S.J.W. Shoop-Worrall[1,2], S.M. Verstappen[3], J.E. McDonagh[4,5,6], W. Thomson[4,7], K.L. Hyrich[3,4] on behalf of CAPS. *[1]Arthritis Research UK Centre for Epidemiology, the University of Manchester; [2]NIHR Manchester Musculoskeletal BRU, Central Manchester University Hospitals NHS Foundation Trust and University of Manchester Partnership; [3]Arthritis Research UK Centre for Epidemiology, the University of Manchester; [4]NIHR Manchester Musculoskeletal BRU, Central Manchester University Hospitals NHS Foundation Trust and University of Manchester Partnership; [5]Centre for MSK Research, the University of Manchester; [6]Manchester Academic Health Science Centre; [7]Arthritis Research UK Centre for Genetics and Genomics, the University of Manchester, Manchester, United Kingdom*

Background: Identifying predictors for early clinically inactive disease (CID) would allow stratified treatment decisions at diagnosis, minimising the burden of unnecessary therapies. JIA core outcome variables (COVs) are routinely collected and would therefore be convenient predictors. However, different groups of children are identified by current CID definitions (Wallace's preliminary criteria vs. clinical Juvenile Arthritis Disease Activity Score in 10 joints (cJADAS10)) and predictors may differ depending on which CID outcome is applied.
Objectives: To assess whether baseline COVs predict achievement of CID according to Wallace's preliminary criteria or the cJADAS10 cut-off in patients with JIA.
Methods: Children and young people enrolled to the Childhood Arthritis Prospective Study (CAPS), a UK multicentre inception cohort, before January 2011, were selected if diagnosed with oligoarticular, RF-negative or RF-positive polyarticular JIA.
At one year following initial presentation to paediatric rheumatology, children were classified as i) CID according to Wallace's preliminary criteria and ii) CID according to cJADAS10. Baseline COVs (active joint count, limited joint count, physician's global, parental global, functional ability (Childhood Health Assessment Questionnaire (CHAQ)) and ESR) were tested for predictive ability for these outcomes using univariate and forced-entry multivariate logistic regressions, adjusting for age and symptom duration at initial presentation, gender and ILAR subtype. Multiple imputation accounted for missing data.
Results: Of 829 children included, 70% were female and the majority had oligoarticular JIA (68%). At one year, 28% had achieved CID according to Wallace's preliminary criteria and 38% according to the cJADAS10 (21% CID on both).
In univariate analyses, increased baseline CHAQ and physician's global assessment score predicted lower odds of achieving both CID states. In addition, increased active joints (OR: 0.97, 95% CI0.94, 0.99), and patient/parent global assessment scores (OR: 0.87, 95% CI 0.81, 0.93) predicted lower odds of CID on the cJADAS10 only. In multivariate analyses, one increased CHAQ point at baseline independently predicted 28% lower odds of CID on the cJADAS10 (95% CI 0.53, 0.98). However, no baseline COVs predicted CID on Wallace's preliminary criteria. No demographic variables were significantly predictive in any model.
Conclusions: There were different predictors for CID on the cJADAS10 vs. Wallace's preliminary criteria. Children with poor functional ability at initial presentation are less likely to achieve CID on the cJADAS10. These children could be targeted with more aggressive treatment strategies to better control their disease.

THU0534 BASELINE CHARACTERISTICS AND DESCRIPTIVE SAFETY DATA OF INTRAVENOUS ABATACEPT-TREATED PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS IN A US HEALTHCARE CLAIMS DATABASE

T. Simon[1], S. Singhal[2], N. Ray[2], Z. Guo[1]. *[1]Bristol-Myers Squibb, Princeton, United States; [2]Mu Sigma, Bangalore, India*

Background: Abatacept (ABA), the first selective co-stimulation modulator approved and used for the treatment of moderate-to-severe polyarticular juvenile idiopathic arthritis (JIA), has a mechanism of action that is different from other biologic (b)DMARDs.
Objectives: To describe the baseline (BL) characteristics and validated safety outcomes of patients (pts) with a diagnosis of JIA in a US healthcare claims database treated with IV ABA and those with a minimum of 12 months (M) of ABA treatment.
Methods: Pts aged <18 years (yrs), diagnosed with JIA and in the Truven Health MarketScan® database between 1 Jan 2006 and 30 Sep 2014 were eligible for inclusion. Pts were required to have ≥180 days (d) of continuous health plan enrolment prior to a diagnosis of JIA based on two International Classification of Diseases, Ninth Revision, Clinical Modification codes (714.3x) within 90 d. BL characteristics and prior bDMARD use were analysed for two IV ABA-treated groups: a total cohort and a subgroup of pts with ≥12M of treatment. Three categories evaluated prior bDMARD use claims: biologic holiday (other bDMARD in history but not within 180 d of BL), biologic switcher (other bDMARD within 180 d of BL) and true initiator (no history of other bDMARD). Incidence rates (IR; number of events/person yrs [p-y] of exposure) per 100 p-y of exposure with 95% CI were calcuated for infections, malignancies and uveitis.
Results: A total of 238 IV ABA-treated pts were identified with 89 pts having ≥12M of ABA treatment. The mean (SD) follow-up duration was 1.73 (1.28) yrs for the total IV ABA cohort and 2.28 (1.03) yrs for the ≥12-M subgroup. Most pts were female, and mean age was 12.4 yrs. Overall, the total IV ABA cohort was more likely to have a claim in the BL period for asthma and cardiovascular disease versus the ≥12-M subgroup; the ≥12-M subgroup was more likely to have uveitis (Table). The most frequent other bDMARD claim for the total IV ABA-treated pts in the biologic holiday group was etanercept (41.9%), and adalimumab for

BL Characteristics	Total IV ABA cohort (n=238)	IV ABA ≥12-M subgroup (n=89)
Female, n (%)	195 (81.9)	78 (87.6)
Age, mean (SD)	12.4 (3.2)	12.4 (3.2)
Uveitis, n (%)	22 (9.2)	11 (12.4)
Asthma, n (%)	21 (8.8)	6 (6.7)
Cardiovascular disease, n (%)	18 (7.6)	6 (6.7)
bDMARDs, n (%)	84 (35.3)	30 (33.7)
Non-biologic DMARDs, n (%)	105 (44.1)	37 (41.6)
Inpatient visits, mean (SD)	0.2 (0.8)	0.1 (0.3)
Outpatient visits, mean (SD)	11.6 (10.7)	10.0 (9.8)

Abstract THU0532 – Table 2

Treatments	I: Anterior uveitis (42)	II: Intermediate uveitis (16)	III: Posterior uveitis (7)	IV: Panuveitis (9)
High dose systemic steroid	45% (19)	80% (12)	71% (5)	100% (9)
Synth DMARDs	66% (27) (MTX-26, AZA-2)	60% (9) (MTX, AZA)	71% (5) (MTX, AZA)	78% (7) (MTX, AZA, COL)
SynthDMARDs + Biologics	34% (14) (IFX-4, ADA-10)	33% (5) (IFX-1, TCZ-1, IFN-4)	43% (3) (IFX-2, IFN-1)	33% (3) (IFX-3)
Surgery	18% (7) (cataracts – 5, glaucoma – 1, keratopathy – 1)	20% (3) (cataracts – 3, vitrectomy – 1)	0	63% (5) (cataracts – 2, glaucoma – 1, vitrectomy – 1, antiangio. inj.– 1)

biologic switchers (34.5%). For the total IV ABA cohort, six hospitalized infection claims were reported with an IR (95% CI) of 2.4/100 p-y (0.9, 5.3) and an IR of 2.8/100 p-y (1.2, 5.9) for new-onset uveitis. There were no validated cases of malignancies in the follow-up period.

Conclusions: Compared with an overall JIA population[1], abatacept pts are slightly older, more likely to use additional prior biologics, and have a history of asthma or cardiovascular disease. The rates of hospitalized infection and new onset of uveitis in this study are within published ranges[2,3] and are consistent with findings in the abatacept JIA registry.[4]

THU0535 LONG-TERM FOLLOW-UP OF 12 CASES OF CORONARY GIANT ANEURYSM AFTER KAWASAKI DISEASE

T. Sato[1], J. Somura[1], S. Hoshino[1,2,3], O. Furukawa[1], N. Okamoto[2,4], Y. Maruo[1]. *[1]Department of Pediatrics, Shiga University of Medical Science; [2]Department of Pediatrics, Omihachiman Community Medical Center; [3]Department of Pediatrics, Nagahama Red Cross Hospital; [4]Department of Pediatrics, Okamoto Kids Clinic, Shiga, Japan*

Background: The incidence of Kawasaki disease has been increasing since it was first reported by Tomisaku Kawsasaki in 1967. Among complications of the condition, the formation of coronary artery aneurysms is the most important. In particular, giant aneurysms with diameters that exceed 8 mm are likely to not regress and result in serious complications, such as acute myocardial infarction.

Objectives: To understand the long-term course of patients with giant aneurysms and Kawasaki disease as well as to consider the cause of aneurysm formation and its appropriate treatment.

Methods: We retrospectively studied the long-term course of 12 cases of giant coronary artery aneurysms accompanied with Kawasaki disease, which were being followed at Shiga University of Medical Science Hospital, Omihachiman Community Medical Center, and Nagahama Red Cross Hospital. These are three major facilities in Shiga prefecture of Japan, whose population is 1.4 million, comprising 200,000 children.

Results: Ten male and two female patients were included. The average current age was 16.8 years, the median age was 14.3 (10.7–18.9) years, and 5 cases were of adults. The average age at the time of onset was 3.5 years, the median age was 3.7 years (1.8 - 4.4), and all experienced onset between 1 and 5 years of age. The mean period from onset to treatment start was 6.7 days (median 5.0 (4.3–8.3)), but the average period until fever declined was 16.0 days and only three patients' temperature was reduced in 10 days. Aneurysm formation occurred at 14.1 days on average (median 12 (10–17)). The average size of the maximum coronary artery aneurysm at onset was 11.3 mm, and the median size was 9.5 mm (8.8 mm – 13.8 mm).The average and median follow-up periods were 13.2 years and 11.7 years (5.4–13.4), respectively. The number of patients received steroid therapy was four, and all their onset was after 2006. None received infliximab or underwent plasmapheresis.

During the course of the condition, all patients underwent multiple centripetal echocardiography. Among all cases, 7 underwent coronary angiography CT, 10 underwent myocardial scintigraphy. All 12 patients underwent cardiac catheterization and the total number of underwent cardiac catheterization for them was thirty-one. Two adult patients had a history of acute myocardial infarction and had undergone cardiac bypass surgery. Through this survey, we found that 9 cases developed giant coronary artery aneurysm between 1983 and 2007, and 3 cases between 2012 and 2015 used prednisolone.

Conclusions: All patients are currently receiving anticoagulant therapy and undergoing diagnostic imaging. In our prefecture, the incidence of giant coronary artery aneurysm accompanied with Kawasaki disease has been decreasing gradually. From 2007 to 2012, in which high dose gamma globulin therapy (2g/kg) has become commonly underwent for Kawasaki disease in Japan, there were no giant aneurysm formation in our hospitals. Three patients in whom giant aneurysms developed between 2012 and 2015 were taking oral prednisolone, thereby suggesting a relationship between prednisolone and giant aneurysm formation.

