (PsA) is an inflammatory arthropathy, which is associated with range of co-morbid diseases and risk factors, such as dyslipidemia, obesity, metabolic syndrome, cardiovascular disease (CVD). Lower heart rate variability (HRV) is a well-established risk factor for CVD and all-cause mortality in the general population.
Objectives: to study dynamic of traditional risk factors (TRF) of CVD and parameters of HRV during antirheumatic therapy, administered inaccordance with "Treat to target" principles in PsA pts.
Methods: 44 (F.-21) DMARD-naive PsA pts, according to the CASPAR criteria, age 36 [27; 46] years (yrs.), PsA duration – 6 [4; 8] yrs, DAS 4.06 [3.51; 4.74]. TRFs of CVD were assessed according to ESC (2016): arterial hypertension (AH) – 11 (22.9%) pts, obesity (body mass index >30kg/m^2) – 11 (22.9%), abdominal obesity – 14 (29.2%), dyslipidemia – 31 (64.5%), family history of early CVD – 6 (12.5%), menopausal status – 5 (10.4%), smoking - 16 (33.3%). All pts were assessed for ECG, 24-h ECG monitoring, carotid ultrasound imaging. Antihypertensive therapy received all pts with AH. Methotrexate (MT) therapy was started in all pts with an escalation of the dose up to 25 mg/week subcutaneously. In case of no remission 3 months later, MT was added with biologic therapy: Adalimumab, Certolizumabpegol, Ustekinumab. 23 subjects were assessed after 18 months of therapy.
Results: After 18 months of therapy DAS and CRP level decreased significantly, p=0.001. DAS remission was achieved in 82.6% of pts. The incidence rate of AH (39% vs 39%), obesity (30% vs 21%), smokers (39% vs 39%), menopausal status (17% vs 17%), atherosclerotic plaques (39% vs 39%), did not change significantly. High-density lipoproteins increased significantly from 1.2 [1.1; 1.6] to 1.5 [1.2; 2.1]mmol/l, p=0.03. We didn't find significant differences between baseline and after treatment levels of total cholesterol/low-density lipoproteins level: from 5.2 [4.6; 6.0] to 5.2 [4.5; 5.9] (p=0.47) mmol/l and from 3.4 [2.8; 3.8] to 3.3 [2.6; 3.6] (p=0.60) mmol/l. HRVs parameters didn't change significant (table 1).

Table 1. HRV parameters in PsA pts baseline and after treatment

Parameters	Baseline	18 months
MeanNN (ms)	783 [734; 883]	803 [773; 852]
SDNN (ms)	132 [124;159]	147 [129; 163]
SDNNi (ms)	59 [45; 69]	61 [42; 80]
SDANN (ms)	121 [101; 146]	127 [109; 160]
RMSSD (ms)	39 [20; 50]	33 [18; 53]

Data are present in median values and interquartile range, *p<0,05 before and after 18 months treatment (nonparametric paired Wilcoxon test).

Conclusions: antirheumatic therapy of early PsA pts in accordance with "T2T" principles improves lipid profile but not HRVs parameters. Lower HRV is a risk factor for cardiovascular disease and mortality that demands the further studying its influence on the cardiovascular prognosis in PsA pts.

SAT0453 EFFICACY OF USTEKINUMAB IN PSORIATIC ARTHRITIS PATIENTS BY PRIOR TREATMENT EXPOSURE AND DISEASE DURATION: DATA FROM PSUMMIT 1 AND PSUMMIT 2

I. McInnes[1], S.D. Chakravarty[2,3], G.J. Morgan[3], I. Apaolaza[4], S. Kafka[3], E.C. Hsia[5,6], M. Song[5], Y. You[5], A. Kavanaugh[7]. *[1]University of Glasgow, Glasgow, United Kingdom; [2]Drexel University College of Medicine, Philadelphia; [3]Janssen Scientific Affairs, LLC, Horsham, United States; [4]Janssen Biologics BV, Leiden, Netherlands; [5]Janssen Research & Development, LLC, Spring House; [6]University of Pennsylvania, Philadelphia; [7]University of California, San Diego, la Jolla, United States*

Background: PSUMMIT 1 and PSUMMIT 2 were Phase 3 trials of ustekinumab (UST) in adults with PsA.
Objectives: Evaluate the efficacy of UST by prior treatment exposure and disease duration in PsA patients (pts) in PSUMMIT 1 and 2.
Methods: Pts had active PsA (≥5 swollen, ≥5 tender joints, CRP ≥3.0mg/dL,) for ≥6 mos despite treatment with DMARDs and/or NSAIDs (PSUMMIT 1) or DMARDs, NSAIDs, and/or anti-tumor necrosis factor (TNF) agents (PSUMMIT 2). In both studies, pts were randomized to SC injections of placebo (PBO) or UST 45mg or 90mg at wks 0, 4 and every 12 wks. PBO pts crossed over to UST 45mg at wk 24. At wk 16, early escape (PBO –> UST45mg; UST45mg –> UST90mg; UST90mg –> UST90mg) was possible. Stable doses of MTX were allowed. Pooled data from both PSUMMIT 1 and 2 were analyzed. Efficacy assessments included ACR response, DAS28-CRP response, DAS28-CRP remission (score <2.6), changes in enthesitis (modified MASES index) and dactylitis scores, and total van der Heijde-Sharp (vdH-S) score for radiographic progression. Pts who were anti-TNF-naïve, MTX- and anti-TNF-naïve, all DMARD- and anti-TNF-naïve were evaluated. ACR response at wks 4 and 16 to assess for early efficacy was also evaluated for anti-TNF-naïve pts with PsA duration <1 year, ≥1 to <3 years, and ≥3 years.
Results: In the pooled data, 747 pts were anti-TNF-naïve (53.8% were male; mean age=47 years); 179 pts were MTX- and anti-TNF-naïve (63.7% were male; mean age =47 years); 146 pts were all DMARD- and anti-TNF-naïve (61.0% male; mean age=46 years). In all three prior treatment populations significantly greater proportions of pts in the combined UST group vs PBO achieved an ACR20, ACR50, or ACR70 at wk 24. (Table). Similarly, greater proportions of pts in the combined UST group had DAS28-CRP response or remission vs PBO across all three prior treatment populations. In anti-TNF-naïve pts, improvements in enthesitis and dactylitis were significantly greater in the combined UST group vs PBO, and mean change in total vdH-S score was significantly greater for pts in the PBO group than the combined UST group; comparable trends were observed for the MTX- and anti-TNF-naïve pts and all DMARD- and anti-TNF-naïve pts, but did not reach statistical significance due to the smaller sample sizes in both subgroups. Among anti-TNF-naïve pts treated with UST, ACR20/50/70 response rates were similar across different PsA disease duration groups at early time-points (either wk4 or wk16).

Table. Efficacy at week 24 in PSUMMIT 1 and PSUMMIT 2 combined.

SAT0454 FINGER FLEXOR TENDON PULLEY COMPLEX INVOLVEMENT IN PSA: AN HIGH RESOLUTION ULTRASONOGRAPHIC STUDY

I. Tinazzi[1], A. Marchetta[2], D. Chessa[3], D. Mc Gonagle[4], P. Macchioni[5]. [1]*UOS Reumatologia, Ospedale Sacro Cuore-Don Calabria, Negar (Verona);* [2]*Ospedale Sacro Cuore Negrar (Verona), Negrar Verona;* [3]*Ospedale Paolo Dettori, Tempio Pausania (OT), Italy;* [4]*Leeds Institute of Rheumatic and Muscoloskeletal Medicine, Leeds, United Kingdom;* [5]*Ospedale S.Maria Nuova UOC Reumatologia, Reggio Emilia, Italy*

Background: Psoriatic Arthritis (PsA) is often associated with hand involvement including synovitis and tenosynovitis and dactylitis. At the micro anatomical level PsA is strongly linked to disease localisation to entheses and other sites of high mechanical stressing. Recently high resolution MRI has shown prominent abnormalities at the mini-entheses of the flexor tendon pulleys, a site of high physical stressing during finger flexion

Objectives: This study tested the hypothesis that sonographic abnormalities were common at the hand flexor tendon mini-entheses in PsA including the A1, A2 and A4 in patients without active hand arthritis or dactylitis at the moment of ultrasound (US) scanning

Methods: Consecutive patients affected by psoriasis (PsO) (23 cases), PsA (17) and healthy controls (HC) (19) were collected. The demographic charateristics are shown in Table 1. The cases were matched for sex, age and BMI. We excluded PsA patients with active arthritis or dactylitis at the moment of US study, the majority being under therapy with conventional DMARDs. The 2nd to 4th flexor tendons of the dominant hand were scanned with a high resolution linear probe (10–22 MHz) using an Esaote MyLab Twice machine. The sonograrapher was expert in muscolo skeletal ultrasound (MSKUS) and was blinded to the clinical details.The following changes were scored: tenosynovitis, A1, A2 and A4 pulley tendon thickness and pseudotensynovitis (peritendinous oedema). Pulleys were explored with transverse e longitudinal scan

Results: The A1, A2 and A4 pulleys were significantly thicker in PsA compared to PsO and healthy controls measuring both longitudinal and transverse scan (table 2 shows mean±SD value of transverse measures).In PsA patients A1, A2 and A4 pulleys thickness were above than the 95th percentile of HCs values respectively in 84%,80% and 100% of cases.Considering HCs and PsA we found that having a A1 thickness over the 95th percentile of HCs shows a sensibility of 82% and specificity of 100% for PsA. Using ROC curve analysis we found that the presence of one A1 thickness over the 95th percentile of HCs have a sensibility of 82% and specificity of 100% for PsA. Peritendinous oedema evaluated scanning the palmar side of proximal and intermediate phalanx was common in PsA patients (6/17) and absent in PsO and HCs

Table 1 Demographic data

	Healthy (n 19)	PsO (n 23)	PsA (n 17)
M/F	7/11 (39%61%)	9/14 (40%60%)	12/5 70%30%
Age (y) med ± SD	57±12	56±9	56±6
BMI med ± SD	25.5±4.0	25.9±3.2	28±3
Nail involvment	0	1 (4%)	8 (47%)
Previous dactylitis	0	1 (4%)	8 (47%)
MS >30'	0	0	9 (53%)
Previous trigger finger	0	7 (32%)	8 (47%)

Table 2 Transverse measures of pulleys thickness (mm)

	PsA	PsO	HCs
A1	0.61±0.15	0.40±0.10	0.33±0.08
A2	0.56±0.11	0.40±0.10	0.34±0.07
A4	0.50±0.13	0.33±0.05	0.30±0.02

Conclusions: This study suggests that PsA cases have a much higher burden of abnormalities in the mini-entheses of the flexor tendons on the hand. With the improving resolution and capabilities of MKUS these findings may be relevant to understand the involvment of flexor tendon in PsA expecially in sites with high mechanical stressing. Measuring A1, A2 and A4 thickness could be useful in detecting PsA cases without clinical signs of sinovitis or dactylitis

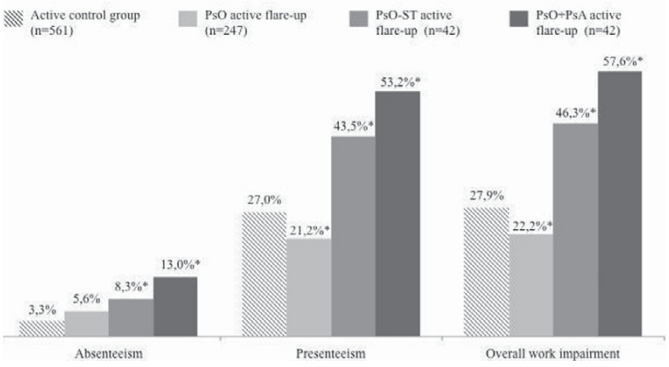
SAT0455 IMPACT OF PSORIATIC ARTHRITIS IN THE WORKPLACE: RESULTS OF THE FRENCH SURVEY PSOPRO

P. Claudepierre[1], I. Bonnet[1], Y. Roquelaure[2], P. Levy[3], R. Aubert[4], H. Bachelez[5]. [1]*Rheumatology, CHU Henri Mondor Créteil, CreteIL;* [2]*Medicine and Occupational Health, CHU Angers, Angers;* [3]*Economics, Université Paris-Dauphine, PSL Research University, LEDa [LEGOS];* [4]*Patient advocacy groups France Psoriasis;* [5]*Dermatology, AP-HP Hôpital Saint-Louis, Sorbonne Paris Cité Université Paris Diderot, Paris, France*

Objectives: The PsoPRO (Psoriasis & PROfessional life) survey, run under the aegis of the patient advocacy groups France Psoriasis, was aimed at measuring, in comparison to the general population, the impacts of psoriasis occurring alone (PsO) or concurring with psoriatic arthritis (PsO+PsA) on patients' working life.

Methods: From 13/07/16 to 08/08/16, 714 PsO patients, 81 of whom were under systemic treatment (PsO-ST), and 84 patients PsO+PsA were surveyed using a questionnaire drawn up by a multi-disciplinary scientific committee and conducted via the Internet. In addition to medical and professional characteristics, patients provided their recent absenteeism and presenteeism data, using a WPAI-PSO standardized self-questionnaire, as well as information about the interactions between psoriasis and their working life. Using the Student, Chi-deux and Fischer tests, patients were compared with a sample of 604 working respondents representative of the French population and questioned about the impact of possible health problems on their working life.



Results: The socio-demographic characteristics of the control group were similar to those of the total patient population with psoriasis, although men were slightly over-represented in the latter group. The duration of disease and cutaneous and rheumatismal locations were in line with those usually found in the literature. The unemployment rate over the previous 5 years and number of days of medical leave over the previous 12 months was higher in the PsO+PsA group as compared to the control group (Table 1). In the sub-group reporting a flare-up at the time of the survey, the impact of the disease on absenteeism, presenteeism and productivity was significantly higher in PsO-ST and PsO+PsA patients (Figure 1). Despite this, PsO-ST and PsO+PsA patients reported greater attachment to their work than did those in the control group (Table 1).

Table 1. Impact of psoriasis and psoriatic arthritis on functioning in the workplace and attachment to work

	Control group	PsO	PsO-ST	PsO+PsA
Unemployment over the past 5 years, % (n)	31 (187)	34 (243)	41 (33)	57* (42)
Number of days of medical leave over past 12 months, n	11	6	6	17*
Work considered more important than other aspects of life, % (n)	8 (45)	10 (62)	28* (20)	25* (17)
Work considered less important than other aspects of life % (n)	42 (236)	49* (301)	21* (15)	27* (18)

*p<0.05 versus control group respondents. PsO: psoriasis; PsO-ST: psoriasis under systemic treatment; PsO+PsA: psoriasis and psoriatic arthritis.

Figure 1: Impact of psoriasis and psoriatic arthritis on absenteeism, presenteeism and productivity over the past 7 day based on WPAI-PSO scores.
* p< 0.05 versus control group respondents PsO: psoriasis; PSO-ST: psoriasis under systemic treatment; PsO + PsA: psoriasis and psoriatic arthritis

Conclusions: In patients with PsO, placement under systemic treatment or the co-existence of PsA appears to be associated with greater impact on patients' working life, though they also reported higher attachment to their work. Close supervision and appropriate care in PSO patients developing PsA should limit these impacts.

SAT0456 THERAPY MODIFICATIONS AMONG PATIENTS WITH PSORIATIC ARTHRITIS TREATED WITH A BIOLOGIC IN THE UNITED STATES – DESCRIPTIVE ANALYSES FROM AN ADMINISTRATIVE CLAIMS DATABASE

J.A. Walsh[1], O. Adejoro[2], B. Chastek[2], G. Chun[3], J.B. Palmer[3]. [1]*University of Utah School of Medicine, Salt Lake City, UT;* [2]*Optum, Eden Prairie, MN;* [3]*Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States*

Background: Biologic therapy used for the treatment of active psoriatic arthritis (PsA) can sometimes be augmented by adding non-biologic medications and/or

escalating the dose of the biologic therapy. Limited data exist on how theses therapy modifications are used in patients with PsA receiving biologic treatment in real-world settings.

Objectives: To describe therapy modifications (adding non-biologic medications or dose escalation of the current biologic therapy) in patients with PsA receiving biologic therapy in the United States.

Methods: This study used US administrative claims data from the Optum Research Database. Adults with PsA who newly initiated (no evidence of use in the 12 months prior) a biologic between January 1, 2013 and January 31, 2015, and were continuously enrolled in a commercial or Medicare Advantage health plan 12 months before (baseline period) and 15 months following the index date, defined as the date of first pharmacy fill or medical infusion, were included. To reduce confounding by patients with an early switch/discontinuation, therapy modifications were identified only in those patients who persisted with their index biologic for >90 days. Therapy modifications identified included initiation of add-on medications (disease-modifying antirheumatic drugs [DMARDs], nonsteroidal anti-inflammatory drugs [NSAIDs], opioids, corticosteroids, antidepressants, anxiolytics, sleeping aids and topical analgesics) after the first 90 days of persistence, and dose escalation of the index biologic. Dose escalation was defined as a patient receiving a dose >10% above the reference dose from the product label for ≥90 days.

Results: Of the 1,010 patients included who persisted on their index biologic for >90 days, 80.5% initiated a subcutaneous tumor necrosis factor inhibitor (TNFi-SC; adalimumab, certolizumab pegol, etanercept or golimumab) as their index biologic, 12.0% initiated an intravenous TNFi (TNFi-IV; infliximab) and 7.5% initiated ustekinumab. During the 12-month baseline period, patients had a mean (standard deviation) number of claims of 2.9 (4.3) for conventional synthetic DMARDs (csDMARDs), 2.6 (5.0) for opioids, 2.2 (3.1) for NSAIDs and 2.0 (2.9) for corticosteroids. Overall, 45.5% of patients received ≥1 additional medication during the period from 90 days after the index date to the end of persistence with the index biologic or immediate 12-month post-index period. The most commonly added medications were corticosteroids (22.0%), opioids (17.1%), NSAIDs (12.9%) and csDMARDs (5.3%) (Table 1). Overall, 9.6% of patients had a dose escalation of the index biologic (33.9% for TNFi-IV, 6.4% for TNFi-SC and 5.3% for ustekinumab) in the immediate 12-month post-index period.

Table 1. Add-on medications initiated from 90 days after the index date to the end of persistence or 12 months among patients with PsA

Add-on Medication, n (%)	Total (N = 1010)	TNFi-SC* (n = 813)	Infliximab (n = 121)	Ustekinumab (n = 76)
Any medication	460 (45.4)	353 (43.4)	62 (51.2)	45 (59.2)
Corticosteroid	222 (22.0)	168 (20.7)	37 (30.6)	17 (22.4)
Opioid	173 (17.1)	126 (15.5)	20 (16.5)	27 (35.5)
NSAID	130 (12.9)	105 (12.9)	14 (11.6)	11 (14.5)
csDMARD	54 (5.3)	43 (5.3)	8 (6.6)	3 (3.9)
Antidepressant	49 (4.9)	34 (4.2)	8 (6.6)	7 (9.2)
Anxiolytic	48 (4.8)	34 (4.2)	10 (8.3)	4 (5.3)
Topical analgesic	31 (3.1)	24 (3.0)	4 (3.3)	3 (4.0)
Sleeping aid	22 (2.2)	17 (2.1)	4 (3.3)	1 (1.3)
tsDMARD	11 (1.1)	9 (1.1)	0 (0.0)	2 (2.6)

csDMARD, conventional synthetic disease-modifying antirheumatic drug; NSAID, nonsteroidal anti-inflammatory drug; PsA, psoriatic arthritis; SC, subcutaneous; TNFi, tumor necrosis factor inhibitor; tsDMARD, targeted synthetic DMARD.
* TNFi-SC includes adalimumab, certolizumab pegol, etanercept and golimumab.

Conclusions: In this descriptive, administrative claims-based study, nearly one-half (≈ 45%) of patients with PsA receiving biologic therapy initiated an add-on medication, most of which were pain medications. Further research is needed to better understand the reasons for therapy modifications during biologic treatment and the impact of insufficient control of pain in patients with PsA in the United States.

SAT0457 MIXED ANXIETY-DEPRESSIVE DISORDER (MADD) IN PATIENTS WITH PSORIATIC ARTHRITIS TREATED WITH BIOLOGICAL THERAPY

C. García-Porrúa[1], J.A. Mosquera-Martínez[2], F.J. Maceiras-Pan[3], L. Fernandez-Dominguez[4], L. Guerra-Vazquez[5], J. Pinto-Tasende[6].
[1]Rheumatology, Hospital Universitario de Lugo, Lugo; [2]Rheumatology, Complejo Hospitalario Universitario de Pontevedra, Pontevedra; [3]Rheumatology, Complejo Hospitalario Universitario de Vigo, Vigo; [4]Rheumatology, Complejo Hospitalario Universitario de Ourense, Ourense; [5]Rheumatology, Complejo Hospitalario Universitario de Ferrol, Ferrol; [6]INIBIC-Rheumatology, Complejo Hospitalario Universitario A Coruña, A Coruña, Spain

Background: Psoriasis makes stress in patients and stress could play a role on the onset and exacerbation of psoriasis. Psoriasis and psoriatic arthritis (PsA) are associated with a variety of psychological problems, mainly anxiety and depression, although most of patients suffer from both anxiety and depressive symptoms of limited and equal intensity accompanied by at least some autonomic features and excluding severe anxiety and depressive symptoms (mixed anxiety-depressive disorder or MADD).

Objectives: The aim of this study was to describe the prevalence of MADD in clinical practice among PsA patients from our registry on treatment with biological therapy (bDMARDs) and to analyze their possible relation with characteristics of the disease or treatments in these patients.

Methods: We included all PsA patients (met CASPAR criteria) following treatment with bDMARDs and included in our regional registry (reference population 2.055.000). Was recorded the history of attending a mental health consultation since PsA diagnoses and before starting biologics therapy and if they were diagnosed as a mixed of anxiety and depression disorder (F41.2, ICD-10) and treated by non severe anxiety and depressive symptoms. We used for this analysis sex, age, disease duration, current bDMARDs with or without current co-medication with csDMARDs (methotrexate or leflunomide or sulfasalazine) and HLA-B27 status. Continuous variables were reported as mean ± standard deviation. Categorical variables were reported as percentages and frequencies. All analyses were performed using SPSS software. Differences were considered statistically significant if $p<0.05$ (two-tailed).

Results: We have registered 604 PsA patients who have been treated with bDMARDs. Three-hundred and twenty nine (54.5%) patients were men, mean age was 53.3±12.6 years and disease duration of PsA was 12.4±8.7 years. MADD was diagnosed in 99 patients (16.4%), and was more frequent in women than in men (21.1% vs 12.5%, p=0.004), with no differences in age of diagnosis and disease duration of PsA, nail disease, dactylitis, uveitis or HLA-B27. MADD was more prevalent in patients with enthesitis (31.9% vs 12.0%, $p<0.0001$) and PsA with axial involvement was associated with MADD (p=0.003). Etanercept (42%) and adalimumab (36%) were bDMARDs more used -56.2% with associated csDMARDs - and 67.9% of patients remained in the first biologic with a mean follow-up of 4.9 years. Infliximab was most used bDMARDs in patients with previous MADD (p=0.001).

Conclusions: Mixed anxiety-depressive disorder was more prevalent in women with PsA in our registry. It was associated more frequently with the axial disease, enthesitis and most use of infliximab like bDMARDs established in these patients.

Background: PsA has a higher heritability than PsV, indicating the existence of additional PsA-specific genetic factors. To date, however, the specific genetic basis underlying PsA is poorly understood.

Objectives: The objective the present study was to identify new genetic variation specifically associated with PsA risk.

Methods: In order to characterize the genetic basis of PsA, we performed a GWAS meta-analysis at the single-marker level as well as at the pathway level (GWPA). A cohort of 835 PsA patients and 1,558 controls from the Spanish population was genotyped for >550,000 SNPs. GWAS data from a second cohort of 1,430 PsA patients and 1,417 controls from the North American population

was also used. In order to confirm the specificity of the new genetic variation associated with PsA risk, we analyzed the association with purely cutaneous psoriasis (PsC, n=614) and rheumatoid arthritis (RA, n=1,191). We performed a pharmacogenetic analysis to investigate the new PsA-specific pathways as a source for drug discovery in PsA.
Results: GWAS meta-analysis identified a new association between *B3GNT2* gene and PsA ($P<5e-08$). In the GWAS pathway analysis, we identified and validated a total of 14 genetic pathways associated with PsA risk. From these, the glycosaminoglycan (GAG) metabolism pathway was also found to be significantly associated with PsA risk when directly contrasted to the PsC cohort as well as the RA cohort. At the functional level, we detected a significant differential expression of GAG metabolism pathway genes in blood samples from PsA patients compared to PsC patients. The pharmacogenetic analysis identified several FDA-approved drugs likely to modify the GAG pathway.
Conclusions: The present study represents an important step towards the characterization of the genetic factors specific to PsA risk.

SAT0459 LOW DOSE IL-2 RESTORES IMBALANCE BETWEEN TH17 AND REGULATORY T CELLS IN PATIENTS WITH PSORIATIC ARTHRITIS

K. Qin[1], Q. Chen[1], J. Fan[1], D. Xu[1], X. Li[1], C. Wang[1], C. Gao[2]. *[1]Rheumatology, the Second Hospital of Shanxi Medical University, Taiyuan, China; [2]Pathology, Joint Program in Transfusion Medicine, Brigham and Women's Hospital/Children's Hospital Boston, Harvard Medical School, Boston, United States*

Background: Psoriasis arthritis is one of chronic, relapsing, inflammatory autoimmune disorders with skin lesions and joint damage. A therapeutic revolution of psoriatic arthritis (PsA) is still a considerable unmet need in the past decades. It has been well known that the imbalance of Th17 cells and regulatory T cells (Tregs) may be a pivotal cause of PsA. Correction of this dysfunction can be a potential therapy of PsA.
Objectives: In this study, we measured and compared both absolute numbers and proportions of CD4+CD17+ Th17 cells and CD4+CD25+Foxp3+ Treg cells in peripheral blood of PsA patients and healthy controls to explore the immunopathogenesis of PsA; on the other hand, the effects of low-dose recombinant human IL-2 (rhIL-2) on Th17 and Treg cells were investigated in patients with PsA.
Methods: Both absolute numbers and proportions of Treg and Th17 cells in peripheral blood, defined as the CD4+CD25+Foxp3+T or CD4+IL-17+ T cell populations, were examined by flow cytometry in 40 healthy controls and 77 patients with PsA, including 39 patients who had never received disease-modifying antirheumatic drugs (DMARDs) and 38 patients who were receiving or had received DMARDs. Among these patients, 20 patients consented at enrollment to receive rhIL-2 treatment. Before and after treatment (50WIU/d for 5 days, IH), Th17 and Treg cells in peripheral blood were analyzed by flow cytometry.
Results: The absolute count of Th17 cells in patients with PsA was very significantly higher than that of healthy controls ($P<0.01$), but the proportions of Th17 cell were not seen difference between PsA and healthy controls ($P>0.05$). In contrast with treated-PsA patients, the absolute count of Th17 cells was significant higher in untreated-PsA patients ($P<0.05$). After the course of rhIL-2 treatment, there was a significant increase in the absolute count of Treg cells ($P<0.05$), but no diference in the absolute count of Th17 cells, Th17/Treg was significantly lower and went back to nomal.
Conclusions: The results suggest that, not the proportion, but the decrease in the absolute count of Th17 cells, defined as the CD4+CD17+ populations, contributes to the pathogenesis of PsA. After the treatment of rhIL-2, there was a more significant increase in the absolute count of Treg cells than that of Th17, and consequently the balance of Th17/Treg was restored to normal, leading to the development of new therapies.

SAT0460 ASSOCIATION BETWEEN INFLAMMASOME-RELATED POLYMORPHISMS AND PSORIATIC ARTHRITIS

K. Juneblad[1], A. Kastbom[2], S. Rantapää-Dahlqvist[1], P. Söderkvist[3], G.-M. Alenius[1]. *[1]Dept of Public Health and Clinical Medicine/Rheumatology, University Hospital, Umeå, Umeå; [2]Department of Clinical and Experimental Medicine, Rheumatology; [3]Division of Cell Biology, Dept of Clinical and Experimental medicine, Linköping University, Linköping, Sweden*

Background: In recent years, research on the interleukin 1β(IL1 β)–regulating protein complex, called the inflammasome, has shown interesting associations with various inflammatory diseases. E.g. for Rheumatoid Arthritis (RA) (1) and psoriasis (Pso) (2, 3) associations with genetic polymorphisms in genes related to the inflammasome has been discovered. So far, no studies investigating genetic polymorphisms in inflammasome genes in Psoriatic Arthritis (PsA) patients have been published.
Objectives: To examine whether polymorphisms in genes related to inflammasomes confer increased risk for psoriatic arthritis.
Methods: DNA from 771 PsA patients and 793 healthy controls from Sweden were analyzed for different single nucleotide polymorphisms (SNPs) in *NLRP3* (rs35829419, rs10733113, rs4353135), *CARD8* (rs 2043211) and *NLRP1* (rs8079034, rs878329).
Results: Significant associations with PsA were found between carriage of allele, C, of rs878329 in *NLRP1* (Chi-2=6.5, OR (95% CI); 0.75 (0.60–0.94), P=0.011) and allele G in rs4353135 in *NLRP3* (Chi-2=4.8, OR (95% CI); 1.25 (1.02–1.53), p=0.028). Genotype distribution were also significantly different between patients and controls and for rs878329 in *NLRP1* there was a significant difference in allele frequency (G/C) between patients and controls (Chi-2=5.8, OR (95% CI); 1.20 (1.03–1.38), p=0.016). No significant associations with PsA were found for the other SNPs analyzed.
In genotype analysis, a significant higher frequency of genotype GG in rs878329 in PsA was detected (32.9% vs 26.9%, Chi-2=6.49, OR (95% CI); 1.34 (1.07–1.67), p=0.011), whilst no significant differences were detected for genotypes GC or CC. For rs4353135, a significantly higher frequency of genotype TG (43% vs 37.6%, Chi-2=4.66, OR (95% CI); 1.25 (1.02–1.53), P=0.033) and a significantly lower frequency of genotype TT (50.5% vs 56.1%, Chi-2=4.85, OR (95% CI); 0.80 (0.65–0.98), P=0.028) was seen in PsA, no significan difference was detected for genotype GG.
Conclusions: Carriage of rs878329C in *NLRP1* was less frequent in patients with PsA compared with controls indicating a protecting effect, but when different genotypes were analysed the difference likely results from an increased risk of PsA with genotype GG. The results are in contrast with the study of Ekman *et al*, where an increased transmission of rs878329C to family members with psoriasis was seen (3), indicating an increased risk of developing skin psoriasis for carriers of C, but in agreement with the study of Sui *et al* on patients with RA, where an association was detected for carriage of C (OR 0.82, p=0.02), with the risk genotype for RA being GG (4). Thus, the genotype GG possibly confers risk of arthritic disease whilst the C-allele seems associated with skin disease. Carriage of rs4353135G in *NLRP3* was more frequent in PsA patients compared with controls indicating an increased risk of disease, but only genotype GT was significantly increased in PsA. The study is, to our knowledge, the first to study possible associations between genes related to the inflammasome and PsA. In the study associations were found between one SNP in *NLRP3* and one SNP in *NLRP1*, indicating a possible involvement in pathogenesis of PsA disease.

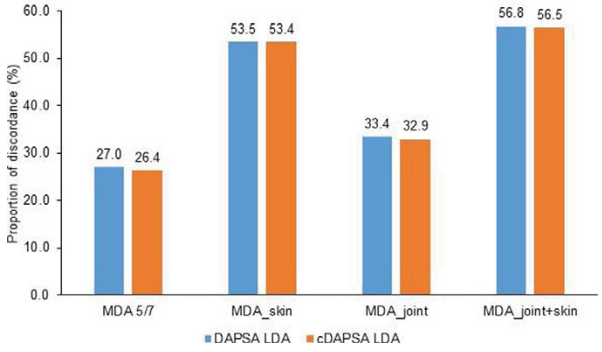
SAT0461 CHARACTERISATION OF DIFFERENT LOW DISEASE ACTIVITY MEASUREMENTS IN PATIENTS WITH PSORIATIC ARTHRITIS

L.C. Coates[1], A.B. Gottlieb[2], J.F. Merola[3], L. Aikman[4], A. Szumski[5], A. Chhabra[6]. *[1]University of Leeds, Leeds, United Kingdom; [2]New York Medical College, New York; [3]Harvard Medical School, Boston, United States; [4]Pfizer, Walton Oaks, United Kingdom; [5]InVentiv Health, Princeton; [6]Pfizer, New York, United States*

Background: Selection of the correct target to guide treatment is crucial for effective disease management in patients with psoriatic arthritis (PsA).
Objectives: To evaluate the prognostic value of several low disease activity (LDA) measurements in patients with PsA and psoriasis to assist physicians choose a valid target that facilitates assessment in clinical practice.
Methods: This was a post-hoc analysis from the PRESTA[1] clinical study. LDA targets analyzed were: Disease Activity in PsA (DAPSA) LDA ≤14 (tender joint count [TJC], swollen joint count [SJC], patient global visual analog scale [Pt VAS], pain VAS, C-reactive protein [CRP]; clinical (c)DAPSA LDA ≤13 (DAPSA without CRP); and minimal disease activity (MDA) measurement defined as 5/7 cut-offs (TJC ≤1, SJC ≤1, psoriasis activity and severity index [PASI] ≤1, Pt pain ≤15mm, Pt VAS ≤20mm, health assessment questionnaire ≤0.5, tender entheseal points ≤1). Additional MDA measurements were investigated where 5/7



Abstract SAT0461 – Table 1. Proportion of patients with residual disease at Week 24

	MDA 5/7, n/N (%)	MDA_skin, n/N (%)	MDA_joint, n/N (%)	MDA_joint + skin, n/N (%)	DAPSA LDA, n/N (%)	cDAPSA LDA, n/N (%)
Dactylitis (1–12)	10/322 (3)	6/131 (5)	5/255 (2)	3/97 (3)	18/475 (4)	17/478 (4)
Enthesitis (1–5)	2/324 (1)	2/132 (2)	1/256 (0)	1/97 (1)	16/477 (3)	16/480 (3)
PASI (2–9)	142/324 (44)	0/132 (0)	119/256 (47)	0/97 (0)	237/477 (50)	237/480 (49)
PASI (≥10)	17/324 (5)	0/132 (0)	14/256 (6)	0/97 (0)	r 38/477 (8)	39/480 (8)
TJC (>1)	46/324 (14)	28/132 (21)	0/256 (0)	0/97 (0)	140/477 (29)	139/480 (29)
SJC (>1)	25/324 (8)	15/132 (11)	0/256 (0)	0/97 (0)	65/477 (14)	65/480 (14)

cut-offs were met but some were mandated: MDA_joint with both TJC and SJC cut-offs mandated, MDA_skin where PASI cut-off was mandated, MDA_joint+skin where the TJC, SJC, and skin cut-offs were mandated.

Results: At Week 24, the proportion of patients achieving LDA were 47%, 20%, 38%, 14% in MDA 5/7, MDA_skin, MDA_joint, MDA_joint+skin, respectively, vs ~71% in DAPSA and cDAPSA LDA. The highest proportion of discordance was observed between MDA_skin or MDA_joint+skin with DAPSA LDA or cDAPSA LDA (Figure). The majority of patients had no residual arthritis although levels were highest in the DAPSA measurements (Table). However, notable residual levels of psoriasis were observed in measurements that did not require skin disease control (Table 1). MDA_joint+skin had the lowest levels of residual disease across all cut-offs (Table 1). At Week 12, a significant difference ($P<0.05$) between the 50mg etanercept (ETN) once a week and 50mg ETN twice a week cohorts was observed in the measurements that required a skin cut-off (MDA_skin and MDA_joint+skin) and MDA 5/7 but not in DAPSA LDA, cDAPSA LDA, or MDA_joint.

Figure. Proportion with discordance for DAPSA LDA or cDAPSA LDA across different low disease activity definitions at Week 24

Conclusions: DAPSA and cDAPSA LDA provided the least stringent cut-offs with the highest percentages of patients with residual disease. Whilst choosing the optimal target for treatment requires more debate, it is clear from these data that levels of residual psoriasis are high in those measurements that do not require skin control. If this is not included in a treatment target for PsA, notable levels of psoriasis can be missed.

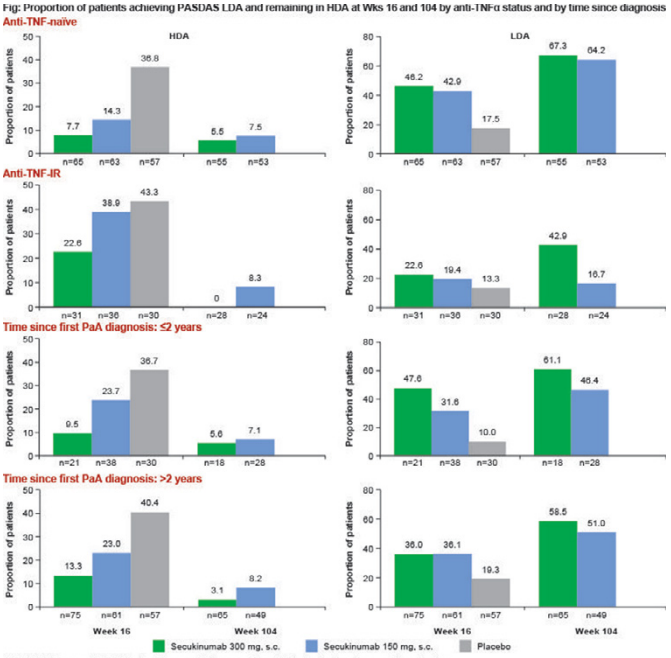
SAT0462 SECUKINUMAB PROVIDES SUSTAINED PASDAS RELATED LOW DISEASE ACTIVITY IN PSORIATIC ARTHRITIS: 2 YEAR RESULTS FROM THE FUTURE 2 STUDY

L.C. Coates[1,2], D.D. Gladman[3], P. Nash[4], O. Fitzgerald[5], A. Kavanaugh[6], L. Rasouliyan[7], L. Pricorp[8], K. Ding[8], C. Gaillez[9] on behalf of the FUTURE 2 study group. [1]*Leeds Teaching Hospitals NHS Trust;* [2]*University of Leeds, Leeds, United Kingdom;* [3]*Toronto western hospital, Toronto, Canada;* [4]*University of Queensland, Brisbane, Australia;* [5]*University College Dublin, Dublin, Ireland;* [6]*UC San Diego School of Medicine, la Jolla, United States;* [7]*RTI Health Solutions, Barcelona, Spain;* [8]*Novartis Pharmaceuticals Corporation, East Hanover, United States;* [9]*Novartis Pharma AG, Basel, Switzerland*



Background: Psoriatic arthritis (PsA) disease activity score (PASDAS) assessing multiple facets of PsA was demonstrated to distinguish treatment effect, perform better in statistical terms than traditional joint-only indices[1] and could be used as a treatment target in clinical trials in PsA.

Objectives: Secukinumab provided sustained improvement in the signs and symptoms of PsA over 104 weeks (wks) in the FUTURE 2 study.[2] Here, we report the ability of secukinumab to reach and sustain PASDAS based low disease activity (LDA) up to 104 wks in the FUTURE 2 study using a *post-hoc* exploratory analysis.

Methods: 397 patients (pts) with active PsA were randomised to subcutaneous (s.c.) secukinumab (300mg, 150mg, or 75mg) or placebo (PBO) at baseline (BL), Wks 1, 2, and 3, and every 4 wks (q4w) from Wk 4. PBO nonresponder and responder pts were re-randomised to secukinumab 300 or 150mg s.c. q4w from Wk 16 and 24, respectively. PASDAS is derived from physician's global VAS, patient's global VAS, SF-36 PCS, tender and swollen joints (TJC 68 and SJC 66), Leeds enthesitis count, dactylitis count and CRP level and has cut-points for high disease activity (HDA≥5.4), low disease activity (LDA<3.2) and remission (REM≤1.9).[3] PASDAS was assessed in the overall population and in pts stratified by prior anti-TNF use (naïve/inadequate response [IR]) and disease duration (≤2 years vs. >2 years since diagnosis) and reported using non-mutually exclusive categories at group level and as observed analysis. Secukinumab 75mg data are not reported as this was not considered an effective dose.[2]

Results: PASDAS score (mean [SD]) at baseline was 5.9 (0.9), 6.0 (1.0) and 5.8 (1.0) in the secukinumab 300mg, 150mg and PBO groups. In the overall population at Wk 16, PASDAS LDA was achieved in 37/96 (38.5%) and 34/99 (34.3%) of pts, treated with secukinumab 300mg and 150mg, respectively; vs. 14/87 (16.1%) with PBO. A high proportion of pts treated with secukinumab 300 and 150mg achieved LDA (49/83 [59.0%] and 38/77 [49.4%], respectively) at Wk 104. The proportion of pts achieving PASDAS LDA and remaining in HDA at Wks 16 and 104 by anti-TNFα status and by disease duration (≤2 years vs. >2 years) for secukinumab 300 and 150mg is reported in the figure.

Fig: Proportion of patients achieving PASDAS LDA and remaining in HDA at Wks 16 and 104 by anti-TNFα status and by time since diagnosis

HDA, high disease activity; LDA, low disease activity; n, number of pts in the treatment group with evaluation

Conclusions: A higher proportion of secukinumab-treated pts at Wk 16 achieved PASDAS LDA than PBO, with LDA sustained at group level at Wk 104. Discriminatory effect of PASDAS was consistent with that previously reported in the GRACE project.[4] A higher proportion of anti–TNFα-naïve pts treated with secukinumab achieved and sustained PASDAS LDA than anti–TNFα-IR pts whereas similar proportion of pts treated with secukinumab achieved PASDAS LDA irrespective of time since diagnosis (≤2 years vs. >2 years).

SAT0463 SECUKINUMAB PROVIDES SUSTAINED REDUCTION IN FATIGUE IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS THROUGH 3 YEARS: LONG-TERM DATA FROM THE FUTURE 1 AND FUTURE 2 STUDIES

L. Gossec[1], T.K. Kvien[2], P.G. Conaghan[3], M. Østergaard[4], D. Gladman[5], P. Mease[6], L. Rasouliyan[7], L. Pricop[8], C. Gaillez[9], S. Jugl[9]. *[1]UPMC University Paris 06, Paris, France; [2]Diakonhjemmet Hospital, Oslo, Norway; [3]University of Leeds, Leeds, United Kingdom; [4]Copenhagen Center for Arthritis Research (COPECARE), Glostrup, Denmark; [5]University of Toronto, Toronto, Canada; [6]Swedish Medical Center, Seattle, WA, United States; [7]RTI Health Solutions, Barcelona, Spain; [8]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States; [9]Novartis Pharma AG, Basel, Switzerland*

Background: Fatigue, a common symptom in patients (pts) with PsA, can negatively impact HRQoL and social functioning. Secukinumab (SEC), a fully human anti–IL-17A mAb, rapidly improved signs and symptoms, physical functioning, HRQoL, and fatigue in pts with PsA.[1,2]
Objectives: To assess the long-term effects of SEC on fatigue in TNF inhibitor (TNF)-naïve PsA pts and those with an inadequate response or intolerance to TNF inhibitor therapy (TNF-IR).
Methods: 606 and 397 pts were randomized to SEC or placebo (PBO) in FUTURE 1 (10 mg/kg IV followed by 150 or 75 mg SC) and FUTURE 2 (300, 150, or 75 mg SC), respectively. At Wk 16, PBO pts with ≤20% reduction in tender/swollen joint count (non-responders) were re-randomized to SEC 150 or 75 mg SC (FUTURE 1) and SEC 300 or 150 mg SC (FUTURE 2); responders were re-randomized at Wk 24. Pts in FUTURE 1 could enter a LTE study at Wk 104 (NCT01892436). Across both studies, approximately 68% of pts were TNF-naïve and 32% were TNF-IR. Fatigue was assessed at baseline (BL) and Wks 4, 8, 12, 16, 24, 52, 104, and 156 (FUTURE 1 only) using FACIT-F (higher scores = less fatigue). Fatigue response was defined by an increase in FACIT-F score of ≥4 from BL (corresponding to the MCID). Correlations between BL characteristics and improvements in fatigue were investigated using a logistical regression model. Only data with approved doses of SEC (300/150 mg) are shown.
Results: FACIT-F was 27.8–28.9 and 26.6–29.2 at BL across groups in FUTURE 1 and 2, respectively. Improvements in fatigue seen with all doses of SEC vs. PBO from Wks 4–24 were sustained through 156 wks in FUTURE 1 and 104 wks in FUTURE 2 in both the overall population and subgroups stratified by prior exposure to TNF (Table). The numerically higher responses with SEC 150 vs. 300 mg in this observed analysis were as a result of a higher rate of discontinuation due to lack of efficacy with the lower dose, which inflated the response rate. In the overall population, the LS mean change (±SEM) from BL in FACIT-F was significantly greater with SEC vs. PBO at Wk 16 in both FUTURE 1 (7.25±0.72 vs. 4.07±0.76; P=0.002) and FUTURE 2 (300 mg: 5.89±0.92 vs. 1.86±0.93, P=0.002; 150 mg: 7.40±0.90 vs. 1.86±0.93, P<0.0001); improvements were sustained throughout the entire follow up in both studies (FUTURE 1 Wk 156: 6.14±0.77; FUTURE 2 Wk 104: 300 mg 7.29±1.04, 150 mg 7.02±1.06). Improvements were generally somewhat larger in TNF-naïve pts than in TNF-IR pts. Correlation analyses did not identify any BL factors that consistently predicted change in fatigue score across Wks 16, 52, and 104.

Table. FACIT-Fatigue responders in FUTURE 1/FUTURE 2 until Week 156/104[a]

Proportion of Patients with FACIT-Fatigue Response[b], % (n/m)	FUTURE 1[c]	FUTURE 2	
	SEC IV–150 mg	SEC 300 mg	SEC 150 mg
Overall Population	**N=161**	**N=100**	**N=100**
Week 16	60.4 (96/159)	50.5 (48/95)	70.0 (70/100)
Week 52	66.9 (107/160)	60.2 (56/93)	68.5 (61/89)
Week 104	63.4 (90/142)	62.4 (53/85)	70.1 (54/77)
Week 156	57.4 (89/155)	–	–
TNF-naïve	**N=120**	**N=67**	**N=63**

[a]Observed data are shown; [b]Defined as improvement ≥4.0 points; [c]Data shown are from patients who entered the FUTURE 1 long-term extension study at Week 104
m, number of patients with sufficient data for evaluation; N, number of patients randomized to SEC 150 mg or SEC 300 mg (FUTURE 2 only); n, number of responders.

Conclusions: SEC-treated PsA pts achieved rapid, sustained, and clinically meaningful improvements in fatigue for up to 156 wks, with higher responses in TNF-naïve pts.

SAT0464 THE IDEAL TARGET FOR PSORIATIC ARTHRITIS? COMPARISON OF REMISSION AND INACTIVE DISEASE STATES IN A REAL LIFE COHORT

L.J.J. Van Mens[1], A.W.R. van Kuijk[2], D.L. Baeten[1,3], L.C. Coates[4]. *[1]AMC; [2]Reade, Amsterdam Immunology and Rheumatology Center, Amsterdam, Netherlands; [3]UCB, Brussels, Belgium; [4]LIRMM, University of Leeds, Leeds, United Kingdom*

Background: Recommendations on psoriatic arthritis (PsA) state that the target of treatment should be remission or inactive disease. Multiple potential targets have been developed and proposed, each with a different composition of clinical measurements.
Objectives: Our aim is to use an existing real life dataset of a large group of patients in a low disease activity state, to compare different targets and provide further evidence to choose a target.
Methods: This analysis uses data from a cross-sectional real life cohort of 250 PsA patients (EULAR16–2124). All patients were considered in an acceptable disease state according to the treating rheumatologist, defined by the fact that the rheumatologist did not consider to modify the current treatment. Remission/inactive disease targets were the DAPSA [TJC; SJC; patient global visual analogue scale (Pt VAS); pain VAS; CRP] and clinical (c)DAPSA [DAPSA minus CRP] remission (≤4), very low disease activity (VLDA) [7/7 of TJC ≤1; SJC ≤1; PASI ≤1; Pt pain ≤15mm; Pt VAS ≤20mm; HAQ ≤0.5; tender entheseal points ≤1], and PASDAS ≤1.9 or near remission (NR).
Results: 113 pts were in cDAPSA remission, 107 in DAPSA remission, 56 met VLDA and 37 in PASDAS NR. There was a very high percentage exact agreement between DAPSA and cDAPSA (96%) reflecting the similarity of the two definitions. DAPSA/cDAPSA and VLDA show a high correlation (pearson of 0,611 and 0,590 resp) but VLDA is more stringent in comparison with both DAPSA scores. The correlation between NR and DAPSA/cDAPSA/VLDA was lower, (pearson 0,400, 0,403 and 0,412 resp). Again PASDAS NR was generally more stringent than DAPSA/cDAPSA remission but greater dissimilarities are seen between PASDAS NR and VLDA where 14 patients are in VLDA but not PASDAS NR and 29 are in PASDAS NR but not VLDA.
Although presence of active joint disease was similar across the different measures, VLDA presents as a more stringent cutoff with less residual disease in PASI, TJC and less impact on DLQI and HAQ. All targets had similar % of patients

with a raised CRP. The DAPSA measures which do not include an enthesitis measure show more patients with an active enthesitis.
There was a limited consequence on QoL measures when residual disease activity was allowed in certain domains in these remission states. In those patients with active enthesitis or skin disease, no differences were found on PROs on quality of life and functionality. The presence of active skin disease with a PASI>2 (present in 20/110 pts achieving DAPSA) was reflected by an impact on DLQI (2,85 (SD2,9)v.s. 1 (2,3)p=0.003). This effect was not seen when the cutoff of for PASI>1 was used.

		cDAPSA (n=113)	DAPSA (n=107)	VLDA (n=56)	PASDASNR (n=37)
PASDAS mean (SD)		2,16 (0,52)	2,13 (0,49)	1,97 (0,42)	1,6 (0,20)
SJC	0	101 (89%)	96 (90%)	53 (95%)	33 (89%)
	1	10	10	3	1
	2	2	1	0	3
TJC	0	93 (82%)	89 (83%)	51 (91%)	28 (75%)
	1	11	11	5	2
	2	7	5	0	4
	3+	2	2	0	3
LEI	0	108 (96%)	102 (96%)	56 (100%)	37 (100%)
	1	1	1	0	0
	2+	4	4	0	0
PASI score	0–1	79 (70%)	74 (69%)	56 (100%)	32 (86%)
	>1	34	33	0	5
CRP >5mg/dl		11 (10%)	8 (7,5%)	5 (9%)	1 (3%)

Conclusions: This comparison of the different remission targets shows that VLDA presented as the most stringent target. Inclusion of laboratory markers seems not to be a necessity although the exclusion of a skin domain might result in a negligence of skin disease in some patients despite an impact on their QoL.

SAT0465 AN INTEGRATED SAFETY DATA ANALYSIS ACROSS ALL PHASE II AND PHASE III CLINICAL PROGRAMS FOR USTEKINUMAB IN PSORIATIC ARTHRITIS, CROHN'S DISEASE, AND PSORIASIS

L.S. Gensler[1], E. Hsia[2], C. Gasink[2], B. Randazzo[3], D. Parenti[4], S. Fakharzadeh[4], L.-L. Gao[3], S.D. Chakravarty[5]. *[1]University of California, San Francisco, San Francisco; [2]Janssen Research & Development, LLC/University of Pennsylvania, Spring House/Philadelphia; [3]Janssen Research & Development, LLC, Spring House; [4]Janssen Scientific Affairs, LLC, Horsham; [5]Janssen Scientific Affairs, LLC/Drexel University College of Medicine, Horsham/Philadelphia, United States*

Objectives: Therapeutic decisions are based on efficacy, but clinicians need to consider medication safety in this process. Here, we report ustekinumab (UST) integrated safety data in patients (pts) with psoriatic arthritis (PsA), Crohn's disease (CD), and psoriasis (PsO). We also compare a subset of PsA pts with & without baseline methotrexate (MTX).
Methods: Integrated safety data from 3 PsA, 5 CD, & 4 PsO trials were analyzed. PsA studies included the Ph2 trial [CNTO743T10] & the 2 Ph3 trials (PSUMMIT 1 & 2) with 222, 615 & 312 pts exposed to UST, respectively. The percentage of pts in the Ph2 study that received MTX was 20.5%. No concomitant DMARDs with the exception of MTX (approximately 50% of pts in each study) were permitted in the 2 Ph3 studies. In the 5 CD trials (Ph2/3Ph3) 1749 pts were exposed to UST. In the 3 Ph3 CD trials, pts received one dose of UST 130mg or ~6mg/kg IV at induction (UNITI-1 & UNITI-2), then 8 weeks later, entered the maintenance phase (IM UNITI) and received UST 90mg SC q8w or q12w for 44 weeks. The percentage of pts on background MTX in UNITI-1 was 9.2% & in UNITI-2, 4.8%. In the PsO studies (1Ph2/3Ph3), a total of 3117 pts received UST 45mg or 90mg SC; *no concomitant DMARD therapy (including MTX) was permitted*. The PsO studies were completed through 5-years of follow-up. All pts who received at least 1 dose of UST are included in this analysis. Safety events are reported in events per 100-pt years. 95% CI for events per 100 PY were estimated.
Results: Through 1 year of follow-up, a total of 1018 PsA pts were treated with UST, of which 465 were co-treated with MTX. Of the 1749 CD pts treated with UST, 139 received MTX. Discontinuation rates of UST due to adverse events (AEs) were comparable across disease states irrespective of MTX use (Table). AE rates (95% CIs for events/100 PY) were noted to be comparable in the UST vs PBO groups for all diseases pooled irrespective of MTX use-UST (420.39, 432.45) vs PBO (534.80, 570.44). Serious adverse event rates (SAEs) were also comparable in the UST vs PBO groups for all diseases pooled-UST (14.25, 16.56) vs PBO (24.05, 32.18). Infections and Serious infections (SIs) had numerically lower event rates in UST vs. PBO groups for all diseases pooled-UST (122.16, 128.72) vs PBO (120.94, 138.27) and UST (2.10, 3.05) vs PBO (2.76, 6.00), respectively (Table). Major adverse cardiovascular events (MACE) did not appear

	Psoriatic Arthritis				Crohn's disease				Psoriasis**		All Diseases Pooled	
	PBO		UST		PBO		UST		PBO^	UST^^	PBO	UST

Infections	104.76	101.16	82.32	74.30	139.59	145.51	137.91	133.64	120.71	127.40	129.38	125.41
Serious infections	1.56	0.00	0.00	1.76	15.95	6.22	13.45	5.80	1.65	1.40	4.15	2.54
MACE*	0.00	1.23	0.25	1.10	0.00	0.00	0.00	0.10	0.55	0.55	0.3	0.46
Malignancies (excluding NMSC)	0.00	0.00	0.00	0.22	0.00	0.00	0.00	0.39	0.55	0.43	0.15	0.35
Deaths	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.19	0	0.11

*MACE adjudicated events includes CV death, non-fatal MI, or non-fatal stroke; **In the psoriasis studies, no concomitant DMARD therapy (including MTX) was permitted. ^includes data from the time of crossover, ^^includes data from the first UST dose onward for patients who crossed over from PBO

to significantly differ in both PBO & UST pts in PsA, PsO and CD. Event rates of malignancy (excluding non-melanoma skin cancer) were comparable across all disease states. No deaths in PsA or CD were reported.
Conclusions: UST demonstrates a favorable safety profile in an integrated safety data analysis across the PsA, CD, & PsO phase 2 & 3 clinical trials. The use of UST in PsA appears to be safe & well-tolerated, with fewer event rates of SAEs & SIs noted vs PBO. Despite higher overall rates of SAEs & SIs observed in CD pts, the data do not suggest an influence of UST on either.

SAT0466 PREGNANCY IN WOMEN WITH PSORIATIC ARTHRITIS: PREGNANCY OUTCOMES AND CHANGES IN DISEASE ACTIVITY

M.E.B. Clowse, G. McDaniel, A.M. Eudy. *Rheumatology, Duke University Medical Center, Durham, United States*

Background: Very little has been published about psoriatic arthritis (PsA) in pregnancy, and it remains unknown whether pregnancy outcomes are impacted by this disease or whether disease activity is changed by pregnancy or delivery.
Objectives: To discover the rate of pregnancy complications for women with psoriatic arthritis, and to determine whether psoriasis and the associated arthritis change during and following pregnancy.
Methods: A retrospective survey was completed by 40 women aged 20–50 years with psoriatic arthritis managed at a university center. Each survey collected information about infertility, pregnancy outcomes and complications, as well as patient-reported assessments of changes in both skin and joint disease activity at the onset of pregnancy, over the course of the pregnancy, and in the months following pregnancy. Simple statistics were used to compare outcomes before and after the diagnosis of PsA.
Results: The survey was completed by 40 women with PsA. The majority (93%) were white, non-Hispanic with a high level of education (40% completed college and another 30% either started or finished a graduate degree); 62.5% were married. The average age at the time of the study was 37.4 (SD 7.9) years and age at PsA diagnosis was 30.9 (8.4) years.
Twenty-five women reported they had ever tried to become pregnant, and of those, 9 had been unable to become pregnant after 12 months of trying or had been diagnosed with infertility by a physician (36%). The reasons for infertility or inability to become pregnant included polycystic ovarian syndrome (44%), problem with ovulation (11%), problem with uterus (11%), elevated prolactin (11%), infection in pelvic area (11%), and/or cervical problems (30%). Infertility was unexplained in 33%.
There were 70 pregnancies to 26 patients, with 37 pregnancies occurring after the diagnosis of PsA (see table). Pregnancy outcomes following PsA diagnosis were worse than those prior to PsA diagnosis, particularly the rate of pregnancy loss (32% compared to 12%; p=0.05) and preterm birth (48% compared to 21%; p=0.02). Only 24% of patients took psoriasis or arthritis medications during pregnancy. The most commonly used medications during pregnancy were TNF inhibitors (16%), corticosteroids (8%), and DMARDs (5%).
The large majority of patients had minimal arthritis and psoriasis during pregnancy.

Table. Pregnancy outcomes before and after psoriatic arthritis diagnosis.

	Overall	Prior to PsA Diagnosis	After PsA Diagnosis
Number of Pregnancies	70	33	37
Live Births	47 (67%)	24 (73%)	23 (62%)
Spontaneous Abortion	15 (21%)	4 (12%)	11 (30%)
Stillbirth	1 (1%)	0 (0%)	1 (3%)
Ectopic Pregnancies	1 (1%)	1 (3%)	0 (0%)
Elective Termination	6 (9%)	4 (12%)	2 (5%)
Preterm Birth	16/47 (34%)	5/24 (21%)	11/23 (49%)
Preeclampsia	11/46 (24%)	5/23 (22%)	8/23 (35%)
Abnormal Infant	1/47 (2%)	2/24 (8%)	2/25* (8%)
Adverse Pregnancy Outcome	33 (47%)	10 (30%)	23 (62%)

*two twin pregnancies

Only 12% had moderate and 6% had severe arthritis. Similarly, only 10% had moderate and 7% had severe psoriasis. During and following pregnancy, about half of all patients reported no change in either joint or skin activity during and follow pregnancy, with fairly equal numbers reporting improved and worsened arthritis. On the other hand, 42% had improved psoriasis during pregnancy compared to 6% with worsened. There did not appear to be a significant postpartum flare.

Conclusions: Our analysis found that among women with PsA who have tried to become pregnant, 36% experienced infertility, primarily due to PCOS. Compared to pregnancies occurring before the diagnosis of PsA, pregnancies after PsA diagnosis had a lower frequency of live births and a higher frequency of preterm births. Overall, in this cohort of women with mostly mild disease during pregnancy, arthritis pain and psoriasis activity did not appear to substantially worsen during pregnancy.

SAT0467 ALL 10-YEAR CARDIOVASCULAR RISK SCORES ARE SIMILAR IN PATIENTS WITH PSORIATIC ARTHRITIS AND PSORIASIS

N. Ikumi[1], F. Farkas[1], A. Szentpetery[1], B. Kirby[2], O. FitzGerald[1].
[1]Rheumatology; [2]Dermatology, St. Vincent's University Hospital, Dublin, Ireland

Background: Psoriatic arthritis (PsA) and Psoriasis (PsO) are associated with higher cardiovascular (CV) risk with higher risk in patients with a severe disease phenotype[1,2]. Long-term CV risk is evaluated using several methods for the general population.

Objectives: The aim of the study was to compare CV risk factors and 10-year CV risk scores between patients with PsA and those with PsO only.

Methods: PsA patients fulfilling the CASPAR criteria and PsO with disease duration <10 years were enrolled consecutively from Rheumatology and Dermatology clinics. Fasting bloods were obtained for glucose, insulin and lipids. Patients underwent thorough physical examination, joint and skin assessments and completed questionnaires on health and quality of life. Four different CV risk scores were calculated: (1) Framingham Coronary risk score (FCS); (2) American College of Cardiology and American Heart Association (ACC/AHA) 10-year atherosclerotic cardiovascular disease (ASCVD) algorithm; (3) Systematic Coronary Risk Evaluation (SCORE) algorithm; and (4) QRISK2 (2016).

Results: 232 patients (100 PsA and 132 PsO) were recruited with mean age 52.4 (±10.5) for PsA and 39.7 (±14.4) for PsO. Mean disease duration for PsA was 17.9 (±10) years. There were significantly more patients with hypertension (HTN) and metabolic syndrome in PsA group, and the patients taking DMARDs and/or biologics treatment were also higher compared to PsO. Fasting glucose, insulin, lipids, BMI and waist/hip ratio did not show significant differences. The mean FCS, ASCVD, SCORE and QRISK2 were significantly higher in PsA as compared to PsO (7.6±7.0% vs. 4.7±6.1%, P=0.0002; 8.4±8.2% vs. 4.5±5.8%, P<0.0001; 2.1±2.6% vs. 1.1±1.8%, P=0.0002; 11.2±9.9% vs. 5.2±6.4%, P<0.0001, respectively). However, after adjusting for age and sex, all CV risk scores were similar (P=0.21). Multiple regression analysis revealed that waist/hip ratio significantly correlated with all CV risk scores in both PsA and PsO.

Conclusions: We found similar 10-year risk of CVD in PsA and PsO patients using FCS, ASCVD, SCORE and QRISK2. Waist/hip ratio had significant effect on all CV risk scores suggesting that central obesity should be managed appropriately to reduce long-term CVD in psoriatic disease.

SAT0468 PRESENCE OF POOR PROGNOSTIC FACTORS MAY PREDICT RESPONSE TO ABATACEPT IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: RESULTS FROM A POST HOC ANALYSIS FROM A PHASE III STUDY

P. Mease[1], I. McInnes[2], V. Strand[3], O. FitzGerald[4], H. Ahmad[5], A. Johnsen[5], J. Ye[5], S. Banerjee[5]. *[1]Swedish Medical Center and University of Washington, Seattle, United States; [2]University of Glasgow, Glasgow, United Kingdom; [3]Stanford University, Palo Alto, United States; [4]St Vincent's University Hospital and University College Dublin, Dublin, Ireland; [5]Bristol-Myers Squibb, Princeton, United States*

Background: Abatacept, a selective T-cell co-stimulation modulator, significantly increased ACR20 response and had an overall beneficial effect on musculoskeletal symptoms in patients (pts) with active psoriatic arthritis (PsA) in the Phase III Active pSoriaTic athritis RAndomizEd triAl (ASTRAEA, NCT01860976).[1] Factors that may predict responses to abatacept were explored in this *post hoc* analysis.

Objectives: To evaluate the relationship between baseline characteristics and abatacept response in a *post hoc* analysis of ASTRAEA.

Methods: Pts were randomized (1:1) to SC abatacept 125 mg weekly or placebo for 24 weeks in this trial. Pts without >20% improvement in joint counts at Week 16 were switched to open-label abatacept (early escape). ACR20 response rate in pts stratified by baseline variables was investigated in a multivariate analysis and odds ratios (ORs) generated to identify differences in response. Using a cut-off of OR 1.2, indicating pt subgroups in whom abatacept appeared to have a meaningful treatment benefit, baseline variables were further investigated in a univariate analysis and estimated differences calculated.

Results: Of 424 pts enrolled, 213 received abatacept and 211 placebo. In abatacept-treated pts, the multivariate model showed a difference in ACR20 response (OR >1.2) for baseline CRP (>upper limit of normal [ULN] vs ≤ULN; OR 1.346 [95% CI 0.668, 2.712]), DAS28 (CRP) (>5.1 vs ≤5.1; 1.489 [0.782, 2.836]), dactylitis (>0 vs 0; 1.372 [0.708, 2.659]), and median baseline erosions (≥3 vs <3; 1.924 [1.032, 3.587]). In placebo-treated pts, the OR was >1.2 for dactylitis only (1.406 [0.619, 3.193]). These factors, which have been identified previously as indicating poor prognosis in PsA, were balanced between treatment arms at baseline. In the univariate model by poor prognostic factors, the differences in ACR20 response rates with abatacept treatment vs placebo in distinct subgroups were numerically greater in pts who were positive for these prognostic factors at baseline than in those who were not (Figure).

Figure. Univariate Analysis of ACR20 Response Rate by Poor Prognostic Factors at Week 24

	Responders, n/N (%)		
	Abatacept	Placebo	Estimated difference (95% CI)
All patients	84/213 (39.4)	47/211 (22.3)	17.2 (8.7, 25.6)
CRP ≤ULN	19/66 (28.8)	16/78 (20.5)	8.3 (–5.9, 22.4)
CRP >ULN	64/146 (43.8)	31/131 (23.7)	20.2 (9.3, 31.0)
CRP ≤ULN and baseline erosion score <3	9/43 (20.9)	10/44 (22.7)	–2.4 (–19.1, 14.3)
CRP ≤ULN and baseline erosion score ≥3	9/22 (40.9)	4/30 (13.3)	25.0 (2.5, 47.5)
CRP >ULN and baseline erosion score <3	28/72 (38.9)	16/69 (23.2)	12.9 (–2.1, 27.9)
CRP >ULN and baseline erosion score ≥3	32/68 (47.1)	14/57 (24.6)	24.5 (8.8, 40.1)

DAS28 (CRP) >5.1	42/99 (42.4)	21/87 (24.1)	19.0 (6.0, 31.9)
No baseline dactylitis digits	46/137 (33.6)	29/144 (20.1)	13.2 (3.0, 23.3)
With baseline dactylitis digits	32/66 (48.5)	14/55 (25.5)	21.5 (5.0, 37.9)
Baseline erosion score <3	37/115 (32.2)	26/114 (22.8)	8.2 (–2.9, 19.3)
Baseline erosion score ≥3	42/91 (46.2)	18/88 (20.5)	26.3 (13.2, 39.3)

ULN=upper limit of normal

Conclusions: These findings identified subgroups of pts with PsA with certain baseline characteristics in whom abatacept is most likely to be effective. The predictive factors identified are aligned with poor prognostic factors in the EULAR and Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA) guidelines,[2,3] and may indicate pts with the highest unmet medical need.

SAT0469 INTEGRATED EFFICACY ANALYSIS OF TOFACITINIB, AN ORAL JANUS KINASE INHIBITOR, IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS

P. Nash[1], L.C. Coates[2], R. Fleischmann[3], K.A. Papp[4], J.J. Gomez-Reino[5], K.S. Kanik[6], C. Wang[6], J. Wu[6], T. Hendrikx[7], W.C. Ports[6]. *[1]Department of Medicine, University of Queensland, St Lucia, Brisbane, Australia; [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; [3]Metroplex Clinical Research Center and University of Texas Southwestern Medical Center, Dallas, TX, United States; [4]Probity Medical Research and K Papp Clinical Research Inc, Waterloo, ON, Canada; [5]Fundacion Ramon Dominguez, Hospital Clinico Universitario, Santiago de Compostela, Spain; [6]Pfizer Inc, Groton, CT; [7]Pfizer Inc, Collegeville, PA, United States*

Background: Tofacitinib is an oral Janus kinase inhibitor under investigation for treatment of psoriatic arthritis (PsA).

Objectives: To determine efficacy based on pooled data from 2 pivotal Phase 3 studies of tofacitinib in patients (pts) with active PsA.

Methods: Data were pooled from 2 placebo (PBO)-controlled, double-blind, multicentre, global Phase 3 studies (OPAL Broaden [N=422; 12 months; NCT01877668]; OPAL Beyond [N=394; 6 months; NCT01882439]). Pts had active PsA and either inadequate response (IR) to ≥1 conventional synthetic disease-modifying antirheumatic drug (csDMARD) and were tumour necrosis factor inhibitor (TNFi)-naïve (OPAL Broaden), or had IR to ≥1 TNFi (OPAL Beyond). Pts were randomised to tofacitinib 5 mg twice daily (BID), 10 mg BID, adalimumab 40 mg subcutaneous injection once every 2 weeks (OPAL Broaden only) or PBO, in addition to a single, stable background csDMARD. PBO pts advanced to tofacitinib 5 mg or 10 mg BID at Month (M)3. Endpoints included ACR20/50/70 response rates (≥20%, ≥50% and ≥70% improvement), change from baseline (Δ) in HAQ-DI (Health Assessment Questionnaire-Disability Index), HAQ-DI response (decrease from baseline [BL] of ≥0.35), PASI75 (≥75% improvement from BL in Psoriasis Area and Severity Index), ΔLEI (Leeds Enthesitis Index) and enthesitis absence, ΔDSS (Dactylitis Severity Score) and dactylitis absence and ΔDLQI (Dermatology Life Quality Index). Pooled data only included tofacitinib 5 mg and 10 mg BID (to M6) and PBO (to M3). Significance was declared for $p \leq 0.05$ without correction for multiplicity.

Results: For pooled data, pts were predominantly white (94.2%) and female (55.4%) with ≥5 peripheral swollen or tender joints (98.0%), enthesitis (LEI>0; 67.5%), dactylitis (DSS>0; 52.5%), psoriatic body surface area ≥3% (67.7%) and CRP levels above the upper limit of normal (>2.87 mg/L; 62.5%) at BL. Mean age was 49.1 years and PsA duration was 8.0 years. Significant improvements vs PBO at M3 were observed for peripheral arthritis and physical function endpoints for tofacitinib 5 mg and 10 mg BID: ACR20, ACR50, ACR70, ΔHAQ-DI (least squares mean [LSM]), and HAQ-DI response (Table 1). Significant improvements in psoriasis, enthesitis and dactylitis endpoints vs PBO were also observed for tofacitinib 5 mg and 10 mg BID at M3: PASI75, ΔLEI, enthesitis absence based on LEI, ΔDSS (LSM), dactylitis absence based on DSS and ΔDLQI (Table 1). Efficacy was maintained or further improved at M6.

Table 1. Efficacy endpoints at Month 3 and Month 6; pooled data from OPAL Broaden and OPAL Beyond (Full Analysis Set[a])

Nominal *p≤0.05; **p<0.001; ***p<0.0001 vs placebo at M3

[a]All randomised patients who received ≥1 dose of study medication; [b]p values not calculated at M6 as the placebo-controlled period ended at M3; [c]primary endpoint in each individual study at M3; [d]among patients with baseline HAQ-DI ≥0.35 (analysis at M6 not performed); [e]among patients with baseline BSA ≥3% and baseline PASI >0; [f]among patients with baseline score >0

Large sample approximation to the difference in binomial proportions was used to analyse ACR20/50/70, HAQ-DI response, enthesitis absence, dactylitis absence and PASI75; missing response considered as non-response. ΔHAQ-DI, ΔLEI, ΔDSS, and ΔDLQI were analysed with a mixed model for repeated measures without imputation for missing values

Δ, change from baseline; ACR20/50/70, American College of Rheumatology ≥20/50/70% improvement; BID twice daily; BSA, body surface area; DLQI, Dermatology Life Quality Index; DSS, Dactylitis Severity Score; HAQ-DI, Health Assessment Questionnaire-Disability Index; LEI, Leeds Enthesitis Index; LSM, least squares mean; M, Month; N, number of patients in the Full Analysis Set; n, number of patients with response; N1, number of patients evaluable at a visit; N2, number of patients included in the model; N3, number of patients evaluable at a visit (denominator); PASI, Psoriasis Area and Severity Index; PASI75, ≥75% improvement from baseline PASI; SE, standard error

Conclusions: In a pooled analysis of csDMARD-IR/TNFi-naïve and TNFi-IR pts, tofacitinib 5 mg and 10 mg BID were superior to PBO at M3 across four PsA disease domains: peripheral arthritis, psoriasis, enthesitis and dactylitis.

SAT0470 SECUKINUMAB PROVIDES SUSTAINED IMPROVEMENTS IN THE SIGNS AND SYMPTOMS OF ACTIVE PSORIATIC ARTHRITIS: 3-YEAR EFFICACY AND SAFETY RESULTS FROM PHASE 3 FUTURE 1 TRIAL

P.J. Mease[1], A. Kavanaugh[2], A. Reimold[3], H. Tahir[4], J. Rech[5], S. Hall[6], P. Geusens[7,8], P. Pascale[9], E.M. Delicha[9], L. Pricop[10], S. Mpofu[9] on behalf of the FUTURE 1 study group. *[1]Swedish Medical Centre and University of Washington, Seattle; [2]UC San Diego School of Medicine, la Jolla; [3]University of Texas Southwestern Medical Center, Dallas, United States; [4]Barts Health NHS Trust, London, United Kingdom; [5]University of Erlangen-Nuremberg, Erlangen, Germany; [6]Monash University, Melbourne, Australia; [7]University of Hasselt, Hasselt, Belgium; [8]Maastricht University Hospital, Maastricht, Netherlands; [9]Novartis Pharma AG, Basel, Switzerland; [10]Novartis Pharmaceuticals Corporation, East Hannover, United States*

Background: Secukinumab significantly improved the signs and symptoms of psoriatic arthritis (PsA) over 2 years (yrs) in the FUTURE 1 study.[1]

Objectives: To report efficacy and safety of secukinumab through 3 yrs in an extension of the FUTURE 1 study (NCT01892436).

Methods: After 2-yr core trial, patients (pts) receiving secukinumab 150/75mg s.c. entered the 3-yr extension phase. Efficacy results at Week (Wk) 156 are presented for those pts originally randomised to secukinumab (n=308) and included ACR20/50/70, PASI 75, DAS28-CRP, SF-36 PCS, HAQ-DI, dactylitis and enthesitis. Multiple imputation was used for analysis of binary variables while continuous variables are reported as observed. Analyses by anti-TNF status (naïve/inadequate response) were prespecified and reported as observed. Safety analysis included all pts (n=587) who received ≥1 dose of secukinumab.

Results: Overall, 457 of the original 606 pts entered the extension study of which 435 (95.2%) pts completed 156 wks (151 [93.8%] pts in IV→150 mg group; 142 [96.6%] in IV→75 mg group; 142 [95.3%] in PBO→ secukinumab groups). Sustained clinical improvements through Wk 156 were observed across all endpoints and were seen regardless of prior anti-TNF use (Table 1). Over

Abstract SAT0470 – Table 1. Summary of efficacy results at Week 156

Variables	Secukinumab IV→150 mg (n=161)	Secukinumab IV→75 mg (n=147)
ACR 20/50/70[a], % responders	77/55/33	65/39/26
PASI 75[a,b], % responders	76	59
DAS28-CRP[c], mean change (SD)	–1.9 (1.3)	–1.9 (1.5)
HAQ-DI[c], mean change (SD)	–0.43 (0.6)	–0.42 (0.6)
Resolution of dactylitis[a,d] (%)	88.1	86.8
Resolution of enthesitis[a,d] (%)	76.7	74.8

Analysis by anti-TNFα status[c]

	Anti-TNFα-naïve		Anti-TNFαIR	
	Secukinumab IV→150 mg (n=120)	Secukinumab IV→75 mg (n=110)	Secukinumab IV→150 mg (n=41)	Secukinumab IV→75 mg (n=37)
ACR20/50/70	81/63/39	67/43/28	62/36/18	56/28/19
PASI 75	76	60	75	56

[a]Multiple imputation (missing binary variables). [b]Analysis performed in pts with psoriasis ≥3% body surface area at time of randomisation (n=89 and n=82 in secukinumab IV→150 and IV→75 mg, respectively). [c]Observed data. [d]Data from the pts with these symptoms at BL (dactylitis, n=83 in secukinumab IV→150 mg and n=77 in secukinumab IV→75 mg and enthesitis, n=99 in secukinumab IV→150 mg and n=91 in secukinumab IV→75 mg). n, number of pts in the extension study.

the entire study period (mean [±SD] exposure to secukinumab of 1025.1±372.7 days), the exposure-adjusted incidence rate with secukinumab for serious infections/infestations, candida infections, Crohn's disease, and malignant/unspecified tumors was 1.7 (27), 1.2 (17), 0.1 (2), and 0.9 (14) per 100 pt-yrs, respectively.
Conclusions: Secukinumab provided sustained improvements in signs/symptoms and across multiple clinical domains of active PsA in pts who completed 3 yrs of therapy. Secukinumab was well tolerated with a favorable safety profile consistent with that previously reported.[1]

SAT0471 TRENDS IN CLINICAL CHARACTERISTICS ASSOCIATED WITH ACHIEVEMENT OF MINIMAL DISEASE ACTIVITY IN RESPONSE TO BIOLOGIC THERAPY IN PSORIATIC ARTHRITIS – ANALYSES FROM THE CORRONA PSORIATIC ARTHRITIS/SPONDYLOARTHRITIS (PSA/SPA) REGISTRY

P.J. Mease[1], C. Karki[2], M. Liu[2], A. Kavanaugh[3], C.T. Ritchlin[4], D.H. Hunyh[5], R. Pandurengan[2], J.B. Palmer[6], J.D. Greenberg[2,7]. *[1]Seattle Rheumatology Associates, Seattle, WA; [2]Corrona, LLC, Southborough, MA; [3]University of California San Diego, San Diego, CA; [4]University of Rochester, Rochester, NY; [5]Scripps Institute, la Jolla, CA; [6]Novartis, East Hanover, NJ; [7]New York University School of Medicine, New York, NY, United States*

Background: Achievement of minimal disease activity (MDA) may represent an objective target for treatment for patients with psoriatic arthritis (PsA).[1] A patient is considered to have achieved MDA when 5 of the following 7 criteria are met: tender joint count (TJC) ≤1, swollen joint count (SJC) ≤1, affected body surface area (BSA) ≤3%, patient pain VAS ≤15, patient global activity VAS ≤20, HAQ score ≤0.5 and tender entheseal points ≤1.[1]
Objectives: To retrospectively report the MDA and patient-reported outcomes (PROs) over time (baseline vs first follow-up [FU] visit vs second FU visit) that may contribute to achievement of MDA in responders versus non-responders to biologic treatment.
Methods: This analysis included all patients with PsA in the Corrona registry aged ≥18 years between March 2013 and March 2016 who received biologics (index biologics) at enrollment (baseline) and had ≥2 FU visits (at ≈ 6-month intervals, mean [SD] 2nd FU visit: 15.7 [3.7] months). Responders were defined as patients who achieved MDA at the second FU visit and remained on their index biologic. Demographics, clinical characteristics, PROs and treatment history were collected at enrollment and at both FU visits. Trend tests of MDA over time were performed using the Wilcoxon rank-sum nonparametric test for responders and non-responders separately.
Results: Of 148 patients who met the inclusion criteria (mean [SD] age, 54.7 [11.0] years; mean [SD] disease duration, 11.8 [10.1] years), 34 patients (23%) were classified as responders and 114 patients (77%) were non-responders at the second FU visit. The core components of MDA in these patients are shown in Table 1. Among responders, there were significant improvements in clinical characteristics and PROs such as mean TJC (3.4 vs 2.1 vs 0.6; P=0.004), SJC (2.5 vs 0.8 vs 0.5; P<0.0001), percentage of affected BSA (5.6% vs 2.4% vs 1.4%; P=0.03), patient pain (34.7 vs 26.1 vs 21.9; P=0.007) and HAQ scores (0.6 vs 0.4 vs 0.3; P=0.04); however, there were no significant changes over time for patient global assessment or enthesitis counts (P>0.05). Non-responders failed to have a significant improvement from baseline to the first and second FU visits in TJC, SJC, enthesitis, pain, patient global assessment and percentage of affected BSA (all P>0.05).
Conclusions: Only 23% of patients achieved MDA on their index biologic at the second FU visit and were considered responders. Over time, responders showed significant improvements in TJC and SJC, percentage of affected BSA, patient pain and HAQ scores; these most likely contributed to achievement of MDA response. A treat-to-target approach may be considered given the low number of patients in MDA.