THU0536 CHILDHOOD ONSET OF BEHÇET DISEASE (BD) SYMPTOMS IN AN ADULT COHORT OF BD PATIENTS

V. Paisal[1], E. Al-Abadi[1], S. Protheroe[2], D. Carruthers[3], D. Situnayake[3], S. Powell[4], D. Mitton[4], T. Southwood[1]. *[1]Paediatric Rheumatology; [2]Paediatric Gastroenterology, Birmingham Children's Hospital; [3]Behçet Syndrome National Centre of Excellence, Birmingham and Midland Eye Centre; [4]Behçet Syndrome National Centre of Excellence, Birmingham and Midland Eye Centre, Birmingham, United Kingdom*

Background: Behçet Disease (BD) is rarely reported in children. It a systemic inflammatory condition characterised by autoinflammatory and vasculitic clinical features including recurrent oral aphthosis, genital ulceration, skin, eye, neurological and vascular inflammation, which is most commonly diagnosed between 20–40 years of age. It is unclear how many adult patients with BD have the onset of symptoms during childhood.

Objectives: The aim of our study was to investigate the age of symptom onset in a large cohort of adult patients with BD.

Methods: Since 2012, the Behçet Syndrome National Centre of Excellence, Birmingham and Midland Eye Centre, has used a multidisciplinary approach aiming to shorten time to diagnosis of BD, reduce blindness and morbidity, improve knowledge and ensure equity in access to biological therapies. Patient demographic and disease information, including patient recalled age at symptom onset, symptom sequence, documented clinical signs, treatment and outcome data are maintained in a secure web-based clinical data archive. For this study, the database was interrogated to determine patient age at recalled onset of the first BD symptoms, the sequence in which symptoms appeared and whether the ISG classification criteria for the diagnosis of BD were fulfilled before the age of 16 years.

Results: To June 2016, 478 patients aged between 11–68 years had data recorded in the BD database. 60 patients (12.7%, 49 females) who fulfilled International Study Group criteria for the diagnosis of BD, reported that the onset of their first symptoms was before the age of 16 years (range 2–15 years). All 60 patients reported recurrent oral ulceration and 55 reported genital ulceration but with a reported time interval between the onset of these 2 features of 0–44 years. Of the 60 patients, 26 patients reported sufficient symptoms to have fulfilled ISG criteria before their 16th birthday, including the coincident onset of recurrent oral and genital ulceration in 15/26 patients. Eye disease was only reported in 1 patient and a positive family history of BD in 5/26 patients. 11/26 patients reported a delay between the onset of oral and genital ulcers of a mean of 5.45 years (range 1–11 years).

Conclusions: Many adults with BD recall the onset of their first symptoms before their 16th birthday, usually with recurrent oral and genital ulceration. We speculate that greater awareness of BD in childhood may reduce the delay in diagnosis of this chronic condition.

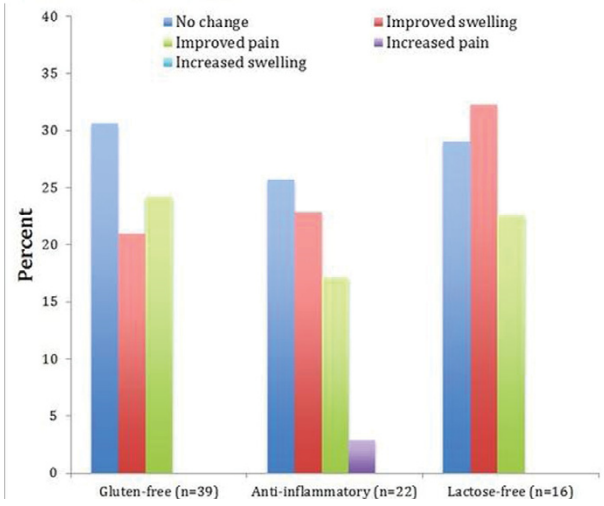
THU0537 FAMILY AND PATIENT'S PERCEPTION OF DIETARY INTERVENTION IN JUVENILE IDIOPATHIC ARTHRITIS (JIA)

E.M. Little[1], S. Grevich[2], J.L. Huber[3], D.L. Suskind[4,5], M.C. Bradford[4], A.M. Stevens[2,6], Y. Zhao[2,4]. *[1]Department of Pediatrics, Alaska Native Medical Center, Anchorage; [2]Pediatric Rheumatology, Seattle Children's Hospital, Department of Pediatrics, University of Washington; [3]Division of Nutrition, Seattle Children's Hospital; [4]Center for Clinical and Translational Research, Seattle Children's Research Institute; [5]Gastroenterology, Seattle Children's Hospital, Department of Pediatrics, University of Washington; [6]Center for Immunity and Immunotherapies, Seattle Children's Research Institute, Seattle, United States*

Background: Juvenile idiopathic arthritis (JIA) is the most common pediatric rheumatologic illness and can lead to significant disability. Complementary and alternative treatments are commonly practiced by families of patients with JIA, and >40% of patients with chronic arthritis seek dietary changes after their diagnosis. Dietary intervention studies in adults with rheumatoid arthritis showed moderate improvement in joint symptoms. Dietary supplements of omega-3 fatty acids have been tested in children with chronic arthritis and found to be associated with less NSAID use and lower serum IL-1 and TNF levels. There is an increasing need to understand if there is a role for dietary therapy in chronic arthritis.

Objectives: We aimed to evaluate the prevalence of special diets and the perception of the effectiveness of these diets on arthritis in JIA. We also assessed the interest of dietary interventions and perceived barriers.

Methods: An online survey was designed through a REDCap database capturing demographic information, self- or parent-initiated special dietary interventions and self- or parent-observing effects on joint symptoms, willingness to participate in a dietary intervention study. The survey link was posted on social media websites and distributed by the Arthritis Foundation. Descriptive statistical analyses were performed.



Results: A total of 265 responses were received from adult patients who had JIA and parents of children with JIA. We excluded 14 patients with inflammatory bowel disease or celiac disease-related arthritis and 24 responders with incomplete answers. Demographic and JIA characteristics of adult and pediatric patients are listed in Table 1. Ninety patients (63 children with JIA, 27 adults with history of JIA) had tried a special diet for arthritis. The top three special diets reported by parents included a gluten-free diet (62%), an anti-inflammatory diet (53%),

and a lactose-free diet (26%). There were similar clinical responses among the three diets (Figure 1). Twenty-five to thirty percent reported no change in joint symptoms whereas 20–30% reported improved pain or joint swelling. Sixty-one (34%) parents were willing to participate in a 3-month dietary intervention study and 78 (44%) parents answered "it depends".

Table 1

Population	Adult patients (n=49)	Pediatric patients (n=178)
Number of joints affected, n (%)		
≥5	43 (88)	125 (70)
<5	5 (10)	51 (29)
Treatment exposure, n, (%)		
Systemic glucocorticoid	40 (82)	108 (61)
DMARDs	44 (90)	146 (82)
Biologicals	35 (71)	114 (64)

Figure 1. Parental report of clinical responses to a gluten-free diet, an anti-inflammatory diet and a lactose-free diet in children

Conclusions: This is the first report of the family/patient perspective of the role of dietary intervention on JIA. Almost half of the affected patients attempted special diets, and many reported improvement in symptoms. Future interventional studies with objective outcome measurements are needed to validate these reports.

Acknowledgements: The authors would like to thank all the patients and families who have taken the survey. Arthritis Foundation and Facebook JA groups have helped distribute the survey.

THU0538 EFFECTS OF GLUCOCORTICOIDS AND METHOTREXATE-BASED THERAPEUTIC REGIMENS ON B CELL SUBPOPULATIONS IN PATIENTS WITH IGG4-RELATED DISEASE

M. Lanzillotta[1], E. Della Torre[1], R. Milani[2], E. Bozzalla[1], L. Rovati[1], E. Bozzolo[1], M. Falconi[3,4], L. Dagna[1,4]. *[1]Internal Medicine, Allergy and Clinical Immunology; [2]Unit of Immuno-hematology and Bone Marrow Transplant; [3]Pancreatic Surgery Unit, San raffaele Scientific Institute; [4]Università Vita-Salute San Raffaele, Milan, Italy*

Background: IgG4-related disease (IgG4-RD) is a systemic fibro- inflammatory disorder characterized by fibrotic lesions infiltrated by IgG4 positive plasma cells (1). The prompt clinical responses obtained after B cell depletion with rituximab in IgG4-RD patients suggest that B lymphocytes drive the pathogenesis of this condition and sustain disease activity (2). This conclusion, however, requires further confirmation because IgG4-RD responds also to non-B cell depleting therapies such as glucocorticoids and methotrexate

Objectives: To evaluate the effects of glucocorticoids and methotrexate-based therapeutic regimens on B lymphocyte subpopulations in patients with IgG4-RD.

Methods: Sixteen patients with active IgG4-RD were studied. FACS analysis was performed on peripheral blood in order to identify the following B cell subpopulations: total B cells (CD19+CD20- and CD19+CD20+ cells), circulating plasmablasts (CD19+CD20- CD27+CD38++ cells), naïve B cells (CD19+CD20+CD27-CD38+ cells), memory B cells (CD19+CD20-CD27+CD38- cells), circulating plasma cells (CD38+CD138+ cells). Disease activity was assessed by means of the IgG4-RD responder index (IgG4-RD RI). Flow cytometry was performed at baseline and after six months of immunosuppressive therapy with glucocorticoids (0.6–1mg/kg/day) and/or methotrexate (10–20mg/week). 16 sex and age matched healthy subjects were used as controls.

Results: At baseline, circulating plasmablasts were expanded in IgG4-RD patients (median 3780 cell/mL; range 330–9300) compared to controls (median 280 cell/mL; range 0–1000) ($p<0.05$); total B cells (median 133000 cell/mL; range 34000–569000) and naïve B cells (median 13080 cell/mL; range 1970–64270) were reduced in IgG4-RD patients compared to controls (median 280 cell/mL; range 194–330; and median 54020 cell/mL; range 21050–106780, respectively) ($p<0.05$). No circulating plasma cells were detected in healthy controls. No differences in memory B cells were observed ($p>0.05$). Circulating plasmablasts but not other B cell subsets positively correlated with serum IgG4 levels, number of organ involved, and IgG4-RD RI ($p<0.05$). At six months follow-up, the median IgG4-RD RI decreased from 9 to 2. Circulating plasmablasts, circulating plasma cells, and naïve B cells counts decreased in all patients together with disease improvement (p=0.0002, 0.0002 and 0.025 compared to baseline values, respectively); total B cells and memory B cells were unaffected by immunosuppressive therapy.

Pt	Age (years)	Sex	Organ involvement	Atopy	Eosinophil (cell/uL) (<400)	ESR (mm/hr) (<12)	CRP (mg/dL) (<6)	IgG4 (mg/dL) (<135)	PBL (cell/mL) (<650)	Naive B Cell (cell/mL)	Memory B Cell (cell/mL)

15	67	M	Pancreas	-	200	-	-	586	940	9900	20070
16	61	M	Pancreas	-	100	<12	<6	137	330	12490	25970

Conclusions: Non-B cell depleting therapies based on glucocorticoids and/or methotrexate induce clinical improvement and deplete circulating plasmablasts, plasma cells and naïve B cells in patients with IgG4-RD; circulating total B cells and memory B cells are not affected by glucocorticoids and methotrexate. Our study, performed with non-B cell depleting agents, provides clinical evidences that circulating plasmablasts are likely linked to IgG4-RD pathogenesis and disease activity.

Objectives: To characterize the main features at presentation of sarcoidosis in a large multicenter cohort from Southern Europe.

Methods: In January 2016, the Autoimmune Diseases Study Group (GEAS-SEMI) created a national registry (SARCOGEAS) of patients with sarcoidosis. Sarcoidosis was diagnosed in agreement with the criteria proposed by the ATS/ERS/WASOG 1999 statement, and extrathoracic disease was classified with the 2014 WASOG instrument.
Results: The cohort consisted of 1082 patients (82% biopsy-proven), including 618 (57%) women and 464 (43%) men, with a mean age at diagnosis of 47yrs; 140 (13%) patients were born outside Spain, 965 (89%) were White, 69 (6%) Hispanic, 30 (3%) Black/African American and 18 (2%) Asian. Thoracic involvement was present at diagnosis in 979 (90%) patients, including 437 (40%) patients with stage I, 374 (35%) with stage II, 123 (11%) with stage III and 26 (2%) with stage IV. The most frequently reported extrathoracic involvements at diagnosis were cutaneous in 385 (36%) patients, extrathoracic lymph nodes in 218 (20%), liver involvement in 151 (14%) and ocular involvement in 118 (11%). Potentially life-threatening WASOG involvements were reported in frequencies less than 10%, including neurological involvement in 77 (7%) patients, kidney involvement in 59 (5%) or cardiac involvement in 21 (2%). Therapeutic approaches at diagnosis included the use of oral glucocorticosteroids in 637 (59%) patients, immunosuppressive agents in 84 (8%, mainly methotrexate in 63 patients) and biological agents in 15 (1%, mainly infliximab in 10 cases).
Conclusions: In this large series of sarcoidosis from Southern Europe, clinical presentation is dominated by adenopathies (both thoracic and extrathoracic) and cutaneous involvement (erythema nodosum), with lower frequencies in the main extrathoracic involvements than that reported in US and Japanese series.

Background: Current information on the use of adalimumab (ADA) in the treatment of ocular Behçet's disease (BD) is still based mainly on small series or case reports; nonetheless preliminary evidence is promising.
Objectives: The study aim was to evaluate the efficacy of ADA in a large series of BD-related uveitis.
Methods: We performed a multicenter retrospective observational study including 40 selected patients (66 eyes) receiving ADA. Clinical data were retrospectively analyzed at baseline, at 3 and 12 months of treatment. Primary end-point was: reduction of ocular inflammatory flares. Secondary end-points were: improvement of Best Corrected Visual Acuity (BCVA), reduction of macular thickness measured by optical coherence tomography (OCT), reduction in the occurrence of vasculitis assessed by fluorescein angiography (FA), evaluation of statistically significant differences between patients treated with ADA monotherapy and those undergoing ADA plus DMARDs and in patients firstly treated with ADA compared to patients previously administered with other biologics; ADA steroid sparing effect was also evaluated.
Results: During the first 12 months of ADA therapy the number of flares significantly decreased from 200 flares/100 patients/year to 8.5 flares/100 patients/year ($p<0.0001$). Similarly BCVA improved if compared to baseline (7.4±2.9 versus 8.5±2.1, $p=0.03$). OCT findings significantly improved showing a mean reduction of central macular thickness (CMT) of 27.27±42.8 microns at the end of follow up ($p<0.006$). FA identified retinal vasculitis in 22 cases at baseline (55%), 8 (20%) cases after 3 months and in only one (2.5%) case at 12-month follow-up. FA improvement was highly significant at 3 and 12-month follow-up if compared to baseline ($p<0.0001$ and $p=0.006$, respectively).
Conclusions: ADA is highly effective and safe for the treatment of BD-related uveitis, providing a long-term control of ocular inflammation.

THU0541 ROLE OF IL-1 INHIBITION IN ADULT ONSET STILL'S DISEASE (AOSD): A RETROSPECTIVE, OBSERVATIONAL MULTICENTRIC STUDY FROM THE ITALIAN SOCIETY OF RHEUMATOLOGY STUDY GROUP ON AUTOINFLAMMATORY DISEASES

S. Colafrancesco[1], R. Priori[1], P. Sfriso[2], G. Valesini[1], L. Punzi[2], M. Galeazzi[3], L. Cantarini[3] on behalf of The Study Group on Autoinflammatory diseases (Italian Society of Rheumatology). *[1]Dipartimento di medicina interna e specialità mediche, Sapienza University of Rome, Rome; [2]Department of Medicine - DIMED, University of Padova, Padova; [3]Department of Medical Sciences, Surgery and Neurosciences, University of Siena, Siena, Italy*

Background: IL-1 pathway plays a major role in the pathogenesis of Adult onset Still's disease (AOSD). IL-1 inhibitors [Anakinra (ANK) and Canakinumab (CAN)] proved their efficacy in AOSD as demonstrated in several case-reports and small case-series. However, due to the disease rarity, large randomized control trials are still lacking.
Objectives: To retrospectively evaluate the efficacy and safety of the use of IL-1 inhibitors (ANK and CAN) in patients with AOSD.
Methods: Data from patients with diagnosis of AOSD (Yamaguchi criteria) referred by 18 different Italian centres were retrospectively collected. Clinical and serological features as well as concomitant treatments, were collected on a dedicated database at the beginning of anti-IL-1 treatment (baseline) and then after 3, 6 and 12 months of follow-up. The Pouchot's score was used to evaluate disease activity.
Results: Data from 140 patients were collected (Table). All were treated with ANK and 4 were subsequently switched to CAN after ANK failure. The systemic pattern vs the chronic-articular were present in ANK and CAN groups in 104/140 (74.2%) and 3/4 (75%), respectively, vs 48/140 (25.8%) and 1/4 (25%), respectively. MTX was the most commonly used DMARD before ANK or CAN [91/140 (75.8%), 2/4 (50%) respectively]. In ANK group, the most commonly used previous biologic drug (bDMARD) was etanercept (79.3%). ANK was adopted as second-line bDMARD in 29/140 (20.7%) patients. In most of the cases it was administered at 100 mg/day in 126/140 patients (90%). CAN was employed at 150 mg every 8 weeks. ANK was effective on all AOSD clinical (fever, rash, pneumonia, pericarditis, pleuritis, sorethroat, lymphadenopathy, hepatomegaly, myalgia, arthritis, MAS) and serological (increased liver enzymes, hyperferritinemia, leucocytosis) manifestations ($p<0.0001$). The Pouchot's score was significantly reduced at all time points ($p<0.0001$). In ANK group no difference in treatment response was identified stratifying patients according to age, sex, pattern of disease, monotherapy vs combination. ANK primary and secondary inefficacy after 12 months were 15/140 (10.7%) and 11/140 (7.8%) cases, respectively. Adverse events (AEs) [mainly represented by in situ (28/47, 59.5%) or diffused (12/47, 25.5%) skin reactions and infections (12/47, 12.7%)] were the main reason for ANK discontinuation. Similarly, in CAN group Pouchot's score and clinical and serological features significantly ameliorated at all time points

Clinical features	ANK group	CAN group
Sex (M/F)	47/93	0/4
Age at onset (mean±SD, years)	35.4 ± 17	34.7 ± 13.3
Age at diagnosis (mean±SD, years)	37.4 ± 16.1	34.2 ± 15.4
Disease duration before treatment (mean±SD, months)	50.33 ± 81.67	58.33 ± 48.4
Previous therapies:	137/140 (97.8%)	4/4 (100%)
- STEROIDS	120/140 (85.7%)	2/4 (50%)
- DMARDs	29/140 (20.7%)	2/4(50%)
- bDMARDs		
Monotherapy	34/140 (24.2%)	2/4 (50%)
Combination therapy (+DMARDs)	106/140 (75.8%)	2/4 (50%)
N° Patient baseline	140 (100%)	4/4 (100%)
N° patients 3 months	118 (84.2%)	4/4 (100%)
N° patients 6 months	109 (77.8%)	4/4 (100%)
N° patients 12 months	97 (69.2%)	3/4 (75%)
N° patients at the time of this study	69 (49.2%)	2/4 (50%)
Mean duration of therapy (mean±SD, months)	35.7 ± 36.1	22.1 ± 16.5
AEs	47/140 (33.5%)	0/4 (0%)
Reasons of discontinuation:		
-AEs	24/71 (33.8%)	0/4 (0%)
-Remission	20/71 (28.1%)	1/4 (25%)
-Primary inefficacy	16/71 (22.5%)	0/4 (0%)
-Loss of efficacy	11/71 (15.4%)	1/4 (25%)
Pouchot's score at baseline	5.5 ± 1.9	4.2±2.6
Pouchot's score at 3 months	1.1 ± 1.4	1.2±1.8
Pouchot's score at 6 months	0.6 ± 1.2	1.5±1.9
Pouchot's score at 12 months	0.4 ± 0.8	1±1.4
% patients with steroids (baseline)	137/140 (97.8%)	4/4 (100%)
% patients with steroids (time of the study)	22/69 (31.8%)	2/2 (100%)
% patients with DMARDs (baseline)	120/140 (85.7%)	2/4 (50%)
% patients with DMARDs (time of the study)	35/69 (50.7%)	0/2 (0%)

($p<0.0001$). No AEs occurred with CAN, only in one case (1/4, 25%) treatment was stopped for loss of efficacy.
Conclusions: To our knowledge this is the largest retrospective observational study evaluating the efficacy and safety of ANK and CAN in AOSD. A prompt response was demonstrated already at 3 months of follow-up both in ANK and CAN groups. ANK proved to be effective in both patterns of disease, appearing also safe on the infectious risk. Nonetheless, skin reaction may represent a not negligible AEs during ANK treatment.

THU0542 ANTI-INTERLEUKIN 1 THERAPY IN FMF AMYLOIDOSIS: A SINGLE CENTER EXPERIENCE (CASE SERIES)

S. Ugurlu, B. Ergezen, A. Hacioglu, H. Ozdogan. *Division of Rheumatology, Department of Internal Medicine, Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey*

Background: Recently there is increasing number of reports investigating the efficacy of anti-interleukin-1 (anti-IL1) therapy in AA-amyloidosis.
Objectives: Here we report our experience in IL-1 blockade in AA amyloidosis secondary to FMF.
Methods: Twenty nine FMF patients with secondary AA-amyloidosis with insufficient response to colchicine were treated with anti-IL-1 agents (canakinumab and anakinra). Creatinine (Cre), 24-hour urine protein (UP), erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were measured before and throughout the treatment to evaluate the response and side effects.
Results: Twenty nine (16 female, 13 male) patients with FMF-related amyloidosis were administered anti-IL1 agents (12 on canakinumab, 17 on anakinra) in addition to colchicine in 27 patients, with a mean dose of 1.4±0.6 mg/day. The mean age was 40.13±11.76, while the mean duration of FMF was 28.79±10.51 years. The mean follow-up was 13.92±11.31 months for anakinra and 11.82±9.92 months for canakinumab.
Initial Cre levels were less than 1.5 mg/dl in 13 patients (range 0.37-.5). In this subgroup proteinuria decreased significantly from 3739.87±4860.41 to 1321.45±2015.62 mg/day while Cre was stable (0.91±0.30 mg/dl to 1.04±0.39 mg/dl) and acute phase response was normalized (CRP from 6.16±7.86 mg/l to 5.20±9.64 mg/l, ESR from 27.3±18.63 to 14±8.04).In the second group there were 11 patients with initial Cre levels higher than 1.5mg/dl (range 1.73–3.76). Proteinuria decreased from 6321.66±5936.43 to 4827.55±6264.43 mg/day, Cre increased from 2.53±0.76 to 3.07±1.70mg/dl, while there was a decrease in the APR in this subgorup (CRP from 40±64.65 mg/l to 26.71±26.76 mg/l, ESR from 57.37±37.65 to 39.11±27.72).
There are two patients on hemodialysis whereas two underwent renal transplantation. Global patient assessment score of the whole group was decreased from 7.44±2.54 to 3.89±3.53 with anti-IL-1.
Anakinra was stopped in 11 and canakinumab in 3 patients, due to irresponsiveness in 8 and 2 patients respectively. Among patients in whom anakinra was terminated 9 were later treated with canakinumab. Twenty four patients are still recieving anti-IL-1treatment (16 on anakinra, 8 on canakinumab).
Conclusions: Anti IL-1 treatments seems to be effective and safe in the treatment of AA amyloidosis secondary to FMF. The beneficial effect of this approach is more pronounced in patients with creatinine levels of less that 1.5 mg/dl.