SAT0472 UTILIZATION OF THE PSORIASIS EPIDEMIOLOGY SCREENING TOOL TO IDENTIFY SIGNS AND SYMPTOMS OF EARLY PSORIATIC ARTHRITIS AMONG THOSE WITH PSORIASIS: ANALYSIS FROM THE CORRONA PSORIASIS REGISTRY

P.J. Mease[1], J.B. Palmer[2], M. Lebwohl[3], C. Karki[4], G.W. Reed[4,5], C.J. Etzel[4,6], J.D. Greenberg[4,7], P.S. Helliwell[8]. *[1]Swedish Medical Center and University of Washington, Seattle; [2]Novartis Pharmaceuticals Corporation, East Hanover; [3]Icahn School of Medicine at Mount Sinai, New York; [4]Corrona, LLC, Southborough; [5]University of Massachusetts Medical School, Worcester; [6]The University of Texas MD Anderson Cancer Center, Houston; [7]New York University School of Medicine, New York, United States; [8]University of Leeds, Leeds, United Kingdom*

Background: The Psoriasis Epidemiology Screening Tool (PEST) is a 5-item questionnaire developed to help identify psoriatic arthritis (PsA) at an early stage, with a score ≥3 indicative of PsA.[1] A recent Korean study found that a PEST score of 2 may be a more favorable cutoff for screening patients with psoriasis (PsO).[2]
Objectives: To assess the risk of undiagnosed PsA among patients with PsO and characterize patients based on PEST scores in a US cohort.
Methods: This study included all patients enrolled in the Corrona PsO Registry with data on all 5 PEST questions. Demographics, disease characteristics, patient-reported outcomes (PROs) and medication use were analyzed at the time of enrollment and stratified by PEST score (0, 1, 2 or ≥3). Pairwise comparisons were made between PEST score =0 (reference) and other PEST score groups using t-tests for continuous variables and χ^2 tests for categorical variables.
Results: As of June 2016, 99.1% (1516/1529) of patients in the Corrona PsO Registry had data on all 5 PEST questions; 612 patients (40.4%) had dermatologist-reported PsA at enrollment. Among the remaining 904 patients, 421 patients (46.6%) had a PEST score =0, 225 (24.9%) had a PEST score =1, 146 (16.2%) had a PEST score =2 and 112 (12.4%) had a PEST score ≥3. Of patients with a PEST score ≥3, patients most commonly answered "yes" to "have you ever had a swollen joint (or joints)?" (89%) and "has a doctor ever told you that you have arthritis?" (86%). Compared with patients with a PEST score =0, patients with a PEST score ≥1 all had a higher BMI, longer duration of PsO, increased family history of PsA, increased prevalence of nail PsO and worse EQ-VAS at enrollment (all P<0.05; Table 1). In addition, patients with PEST scores ≥2 were older, more likely to be female, less likely to be employed and had an increased family history of PsO, worse pain and fatigue, worse dermatology-related quality of life and higher percentage impairment of daily activities due to psoriasis at enrollment vs patients with a PEST score =0 (all P<0.05). There were no significant differences across PEST scores in affected body surface area or PASI scores.
Conclusions: In this cohort of PsO patients with no diagnosis of PsA, patients with PEST scores ≥2 were significantly different from those with PEST scores =0

Table 1. Baseline characteristics of patients with PsO and no diagnosis of PsA stratified by PEST score (0-5)

Characteristic*	PEST Score = 0 n = 421	PEST Score = 1 n = 225	PEST Score = 2 n = 146	PEST Score ≥ 3 n = 112
Age, years	48.0 (15.5)	48.5 (14.9)	53.7 (13.8)†	52.9 (14.4)†

Background: Few studies have analized the persistence of ultrasound (US) abnormalities in patients (pts) with Psoriatic Artritis (PA) during the phase of minimal disease activity (MDA)

Objectives: To investigate the prevalence of US alterations at enthesis, joint and tendon levels in pts with psoriatic arthritis (PA) during a phase of MDA.

Methods: Pts treated with anti-tumor necrosis factor (TNF) for at least 12 months and with at least 6 months duration of MDA were consecutively recruited at 6 Italian centers. In every center, the local rheumatologists provided PA pts to be examined by US. Personal history, demographic and clinical data were recorded. Each patient underwent the following US examinations: metacarpophalangeal (MCP), knee and tibio-tarsal (TT) joint, flexor and extensor tendon of hand digit, flexor and extensor tendon at carpal area, flexor and extensor tendon of foot, and enthesis of common extensor tendon insertion on the lateral epicondyle of the humerus, quadriceps tendon, patellar tendon, Achilles tendon and plantar fascia insertions on the calcaneus. Each examination were performed by rheumatologists expert in US, to assess synovitis (joint effusion, synovial proliferation, and power Doppler (PD) signal), and bone erosions, flexor tendon tenosynovitis, hand finger extensor tendon tenonitis, and enthesel involvement using an Esaote MyLabClass with a 5–13 or 6–18 MHz linear probe. The following elementary lesions were assessed at each enthesis: morphologic abnormalities (hypoechogenicity and/or thickening), entheseal calcific deposits, cortical abnormalities (bone erosion and/or proliferation), adjacent bursitis and intraenthesis and perienthesis (tendon body and/or bursa) PD signal. All US findings were scored using a 4 degree semiquantitative scoring system. US acute enthesitis was defined by the presence of entheseal edema or PD signal. US chronic entheseal alterations by the presence of calcifications, erosions, or enthesophytes. US peripheral active synovitis if synovial hypertrophy was associated with the presence of PD signal. US examinator were blind of clinical data of the pts.

Results: Sixty-three pts were recruited (mean age 53±13y, mean PA duration 13±8y, mean MDA duration 21±11m). At US examination 66.7% of pts had at least one peripheral joint involved (17.5% had peripheral active synovitis), 47.6% had acute enthesitis and 95.2% chronic enthesopathy. US bursitis was present in 22.2% of pts, 3.7% had hand extensor finger tendon involvement.

Table 1 shows clinical and demographical data of the pts and table 2 the US results

	Nail involvement	Previous dactylitis	FamHyst	IBP
Patients with abnormality (%)	28.3	42.9	23.9	19.7

Table 2. US abnormalities in 63 pts in MDA

	Perypheral active sinovitis	Joint peripheral involvement	Chronic entheseal alterations	Acute entheseal alterations	Tenosynovitis
Patients with abnormality (%)	17.5	66.7	95.2	47.6	29.6

Conclusions: Joint, entheseal and tendon abnormalities have a high prevalence in PA patients treated with anti-TNF during MDA.

SAT0474 VERY LOW DISEASE ACTIVITY AND IMPACT OF DISEASE IN A SPANISH POPULATION WITH PSORIATIC ARTHRITIS

R. Queiro, J.D. Cañete, C. Montilla, M.A. Abad, S. Gómez, A. Cábez.
Rheumatology, Hospital Universitario Central de Asturias, Oviedo, Spain

Background: The target of treatment in psoriatic arthritis (PsA) should be remission or inactive disease. A potential definition that would fit with the Treat-to-Target Recommendations would be MDA meeting all 7 criteria[1], proposed as a definition of very low disease activity (VLDA) in PsA. Patient reported outcomes (PROs), such as those provided by the novel PsAID questionnaire [2], are also important to evaluate healthcare interventions and to reflect the impact of PsA on patients' lives.

Objectives: The aims of the present study were to evaluate the prevalence of VLDA in patients with PsA and how much residual active disease is still present, so as to determine whether PsAID could be an additional useful tool to assess PsA interventions in clinical practice.

Methods: This was a post-hoc analysis of data from a cross-sectional observational and multicenter study (MAAPS), aimed at evaluating the prevalence of MDA in a Spanish population with PsA, to describe their characteristics and to evaluate the association between MDA and the impact of the disease as assessed by the PsAID questionnaire in routine clinical practice The original study included adult patients of both genders diagnosed with PsA according to CASPAR criteria with at least one year of evolution time of disease and on treatment with biological and/or conventional synthetic disease modifying anti-rheumatic drugs (cDMARD). Patients were considered in VLDA when they met all the MDA criteria[1]: tender joint count $\leq$1, swollen joint count $\leq$1, Psoriasis Area Severity index (PASI) score $\leq$1 or body surface area $\leq$3%, patient pain visual analog scale (VAS) score $\leq$15, patient global disease activity VAS score $\leq$20, Health Assessment Questionnaire (HAQ) score $\leq$0.5, and tender entheseal points $\leq$1. Patient acceptable symptoms state (PASS) has been defined as a PsAID value $<$4.

Results: 227 patients were included, 133 (58.6%) in MDA state and 58 (25.6%) in VLDA state. VLDA patients suffered from a mild impact of the disease according to PsAID: the majority (82.5%) had a PsAID score $<$4 and a mean total score (SD) of 2.1 (2.6) IC95% [1.55–2.64], while, 66.7% of MDA patients had a PsAID score $<$4 and a mean total score (SD) of 3.3 (3.1) IC95% [2.82–3.87]. Disability, as measured by HAQ was greater in MDA patients (mean (SD) 0.3 (0.5) IC95% [0.21–0.43]) than in those who reached VLDA state (mean (SD) 0.2 (0.3) IC95% [0.11–0.25].

Conclusions: 26% of Spanish PsA patients achieve VLDA state in routine clinical practice. PsA patients who reached this state also had a very low impact of disease according to PsAID. VLDA state could represent a situation of clinical remission in PsA.

SAT0475 RECENT ONSET PSORIATIC ARTHRITIS: BASELINE DATA FROM THE REAPSER STUDY

R. Queiro, A. Laiz Alonso, H.S. Park, C. Montilla Morales, E. Galíndez Agirregoikoa, J.J. Bethencourt Baute, S. Bustabad Reyes, P. Tejón Menéndez, M.Á. Belmonte, J.A. Pinto Tasende, E.A. Blanco Morales, J. Ramír.
Rheumatology, Hospital Universitario Central de Asturias (Coordinating Center), Oviedo, Spain

Background: The natural history of psoriatic arthritis (PsA) is very little known and the information regarding prospective cohorts is very scarce worldwide, including our country. REAPSER (Spanish Rheumatology Society Registry of Psoriatic Arthritis) is the first registry of Spanish patients with recent onset PsA.
Objectives: To describe the baseline characteristics of patients included in the REAPSER cohort.
Methods: Observational, multicentric study (34 centers), with consecutive inclusion. We included adults of both sexes 18 years of age or older with PsA that met CASPAR criteria, and duration of less than two years since the appearance of symptoms attributed to PsA. Annual follow-up visits will be carried out for 5 years. Measurements: socio-demographic data; employment status and impact of the disease; family history of PsA and other inflammatory diseases; comorbidities and treatment; lifestyle; use of health services; clinical status at the time of diagnosis of PsA; anthropometric data; clinical evaluation of PsA manifestations; radiographic evaluation; analytical determinations; treatment of PsA. The study has been approved by the ethical committees of the participating centers.
Results: Two hundred and fifteen consecutive patients were included, mean age 49.8±13.9 years.

Baseline characteristics of the cohort

Parameter	N: 215
Men	67.4%
Women	32.6%
Active worker	59.5%
Unemployed	12.1%
Retired/pensioner	17.7%
Job change last year	4.7%
University studies	20%
Smoking	30.2%
BMI	27.7±5.2
Weekly alcohol consumption	0 SDU (0–4)
Family history of psoriasis	41.4%
Family history of PsA	9.3%
Family history of other arthritis	6.5%
Charlson's Comorbidity Index	0: 46.5%. 1–2: 35.3%. 3–4: 14.4%. >4: 3.8%
Psoriasis at baseline	88%
PASI	1.5 (0.6–4.3)
Joint pattern	Peripheral: 81.5%. Axial: 5.2%. Mixed: 13.3%
TJC68	4 (2–8)
SJC66	2 (1–4)
BASDAI	3.9 (3–4.4)
Dactylitis	41.9%
Enthesitis	25%
Uveitis	0.5%
Pain	5 (3–7)
Patient's global disease activity	5 (3–7)
PsAID	3.8 (1.8–6)
Steinbrocker Index (0–168)	0 (0–4)
Cardiovascular events	5.7%
HLA-B27	12.3%
ESR	13 (6–25)
NSAIDs	75%
GC	28.3%
Synthetic DMARDs	53.2%
Biological DMARDS	1.5%

Values are expressed as percentages, means with standard deviation and medians with their IQR (interquartile range). SDU: Standard Drink Units. PsAID: Psoriatic Arthritis Impact of Disease.
Conclusions: The baseline situation of Spanish patients with newly diagnosed PsA corresponds to that of a disease with slight cutaneous involvement and predominance of oligoarticular arthritis. Unsurprisingly, structural damage is scarce but not zero. The impact of the disease is still low in these early stages, however 18% of patients have a high Charlson's comorbidity index (>3) and almost 5% of patients have had to change their employment status in the last year due to its PsA.

SAT0476 DEMOGRAPHIC, CLINICAL, AND LABORATORY CHARACTERISTICS OF ELDERLY ONSET PSORIATIC ARTHRITIS

S. Kobak[1], M. Orman[2]. *[1]Rheumatology, Istinye University Faculty of Medicine, LIV Hospital, Istanbul; [2]Statistics, Ege University Faculty of Medicine, Izmir, Turkey*

Background: Psoriatic arthritis (PsA) is a chronic inflamatory disease characterized with axial and peripheral joints involvement. It is rarely affects patients older than 65 years old.
Objectives: The purpose of this study is to compare and evaluate the demographic, clinical and laboratory features of elderly-onset psoriatic arthritis (EOPsA) and young-onset (YOPsA) patients.
Methods: One hundred and eighty patients diagnosed with PsA according to CASPAR criteria and followed-up in single center were included in this study. The patients with initial symptoms started after age 65 were accepted as EOPsA. Demographic, clinical, and laboratory data and the medications which the patients recieved were recorded and retrospectively evaluated.
Results: Nineteen (10.5%)of 180 patients were diagnosed as EOPsA, and 161 (89.5%) patients were evaluated as YOPsA. Mean patient age was 42.1years for YOPsA group and 68.3years for elderly onset group. Mean duration of disease was 5.6 years for early onset group and 1.3 years for elderly onset group (p=0.001). Fourteen (73.3%) of 19 EOPsA patients were female and 5 of them were male. Higher rates of fatique, pain scores, comorbid diseases and acute phase reactants were detected in EOPsA patients comparing to YOPsA (p=0.000, p=0.000, p=0.001 and p=0.001 respectively). YOPsA patients have more dactilitis, nail involvement, elevated PASI scores, and smoking habitus when compared with EOPsA patients (p=0.019, p=0.03, p=0.005, p=0.004 respectively). In terms of the treatment options chosen, there was no significant difference in the use of non-steroidal anti-inflammatory drugs (NSAIDs), corticosteroids (CS), methotrexate (MTX), and sulfasalazine (SSL), but there was a more frequent use of anti-tumor necrosis factor -alpha in YOPsA group.
Conclusions: Herein we showed that YOPsA and EOPsA patients may have different demographic, clinical, and laboratory features. EOPsA patients are characterized with higher rates of fatique, pain scores, comorbid diseases, and acute phase reactants and less dactilitis, nail involvement and anti-TNF-alpha usage.

SAT0477 THE COMPARISON OF ULTRASOUND SYNOVITIS AND ENTHESITIS FINDINGS AND CLINICAL FINDINGS IN PATIENTS WITH PSORIATIC ARTHRITIS AND SKIN PSORIASIS

T. Okano[1], K. Inui[1], Y. Sugioka[2], K. Mamoto[1], H. Yoshimura[1], T. Koike[2,3], H. Nakamura[1]. *[1]Department of Orhopedic surgery; [2]Center for Senile Degenerative Disorders (CSDD), Osaka City University Graduate School of Medicine, Osaka; [3]Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama Foundation for Health and Welfare, Wakayama, Japan*

Background: Conventionally, the assessment of affected joint count in patients with psoriatic arthritis (PsA) was relied for the detection of swelling and tenderness in the joints and enthesis by clinical physical assessment. To date, the modern imaging tool such as ultrasound (US) can detect inflammation in the joint and enthesis more sensitively than clinical assessment.
Objectives: The aim of this study was to research the prevalence of US syovitis and enthesitis findings in patients with PsA and psoriasis (PsO) comparing with clinical assessment.
Methods: Total 100 patients, 54 patients with PsA and 46 patients with PsO, were consecutively included. HI VISION Ascendus (HitachiAloka Medical, Tokyo, Japan) was used with a 18-MHz linear array transducer. US examination was performed in MCP, PIP, DIP and wrist joints in both hand. Grayscale (GS) and power Doppler (PD) US were scored on a 0–3 semiquantitative scale for each joint. Moreover, the US assessment of enthesis was performed. Lateral epicondyle, triceps enthesis, the proximal and distal patella tendon enthesis, Achilles tendon and fascia plantaris tendon enthesis was scanned in both GS and PD assessment. Abnormal findings of enthesis was defined structure thickness, bursitis erosion, calcification and power Doppler signal.
Results: US synovitis was found in 81.5% (n=44) and 60.9% (n=28) by GS, 66.7% (n=36) and 45.7% (n=21) by PD assessment, respectively in patients with PsA and PsO. Active synovitis (GS grade ≧ 2 and/or PD grade ≧ 1) was found

	PsA (n=54)	PsO (n=46)	P value
Male (%)	26 (48.1%)	26 (56.5%)	0.429
Age (years)	55.4±15.0	57.5±15.3	0.508
Height (cm)	161.6±9.8	161.6±9.5	0.969
Weight (kg)	62.7±15.5	63.1±13.9	0.905
BMI	23.8±3.9	24.0±3.6	0.883
Duration of psoriasis (years)	15.6±13.6	17.5±19.7	0.584
PASI	11.7±13.4	8.9±7.5	0.432
PASE	45.8±14.6	29.8±11.9	<0.001
Active US synovitis (GS≥2, PD≥1)	37 (68.5%)	21 (45.7%)	0.026
US enthesitis (any pathological findings)	47 (87.0%)	26 (56.5%)	<0.001

68.5% (n=37) in PsA and 45.7% (n=21) in PsO. US synovitis was more frequently found than clinical assessment. The most common sites of inflammatory synovitis were the wrist. US enthesopathy was found in 87.0% (n=47) in patients with PsA 56.5% (n=26) in patients with PsO. US enthesitis was also more frequently found than clinical assessment. The most common sites of enthesopathy were the enthesis in lateral epicondyle, quadriceps and Achilles tendon.

Conclusions: Our results showed that US was able to detect a high prevalence of inflammatory synovitis in peripheral joints and enthesis in patients with PsA. Moreover, subclinical inflammatory findings were also found in patients with PsO by US. US examination is useful to detect the inflammatory condition in patients with PsA and PsO than clinical examination.

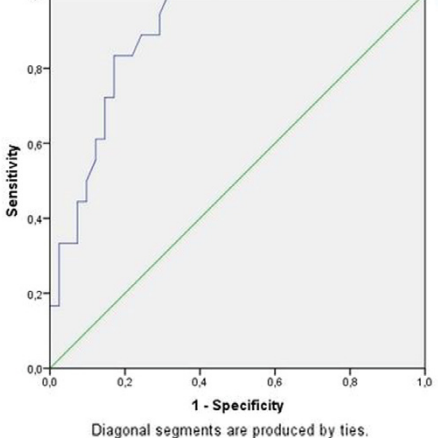
SAT0478 RAPID3 QUESTIONNAIRE HAS HIGH DISCRIMINATING ABILITY IN MINIMAL DISEASE ACTIVITY ATTAINMENT IN PATIENTS WITH EARLY PSORIATIC ARTHRITIS TREATED ACCORDING TO TIGHT CONTROL STRATEGY IN DAILY CLINICAL PRACTICE (RESULTS OF ONE-YEAR OPEN-LABEL REMARCA STUDY)

T. Korotaeva, E. Loginova, A. Koltakova, L. Denisov, M. Chamurlieva, D. Karateev, E. Nasonov. *V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: RAPID3 is an instrument based on patient's report outcomes (PROs) for the assessment of remission and disease activity in rheumatoid arthritis. The advantages of this questionnaire in treat-to-target (T2T) strategy in early psoriatic arthritis (EPsA) have not been studied properly.



Objectives: to study discriminating ability of RAPID3 in minimal disease activity (MDA) attainment in patients with EPsA treated during one year according to tight control strategy.

Methods: 61 (M/F–29/32) patients (pts) with active EPsA, according to CASPAR criteria, mean age 37±10.6 years, PsA duration 11.3±10.2 months, psoriasis duration 75.4±80.9 months were included. All pts signed a consent form for participation in the open-label REMARCA study. At baseline and after 1year (yr.) of therapy all pts underwent evaluation of PsA activity by Tender Joint count (TJC78), Swollen Joint Count (SJC76), physician's global disease activity (PhGA) VAS, DAS, CRP (mg/l) and by PROs - patient pain global assessment VAS, Patient global disease activity (PGA) VAS, Health Assessment Questionnaire (HAQ) and RAPID3. The dose of Methotrexate (MTX) subcutaneous (s/c) was escalated by 5 mg every 2 weeks from 10 mg/wk up to 20–25 mg/wk. If pts did not achieve MDA after 3–6 months of MTX mono-therapy, combination therapy (CoT) of MTX+Adalimumab (ADA) was started in a standard regime; CoT was continued up to 1 yr. The proportion of pts who achieved MDA was calculated. M±SD, Me [Q25;Q75], %, Spearman rank correlation R, W-test, U-test, ROC-curve analysis were performed. All $p<0.05$ were considered to indicate statistical significance.

Results: By 1 yr. of therapy 36 out of 61 pts (59%) and 25 out of 61 pts (41%) were treated with MTX and with MTX+ADA accordingly. Significant improvements in PsA activity and PROs from baseline up to 1 yr. were observed: DAS 3.93 [3.20–4.58]/1.36 [0.82–2.25], SJC 7 [5–11]/1 [0–3], TJC 8 [6–1]/1 [0–3], PhGA 56 [48–69]/10 [5–20] and VAS pain 54 [48–68]/11 [1–20], PGA 55 [49–68]/14 [7–24], HAQ 0.75 [0.50–1]/0 [0–0.63] accordingly (for all W-test $p<0.001$). Significant positive correlations between RAPID3 and PsA activity, PROs and CRP are shown in table 1 (for all R $p<0.001$).

MDA was seen in 43 out of 61% pts (70.5%). At the same time RAPID3 and CRP significantly decreased from 12.7 [9.2–16.8] to 4.3 [2.0–7.8] and from 16.6 [8.6–34.6] to 2.1 [0.9–6.7] mg/l accordingly (for all W-test, $p<0.001$). Among those who have achieved MDA RAPID3 was in "near remission" status and significantly less compared to pts that did not achieve MDA-2.5 [1.3–5.3] and 8.1 [6.0–15.1] accordingly (U-test, $p<0.001$). According to the results of ROC-curve analysis RAPID3 score had a high discriminating ability for the presence of MDA - AUC 0.888 [0.808–0.969] (Fig. 1).

ROC-curve analysis: association of RAPID-3 values and presence of MDA

Diagonal segments are produced by ties.

Parameters	R
DAS	0.74
TJC78	0.68
SJC76	0.63
PGA VAS	0.82
Pain VAS	0.83
PtGA VAS	0.81
CRP	0.69

Conclusions: RAPID3 based on PROs is a simple instrument for evaluating PsA activity. RAPID3 has shown high discriminating ability in MDA attainment in EPsA pts treated according to tight-control strategy, and could be useful in daily clinical practice.

SAT0479 INCREASED CAROTID INTIMA-MEDIA THICKNESS CAN DISCRIMINATE SIGNIFICANT CORONARY ARTERY STENOSIS BY CORONARY CT ANGIOGRAM IN PATIENTS WITH PSORIATIC ARTHRITIS

T.H. Cheng[1], Q. Shang[1], E.K.M. Li[1], K.T. Wong[2], A.P.W. Lee[1], C.C. Szeto[1], L.S. Tam[1]. *[1]Department of Medicine and Therapeutics, the Chinese University of Hong Kong; [2]Department of Diagnostic and Interventional Radiology, The Prince of Wales Hospital, Hong Kong, Hong Kong*

Background: PsA patients have increased morbidity & mortality due to cardiovascular disease (CVD). However, their CV risk were underestimated by various CV risk score[1]. Subclinical carotid atherosclerosis may be considered as surrogate marker of coronary artery disease (CAD) in the general population[2]while it remained uncertain for PsA patients

Objectives: To assess the relationship between carotid artery disease by ultrasound (US) and CAD by coronary computed tomography angiography (CCTA) and identify US parameters predictive of significant CAD

Methods: 91subjects (56 males; age: 50±11 years; disease duration 9.4±9.2 years) without overt CVD who underwent CCTA & carotid US (interval between two exams:2 [1–7] months) were recruited. Carotid intima-media thickness (cIMT)& the presence of plaque were determined by high resolution US in the distal CCA, bulb & proximal ICA bilaterally. Significant coronary artery stenosis was defined as stenosis of the lumen >50%

Results: Carotid plaque was present in 33 (36%) patients & coronary plaque was present in 55 (60%) patients while 9 (10%) patients had significant coronary artery stenosis. 36 (40%) patients had non-zero calcium score (CAC+ group).The mean cIMT was significantly higher in CAC+ group compared to CAC=0 group [0.70±0.11mm vs0.64±0.11mm, p=0.031]. There was a trend suggesting the mean cIMT increases with increasing CAC score, while the prevalence of carotid plaque increased significantly with rising calcium score (Table1). The mean cIMT increased significantly with number of coronary vessels habouring plaque, while there was a trend suggesting the max cIMT and the prevalence of carotid plaque may increase in patients with rising number of coronary vessels harboring plaques The mean & max cIMT were significantly higher in SS+ group than SS- group [mean cIMT: 0.76±0.07mm vs0.65±0.12mm, p=0.011; max cIMT: 0.93±0.14mm vs 0.80±0.16mm, p=0.020] (Table1). The prevalence of carotid plaque was similar between SS+ & SS- group [29 (35.4%) vs 4 (44.4%), p=0.421]. Using multivariate logistic regression, mean & max cIMT were independent explanatory variable of significant coronary stenosis after adjusting age, gender, disease duration & damaged joint count. The OR of significant coronary stenosis of every 0.01mm increase in mean & max cIMT were 1.07 (95% CI: 1.00–1.15, p=0.042) and 1.06 (95% CI: 1.00–1.11,p=0.036). Mean cIMT of 0.66mm was the optimal cut off

	Coronary Artery Calcium (Agatston Score)						
	Normal (CAC=0) (n=55)		Minimal-mild (1-399) (n=25)		Severe (400+) (n=11)		p
Mean carotid IMT, mm	0.64 ± 0.11		0.70 ± 0.13		0.70 ± 0.07		0.099
Maximum carotid IMT, mm	0.79 ± 0.16		0.84 ± 0.16		0.86 ± 0.15		0.223
Carotid Plaque, n, %	16	29.1%	10	40.0%	7	63.6%	0.031
	Number of coronary artery with any plaques						
	0 (n=36)		1-2 (n=43)		3 (n=12)		p
Mean carotid IMT, mm	0.63 ± 0.12		0.68 ± 0.11		0.69 ± 0.08		0.029
Maximum carotid IMT, mm	0.77 ± 0.17		0.83 ± 0.17		0.83 ± 0.15		0.065
Carotid Plaque, n, %	10	27.8%	16	37.2%	6	58.3%	0.068
	Significant coronary artery stenosis						
	No (n=82)				Yes (n=9)		p
Mean carotid IMT, mm	0.65 ± 0.12				0.76 ± 0.07		0.011
Maximum carotid IMT, mm	0.80 ± 0.16				0.93 ± 0.14		0.020
Carotid Plaque, n, %	29	35.4%			4	44.4%	0.421

Table 1. Relationship between carotid artery disease by ultrasound and coronary artery disease by coronary computed tomography angiography.

for discriminating patients with significant coronary stenosis (sensitivity: 100%; specificity: 44%). ROC analyses demonstrated that mean cIMT (AUC=0.801, p=0.003)has higher power than Framingham CVD risk score (FRS) (AUC=0.756, p=0.012)

Conclusions: Increased cIMT is associated with the presence & severity of coronary calcification & obstructive coronary disease on CCTA in PsA patients. cIMT measurement can discriminate PsA patient with significant coronary stenosis better than FRS. PsA patients with moderate CVD risk should have carotid US for better CV risk stratification

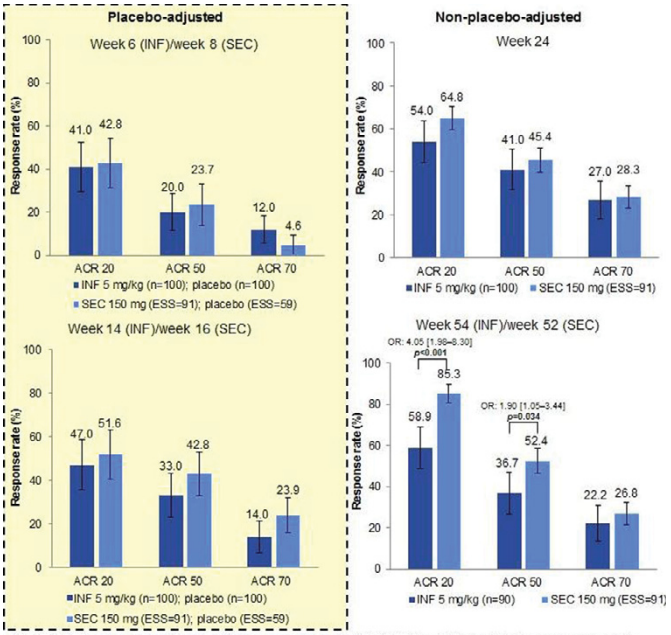
SAT0480 COMPARATIVE EFFECTIVENESS OF SECUKINUMAB AND INFLIXIMAB IN PSORIATIC ARTHRITIS ASSESSED BY MATCHING-ADJUSTED INDIRECT COMPARISON USING PIVOTAL PHASE 3 CLINICAL TRIAL DATA

V. Strand[1], I. McInnes[2], P. Mease[3], E. Choy[4], P. Nash[5], H. Thom[6], C. Kalyvas[7], K. Gandhi[8], L. Pricop[8], S. Jugl[9]. *[1]Stanford University, Palo Alto, United States; [2]University of Glasgow, Glasgow, United Kingdom; [3]Swedish Medical Center and University of Washington, Seattle, United States; [4]University of Cardiff, Cardiff, United Kingdom; [5]University of Queensland, Brisbane, Australia; [6]University of Bristol, Bristol, United Kingdom; [7]MAPI Group, Houten, Netherlands; [8]Novartis Pharmaceuticals Corporation, East Hanover, United States; [9]Novartis Pharma AG, Basel, Switzerland*

Background: Therapeutic options with discrete modes of action are now available for psoriatic arthritis (PsA). Clinicians require evidence to guide decision-making. No head-to-head RCTs have compared secukinumab 150 mg (SEC; anti-IL-17A) with infliximab 5 mg/kg (INF; TNFi) in patients with PsA. Matching-Adjusted Indirect Comparison (MAIC) can be used to estimate comparative effectiveness and enables treatment outcomes to be compared across effectively balanced trial populations. MAIC is an established method in health technology assessments, with NICE having recently published guidance.



Objectives: To use MAIC to assess the comparative effectiveness of SEC and INF for up to 1 year using pooled FUTURE 1 (F1) and FUTURE 2 (F2) individual patient data (IPD) and published aggregate IMPACT 2 data, respectively.

Methods: Pooled F1 and F2 data were used to maximize the effective sample size (ESS) for SEC. IPD from the SEC arms of F1 and F2 (n=302) were weighted to match selected baseline characteristics of the INF arm of IMPACT 2 (n=100). Placebo arms were also matched; placebo-adjusted comparisons were possible only until week 16 because patients could receive active treatment from this time point onwards. Logistic regression was used to determine weights for age, sex, race, body weight, methotrexate use, presence of psoriasis (≥3% body surface area), mean PASI score, dactylitis, enthesitis, mean HAQ-DI score and previous TNFi therapy. Recalculated outcomes from F1 and F2 (SEC, ESS=91; placebo, ESS=59) were compared with data from IMPACT 2 (INF, n=100; placebo, n=100). Pairwise comparisons using odds ratios (ORs [95% CIs]) were performed for ACR 20, 50 and 70 responses at nearest-equivalent time points across trials: weeks 6/8, 14/16, 24 and 54/52. Mean changes from baseline in SF-36 Physical and Mental Component Summary (MCS) scores were also compared. Strict thresholds were avoided when interpreting p values, in line with American Statistical Association 2016 guidance.

Results: There was no evidence of differences in ACR 20, 50 and 70 responses between SEC and INF at weeks 6/8, 14/16 (both placebo-adjusted) and 24 (non-placebo-adjusted). At week 54/52, ACR 20 and 50 responses were higher with SEC than INF (OR [95% CI]: 4.05 [1.98–8.30], p<0.001 and 1.90 [1.05–3.44], p=0.034, respectively). Improvements in SF-36 MCS scores were greater with SEC than INF at weeks 14/16 (p=0.063), 24 (p=0.001) and 54/52 (p<0.001). A sensitivity analysis that added PsA duration, swollen joint count and CRP levels to the matching parameters yielded similar results.

Conclusions: In this MAIC, SEC showed evidence of superiority for symptomatic improvement (non-placebo-adjusted ACR 20 and 50) over INF for active PsA at 1 year. This was accompanied by greater improvements in SF-36 MCS scores. At earlier time points, there was no evidence of differences in ACR responses between SEC and INF.

SAT0481 THE RELATIONSHIP BETWEEN THE PATIENT ACCEPTABLE SYMPTOM STATE (PASS) AND DISEASE ACTIVITY IN PATIENTS WITH PSORIATIC ARTHRITIS (PSA)

J.Z. Fei[1], A. Perruccio[2], Y. Ye[1], D.D. Gladman[1], V. Chandran[1]. *[1]Rheumatology; [2]Orthopaedics, Toronto Western Hospital, Universtiy of Toronto, Toronto, Canada*

Background: PASS is the highest level of symptoms beyond which patients consider themselves well. Psoriatic Arthritis Disease Activity Score (PASDAS) is a recently developed composite disease activity measure that summarizes a patient's disease in a single 0–10 score.

Objectives: In this study, we aimed to identify the PASDAS cut-off points for PASS, and to examine the agreement between PASS and the PASDAS thresholds for low (<3.2), moderate (3.2–5.4), and high disease activity (>5.4).

Methods: Patients were prospectively recruited from the University of Toronto PsA clinic. A standard protocol including physician assessment and patient-reported outcomes was used to record variables required to calculate PASDAS. In addition, each patient was asked to "think about all the ways your PsA has affected you during the last 48 hours. If you were to remain in the next few months as you were during the last 48 hours, would this be acceptable to you?" to assess PASS. For analysis, the PASDAS threshold for PASS was identified with the ROC analysis to maximize specificity and sensitivity. Furthermore, the agreement between PASS and low, moderate, and high PASDAS disease activity cut-offs were evaluated.

Results: 169 patients [61% male, mean age 56.1, mean disease duration 16.9 years, mean (SD) PASDAS 3.25 (1.1)] were recruited. The PASDAS threshold for the patient acceptable symptoms state (PASS+) was identified to be 3.84 (AUC – 0.88, sensitivity 0.82, specificity 0.94) using ROC curve analysis. 91% of patients with low disease activity (PASDAS <3.2) considered their symptoms state acceptable (PASS+), and 100% of the patients with high disease activity (PASDAS >5.4) considered their symptom state as unacceptable (PASS-). Furthermore, the mean (SD) PASDAS was 4.5 (1.0) in the PASS- group and 2.8 (1.1) in the PASS+ group.

Conclusions: The PASDAS threshold for patient acceptable symptoms state is 3.84, which is within the moderate disease activity range. Thus with a PASDAS of 3.84 or lower, PsA patients consider their symptom state acceptable for the next few months. This cut-off should be considered for shared decision making regarding treatments in PsA patients.

SAT0482 SUBCLINICAL ENTHESOPATHY IN PSORIATIC PATIENTS AND ITS RELATION TO OTHER DISEASE PARAMETERS: AN ULTRASOUND STUDY

W. Gouda[1], M. Ismail[2], M. Doma[2]. [1]*Rheumatology, Aswan University, Aswan;* [2]*Rheumatology, Al-Azhar University, Assiut, Egypt*

Background: Psoriasis is a chronic immune-mediated inflammatory skin disease characterized by reddish, thick patches covered with marked silvery scaling [1]. In about 70% of the patients, psoriasis is present many years before the onset of psoriatic arthritis [2]. The early recognition and therapeutic intervention especially with the new biologic treatments is critical to prevent the destructive and debilitating changes of psoriatic arthritis [3]. Enthesitis is inflammation at the attachment of tendons and ligaments to the bones, has been suggested as being the unifying feature of psoriatic arthritis, and the disease can be considered an enthesis associated disorder rather than primary synovitic arthropathy [4].
Objectives: We aimed to correlate the subclinical enthestitis in patients with psoriasis detected by means of power Doppler (PD) ultrasonography (US) with other disease parameters.
Methods: 50 persons with a definite diagnosis of psoriasis with no clinical evidence of arthritis or enthesitis were selected. All patients underwent complete clinical assessment included Psoriasis severity (PASI) score, body mass index (BMI), PDUS evaluation of Achilles, quadriceps, patellar entheses and plantar aponeurosis. US findings were scored according to the Glasgow Ultrasound Enthesitis Scoring System (GUESS).
Results: In 18 of 50 of patients (36%) PDUS found signs indicative of enthesopathy. The Achilles enthesis had the highest number of PDUS signs of enthesopathy (33.3%), followed by distal patellar enthesis (22.2%), proximal patellar enthesis (16.7%), quadriceps enthesis (16.7%), and plantar aponeurosis enthesis (11.1%) with variable enthesial morphostructural abnormalities. The GUESS score was directly correlated with age (p=0.012), disease duration (p=0.044), PASI (p=0.035), BMI (p=0.011), hyperuricemia (p=0.011).

Demographic findings of the study population

Characters	Patients
Age (range) mean (SD)	(19–70) 33.8±11.2
Gender	
Female N (%)	31 (62)
Male N (%)	19 (38)
Disease duration (range) mean (SD)	(2–12) 7.7±3.4
PASI score mean ±SD (range)	21.1±7.3 (2.7 - 33.2)
BMI mean ±SD (range)	29.9±6.4 (19.5–42)
Rheumatoid factor: N of patients (%)	
Positive (>1/8)	4 (8%)
Negative	46 (92%)
SUA: N of patients (%)	
Normal (<6 mg/dl)	38 (76%)
Elevated	12 (24%)
Radiographic sacroiliitis: N of patients (%)	6 (12%)
Ultrasonographic findings: (%)	
Normal	32 (64%)
Abnormal (enthesitis)	18 (36%)

Conclusions: In addition to the importance of PDUS as a complimentery tool in examination of entheses in psoriatic patients, the presence of high PASI score together with the increased BMI and hyperuricemia in addition to long disease duration could be considered as predictive parameters for the presence of psoriatic enthesitis.

Osteoarthritis

SAT0483 OSTEOARTHRITIS (OA) AND SOCIO-ECONOMIC STATUS (SES) PREDICTS THE ONSET OF COMORBIDITIES LINKED TO FREQUENT HEALTHCARE CONSULTATION

R. Hayward[1], K. Kaur[2], R. Wilkie[1]. [1]*Research Institute for Primary Care & Health Sciences;* [2]*Medical Student, Keele University, Keele, United Kingdom*

Background: OA is the most common joint condition, the fourth leading cause of disability globally and the fastest increasing major health condition. In older adults, OA frequently coexists with other morbidities, but the temporal nature is unclear. There is abundant evidence that markers of low SES are associated with poor outcomes among people with musculoskeletal conditions, however the mechanism linking comorbidity may vary with SES.
Objectives: To examine if OA predicted the onset of comorbidities that are the reason for frequent consultation to primary care, and if this association was moderated by SES.
Methods: Cohort study combining questionnaire data at two time points (2005, 2008) in the North Staffordshire Osteoarthritis Project, and medical record data from 2000 to 2005 (n=3910). OA was defined by consultation to primary care for OA between 2000 and 2005, and the indication of moderate to extreme pain interference in the questionnaire (2005). Logistic regression examined the association between OA and the onset of seven comorbidities (anxiety, depression, widespread pain (WP), insomnia, cognitive impairment, neurosis, stress between 2005 and 2008) and restricted social participation, first unadjusted and then adjusting for putative confounders (comorbidity, socio-demographic and lifestyle factors). Moderation of the association between OA and new onset comorbidity by change in income, education and area-level deprivation was examined by including interaction terms in regression and stratified analyses. Results were reported as odds ratios with a 95% Confidence Interval (OR; 95% CI).
Results: Mean age was 63, 55% were female, and 942 (24%) had OA. In the unadjusted analysis, OA was significantly associated with new onset of seven comorbidities ($p<0.05$). After adjusting for confounders, OA was associated with the onset of WP (2.49; 1.96–3.17) and insomnia (1.58;1.14–2.19) There was a significant non-multiplicative interaction between OA and income and new onset cognitive impairment (P=0.047); new onset of cognitive impairment in those with OA whose income remains adequate 29.1% cf 38.1% in those with OA whose income remains inadequate), and between OA and education and new onset WP (P=0.012; new onset in those with OA and secondary education only was 37.4% cf 50% in those with OA and had more than a secondary education).
Conclusions: Consulters for OA were more likely to develop new physical and psychological comorbidities that lead to more frequent consultation to primary care than those without OA. Whilst confounders explained some of these associations, OA consulters may benefit from more proactive strategies to prevent further morbidity. Despite no significant multiplicative interactions, there were differences in the prevalence of new onset of morbidity in those with OA when stratified by SES. Onset of cognitive impairment was associated with inadequate income but WP was associated with those with higher education suggesting a "worried well" population seen both in other health surveys and in screening. OA and baseline morbidities were higher with lower SES and further exploration across the life-course will help to establish the role of SES on the natural history OA.

SAT0484 LOW MAGNESIUM INTAKE IS ASSOCIATED WITH INCREASED PAIN IN SUBJECTS WITH RADIOGRAPHIC KNEE OSTEOARTHRITIS: DATA FROM THE OSTEOARTHRITIS INITIATIVE

A. Shmagel[1], N. Onizuka[1], T. Vo[2], L. Langsetmo[2], K. Ensrud[3,4], R. Foley[5], P. Valen[1,6]. [1]*Medicine/Rheumatology;* [2]*School of Public Health;* [3]*Medicine, University of Minnesota;* [4]*Medicine, VA Medical Center;* [5]*Nephrology/Medicine, University of Minnesota;* [6]*Medicine/Rheumatology, VA Medical Center, Minneapolis, United States*

Background: Osteoarthritis pain appears to be caused, at least in part, by alterations in peripheral and/or central nociceptive pathways.[1] As magnesium is a known mediator of nociception, we hypothesized that low magnesium intake may be associated with increased pain in radiographic knee OA.
Objectives: To evaluate whether magnesium intake is associated with knee pain in radiographic knee osteoarthritis.
Methods: We investigated the associations between knee pain and magnesium intake from food and supplements in 2549 participants with prevalent radiographic knee OA (Kellgren-Lawrence score $\geq$2) in the Osteoarthritis Initiative cohort.[2] WOMAC pain scores in the affected knee were reported annually with total follow up period of 48 months. Magnesium intake was assessed at baseline by food frequency questionnaire and dietary supplement questionnaire, and expressed in gender-specific calorie-adjusted quintiles. Analyses used generalized linear mixed effects models with repeated measures.
Results: Among participants with baseline radiographic knee OA the mean total magnesium intake was 310 mg/day (SD 133) for men, and 288 mg/day (SD

118) for women, with 68% of men and 44% of women below the estimated average requirement (EAR). The mean WOMAC pain score at 0, 12, 24, 36, and 48 months of follow up was 3.5 (SD 3.8), median score 2 (IQR 0; 6). After adjustment for age, gender, BMI, caloric intake, physical activity, smoking status, alcohol use, renal insufficiency, and the use of analgesics, subjects in the lowest gender-specific quintile of magnesium intake (Q1) had, on average, 1 point higher WOMAC knee pain scores than subjects in the highest quintile (Q5): Q1 β (95% CI) 1.00 (0.61–1.39), Q2 0.69 (0.32–1.06), Q3 0.25 (-0.12–0.62), Q4 0.25 (-0.14–0.64); $p<0.0001$.

Conclusions: In a cohort of adults with prevalent radiographic knee osteoarthritis, magnesium intake overall was below recommended. Low magnesium intake at baseline was associated with increased pain in the affected knee over 48 months of follow up. These findings may be of growing importance as the average dietary magnesium intake for humans is declining.[3]

SAT0485 INCREASED EXPRESSION OF OSTEOPROTEGERIN IN CD271+ MULTIPOTENTIAL STROMAL CELLS FROM FEMORAL HEADS OF PATIENTS WITH HIP OSTEOARTHRITIS

D.C. Ilas[1], S.M. Churchman[1], J. Aderinto[2], P.V. Giannoudis[1], D. McGonnagle[1], E. Jones[1]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]Department of Orthopaedics, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

Background: Osteoarthritis is a disease of the whole joint, but subchodral bone marrow lesions (BMLs) closely correlate with disease progression [1]. We have previously shown that in OA femoral heads, subchondral bone multipotential stromal cells (MSCs) were 5-fold more abundant in MRI determined BML areas where they also showed reduced mineralisation capacity and altered RANKL expression compared to non-BML areas [2]. This offered novel insight into MSC involvement in the bone remodeling process in OA.

Objectives: The current study investigated a multi-lineage gene expression profile of native CD271+ MSCs from OA femoral heads focusing on osteogenesis and bone remodeling related genes compared to CD271+ MSCs from healthy trabecular bone.

Methods: Femoral heads were obtained from 17 OA patients undergoing total hip arthroplasty. Control samples included healthy iliac crest bone from 12 patients undergoing autograft harvesting for bone reconstruction and healthy femoral neck bone from 2 patients, extracted following core decompression surgery for avascular necrosis of the femoral head. CD271+ MSCs were extracted by enzymatic digestion and purified by FACS, as previously described [3, 4]. MSC cultures were generated by standard methods [4]. Quantitative real-time PCR was performed using TaqMan assays for 12 transcripts and gene expression was normalised to *HPRT1*.

Results: Sorted CD271+ cells from both groups displayed gene expression profiles indicative of their steady-state osteogenic, adipogenic, bone remodeling and stromal-support functions (Table 1). Three out of 11 transcripts showed significant increases in OA: alkaline phosphatase, melanoma cell adhesion molecule and osteoprotegerin (OPG) ($p<0.05$, Mann Whitney test). The proportion of CD271+ cells in relation to total live cells was more variable but on average 2-fold higher in OA (medians of 2.3 and 5.2%, respectively, not significant). Consistent with previous findings [4, 5], gene expression levels for the majority of transcripts were altered following MSC culture expansion (3 up-regulated and 8 down-regulated).

Table 1. Transcripts expression levels in CD271+ MSCs from OA and healthy bone

Transcript	Median (Range)		Fold increase in OA (*=p<0.05)
	OA	Healthy	
Osterix	0.5 (0.1-16.3)	0.2 (0.1-1.6)	2.4
Alkaline phosphatase	**17 (2.4-71.3)**	**7.1 (0.5-16.3)**	**2.4***
Collagen 1a1	3.1 (0.2-18.7)	1.1 (0.4-8.9)	2.9
Osteonectin	89.8 (6.1-163.1)	15.3 (11.3-81.6)	5.9
Osteopontin	49.2 (9.6-693)	46 (6.9-212.5)	1.1
Cadherin-11	15.6 (1.3-37.9)	5.0 (3.2-29.2)	3.1
Fatty acid-binding protein-4	1.9 (0.3-10.1)	0.8 (0.4-11)	2.5
Receptor activator of nuclear factor kappa-B ligand (RANKL)	0.3 (0.2-2.3)	0.2 (0.1-0.5)	1.1
Osteoprotegerin (OPG)	**0.5 (0.1-0.8)**	**0.1 (0.1-0.4)**	**3.8***
Stromal cell-derived factor 1	164.6 (22-1377)	128.3 (91.1-1956.8)	1.3
Melanoma cell adhesion molecule	**4.5 (1.0-16.3)**	**0.9 (0.9-3.1)**	**5.1***

Conclusions: This is the first study to show gene expression alterations in uncultured CD271+ MSCs from OA patients. A notable increase in OPG is suggestive of MSCs' bias towards inhibition of bone resorption in late hip OA and further incriminates the RANKL/OPG pathway, specifically in MSCs, in OA pathophysiology. Further studies are needed to define the role of native MSCs in lesion associated OA disease progression and to evaluate these as a possible target for treatment.

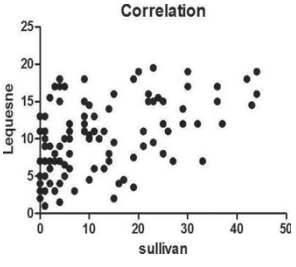
SAT0486 CATASTROPHIZING IN OSTEOARTHRITIS OF THE KNEE: DOES THE LEQUESNE SCORE TAKE IT IN COUNT? A PROSPECTIVE STUDY



J. Lecorney, M. Chouk, X. Guillot, C. Prati, D. Wendling, F. Verhoeven. *Rhumatologie, CHRU de Besançon, Besançon, France*

Background: knee osteoarthritis is a frequent matter of consultation in both general practice and rheumatology. Pain is the main symptom leading to a consultation. This painful experience can be influenced by various factors such as the anxio-depressive state or catastrophizing. Catastrophizing is known to be associated with lower analgesia results in total knee arthroplasty (1).

Objectives: The aim of this study is to evaluate the correlation between the functional status (assessed by the Lequesne score) and the catastrophizing (assessed by the Sullivan score) in patient with osteoarthritis of the knee.

Methods: We included patients consulting for knee osteoarthritis, meeting the OARSI criteria (2), one of the three general practitioners participating in the study or a rheumatologist at University Hospital. We excluded those with surgical indication. For each patient we registered the epidemiological data, the radiographic stage as well as the scores of Lequesne and Sullivan questionnaires. The correlation between the different scores were assessed with a Spearman test.

Results: A total of 100 patients were included, 50 consulting a general practitioner and 50 consulting a rheumatologist, between November 2015 and April 2016. Among these 100 patients, there were mainly women (57%) with a mean age of 64.8±1.17 years old. The mean radiographic stage was 2.66±0.11 on the Kellgren and Lawrence scale. The Mean Sullivan score was 12.98±1.18 and the mean Lequesne score was 10.46±0.47. There was a close correlation ($r=0.3$, $p=0.006$) between the Lequesne score and the radiographic scale. There was no correlation between the Sullivan score and the radiographic scale. Howerver, the correlation between the Sullivan and the Lequesne scores was modest ($r=0.47$; $p<0.0001$) (Figure 1). Thus, the Lequesne score is correlated with the radiographic scale and the Sullivan score. When we compare the two populations, it appeared that the people consulting a rheumatologist are majority of women (72%) and younger (62.58±1.8 VS 67, 18±1.38 years, $p<0.05$) and with a shorter duration of symptoms (6.02±1.12 VS 12.96±1.5 Years, $p<0.001$). In terms of radiographic and functional impairment, the two populations were similar (Kellgren score of 2.59±0.15 VS 2.7±0.158 and Lequesne score of 11.13±0.67 VS 9.78±0,66. $p>0.05$) but there was a clear difference for the Sullivan score (16.96±1.67 VS 9±1.4; $p<0.001$).

Conclusions: Our study is the first to highlight a correlation between the Sullivan and the Lequesne scores in patient consulting for osteoarthritis of the knee. Moreover, unlike the Sullivan, score the Lequesne score is correlated with the radiographic scale. The strength of this study is the inclusion of both patients consulting the general practitioner and those consulting the rheumatologist to avoid a recruitment bias. Indeed, patients consulting the rheumatologist had a catastrophizing score more important for the same functional and radiological impairment than those consulting the general practitioner. Thus, our population is representative of the global population suffering from osteoarthritis of the knee in terms of age, sex-ratio, BMI.The Lequesne score is a global score correlated with structural damage and with psychological factors like catastrophizing.

SAT0487 A RANDOMIZED, BLINDED, COMPARATOR-CONTROLLED TRIAL INVESTIGATING A 4-WEEK COURSE OF LYRICA IN SUBJECTS WITH KNEE OSTEOARTHRITIS WHO EXHIBIT NEUROPATHIC PAIN, COMPARED WITH A 4-WEEK COURSE OF PARACETAMOL

A. Wright[1], P. Moss[1], H.A. Benson[2], R. Will[3], P. Chowalloor[4]. *[1]School of Physiotherapy and Exercise Science; [2]School of Pharmacy, Curtin University; [3]School of Medicine and Pharmacology, University of Western Australia; [4]Department of Rheumatology, Royal Perth Hospital, Perth, Australia*

Background: Knee osteoarthritis (OA) has been considered the archetypal model of inflammatory or nociceptive pain [1] but it is apparent that people with knee OA may present with different pain phenotypes including some with features of neuropathic pain [2,3].
Objectives: The aim of the present study was to select people with knee OA who exhibited features of neuropathic pain based on elevated cold pain thresholds (≥15℃) and elevated PainDETECT scores (≥13) and to determine if pregabalin would be more effective in reducing pain and improving function in this cohort than paracetamol.
Methods: The study used a double-blind, randomized, comparator-controlled design in participants with knee OA to compare the effectiveness of a standard dose of paracetamol (1000mg qid) with a titrated dose of pregabalin (Lyrica) taken daily over 28 days. A cohort of 90 participants with moderate to severe painful knee OA (Pain rating ≥4/10) who demonstrated features of neuropathic pain were included in the study. Participants were selected from an initial cohort of 271 OA sufferers recruited from the Perth community based on screening of CPT and PainDETECT. Included participants were randomly assigned to receive either a four week course of pregabalin titrated to a maximum dose of 300mg or a four week course of paracetamol (4,000mg).
Participants were assessed at baseline, 14 and 28 Days. They completed the PainDETECT, WOMAC and PQAS questionnaires. Quantitative sensory testing was carried out at three sites (index knee, contralateral knee, ECRB) using standard methods. Cold and heat pain thresholds were tested using a Peltier thermode and pressure pain thresholds were assessed using a digital algometer. Physical function was assessed using three timed locomotor function tests (sit-to-stand, walk, stairs).
Results: Participants receiving pregabalin (300mg) exhibited greater reductions in WOMAC Pain scores (P=0.0001) and PainDETECT scores (P=0.0001) at Day 28 compared to the paracetamol group and a greater increase in pressure pain thresholds (reduced tenderness) (P=0.025) at the index knee. There was no significant difference between the groups in cold pain thresholds (P=0.33). Participants in the pregabalin group completed the physical tests more quickly than the paracetamol group (Sit-to-stand p=0.05, walk p=0.001, stairs p=0.05). The pregabalin group also had a significantly increased likelihood of reducing their PainDETECT score below the entry value of 13 compared to the paracetamol group (OR 9.20; P=0.001) but there was no significant difference in the likelihood of reducing their cold pain threshold below the 15℃ entry value (OR 2.26; P=0.14).
Conclusions: The group receiving pregabalin 300mg showed greater reductions in pain, reduced features of neuropathic pain and reduced tenderness at the affected knee. Further research is warranted to evaluate pregabalin in this specific patient cohort.

SAT0488 COMPARATIVE EFFECTIVENESS OF AYURVEDA AND CONVENTIONAL CARE IN KNEE OSTEOARTHRITIS – A RANDOMIZED CONTROLLED TRIAL

C.S. Kessler[1], K. Dhiman[2], A. Kumar[3], T. Ostermann[4], S. Gupta[5], A. Morandi[6], M. Mittwede[7], E. Stapelfeldt[1], M. Spoo[1], K. Icke[8], A. Michalsen[1], C. Witt[8]. *[1]Complementary and Integrative Medicine, Immanuel Hospital Berlin, Berlin, Germany; [2]Central Council for Research in Ayurvedic Sciences; [3]All India Institute of Ayurveda, New Delhi, India; [4]Department of Psychology and Psychotherapy, University of Witten Herdecke, Witten, Germany; [5]Department of Kaya Cikitsa, J.S. Ayurveda College & P.D. Patel Ayurveda Hospital, Nadiad, India; [6]School of Ayurvedic Medicine, Ayurvedic Point, Milan, Italy; [7]European Academy of Ayurveda, Birstein; [8]Institute for Social Medicine, Epidemiology and Health Economics, Charité Medical University, Berlin, Germany*

Background: Traditional Indian Medicine Ayurveda is used to treat knee osteoarthritis (OA) despite limited evidence.
Objectives: We aimed to evaluate the effectiveness of complex Ayurvedic treatment compared to complex conventional care in knee OA patients.
Methods: According to ACR criteria patients with knee OA were included in a multicenter randomized, controlled trial and treated in 2 hospital outpatient clinics and 2 private outpatient clinics in Germany with 5 physicians and 20 therapists participating. Patients received either Ayurvedic treatment (n=77) or conventional care (n=74) with 15 treatments over 12 weeks. Primary outcome was the change on the Western Ontario and McMaster University Osteoarthritis (WOMAC) Index after 12 weeks (validated German version). Secondary outcomes included the WOMAC subscales; a pain disability index, numeric rating scales for pain and sleep quality, a pain experience scale, a quality-of-life index, a profile of mood index, rescue medication use, and safety issues.
Results: A total of 151 patients (Ayurveda n=77, conventional care n=74) were included. Changes of the WOMAC Index from baseline to 12 weeks were more pronounced in the Ayurveda group (mean difference 61.0 [95% CI 52.4;69.6]) than in the conventional group (32.0 [95% CI 21.4;42.6]) resulting in a significant difference between groups ($p<0.001$) and a clinically relevant effect size (Cohen's d 0.68 [95% CI 0.35;1.01]). Similar tendencies were observed for all secondary outcomes at week 12. Effects were sustainable at follow-ups after 6 and 12 months.
Conclusions: The results suggest that a complex Ayurvedic treatment might be clinically superior to a complex conventional intervention in the treatment of OA of the knee.

SAT0489 ASSOCIATION OF CHILDHOOD OVERWEIGHT MEASURES WITH ADULTHOOD KNEE CARTILAGE DEFECTS AND BONE MARROW LESIONS: A 25-YEAR COHORT STUDY

T. Meng[1], S. Thayer[2], A. Venn[1], F. Cicuttini[3], L. March[4], T. Dwyer[5], A. Halliday[2], M. Cross[4], L. Laslett[1], G. Jones[1], C. Ding[1,3,6], B. Antony[1]. *[1]Menzies Institute for Medical Research; [2]Department of Radiology, Royal Hobart Hospital, Hobart; [3]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne; [4]Institute of Bone and Joint Research, Sydney; [5]Murdoch Childrens Research Institute, Melbourne, Australia; [6]Translational Research Centre, Academy of Orthopaedics, Southern Medical University, Guangzhou, China*

Background: Obesity and overweight have been associated with increased risk of knee osteoarthritis (OA). Cartilage defects and bone marrow lesions (BMLs) are imaging biomarkers that predict the development and progression of knee OA. However, there are no studies describing the effect of childhood obesity or overweight on risk of adulthood knee structural abnormalities including cartilage defects and BMLs.
Objectives: To describe associations between body weight, body mass index (BMI), overweight status and fat mass in childhood and knee cartilage defects and BMLs measured using magnetic resonance imaging (MRI) in adulthood 25 years later.
Methods: Subjects broadly representative of the Australian population (n=327, aged 31–41 years) were selected from the Australian Schools Health and Fitness Survey of 1985 (n=8498, aged 7–15 years). Childhood measures, including weight, height and skinfolds were measured in 1985. BMI and fat mass were calculated. They underwent T1-weighted fat-suppressed and proton density-weighted fat-suppressed MRI scans 25 years later. Cartilage defects and BMLs were measured from MRI using a semi-quantitative scoring system. Log binomial regression analyses were used to determine the associations of childhood overweight measures with adulthood knee cartilage defects and BMLs.
Results: There were no associations between childhood overweight measures and adulthood tibio-femoral cartilage defects; however, body weight, BMI and overweight status were positively associated with patellar cartilage defects after adjustment for childhood age, duration of follow-up, sex, childhood height (if weight or fat mass was the predictor), childhood injury, adulthood injury and corresponding adulthood measures (RR 1.05, 95% CI 1.01 to 1.09 for weight; RR 1.10, 95% CI 1.01 to 1.19 for BMI; RR 2.06, 95% CI 1.19 to 3.58 for overweight). After further adjustment for patellar BMLs, these associations remained largely unchanged and the association of fat mass with patellar cartilage defects became significant (RR 1.10, 95% CI 1.01 to 1.21).
Childhood overweight measures were not associated with adulthood BMLs in either tibio-femoral or patellar compartments. However, sex-specific analyses showed BMI and overweight status were associated with higher risks of patellar BMLs after adjustment for covariates in men (RR 1.36, 95% CI 1.03 to 1.81 for BMI; RR 4.37, 95% CI 1.01 to 18.91 for overweight) but not in women.
Conclusions: Childhood overweight measures were significantly associated with increased risk of patellar cartilage defects and BMLs in young adults. In addition, overweight status was significantly associated with patellar BMLs in men which may explain why overweight was only associated with increased knee pain in men as we reported earlier. These results indicate the importance of addressing overweight in childhood to aid in preventing adulthood knee structural abnormalities which increase the risk of OA in later life.

SAT0490 GENOME-WIDE DNA METHYLATION PROFILING OF OSTEOARTRHITIS PERIPHERAL BLOOD MONONUCLEAR CELLS REVEALS SLOWED EPIGENETIC AGING AMONG RAPID RADIOGRAPHIC PROGRESSORS: DATA FROM THE OSTEOARTHRITIS INITATIVE (OAI)

A. Rivas[1], M. Jeffries[1,2]. [1]*Rheumatology, Immunology, and Allergy, University of Oklahoma Health Sciences Center;* [2]*Arthritis & Clinical Immunology Program, Oklahoma Medical Research Foundation, Oklahoma City, United States*

Background: Extensive evidence has correlated epigenetic alterations in articular tissues with both the presence and progression of human osteoarthritis, but few analyses of blood cell epigenetic patterns have been done in OA.
Objectives: We examined the DNA methylation aging rate in peripheral blood mononuclear cells (PBMCs) at baseline from knee OA patients with rapid radiographic progression compared to well-matched nonprogressors enrolled in the Osteoarthritis Initiative (OAI).
Methods: PBMC DNA was obtained from baseline blood draws of 64 OA patients enrolled in the OAI longitudinal study. All patients had baseline symptomatic and radiographic OA. 32 rapidly-progressive OA patients, defined as $\geq$1.0mm radiographic joint space loss within 24 month follow-up were compared to 32 non-progressive patients. There were no differences in age, sex, race, BMI, baseline K/L grade, or calculated PBMC subset composition between rapid- and non-progressors. DNA methylation was quantified with Illumina HumanMethylation 450k arrays. Preprocessing was performed in GenomeStudio and normalized to internal controls. Epigenetic age was estimated with the algorithm described by Horvath et. al., using 353 age-associated CpG sites. This epigenetic age was compared to chronological age to calculate epigenetic-chronological age discordance (ΔAge) and group differences compared with a Student t-test. ΔAge was correlated with individual CpG methylation sites of rapid progressors, and Pearson values calculated. Correlation was considered significant if Pearson's r values were $\leq$-0.55 or $\geq$0.55 ($p \leq 0.001$). Pathway analysis of correlated genes was performed with the Ingenuity Pathway Analysis (IPA) system.
Results: The baseline DNA methylation aging rate in rapidly progressive (RP) knee OA patients was decelerated compared to nonprogressors (NP) and to chronological age (ΔAge-RP: -4.9±1.4 vs. ΔAge-NP: -0.071±1.3 mean±SEM years less than chronological age, p=0.015). 1165 CpG sites were correlated with ΔAge in rapid progressors, corresponding to 755 genes. Ontologic analysis of highly correlated genes showed association of the STAT3 pathway (p=6E-4), Notch signaling (p=1E-3), axonal guidance signaling (p=7E-3), CREB signaling (p=2E-2), NFAT signaling (p=2E-2), and autophagy (p=4E-2) among others. Associated upstream regulators included FGF2 (p=3E-5), SMAD4 (p=9E-4), SMAD5 (p=1E-3, TNF (p=4E-3), and TGFB1 (p=4E-3), among others
Conclusions: Our data reveal that a decelerated peripheral blood differential DNA methylation age epigenotype is present at baseline in rapidly progressive knee OA patients, but not in nonprogressive knee OA patients. The genes correlated with this methylation age deceleration cluster in pathways previously associated with OA in articular tissues, suggesting that these pathways may systemically epigenetically dysregulated. Our data reinforce the notion that OA is a heterogeneous disease composed of distinct subgroups, and suggests that future epigenetic investigation of immune cell subsets may be beneficial in unraveling OA pathogenesis.

SAT0491 USE OF HISTAMINE H1-RECEPTOR ANTAGONISTS IS ASSOCIATED WITH DECREASED PREVALENCE OF RADIOGRAPHIC KNEE OSTEOARTHRITIS: A CROSS-SECTIONAL ANALYSIS OF OSTEOARTHRITIS INITIATIVE DATA

I. Shirinsky, V. Shirinsky. *Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation*

Background: Mast cells are prevalent in osteoarthritis (OA) synovial tissue and their presence is associated with structural damage [1]. H1-receptor antagonists block the action of histamine, which is the major mediator of mast cells, on specific receptors. Therefore, H1 receptor blockade may represent a way to prevent and treat OA. Currently, there is a lack of data investigating the effects of H1-receptor blockade on knee OA in humans.
Objectives: To evaluate cross-sectional association between the use of histamine H1-receptor antagonists and radiographic knee OA.
Methods: For the current analysis we used data from the publically available Osteoarthritis Initiative (OAI). We compared cross-sectionally the knees of OAI participants taking H1-receptor antagonists at baseline with knees of control participants. We used logistic regression models to assess the association between radiographic knee OA (defined as KL$\geq$2 and JSN) and the use of H1-receptor antagonists. Generalized estimating equations (GEE) were used to adjust for the correlation between knees. The models were adjusted for multiple covariates including age, race, and body mass index.
Results: A sample of 4377 OAI participants (8753 knees) was analyzed, 457 of them (914 knees) used histamine H1-receptors at baseline. The use of histamine H1-receptor antagonists was associated with lower prevalence of radiographic knee OA in both crude (OR 0.77, 95 CI 0.64–0.91, $p<0.01$) and adjusted (OR 0.79, 95 CI 0.66–0.95, p=0.01) analyses.
Conclusions: Histamine H1-receptor antagonists are associated with decreased prevalence of knee OA. Further studies are warranted to determine whether H1-receptor blockade may be of benefit in the prevention and treatment of knee OA.

SAT0492 INTRAMUSCULAR CORTICOSTEROID INJECTION VERSUS PLACEBO INJECTION IN HIP OSTEOARTHRITIS: A 12- WEEK BLINDED RANDOMIZED CONTROLLED TRIAL

D. Dorleijn[1], P. Luijsterburg[1], M. Reijman[2], M. Kloppenburg[3], J. Verhaar[2], P. Bindels[1], K. Bos[2], S. Bierma-Zeinstra[1]. [1]*General Practice;* [2]*Orthopeadics, Erasmus MC, Rotterdam;* [3]*Rheumatology, LUMC, Leiden, Netherlands*

Background: Several international guidelines recommend intra-articular (IA) corticosteroid injections for patients with hip OA experiencing moderate to severe pain and no responding to oral analgesics. Previous research has shown a systemic effect of an intramuscular (IM) gluteal corticosteroid injection in patients with subacromial impingement shoulder pain. A clinically relevant effect of IM corticosteroid injections would offer a less complex, alternative treatment for patients' episodes of increased pain in hip OA.
Objectives: The trial aim was to assess the efficacy of an IM gluteal corticosteroid injection compared to a placebo injection on patients' reported hip pain severity in patients with hip OA, who were not responding on oral analgesics.
Methods: Patients in primary and secondary care were included if they met the clinical ACR and radiographic (KL score $\geq$2) criteria for hip OA and scored a severity of hip pain $\geq$3 on a scale of 0–10 (0=no hip pain). Patients were randomized to receive either 40mg of triamcinolone acetate or saline (placebo) with an IA injection into the ipsilateral gluteus muscle. Primary outcome was severity of hip pain at 2 weeks, measured with numerical rating scale (NRS) in rest and during walking (0–10;0=no pain) and with the WOMAC pain subscale (0–100;0=no pain). Secondary outcomes included hip pain severity (NRS, WOMAC pain, ICOAP), function (WOMAC function), stiffness (WOMAC stiffness), adverse events, and medical co-interventions at 2, 4, 6, and 12 weeks follow-up. Statistical analyses were performed based on the intention to treat principle. Linear mixed models with repeated measurements were used to analyze between group differences. The models were adjusted for variables that changed the effect estimate >10%.
Results: 107 of 422 screened patients were randomized. After informed consent, one randomized patient did not show up at the appointment for baseline measurement and subsequent injection and could, because of lack of data, not be included in the analyses. Finally, 52 patients in the corticosteroid injection group, and 54 in the placebo injection group were included in the analyses. 68% of the patients were female, and 25% were recruited by orthopedic surgeons. Mean age was 64 years (SD 11) and duration of OA was $\geq$1 year for 70%. At 2 weeks follow-up (table), the corticosteroid injection was statistically significant and clinically relevant associated with hip pain reduction at rest (coefficient -1.3, 95% CI -2.3 to -0.3) compared to placebo. The corticosteroid injection was also associated with significant hip pain reduction at 4, 6 and 12 weeks. Moreover, at almost all follow-up measurements the estimates showed significant differences in favor of the corticosteroid injection on WOMAC pain, function, stiffness and total score, and ICOAP. No significant differences between groups were found for adverse events and medical co-interventions.

Table. Results of the multivariable linear mixed model analyses with repeated measurements regarding primary outcomes between corticosteroid and placebo group.

				Adjusted mixed model	
		Corticosteroid (n=52)	Placebo (n=54)	Between group difference * (95% CI)	p- value

	6 w	32 (18)	40 (20)	-9.9 (-17.7 to -2.2)	0.01
	12 w	33 (18)	40 (23)	-9.6 (-18.0 to -1.2)	0.03

Models adjusted for baseline hip KL-score, ethnicity, hip stiffness, and patients expected effect; * placebo group is reference group; SD = standard deviation; 95%CI = 95% confidence interval; WOMAC = Western Ontario and McMaster Universities Index (0 = no pain); NRS = Numerical Rating Scale (0 = no pain); ICOAP = Intermittent and Constant OsteoArthritis Pain (0 = no pain); w = weeks

Conclusions: An IM gluteal corticosteroid injection was effective in hip pain reduction compared to placebo injection in patients with hip OA at 2 weeks

folow-up. Moreover, the effect of the corticosteriod injection prolonged the entire 12 week follow-up period.

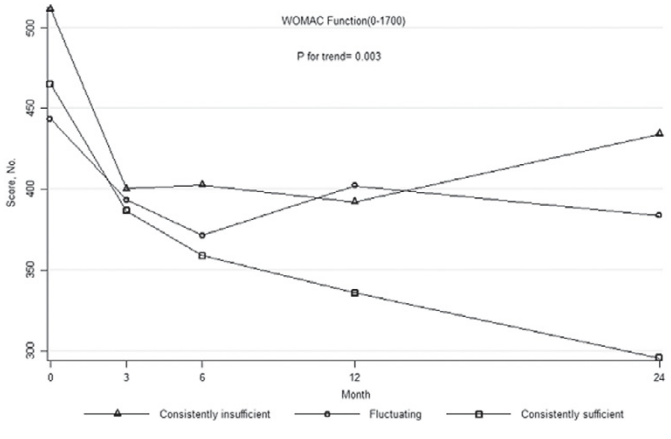
SAT0493 MAINTAINING SUFFICIENT SERUM VITAMIN D LEVELS OVER TWO YEARS IS ASSOCIATED WITH IMPROVED KNEE STRUCTURAL AND SYMPTOMATIC OUTCOMES IN PEOPLE WITH KNEE OSTEOARTHRITIS: A POST HOC ANALYSIS OF THE VIDEO TRIAL

S. Zheng[1], X. Jin[1], F. Cicuttini[2], X. Wang[1], Z. Zhu[1], A. Wluka[2], W. Han[1], T. Winzenberg[1], B.E. Antony[1], D. Aitken[1], L. Blizzard[1], G. Jones[1], C. Ding[1].
[1]Menzies Institute for Medical Research, University of Tasmania, Hobart; [2]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne, Australia



Objectives: To describe whether maintaining sufficient serum vitamin D levels in people with knee osteoarthritis (OA) and baseline vitamin D insufficiency has an association with change in knee structures and symptoms over two years.
Methods: Participants (n=413, age 63.2; 50% females) with symptomatic knee OA and vitamin D insufficiency were enrolled in a clinical trial. 340 participants (82.3%) completed the study with 25-hydroxyvitamin D [25(OH)D] measurements at month 0, 3 and 24. Participants were classified as consistently insufficient (serum 25(OH)D $\leq$50nmol/l at month 3 and 24, n=45), fluctuating (25(OH)D $>$50nmol/l at either point, n=68) and consistently sufficient (25(OH)D $>$50nmol/l at month 3 and 24, n=226) vitamin D groups. Knee cartilage volume, cartilage defects, bone marrow lesions (BMLs) and effusion-synovitis volume were assessed using MRI at baseline and month 24. Knee symptoms were assessed at baseline, month 3, 6 12 and 24 using Western Ontario and McMaster Universities Arthritis Index (WOMAC).
Results: The consistently sufficient group had significantly less loss of tibial cartilage volume (β: 2.1%, 95 CI%: 0.3%, 3.9%), less increase in effusion-synovitis volume (β: -2.5ml, 95 CI%: -4.7, -0.2) and less loss of WOMAC physical function (β: -94.2, 95% CI: -183.8, -4.5) compared to the consistently insufficient group in multivariable analyses. In contrast, there were no significant differences in these outcomes between the fluctuating and consistently insufficient groups. Changes in tibiofemoral cartilage defects, BMLs and knee pain were similar between groups.

Table 1. Associations between maintaining sufficient 25-(OH)D levels and changes in cartilage volume and effusion -volume over 24 months in patients with knee osteoarthritis

	Multivariable analysis	
	β (95% CI)	P Value
Total tibial Cartilage Volume Change (%/y)		
Consistently insufficient	*Reference*	
Fluctuating	1.5 (-0.5, 3.5)	0.15
Consistently sufficient	2.1 (0.3, 3.9)	**0.03**
P for trend		**0.02**
Effusion-Synovitis Absolute Volume Change (ml)		
Consistently insufficient	*Reference*	
Fluctuating	0.7 (-2.5, 3.9)	0.66
Consistently sufficient	-2.5 (-4.7, -0.2)	**0.03**
P for trend		**<0.01**

Adjusted age, sex and BMI and change in season of blood sampling.

Figure 1 Changes in WOMAC Function in knee OA patients with or without sufficient serum vitamin D levels over 24 months

Conclusions: This post hoc analysis suggests beneficial effects of maintaining vitamin D sufficiency on cartilage loss, effusion-synovitis and physical function in people with symptomatic knee OA.

SAT0494 EARLY TOLL-LIKE RECEPTOR 4 BLOCKADE IMPEDES THE BEHAVIOURAL AND HISTOLOGICAL CHARACTERISTICS OBSERVED IN A MIA-INDUCED ANIMAL MODEL OF OSTEOARTHRITIC PAIN

M.M. Garcia[1,2], D. Pascual[1,2], E. Quesada[2,3], J.A. Uranga[4], C. Goicoechea[2,5].
[1]Pharmacology, Universidad Rey Juan Carlos, Alcorcón; [2]Unidad Asociada URJC-IQM-CSIC, Madrid- Alcorcón; [3]Grupo Nucleósidos, Instituto química médica CSIC, Madrid; [4]Histología, Universidad Rey Juan Carlos, Alcorcón; [5]Pharmacology, Universidad Rey Juan Carlos, Madrid, Spain

Background: Contribution of Toll-Like Receptor 4 (TLR4) to pain sensitisation has been demonstrated to occur under chronic pain conditions. We previously described an antinociceptive effect of TLR4-A1, a TLR4 inhibitor, in two chronic pain conditions, peripheral neuropathic pain and osteoarthritis (OA).
Objectives: The aim of this study was to evaluate TLR4-A1 effect on allodynia and hyperalgesia in OA model, and to evaluate whether this effect is correlated with changes in spinal glial activation.
Methods: Wistar rats weighing 200–250g were used. OA was induced by a single intraarticular injection of 2mg of monosodium iodoacetate (MIA) into the right knee joint of anaesthetised rats. TLR4-A1, 10 $mgkg^{-1}$, was intraperitoneally administered during the first five days post-MIA injection. TLR4-A1 was synthesised by Dr Quesada. Vehicle-treatment (ethanol:saline, 1:9) was used as control. Each group was composed of 6 animals. After three weeks (day 22 post-MIA injection), animals were sacrificed for tissue collection. L3-L5 spinal segments were collected and embedded in paraffin wax. Eventually, samples were immune-stained with anti-GFAP or Iba-1 antibodies. Photomicrographs were recorded to make montages of the entire spinal cord at a final magnification of 20x (n=3 per lumbar section). Total number of GFAP or Iba-1 positive cells were counted separately in laminas I-II, III-IV and V-VI.
Results: Intraarticular injection of MIA increased microglial expression (Iba-1 labelling) in the ipsilateral spinal cord compared to the contralateral side, being the difference statistically significant for the superficial (I-II, +72.25%; $P<0.01$) and deeper (V-VI, +95.31%; $P<0.001$) laminae of L3 and for the superficial laminae of L4 (+87.5%; $P<0.01$). In animals treated with TLR4-A1, Iba-1 labelling in the ipsilateral dorsal horn showed a similar pattern to the contralateral dorsal horn. Pre-treatment with TLR4 blocker prevented microglia activation after MIA-injection in L3 and L4 segments.
Intraarticular injection of MIA also increased the number of GFAP-positive activated astrocytes in the ipsilateral spinal cord compared to the contralateral side; in this case, statistically significant differences were found for the superficial (I-II; +41.62%; $p<0.01$) and middle (III-IV; +64.35%, $p<0.001$) laminae of L3 sections. GFAP in TLR4-A1-treated rats showed a similar pattern for the ipsi- and the contra-lateral sides. That is, TLR4-A1 prevented L3 increased activated astroglia following MIA-injection.
Conclusions: Early toll-like receptor 4 blockade hampers spinal glial activation, which correlates with diminished allodynia and hyperalgesia observed in TLR4-A1-treated animals in a model of MIA-induced OA. Although further studies are needed, TLR4 blockade could be a good option in the treatment of osteoarthritis.

SAT0495 KNEE FUNCTION AND ENTHESITIS IN LONG STANDING OSTEOARTHRITIS, WHAT ULTRASOUND COULD TELL US?

A. Abogamal, H. Aly, S. Ghanem, H. Saad on behalf of AL-Azhar MSUS school.
Rheumatology, Alazhar Faculty of Medicine, Cairo, Egypt

Background: The enthesis around the knee including the quadriceps tendon and infrapatellar ligament insertions could be responsible for a significant cause of knee pain functional deterioration in long standing knee osteoarthritis.
Objectives: Ultrasound evaluation of the enthesis at the quadriceps tendon patellar insertion, infrapatellar ligament patellar and tibial insertions in patients with long standing knee osteoarthritis (KOA) and low knee function.
Methods: 410 Patients with KOA attending the outpatient rheumatology clinic of AL-Azhar university hospitals who had met the inclusion criteria:
- Primary Knee osteoarthritis.
- Kellegren – Lawrance scale grade III.
- At least 5 years disease duration.

Exclusion criteria:
- Patients with chronic diseases affects the patient function.

• Patients with previous knee surgery, recent trauma, or intraarticular intervention.
• Patients with knee effusion, active synovitis, or popliteal cysts.
All patients were subjected to ultrasound assessment in gray scale and Power Doppler was performed using a scanner with a multifrequency 12L linear array transducer (General electric Systems; LOGIQU-E). Ultrasound techniques were used for all patients included in the study. Knee was assessed for the following items in both sides while Patient lying supine with the knee flexed 40 degrees:
1) Superior pole of the patella – quadriceps tendon enthesis: • Quadriceps tendon thickness >6.1 mm • Suprapatellar bursitis • Superior pole of patella erosion • Superior pole of patella enthesophyte.
2) Inferior pole of the patella – proximal patellar ligament enthesis: • Patellar ligament thickness >4 mm • Inferior pole of patella erosion • Inferior pole of patella enthesophyte.
3) Tibial tuberosity – distal patellar ligament enthesis • Patellar ligament thickness >4 mm • Infrapatellar bursitis • Tibial tuberosity erosion • Tibial tuberosity enthesophyte.
Knee functional status was assessed using KOOS scale for Pain, other Symptoms, Activities of Daily Living (ADL), Sport and Recreation Function (Sport/Rec) and knee-related Quality of Life (QOL). Low knee function was considered if the patient had score 50 or more in any KOOS scale parameter.
Results: 172 (42%) patients were found with low knee function among them quadriceps enthesitis found in 114 (66.3%) patients, at the patellar attachment of infrapatellar ligament in 160 (93%) patients, and enthesitis at the tibial attachment of infrapatellar ligament in 44 (26%) patients. Good knee function were found in 238 (58%) patients among them quadriceps enthesitis found in 76 (31.9%) patients, at the patellar attachment of infrapatellar ligament in 87 (36.3%) patients, and no enthesitis at the tibial attachment of infrapatellar ligament were detected.
Conclusions: Enthesitis at the quadriceps and infrapatellar ligament represent a common ultrasonographic finding in patients with longstanding KOA, and significantly associated with low knee function.