THU0543 A RETROSPECTIVE OVERVIEW OF THE TREATMENT MODALITY, OUTCOME AND RELAPSE RISK OF IGG4 RELATED DISEASE IN HONG KONG: A DATASET OF 108 PATIENTS FROM FOUR REGIONAL HOSPITALS

C.P. Tang[1], K.L. Lee[1], K.W. Lee[2], W.L. Ng[3], M.C. Wan[4], K.Y. Yuen[5]. *[1]Medicine, PYNEH; [2]Medicine, HKSH; [3]Medicine, UCH; [4]Medicine, RH; [5]Medicine, QMH, HK, Hong Kong*

Background: Currently most consensus suggests treating IgG4 related disease (IgG4RD) with prednisolone 0.6mg/kg/day tapering over 6 months while some experts prefer continuation of steroid up to 3 years (1–3).
Objectives: In this retrospective study, the treatment modality, response and relapse risk of IgG4RD patients over the past ten years from four regional hospitals in Hong Kong were analyzed.
Methods: Four regional hospitals participated with study period from 1/1/2006 to 30/6/2016. Patients were diagnosed IgG4RD according to the Japanese Comprehensive Diagnostic Criteria for IgG4RD. Treatment response at 6 months was recorded as complete, partial or non-remission based on the patient's and physician's perspective. Relapse was defined as disease progression either clinically or radiologically.
Statistical analysis: The association between treatment response and steroid dosage was analyzed by multivariate logistic regression. Risk factors for relapse were analyzed by multivariate cox regression and the hazard ratio was reported.
Results: 37 cases had surgical excision and disease recurred in 5 cases (relapse rate =13.5%). 87 patients (81%) received steroid treatment. The mean starting prednisolone was 33.5mg daily, with a mean duration of 95.2 weeks. At 6 months, 5 patients (6%) had no response, 34 patients (41%) had partial remission and 44 patients (53%) had complete remission.
29 patients also received other immunosuppressants, including azathioprine (n=25), mycophenolate mofetil (MMF) (n=6), cyclosporine A (n=4), mercaptopurine (n=2) and rituximab (n=1). The overall response rate for azathioprine and MMF was 64% and 67% respectively.
In the final multiple logistic regression, an initial prednisolone 30mg daily or above was associated with a higher complete remission at 6 months (OR=3.4, p=0.079) and the effect was more seen in patients with salivary and orbital involvement (OR=6.8, p=0.10)
18 patients relapsed after steroid was stopped and 6 patients relapsed while on prednisolone 2.5–7.5mg daily. The one year, two year and three year relapse rate were 13.3%, 24.1% and 26.5% respectively.
In the final multivariate cox regression, the presence of maintenance steroid was associated with a lower relapse risk (Hazard ratio=0.121, p=0.000) while serum IgG4 level above twice upper limit of normal (Hazard ratio=5.283, p=0.029) and hepatobiliary involvement (Hazard ratio=2.164, p=0.095) were associated with a higher relapse risk.
Conclusions: Most patients (94%) had good response to steroid. Patients with hepatobiliary involvement and serum IgG4 level above twice upper limit of normal were at higher relapse risk and a low dose, maintenance prednisolone for longer period is recommended.

THU0544 THE IMPORTANCE OF R202Q POLYMORPHISM IN CLINICAL EXPRESSION OF FMF: A SINGLE CENTER CROSS-SECTIONAL STUDY

S. Yilmaz[1], E. Tekgoz[1], F.I. Cinar[2], M. Cinar[1]. *[1]Department of Internal Medicine, Division of Rheumatology, University of Health Sciences, Gulhane Medical Faculty; [2]Gulhane School of Nursing, University of Health Sciences, Ankara, Turkey*

Background: Familial Mediterranean fever (FMF) is an autosomal recessive inherited disease with recurrent fever and inflammatory episodes of serous membranes. The MEFV (Mediterranean fever) gene in the short arm of chromosome 16 is affected in the FMF. This gene encodes for a protein called 'Pyrin'. The erroneously synthesized Pyrin protein due to MEFV mutations is unable to control the post inflammatory process. Although there have been many efforts to find out genotype-phenotype association in FMF, no clear relationship has been clarified.
Objectives: In this study, the relationship between FMF clinical symptoms and MEFV gene mutations and polymorphism was investigated.
Methods: Total of 158 patients with FMF was included to the study that was conducted in a tertiary rheumatology outpatient clinic. The demographic and clinical features, as well as MEFV gene mutations were recorded in a "Patient Assessment Form". The clinical status of the disease was evaluated with FMF-severity score-2 (F-SS-2). The associations between clinical features and genetic alterations were calculated with Pearson Chi-square test.
Results: The mean age of patients was 24.3±5.1, mean delay in diagnosis was 5.6±6.3 years, and 155 of the patients (%98.1) were male. The percentage of patients stating they use colchicine regularly was 136 (86.1%), and mean dose was 1.4±0.3 mg/day. The most frequent mutation was M694V (76.6%), and R202Q, M680I and E148Q were found in a descending order (60.8%, 19.0% and 13.9%, respectively). The FMF severity score was found to be higher in patients carrying M694V mutation (p=0.01). In comparison with negative family history for FMF, M694V was more prevalent in patients with positive family history (82.0% vs 67.2%, p=0.035). Besides, M694V mutation found to be associated with arthritis (p=0.045). E148Q mutation was associated with the history of orchitis (p=0.029). The most significant relation between E148Q and clinical feature was family history of hemodialysis (p=0.005). The prevalence of non-periodic myalgia was %34.2, and this symptom was not present in patients carrying V726A mutation (p=0.005). M694V/R202Q was the most prevalent compound heterozygosis and found in 16 patients (10.1%). This mutation (M694V/R202Q) was associated with fewer frequencies of myalgia and peritonitis, and with good response to colchicine.
Conclusions: The presence of R202Q polymorphism is associated with FMF, and should be considered in the routine genetic analysis of the disease. In our patients, its co-existence with M694V seems to be associated with good response to colchicine, and to alleviate the severity of the disease expression of M694V, which is known to be associated with severe course.

THU0545 COMPARISON OF THE CLINICAL AND LABORATORY FEATURES AT ONSET BETWEEN MULTICENTRIC CASTLEMAN'S DISEASE AND ADULT-ONSET STILL'S DISEASE

A. González García[1], W.A. Sifuentes Giraldo[2], J.L. Morell Hita[1], J.L. Patier de la Peña[2]. *[1]Rheumatology; [2]Internal Medicine, Ramon y Cajal University Hospital, Madrid, Spain*

Background: Multicentric Castleman's disease (MCD) is a disorder characterized by polyclonal proliferation of B lymphocytes that is frequently associated with autoimmune manifestations and connective tissue diseases. MCD presents high levels of IL-6 and systemic symptoms such as fever, arthralgia, hepatosplenomegaly and serositis, so it is recommended to include MCD in the differential diagnosis of adult-onset Still's disease (AOSD). However, there are no studies comparing both groups of patients.
Objectives: To compare the clinical and laboratory features at onset between patients with MCD and AOSD seen in a Madrid tertiary care hospital.
Methods: We performed a retrospective observational study in patients with diagnosis MCD and AOSD attended our center between January 1989 and December 2015. The variables included demographics, clinical manifestations, laboratory tests and Yamaguchi's criteria.
Results: A total of 34 patients were included, 17 with MCD and 17 with AOSD. The comparison of the characteristics of both groups is presented in the table. There were no differences in age, uration of disease (MCD 158,6 days and AOSD 250,5 days, p=0,3919), diagnostic delay (MCD 18,4 and AOSD 52,2, p=0,2711), arthritis, myalagias, pleuritis or macrophagic activation syndrome, but persistent fever, rash, arthralgia, pharyngitis and pericarditis were significantly more frequent in ESA, whereas male gender, human immunodeficiency virus (HIV) and/or human herpes virus 8 (HHV8) infection, hepatosplenomegaly and lymphadenopathy were significantly higher in MCD. In the laboratory test results, leukocytosis and hypertransaminasemia were significantly higher in AOSD. 52.9% of patients with MCD met 5 or more Yamaguchi's criteria for AOSD.

	Multicentric Castleman's disease (n=17)	Adult-onset Still's disease (n=17)	p-value
Male:female ratio	2.4:1	0.4:1	0.0163
Age at diagnosis (mean ± SD)	46.4±13.1	37.5±13.5	0.0598
HIV infection	35.2%	0%	0.0154
HHV8 infection	35.2%	0%	0.0154
Persistent fever	47.1%	94.1%	0.0078
Rash	29.4%	64.7%	0.0392
Arthralgias	35,3%	88.2%	0.0014
Arthritis	0%	17.6%	0.0696
Pharyngitis	0%	41.2%	0.0029
Hepatosplenomegaly	47.1%	5.9%	0.0065
Pericarditis	0%	23.5%	0.0332
Pleuritis	17.6%	11.7%	0.6217
Lymphadenopathy	100%	17.6%	0.0001
Macrophage activation syndrome	11.7%	17.6%	0.6282
Leucocytes >10000/mm^3	35.2%	76.5%	0.0156
Increased transaminases	0%	58.8%	0.0002
Erythrosedimentation rate (mm/Hg)	52	77.5	0.1104
C-reactive protein (md/dl)	75.1	109.5	0.3699
Ferritin (ng/ml)	240	1926	0.1234

Conclusions: Patients with MCD may present common systemic manifestations and laboratory abnormalities at onset with AOSD and up to 50% of them may fulfill Yamaguchi's criteria for this disease, so MCD should be taken into account in its differential diagnosis.

THU0546 IMPACT OF BONE LOCALISATION ON THE PROGNOSTIC OF LANGERHANS CELL HISTIOCYTOSIS: A MONOCENTRIC RETROSPECTIVE STUDY

J.-G. Letarouilly[1], N. Segaud[1], B. Wallaert[2], P.-Y. Hatron[3], R.-M. Flipo[1]. *[1]Rhumatologie, CHRU Lille Hôpital Roger Salengro; [2]Pneumologie, CHRU Lille Hôpital Calmette; [3]Médecine interne, CHRU Lille Hôpital Huriez, Lille, France*

Background: Langerhans cell histiocytosis (LCH) is a rare condition, and mostly affects children. Bone is the most commonly involved organ, with bone lesions in 50% of patients. In a recent work, Aricò et al. described that the probability of survival in children suffering from a multisystemic LCH with risk organ involvement was reduced if patient did not have any bony lesion [1]. There is no such a study in adult patients.
Objectives: The objective of the study was to know the bone impact on the prognosis of adult LCH.
Methods: A retrospective monocentric study was performed using data from the patients hospitalized for a LCH at Centre Hospitalier Régional Universitaire de Lille, a university hospital between 2001 and 2015. All patients with LCH and at an age of 18 years or older were included. Patients were excluded if they did not receive any osteoarticular imaging (radiography, scintigraphy, PET, MRI).
Results: Our study initially included 70 patients had LCH. After screening 54 patients met the inclusion criteria: 31 had bone localization (BLG) and 23 none (NBLG). The two groups showed differences. The lesion leading to the diagnosis was mostly osteoarticular (18 patients) in BLG and pulmonary (18 patients) in NBLG. The BLG presented more multisystemic form than the NBLG (20 vs 2, p<0.0001). Both groups were equivalent for comorbidities (p=0,206 for cancer and p=0,756 for cardiovascular disease), number of smokers and age at diagnosis (36.8+/- 14.15 years vs 36.7+/- 12.6 years, p=0.96 and 25 vs 22, p=0.06).
Treatment was required for 14 patients in BLG and for 2 in NBLG. In BLG, 8 patients were treated medically, mostly by corticosteroid therapy and chemotherapy (7), one patient underwent radiotherapy. 6 patients were treated by surgery. In NBLG, 2 patients were treated by corticosteroid therapy. There was no surgery in NBLG (table 1). 3 patients died in BLG, 2 directly related to LCH and one from postoperative infectious complications. One patient died in NBLG from hematologic pathology (chronic myelomonocytic leukemia). The time between diagnosis and death was one, six and 22 months in BLG, 36 months in NBLG. 7 patients presented relapses in BLG. 5 had been treated by medical treatment, one surgically and one had no previous treatment. The time of relapse was six, 8, 12, 14, 16, 52 and 72 months. 4 presented new bone lesions, 1 pulmonary lesions, 1 dermatologic lesions and 1 neurologic lesion (table 1). There was no relapse in NBLG. Unfortunately, there was a lack of statistical power to conclude about the bone impact on the prognosis.
Conclusions: Patients with bone location and those with no bone location are two different phenotypes of adult LCH. Patients with bone location are more proned to have a multisystemic relapsing disease. A multicentric study with a larger number patients is needed to bring more robust data to answer about bone impact on the prognosis of adult LCH.