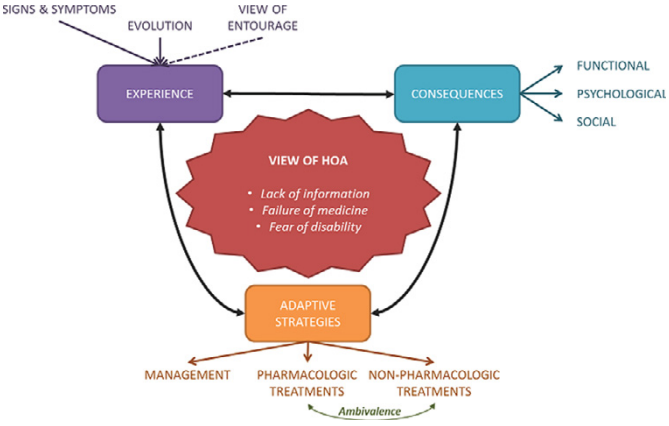
SAT0496 SAFETY OF DIACEREIN IN PATIENTS WITH OSTEOARTHRITIS – A REAL WORLD EXPERIENCE WITH UNEXPECTED RESULTS



A. Malpica[1], K. Mendez[2], P. Santos-Moreno[3,3,3], L. Villarreal[4], D. Buitrago-Garcia[1]. *[1]Epidemiology; [2]Pharmaceutical chemist; [3]Rheumatology; [4]Psychology and processes, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia*

Background: Osteoarthritis (OA) is a common joint disorder and may occur in any synovial joint in the body, the condition is common in hands, knees, hips and spine. Diacerein is a antraquinone derivate has shown the inhibition of cytokine interleukine 1-B (1). A Cochrane review published in in 2014 showed that diacerein could be effective for this condition, however the most frequent adverse event with this medication was diarrhea compared to placebo RR 3.52 (95% CI 2.42 to 5.11) or other symptomatic slow acting drugs for OA 3.20 (95% CI 1.58 to 6.49) (2).
Objectives: To describe the real-world safety of Diacerein in patients with OA in a specialized center in Bogotá, Colombia.
Methods: We performed a cross-sectional study; patients with confirmed criteria of osteoarthritis and treated on a regularly basis with Diacerein were included. Patients were followed during a 18 month period. Adverse events were classified according the Common Terminology Criteria for Adverse Events (CTCAE) of the World Health Organization. Descriptive epidemiology for continuous variables, measure of central tendency and dispersion for qualitative and categorical variables through percentages and averages were calculated, we analyzed bi-variated correlations with X2 test.
Results: 1278 patients meet inclusion criteria; mean age was 62 year ± 10 years. 88% were female and 12% male, due to our patient's condition 80% of them were polimedicated. 93% of our patients received diacerein in usual dose of 100 mg daily and remaining 7% in a 50 mg day dose. Regarding safety 7.5% (n=96) of our patients reported any event adverse, the most frequent event was diarrhea with 50%, followed by nausea and abdominal disturbances among others. According to the CTAE classification the events adverse were mild 98% and only 2% severe; that means only 0.075% of total of patients receiving Diacerein had severe AE. On the other hand, correlation between adverse events and polymedication were statistical significant (P=0.000). For this reason we consider that AE such as diarrhea can be attributed more to patients' polymedication than diacerein.
Conclusions: This evidence showed a low proportion of patients with adverse events taking Diacerein; also most of these patients were polymedicated giving as a result a higher risk of having an adverse event. When we compared our results to other studies diarrhea was the most frequent event, followed by nausea, but only a very low proportion of patients were forced to discontinue medication. It is important to continue following patients that take diacerein in order to report its true safety and effectiveness.

SAT0497 WHAT ARE THE PATIENTS' EXPERIENCE, NEEDS AND EXPECTATIONS IN HAND OSTEOARTHRITIS? A QUALITATIVE EVALUATION

M.-A. Offroy, A. Frazier-Mironer. *Centre Viggo Petersen, Rheumatology Department, APHP Lariboisière Hospital, Paris, France*

Background: The objective of this study was to evaluate the patients' experience and needs with HOA, in order to establish a therapeutic education program for HOA patients.
Objectives: As the subject was about descriptive, not quantifiable elements, qualitative methodology was chosen. Patients were submitted to individual semi-directive interviews. Verbatim were analyzed following the grounded theory until saturation of data.
Methods: Twelve HOA patients accepted to participate to the study. There were 10 women and 2 men, aged 45 to 79 years. Body-mass indexes varied from 18.7 to 31.6 kg/m^2. Clinical and radiological severity of HOA varied among patients.
They provided data on the experience of HOA, which is influenced by clinical and functional signs and the evolution of the disease. Pain and deformity are the main clinical signs, and lead to severe functional impairment. The functional, psychological, social consequences of HOA also have an impact on the patient experience. Patients develop adaptive strategies, mainly recourse to medical management, and pharmacological and non-pharmacological therapies. The needs of HOA patients were also explored, and three main ideas emerged. First, they want to be better informed on HOA. Second, they have a feeling of failure of conventional medicine, and often use alternative medicines. Third, the fear of disability with the course of the disease is very strong. They have difficulty accepting pharmacological treatments, but often do not realize the therapeutic nature of non-pharmacological treatments.
Results: The main concerns of HOA patients are: information, non-pharmacological treatments and evolutionary risks. These themes should be included in the development of therapeutic education programs for HOA.

SAT0498 THE PERFORMANCE OF URINARY COLLAGEN TYPE II C-TELOPEPTIDE (UCTX-II) IN KNEE OSTEOARTHRITIS: A META-ANALYSIS

B. Jeremiasse, F.P. Lafeber, W.E. Van Spil. *Department of Rheumatology and Clinical Immunology, UMC Utrecht, Utrecht, Netherlands*

Background: Among the currently available biochemical markers for osteoarthritis (OA), urinary collagen type II C-telopeptide (uCTX-II) is one of the most frequently investigated markers[1]. Much research has been performed into the performance of uCTX-II, but most of it in relatively small cohort studies[1]. Therefore, we performed a meta-analysis to summarize uCTX-II studies in a quantitative way.
Objectives: To perform a meta-analysis of the performance of uCTX-II as a biomarker for diagnosing knee osteoarthritis (KOA) and its association with radio-

graphic KOA severity. Furthermore, to look for patient and study characteristics that determine uCTX-II performance.

Methods: Medline and Embase databases were searched for studies into uCTX-II levels in adult subjects with radiographic KOA according to the Kellgren and Lawrence (K&L) classification system. uCTX-II levels were compared between subjects with KOA K&L ≥2 versus healthy control subjects and between subjects with KOA K&L 2 versus K&L 3–4 (i.e. moderate vs severe KOA). Controls were either selected based on lack of knee symptoms, based on K&L score, or were randomly selected from the general population. Differences between KOA subgroups were expressed as standardized mean differences (SMD). Subgroup analyses were performed to compare uCTX-performance between genders, ethnicities, and large and small studies. Differences between subgroups were considered relevant when SMDs differed >25% between groups.

Results: 2035 Studies were screened for eligibility, of which ten studies were included. A moderate pooled SMD of 0.52 (confidence interval (CI): 0.40–0.65, P<0.0001) was found for subjects with KOA K&L ≥2 versus controls, based on ten SMDs. For K&L3–4 versus K&L2 a moderate pooled SMD of 0.47 (CI: 0.32–0.63, P<0.0001) was found, based on five SMDs. No indications for publication bias were identified using funnel plots. Subgroup analyses of the K&L ≥2 versus control comparison showed that uCTX-II performs better in women as compared to men and in Caucasian subjects as compared to other ethnicities. Study size did not influence the pooled SMD. Subgroup analysis was considered infeasible for the K&L 2 versus K&L 3–4 comparison due to a limited number of studies.

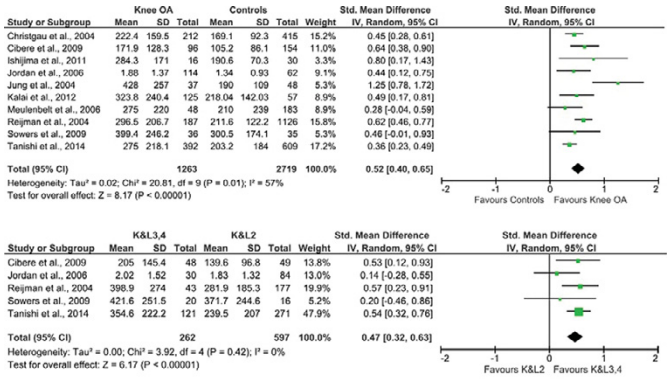

Figure 1: Forest plots for the comparisons of uCTX-II levels between subjects with radiographic KOA and controls and between subjects with KOA K&L3,4 and K&L2.

Conclusions: This is the first meta-analysis of uCTX-II performance in subjects with radiographic KOA. It appeared that uCTX-II levels can distinguish with moderate strength between radiographic KOA subjects and controls. Moreover, uCTX-II levels are consistently increased in severe versus moderate radiographic KOA. Female gender and Caucasian ethnicity were found to enhance uCTX-II performance in distinguishing radiographic KOA from controls. Yet, the number of studies was relatively small and criteria for KOA and control subjects differed between studies.

SAT0499 IDENTIFICATION OF BIOCHEMICAL PHENOTYPES IN KNEE OSTEOARTHRITIS: LONGITUDINAL DATA FROM THE FNIH OA BIOMARKER CONSORTIUM

B. Jeremiasse[1], P.M. Welsing[1], C. Fellows[2], F.P. Lafeber[1], W.E. Van Spil[1].
[1]Department of Rheumatology and Clinical Immunology, UMC Utrecht, Utrecht, Netherlands; [2]School of Veterinary Medicine, University of Surrey, Guildford, United Kingdom

Background: It is hypothesized that patients with knee osteoarthritis (OA) can be classified into different phenotypes. Knowledge of these phenotypes may contribute to developing effective targeted treatment strategies.

Objectives: To identify different longitudinal phenotypes of knee OA using biochemical markers and to compare these phenotypes with regard to radiographic joint space loss (JSL) and/or pain progression.

Methods: Baseline, 1-year, and 2-year biochemical marker data from the FNIH OA Biomarker Consortium were used. This consortium is a nested case-control study of 600 subjects with one symptomatic index knee showing radiographic OA changes of Kellgren and Lawrence grade 1 to 3[1]. Subjects were classified as either JSL progressors, pain progressors, JSL+pain progressors, or non-progressors according to predefined criteria (pain progression=persistent increase in WOMAC pain≥9 points (0–100 scale) from baseline to 2, 3 or 4 years, JSL progression=decrease in JSW≥0.7mm from baseline to 2, 3 or 4 years).
Biochemical markers included in the current analysis were sCTX-I, uαCTX-I, uβCTX-I, sNTX-I, uCTX-II, sCPII, sC2C, sC1,2C, sColl2–1 NO2, sCOMP, sHA, and sMMP (u=urinary, s=serum). First, using principal component analysis (PCA), the individual markers were reduced into a number of clusters of markers (components) that may represent common underlying domains. Second, a hierarchical cluster analysis (HCA) was performed to differentiate between longitudinal courses (phenotypes) of these marker clusters. The optimum number was determined from the additive value of each newly identified phenotype as compared to already identified phenotypes. Third, these longitudinal phenotypes were compared with regard to percentages of patients in each of the JSL and/or pain progression categories.

Results: PCA showed an optimal solution of three components. Looking at the markers that loaded maximally onto each of the components, they were interpreted as cluster of bone (sCTX-I, uαCTX-I, uβCTX-I, sNTX-I, uCTX-II), cartilage (sCPII, sC2C, sC1,2C, sColl2–1 NO2), and synovial (sCOMP, sHA, and sMMP) metabolism, respectively. HCA revealed an optimum of seven longitudinal phenotypes. Based on the relative predominance of the component(s) throughout follow-up, phenotypes were named “high bone”, “high cartilage”, “high synovium”, “low cartilage”, “low synovium”, “low bone, cartilage and synovium” and “low bone and high synovium” phenotype, respectively (Figure 1, dendrogram and heatmap). Phenotypes differed with regard to percentages of patients in JSL and/or pain progression categories (Figure 1, pie charts) as well as other demographic, clinical, and radiographic parameters (data not shown).

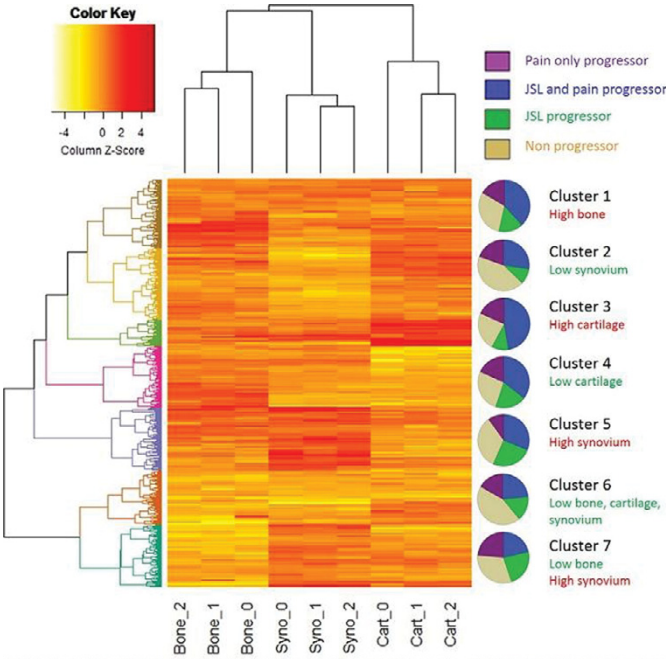

Figure 1: Heatmap depicting scores for the bone (bone), synovium (syno), and cartilage (cart) component for individual knee OA patients at baseline (_0), 1 year (_1), and 2 years (_2). Patients were classified into seven phenotypes using HCA, represented by the dendrogram at the left side. Percentages of subjects in the pain, JSL, pain+JSL, and no progression subgroups in each of the phenotypes are represented in the pie charts at the right side.

Conclusions: Seven longitudinal phenotypes of knee OA could be identified based on biochemical markers representing bone, cartilage and synovial metabolism. These phenotypes showed relevant differences in other characteristics, such as JSL and/or pain progression.

SAT0500 SLEEP DISTURBANCE, KNEE INFLAMMATION, AND SYMPTOMS IN KNEE OSTEOARTHRITIS

C.K. Kwoh[1], E. Ashbeck[1], A. Guermazi[2], F.W. Roemer[2,3], S. Parthasarathy[4].
[1]Univ. of Arizona Arthritis Center, Univ. of Arizona (UA), Tucson; [2]Radiology, Boston Univ., Boston, United States; [3]Radiology, Univ. of Erlangen-Nuremberg, Erlangen, Germany; [4]UAHS Center for Sleep & Circadian Sciences, UA, Tucson, United States

Background: Sleep disturbance has been shown to contribute to systemic inflammation, as well as increased pain sensitization. The role of sleep disturbance in knee osteoarthritis (OA) has not been established. Sleep disturbance may be an aggravating contributor to and/or a consequence of knee OA symptoms, with inflammation serving as a potential mediator.

Objectives: To compare knee symptoms over nine years of follow-up by

frequency of sleep disturbance at baseline, among participants with or at risk for radiographic knee OA (ROA), and to estimate the association between the presence of inflammation on knee MRI and pain that disturbs sleep among knees that developed ROA.

Methods: Knees from the Osteoarthritis Initiative (OAI) with or at risk for ROA were included in this longitudinal analysis. Self-reported frequency of restless sleep in the past week was assessed using a CES-D question. Knee symptoms were assessed annually using the WOMAC. Knees that developed incident ROA (i.e., ≥2 Kellgren-Lawrence grade, KLG) through four years of follow-up were assessed for effusion-synovitis on non-contrast-enhanced 3T MRI using the MRI Osteoarthritis Knee Score (MOAKS) from annual clinic visits between four years prior to incident ROA and up to one year after ROA detection. Effusion-synovitis represents a combination of joint effusion and synovial thickening on fluid-sensitive sequences and scored as 0 (normal), 1 (mild), 2 (moderate), or 3 (severe). Annual mean WOMAC total score was estimated using a mixed model with participant and knee treated as random effects, in 5,028 knees at risk for ROA at baseline, and in 3,893 knees with ROA at baseline. Log-binomial regression with generalized estimating equations was used to estimate the association between effusion-synovitis and knee pain in bed that disturbs sleep, adjusted for age, sex, and BMI in a sample of 355 knees with an average of 3.8 MRI assessments.

Results: There was dose-dependent effect, with participants reporting restless sleep 1–2 days, 3–4 days, and 5–7 days in the past week having higher mean WOMAC total scores compared to those who reported <1 day of restless sleep (i.e., difference in means: 2.5 [95% CI: 1.3 to 3.8], 5.1 [95% CI: 3.2 to 7.1], and 10.1 [95% CI: 7.6 to 12.6], respectively) among knees with ROA (KLG≥2) at baseline. Differences in average WOMAC total score between groups were relatively persistent over nine years (Figure 1). A similar dose-dependent effect of restless sleep was observed among knees at risk of ROA (i.e., KLG 0 or 1). Among knees that developed incident ROA, those with mild effusion-synovitis had a 52% higher risk of knee pain in bed that disturbs sleep at the same visit (RR=1.52; 95% CI: 1.13 to 2.04), while knees that had moderate/severe effusion-synovitis had more than double the risk of knee pain that disturbs sleep (RR=2.55; 95% CI: 1.87 to 3.47), compared to knees with no MRI-detected effusion-synovitis.

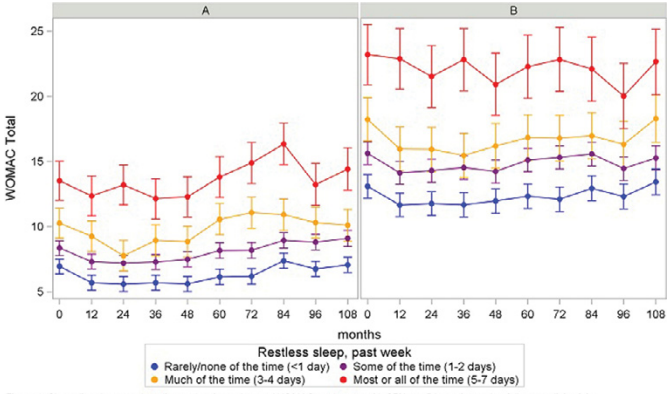

Figure 1. Sleep disturbance at baseline and estimated mean WOMAC total score with 95% confidence interval at follow-up clinic visits
A. Knees at risk for radiographic knee OA at baseline (KLG 0 or 1), B. Knees with radiographic knee OA at baseline (KLG 2+)

Conclusions: Restless sleep was associated with knee symptoms and disability in a dose-dependent manner, with average levels persistent over nine years of follow-up among knees with and at risk of ROA. Effusion-synovitis was associated with pain that disturbs sleep among knees that developed incident ROA. Sleep disturbance and knee inflammation may be important targets for interventions in knee osteoarthritis.

SAT0501 PREVALENCE OF HAND OSTEOARTHRITIS IN A MODEL OF AUTO-IMMUNE DISEASE, SJÖGREN SYNDROME: RESULTS OF A PROSPECTIVE STUDY

C. Glanowski[1], J. Sellam[1], E. Bergé[2], R. Seror[2], A.-L. Tomi[3], X. Chevalier[3], F. Berenbaum[1], X. Mariette[2], R. Belkhir[2]. *[1]Rheumatology, Hôpital Saint Antoine, Paris; [2]Rheumatology, Hôpital de Bicêtre, le Kremlin-Bicêtre; [3]Rheumatology, Hôpital Henri Mondor, Créteil, France*

Background: Despite the role of chronic low-grade inflammation in osteoarthritis (OA), prevalence of OA during inflammatory or auto-immune diseases remains poorly assessed. A single study without a valid control group [1] and daily practice suggest an increased frequency of hand OA (HOA) in primary Sjögren Syndrome (pSS).

Objectives: We aimed investigate the prevalence of radiographic, symptomatic or erosive HOA in pSS and to compare these results with age and sex-matched control population suffering from dry eyes and mouth without auto-immune manifestation (sicca patients).

Methods: We included women with pSS fulfilling 2002 AECG European-American criteria and control women suffering from sicca symptoms without autoimunity who underwent a multidisciplinary day hospital. Standardized radiographs of hands were performed and were all read by an experimented reader. Radiographic HOA was defined as Kellgren-Lawrence score ≥2 on at least one joint. Erosive HOA was defined using the Verbruggen scoring system (phase E, subchondral erosion or R, remodelling of subchondral plate). Symptomatic HOA was defined as radiographic HOA associated with spontaneous hand joint pain and/or with a FIHOA ≥5 at the time of radiographs. We compared pSS versus sicca patients, pSS with radiographic HOA (pSS+, HOA+) versus pSS without radiographic HOA (pSS+, HOA-), and finally pSS with radiographic HOA (pSS+, HOA+) versus sicca patients with radiographic HOA (pSS-, HOA+).

Results: We included 34 patients with pSS (median age [range] 54.5 [28–84] years) and 54 patients with only sicca symptoms (57 [24–85] years). Among pSS patients, 41% had radiographic HOA, 12% had symptomatic HOA and 9% had erosive HOA. These prevalences did not differ from sicca patients (52% radiographic HOA p=0.45, 28% symptomatic HOA p=0.11, 9% erosive HOA p=1.0). The trend for a higher prevalence of symptomatic HOA in sicca patients compared to pSS is expected since these patients frequently suffer from dryness associated with fibromyalgia. In pSS patients, radiographic HOA was associated with a higher average age (pSS+HOA+:63,5 versus pSS+HOA-: 48,5 years old, p<0,01), with menopause (pSS+HOA+: 100% versus pSS+HOA-: 45%, p<0,01) and hypothyroidism (pSS+HOA+: 64% versus pSS+HOA-: 25%, p=0.04). There was no pSS feature such as autoantibodies profile or pSS disease activity, associated with radiographic or symptomatic HOA. Finally, HOA symptoms did not differ between patients with pSS and sicca symptoms. The prevalence of radiographic and erosive HOA in pSS and non-autoimmune sicca group seems in the same range as that observed in women from Framingham's cohort (44% and 10% respectively). And prevalence of symptomatic HOA seems similar in the pSS (12%) and in women from Framingham's cohort (16%).

Conclusions: The prevalence of HOA is not increased in pSS, a model of auto-immune diseases. Patients with pSS have the same HOA risk factors than in general population (age and menopause) and also hypothyroidism that may be involved in OA pathophysiology.

SAT0502 A RANDOMIZED, PLACEBO-CONTROLLED, PROOF-OF-CONCEPT EFFICACY STUDY OF A MICROSOMAL PROSTAGLANDIN E SYNTHASE-1 (MPGES1) INHIBITOR AND A PROSTAGLANDIN E RECEPTOR (EP4) ANTAGONIST IN THE TREATMENT OF CANINE OSTEOARTHRITIS PAIN

C. Robertson-Plouch[1], J.R. Stille[2], P. Liu[1], S. Malcolm[2], D. Brown[3], M. Warner[1], M.J. Fisher[1]. *[1]Lilly Research Laboratories; [2]The Chorus Group, Eli Lilly and Company, Indianapolis; [3]School of Veterinary Medicine, University of Pennsylvania, Philadelphia, United States*

Background: Inflammation is a known contributor to osteoarthritis (OA) pain in animals and humans. While translation of human treatments to companion dogs is common, translation from companion dogs to humans is less frequent. We present results of a clinical study, in client-owned canines with moderate OA pain, which evaluated the efficacy of 2 molecules targeting the actions of prostaglandin E, either by modulating its production (mPGES1 inhibitor; LYA), or subsequent pharmacology through 1 of its 4 receptors (EP4 antagonist, LYB).

Objectives: To provide translational and comparative data to inform the potential utility of each of these mechanisms for treatment of chronic OA pain in humans and dogs.

Methods: A multicenter, randomized, double-blind, placebo (PBO)- and active-controlled trial in client-owned canine patients with moderate OA pain in ≥1 hindlimb/forelimb joint. Dogs ≥2 years of age with Liverpool Osteoarthritis in Dogs (LOAD) Mobility total score ≥13 to <46 were randomized (1:1:1:1) to 2 weeks of LYA (1.5 mg/kg/day), LYB (25 mg/kg/day), carprofen (4.4 mg/kg/day), or PBO. Efficacy versus PBO was assessed by mean change from baseline (CFB) to Week 2 in the Canine Brief Pain Inventory (CBPI) Pain Interference (PI) Score (primary endpoint), and for secondary endpoints: CBPI Pain Severity (PS) and Overall Impression (OI) subscores, and LOAD Mobility score. Data were analyzed by mixed-effect model for repeated measures with treatment, time, and interaction of treatment and time as fixed effects, and with baseline score, site, and weight as covariates. Posterior probability of treatments being superior to PBO was calculated with Bayesian methods.

Results: Of 163 dogs randomized, 158 (96.9%) completed the study. Treatment arms were well-balanced for baseline characteristics (mean [standard deviation] age: 9.3 [3.0] years, weight: 54.6% 15–32 kg, 45.4% >32–50 kg, CBPI PI: 5.1 [2.1]; CBPI PS: 4.2 [1.9]; LOAD Mobility: 24.1 [5.6]). Improvements (CFB) in CBPI PI were observed in all treatment groups after 2 weeks (Table). For LYA,

the probablility of superiority to PBO was 80% for CBPI PI and 89% to 96% for secondary endpoints. LYB showed inconsistent separation from PBO across the endpoints, with probablilty of superiority to PBO 54% to 89%. The separation of carprofen and PBO arms demonstrated assay sensitivity. The incidence of adverse events for LYA (35.9%) was comparable to that of carprofen (25.6%) and PBO (32.6%). For LYB, the incidence was significantly higher versus PBO (59.5%, P=.017).

Mean CFB to Week 2 in primary and secondary efficacy endpoints and probability of being superior to PBO

	LYA (n=39)	LYB (n=42)	Carprofen (n=39)	PBO (n=43)
CBPI PI (Primary)				
LS mean CFB (95% CI)	-1.85 (-2.44, -1.25)	-1.54 (-2.14, -0.95)	-2.12 (-2.73, -1.52)	-1.50 (-2.07, -0.92)
Prob. superior to PBO, %	80	54	93	
CBPI PS				
LS mean CFB (95% CI)	-1.66 (-2.14, -1.18)	-1.39 (-1.87, -0.91)	-1.56 (-2.05, -1.08)	-1.14 (-1.60,-0.68)
Prob. superior to PBO, %	94	78	90	
CBPI OI

SAT0503 CAN BALNEOTHERAPY MODIFY MICRORNA EXPRESSION LEVELS IN OSTEOARTHRITIS? A COMPARATIVE STUDY IN PATIENTS WITH KNEE OSTEOARTHRITIS TREATED WITH MUD-BATH THERAPY

C. Giannitti, A. De Palma, S. Cheleschi, J. Facciolo, N.A. Pascarelli, M. Galeazzi, A. Fioravanti. *Department of Medicine, Surgery and Neurosciences., Rheumatology Unit, Policlinico le Scotte, Siena, Italy*

Background: MicroRNAs (miRNAs) are a class of 19–23 nucleotides long non-coding RNAs that post-transcriptionally regulate the activity of target mRNAs. MicroRNAs are involved in cartilage homeostasis and play an important role in the pathogenesis of osteoarthritis (OA). They have been detected in human plasma and in synovial fluid and are considered as potential diagnostic biomarkers and therapeutic targets of OA. Balneotherapy is a common non-pharmacological treatment for OA patients. In a previous published prospective single-blind randomized clinical trial in patients with knee OA, we showed that a cycle of mud-bath therapy (MBT) in addition to conventional treatments induced an improvement on pain, functional capacity and quality of life in comparison to standard treatment alone.

Objectives: as part of this study we evaluated the whole blood levels of miR-155, 223, 181a, 146a and miR-let-7e, which are involved in the pathogenesis of OA.

Methods: Thirty-two patients aged between 50 and 75 years with knee OA defined by the ACR criteria were included for the current analysis, based on the availability of blood sample at basal time and after 2 weeks. Twenty-one patients (MBT group) were daily treated with a combination of daily local mud-packs at 42°C and baths in mineral water, at 37°C for 15 min, for a total of 12 applications over a period of 2 weeks, in addition to standard therapy; the other eleven patients (control group) continued their conventional treatment alone.

Clinical parameters [global pain score by a 0–100 mm Visual Analog Scale (VAS); physical function, total pain score and total stiffness score (WOMAC)] and microRNAs expression were performed at basal time and after 2 weeks. Peripheral whole blood was collected into PAXgeneTM Blood RNA tubes and then stored a -80°C. Total RNA was extracted using the PAXgeneTM Blood miRNA kit and the relative expression of miR-146a, miR-155, miR-223, miR-181a and miR-let-7e were determined by qRT-PCR.

Results: At the end of MBT we observed a statistically significant improvement of clinical paramethers. Furthermore, we observed a significant decrease of miR-155, 181a and miR-146a ($p<0.001$) and of miR-223 ($p<0.01$) expression levels. On the contrary, no clinical and biochemical modifications were detected in the control group. Concerning miR-let-7e expression levels no significant variations were showed in both groups after 2 weeks.

Conclusions: Our data showed that MBT can modify the expression levels of miR-155, 181a, 146a and 223 expression levels, that are up-regulated in OA. This MBT effect could be explained considering the role of the heat stress and of the hydrostatic pressure, since some miRNAs were found to be temperature and mechano-responsive. Further studies are needed to better explain the mechanism of action of MBT and the role of miRNAs in OA.

SAT0504 PREDICTIVE ABILITY OF BIOMARKERS LINKED WITH SYNOVITIS FOR FUTURE INCIDENCE OF PAINFUL KNEE OSTEOARTHRITIS IN A COMMUNITY BASED COHORT OF MIDDLE-AGE WOMEN

C.S. Thudium[1], S. Kluzek[2], J.L. Newton[2], T. Spector[3], D. Hart[3], M.A. Karsdal[1], A.C. Bay-Jensen[1], N. Arden[2]. *[1]Biomarkers & Research, Nordic Bioscience, Herlev, Denmark; [2]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford; [3]Department of Twin Research, King's College London, St. Thomas Hospital, London, United Kingdom*

Background: Radiographic knee osteoarthritis (RKOA) is associated with the knee pain. However, more than half of the middle-aged individuals with RKOA will report no concurrent knee pain. Specific matrix metalloproteinases (MMPs) generated protein fragments have been associated with knee synovitis and suggested as specific neo-epitope biomarkers of joint remodelling.

Objectives: The aim of the study was to evaluate the association between MMP-derived neo-epitope biomarkers measured in serum, and future incidence of either painful RKOA or RKOA without pain, in a cohort of middle-aged women with no RKOA at baseline.

Methods: 585 participants (mean age 53.2, mean BMI 25.1) from the Chingford 1000 Women Study Chingford Women Study had serum biomarker levels of MMP- degraded of CRP (CRPM), collagen type II (C2M) and collagen type III (C3M) measured at year 2 or 3 of the study. All participants had a Kellgren Lawrence (KL) score of 0 in both knees at baseline. Ten years following the recruitment, incidence of RKOA was determined as KL $\geq$2 and painful RKOA was defined as the presence of pain on any number of days in the preceding month in the knee with RKOA. Log-transformed normalised biomarker levels were utilised in separate logistic regression models adjusted for age. Outcomes were defined as either RKOA without pain or painful RKOA. Further analyses were performed adjusting for both age and BMI.

Results: 24.6% of women developed RKOA during 10 years after the recruitment, but only 8.9% of developed RKOA associated with concurrent knee pain. After adjusting for age, statistically significant positive associations were found between C3M and CRPM and the risk of developing painful RKOA with odds ratio (OR) =3.4 (95% confidence interval (CI): 1.4 to 8.2), and OR=2.5 (95% CI: 1.2, 5.2) respectively. After adjusting for age and BMI, only C3M was positively associated with risk of developing painful RKOA with OR=3.2 (95% CI: 1.3, 7.8).

Conclusions: In a population of middle-aged women without knee osteoarthritis, an MMP generated neo-epitope of collagen III previously linked with knee synovitis (C3M) can independently identify high-risk individuals for developing painful RKOA. These findings indicate that targeting MMP activity may be a promising therapeutic strategy in well-targeted populations.

SAT0505 SELF-REPORTED KNEE INSTABILITY ASSOCIATED WITH PAIN AND ACTIVITY LIMITATIONS PRIOR AND ONE YEAR AFTER TOTAL KNEE ARTHROPLASTY IN PATIENTS WITH KNEE OSTEOARTHRITIS

C. Leichtenberg[1], J.J. Meesters[1], J. Dekker[2,3], R.G. Nelissen[1], T.P. Vliet Vlieland[1], M. van der Esch[4]. *[1]Orthopedics, Leiden University Medical Center, Leiden; [2]Rehabilitation Medicine; [3]Psychiatry, VU University Medical Center; [4]Rehabilitation Research, Reade, Amsterdam, Netherlands*

Background: Sixty to 80% of the patients with knee osteoarthritis (OA) reported self-reported knee joint instability, which was associated with pain and activity limitations. One previous randomized control trial described the prevalence of retained self-reported knee joint instability after total knee arthroplasty (TKA) (32%). To better understand self-reported knee joint instability in usual care there is a need to replicate and extend the results.

Objectives: The aims of the study were to determine (i) the prevalence of self-reported knee instability prior and one year after TKA, (ii) the associations between self-reported knee instability, pain, activity limitations and quality of life prior and one year after TKA, (iii) the course of self-reported knee instability over time and (iv) the associations between retained knee instability, pain, activity limitations and quality of life.

Methods: Consecutive patients with knee OA undergoing primary TKA, extracted from the Longitudinal Leiden Orthopaedics and Outcomes of OsteoArthritis Study (LOAS Study), were included. Self-reported knee joint instability and the Knee injury and Osteoarthritis Outcome Score (KOOS) Pain, Activity Daily Living (ADL) and QoL subscales (0–100; worst-best) were assessed by questionnaires prior and one year after surgery. Multivariable regression analyses were performed to determine associations between knee joint instability, pain, activity limitations and quality of life, adjusted for potential confounders including age, sex, comorbidities, physical activity and preoperative frailty.
Results: 908 patients were included of which 649 patients (72%) reported preoperative knee joint instability (mean age 67 years (SD8.6), 453 females (70%)) and 187 patients (21%) postoperative knee joint instability. Preoperative knee joint instability was associated with preoperative KOOS Pain (B-7.2;95% CI-10.9–3.5) and ADL (B3.8;95% CI-7.5–0.09), but not QoL (B-0.4;95% CI-2.1–1.2). In addition, postoperative knee joint instability was associated with postoperative KOOS Pain (B-13.5;95% CI-17.0–10.0), ADL (B-15.1,95% CI-18.4–11.8) and QoL (B-11.0;95% CI-13.5–8.5). Among the patients with preoperative self-reported knee joint instability, 165 patients (25%) retained knee instability and among the patients with no preoperative self-reported knee joint instability, 22 (8%) developed knee instability one year after surgery. After adjusting for baseline scores and potential confounders, retained knee joint instability was associated with postoperative KOOS Pain (B-19.6;95% CI-30.9–8.3), ADL (B-16.5;95% CI-27.0–5.9) and QoL (B-13.0;95% CI-17.9–8.1).
Conclusions: In usual care, knee joint instability is prevalent one year after TKA (21%). Reported knee joint instability is associated with more pain, worse physical function (pre- and postoperatively) and worse QoL postoperatively. Besides, retained knee joint instability was associated with worse pain, physical function and QoL. This emphasizes the importance of further research into the genesis of pre- and postoperative knee joint instability.

SAT0506 EARLY POSTOPERATIVE IDENTIFICATION OF PATIENTS AT RISK FOR UNFAVOURABLE LONG-TERM OUTCOMES

C. Leichtenberg[1], H.H. Kaptijn[2], S.H. Verdegaal[3], R. Onstenk[4], H.M. van der Linden-van der Zwaag[1], S.B. Vehmeijer[5], W.-J.C. Marijnissen[6], P.-J. Damen[7], R.G. Nelissen[1], T.P. Vliet Vlieland[1], M.G. Gademan[1] on behalf of LOAS Studygroup. *[1]Orthopedics, Leiden University Medical Center, Leiden; [2]Orthopedics, LangeLand Hospital, Zoetermeer; [3]Orthopedics, Alrijne Hospital, Leiden and Leiderdorp; [4]Orthopedics, Groene Hart Hospital, Gouda; [5]Orthopedics, Reinier de Graaf Hospital, Delft; [6]Orthopedics, Albert Schweitzer Hospital, Dordrecht; [7]Orthopedics, Waterlandziekenhuis, Purmerend, Netherlands*

Background: Identification of patients who benefit from Total Hip or Knee Arthroplasty (THA or TKA) is necessary to indicate the need for surgery. This seems difficult as 20% of all patients report unfavourable outcomes. To provide better treatment options for patients with unfavourable outcomes, they should be identified at an early stage after surgery.
Objectives: I To investigate the prevalence of four trajectories in THA and TKA patients for both pain and function separately: (1) Patients with favourable initial and long-term outcomes, (2) patients with favourable initial but unfavourable long-term outcomes, (3) patients with unfavourable initial and favourable long-term outcomes and (4) patients with unfavourable initial and long-term outcomes. II To determine if long-term outcomes in all patients and in patient groups stratified by initial outcome (favourable/unfavourable) can be predicted on the basis of pre- and early postoperative variables.
Methods: Prospective, multicentre, observational study including consecutive patients undergoing primary THA and TKA (Longitudinal Leiden Orthopaedics and Outcomes of OsteoArthritis Study (LOAS). Measurements were done preoperatively and at 6 and 12 months. Pain and function were assessed with the Hip Disability/ Knee injury and Osteoarthritis Outcome Scores (HOOS or KOOS) Pain and Activity Daily Living (ADL) subscales (score range 0–100). In addition, preoperative variables (sex, age, comorbidities) and early postoperative complications (reoperations or readmissions) were gathered by questionnaire. Scores of the Pain and ADL subscales above and below 70 were defined as favourable and unfavourable outcomes, whereas initial and long-term outcomes were defined as 6 months and 12 months after surgery, respectively. First the prevalence's of the trajectories were determined. Secondly, multivariable logistic regression analysis were done to examine if preoperative variables, postoperative complications and initial outcomes predicted long-term pain and function outcomes. Identical analyses were performed in the patients with favourable and unfavourable initial outcomes separately.
Results: 972 THA and 892 TKA patients were included. With respect to pain, the prevalence of trajectories 1, 2, 3 and 4 were 79% (n=740), 5% (n=47), 7% (n=63) and 9% (n=88) in THA and 75% (n=606), 4% (n=33), 9% (n=71) and 12% (n=93) for TKA. With respect to function, the prevalence's were 74% (n=696), 6 (n=53), 7% (n=63) and 14% (n=131) for THA and 72% (n=624), 5% (n=49), 9% (n=78) and 14% (n=119) for TKA, respectively. Moreover, one-third of the patients with initial unfavourable pain or function outcomes attained favourable long-term outcomes. Overall, only the initial postoperative HOOS/KOOS pain and function predicted long-term outcomes (Table 1).

Table 1. Multivariable associations of preoperative or early postoperative pain or function outcomes with long-term pain or function outcomes

	Early postoperative associations with long-term outcomes in all patients		Early postoperative associations with long-term outcomes in patients with unfavourable early outcomes		Early postoperative associations with long-term outcomes in patients with favourable early outcomes	
THA	Pain N=151, ADL N=194		Pain N=88, ADL N=131		Pain N=63, ADL N=63	
	OR	95% CI	OR	95% CI	OR	95% CI
HOOS Pain*	1.10	1.08-1.12	1.06	1.01-1.11	1.12	1.06-1.17
HOOS ADL*	1.13	1.10-1.16	1.07	1.02-1.12	1.13	1.06-1.20
TKA	Pain N=221, ADL N=197		Pain N=121, ADL N=119		Pain N=100, ADL N=78	
	OR	95% CI	OR	95% CI	OR	95% CI
KOOS Pain*	1.10	1.08-1.13	1.06	1.02-1.11	1.14	1.01-1.21
KOOS ADL*	1.11	1.08-1.13	1.06	1.02-1.10	1.12	1.06-1.18

*Included in the multivariable model were age, sex, comorbidities (musculoskeletal and non-musculoskeletal), postoperative complications and the HOOS/KOOS pain or ADL subscale.
THA or TKA = Total Hip or Knee Arthroplasty
ADL = Activity Daily Living
HOOS = Hip Disability and Outcomes of Osteoarthritis Score
KOOS = Knee Injury and Outcomes of Osteoarthritis Score
OR = Odds Ratio
CI = Confidence Interval

Conclusions: One-third of patients with unfavourable initial outcomes improved further after the first six months after surgery. More research into the recovery early after surgery may help to identify patients at risk for unfavourable outcomes and modify their course by appropriate interventions.

SAT0507 OXYTOCINE IN OSTEOARTHRITIS: FROM IN VITRO TO IN VIVO

C.H. Roux[1], E. Fontas[2], L. Euller-Ziegler[3], V. Breuil[3], E.Z. Amri[4]. *[1]Rheumatology, University of Nice Sofia Antipolis, IBV; [2]Biostatistical Department; [3]Rheumatology, CHU Nice, University Nice Sofia Antipolis; [4]Biological Department, University of Nice Sofia Antipolis, IBV, nice, France*

Background: The relationship between oxytocine (OT) and osteoarthritis (OA) is poorly studied and remains unknown. However the subchondral bone is considered as a major player in osteoarthritis, and a protective effect of OT on bone mineralization is described in recent studies.
Objectives: The aim of our work was to investigate a possible link between OT and OA
Methods: we used three different approaches: i) In vitro using MSC (adipose and bone marrow derived stem cells) that were maintained as mono-layer (2D) or as pellets in three dimension (3D) in the absence or the presence of OT. RT-PCR, histological and immunohistochemical analysis were performed. ii) in vivo using a rat animal model developing OA upon anterior cruciate ligament transection (ACLT). Twenty female Wistar rats were divided in 2 groups: one group was sham operated whereas the second was ACL transected. Half of each group received either OT (1 mg/kg/day) injections or saline buffer. Histological analysis was performed on day 28. The severity of OA lesions was assessed on a scale adapted from Mankin's score at medial part of the femur. iii) Clinical analysis using a *human cohort*. Samples issued from a hand OA cohort (ADEM). 63 OA women have been included; men were excluded because of their low number. At baseline, all subjects benefited of OT and leptin circulating levels measurements and hand X rays (Scoring systems including Kelgren and Lawrence and Verbruggen scores). The control group consists in subjects of the same age range without osteoporosis, OA or inflammatory disease.
Results: OT treatment of differentiating MSCs for 21 days induced a significant increase of agrecan, Col X and COMP mRNA levels without variation of Col 1a. Immunostaining experiments showed an improvement of Sox9 and Col II expression in the presence of OT. The histological analysis of rat knee showed no differences in the severity of lesions between the different ACLT groups. The characteristics of the women cohorts is as follow: 63 OA women age = 65 (+/-11), Body Mass Index (BMI) = 24 (+/-4), OT=1.4 (+/-2) and 19 control women age=63 (+/-10), BMI=26 (+/-5), OT=6.5 (+/-7).The multivariate analysis adjusted for age, BMI and leptin levels, showed a significant lower level of OT in hand OA women ($p=0.002$, $\beta=3.4$). In univariate analysis, there was no relationship between OT blood levels and the severity of OA (Verbruggen: p=0.7, KL: p=0.2), Joint Space Narrowing (p=0.2) and osteophytes (p=0.1).
Conclusions: Our study shows an anabolic effect of OT on chondrogenesis and that OT circulating levels was significantly lower in OA patients. OT might represents an interesting player in the pathophysiology of osteoarthritis and further studies will shed some light on its mechanism of action.

SAT0508 LACK OF A CLEAR DISEASE MODIFYING ACTIVITY OF CELECOXIB IN TREATMENT OF END-STAGE KNEE OSTEOARTHRITIS: A RANDOMIZED OBSERVER BLINDED CLINICAL TRIAL

E.M. Van Helvoort[1], K. Coeleveld[1], T.N. de Boer[1], A.M. Huisman[2], A.A. Polak[3], J.W.J. Bijlsma[1], J.M. van Laar[1], F.J.P.G. Lafeber[1], S.C. Mastbergen[1].
[1]Rheumatology and Clinical Immunology, University Medical Centre Utrecht, Utrecht; [2]Rheumatology; [3]Orthopedics, Sint Franciscus Gasthuis, Rotterdam, Netherlands

Background: Several studies suggest that celecoxib has beneficial effects on degenerated cartilage (1, 2). Together with effects on synovial tissue and bone, celecoxib was postulated to have disease modifying osteoarthritic drug (DMOAD) activity.
Objectives: This study evaluated the DMOAD activity of celecoxib, a selective cyclooxygenase 2 (COX-2) inhibitor compared to no treatment and naproxen, treating end-stage knee osteoarthritis (OA), after in vivo exposure using detailed *ex vivo* tissue analyses.
Methods: 172 patients with end-stage knee OA were randomized to 4 groups and treated for 4 weeks prior to knee replacement surgery: celecoxib 2dd200g, naproxen 3dd250mg, celecoxib 2dd200mg stopped 3 days prior to surgery, or no treatment. To determine if treatment had reached the joint, intra-articular COX-2 expression was determined by Western Blot analysis in the celecoxib until surgery and no treatment group, considering these as most extremes. Proteoglycan release, as primary outcome and content were determined by staining and precipitation of glycosaminoglycans (GAGs) with Alcian Blue. Release of newly formed proteogylcans, as a measure of proteoglycan retention, was determined by loss of $^{35}SO_4^{2-}$-labeled GAGs in culture medium by precipitation of GAGs and subsequent liquid scintillation analysis. Synovial tissue inflammation markers interleukin-1β (IL-1β) and tumor necrosis factor-α (TNF-α) were determined by Enzyme Linked Immuno Sorbet Assay (ELISA) and nitric oxide (NO) production by standard Griess reaction. Western Ontario and McMaster University (WOMAC) questionnaire was used to evaluate clinical parameters.
Results: Intra-articular COX-2 expression was significantly decreased in both cartilage and synovial tissue (figure 1) indicating proper in vivo exposure of the treatment.
Despite this reduction, no significant effect on proteoglycan release, retention or content was found for none of the treatment groups (table 1). Synovial tissue showed only a small decrease in nitric oxide levels in celecoxib treated patients. No clear clinical effects could be observed as indicated by the WOMAC scores.

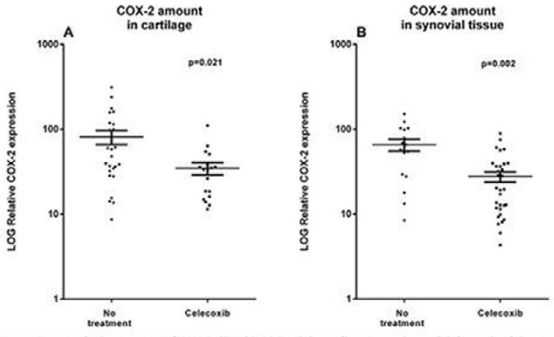

Figure 1. Intra-articular amount of COX-2. The COX-2 levels in cartilage (A) and synovial tissue (B) of the no treatment group and celecoxib until surgery group. Results are presented for each individual patient (dots) and mean ± SEM (dash with whiskers). P-values are given for celecoxib treated group compared to no treatment group. Due to limited amount of tissue available the analyses of COX-2 for cartilage was limited to 18 treated and 25 non-treated patients and for synovial tissue to 31 treated and 16 non-treated patients.

Table 1: Effects of 4 week treatment with celecoxib or naproxen on cartilage biochemistry, synovial tissue inflammation and WOMAC scores. Results are expressed as means (SD) and P-values represent comparison with no treatment

	No treatment	Celecoxib		Celecoxib -3		Naproxen	
	Mean (SD)	Mean (SD)	P-value	Mean (SD)	P-value	Mean (SD)	P-value
Cartilage biochemistry							
- % total PG release	12 (4.36)	11 (2.86)	0.630	11 (2.61)	0.826	12 (3.98)	0.720
- % newly formed PG release	15 (8.97)	14 (5.48)	0.795	13 (4.54)	0.531	15 (7.24)	0.755
- PG content	25 (6.63)	24 (4.81)	0.525	25 (4.61)	0.901	23 (6.02)	0.243
Synovial tissue inflammation							
- IL1β production (pg/ml/mg tissue)	17.88 (45.02)	15.71 (28.24)	0.901	14.04 (19.86)	0.481	11.44 (17.04)	0.880
- TNF-α production (pg/ml/mg tissue)	2.70 (2.56)	2.44 (2.42)	0.655	3.93 (5.21)	0.393	2.35 (1.77)	0.985
- NO production (uM/mg tissue)	0.08 (0.04)	0.06 (0.05)	***0.041***	0.07 (0.06)	0.270	0.09 (0.09)	0.745
WOMAC change after treatment							
- Pain	-3.93 (11.64)	2.13 (18.09)	0.127	4.91 (14.40)	***0.026***	0.46 (12.21)	0.258
- Stiffness	3.13 (21.74)	3.65 (20.01)	0.865	10.19 (19.62)	0.245	6.00 (14.03)	0.363
- Function	-1.82 (8.95)	2.98 (15.18)	0.115	2.07 (14.50)	0.191	1.73 (12.39)	0.193
- Total	-1.76 (8.03)	2.80 (15.12)	0.109	3.44 (13.84)	0.124	1.87 (10.77)	0.138

No treatment (n=38); Celecoxib until surgery (n=34); Celecoxib -3 represents celecoxib stopped 3 days before surgery (n=33); Naproxen stopped 3 days before surgery (n=32). P-values represent comparison to no-treatment group.

Conclusions: No effect of a 4-week in vivo celecoxib treatment on joint tissue in knee OA patients could be detected, although decreased expression of COX-2 confirmed its intra-articular availability. Effects on synovial inflammatory mediators and clinical outcome were very limited. No adverse effects were found either. As such the previous reported disease modifying effects of celecoxib in *in vitro* and pilot clinical studies could not unambiguously be confirmed in this randomized trial.

SAT0509 DYNAMICS IN THE LEVELS OF ADIPOKINES AND CYTOKINES IN PARALLEL WITH WEIGHT LOSS AND THEIR RELATIONSHIP WITH CLINICAL MANIFESTATIONS OF KNEE OSTEOARTHRITIS

E. Strebkova[1], I. Solovyova[2], A. Mkrtumyan[2], L. Alekseeva[1]. *[1]Nasonova Research Institute of Rheumatology; [2]Moscow State Medical Stomatological Institute, Moscow, Russian Federation*

Background: Untoward effects of pro-inflammatory cytokines on a chondrocyte are implied in pathogenesis of osteoarthritis (OA), while adipokines would enhance these pathogenetic mechanisms and facilitate maintenance of inflammation and progression of OA when the latter is associated with obesity.
Objectives: To asses dynamic changes of adipokine (leptin) and pro-inflammatory cytokines (IL-6, TNF-α) levels and their relationship with clinical manifestations of knee OA in pts losing weight during orlistat therapy.
Methods: The study included 50 female pts aged 45–65 years with knee OA, Kellgren-Lawrence stage II-III, and obesity (BMI>30kg//m^2). Pts form Group 1 (n=25) were receiving orlistat 120 mg x 3 times a day for 6 month combined with low-caloric diet and therapeutic physical exercise. Pts from Group 2 (n=25) were administered only low-caloric diet and therapeutic physical exercise for 6 month. Anthropometry data (height, body weight, BMI), WOMAC and quality of life EQ-5D scores, as well as serum levels of leptin, IL-6 and TNF-α using ELISA were assessed at baseline and at 6 months in all pts.
Results: Following pharmacological and non-pharmacological therapy of obesity in pts with knee OA subjects from Group 1 reduced their body weight by 10,07% (p<0,05), and pts from Group 2 - by 0,84% (p>0,05). At baseline pts from both groups did not differ (p>0,05) by leptin, IL-6 and TNF-α levels. Decreased leptin levels were documented in pts from Group 1 after 6 months of orlistat therapy (p=0,05), which directly correlated with body weight loss (r=0,5, p=0,02), total WOMAC score reduction r=0,5, p=0,01), and score reduction in WOMAC subscales measuring pain r=0,5, p=0,01; stiffness r=0,4, p=0,04; and functional insufficiency r=0,4, p=0,03, thus reflecting improvement of OA symptoms; and inversely correlated with increased EQ-5D score (r=-0,4, p=0,03) reflecting improvement in quality of life. Besides, orlistat therapy was associated with decreased IL-6 levels (p<0,05). Both groups demonstrated high TNF-α levels, although some insignificant decrease was noticed in Group 1 (p=0,14) following weight loss with orlistat therapy. Persisting leptin, IL-6 and TNF-α levels were registered in pts from Group 2, who maintained their body weight following only life-modifying therapy of obesity. Clear correlations between IL-6 and TNF-α levels and changes in body weight and clinical manifestations of OA were not found in both groups.
Conclusions: Significant decrease in leptin and IL-6 levels were observed in knee OA pts following orlistat therapy and associated weight loss. There was a direct correlation between decreased leptin levels and body weight loss, as well as reduction in WOMAC scores reflecting improvement of knee OA clinical manifestations, and inverse correlation with EQ-5D score resulting in quality of life improvement. Therefore, body weight loss following pharmacotherapy of obesity is associated not only with improvement of OA clinical symptoms, but also with down-regulation in production of pro-inflammatory leptin and IL-6, most probably resulting in reduction of meta-inflammation in obese pts with OA.

SAT0510 EFFECT OF PHARMACOLOGICAL AND NON-PHARMACOLOGICAL THERAPY OF OBESITY ON THE CLINICAL MANIFESTATIONS OF OSTEOARTHRITIS

E. Strebkova, L. Alekseeva. *Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Osteoarthritis (OA) and obesity are inter-related and most challenging conditions for the public health, leading to significant deterioration in quality of

life. Obesity is considered to be associated with the incidence and progression of OA, thus weight loss is of paramount importance in OA management.
Objectives: To evaluate the efficacy of pharmacological and non-pharmacological therapy of obesity in pts with knee OA.
Methods: The study included 50 female pts aged 45–65 years with knee OA, Kellgren-Lawrence stage II-III, and obesity (BMI>30kg//m^2). Pts form Group 1 (n=25) were administered orlistat at 120 mg x 3times a day for 6 month alongside with low-caloric diet and therapeutic physical exercise. Pts from Group 2 (n=25) adhered to life-modifying therapy only, i.e. low-caloric diet and therapeutic physical exercise for 6 month. Anthropometry data (height, body weight, BMI), as well as WOMAC and quality of life EQ-5D scores were assessed at baseline, at 6 and 12 months (i.e, 6 months after discontinuation of therapy) after initiation of treatment in all pts.
Results: After 6 months of pharmacological therapy pts from Group 1 achieved significant mean weight loss by 10,07% (p<0,05), while pts from Group 2 with non-pharmacological therapy demonstrated only <1% (0,84%) (p>0,05) weight loss. Pts receiving pharmacological therapy with orlistat demonstrated the following improvements by WOMAC subscales: pain reduction by 52,5% (p<0,05), stiffness reduction by 47,98% (p<0,05), and 51,55% function improvement, while total WOMAC score improved by 51,49% (p<0,05). Respective WOMAC subscale scores in pts from Group 2 were considerably less impressive vs Group 1. Pts from Group 1 demonstrated statistically significant improvement in the quality of life by 52,27% EQ-5D (p<0,05). EQ-5D score remained unchanged only in 2 pts from Group 1 who failed to lose weight. During the following 6 months after discontinuation of orlistat pts from Group 1 regained 5,6% of their body weight (p<0,05) (Fig.1), which was associated with OA worsening OA (deterioration of pain by 42,63% (p<0,05) WOMAC, and total WOMAC score decrease by 23,15%). After 12 months of follow up pts from Group 2 showed body weight loss by 3,5%, and continuing decrease of pain in knee joints by WOMAC pain subscale, reaching 22,3% (p<0,05) as compared to baseline.

Fig 1. Body weight dynamics during the study

Conclusions: The results of our study demonstrate significant >10% weight loss in OA pts induced by orlistat therapy. Such a noticeable weight loss was associated with reduced pain intensity, improved function and quality of life in OA pts. Partial regain of body weight during 6 months after discontinuation of orlistat was accompanied by worsening of OA clinical course. Thus, effective maintenance of optimal body weight in OA pts requires longer pharmacotherapy of obesity.

SAT0511 THUMB BASE OSTEOARTHRITIS: ASSOCIATIONS BETWEEN SYNOVITIS ON ULTRASOUND AND PAIN

S. Ermurat[1], F. Kroon[2], M. Kortekaas[2], M. Reijnierse[3], M. Kloppenburg[2,4].
[1]Rheumatology, Uludag University Medical Faculty, Bursa, Turkey; [2]Rheumatology; [3]Radiology; [4]Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands

Background: Hand osteoarthritis (OA) affects the interphalangeal (IP) joints but also the first carpometacarpal (CMC1) joint in the thumb base. Previous ultrasonography (US) studies of the IP joints have shown that inflammatory and structural features are frequently present and associated with clinical signs and symptoms. Until now, US studies specifically assessing the CMC1 joint have not been performed.
Objectives: To investigate associations between inflammatory features, structural damage and pain in CMC1 OA.
Methods: Cross-sectional data of 87 hand OA patients participating in the EChography in Hand OA (n=63) and the Etanercept in Hand OA (n=24) study at the Leiden University Medical Center were used in this analysis. Both CMC1 joints were assessed with US for synovial thickening, effusion and power Doppler signal (PDS) on a 0–3 scale by experienced ultrasonographers. Presence of pain upon palpation of the thumb base was assessed by trained research nurses on the same day as the US. Hand radiographs were scored blinded for clinical and US features, according to the Osteoarthritis Research Society International atlas for osteophytes (0–3), joint space narrowing (JSN, 0–3), sclerosis (0–1) and malalignment (0–1) in the CMC1 joint. Risk ratios (RRs) with 95% confidence intervals (CIs) were calculated using generalized estimating equations to investigate associations between US or radiographic features and thumb base pain on joint level.
Results: Of 87 patients (mean age 60.3 years, 82% women, mean BMI 27.2 kg/m^2) 174 CMC1 joints were assessed, of which 54 (31%) were painful. The US features synovial thickening, effusion and PDS were found in 26%, 33% and 25% of the joints, respectively. Radiographic features were present in 55% (osteophytes), 79% (JSN), 20% (sclerosis) and 12% (malalignment) of the joints. No associations were seen between inflammatory US features and pain upon palpation of the thumb base (Table). However, osteophytes and sclerosis were associated with more pain (RR 2.5 [95% CI 1.4 to 4.6] for osteophytes grade 3 versus no osteophytes, and RR 2.0 [95% CI 1.3 to 3.2] for presence of sclerosis). Other radiographic features (JSN, malalignment) showed a trend for increased risk of pain on palpation, and for osteophytes and JSN a dose-response relation was apparent.

Table. Associations of US and radiographic features with pain on palpation in thumb base OA (n=171 joints*)

	Tenderness yes/no, n	RR (95% CI)
US features		
Synovial thickening		
Absent	40/85	1
Grade 1	10/22	1.1 (0.6-1.8)
Grade 2/3	4/10	0.9 (0.4-2.4)
Effusion		
Absent	35/79	1
Grade 1	13/25	0.8 (0.4-1.5)
Grade 2/3	6/13	0.8 (0.3-2.0)
Power doppler signal		
Absent	41/86	1
Grade 1	8/24	0.9 (0.5-1.6)
Grade 2/3	5/7	1.2 (0.7-2.0)
Radiographic features		
Osteophytes		
Absent	18/58	1
Grade 1	16/40	1.2 (0.7-2.2)
Grade 2	11/13	1.5 (0.7-2.9)
Grade 3	9/6	2.5 (1.4-4.6)
Joint space narrowing		
Absent	8/27	1
Grade 1	36/77	1.6 (0.8-3.3)
Grade 2	7/9	2.1 (0.8-5.3)
Grade 3	3/4	2.5 (0.9-7.0)
Sclerosis		
Absent	38/104	1
Present	16/13	2.0 (1.3-3.2)
Malalignment		
Absent	44/107	1
Present	10/10	1.4 (0.7-2.7)

*3 joints no information on tenderness. CI, confidence interval; n, number; OA, osteoarthritis; RR, risk ratio; US, ultrasound.

Conclusions: Radiographic features, especially osteophytes and JSN, were prevalent and more frequently present than US inflammatory features in the CMC1 joints of hand OA patients. In contrast to what is known from studies in IP joints, the presence of inflammatory US features was not associated with pain in the thumb base, but structural damage was. These results suggest differences in etiology of pain in thumb base compared to IP OA, with a larger role for structural damage in thumb base OA.

SAT0512 MRI PROVIDING INSIGHTS IN ASSOCIATION OF SYNOVITIS AND BONE MARROW LESIONS (BMLS) WITH PAIN IN THUMB BASE OSTEOARTHRITIS (OA)

F. Kroon[1], S. van Beest[1], W. Damman[1], R. Liu[1], M. Reijnierse[2], M. Kloppenburg[1,3]. *[1]Rheumatology; [2]Radiology; [3]Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands*

Background: Hand OA affects the interphalangeal (IP) and thumb base joints (first carpometacarpal [CMC1] and scaphotrapeziotrapezoid [STT]). Much is still unknown about the pathophysiology of thumb base OA. Magnetic resonance imaging (MRI) studies have led to new insights in IP OA, but in absence of a scoring system thumb base MRI studies are lacking.
Objectives: Investigate the prevalence of MRI synovitis and BMLs in the thumb base, and their association with pain, using the novel OMERACT thumb base OA MRI scoring system (TOMS)[1].
Methods: Cross-sectional data of the Hand OSTeoArthritis in Secondary care (HOSTAS) study, including consecutive patients diagnosed by their treating rheumatologist with primary hand OA, were used. Patients with an MRI of the right thumb base at baseline were included in the analysis. MRIs were scored by two readers using the TOMS for synovitis and bone marrow lesions (BMLs) in the CMC1 and STT joints (grade 0–3). BMLs were evaluated in the proximal and distal joint parts separately, resulting in a 0–6 and 0–9 sum score for CMC1 and STT, respectively. Pain on palpation of the thumb base was assessed by trained research nurses. Hand radiographs were assessed for presence of osteophytes in the CMC1 and STT joints. Associations between MRI lesions and thumb base tenderness were analysed using logistic regression, presented as odds ratios (ORs) with 95% confidence intervals (CIs), stratified for absence or presence of radiographic osteophytes. For the analyses synovitis and BML scores were

aggregated into a dichotomous total thumb base involvement score (0–1 in both joints vs ≥2 in at least one joint).
Results: 85 out of 202 patients (84% women, mean age 60.1 years) reported pain on palpation in the thumb base. Synovitis was seen in both thumb base joints (CMC1 42%, STT 37%), although prevalence of grade 2–3 synovitis was low in both the CMC1 (16%) and STT (14%). BMLs were present in CMC1 and STT in 54 and 53%, respectively, with 18 and 21% having a sum score of 2–3, and 16 and 7% a sum score ≥4. In absence of radiographic osteophytes, presence of synovitis or BMLs in either thumb base joint was not statistically significantly associated with thumb base tenderness (ORs 1.9 [95% CI 0.6–6.4] and 1.5 [0.5–4.3], respectively). However, in absence of synovitis or BMLs, radiographic osteophytes and pain were associated, with increasing ORs when MRI lesions were additionally present (Table). Similar results were found for self-reported thumb base pain (not shown).

Table. Number of tender joints (yes/no) and associations of MRI inflammation and radiographic osteophytes with pain on palpation in thumb base osteoarthritis (n=196*)

		Osteophyte CMC1 or STT	
		absent	*present*
Synovitis	*CMC1 and STT grade 0-1*	1 23/70	4.2 (2.0-8.6) 30/22
	CMC1 or STT grade ≥ 2	1.9 (0.6-6.4) 5/8	5.9 (2.6-13.3) 25/13
BML	*CMC1 and STT grade 0-1*	1 21/64	4.3 (1.7-11.0) 14/10
	CMC1 or STT grade ≥ 2	1.5 (0.5-4.3) 7/14	5.3 (2.6-10.8) 42/24

BML, bone marrow lesion; CI, confidence interval; CMC1, first carpometacarpal; MRI, magnetic resonance imaging; OR, odds ratio; STT, scaphotrapeziotrapezoid.
*n=196 patients with available radiographs and evaluable MRI for synovitis and BMLs.

Conclusions: Synovitis and BMLs are present in the thumb base, although severe MRI lesions were uncommon. Prevalence of synovitis was similar in the CMC1 and STT joints, although higher BML scores were more frequently seen in CMC1. Radiographic osteophytes seemed more important in predicting thumb base tenderness than MRI inflammation alone. Combined presence of radiographic osteophytes and MRI lesions had a small additive effect. These findings are in contrast to results from IP OA studies, supporting thumb base OA as a distinct hand OA subset. It might also explain why trials investigating intra-articular corticosteroids in thumb base OA have led to equivocal results.

SAT0513 FUNCTIONAL IMPAIRMENT RATHER THAN BURDEN OF CO-MORBIDITIES IS ASSOCIATED WITH A 5-YEAR CHANGE IN HEALTH STATE UTILITY IN HIP AND KNEE OSTEOARTHRITIS: RESULTS FROM THE KHOALA COHORT STUDY

A.Y. Omorou[1,2], H. Achit[2], M. Wieczorek[1], B. Fautrel[3], A.-C. Rat[1], F. Guillemin[1,2]. [1]*Ea 4360 Apemac, University of Lorraine;* [2]*CIC-1433 Clinical Epidemiology, CHRU Nancy, Nancy;* [3]*UPMC Université Paris 6, Grc-Upmc 08 (Eemois), Sorbonne Universités, Paris, France*

Background: Functional impairment of hip and knee osteoarthritis (OA) and associated co-morbidities can independently impact patient's health state utility (HSU), a useful indicator for valuing health in medico-economic studies.
Objectives: This study aimed to examine the respective influence of the evolution of functional impairment and of burden of co-morbidities on a 5-year change in HSU for patients with OA.
Methods: 548 patients (Mean age of 61.1 years, 66.6% of women and 68.1% with knee OA) from the KHOALA study with 5 years follow-up were included. Functional impairment, co-morbidities and HSU were measured annually using the WOMAC (0–100) [1], FCI (1–18) [2] and SF-6D (0–1) [3], respectively. First, baseline clinical patterns were identified using hierarchical clustering methods [4]. Then, the role of these patterns as determinants of 5-year change in HSU was analysed using hierarchical mixed models.
Results: Two clusters were identified: cluster 1 *"Low functional impairment and few co-morbidities"* (65.3%) and cluster 2 "*Severe functional impairment and many co-morbidities*" (34.7%). Compared to the cluster 1, the functional impairment of cluster 2 significantly decreased (-14.5 [-18.1; -10.92]) at 5 year follow up, while the co-morbidity index significantly increased in the two clusters (+0.18 [-0.22; 0.57]). The mean baseline HSU score was 0.66 (0.70 for cluster 1 and 0.59 for cluster 2). Compared to cluster 1, patients in cluster 2 had a significantly higher increased in 5-year HSU (β=+0.0335 [0.0088; 0.0583]) (R^2=21%). The difference of 5-year change in HSU was no more significant when adjusted for change in functional impairment (β=+0.0335; p=0.008 vs. -0.0153; p=0.30) (R^2=42%) while it remained significant when adjusted for change in co-morbidity index (β=+0.0335; p=0.008 vs. +0.0386; p=0.002) (R^2=27%).
Conclusions: Cluster analysis showed that patients with severe functional impairment also had high rate of co-morbidities à baseline. The reduction of OA functional impairment is an important determinant of 5-year improvement of HSU while burden of co-morbidities was not associated with change in hip and knee OA HSU. This result highlights the importance of reducing functional impairment in clinical management of patients with hip and knee OA, and gives clues for interpretation of medico-economic analyses.

SAT0514 CAN IMMUNOPHENOTYPING OF SYNOVIAL FLUID CELLS HELP DISTINGUISH BETWEEN PATIENTS WITH OSTEOARTHRITIS?

G. Gabcova[1], G. Manukyan[2], Z. Mikulkova[1], E. Kriegová[1], J. Gallo[3]. [1]*Department of Immunology, Faculty of Medicine and Dentistry, Palacky University, Olomouc, Czech Republic;* [2]*Group of Molecular and Cellular Immunology, Institute of Molecular Biology NAS RA, Yerevan, Armenia;* [3]*Department of Orthopaedics, Palacky University, Teaching Hospital Olomouc, Olomouc, Czech Republic*

Background: Osteoarthritis (OA) is a leading cause of chronic pain and functional disability in elder people. It is not a homogeneous but diverse group of synovial joint diseases. This could stay behind the therapeutic inconsistency observed in clinical practice caused probably by different diseases and/or different stages of a single disease. The comprehensive immunophenotyping of immune cells and their cell counts in synovial fluid (SF) might therefore advance our understanding of a particular type/stage of OA. This could have diagnostic value as well as provide novel insights into the pathophysiology of OA.
Objectives: To characterize immune cells present in SFs from OA patients in different stages of a disease.
Methods: We performed immunophenotyping of SFs from 63 patients with OA and 10 SFs from control patients (non-OA) without clinical/radiographic signs of OA using flow cytometry. We were able to characterize the following immune cells in the sampled SFs: T helper lymphocytes ($CD3^+/CD4^+$), T cytotoxic lymphocytes ($CD3^+/CD8^+$), NK cells ($CD3^-/CD16^+/CD56^+$), B lymphocytes ($CD19^+$), T regulatory (Treg) cells ($CD4^+/CD25^+/CD127^-$), mast cells ($CD203c^+/CD117^+$), M1- ($CD14^+/CD86^+/HLA\text{-}DR^{high}$) and M2-polarized macrophages ($CD14^+/CD163^+/CD206^+$), and neutrophils ($CD15^+/CD16^+$).
Results: A comparison between OA and control (non-OA) SFs revealed phenotypic alterations mainly in T cells, NK cells, macrophages, and neutrophils. T cells were the predominant population in the SFs, with $CD4^+$ T lymphocytes being more prevalent than $CD8^+$ T cells in OA (increased CD4/CD8 ratio). The second largest cell population was macrophages. Despite the dominant mixed-polarized (M1-M2) macrophage subpopulations in both the studied groups, SFs from the OA patients displayed a tendency towards greater M1 activity comparing to the controls. A markedly increased percentage of neutrophils found in the OA group was associated with their activated state compared to the controls (increased CD11b). No difference was found in percentages of B, Treg and mast cells. Despite the similar numbers of NK cells in both the groups, the activation-associated marker CD69 was up-regulated in NK cells from the OA patients. Representative dot-plots (FCS-SSC) of inter-individual variability of the main immune cell populations in synovial fluids from osteoarthritic patients is shown in Figure 1.

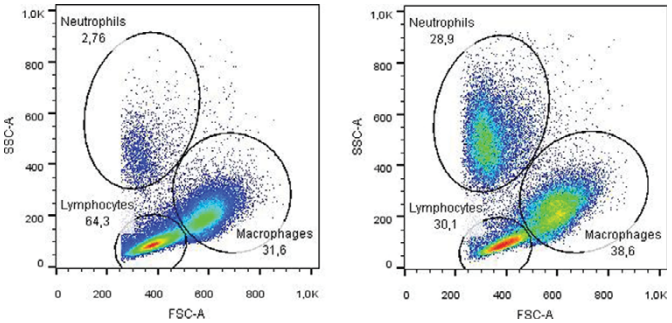

Figure 1. Representative dot-plots (FCS-SSC) of inter-individual variability of the main immune cell populations in synovial fluids from osteoarthritic patients.

Conclusions: We were able to distinguish between the OA cases and controls

in terms of their immune cells profiles (i.e. their numbers, activation status etc.). Additionally, we were able to follow specific immune cell patterns inside the OA group. Our study further emphasized the role of immune cells in the pathogenesis of OA. In particular, the results provide evidence suggesting ongoing activation of innate immunity as well as a shift towards T helper lymphocytes in fluids of the patients with OA. Our findings give a rational starting point to be addressed by the future research for clinically useful biomarkers associated with the OA development and progression.

SAT0515 SONOGRAPHIC AND CLINICAL EXAMINATION OF TENDON INVOLVEMENT IN HAND OSTEOARTHRITIS

I. Gessl, A. Vinatzer, G. Supp, A. Kerschbaumer, P. Studenic, M. Zauner, D. Aletaha, J. Smolen, P. Mandl. *Dep. of Medicine 3, Div. of rheumatology, Medical University of Vienna, Vienna, Austria*

Background: Persistent tenosynovitis and degenerative tendinitis is associated with pain and can lead to dysfunction and tendon damage. While tenosynovitis is a common finding in rheumatoid arthritis, data on tendon involvement in hand osteoarthritis (HOA) is clearly limited. The clinical assessment of tendons is difficult and not fully standardized, but muculoskeletal ultrasound (MSUS) has been used successfully in inflammatory rheumatic disease as a sensitive method to detect tenosynovitis, tendon damage and osteophytes.

Objectives: To characterize tendon involvement in hand osteoarthritis and compare ultrasound with clinical assessment.

Methods: In this cross-sectional observational study 34 patients with HOA underwent MSUS and clinical examination on the same day. Each flexor and extensor tendon of the hand was scored independently for tenosynovitis and tendon damage (presence/absence) respectively by an expert in MSUS, blinded to the results of the clinical examination. Additionally, osteophytes in the proximal and distal interphalangeal joints of the fingers were assessed. Clinical assessment of tendons for tendon involvement included volar or dorsal pain, crepitus and swelling involving the hand, wrist or forearm during active movement of the tendon against resistance according to the Birmingham consensus criteria, by assessors who were blinded to the results of the MSUS. Conventional radiographs (CR) of the hands were also acquired and evaluated by the Interphalangeal Osteoarthritis Radiographic Simplified score.

Results: The majority of patients (30/34, 88.2%) were female, with a mean age of 69.5±8.5 years and a median of 10 (9–22.5) years disease duration. Clinical examination revealed tendon involvement in 21 (61.8%) patients with a median of 3 (range 1–14) affected tendons. In MSUS tenosynovitis was detected in 17/33 patients (51.5%) with a median of 1 (1–4) tendon involved. Tendon damage was found in 8/33 patients (24.2%) with a median of 2 (1–11) tendons involved. A total of 20/33 (60.6%) patients exhibited sonographic signs of tendon involvement (tenosynovitis/tendon damage) with a median of 2 (1–12) involved tendons. Tendon damage was found more often on the right hand ($p<0.05$) while tenosynovitis did not significantly differ. Similarly, no significant difference between male and female patients was found. The extensor digitorum and the extensor carpi ulnaris tendons were the most commonly affected tendons under US. Tenosynovitis was found to be more prevalent among extensor tendons ($p<0.001$), while tendon damage was demonstrated at a higher frequency in flexor tendons ($p<0.05$) (Fig. 1). The agreement between MSUS and clinical examination was moderate on the patient level and poor on the level of individual tendons. Osteophytes were found in 96.8% patients using MSUS and in 100% of patients assessed using CR. Osteophytes detected on MSUS or CR showed good agreement (p=0.01, Cronbach's Alpha=0.66).

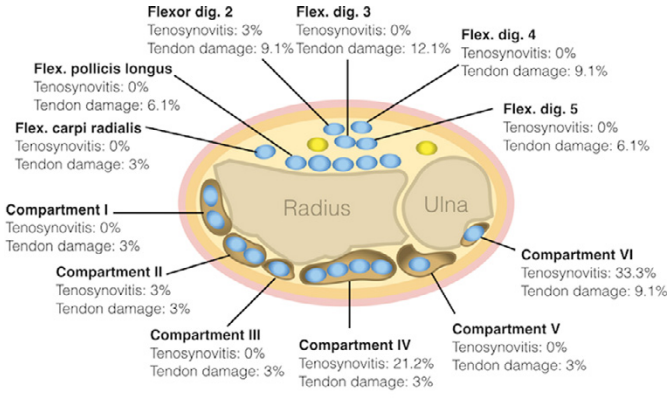

Fig.1 Distribution of tenosynovitis and tendon damage

Conclusions: The findings of our study reveal a high prevalence of tendon involvement in patients with hand OA. Sensitivity of MSUS in detecting tendon involvement coupled with the lack of agreement between clinical examination and MSUS on the level of individual tendons may suggest that while clinical examination is able to identify patients with overall tendon involvement, it does not allow the specific identification of involved tendons.

SAT0516 INFLUENCE OF ETHNICITY ON CLINICAL PAIN IN PATIENTS WITH OSTEOARTHRITIS VERSUS RHEUMATOID ARTHRITIS: CONTRIBUTION OF LEVEL OF EDUCATION AND DEPRESSION

I. Castrejon[1], J. Chua[1], J.A. Block[1], L.A. Bradley[2], Y. Yazici[3], N. Shakoor[1]. *[1]Rheumatology, Rush University Medical Center, Chicago; [2]Clinical Immunology and Rheumatology, University of Alabama, Birmingham; [3]Rheumatology, NYU Hospital for Joint Diseases, New York, United States*

Background: The experience of pain is characterized by inter-individual and group variability, with ethnicity being one potential contributing factor. In a systematic review, it was shown how African Americans (AA) demonstrated lower pain tolerance in experimental studies[1]. Pain is the most common and troubling symptom in patients with osteoarthritis (OA) -maybe reflecting damage- and in patients with rheumatoid arthritis (RA) -maybe reflecting synovitis- but other pain mechanisms are important.

Objectives: To investigate the influence of ethnicity on clinical pain and other outcomes and to identify potential predictors of higher scores for pain in AA and Hispanic patients with OA or RA seen in routine care.

Methods: As part of their clinic visit, all patients complete a multidimensional health assessment questionnaire (MDHAQ) at 2 academic sites. MDHAQ includes 0–10 visual analogue scales (VAS) for pain, physical function, and a patient global evaluation (PATGL), and a depression score between others. The MDHAQ also include demographic data and patients "self-identify" their ethnicity. One random visit with complete questionnaire data for each OA (ICD-9=715.0) and RA (ICD-9=714.0) patient from each site was included in this analysis. Comparison according to patients' self-reported ethnicity -White, African-American (AA) or Hispanics- were performed using ANOVA and chi-squared. Multiple regression models were performed to identify independent explanatory variables for clinical pain in AA and Hispanics groups versus White.

Results: The study included 402 OA patients and RA 373. There were no differences in age and gender between ethnicity groups in both diagnostic groups. Years of education were highest in the White followed by AA and then Hispanics in both OA and RA. AA and Hispanics showed statistically significantly higher scores for pain (6.6 vs 5.3 in OA, $p<0.001$; 5.7 vs 4.4 in RA, $p<0.001$) and lower physical function (3.2 vs 1.9 in OA, $P<0.001$; 3.2 vs 1.9 in RA, $p<0.001$) in comparison with Whites in both diagnostic groups. A lower level of education and a higher level of depression predicted greater pain on a MDHAQ in OA in separate models for AA and Hispanic patients and in RA in Hispanic patients (Table).

Table 1. Multiple regression models predicting clinical pain on a MDHAQ stratified by ethnicity

DV: MDHAQ-Pain (0–10)	Osteoarthritis			Rheumatoid Arthritis		
	β	p	R squared	β	p	R squared
Model 1						
Age	-0.04	0.49	0.13*	0.08	0.25	0.10*
Sex	-0.07	0.21		0.03	0.65	
African-Americans	0.12	0.06		0.04	0.94	
Education	**-0.19**	**0.005**		-0.09	0.19	
Depression	**0.19**	**0.002**		**0.29**	**<0.001**	
Model 2						
Age	-0.05	0.39	0.15*	0.05	0.40	0.16*
Sex	-0.12	0.07		0.02	0.68	
Hispanic	0.09	0.19		0.03	0.63	
Education	**-0.19**	**0.01**		**-0.19**	**0.01**	
Depression	**0.21**	**0.002**		**0.30**	**<0.001**	

Conclusions: AA and Hispanic patients had higher level of pain than Whites, but these differences are mainly influenced by level of education and level of depression in OA and RA patients. These results support the biopsychosocio-cultural model of pain in which, ethnic group differences may be determined by multiple mechanisms including socio-cultural as education, and psychological as depression, in addition to biological pathways.

SAT0517 FACTORS RELATED TO ANALGESIC USE IN PATIENTS WITH KNEE AND/OR HIP OSTEOARTHRITIS REFERRED TO AN OUTPATIENT CENTER: RESULTS FROM THE AMSTERDAM OSTEOARTHRITIS COHORT

J. Knoop[1], J. van Tunen[2], M. van der Esch[1], L.D. Roorda[1], J. Dekker[3], M. van der Leeden[1,3], W.F. Lems[4,5]. *[1]Amsterdam Rehabilitation Research Center, Reade, Center for Rehabilitation and Rheumatology, Amsterdam, Netherlands; [2]Department of Sports Science and Clinical Biomechanics, University of Southern Denmark, Odense, Denmark; [3]Department of Rehabilitation Medicine, VU University Medical Center; [4]Jan van Breemen Research Institute, Reade, Center for Rehabilitation and Rheumatology; [5]Department of Rheumatology, VU University Medical Center, Amsterdam, Netherlands*

Background: Analgesics are recommended in current guidelines, but non-use and inadequate prescription have been reported in patients with knee and/or hip osteoarthritis (OA). Furthermore, predictors of analgesic use have not yet been clarified.
Objectives: To (i) describe the use of analgesics; and (ii) determine factors that are related to analgesic use in patients with knee and/or hip OA referred to an outpatient center.
Methods: Data from 656 patients with knee and/or hip OA referred to an outpatient center (Amsterdam Osteoarthritis (AMS-OA) cohort) were used. Self-reported use of analgesic (yes/no) was administered and subdivided into acetaminophen, non-steroidal anti-inflammatory drugs (NSAIDs, including coxibs) and opioids. Logistic regression analyses were performed to analyze the association between analgesic use and disease-related, predisposing, and enabling factors.
Results: Analgesic use was reported by 62% of the patients, with acetaminophen, NSAIDs and opioid use reported by 50%, 30% and 12%, respectively. Factors related to analgesic use were higher pain severity, longer duration of symptoms, higher radiographic hip OA severity, overweight/obesity, and psychological distress. These factors explained 21% of the variance of analgesic use.
Conclusions: Less than two-third of patients with knee and/or hip OA referred to an outpatient center reported analgesic use, which seems to be indicative for under-use. Although multiple, mostly disease-related factors were associated with analgesic use, it remained predominantly unexplained. Our findings may indicate that prescription of analgesics should be guided more dominantly by clinical symptoms and needs, and preceded by a thorough shared decision making process between patient and physician.

SAT0518 ASSOCIATION BETWEEN GRIP STRENGTH AND HAND AND KNEE RADIOGRAPHIC OSTEOARTHRITIS IN OLDER ADULTS: DATA FROM THE DONG-GU STUDY

J.-E. Kim, J.-H. Kang, K.-E. Lee, D.-J. Park, S.-S. Lee on behalf of Chonnam. *Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic Of*

Objectives: Although some studies have shown a negative relationship between grip strength and hand osteoarthritis (OA), little is known about how grip strength is related to specific radiographic features of hand OA, such as osteophytes, joint space narrowing, and erosion. In addition, no reported study has examined whether grip strength, as a measure of muscle activity, is related to knee OA, which may also show a one-way effect of reduced muscle strength on OA. In this large, population-based cohort study, we took advantage of the availability of subjects without hand pain to evaluate the effect of grip strength on OA using a novel, semi-quantitative grading system. We also examined whether grip strength was related to detailed radiographic features of OA.
Methods: Data from 2,251 subjects enrolled in the Dong-gu study, who had no hand joint pain, were analyzed to investigate the relationship between grip strength and OA. Hand grip strength was measured using a hand-held dynamometer, and radiographs of the hand and knee were scored according to a semi-quantitative grading system. Multiple linear regressions were used to explore associations between grip strength and radiographic features of OA.
Results: Grip strength in men and women was negatively related to hand (both $p<0.001$) and knee (men, $p<0.001$; women, $p=0.010$) OA after adjusting for confounders. Hand (men, $p<0.001$; women, $p=0.001$) and knee (both $p<0.001$) joint space narrowing showed the strongest associations with low grip strength, regardless of sex. Moreover, the severity of hand osteophytes in women ($p=0.001$), knee osteophytes in men ($p=0.006$), hand malalignment (men, $p=0.008$; women, $p=0.041$), and subchondral cysts (men, $p<0.001$; women, $p=0.007$) was correlated with low grip strength in both sexes.
Conclusions: Among subjects without hand joint pain, low grip strength was associated significantly with hand and knee radiographic OA, regardless of sex. Among all types of OA radiographic damage, low grip strength showed the strongest association with joint space narrowing.

SAT0519 THE VALUE OF HIGH-SENSITIVITY C-REACTIVE PROTEIN IN HAND AND KNEE RADIOGRAPHIC OSTEOARTHRITIS: DATA FROM THE DONG-GU STUDY

J.-E. Kim, J.-H. Kang, K.-E. Lee, D.-J. Park, S.-S. Lee[1,1]. *Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic Of*

Objectives: Due to the inconsistent association between high-sensitivity C-reactive protein (hs-CRP) and osteoarthritis (OA), we evaluated the relationship between hs-CRP and various radiographic findings in older adults with OA.
Methods: This cross-sectional study recruited 2,400 participants from the population-based Dong-gu cohort. The scores of radiographic features in OA on X-rays of the knees and hands were computed using a semi-quantitative grading system. The hs-CRP levels were measured using a particle-enhanced immunonephelometry assay. Correlations showing the relationship between hs-CRP and OA were calculated using multiple linear correlation analysis.
Results: The hs-CRP levels were significantly higher in older subjects ($p<0.001$), those with a higher body mass index (BMI) ($p<0.001$), current smokers ($p<0.001$), current alcohol drinkers ($p=0.012$), those who were less physically active ($p=0.002$), and those with a lower level of education ($p=0.036$). After adjusting for BMI and other confounders, the total OA scores (knee, $p=0.048$; hand, $p=0.010$), erosion scores (knee, $p=0.035$; hand, $p=0.031$), and sclerosis (knee, $p=0.021$; hand, $p=0.029$) in the knees and hands were all significantly positively correlated with hs-CRP. A significant association was also observed between hs-CRP and the hand malalignment score ($p=0.012$).
Conclusions: In this large cross-sectional study, the hs-CRP level was a significant predictor of radiographic OA. Of the various types of OA radiographic damage, erosion, sclerosis, and malalignment showed significant associations with hs-CRP.

SAT0520 MARKED REDUCTION OF OSTEOARTHRITIS PAIN WITH A HYDROGEN SULFIDE-RELEASING NAPROXEN DERIVATIVE

J.L. Wallace[1], D. Vaughan[2]. *[1]University of Calgary, Calgary; [2]Antibe Therapeutics Inc, Toronto, Canada*

Background: Nonsteroidal anti-inflammatory drugs (NSAIDs) remain a mainstay of therapy for osteoarthritis, but their use is limited by their propensity to cause significant gastrointestinal (GI) bleeding and ulceration. Hydrogen sulfide (H2S) is an endogenous signaling molecule that has been shown to exert protective and pro-healing effects in the GI tract. We developed a series of H2S-releasing NSAIDs, and have now tested the lead drug (ATB-346) in a phase 2a clinical trial in patients with osteoarthritis. ATB-346 is a derivative of naproxen, the most cardiovascular-safe of the NSAID family. Data from a phase 1 clinical trial suggested that ATB-346 was significantly more potent and long-lasting than naproxen in terms of suppressing cyclooxygenase (COX) activity.
Objectives: An open-label phase 2a trial was performed to determine if a low dose of ATB-346 (250 mg; equimolar to 160 mg naproxen), given once daily, would provide significant pain relief in patients with osteoarthritis. To be admitted to the trial, patients had to exhibit a $\geq$10 point increase in the WOMAC Visual Analog Score between their screening visit and the baseline study entry visit.
Methods: 12 patients with osteoarthritis of the knee who met the inclusion criteria were recruited for the trial (diagnosis of OA $\geq$2 years; age 40–75; BMI $\leq$40). The WOMAC subscale pain score (0–20) was the primary endpoint. The patients were off anti-inflammatory medication for 5 days prior to starting this study. After recording the initial WOMAC subscale pain score, they began once daily oral treatment with ATB-346 (250 mg). Pain scores were recorded on the day prior to starting ATB-346 treatment ("day -1"), and on days 4 and 10 of treatment. Blood samples were collected for measurement of COX activity on days -1, 1, 4 and 10.
Results: ATB-346 was safe and well tolerated. The mean WOMAC subscale pain score the day prior to initiation of treatment was 14.0 + 0.7. A significant decrease in the WOMAC subscale pain score was observed on day 4 (-4.3±1.0; $p<0.01$), with an even greater decrease on day 7 (-7.6±1.5; $p<0.001$). Whole blood COX activity was suppressed by more than 80% ($p<0.01$) on the first day of treatment, and continued to be suppressed throughout the study.
Conclusions: The results of this study demonstrate that a low dose of ATB-346, given only once daily, produces a clinically and statistically significant reduction of pain in patients with osteoarthritis, that may exceed what can be achieved with standard doses of napoxen or celecoxib (1,2). The observed suppression of COX activity was consistent with the pain reduction data, supporting the conclusion that ATB-346 is considerably more potent and long-acting than naproxen. Extensive pre-clinical studies have demonstrated that ATB-346 has greatly improved GI safety as compared to naproxen and other commonly used NSAIDs.

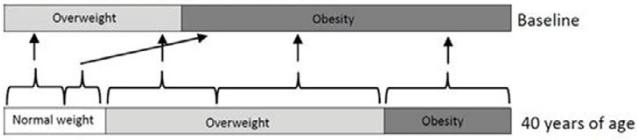
SAT0521 INCREASING PHYSICAL ACTIVITY IN OLDER PEOPLE WITH PAIN. PRELIMINARY RESULTS OF THE IPOPP PILOT TRIAL

J. McBeth[1,2], E. Nicholls[2,3], E. Healey[2], N.E. Foster[2,3], E.M. Hay[2], T. Pincus[4], S. Dent[2], C.A. Chew-Graham[2], L. Hartshorne[3], C. Jinks[2] on behalf of iPOPP team. *[1]Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester; [2]Research Institute for Primary Care and Health Sciences; [3]Keele Clinical Trials Unit, Keele University, Keele; [4]Department of Psychology, University of London, London, United Kingdom*



Background: Chronic (≥3 months) pain is associated with physical inactivity in older (≥65 years) people. Walking is an acceptable form of physical activity with health benefits. We have developed Increasing Physical Activity in Older People with Pain (iPOPP), a brief intervention to increase walking.
Objectives: To assess the acceptability and credibility of iPOPP, and to test the feasibility of trial processes, in a pilot randomised controlled trial.
Methods: Eligible responders to a screening questionnaire (≥65 years; consulted their general practitioner for chronic pain; Chronic Pain Grade score ≥2) collected 7-day accelerometer data before randomisation and at the end of follow-up. Participants were randomised to one of Usual primary care; Pedometer, walking diary, pain toolkit (written pain management information); or iPOPP comprising *week 1* face-to-face Health Care Assistant (HCA) consultation to develop a walking action plan, pedometer, walking diary, pain toolkit, discussion of walking behaviour and barriers, goal setting; *week 2* follow up face-to-face or telephone (participant preferred) HCA consultation to review progress and goals, relapse prevention strategies; *weeks 3–10* weekly motivational prompts (participant preferred postcard, email or text). A follow-up questionnaire was sent 12 weeks post-randomisation.
Success criteria were: 7% of those screened would be eligible, return an accelerometer and be randomised; follow-up rates ≥75% of those randomised; ≥50% of those in iPOPP would complete week 1 and 2 intervention sessions; and a median score of ≥5/10 across a four-item intervention acceptability and credibility questionnaire.
Results are number (%) or median (inter quartile range (IQR)).
Results: Of 2326 people mailed, 1256 (54%) responded and 695 (30%) were eligible. After mailing study information to 425 eligible participants, 161 (38%) agreed to participate, 159 (12% of those mailed) returned an accelerometer and were randomised, 7 withdrew, and 136 (86%) returned a follow-up questionnaire. Of those randomised to iPOPP 82% completed week 1 and 2 intervention sessions; 32% had a face-to-face week 2 follow-up; 48% preferred postcard motivational prompts, 10% email, 22% text, and 20% had no preference. Median (IQR) acceptability and credibility scores were: "how logical is treatment?" 8 (3, 9.8), "confidence in treatment success" 5.5 (3, 8), "would recommend treatment to friend" 7 (3.3, 9), and "treatment would be successful for another pain problem" 5 (3, 7.8). 152 participants were mailed a follow-up accelerometer and 144 (95%) were returned. 147 (91%) baseline and 117 (81%) follow-up accelerometers had useable data.
Conclusions: These data demonstrate the acceptability and credibility of the iPOPP intervention, and the feasibility of proposed trial processes. The effectiveness of iPOPP compared with usual care will be tested in a future main trial.

SAT0522 SEARCHING FOR THE OPTIMAL TIMING FOR PREVENTIVE WEIGHT REDUCTION STRATEGIES FOR KNEE OSTEOARTHRITIS DEVELOPMENT

J. Runhaar[1], M. Landsmeer[1], M. van Middelkoop[1], S.M. Bierma-Zeinstra[2]. *[1]General Practice; [2]General Practice and Orthopaedics, Erasmus University Medical Center Rotterdam, Rotterdam, Netherlands*

Background: We previously showed that middle-aged women free of clinical knee osteoarthritis (OA), but at high-risk for future OA development due to a BMI ≥27 kg/m^2, had a high prevalence of OA features on MRI [1]. Subjects with a steadily decrease in body weight over 30 months (-9.0±7.2 kg), did not show a significantly different progression of these features, compared to those without loss in body weight [2].
Objectives: To explore the effects of differences in body weight in the years prior to inclusion on the prevalence of knee OA on MRI at baseline, to discuss the optimal timing for preventive weight loss strategies for OA development.
Methods: Data from the PROOF study (ISRCTN 42823086) were used [3]. At baseline, women aged 50–60, with a BMI ≥27 kg/m^2 were recruited. At inclusion, the women were free of clinical knee OA. At baseline, all participants filled-in a questionnaire for demographic data, including body weight at age 40, and body weight and height were measured. BMI at 40 years and at baseline was calculated and classified into normal weight (BMI <25 kg/m^2), overweight (BMI ≥25 and <30 kg/m^2) and obesity (BMI ≥30 kg/m^2). MRI scans of both knees was made on a 1.5 Tesla scanner. All MRIs were scored using the semi-quantitative MRI Osteoarthritis Knee Score (MOAKS) and MRI OA was defined in all knees was defined using published definitions [4]. Using logistic regression, the percentages of women with MRI OA, with unilateral MRI OA, bilateral MRI OA, and with ≥2 affected compartments were compared, using the normal/overweight group as reference.
Results: 374 women had all baseline measurements available and were selected. At baseline, 127 women were overweight and 248 were obese. Mean age was 55.7±3.2 years. Of the baseline obese women, 11% (26 women) reported normal weight, 52% (130 women) overweight and 37% (92 women) obesity at 40 years. Of the baseline overweight women, 39% (49 women) reported normal weight, 61% (77 women) overweight and 1 woman reported obesity at 40 years (see figure).
Baseline prevalence of MRI OA, of unilateral/bilateral MRI OA, and the percentage of women with ≥2 affected compartments, out of both TF and both PF compartments, are presented in the table.

Baseline and 40-years BMI groups and their course*.

*the one overweight woman at baseline that reported obesity at 40 years was omitted for clarity reasons

Prevalence of MRI OA for different subgroups by BMI course.

BMI group at 40 years	BMI group at baseline	N*	Prevalence of MRI OA overall (uni-/bilateral/2+ compartments)
Obesity	Obesity	92	44%# (25%# / 19%# / 23%#)
Overweight	Obesity	130	32%# (25%# / 7% / 9%)
Normal weight	Obesity	26	23% (15% / 8% / 12%)
Overweight	Overweight	77	27% (22% / 5% / 12%)
Normal weight	Overweight	49	16% (10% / 6% / 6%)

N = number of women. *the one overweight woman at baseline that reported obesity at 40 years was omitted for clarity reasons. #Significant difference compared to 'normal/overweight' group (p < 0.05).

Conclusions: Women with higher body weight at 40 years showed higher prevalence of knee OA on MRI at the age of 56. It is highly questionable whether OA related structural abnormalities seen on MRI are reversible. It is suggested that body weight reduction around the age of 40 might be much more effective for the prevention of future knee OA development than it would be at the age range of 50 to 60 years, where radiographic and clinical knee OA usually develops.

SAT0523 NO TREATMENT EFFECTS OF ORAL GLUCOSAMINE FOR SUBGROUPS OF KNEE AND HIP OSTEOARTHRITIS PATIENTS; AN INDIVIDUAL PATIENT DATA META-ANALYSIS FROM THE OA TRIAL BANK

J. Runhaar[1], R. Rozendaal[1], M. van Middelkoop[1], J. Bijlsma[2], M. Doherty[2], K. Dziedzic[2], L. Lohmander[2], T. McAlindon[2], W. Zhang[2], S. Bierma-Zeinstra[2]. *[1]General Practice, Erasmus University Medical Center Rotterdam; [2]OA Trial Bank Steering Committee, Rotterdam, Netherlands*

Background: The effectiveness of oral glucosamine for symptoms of osteoarthritis (OA) is debated. Individual trials are not powered to show effects within subgroups of patients.
Objectives: To evaluate the effectiveness of oral glucosamine in clinical relevant subgroups of hip and knee OA patients based on pain severity, BMI, sex, structural abnormalities and inflammation, using individual patient data from published trials.
Methods: A systematic search for published randomized controlled trials on the effectiveness of any oral glucosamine substance in patients with clinically or radiologically defined knee or hip OA was performed. Additionally, trail registries were searched for ongoing studies. All authors and institutions of all eligible studies were approached and asked to share the trial data. All shared trials were assessed for their risk of bias, using the criteria recommended by the Cochrane. Missing data for covariates and outcome measures were imputed, using multiple imputation methods, within each original study. Subgroup factors were dichotomized, based on consensus of the OA Trial Bank Steering Committee. A multilevel regression analysis was performed to estimate the magnitude of the effect of glucosamine over the control intervention in the different subgroups with the individuals nested within each study. Pain at short-term (3 months)

and long-term (24 months) served as primary outcomes measure, function as secondary. Outcome measures measured on different scales were standardized to a 0–100 scale to pool the data. All analyses were performed with and without stratifying for affected joint and type of glucosamine substance.
Results: Out of 21 eligible studies, six studies (N=1663) shared their trial data with the OA Trial Bank. Only one of these studies (N=40) was industry driven. All six studies had a low risk of bias, of which five trials (all not industry driven) compared glucosamine to placebo. These five studies represented 50% of the total number of randomized subjects in all published trials for this comparison. No main effects of glucosamine were found on pain or function at short-term (mean difference 0.31 95% CI [-2.02 to 2.64] and 1.56 [-0.56 to 3.69], respectively) and at long-term follow-up (0.98 [-1.76 to 3.73] and 1.40 [-1.27 to 4.06], respectively). Also, no significant interactions with treatment were found for subgroups based on pain severity (WOMAC pain <70 vs. ≥70), BMI (<27 kg/m^2 vs. ≥27kg/m^2), sex (male vs. female) and structural abnormalities (KL-grade 0–2 vs. 3–4), see Table. Stratification for knee OA patients only and for type of glucosamine did not result in any differences in the outcomes. No data was available to adequately form subgroups based on degree of inflammation.

Estimated pooled differences between glucosamine and placebo on a 0-100 scale and p-values for treatment-subgroup interactions.

	KL subgroup	-	0.77	-	-	-

*measured using WOMAC pain (0-100) and adjusted for age sex, BMI, WOMAC pain at baseline and study number. **measured using WOMAC function (0-100) and adjusted for age sex, BMI, WOMAC function at baseline and study number. Positive estimated pooled differences indicate a greater reduction in the outcome in the glucosamine group compared to the placebo group. GS = glucosamine sulphate; GH = glucosamine hydrochloride.

Conclusions: The majority of industry-led glucosamine studies for osteoarthritis did not wish to share data, challenging optimal use of available data. There is currently no evidence for the use of glucosamine for the treatment of hip or knee osteoarthritis and an absence of support for clinically relevant subgroups of OA patients according to baseline pain severity, BMI, sex, and structural abnormalities.

SAT0524 UTILITY OF TOCILIZUMAB IN CLINICAL MANIFESTATIONS OF EROSIVE OSTEOARTHROSIS OF HANDS REGIONAL HOSPITAL ISSSTE PUEBLA, MÉXICO

J.M. Sánchez Huerta[1], J. Gálvez-Romero[2], W. López-Rodriguez[1], A. López[3]. *[1]Rheumatology; [2]ISSSTE, Puebla, Puebla; [3]UDLAP, Cholula, Puebla, Mexico*

Background: Erosive osteoarthritis (EOA) is a form of severe involvement of osteoarthrosis in the hands, characterized by inflammation of the synovium of the proximal interphalangeal (PIF) and distal joints (DIF); the last ones are the most affected in a symmetrical manner. Inhibition of interleukin 6 (IL-6) in joints with osteoarthrosis helps to improve the production of the cartilaginous matrix and microfractures of articular cartilage.
Objectives: To know if the application of TCZ is useful for the control of the clinical manifestations of EOA of the hands.
Methods: Twenty-four patients with EOA were studied, 18 females and 6 males with ages ranging from 42 to 72 years, with an evolution time of 4 to 30 years. The application of TCZ was intravenous (8 mg/kg of body weight per month).
Articular pain in the PIF and distal joints was evaluated by the visual analogue scale (VAS) (0 to 10) and joint pain (0 to 50), morning stiffness (0 to 10), and functional limitation (0–90) by the AUSCAN index.
Results: The VAS showed improvement of 30% (0% to 100%). The AUSCAN index showed improved pain (16.2), morning stiffness (0.6) and functional limitation (17.5). Decreased ESR, CRP, and IL-6 levels less than 1.56 to 59.1 pg/ml.
Conclusions: IV Tocilizumab is useful for the control of the clinical manifestations of OAE of the hands. More precise studies are needed to evaluate the improvement of the cartilaginous matrix in EOA by TCZ.

SAT0525 THE EFFICACY OF PELOID THERAPY IN MANAGEMENT OF HAND OSTEOARTHRITIS

M. Aksoy Kasapoğlu[1], L. Altan[2], R. Eröksüz[3], B. ÖkmenMetin[1]. *[1]Physical Medicine and Rehabilitation, University of Health Sciences Bursa Yüksek Ihtisas Training and Research Hospital; [2]Physical Medicine and Rehabilitation, Uludağ University Medical Faculty; [3]Ecology and Hydroclimatology, University of Health Sciences Bursa Yüksek Ihtisas Training and Research Hospital, Bursa, Turkey*

Background: Hand osteoarthritis (OA) is associated with pain, reduced grip strength, loss of range of motion (ROM), and joint stiffness, leading to impaired hand function and difficulty in performance of daily living activities. Various randomized controlled clinical trials were conducted to assess the efficacy and tolerability of mud-pack therapy in patients with knee OA. Data from these clinical trials support the beneficial effect of mud-pack therapy on pain, function, and quality of life in knee OA. However, to the best of our knowledge, in spite of its significant impact of on the activities of daily life, there is a lack of adequate randomized controlled studies on peloid therapy in management of osteoarthritis of the hand
Objectives: To investigate the effects of peloid therapy in the patients with hand OA on pain, functional state, grip strength, and the quality of life
Methods: 63 patients aged between 35 and 75 years, who had been diagnosed with hand OA were included in the study. Patients were randomized into 2 groups with a random number table. Patients in Group 1 (n=33) underwent peloid therapy over 2 weeks, 5 sessions a week, for a total of 10 sessions and home exercise program. Patients in Group 2 (control, n=30) received only the same home exercise program as in Group 1. Patients were evaluated just before, and 2 and 6 weeks after the start of the study with Visual Analogue Scale (VAS), Australian/Canadian Osteoarthritis Hand Index (AUSCAN) Health Assessment Questionnaire (HAQ), Hand Grip Strength (HGS), Pinch strength (PS).
Results: Statistically significant improvements were observed in all parameters assessed at week 2 and week 6 in the Group 1 ($p<0.05$). Statistically significant differences were observed in HGS scores in the Group 2 at week 2, and in AUSCAN scores at week 6 ($p<0.05$). Intergroup comparisons of the scores revealed significant differences between the peloid therapy group and control group in VAS, HAQ, AUSCAN, HGS and PS scores at week 2 and week 6 ($p<0,05$).
Conclusions: This study demonstrates that peloid therapy is an effective and confident treatment modality in the management of symptomatic osteoarthritis of the hand and provides effective pain control and improvements in the hand functions, quality of life and grip strength

SAT0526 POSSIBILITY OF CARTILAGE REPAIR WITH PLATELET AUTOLOGOUS PLASMA (PAP)

L.V. Khimion[1], O.A. Burianov[2], L.O. Smolina[1], H. Havryliuk[1], T. Omelchenko[3]. *[1]Department of Family Medicine, Shupyk National Medical Academy of Postgraduate Education; [2]Traumatology and Orthopedic Department; [3]Traumatology and Orthopedic Department, Bogomolets National Medical University, Kiyv, Ukraine*

Background: The investigations of the platelet-derived biologic agents in osteoarthritis treatment had shown promising but often controversial results.
Objectives: To study the efficacy (in clinic & experiment) & safety (in clinic) of the platelet autologous plasma (PAP) in cartilage repair and treatment of early knee OA.
Methods: The study was conducted at the Department of Family Medicine and Traumatology and Orthopedic Department and consisted of 2 parts: experimental (20 rabbits with the traumatic damage of the knee cartilages) and clinical (included 146 patients with diagnosed knee OA (radiological stage I-II). Rabbits

were randomly divided in 4 groups: in 1st and 2nd grs. 10 animals received 3 intra-articular injections of PAP (on 5th,7th,14th day after knee trauma) as a control (gr.3 and 4) 10 rabbits received 3 intra-articular injections of 0,9% NaCl at the same days after trauma; histopathology was performed at 45th (1st and 3rd gr.) & at 90th day (2nd and 4th gr.) after trauma. 146 patients - 58 men (39.7%) & 88 women (60.3%), were divided into 2 grs. Gr.1 included 68 patients who consented to receive standard OA treatment and 3 weekly intra-articular injections of PAP (total 2 courses in 12 months) (plasma volume 12–15ml/course, total platelets number per injection 1260,24±22,1x10^9); Gr.2 consisted of 78 patients with the same diagnosis who received only standard OA treatment (non-steroidal anti-inflammatory drugs, physiotherapy, exercises). Both groups were of comparable age, gender and initial WOMAC data (Gr.1 40,9±0,7 Gr.2 39,7±0,9, $p>0,05$). WOMAC scale parameters were analyzed before treatment and after 3 weeks; 6 & 12 months after course of treatment in both groups.

Results: In animals histopathology has found better repair, ↓ inflammation, better structure of the knee cartilage after PAP injections comparing with the control groups animals; in addition in 3rd group of rabbits ↓ signs of early posttraumatic osteoarthritis were found (comparing to 4th gr.).

Clinical study demonstrated better changes in pain, stiffness and function in 3 weeks after treatment in patients of Gr.1 comparing to Gr.2 (WOMAC had decreased by 35.8% in Gr.2 and by 74.1% in Gr.1), $p<0,05$.

After 6 months of follow-up (before 2 course of PAP treatment), the mean number of OA exacerbations was (0,7±0,02) in Gr.1 & (1,6±0,04) in Gr.2 ($p<0,05$) and general WOMAC index in Gr.1 was significantly lower than in Gr.2 (accordingly (22,8±0,3) and (36,5±0,8); $p<0,05$).

In the next 6 months again patients in Gr.1 had less exacerbations (0,51±0,03) then patients in Gr.2 (1,4±0,03),$p<0,05$; & better WOMAC performance (Gr.1-(17,5±0,6 & Gr.2–37,1±0,5 accordingly,$p<0,05$).

Conclusions: 1. Histopathology of the knee cartilage has shown promising results concerning possibility of cartilage repair after trauma and prophylaxis of the early posttraumatic OA after PAP injections in animal model.

2. Repeating intra-artricular injections of PAP, added to the standard care in knee OA improves functional activity, reduces pain and number of OA exacerbations in 12 months of follow up.

3. The further studies (both experimental and clinical) are needed to obtain more accurate information and determine the most effective methods of PAP use in OA patients.

SAT0527 ASSESSMENT OF SHORT-TERM EFFECTIVENESS OF FIVE LOCAL TREATMENT MODALITIES IN PATIENTS WITH SYMPTOMATIC KNEE OSTEOARTHRITIS

M.L. Ladehesa Pineda, M.C. Castro Villegas, R. Ortega Castro, P. Font Ugalde, L. Bautista Aguilar, C. López Medina, R. Jiménez Gasco, L. Pérez Sánchez, M.Á. Caracuel Ruiz, A. Escudero Contreras, E. Collantes Estévez on behalf of Rheumatology, Hospital Universitario Reina Sofía de Córdoba/Instituto Maimónides de Investigación Biomédica (IMIBIC). *Rheumatology, Hospital Universitario Reina Sofía of Córdoba, Córdoba, Spain*

Background: Inside the therapeutic algorithm of knee osteoarthritis (OA) it is included the Non-Arthroscopic Joint Lavage (NAJL) since around 1934 Burman reported that arthroscopies improved the symptoms. Current medical treatment strategies are aimed at pain reduction and symptom control rather than disease modification (1). The large variety of potentially interventions available has raised the need to assess their effectiveness.

Objectives: To compare the short-term effectiveness among five treatment strategies in patients with symptomatic knee OA.

Methods: An open, controlled, randomized prospective study involving 150 patients of whom 76.7% were females. The average age was 65.37±8.35. Patients had knee OA according to American College of Rheumatology criteria, with Kellgren-Lawrence radiographic grades II-III. They were randomly assigned to five groups of treatment, 1)NAJL (n=30), 2)NAJL+hyaluronic acid (HA) (n=32), 3)NAJL+ corticosteroid (CS) (n=32), 4)HA (n=31), and 5)CS (n=25). Evaluations took place at baseline, one and three months. Western Ontario and McMaster University Osteoarthritis Index (WOMAC) and Lequesne scores were recorded. Statistical analysis included mixed analysis of variance, with post-hoc comparisons with Sidak's adjustment, and multiple linear regression (MLR) to identify those possible factors associated to WOMAC total at 3 months.

Results: Regarding WOMAC pain, significative differences were found in NAJL, at one month and at 3 months; and in NAJL+CS at one month. For WOMAC stiffness, there were significative differences in NAJL at one month and at 3 months; in NAJL+HA after one month and 3 months versus one month; and in NAJL+CS, at one month. For WOMAC function, significative differences were found in NAJL at one month and at three months; in NAJL+CS at one month; and in HA at 3 months. Regarding WOMAC total, significative differences were found in NAJL at one month ($p<0.001$) and at 3 months ($p<0.001$); and in NAJL+CS at one month ($p=0.018$). For Lequesne, significative differences were found in HA at one month ($p=0.003$) and at 3 months ($p=0.019$) versus baseline; and in CS, at one month ($p<0.001$). The WOMAC function at baseline, NAJL+HA, and infiltration with CS are the variables that show a significant association with WOMAC total at 3 months. The group that received NAJL+HA had poorer outcomes.

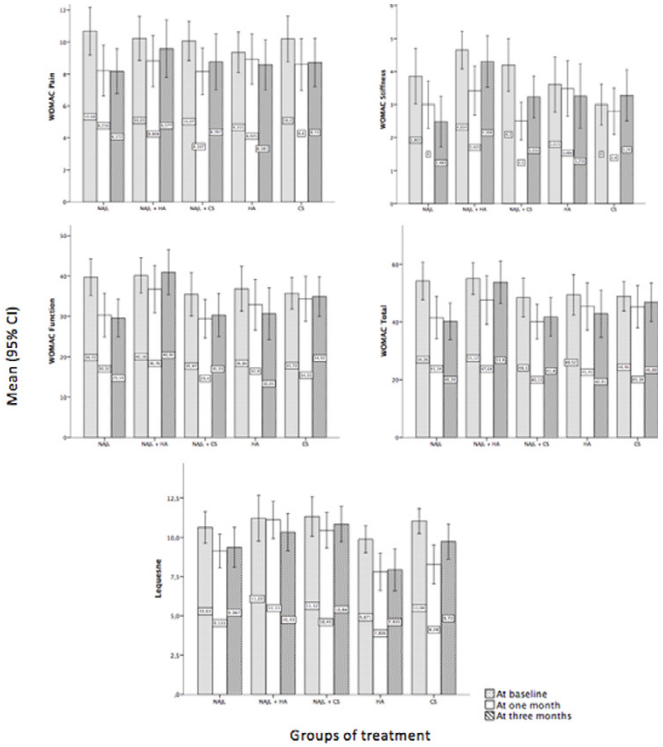

Figure 1. Clinical outcomes. WOMAC pain, stiffness, function and total, and Lequesne at baseline, at one month after treatment and three months after treatment.
Data are expressed as mean and confidence intervals are shown.
CI, confidence interval; NAJL, non arthroscopic joint lavage; HA, hyaluronic acid; CS, corticosteroid; WOMAC, Western Ontario and McMaster Universities Osteoarthritis Index

Conclusions: One month after treatment, best outcomes were obtained with HA due to the results found in Lequesne scale when comparing HA versus NAJL+HA, and NAJL+CS. Three months after the treatment, the most effective modality treatment was NAJL; since we did find significant differences regarding articular stiffness, physical function and Lequesne scale. The treatment with NAJL+HA appears to be less effective than the other modalities.

SAT0528 MOLECULAR MODIFICATIONS INDUCED BY MUD-BATH THERAPY IN PATIENTS WITH OSTEOARTHRITIS

M.M. Angioni [1], A. Denotti [2], S. Pinna [1], C. Sanna [2], A. Floris [1], M. Piga [1], A. Loi [2], A. Cauli [1]. [1]*Scienze Mediche e Sanità Pubblica, Università degli Studi di Cagliari, Monserrato (CAGLIARI);* [2]*Antiche Terme di Sardara, Sardara (VS), Italy*

Background: Mud-bath therapy (MBT) is a non-pharmacological approach commonly used to treat osteoarthritis (OA). Several data indicate that MBT improve patient's symptoms (1), exerting a beneficial effect on pain and joint function, although the biological mechanisms involved in the therapeutic response are poorly defined.

Objectives: This study aimed to find molecular changes (proteins and mRNA variations) in patients with OA after MBT treatment.

Methods: The study included 39 patients whit primary diffuse osteoarthritis, assigned to receive a cycle of mud-bath therapy over a period of 2 weeks added to usual pharmacologic treatment. Whole blood and serum were collected before and after standard MBT treatment: for each time points two pools of patients sera were analyzed by the direct antigen-labeling technology (RayBio® Biotin Label-based Antibody Array, RayBiotech) obtaining a broad, panoramic view of protein expression. Using this semi-quantitative technique up to 1000 target proteins was simultaneously detected, making this approach ideally suited for proteomic studies. Again, pooled samples of mRNA were used to investigate genes expression and to perform the transcriptomic analysis using an high-resolution array design that contains >6.0 million distinct probes, covering coding and non-coding transcripts (GeneChip® HTA 2.0, Affymetrix).

Results: At the end of mud-bath therapy, using first a semi-quantitative approach, we observed in both biological replicates increased levels (>1.5 fold change) of: inhibin beta A subunit (INHBA), activin A receptor type 2B (ACVR2B), angiopoietin-1 (ANGPT1), beta-2-microglobulin (B2M), growth differentiation factor 10 (BMP-3b/GDF10), C-X-C motif chemokine ligand 5 (CXCL5), fibroblast growth factor 2 (FGF2), fibroblast growth factor 12 (FGF12), oxidized low density lipoprotein receptor 1 (OLR1), matrix metallopeptidase 13 (MMP13). We observed that some increased proteins belongs to the same family or pathway: INHBA, ACVR2B and BMP-3b are members of TGF-Beta superfamily; CXCL5 and MMP13 participate into IL-17 signaling pathway; FGF2 and FGF12 are proteins of FGF family. We are currently performing the transcriptome analysis, and the next step will be to correlate detected proteins with mRNA levels considering also post-transcriptional or epigenetic modifications. Finally we will validate these findings with other quantitative techniques (like ELISA and RT-PCR).
Conclusions: Our first proteomic and broad spectrum analysis suggest the implication of molecular pathways involved in a wide variety of cellular functions such as gene expression modulation, differentiation, angiogenesis, tissue repair, acute and chronic inflammatory response which may explain the beneficial effects of MBT observed in osteoarthritis. This "omic" approach (proteomic and transcriptomic), generated a huge amount of data that is currently under statistical and bioinformatic analysis.

SAT0529 PROLONGED TNF-INHIBITOR TREATMENT DURATION IS ASSOCIATED WITH LOWER RISK OF HAND OSTEOARTHRITIS PROGRESSION IN PATIENTS WITH RECENT-ONSET RHEUMATOID ARTHRITIS AFTER 10-YEAR FOLLOW-UP

M. Loef[1], F.P. Kroon[1], S.A. Bergstra[1], J.A. van der Pol[1], W.F. Lems[2], P.J. Kerstens[3], C.F. Allaart[1], M. Kloppenburg[1,4]. [1]*Rheumatology, Leiden University Medical Center, Leiden;* [2]*Rheumatology, VU University Medical Center, Amsterdam;* [3]*Rheumatology, Westfriesgasthuis, Hoorn;* [4]*Epidemiology, Leiden University Medical Center, Leiden, Netherlands*

Background: Increasing evidence indicates involvement of the pro-inflammatory cytokine TNF-α in hand osteoarthritis (OA) pathogenesis. Ten years clinical and radiologic follow-up of the BeSt study, a randomized trial primarily designed to investigate targeted treatment in rheumatoid arthritis (RA) patients, offered the unique opportunity to study the long-term effects of TNF inhibitors (TNFi) on the development and progression of hand OA. The distal interphalangeal joints (DIPs) are rarely affected in RA, which allowed to evaluate primary OA separately.
Objectives: To investigate the effect of TNFi on incidental and progressive radiographic hand OA after 10-year follow-up in recent-onset RA patients.
Methods: At baseline and 10-year follow-up 262 patients (mean age 52 years, 66% women) were available for radiologic assessment of hand OA. Eighteen interphalangeal joints (IPs) were scored for osteophytes (OP) using the Osteoarthritis Research Society International (OARSI) atlas (0–3; summated score 0–54), and according to the Kellgren-Lawrence (KL) scoring method (0–4; summated score 0–72). Incidental OA was defined as an increase ≥1 in summated OP score or ≥2 in summated KL score in absence of OA at baseline, and progressive OA as an increase ≥3 in summated OP or KL score in presence of OA at baseline, based on the smallest detectable change. TNFi treatment and disease activity score (DAS) were assessed on standardized visits at a three-monthly interval. Associations between duration of TNFi treatment in months and incidental and progressive OA were analyzed using generalized linear models with Poisson distribution and robust standard errors, while adjusting for age, gender, time averaged DAS, time averaged Sharp-van der Heijde score and hand OA severity at baseline.
Results: Based on the OP score, 126 patients (48%) were classified with OA at baseline in the DIPs and 82 patients (31%) in the proximal IPs (PIPs). Incidental OA developed in 33% of patients in DIPs and in 42% in PIPs. Progressive OA occurred in 30% of patients in DIPs and in 38% in PIPs. Of patients with and without OA at baseline, irrespective of joint location, 63% and 55% were treated with TNFi, with a median treatment duration of 47 and 36 months, respectively. No effect of TNFi treatment duration was seen on incidental hand OA. On progressive hand OA, every month of TNFi treatment resulted in a reduced relative risk (RR) of OA progression in DIPs with a RR (95% confidence interval) of 0.987 (0.978–0.996), but not in the PIPs. The results from the analyses with the KL scoring method were comparable to the OP score, as shown in table 1.

Table 1. Associations between TNFi treatment duration and progressive hand OA in 261* patients, defined by osteophyte score and Kellgren-Lawrence score.

Joint type	Number of patients treated/ median (IQR) duration of treatment	Adjusted RR (95% CI)^	P value
Patients with a ΔOP score ≥3 units in presence of OA at baseline			
DIPs	67/ 33 (12-72)	0.987 (0.978-0.996)	0.003
PIPs	43/ 30 (12-72)	0.995 (0.985-1.005)	0.321
Patients with a ΔKL score ≥3 units in presence of OA at baseline			
DIPs	51/ 39 (12-87)	0.991 (0.984-0.998)	0.007
PIPs	32/ 36 (12-72)	0.995 (0.986-1.004)	0.303

*1 patient missing due to poor quality of hand radiographs at 10 years. ^Adjusted for age, gender, time averaged DAS, time averaged SHS, severity of OA at baseline

Conclusions: Prolonged TNFi treatment is associated with a reduced relative risk on radiologic hand OA progression in DIPs, but not in PIPs, after 10 years. Although the effect sizes are small, these results provide evidence for influence of TNF-α in hand OA pathogenesis.

SAT0530 CENTRAL SENSITISATION IN HAND OSTEOARTHRITIS: THE ANTERIOR CINGULATE CORTEX IS INVOLVED IN PAIN PROCESSING

M. Russell[1], F. Howe[2], T. Barrick[2], N. Sofat[1]. [1]*Institute of Infection & Immunity;* [2]*St George's, University of London, London, United Kingdom*

Background: We have previously shown that people suffering with chronic pain in hand OA have activation of central brain pain processing centres localised to the anterior cingulate cortex, insular cortex and thalamus by functional neuroimaging (1) and algometry (2).
Objectives: We hypothesised that hand OA subjects will have structural differences in 3 pain-processing regions of the brain - the anterior cingulate cortex (ACC), insular cortex and thalamus - based on activation of brain centres we have found previously (1). Our brain neuroimaging work was part of a randomised, placebo-controlled trial to assess the effect on clinical pain outcomes by intervention with centrally-acting analgesic agents: pregabalin or duloxetine.
Methods: The primary outcome measures for our clinical trial were hand pain Numerical Rating Scale (NRS) and AUSCAN pain after 12 weeks' treatment. In secondary outcome analyses, participants with hand OA (n=28) underwent T1-weighted MRI of the brain before and after 12 weeks of treatment with pregabalin, duloxetine or placebo therapy. Grey matter brain structure was compared using FreeSurfer regional volumetric analysis and voxel-based morphometry (VBM) to age-matched controls (n=11), and evaluated for volume changes in the ACC, insular cortex and thalamus.
Results: In our clinical trial, we observed clinically significant improvement in pregabalin, duloxetine and placebo treatment groups after 12 weeks (ANOVA p=0.0078). Most notably, pairwise comparisons for pregabalin vs placebo showed significant improvement for NRS pain and AUSCAN pain outcomes in the ITT analysis ($p<0.05$), but not for duloxetine vs placebo after 12 weeks' ($p>0.05$). Both voxel-wise and regional volumetric analyses demonstrated areas of reduced grey matter volume in the ACC of hand OA subjects, relative to control subjects, at baseline ($p<0.05$) (Figure 1). The structural differences in the ACC persisted following 12 weeks of treatment with pregabalin, duloxetine or placebo therapy ($p<0.05$). We did not observe structural differences in the insular cortex or thalamus in any of the three groups.

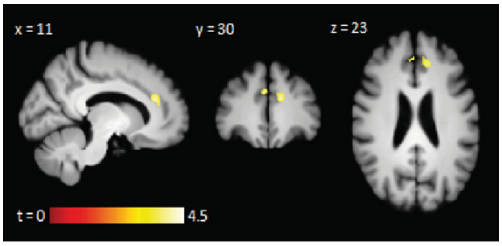

Figure 1. VBM analysis demonstrating clusters of reduced grey matter volume in the ACC in participants with hand OA, relative to control subjects, at baseline. The left side of the figure represents the left side of the brain.

Conclusions: We found that the ACC volume was reduced in participants with hand OA. The ACC is a key pain-processing region of the brain. Changes in ACC grey matter volume have previously been described in other painful conditions, but not hand OA. ACC grey matter volume reduction is thought to represent neural plasticity in chronic pain states. Our data supports the role of central sensitisation in hand OA and provides a rationale for the further investigation of centrally-acting analgesics in its management. Our trial demonstrated improvement in clinical endpoints for pain for pregabalin vs placebo and duloxetine vs placebo, respectively ($p<0.05$). However, structural differences in the ACC were still evident following 12 weeks of treatment with pregabalin or duloxetine. This may relate to the relatively short duration of treatment in our study. Alternatively, the baseline differences in the ACC may represent irreversible changes. Longitudinal studies with greater follow-up periods are necessary to further investigate this.

SAT0531 MATRIX ASSISTED LASER DESORPTION IONIZATION IMAGING MASS SPECTROMETRY APPLIED TO HUMAN OSTEOARTHRITIS CARTILAGE REVEALS THE INTRA-TISSUE METABOLIC HETEROGENEITY

M. Eveque-Mourroux[1], P. Emans[2], T. Welting[2], A. Boonen[3], R. Heeren[1], B. Cillero-Pastor[1]. *[1]Division of Imaging Mass Spectrometry, Maastricht MultiModal Molecular Imaging (M4I) Institute; [2]Department of Orthopaedic Surgery; [3]Caphri Research institute, Maastricht University Medical Center, Maastricht, Netherlands*

Background: Osteoarthritis (OA) is one of the most common diseases, caused by a chronic degenerative disorder of the joint. OA can be related to the metabolic syndrome or metabolic abnormalities being recently defined as a subtype of the disease[1]. Matrix-assisted laser desorption/ionization (MALDI) imaging mass spectrometry (IMS) technology allows for the investigation of the bimolecular distribution of proteins, lipids or metabolites through the in situ analysis of tissue sections. In order to better understand the metabolic OA phenotype, the study of the endogenous metabolic profiles using MALDI-IMS should be considered.
Objectives: The main goal of this study is to apply MALDI-IMS methodology to study the metabolic spatial distribution of cartilage and to reveal intra-tissue and inter-patient heterogeneity.
Methods: Human OA cartilage was obtained from donors undergoing total knee joint replacement. Samples were heat stabilized by a stabilizer system, before being snap frozen. Cartilage punches were sectioned at 12 μm thickness in a cryostat and deposited on indium tin oxide (ITO) glass slides. 9-Aminoacridine (9AA) and N-(1-Naphthyl) Ethylenediamine DihydroChloride (NEDC) matrices were sprayed on the tissues. MALDI-MS profiling and imaging experiments were performed using different mass spectrometers. Data were analyzed by different software dedicated to mass spectrometry.
Results: Results showed that 9AA and NEDC matrices were both able to extract several and different compounds. MALDI-MS/MS was employed with 9AA matrix for molecular identification, confirming for the first time the presence of several metabolites in cartilage such as adenosine triphosphate, adenosine diphosphate, uridine triphosphate or N-Acetylglucosamine. Punches from lesioned and non-lesioned areas from the same OA patient were heat stabilized and sprayed with NEDC matrix. MALDI-IMS experiments at 40-μm of spatial resolution showed a different metabolic distribution between deep and superficial areas but also between lesioned and non-lesioned regions suggesting an evidence in the existence of intra-tissue heterogeneity (figure 1).

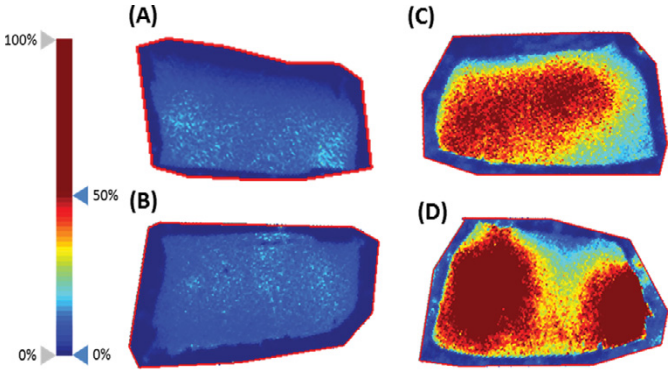

figure 1: Distribution of Hexose species (m/z 215. 03) in OA cartilage tissue sections from the same patient. (A, B) Duplicate of non-lesioned cartilage tissues sections. (C, D) Duplicate of lesioned cartilage tissues sections.

Conclusions: MALDI-IMS methodology is a useful technique for metabolite profiling of cartilage and could be employed to study OA patient heterogeneity. This fact will be especially relevant for OA patients suffering of metabolic syndrome.

SAT0532 SLEEP QUALITY IN PATIENTS WITH KNEE OSTEOARTHRITIS

M. Sezgin[1], E. Yeşildal[1], S. Sevim[2], H. Ankaralı[3], G. Sahin[1]. *[1]Department of Physical Medicine and Rehabilitation; [2]Department of Neurology, Mersin University Medical Faculty, Mersin; [3]Department of Biostatistics and Medical Informatics, Duzce University Medical Faculty, Düzce, Turkey*

Objectives: The aim of this study was to investigate sleep quality in patients with knee osteoarthritis (OA).
Methods: One hundred patients with knee OA and age and gender-matched 75 healthy controls were enrolled into the study. Demographic characteristics of the participants were recorded. All patients was examined by a single physician, the findings were recorded. Knee radiographs of the patients were staged according to the Kellgren-Lawrence grading. In addition, to evaluate the clinical status and quality of life of patients was performed Western Ontario ve McMaster Universities Osteoarthritis Index (WOMAC) and Nottingham Health Profile (NHP). The sleep quality of two groups with MOS sleep scale and polysomnography (PSG) were subjectively and objectively evaluated.
Results: All scores of MOS sleep scale were significantly lower in patients with knee OA than controls ($p<0.001$). When PSG outcomes of the patients compared with the controls,waketime during sleep period (WTSP) (37.2±35.9, 13.1±19.4 p=0.012 respectively) and number of awakeness (NOAW) (9.2±18.2, 2.6±3.5, p=0.05 respectively) were significantly higher, sleep efficiency (SE) (84.2±21.1, 96.7±4.6 p=0.009 respectively) was significantly lower in patients with knee OA. There were significantly positive correlations between MOS sleep scale and PSG (sleep period, sleep onset, REM duration and REM latans) outcomes of the patients (r:0.44–0.59 p=0.04–0.006).
In addition, MOS sleep scale scores of patients were negatively related with both NHP (pain, emotional reaction, sleep and social isolation subgroup scores) and WOMAC (total and functional) scores (r:-0.20–0.47, p=0.04–0.0001).
Conclusions: The sleep quality of patients with knee OA was worse compared to healthy controls. The poor sleep and sleep quality in knee OA had adversely affected the clinical status and quality of life.

SAT0533 ASSOCIATION OF OSTEOARTHRITIS AND PERIODONTITIS BASED ON THE KOREA NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY

M.K. Chung, N. Koo, B.W. Lee, J. Lee, S.-K. Kwok, S.-H. Park, J.H. Ju. *Division of Rheumatology, Department of Internal medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Korea, Republic Of*

Background: Osteoarthritis (OA) is a chronic joint disease with complex etiologies characterized by synovial inflammation, subchondral bone remodeling, and the formation of osteophytes, which leads to cartilage deterioration. Periodontitis (PD) is also a chronic inflammatory disease characterized by loss of periodontal ligament and alveolar bone. Recently, the association between OA and metabolic diseases has been proposed, and the association between several systemic diseases such as rheumatoid arthritis, metabolic syndrome and periodontitis has been also revealed.
Objectives: The aim of this study was to investigate the association between OA and PD in South Korea using data from the Korea National Health and Nutrition Examination Survey (KNHANES) during 2010–2014.
Methods: Cross-sectional data of 7,969 adults who completed the KHANES, and participated in both a periodontal examination and a knee imaging were analyzed. OA of knee was defined when a participant had knee arthralgia and showed radiographic change of Kellgren-Lawrence (KL) grade over 1. OA patients were grouped into mild (KL grade 1–2) and severe (KL grade 3–4) OA. The periodontal status was assessed by the Community Periodontal Index. Binary logistic regression analysis was performed according to the OA and PD status, severity of OA, and subgroups (age, gender) adjusting for the socio-demographics, oral health behaviors and status, smoking, and drinking.
Results: Of the 7,969 participants, 1408 (17.7%) had OA and 2987 (37.5%) had PD. OA and PD showed no significant association in overall analysis. However, in subgroup analysis, female patients with severe OA were more likely to have PD (adjusted odd ratio (OR) 1.377, P=0.0316); likewise, OR for severe OA in female patient with PD was 1.367. (P=0.0.54)
Conclusions: Severe OA and PD were associated with each other especially in

female in the Korean population. Further prospective and experimental studies are necessary to identify the impact and mechanisms of association between severe OA and PD in female.

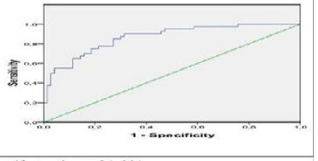
SAT0534 EFFECT OF SUSTAINED- RELEASE SYMPTOMATIC DRUGS ON PROGRESSION OF KNEE JOINT OSTEOARTHROSIS IN PATIENTS WITH LESS THAN 5 YEARS DISEASE DURATION IN A 5-YEAR PROSPECTIVE STUDY

N. Kashevarova, E. Taskina, L. Alekseeva. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*



Objectives: To assess the effect of sustained release symptomatic drugs chondroitin sulfate (CS) + glucosamine hydrochloride (GH) on progression of knee OA in pts with <5 years disease duration during the 5year follow-up period (FUP).

Methods: This 5-year study included 52 female-patients with primary knee OA (ACR criteria), disease duration did not exceed 5 yrs (mean age–59,1±8,9). On each pts the individual file including 200 parameters was filled. Diagnostic modalities used in each patient included plain radiography of knee joints (gonarthrosis stage was classified using Kellgren J.- Lawrence J. scale), DEXA subchondral portions of the hip and tibia, ultrasound (US) and MRI examination of knee joints. First OA stage was documented in 22 (42,3%)pts, 2-nd - in 24 (46,2%), 3d- in 6 (11,5%). During 5 years of FUP 31 (60%) pts were administered the combined CS+GH regimen for more than 6 months a year. OA progression was documented based on radiographic criteria.

Results: During the 5 year FUP radiographic progression (upgrade in radiographic stage) of knee OA was documented in 14 pts (Group 1 - with OA progression), while in 38 pts radiographic stage remained unchanged (Group 2 - without progression). Patients from both groups were comparable in terms of age and disease duration (p>0,05). Although, pts from Group 1 with OA progression had more intense knee pain when walking: 60,4±18,3 vs 48,7±17,8mm, p=0,04; and higher BMI values: 34,5±4,6 vs 28,9±4,9 kg/m^2, p=0,001; US-findings based higher rate of synovitis:57,1% vs 18,4%, OR=5,9, 95% CI 1,6–22,5, p=0,009; bone marrow edema in medial tibia aspect 64,3% vs 13,2%, OR=11,9, 95% CI 2,8–50,3, p=0,0006 based on MRI findings. In pts with OA progression DEXA examination identified significantly higher absolute BMD values in the medial condyle of the tibia (0,9 (0,8–1,2) vs 0,8 (0,7–0,8) g/cm^2, p=0,001) as compared to pts from Group 2. Re-examination in 5yrs showed that statistically significant differences between the two groups still remained. Analysis of 5year therapy revealed, that the majority of pts without OA progression (68,4%) were taking combined CS+GH regimens for more than 6 months a year during 5-year FUP, while only 35,7% of pts who progressed (OR=4,3, 95% CI 1,1–16,3, p=0,03) managed to adhere to this regimen. Discriminant analysis showed that 5-year intake of combined CS+GH therapy for more than 6 months a year should be considered as a predictor of decreased risk of disease progression, while on the contrary, such symptoms as synovitis, bone marrow edema, and high BMD values in the medial condyle of the tibia should be viewed as predictors and risk factors for knee OA progression in pts with <5 years disease duration. Based on identified factors and their coefficients the authors designed a model (with area under the ROC curve equal to 0,93), allowing to predict the future course of the disease in an individual patient with high accuracy, i.e. 85,7% sensitivity and 84,2% specificity.

Factors	Discriminant function coefficients
US: synovitis	2,17
MRI: bone marrow edema	3,19
BMI in the medial condyle of the tibia	5,19
CS+GH	–1,03
Constant	11,83

ROC-curve (AUC=0,93)

The accuracy of prediction based on the variables (factors) was 84,6 %.

Conclusions: Use of combined CS+GH regimens for more than 6 months a year during 5 years is an important factor, decelerating the progression of knee OA in pts with <5 years disease duration by the factor of 4. While synovitis, bone marrow edema, and high BMD values in the medial condyle of the tibia are responsible for further OA progression on this group of pts.

SAT0535 IMPACT OF THE METABOLIC SYNDROME ON THE PREVALENCE, SEVERITY INCIDENCE AND PROGRESSION OF KNEE OSTEOARTHRITIS

N. Oreiro-Villar[1,2], M. Fernandez-Moreno[1,2], E. Cortes-Pereira[1], M.E. Vazquez-Mosquera[1], S. Relaño[1], S. Pertega[3], C. Fernandez-Lopez[1], F.J. Blanco[1], I. Rego-Perez[1]. *[1]Servicio de Reumatología, Instituto de Investigación Biomédica de A Coruña (INIBIC). Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas. Universidade da Coruña (UDC). As Xubias, 15006, A Coruña; [2]Centro de Investigación Biomédica En Red, Ciber-Bbn, Madrid; [3]Unidad de Epidemiología Clínica y Bioestadística, Instituto de Investigación Biomédica de A Coruña (INIBIC). Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas. Universidade da Coruña (UDC). As Xubias, 15006, A Coruña, Spain*

Background: The contribution of metabolic factors on the development of OA has not been fully elucidated.

Objectives: The aim of this work is to analyze the influence of metabolic syndrome in the rate of radiographic incidence and progression of knee osteoarthritis, as well as its impact on the prevalence and severity of the disease.

Methods: For this work we used data from the Spanish cohort PROCOAC (PROgnostic Cohort of OsteoArthritis A Coruña). This cohort consists of subjects that visited the Rheumatology consultations at different time points and comprises 984 subjects at baseline including radiographic knee and hip KL grade, radiographic hand OA status, demographic and clinical data as well as the necessary information to assess the metabolic syndrome at baseline, that is, abdominal circumference (in cm) in addition to at least two of the following parameters: triglycerides above 200mg/dL, low HDL (<35 mg/dL), hypertension and increased glucose blood levels (>110 mg/dL). To assess the severity of the disease, the number of affected joints was coded as 0–1 and 2–3, according to the radiographic information of hands, knees and hips. Appropriate statistical analyses including Cox regression models with Kaplan-Meier survival curves and chi-square contingency tables were performed with SPSS v19.

Results: The mean age of subjects was 63,86 [32–88] years; 75,6,% were women. A total of 85% had radiographic hand OA and 11,8% suffered metabolic syndrome at baseline. In those OA patients that experienced radiographic knee OA progression over time (any KL increase from KL≥2 at baseline) the metabolic syndrome appeared as a significant risk factor (HR=3.696;95CI:1.085–14.520;p-value=0.037) (Figure 1). Similarly, in those subjects that developed incident radiographic knee OA over time (a new-onset KL grade 2), the metabolic syndrome at baseline also appeared as a significant risk factor with an increased magnitude (HR=12.931;95CI:3.037–55.051;p-value<0.001) (Figure 1). In addition, to have contralateral knee OA at baseline (HR=12.837;95CI:5.044 – 32.673;p-value <0.001) as well as radiographic hand OA (HR=5.671;95CI:0.854–37.649;p-value=0.07) associates with an increased rate of incident knee OA too. In terms of prevalence and severity of the disease, the metabolic syndrome associates with an increased risk of knee OA (OR=1.865;95% CI=1.080–3.220;p=0.024) as well as with increased number of affected joints, though in a non-significant manner (OR=1.582;95% CI=0.916–2.733;p=0.098)

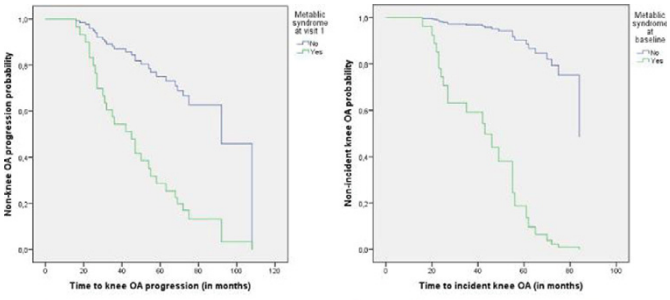

Figure 1. Kaplan-Meier survival curves showing the influence of the metabolic syndrome in the rate of radiographic knee OA progression and incidence over time

Conclusions: The alterations that underlie the metabolic syndrome condition the severity and prevalence of knee osteoarthritis, as well as the rate of incidence and progression of the disease

SAT0536 AXIAL ALIGNMENT OF THE KNEE – IMPORTANCE IN CARTILAGE REPAIR? HIGH TIBIAL OSTEOTOMY VS. DISTRACTION

N. Besselink[1], R. van Heerwaarden[2], J. van der Woude[3], K. Wiegant[4], S. Spruijt[5], F. Lafeber[1], W. van Spil[1], S. Mastbergen[1]. *[1]Rheumatology and Clinical Immunology, University Medical Centre Utrecht, Utrecht; [2]Orthophedics, ViaSana, Mill; [3]Orthophedics, Alrijne Hospital, Leiden; [4]Orthophedics, Sint Maartenskliniek, Nijmegen; [5]Orthophedics, Sint Maartenskliniek, Woerden, Netherlands*

Background: Opening-wedge high tibial osteotomy (HTO) is primarily indicated in treating varus gonarthrosis. The rationale behind HTO treatment of knee

osteoarthritis (OA) is to unload the affected compartment, this is accomplished by correcting the angular deformity towards the unaffected compartment, i.e. shifting the hip-knee-ankle angle (HKA; mechanical axis) towards varus for a medial lesion. Knee joint distraction (KJD) is an alternative joint-sparing treatment for knee OA and has been demonstrated to decrease pain, improve function, and increase joint space width (JSW)[1].

Objectives: To investigate the importance of axial alignment (and correction) in these two effective (joint-sparing) treatments of medial knee OA.

Methods: Patients with medial knee OA, a HKA less than 12° varus, normal knee stability, younger than 65 years, and a BMI less than 35 kg/m^2 were randomized to HTO (n=46) or KJD (n=23). WOMAC and VAS pain were collected at baseline and after twelve months. To assess structural outcome, JSW was measured on knee radiographs, before and after both treatments. HTO patients had full leg standing anteroposterior radiographs taken before and after surgery, KJD patients only had these taken before surgery. Therefore, the femur-tibia angle (FTA; anatomical axis), acquired using Knee Image Data Analysis (KIDA), was investigated as an alternative for assessing axial alignment. Agreement between axial alignment as defined by HKA and by FTA appeared to be fair (ICC=-0.414). WOMAC and VAS Pain were then related to (changes in) axial alignment, Kellgren & Lawrence (K&L) grade, BMI, gender, pre-operative range of motion (ROM), and age as independent variables in linear regression models.

Results: Patient baseline characteristics were not statistically significantly different between patients treated with KJD or HTO (see table 1). WOMAC increased statistically significantly one year after either treatment (KJD:Δ21.05±19.93; HTO:Δ27.80±15.32; both p<0.001). Likewise, VAS pain decreased (KJD:Δ-23.89±29.67,p=0.001; HTO:Δ-35.42±24.06,p<0.001). KJD led to a statistically significant increase in mean JSW (Δ0.50±0.88mm,p=0.014), and both treatments led to a statistically significant increase in medial (KJD:Δ0.81±1.16mm,p=0.004; HTO:Δ0.47±0.69mm,p<0.000) as well as minimal JSW (KJD:Δ0.85±0.96mm,p<0.000; HTO:Δ0.35±0.51mm,p<0.000) after one year. The FTA changed significantly in the HTO group after one year (Δ0.73°,p=0.005), while the KJD group showed a trend (Δ0.77°,p=0.105). In the KJD group, changes in clinical outcomes were not associated with pre-operative HKA, changes in FTA, K&L grade, BMI, gender, pre-operative ROM, or age. In contrast, in the HTO group a significant association was demonstrated for a change in WOMAC with a change in FTA (std.β=-0.341) and for a change in VAS Pain with baseline age (std.β=-0.323), as seen in table 2.

Table 1. Baseline characteristics

Characteristics	High tibial osteotomy	Knee joint distraction	
Mean (± SEM)	(n = 45)	(n = 22)	p-value
Male gender (n)	27/45 (60%)	16/22 (73%)	n.s.
Height (cm)	177 ± 2	178 ± 2	n.s.
Weight (kg)	85.2 ± 2.1	87.2 ± 2.8	n.s.
Body mass index (kg/m²)	27.2 ± 0.5	27.5 ± 0.7	n.s.
Affected knee (left)	20/45 (44%)	10/22 (45%)	n.s.
Age at surgery (yr)	49.4 ± 1.0	51.2 ± 1.1	n.s.
Kellgren & Lawrence			n.s.
Grade 0 (n)	1 (2%)	0 (0%)	
Grade 1 (n)	5 (11%)	6 (27%)	
Grade 2 (n)	12 (27%)	4 (18%)	
Grade 3 (n)	23 (51%)	11 (50%)	
Grade 4 (n)	4 (9%)	1 (5%)	
Tibiofemoral axis (°)	6.2 ± 0.3	5.8 ± 0.6	n.s.

Table 2: Linear regression with change in WOMAC and VAS Pain as dependent variables, and change in KIDA angle, pre-operative axial alignment, pre-operative range of motion (ROM), age, gender, BMI, baseline K&L grade, and either baseline WOMAC or VAS Pain as independent variables. [1]Standardized beta coefficients, *P<0.05

	High tibial osteotomy				Knee joint distraction			
	Δ WOMAC		Δ VAS Pain		Δ WOMAC		Δ VAS Pain	
	Std β[1]	Sig.*	Std β[1]	Sig.*	Std β[1]	Sig.*	Std β[1]	Sig.*
Δ Femur-tibia angle (FTA)	-0,341	0,029*	0,255	0,124	-0,049	0,840	-0,077	0,753
Pre-operative axial alignment (HKA)	0,128	0,368	-0,048	0,755	-0,076	0,768	-0,131	0,609
Pre-operative ROM	-0,172	0,234	0,083	0,595	0,124	0,684	0,033	0,902
Age	0,245	0,084	-0,323	0,045*	0,161	0,627	-0,077	0,786
Gender	-0,160	0,283	0,026	0,875	0,049	0,836	-0,159	0,481
BMI	-0,201	0,154	0,027	0,857	0,177	0,471	-0,150	0,537
Baseline K&L	-0,081	0,556	0,078	0,611	0,191	0,516	-0,037	0,885
Baseline WOMAC	-0,301	0,036*			-0,816	0,033*		
Baseline VAS Pain			-0,231	0,147			-0,682	0,016*

Conclusions: Both KJD and HTO lead to a statistically significant clinical and structural benefit after one year. Nevertheless, the change in FTA was associated with WOMAC change after one year in the HTO group, but not in the KJD group. This indicates that axial alignment correction may not per se be necessary for clinical benefit.

SAT0537 INFLUENCE OF MELOXICAM IN ORODISPERSIBLE FORM ON PLATELET AGGREGATION AND VON WILLEBRAND FACTOR IN PATIENTS WITH OSTEOARTHRITIS

O.S. Khmel, V.V. Rodionova. *Occupational Diseases and Clinical Immunology, State Establishment "Dnipropetrovsk Medical Academy, of Health Ministry of Ukraine", Dnepr, Ukraine*

Background: Meloxicam, which selectively inhibits COX-2, can cause inhibition of the biosynthesis of vascular endothelium vasodilator - prostacyclin, without impacting significantly on production of thromboxane, which promotes vasoconstriction [1]. Therefore, the effect of Meloxicam on the possibility of thrombotic complications need to be learn more accurately.

Objectives: To investigate the effect of orodispersible form of Meloxicam on platelet aggregation and von Willebrand factor in patients with knee osteoarthritis.

Methods: The study included 24 patients with knee osteoarthritis (OA) of the II stage according to the Kellgren-Lawrence. The control group consisted of 15 healthy individuals. Patients were prescribed the orodispersible form of Meloxicam in dose of 15 mg 1 time per day orally during 10 days. The survey was carried out before and after treatment. Patients had all-clinical studies, questionnaires (visual analogue scale (VAS), Western Ontario and McMaster Universities Arthritis Index (WOMAC), questionnaire Lequesne), optical aggregometry with adenosine diphosphate (ADP), collagen, thrombin and ristocetin for revealing the level of von Willebrand factor.

Results: As a result of treatment patients had a significant improvement of overall health and reduction of pain in knee joints according to the VAS (before treatment – 54.5 [50 – 71] mm, after treatment – 27 [18 – 41] mm; p≤0.05), WOMAC (before treatment – 143 [109 – 187] points, after treatment - 98 [13–168] points; p≤0.05), questionnaire Lequesne (before treatment – 16 [13 – 21] points, after treatment – 12 [3 – 22] points; p≤0.05). After treatment patients experienced a significant increase in the degree of platelet aggregation with ADP (before treatment – 52.6 [39.6 – 98.2]% after the treatment – 83.5 [41.3 – 127]%; p≤0.05), which may indicate a probable increase in the initiation of irreversible aggregation of circulating platelets. The degree of platelet aggregation with collagen also increased (before treatment – 46.5 [29.5 – 89]%, after treatment – 68.6 [37.9 – 115.4]%; p≤0.05), indicating the increased adhesion of platelets to collagen of the vascular endothelium. Before and after treatment, patients remained significantly elevated degree of aggregation with thrombin in comparison with the control group (before treatment – 65.6 [24.7 – 86.7], after treatment – 78 [62.3 – 92.7]%, control group – 37.8 [32.11 – 42.26]%; p≤0.05) which indicates the stimulation of the of the endothelin-1 synthesis with further infringements of procoagulants and anticoagulants. Von Willebrand factor, as an indirect indicator of endothelial damage, was significantly increased after treatment (before treatment – 151.4 [138.9 – 224]% after treatment – 206.8 [171.9 – 257.4]%), which may indicate increase of endothelial lesions because of meloxicam with further endothelial dysfunction (p≤0.05).

Conclusions: Intake of the orodyspersible form of Meloxicam in patients with osteoarthritis can cause an increase of platelet aggregation and level of von Willebrand factor that may contribute to the vascular endothelial dysfunction and increase in risk of thrombosis.

SAT0538 PROGRESSION OF PAIN, NUMBER OF CLINICALLY SWOLLEN JOINTS AND ULTRASOUND DETECTED SYNOVITIS AND OSTEOPHYTE FORMATION IN PATIENTS WITH HAND OSTEOARTHRITIS OVER TWO YEARS

O. Sleglova, O. Ruzickova, K. Pavelka, L. Senolt. *Institute of Rheumatology, Prague, Czech Republic*

Background: Hand osteoarthritis (HOA) is a common and frequent cause of pain. HOA is a heterogeneous group of disorders with two main subsets including non-erosive and erosive disease. Few studies demonstrated inflammatory ultrasound changes and more severe clinical symptoms in patients with erosive compared with non-erosive disease, however the results are inconsistent.

Objectives: he aim of this study was to evaluate progression of pain, stiffness, physical impairment and ultrasound features in patients with erosive and non-erosive HOA in a two years longitudinal study.

Methods: Consecutive patients with symptomatic HOA fulfilling the American College of Rheumatology (ACR) criteria were included in this study. Joint pain and swelling were assessed. Patients reported joint pain on 100 mm visual analogue scale (VAS). Pain, joint stiffness and disability were assessed by the Australian/Canadian OA hand index (AUSCAN). Radiographs of both hands were examined and erosive disease was defined by at least one erosive interphalangeal joint. Synovial hypertrophy and power Doppler signal (PDS) were scored with ultrasound. Synovitis was graded on a scale of 0–3 and osteophytes were defined as cortical protrusions seen in two planes. Patients were examined at baseline and at the two years follow-up.

Results: Altogether, 129 patients (12 male) with symptomatic nodal HOA were included in this study and followed between April 2012 and January 2017. Out of these patients, 72 had erosive disease. The disease duration ($p<0.01$) was significantly higher in patients with erosive compared with non-erosive disease.
Pain ($p<0.05$) and the number of clinically swollen joints ($p<0.05$) were significantly higher in patients with erosive compared with non-erosive disease at baseline. There were significant progression of pain ($p<0.05$) and the number of clinically swollen joints ($p<0.01$) at the two years follow up. The progression in clinically swollen joint count was about 21% higher in patients with erosive disease.
According to the AUSCAN, patients with erosive compared with non-erosive disease had more pain ($p<0.05$) and stiffness ($p<0.01$) at baseline. Pain and stiffness, but not function, got worse ($p<0.01$) in patients with erosive compared with non-erosive disease at the two years follow up.
US-detected pathologies such as gray-scale synovitis total score ($p<0.001$), intensity of PDS ($p<0.01$) and number of osteophytes ($p<0.01$) were significantly higher in patients with erosive compared with non-erosive disease at baseline. There were improvements in gray-scale synovitis total score and intensity of PDS in patients with non-erosive disease while patients with erosive disease worsened at the two years follow up. On the other hand, the progression of US-determined osteophyte formation was observed in both groups.
Conclusions: The findings of this study show that pain and number of clinically swollen joints associated with US-detected synovial hypertrophy inflammatory signs and osteophyte formation is more severe in patients with erosive HOA than in patients with non-erosive disease. In addition, osteophyte formation is more likely to progress independent of synovial inflammation.

SAT0539 DIFFERENTIAL PROFILE OF ENDOGENOUS PEPTIDES DETECTED BY TARGETED PROTEOMICS IN HIP AND KNEE CARTILAGE SECRETOMES FROM OSTEOARTHRITIS PATIENTS

P. Fernandez-Puente, L. Gonzalez-Rodriguez, V. Calamia, L. Lourido, M. Camacho, C. Ruiz-Romero, F.J. Blanco. *Grupo de Proteomica-PBR2-ProteoRed/ISCIII-Servicio de Reumatología., Instituto de Investigación Biomédica de A Coruña (INIBIC), Complexo Hospitalario Universitario de A Coruña (CHUAC), Sergas. Universidade da Coruña (UDC), A Coruña, Spain*

Background: Peptidomics can be defined as the comprehensive, qualitative and quantitative study of all native peptides in a sample in a defined space at a defined time under defined biological conditions. LC-MS/MS targeted proteomics have been used to identify and quantify candidate molecular biomarkers in diverse range of samples, including cells, tissues, serum/plasma, and other types of body fluids.
Objectives: In the present work, we have developed a targeted method to detect a panel of endogenous peptides that were identified as released from human healthy (N) and/or osteoarthritic (OA) hip and knee cartilage. Secretomes were obtained separately from the wounded (WZ) and unwounded (UZ) zones of OA cartilage. The enrichment of endogenous peptides was achieved by ultrafiltration and solid phase extraction (SPE). After peptide extraction, the different peptide profiles of these secretomes were relative quantified by target proteomics.
Methods: Proteins secreted from human articular cartilage (secretomes) were obtained by culture of tissue explants [1]. The enrichment of endogenous peptides was standardized using ultrafiltration procedures and solid phase extraction with reversed phase (C18) resins. A method for the targeted identification and relative quantitation of endogenous peptides by Multiple Reaction Monitoring (MRM)-mass spectrometry was developed employing cartilage secretome samples, and then applied on synovial fluid and serum. The peptides were separated by nano-LC coupled to a 5500 QTRAP mass spectrometer using stable isotope-labeled (SI) peptides as an internal control. Peptide identifications were searched using the ProteinPilot program. Data analysis was performed using the Skyline software.
Results: 23 endogenous peptides belonging to 9 proteins related with OA, as Cartilage Oligemeric Matrix Protein (COMP), Cartilage Intermediate Layer Protein (CILP), Prolargin (PRELP), Dermcidin (DCD), Fibronectin (FINC) and Glia Derived Nexin (GDN) among others, were differentially detected and relatively quantified in the cartilage secretomes. Some of the endogenous peptides belonging to COMP, FINC and GDN were found with a significant high release in the UZ of hip cartilage, however in knee cartilage the release is higher in the WZ. On the other hand, certain peptides belonging to proteins like CILP or PRELP were found to be mostly increased in the UZ of both hip and knee OA cartilages when compared to healthy tissue.
Conclusions: A panel of endogenous peptides has been identified in articular cartilage, which are differentially released between OA and healthy patients, as well as between knee and hip OA patients. These endogenous peptides may be potential biomarkers to differentiate osteoarthritis from hip and knee. Our targeted proteomics approach would be widely applicable to quantify low abundant peptides of interest in complex biological samples as synovial fluid and serum in order to unravel their putative biomarker value for osteoarthritis.

SAT0540 THE REDUCTION IN ADRENERGIC AND INFLAMMATORY SERUM MARKERS IN OSTEOARTHRITIS PATIENTS AFTER TREATMENT WITH CHONDROITIN SULFATE/GLUCOSAMINE HYDROCHLORIDE AND CELECOXIB IS DIFFERENT ACCORDING TO THE PRESENCE OF BACTERIAL DNA IN BLOOD

P. Zapater[1], M. Herrero[2], H. Martínez[2], R. Francés[3,4], J. Vergés[5], J.F. Horga[6]. *[1]Pharmacology Department, Miguel Hernández University, Alicante; [2]Clinical R&D, Bioiberica, Barcelona; [3]CIBERehd. Instituto de Salud Carlos III, Madrid; [4]Medicine Department, Miguel Hernández University, Alicante; [5]Osteoarthritis Foundation International (OAFI), Barcelona; [6]Pharmacology Department, Miguel Hernández University, Alicante, Spain*

Background: Inflammation in osteoarthritis (OA) has been characterized by infiltration of immune cells and secretion of cytokines into synovial tissues. Synovial macrophages production of IL-1beta and TNF-alfa is increased in response to lipopolysaccharide (LPS) suggesting a potential role of pathogen-associated molecular patterns (PAMPs) in OA development and/or evolution. Adrenergic activity have been associated with subchondral bone loss and increased osteoclast activity. Also, adrenergic activity is a main modulator of immune response to PAMPs in different settings. However,the relationship between activation of adrenergic and immune system with OA progression and treatment response remains still unknown.
Objectives: To assess the adrenergic and immune activation in OA patients according to the presence of bacterial DNA (bDNA) fragments in blood before and after Chondroitin Sulfate/Glucosamine Hydrochloride (CS/GH) or Celecoxib (CE) treatment.
Methods: Serum samples from patients participants in a 6-month controlled, double blind and randomized clinical trial comparing the analgesic efficacy of CS/GH and CE were analyzed to determine cytokines (IL-2, IL-4, IL-6, IL-10, IL-8, IL-1beta), catecholamines (noradrenaline, adrenaline and dopamine) and the presence of endotoxin or LPS and bDNA. Results are shown as mean±sd or median with ranges (Q25-Q75).
Results: Samples from 100 OA patients (age: 62±8yr.; BMI: 31±6kg/m^2 86 females; VAS: 73±15; WOMAC: 369±43) treated with CS/GH (50) or CE (50) were analyzed.There were no baseline significant differences between the two treatment groups regarding demographics,clinical and experimental variables. Thirty-four patients (17-CS/GH and 17-CE) showing bDNA in blood had significantly higher levels of noradrenaline compared with patients without bDNA (1993 [1354–3183] vs. 1324 [738–1899]; p=0.0002). After 6 months, both groups of treatment showed a similar reduction in VAS and WOMAC score (pain assessment) and serum adrenaline levels independent of presence or absence of bDNA (Table 1).Thirty-three patients showed bDNA presence at the end of the study (23 negative and 10 positive at baseline). Patients with bDNA at 6 months after treatment showed reduced serum noradrenaline levels compared with those observed in patients with bDNA at baseline (1993 [1354–3183] vs. 1561 [1174–2193]; p=0.0325). IL-8 was significantly reduced after 6 months of treatment only in patients without bDNA.There were no significant differences between baseline and 6 months samples in the other experimental variables.

Table 1

	Baseline				6 months			
	No bDNA		bDNA		No bDNA		bDNA	
	CS/GH	CE	CS/GH	CE	CS/GH	CE	CS/GH	CE
Adrenaline (pg/mL)	98 (88-127)	100 (77-118)	92 (78-114)	98 (75-115)	78* (65-92)	81* (62-92)	76* (58-97)	77* (66-105)
Noradrenaline (pg/mL)	1357 (790-1693)	1228 (738-1967)	1723# (1385-2381)	2765# (1232-3250)	1050 (811-1600)	1588 (882-2133)	1563 (1209-2180)	1528 (1174-2229)
IL-8 (pg/mL)	5.5 (1.3-9.4)	5.6 (1.7-14)	4.8 (3.9-5.7)	11 (1.9-15)	3.3* (0.0-11)	0.0* (0.0-5.9)	6.1 (3.7-14)	5.6 (1.5-16)
VAS score (0-100)	72 (66-82)	75 (65-81)	79 (67-90)	76 (70-80)	32* (22-45)	20* (10-60)	37* (27-50)	52* (24-60)
WOMAC score	364 (341-389)	354 (321-389)	382 (372-407)	360 (340-400)	150* (87-217)	135* (64-238)	180* (84-218)	282* (139-318)

* p < 0.05 vs baseline values (Mann-Whitney-Wilcoxon Test, # p<0.05 vs No bDNA values

Conclusions: OA patients show bDNA fragments in blood associated to higher serum noradrenaline levels. Six month treatment with CS/GH or CE reduces significantly and in a similar fashion the pain intensity and adrenaline levels. IL-8 levels were reduced with the treatment except in patients with presence of bDNA fragments in blood. Systemic adrenergic and inflammatory activity in OA patients is influenced by the presence of PAMPs as bDNA in blood and this may be a factor to take into consideration to evaluate the severity, evolution and response to treatments.

SAT0541 INHIBITING αVβ3 INTEGRIN AND CD47 SIGNALING AMELIORATES THE PROGRESSION OF OSTEOARTHRITIS

Q. Wang[1], K. Onuma[2], R. Mao[1], H. Wong[1], W.H. Robinson[1]. [1]*Medicine;* [2]*Stanford University, Stanford, United States*

Background: Osteoarthritis is leading cause of disability, and its prevalence is rising due to the aging population and obesity epidemic[1]. Despite the substantial morbidity and health costs attributed to osteoarthritis, no treatment has been approved to prevent or slow disease progression, largely because the underlying pathogenic mechanism remains elusive. Both integrin αVβ3 and the integrin-associated receptor CD47 are considered important therapeutic targets for a number of diseases, but the potential involvement of these receptors in osteoarthritis remains unclear[2].
Objectives: Our study aimed at assessing the role of integrin αVβ3 and the integrin-associated receptor CD47 signaling pathways in the pathogenesis of osteoarthritis, and identifying potential targets for disease-modifying therapy.
Methods: We performed transcriptomic and proteomic analyses of human and murine osteoarthritic tissues to examine the involvement of integrin αVβ3 and CD47 with osteoarthritis. Further, we evaluated the effects of genetic deficiency in and pharmacological modulations of integrin αVβ3 subunits, CD47, and their downstream signaling molecules Fyn and FAK on the destabilization of the medial meniscus (DMM) mouse model. Additionally, we used microPET/CT imaging of the DMM mouse model to assess the ligand-binding capacities of integrin αVβ3 and CD47 in osteoarthritic joints. Finally, we carried out multiple *in vitro* assays to determine how integrin αVβ3 and CD47 signaling might become activated in osteoarthritis, and what the molecular consequences of such activation might be.
Results: Our transcriptomic and proteomic analyses revealed the involvement of dysregulated integrin αVβ3 and CD47 signaling in osteoarthritis. Data from investigations of genetically deficient mice and pharmacological modulations showed that αVβ3, CD47, Fyn, and FAK are crucial to the pathogenesis of arthritis. We detected elevated ligand-binding capacities of integrin αVβ3 and CD47 in osteoarthritic joints by microPET/CT imaging of mice subjected to DMM. Our *in vitro* studies demonstrated that chondrocyte breakdown products, derived from the articular cartilage of individuals with osteoarthritis, induced αVβ3/CD47-dependent expression of inflammatory and degradative mediators, and revealed that the signaling network involved the Ras-CRAF-MEK-ERK pathways.
Conclusions: Our findings identify a central role of deregulated αVβ3 and CD47 signaling in the pathogenesis of osteoarthritis, and provide a rationale for targeting these signaling pathways as a disease-modifying therapy.