THU0547 CHARACTERIZATION OF A GROUP OF 12 PATIENTS WITH MEVALONATE KINASE DEFICIENCY: SYMPTOMS AND TREATMENT WITH IL-1 INHIBITORS

A. Kozlova[1], V. Burlakov[1], N. Kuzmenko[1], S. Zimin[2], T. Varlamova[1], O. Barabanova[2], E. Raikina[1], A. Shcherbina[1]. *[1]Immunology, Federal State Budgetary Institution "National Scientific and Practical Center of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev" of the Ministry of Healthcare of the Russian Federation; [2]Immunology, Children's Clinical Hospital N9, Moscow, Russian Federation*

Background: Mevalonate kinase deficiency (MKD) is a rare autosomal recessive autoinflammatory disease caused by mutations in MVK gene. MKD patients typically have an early onset of symptoms including recurrent episodes of high fever, abdominal pain, diarrhea and vomiting, arthralgia and lymphadenopathy (AIDAI criteria for HIDS). However not all patients have typical symptoms at the time of onset. MKD treatment remains an unsolved problem, since none of the modalities previously used for MKD treatment are fully effective in the disease control.
Methods: We conducted a retrospective analysis of clinical features of twelve patients (6 females, 6 males) with genetically confirmed MKD. Nine patients received therapy with inhibitors of IL-1 (Anakinra and/or Canakinumab). One of the patients died from amyloidosis and macrophage activation syndrome (MAS) prior to treatment initiation, her diagnosis was verified *post mortem*.
Results: Ten patients had manifested within the first 6 months of life, one – at the age of 1.5 years, one – at three years of age,. During the course of the disease all patients had periodic fever and peripheral lymphadenopathy (mainly cervical group), as well as abdominal pain, nausea/vomiting. Five patients had diarrhea, sometimes with blood, one patient suffered from severe constipation. Rash was seen in eight patients, myalgia, artralgia were observed only in six. Oral ulcers were noted in seven children. Three patients had neurological involvement, one patient had it as the main symptom. One patient had periorbital edema and hyperemia during attacks, which to our knowledge, have not been reported previously in MKD. One patient developed amyloidosis and MAS before IL1 inhibitor treatment initiation, which led to her death. In patients receiving anti-IL-1 therapy AIDAI index decreased from 58.3±11,2 before to 1,5±1,4 after 6 month of therapy (p=0.003).
Conclusions: MKD symptoms can be variable and sometimes atypical, which requires physician's awareness. In our cohort of MKD patients anti IL-1 therapy was highly effective.

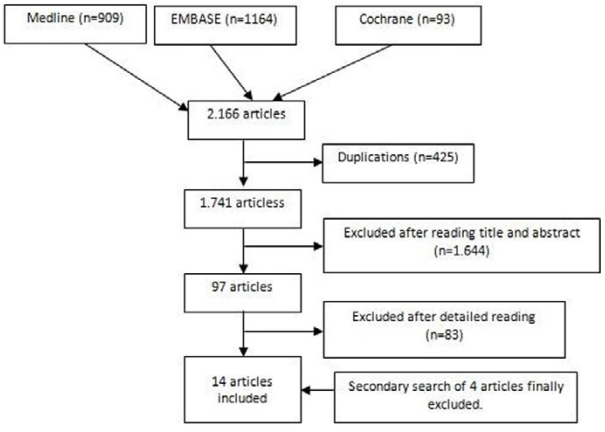
THU0548 PSORIASIS IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER

A. Erden[1], E.D. Batu[2], E. Bilgin[3], H.E. Sonmez[2], E. Seyhoglu[3], S. Demir[2], L. Kilic[1], A. Sari[1], B. Armagan[1], O. Karadag[1], A. Akdogan[1], I. Ertenli[1], S. Kiraz[1], S.A. Bilgen[1], S. Ozen[2], U. Kalyoncu[1]. *[1]Department of Rheumatology; [2]Department of Pediatrics Rheumatology; [3]Department of Internal Medicine, Hacettepe University Faculty of Medicine, Ankara, Turkey*

Background: Familial Mediterranean fever (FMF) is a periodic fever syndrome caused by *MEFV* mutations. FMF may be associated with psoriasis in some cases. Previous study has shown that psoriasis was more common in the relatives of FMF patients [1].
Objectives: We aimed to investigate the prevalence of psoriasis among FMF patients and their relatives.
Methods: FMF patients followed at Hacettepe University Adult and Pediatric Rheumatology Departments between January and August 2016 were consecutively enrolled to this study. Demographic data, clinical manifestations, laboratory data and *MEFV* variant analysis were documented by medical file screening and face-to-face interview. The presence of psoriasis and psoriatic arthritis in patients and their relatives (first [Mother, father, children]-second [Brothers, grandchildren, grandfather and grandmother]-third degree [Nephew, uncle, maternal uncle, aunt, paternal aunt] relatives) and drug use history were also questioned. The patients were accepted to have psoriasis if the diagnosis was made by a dermatologist.
Results: 351 FMF patients (177 adults; 174 children) were included in this study (Table). 70.1% of adult patients were female, 29.9% were male. 53.4% of pediatric patients were female, 46.6% were male. The median age (min-max) of the adult patients was 35 (19–63), while the median age of the pediatric patient group was 10 (2–18). The onset age of symptom was 12 (0–39) in the adult group and 3 (1–14) in the pediatric group. The median age at diagnosis was 25 (2–52) in the adult group and 5 (1–18) in the pediatric group. Thirteen (3.7%) patients had psoriasis. Psoriasis was more common in adult patients than pediatric patients (p=0.02). Psoriasis was present in 22 (12.4%) of adult patients' and 9 (5.2%) of pediatric patients' relatives (p=0.023). The frequency of psoriasis in one or more relatives of all FMF patients was found to be 8.8%.

Table. Demographic and clinical characteristics of 177 adult and 174 pediatric patients with familial Mediterranean fever (FMF)

Characteristics	Adult patients (n=177)	Pediatric patients (n=174)	p value
Gender, female, n (%)	124 (70.1)	93 (53.4)	**0.001**
Abdominal pain, n (%)	159 (89.8)	166 (95.4)	**0.046**
Fever, n (%)	152 (85.9)	170 (97.7)	**<0.0001**
Arthralgia, n (%)	147 (83.1)	76 (43.7)	**<0.0001**
Arthritis, n (%)	93 (52.5)	27 (15.5)	**<0.0001**
Pleuritic chest pain, n (%)	104 (58.8)	14 (8)	**<0.0001**
Erysipelas-like erythema, n (%)	57 (32.2)	6 (3.4)	**<0.0001**
Pericarditis, n (%)	7 (4)	0 (0)	**0.007**
Amyloidosis, n (%)	5 (2.8)	1 (0.6)	0.215
Family history of FMF[a], n (%)	99 (55.9)	94 (54)	0.719
Parental consanguinity, n (%)	44 (25)	25 (14.4)	0.012
Hemodialysis history in family associated with FMF, n (%)	20 (11.3)	11 (6.3)	0.132
Psoriasis, n (%)	11 (6.2)	2 (1.1)	**0.020**
Psoriatic arthritis, n (%)	3 (1.7)	1 (0.6)	0.623
Psoriasis in any degree relatives, n (%)	22 (12.4)	9 (5.2)	**0.023**
Psoriasis in 1° relatives, n (%)	5 (2.8)	2 (1.1)	0.44
Psoriasis in 2° relatives, n (%)	5 (2.8)	6 (3.4)	0.73
Psoriasis in 3° relatives, n (%)	15 (8.5)	1 (0.6)	**<0.0001**



Conclusions: IL-1 has an essential role for signaling early T helper 17 (Th17) differentiation and Ashida et al have shown the presence of Th17 cells in the upper dermis of psoriasis-like lesions in a patient with FMF [2]. We may speculate that high IL-1 in FMF may cause Th17 activation and stimulation of keratinocytes; and this may be the reason for higher frequency of psoriasis in FMF patients. Thirteen (3.7%) patients had psoriasis; more common than the normal population (0.40%) (p<0.0001). FMF increases the likelihood of psoriasis in relatives of FMF patient. Thus, FMF patients should be questioned and carefully examined for psoriasis lesions and psoriasis family history.

THU0549 SYSTEMIC TREATMENT FOR ACUTE ANTERIOR UVEITIS (SYNTHETIC AND BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS): A SYSTEMATIC REVIEW

A. Gómez-Gómez[1,2], E. Loza[3], M.P. Rosario[3], L. Carmona[3], G. Espinosa[4], J.M. García Ruíz de Morales[5], J.M. Herrera[6], S. Muñoz-Fernández[2,7], M. Cordero[8]. *[1]Rheumatology, Hospital Universitario Madrid Sanchinarro; [2]Rheumatology, Hospital Universitario Infanta Sofía; [3]Instituto de Salud Musculoesquelética (InMUSC), Madrid; [4]Autoimmune diseases unit, Institut Clinic de Medicina i Dermatología, Hospital Clínic, Barcelona; [5]Immunology unit, Complejo Asistencial Universitario e Instituto de Biomedicina Universidad de León (IBIOMED), León; [6]Instituto Universitario de Oftalmobiología (IOBA), Universidad de Valladolid, CIBER-BBN. Hospital Clínico Universitario, Valladolid; [7]Department of Medicine, Universidad Europea de Madrid, Madrid; [8]Uveitis Unit, IBIOMED, León, Spain*

Background: Acute anterior uveitis (AAU) is the most common form of uveitis. Most of them are idiopathic, followed by those related to rheumatic conditions. One third of AAU patients may present recurrences, some requiring systemic disease-modifying antirheumatic drugs (DMARDs). The use of DMARDs in AAU is heterogeneous.
Objectives: To perform a systematic and critical review of the literature about the use of synthetic and biologic DMARDs in adult patients with AAU.
Methods: *Selection criteria:* Articles including adult patients with non-infectious AU treated with synthetic or biologic DMARDs including efficacy, and/or safety or cost-effectivity data were selected. Only meta-analysis, systematic reviews, clinical trials and observational studies (OS) were included.
Search strategies for Medline, Embase and Cochrane Library databases up to 3–2016 were designed.
Article selection: 2 independent reviewers. Selected articles were analyzed in detail.
Quality asessment of the studies: Oxford scale and Jadad scale were used.
Analysis and data presentation: evidence and results tables.
Results: 14 articles included, 2 RCTs and 12 OSs, with low or moderate quality. The mean duration/follow-up, number (n) and patients characteristics were highly variable. The definition of the anatomic classification of AUs was generally not clear. Systemic DMARDs were used, including Methotrexate (MTX), Azathioprine (AZA), Cyclosporine A (CsA) and anti-TNFα (Adalimumab (ADA), Golimumab (GLM)), at usual dosage prescription. Number of flares, disease activity and corticoid sparing (CS) effect were the most common outcomes, with big differences between studies in variables included and their definitions.
MTX showed efficacy in disease remission, n of flares, time between flares, lower activity and CS effect. *SSZ* showed lower n of flares and improvement in visual acuity (VA) in AS-associated AAU patients. *AZA* (low quality RCT) showed no differences in VA, Tyndall, flares or IOP. A prospective OS showed lower activity and CS effect. *CsA* (moderate quality OS) showed efficacy improving activity and as CS agent (mid/long term). *Anti-TNFα: ADA*, (2 OSs) with SpA-associated AU patients lowered n of flares (mid/long term), can improve VA, Tyndall and be used as CS agent. *GLM* in AU patients refractory to DMARDs (some to other biologics), showed CS effect in 2 studies. One showed improvement in VA and Tyndall, but not in OCT or n of flares. Adverse events recorded were those usually registered for all these drugs.

Figure 1. Article selection strategy.

Conclusions:
1. Evidence quality is low.
2. Great variability.
3. MTX showed efficacy in idiopathic and systemic disease-associated (SDA) AU.(EL 2c; RG B).
4. SSZ showed efficacy in idiopathic and SDA AU.(EL 3a; RG B-C).
5. AZA seems to be effective in naïve and DMARDs-refractory AU (EL 3a; RG C).
6. CsA showed efficacy in idiopathic and SDA AU (EL 2c; RG B-C).
7. ADA showed efficacy in idiopathic and SDA AU, naïve or DMARDs-refractory AU (EL 2c; RG B).

8. GLM showed efficacy in DMARD-refractory AU (2nd line and further) and other biologic therapies (EL 3a; RG B-C).

THU0550 TREATMENT AND OUTCOMES IN SPANISH PATIENTS WITH IGG4-RELATED DISEASE

A. Fernández-Codina[1], I. Pinal-Fernández[2], B. Pinilla[3], C. López[4], R. Solans-Laque[1], G. Fraile-Rodríguez[5], E. Fonseca-Aizpuru[6], J.M. Cameselle-Tejeiro[7], S. Prieto-González[8], J. Pardos-Gea[1], J. Gil[9], T. Rossinyol[10], M.J. Núñez-Fernández[11], G. Salvador-Cervelló[12], F. Martínez-Valle[1] on behalf of Spanish Registry of IgG4-related disease (REERIGG4). GEAS-SEMI. *[1]Systemic Autoimmune Diseases Unit, Hospital Universitari Vall d'Hebron, Barcelona, Spain; [2]Muscle Disease Unit, National Institute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, United States; [3]Internal Medicine, Hospital General Universitario Gregorio Marañón; [4]Internal Medicine, Hospital General Gregorio Marañón; [5]Internal Medicine, Hospital Ramón y Cajal, Madrid; [6]Internal Medicine, Hospital de Cabueñes, Gijón; [7]Pathology, Hospital Clínico Universitario, Santiago de Compostela; [8]Vasculitis Research Unit, Hospital Clinic i Provincial, Barcelona; [9]Internal Medicine, Hospital Río Hortega, Valladolid; [10]Internal Medicine, Hospital de Manacor, Manacor; [11]Internal Medicine, Complejo Hospitalario de Pontevedra, Pontevedra; [12]Internal Medicine, Hospital la Fe, Valencia, Spain*

Background: There is a lack of strong evidence on IgG4-related disease (IgG4-RD) treatment. There is only one clinical trial published, supporting the use of rituximab in American patients.
Objectives: To describe the treatments used in a series of patients diagnosed with IgG4-RD in Spain and to review the outcomes.
Methods: Clinical data were obtained from the Spanish Registry of IgG4-RD from October 2013 to January 2016, including 14 centers. Outcomes were assessed by a self-made response scale and the IgG4 responder index (RI). We categorized the outcomes as a total response (disappearance of the pseudotumoral lesions and absence of symptoms), partial response (<50% regression of the tumefactive lesions or persistence of inflammation without symptoms) and no response if no changes were noticed. Treatment failure was considered if an increase of the activity, mass size or reappearance of symptoms were noticed among patients under treatment.
Results: Sixty-eight patients were included. Twenty-six (38%) were females, mean age 53.4 years. Thirty-six patients (52.9%) had systemic IgG4-RD involving >1 tissue. The most commonly involved tissues were: retroperitoneum (33%), orbital pseudotumor (28%), and maxillary and paranasal sinuses (24%). The main treatments used were: steroids (90%), surgery (45%) and azathioprine (19%).
All treatments were successful in achieving complete or partial response. The mean pre and post-treatment RI values were 6.7 (SD 4.6) and 1.9 (SD 2.6) respectively. There were no differences between systemic and non-systemic disease regarding the chosen treatments and the outcomes. The combination azathioprine-steroids was used in 12 patients. Fourteen percent of them relapsed (considering relapse as an increase of the inflammation, mass size or reappearance of symptoms, since the first month after the treatment withdrawal). The treatment failed in 28.6% of them. The combination steroids-rituximab was indicated in 6 patients, showing no relapses and 1 treatment failure. The majority of patients treated with azathioprine or rituximab combined with steroids had a systemic disease (6.6 and 80%, respectively). Nearby all of them had already failed other previous treatments.
Conclusions: In our series, IgG4-RD has been treated with a myriad of drugs and procedures. The outcomes have been acceptable but the disease tended to relapse (21%) and the treatment failures were common (27%), probably due to the lack of well-defined treatment schemes supported by solid studies. Steroids were still the cornerstone of the treatment. Rituximab results were promising in our study but the number of patients was limited. Azathioprine, in combination with steroids, may be an accessible alternative treatment for IgG4-RD that should be explored. The RI correlated with the treatment outcomes and will have an important role monitoring future studies on IgG4-RD therapies.

THU0551 ARTHRITIS IN SARCOIDOSIS - A MULTI-CENTRE STUDY FROM INDIA

A. Jain, V. Agarwal on behalf of Arthritis in Sarcoidosis Group (A.S.G.): Jain A, Agarwal Vikas, Agarwal Vinita, Aggarwal A, Aggarwal P, Chowdhury AC, Ghosh P, Lawrence A, Misra DP, Misra R, Mohapatra M, Nath A, Negi VS, Pandya SC, Reddy VV, Prasad S, Shobha V, Singh YP, Tripathy SR, Wakhlu A. *Clinical Immunology, SGPGIMS, Lucknow, India*

Background: 10–15% of sarcoid patients have associated arthropathy. Chronic arthritis is less common varying from 1–2% [1].Data on articular manifestations of the disease from India is sparse.[2]
Objectives: To study the clinical manifestations of sarcoid arthritis patients from India.
Methods: Case records of patients presenting to ten rheumatology centres from 2005 to 2016 with sarcoidosis were retrospectively reviewed. Joint involvement was assessed clinically, classified as acute or chronic depending on duration of symptoms lesser or greater than 6 months respectively.
Results: A total of 103 patients with sarcoid arthritis were reviewed. 58 patients were classified as Lofgren syndrome. Pattern of joint involvement revealed ankle as most commonly affected in both the groups (Table1). Wrist, MTP and PIP involvement was significantly more common in chronic sarcoid arthritis (table 1). Peripheral lymphadenopathy, plaques and uveitis were more frequent ($p<0.05$) in chronic sarcoid arthritis (50%, 20.8%, 25% respectively) compared to those with acute sarcoid arthritis (16.5%,6.3%,6.4% respectively). 45 of 62 patients with acute arthritis with follow up details had achieved complete remission.15/24 patients with chronic sarcoid arthritis patients with a median follow up of 2 years had achieved complete remission with 14, 11 and 5 patients on steroids, methotrexate and hydroxychloroquine respectively. One patient with concomitant interstitial lung disease had died due to lung infection.

Table 1. Clinical characteristics of patients with sarcoid arthritis from India

	Acute, n=79	Chronic, n=24
Age (years)	40† (33.5 TO 51)**	42.5† (35–55)**
Male : Female	0.9:1	1.7:1
Duration of Symptoms (years)	0.25† (0.08 to 1.5)**	0.72† (0.5 to 4)**
Oligoarthritis (≤4 joints)	58 (73.4)*#	12 (50)*
Polyarthritis (≥5 joints)	19 (24.1)*	12 (50)*
Ankle	71 (89.9)*	21 (87.5)*
Wrist	22 (27.8)*	16 (66.7)*‡
MTP	5 (6.3)*	5 (20.8)*‡
PIP	12 (15.2)*	9 (37.5)*‡
Hilar/Mediastinal Lymphadenopathy	66 (83.5)*	21 (87.5)*
ILD	23 (29.1)*	12 (50)*

*Percentage; †Median; **IQR. ‡$p<0.05$. #One patient each had dactylitis and enthesitis as the only musculoskeletal manifestation.

Conclusions: Acute oligoarthritis was the commonest presentation with ankle most commonly affected joint. Wrist, PIP, MTP involvement were more common in chronic sarcoidosis. One of the limitation was retrospective analysis.

THU0552 COMPLIANCE TO COLCHICINE TREATMENT IN FAMILIAL MEDITTERRANEAN FEVER RELATED AMYLOIDOSIS

B. Yurttas[1], S. Ugurlu[2], H. Ozdogan[2]. *[1]Department of Internal Medicine; [2]Department of Internal Medicine, Division of Rheumatology, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey*

Objectives: To assess the colchicine compliance in patients diagnosed with Familial Mediterrenean Fever (FMF) related amyloidosis in our center.
Methods: Fourty one patients (18 male/23 female) were questioned with regards to colchicine compliance by using retrospective scanning of patient data.
Results: The mean age at the symptomatic onset of FMF was 7.13±5.24 years. The mean age at the time of the FMF diagnosis was 21.21±14.85 years. The mean age at the initiation of colchicine treatment was 21.42±14.75 years and the mean age at time of the diagnosis of amyloidosis was found 29.57±12.14 years. Mean duration of the disease was 31.702±11.84 years and the duration of delayed diagnosis was 14.35±13.84 years. Maximum dose of colchicine was 2,103±0,673 mg/day. Compliance of colchicine treatment was poor in FMF related amyloidosis during their follow-up (11/25, %44), rates of skipped doses were also high (17/25, %68). Compliance rates were high in patients in whom FMF and amyloidosis were diagnosed simultaneously (12/13, %93), rates of skipped doses were also low (2/13, %14). One of the patients diagnosed with FMF after the diagnosis of amyloidosis was compliant, two of them were non-compliant; with regards to skipping doses, two patients were found to be compliant and therefore never skipped doses while one was skipping doses. The compliance to colchicine was high in all FMF patients once amyloidosis was evident (31/41, %75), and rates of skipped doses were also low (12/41, %30). In five FMF patients, amyloidosis was observed despite their compliance to treatment.
Conclusions: The overall delay of diagnosis in FMF patients with amyloidosis was found to be high. Particularly the FMF patients who were diagnosed with amyloidosis during their follow up were found to have lower rates of compliance. There were also a group of patients who were diagnosed with amyloidosis despite adequate and convenient colchicine treatment. It was emphasized that not only the early diagnosis and adequate treatment, but also the close follow up is important in managing FMF patients.

THU0553 LOW ALKALINE PHOSPHATASE LEVELS: COULD IT BE HYPOPHOSPHATASIA?