SAT0542 SUBCLINICAL CRYSTAL ARTHROPATHY MIGHT INFLUENCE FUNCTIONAL DISABILITY IN PATIENTS WITH KNEE OSTEOARTHRITIS? AN EGYPTIAN CROSS SECTIONAL STUDY

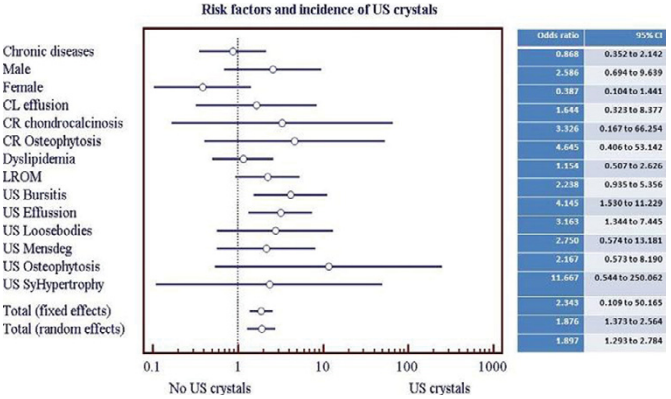
R.H.A. Mohammed. *Department of Rheumatology and Rehabilitation, MD, FRCP, FACR, School OF MEDICINE, Cairo University Hospitals, Cairo, Egypt*

Background: Osteoarthritis is a complex slowly progressive degenerative disease that affects joint components.Concomittant articular crystal deposits are able to stimulate an inflammatory response in OA through stimulation of the innate immune system.
Objectives: Assess the contribution of sonographically detected crystal deposits to pain severity and functional disability in patients with knee OA (WOMAC score)
Methods: Single-center cross sectional study. Adult patients diagnosed with knee OA diagnosed in accordance with ACR criteria from the Department of Rheumatology and Rehabilitation, Kasr Alainy School of Medicine, Cairo University were recruited. Clinical assessment of pain and functional status in patients with knee osteoarthritis was measured using: Western Ontario and McMaster Universities Arthritis Index score. The Logic p5 ultrasound machine (GE) with linear array probe (8–13 MHz). Examination of the articular and periarticular structures was performed by a trained rheumatologist according to the standard EULAR guidelines for exam of the knee. Serum uric acid was investigated. Plain radiography was done for comparison.
Results: 53 patients (44 females 83% & 9 males 17%) were included, mean age 53.5 years ± 8.3 SD, disease duration 42.5 months ± 49.5 SD, body mass index mean 34.9±6.3 SD. Crystal deposits were sono-graphically diagnosed in 73 knees (68.9%), Monosodium urate deposits found in 33 knees (31.1%) and Calcium Pyrophosphate Dihydrate deposits were diagnosed in 67 knees (63.2%). Pain, stiffness and disability scores were significantly higher in OA knees with crystal deposition as compared to those without ($p<0.05$) that was in fact resistant to conventional analgesics, chondro-protectives and physiotherapy demanding the ongoing use of NSAIDs.

Table 1. WOMAC pain, stiffness and disability scores in the studied Patients with knee OA showing sonographic evidences of CDDs versus those without

WOMAC score	OA with CDDs (Mean ± SD)	OA without CDD (Mean ± SD)	Mann-Whitney U- test r	P-value (significance)
WOMAC pain score	15. 6±3.6 (8–20)	12.0 ±3.8 (5–20)	596	0.00*
WOMAC stiffness score	5. 5 ±2.0 (0–8)	3.8 ±1.8 (0–8)	643	0.00*
WOMAC disability score	53.4 ±11.6 (25–67)	41.5±12.8 (14–67)	606	0.00*

WOMAC = Western Ontario and McMaster Universities Arthritis Index score. *Significant difference ($p\leq0.05$).



Conclusions: Crystal deposition was associated with significantly increased pain intensity, knee joint stiffness and functional disability as measured by WOMAC in patients with knee OA.

SAT0543 CLINICAL PREDICTORS AND RADIOGRAPHIC EVIDENCES OF OCCULT CRYSTAL DEPOSITION DISEASE WITH KNEE OSTEOARTHRITIS

R.H.A. Mohammed. *Department of Rheumatology, Rehabilitation and Clinical Immunology, MD, FRCP, FACR, School of Medicine, Cairo University Hospitals, Cairo, Egypt*

Background: Osteoarthritis is a slowly progressive degenerative disorder that affects joint components from cartilage to meniscus, subchondral bones and might even lead to synovial inflammation.
Objectives: To investigate the clinical and radiographic findings associated with asymptomatic crystal deposition disease in patients with knee osteoarthritis.
Methods: A single-center cross sectional study, sixty adult patients with knee OA diagnosed according to the ACR criteria were enrolled. Participants were all subjected to history taking, general as well as musculoskeletal clinical examination, serum uric acid, and plain radiography. Examination of the knee joints for intraarticular/periarticular crystal deposits was done using a Logic p5 ultrasound machine (GE) with linear array probe (8–13 MHz) according to the standard EULAR guidelines.
Results: A total of sixty adult patients were enrolled, fifty three patients satisfied the inclusion criteria, 44 females (83%) & 9 males (17%), mean values for; ages

Abstract SAT0543 – Table 1. Odds ratio and Forest plot analysis

Risk factors	Knees with sonographic crystals (Total: 73 knees) r	Knees without sonographic crystals (Total: 33 knees)	Odds ratio	95% CI	p value (significance)
Male Gender	15	3	2.6	0.7 to 9.6	0.16
Female Gender	58	30	0.4	0.1 to 1.4	0.16
Dyslipidemia	38	16	1.2	0.5 to 2.6	0.73
Chronic medical illness as Diabetes mellitus and hypertension	20	10	0.9	0.4 to 2.1	0.76
Clinically detected knee effusion	7	2	1.6	0.3 to 8.4	0.55
Limitation in ROM	36	10	2.2	0.9 to 5.4	0.07
Bursitis by sonography	35	6	4.1	1.5 to 11.2	**0.01***
Effusion by sonography	47	12	3.2	1.3 to 7.4	**0.01***
Total (fixed effects)	430/1022	156/462	1.9	1.4 to 2.6	0.23
Total (random effects)	430/1022	156/462	1.9	1.3 to 2.8	

53.5 years ± 8.3 SD, disease duration 42.5 months ± 49.5 SD. Crystal deposits were sono-graphically diagnosed in 73 knees with normal serum uric acid values (68.9%> MSU in 31.1%, CPPD in 63.2%, a picture of mixed deposits in 5.7%). Plain radiography revealed chondrocalcinosis in 3 patients only. Regression analysis models and Forest Plot test revealed a 4.1 fold incidence of crystal deposition in patients with sonographic bursitis than those without (OR=4.13, CI=1.5–11.2, p=0.01) and a 3.2 fold incidence of crystal deposition in patients with sonographic effusion than those without (OR=3.16, CI=1.34–7.44, p=0.01).

Conclusions: The study concluded a number of clinical as well as radiographic associates that might be considered as predictors of silent CDD in patients with knee OA as diagnosed by ultrasonography, the most commonly reported clinical associates were bursitis and effusion.

SAT0544 SUBGROUPS IN RADIOGRAPHIC FEATURES IN PATIENTS WITH HIP OSTEOARTHRITIS: RESULTS OF THE AMS-OA COHORT

R.A.M. Pouw[1,2], M. van der Esch[1], M. van der Leeden[1,3], D. Reiding[4], L.D. Roorda[1], J. Dekker[5], W.F. Lems[6,7]. *[1]Amsterdam Rehabilitation Research Center, Reade, Center for Rehabilitation and Rheumatology; [2]Faculty of behavioural and movement sciences, VU University; [3]Department of Rehabilitation Medicine, VU University Medical Center; [4]Department of radiology, Reade, Center for Rehabilitation and Rheumatology; [5]Rehabilitation Medicine; [6]Department of Rheumatology, VU University Medical Center; [7]Jan van Breemen Research Institute, Reade, Center for Rehabilitation and Rheumatology, Amsterdam, Netherlands*

Background: Radiographic features are important in diagnosing hip osteoarthritis (OA)[1,2]. In daily practice, only the anterior-posterior view is visualized but not the false profile view. Since we assessed radiographic features in both types of radiographic hip images in the AMS-OA cohort, we were able to examine the differences in radiographic features in two regions of the hip (superior-lateral and central-axial region).

Objectives: (i) To describe the presence of radiographic features in patients with hip OA; and (ii) to determine whether radiographic features differ between the superior-lateral and central-axial region of the hip.

Methods: Data from 97 patients with bilateral hip pain and a Kellgren and Lawrence score of ≥1 of the Amsterdam Osteoarthritis (AMS-OA) cohort of patients with knee and/or hip OA were used. Standard radiographic images were examined of patients in an erect position, both with an anterior posterior view and with a false profile view, which is an oblique lateral view of the hip. Radiographic images were scored by an experienced radiologist (DR) and an independent researcher (ME). Consensus between two raters was achieved for each score. Four radiographic features were scored: presence of joint space narrowing, osteophytes, sclerosis and cysts. All joint features were scored separately for the superior-lateral and the central-axial region of the hip. A Fisher's exact test was performed for testing the significance of the differences between the two regions of the hip.

Results: Table 1 shows the frequencies of radiographic features (joint space narrowing, osteophytes, sclerosis and cysts) in the superior-lateral and the central-axial region of the left and right hip joint of patients with hip OA. Significant differences between the two regions were found for osteophytes, sclerosis and cysts with the highest frequency of these features in the superior-lateral region of the hip.

Conclusions: In our cohort we found as expected, that joint space narrowing of the hips was the most frequent feature (>80% in both the superior- lateral and central-axial region). Moreover, osteophytes, sclerosis and cysts were more frequently present in the superior-lateral region. Our findings indicate that hip OA may exist of two subgroups with differences in radiographic features (i.e., superior-lateral and central-axial). Future research should confirm these results and focus on possible associations with biomechanical and physical function variables.

Radiographic feature	Superior Lateral part				Central Axial part				Fisher's exact test	
	Left		Right		Left		Right		Left	Right
	N	%	N	%	N	%	N	%	P-value	P-value
JSN	77	79.4	78	80.4	81	84.4	83	85.6	NS	NS

SAT0545 PREDICTIVE FACTORS FOR RESPONSE TO ULTRASOUND-GUIDED INTRA-ARTICULAR GLUCOCORTICOIDS IN KNEE OSTEOARTHRITIS

S. Slimani[1], A. Aissoug[2], S. Aouidane[1], H. Bounecer[1], M.M. Makhloufi[1], A. Ladjouze-Rezig[3]. *[1]Medicine, Univeristy of Batna 2; [2]Private practice, Batna; [3]Medicine, University of Algiers 1, Algiers, Algeria*

Objectives: To investigate predictive factors for good outcome of ultrasound intra-articular glucocorticoids in knee osteoarthritis (OA).

Methods: We conducted a prospective monocenter cohort study including 116 patients with knee OA, after failure to standard treatments, with pain >4 (numerical rating scale NRS 0–10). Patients received an ultrasound-guided injection of 40 mg triamcinolone acetonide in their most painful knee. We exhaustively collected demographic and clinical data at inclusion, as well as lab, radiographs and ultrasound parameters of the included knees. WOMAC score was calculated at inclusion and after 4 weeks. Responders were defined as patients with at least 40% improvement of their WOMAC score. Univariate analysis was performed in order to select possible predictive factors, and stepwise multiple logistic regression analyses were conducted to identify predictors of response.

Results: Among the 116 patients, 101 were females. Median age was 64 years (40–85) and mean duration of the disease was 14.1±14,8 years. Mean BMI was 29.9±3.8 Kg/m^2. Mean NRS of pain was 8.4±1.2 and mean WOMAC was 73.3±11,8 at inclusion. 70.0% of the knees were grade 3 or 4 of Kellgren-Lawrence. 98% of knees expressed ultrasound synovial effusion and/or hypertrophy at inclusion. After 4 weeks, 61.2% of patients were responders. Regression analysis showed that patients with a BMI <30 Kg/m^2 (OR=0.38, 95% CI 0.16–0.89) and an ESR <20 mm (OR=0.27, 95% CI 0.08–0.90) were more likely to respond to ultrasound-guided glucocorticoids injection. Having both predictive factors of good response increases the response rate to 73.5%, whereas having no predictive factor decreases the response rate to 25.0%.

Conclusions: Our study is the largest study evaluating predictive factors of response for intra-articular glucocorticoids injections in knee OA. Also, it is the first study of predictive factors for ultrasound-guided injections. Patients with high BMIs and high ESR seem less likely to respond to intra-articular injections.

SAT0546 TOTAL OSTEOPHYTE SCORE IS A BIOMARKER OF CURRENT AND PERSISTENT PAIN IN KNEE OSTEOARTHRITIS SUBJECTS

S. Feng, M.C. Levesque. *AbbVie Inc., Worcester, MA, United States*

Background: X-ray and magnetic resonance imaging (MRI) demonstrated associations between osteophyte severity and current pain in knee osteoarthritis (OA) patients. Persistent pain over 5 years was also associated with x-ray osteophyte severity. A biomarker to identify knee OA subjects with persistent pain may reduce placebo response rates in clinical trials.
Objectives: To determine whether the total knee osteophyte score (TKOS), as measured by MRI Osteoarthritis Knee Score (MOAKS), is a biomarker of current and persistent pain severity in knee OA subjects.
Methods: Knee OA subjects from the Foundation for the National Institutes of Health Biomarker Consortium were longitudinally assessed over 4 years and categorized as pain and x-ray progressors (n=194), x-ray–only progressors (n=103), pain-only progressors (n=103), and non-progressors (n=200). Knee osteophyte severity was scored at baseline by MOAKS at 12 positions across the knee and summed to obtain the TKOS. TKOS was summarized as means and SDs in the 4 progression groups; each progression group TKOS was compared with the non-progression group using Wilcoxon rank sum tests (Table 1). The longitudinal Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain scores were plotted and tested with a linear mixed model, by high and low TKOS status, defined as above and below the TKOS median of 6 (Figure 1). Subjects with persistent pain were defined based on WOMAC pain scores at 4 out of 5 time points higher than the thresholds listed in Table 2; at each threshold, mean differences in TKOS were tested using analysis of variance among those with and without persistent pain.
Results: The distribution of baseline TKOS differed by progression group, with the highest TKOS among pain and x-ray progressors (Table 1). In all 4 progression groups, baseline WOMAC pain scores were higher in subjects with high (>6) versus low (≤ 6) baseline TKOS status (P=0.0001, 0.0383, 0.0035, and 0.0466, respectively). The difference in WOMAC pain scores between TKOS high and low subgroups was constant over time (Figure 1; solid curves above and parallel to dashed curves with TKOS main effect always significant [$P<0.01$] in all 4 progression groups), but the TKOS$\times$Time interaction term in the longitudinal mixed model was not statistically significant, indicating that the pain difference between the TKOS high and low subgroups did not change over time. TKOS was highly associated with persistent pain, with TKOS higher at all thresholds (Table 2).

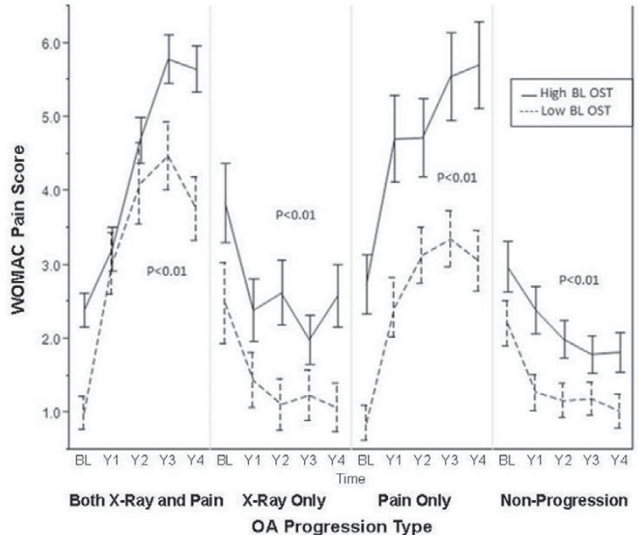

Table 1. Distribution Parameters of TKOS at Baseline by OA Progression Type

Progression Type	TKOS			*P* value)
	n	Mean	SD	
X-ray and pain	194	10.43	6.60	<0.0001
X-ray only	103	8.79	6.56	0.06
Pain only	103	8.03	5.91	0.22
None	200	7.32	6.07	–

Table 2. Group Sizes and TKOS Mean Differences for Different WOMAC Pain Thresholds for Persistent Pain

WOMAC Pain Threshold	Subjects With Persistent Pain, n	TKOS Difference for Subjects With Persistent Pain vs Those Without	*P* Value
2	211	2.5	<0.0001
3	150	2.4	<0.0001
4	112	2.4	0.0001
6	52	3.6	<0.0001
8	21	2.5	0.06

Figure 1. WOMAC pain score over 4 years stratified by baseline TKOS status and OA progression type.

Conclusions: TKOS is a candidate biomarker for current and persistent pain in knee OA patients and may be a predictive biomarker for reduced placebo response rates in clinical trials.

SAT0547 THE INFLUENCE OF OSTEOARTHRITIS ON CLINICAL, LABORATORY AND ULTRASOUND PARAMETERS OF PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

T. Serban[1,2], I. Satulu[3], O. Vutcanu[2], M. Milicescu[1,2], C.M. Mihai[1,2], M. Bojinca[1,2]. *[1]Internal Medicine and Rheumatology, "Carol Davila" University of Medicine and Pharmacy; [2]Internal Medicine and Rheumatology, "Dr. I. Cantacuzino" Clinical Hospital, Bucharest, Romania; [3]Rheumatology, Kalmar County Hospital, Kalmar, Sweden*

Background: Osteoarthritis (OA) and rheumatoid arthritis (RA) are not infrequent in the general population. The two pathologic entities can overlap and the presence of OA can interfere with the evaluation of patients with RA.
Objectives: This study aims to evaluate the possible impact of OA on the clinical, laboratory and ultrasound parameters currently evaluated in patients with early RA (ERA).
Methods: We have evaluated the data obtained from patients with ERA referred to our Early Arthritis Research Center (EARC). Only data from patients who fulfilled EULAR/ACR 2010 criteria for RA (1) and had a symptom duration of less than 12 months were analyzed. 43 patients were diagnosed with ERA in the EARC between 2012 and 2016 and were enrolled in this study. Patients were evaluated at baseline and after 12 months. All patients underwent clinical examination, laboratory tests and ultrasound (US) examination. For the US examination we have calculated the score proposed by Naredo et al. considering that this simplified US score includes the evaluation of the hand and knee. (2)
Results: There was a clear predominance of women (62.8%). The mean age was 55.47±13.71 years. At baseline, 21 patients (48.8%) were diagnosed with OA. 15 patients (34.9%) presented hand OA and 9 patients (20.9%) presented knee OA. Hand OA didn't influence the values of DAS28, SDAI, patient's and physician's visual analogue scale (VAS) or ultrasound scores ($p>0.05$). For patients with knee OA, significantly higher values for DAS28 were observed at baseline (p=0.018) and were maintained significantly higher after 12 months of observation (p=0.031). All the other parameters were not influenced by the presence of knee OA ($p>0.05$). The median value and interquartile range for lab tests and for disease activity indices are shown in Table 1.

Table 1. Values for disease activity indices, laboratory tests and US scores for patients with ERA with/without OA

Lab test - Median (Interquartile range)	ERA patients with OA (n=21)	ERA patients without OA (n=22)	p
DAS28	5.07 (4.62–5.73)	4.94 (3.87–5.44)	0.280
SDAI	29.02 (24.95–36.59)	28.87 (16.18–33.97)	0.644
VAS patient (mm)	72.00 (55.00–81.00)	62.50 (50.50–72.25)	0.144
VAS physician (mm)	52.00 (40.00–66.50)	50.00 (33.75–57.00)	0.456
Naredo score - GS	8.00 (5.50–12.00)	9.00 (5.00–12.25)	0.932
Naredo score - PD	4.00 (0.00–6.50)	3.00 (0.00–4.00)	0.700

Conclusions: Significantly higher values of DAS28 were observed in patients with ERA who associated knee OA, while the values of SDAI were not influenced, suggesting that SDAI may be superior to DAS28 in evaluating patients with ERA and knee OA. Not the same tendency was observed in patients with ERA and hand OA. The values of patient's VAS were not influenced by the presence of hand or knee OA suggesting that these types of OA do not influence the patients' perception of the disease activity. Moreover, the values of ultrasound scores were not influenced by the presence of OA.

SAT0548 PLASMA CGRP CONCENTRATIONS WERE NOT ASSOCIATED WITH PATIENT OA SYMPTOMS OR RESPONSE TO GALCANEZUMAB, A MONOCLONAL ANTIBODY AGAINST CGRP

T.A. Mcnearney[1], C. Smith[2], R. Brown[3], A. Camporeale[4], M. Deeg[3], D. Montieth[5], E.C. Collins[3], T.J. Schnitzer[6], A.J. Kivitz[7], J. Talbot[3], Y. Jin[3]. *[1]Neuroscience/Pain, Eli Lilly and Company, Indianapolis, United States; [2]Eli Lilly and Company, Windlesham, United Kingdom; [3]Eli Lilly and Company, Indianapolis, United States; [4]Eli Lilly and Company, Sesto Fiorentino, Italy; [5]Xenon Pharmaceuticals Inc, Burnaby, Canada; [6]Northwestern University, Chicago, IL; [7]Altoona Center for Clinical Research, Duncansville, United States*

Background: The safety and efficacy of galcanezumab, a monoclonal antibody

directed against CGRP, were assessed in a phase 2 clinical trial NCT02192190 in patients with moderate to severe osteoarthritis (OA) knee pain. Patients were randomized to placebo, galcanezumab (5, 25, 120 and 300 mg subcutaneously every 4 weeks, at weeks 0 and 4) or celecoxib (200 mg once daily) for 16 weeks in a 2:1:1:1:1:1 ratio. The study was terminated after an interim analysis due to inadequate efficacy for OA pain.

Objectives: This study assessed the correlation of baseline plasma CGRP concentrations with signs, symptoms and radiographic severity of OA, and response to galcanezumab and celecoxib treatments.

Methods: Plasma samples were collected at baseline and weeks 4, 8, 12 and 16 after study drug treatment. CGRP concentrations were determined by a validated high sensitivity (HS) assay. Correlation of baseline CGRP levels to WOMAC scores, PGA and radiographic Kellgren-Lawrence (K-L) grades were assessed using Spearman's correlation and Wilcoxon test. Patients were stratified into high vs low groups by baseline CGRP concentrations and post-treatment changes from baseline WOMAC scores evaluated by mixed effect model repeated measures for each subset.

Results: At the interim analysis, baseline plasma CGRP samples were available for 262 patients with 54 patients providing samples at study termination through the week 8 visit. The median CGRP concentration at baseline was 1.07 pg/ml, range <0.78 to 33.91, and 31% of patients were below the level of quantitation (BLQ, <0.78 pg/ml). Median baseline CGRP levels were 1.0 pg/ml for K-L grade 2 (N=178), and 1.2 pg/ml for K-L grade 3 (N=84) (p=0.06). Correlations of WOMAC or PGA scores with baseline CGRP levels were all r <0.01 (showed no significant correlations). In OA patients receiving galcanezumab 300mg SC at week 0 and week 4, those with high baseline CGRP levels demonstrated a 14mm improvement in WOMAC Pain response at week 12, (95% CI 0, 29mm). The pain response to galcanezumab 300mg did not reach the magnitude of celecoxib response and no effects were seen at 5–120mg doses. Celecoxib treatment had larger pain reduction among patients with high baseline CGRP compared to low baseline CGRP levels. Treatment with celecoxib did not alter plasma CGRP concentrations.

Conclusions: At baseline, CGRP levels in OA patients were not associated with WOMAC or PGA scores. There was a modest association to radiographic K-L grade. Subgroup analyses of patients with high (>median) CGRP levels at baseline suggested a potential response to galcanezumab for the highest dose, 300mg, but not lower doses. Celecoxib response was greater in those with higher CGRP levels. However, interpretation was limited by small samples sizes at the latter time points. Further studies may determine if enriching the OA population for higher CGRP levels at baseline, or if increased or longer dosing of galcanezumab would improve pain responses or if CGRP blockade is relevant in relieving OA knee pain.

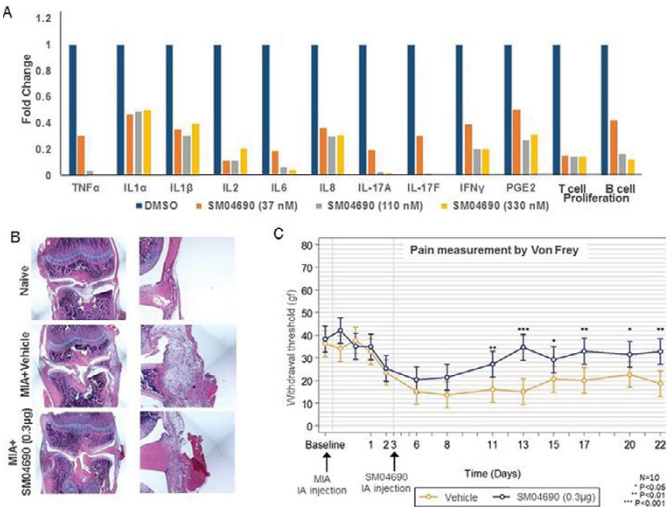
SAT0549 ANTI-INFLAMMATORY PROPERTIES OF SM04690, A SMALL MOLECULE INHIBITOR OF THE WNT PATHWAY AS A POTENTIAL TREATMENT FOR KNEE OSTEOARTHRITIS

V. Deshmukh, C. Barroga, M. Ibanez, T. Seo, S. Kc, Y. Yazici. *Samumed, LLC, San Diego, CA, United States*



Background: Osteoarthritis (OA) is characterized by pain, deformity, and reduced function in the knee joint. Upregulated Wnt signaling affects the pathogenesis of OA through increased inflammation, increased subchondral bone and thinning cartilage. SM04690, a novel small molecule, was previously shown to inhibit the Wnt pathway and induce chondrogenesis *in vitro* and *in vivo*.[1]

Objectives: SM04690 was evaluated in preclinical studies to determine its capacity to reduce inflammation, and reduce pain in OA.

Methods: Anti-inflammatory activity was evaluated by measuring cytokine (IL-6 and TNF-α) secretion using ELISA with IL1-b stimulated synovial fibroblasts. A panel of pro-inflammatory cytokines (TNF-α, IL-1α, IL-1β, IL-2, IL-6, IL-8, IL-17A, IL-17F, IFN-γ and PGE2) was evaluated by ELISA; T and B cell proliferation by flow cytometry in peripheral blood mononuclear cells (PBMCs), and T and B cell co-cultures stimulated with super-antigen (SAg) or lipopolysaccharides (LPS), compared to vehicle or benchmark immunosuppressant or steroid (cyclosporin A and prednisolone). SM04690 effects on LPS-induced expression and phosphorylation of JNK, NFkB, Erk, cJun, Akt, Stat3 in THP-1 cells were measured by qPCR and Western Blot. *In vivo* SM04690 activity was evaluated in a rat monosodium iodoacetate (MIA) injection-induced OA model, immediately followed by a single intra-articular SM04690 or vehicle injection. Joint inflammation was evaluated by measuring synovial thickness and infiltrating cells histology; inflammatory cytokines (IL-1α, IL-1β, IL-2, IL-5, IL-6, IL-8, TNF-α and IFN-γ) by qPCR and ELISA and cartilage protection by qPCR for matrix metalloproteinases (MMPs). Pain was measured as paw withdrawal threshold using Von Frey apparatus.

Results: SM04690 inhibited IL-1b-induced TNF-α and IL-6 secretion in synovial fibroblasts (EC_{50} @30nM). SM04690 significantly inhibited ($p<0.01$) SAg and LPS stimulated pro-inflammatory cytokine production (TNF-α, IL1-α, IL1-β, IL-2, IL-6, IL-8, IL-17A, IL-17F, IFN-γ, PGE2), T and B cell proliferation in PBMCs and T and B cell co-cultures (Figure A), with activity comparable to or better than cyclosporin A and prednisolone. SM04690 treatment specifically decreased LPS-induced gene expression ($p<0.01$) and phosphorylation of NFkB in THP-1 cells with no effect on JNK, Erk, cJun, Akt and Stat3. Compared to vehicle in the rat MIA OA model, SM04690 injection reduced inflammatory cells, decreased synovial thickness ($p<0.05$,Figure B), inhibited production of pro-inflammatory cytokines and MMPs ($p<0.05$). SM04690 increased ($p<0.01$) paw withdrawal threshold in treated rats compared to vehicle at multiple time points (Figure C).

Figure. SM04690 inhibited inflammatory cytokine production *in vitro* and decreased inflammation and pain in the MIA model of OA

Conclusions: SM04690 demonstrated potent anti-inflammatory properties, comparable to or greater than cyclosporin A and prednisolone. In a rat knee OA model, SM04690 injection reduced inflammation, protease production and pain compared to vehicle. The anti-inflammatory properties of SM04690 may provide beneficial effects in the treatment of OA. Clinical studies are ongoing.

SAT0550 NEUROPATHIC PAIN AMONG PATIENTS WITH PRIMARY KNEE OSTEOARTHRITIS- RESULTS OF A CROSS SECTIONAL STUDY FROM A TERTIARY CARE CENTRE IN SOUTHERN INDIA

V. Narayan R[1], M.M. Thabah[2], M. Poduval[3]. [1]*MBBS Student;* [2]*Medicine;* [3]*Orthopedic Surgery, Jawaharlal Institute of PostgraduateMedical Education and Research, Puducherry, India*

Background: Pain in osteoarthritis (OA) is generally believed to be nociceptive because of local structural pathology and joint failure which so characterizes OA. However, there is often a discordance between the radiographic knee OA and pain, suggesting that the pain can be contributed by other mechanisms other than nociception.[1] Recently it is shown that pain in knee OA may have a neuropathic component.[2]

Objectives: The objective of the study was to assess the level of neuropathic pain in patients with knee OA, and identify the clinical and socio-demographical factors associated with neuropathic pain

Study design: Cross sectional study.

Setting: Medicine and Orthopaedic outpatient department (OPD) of a tertiary care centre located in southern India

Methods: One-hundred and sixty-one patients with knee OA satisfying the American College of Rheumatology 1986 clinical and radiographic classification criteria for knee OA were studied. Neuropathic pain was assessed by the Douleur Neuropathique in 4 questions (DN4) questionnaire;[3] score of 4/10 or more was classified as diagnostic for neuropathic pain. The Indian version of Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC)[4] was used to assess pain, stiffness and physical function of the patients. Factors associated with neuropathic pain were explored.

Results: Mean age was 55.7±8.8 years. The mean total Indian WOMAC was

75.07±13.8, WOMAC pain score was 16.1±3.6. Eighty-two patients of 161 (50.9%) had neuropathic pain. When diabetics were excluded (n=58), the proportion of patients with neuropathic pain reduced to 45.6%. The most frequently described pain characteristic was sensation of electric shock (58.4%). Mean total WOMAC and physical function subscale was significantly higher in neuropathic pain group when compared to no neuropathic pain group (DN4 score 3 or less), 77.5±11.5 versus 72.6±15.5, p=0.024; and 54.3±8.8 and 49.8±12.6 respectively, p=0.008

Conclusions: Neuropathic pain was seen in up to 50% patients with knee OA. Centrally acting drugs like tricyclic anti-depressants or duloxetine can be used to improve pain and physical function in patients of knee OA with neuropathic pain.

SAT0551 INCREASED SERUM AND SYNOVIAL LEVELS OF MIDKINE ARE ASSOCIATED WITH RADIOLOGICAL PROGRESSION IN KNEE OSTEOARTHRITIS PATIENTS

W.A. Hassan[1], A.I. Mansour[2]. *[1]Rheumatology and Rehabilitation; [2]Clincal and Chemical Pathology, Benha university, Benha, Egypt*

Background: Midkine is a heparin-binding growth factor that plays an important role in mesoderm remodeling as in chondrogenesis and adipocyte formation. There is an increased expression of midkine in damaged tissues and it is believed to have functional antagonism, as it helps in tissue repair and survival while, on the other hand it can enhance inflammatory reactions resulting in more tissue injury [1].

Objectives: This study aimed to determine serum and synovial fluid (SF) levels of midkine in patients with primary knee osteoarthritis (KOA) and to examine the relationship between these levels with the clinical and functional parameters as well as radiological progression of KOA.

Methods: We measured midkne in the serum (n=52) and SF samples (n=23) from 52 KOA patients as well as in the serum from 20 healthy control (n=20). In the patients, numerical rating scale of pain (NRSP), body mass index (BMI) and The Western Ontario Mc Master scale (WOMAC) were recorded. Graded plain radiographs using Thomas score, and musculoskeletal ultrasound examination (MSUS) of both knees were performed at baseline and after 24 months to assess radiological progression [2,3]. Radiological progression was considered if there is an increase in the Thomas grading score or MSUS transition to a higher grade at the 24 months follow up period compared to baseline evaluation.

Results: Serum and SF midkine levels were significantly increased in KOA patients (mean ± SD 80.79±31.8 pg/mL and 216.31±94.93 pg/mL respectively) compared to serum level in the healthy controls (mean ± SD 65.6±14.76 pg/mL),$p<0.05$ and $p<0.001$ respectively. In KOA patients, the serum and SF concentrations of midkine significantly correlated with the baseline thickness of the cartilage on the medial condyle ($r= -0.41$ and -0.52 respectively, $p<0.05$) but not on the lateral condyle of the femur ($r=0.12$ and 0.15 respectively, $p>0.05$). Patients with elevated serum and SF midkine (defined as midkine level more than the mean plus 2 standard deviation of healthy controls's level) had a twofold increased risk of radiological progression with MSUS (age, sex and BMI adjusted RR 2.4 and 2.6, 95% CI respectively).With elevated serum and SF midkine levels, there was no increased risk of radiological progression detected with plain radiography in KOA Patients (age, sex and BMI adjusted RR 1.3 and 1.6, 95% CI respectively).

Conclusions: Osteoarthritis patients have significantly elevated serum and synovial levels of midkine that were obviously associated with radiological progression on MSUS suggesting that it could be a useful marker to reflect OA severity and implies a possible role in the pathogenesis of OA.

SAT0552 CLINICAL OUTCOMES FROM A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED, PHASE 2 STUDY OF A NOVEL, INTRA-ARTICULAR, INJECTABLE, WNT PATHWAY INHIBITOR (SM04690) FOR THE TREATMENT OF KNEE OSTEOARTHRITIS: WEEK 26 INTERIM ANALYSIS

Y. Yazici[1], A. Gibofsky[2], N.E. Lane[3], N. Skrepnik[4], E. Armas[5], C.J. Swearingen[1], A. DiFrancesco[1], J.R. Tambiah[1], T.E. McAlindon[6]. *[1]Samumed, LLC, San Diego, CA; [2]Weill Cornell Medical College and Hospital for Special Surgery, New York, NY; [3]UC Davis Medical Center, Davis, CA; [4]Tucson Orthopedic Institute, Tucson, AZ; [5]Well Pharma, Miami, FL; [6]Tufts Medical Center, Boston, MA, United States*

Background: Knee osteoarthritis (OA) is characterized by pain, disability and joint deformity due to degradation of articular cartilage and bone remodeling. The Wnt signaling pathway has a role in these cellular processes, and it is also linked to inflammation. SM04690, a small molecule Wnt pathway inhibitor, is in development for the treatment of knee OA as a potential disease modifying drug. A phase 2, multicenter, 52-week, randomized controlled trial of a single intra-articular (IA) injection of SM04690 is ongoing in subjects with moderate to severe knee OA. Clinical results from an interim analysis are reported.

Objectives: To evaluate clinical outcomes from the treatment of moderate to severe knee OA by SM04690.

Methods: Subjects with ACR defined knee OA, Kellgren-Lawrence (KL) grades 2–3, received a 2 mL injection of 0.03 mg, 0.07 mg, 0.23 mg SM04690 or placebo in the target (most painful) knee. Clinical outcomes (Western Ontario and McMaster Universities Arthritis Index [WOMAC], patient global assessment [PTGA], physician global assessment [MDGA]), were assessed at 4, 13 and 26 weeks by analysis of covariance adjusted for subject baseline in the intention-to-treat (ITT) population and two subgroups: 1) with unilateral knee OA (pre-specified); 2) without chronic pain (Widespread Pain Index [WPI]≤4, post-hoc).

Results: 455 subjects (average age 60.3 [±8.7], female 58.9%, average BMI 29.9 [±4.6] kg/m^2, KL 3 [64.4%], and bilateral OA [64.0%]) were enrolled. SM04690 appeared well tolerated. In the ITT population clinically meaningful improvements in all clinical outcomes compared to baseline were seen for all groups and placebo at weeks 13 and 26 (Table). Moreover, clinically meaningful improvements in clinical outcomes were also seen in multiple groups over several outcomes at various time points compared to placebo. In the unilateral knee OA subgroup, PTGA (0.03 mg) and MDGA (0.07 mg) were significantly improved compared to placebo. In the WPI≤4 subgroup, WOMAC Pain (0.07 mg), PTGA (0.03 mg) and MDGA (0.07 mg) were significantly improved compared to placebo.

Table. Mean (SD) Baseline and Change in Clinical Outcomes over Time by Treatment Groups

All Subjects (ITT)	Timepoint	0.03 mg	0.07 mg	0.23 mg	Placebo

*Ns represent observations at Week 26.†P<0.05 compared to placebo. ‡ P<0.01 compared to placebo.

Conclusions: In this phase 2 interim analysis, the ITT population (SM04690 and placebo groups) demonstrated clinically relevant improvements in clinical outcomes at weeks 13 and 26 compared to baseline. In two subgroups, consistent

improvements over placebo were seen in 0.03 mg and 0.07 mg treatment arms, achieving statistical significance for PTGA and MDGA. Further studies to identify relevant sub-populations and evaluate the safety and efficacy of SM04690 are ongoing.

SAT0553 DETECTION OF SERUM LEVEL CHANGES OF MATRIX METALLOPROTIENASE-13 AND INTER LEUKIN-1 BETA DURING REMISSION AND FLARE-UPS OF PRIMARY OSTEOARTHRITIS OF THE KNEES

Y. Hussein Gazar, H. Bassiouni. *Alazhar University Hospital, Cairo, Egypt*

Background: The diagnosis of osteoarthritis is currently based on radiographic criteria (eg, joint space width) and clinical symptoms (eg, pain and loss of function).

The evaluation of new disease-modifying osteoarthritis drugs (DMOADs) is performed on the same basis, since the regulatory bodies currently require evidence for an impact on radiographic joint space narrowing (JSN) and an impact on symptoms However, the limitations of radiography have led to research into alternative parameters for monitoring osteoarthritis that could serve as biomarkers in drug development.

Objectives: Detection the serum level of MMP-13 and IL-1 β In OA of the knee during remission and exacerbation and if these Biomarkers can be validated as gold biomarkers in assessing OA progression and drug development in OA treatment.

Methods: This study was performed on 60 patients with knee osteoarthritis, 18 males (30%) and 42 females (70%), all diagnosed as osteoarthritis of one or both knees. Their ages ranged from (40 -65) years. The duration of their disease ranged from one to 15years. The control groups were 8 males (32%) and 17 females (68%). their ages ranged from (40–65) years.

- The patients were allowed to continue on the medications that they have pro inflammatory cytokines (IL-1β) and degradative enzymes (MMP-13) are measured.
- Clinical assessing for pain using visual analogue scale (0–10)
- Assessing for pain, stiffness and physical functions by:
  (A) the WOMAC osteoarthritis index
  (B) Lequesne's algo functional index
- Asssesing the flare-ups using Knee Osteoarthritis Flare Ups Score (KOFUS).

Results: Patients who had 3 flare-ups (during one year follow up) showed the statistically significantly highest mean IL-1β & MMP13 level.

There was no statistically significant difference between patients with no flare-up, 1 flare-up and 2 flare-ups; all showed statistically significantly lower mean levels.

There was a statistically significant positive (direct) correlation between IL-1β, disease duration, KL, VAS, stiffness score, pain score, functional score, WOMAC and KOFUS. An increase in all these variables is associated with an increase in IL-1β & MMP13.

Conclusions:

- There is a potential role for IL1 beta and MMP 13 biomarkers in assessing the development in osteoarthritis.
- IL 1 β and MMP 13 were founded to be correlated positively in patients with knee OA this correlation sounded right as the expression of MMP 13 depends on the level of IL1 β.
- Although all medications groups failed to lower the level of IL 1 β and MMP 13,yet there was a numerical difference in favor of Diacerine and NSAID.
- patients on both Diacerine and NSAID had the lowerest rate of flare ups
- It is recommended that the early measurement of biomarkers may detect cases to progress and thus stronger treatment may be given for these groups.

SAT0554 INVESTIGATION OF SELECTED BIOCHEMICAL MARKERS IN KNEE OSTEOARTHRITIS: THE FRAMINGHAM OSTEOARTHRITIS COHORT

Y. Luo[1], Y. He[1], A.S. Siebuhr[1], S. Hoielt[1], D. Felson[2], M. Karsdal[1], A.-C. Bay-Jensen[1]. *[1]Biomarkers & Research, Nordic Bioscience, Herlev, Denmark; [2]Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, United States*

Background: Osteoarthritis (OA) is a major cause of functional impairment and disability among the elderly. There is an unmet need for the development of biomarkers for identifying patients with high risk for OA and for monitoring drug efficacy. Specific and sensitive biochemical markers revealing the turnover of bone, cartilage, and synovial tissue may be useful for investigation and monitoring of OA.

Objectives: To investigate a targeted set of five biochemical markers, which reflect joint tissue turnover, for their ability to evaluate the prevalence of radiographic and symptomatic knee osteoarthritis (OA) in a substudy from the cross-sectional Framingham OA cohort (FOA).

Methods: The subjects from the community-based FOA cohort were divided up based on a terminology proposed by the FNIH-OAI consortium. Two main groups were defined: subjects with radiographic knee OA (RKOA, n=80) and a group with no radiographic OA (NRKOA, n=136). The presence of ROA as any Kellgren-Lawrence (KL) grade =2 or 3. The RKOA group were further divided into two groups; those with persistent symptoms of a joint (RKOA+S, n=30) and those without (RKOA-S, n=50). +S was defined as having pain, aching or stiffness in either knee on most days.

Serum levels of C1M, CRPM and huARGS (matrix metalloproteinases cleaved type I collagen and C-reactive protein neo-epitopes, aggrecanase cleaved ^{374}ARGS neoepitope of aggrecan, Nordic Bioscience) were determined by ELISA. Serum levels of cartilage synthesis and degradation biomarkers, hsPro-C2 and hsAGNx-1 (procollagen type IIB N-terminal propeptide, aggrecanase cleaved TEGE^{373} neoepitope of aggrecan, Nordic Bioscience) were measured by electrochemiluminescence immunoassay (ECLIA). Each measure was fisher transformed in order to be comparable across the biomarkers. The correlation between the biomarkers and covariates was assessed.

The subjects of substudy were segregated into two groups based on the cut-off values of each biomarker. The cut-off values of these markers were set as mean of their reference levels. We used logistic regression to compare these two groups, and to examine the association between each marker and the presence of OA and/or pain. All confounding factors were adjusted.

Results: The two main groups were well-matched by age, sex, and BMI. Two biomarkers correlated negatively with BMI: C1M and CRPM. Aggrecan degradation biomarker, hsAGNx-1 was negatively associated with age while the huARGS was not associated with it (Table 1).

CRPM was associated with a lower risk of RKOA+S. Interestingly, hsPro-C2 was associated with a higher risk of it (Table 2).

Table 1. Subject characteristics of substudy

Covariates	NRKOA (n=136)	RKOA-S (n=50)	RKOA+S (n=30)	Biomarker (Fisher transformed) associations with covariates
BMI, mean kg/m^2 (SD)	31.3 (3.79)	32.3 (6.05)	31.6 (5.12)	C1M, CRPM
WOMAC pain	0.182 (0.657)	0.820 (1.66)	4.83 (3.64)	
Age, mean years (SD)	62.6 (8.18)	63.7 (7.06)	62.4 (7.09)	hsAGNx-1
Sex, n (%) female	82 (60.3%)	33 (66.0%)	18 (60.0%)	C1M

Table 2. Odds ratio of OA in the substudy. Values in bold represent associations of p≤0.05. OR data are for each definition of OA, using logistic regression and adjusted for age, sex, and BMI (Upper: unadjusted, Lower: adjusted). ORs are for comparison with knees with NRKOA subjects.

Biomarker	OR of RKOA-S (95% CI)	OR of RKOA+S (95% CI)
C1M	1.07 (0.54 - 2.10)	0.47 (0.18 - 1.24)
CRPM	0.97 (0.51 - 1.88)	0.41 (0.16 - 1.02)
hsAGNx-1	1.20 (0.61 - 2.38)	0.68 (0.27 - 1.72)
hsPro-C2	1.27 (0.63 - 2.57)	**2.51 (1.10 - 5.73)**
huARGS	1.43 (0.71 - 2.88)	1.19 (0.50 - 2.84)
Biomarker	**OR of RKOA-S (95% CI)**	**OR of RKOA+S (95% CI)**
C1M	0.96 (0.47 - 1.95)	0.45 (0.17 - 1.20)
CRPM	0.87 (0.44 - 1.71)	**0.39 (0.16 – 1.00)**
hsAGNx-1	1.11 (0.55 - 2.23)	0.68 (0.27 - 1.72)
hsPro-C2	1.32 (0.64 - 2.72)	**2.55 (1.11 - 5.82)**
huARGS	1.49 (0.73 - 3.03)	1.21 (0.50 - 2.92)

Conclusions: This study provides two major findings: 1) aggrecan degradation is not just aggrecan degradation and different neo-epitopes have distinct clinical relevance; 2) CRPM is a candidate biomarker of disease activity and for patient profiling. These data suggest a reference for interpretation of OA subject biomarker data in future human studies.

SAT0555 MRI-DETECTED KNEE OSTEOPHYTE: NATURAL HISTORY AND STRUCTURAL RISK FACTORS AFFECTING CHANGE

Z. Zhu[1], W. Han[2], S. Zheng[2], T. Winzenberg[2], F. Cicuttini[3], C. Ding[2], G. Jones[2] on behalf of Musculoskeletal Unit, Menzies Institute for Medical Research. *[1]12779, Hobart, Australia; [2]Musculoskeletal Unit, 12779, Hobart; [3]Department of epidemiology and Preventive Medicine, Monash University, Melbourne, Australia*

Background: Although magnetic resonance imaging (MRI) has been proved to be far more sensitive than conventional radiographs to detect OP, the natural history of MRI-detected OP in older adults has not yet been described, and it is unclear whether knee structural abnormalities, including cartilage defects, cartilage volume, bone marrow lesions (BMLs), meniscal extrusion, infrapatellar fat pad (IPFP), and effusion-synovitis, can predict osteophyte change.

Objectives: To describe the natural history of knee MRI-detected OP, and to determine if knee structural risk factors are associated with change of MRI-detected OP in a longitudinal study of older adults.

Methods: 413 randomly selected older adults (mean age 63 years) had magnetic resonance imaging at baseline and approximately 2.6 years later to measure knee OP, cartilage defect, cartilage volume, BMLs, meniscal extrusion, IPFP quality score/maximum area and effusion-synovitis. Weight, height, body mass index (BMI) and leg muscle strength were measured by standard protocols.
Results: 85% participants had MRI-detected OP at baseline. Over 2.6 years, the average OP score increased significantly in all compartments. The OP score remained stable in 53% participants and worsened in 46% (≥1-point increase) OP, with 1% decreasing. Baseline factors associated with an increase in MRI-detected OPs over 2.6 years included BMI, cartilage defects, BMLs, meniscal extrusion, IPFP quality score and Effusion. In multivariable analyses, baseline cartilage defects, BMLs and meniscal extrusions and IPFP quality score were site-specifically and significantly associated with increased OP at medial tibiofemoral, lateral tibiofemoral and total compartments (p all <0.05). In contrast, total and suprapatellar pouch effusion-synovitis were significantly associated with increased OP at total and lateral compartments (p all <0.01). The significant associations between baseline cartilage volume and increased OPs at medial and total compartments became non-significant after further adjustment for other knee structural abnormalities. Age sex and smoking status were not associated with increased OPs over time.

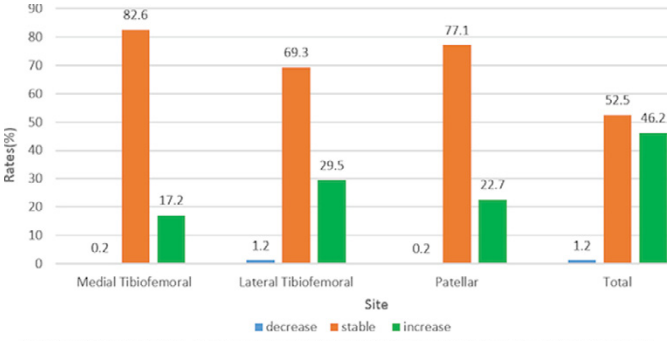

Figure 2. Change in MRI-detected osteophyte scores by site over 2.6 years. Total score was calculated by summing medial tibiofemoral, lateral tibiofemoral and patellar scores.

Conclusions: Knee MRI-detected OP in older adults is common and, in contrast to radiographs, is likely to progress over a relatively short period. Progression can be predicted by structural risk factors suggesting they are a consequence of these abnormalities.

Infection-related rheumatic diseases

SAT0556 RISK FACTORS FOR SEVERE INFECTION AND RATIONALE FOR IMMUNOGLOBULIN MONITORING DURING RITUXIMAB TREATMENT IN AUTOIMMUNE RHEUMATIC DISEASES

M.Y. Md Yusof [1,2], E.M. Vital [1,2], D. McElvenny [3], E.M. Hensor [1,2], S. Das [1], M.H. Buch [1,2], P. Emery [1,2], S. Savic [1,2]. [1] *Rheumatology, Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds;* [2] *NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds;* [3] *Institute of Population Health, University of Manchester, Manchester, United Kingdom*

Background: Rituximab (RTX) has been used in the treatment of various autoimmune rheumatic diseases (AIRDs) for over a decade. Repeat cycles are effective for maintenance but may lead to hypogammaglobulinaemia. Low IgG at baseline has been associated with post-treatment infection rate but may be confounded by other clinical variables and fully adjusted models with method for handling missing data have not been presented. Importance of post-treatment change in Igs has also not been proven.
Objectives: To evaluate risk factors for severe infection in multivariable analysis and assess outcome of hypogammaglobulinaemia.
Methods: The first 700 consecutive patients with AIRDs treated with RTX at a single centre were studied. Each cycle of RTX consisted of 2x1000mg infusions repeated on clinical relapse. IgM, IgA and IgG levels were measured at baseline and 4–6 months after each cycle. Multiple imputation was used for missing data. Baseline factors for predicting serious infection and low Ig were tested using univariable and multivariable (MVA) logistic regression analyses.
Results: 550 patients were female, median age (IQR) at RTX initiation 58 (46–68) years and median disease duration (IQR) 7.9 (3.4–15.0) years. 506 (72%) had RA, 94 (13%) SLE, 49 (7%) AAV, 14 (2%) DM, 5 (1%) APS, 6 (1%) SSc and 26 (4%) other CTD. 364 (52%) were biologic-naïve and 515 (74%) were on concomitant DMARDs. Total follow-up: 2940 patient-years (PY). 284 serious infections were recorded in 179 patients (9.7/100 PY); 88 cases within 12 months of cycle 1 (C1). In MVA, previous severe infection (OR 10.7, 95% CI 5.8–19.5), low IgG (OR 3.6, 95% CI 1.5–8.6), previous cancer (OR 2.9, 95% CI 1.2–6.6) and chronic lung disease (OR 1.7, 95% CI 0.9–3.1) increased the odds of a severe infection within 12 months of C1. A diagnosis of CTD was associated with lower risk (OR 0.5, 95% CI 0.2–0.9). Low IgG at RTX initiation was predicted by older age, previous cancer, RA diagnosis, previous severe infection and previous treatment with cyclophosphamide. In C1-C3, higher rate of change in IgA and IgG levels were associated with serious infections (Figure 1). Overall, only 7 (1%) of the patients required Ig replacement in this cohort.

Conclusions: Factors associated with serious infection at RTX initiation include previous serious infection, low IgG, previous cancer, a diagnosis of RA and chronic lung disease. This is the first study to show the rationale for monitoring the rate of change in Ig levels during repeat cycles of RTX, with reduction in all Ig subclasses being associated with increased risk of post-treatment infection. Further analysis including predictors of serious infections in repeat cycles is in progress and will be used to develop guidelines for safety monitoring of rituximab.

SAT0557 CHIKUNGUNYA OUTBREAK IN BRAZIL: DEMOGRAPHIC AND CLINICAL CHARACTERIZATION OF 732 PATIENTS – CHIKBRASIL COHORT

A.L. Duarte [1], C.D.L. Marques [1], P.R. Santos [1], A. Ranzolin [2], N.G. Cavalcanti [1], R.S. Gonçalves [3], A.T. Dantas [1], M.S. Luna [1], C.A. Andrade [1], L.F. Rocha Junior [3], M.R. Freitas [3], P.R. Melo [1], L.D. Valadares [4], C.A. da Fonte [4], M.L.D. Valadares [4], E. Freire [5], A.K.G. Melo [5], M.M. Medeiros [6], M.C. Bezerra [6], V.B. Marques [6], R.A. Océa [7]. [1] *Internal Medicine, Universidade Federal de Pernambuco;* [2] *Rheumatology;* [3] *Internal Medicine, Instituto de Medicina Integral Prof. Fernando Figueira;* [4] *Rheumatology, Hospital Getulio Vargas, Recife;* [5] *Rheumatology, Universidade Federal da Paraíba, João Pessoa;* [6] *Rheumatology, Universidade Federal do Ceará, Fortaleza;* [7] *Rheumatology, Universidade Federal de Sergipe, Aracaju, Brazil*

Background: Chikungunya Fever (CF) is a disease characterized by acute febrile arthritis and caused by a mosquito-transmitted alphavirus. Considering the wide distribution of the vector, the presence of imported cases from 2010 and Brazilian population's susceptibility, there was a dispersal and establishment of Chikungunya virus (CHIKV) throughout the country. Since 2014, the CF has achieved a large proportion of the Brazilian population and has been responsible for the development of chronic joint symptoms in thousands of people.
Objectives: To describe the demographic, clinical and serological characteristics of patients from specialized Rheumatology services from northeastern Brazil, in a large, multicenter cohort.
Methods: Data from 732 patients in a prospective, multicenter, observational cohort conducted in six research rheumatology centers were analyzed. Patients

18 years or older who fulfilled the clinical and epidemiological Health Ministry criteria for case definition of CF were included in the study, from April to December 2016.

Results: From 732 patients included, 83.1% were women. The mean age was 54.1 (± 13.4) years; 92.4% lived in urban area and 58.6% had only primary education. The most common comorbidities were hypertension (43.8%), hyperlipidemia (25.3%) and diabetes mellitus (13.7%). Prior rheumatologic disease was observed in 16.4% patients, being the most frequent rheumatoid arthritis (32.5%), osteoarthritis (32.5%) and spondyloarthritis (11.7%). Arthralgia was the most frequent symptom referred by all patients; fever and fatigue were also common manifestations, being referred by 95.3% and 87.1% of patients, respectively. Arthritis occurred in 84.3%. The most frequent joint pattern involvement was polyarticular (67.8%) and the additive (84.0%). At the first appointment with the rheumatologist, 75.9% had been or were under corticosteroid use, with the average dose of 15.4 mg (±8.7) of prednisone or equivalent; was observed an median of 8 painfull joints (IQR 4–21) and arthritis was found in 73.6% patients, with an median of 2 swollen joints (IQR 0–5). The median score of patient global assessment at the time of the initial evaluation was 6 (IQR 4–8) using a 10 points visual analogue scale. After resting stiffness was referred by 86.0%, with 58.4% of these longer than 30 minutes. The most commonly prescribed medications were corticosteroids (58.3%) and hydroxychloroquine (59.1%). The serological tests for CHIKV were positive for IgM in 97.1% and for IgG in 71.7% of patients.

Conclusions: This is the first descriptive study of a cohort Brazilian patients with CF, with an expressive number of patients when compared to those described in the literature. Most of the features of patients in our cohort were similar to the results described in studies/cohorts published.

SAT0558 CONCORDANCE BETWEEN CLINICAL-EPIDEMIOLOGICAL CRITERIA AND CHIKUNGUNYA FEVER SEROLOGY

C.D.L. Marques[1,1,1], C.A. Andrade[1], M.S. Luna[1], P.R. Santos[1], A.T. Dantas[1], A. Ranzolin[2], N.G. Cavalcanti[1], R.S. Gonçalves[3], L.F. da Rocha Jr[4], P.R. Melo[1], R.M. Correia[3], L.D. Valadares[5], C.A. da Fonte[5], M.L.D. Valadares[5], E. Freire[6], A.K.G. Melo[6], M.M. Medeiros[7], M.C. Bezerra[7], V.B. Marques[7], R.A. Océa[8], A.L. Duarte[1]. *[1]Internal Medicine, Universidade Federal de Pernambuco; [2]Rheumatology; [3]Internal Medicine, Instituto de Medicina Integral Prof. Fernando Figueira; [4]Rheumatology, Instituto de medicina integral professor Fernandes Figueira; [5]Rheumatology, Hospital Getulio Vargas, Recife; [6]Rheumatology, Universidade Federal da Paraíba, João Pessoa; [7]Rheumatology, Universidade Federal do Ceará, Fortaleza; [8]Rheumatology, Universidade Federal de Sergipe, Aracaju, Brazil*

Background: The first autochthonous reports of Chikungunya fever (CF) in Brasil was confirmed in 2014, and by December 2016, there were 263.980 probable cases of CF, 55.03% confirmed. According to recommendations of the Ministry of Health (MH) of Brazil, in an established epidemic situation, the diagnosis of CF should be made by appliyng clinical and epidemiological criteria. There is no indication for the serology for Chikungunya virus (CHIKV) in the acute phase, except in atypical cases and complicated clinical situations, which may generate doubts in clinical practice about the correct diagnosis of these patients.

Objectives: The objective of this study was to evaluate the concordance of the clinical and epidemiological criteria with the serology results for CHIKV in a cohort of patients with CF.

Methods: The multicenter cohort CHIKBRASIL from the Northeast of Brazil has enrolled CF patients with joint manifestations since April 2016, using as inclusion criteria the presence of fever and arthralgia/arthritis in a patient residing or who had visited an endemic or epidemic area within 15 days prior to the onset of symptoms. For the present study, we selected patients in which IgM and/or IgG serology was performed, regardless of the results. For the analysis of agreement with the serology, the most characteristic symptoms of CF were used individually (fever, arthritis/arthralgia or exanthema) and three models of association of symptoms were created: (1) fever and arthralgia; (2) fever and arthritis; (3) fever, arthralgia/arthritis, and exanthema. The sensitivity (SENS), specificity (SPEC), positive predictive value (PPV) and negative predictive value (NPV) of the criteria were also assessed, with the serology result considered the gold standard.

Results: A total of 143 patients were evaluated, 119 (83.2%) of which were female, with a mean age of 53.89 years (± 13.5); 52.4% of the cases were in the subacute phase of the disease (15 days to 3 months) and 42.7% were in the chronic phase (over 3 months). The IgM positivity was observed in 95.1% of cases and IgG in 71.67%. The concordance rate between the IgM serology or combined positive serology (IgM or positive IgG) was over 80% for any of the symptoms/symptoms model analyzed, as well as the SENS and PPV of the symptoms/ symptoms model, which was over 95% in all situations evaluated. The concordance rate for IgG serology ranged from 51.9 to 72.1%. Model 1 presented the highest agreement with the result of positive combined serology.

Conclusions: During an epidemic situation, the use of clinical and epidemiological criteria shows high agreement with the serology result, regardless of the combination of symptoms presented, with high sensitivity and positive predictive value.

SAT0559 SEPTIC ARTHRITIS IN COVENTRY IN THE UK: 5 YEAR DATA

A. Vivekanantham[1], A. Kahlon[1], M. Ali[1], A. Metcalfe[2], S. Dubey[1]. *[1]Rheumatology; [2]Orthopaedics, University Hospitals Coventry and Warwickshire, CV2 2DX, United Kingdom*

Background: Septic arthritis (SA) is a serious condition associated with significant morbidity and prolonged hospital stays, posing a large economic burden to healthcare systems. It affects 2–10 people per 100,000 and there has been a suggestion that the incidence is increasing due to iatrogenic causes [1]. Our local secondary centre, University Hospitals Coventry and Warwickshire NHS Trust (UHCW NHS Trust), provides care to Coventry and Rugby covering an estimated population of 550,000.

Objectives:

- To investigate the incidence of native joint SA in the adult population in a secondary care hospital in the UK.
- To investigate whether immunosuppression contributes significantly to the burden of SA.

Methods: Patients were retrospectively identified on the basis of the International Classification of Diseases (ICD)-10 coding generated following discharge from hospital for all patients between 2007–11. Exclusion criteria included paediatric patients, diabetic foot, prosthetic joint infections and those who on review were not thought to have SA. The data was analysed using Excel. Formal ethical approval was obtained via the research and development department within the UHCW NHS Trust.

Results: A total of 189 admissions were coded as SA. Of these, 103 were excluded (n=74 not thought to have SA on review of the notes, n=26 paediatric patients and n=3 prosthetic joints). Therefore, there were 86 adult admissions for 64 patients with SA.

The average age of these patients was 53.4 years, with the majority of them being males (n=43, 67.2%). The majority of patients had co-morbidities (n=44, 65.7%), with hypertension (n=10, 14.9%) and type 2 diabetes (n=10, 14.9%) being the most prevalent. Joint aspirates were performed on 63.2% (n=56) of admissions and blood cultures on 70.8% (n=63) of admissions. Staphylococcus aureus was the most commonly cultured microbe in both joint fluid (46.4%, n=13) and blood (42.9%, n=3). The knee was the commonest joint involved (n=31, 46.3%). Other commonly affected joints included the small joints of the hands (n=9, 13.4%) and shoulder/acromioclavicular/sternoclavicular joints (n=9, 13.4%).

Interestingly, 23 (35.9%) of the patients were immunocompromised. Of these, 4 patients had a diagnosis of rheumatoid arthritis (RA) and were on steroid treatment alone (n=2), or in combination with disease-modifying anti-rheumatic drugs (n=2). A total of 11 patients had a pre-existing rheumatological diagnosis of which RA was the most common condition (n=6). Two of these patients were not on immunosuppressants. The 5-year mortality was significant at 29.7% (n=19).

Conclusions: Our local data showed the incidence of SA to be approximately 3 per 100,000, which is in keeping with proposed figures. Our cohort highlighted that those with pre-existing co-morbidities or those who were immunocompromised were at greatest risk. An ageing population with multiple co-morbidities means the incidence of SA is set to rise. Greater emphasis therefore needs to be placed on improving awareness and optimising treatment.

SAT0560 COEXISTENCE OF SEPTIC AND CRYSTAL-INDUCED ARTHRITIS: A DIAGNOSTIC CHALLENGE

Y. Garcia-Mira, A. Prior-Español, S. Minguez, J. Camins, M. Martínez-Morillo, S. Holgado, A. Olive, J. Cañellas, L. Gifre, L. Mateo. *H.UNIVERSITARI Germans Trias I Pujol, Badalona, Spain*

Background: Septic arthritis (SA) is a rheumatologic emergency as joint destruction occurs rapidly and can lead to significant morbidity and mortality. Accurate diagnosis can be particularly challenging in patients with underlying inflammatory joint disease. Crystal-induced arthritis (CA) is a risk factor for its appearance. When both conditions appear simultaneously, CA may mask diagnosis of infection and delay the antibiotic treatment.

Objectives: To describe the characteristics of patients with concurrent septic and CA.

Methods: Retrospective analysis of patients with coexistence of septic and CA attended between 1985 and 2015 in a university hospital with a reference area of 850,000 inhabitants. We collect demographic, clinical, laboratory and imaging data as well as patient medical treatment, complications and evolution records. All patients had positive bacterial culture (blood and/or joint fluid) and crystals in synovial fluid.

Results: A total of 123 patients with SA were identified. 20.3% (n=25) of them had concomitant CA, with mean age of 67 years (SD 14), 17 (68%) males and 8 (32%) females. Risk factors were: diabetes (24%), diuretic drugs (24%), chronic renal failure (16%) -2 of them undergoing hemodialysis and 4 kidney

transplant patients with immunosuppressive treatment. In only 2 cases there was a previous arthrocentesis. The mean diagnostic delay was 14 days (SD 13) (data available in 14 cases). The most commonly affected joint was the knee (48%), followed by the foot (20%) and the hip (12%). In 2 cases several joints were involved at the same time. In synovial fluid cytological studies, the most frequently identified crystals were: urate (60%), calcium pyrophosphate (20%) and hydroxyapatite (8%). In 32% of cases gram staining was positive, but 88% of patients had a positive joint fluid culture, with the most frequently isolated germs being methicillin-sensitive *S. aureus* (48%), methicillin-resistant *S. aureus* (MRSA) (12%) and *M. tuberculosis* (12%). 32% of patients presented positive blood cultures (12% with negative synovial fluid culture), although 48% of patients had fever at the time of diagnosis. It should be noted that 48% had radiological baseline damage. Surgical debridement was performed in 32% of patients. Evolution was successful in 56% of patients; although intercurrent complications were usual (40%). Mortality was 8% -one case due to acute pulmonary edema and the other because of septic shock.

Conclusions: Coexistence of infectious and CA represents a diagnostic challenge and requires a high suspicion index. It usually appears in elderly patients with comorbidities. Gout was the most prevalent CA. *S. aureus* was the most commonly causative pathogen, with a high rate of MRSA infection. If it's treated early the evolution is usually favorable, which makes synovial fluid microbiological study imperative.

SAT0561 USEFULNESS OF POLYMERASE CHAIN REACTION FOR DIAGNOSING WHIPPLE'S DISEASE IN RHEUMATOLOGY

M. Herbette [1], J.B. Cren [2], L. Joffres [3], C. Lucas [4], E. Ricard [5], C. Salliot [6], J. Guinard [5], A. Perdriger [4], E. Solau-Gervais [3], B. Bouvard [2], A. Saraux [1] on behalf of Reseau Victor Hugo. *[1] Rheumatology, CHU Brest and Université Bretagne Occidentale, Brest; [2] Rheumatology, CHU, Angers; [3] Rheumatology, CHU, Poitiers; [4] Rheumatology, CHU, Rennes; [5] Rheumatology; [6] CHU, Orleans, France*

Background: No consensus exists about the combination of clinical, laboratory, and radiological findings that warrant tests for Whipple's disease.

Objectives: The primary aim of this multicentre retrospective study was to determine when patients evaluated for rheumatological symptoms should undergo *T. whipplei* PCR testing. Secondary aims were to describe the clinical patterns and treatments used, to determine the diagnostic yield of PCR testing, and to assess whether centres with higher numbers of tests also had a larger number of Whipple's disease diagnoses.

Methods: In a retrospective observational study done in five hospitals, we assessed the clinical and radiological signs that prompted *T. whipplei* PCR testing between 2010 and 2014, the proportion of patients diagnosed with Whipple's disease, the number of tests performed and the number of diagnoses according to the number of tests, the patterns of Whipple's disease, and the treatments used.

Results: At least one PCR test was performed in each of 267 patients. Rheumatic signs were peripheral arthralgia (n=239, 89%), peripheral arthritis (n=173, 65%), and inflammatory back pain (n=85, 32%). The main extra-articular signs were constitutional symptoms (n=111, 41.8%), diarrhoea (n=70, 26.5%), fever (n=53, 20%), lymphadenopathy (n=14, 5.3%), and neurological signs (n=11, 4.2%). Whipple's disease was diagnosed in 13 patients (4.9%). The main samples tested and the more frequently positive tests in the centres with diagnoses of Whipple's disease were saliva and stool. In the centres with no diagnoses of Whipple's disease, arthritis was less common, whereas constitutional symptoms, fever, and lymphadenopathy were more common. 11 patients with Whipple's disease had CRP elevation. The annual incidence ranged across centres from 0 to 3.6/100000 inhabitants. The patients group with Whipple's disease had a higher proportion of males, older age, and greater frequency of arthritis.

Conclusions: Males aged 40–75 years with unexplained intermittent seronegative peripheral polyarthritis, including those without constitutional symptoms, should have *T. whipplei* PCR tests on saliva, stool and, if possible, joint fluid.

SAT0562 CHIKUNGUNYA FEVER IN PATIENTS WITH PRIOR RHEUMATIC DISEASES: IS IT MORE SEVERE?

A.T. Dantas [1], M.S. Luna [1], P.R. Santos [1], C.A. Andrade [1], C.D.L. Marques [1], A. Ranzolin [2], N.G. Cavalcanti [1], R.S. Gonçalves [3], L.F. Rocha Junior [2], H.D. Lima [2], P.R. Melo [3], L.D. Valadares [4], C.A. da Fonte [4], M.L.D. Valadares [4], E. Freire [5], A.K.G. Melo [5], M.M. Medeiros [6], M.C. Bezerra [6], V.B. Marques [6], R.A. Océa [7], A.L. Duarte [1]. *[1] Internal Medicine, Universidade Federal de Pernambuco; [2] Rheumatology; [3] Internal Medicine, Instituto de Medicina Integral Prof. Fernando Figueira; [4] Rheumatology, Hospital Getulio Vargas, Recife; [5] Rheumatology, Universidade Federal da Paraíba, João Pessoa; [6] Rheumatology, Universidade Federal do Ceará, Fortaleza; [7] Rheumatology, Universidade Federal de Sergipe, Aracaju, Brazil*

Background: Chikungunya fever (CF) is an infectious disease caused by a RNA virus and its transmission occurs by the inoculation of the virus by the female bite of *Aedes aegypti* mosquito. In Brazil, where the vetor is endemic, the virus rapidly disseminated and there was an epidemic, specially in the Northeast region of the country with 263.980 notified cases in 2016. It is known that CF may have a chronic course with articular symptons, however there is not consistent data in the medical literature on CF evolution in patients with prior rheumatic diseases.

Objectives: To assess whether there is any difference in the characteristics of articular manifestations of CF in patients with prior inflammatory rheumatic diseases (IRD), non-inflammatory rheumatic diseases (NIRD) and controls (patients with no diagnosed prior rheumatic diseases).

Methods: Cross-sectional study using a database from CHIKBRASIL cohort. Patients enrolled had clinical and epidemiological characteristics of CF and were classified in three groups: IRD (rheumatoid arthritis, axial spondyloarthritis and systemic lupus erythematosus), NIRD (fibromyalgia and osteoarthritis) and controls (no prior rheumatic diseases).

Results: A total of 150 patients were enrolled. There were 55 patients with IRD, 40 patients with NIRD and 55 controls, paired by age and sex. There were no differences in acute phase symptoms in the groups. There a was more frequent occurrence of arthritis in patients with IRD compared to NIRD (p=0.001) and to controls (p=0.002). In 89.1% of the patients with IRD there was an underlying disease exacerbation and 74% described an expressive worsening of symptoms compared to the period prior to infection. Patients with IRD had an increase in the current dose of corticosteroids (median 10mg, IQR 10–20) compared to previous dose used (median 6mg, IQR 5–10) after the onset of CF (p=0.0007). Importantly, there was more methotrexate prescription (23.5%) in IRD group, compared to NIRD group (0, p-0.001) and to controls (3.7%, p=0.003).

Conclusions: Patients with IRD and CF presented significantly more arthritis compared to NIRD or to controls. CF seems to induce underlying rheumatologic disease exacerbation in patients with inflammatory disease and a more aggressive therapeutic approach might be necessary in this group of patients.

SAT0563 EVALUATION OF ROLE OF SLEEP DISTURBANCE, DEPRESSION, OBESITY, AND PHYSICAL INACTIVITY IN FATIGUE IN CHIKUNGUNYA ARTHRITIS

M. Bhama. *Orthopedics, Sardar Patel Medical College, Bikaner, India*

Background: Chikungunya virus (CHIKV) is a mosquito-borne alphavirus that circulates predominantly in tropical and subtropical regions, potentially affecting over 1 billion people.

Objectives: Fatigue is a major concern in individuals where CHIKV results severe chronic arthralgia and/or arthritis lasting months to years. However, in order to treat fatigue adequately, its sources need to be identified.

Methods: All participants had physician-diagnosed CHIKV arthralgia. Data regarding self-reported sleep quality, depression, physical activity, disease activity, muscle strength, functional limitations, and body composition were collected during a single home visit (number of participants=117). Information on demographics, medications, alcohol intake and smoking was collected. The Fatigue Severity Inventory (FSI; measuring average fatigue over the past 7 days) was used as the primary outcome. Analyses were conducted to evaluate bivariate relationships with fatigue and correlations among risk factors. Multivariate analyses identified independent predictors of fatigue.

Results: The mean age was 48±16 years, the mean disease duration was 7±6 years, and 71% (M:33, F:84) of subjects were female. The mean FSI rating was 4.1±2.0 (range 0–10). In multivariate analyses, self-reported disease activity, poor sleep, depression, and obesity were independently associated with fatigue. Physical inactivity was correlated with poor sleep, depression, and obesity. Mediation analyses indicated that physical inactivity had an indirect association with fatigue, mediated by poor sleep, depression, and obesity.

Conclusions: This cross-sectional study suggests that fatigue may not be solely a result of CHIKV arthralgia, but may result from a constellation of factors that includes CHIKV arthralgia disease activity or pain, but also includes inactivity, depression, obesity, and poor sleep. The results suggest need of various interventions to improve fatigue in individuals with CHIKV arthritis, including increasing physical activity or addressing depression or obesity.

SAT0564 SUBLINGUAL VACCINE: NEW CHALLENGE IN THE PREVENTION OF RECURRENT INFECTIONS IN AUTOIMMUNE DISEASES

K. Llano Hernández[1], S. Sanchez Ramón[1], J. Ochoa Grullon[1], P. Macarron[2], C. Morado[2], C. Martínez-Prada[2], A. Rodríguez De La Peña[1], E. Rodríguez Frías[1], M. Nuñez Beltran[1], B. Fernández[2], J.Á. Jover[2], G. Candelas[2]. *[1]Inmunology; [2]Rheumatology, Madrid Clinic Hospital, Madrid, Spain*

Background: Disease-modifying antirheumatic drugs (DMARDs) and new biologicals have improved the prognosis of systemic autoimmune diseases (SAD), but reciprocally increase the risk of recurrent respiratory tract (RRTI) and urinary tract (RUTI) infections. Given the rising of antibiotic resistance, the search for new strategies for the prevention of recurrent infections is a priority.
Objectives: The purpose of this study was to evaluate the clinical benefit of the sublingual polybacterial vaccines on infections' rates in SAD patients.
Methods: A retrospective observational study on a cohort of SAD patients on active inmunosuppression with RRTI and RUTI was conducted. Patients were treated with multibacterial sublingual vaccine formulations either for RRTI (*Staphylococcus spp., S. pneumoniae, K. pneumoniae, M. catarrhalis, H. influenzae*)[3] or/and RUTI (*K. pneumoniae, E. coli, E. faecalis, P. vulgaris*)[4] (Bactek/Uromune®, Inmunotek SL Madrid, Spain) for 3-months period and clinical follow-up at 6- and 12-months. We monitored the frequency of infections, the intensity and severity of infections during follow-up. Immunological evaluation was performed, including: Serum immunoglobulin levels, IgG subclasses, specific antibodies' production: anti-pneumococcal, anti-Typhi polysaccharide and anti-tetanus toxoid antibodies, and B and T cell phenotype.
Results: A total of 50 patients were evaluated, and 34 were eligible at 12-months.The mean age of the patients was 58±13 years, 31 women (91.17%) and 3 men (8.82%), 44.11% (n=15) with rheumatoid arthritis (RA), 23.52% (n=8) with systemic lupus erythematosus (SLE), 8.82% (n=3) mixed connective tissue disease, 2.94% (n=1) ankylosing spondylitis, 2.94% (n=1) sacroileitis, 2,94% (n=1) psoriatic arthritis, 2,94% (n=1) SLE/RA, 2.94% (n=1) discoid LE/Sjögren, 2.94% (n=1) adult onset Still disease, 2,94% (n=1) sarcoidosis, 2.94% (n=1) SLE-like. All patients showed a significant decrease in RRTI (3.15±2.66 vs 0.46±1.07, $p<0.01$) and RUTI (1.85±2.49 vs 0.35±1.06, $p<0.01$) frequency and use of antibiotics at 6-months of vaccine, except one with sarcoidosis. 23 of 34 patients (67.64%) disclosed defects on specific antibody production to polysaccharide and protein immunization. Three patients with antibody production deficit and pneumonia required prophylactic intravenous Ig. No adverse effects or SAD relapses were noted during the 1-year observational period.
Conclusions: Mucosal vaccination in immunosuppressed patients due to SAD with recurrent infections resulted in lower rates of RRTIs and RUTIs with subsequent improvement in their quality of life. Our preliminary results need to be validated in controlled trials.

SAT0565 THE FREQUENCY OF SEPTIC ARTHRITIS AFTER ARTHROCENTESIS AND INTRA ARTICULAR GLUCOCORTICOID INJECTION IS LOW

S.K. Petersen, R.A. Andreasen, I.M.J. Hansen. *Rheumatology, Odense University Hospital, Svendborg Hospital, Svendborg, Denmark*

Background: Intraarticular (IA) procedures have both diagnostic and therapeutic purposes in patients with arthritis. The therapeutic benefit of IA glucocorticoids (GC) injection in patients with rheumatologic diseases is well described. However, IA procedures are associated with increased risk of Septic arthritis (SA). Rapid diagnose and correct treatment is crucial to avoid joint damage, sepsis and potential fatal outcome. However, patients in risk of evolving SA secondarily to GC injection or arthrocentesis are not well defined.
Objectives: The aim of this study was to evaluate the risk of SA in patients who received an IA GC injection or an isolated joint puncture, and to describe possible characteristics for these patients.
Methods: All patients' undergoing IA procedures at the orthopaedic and rheumatological departments of Fuhnen from January 2006 to December 2013 were identified in the central database and included by register extraction. Patients who developed SA within 30 days after IA GC injection were registered as cases. SA was defined as clinically inflamed joint and positive synovial fluid culture.
Retrospectively, data on age, gender, affected joint location, bacterial agent, pre-existing inflammatory disorder and death within 30 days were extracted from the patient files.
According to local recommendations a non-touch sterile technic where used for IA procedures. Patients were informed about the risk for SA and motivated to seek medical attention if suspicion of infection or lack of improvement.
Results: 22370 IA procedures were registered; 14118 IA GC injections and 8252 arthrocentesis. Eleven patients with SA were registered.
Eleven patients developed SA subsequently to IA GC injection (0.08% of all GC injections). For patients' demography, joint distribution, bacterial agent and pre-excisting joint disease (Table 1). One patient died within 30 days after IA GC injection.

Sex	Age	Joint	Bacterial agent	Inflammatory Disease	Death, 30 days
M	83	Shoulder	Grp. A streptococcus	No	+
M	53	Elbow	S. Aureus	No	–
M	55	Ancle	S. Aureus	Gout	–
M	67	Knee	Grp. A streptococcus	No	–
F	83	Knee	E. Faecalis	No	–
M	58	Knee	S. Aureus	No	–
M	73	Knee	S. Aureus	Gout	–
F	50	Shoulder	Grp. A streptococcus	RA	–
F	66	Knee	S. Aureus	No	–
F	80	Knee	S. Aureus	RA	–
M	73	Elbow	E. coli	RA	–

Conclusions: This study demonstrates that IA procedures can be performed with little risk of SA. The risk factors identified i.e. elderly patients with inflammatory joint diseases are consistent with those described in the literature [1].
We consider joint puncture technique and patient information for being essential when doing IA procedures. However, if SA occurs it is potentially fatal and therefore GC injection should be preserved for doctors with experience in joint diseases.