C. Tornero[1], P. Aguado[1], S. García[1], J. Tenorio[2], P. Lapunzina[2], A. Buño[3], J.M. Iturzaeta[3], C. Plasencia[1], I. Monjo[1], A. Balsa[1]. *[1]Rheumatology; [2]Genetics; [3]Clinical Laboratory, la Paz University Hospital, Madrid, Spain*

Background: Hypophosphatasia (HPP) is a rare inherited disorder of bone and mineral metabolism, caused by mutations in the ALPL (alkaline phosphatase liver type) gene, with reduction of activity of the tissue-non-specific isoenzyme of ALP (TNSALP). The clinical presentation is variable and adult forms of the disease are usually milder than those affecting infants and children, easily overlooked or misdiagnosed, which can lead to erroneous therapeutic decisions.
Objectives: The primary objectives of our study are to estimate the prevalence of patients with adult forms of HPP in a group of patients with persistent hypophosphatasemia, to analyze their clinical and functional characteristics and to compare these findings between those presenting or not these mutations.
Methods: In this Cross-sectional study, 1.536.711 ALP measurements owing to 386.356 patients were evaluated during a six-year period (2009–2015). Patients having at least two values below 35 IU/l and none above 45 IU/l constituted the study population. In total, 427 patients were included. Among them, 31 patients were excluded because of presenting causes of secondary HPP and 13 because of lost to follow-up. 108 patients were contacted by phone to fulfill a questionnaire about manifestations related to HPP and health assesment and in order to obtain blood samples to perform the genetic test.
Results: Demographic and clinical characteristics of both groups are shown in Table 1. Of the 108 patients evaluated, the genetic test results of 39 patients are available at this moment (the rest of the results are currently pending). 59% (23/39) tested positive for the genetic mutation.Despite data are still partial and although the results did not achieve statistical significance, we observed with a greater relevance a higher proportion of patients with HPP presenting with chronic bone pain (48,7% vs 25,6%,p=0,157), muscle weakness (15,4% vs 2,6%, p=0,112) and more necessity of analgesic medication (p=0,107) in patients with HPP in comparison with the control group. Furthermore, there was a non-significant trend in the HPP-group to present dental abnormalities and premature dental loss (7,6%), absent manifestations in the control group (p=0,123). In addition, orthopedic surgery was more common in the HPP group (12,8%) compared with the other group (0%), p=0,04. The prevalence of stress fractures was also higher in patients with HPP (7,69%). No significant differences were found in demographic characteristics, vertebral fractures, calcific periarthritis, condrocalcinosis, or FRAX index. In terms of biochemical tests, serum phosphate levels were higher in the HPP group (4,18 mg/dl) in relation to the control group (3,52 mg/dl), p=0,05. No differences were observed neither in pain assessment, measured with the Visual Analogue Scale nor in the Health Assessment Questionaire for disability between both groups.
Conclusions: The diagnosis of HPP can be difficult and is often missed or delayed, particularly in adults. The prevalence of HPP between patients with persistent low ALP is high and although the clinical presentation is milder in adults, it often presents with chronic bone pain, weakness, stress fractures and dental abnormalities. These data should promote a more proactive attitude towards detection of adult HPP.

THU0554 IMMUNOGLOBULIN G4-RELATED DISEASE IN HONG KONG – CLINICAL FEATURES, TREATMENT PRACTICES AND ASSOCIATIONS

P.H. Li, C. Ho, C.-S. Lau. *Department of Medicine, Queen Mary Hospital, Hong Kong, Hong Kong*

Background: Immunoglobulin (Ig) G4-related disease (IgG4-RD) is a systemic immune-mediated disease unifying what were previously considered to be unrelated individual organ disorders. The diagnosis and treatment of this characteristic fibroinflammatory condition continues to evolve, but generally remains an under-recognised disease. Local data outside Japanese and Caucasian populations is lacking and few studies have examined factors to predict disease severity or disease prognostication.
Objectives: We conducted this study to review the clinical features, treatment practices and factors associated with more extensive disease involvement in Hong Kong.
Methods: We retrospectively evaluated all patients with IgG4-RD over the past 13 years in our centre and combined this with patient data extracted from previous local publications. We analysed the clinical features, treatment practices and factors associated with the number of organ systems involved.
Results: One hundred and four patients (55 from our centre and 49 from literature review) were identified. Patients were predominantly older men (mean age 61.9 years, male:female ratio 3:1). Hepatobiliary and pancreatic (40.4%), salivary gland (33.6%), lymph nodes (29.8%) and eye (19.2%) were the most common systems involved. Lymphadenopathy was associated with glucocorticoid use (OR=2.65, p=0.034). Over 90% of patients had a serum greater than 135 mg/dl and a IgG4/total IgG ratio greater than 8%. Pre-treatment serum IgG4 levels correlated with the number of organ systems involved (β=0.347, p=0.004), and specifically with salivary gland involvement (mean 1109 mg/dl vs. 599 mg/dl, p=0.012).
Conclusions: We identified pre-treatment serum IgG4-RD to be associated with multi-system disease, especially with salivary gland involvement, highlighting the potential for its use in disease prognostication and monitoring. The reason for this particular correlation remains uncertain but highlights the importance of screening for salivary gland involvement in all IgG4-RD patients, especially in the presence of higher serum IgG4 levels. We also describe the clinical features and treatment modalities of the largest cohort of IgG4-RD in Hong Kong thus far. Increased physician awareness and multidisciplinary efforts are required for optimal management of this masquerading disease. Future studies, especially focusing on treatment strategies within the contexts of different epidemiology and patient characteristics, are urgently needed.

THU0555 THE RELIABILITY OF TWO VASCULITIS ACTIVITY SCORES (BIRMINGHAM VASCULITIS ACTIVITY SCORE AND BEHCET'S DISEASE CURRENT ACTIVITY FORM2006) IN ANTICIPATING DAMAGE IN A GROUP OF PATIENTS DIAGNOSED WITH BEHCET'S DISEASE

C.G. Buzatu, S.E. Daia-Iliescu, I. Saulescu, A. Borangiu, T. Gudu, V. Bojinca, D. Predeteanu, A. Balanescu, R. Ionescu, D. Opris-Belinski. *Internal Medicine and Rheumatology, "Saint Mary" Clinical Hospital, Bucharest, Romania*

Background: Validated disease activity scores and damage measurements were developed over time in order to allow a better way to evaluate patients and decide treatment plans.There are scores designed for a great variety of vasculitis like Birmingham Activity Score and others that are more specific like Behcet's Disease Current Activity Form2006.
Objectives: To evaluate the ability of the activity scores (BVASv3and BDCAF)to predict damage,and the influence of immunosuppressive therapy on damage progression,as measured byVDI, in a group of patients with Behcet's Disease.
Methods: A study was performed on a cohort of patients diagnosed with Behcet's Disease under surveillance in one tertiary Rheumatology Centre, from a non-endemic area.All documented cases of Behcet's Disease have been diagnosed according to The International Criteria for Behçet's Disease.The Birmingham Activity Score (BVAS)v3, Behcet's Disease Current Activity Form2006 (BDCAF)and Vasculitis Damage index (VDI) were calculated for all patients. Spearman's correlation coefficients were calculated between BVASv3 Score, BDCAF, VDI and immunosuppressive treatment.WindowsExcel/SPSS20.0 has been used to analyse the data.
Results: 20 patients were included in the study, with ages at the time of the

diagnosis between 13and 60years, 14 (70%) under the age of 40,with a male predominance 60% (12 patients). All patients presented active disease at the time of the diagnosis. In the clinical case series, Spearman's rank correlation coefficient between BVASv3 and BDCAFwas strong r=0,862with p<0,001.The outcome analysis after remission was calculated and rank correlation coefficient betweenVDI, and both BVASv3 and BDCAF was moderate (VDI-BVASv3 r=0,747, p<0,001, VDI- BDCAF r=0,795, p<0,001).As for immunosuppression induction decision and activity scores,the correlation coefficient was moderate (r=0,734 for BVASv3,r=0,647 for BDCAF)with p<0,001. There was a moderate correlation between immunosuppressive treatment and VDI (r=0,700, p<0,001). Since the cause of damage (vasculitis vs. treatment)is not taken into consideration when we calculate VDI, we tried to observe if there are any connections between this and immunosuppression duration. There was a mild correlation and no statistical impact between cyclophosphamide treatment duration and damage calculated as VDI (r=0,474, p=0,36).In contrast, when rank correlation coefficient between cortisone therapy and VDI was calculated, a moderate statistical impact was observed (r=0,609, p<0,001).

Conclusions: Birmingham Vasculitis Activity score (BVAS) v3 and Behcet's Disease Current Activity Form2006 (BDCAF) are reliable tools for evaluating disease activity in patients with Behcet's Disease. They are able to anticipate the need for immunosuppressive therapy and the damage progression, as calculated with Vasculitis Damage Index (VDI).

THU0556 SALIVARY GLAND ENLARGEMENT IN IGG4-RELATED DISEASE IS ASSOCIATED WITH MULTIORGAN INVOLVEMENT AND HIGHER BASAL DISEASE ACTIVITY

E. Martin-Nares[1], A. Angeles-Angeles[2], G. Hernandez-Molina[1].
[1]Rheumatology; [2]Pathology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

Background: IgG4-related disease (IgG4-RD) is an immune-mediated condition which clinical spectrum encompasses single or multiple organ involvement. Enlargement of major and minor salivary glands is one of the main disease features. Whether salivary gland enlargement is associated with systemic involvement has not been previously evaluated.

Objectives: To elucidate if salivary gland enlargement is associated with systemic disease.

Methods: We included patients with an established diagnosis (definitive: organ involvement, biopsy proven and high IgG4 levels, probable: organ involvement, biopsy proven without high IgG4 levels, possible: organ involvement, high IgG4 levels without histology) of IgG4-RD according to the Comprehensive Diagnostic Criteria, who regularly attend a tertiary referral center in Mexico City (2000–2017). We retrospectively collected demographics, clinical (organ involvement, disease activity and damage assessed by the IgG4-RD Responder Index [IgG4-RD RI] at basal and at 6 months of follow-up, number of relapses, remission and treatment), basal laboratory (C3, C4, ESR, PCR, total eosinophil count, IgG4 levels) as well as imaging and histologic data.

Results: We included 32 patients, 17 (53.1%) men, mean age 50.2±14.1 years and median disease duration 20.5 months. Seven (21.9%) have a definitive diagnosis, 12 (37.5%) probable and 13 (40.6%) possible. Overall we identified 21 anatomic sites affected, mainly pancreas 56.2%, lymph nodes 56.2%, lacrimal glands 37.5% and bile duct 34.3%. Salivary gland involvement was present in 12 (37.5%) patients (2 parotid, 3 minor salivary gland and 7 both). Among these patients, only 5 (41.6%) referred dry mouth and in 7 patients (58.3%) glandular enlargement was the onset disease feature. Salivary glandular enlargement was identified only radiologically in 5 patients (41.6%) and both clinical and radiologically in 7 (58.3%) patients. When we compared patients with (n=12) vs. without (n=20) salivary gland enlargement, the first group had a higher number of affected organs (6.5 vs. 2, p=0.0001) and absolut eosinophil's count (348 vs. 137.5/mm^3, p=0.05), a higher prevalence of lacrimal glands (75% vs. 15%, p=0.002), lymph nodes (91.7% vs. 35%, p=0.002) and lung involvement (33.3% vs. 0%, p=0.01), azathioprine use (83.3% vs. 30%, p=0.003), as well as a higher basal IgG4-RD RI (12 vs. 6, p=0.001) and a longer delay in diagnosis (64 month vs. 6.5 months, p=0.001). We did not find differences regarding gender, age, IgG4 serum levels, C3, C4, ESR, PCR, antinuclear antibodies, rheumatoid factor, anti-Ro/SSA and anti-La/SSB antibodies (negative in all patients), number of relapses, remission at 6 months and damage. We performed a logistic regression analysis (only including the number of organs, the basal IgG4-RD RI and time of follow-up) and found an association of salivary glandular enlargement with the basal IgG4-RD RI (OR 1.63, 95% CI 1.12–2.35, p=0.009).