SAT0566 ELECTRONEUROGRAPHIC FINDINGS IN PATIENTS WITH SUBACUTE/CHRONIC ARTICULAR SYMPTOMS OF CHIKUNGUNYA FEVER AND NEUROPATHIC COMPLAINTS – PRELIMINARY RESULTS

L.F. da Rocha Jr[1,2], H.D. de Lima[1], R.M. Correia[1], M.R.D.A. Freitas[1], P.R.S. de Melo[1], A.G.L. de Mattos[1], A.F.R. de Oliveira[1], C.D.L. Marques[2], A.L.B.P. Duarte[2], O. Lins[1], A. Ranzolin[1,2]. *[1]Instituto de Medicina Integral Professor Fernando Figueira; [2]Hospital Das Clínicas of Pernambuco, Recife, Brazil*

Background: The mechanisms of nonarticular pain associated with Chikungunya virus (CHIKV) infection are still poorly understood. Many patients that progress to Subacute/Chronic phases have neuropathic pain (NP) besides the articular symptoms. The NP is associated with a less favorable outcome, with greater impact on quality of life and lower efficacy of treatment. The NP can reflect a dysfunction of the nervous system, rather than a neurological lesion induced by CHIKV, but the pathophysiology of the neural disfunction is not completely understood. There are no studies evaluating the electroneurographic findings in patients with CHIKV infection and neuropathic symptoms.
Objectives: To evaluate the results of electroneurography (ENoG) of patients with Chikungunya Fever (CF) and neuropathic symptoms.
Methods: Patients with diagnosis of CF (clinical and epidemiological) and symptoms of paresthesias underwent ENMG of upper and lower limbs. The electrodiagnostic evaluation consisted of nerve conduction study of median, ulnar, tibial, fibular, sural and plantar nerves. Clinical and epidemiological data were also recorded.
Results: The sample was composed by 18 patients (82.3% females) with mean age of 56 (±9.9) years. The mean duration of symptoms of CF at the time of the ENoG was 23.8 (±10.8) weeks and the average of tender and swollen joints (including ankle and foot) was 29.6 (±21.5) and 9 (±9.9), respectively. The mean score of visual analogic scale (VAS) for pain was 4.4 (±2.4) and for fatigue was 5.9 (±2.9), considering values between 0 and 10. No patient presented axial pain and the number of painful joints was higher in upper (19.4±13.9) compared to lower limbs (10.2±8.4). Only 3 patients reported unspecific paresthesias prior to the onset of arbovirosis and worsening after CF. However, these 3 patients had normal ENoG. Six patients had diabetes. Mononeuropathy was the most frequent result occurring in 12 subjects (67%). Bilateral mononeuropathy of median nerve (at carpal tunnel) was found in 11 patients and one subject had median neuropathy just on the left hand. Other mononeuropathies were also present: bilateral tibial nerve in 4, bilateral plantar nerve in 2 and bilateral fibular nerve in 1 patient. Distal axonal polyneuropathy was present in 8 cases (6 sensory and 2 sensorimotor); 5 of these were diabetic. The ENoG was normal in 4 cases. Ten patients were in use of prednisone (mean dose 11.4mg/d) and just 6 were using antineurophatic agents.
Conclusions: Our preliminary results indicate that the ENoG is altered in most patients with chronic articular manifestations of CF and associated paresthesias. Mononeuropathy is the most commom finding, even in the chronic phase of the disease when the nonarticular edema is not common. Further clinical studies with a larger number of patients and follow-up tests will be needed to confirm our data.

SAT0567 IMPACT OF CHIKUNGUNYA FEVER ON FUNCTIONAL STATUS AND QUALITY OF LIFE – A PROSPECTIVE COHORT STUDY OF BRAZILIAN PATIENTS

L.F. da Rocha Jr[1,2], M.R.D.A. Freitas[1], A.G.L. de Mattos[1], H.D. de Lima[1], R.M. Correia[1], F.G.T. Vieira[1], A.L.B.P. Duarte[2], C.D.L. Marques[2], W.L.M. de Oliveira[1], P.R.S. de Melo[1], A. Ranzolin[1,2]. *[1]Instituto de Medicina Integral Professor Fernando Figueira; [2]Hospital Das Clínicas of Pernambuco, Recife, Brazil*

Background: An epidemic of Chikungunya Fever (CF) spread throughout South America in 2014. The acute manifestation of CF typically consists of febrile arthritis. The burden of the chronic articular manifestations remains a public health issue affecting activities of daily life. There is a very important impact on quality of life in patients affected by CF, even at chronic phase. The long-term functional status may also be affected by CF.
Objectives: To evaluate longitudinally the disability, Health Related Quality of Life (HRQOL) and functional status of patients with CF and analyze the clinical and epidemiological factors associated with different outcomes.
Methods: Patients with clinical and demographic diagnosis of CF and persistent articular symptoms were evaluated in a cohort study between May 2016 and December 2016. HRQOL was rated by Short-Form 12 (SF-12) and the functional status was checked through Health Assessment Questionnaire (HAQ) and the Global Functional Status (GFS). Data were divided per weeks after disease onset and were analysed (Spearmans's correlation coefficient and Mann-Whitney test).
Results: Sixty-five patients (58 females), mean age of 51.3 (±13.3) were assessed. As expected, a significant correlation between pain related scores and Physical Health Composite Scale Score (PCS), HAQ and GFS was found ($p<0.05$)). Edema and morning stiffness correlated with PCS, HAQ and GFS status from 4 to 20 weeks after disease onset ($p<0.05$). There was improvement in scores of all instruments used from 4–8 weeks of disease to 12–16 weeks of disease (table 1). The worst indices of PCS, Mental Health Composite Scale Score (MCS) and GFS were scored in the first month, mean scores of 30.07±5.77, 38.13±8.54 and 3.15±1.07 respectively. Higher HAQ values were demonstrated between 4 and 8 weeks after disease onset (mean score 1.87±0.82).

HRQOL and Functional Status in patients with CF

	4–8 weeks of disease (mean score)	12–16 weeks of disease (mean score)	P value
PCS	30.12±8.21	35.86±11.11	0.0487
MCS	40.95±12.23	47.02±12.09	0.0326
HAQ	1.87±0.82	1.36±0.86	0.0228
Global Functional Status	3.03±0.98	2.53±0.95	0.0438

Conclusions: We demonstrated the impact of CF on HRQOL and Functional Status of patients. The SF-12 Health Survey, HAQ and GFS are influenced mostly by patients pain and worsening of this status are more prominent in the first 8 weeks of disease. Further clinical studies of the impact of CF on quality of life and functional studies are needed

SAT0568 RHEUMATOLOGICAL MANIFESTATIONS IN A SERIES OF PATIENTS WITH CHIKUNGUNYA FEVER

A.M. Sapag Duran[1], A.M. Beron[2], S. Sapag Duran[2], C. Coral Cristado[1], G. Medina[2], G. Nasswetter[2], D. Dubinsky[2]. *[1]Rheumatology, Hospital Universitario Japones, Santa Cruz, Bolivia, Plurinational State Of; [2]Rheumatology, Clinical Hospital "Jose de San Martin", University of Buenos Aires., CABA, Argentina*

Background: Chikungunya fever is characterised by a high probability of persistent rheumatological manifestations, producing a negative impact in the work, social and economic fields.
Objectives: To determine the frequency and type of rheumatologic involvement in the subacute and chronic phase of Chikungunya fever.
Methods: Descriptive, cross-sectional study. We included patients>16 years old with Chikungunya infection (real time PCR, IgM or IgG for Chikungunya) who consulted consecutively for rheumatic symptoms/signs from March 2015 to March 2016. According to the time of evolution, the disease was divided in 2 Phases: acute ($\leq$10 days of duration) and subacute/chronic ($\geq$11 days). According to clinical presentation, patients were classified in two groups: 1) non-autoimmune rheumatologic compromise (NARC) and 2) autoimmune rheumatologic compromise (ARC). Current ACR/EULAR criteria for classification of autoimmune diseases were used.
Results: Two hundred and two patients were evaluated, 80 were excluded due to negative serology for Chikungunya. 122 were included: 107 (88%) female, mean age 52.52±13.19 years, and time of evolution of 116.66±91.61 days.
Acute phase. 122 patients: fever 85 (69.67%), rash and pruritus 54 (44.26%), tenosynovitis 23 (18.8%), polyarthralgias 100 (82%) and arthritis 56 (45.90%).
Chronic phase. 122 patients: 71 (58%) patients had a chronic persistent rheumatologic symptoms and 51 (42%) presented remission of symptoms but all of them presented subsequent recurrence in an 91±40 days. NARC in 33 patients (27%) and ARC in 89 (73%), with no significant differences in age and time of evolution was observed.
NARC: 14 (42.4%) exacerbation of previous osteoarthritis pain, 9 (27.3%) developed fibromyalgia and 10 (30.3%) had localized soft tissue pain.
ARC: 13 (14.6%) with a history of RA, SLE, psoriasis or DM reactivated the underlying disease and 76 (85.4%) developed ARC: Undifferentiated polyarthritis with negative antibodies 61 (80%), RA with positive antibodies 5 (6.5%), scleroderma 2 (2.6%), cutaneous vasculitis 2 (2.6%), polymyalgia rheumatica 1 (1.3%), Sjogren's Syndrome 2 (2.6%), Dermatomyositis 1, Erythema nodosum 1 (1.3%) and vitiligo 1 (1.3%).
Antibodies were requested according to clinical suspicion: FAN $\geq$320 in 5 patients, RF in 6, ACPA in 4 and anti RO in 1. Thyroid dysfunction was observed in 7 patients who had a previous normal thyroid profile.

	Acute Fase n 122 (%)	Chronic Fase n 122 (%)	p
Fever	85 (69,7)	0	0,01
Rash and pruritus	54 (44,2)	0	0,01
Tenosynovitis	23 (18,8)	41 (33,61)	NS
Polyarthralgias	100 (82)	83 (68,03)	NS
Arthritis	56 (45.9)	81 (66,39)	0,0005

Conclusions: The frequency of rheumatological manifestations post Chikungunya fever in our sample was high, and can trigger ARC. Patients presenting new immunological manifestations in an endemic area for Chikungunya fever should have a serologic test performed. This series of patients must be evaluated with long-term studies to define their evolution, under the possibility of developing definite autoimmune disease or remission.

SAT0569 OUTCOME OF PATIENTS WITH SYSTEMIC RHEUMATIC DISEASES ADMITTED IN INTENSIVE CARE UNIT: A PROGNOSTIC STUDY OF 98 PATIENTS

A. Malézieux-Picard[1], H. Hivernat[2], N. Martis[1], J.-G. Fuzibet[1], G. Bernardin[2], V. Queyrel[1]. *[1]Internal medecine departement; [2]Intensive care unit, Centre Hospitalier Universitaire de Nice, Nice, France*

Background: Systemic rheumatic diseases (SRD) are a rare and heterogeneous group of diseases, associated with a high mortality rate due to the natural evolution of the disease and/or consequences of their specific treatments (infections, toxicity).
Objectives: To describe the clinical features, outcomes and prognostic factors for patients with SRD admitted to the intensive care unit (ICU).
Methods: Single-center retrospective observational cohort study of 98 patients with SRD over an 11-year period in an ICU of a French teaching hospital.
Results: Ninety-eight patients (57% women; median age, 57 years [19–81years]) accounted for 108 admissions. Connective tissue disease (primarily systemic lupus erythematosus) and systemic vasculitides (mainly ANCA-associated vasculitides) represented respectively 55% and 30% of SRD. For nineteen patients, diagnosis of SRD was made at admission. Reasons for admission were: SRD exacerbations (43%), isolated infections (34%), SRD exacerbations associated with infections (12%) or other (11%). Respiratory failure was the most common organ dysfunction. Mechanical ventilation was necessary for 43 patients (44%), vasoactive drugs for 47 (48%) and extra-renal replacement therapy for 38 (39%). The ICU mortality rate was 30% and 37% one year after admission. Infection was the main cause of death (69%). The factors significantly associated with mortality in the ICU were (multivariate analysis): diabetes, cardiovascular diseases and immunosuppressive treatments on admission. At 1 year of follow-up, additional risk factors were: number of organ dysfunction at ICU admission and mechanical ventilation. It is to be noted that at 1 year of follow-up, diabetes was not anymore a prognostic factor.
Conclusions: Patients with SRD admitted to the ICU have a severe prognosis. Causes of mortality are mainly infections. Our study points out the importance of vaccination and developing new therapeutic strategies. Diagnosis of SRD in the ICU is not rare and should be systematically considered on admission. Prognostic factors of mortality in the ICU were patient comorbidities and immunosuppressive

therapy at admission. In addition, mechanical ventilation and multiple organ failure were risk factors for mortality at 1 year.

SAT0570 AN IGNORED DISEASE IN ADULTS: ACUTE RHEUMATIC FEVER

B. Bitik[1], O. Kucuksahin[2], N. Karahan Yesil[1], H. Yesil[2], S. Erten[2].
[1]Rheumatology, Ankara Research and Education Hospital; [2]Rheumatology, Yildirim Beyazit University, Ankara, Turkey

Background: Acute rheumatic fever (ARF) is a delayed, inflammatory sequela of pharyngitis secondary to Group A Streptococcus infection. ARF remains one of the most important causes of cardiovascular morbidity and mortality in developing countries. Although it is mainly known as a childhood disease, it is also encountered in adult clinics in developing countries.
Objectives: To investigate the clinical and laboratory characteristics of patients who were diagnosed with ARF in two rheumatology outpatient clinics from June 2015 to January 2017.
Methods: The data of 20 patients (12 female; median age 29.5 (21–40) years) were evaluated. The diagnosis of ARF was based on the 2015 Jones criteria. The data collected included patient age, gender, arthralgia, arthritis, erythema marginatum (EM), subcutaneous nodules (SN), ECG/ Doppler transthoracic echocardiography findings, and other rare findings. The erythrocyte sedimentation rate (ESR), antistreptolysin O (ASO) and CRP levels of the patients and the drugs initiated were also recorded. Anti-streptolysin O (ASO) test or throat culture were used for the evidence of preceding Streptococcus infection. Patients with post-streptococcal reactive arthritis were differentiated and excluded by clinically. Patients with positive rheumatoid factor or ACPA were also excluded. Joint fluid examination was done to exclude septic arthritis in patients with monoarthritis.
Results: All patients were referred to rheumatology for arthralgia or arthritis. Patients were taking some sort of nonsteroidal antiinflammatory (NSAI) drugs before the referral. The median follow-up time was 9 months (0–18). Sixteen out of 20 patients had mono-, oligo- or poliarthritis (25%, 25% and 30%, respectively). Knees and ankles were the most common involved joints. The median duration of arthritis was 1 week (1–50 weeks). Six out 20 patients had subclinical carditis (30%). Nine out of 20 patients had a history of ARF attack previously. Three patients had chronic rheumatic mitral valve thickening without any severe insufficiency. EM and SN were observed in 15% and 60% of patients, respectively. Chorea was diagnosed in one patient. NSAI drugs were given to all patients with maximum dosages. High dose salicylate therapy were not given to patients due to intolerance or side effects. Nine patients were given prednisolone therapy (5–20 mg/d). The median duration of prednisolone therapy was 2 weeks (0–6 weeks). Sulfasalazine was given to two patients for the prolonged arthritis. All patients received secondary prophylaxis with penicillin.
Conclusions: ARF should be considered in the differential diagnosis of arthritis in young adults in developing countries. Arthritis of ARF in adults seems to be resistant to classical NSAI drugs. Our data show that steroid therapy can be given safely instead of salicylates in carditis or arthritis.

SAT0571 PERFORMING SEPTIC ARTHRITIS DIAGNOSIS IN SCENARIOS WHERE SYNOVIAL FLUID IS NOT AVAILABLE: MULTIVARIATE LOGISTIC REGRESSION ANALYSIS

C.A. Guillen-Astete[1], G.A. Gabilondo-Alvarez[2]. *[1]Rheumatology Department; [2]Microbiology, Ramon y Cajal University Hospital, Madrid, Spain*

Background: In order to establish the diagnosis of septic arthritis (SA) it is necessary to demonstrate the presence of bacteria into the synovial fluid. However, clinics should act according to its suspicious when the differential diagnosis included this possibility even when the microbiologic study of the synovial fluid in unavailable by any cause (small joints, lack of training or logistic deficiencies).
Objectives: The purpose of our study is to determine the relative weight of other clinical or analytical variables that should be useful in these scenarios.
Methods: A retrospective multivariate logistic regression analysis about the registries of monoarthritis assessed in our unit between 2013 and 2016. There were included only registries with cases of synovial joints with all parameters of interest available. The binary response variable was the microbiological demonstration of septic arthritis (culture/Gram stain of synovial fluid or tissue). Explanatory variables were age (stratified in <30, 30–39, 40–49, 50–59, 60–69 and >70 years old), gender, temperature above of 37.9ºC, recount of neutrophils in peripheral blood sample, measure of procalcitonine (PCT), and measure of C reactive protein (CRP). Synovial fluid study, although was available in almost all cases was deliberately omitted for purpose of this study. The logistic regression analysis used the forward model strategy.
Results: There were included 449 registries. One hundred an sisteen of them were SA. The fixed model showed a Chi-square=226.64 with 5 degrees of freedom and a P<0.0001. Explanatory variable gender was excluded from the forward model strategy due to its lack of impact on the binary response variable. The Odds Ratio for PCR, PCT >1.3 ng/dL, age, neutrofils recount and body temperature were 1.0175, 8.1588, 0.5135, 1.0001 and 3.4147, respectively. The model showed a sensibility of 68.1%, specificity of 94.8%, PPV of 82.2% and NPV of 89.5%. The following table shows the full results of the logistic regression analysis: Standard error, Wald index, p value and R coefficients.

Variable	Coefficient	E. E.	Chi2-Wald	G.F.	p-value
PCR	0.0174	0.0024	52.0092	1	<0.0001
PCT	2.0991	0.3407	37.9640	1	<0.0001
Age	-0.6665	0.1326	25.2763	1	<0.0001
Neutrophils recount	0.0001	0.0001	14.9630	1	0.0001
T>37.9	1.2281	0.3286	13.9674	1	0.0002
Constant	-3.7227	-	-	-	N.A.

Conclusions: Previous studies have demonstrated the usefulness of PCT measure for the diagnosis of SA however all of them have been based on joints which synovial fluid is quite easy to obtain for further analysis. Present study allows laying the ground for creation of future diagnostic models based on five clinical variables that could be useful on scenarios where the assessment by joint puncture is not available.

SAT0572 LEVELS OF SERUM PROCALCITONINE AS DIAGNOSIS DISCERNING TOOL BETWEEN GOUT AND SEPTIC ARTHRITIS

C.A. Guillen-Astete, M. Terán-Tinedo. *Rheumatology Department, Ramon y Cajal University Hospital, Madrid, Spain*

Background: In a previous study we demonstrated the potential usefulness of the procalcitonine serum measure in order to diagnose septic arthritis. This utility is quite important on the differential diagnosis of knee arthritis in patients with known gout or other inflammatory joint disease which can express as a monoarthritis.
Objectives: Due to that, this study aims to determine sensibility, specificity, positive predictor value and negative predictor value of procalcinonine sereum measure (PCT) in patients with knee arthritis for the diagnosis of septic arthritis.
Methods: We reviewed the registries of patients who consulted due to knee acute monoarthritis between 2013 and 2015 in which a PCT was obtained. Registries were grouped according to the final diagnosis (gouty arthritis only (group I) and septic arthritis with or without gout (group II). Based on a previous study, PCT value of 1.47ng/mL was considered the cut point. Validation tests were applied fixed to demographic and clinical specific scenarios.
Results: Registries of 121 patients with gout and 47 patients with septic arthritis (SA) were included. From the 47 patients with SA, 9 were previously diagnosed by gout. All diagnosed were based on guidelines and clinical recomendations for SA and gout (Coakley et al. Rheumatology, 2006 and Zhang et al. Ann Rheum Dis, 2006).
Using the cut point of 1.47 ng/mL, test validation results were as follows: sensibility of 87.2%, specificity of 92.5%, PPV of 82.0% and NPV of 94.9%. Excluding patients with less than 48 hours of onset, there were 44 registries of patients with SA and 83 with gout. In this scenario the results of the validation tests were as follows: Sensibility of 93.1%, specificity of 96.3%, PPV of 93.1% and NPV of 96.38%. Excluding all patients with body temperature above 37.5ºC there remained 11 with SA and 81 with gout. In this scenario the results of the validation tests were as follows: Sensibility of 72.7%, specificity of 95.1%, PPV of 66.6% and NPV of 96.2%.
Conclusions: This is the first study aimed to validate previous observations about the usefulness of PCT determination in patients with acute knee monoarthritis. Altough the global results in the validation test are a bit inferior that our original observations in a shorter pilot study in terms of sensibility, the NPV remains over 95% in scenarios where the differential diagnosis could be harder to establish such as recent onset flares or cases without an associated febrile syndrome.

SAT0573 SOCIODEMOGRAPHIC, CLINICAL CHARACTERISTICS AND JOINT INVOLVEMENT OF A CHIKUNGUNYA EPIDEMIC IN COLOMBIA

J.C. Rueda[1], J.-I. Angarita[1], A.M. Santos[1], E.-L. Saldarriaga[1], I. Pelaez-Ballestas[2], E. Couto-Luvie[1], J. Londono[3]. *[1]Reumatología, Universidad de la Sabana, Chia, Colombia; [2]Reumatología, Hospital General de México, México, Mexico; [3]Reumatología, Universidad de la Sabana-Hospital Militar Central, Bogotá, Colombia*

Background: During 2014 and 2015 a chikungunya epidemic took place in Colombia concurrently with a COPCORD study across the country.
Objectives: To describe the clinical characteristics of CHIKV infection in 6 different cities in Colombia and determine the most frequently associated clinical picture with CHIKV.
Methods: World Health Organization criteria was used to identify CHIKV patients. A complete characterization and confirmation was established with CHIKV immunoglobulin G and IgM serology. Four possible scenarios were stablished: patients who met or not the criteria for probable case, and patients who met or not the criteria for confirmed case. *P* values were calculated between patients who met or not met the criteria. Sensibility and specificity was calculated for the WHO criteria.
Results: A total of 604 patients with MSK symptoms were evaluated in 6 different cities. The sociodemographic, clinical characteristics and joint involvement of the studied population is depicted in tables 1 and 2. Sensibility and specificity of the WHO criteria were 56.2% and 91.1% respectively (PPV: 83.3%, NPV: 74.4%).

Table 1. Sociodemographic and Clinical Characteristics of Patients with Positive COPCORD

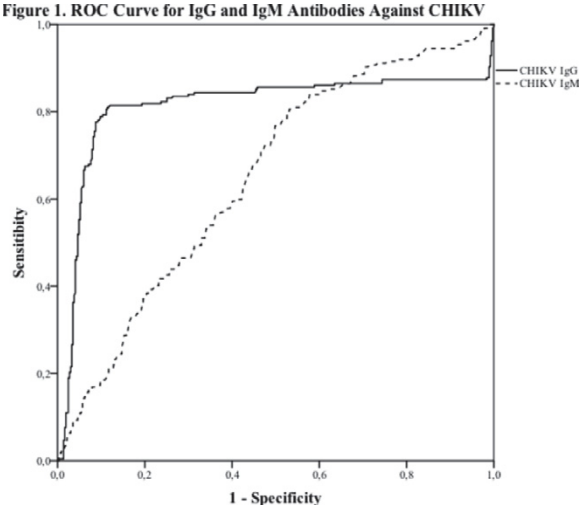
Fatigue (%)	165 (91,7)*	41 (9,7)	137 (91,3)*	69 (15,2)

*$p<0,005$.



Conclusions: Our study shows a clear clinical picture of systemic symptoms, high titters of CHIKV immunoglobulins, and a defined joint involvement, which will help clinicians to identify and differentiate CHIKV infection from other viral infections and MSK diseases. Also, the sensibility of the WHO criteria applied to our cohort of patients demonstrates the need to improve clinical criteria without the use of laboratory tests.

SAT0574 PERFORMANCE OF IMMUNOGLOBULIN M AND G (IGM AND IGG) ANTIBODIES AGAINST CHIKUNGUNYA VIRUS (CHIKV) BY ENZYME-LINKED IMMUNOSORBENT (ELISA) TECHNIQUE

J.C. Rueda[1], J.-I. Angarita[1], A.M. Santos[1], E.-L. Saldarriaga[1], I. Pelaez-Ballestas[2], P. López-Morales[1], J. Londono[3]. *[1]Reumatología, Universidad de la Sabana, Chia, Colombia; [2]Reumatología, Hospital General de México, México, Mexico; [3]Reumatología, Universidad de la Sabana-Hospital Militar Central, Bogotá, Colombia*

Background: CHIKV is suspected based on epidemiological and clinical criteria, however confirmation of the disease is only achieved by laboratory tests. Laboratory diagnosis is made by two approaches: the detection of viral RNA and identification of the specific immune response by serological methods. Serological tests are the most frequently used laboratory methods for the diagnosis of CHIKV. IgM is the first detected antibodies during 4 to 6 days after onset of symptoms followed by IgG. In Colombia, CHIKV's probable cases are not mandatory to be confirmed, so there is no standardization for laboratory confirmation tests
Objectives: To evaluate the performance of IgM and IgG antibodies against CHIKV in a cohort of patients with CHIKV
Methods: IgM and IgG antibodies against CHIKV were measured by ELISA (AbcamÒ ab177835 and ab177835 anti-chikungunya virus IgM and IgG human ELISA kit, Cambridge, UK) technique in 604 patients with CHIKV suspicion. A typical case of CHIKV with high sensitivity and specificity obtained from a previous study was used as gold standard for diagnosis of CHIKV. Since CHIKV epidemic of 2014–2015 was the first to be reported in our country (Colombia), no second measurements of IgG were needed to confirmed infection.
Results: Cut off point for IgG was 14,3 SU and for IgM was 11,2 SU. Mean values for IgG was 36,7 SU (±22,7) in patients with CHIKV and 8,6 SU (SD± 6,3) for IgM. Statistical significance was obtained for both IgG and IgM ($p<0,0001$) when comparing patients with and without CHIKV. Receiver operating characteristic (ROC) curves showed and area under the curve (AUC) of 0,81 for IgG and 0,65 for IgM (figure 1).

Figure 1. ROC Curve for IgG and IgM Antibodies Against CHIKV

Conclusions: Our study revealed a good performance of IgG and regular performance of IgM for the diagnosis of CHIKV in a cohort of CHIKV patients from Colombia's epidemic. Cut off points for both IgG and IgM were measured for future reference.

SAT0575 ASSOCIATION OF HUMAN LEUKOCYTE A, B AND DR ANTIGENS IN PATIENTS WITH CHIKUNGUNYA VIRUS INFECTION

J.C. Rueda[1], J.-I. Angarita[1], A.M. Santos[1], E.-L. Saldarriaga[1], I. Pelaez-Ballestas[2], B. Zaldivar-Castaño[1], J. Londono[3]. *[1]Reumatología, Universidad de la Sabana, Chia, Colombia; [2]Reumatología, Hospital General de México, México, Mexico; [3]Reumatología, Universidad de la Sabana-Hospital Militar Central, Bogotá, Colombia*

Background: Host factors like innate and adaptive immune response play an important part in disease susceptibility. Also, the role of host genetics factors in the pathogenesis of viral diseases have been reported. Human leukocyte antigen (HLA) is responsible for initiating innate and adaptive immune responses. Studies have demonstrated HLA class II alleles association to susceptibility or resistance to chikungunya virus infection (CHIKV), however there is no evidence of association studies of HLA class I and II in the Latin-American CHIKV epidemic.
Objectives: To evaluate the association of human leukocyte A, B and DR antigens in a group of Colombian patients with CHIKV.
Methods: Characterization of HLA allele A, B, and DR of 62 patients with confirmed CHIKV was compared with 100 unrelated healthy subjects as a control group. The comparison between the different allele frequencies in the patient group and the control population was performed using chi^2, with Bonferroni correction. A p value <0.05 was considered to be significant. The magnitude of associations was assessed using odds ratio (OR) and confidence intervals (CI) of 95%. To establish the homogeneity of the studied groups, the Hardy-Weinberg disequilibrium was used.
Results: Of the 62 patients studied 46 were female (74,2%). The mean age was 45,0 (SD±16,8) years. Most of the patients were from Barranquilla (64,5%; n: 40). Mean CHIKV immunoglobulin G (IgG) was 38,6 SU (SD±21,7), while IgM was 13,3 SU (SD±7,6). Also C reactive protein levels were high (mean: 14,7

mg/L; SD±8,4). Association alleles of HLA-A, and DR are depicted in table 1. No association was found with HLA-B alleles.

Table 1. Associated Alleles with CHIKV

	Patients	Control	Odds Ratio	CI	*p*	C*p*
Resistance						
*A*28*	0	11	0,0	0,0-INF	0,002	0,040
*A*29*	6	24	0,2	0,0–0,6	0,002	0,048
Susceptibility						
*A*68*	14	2	9,9	2,1–45,1	0,000	0,008
*DRB1*01*	21	5	6,4	2,3–17,9	0,000	0,001
*DRB1*04*	26	11	3,6	1,6–8,0	0,000	0,010
*DRB1*13*	24	8	4,6	1,9–11,1	0,000	0,004

CHIKV: chikungunya virus infection; CI: confidence interval 95%; C*p*: Bonferroni corrected *p* value.

Conclusions: Our study demonstrated the alleles *A*28* and *A*29* to be associated with resistance to CHIKV, and alleles *A*68*, *DRB1*01*, *DRB1*04* and *DRB1*13* to be associated with susceptibility to CHIKV. No association was found in any HLA-B alleles.

SAT0576 IMPROVED CLINICAL SCENARIO FOR CHIKUNGUNYA DIAGNOSIS

J.C. Rueda[1], J.-I. Angarita[1], A.M. Santos[1], E.-L. Saldarriaga[1], I. Pelaez-Ballestas[2], M.J. Soares-Santeugini[1], J. Londono[3]. *[1]Reumatología, Universidad de la Sabana, Chia, Colombia; [2]Reumatología, Hospital General de México, México, Mexico; [3]Reumatología, Universidad de la Sabana-Hospital Militar Central, Bogotá, Colombia*

Background: The World Health Organization (WHO) criteria for chikungunya virus infection (CHIKV) have a specificity of 91,1% with a low sensibility of 56,2%, which decreases the ability to detect patients with the infection. Because of this issue a group of rheumatology, epidemiology and bacteriology experts in diagnosing and treating CHIKV patients performed an agreement consensus on the clinical characteristics of CHIKV infection and proposed a set of clinical criteria. In order to test the performance of the new criteria and improve sensibility and specificity a clinical scenario was developed with the agreements from the expert panel and the clinical characteristics with higher odds ratios.

Objectives: To improve sensibility and specificity of a set of clinical criteria for the diagnosis CHIKV.

Methods: Odds ratios of the clinical features of patients with CHIKV infection were analysed. A clinical scenario was developed and sensitivity and specificity was calculated.

Results: 37 clinical characteristics were evaluated in a cohort of 604 patients with suspicion of CHIKV. From those, 29 exhibited statistical significance and only 10 had high odds ratios (table 1). A clinical scenario with the following joint involvement (symmetrical arthritis of shoulders or wrists or hands or knees or ankles or feet) or systemic symptoms (fever or rash or myalgia or fatigue) poised a sensitivity of 74,2% (PPV: 83,5%) and a specificity of 88,4% (NPV: 81,2%). The following clinical characteristics extracted from the agreements of the consensus group were added to the clinical picture: origin from an epidemic area and abrupt onset of symptoms.

Table 1. Clinical Characteristics with High Odds Ratios

	WHO Confirmed Case Criteria		Odds Ratio	CI (95%)	*p*
	Met Criteria (n: 150)	Did Not Met Criteria (n: 454)			
Symmetry (%)					
Arthritis	80 (53,3)	19 (4,2)	24,8	11,2–54,6	<0,0001
Arthritis (%)					
Wrists	16 (10,7)	5 (1,1)	22,2	3,6–204,1	<0,0001
Hands	42 (28,0)	8 (1,8)	36,7	8,8–152,6	<0,0001
Knees	20 (13,3)	5 (1,1)	10,0	2,8–33,8	<0,0001
Ankles	42 (28,0)	9 (2,0)	24,4	7,5–79,3	<0,0001
Feet	39 (26,0)	8 (1,8)	69,3	9,6–510,8	<0,0001
Myalgia (%)	106 (70,7)	59 (13,0)	13,0	8,1–20,7	<0,0001
Fatigue (%)	137 (91,3)	69 (15,2)	16,9	10,9–26,8	<0,0001
Fever (%)	150 (100)	30 (6,6)	13,1	8,4–20,5	<0,0001
Rash (%)	109 (72,7)	45 (9,9)	14,0	8,5–22,9	<0,0001

WHO: World Health Organization; CI: Confidence Interval.

Conclusions: Our study demonstrated that the proposed clinical scenario for suspicion of CHIKV improves diagnostic sensibility with a slight decrease in specificity, increasing the chance of diagnosis without the need for laboratory tests. We propose that a patient from an epidemic area (fulfilling epidemiological criteria according to the WHO) with an abrupt onset of a clinical picture of symmetrical arthritis of any of the following joints: hands, wrists, shoulders, knees or feet, or the presence of any of the following systemic symptoms: fever, rash, fatigue or myalgia, is more likely to have CHIKV infection.

SAT0577 MUSCULOSKELETAL MANIFESTATIONS OF TUBERCULOSIS: AN OBSERVATIONAL STUDY

N. Gupta[1], A. Bhatnagar[2]. *[1]Clinical Immunology & Rheumatology, CHRistian Medical College, VELLORE; [2]Pulmonology, Rajan Babu Tuberculosis Hospital, Delhi, India*

Background: Data of musculoskeletal manifestations of tuberculosis is limited to case reports, series or retrospective study. To our knowledge there is no prospective study which has addressed this issue. So, we conducted this study to create awareness among the doctors about musculoskeletal manifestations of tuberculosis.

Objectives: To study the musculoskeletal manifestations of tuberculosis.

Methods: It was a prospective observational study which was conducted at a referral Tuberculosis Hospital in North India in the month of September & October 2016. Patients from outpatient and inpatient department of pulmonology were recruited irrespective of the duration of anti tubercular therapy.

We included patients who had active tuberculosis as per World Health Organization (WHO) 2010 criteria. Patients with other chronic illnesses were excluded. A detailed history, examination and appropriate investigations (blood, urine, serological and radiological) of the 100 consecutive patients fulfilling the inclusion criteria was recorded

Results: Mean age of patients was 32.16±12.93 years. Male to female ratio was 43:57. Mean duration of disease was 6.85±8.83 months. Of the 100 patients, 60 (60%) had pulmonary tuberculosis. Pleural tuberculosis presenting as pleural effusion was seen in 17 (17%) patients. Abdominal tuberculosis was seen in 9 (9%), tuberculous lymphadenopathy in 8 (8%) and pott's spine in 4 (7%). Eye tuberculosis and tubercular breast lump was seen in 1 patient each.

83 (83%) patients had first episode of tuberculosis while the other 17 (17%) patients had second episode of tuberculosis. 74 (74%) patients were on category 1 anti tuberculosis treatment (ATT), while 23 (23%) were on category 2 ATT and 3 (3%) were on modified ATT. Mean duration of ATT was 1.79±1.34 months.

Fibromyalgia was classified in 21 (21%) patients, polyarthralgia's were seen in 9 (9%), pott's spine in 7 (7%), osteomyelitis in 4 (4%) and scleritis in 2 (2%) patients. Uveitis, tenosynovitis, erythema induratum, subcutaneous abscess and dactylitis was seen in 1 (1%) each. Rheumatological manifestations as septic arthritis, DILE, poncet's arthritis, tendinopathy, amyloidosis, gout, erythema nodosum and myositis were not seen in any patient.

In 21 patients who had fibromyalgia, 11 patients developed fibromyalgia with 2nd episode of tuberculosis amounting to 60.75% patients.

Conclusions: This is the first prospective study to look at the musculoskeletal manifestations of tuberculosis. Patients with active tuberculosis were found to have various rheumatological manifestations.

Acknowledgements: I acknowledge Dr Sushil Gupta, director of the Rajan Babu TB Hspital for allowing me to conduct this study

SAT0578 LEFLUNOMIDE INHIBITS THE APOPTOSIS OF HUMAN EMBRYONIC LUNG FIBROBLASTS INFECTED BY HUMAN CYTOMEGALOVIRUS

Q. Ren[1], H. Zeng[2]. *[1]Department of Pediatric Allergy, Immunology and Rheumatolog; [2]Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children's Medical Center, Guangzhou, China*

Background: The immunomodulatory drug leflunomide (LEF) is frequently used for treating human cytomegalovirus (HCMV), but its antiviral mechanism is still unclear.

Objectives: In this study,we therefore investigated the effects of the active LEF metabolite A771726 on the HCMV lifecycle in human embryonic lung fibroblasts. We clarified the mechanism of LEF antiviral infection, and provide a new way to treat immune dysfunction patients with HCMV infection.

Methods: The experiment was divided into four groups:the control group, the HCMV group, the ganciclovir + HCMV group as well as the LEF + HCMV group. MTT was usedfor assessmentof the cell inhibitory rate. Apoptosis was measured by staining with fluoresceinisothiocyanate Annexin V and propidium iodide. Statistical significance was determined by paired *t*-test using SPSS software.

Results: The results of the study showed that cell proliferation was significantly inhibited by HCMV at 24 hours and 48 hours. With increasing HCMV concentration, the value-added inhibition of the cells was significantly decreased compared with the control group, and was statistically significant ($P<0.01$). Ganciclovir can increase proliferation of cellsinfected with HCMV;compared with the control group it was statistically significant ($P<0.05$). Meanwhile,with LEF treatment cell proliferation was significantly improved at 24 hours and 48 hours, with statistical significance ($P<0.05$). The apoptosis rate of human embryonic lung fibroblasts infected with HCMV increased significantly at 24 hours, 48 hours and 72 hours,and as time goes on the apoptosis rate increases statistically significantly ($P<0.01$) compared with the control group The apoptosis rate of theHCMV infection group decreased by adding LEF,and was statistically significant ($P<0.05$).

Conclusions: In this studywe show that LEF is an exciting new drug for cytomegalovirus infection. LEF significantly inhibited HCMV infection-induced apoptosis and proliferation, playing an important role in the treatment of patients infected by HCMV. In this study we explored the potential usefulness of LEF for

cytomegalovirus infection and found it to be a cost-effective new treatment for cytomegalovirus infection that deserves further study.

SAT0579 LOW DOSE IL-2 RESTORES IMBALANCE BETWEEN TH17 AND REGULATORY T CELLS IN PATIENTS WITH CONNECTIVE DISEASE COMBINED EBV/CMV VIREMIA

Q. Wang, C. Wang. *Rheumatology, The second hospital of Shanxi medical university, TaiYuan, China*

Background: DMARDs are the most important medicine in treatment of autoimmune disease. However, excessive using DMARDs lead to decrease immune-function, which increasing opportunistic infection, such as EBV, CMV viremia. Recent study show the imbalance between T help cell 17 (Th17) and regulatory T cell (Treg cell) is a pivotal cause of autoimmune disease and correction of this imbalance to be a potential therapy. So whether low dose IL-2 restores the balance of Th17/Treg and improve immune function?
Objectives: To investigate the effect of low-dose IL-2 on Treg and effector lymphocyte subsets in patients with connective tissue disease (CTD) combined EBV or CMV viremia.
Methods: Clinical records of 70 CTD patients combined EBV or CMV viremia, hospitalized from May 2012 to January 2017 in the second Hospital of ShanXi medical university (Group infection), were analyzed. The group includes 21 patients who received rhIL-2 after infected CMV or EBV, and 12 continue receiving DMARDs. As control, we selected 70 health persons (Group health) whose age matched with group infection, 70 naïve CTD patients with no treatment (Group treatment-naïve), and 70 CTD without viremia patients having glucocorticoid and DMARDS medical history (Group Treatment-DMARDS). The two groups' underlying diseases are matched with the Group infection. The absolute numbers and proportions of peripheral lymphocytes (T cells, B cells, NK cells, the total number of the three cells, CD4+ T cells, CD8+ T cells), and CD4+ T cell subsets (Th1, Th2, Th17, Treg cells and Th1/Th2, Th17/Treg) were examined by flow cytometry.
Results: 1. The absolute count of Treg cells in the Group treatment-naïve was significantly low and Th17/Treg was notable increase compared with the Group health ($P<0.05$). The peripheral lymphocytes and Treg cells are notable low ($P<0.05$) and Th17/Treg was significantly increase ($P<0.05$) in the Group treatment-DMARDs compared with the Group treatment-naïve.
2. The peripheral lymphocytes, CD4+T cells subsets except Treg cells and Th1/Th2, Th17/Treg are significantly decrease in the Group infection compared with the Group treatment-DMARDs ($P<0.05$). While the absolute count of Treg cell was no different between the two groups.
3. After the course of rhIL-2 treatment, there were significantly increase of the peripheral lymphocytes and CD4+T cells subsets ($P<0.01$). Th17/Treg was significantly low after treatment. Compared with the patients who continue receiving DMARDs, all lymphocytes subsets had a rising trend in patients receiving rhIL-2 treatment.
Conclusions: The decrease of Treg cell number and imbalance of Th17/Treg may contribute to the pathogenesis of CTD. Excessive using glucocorticoid and DMARDs may augment this imbalance. On the other hand, these medicines decrease immune function, which leads to EBV and CMV viremia. Over the treatment of rhIL-2, immune function was improved and there was a more significant increase in the absolute count of Treg cells than Th17, and a consequently restore the balance of Th17/Treg.

SAT0580 OSTEOARTICULAR TUBERCULOSIS: A RETROSPECTIVE STUDY OF 119 CASES

R. Sonia, S. Boussaid, I. Abdelkafi, S. Hela, C. Ilhem, E. Mohamed. *Rheumatology, la Rabta, Tunis, Tunisia*

Background: Bone and joint involvement in tuberculosis is uncommon. Wile osteoarticular tuberculosis most commonly occurs in the vertebral column, less frequently affected sites are the hip, knee and sacroiliac joints. The multifocal form of skeletal tuberculosis is exceptional.
Objectives: To evaluate the clinical and diagnostic features of osteoarticular tuberculosis.
Methods: We reviewed the files of all patients admitted to our department from 2000 to 2015 with a diagnosis of osteoarticular tuberculosis.
Results: We identified 119 patients (52 men, 67 female), having osteoarticular tuberculosis lesions. Mean age was 43 years [21–82]. Diagnosis delay was 4 months. Pain, low-grade fever and loss of weight were the most common presenting symptoms. All the patients consulted because of pain. The spine was involved in 81 patients. Peripheral osteoarticular tuberculosis was diagnostic in 38 cases, mainly in the knee (21 cases). Five patients have a multifocal involvement of the osteoarticular tuberculosis. The tuberculin skin test was positive in 75% of the cases. The diagnosis of spondylodiscitis was provided by CT-scan and /or magnetic resonance imaging. Paraspinal and epidural abscesses has been reported in 11 cases. Bacteriological and /or pathological diagnosis was made in 72 cases (60.5%). The Quantiferon test was done in 7 cases and was positive. The antibiotic treatment led to recovery in all cases. Tree patients have presented neurological signs.
Conclusions: Our results were similar to those of the literature. Elderly population was especially at risk. The idiagnosis can be delayed espacially in negative investigations. Therefore it is recommendable to do a very large screening tests especially in endemic areas.

SAT0581 NON-TUBERCULOUS MYCOBACTERIAL (NTM) INFECTION IN PATIENTS WITH RHEUMATIC DISEASES: POSSIBLE IMPORTANCE OF PULMONARY BARRIER FUNCTION RATHER THAN SYSTEMIC IMMUNE STATE IN THE DEVELOPMENT AND EXACERBATION OF NTM INFECTION

S. Takenaka[1], H. Kameda[1], T. Ogura[1], H. Oshima[2], K. Izumi[3], A. Hirata[1], H. Ito[1], Y. Fujisawa[1] on behalf of Department of Connective Tissue Diseases, National Tokyo Medical Center. *[1]Rheumatorogy, Toho University Ohashi Medical Center; [2]Rheumatorogy, Department of Connective Tissue Diseases, National Tokyo Medical Center; [3]Rheumatorogy, Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan*

Objectives: To identify the risk factors of the development and exacerbation of NTM infection in patients with rheumatic diseases.
Methods: Among 7013 patients with rheumatic diseases visiting Toho University Ohashi Medical Center and Tokyo Medical Center, 20 patients were enrolled in this study by fulfilling the diagnostic criteria of NTM infection by The Japanese Society for Tuberculosis and The Japanese Respiratory Society, and being followed-up for more than 1 year. The medical records of enrolled patients were retrospectively reviewed.
Results: Eleven patients with rheumatoid arthritis, 4 patients with vasculitis, 3 patients with Sjögren's syndrome and 1 patient with dermatomyositis and systemic lupus erythematosus for each were enrolled in this study. *Mycobacterium avium* complex (MAC) was detected in 13 patients, *M. chelonae* in 2 patients, *M. abscessus* and *M.kansasii* in 1 patient each, and undetermined mycobacterium in 3 patients. Notably, bronchiectasis was the predominant pulmonary complication observed in 13 patients, and interstitial lung disease was observed in 5 patients. Although 7 patients experienced the exacerbation of NTM during the observation period, immunological state on NTM diagnosis including peripheral blood leukocyte (median 5.8×10^3 versus $7.0\times10^3/\mu L$; p=0.72), lymphocyte (median 1.3×10^3 versus $1.1\times10^3/\mu L$; p=0.10) and the serum IgG level (median 1379 mg/dL versus 1207 mg/dL; p=0.20) were within normal ranges and comparable between ever and never exacerbated patients, respectively, as well as the treatments for rheumatic diseases such as glucocorticoids and biological agents.
Conclusions: NTM infection in patients with rheumatic diseases develops based on the dysfunction of pulmonary barrier rather than the systemic immunosuppression.

SAT0582 CHAGAS' DISEASE IN PATIENTS WITH AUTOIMMUNE DISEASES RECEIVING IMMUNOSUPPRESSIVE THERAPY. ANALYSIS OF 48 CASES

S. Retamozo[1,2], M.J. Haye Salinas[2], A. Alvarellos[2], V. Saurit[2], F. Caeiro[2], J.P. Caeiro[3], V. Carballo[4], M. Medeot[4], O. Salomone[5], R. Albertini[6], F. Merschon[7], F. Bonisconti[8], A. Sanchez[8], T. Alvarellos[8]. *[1]INICSA, CONICET; [2]Rheumatology; [3]Infectious Diseases, Hospital Privado Universitario de Córdoba; [4]Infectious Diseases, Hospital Raúl A Ferreyra; [5]Cardiology, Hospital Privado Universitario de Córdoba; [6]Internal Medicine, Hospital Privado Universitario; [7]Cátedra de Física Biomédica, Secretaria de Ciencia y Tecnología (SECyT), Universidad Nacional de Córdoba; [8]Molecular Biology, Hospital Privado Universitario de Córdoba, Cordoba, Argentina*

Objectives: To analyze the main features at diagnosis and Chagas' Disease (CD) reactivation in patients with autoimmune diseases (AD) receiving immunosuppressive therapy (IT).
Methods: 13 patients with AD diagnosed with CD admitted to our Units between January to December 2016. In addition, we performed a systematic analysis of cases reported to date through a MEDLINE search. Inclusion criteria 1) adults with AD treat with iT (glucocorticoids [GC], disease-modifying anti rheumatic drugs [DMARDs] and biological drugs [BD]); 2) had confirmed or were positive for 2 serological test for CD. Reviews, experimental studies, duplicate publications, and abstracts were excluded.
Results: A total of 48 patients (13 from our Units and 35 from the literature search) fulfilled the inclusion criteria. There were 41 (85.4%) women, mean age of

43.8 years (range: 17–80). The main underlying disease was SLE in 22 (45.8%). Previous/current treatment at time CD diagnosis included GC >40mg/day in 27/48 (56.3%), DMARDs in 32/48 (66.7%) and 7 patients had previously received DB. CD was reactivated in 36 (75%) cases (mean 40.9 months [range: 0–252]) with the following patterns: high *T. cruzi* load by quantitative real-time polymerase chain reaction (qRTPCR) in 23 (63.8%) from which 20 (86.9%) had no clinical manifestation and 3 (13%) had panniculitis, the remaining 11 patients (30.5%) had positive XD with one of them had myositis, only one patient (2.7%) had fever. After a mean follow-up of 47 (range: 1–120) months, 4 patients with SLE died (8.3%), all had received GC>40mg/day, 3 had CD reactivation and all died due to SLE flare. No statistical differences were found with respect to CD diagnosis, use of GC, DMARDs, BD; in contrast, patients who had CD reactivation on therapy with GC >40mg/day showed higher cardiac involvement (83.3% vs 43.5%, p=0.03 OR 6.50 CI95% 1.15–36.57) where the time of immunosuppression in this group was lower in those who died median 0.53 (IQR 0.46–0.53) vs 3.00 (IQR 1.26–78.00) months, p=0.04. Patients with SLE and CD reactivation showed a higher risk of death (18.8% vs 0.0%, p=0.04, OR: 1.23, CI95% 0.97–1.57). Survival rate of the entire cohort was 91.5%. The poorest survival rates were observed in who had CD reactivation (log rank p=0.037).

Conclusions: Reactivation was presented mainly as high *T. cruzi* load by qRTPCR without clinical manifestation of CD. Use GC>40mg/day showed a higher risk of CD reactivation with cardiac involvement. Considering this data it's reasonable to screen serologic and molecular tests before to start treatment with immunosuppressive drugs.

Back pain, mechanical musculoskeletal problems, local soft tissue disorders

SAT0583 LATERAL EPICONDYLITIS: WHAT IS NEW? DIAGNOSTIC, IMAGING AND TREATMENT. A SYSTEMATIC LITERATURE REVIEW

A. Pieren[1], M. Dougados[2], P. Le Goux[3], M. Lavielle[2], C. Roux[2], A. Moltó[2]. *[1]Rheumatology, Hospital Ia Paz, Madrid, Spain; [2]Rheumatology B., Hôpital Cochin; [3]Rheumatology, Hôpital Ambroise-Paré., Paris, France*

Background: Lateral epicondylitis or tennis elbow is an extremely frequent disease, secondary to intratendinous degeneration of the common carpi extensor tendon. However, diagnosis and therapeutic management are still a challenge for the rheumatologist.

Objectives: To determine the available evidence regarding the diagnostic, imaging and treatment of epicondylitis.

Methods: A systematic review literature was performed.using PUBMED. Only controlled trials, systematic literature reviews and meta-analysis were selected (Jan 1990 to May 2016). The MESH search words were " Tennis elbow "," Lateral elbow tendinopathy ", " Diagnostic imaging" and" Therapeutics ".

Results: 1314 potential articles were screened; 7 articles of clinical diagnosis, 21 of imaging and 18 of treatment were finally selected.

Diagnostic: No controlled trials were found about the diagnosis of the epicondylitis. The clinical tests employed in the retrieved clinical trials were based upon the experts' recommendation: lateral epicondyle palpation, resisted extension of the carpe and resisted extension of the 3rd and 4th fingers.

Imaging: Among the 21 articles identified, 1 article concerning plain Xray, 1 about scintigraphy, 10 of US and 10 of MRI were selected. One clinical trial, found plain Xrays were not helpful for the initial diagnosis. Ultrasound was found to be a sensitive (64–100%) and specific (36–100%) tool for the diagnosis, in one meta-analysis. Ten studies, within a systematic review, showed MRI was reported to be as sensitive (90–100%) as the ultrasound, with a greater specificity (83–100%). In addition, MRI showed better reliability (0.41–0.53 vs 0.73–1.00). Also, the two techniques showed a good correlation between the observed lesions and symptoms, severity and involvement of other structures. On the contrary, no data was found to support the use of imaging tests for follow-up.

Treatment: Among the 18 articles, 9 articles (within 4 systematic review and 5 randomized clinical trials) about pharmacological treatment, 10 about the non-pharmacologic approach and 1 about surgery were selected. Corticoids injections were found to be effective in one meta-analysis at short-term and preferably for acute epicondylitis (Pain reduction at 1–3 weeks =1.18 (95% CI 0.27–2.09), 4–8 =1.30 (95% CI 0.55–2.04), 12–24 =-0.38 (95% CI -0.85–0.08). Similar results were found for NSAIDs. Five prospective randomized clinical trials, showed braces and carpal extension splints were reported to improve pain at rest and during exercice, in short term. Physical therapy was reported to be efficacious in pain and function too, in a systematic review. Therapies like rich platelet plasma injections, autologous serum and botulinim toxin showed weak evidence.

Conclusions: No high quality trials for epicondylitis management were found in this systematic review. The diagnostic was based upon clinical presentation and physical exam. Ultrasounds and MRI seem to play a role on imaging diagnosis but not in follow-up. Corticoids injections and NSAIDs are effective in short term. Other studies are needed to evaluate other therapeutic modalities.

SAT0584 THE ROLE OF MRI INTERPRETATION IN PATIENTS WITH ROTATOR CUFF DISEASE

S. Albina[1], A.-M. Ramazan[2], E.V. Ionescu[3], M.G. Iliescu[3]. *[1]Rehabilition Clinic, Clinical Hospital of Rehabilitation Eforie Nord; [2]Rheumatology, Emergency County Clinical Hospital "Sf Apostol Andrei"; [3]Faculty of Medicine, Ovidius University, Constanta, Romania*

Background: Shoulder pain is a common musculoskeletal complaint, roughly equal in incidence to neck pain (1). The shoulder pain syndrome has a prevalence to 47% in general population (2) and an incidence to 87–100.000 persons per year, an increasing indicator in the latest years (3). The identified etiology of painful shoulder were: rotator cuff tendinopathies (85%), impingement syndrome (74%), acromioclavicular joint involvement (24%), adhesive capsulitis (15%) si radiated pain (7%) (4). MRI imaging of rotator cuff disease, features of impingement are the techniques of choice at most institutions (5,6).

For all physicians, the shoulder is a complex joint, with difficulty in clinical and MRI examination. The type of therapy (medical, physical or surgical) can be estabilished according with MRI conclusion, but sometimes this was a debate between physicians.

Objectives: To assess the concordance between two radiologists in interpretation of the same shoulder MRI in patients with rotator cuff disease.

Methods: Our prospective observational study included 51 patients (median age 57±9.9 years, 70.6% female) with nontraumatic shoulder pain. The assessment had included a clinical examination of the shoulder for inclusion criterias, lab tests for exclusion an inflammatory diseases and shoulder MRI with purpose to pathological diagnose of cuff rotator disease. Two experienced radiologists independently, blindly and retrospectively interpreted the MRI images. One of the radiologist had more MRI trainnings and do daily musculoskeletal MRI images. We have analized the each MRI changes, as rotator cuff tendinopathies (tendinitis, tendinosis, tears), bicipital tendinopathy and other changes (subacromial bursitis, impingement syndrome, retractile capsulitis). Statistical analysis was performed using SPSS-18 and a p-value <0.05 was considered for statistical significance.

Results: There was identified a statistically significant difference between readers. There was a poor to moderate concordance (Cohen's Kappa$<$0,40, p$<$0.05) between MRI interpretations for supraspinos tendinopathy, subacromial bursitis, capsulitis, but a good agreement between for subscapular tendinosis (accuracy=98%, Kappa=0,79, p=0.000) and perfect compatibility (accuracy=100%, Kappa=1, p=0,000) for terres minor tendinitis. The poorest concordance between readers was in impingement syndrome (compatibility=55%, kappa=0,11, p$>$0,05).

Conclusions: The MRI examination is significant in rotator cuff disease only when the radiologist is overtrained for shoulder, otherwise the technique is unuseful and doubtful in clinical practice.

SAT0585 IS IT SAFE TO PERFORM JOINT PUNCTURES IN PATIENTS TREATED WITH DABIGATRAN?

C.A. Guillen-Astete, J.R. Quiñones-Torres. *Rheumatology Department, Ramon y Cajal University Hospital, Madrid, Spain*

Background: The introduction of new oral anticoagulants provides us with a new therapeutic intervention and secondary prevention opportunity in stroke patients previously not well controlled with acenocumarol due to not compliance or other issues.

As with other anticoagulants or even antiplatelet agents, the attending doctor may hesitate to perform a joint puncture in patients receiving such treatments.

Objectives: The purpose of this study is to describe the four-year cumulative experience of joint and peri-articular punctures in patients receiving Dabigatran, a new oral anticoagulant recently introduced in our country.

Methods: We performed a systematic review of the records of patients who underwent a knee joint aspiration or periarticular shoulder joint puncture for diagnostic or therapeutic purposes and who were under treatment with dabigatran between the years 2012 and 2016.

For this purpose we conducted an search for electronic records within that period, using the search terms: "infiltration", "arthrocentesis" or "joint puncture" and "shoulder" or "knee" and "dabigatran" or it's brand names.

Follow up visits in either primary care (HORUS® Application) or emergency settings (CAJAL® Application) were analyzed, regardless of the main complain at admission, and the data was collected from this records.

Results: Between 2012 and 2016, 68 joint knee punctures and 49 periarticular shoulder punctures were performed in dabigatran patients. Of the 117 procedures, 78 (66.6%) were performed by attending physicians in Traumatology, Rheumatology or Physical Medicine and Rehabilitation, and the rest by internal medicine residents.

Of the 68 knee arthrocentesis, in 48 (70.5%) of the cases synovial fluid collection and infiltration were performed, while in the rest only infiltration was needed.

Of the 49 shoulder punctures, in 12 (24.4%) a bursocentesis was performed while in the rest only an infiltration was done.

16 knee and 17 shoulder punctures (23.5% and 34.6%) were ultrasound assisted procedures.

Among the patients with knee puncture, 11 (16.1%) came back before 15 days due to procedure related symptoms. Of these, 9 did so because of persistence of the main symptom or persistent pain and 2 because of increased pain. These two patients were studied sonographically and one of them had a hemarthrosis that was treated conservatively.

In the group of patients with shoulder puncture, 7 (14.2%) came back before the first 15 days and in all of them the cause was persistence of the main symptom. None of the patients required admission at the hospital. None of the patients with ecography-assisted procedures came back before the first 15 days.

No patient consulted due to bleeding after the first fifteen days. (There were no hemarthrosis cases after the fists 15 days). The outcome of the procedure was not influenced by the person performing it (attending vs resident), however, all the echocardiographic procedures were performed by an attending.

Conclusions: Although it is a small population, this is to the best of our knowledge, the biggest published serie of dabigatran anticoagulated patients who underwent a large joint or periarticular puncture. We can conclude that this type of punctures are safe in patients with this characteristics. On the other hand, there is evidence that ecography-assisted procedures are more effective in this group of patients.

SAT0586 RELATIONSHIP BETWEEN CORE STABILIZATION AND LOW BACK PAIN IN YOUNG PEOPLE

E. Mete[1], V. Akduman[1], I. Demirbuken[1], G. Ogren[2]. *[1]Physiotherapy and Rehabilitation; [2]Nutrition and Dietetic, Marmara University, maltepe, Turkey*

Background: Low Back Pain (LBP) is a very common health problem that affects people of all ages. It has been observed that the increase in lumbar stabilization is effective in reducing back pain risk. A combination of local and global stability system is used to describe to core stability which is a key factor for enhancing lumbar stabilization. Exercise training focused on these groups of muscles could contribute to pain alleviation and spinal functional improvement.

Objectives: The aim of the study was to define relationship between core stabilization and low back pain in young people who were suffering from low back pain.

Methods: 290 individuals (144 male, 146 female), between 18 and 25 years of age were included in this study. Disability arising from low back pain was identified by using the Oswestry disability index, consisting of 10 questions with 6 choices (0–5 points for each question). The higher score is associated with more low back pain. The period of core stabilization was determined using Plank test in which the body is stand flat from shoulder to heels on foot and forearm and Side Plank test in which sitting on the forearm and standing on one side of the body with the legs parallel and the feet perpendicular and the body is held flat from the shoulder to the heels. The duration of ability to maintain Plank test was measured by a chronometer. Spearman correlation test used for statistical analyzing.

Results: In this study, the average of Plank test duration was 76.9±44.2 (sec), while the mean of the Side Plank test duration was 43.9±28.2 (sec) and Oswestry disability index total score was 6.3±5.5. A weak negative correlation was found between the Plank test and the Oswestry disability index (p=0,03; r =-0,111). And negatively correlated between the Side Plank and the Oswestry disability index (p>0.05). On the other hand, there was a positively modarate correlation between the Plank test and the Side Plank test (p=0,00; r =0,656). There was a weak negative correlation between age and Oswestry disability index (p=0,014; r =- 0,151).

Conclusions: Results of the study indicated that increasing the duration of stabilization reduces the low back pain. For this reason, core muscles deserve a great deal of interest in order to reduce the problem of low back pain which is common among young population.

SAT0587 SCHOOL BAGS WEIGHT ARE NOT ASSOCIATED WITH LOW BACK PAIN IN SCHOOLCHILDREN IN CAMEROON

F. Kemta Lekpa, M.S. Doualla, H. Namme Luma. *Service de Médecine Interne, Douala General Hospital, Douala, Cameroon*

Background: Data are mixed on the role of school bags in the occurrence of low back pain in pupils.

Objectives: Thus, we carried out this study with the aim to determine if the school bags were a factor associated with low back pain in Cameroonian schoolchildren.

Methods: We performed a cross-sectional study between December 2015 and April 2016 in 10 primary schools of the city of Douala, Cameroon. A questionnaire was submitted to the students of these different schools. Informed and signed consent of their parents were obtained. Sociodemographic and clinical data were collected, as well as the weight of each school bags. A p<0.05 was significant.

Results: We included 1075 pupils (543 boys, 532 girls). The mean age was 11±1 years (8–16 years). BMI was normal in 928 children (86.5%). The prevalence of low back pain was 12.3% (132 children: 81 girls and 51 boys). Sixteen children had already met a physician for low back pain.

The mean weight of the school bag was 4.9±1.9 kg, with 369 children (57.7%) with a school bags weight ≥15% of their body weight in private schools compared with 56 (12.9%) in public schools. We had 99 children with low back pain with a school bag weight ≥10% of their body weight (Table 1). We didn't find any relationship between low back pain and the weight of the school bag, regardless of gender, BMI, age of pain, type of school, distance from home to school, way of transportation, and age (p>0.05). However, the exception was found in girls aged from 8 to 10 years with a school bag weight >15% of their body weight (p=0.05). Furthermore, in univariate analysis, factors associated with low back pain were (p<0.05): age, history of low back pain in at least one parent, competitive sport, a bad seated position on school benches. In multivariate analysis, factors associated with low back pain were female, competitive sport, and low back pain in at least one parent (Table 2).

Table 1. Relationship between weight of school bag and body weight of pupils with low back pain (n=132)

Weight of the school bag in relation to the weight of the child	Number of pupils, n (%)	*p*
<5%	3 (5,5)	–
5–10%	30 (11,7)	0,09
10–15%	46 (13,6)	0,10
>15%	53 (12,5)	0,19

Table 2. Factors associated with low back pain in children

Variable	OR	95% CI	*p*
Age	0.93	0.81–1,06	*0.25*
Sex	1.73	1.19–2,52	*0.004*
Competitive sport	1.61	1.03–2.53	*0.038*
Low back pain in parents	1.88	1.23–2.89	*0.004*

Conclusions: The weight of the school bags was not associated with low back pain in Cameroonian schoolchildren (except for girls aged from 8 to 10). However, female, competitive sport and low back pain in at least one parent were associated to low back pain.

SAT0588 HEALTHCARE WORKERS ARE NOT MORE AT RISK TO LOW BACK PAIN THAN OTHER OCCUPATIONS

F. Kemta Lekpa, M.S. Doualla, H.B. Ngahane Mbatchou, A.S. Mkoh, H. Namme Luma. *Service de Médecine Interne, Douala General Hospital, Douala, Cameroon*

Background: Low back pain is common among healthcare workers but is it more frequent than in other occupations?

Objectives: In order to answer this question, we carried out this study with the aim of determining if healthcare workers was more at risk for low back pain in the same institution than non-healthcare workers, administrative and technical workers.

Methods: We performed a survey on all permanent workers (n=584) of the Douala General Hospital in Cameroon from January to May 2016. Socio-demographic characteristics of workers (distinction with different occupations – healthcare workers, administrative workers, technical workers) and the main features of low back pain were collected. A p<0.05 was significant.

Results: Of the 584 questionnaires distributed, 474 responses were obtained (81.1%). We excluded 27 for incomplete data. 447 were retained for the final analysis: 296 healthcare workers, 79 administrative workers, and 72 technical workers. The mean age was 40±10 years [22–66 years] and 258 (57.7%) were female. Mean BMI was 27±4.3 kg/m^2 with 103 (23%) obese.

At the end of the study, 252 (56.4%) workers described low back pain, including 170 (57.4%) healthcare workers, 44 (55.7) administrative workers and 38 (52.7) technical workers. There was no significant difference between the different groups (p>0.05). Same for sex (p=0.9). The overall independent risk factors associated with low back pain were: seniority in their current position (OR 4.97, 95% CI 1.80–13.68, p=0.002), office chair quality (OR 3.06, 95% CI 1.29–7.26,

Table 1. Risk factors for low back pain according to occupational class

Risk factors	Healthcare workers OR (95% CI)	Administrative workers OR (95% CI)	Technical workers OR (95% CI)
Age (years)	1.00 (0.98–1.03)	1.10 (1.04–1.16)***	1.04 (1.01–1.09)
Sex ratio	1.15 (0.71–1.84)	1.99 (0.55–7.24)	0.84 (0.28–2.54)
Seniority in the firm	1.42 (0.76–2.64)	0.95 (0.24–3.83)	5 (1.4–17.83)**
Seniority in their current position	3.5 (1.2–10.6)*	1.04 (0.35- 3.12)	11.3 (1.1–112.1)*
Number of hours worked per week	0.76 (0.26–2.21)	10.07 (1.02–99.69)*	–
Office chair quality	3.3 (1.1–10.4)*	5.97 (1.16–30.63)*	10 (0.6–164.9)
Heavy weight	1.10 (0.62–1.97)	2.27 (0.52–9.84)	4.2 (1.3–13.3)**
Vibrations	1.23 (0.67–2.27)	10.30 (0.81–130.73)	3.6 (1.2–10.6)**
Job satisfaction	0.35 (0.14–0.89)*	0.74 (0.10–5.58)	0.66 (0.17–2.53)

*p<0.05; **p<0.01; ***p<0.001.

p=0.01), and job satisfaction (OR 1.55, 95% CI 105–2.54, p=0.048). The specific risk factors for each occupation are presented in Table 1.

Conclusions: In an institution like Douala General Hospital, where the administrative, technical and healthcare workers are subjected to the same professional stress in terms of quality of care and performance, we did not find any difference on prevalence among these 3 occupations.

Preventive measures must be performed for all staff but need to be tailored to each occupation.

SAT0589 THERAPEUTIC EDUCATION IN THE MANAGEMENT OF FEARS AND BELIEFS IN PATIENTS WITH CHRONIC LOW BACK PAIN

R. Maaoui[1], A. Khezami[1], I. Ksibi[1], I. Lajnef[1], H. Rahali[1], R. Dhahri[2], I. Gharsallah[2], L. Metoui[2], F. Lajili[2], S. Othmani[2]. *[1]Physical and Rehabilitation Medicine; [2]Internal Medicine, military hospital Tunis, tunis, Tunisia*

Background: The notions of apprehension-avoidance and beliefs are among the psychosocial factors associated with the occurrence, maintenance and strengthening of the chronic painful process.

Therapeutic education is increasingly described in the literature as a means to manage these factors in order to limit the transition to a chronic stage.

Objectives: The aim of this study is to examine the effect of therapeutic education on fears and beliefs in chronic low back pain.

Methods: A prospective, comparative study was conducted with two groups of 50 patients each one having chronic low back pain. Both groups had benefited from the same physical rehabilitation program. The second group concurrently attended therapeutic education sessions.

Fears and beliefs of patients and their kinesiophobia were evaluated with the FABQ: Fear-Avoidance beliefs questionnaire and the TSK: Tampa scale of kinesiophobia for the evaluation of kinesiophobia index.

Results: The initial evaluation of apprehension-avoidance showed a high FABQ score in two groups. Management that was limited to physical rehabilitation demonstrated no effect on the apprehension-avoidance indices evaluated by the FABQ scale. However, there was a clear improvement in apprehension and avoidance in the G2 and with a statically significant difference (P=0.03).

An initial and high kinesiophobic score (≥48) was noted in two groups. G1 patients showed no significant improvement in their TSK scores after the end of the program. G2 patients who benefited from a therapeutic education workshop improved their TSK scores significantly after the program completion compared to G2.

Conclusions: The integration of the patient into the therapeutic education workshops improved the behavior of apprehension and kinesiophobia. This further supports the usefulness of applying cognitive therapy to our patients when restructuring of preconceived ideas about movement and physical activities.

SAT0590 FEARS AND BELIEFS IN PATIENTS WITH CHRONIC LOW BACK PAIN AND SICK LEAVE: WHAT RELATIONSHIP?

R. Maaoui[1,1], A. Khezami[1], I. Ksibi[1], I. Lajnef[1], H. Rahali[1], R. Dhahri[2], I. Gharsallah[2], L. Metoui[2], B. Louzir[2], F. Lajili[2], S. Othmani[2]. *[1]Physical and Rehabilitation Medicine; [2]Internal Medicine, military hospital Tunis, tunis, Tunisia*

Background: The occupational impact of low back pain is generally assessed in terms of absenteeism and duration of sick leave. A non-return to work greater than eight days has been considered a poor prognosis factor. Several psychosocial factors have been identified as the original cause.

Objectives: Studying the impact of erroneous beliefs, avoidance behaviors, apprehension and fear of movement on sick leave in patients with chronic low back pain.

Methods: A prospective study was conducted in patients with chronic low back pain patients. The notion of apprehension-avoidance was evaluated by the Fear Avoidance Beliefs questionnaire (FABQ), fear of movement by the Tampa scale of kinesiophobia (TSK) and functional disability by the Functional Disability Scale Of low back pain: EIFFEL (French version of Roland Disability Questionnaire).

A study of the correlations between these different parameters and the duration of sick leave was carried out subsequently.

Results: Our study included 100 patients. The findings revealed a 95% absenteeism rate including 67% with a sick leave of more than one month. The FABQ, TSK and EIFFEIL scores were high.

The statistical study concluded that there was a positive and significant correlation between sick leave time, fears and erroneous beliefs (r =0.147, P=0.033). We also found a positive and significant correlation between the duration of sick leave and kinesiophobia. There were no statistically significant correlations between sick leave and functional disability.

Conclusions: The high scores of FABQ and TSK confirm the important role of false beliefs and fear of movement in the genesis of chronicity in chronic low back pain as reported in the literature. The positive correlations found in our study reinforce the theory of the deconditioning of these patients following their beliefs. Management of these factors would be an important contribution to limit sick leave times in chronic low back pain.

SAT0591 LOCAL STEROID INJECTION VERSUS WRIST SPLINTING FOR CARPAL TUNNEL SYNDROME: A RANDOMIZED CLINICAL TRIAL

H. So[1], V. Chung[2], J. Cheng[3], M.L. Yip[4]. *[1]Medicine and Geriatric, Kwong Wah Hospital, Kowloon; [2]Faculty of Medicine, The Chinese University of Hong Kong, New Territories; [3]Department of Occupational Therapy, Kwong Wah Hospital; [4]Integrated Diagnostic and Medical Centre, Tung Wah Groups of Hospitals, Kowloon, Hong Kong*

Background: Carpal tunnel syndrome (CTS) can lead to significant symptoms and loss of hand function. It also has a great socio-economic impact. However, there is no consensus regarding its best treatment up to this moment. Local steroid injection and wrist splinting are among the most popular nonsurgical treatment options. Previous studies have confirmed their respective effectiveness. However, there is no high quality head to head comparative study regarding the two treatments in the literature.

Objectives: To compare the efficacy of local steroid injection and nocturnal wrist spiniting for CTS.

Methods: We conducted a prospective randomised parallel clinical trial comparing the efficacy of local steroid injection and nocturnal wrist splinting in patients with CTS. The well validated and disease specific Boston Carpal Tunnel Questionnaire (BCTQ) was employed and its score at 4 weeks after treatment was used as the primary outcome measure. Important secondary outcomes included the patient satisfaction, the change of an objective finger dexterity test 9-hole-peg test, and the side effects.

Results: Twenty-five patients in the local steroid group and 25 patients in the wrist splinting group completed the study procedures. The baseline patient and clinical characteristics of the two treatment groups were similar. At 4 weeks after treatment, there was significant improvement of the BTCQ scores in both the steroid group and splinting group. There was improvement of the 9-hole-peg test only in the steroid group but not in the splinting group. However, there was no statistically significant difference in the changes of BTCQ scores between the two groups after treatment. Patient satisfaction score was higher in the steroid group. Patient in the steroid group took less painkillers after treatment. Four patients developed side effects after splinting and 3 after local steroid injection, which was not statistically significant.

Conclusions: Although local steroid injection and nocturnal wrist splinting were equally effective in the treatment of patients with CTS, only the former improved objective hand function. Local steroid injection also resulted in better patient satisfaction and less painkiller use without causing more side effects.

SAT0592 EFFECT OF INTERFERENTIAL CURRENT THERAPY IN PATIENTS WITH SUBACROMIAL IMPINGEMENT SYNDROME: A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY

T. Nazligul, P. Akpinar, I. Aktas, F. Unlu Ozkan, H. Cagliyan. *Department of Physical Medicine and Rehabilitation, Fatih Sultan Mehmet Education and Research Hospital, Istanbul, Turkey*

Background: Shoulder pain is one of the most common types of musculoskeletal pain in the adult population. Subacromial impingement syndrome (SIS) has been reported to be the most frequent etiologic factor for shoulder pain (1). A conservative approach comprising non-steroid anti-inflammatory drugs (NSAID), subacromial injections, exercise, and several physical therapy agents is recommended as the first step treatment for SIS (2). Although interferential current (IFC) is a common electrotherapeutic modality used to treat musculoskeletal pain, there isn't any randomized controlled trial investigating its clinical efficacy on SIS (3).
Objectives: To investigate the effectiveness of IFC treatment in patients with SIS.
Methods: In this double blind, placebo controlled study, patients with shoulder pain, who had been diagnosed SIS according to clinical evaluation and subacromial injection test were randomly assigned to the IFC or placebo groups. Exercise, cryotherapy, and NSAID were applied to the all groups. Daily 20 min per session, 5 days per week, for 2 weeks 10 sessions IFC with alternative method were applied to the IFC group while sham IFC therapy were applied to the placebo group with the same protocol. Visual analog scale (VAS), Constant Murley Scale (CMS) and Shoulder Disability Questionnaire (SDQ) were used for evaluation at baseline, post-treatment and 1 month post-treatment.
Results: A total of 60 patients were completed the study; 26 (43.3%) were male and mean age was 50.02±9.10 years. There was not a significant difference in demographic and clinical data of the patients between the IFC (n=30) and placebo (n=30) groups ($p>0.05$). Significant improvement in all parameters was observed on post-treatment and 1 month post-treatment evaluations compared to baseline evaluations in both groups ($p<0.01$). Comparison of the VAS, CMS and SDQ scores between the two groups did not show significant difference either pre-treatment or post-treatment ($p>0.05$).
Conclusions: This study showed that IFC treatment does not provide additional benefit to NSAID, cryotherapy and exercise program in the treatment of SIS. Further studies are needed to investigate the long-term effects of IFC therapy.

SAT0593 GENDER-SPECIFIC ASSOCIATIONS BETWEEN FAT MASS AND MUSCULOSKELETAL PAIN IN COMMUNITY RESIDENTS: A 3-YEAR LONGITUDINAL STUDY

K.M. Son[1], N.H. Cho[2], S.H. Lim[2], H.A. Kim[3]. *[1]Department of rheumatology., Hallym University Dongtan Sacred Heart Hospital; [2]Ajou University school of Medicine; [3]Hallym University Sacred Heart Hospital, Gyeonggi-Do, Korea, Republic Of*

Background: Increase in fat mass is correlated with musculoskeletal pain
Objectives: In this study, we sought to delineate the prospective relationship between fat mass parameters and the musculoskeletal pain in Korean community residents.
Methods: In the Korean Health and Genome Study, 1,325 participants (mean age 60.2 years, 56.2% women) who completed pain questionnaires and underwent dual x-ray absorptiometry to calculate body composition had 3 year follow-up data on pain. Pain was categorized according to number of pain regions. After 3 years of follow-up, subjects were classified into the followings: 1) no pain both at baseline and at 3 years (no pain), 2) any pain (one, two or more, or widespread regions) at baseline and no pain at 3 years (transient pain), 3) no pain at baseline and any pain at 3 years (new pain) 4) any pain both at baseline and at 3 years (persistent pain). 1) and 2) were grouped as no/transient pain group (no pain) and 3) and 4) as new/persistent pain group (pain)
Results: Female gender and obesity were 2 significant factors associated with the persistence or development of pain. Total fat mass and fat:muscle mass ratio were significantly correlated with pain, and the odds ratios for pain were significantly increased in subjects in the highest quartile of fat muscle ratio after adjustment among female subjects only. Among normal weight subjects, those without metabolic syndrome were less likely to belong to the pain group, especially among women.
Conclusions: The association of fat mass and pain was only significant among females
Disclosure of Interest: None declared

SAT0594 THE EFFECT OF RADİAL EXTRACORPOREAL SHOCK WAVE THERAPY (RESWT) İN THE TREATMENT OF TRİGGER FİNGER

M. Dogru[1], S. Narin[1], M. Erduran[2]. *[1]Department of Physiotherapy and Rehabilitation, Institute of Healty Science; [2]Department of Orthopedics and Traumatology, Faculty of Medicine, Izmir, Turkey*

Background: Trigger finger is a stenotic tendovaginitis characterized by hand pain and dysfunction, commonly encountered and easily recognizable (1). RESWT is frequently used in the treatment of soft tissue pathologies such as lateral epicondylitis, plantar fasciitis and calcific rotator cuff tendinitis (2–3). However, there is no study examining whether RESWT is effective on the trigger finger or not.
Objectives: The aim of this study was to investigate the effect of Radial Extracorporeal Shock Wave Therapy (RESWT) in the Treatment of Trigger Finger.
Methods: This study was carried out on 16 patients (18 patient hand) who had been diagnosed with trigger finger that grade 1,2,3 according to quinnel classification. Patients were carried out as a single group. 16 patients (18 patient hand) with trigger fingers were applied to ten-sessions,twice a week of RESWT (2000 impulses, 2 bar, 10 Hz). Pain scores (Numeric Pain Rating Scale - NRS), general funtional capasities (The Disabilities of the Arm, Shoulder and Hand Score (Quick-DASH)), range of motion, grip strength (GS) and pinch strenght (PS) were assessed at every week for five weeks during treatment and 3 months after treatment.
Results: 13 female and 3 male patients over 18 years of age were evaluated. In the evaluations performed every week during 10 sessions of RESWT treatment and 3 months after treatment, decrease in pain levels and increase in general functional capacity, range of motion, grip strength and pinch strength were observed in the patients treated ($p<0.001$) (tablo 1).

Tablo 1: Comparison of range of motion of the thump finger and 2-5. Finger , comparison of pain, grip streght, pinch streght and general functional capacity

	1.week (IQR)	2.week (IQR)	3.week (IQR)	4.week (IQR)	5.week (IQR)	3.month (IQR)	p value

SAT0595 EFFECTIVENESS OF SHORT WAVE DIATHERMY TREATMENT IN PATIENTS WITH SUBACROMIAL IMPINGEMENT SYNDROME AND VALUE OF NIGHT PAIN ON PATIENT SELECTION: A DOUBLE-BLIND, RANDOMIZED, PLACEBO-CONTROLLED TRIAL

M. Yilmaz Kaysin[1], P. Akpinar[1], I. Aktas[1], F. Unlu Ozkan[1], D. Karamanlioglu[2], H. Harteviogl u[1], N. Vural[1]. *[1]Department of Physical Medicine and Rehabilitation, Istanbul Fatih Sultan Mehmet Training and Research Hospital; [2]Department of Physical Medicine and Rehabilitation, Sultanbeyli State Hospital, Istanbul, Turkey*

Background: Shoulder impingement syndrome (SIS) is a common causes of shoulder pain and the night pain is a frequent symptom of this condition (1,2). Short wave diathermy (SWD) is a deep diathermic agents used in the treatment of

musculoskeletal system disorders. Local inflammation could be the major cause of night pain, and using a deep diathermic modality might be contradictory.
Objectives: Investigation of the effectiveness of short wave diathermy SWD treatment in patient with SIS and to emphasize the significance of night pain (NP) status on treatment response.
Methods: In this double-blind, randomized placebo controlled trial, 57 patients aged between 35 to 65 years, diagnosed as SIS were classified into two groups as night pain positive NP(+) (n=28) and night pain negative NP(-) (n=29). Both groups were randomly assigned to SWD treatment NP(+) n=14, NP(-) n=14 and sham NP(+) n=15, NP (-) n=14 subgroups. Exercise, cold pack application and a non-steroidal anti-inflammatory drug treatment were applied to all groups. 27.12 MHz continuous SWD (daily 20 min per session, 5 days per week, for 2 weeks, 10 sessions) was applied to the treatment groups while sham SWD was applied to the sham groups with the same protocol. Rest, activity and night visual analog scale (VAS), Constant (Murley) Score (CS) and Shoulder Disability Questionnaire (SDQ) were used for evaluation of patients at 2 weeks before the treatment, 1 month and 2 months after the treatment.
Results: There were no statistical differences between the SWD treatment and sham groups in all outcome parameters except for the Constant pain scores in NP (+) group. In NP(-) group, SWD treatment improved the parameters of pain, strength, total scores of CS, and SDQ compared to sham group at 1 month. SWD treatment was superior to sham for all parameters except for the Constant daily living activity scores at 2 months.
Conclusions: In conclusion, addition of 27.12 MHz continuous SWD treatment to conventional therapies provides long term benefits when compared to sham SWD in terms of rest and activity VAS scores, Constant-Murley scores, and SDQ scores in SIS patients without night pain. However, there was no convincing evidence that SWD treatment is of additional benefit in SIS patients with NP. Therefore; night pain as a symptom should be regarded in the selection of treatment modalities in order to use the deep heaters effectively in the management of SIS.

SAT0596 EFFICACY OF EPIDURAL STEROID INJECTION IN LUMBAR SPINAL STENOSIS IS NOT RELATED TO THE DEGREE OF SEVERITY BY MRI

E.S. Elsayad[1], M.A. Mortada[1], T. Abd El Samad Elhawala[2], E.S.A. Abd El Hady[3], A. Hijab[4]. *[1]Rheumatology & Rehabilitation; [2]Orthopaedic Surgery, Zagazig University, Zagazig; [3]Rheumatology & Rehabilitation, El Mataria Hospital, Cairo; [4]Anesthesia, Zagazig University, Zagazig, Egypt*

Background: Lumbar spinal stenosis (LSS) is a common degenerative disease. Treatment modalities for LSS vary and include medication, exercise, interventional techniques, and surgery. Epidural steroid injection has been used for the treatment of LSS with variable results. The relationship between severity of lumbar spinal stenosis and efficacy of lumbar epidural steroid injection is still undetermined.
Objectives: The aim of our study was to determine the relationship between the severity of LSS using MRI grading system and the response to lumbar epidural steroid injection.
Methods: Thirty patients with degenerative LSS were enrolled in this prospective study. All subjects underwent lumbar spine MRI (T2-weighted axial images). LSS was graded using MRI grading system (grade 1 = mild stenosis with separation of all cauda equine; grade 2 = moderate stenosis with some cauda equine aggregated; grade 3 = severe stenosis with none of the cauda equine separated). All fluoroscopy guided transforaminal epidural steroid injections (FG- TFESI) were performed in the procedure room. Outcome measures were obtained using the visual analogue scale (VAS) for both back and leg pain, Oswestry disability index (ODI), Roland 5-point pain scale, walking tolerance and patient's satisfaction scale at 2 and 8 weeks post-treatment.
Results: Thirty LSS patients treated with FG- TFESI, who were completely followed up, were included in this study, the injection rate was one injection per patient. The patients were followed at 2 weeks and 8 weeks. Fifty-six percent of patients at 2 weeks and 70%% at 8 weeks had a successful outcome, reporting at least a >50% reduction between pre-injection and post-injection visual analogue pain scores.Roland 5 point pain scale showed pain reduction in 50% of patients by (26%) at 2 weeks and in 70% of patients by50%pain reduction at 8 weeks. Oswestry low back pain disability questionnaire (ODI) scores showed statistically significant improvement from initial scores to 2 weeks and from to 8 weeks in 70% of patients. Walking tolerance showed improvement at 2 weeks in 50% of patients and at 8 weeks in 70% of patients. The outcome was statistically significant even in severe stenotic patients when comparing initial scores of moderate and severe stenosis at 2 weeks and 8 weeks scores in walking tolerance (P=0.006), Back VAS (P=0.717), Leg VAS (P=0.139), ODI (0.139), and Roland (P=0.001).
Conclusions: FG-LESI may reduce pain and improve walking tolerance in the short term for the treatment of patients with LSS for a period of 8 weeks. The outcome does not seem to correlate with the degree of lumbar spinal stenosis. Patients with severe LSS may have the same chance to get benefits from FG-LESI as patients with moderate LSS.

SAT0597 RELATIONSHIP BETWEEN LUMBAR DISC HERNIATION AND BENIGN JOINT HYPERMOBILITY SYNDROME

M.R. Albeer[1], F.K. Abd alrazaq[2], M.H. Alosami[3]. *[1]Radiology, College of Medine of Baghdad; [2]Medicine, Baghdad Teaching Hospital; [3]Medicine, College of Medicine of Baghdad, BAGHDAD, Iraq*

Background: Benign joint hypermobility syndrome (BJHS) can present with a wide variety of musculoskeletal disorders.Benign joint hypermobility syndrome (BJHS) is a hereditary disorder characterized by the presence of musculoskeletal symptoms in persons with generalized joint laxity in the absence of systemic rheumatologic disease (1–3). Lumbar disc herniation (LDH) is a common cause of low back pain. On the other hand, low back pain may be a presenting symptom in patients with BJHS.
Objectives: to evaluate relationship between Lumbar disc herniation and BJHS.
Methods: The study included 100 patients diagnosed with LDH depending on history, clinical examination and MRI findings and another 100 healthy control participants. All, patients and healthy controls were assessed for BJHS using the revised (Brighton 1998) criteria.
Results: the mean age was (35.4±8.9) year and (33.72±8.3) for patients and controls respectively, there were 43 males and 57 females in each group. The mean BMI was (27.6±4.8) kg/m^2 in patients and (28.3±4.6) in controls. No significant differences found between the groups regarding the age, sex and BMI in all comparisons (P.value>0.05). The mean Beighton score was significantly higher among patients in comparison to controls; itwas (2.3±1.62) versus (1.2±1.35) in controls group; on the other hand major and minor criteria were significantly more prevalent among patients rather than controls, in all comparisons (P.value<0.05). BJHS was more prevalent among patients rather than controls, 55% of the patients had BJHS compared to 21% of controls, the odds ratio was (4.6) and (P.value <0.05). BJHS was more prevalent among females compared to males, from the total number of all participants, BJHS was present in 76 participants, and of them 47 were females versus 29 males, (P.value <0.05).
It had been significantly found that subjects with BJHS in both groups (patients and controls) were relatively shorter than those without BJHS, P.value <0.05. The correlation analysis of BJHS with the MRI findings of LDH in patients group showed no significant differences among patients with and without BJHS, in all comparisons P.value >0.05.
Conclusions: BJHS is more prevalent among patients with LDH. There is no significant relationship between presence of BJHS in LDH patients and MRI findings.

SAT0598 EVALUATION OF THE QUALITY OF SEXUAL LIFE DURING CHRONIC LOW BACK PAIN

I. Haddada[1], M. Brahem[1], H. Hachfi[1], S. Ben Hammouda[1], M. Maraoui[1], M. Jguirim[2], M. Younes[1]. *[1]Rheumatology, Taher Sfar Hospital Mahdia, mahdia; [2]Rheumatology, Fattouma Bourguiba Hospital Monastir, Monastir, Tunisia*

Background: Sexual life has an important role in preserving the good quality of life of patients and their partners. Chronic low back pain (CLBP) as well as other musculoskeletal diseases, can affect all life activities including sexual function.
Objectives: The aim of this study is to assess the impact of chronic low back pain on sexual life and to identify the associated factors.
Methods: It's a study of 144 patients suffering from chronic low back pain, during a period of nine months (from February to October 2016).We have specifically studied the relationship between chronic low back pain and sexual quality of life, using the Sexual Quotient (QS) (a validated questionnaire), which consists in 10 questions, rated each one from 0 to 10, to have a final score rated from 0 to 100.
Results: The average age of our patients was 53.87years [23–79 years], with a female predominance in 64% of cases. The mean visual analogue scale for pain was 4.72 [1–9].
The average duration of low back pain was 6.5 years. The average score of Quebec was 45.3 [5–92], concerning the mean Dallas score,the segmental results were as follows: 53.1% of impact on daily activities, 47.6% of impact on work/leisure ratio, 45% of impact on anxiety/depression ratio and 33.4% of impact on sociability.
In our study, 57.2% of cases were under analgesic treatment, 85.5% were under

non-steroidal anti-inflammatory drugs, 20% had at least one local corticosteroid infiltration, 34% had functional rehabilitation and 4, 1% had surgical treatment.
Regarding sexual dysfunction, 34.5% of our patients didn't have any sexual activity, 2.1% had a catastrophic sexual life (score <20), 9% had a disappointing sexual life (score between 20 and 40), 20% had an average sexual life (score between 40 and 60), 17.9% had a satisfying sexual life (score between 60 and 80), while only 13.1% had a very fulfilling sexual life (score between 80 and 100. we showed that the alteration of the sexual quotient in our patients is more marked when the age of the patients is more advanced. But we didn't found a significant correlation with the duration of the disease, the mean visual analogue scale for pain and the functional scores of Quebec and Dallas.
Conclusions: Our study suggests that sexuality is profoundly disrupted in chronic low back pain. The advanced age is proved to be correlated with the deterioration of the sexual life. So, sexuality must be taken into account in the management of patients with chronic low back pain.

SAT0599 LOW BACK PAIN IN MEDICAL STUDENTS LINKED TO POOR SLEEP QUALITY: RESULTS FROM THE PAX-I STUDY

N.R. Ziade[1,2], F. Fayad[1], B. Badra[3]. [1]*Rheumatology, Hotel Dieu de France;* [2]*Rheumatology;* [3]*Medicine, St-Joseph University, Beirut, Lebanon*

Background: Low Back Pain (LBP) is a major public health problem and is classified by the Global Burden of Disease Study among the ten diseases most responsible for Disability-Adjusted Life Years worldwide. All ages may be affected, mostly young adults, with a prevalence going up to 50%. Medical students may be particularly vulnerable due to sedentary lifestyle and high stress levels.
Objectives: The primary objective is to evaluate the prevalence of LBP in Lebanese medical students. The secondary objective is to identify predictive factors associated with LBP and to identify prevalence and components of inflammatory back pain (IBP).
Methods: PAX-I is a cross-sectional study, completed at the St-Joseph University of Beirut from April to June 2016. All students from the first to the sixth year of medicine were invited to fill a questionnaire about their demographic data, lifestyle habits, Patient Health Questionnaire for Depression and Anxiety (PHQ4) and LBP characteristics, including components of IBP as per ASAS criteria. Student test and ANOVA were used for quantitative variables, chi-square test was used for qualitative variables and logistic regression was used for predictive factors for low back pain. Analysis were performed on IBM SPSS Statistics 23.
Results: Response rate was 51.3% (258/502). Mean age was 20.86 years (SD 1.92). 54.3% were female, 76.7% drank caffeine, 66.3% had a regular sports activity and 9.7% were smokers. 38% had the habit of walking while studying. All habits were similar across years of studying except for sports activities which decreased over the years (p 0.018). 80% were satisfied with their studies. Only 46% were satisfied with their quality of sleep. Mean PHQ4 score was 7.17 and increased with the years of studies (p 0.045).
55.8% of students reported a LBP event during the past year, with a mean number of 3.6 episodes per year. 91% of these students had LBP while studying, with high reported intensity (5.18/10), 62.5% reported LBP after exercise. 80% had episodes of less than one month and 7% of more than three months duration. 12% had IBP according to the ASAS criteria (Details of IBP in Figure 1). Predictive factors for LBP in univariate analysis were: smoking (p 0.040), alcohol consumption (p 0.005), caffeine consumption (p 0.041), television watching (p 0.042) –positive association-, and number of hours of sleep (p 0.011) and satisfaction with sleep quality–negative association- (p 0.017). Satisfaction with sleep quality remained the only significant association in multivariate analysis (p 0.014).

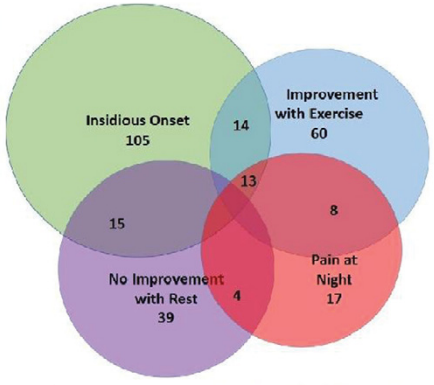

Figure 1. Components of Inflammatory Back Pain according to the ASAS criteria.

Conclusions: LBP is a frequent problem among medical students with high intensity, especially when studying, and a high recurrence rate. The main predictive factor was poor satisfaction with sleep quality. A significant percentage fulfills IBP criteria by auto-questionnaire and should benefit from further investigation.

SAT0600 USEFULNESS OF VERTEBROPLASTY IN VERTEBRAL FRACTURES WITH PERSISTANT BACK PAIN. A REPORT OF 64 VERTEBRAL AUGMENTATION FROM A UNIVERSITY HOSPITAL

O. Fernandez-Berrizbeitia[1], M. González-de-Garay-Sanzo[2], A. López-Medina[2], M. García-Vivar[1], E. Ruíz-Lucea[1], I. Torre-Salaberri[1], A. Intxaurbe-Pellejero[1], J. Blanco-Madrigal[1], E. Guerrero-Basterretxea[1], I. Calvo-Zorrilla[1], O. Ibarguengoitia-Barrena[1], C. Pérez-Velásquez[1], L. Estopiñán-Fortea[1], C. Gómez-Arango[1], N. Rivera-García[1], M. Allande-López-Linares[1], A. Bilbao-González[3], E. Galíndez-Aguirregoikoa[1]. [1]*Rheumatology;* [2]*Radiodiagnostic;* [3]*Research, Basurto University Hospital, Bilbao, Spain*

Background: Management options for patients with persistent back pain after a vertebral fracture include vertebral augmentation, but its use is controversial.
Objectives: Our iam was to evaluate the fracture cause, efficacy and complications of consecutive vertebroplasties performed in our Hospital in a 12 years period.
Methods: Retrospective study of vertebroplasties performed at a University Hospital in the last 12 years (April 2004 to April 2016). The duration of follow-up was more than 12 months. Epidemiological variables, indications, time elapsed, efficacy and complications of the procedure were collected. The indication of vertebroplasties in fractures was pain refractory to usual symptomatic treatment in these pathologies: osteoporosis, trauma, leukemia/lymphoma, metastasis and hemangioma. Efficacy was assessed at 6 and 12 months with a simple verbal scale according to the pain response (improvement/non-improvement). Patients who died before 12 months period were excluded for the that parameter. A comparative study of the efficacy between a)cause of fracture, b)location, c)time elapsed, d)access route and e)complication was performed. For the descriptive analysis we used frequencies and percentages in the case of qualitative variables, and mean and standard deviation (SD) or median and interquartile range for quantitative variables. Chi-square test or Fisher's exact test was used in for qualitative variables, and Wilcoxon's non-parametric test for evolution time. Statistic analysis was performed with the SAS System for Windows V 9.2.
Results: 66 vertebroplasties were performed in 44 patients (75% female/25%

Lack of improvement	26 (40.63)/14 (24.56)

male). Their mean age was 70.63±10.60 years (range, 46–96 years). The description of the causes of fracture, its level, the access route and the cement leaks are expressed in TABLE. The median time from fracture to vertebroplasty was 3 months [1–6]. 78% of the fractures were osteoporotic and had a better response to pain at 6 months than all other fractures ($p<0.05$), although at 12 months there were no differences ($p=0.42$). Only 12.5% had refracture. Pain control and vertebral refracture did not differ between neither the access rout nor the cement leakage and its magnitude. In the 12-month follow-up, 7 patients died (6 due to neoplasia, 1 due to sudden death) and no case was related to vertebroplasty.

Conclusions: In our experience vertebroplasty has been shown to be an effective technique for the control of refractory pain in vertebral fractures regardless of cause and time of evolution. Likewise, only 12.5% presented refracture in the following 12 months to the procedure. According to our study we can consider vertebroplasty as an effective and safe alternative in this type of patients.

SAT0601 TREATMENT OF CARPAL TUNNEL SYNDROME (CTS) WITH ESWT: A SHAM CONTROLLED DOUBLE BLINDED RANDOMISED STUDY

Ö. Karataş[1], S. Catal[2], E.A. Gökmen[3], N. Samanci[4]. *[1]Physical Medicine and Rehabilitation, Korkuteli Public Hospital; [2]Physical Medicine and Rehabilitation, Akdeniz University School of Medicine; [3]Physical Medicine and Rehabilitation, Antalya Training and Research Hospita; [4]Physical Medicine and Rehabilitation, Akdeniz University School of Medicine, Antalya, Turkey*

Background: The carpal tunnel syndrome (CTS) is the most common neuropathy (1). The etiology isn't properly known, but CTS is produced by the chronic compression of median nerve while passing through carpal canal can be associated with this disease (2).

Objectives: The aim of this study was to investigate the efficiency of extracorporeal shockwave therapy (ESWT) in the treatment of CTS.

Methods: 49 hand with the diagnosis of CTS were included in the study. Patients were randomised in ESWT (n=29 hands) and sham (n=20 hands) groups. Patients were randomly allocated to receive 1 session per week for 3 weeks of either sham or active ESWT. All patients were prescribed with tendon and nerve gliding exercises and hand-wrist splint which used night. Patients were evaluated before the treatment, and at the end of the first week, first month and third month after the last ESWT treatment session with Boston Scale (symptom severity and functional capacity), Visual Analogue Scale (VAS) for pain and paresthesia assessment, for muscle strength hand gross grasp and electroneurophysiological parameters.

Results: A total of 38 patients completed the study with 29 wrists in active ESWT and 20 wrists in sham ESWT groups. Groups were similar in age, sex, duration of symptoms, hand gross grasp and electrodiagnostic parameters ($P>0.05$). In both groups, significant improvements were observed in VAS, Boston Scale and hand gross grasp after treatment. In both groups, there was no statistically significant improvement in electromyographic variables after treatment ($p>0.05$). However there was no significiant differrence between two groups in all of clinical and electrodiagnostic parameters.

Conclusions: Although ESWT was effective in symptoms in CTS but this efficacy isn't superior to placebo. Our results indicated that ESWT was effective in pain and clinical variables in CTS. Wider and high-quality studies are needed to further demonstrate the effectiveness of ESWT in treatment of CTS.

SAT0602 MANAGEMENT OF EPICONDYLITIS WITH SINGLE LOCAL INJECTION OF SODIUM HYALURONATE

R. Petrella, A. Cogliano, A. Decruze. *Western University, London, Canada*

Background: Lateral elbow epicondylitis, also known as tennis elbow, is a common musculoskeletal condition causing pain and functional impairment in daily activities.[1] It affects between 40–50% of recreational tennis players at some time.[2] Sodium Hyaluronate (SH) is a natural biological substance which has proven to be effective to improve pain and function in osteoarthritic patients with low incidence of side effects.[3] Similarly, the administration of periarticular injections of SH can be an alternative approach to treat chronic epicondylitis.[4]

Objectives: To evaluate the efficacy and safety of a single periarticular injection with SH in the treatment of epicondylitis.

Methods: A single-site, and placebo-controlled trial was conducted in patients with chronic epicondylitis. Patients' condition was assessed at baseline and afterwards they were randomized 1:1 to receive a single 2.5ml injection of SH (manufactured by Tedec Meiji Farma SA) or placebo (saline) at the point of maximal pain at the lateral epicondyle. Additionally, standard of care (RICE: Rest, Ice, Compression and Elevation) was prescribed to both groups. Efficacy assessments were done at days 30 and 90 and included VAS (0–10cm) pain at rest and assessment of grip strength, patient global satisfaction, patient assessment of normal function and physician global assessment of elbow injury (all measured using 5-point categorical scale). Adverse events were recorded for safety purposes.

Results: A total of 60 patients were included and completed the study procedures. Both groups were homogeneous at baseline. A statistically significant reduction from baseline in VAS pain at rest and after grip testing was observed at 30 and 90 days in both treatment groups ($p<0.05$). Besides, inter-group comparison showed statistically significant differences in favour of SH group at 30 and 90 days ($p<0.05$). This was associated with significantly greater grip strength, patient global satisfaction and assessment of normal elbow function in SH group vs placebo ($p<0.05$). Improvement of elbow injury assessed by the physician was also statistically greater in patients treated with SH compared to placebo ($p<0.05$). No adverse events were recorded.

Conclusions: A single local injection of SH administered to patients with epicondylitis was significantly superior to placebo improving pain at rest and after grip testing, through all the study follow up period. The treatment was highly satisfactory for both physicians and patients and there were no safety concerns.

SAT0603 AN INNOVATIVE TREATMENT MODALITY FOR ACUTE ILIO-TIBIAL BAND SYNDROME IN RUNNERS: LOCAL HYALURONATE + BOTULINUM TOXIN IN A PROSPECTIVE COHORT OF 45 ATHLETES

R. Petrella, A. Decruze, J. Decaria. *Western University, London, Canada*

Background: Iliotibial band syndrome (ITBS) is the most common cause of lateral knee pain in runners[1]. It is an overuse injury that results from repetitive friction of the iliotibial band (ITB) over the lateral femoral epicondyle. Initial treatment includes activity modification, nonsteroidal anti-inflammatory medication, taping, stretching exercise and in severe cases, a corticosteroid injection[2]. Treatment of symptoms and return to activity are variable and can be intractable.

Objectives: To evaluate the efficacy and safety on pain and return to activity of a single, local injection of ITBS with combination hyaluronate and Botulinum toxin in 45 runners.

Methods: 45 runners with at least grade 2 ITBS underwent baseline investigations including pain following symptom-limited treadmill running test during which pain was recorded on a visual analogue scale (VAS 0–10) every minute. Runners then had injection in the area where the iliotibial band crosses the lateral femoral condyle with 2.5 ml combination hyaluronate (750–1300 kDa) with 40 U Botulinum toxin. Additionally, standard of care (RICE: Rest, Ice, Compression and Elevation) and stretching was prescribed but participants were instructed not to use NSAIDS or taping. The same pain VAS measures as well as peak exercise time, patient global satisfaction and patient assessment of normal running function (all measured using 5-point categorical scale) were repeated after 2, 7, 14 and 30 days. The primary outcome was peak pain during symptom-limited treadmill running.

Adverse events were recorded for safety purposes.

Results: 45 consecutive runners with acute (within 7 days) ITBS were included and completed the study procedures. A statistically significant reduction from baseline in VAS peak treadmill exercise was observed at all time points ($p<0.05$). This was associated with significantly longer exercise time at 7, 14 and 30 days. Patient global satisfaction was increased progressively after 7, 14 and 30 days and assessment of normal running function was described in >75% at 14 days. No serious adverse were reported. 3 subjects described transient (<24 hours) weakness in knee extension and 2 subjects described mild pain at the time and location of injection.

Conclusions: A single local injection of combination hyaluronate + Botulinum toxin for ITBS in runners improved pain and exercise time with treadmill running by 7 days post treatment and continued to 30 days. This treatment was satisfactory to runners and resulted in few, limited adverse events.

SAT0604 AUTOLOGOUS BLOOD AND CORTICOSTEROID LOCAL INJECTION IN TREATMENT OF PLANTAR FASCIITIS (RANDOMIZED, CONTROLLED MULTICENTER CLINICAL TRIAL)

A. Karimzadeh, S.A. Raeissadat, S. Erfani fam, L. Sedighipour. *Physical Medicine & Rehabilitation Research Center, Tehran, Iran, Islamic Republic Of*

Background: Plantar fasciitis is the most common cause of heel pain. Local injection modalities are among treatment options in patients with resistant pain.
Objectives: The aim of the present study was to evaluate the effect of local autologous blood compared with corticosteroid local injection in treatment of plantar fasciitis.
Methods: In this randomized controlled multicenter study, 36 patients with chronic plantar fasciitis were recruited. Patients were allocated randomly into 3 treatment groups: local autologous blood, local corticosteroid injection and control groups receiving no injection. Patients were assessed with Visual Analogue Scale (VAS), Pressure Pain Threshold (PPT) and Plantar Fasciitis Pain/Disability Scale (PFPS) before treatment, 4 and 12 weeks post therapy.
Results: Variables of pain and function improved significantly in both corticosteroid and autologous blood groups compared to control group. At 4 weeks following treatment, patients in corticosteroid group had significantly lower levels of pain than patients in autologous blood and control groups (higher PPT level, lower PFPS and VAS). After 12 weeks of treatment both corticosteroid and autologous blood groups had lower average levels of pain than control group. The corticosteroid group showed an early sharp and then more gradual improvement in pain scores but autologous blood group had steady gradual drop in pain.
Conclusions: Autologous blood and corticosteroid local injection both can be considered as effective methods in the treatment of chronic plantar fasciitis. These treatments decrease pain and improve function significantly compared to control group.

SAT0605 LOCAL PROGESTERONE INJECTION: NEW OPTION FOR MANAGEMENT OF CARPAL TUNNEL SYNDROME

S.A. Raeissadat[1], L. Sedighipour[1], S. Shahraeeni[2]. [1]*Physical Medicine & Rehabilitation Research Center;* [2]*Physical medicine and rehabilitation research center, Tehran, Iran, Islamic Republic Of*

Background: A number of studies, have demonstrated the neuroprotective effects of progesterone and its influence on the recovery after neural injury. Few studies investigated the efficacy of local progesterone in Carpal Tunnel Syndrome.
Objectives: The objective of this study was to compare the long term effects of progesterone versus corticosteroid local injections in patients with mild and moderate carpal tunnel syndrome.
Methods: In this randomized clinical trial, 78 hands with Carpal Tunnel Syndrome were assigned to two groups. Patients were treated with a single local injection of triamcinolone acetonide in one group and single local injection of hydroxy progesterone in the other group. Variables including pain (based on Visual Analogue Scale), symptom severity and functional status (based on Bostone/Levine symptom severity and functional status scale) and nerve conduction study were evaluated before and 6 months after the treatments.
Results: All outcome measures including pain, functional scales and electrophysiologic findings improved in both corticosteroid and progesterone groups and there were no meaningful differences between two groups regarding mentioned variables. However, functional outcome was significantly better in progesterone compared to corticosteroid group at 6 month follow up (P=0.04).
Conclusions: This study demonstrated the efficacy of progesterone local injection in mild and moderate CTS at long term follow up. Furthermore, local progesterone can be superior to corticosteroid injection for relieving symptoms and improving functional and electrophysiologic findings at long term follow up.

SAT0606 IS THE LEVEL OF PHYSICAL ACTIVITY AN IMPORTANT FACTOR FOR LOW BACK PAIN AMONG STUDENTS OF UNIVERSITY?

V. Akduman[1], E. Mete[1], I. Demirbuken[1], G. Ogren[2]. [1]*Physiotherapy and Rehabilitation;* [2]*Nutrition and Dietetic, Marmara University, Istanbul, Turkey*

Background: Back pain is a major global health problem, causing greater disability worldwide than any other condition. Regular physical activity is widely believed to have important health benefits, such as improving quality of life and mobility, and reducing disabilities. Conversely, lack of physical activity is considered a risk factor for increasing chronic diseases, functional dependence and mortality. Patients with low back pain (LBP) often report disability to perform daily activities. Also, decreased physical activity level can lead to low back pain.
Objectives: The aim of the study was to determinewhether increasing the level of physical activity affects the low back pain or not in the population of univesity students.
Methods: The cross-sectional study included 350 students (181 females and 169 males) with a mean age of 19.8±1.9 years. LBP was determined using the validated Oswestry Disability Index (ODI). ODI consist of ten items and are completed in reference to the patient's functional status "today". Physical activity level was evaluated by the short form of the International Physical Activity Questionnaire (IPAQ). IPAQ is a scale to be recorded at different levels of physical activity time in the last week. IPAQ is a scale to be recorded at different levels of physical activity time in the last week. Individuals whose score is lower than 600 MET are described as inactive (IPAQ 1), between 600–1500 MET (IPAQ 3) are described as minimal active and higher than 3000 MET (IPAQ 5)are described as active. For the statistical analyzing we used spearman correlation test.
Results: According to the short form of IPAQ, %14.8 percent of students were found inactive, % 48.1 percent of students were found minimal inactive and %37.1 percent of students were found active. The total score of Oswestry disability index was found 6,2±5,0. There was a significant difference between the Oswestry disability index score of inactive, minimally active and active groups (p=0,02). In addition to this, between the Oswestry disability index and total score of IPAQ was found a weak correlation in the negative direction (p=0,01; r=-0,184). Between the IPAQwhich means vigorous intensity activity, and Oswestry disability index was found a weak correlation in the negative direction (p=0,00; r=-0,190). And also between IPAQ3, which means modarate intensity activity, and Oswestry disability index was found a significant but weak correlation in the negative direction (p=0,03; r=-0,157). Between Oswestry disability index and sedentary activity and walking was not found any significant correlation ($p>0.005$).
Conclusions: According to our study, increasing the level of physical activity may reduce low back pain. Especially vigorous and modarate intensity activity can be effective in prevention from low back pain. For reducing of low back pain, sedentary activity and walking did not have any significant effect in our study. Therefore, the level of physical activity should be increased at the young age to prevent of low back pain which is a major health problem.

SAT0607 DISCOVERY OF A SMALL MOLECULE INHIBITOR OF THE WNT PATHWAY (SM04755) AS A POTENTIAL TOPICAL TREATMENT FOR TENDINOPATHY

V. Deshmukh, T. Seo, M. Ibanez, J. Stewart, B. Hofilena, Y. Yazici. *Samumed, LLC, San Diego, CA, United States*

Background: Tendinopathy is an inflammatory and degenerative disorder caused by injuries or overuse. It can progress to a chronic condition with failed healing, tendon fibrosis and micro-tears that lead to pain and sometimes rupture. Current therapeutic options focus mainly on pain relief rather than treatment of underlying disease. The Wnt pathway is upregulated in tendinopathy and has an important role in inflammation, fibrosis and tenocyte differentiation.
Objectives: SM04755, a novel, topical Wnt pathway inhibitor, was evaluated in preclinical studies to determine its potential to inhibit inflammation, reduce fibrosis and increase tenocyte differentiation, thereby promoting tendon healing.
Methods: Anti-inflammatory activity was measured by TNF-α and IL-6 secretion using ELISA in lipopolysaccharides (LPS) or anti-CD3/anti-CD28 stimulated peripheral blood mononuclear cells (PBMCs). Differentiation of human mesenchymal stem cells (hMSCs) and rat tendon derived stem cells (rTDSCs) into tenocytes was measured by high-content imaging for tenocyte markers scleraxis A (SCXA), tenomodulin and tenascin C. Pharmacokinetics were evaluated following topical application in rats. *In vivo* efficacy of SM04755 was evaluated in a single injection, collagenase-induced acute rodent tendinopathy model and a chronic, multiple injection, failed healing model, by scoring histological indicators of tendon health. Inflammation was measured by chemokine ligand 1 (CXCL1) levels in plasma by ELISA and pro-inflammatory markers (IL-6, TNF-α, IL-1β, IFN-γ, IL-8) in the tendon by qPCR. Tendon regeneration and healing were evaluated by qPCR based gene expression of tenocyte differentiation markers SCXA, tenomodulin and tenascin C, Type I/Type III collagen ratio and polarized light microscopy using Sirus Red staining. Pain in the rodent model was evaluated by measuring weight distribution with an incapacitance meter.
Results: SM04755 potently inhibited cytokine secretion in LPS and anti-CD3/anti-CD28 stimulated PBMCs (EC_{50}=500nM). SM04755 induced expression of tenocyte markers in differentiated hMSCs and rTDSCs (EC_{50}=200nM). A single topical application of SM04755 resulted in tendon concentrations $>EC_{50}$ for up to 24hrs, with minimal systemic exposure or toxicity. In both the acute and failed healing tendinopathy models, SM04755 (10mg/ml) treatment improved tendon morphology (Figure A), significantly increased mean tendon health

score ($p<0.01$), decreased plasma levels of CXCL1 ($p<0.05$) and reduced gene expression of pro-inflammatory markers (IL-6, TNF-a, IL-1b, INF-g, IL-8; $p<0.05$) compared to vehicle. SM04755 treatment promoted tendon regeneration measured as increased expression of tenocyte markers ($p<0.05$), increased Type I/Type III collagen ratio (Figure B; $p<0.01$) and Sirus Red stained collagen fibers in tendon compared to vehicle. SM04755 treatment increased % total weight bearing on the affected limb ($p<0.01$), at multiple time points (Figure C), indicating reduced pain in the rodent model.

Figure. SM04755 inhibited inflammation, promoted tendon healing and reduced pain in a rat collagenase-induced tendinopathy model

Conclusions: Topical SM04755, a Wnt pathway inhibitor, reduced inflammation, promoted tendon regeneration and healing, and reduced pain compared to vehicle in rodent tendinopathy models. SM04755 is a potential treatment for tendinopathy. Clinical studies are in progress.

SAT0608 RELATION BETWEEN SCAPULAR MUSCLE ENDURANCE, MUSCLE STRENGTH, PAIN AND FUNCTION IN PATIENTS WITH ROTATOR CUFF LESION

U. Sozlu, S. Basar, U. Kanatli, Z.B. Alkan. *Gazi University, Ankara, Turkey*

Background: Rotator cuff lesion (RCL) is an term that encompasses a spectrum of shoulder conditions including; subacromial impingement syndrome (SIS), partial and full thickness rotator cuff tears (RCT) and calcific tendinitis. Symptoms include pain, limited motion, muscle weakness and functional disability.

Objectives: To investigate the relationship between scapular muscle endurance (SME), muscle strength, pain and function in patients with shoulder RCL.

Methods: This study was conducted on 53 patients in shoulder RCL and 23 healthy controls. SIS was present in 25 patients (14 males, 11 females; mean age 41±9 years) and partial RCT in 28 patients (16 females, 12 males; mean age was 54±5 years) in the study group. In the control group, there were 12 females and 11 males and the mean age was 48±10 years. SME was measured as isometric based on the exercise developed by Sahrmann. Strength of the shoulder and scapular muscles were evaluated with digital manuel muscle dynamometer. Activity, night and rest pain levels were evaluated by visual analog scale. Functional activity status was assessed by the Functional Impairment Test-Head, and Neck/Shoulder/Arm (FIT-HaNSA).

Results: Statistically significant relationship was found positively in varying grades between SME and serratus anterior, middle trapezius, shoulder flexor, extensor, abductor, supraspinatus, pectoralis majör strength in partial RCT group and between lower trapezius muscle strength and SME in addition to these muscles in SIS group ($p<0.05$). Statistically significant relationship at varying degrees was found between SME and all muscles excluding shoulder internal, external rotators in control group ($p<0.05$). In SIS and partial RCT groups, negative, moderate and statistically significant relationship was found between SME and activity pain ($p<0.05$). In SIS and partial RCT groups significant correlation was not observed between SME and rest, night pain levels ($p>0.05$). In SIS and partial RCT groups, positive, excellent and statistically significant relationship was detected between SME and FIT-HaNSA ($p<0.05$). In control group, positive, moderate, again statistically significant relationship was detected ($p<0.05$).

Conclusions: Muscle strength may be reduced, upper extremity function may worsen and activity pain may increase in patients with reduced SME. It was concluded that shaping of exercise programs of muscle groups related to SME in rehabilitation studies and SME should be increased in patients with SIS and partial RCT in order to reduce shoulder pain and improve its functionality.

Diagnostics and imaging procedures

SAT0609 GIANT CELL ARTERITIS: ATHEROSCLEROSIS AS PITFALL IN THE HALO SIGN

E. De Miguel[1], L.M. Beltran[2], F. Deodati[2], I. Monjo[1], W.A. Schmidt[3], J. García-Puig[2]. *[1]Rheumatology; [2]Internal Medicine, Hospital Universitario la Paz, Madrid, Spain; [3]Rheumatology, Immanuel Krankenhaus, Berlin, Germany*

Background: The halo sign (defined as an homogenous, hypoechoic wall thickening, well delineated towards the luminal side, visible in longitudinal and transverse planes). is the more accurate ultrasonographic (US) finding for the diagnosis of Giant Cell Arteritis (GCA). False-positive halos are seen in malignant and infectious diseases. The new US high frequencies probes make possible not only to see the halo sign but also measure the increase of the intima-media-thickness (IMT). Moreover, the US appearance of the IMT in atherosclerotic carotid artery may be hypoechoic as the halo sign.

Objectives: The aim of this study was to explore if the increase of the atherosclerotic IMT can mimic the halo sign in temporal arteries (TA) and to produce false positives in the diagnosis of GCA.

Methods: Consecutive non selected patients, ≥50 years-old with high vascular risk according to European Guidelines on Cardiovascular Disease Prevention, and without signs or symptoms of GCA, were included.

Ultrasonography of carotid artery: Carotid ultrasound examinations were performed on a Mylab Seven (Esaote Medical Systems, Italy) with a 4–13 MHz linear-array. The system employed dedicated software radiofrequency-tracking technology to obtain IMT (QIMT®).

Ultrasonography of temporal superficial artery: A color Doppler ultrasound (CDU) and grey scale measure of the IMT/halo sign in the branches of both TA was performed by a second experienced sonographer. A Mylab Twice equipment (Esaote, Geneve, Italy) was used, with a 22 MHz frequency for grey scale and a 12.5 MHz for CDU, with a color gain of 51 and a PRF of 2 kHz. The sonographer was blind to the clinical data and carotid ultrasound IMT measures. Examination videos were stored for reliability and an intra-reader was performed months after the examination.

Statistical analysis: Descriptive frequencies, Student's *t*-test, Cronbach's alpha and Spearman correlations was used.

Results: Forty patients were studied, 28 men (70%), with a mean age of 70,6±6,9 years. Three patients were active smoker and 27 ex-smokers. Arterial hypertension was present in 39 (97.5%), dyslipidemia in 34 (85%) and diabetes in 19 (47.5%). The mean erythrocyte sedimentation rate was 13.6±11.0. Eighty carotids were studied, 50 had plaques and 30 did not with a IMT ranged from 0.528 to 1.480 mm. The mean values of TA related with the carotid IMT are presented in the table: the increase in the carotid IMT is associated with an increase in the IMT of the TA with a weak Spearman correlation (parietal branches 0.282 p=0.012 and frontal branches 0.228 p=0.048).

Patients with a final GCA diagnosis (n=22)

Carotid IMT mm	Branches of Temporal arteries parietal and frontal			
	n	Mean Halo/IMT mm	SD	Min–Max
≤0.7	12	0.247	± 0.043	0.16–0.29
≤0.9	46	0.254	± 0.037	0.18–0.33
≤1	42	0.269	± 0.034	0.18–0.36
≤1.2	50	0.282	± 0.052	0.17–0.45
>1.2	10	0.284	± 0.067	0.19–0.40

From reliability a Cronbach's alpha of 0.900 and 0.876 were achieved for parietal and frontal branches respectively.

Some patients had a TA IMT that can be interpreted as halo sign: 18 (45%) patients and 33 (20.6%) TA branches if we choose a cutoff >0.30 mm of IMT/halo sign; 4 (10%) patients and 7 (4.4%) TA branches if the cutoff were >0.34 mm.

Conclusions: The atherosclerotic disease can produce false-positive GCA diagnosis. Carotid IMT >0.9 mm is associated with halo sign in TA. The IMT cutoff value for the diagnosis of GCA should be established.

SAT0610 TEMPORAL ARTERY ULTRASOUND IN THE DIAGNOSIS OF GIANT CELL ARTERITIS IN A COHORT WITH ELEVATED CLINICAL IMPRESSION

P.V. Estrada[1], D. Reina[1], V. Navarro[1], D. Roig[1], D. Cerdà[2], V. Torrente[1], S. Heredia[1], H. Corominas[1]. *[1]Rheumatology; [2]Hospital Moisès Broggi-Hospital General de L'hospitalet. Consorci Sanitari Integral. Sant Joan Despí, Barcelona, Barcelona, Spain*

Background: Giant cell arteritis (GCA) is the most frequent vasculitis in adulthood. The delay in diagnosis sets back treatment and can lead to serious consequences. Diagnosis is complex, and is followed by the classification criteria according to the American College of Rheumatology (ACR). The is an increasing interest on the utility of temporal artery ultrasound (TAUS) as a tool to evaluate inflammation on the vessel wall.
Objectives: to evaluate the utility of TAUS in GCA.
Methods: During 2016, 120 TAUS were carried out in 60 patients with clinical suspicion for GCA. The TAUS was carried to completion by rheumatologist with experience. The symptoms that lead to a TAUS was either one or more of these clinical scenarios: 1) cranial symptoms (recent onset headache, mandibular claudication, visual disturbances) 2) polymyalgic syndrome 3) toxic o febril unspecific syndrome 4) vertebrobasilary (VB) stroke. Demographic and laboratory data were collected, and a follow-up was done to learn the final diagnosis. As for TAUS, the "halo" sign was considered positive if an anechoic image surrounded the vessel was present, and measured >0,30 mm in both, longitudinal and transverse cuts. Other more unspecific signs as stenosis or occlusion were also registered. A temporal artery biopsy was performed whenever the physicians considered necessary, based on clinical criteria, every case in no more than 30 days.
Results: Fifty-two percent were women, mean age 76±7.8 years old. Mean laboratory parameters: eritrosedimentation rate 85±41.9 mm/h, C-reactive protein 77±80 mg/L, Haemoglobin 11.4±2.2 g/L, white blood count 10,228±3,520, platelet count 310,603±123,918. The symptoms that motivated requesting the TAUS were: cranial symptoms (62.2%), toxic, unspecific, febrile syndrome (44%), polymyalgic syndrome (30%), VB stroke (5%). A temporal artery biopsy was carried out in 45% of patients (N=27); it was positive in 40.7%, negative in 40.7% and unspecific (given it reported an inflammatory histologic pattern, but without the characteristic giant cells) in 18.5%. From all 60 patients in whom a TAUS was performed, 36% were diagnosed with GCA, based on ACR criteria.

Patients with a final GCA diagnosis (n=22)

Ultrasound	Biopsy	%
Positive	Positive	40.7%
Positive	Unspecific	22.7%
Positive	Not done	9%
Negative	Not done	9%
Non-conclusive	Negative	9%
negative	Positive	9%

The sensibility and specificity for TAUS was 80% and 94% respectively, with a posivite predictive value of 88.9% and a negative predictive value of 89.2%
Conclusions: TAUS is a useful, non-invasive, fast, accessible tool for evaluating temporal arteries with a great diagnostic valu

SAT0611 INTIMA-MEDIA THICKNESS REFERENCE RANGES DEPICTING HALO SIGN FOR THE DIAGNOSING OF LARGE VESSEL GIANT CELL ARTERITIS BY ULTRASOUND

M. Milchert, M. Brzosko. *Department of Rheumatology Internal Medicine and Geriatrics, Pomeranian Medical University, Szczecin, Poland*

Background: Color duplex ultrasonography (CDU) is most promising tool for the assessment of large vessel giant cell arteritis (LV-GCA). There is a need to define ultrasound findings consistent with the diagnosis of GCA.
Objectives: We aimed to score intima-media thickness (IMT) reference ranges for LV-GCA in polish patients.
Methods: 214 patients suspected for GCA and evaluated with CDU were included in the study and followed up for min 9 months. Large vessel CDU, together with arteritis/non-arteritis categorization, were performed before or within 1 week after treatment initiation by a single physician. Vasculitis was defined as hypoechoic, homogenous, increase of IMT with distorted wall structure resulting in no clear intima-media structure, over long distance (not limited only to the place of arterial bifurcations). ROC curves were calculated.
Results: GCA was diagnosed in 81 patients, polymyalgia rheumatica (PMR) in 131 (characteristics – Table 1). Extracranial LV-GCA was diagnosed in 43 patients: axillary vasculitis in 23 patients, common carotid artery (CCA) – 24, subclavian – 18, superficial femoral – 11, brachial (all spreading per continuum from axillary arteritis) – 8. In 83 remaining patients other diagnosis was confirmed, and they served as non-GCA/PMR controls. Mean IMT in LV-GCA was significantly higher versus controls and isolated PMR (Fig. 1). IMT in GCA was not significantly influenced by gender, hypertension and smoking in contrast with IMT in controls. Proposed cut off values for IMT depicting vasculitis in GCA patients are presented in Table 2. 100% specificity for vasculitis (vs GCA without large vessel vasculitis) was reached with axillary IMT of 1.06 mm (62% sens.), subclavian – 1.35 mm (38% sens.), superficial femoral – 1.55 mm (60% sens.), CCA – 1.27 mm (22% sens.).

Table 1. Patient characteristics

	GCA (N=81)	Isolated PMR (N=50)	Non-GCA/PMR controls (N=83)	p
Female	53 (65%)	37 (74%)	54 (65%)	0.512
Age (mean ± SD; min-max)	73* ± 9; 55–95	69±9; 52–87	65±10; 44–89	0.001
Hypertension	53 (65%)	31 (62%)	44 (53%)	0.251
Smoking	36 (44%)	14 (28%)	29 (35%)	0.148
Diabetes	13 (16%)	6 (12%)	15 (18%)	0.649
Hypercholesterolemia**	25/66 (38%)	12/33 (36%)	19/38 (50%)	0.400
Arterial calcifications***	34 (42%)	11 (22%)*	33 (40%)	0.058
Upper limbs claudication	4 (4.9%)	0 (0.0%)	1 (1.2%)	0.131

*Significant findings ($p<0.05$); **Assessed in 137 patients; ***Of medium to high grade.

Table 2. Cut off values for IMT depicting vasculitis in GCA patients

Artery	IMT (mm)	AUC	Sens. (%)	Spec. (%)
Arteries classified as vasculitis vs GCA without large vessel vasculitis				
Axillary	0.82	0.959	85.7	92.7
Subclavian	0.84	0.954	87.5	96.8
Superficial femoral	0.97	0.945	90.0	96.3
Common carotid	0.96	0.877	72.2	93.7
Arteries classified as vasculitis vs controls				
Axillary	0.81	0.969	87.0	93.7
Subclavian	0.66	0.974	100	83.7
Superficial femoral	0.92	0.958	90.9	96.6
Common carotid	0.73	0.910	91.7	79.0

Maximal IMT value from bilateral CDU measurements was chosen. AUC = area under the curve.

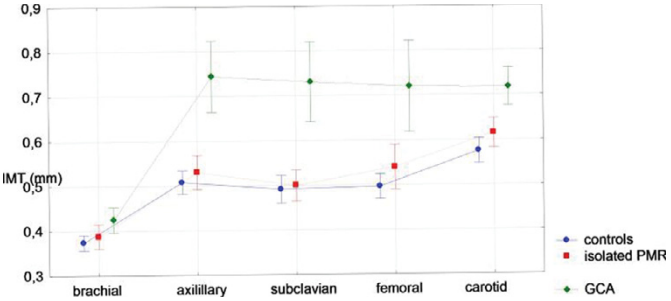

Figure 1. Mean IMT in different arteries in GCA, isolated PMR and controls.

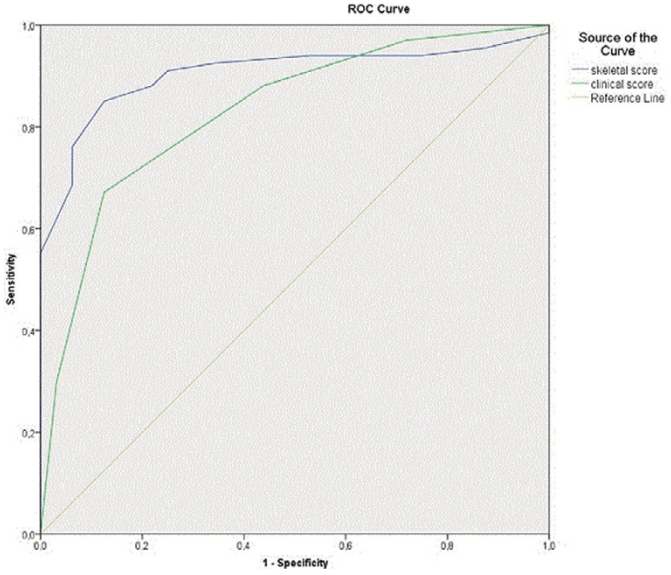

Conclusions: We demonstrated that cut off values may discriminate between GCA and its mimics as well as between presence and lack of vasculitis in different arteries in GCA.

SAT0612 THE USE OF 18F-FDG-PET IN THE DIAGNOSIS OF POLYMYALGIA RHEUMATICA (PMR) – A PROSPECTIVE STUDY OF 99 PATIENTS SUSPECTED OF PMR

L. Henckaerts[1], O. Gheysens[2], S. Vanderschueren[1], K. Goffin[2], D. Blockmans[1]. *[1]General Internal Medicine; [2]Nuclear Medicine Department, University Hospital Gasthuisberg, Leuven, Belgium, Leuven, Belgium*

Background: Previous studies have shown that the majority of patients with polymyalgia rheumatica (PMR) have increased fluorodeoxyglucose (FDG)-uptake around the shoulders, hips and processes of the cervical and lumbar spine on positron emission tomography (PET) (1). The specificity of these findings for PMR is not known.
Objectives: To determine the specificity and sensitivity of FDG-PET findings for the diagnosis of PMR.
Methods: A prospective monocentric study in a tertiary care centre. All patients underwent FDG-PET scanning before treatment with glucocorticoids was started. The clinical suspicion of PMR was quantified by the treating physician on a scale from 1 to 5. FDG-uptake was scored visually in 12 articular regions (cervical spinous processes, lumbar spinous processes, left and right sternoclavicular joint, left and right ischial tuberosity, left and right greater trochanter, left and right hip and left and right shoulder) (score 0–2) and a total skeletal score was calculated reflecting the FDG-uptake in these 12 articular regions. ROC analysis was performed to determine the optimal clinical and total skeletal score for diagnosing PMR. The golden standard for a diagnosis of PMR was the judgment of an experienced clinician after at least six months of follow-up.
Results: 99 consecutive patients with a possible clicinal diagnosis of PMR were included in this study. Sixty-seven patients were finally diagnosed with PMR while 32 patients got another diagnosis. A clinical score of 4 or more had a sensitivity

of 67.2%, specificity of 87.5%, positive predictive value (PPV) of 91.8% and a negative predictive value (NPV) of 56.0% for the diagnosis of PMR. A total skeletal score of 16 or more had a sensitivity, specificity, PPV, NPV of respectively 85.1%, 87.5%, 93.4% and 73.7%.

Conclusions: FDG-PET before starting glucocorticoid therapy improves the diagnostic accuracy compared to a clinical scoring system in patients with clinical suspicion of PMR.

SAT0613 HIGH PREVALENCE OF SUBCLINICAL ATHEROSCLEROSIS IN GOUT AND ASYMPTOMATIC HYPERURICEMIA: A STUDY BASED ON CAROTID ULTRASOUND

C. Bertolazzi[1], M. Gutierrez[2], R. Espinosa[3], M. Martínez-Lavin[4], L.H. Silveira[4], C. Lozada[2], J. Moreno[3], E. Cruz[5], B. Olivares[5], C. Pineda[3], A.C. Lozada[2]. *[1]Division of Neuroscience; [2]Division of Musculoskeletal and Rheumatic Diseases; [3]Rheumatology Department, Instituto Nacional de Rehabilitación; [4]Rheumatology Department, Instituto Nacional de Cardiología Ignacio Chavez; [5]Epidemiology and Social Medicine Department, Instituto Nacional de Rehabilitación, Ciudad de Mexico, Mexico*

Background: Accelerated atherosclerosis is known in gout. Hyperuricemia is considered an independent risk factor for cardiovascular (CV) disease. Evidence supporting both proatherogenic and prothrombotic states in HU is also published Ultrasound (US) measurement of the carotid intima-media thickness (cIMT) is a recognized measure of premature subclinical atherosclerosis with a predictive value respect to vascular events.

Objectives: To determine the prevalence of increased cIMT, as sign of subclinical atherosclerosis, by an automated US method, and the associated risk factors in patients with gout and asymptomatic hyperuricemia (aHU)

Methods: 138 patients with gout, 105 with aHU and 99 age and sex matched healthy controls were enrrolled. For all patients were recorded: clinical history, disease duration, smoking, ischemic heart disease, comorbidities (diabetes mellitus, high blood pressure, dyslipidemia, renal insufficiency, obesity), and current therapy. ESR and serum CRP, total and HDL cholesterol, triglycerides, glucose, creatinine and uric acid were recorded. Patients with history of CV and cerebrovascular events or autoimmune diseases were excluded.

US examinations of both common carotids were performed by an experienced sonographer trained in cIMT examination, with a Esaote My Lab 70XVG, equipped with a linear probe (4–13 MHz) and an automatic IMT measure software. The definitions of Mannheim cIMT Consensus were adopted

Results: A total of 684 common carotids were assessed. The prevalence of increased cIMT was 47.1%, 47.6% and 1% in patients with gout, aHU, and control group, respectively. The final adjusted logistic regression for patients with gout showed that time of disease progression (OR =0.79, 95% CI 0.66–0.95) and previous smoking (OR =0.32, 95% CI, 0.10–0.97) were associated with cIMT increase ($p<0.05$) whereas the uric acid levels (OR =1.66, 95% CI 1.07–2.56) was associated with an increased cIMT in aHU. No significant correlation was found with the other variables. No differences in US findings were found between gout and aHU (p=0.936). There was a significant difference in cIMT in gout versus control (p=0.0001) and aHU versus control (p=0.0001).

Conclusions: Our results demonstrate that patients with gout and aHU without clinically evident cardiovascular disease have a high prevalence of subclinical atherosclerosis. Disease duration and levels of uric acid are independent factors related with increased cIMT in gout and aHU respectively. These results support the importance of screening for CV risk and to include carotid ultrasound in CV prevention strategies in these patients.

SAT0614 ULTRASOUND AND URATE CRYSTAL DEPOSITION: HOW MANY JOINTS TO SCREEN?

D. Bhadu[1], S.K. Das[2], A. Wakhlu[3], U. Dhakad[2]. *[1]Department of Rheumatology, All India Institute of Medical Sciences, New Delhi; [2]Department of Rheumatology; [3]Department of Radiodiagnosis, King george medical university, lucknow, India*

Background: Gout is one of the most common inflammatory joint disease in males. The new ACR/EULAR 2015 gout classification criteria has included imaging as a scoring item [1]. Naredo et al [2], found that in intercritical gout, assessment of one joint (ie, radiocarpal) and two tendons (ie, patellar and triceps) for HAGs, and three articular cartilages (ie, first metatarsal, talar and second metacarpal/femoral) for double contour sign (DCS) showed the best balance between sensitivity and specificity (84.6% and 83.3%, respectively). Ultrasound screening at these 6 sites is time consuming and not feasible in a busy outpatient service. So we aimed to compare the two sites (knee and 1st MTP joints) with these 6 sites for the ultrasound detected abnormalities namely DCS and HAGs in patients of gout particularly with the idea to find the best possible minimum joint combination without compromising the sensitivity and specificity.

Objectives: To compare the ultrasound-detected abnormalities namely double contour sign (DCS) and hyperechoic aggregates (HAGs) at knee and first metatarsophalangeal (1st MTP) joint (two sites) verses six sites (knee joint, 1st MTP joint, radiolcarpal joint, patellar tendon and triceps tendon) in patients of gout.

Methods: Forty seven gout and fifty controls (serum uric acid <7mg/dl) with age more than 18 years were included in this study. DCS was looked for at three articular cartilage sites (first metatarsal, tibiotalar and femoral condyle) whereas HAGs were looked for at one joint site (radiocarpal joint) and two tendon sites (patellar tendon and triceps tendon). Ultrasound findings of all three groups were compared.

Results: We found sensitivity, specificity, positive predictive value, negative predictive value and positive likelihood ratio of two joint areas (knee and 1st MTP) ultrasound findings for gout were 87.2%, 84%, 83.7%, 85.6% and 5.5 respectively. Similar sensitivity, specificity, positive predictive value, negative predictive value and positive likelihood ratio were observed with 6 sites ultrasound findings. Amongst controls 17.5% were found to have these abnormal ultrasound findings by both two joint area and 6 sites exams.

Applied Diagnostics	Sensitivity	Specificity	PPV	NPV	LR+	LR–
Knee joint DCS	53.2	94.0	89.3	68.1	8.9	0.49
1st MTP Joint DCS	51.1	84.0	75.0	64.6	3.2	0.58
1st MTP joint HAGs	44.7	100.0	100.0	65.8	–	0.55
1st MTP Joint DCS+HAGs	72.3	84.0	81.0	76.4	4.5	0.32
Talar joint DCS	40.5	100.0	100.0	69.4	–	0.59
Patellar tendon HAGs	23.4	100.0	100.0	58.1	–	0.76
Triceps tendon HAGs	14.9	100.0	100.0	55.6	–	0.85
Radiocarpal joint HAGs	4.3	100.0	100.0	52.6	–	0.95
Knee and MTP joint abnormalities	87.2	84.0	83.7	85.6	5.5	0.15
Ultrasound abnormalities at Six examined site	87.2	84.0	83.7	85.6	5.5	0.15

Conclusions: Screening of two joint areas (knee and 1st MTP) has similar sensitivity, specificity and positive likelihood ratio as compared to six sites in diagnosing gout. While utilizing lesser time in examination.

SAT0615 THE RS11803505 IL-23R POLYMORPHISM IS A RISK FACTOR FOR THE DEVELOPMENT OF MSUS-DETECTED EROSIONS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

C. Perricone[1], F. Ceccarelli[1], V. Iorgoveanu[1], C. Ciccacci[2], S. Rufini[2], C. Alessandri[1], F.R. Spinelli[1], E. Cipriano[1], G. Novelli[2], G. Valesini[1], P. Borgiani[2], F. Conti[1]. *[1]Lupus Clinic, Rheumatology, Department of Internal Medicine, Sapienza University of Rome; [2]Department of Biomedicine and Prevention, University of Rome Tor Vergata, Rome, Italy*

Background: Articular involvement is a frequent and invalidating manifestation in patients with Systemic Lupus Erythematosus (SLE) ranging from arthralgia to erosive arthritis. Bone erosions are far less common in SLE but require a different management and may display a distinct pathogenesis. Musculoskeletal ultrasonography (MSUS) has proven useful in the assessment of inflammatory arthritis and it is now known that MSUS is more sensitive than radiography in detecting bone erosions.
Objectives: We aimed at analyzing, in a large monocentric cohort of SLE patients who suffered from arthritis, the relationship between 31 polymorphisms in 18 genes previously associated with SLE or other autoimmune/inflammatory arthritis [1] and the presence of bone erosions detected by MSUS.
Methods: Consecutive SLE patients who complained articular involvement (defined by 1997 ACR criteria, i.e. $\geq$2 joints with tenderness, swelling or effusion) were enrolled. Patients RF+ve and/or anti-CCP+ve were excluded. Thirty-one SNPs in 18 genes (STAT4, IL10, IL23R, IRAK1, PSORS1C1, HCP5, MIR146a, PTPN2, ERAP1, ATG16L1, IRGM, TRAF3IP2, VKORC1, CCR5, ATG5, TRAF6, TNFSF4, CD40) were genotyped by allelic discrimination assays. Bilateral high-resolution MSUS of the hands and feet was performed. Erosion number was recorded, the presence of erosive damage was assessed with a dichotomous score.
Results: Clinical and laboratory features of the 95 enrolled patients are described in table.

Clinical and laboratory features	N.	%
Sex	92	96.8
Age (mean ± SD)	43.38±11.49	
Age at diagnosis (mean ± SD)	31.14±11.83	
Anti-dsDNA	69	72.6
MSUS Erosive score (mean ± SD)	0.44±1.34	
MSUS Erosions (yes/no)	15/80	15.8

The presence of MSUS-detected erosions was demonstrated in 15/95 (15.8%) patients, with a mean±SD of 0.44±1.34. Bone erosions were more frequently observed at II metacarpophalangeal joint of the hands (29.4%), followed by the V metatarsophalangeal joint of the feet (16.1%). An association was found between anti-dsDNA and the presence of bone erosions (P=0.009, Fisher's exact test); indeed, all the 15 patients (100%) with bone erosions were anti-dsDNA positive vs 54/80 (67.5%) of those without erosions. After Bonferroni correction, IL-23R rs11803505 was found to be associated with the presence of MSUS-detected bone erosions both at genotypic (P_c=0.045) and at the allelic level [P_c=0.022, OR=8.27 (95% CI 1.02–66.90)]. The association of bone erosions with anti-dsDNA and IL-23R11803505 genotype was confirmed in a logistic regression analysis including also age, sex and disease duration (P=0.005 and P=0.02, respectively).
Conclusions: Our study is the first reporting a contribution of IL-23R gene to MSUS-detected erosive damage in SLE. IL-23R gene is a key player in several inflammatory conditions such as psoriatic arthritis, and variants of this gene have already been associated with peripheral erosive disease [2]. Moreover, we confirmed an association between anti-dsDNA and bone erosions in SLE [3], suggesting that the presence of these antibodies is linked with a more aggressive inflammatory pattern of disease.

SAT0616 DIAGNOSTIC MODELING OF SYSTEMIC LUPUS ERYTHEMATOSUS BASED ON NEW AND TRADITIONAL AUTOANTIBODIES- DEMONSTRATION OF FEASIBILITY

P. Budde[1], H.-D. Zucht[1], J. Schulte-Pelkum[1], D.S. Wirtz[1], P. Rengers[1], T. Witte[2], P. Schulz-Knappe[1], M. Schneider[3]. *[1]Protagen Ag, Dortmund; [2]Department of Clinical Immunology, Medical School Hannover, Hannover; [3]Policlinic of Rheumatology, Heinrich-Heine-University Düsseldorf, Düsseldorf, Germany*

Background: Given the heterogeneity of clinical presentations, the diagnosis of Systemic Lupus Erythematosus (SLE) can be challenging, in particular in those patients presenting with early or incomplete disease, or with overlapping or atypical features. Autoantibodies (AABs) are important in aiding the clinical diagnosis of SLE, with some few AABs, anti-double-stranded DNA (dsDNA), anti-Smith (Sm), and anti-ribosomal P (riboP) being highly associated with SLE. As none of the traditional AABs has sufficient sensitivity to achieve diagnosis of SLE, current testing is based on measuring multiple AAB assays either in parallel or serial. We have recently identified novel AABs in SLE, which hold promise for improving diagnostic testing of SLE (1). We have developed quantitative ELISA-prototypes for five new AABs, which were tested in combination with traditional AABs.
Objectives: The objectives of this study were to evaluate the diagnostic value of novel AABs and to screen for an optimized combination of novel and traditional AABs using logistic regression to increase the diagnostic accuracy of SLE testing.
Methods: Serum samples were obtained from 156 SLE patients with European ancestry at the rheumatology department of the Heinrich-Heine University (Düsseldorf, Germany), and Hannover Medical School (Hannover, Germany). SLE samples were compared against 126 samples from autoimmune diseases (AID; myositis: n=20; Sjögren's syndrome (SjS): n=31; rheumatoid arthritis (RA) n=36; systemic sclerosis (SSc): n=39), and 77 healthy control samples. Prototype bead based ELISAs were developed for five novel antigens described in (1). Traditional diagnostic AABs were measured using IVD ELISAs and included: SSA/Ro60, SSA/Ro52, La/SSB, Sm, RNP, dsDNA, Scl70, CENPB, Jo-1, CCP, phospholipid and dsDNA. Optimized marker combinations of new and traditional markers were tested using logistic regression and receiver operating curve analysis (ROC).
Results: When comparing 156 SLE patients with 203 control samples, the area under the curve (AUC) of the five novel SLE ELISAs ranged from 0.63 to 0.75. A cut-off was set at a specificity of 95% and yielded a sensitivity ranging from 13.5% to 21.2% for the five novel assays. The sensitivity and specificity of new ELISAs was comparable to traditional ELISAs, which was in this cohort for anti-dsDNA 35% and 97%, anti-Sm 15% and 97%, and anti-RiboP 26% and 97%. A logistic regression model was used to combine the results of multiple tests. Compared to a logistic regression with traditional assays, a logistic regression with novel markers achieved higher sensitivity by pertaining high specificity. The logistic regression model based on a multimarker IVD assay with ten extracted nuclear antigens (ENA) yielded an AUC of 0.87 and a sensitivity of 58% at a specificity of 95%. By contrast, the optimal combination of traditional and novel ELISAs reached an AUC of 0.92 and a sensitivity of 75% at a specificity of 95%.
Conclusions: This study demonstrates the feasibility of combining test results of novel and traditional AABs using logistic regression to increase the diagnostic accuracy for SLE. Further studies are required to assess the impact of different ethnicities on marker selection and algorithm performance.

SAT0617 SALIVARY GLAND ULTRASOUND CAN DIFFERENTIATE PRIMARY SJÖGREN'S SYNDROME FROM SYSTEMIC DISEASES WITH SALIVARY GLAND INVOLVEMENT

K. Delli[1], J.F. Van Nimwegen[2], S. Arends[2], A.J. Stel[2], M. Van den Berge[3], W.F. Bierman[4], H. Bootsma[2], F.K.L. Spijkervet[1], A. Vissink[1] on behalf of EULAR US-pSS Study Group. *[1]Oral and Maxillofacial Surgery; [2]Rheumatology & Clinical Immunology; [3]Pulmonology; [4]Internal Medicine, Infectious Diseases Service, University of Groningen, University Medical Center Groningen, Groningen, Netherlands*

Background: Ultrasound of the major salivary glands (SGUS) has shown high diagnostic accuracy for primary Sjögren's syndrome (pSS) [1,2]. None of the existing studies, however, included a control group of patients with sarcoidosis, amyloidosis, human immunodeficiency virus (HIV) or hepatitis C (HCV) infection [2]. These diseases are known to frequently affect the major salivary glands, cause dry mouth or may have histopathology similar to pSS.
Objectives: To assess the diagnostic accuracy of SGUS to differentiate pSS from systemic diseases with salivary gland involvement.
Methods: Twenty consecutive patients fulfilling the AECG criteria for pSS and 20 consecutive patients with well-established systemic diseases, i.e., 5 patients with sarcoidosis, 5 patients with amyloidosis, 5 patients with HIV infection and 5 patients with HCV infection, were included. Echogenicity, parenchymal homogeneity, presence of hypoechogenic areas and clearness of posterior glandular border of both parotid and submandibular salivary glands were scored independently by two blinded observers and rated according to the Hocevar et al scoring system (ultrasound total score (UTS), range: 0–48) [3]. The optimal cut-off point was determined by using ROC curve. The agreement between SGUS positivity and classification as pSS was assessed.
Results: The median age of patients with pSS and systemic diseases was 50 and 53 years, respectively. Daily complaints of dry mouth longer than 3 months, need of liquid to swallow food and recurrent or persistent swelling of the major salivary glands were reported by 95%, 85% and 70% of patients with pSS compared to 45%, 30% and 20% of patients with systemic diseases. The accuracy of SGUS to discriminate pSS was excellent, with an area under ROC of 0.91 and optimal cut off point of 15. The agreement between SGUS and diagnosis for pSS was good (κ=0.75, percentage of absolute agreement 87.5) with a sensitivity of 90%,

specificity of 85%, positive predictive value of 86%, negative predictive value of 89% and diagnostic odds ratio of 51. UTS was positive in 2 patients with HIV infection and one patient with sarcoidosis. Patients with pSS had significantly higher UTS than patients with systemic diseases (median UTS 27 vs. 10, $p<0.001$) and patients of the various subgroups ($p<0.05$; Fig).

Figure: UTS in patient (sub)groups. ** p<0.001, * p<0.05. Black horizontal lines indicate median values. The intermittent horizontal line shows the cut-off point. The intermittent black vertical line separates the two major patient groups (pSS vs. systemic diseases) from the subgroups of patients with sarcoidosis, amyloidosis, HIV and HCV infection.

Conclusions: This pilot study indicates that SGUS has a high diagnostic accuracy to discriminate pSS from associated systemic diseases with salivary gland involvement. A minority of HIV and sarcoidosis patients, however, may show SGUS findings mimicking pSS.

SAT0618 DISTURBANCES OF THE ACRAL PERFUSION DETECTED BY FLUORESCENCE OPTICAL IMAGING ARE ASSOCIATED WITH THE DEVELOPMENT OF ISCHEMIC COMPLICATIONS IN PATIENTS WITH SYSTEMIC SCLEROSIS

S. Lüders[1], S. Friedrich[1], S. Ohrndorf[1], S. Werner[1], G.-R. Burmester[1], G. Riemekasten[2], M. Backhaus[3]. *[1]Division of Rheumatology and Clinical Immunology, Charité - Universitätsmedizin Berlin, Berlin; [2]Department of Rheumatology, Universität zu Lübeck, Lübeck; [3]Department of Rheumatology, Park-Klinik Weißensee, Berlin, Germany*

Background: Systemic sclerosis (SSc) is a condition causing an impaired microcirculation with the risk of ischemic complications such as digital ulcers and pitting scars (DU/PS). Fluorescence optical imaging (FOI) is an imaging method that detects enhanced microcirculation as a sign of joint inflammation in both hands of patients with rheumatoid arthritis and other arthritides [1, 2]. FOI's impact to record disturbed microcirculation in the hands of patients with systemic sclerosis has not yet been sufficiently investigated.

Objectives: To find associations of disturbed microcirculation initially detected by FOI and the development of new DU/PS throughout a follow-up of 12 months.

Methods: Sixty-three patients with SSc were included and received FOI examination following the Xiralite-System guidelines (ICG 0.1mg/kg BW i.v.; 6 minute duration) as well as capillaroscopy at baseline. After a mean follow-up time of 12 months (min-max: 8–20 months), all participants were followed regarding the development of new ulcers and pitting scars.

Results: A disruption of microcirculation in FOI was defined as a lack of a sufficient fluorescent signal in at least one fingertip over the entire course of the examination and was found in 11 of 63 SSc patients. All patients had a history of DU/PS and frequently presented with a *late pattern* capillaroscopy (9 out of 11) at baseline. Fingers with a disrupted microcirculation also showed a reduced capillary density to a greater extend (96.0%) than fingers with a sufficient signal in FOI (76.0%; p=0.0241).

30 of 60 patients developed digital ulcers or pitting scars during follow up (3 drop outs due to death (n=2) or withdrawal). 81.8% of patients with a disturbed microcirculation in FOI developed these complications during follow-up compared with 42.9% of patients without a disruption in FOI (p=0.0419; OR=6.0 [95% CI 1.2 - 30.7]). A disruption of microcirculation especially increased the risk of developing DU/PS in the same finger: 20.1% of fingers with normal, but 65.4% with a missing FOI signal in the fingertip presented with an ischemic complication during follow-up ($p<0.0001$; OR=7.5 [95% CI 3.3 - 17.3]).

Conclusions: Fluorescence optical imaging can reveal an impaired microcirculation in patients with systemic sclerosis, which is associated with microangiopathic changes as seen in capillaroscopy as well as the subsequent development of digital ulcers and pitting scars. Therefore, FOI might help to identify patients at risk for these complications.

SAT0619 ANKLE EVALUATION IN ACTIVE RHEUMATOID ARTHRITIS BY ULTRASOUND: A CROSS SECTIONAL STUDY

A.M. Elsaman[1], E.S. Mostafa[2], A.R. Radwan[1]. *[1]Rheumatology, Sohag University Faculty of Medicine; [2]Rheumatology, Qena faculty of medicine, Sohag, Egypt*

Background: Ankle joint evaluation is underestimated in many clinical and sonographic scores used for evaluation and follow-up of rheumatoid arthritis (RA) patients. Moreover, sonographic scores which included the ankle joint had no agreement on examination parameters. More effort is needed to detect the value of the ankle joint examination in RA and also a description of the earliest and the most frequent ultrasonographic signs that should be considered in ankle assessment (1).

Objectives: detection of ankle affection by ultrasound (US) in active RA and correlate this finding with disease duration, DAS28-ESR 28 score and rheumatoid factor (RF).

Methods: 126 ankle joints and tendons of 63 active RA patients, aged above 18 years old were included in the study. US examination was done to the tibiotalar and talonavicular joints for synovitis and/or effusion on Greyscale (GS) mode and power doppler (PD). The anterior, lateral and posterior ankle tendons were examined for tenosynovitis and tendinosis.

Results: The mean age and ± standard deviation were 35.1±8.3 with the female-to-male ratio 2:1. The mean disease duration was 22.7±9.6 months. The mean DAS28-ESR 28 score was 3.05±0.66. The most frequent pathologies detected were tenosynovitis of the flexor, extensor or peroneal tendons (found in 30.2% of the affected ankles); followed by synovitis of the tibiotalar and talonavicular joints (18.3%); next was erosion (8.7%) and lastly tendinosis (4%). The earliest sonographic signs were tenosynovitis, followed by synovitis, erosion, and lastly tendinosis.

Conclusions: It can be stated that ankle evaluation should be considered more in RA assessment. The tibialis anterior and posterior tendons, the tibiotalar and talonavicular joints were the commonest and most frequent sites to be involved in the ankle. Tenosynovitis appears earlier than synovitis. DAS28-ESR score was correlated to synovitis and tenosynovitis but not to erosion. Bilaterality and erosion were correlated with disease duration. RF positivity has a positive correlation with positive US findings in the ankle region.

SAT0620 POTENTIAL ROLE OF METACARPOPHALANGEAL JOINTS ULTRASOUND IN THE DIFFERENTIAL DIAGNOSIS BETWEEN EARLY RHEUMATOID ARTHRITIS AND EARLY SPONDYLOARTHRITIS

A. Batticciotto, G. Prato, M. Antivalle, M.C. Ditto, M.C. Gerardi, R. Talotta, F. Atzeni, P. Sarzi-Puttini. *Rheumatology Department, ASST-Fatebenefratelli–Sacco."L. Sacco" University Hospital, Milan, Italy*

Background: Several studies have demonstrated that musculoskeletal ultrasound (MSUS) is more sensitive in diagnosing arthritis when compared to clinical examination, although, as underlined in a recent review, still remains controversial whether it can improve substantial discriminatory value in an early arthritis (EA) setting.(1) In 2011 Gutierrez M. et al. published preliminary data on high frequency of peritenon extensor tendon inflammation in Psoriatic arthritis (PsA) patients, suggesting a relevant potential role for US in differential diagnosis between Rheumatoid Arthritis (RA) and PsA at metacarpophalangeal (MCP) joints level and recommending additional research in order to confirm these data.(2)

Objectives: To compare MSUS findings between early RA and early Spondyloarthritis (SpA) patients at MCP joints level.

Methods: From a consenting cohort of EA patients presenting to our Rheuma-

tology Department, we retrospectively selected 35 patients that within one year from the first visit had a defined diagnosis of RA (according with the 2010 ACR/EULAR criteria) or of axial/peripheral SpA (according with the 2009 ASAS criteria). Demographic, clinical parameters and MCPs' MSUS assessment at baseline were recorded during the patients' first EA clinic visit by an experienced Rheumatologist and by a blinded skilled sonographer. ESAOTE MyLAB 70 with 6–18 MHz linear array transducer was used for all patients scanning and US were scored according with OMERACT guidelines.

Results: MSUS data of twenty RA patients (17 F – 3 M; median age of 59 yrs with range 35–83 yrs, median time for defined diagnosis of 2,4 months with range 1–11 months) and 15 SpA patients (9F–6M; median age of 53 yrs with range 18–78 yrs, median time for defined diagnosis of 1,7 months with range 1–8 months) were retrospectively analyzed. At the first EA clinic visit, all patients showed at least one joint with synovial fluid and/or synovial hypertrophy in Grey scale (GS) with a score >1 and no statistically significant differences were found in the percentage of patients that presented at least one joint with power Doppler (PD) positivity (55% RA Vs 53% SpA,p=0,92) and that presented PD positivity tenosynovitis of the flexor tendons in at least one finger (10% RA Vs 33% SpA, p=0,08). A statistically significant difference was found in the percentage of patients with erosions in at least one MCP (25% RA Vs 0% SpA, p=0,036) and in the percentage of patients with PD positive paratenonitis of the extensor tendons in at least one finger (30% RA Vs 80% SpA pts, p=0,003).

Conclusions: Early RA patients showed a statistically higher percentage of erosions at MCPs' MSUS evaluation of the first visit of the EA clinic, when compared with early SpA group and early SpA patients presented at the level of the extensor tendons an higher percentage of PD positive paratenonitis when compared with the early RA group.

SAT0621 AGREEMENT BETWEEN SEMIQUANTITATIVE AND QUANTITATIVE DOPPLER SCORING SYSTEMS FOR THE ASSESSMENT OF SYNOVIAL PATHOLOGICAL VASCULARIZATION IN RHEUMATOID ARTHRITIS

E. Naredo[1,2], I.M. Rutigliano[3], I. Janta[1], C. Scirocco[3], L. Valor[1], F. Figus[4], L. Carreño[1], J. Garrido[5], A. Iagnocco[6]. *[1]Department of Rheumatology, Hospital General Universitario Gregorio Marañón; [2]Department of Rheumatology, Hospital Universitario Fundación Jiménez Díaz. Autonoma University, Madrid, Spain; [3]Dipartimento Medicina Interna e Specialità Mediche, Sapienza Università di Roma, Rome; [4]Dipartimento Reumatologia, Università degli Studi di Cagliari, Cagliari, Italy; [5]Department of Social Psychology and Methodology, Faculty of Psychology, Autonoma University of Madrid, Madrid, Spain; [6]Dipartimento Scienze Cliniche e Biologiche, Università degli Studi di Torino, Turin, Italy*

Objectives: To compare power Doppler (PD) vs colour Doppler (CD) semiquantitative and quantitative scoring of synovial vascularization (RA) and to evaluate the relationship between semiquantitative and quantitative scores in patients with rheumatoid arthritis (RA).

Methods: One hundred RA patients underwent B-mode, PD, and CD assessments of 12 joints at two European centres. Each joint with synovial hypertrophy detected on B-mode was semiquantitatively scored (0–3) for PD (SPD score) and CD (SCD score) synovial signal. PD and CD synovial signal were also quantitatively scored (0–100%) (QPD and QCD scores, respectively) using a software for counting the colour fraction.

Results: We found SH in 184 joints. SPD and SCD agreed in 92.3% (95% CI: 88.4; 96.2%) of paired scores, with Kendall rank correlation coefficient tau-b=0.95. Significant differences between marginal distributions of SPD and SCD were not found (p=0.565). QPD and QCD scores were highly correlated (Pearson's coefficient=0.70) but Blamd-Altman plot showed insufficient agreement, being the QCD scores systematically slightly higher than the QPD scores. The distribution of QPD and QCD values between SPD and SCD scores, respectively, showed significant differences between grade 0 and grade 1 ($p<0.001$), and grade 2 and grade 3 (p=0.042 and p=0.007, respectively) but not between grade 1 and 2 (p=0.154 and p=0.150, respectively).

Conclusions: SPD and SCD scores were concordant and QPD and QCD scores highly correlated although were not concordant. There was consistency between SPD and SCD moderate and severe scores and QPD and QCD scores. There was an overlapping between SPD and SCD mild and moderate scores regarding QPD and QCD scores.

SAT0622 MULTICENTER 14-3-3ETA BIOMARKER REPRODUCIBILITY; THE JAPANESE EXPERIENCE

S. Hirata[1,2], M. Kaneda[3], T. Isayama[3], Y. Gui[4], A. Marotta[4], W.P. Maksymowych[5], Y. Tanaka[2]. *[1]Hiroshima University Hospital, Hiroshima; [2]University of Occupational and Environmental Health, Kitakyushu; [3]Medical & Biological Laboratories, Nagano-ken, Japan; [4]Augurex Life Sciences Corp, Vancouver; [5]University of Alberta, Edmonton, Canada*

Background: The soluble biomarker sub-committee of OMERACT has published validation criteria for biomarkers reflecting structural damage end-points. Within these, categories of Discrimination and Feasibility relate to assay reproducibility and performance. 14–3-3eta (η) is a joint-derived biomarker that drives joint damage processes and informs radiographic progression independently of acute phase reactants. As an ELISA assay, 14–3-3η is currently available for clinical use as a laboratory developed test (LDT) in the United States (US) and as an in-vitro diagnostic (IVD) in Canada. The ELISA is (CE) marked for Europe and is Therapeutics Good Administration (TGA) approved for Australia. Previous studies have described 14–3-3eta assay equivalence at independent laboratories in the US and Canada.

Objectives: The purpose of this study was to demonstrate the reproducibility of 14–3-3eta measurements at two independent laboratories in Japan and one in Canada.

Methods: A total of 212 samples from the University of Occupational and Environmental Health were provided for this study. Serum 14–3-3eta measurements were performed using the 14–3-3eta ELISA provided by Augurex. Testing in Canada occurred in August 2015; these 14–3-3eta values were set as the "standard". The 212 samples were shipped from Canada to Japan in January 2016 with testing being performed in February 2016. Testing at MBL was performed on a blinded-basis. Upon completion of testing, results were sent to the investigators at which point in time, MBL was unblinded. 14–3-3eta positivity was defined at $\geq$0.19ng/ml. Contigency and Spearman analyses were performed to assess the strength of the results between the two testing centres. Values above the linear range of the assay i.e. $\geq$20ng/ml were excluded for the Spearman analyses and determination of the median (IQR). A p-value of <0.05 established statistical significance.

Results: In Canada, of the 212 samples tested, 146 (68.8%) were 14–3-3eta positive and in Japan, 147 (69.3%) were positive. In Canada, 187 patients had reportable values in the linear range and in Japan 186 did. Median 14–3-3eta levels in Canada were 0.51 ng/ml (IQR: 0.11–2.09) and in Japan they were 0.58 ng/ml (IQR: 0.02–2.68), respectively. Spearman correlation analysis revealed a highly significant correlation between the two testing sites, r=0.92; $p<0.00001$. Contingency analysis revealed a strong concordance between the two sets of results delivering a likelihood ratio (LR) of 156, $p<0.0001$. Between the two sites, 58 of the samples were 14–3-3eta negative and 139 were positive; there was agreement in 197 (93%) of the 212 samples.

Conclusions: As defined by the soluble biomarker sub-committee of OMERACT, reliability and standardization of biomarker assessments in routine clinical practice across the globe and in clinical studies is of high importance. The results presented herein demonstrate that the 14–3-3eta assay is highly reliable, that testing/delivery of results can be standardized between two independent laboratories, and that it is very stable over time and when shipped between continents.

SAT0623 CORRELATIONS BETWEEN CLINICAL, ULTRASOUND AND DISEASE ACTIVITY SCORES OF PERIPHERAL ENTHESITIS IN SPONDYLOARTHRITIS (SPA)

A. Haddouche, S. Haid, S. Bencheikh, S. Slimani, A. Abdessemed, N. Brahimi, A. Ladjouze. *Medicine, University of Algiers 2, Algiers, Algeria*

Objectives: To look for correlations between clinical, ultrasound (US) and disease activity scores of peripheral enthesitis in an SpA cohort.

Methods: A prospective study of all SpAs meeting SpA ASAS criteria followed at EHS Ben Aknoun, over a period from January 2015 to April 2016. Seventeen entheseal sites were assessed bilaterally: insertions of supra-spinatus, infra-spinatus, sub-scapular, medial and lateral epicondylars, triceps brachialis, gluteus midius and minimus, quadricipital, proximal and distal insertion (patellar ligament, medial and lateral collateral ligament), Achilles tendon and plantar aponeurosis. Peripheral entheses was assessed by the following clinical scores: Enthesitis Peripheral Score (PES= Sum of symptomatic peripheral entheses sites on clinical examination), Visual Analog Scale of peripheral enthesitis (VAS), Spondyloarthritis Research Consortium of Canada score (SPARCC) as well as the following US enthesitis scores: Acute Enthesitis score (Sum of acute enthesitis US scores for each site), Chronic Enthesitis score (Sum of US chronic enthesitis scores for each site), Global Enthesitis score (Sum of the acute and chronic US scores of enthesitis), Doppler signal Enthesitis score (Sum of Doppler signal scores less than 2mm from cortical bone for each site), Madrid Sonography Enthesitis Index (MASEI), Simplified Echographic Score (SES) wich assesses only the Achilles

tendon and the plantar aponeurosis. Correlations between clinical, activity and US scores were investigated by SPPSS software.

Results: A total of 208 patients were included. At examination 88.9% had an active disease and 64.4% of SpA were taking NSAIDs. 6240 entheses were assessed clinically and with US. A positive correlation was found between activity scores and two clinical scores (Peripheral Enthesitis Score, SPARCC). A good correlation was found between Activity scores and all US scores on one hand and with SPARCC scores and PES scores on the other hand. For US and clinical correlations, only Doppler scores was positively correlated with 2 clinical scores (SPARCC and PES scores), Acute Enthesitis scores was correlated with the PES scores. No correlation was found between clinical scores and MASEI or SES scores. No correlation was found with the mean enthesitis VAS scores.

Table 1. Correlations between clinical scores and activity scores with ultrasound scores

scores	PES	VASm Enthestis	SPARCC	ASDAS-vs	ASDAS-crp
Acute Enthesitis	r: 0,14	r: -0,03	r: 0,16	r: 0,43	r: 0,52
	p: 0,04	p: 0,72	p: 0,07	**p<0,001**	**p<0,001**
Chronic Enthesitis	r: 0,07	r: -0,15	r: 0,06	r: 0,19	r: 0,22
	p: 0,30	p: 0,03	p: 0,41	**p: 0,006**	**p: 0,002**
Global Enthesitis	r: 0,15	r: -0,08	r: 0,13	r: 0,43	r: 0,52
	p: 0,03	p: 0,24	p: 0,07	**p<0,001**	**p<0,001**
Doppler Enthesitis	r: 0,16	r: -0,001	r: 0,18	r: 0,34	r: 0,36
	p: 0,02	p: 0,99	**p: 0,01**	**p<0,001**	**p<0,001**
MASEI	r: 0,09	r: -0,08	r: 0,12	r: 0,44	r: 0,34
	p: 0,19	p: 0,23	p: 0,07	**p<0,001**	**p<0,001**
SES	r: 0,04	r: -0,04	r: 0,09	r: 0,31	r: 0,38
	p: 0,55	p: 0,59	p: 0,18	**p<0,001**	**p<0,001**

Table 2. Correlations between clinical scores and activity scores

	PES	VASm Enthestis	SPARCC
ASDAS-vs	r: 0,32	r: -0,04	r: 0,27
	p<0,001	p: 0,62	**p<0,001**
ASDAS-crp	r: 0,31	r: -0,03	r: 0,27
	p<0,001	p: 0,62	**p<0,001**

Conclusions: All US enthesitis scores were correlated with disease activity scores but those correlated with the clinical symptoms and not with its intensity were: Acute Enthesitis Scores, Global Enthesitis Scores and especially Doppler signal Enthesitis Scores.

SAT0624 QUANTITATIVE 3D IMAGING OF TENOSYNOVITIS AND BONE MARROW EDEMA BY DCE-MRI IS A SENSITIVE MEASURE OF RESPONSE TO THERAPY IN RHEUMATOID ARTHRITIS

C. Roberts[1], G. Guillard[2], M.A. Bowes[2], J. Burlison[2], A. Khan[2], N. Maguire[1], S. Gotla[1], A. Morgan[1], G.J. Parker[1,3], R. Hodgson[3,4], J. Freeston[4], E.M. Vital[4], P. Bird[5], P. Emery[4], P.G. Conaghan[4]. *[1]Bioxydyn; [2]Imorphics; [3]Centre for Imaging Sciences, University of Manchester, Manchester; [4]University of Leeds, Leeds, United Kingdom; [5]Combined Rheumatology Practice, Sydney, Australia*

Background: Quantitative analysis of tissue microvascular function using dynamic contrast-enhanced MRI (DCE-MRI) shows promise for improved understanding of synovial pathophysiology in rheumatoid arthritis (RA). Assessing tenosynovitis and bone marrow edema (BME) using physiologically-interpretable measures such as *K*trans may offer additional insights; this will require increased precision in quantification.

Objectives: To apply a 3D DCE-MRI method to quantify capillary permeability (K^{trans}) in tendons, bone marrow edema, and to explore muscle involvement. To generate precise and consistent 3D regions of interest (ROI) of tenosynovitis and BME using active appearance models (AAMs)? and evaluate response to therapy within these regions.

Methods: MR images of the hand were acquired in 27 patients with established RA who had recently commenced the same biological therapy. Subjects were imaged at 0,3,6 months. The MRI protocol included pre- and post-contrast high-resolution 3D FLASH acquisitions. The DCE-MRI scan protocol included T1 mapping sequences followed by 15 sequential volumes acquired over 5 minutes, during which a bolus of gadolinium (0.1 mmol/kg) was administered at 2 ml/s at the beginning of the 5th volume measurement. The Extended Kety model was applied to each voxel concentration-time series within ROIs, allowing voxelwise estimates ofK^{trans}. Pre-contrast T1-weighted mages were searched using 3D active appearance models (AAMs) to reliably identify tendons and their sheath in the carpal tunnel region as well as bones and marrow area. Images from the dynamic series were registered to the high-resolution pre-contrast images, providing standardised 3D ROIs for each of the regions. Median K^{trans} was summarised in each patient for each ROI. T-test ($p<0.05$) determined significant differences from baseline.

Results: Differences in baseline *K*trans were observed in each tissue type and demonstrated that highest levels of inflammation within the synovium, followed by tenosynovitis, BME and detection of low grade inflammation in the muscle (Fig. 1). Significant post-therapy responses in *K*trans, indicating a reduction in perfusion and capillary permeability associated with reduced inflammation, were seen in each of these tissue types (Fig.1). RAMRIS scoring showed no significant change at either 3 or 6 months. 3D visualisation of *K*trans in tenosynovitis revealed additional spatial response to the biological treatment (Fig. 2) – most of the remaining tenosynovitis at 6 months had lower permeability with almost all of the higher permeability class of synovitis disappearing after therapy.

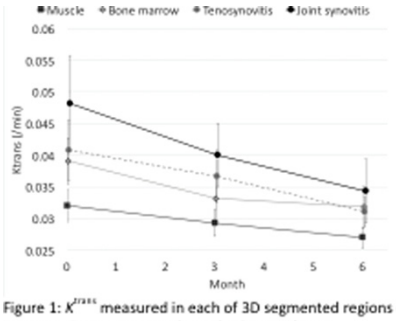

Figure 1: K^{trans} measured in each of 3D segmented regions of interest. Group mean and standard error shown.

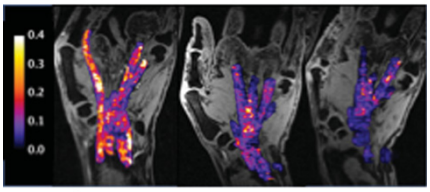

Figure 2: K^{trans} (/min) maps overlaid on post-contrast T_1-weighted images from an example patient imaged at baseline (left), 3 months post-therapy (centre) and 6 months (right).

Conclusions: 3D DCE-MRI measures of tenosynovitis and bone marrow edema are practical in RA MR imaging trials, and offer sensitivity to change and differential tissue response not visible with other methods. Therapy-induced response in muscle suggests that there may be an inflammatory process in RA affecting local muscle groups.

SAT0625 ULTRASOUND ASSESSMENT OF JOINTS AND ENTHESIS IN A COHORT OF PATIENTS AFFECTED BY OCHRONOSIS: HOW COMMON IS INFLAMMATION?

C. Toscano[1], V. Di Sabatino[1], A. Adinolfi[1], M. Bardelli[1], V. Picerno[1], E. Selvi[1], A. Santucci[2], M. Galeazzi[1], B. Frediani[1], G. Filippou[1]. *[1]Department of Medicine, Surgery and Neuroscience; [2]Department of Biotechnology, Chemistry and Pharmacy, University of Siena, Siena, Italy*

Background: Ochronosis, the musculoskeletal manifestation of alcaptonuria (AKU), is characterized by alterations of the spine and large joints of the limbs similar to those of osteoarthritis. However, some cases of spinal involvement that resembles spondiloarthritis (SpA) have been describe, suggesting a prevalent inflammatory involvement of the joints.

Objectives: To evaluate the prevalence of inflammatory abnormalities in peripheral joints and enthesis of a cohort of patients affected by AKU.

Methods: consecutive patients with definite diagnosis of AKU (with or without clinical manifestations) referred at our clinic from 2014 to 2016 were enrolled. All patients underwent a US examination of the following sites bilaterally: metacarpo-phalangeal joints (MCP), proximal interphalangeal joints (PIP), radiocarpal/mid carpal joints, elbow, gleno-humeral, hip, knee, ankle and metatarso-phalangeal (MTP) joints; flexor and extensor tendons of fingers and wrist and the ankle tendons. Further, the enthesis of the rotator cuff of the shoulder, triceps, quadriceps, patellar and Achilles tendon were assessed. Joints and tendons with a synovial sheath were assessed for effusion, synovial hypertrophy and power Doppler (PD) signal while enthesis were evaluated for the presence of PD signal, enthesophytes and calcifications. All the US lesions were scored using a dichotomous scale (presence/absence). All US exams were performed by an expert sonographer blind to clinical history, using an Esaote MyLab70 scanner equipped with high resolution linear probes.

Results: 11 patients (6 women) were enrolled in this study with a mean age of 57 yo (SD±11,50). the mean number of joints with effusion was 3,9 for each patient (median 3, range 2–8) while the mean number of joints with synovial hypertrophy was of 2,9 (median 2, range 2–7). =0,18 joints (median 0, range 0–2) presented also PD signal. I The mean number of exudative tenosynovitis was0,81 (median 2, range 0–3) while proliferative tenosynovitis (mean 0,54, median 0, range 0–2) and PD in tendons with sheaths (mean 0,27, median 0, range 0–2) were rare. Finally, the mean number of enthesis with PD was 1,27 (median 1, range 0–7), the mean number of enthesophytes was 0,63 (median 0, range 0–3) and for calcifications 4,27 (median 5, range 1–8).

Conclusions: Ochronotic arthropathy is believed to be characterized by a widespread articular damage, correlated mainly to degenerative processes due to the deposition of Homogentisinic Acid in the joints. The results of this US study

showed that joint inflammation is common in ochronotic patients, associated in some cases with peripheral enthesis involvement confirming previously published data (1). The prevalence and the characteristics of the inflammatory manifestations should be further studied in larger cohorts of patients as they could play an important role in the joint damage process in these patients and provide a rationale for the use of new drugs.

SAT0626 METACARPOPHALANGEAL JOINT SWELLING IN PSORIATIC ARTHRITIS: WHAT DOES IT MEAN?

C. Macía[1], S. Falcao[2], M. Gutierrez[3], J. Medina[4], H.B. Hammer[5], E. De Miguel[6]. *[1]Rheumatology, Hospital Universitario Severo Ochoa, Madrid, Spain; [2]Rheumatology, Chronic Diseases Study Center (CEDOC), NOVA Medical School, UNL, Lisboa, Portugal; [3]Rheumatology, Division of Musculoskeletal and Rheumatic Disorders. Instituto Nacional de Rehabilitación, Mexico City, Mexico; [4]Rheumatology, Hospital Clínico Universitario, Valladolid, Spain; [5]Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; [6]Rheumatology, Hospital Universitario la Paz, Madrid, Spain*

Background: Clinical metacarpophalangeal joint (MCPj) swelling is a frequent finding in psoriatic arthritis (PsA). It is assumed to be caused by intra-articular synovitis (IAS). However, ultrasound (US) have also demonstrated in PsA peritenon inflammation of the extensor digitorum tendon (PTI).To date the data about the significance of this two lesions (IAS and PTI) in MCPj swelling are sparse.
Objectives: Our objective was to explore PTI and IAS as the cause of clinical MCPj swelling in PsA patients.
Methods: 27 consecutive non selected PsA patients, fulfilling CASPAR criteria, with clinical involvement of at least one 2nd to 5th MCPj were included. A MyLab 70 XVG machine, Esaote, Genova, Italy, with a greyscale (GS) 13 MHz probe, and a 7.1 MHz power Doppler (PD) frequency (PRF 750 Hz, Gain 60) was used. Videos (3–5 sec) of each MCPj 2nd to 5th of both hands in transversal and longitudinal views were obtained for central reader analysis, scoring US as presence or absence in GS and PD of: 1) PTI (defined as an hypoechoic swelling of the soft tissue surrounding the extensor tendon at MCPj level with or without PD) and 2) IAS (OMERACT definition). US pathology for each joint and lesion was defined as at least three of five central readers having the same score. SPSS analysis was performed for frequencies, percentage of agreement and Cohen's Kappa test.
Results: 27 PsA patients with a mean (SD) age of 56 (11) years and disease duration 109 (101) months were included. Isolated peripheral involvement was present in 21 patients (78%) and 6 (22%) had both axial and peripheral affection. Mean (SD) CRP level was 8.3 (8.2) mg/l and ESR 21.9 (19.3) mm. The mean DAS28 ESR was 3.88 (1.23). Psoriasis involvement included skin and nails in 15 (55.5%) of the patients.
A total of 216 MCPj were examined, with 60 (27,7%) being clinically swollen. The figure illustrates the agreement between clinical and US assessments, and the table shows the kappa values for the agreements. PTI in at least one MCPj was found in 19/27 patients (70%) with a total of 41/216 locations (19%) in GS. For IAS, there was GS in at least one MCPj in 23/27 patients (85%) with a total of 63/216 locations (29%). 28 of 41 (68.3%) joints had both PTI and IAS.

Table 1. US findings versus Clinical joint swelling

	Agreement n (%)	Kappa
Any US lesion (vs. clinical swelling)	167/216 (77.3%)	0.471
Any grey scale lesion (vs. clinical swelling)	166/216 (76.8%)	0.426
Any power Doppler lesion (vs. clinical swelling)	169/216 (78.2%)	0.550
Grey scale IAS (vs. clinical swelling)	166/216 (76.8%)	0.426
Power Doppler IAS (vs. clinical swelling)	177/216 (81.9%)	0.499
Grey scale PTI (vs. clinical swelling)	175/216 (81.0%)	0.474
Power Doppler PTI (vs. clinical swelling)	176/216 (81.5%)	0.478

Conclusions: Our study identifies two different US lesions (IAS and PTI) causing clinical joint swelling. PTI is near as frequent as IAS as a cause of MCPj swelling, and future studies are necessary to explore the added value of assessing PTI for prognosis or treatment.

SAT0627 MUSCLE BIOPSY: MASTER ROLE IN DIFFERENTIAL DIAGNOSIS IN PATIENTS WITH SUSPECTED MYOPATHY

D. Santos-Faria, J. Sousa-Neves, M. Cerqueira, J.L. Silva, J.R. Rodrigues, D. Peixoto, J. Tavares-Costa, S. Alcino, C. Afonso, F. Teixeira. *Rheumatoloy, Unidade Local de Saúde do Alto Minho, Ponte de Lima, Portugal*

Background: The muscle biopsy may be a fundamental technique in the suspicion of myopathy, with high specificity to distinguish between normal or abnormal muscle tissue. In association with clinical and laboratory findings, the muscle biopsy has an important role to a more accurate diagnosis.
Objectives: To evaluate the usefulness and safety of muscle biopsies performed in a Rheumatology Unit in patients with suspected myopathy.
Methods: Retrospective analysis of the clinical charts of patients submitted to muscle biopsy between January 2010 and December 2016 at our Rheumatology Unit. Demographic, clinical, laboratory, electromyographic and histological data were collected. The histological study was performed in a Neuropathology Specialized Unit.
Results: A total of 46 patients, 19 men and 27 women, with a mean age of 53.3±17.1 years, were evaluated. Clinical manifestations included muscle weakness, myalgia and decreased muscle strength. Most patients also had increased muscle enzymes, particularly creatine kinase, but in a patient with generalized muscle atrophy, muscle enzymes were overall diminished. Of the 46 biopsies, 12 (26.1%) did not show alterations, 8 (17.4%) showed nonspecific alterations and only 1 biopsy was not conclusive because the sample was inadequate. In 4 patients, the histological features did not present specific characteristics of a myopathy, but revealed a preferential atrophy of type 2 fibbers, usually associated with prolonged corticosteroid therapy. Among the others, 9 (19.6%) were compatible with inflammatory myopathies, namely polymyositis (6), dermatomyositis (1), inclusion body myopathy (1), and localized nodular myositis (1). In the latter case, the patient had a different clinical presentation, with intermittent episodes of pain, oedema and flushing of different muscle groups. In addition, 5 metabolic myopathies (2 McArdle's diseases and 3 non-specific metabolic disorders), 2 muscular dystrophies (1 Becker's muscular dystrophy and 1 dystrophinopathy), 1 suspected case of myotonic dystrophy and 1 myopathy associated with statins use were diagnosed. In a patient with muscle weakness and prior diagnosis of systemic vasculitis, the histology showed a chronic inflammatory process with no specific alterations. In the patient with overall decrease in muscle enzymes, the biopsy revealed neurogenic atrophy, without inflammatory infiltrates. Overall, the results of electromyography (EMG) did not correlate with the histological findings, because EMG identified alterations both in cases with histologically compatible inflammatory myopathy and in cases without histological pathology. On the other hand, EMG did not reveal any changes in some of the metabolic myopathies. Muscle biopsies were performed mainly in the deltoid muscle. There were no relevant immediate or late complications with this technique.
Conclusions: Although muscle biopsy is an invasive technique, it is a safe technique and allows the differential diagnosis between the various myopathies, which is fundamental to an appropriate treatment.

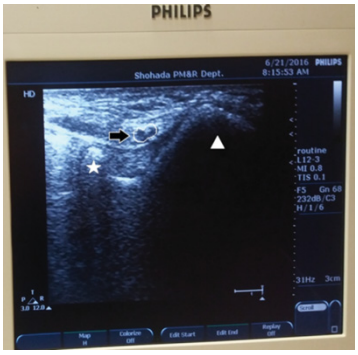
SAT0628 INCREASE OF CORTICAL MICRO-CHANNELS (COMICS) AS A NEW FEATURE OF STRUCTURAL DAMAGE IN PAIENTS WITH RHEUMATOID ARTHRITIS

D. Werner[1,2], D. Simon[1], M. Englbrecht[1], F. Stemmler[1], A. Berlin[1], J. Haschka[3], N. Renner[4], T. Buder[5], J. Rech[1], K. Engelke[6], A.J. Hueber[1], G. Schett[1], A. Kleyer[1]. *[1]Department of Internal Medicine 3 – Rheumatology and Immunology, Universitätsklinikum Erlangen, Friedrich-Alexander-University Erlangen-Nürnberg (FAU), Erlangen; [2]Rheumatologie & Nephrologie, Städtisches Klinikum Dresden, Dresden, Germany; [3]St.Vincent Hospital, Medical Department, Academic Teaching Hospital of Medical University of Vienna, Vienna, Austria; [4]Department of Trauma and Orthopedic Surgery, Friedrich-Alexander-Unviersity Erlangen-Nuremberg; [5]Institute of Anatomy, Friedrich-Alexander-University Erlangen-Nürnberg (FAU); [6]Institute of Medical Physics, Friedrich-Alexander-University Erlangen-Nuremberg Erlangen, Erlangen, Germany*

Background: Bone damage in rheumatoid arthritis (RA) typically emerges at certain anatomical hotspots corresponding to the so-called "bare area", an intra-articular region between the cartilage and the insertion site of the joint capsule (1,2). We hypothesized that this region exhibits certain micro-anatomical properties, which facilitates the emergence of bone erosions.

Objectives: To find the micro-structural correlate of the origin of bone erosions in the bare area of the human joint
Methods: Bare areas of human joints were analyzed for early microstructural changes by in-vivo high-resolution peripheral computed tomography (HR-pQCT). First, bare areas were exactly defined by scanning 6 cadaveric hands for localization of the bare area in the human metacarpal head. Bone lesions found in the cadaveric hand by HR-pQCT were additionally by super-resolution ex vivo micro-CT (μCT40). Then, number and distribution of the type of bare area bone lesion found in cadaveric study were analyzed in a cohort of 105 healthy individuals and 107 anti-citrullinated peptide (ACPA) positive RA patients with similar sex and age distribution.
Results: HR-pQCT combined with adaptive thresholding allowed the definition of a new type of bone lesions in the bare areas of the human joint termed "COMIC" standing for "cortical micro-channel". Their existence in the bare area was additionally validated by microCT (Figure 1). RA patients showed significantly ($p<0.001$) more CoMiCs (112.9±54.7/joint) than healthy individuals (75.2±41.9/joint) with 20–49 years old RA patients exhibiting similar CoMiC numbers as observed in over 65 year old healthy individuals. Importantly, CoMiCs were found in RA patients already very early in their disease course with enrichment in the erosion-prone radial side of the joint.



Conclusions: CoMiCs represent a new structural feature of the joint, which is characteristic for the bone of the bare area. COMICS at low level are also found in young healthy individuals but they significantly increase with age and particularly with RA. COMICs develop much earlier and much more pronounced in RA patients than in healthy individuals and therefore represent an interesting new early indicator for erosion development in ACPA positive RA patients.

SAT0629 ELECTRODIAGNOSTIC VS ULTRASONOGRAPHY: WHICH ONE IS BETTER TO CONFIRM DIAGNOSIS OF ULNAR NEUROPATHY AT ELBOW?

S.M. Rayegani[1], E. Loni[2], S.A. Raeissadat[3], E. Kargozar[4], S. Rahimi Dehgolan[1]. *[1]Physical Medicine and Rehabilitation Research Center, Shahid Beheshti University of Medical Sciences; [2]Rofeideh rehabilitation Hospital, University of Social Welfare and Rehabilitation Sciences; [3]Physical Medicine and Rehabilitation Research Center, ShahidBeheshti University of Medical Sciences; [4]Physical Medicine and Rehabilitation, Baharloo Hospital, Faculty of Medicine, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic Of*

Background: Ulnar neuropathy at the elbow is the second most common compression neuropathy preceded by carpal tunnel syndrome. Although this diagnosis has been traditionally confirmed by electrodiagnosis (EDX), ultrasonography (US) is a re-emerging alternative method which can also evaluate the cubital zone anatomy. This study determines the maximum amount of US sensitivity and specificity by assessing different sonographic parameters and evaluates consistency and diagnostic value of the best US method in compare with EDX.
Methods: We included 66 participants (32 elbows of patient and 34 normal elbows) and performed physical exam, US and EDX for both groups. Patients were classified into four severity grades using EDX criteria. The parameters of US were cross sectional area (CSA) of ulnar nerve at three levels: medial epicondyle (CSA med), 2cm distal (CSA dist) and 2cm proximal (CSA prox) to medial epicondyle. Then we would be able to evaluate consistency between two tests using area under receiver operating curve (AU-ROC) method and also to determine the optimum CSA cut-off point to better diagnosis of ulnar neuropathy by US.
Results: Our findings showed that CSA med and CSA dist had significantly larger size in patients compared to normal participants (P-value =0.01 and 0.05, respectively). This increase in nerve size was more prominent among those who had axonal lesion rather than patients with demyelinated lesion (p-value <0.01). Moreover those who had longer duration of symptoms had significantly higher CSA med. and CSA dist. (p-value=0.015 and 0.001 respectively). The other promising findings were two important points; First a strong correlation between CSA med. and severity grade (p-value=0.034) and the second correlation was between CSA med and CSA dist. with a cross-elbow nerve conduction velocity (NCV) (p-value=0.01 and 0.02, respectively). Finally we assessed US diagnostic value as it showed AU-ROC =0.871, that means a very good coverage for an alternative diagnostic method. Also our results showed specificity of 80% and sensitivity of 84% for US in the CSA med cut-off point =9mm^2 for diagnosis of ulnar nerve entrapment at elbow.

Conclusions: Based on these results we can conclude that US is a highly sensitive and specific method to diagnose ulnar neuropathy at elbow and can be used as an alternative and complementary method in diagnosis of ulnar neuropathy at elbow in particular when EDX is not available. However it could not be still a definitive and substitute mutually exclusive method to EDX in diagnosis of ulnar neuropathy

SAT0630 EXTRA-ARTICULAR MUSCULOSKELETAL INVOLVEMENT IN JUVENILE IDIOPATHIC ARTHRITIS: CLINICAL AND ULTRASONOGRAFIC FINDINGS

V. Ravagnani[1], F. Licciardi[2], D. Montin[2], F. Santarelli[3], S. Martino[4], C. Cirone[5]. *[1]Internal Medicine, ASST MANTOVA - C. Poma Hospital, Mantova; [2]ImmunoRheumatology Unit, Regina Margherita Children Hospital Città della Salute e della Scienza; [3]ImmunoRheumatology Unity, Regina Margherita Children Hospital, Città della Salute e della Scienza; [4]ImmunoRheumatology Unity, Regina Margherita Children Hospital Città della Salute e della Scienza; [5]ImmunoRheumatology Unit, Regina Margherita Children Hospital, Città della Salute e della Scienza, Torino, Italy*

Background: in Juvenile Idiopathic arthritis (JIA), musculoskeletal ultrasound (MSUS) has been proven to be more sensitive than clinical evaluation in detecting articular synovitis. Nevertheless, many studies report a variable percentage of clinically active joints, that are judged normal by ultrasound examination. In absence of a feasible and reliable gold standard for pediatric synovitis (histology or MRI), this point may weaken the confidence in ultrasound, that is nevertheless perceived as an interesting tool, in the management of JIA.
Objectives: This preliminary study investigates the possibility that sometimes the clinically detected synovitis could be missed by ultrasound, because of its extra-articular localization.
Methods: 43 consecutive children affected by JIA underwent separated clinical and ultrasound assessments, blindly, in the same day. Patients were followed up in a pediatric Rheumatology Unit. The following clinical data were collected: age, sex, disease duration, subset of JIA, ongoing therapy, previous therapy, disease activity. By MSUS, the synovitis was investigated bilaterally, both in gray scale and power Doppler, in the MCP and subtalar joints, wrists, knees, ankles, in the flexor and extensor tendons of the wrist and hand, in the anterior, medial and lateral tendons of the ankle, in the synovial bursae of knee and ankle. The possible involvement of the entheses was also investigated. The definition of ultrasonographic synovitis was based on the preliminary OMERACT definitions of synovitis in children. The inter and intra observer reproducibility of the MSUS examination was tested, independently, both between two operators and through a second assessment of the stored images.
Results: 43 children affected by JIA were recruited, in the outpatient clinic of the Regina Margherita Pediatric Hospital of Torino, Italy. They were 9 boys and 34 girls, median age 7,7 (IQR 5,5–10,1), 27 oligoarticular, 11 poliarticular, 4 psoriatic arthritis, 1 undifferentiated arthritis. The median disease duration was 44 months (IQR: 20,5–61,5), 20 patients in remission, 23 with active disease. 774 joints, 1548 synovial sheaths, 430 entheses and 258 synovial bursae were assessed. The physical examination detected inflammation in 54 joints, 33 tendons, 0 entheses,

0 bursae. Ultrasound abnormalities were found in 62 joints, 73 tendons, 8 bursae, 0 entheses. Overall physical examination and MSUS showed good concordance even if MSUS was more sensitive especially in detecting extra-articular locations.
Conclusions: If the extra-articular locations of synovitis are taken in consideration during the ultrasound examination, there is a good sensitivity of MSUS and a better concordance between clinical and MSUS assessment of JIA. MSUS seems more accurate than physical assessment in detecting the exact position of the inflamed synovial membrane in each anatomical location (joint, synovial sheath, synovial bursa). It could be helpful not only for better addressing the injective procedures, but also for a global quantification of the synovitis (both intra and extra-articular), even if the exact clinical meaning of these ultrasound findings is still unknown, in terms of response to treatments and prognosis.

Background: The OMERACT US subtask force "US in CPPD" recently created the definitions for US identification of crystal deposits in joints and tested the reliability at the knee [1].
Objectives: To assess the inter/intra-observer reliability of US on detecting CPPD at triangular fibrocartilage complex (TFCC) of the wrists, fibrocartilage of the AC joint, hip labrum (HL), hyaline cartilage (HC) of the metacarpal (MC) and femoral head.
Methods: The OMERACT criteria for CPPD were used for the exercise [1] using a 2 steps approach. First, the panel of experts gave a dichotomous score (presence/absence of CPPD) of 120 images of the sites included, using a web platform. The images were evaluated twice to assess the inter/intra-observer reliability. Then, the experts met in Siena for a patient based exercise. Bilateral evaluation of TFCC, AC, HL /HC of the hip and HC of the II-III MCP of 8 patients was carried out twice in a day, using a dichotomous score for CPPD. 8 US machines (3 GE, 1 Samsung and 4 Esaote) equipped with high resolution linear probes were used.
Results: Reliability values of static exercise were high for all sites, demonstrating that definitions were clear. The results of the second step are presented in table 1. On live scanning, the TFCC resulted the most reliable site for CPPD assessment, followed by AC. Other sites demonstrated lower kappa values and thus are not reliable for CPPD assessment.
Conclusions: TFCC of the wrist is the most reliable site for CPPD. By adding these results to the previous [2], we confirm that the OMERACT definitions for CPPD can be applied reliably at the knee (meniscus and HC), TFCC and AC, usually the most involved sites in CPPD. The next step of the OMERACT subtask force will be to test these findings in a longitudinal observational study.

SAT0632 IMPACT OF LUMBAR SPINE MORPHOLOGY (SCOLIOSIS) ON EARLY SPONDYLOARTHRITIS PATTERN (THE IMPALA-DESIR STUDY)

M. Voirin-Hertz[1], G. Carvajal Alegria[1], F. Garrigues[2], A. Simon[3], A. Feydi[4], F. de Bruin[5], M. Reijnierse[6], D. van der Heijde[7], D. Loeuille[8], P. Claudepierre[9], T. Marhadour[1], A. Saraux[1] on behalf of DESIR. *[1]Rheumatology; [2]Radiology; [3]Neurosurgery, CHU Brest and Université Bretagne Occidentale, Brest; [4]Radiology, CHU Cochin, Paris, France; [5]Radiology, 5Leiden University Medical Center; [6]Radiology; [7]Rheumatology, Leiden University Medical Center, Leiden, Netherlands; [8]Rheumatology, CHU, Nancy; [9]Rheumatology, CHU Creteil, Paris, France*

Objectives: To evaluate the impact of scoliosis on both clinical presentation and lumbar imaging of early inflammatory back pain suggestive of spondyloarthritis.
Methods: The DESIR cohort is a prospective longitudinal cohort study of adults aged 18–50 with inflammatory back pain (IBP) $\geq$3 months, $\leq$3 years. Baseline lumbar X-Rays of patients included in DESIR cohort were read by two central blinded fellow readers (and a rheumatologist spine specialist in case of discrepancy) for presence or not of scoliosis (defined as a Cobb angle$>$10° and a Nash Moe grade$\geq$1). Associations between scoliosis and baseline clinical variables, presence of X-Rays (New York) and MRI (ASAS and MORPHO proposal definition) sacroiliitis, presence of spinal signs of spondyloarthritis (mSASSS, BASRI-total, SPARCC scores), presence of spinal degenerative MRI signs on X-rays (yes or no) and MRI (presence of Modic abnormalities, Pfirrmann score, Canal stenosis, Extrusion, High intensity zone Facet osteoarthritis) according to central reading (two readers) and axSpA diagnostic confidence (according to local clinician's confidence on a 0–10 visual analogic scale) were assessed by univariate analysis using the chi-square test (or Fisher's exact test where appropriate) and the Mann-Whitney test. Adjustment for multiple testing was performed according to Bonferroni method.
Results: 675 patients (47.1% men, mean age of 33.6 years, 89.6% had lumbar pain, 65% fulfilling ASAS criteria) were studied. The mean Cobb angle was 3.2° (± 4.8) and 49/675 (7.3%) patients had lumbar scoliosis. The only significant difference was the lumbosacral sagittal balance. Indeed, scoliotic patients had greater lumbar lordosis (57.8° versus 50.9°; $p<0.001$) than non-scoliotic. About MRI findings, spinal degenerative manifestations were very scarce in both groups. The major part of degenerative changes was in the two last lumbar discs and vertebras, without significant difference between scoliotic and non-scoliotic patients.
Conclusions: Scoliotic patients with inflammatory back pain suggestive of spondyloarthritis do not have more lumbar degenerative lesions than non-scoliotic patients, nor difference of clinical presentation, but they have greater lumbar lordosis.

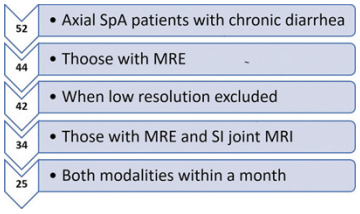
SAT0633 NOT A REPLACEMENT BUT A POSSIBLE SUBSTITUTION: DETECTION OF SACROILIITIS ON MAGNETIC RESONANCE ENTEROGRAPHY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

I. Ergenç[1], R. Ergelen[2], A.U. Ünal[3], Z. Ertürk[3], Y. Yalçınkaya[3], N. İnanç[3], N. İmeryüz[4], H. Direskeneli[3], G. Ekinci[2], P. Atagündüz[3]. *[1]Internal Medicine; [2]Radiology; [3]Rheumatology; [4]Gastroenterology, Marmara University School of Medicine, Istanbil, Turkey*

Background: MR Enterography (MRE), a part of the diagnosis in patients with inflammatory bowel disease (IBD), is increasingly used to exclude Crohn's Disease (CD) in SpA patients with diarrhea. Two important retrospective studies[1,2], on IBD



suggest that acute and structural findings of sacroiliitis can be evaluated on MRE. But, it needs to be verified whether it really correlates with sacroiliac MRI.

Objectives: We aimed to determine whether assessment of sacroiliitis on MRE correlates with magnetic resonance imaging (MRI) of sacroiliac (SI) joint.

Methods: MREs used for screening of IBD in Axial SpA patients with chronic diarrhea and routine semi-coronal SI joint MR images were screened for the presence of acute inflammatory lesions and structural changes of the SI joint by the same radiologist in a blinded fashion to time and diagnosis. Firstly, MRE images and then MR images were evaluated on two separate occasions. Only patients with two imaging modalities with a maximum time distance of a month were evaluated.

Results: Forty-four patients with MRE imaging were included. Two MRE studies were excluded because of low resolution. Of those 11 patients (26%) had active inflammatory lesions involving mostly both SI joints and 3 had accompanying chronic structural changes. Ten patients (%24) in the MRE group had chronic structural changes, only. In the remaining 20 (47%) MRE evaluated patients SI joint were not affected. Twenty-five axSpA patients had both MRE and SI joint MRIs performed within a month. In 19 cases, out of 25 with both modalities the finding "no sacroiliitis" overlapped. An additional four patients had acute inflammatory lesions on both investigations. In only two patients either MRE or SI joint MRI had acute inflammatory lesions. In general, chronic structural changes overlapped in both modalities as well; Fourteen out of 25 patients with no changes and eight with chronic changes overlapped in both examinations. Both modalities differ in only three patients; Chronic changes was present in two patients in SI joint MRI and one patient in MRE only.

		MRE (Sacroiliitis)	
		(+)	(–)
SI joint MRI (Sacroiliitis)	(+)	4	1
	(–)	1	19
		MRE (Structural Findings)	
		(+)	(–)
SI joint MRI (Structural Findings)	(+)	8	2
	(–)	1	14

Conclusions: In SpA patients with chronic diarrhea a present MRE may substitute a conventional semi-coronal MRI of the SI joints and may hence decrease diagnostic expenses. Evaluation of MRE for the acute inflammatory and chronic structural changes of the SI joints may also have a place in the diagnostic flow in IBD patients referred by the gastroenterology clinics, as well.

SAT0634 MUSCULOSKELETAL ULTRASOUND IN PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATISM POST-CHIKUNGUNYA

I. Monjo Henry[1], F. De la Calle[2], E. Trigo[2], E. Fernandez[1], D. Benavent[1], E. De Miguel[1], A. Balsa[1]. *[1]Rheumatology, Hospital la Paz; [2]Tropical Diseases and Travel Unit, Hospital la Paz-Carlos III, Madrid, Spain*

Background: Since 2013, Chikungunya fever (CHIK) has become a re-emerging disease, with an important number of cases imported in Europe, mainly from South America. At chronic stage (after third month) it can develop a chronic inflammatory rheumatism (CIR), in some cases indistinguishable from rheumatoid arthritis (RA) or spondyloarthritis (SpA).

Objectives: The aim of this study was to investigate the ultrasound (US) alteration in patients with persistent arthralgia at chronic stage of CHIK.

Methods: Observational study of patients with persistent arthralgias at the chronic stage of CHIK. We designed a protocol of derivation patients from the Tropical Diseases Unit to the Rheumatology Department which included patients had persistent arthritis after 6 weeks who did not respond to steroids, presence of bone erosion or any diagnosis doubt. In the basal rheumatological visit, we made the clinical history, physical examination, blood analysis, X-ray and US examination. A Mylab Twice equipment (Esaote, Geneve, Italy) was used, with a 5–13 MHz frequency for grey scale and 5–12.5 MHz for Power Doppler (PD). Wrist, metacarpophalangeal (MCP), interphalangeal (IP), knee, ankle and metatarsophalangeal joint were assesed and also enthesis if symptomatic. Three patterns of post-CHIK CIR were defined: 1) Post-CHIK RA (if meet RA ACR/EULAR 2010 criteria). 2) post-CHIK SpA (if meet ASAS criteria) and 3) post-CHIK undifferentiated arthritis (arthritis without meeting the previous criteria). Post-CHIK musculoskeletal disorders were defined as chronic polyarthralgia without objective physical signs of inflammation (without arthritis, tendinitis or enthesitis).

Results: 59 patients were included, 76.3% women, mean age of 46.08±13.65 years. 6 patients (10.2%) were derived to the Rheumatology Department, 5 women and 1 man. In one rheumatoid factor and anti-cyclic citrullinated peptide antibodies were detected. HLA B27 and antinuclear antibodies were negative in all patients. The physical and US data of these patients are shown in the table. 5 of these patients were diagnosed with post-CHIK CIR: 1 post-CHIK RA, 1 non-radiographic axial SpA with peripheral affectation (arthritis and enthesitis) and 3 patients with post-CHIK undifferentiated arthritis. The other patient was diagnosed with post-CHIK musculoskeletal disorder. All 59 patients received NSAIDs and steroids. In addition, post-CHIK CIR received methotrexate (2 patients) and sulfasalazine (1 patient), all with improvement. In the full cohort, only 5.9% of patients had arthralgias prior to CHIK infection, vs. 33.3% in the post-CHIK CIR (p=0.081). 3 patients (5.08%) had a family history of arthritis, all in the post-CHIK CIR.

Patient (n°)	Painful joints (n°)	Swollen joints (n°)	Tendinitis	Enthesitis	Sinovitis PD (n° joints)	Tenosynovitis PD (n°)	Enthesitis PD (n°)	Sacroiliitis magnetic resonance
1	33	3	1	0	1	2	0	
2	6	2	0	1	4	0	1	positive
3	5	0	0	0	0	0	0	
4	6	3	0	0	2	0	0	
5	11	1	1	1	2	2	0	
6	6	8	0	0	8	0	0	

Conclusions: Arthralgias are a frequent symptom even at chronic stage of CHIK. Sometimes it is true arthritis and in others cases edema. For this reason US is very useful in doubtful cases. In our cohort, patients that developed post-CHIK CIR were more frequently women, with a higher percentage of family history of arthritis. To the best of our knowledge, this is the first US study in patients with post-CHIK CIR.

SAT0635 DESCRIPTIVE ANALYSIS OF THE QUANTICAP STUDY: A MULTICENTRIC PROSPECTIVE STUDY FOR THE VALIDATION OF QUANTITATIVE AND QUALITATIVE PARAMETERS OF NAILFOLD CAPILLAROSCOPY

I. Castellví[1], P. Reyner[2,3], S. Martinez[4], M. Moreno[5], M.S. Gelman[6], V. Ortiz-Santamaría[7], S. Ordoñez[8], P. Santo[9], S. Heredia[10], X. Juanola[11], H. Corominas[10]. *[1]Rheumatology, Hospital Universitari de la Santa Creu I Sant Pau, Barcelona; [2]Rheumatology, Hospital Universitari Dr. Josep Trueta, GIRONA; [3]Hospital de Santa Caterina, SALT; [4]Rheumatology, Hospital Universitari Mutua de Terrassa, Terrassa; [5]Rheumatology, Corporació Sanitaria Parc Taulí, Sabadell; [6]Rheumatology, Fundació Althaia, MANRESA; [7]Rheumatology, Hospital General de Granollers, Granollers; [8]Rheumatology, Hospital Universitari Arnau de Vilanova, LLEIDA; [9]Rheumatology, Hospital General Parc Sanitari Sant Joan de Deu, Sant Boi de Llobregat; [10]Rheumatology, Hospital Comarcal Sant Joan Despí-Moises Broggi, Sant Joan Despí; [11]Rheumatology, Hospital Universitari de Bellvitge, Hospitalet de Llobregat, Spain*

Background: Nailfold capillaroscopy (NC) is a useful tool to study Raynaud's phenomenon (RP) and other diseases. Different findings and patterns has been described however there is currently no work that validates the qualitative and quantitative NC findings.

Objectives: To describe the morphological and metrological findings of NC in patients with RP and autoimmune diseases.

2-Describe the morphological and metrological findings of CP in patients with RF and several systemic autoimmune diseases.To Describe the morphological and metrological findings of NC in patients with RP and other autoimmune diseases.

Methods: Observational study performed in 10 hospitals by rheumatologists with experience in NC. Patients with diffuse systemic sclerosis (dSSc), limited systemic sclerosis (lSSc), dermatomyositis (DM), polimyositis (PM), systemic lupus erythematosus (SLE) Primary Sjögren's syndrome (PSS), rheumatoid arthritis (RA), primary RP and a control group without RP or rheumatological condition were collected.A video NC 200x magnification were made in all patients. 8 Fingers in each hand were analyzed to find: megacapillary and dilated capillaries, giant capillaries, loss of density (<7/mm), tortuous capillaries, ramifications, haemorrhages, thrombosis and destructuration. Also we analyzed the diameter of the afferent and efferent loop, the capillary apex, the capillary diameter and density/mm. The following variables were also collected: sex, age, years of evolution of the disease and RP, history of digital ulcers or medication for

RP, smoking and presence of hypertension or diabetes. To compare qualitative variables, the test was used Chi-square or Fisher's test. To compare quantitative vs qualitative variables Student's T test was used. Significance was considered for those values with $p<0.05$.

Results: Between May 2014 to December 2016 images of 406 patients were collected: 24 dSSc, 41 lSSc, 19 DM, 14 PM, 40 SLE, 39 PSS, 37 RA, 44 PRP and 145 controls. C 84.5% were women, the age of the sample were 51.32±15.21 years. 28.9% had a history of smoking and 21.1% and 5.5% of hypertension or diabetes, respectively. Excluding the cases of dSSc, lSSc, PRP and the 145 controls, the presence of RP was observed in 18/152 (11.84%). The afferent, efferent, apical diameter And capillary was 26.01±19.01; 31.93±24.51um; 37.95±36.67um and 82.68±58.10um respectively. The most frequent qualitative finding were tortuosities. The control group showed no difference in the presence of hypertension or diabetes except in patients with PM. We also observed more women in SLE and PSS patients vs control group and greater presence of digital ulcers in lSSc, dSSc, SLE and DM. Only the lSSc presented differences in the presence of tortuosities with respect to the control group.

Conclusions: Except in the lSSc no differences were observed in the presence of tortuosities with the rest of groups and its presence may not be relevant in different diseases.

Background: Ultrasound (US) was found to have face and content validity for detecting synovitis in juvenile idiopathic arthritis (JIA) with higher sensitivity than clinical examination. In order to test validity and improve the applicability of US in JIA, the OMERACT US pediatric subtask force recently published preliminary definitions for the sonographic features of synovitis in children.

	B-mode (GS)	color power/Doppler (PD)
0	No signs of synovial effusion or synovial hypertrophy (ie. no joint recess enlargement/capsular distension).	Absence of color/power Doppler signal within synovial hypertrophy with or without detection of normal physiological Doppler signals.
1	Synovial effusion and/or synovial hypertrophy that leads to a mild change of the joint recess appearance (ie. mild joint recess enlargement/capsular distension).	Detection of up to 3 single Doppler signals within the area of synovial hypertrophy with or without normal physiological Doppler signals.
2	Synovial effusion and/or synovial hypertrophy that leads to a moderate change of the joint recess appearance (ie. moderate joint recess enlargement/capsular distension).	Detection of more than 3 single Doppler signals but less than 30% of the area of synovial hypertrophy with or without normal physiological Doppler signals.
3	Synovial effusion and/or synovial hypertrophy that leads to a severe change of the joint recess appearance (ie. severe joint recess enlargement/capsular distension).	Detection of Doppler signals at more than 30% of the area of synovial hypertrophy with or without normal physiological Doppler signals

	Intra-observer				Inter-observer			
Grade	Percentage agreement		kappa Cohen		Percentage agreement		kappa PABAK	
	GS	PD	GS	PD	GS	PD	GS	PD
0	100	94	1.0	0.83	100	100	1.0	1.0
1	80	83	0.5	0.5	60	50	0.47	0.33
2	89	83	0.7	0.67	50	71	0.5	0.62
3	81	92	0.92	0.8	86	71	0.81	0.71

Figure 1. Synovitis grading definitions in children and inter- and intra-observer reliability in B-mode (GS) and color power/Doppler (PD).

Objectives: Aim of this study was to confirm and improve B-mode and color power/Doppler (PD) US definitions for synovial components and grading in children, by using an image and patient based exercise.

Methods: The definitions were confirmed and modified in a multi-step process. In the 1st step, definitions were developed in multi-round Delphi web based consensus process were ≥80% of participants would need to reach ≥80% of agreement on a Likert scale from 1–5 (1 strongly disagree, 2 disagree, 3 neutral, 4 agree, 5 strongly agree). In the 2nd step, in a face to face meeting, a subgroup of these experts revised the definitions for final wording and performed intra- and inter-observer reliability exercise study in JIA patients as the final 3rd phase of the process. The definitions were tested in four joints (wrist, 2nd MCP, knee and ankle) of JIA patients divided in four age groups following standardized image acquisition and machine setting protocol. Statistics program R (version 3.3.0) was used for the statistical analyses. For intra-rater agreement Cohen kappa and for inter-rater agreement prevalence and bias adjusted kappa (PABAK) were calculated if needed.

Results: Reliability exercise included 20 JIA patients (distributed in equal numbers by age groups), 14 observers, 4 joints/observer, 3 observers/joint, 360 intra- and 360 inter-observer tests. A 0–3 semi-quantitative B-mode and color power/Doppler US definitions for synovial components and grading, were agreed (presented in Figure 1).

Conclusions: The proposed synovitis grading for children showed to be reliable why the next step should be to test sensitivity to change in order to possibly be used as an outcome tool in JIA.

SAT0637 ULTRASOUND ASSESSMENT OF SKIN THICKNESS IN SYSTEMIC SCLEROSIS PATIENTS: CORRELATION WITH CLINICAL FEATURES

J. Sousa-Neves[1], M. Cerqueira[1], D. Santos-Faria[1], J. Leite Silva[1], A. Raposo[2], C. Afonso[1], F. Teixeira[1]. *[1]Rheumatology, Hospital Conde de Bertiandos, ULSAM, Ponte de Lima; [2]Rheumatology, Centro Hospitalar Trás-os-Montes e Alto Douro, Vila Real, Portugal*

Background: Although modified Rodnan skin score (mRSS) is the most widely used measure for assessment of skin involvement in Systemic Sclerosis (SSc), ultrasound (US) of skin thickness seems to be a promising complementary tool. (1)

Objectives: To compare skin thickness measured by US of a defined anatomical point between SSc patients and age and sex matched controls. To compare, among patients, US measurements of skin thickness with local and total mRSS and other specific clinical variables.

Methods: Forty-eight SSc patients and 45 age and sex matched controls were evaluated in a cross-sectional study at our Rheumatology Unit. SSc patients had a mean age of 56.98±12.73 years and mean disease duration of 9.77±6.12 years; 42 patients had limited cutaneous disease. Regarding US assessment, skin thickness was arbitrarily defined as thickness of epidermis, dermis and subcutaneous tissue, in millimetres, measured at the 2nd finger of both hands of each subject on the dorsal aspect of the proximal phalange. Examination was performed with a 15 MHz linear probe of a General Electric LOGIQ S8 US. For comparison between groups, mean skin thickness (mST) of combined right and left side was used. Patients' local and total mRSS were also assessed. Hand mobility in SSc (HAMIS) was calculated to evaluate functional disability and SSc Severity Scale (SScSS) to estimate activity and damage. Additional data was also collected from patients' clinical charts. Statistical analysis included Mann-Whitney U-test, Kruskal-Wallis and Spearman correlation coefficient test. Statistical significance was defined as P value <0.05.

Results: SSc patients showed higher mST (3.17 mm [2.56 to 3.58]) (median [interquartile range]) compared with controls (1.89 mm [1.55 to 2.08]) ($p<0.001$). Among SSc group, skin thickness measured by US of both 2nd fingers of each patient strongly correlated with local mRSS assessed by palpation (Spearman's rho=0.698, $p<0.001$ and rho=0.645, $p<0.001$ for right and left sides, respectively). US mST was also correlated with total mRSS (rho=0.568, $p<0.001$), HAMIS (rho=0.520, $p<0.001$) and SScSS (rho=0.524, $p<0.001$). A higher mST was found in patients clinically classified with oedematous phase ($p<0.001$) and in diffuse cutaneous subtype (p=0.039). A mild association was observed for patients with digital ulcers (p=0.05). Age, gender, disease duration and the presence of calcinosis were not associated with US mST ($p>0.05$).

Conclusions: US measurements of skin thickness of 2nd fingers were significantly higher in SSc patients compared with age and sex matched controls. US mST strongly correlated with local and total mRSS and was significantly higher in the presence of oedema, digital ulcers and in patients with diffuse subset. US mST also reflected functional disability and damage.

SAT0638 CLINICAL ACTIVITY, ULTRASOUND ASSESSMENT AND DRUG MONITORING IN RHEUMATOID ARTHRITIS PATIENTS RECEIVING ANTI-TNF-α THERAPY WITH EXTENDED INTERVAL OF ADMINISTRATION

J.M. Senabre Gallego[1], J. Rosas Gómez de Salazar[1], M. Marco Mingot[2], A. Naranjo[3], F. Llinares-Tello[2], A. Pons[1], X. Barber-Vallés[4], G. Santos-Soler[1], E. Salas-Heredia[1], C. Cano[1], M. Lorente[1], J.A. García Gómez[4], J. Molina[2] on behalf of Asociación para la Investigación en Reumatología de la Marina Baixa (AIRE-MB). *[1]Rheumatology; [2]Laboratory, Hospital Marina Baixa, Villajoyosa (Alicante); [3]Rheumatology, Hospital Dr. Negrín, Las Palmas de Gran Canaria; [4]Centro de Investigación Operativa, Universidad Miguel Hernández, Elche, Spain*

Objectives: To assess clinical activity, ultrasound synovitis and drug levels in rheumatoid arthritis (RA) patients receiving anti-TNFα therapy with extended interval of administration (EIA).
Methods: Prospective observational study. Population: RA patients, in clinical remission, receiving adalimumab (ADL) or etanercept (ETN) with EIA. Clinical activity was assessed by DAS28-ESR, DAS28-CRP, CDAI and SDAI scores at each visit. Twelve-joint ultrasound assessment (elbows, wrists, 2nd and 3rd metacarpophalangeal joints, knees and ankles) was performed evaluating synovitis through B-mode (BM) and Color Doppler signal (CD). A BM and CD score was calculated summing the highest score from each joint to a maximum of 36 points. We consider positive score >1 point. Serum drug levels were measured using Promonitor® ELISA kits (Progenika Biopharma-Grifols, Spain).
Results: A total of 39 patients were included since February 2011 to December 2016. One patient was excluded due to blindness violation and 2 patients never reduced anti-TNFα due to low drug levels. 31 patients were women (82%) and the mean age was 61 (39–81) years. Most patients were RF positive (87%) and ACPA positive (74%). 22 patients were with ADL treatment and 16 with ETN. 32 patients (82%) were with DMARD concomitant treatment (18 MTX (46%), 11 LEF (18%), 2 HCQ (5%), 1 SSZ (2%)) and 7 patients were with low-dose CS (18%). Mean time from diagnosis was 14,95 years (range 2,15 – 52,31) and Mean time with current biologic drug was 4,21 years (range 1,39 – 11,07). Nine patients (24%) returned to standard interval due to worsening of clinical activity and one discontinued treatment due to septic arthritis. All of them returned to clinical remission and no anti-drug antibodies were detected. Clinical activity scores, ultrasound scores and drug levels are summarized in table 1.

Table 1. Clinical activity scores, ultrasound scores and drug levels

	Basal visit	6 months	12 months
N	32	31	20
DAS28-ESR	2,0 (0,91)	1,83 (0,83)	1,61 (0,70)
DAS28-CRP	1,71 (0,51)	1,78 (0,52)	1,62 (0,48)
SDAI	4,25 (2,55)	4,27 (3,04)	3,64 (3,13)
CDAI	3,82 (2,48)	3,61 (2,33)	2,76 (1,3)
BM score	3,57 (4,57)	3,29 (3,81)	4,7 (4,32)
CD score	0,78 (0,80)	1,19 (1,7)	1,15 (1,42)
BM score (%)	73,91	77,42	90,00
CD score (%)	56,52	45,16	50,00
ETN	4,61 (2,74	3,59 (2,9)	3,03 (0,84)
ADL	12,05 (6,88)	8,49 (5,01)	6,49 (2,78)*

*p<0,05. All results mean (SD) otherwise specified.

Conclusions: 1. Clinical remission was sustained in most patients receiving ADL or ETN in extended interval of administration (EIA). 2. Drug levels decrease over time. 3. Some patients (24%) returned to standard interval of administration due to clinical worsening. 4. Some patients show subclinical ultrasound synovitis in B-mode (90%) or Color Doppler (50%) 5. It would be advisable to perform periodic ultrasound and monitoring of anti-TNFα levels to maintain clinical remission in patients with EIA.

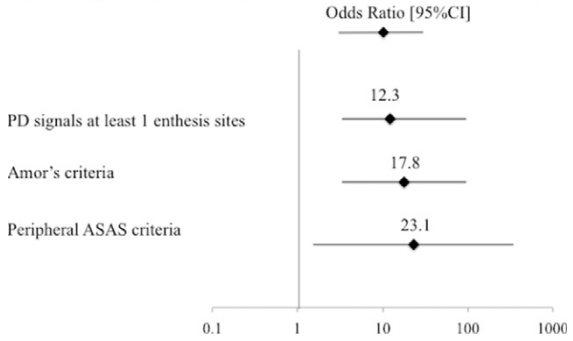
SAT0639 BIOLOGIC-ELIGIBLE RHEUMATOID ARTHRITIS PATIENTS DEMONSTRATE ABSENCE OF SYNOVITIS – UTILITY OF ULTRASOUND IN THE MANAGEMENT OF RA-BIOLOGIC POPULATION

K. Naraghi[1], T. Vojinovic[2], J. Nam[1], J. Freeston[1], P. Emery[1], R.J. Wakefield[1], M.H. Buch[1]. *[1]Leeds Institute of Rheumatic & Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; [2]Faculty of Medicine and Surgery, University of Pavia, Pavia, Italy*



Background: Biologic drugs act by suppressing synovitis in patients with rheumatoid arthritis (RA). Clinical disease activity scores (DAS) are used to determine eligibility and assess biologic drug response. However, several drivers aside from synovitis may drive the DAS. Joint ultrasound (US) scan is more accurate than clinical examination in detecting inflammatory synovitis [1, 2], and is frequently used in clinical practice to assess need for biologic drug change [3].
Objectives: To phenotype DAS using US in patients eligible for a first/switch in biologic therapy and to evaluate whether and how this changed decision making.
Methods: A retrospective evaluation of RA patients who attended our tertiary centre biologic clinic between 2014 and 2016 and had an US to clarify basis for raised disease activity. Three-variable DAS28-CRP 28 joints (DAS28-CRP) was recorded and US reports were evaluated to determine which of the following characteristics were observed: presence of synovitis, tenosynovitis, osteoarthritis, tendinopathy and no abnormality. Clinic notes were reviewed to record change in the management of patients as a result of combined clinical and US scan findings.
Results: We identified 70 patients who had not received steroids within 4 weeks of the US, 84.3% female, median (range) age 58 (20–88) years. 66 (94.3%) patients were biologic experienced with 59 on ongoing treatment [3 (5.1%) abatacept, 22 (37.3%) anti-TNFα, 22 (37.3%) rituximab and 12 (20.3%) tocilizumab] of whom 47 (79.7%) were on combination with csDMARD therapy. 4 (5.7%) patients were biologic naive. 42 (63.6%) of bio-experienced patients, had a DAS28 ≥3.2 and were eligible for a change in their biologic however, only 17 of these patients had US-confirmed synovitis, 21 had evidence of osteoarthritis (OA), 1 tenosynovitis and 3 had no abnormalities. All biologic naïve patients had DAS28-CRP ≤5.1 before US however, 3 had US-confirmed synovitis and 1 had OA. Of bio-experienced, 13/66 (19.4%) patients, including 4 with DAS-28 <3.2 but US-confirmed synovitis, had a new biologic started. 3 rituximab patients (including one with subclinical synovitis) had re-treatment. Concomitant treatment was escalated in 13 (24.2%) patients. 35 (53.0%) patients, including 4 with US synovitis/tenosynovitis, had no change in their treatment. 2 (3.0%) patients self-discontinued treatment.
Conclusions: By identifying lack of inflammatory synovitis in biologic eligible patients US reduced the need for unnecessary and costly change of biologics. US also detected subclinical synovitis warranting modification of their treatment.

SAT0640 DIAGNOSTIC UTILITY OF DETECTING ENTHESITIS BY ULTRASOUND IN PERIPHERAL SPONDYLOARTHRITIS

K. Fujikawa[1], Y. Endo[1], A. Mizokami[1], M. Mine[2], A. Kawakami[3]. *[1]Rheumatology, Japan Community Healthcare Organization, Isahaya General Hospital; [2]Rheumatology, Suga Orthopedic Hospital, Isahaya; [3]Department of Immunology and Rheumatology, Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan*

Objectives: To evaluate the diagnostic utility of detecting enthesitis by ultrasound in patients with peripheral spondyloarthritis (SpA).
Methods: A single-center cohort study was performed in patients with symptoms suggestive of peripheral SpA (inflammatory back pain, arthritis of the lower limbs, tenderness of the entheses and dactylitis). Patients with only axial symptoms in the absence of peripheral symptoms were excluded. Fourteen sites of enthesis (both sides of lateral epicondyle, quadriceps tendon insertion into the patella, patellar ligament insertion into the patella and tibial tuberosity, medial and lateral femoral condyles, and Achilles tendon) were assessed at baseline by ultrasound. Ultrasound assessment was made by Japan College of Rheumatology (JCR)-registered sonographers. Furthermore, articular synovitis and tenosynovitis of both wrist and finger joints as well as symptomatic sites were examined. Clinical, laboratory (CRP, HLA typing), radiological (X-ray and MRI of sacroiliac joint) findings and SpA classification criteria (Amor's, ESSG and ASAS) were also evaluated. The gold standard was the diagnosis made by the JCR-certified rheumatologists during a six-month follow-up period.
Results: Between April 2014 and November 2016, one hundred-thirty six patients were consecutively enrolled. A definite diagnosis was obtained in 112 patients (72 SpA and 40 non-SpA). Diagnosis was not made in the remaining 24 patients. Seventy-two SpA patients (62 with undifferentiated SpA, 6 with psoriatic arthritis, 2 with AS, 1 with inflammatory bowel disease-associated arthritis and 1 with reactive arthritis) and 40 non-SpA patients were investigated in this study. In ultrasound findings, SpA patients showed power Doppler (PD) signals of the articular synovium (57%), tendon sheath synovium (71%) and enthesis (94%). A PD signal for at least one enthesis sites was the most useful finding for differentiation of SpA from non-SpA (sensitivity 94%; specificity 85%; accuracy 91%; positive likelihood ratio 6.3) regarding ultrasound findings. In logistic regression analysis, fulfillment of peripheral ASAS criteria, that of Amor's criteria, and presence of PD signals at least one enthesis sites were independent variables to the contribution of diagnosis of SpA (Figure 1).

Figure 1. Logistic regression analysis for the contribution of diagnosis of SpA

Conclusions: PD signals of entheses by ultrasound are useful for the diagnosis of SpA with peripheral joint symptoms. In addition to the consideration of axial SpA, the combination use of ultrasound with clinical classification criteria including ASAS and Amor's criteria is beneficial to diagnose peripheral SpA.

SAT0641 THE DIAGNOSTICS OF OSTEOPOROSIS IN MALE REUMATOID PATIENTS

K. Aminov. *Medical Radiology, Tashknet Institute for Postgraduate Medical Education, Tashkent, Uzbekistan*

Background: Rheumatoid arthritis (RA) - chronic immune inflammatory joint disease leading to early disability of patients at high risk for cardiovascular events and osteoporotic fractures. Of particular relevance, this problem becomes in men with RA, due to more frequent severe disease and increased mortality in the year after the fracture. Reduced bone mineral density (BMD) and muscle mass are significant predictors of fracture, which leads to the high importance of studying the state of the IPC and body composition.
Objectives: To improve the diagnosis of osteoporosis in patients with RA male subjects.
Methods: A total of 146 male patients with definite diagnosis of RA at the age of 59 years. Depending on the reception of glucocorticosteroids (GCS) is allocated two subgroups: I subgroup - 40 patients not receiving corticosteroids and II subgroup - 66 patients receiving corticosteroids. The control group consisted of 24 healthy men, matched by age and body mass index. IPC Study in the lumbar spine (L1-L4) and femoral carried out by dual-energy X-ray absorptiometry using osteodensitometry. Evaluation of body composition was carried out with the help of "Pod" program.
Results: In 63% of patients with RA revealed male BMD reduction corresponding to osteopenia/OP (OP was diagnosed in 36 (24.7%) patients with RA, and osteopenia - in 56 (38.4%)). The incidence of OP in the II subgroup was significantly higher ($p<0,05$), than in the I subgroup (48.5% and 5% respectively). The most significant decrease in BMD observed in femoral neck in the study group as a whole, and in individual subgroups. There was a negative correlation between the degree of RA activity and performance of the IPC as a lumbar spine ($r = -0,4$, $p<0.05$), and the proximal femur ($r = -0,38$, $p<0.05$). Evaluation of body composition showed that the treatment group had a significant decrease in total lean mass (TM) body, as well as the trunk and extremities TM compared with those of control group ($p<0,05$). Sarcopenia detected in 80 (55.8%) of RA patients, whereas in the control group it was absent. In 50 (67.6%) of patients with RA male sarcopenia observed to decrease the level of the IPC osteopenia (35.2%) and OD (32.4%). After receiving a negative correlation parameters TM and the absolute 10-year risk of osteoporotic fractures ($r = -0,302$, $p<0,05$) on the FRAX.
Conclusions: 63% of men suffering from RA, observed BMD decrease corresponding OP/osteopenia with a primary decrease in BMD at the femoral neck. Reduced BMD in patients with RA was significantly associated with a high degree of disease activity ($r = -0,4$, $p<0.05$). Receiving corticosteroids had no significant effect on BMD at the femoral neck. Analysis of body composition in 55% of RA patients revealed a decrease in TM limbs to the level of sarcopenia. Received correlation decrease BMD and TM limbs ($p<0,05$; $r =0,28$). Thus, in patients with RA males along with OP/osteopenia revealed a significant decrease in TM, that in view of the biomechanics of the movements may be an additional risk factor for falls and fractures.

SAT0642 ULTRASONOGRAPHY AND INTRA-ARTICULAR INJECTION THERAPY IN EARLY RHEUMATOID ARTHRITIS: RESULTS FROM THE RANDOMISED ARCTIC TRIAL

L.B. Nordberg[1], S. Lillegraven[1], A.-B. Aga[1], I.C. Olsen[1], E. Lie[1], H.B. Hammer[1], T. Uhlig[1], D. van der Heijde[2], T.K. Kvien[1], E.A. Haavardsholm[1] on behalf of the ARCTIC study group. [1]*Diakonhjemmet Hospital, oslo, Norway;* [2]*Leiden University medical center, Leiden, Netherlands*

Background: Intra-articular (i.a.) corticosteroid injections are in many countries an integral part of rheumatoid arthritis (RA) treatment. Ultrasonography (US) is increasingly used in the management of RA as a tool to select joints for i.a. injections. How selection of joints based on US information affects distribution of injections has not been previously studied. US can detect joints with subclinical inflammation, however, it is unknown whether there is any added value of injecting these joints.
Objectives: We aimed to explore how US information influences the selection of joints for corticosteroid injection therapy. Additionally, we wanted to examine the efficacy of injecting joints with subclinical inflammation detected by US in terms of reduction of subclinical inflammation and prevention of clinical synovitis.
Methods: In the ARCTIC trial, DMARD-naive RA patients fulfilling the 2010 ACR/EULAR criteria were randomised 1:1 to follow-up with or without US.[1] In both arms the same DMARD treatment strategy was applied, and clinically swollen joints were treated with i.a. steroids when indicated. In the US arm, clinicians could also inject non-swollen joints with PD activity. Patients were assessed at 13 visits during 2 years of follow-up and injections could be performed at all visits. Distribution of injections in patients followed with and without US was assessed. The proportion of patients with any injection was compared between arms using logistic regression, adjusted for gender. In addition, we examined the effect of injections in clinically non-swollen joints with PD $\geq$2 (range 0–3) by comparing clinical joint swelling and estimated mean change in PD activity at the next visit in injected versus non-injected joints. We used logistic and linear mixed model with random intercept by patient in order to adjust for within-patient dependencies.
Results: 230 patients were included (US arm 118, conventional arm 112). Mean (SD) age was 50.6 (13.3)/ 52.3 (14.1) years, 71/51% were females and mean (SD) baseline DAS was 3.5 (1.2)/3.4 (1.2) in the US/conventional arms. [1] More injections occurred in the US arm than in the conventional arm (770 vs 548), especially in intercarpal (58 vs 5) and MTP joints (200 vs 104) (Table 1). In the US arm, 193 joints were clinically non-swollen, but had PD score $\geq$2. Of these, 77 joints were injected. 72/77 injected joints (93.5%) remained non-swollen at next visit compared to 88/116 non-injected joints (75.9%), with an odds ratio of 3.97 (CI: 1.25–12.57, p=0.019, NNT:6). Estimated mean (SE) reduction of PD activity was 2.3 (0.1) compared to 2.0 (0.1) in injected versus non-injected joints ($p<0.001$).

Joint	Number of injections, 0-24 months		Patients with any injection n (%)			
	Ultrasonography N=118	Conventional N=118	Ultrasonography N=118	Conventional N=112	OR (95% CI)	p-value*
DIP 2-5	2	5	2 (1.7)	3 (2.7)	0.62 (0.10-3.93)	0.61

Ankle	35	35	18 (15.3)	17 (15.2)	1.02 (0.49-2.13)	0.96
Knee	58	31	27 (22.9)	17 (15.2)	1.65 (0.83-3.28)	0.15
Other joints	34	20	14 (12.5)	22 (18.6)	1.59 (0.76-3.35)	0.20
Total	770	548	103 (87.3)	86 (76.8)	2.40 (1.17-4.93)	**0.017**

*Adjusted for gender

Conclusions: Our study shows that follow-up with US may lead to an increased number of joint injections with a different distribution of injected joints compared to follow-up without US. Joints with subclinical inflammation were more likely to remain non-swollen at next visit if injected. However, as the number of joints needed to treat to prevent one swollen joint was six, the clinical relevance of injecting joints with subclinical inflammation may be questionable.

SAT0643 VALUE OF POWER DOPPLER ULTRASONOGRAPHY FOR PREDICTION OF TREATMENT FOR RHEUMATOID ARTHRITIS (RA) IN EARLY ARTHRITIS DURING THE FIRST 12 MONTS OF FOLLOW-UP

L. Mayordomo [1,1], M.L. Velloso [1], C. Jurado [2], P. González-Moreno [3], C. Gomez-Cano [1], J.L. Marenco [1], C. Almeida [4]. *[1]Rheumatology Department; [2]Radiology Dp, Hospital Universitario Valme; [3]Rheumatology Department, HVM; [4]Research and Statistics Dp, Hospital Universitario Valme, SEVILLA, Spain*

Background: There is a short window of opportunity for early diagnosis and treatment of rheumatoid arthritis, that may be crucial for reaching remission and a low rate of radiographic progression. High resolution power doppler ultrasonography (PDUS) is helpful in early detection of synovitis and may help to select patients that will need early establishmet of treatment for RA.
Objectives: To study whether the presence of basal power doppler signal in patients with early arthritis in a clinical basis treatment decision could predict the risk of receive treatment for AR at 3 and 12 months of follow-up.
Methods: We studied the presence of ultrasonographic Power Doppler (PD) signal on 28 joints (shoulders, elbows, wrists, MCPs, knees) and 44 joints (28 joints and in addition hips, Tarsus, ankles and MTPs), with a mid-range equipment GE L5, in 70 patients with suspected early arthritis. The patients were included with at least one of the following inclusion criteria: a) Swelling in 2 or more joints b) pain in MCPs, MTPs and/or the wrists c) morning stiffness of more than 30 minutes with <12 months duration of the symptoms. Clinical treatment decision was not awared to basal power doppler results. Statistical study: Chi-square, Fisher exact test, p univariant and Odds Ratio calculation.
Results: The presence of basal power doppler signal in ≥1 joints of 44 (PD44) at baseline shows statistically significant association with treatment with oral steroids (p<0.001, OR 8,6 (2,4–30,5), DMARD p 0.028, OR 4,2 (1,3–13,3), metotrexato (MTX) p 0.002 OR 6,6 (1,9–22,1) but not sulfasalazine (SSZ) (p 0.145) at 3 months and with steroids (p<0.0005 OR 14,8 (3,9–44,4), DMARDs (p<0.0005, OR 10,3 (2,6–40,4), MTX (p<0.0005, OR 8,67 (82,6–29,2)), sulfasalazine (p=0.001, OR 8,7 (2,2–33,9), at 12 months The presence of at least one joint with power doppler signal of 28 joints (PD28) was significantly associated to esteroids (p=0.003, OR 5,4 (1,8–16,8) and metotrexate (p=0.016, OR 4,1 (1,4–12,7) treatments in the first 3 months but not to other DMARDs p=0.146 (including sulfasalazine p=0.416) and with esteroid (p=0.01 OR 7,3 (2.2–24,9), DMARD, (p=0.03, OR 5,8 (1,8–18,7), MTX (p=0.012, OR 4,3 (1,4–12,8),and sulfasalazine (p=0.008, OR 4,9 (1,5–15,6) during first 12 months of follow-up. Predictive value of other risk factors for RA (RF, basal erosions=EROS BAS) is shown in the table below.

BASAL N=70		ESTEROID 12M P univariate OR IC 95%	DMARD 12M P univariate OR IC 95%	MTX 12M P univariate OR IC 95%	SSZ 12M P univariate OR IC 95%

Conclusions: Power doppler ultrasonography in at least one joint of 44 (PD44) may predict the patients that will need esteroids, any DMARD, MTX and SSZ teraphy in early arthritis at 3 and 12 months of follow-up. PD28 may predict the patients that will need esteroids, any DMARD, MTX and SSZ teraphy in early arthritis at 12 months, but may only predict the need of esteroid and MTX at three months.

SAT0644 IS ANKLE INVOLVEMENT IMPORTANT IN RHEUMATOID ARTHRITIS?

L. Enache, C. Mogosan, C. Popescu, G. Gutoiu, C. Codreanu. *Rheumatology, Clinical Center of Rheumatic Disease, Bucharest, Romania*

Background: The ankles may be affected by rheumatoid arthritis (RA). In daily evaluation of RA patients, the ankles are often neglected by clinical examinations, while composite activity scores do not include them
Objectives: The aim of the study is to assess the inflammatory lesions in RA ankles, regarding frequency and possible correlation with activity disease
Methods: The study included 76 RA patients fulfilling the 2010 ACR/EULAR classification criteria. In every patient we recorded clinical ankle involvement (ankle swelling and/or tenderness on physical examination); both ankles were evaluated by gray scale (GS) and Power Doppler (PD) ultrasound examination, graded from 0–3. In each joint we assessed: tibio-talar joint (TT); tibialis anterior (TA) tendon; extensor hallux (EH) and extensor digitorum (ED) tendons; talo-navicular joint (TN); tibialis posterior (TP) tendon; flexor digitorum (FD) and flexor hallux (FH) tendons; peroneus brevis (PB) and longus (PL) tendons; Achilles tendon (AT); subtalar joints (SJ; posterior, lateral, medial recesses); plantar fascia (PL). We recorded the following abnormalities: synovitis, tenosynovitis, bursitis, entesopathy and rupture. Activity scores (DAS28, DAS44, SDAI), inflammatory markers (ESR, CRP), serology (FR, ACPA) and HAQ were also assessed
Results: The mean age was 57.2±14.2 years; 88% were women; mean disease duration was 12.2±9.2 years; 56.6% had symptomatic ankles; 81.6% had ultrasound ankle abnormalities. The most frequent ultrasound pathology encountered was ST synovitis (56.6%), followed by TT synovitis (48.7%), TN synovitis (38.2%), TP tenosynovitis (30.3%), PL tenosynovitis (15.8%). Ultrasound abnormalities were recorded in 93% of the symptomatic ankle patients and in 66.7% of the asymptomatic ankle patients (p=0.008). Overall, 43% had positive PD signals, but the prevalence of positive PD signals was significantly higher in symptomatic ankle patients than in asymptomatic ankle patients (60.5% compared to 21.2%, p=0.011). Statistically significant correlations were found between ultrasound inflammatory pathology (synovitis and tenosynovitis), activity disease markers and quality of life (Table 1).

Table 1. Correlations of GS ultrasound measures with disease activity and HAQ

	ESR	CRP	$DAS28_{CRP}$	$DAS28_{ESR}$	DAS44	SDAI	HAQ
TT	0.104	0,360**	0,395***	0,283*	0,317**	0,352**	0.150

TP	0.408***	0.466***	0.543***	0.548***	0.558***	0.542***	0,268*
FD	0.166	0.145	0.254*	0.260*	0.285*	0.259*	0,256*

Note: the reported values represent the *rho* coefficients of bivariate Spearman correlations: *p<0,05; **p<0,01; ***p<0,001.

Conclusions: Musculoskeletal ultrasound detected a high prevalence of inflammatory abnormalities in rheumatoid arthritis ankles, in both symptomatic and asymptomatic patients, while power Doppler signal was present mostly in symptomatic patients. The ultrasound pathology was highly correlated with activity disease markers and quality of life

SAT0645 MAGNETIC RESONANCE IMAGING AND HISTOPATHOLOGICAL CORRELATION IN DERMATOMYOSITIS

M.V. Collado [1], J.C. Milisenda [2], X. Tomás [3], A.I. García [3], M. Faruch [4], J.M. Grau [2] on behalf of Muscle Research Unit, Internal Medicine Service, Hospital Clínic de Barcelona, Universidad de Barcelona and CIBERER. *[1]Reumatology, Instituto de Investigaciones Médicas Alfredo Lanari (UBA), Buenos Aires, Argentina; [2]Internal Medicine; [3]Radiology, Hospital Clínic de Barcelona, Barcelona, Spain; [4]Radiology, CHU Toulouse Purpan, Toulouse, France*

Background: Dermatomyositis represents one of the major forms among the inflammatory myopathies (IIM). Although the muscle biopsy remains the definitive test, MRI has been used to detect unique patterns of muscle involvement. To date, no studies have compared MRI with muscle pathology in naïve DM.
Objectives: To compare the pattern of muscle MRI with muscle pathology.
Methods: All the patients enrolled in the Hospital Clínic de Barcelona (HCB) from January 2009 to December 2016 with an available MRI, performed just before muscle biopsy were included. The HCB ethics committee approved this study, and written informed consent was obtained from each participant.
MRI data and the clinical and demographic features were prospectively collected. Patients were classified as having definite DM (ref 4). MRI was performed on a 1.5T with standardized protocol of whole body or scapular and pelvic girdle MRI, which include coronal and axial T1-weighted and STIR images. Image analysis was performed by two experienced musculoskeletal radiologists masked

to the disease activity. The presence of oedema, fatty replacement and fascial oedema was evaluated in the biopsied muscle. Muscle and fascial inflammation was scored using a 0–3 point scale. The extent of muscle involvement was also evaluated by the analysis of 12 to 14 axial images and a percentage of muscle volume was calculated. Fatty replacement was scored using a 0–3 point scale. Muscle biopsies were evaluated by two trained pathologists at the HCB. Muscle biopsies were routinely processed. Quantification of fiber necrosis, regeneration and inflammation infiltrate were recorded. All statistical analyses were performed using "SPSS v22.0 ®". In all statistical tests performed p value of 0.05 was considered significant.

Results: A total of 16 (13 female) patients were included. Except in one patient all of them had proximal muscle weakness, and all of them except one had typical DM skin lesions. In 12% of the patients a solid cancer was diagnosed. All patients had fascial edema at muscle MRI while no one had fatty replacement, and 65% had muscle oedema. Only one biopsy was normal. A significant correlation was found between muscle inflammation and MRI muscle edema (p=0,036) and the percentage of volume muscle involvement at MRI (p=0,027). Muscle necrosis was seen in those patients with moderate and severe fascial edema compared with those with mild fascial edema (p=0,032). More regenerating cells were seen in those patients with moderate and severe muscle edema compared with negative or mild muscle oedema (p=0,018).

Conclusions: A strong and significant correlation between histological and imaging findings was found. Fascial and muscle edema were the predominant findings in DM patients

SAT0646 COMPARISON OF US, CT, X-RAY AND MRI EFFICACY FOR SEQUENTIAL ASSESSMENT OF CHRONIC GOUT MANIFESTATIONS

M. Eliseev, O. Zhelyabina, S. Vladimirov, M. Chikina, M. Severinova, A. Smirnov, D. Kudinsky, O. Mirovich. *V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Ultrasonography (US), magnetic resonance imaging (MRI), computed tomography (CT), and X-ray are the alternative diagnostic modalities used to identify affected joints and surrounding tissues (tophi, erosions and synovitis) in gout patients, but the potential of each method for sequential assessment of disease regression in pts receiving urate-lowering therapy is not sufficiently studied [1]

Objectives: Comparison of US, CT, X-ray and MRI efficacy for sequential assessment of affected joints in pts treated with urate-lowering agents.

Methods: The open prospective study was conducted in 2013–2015 yy at V.A. Nasonova Research Institute of Rheumatology. 22 pts with crystal-verified gout (4 (15%) f and 18 (85%) m), mean age – 54,5±12,7 years, were included. The dose of allopurinol administered in all pts was adjusted by titration starting from 100 mg/day. Instrumental diagnostic examination (US, MRI, CT and plain X-ray of knee joints) was performed at baseline and after one year of follow up. US of knee joints was performed using multi-frequency linear array transducer, at 7 to 17 MHz frequencies; for MRI examination "Esaote Artrosan 0.25TI" was used, GE "Light Speed" - for CT scans, and Stephanix – for plain X-ray examination. Applied descriptive statistics STATISTICA 10.0 (StatSoft/Inc., USA) package was used for statistical analysis.

Results: Mean serum level of uric acid decreased from 568±115 μmol/l to 302±135 μmol/l. The target level (<360 μmol/l) was achieved in 20 pts (91%), (<300 μmol/l) was achieved in 11 pts (50%). Median allopurinol dose was 400 [300; 600] mg/day, 9 (45%) pts had to take 600 mg/day and more. At baseline US examination detected periarticular tophi in 13 (59%) pts, MRI - in 6 (28%) pts, CT in 3 (14%), X-ray - 1 (5%) pts, after one year - by US in 9 (41%) pts and MRI - 3 (14%) pts, CT in 2 (9%), X-ray - 1 (5%) pts. At baseline intraosseous tophi were detected only by CT and X-ray in 18 (81%) and 2 (9%) pts respectively, after one year 17 (77%) pts and 3 (14%) pts respectively. At baseline erosions were detected in 19 (86%) pts by MRI, in 11 (50%) pts – by US, in 14 (65%) pts – by CT, and in 9 pts (41%) – by X-ray, after one year in 14 (64%) pts by MRI, 10 (45%) pts by US, 12 (54%) pts by CT, 8 (36%) pts by X-ray. At baseline synovitis was reliably diagnosed by MRI and US: in 15 (68%) pts and 17 (77%) pts, after one year in 2 (9%) pts and 3 (14%) pts respectively

Conclusions: MRI and US, as for synovitis, erosions and tophi dynamics, are comparable, at that for erosions MRI is more accurate. CT is the most informative approach to monitor intraosseous tohhi regression. X-ray is low- informative modality for sequential assessment of gout.