Conclusions: Our study highlights the systemic nature of IgG4-RD. Patients with salivary gland enlargement should be routinely screened for systemic involvement.

THU0557 VENOUS VESSEL WALL THICKNESS IN LOWER EXTREMITY IS INCREASED IN MALE BEHCET'S DISEASE PATIENTS WITHOUT VASCULAR INVOLVEMENT

F. Alibaz-Oner[1], A. Mutis[1], R. Ergelen[2], Z. Erturk[1], T. Ergun[3], H. Direskeneli[1].
[1]Rheumatology; [2]Radiology; [3]Dermatology, Marmara University, School of Medicine, Istanbul, Turkey

Background: Vascular involvement is seen in up to 40% of the patients with Behcet's Disease (BD), especially in young males and is one of the major causes of mortality and morbidity. Lower extremity vein thrombosis due to vascular inflammation is the most frequent form of vascular involvement in BD. Recently, assessment of vessel wall thickness (VWT) and venous dilatation by US is suggested to be valuable in patients with vascular inflammation.

Objectives: In this study, we investigated whether vessel wall thickness or dilatation is present in young male BD patients prone to venous vascular disease.

Methods: Fifteen male patients with BD without major organ involvement followed in Marmara University Behcet's Clinics, 14 healthy male controls and 14 male patients with Ankylosing Spondylitis (AS) were included the study. Bilateral lower extremity venous doppler ultrasonography (US) was performed by an experienced radiologist blinded to cases. No patient was under immunosuppressive treatment. Bilateral common femoral vein (CFV) wall thickness and great/small saphenous vein dilatations were examined. Behçet Syndrome Activity Score (BSAS) was used for the general assessment of disease activity.

Results: The mean disease duration was 9.1±6.3 years in patients with BD. BSAS score was 28.9±19. Bilateral CFV wall thickness was significantly higher in BD patients compared to healthy controls and AS (p=0.001, p=0.002, respectively for right CFV; p=0.001, p<0.001, respectively for left CFV) (Table 1). The width of great and small saphenous veins were also higher in patients with BD, but without reaching statistical significance. There were no correlations between BSAS and wall thickness of any vessel.

Table 1. Venous wall measurements of lower extremity in study groups

	Behçet's Disease (n=15)	Healthy Controls (n=14)	Ankylosing Spondylitis (n=14)	P value
Age, years	30.2±4.5	30±5.9	30.8±4.2	0.891
Body Mass Index (kg/m^2)	23.5±3.5	23.8±2.8	26.3±3.8	0.080
Right Common femoral VWT (mm)	0.69±0.4	0.26±0.08	0.28±0.27	<0.001
Left Common femoral VWT (mm)	0.74±0.4	0.31±0.13	0.23±0.13	<0.001
Right Great saphenous width (mm)	2.94±2.6	2.1±0.71	2.5±0.73	0.436
Left Great saphenous width (mm)	3.1±2.2	2.5±0.65	2.4±1.1	0.512
Right Small saphenous width (mm)	2.4±1.8	1.4±0.3	1.7±0.5	0.126
Left Small saphenous width (mm)	2.1±1.5	1.5±0.8	1.8±0.6	0.315

VWT: Venous wall thickness.

Conclusions: In preliminary results of our study, an increased venous vessel wall thickness in lower extremity was shown in male BD patients without vascular involvement. As a similar change was not observed in controls, we think, increased VWT might be an early sign of venous inflammation in patients with BD rather than a result of non-specific systemic inflammation. Further studies with a larger group of patients is planned.

THU0558 THERAPEUTIC RESPONSE TO PREDNISONE ACCORDING TO THE AGE IN POLYMYALGIA RHEUMATICA: A CONTROLLED STUDY

A. Charpentier[1,2], F. Verhoeven[1], M. Sondag[1], X. Guillot[1,2], C. Prati[1,2], D. Wendling[1,3]. *[1]Rhumatologie, CHRU de Besançon; [2]Ea 4267 " Pepite "; [3]EA 4266 " Agents pathogènes et inflammation ", Université de Bourgogne Franche-Comté, Besançon, France*

Background: Polymyalgia rheumatica (PMR) is an inflammatory rheumatic disorder which usually affect patients over 65 years old. Different poor prognostic factors are involved in prednisone response including rapid decrease of prednisone dose or female sex. To date, there is no data relating the impact of the age on therapeutic response in PMR.

Objectives: The aim of this study was to compare, in case of PMR, the response to prednisone in patients younger than 60 to patients over 65 years old.

Methods: This was a retrospective, monocentric study. We included patients suffering from PMR, meeting ACR 2012 criteria. Patients were classified into two groups, one group with patients less than 60 years, and one group with patients over 65 years. We registered demographic, clinical, biological, and imaging data as well as therapeutic response profile. The local inflammation was evaluated with PET scan, by studying each anatomical site usually affected by PMR. Then, the rate of inflammation was scored from 0 to 3, according to the intensity of uptake compared to liver. The treatment was standardized. The initial dose of prednisone was of 0.3mg/kg/j during the two first weeks, then, the dose was slowly decreased

by 10% each month. The main endpoint was a steroid dependence defined by the recurrence of PMR symptoms and/or the increase of CRP at two times during the decrease of prednisone.
Results: We included 14 patients younger than 60 years old (average age 54+/- 0.8 years) and 28 patients older than 65 years old (average age 75.8 +/- 1.5 years). The population younger than 60 years was mainly male (60% VS 27%, $p<0.05$). Both groups were similar in terms of morning stiffness (2,1±0,4 VS 1,9±0,3 hours; $p>0.05$), disease duration (4,2±0,8 VS 4,1±0,6 months; $p>0.05$), leukocytes rate (8,3±1,37 VS 8±0,7 G/L; $p>0.05$) and percentage of antinuclear antibodies rate over 1/320 (20% VS 10%; $p>0.05$). However, regarding to local inflammation, the intensity of FDG uptake highlighted by the Pet scan was lower among young patients (score of 16,9±1,7 VS 26,5±3,0; $p<0.05$). Furthermore, we observed a significant difference concerning therapeutic response according to the age: 60% of the young patients developed a steroid dependence compared to20% in group of old patients ($p<0.05$). Moreover, the introduction of methotrexate was necessary for 35% of the young patients against 6.5% ($p<0.05$).
Conclusions: Our study is the first to highlight the age as a bad prognosis factor in case of PMR. This difference is independent to the systemic inflammation and surprisingly, local inflammation (assessed by the TEP score) is more important in elderly people. Young patients suffering from PMR are mostly men and are more dependent on steroids. Thus, methotrexate could be straightaway proposed, particularly in patient younger than 60 years old.

THU0559 PERSISTENT PRURITIC SKIN LESIONS WITH DYSKERATOTIC CELLS IN UPPER LAYER OF EPIDERMIS ARE SPECIFIC AND ASSOCIATED WITH HIGH LEVELS OF SERUM IL-18 IN ADULT-ONSET STILL'S DISEASE

H. Nishikawa, Y. Taniguchi, N. Aoyama, Y. Terada. *Kochi Medical school, Nankoku, Japan*

Background: Adult-onset Still's disease (AOSD) is an acute and systemic inflammatory disorder that is characterized by high spiking fever, evanescent rash, arthralgia/arthritis and hyperferritinemia. However, recent reports showed that not only typical evanescent salmon-colored rash but also atypical skin lesions, persistent pruritic papules and plaques, could be associated with AOSD.
Objectives: The aim of this study is to assess the clinical significance of dyskeratotic cells in skin lesions of Japanese patients with AOSD.
Methods: We retrospectively assessed clinical and histological findings of skin lesions including persistent pruritic skin lesions in Japanese patients with AOSD (n=12). Moreover, we compared serological and histological finding of AOSD with that of dermatomyositis (DM) (n=6), drug eruptions (DE) (n=6), and Graft versus Host disease (GVHD) (n=6).
Results: AOSD with persistent pruritic skin lesions (n=7) histologically showed dyskeratotic cells only in upper layer of epidermis and horny layer without intraepidermal infiltrations of inflammatory cells. These dyskeratotic cells were positive by TUNEL and single stranded DNA (ssDNA) stainings, suggesting apoptotic cells. AOSD with evanescent rash (n=5) histologically showed no dyskeratosis. On the other side, the pathological findings of DM (n=6), DE (n=6) and GVHD (n=6) had dyskeratotic cells in all layers of epidermis with inflammatory cells infiltrations. Notably, AOSD with dyskeratosis (n=7) had significant higher levels of serum IL-18 (74,300∼307,000 pg/ml) than AOSD without dyskeratosis (n=5).
Conclusions: AOSD with persistent pruritic skin lesions is characterized and specific by prominent epidermal apoptosis, especially involving the upper layers. Therefore, it could play a pivotal role to recognize the atypical skin lesions of AOSD for correct early diagnosis. Finally, the high levels of serum IL-18 might be related with epidermal apoptosis of keratinocyte in AOSD.

DOI: 10.1136/annrheumdis-2017-eular.1766

THU0560 DEVELOPMENT OF SYMPTOMS IN VERY EARLY PHASE IN PATIENT WITH ADULT ONSET STILL DISEASE

H. Tamai, Y. Kaneko, N. Nishina, J. Kikuchi, T. Takeuchi. *Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan*

Background: Adult onset Still Disease (AOSD) is a systemic inflammatory disease presenting various non-specific symptoms like fever, arthralgia and pharyngalgia. Those symptoms are mimicking common cold, which could lead to the delayed diagnosis. However, little is known about the profiles and development of symptoms in very early phase before diagnosis.
Objectives: To clarify the clinical course of AOSD symptom development in very early phase and its effect on the diagnosis delay.
Methods: Consecutive patients with AOSD with enough information in our hospital were enrolled. Initial symptoms before and at diagnosis were investigated in detail. The gradual course from the initial symptoms to the fulfilment of Yamaguchi criteria for AOSD was examined.
Results: A total of 51 patients were enrolled. The mean age at diagnosis was 45.0±18.9 years old and 41 (80%) were female. All patients were met with the Yamaguchi criteria. The mean duration from the first symptom to diagnosis was 50.4 days. The duration from the first symptom to the first visit to the medical facility including a general physician was 19.1 days, and that from the first medical facility visit to the first blood test was 8.0 days. While the first symptom was arthralgia in 29 (34.1%), fever in 20 (23.5%), and eruption in 20 (23.5%), pharyngalgia in 13 (15.3%), at diagnosis, fever was found in all patients, eruption in 47 (92.2%), arthralgia in 45 (88.2%), pharyngalgia in 34 (66.7%), lymphadenopathy and/or splenomegaly in 35 (68.6%), increased white blood cell (WBC) count in 44 (86.3%), ferritin elevation in 42 (82.4%), liver enzyme elevation in 41 (80.4%), negative rheumatoid factor (RF) and anti-nucleolar antibody (ANA) in 30 (58.8%). Arthralgia developed 41.9 days prior to the diagnosis, fever 40.9 days, eruption 29.5 days, pharyngalgia 24.5 days and lymphadenopathy and/or splenomegaly 14.8 days. WBC increase was detected 17.8 days prior to the diagnosis, negative RF and ANA 15.1 days, liver enzyme elevation 14.6 days, and ferritin elevation 10.9 days. At 14 days from the first symptom, 32 (62.7%) met 3 of Yamaguchi criteria, 23 (45.1%) met 4, and 19 (37.3%) met 5. At 28 days, 40 (78.4%) met 3 of Yamaguchi criteria, 32 (62.7%) met 4, and 27 (52.9%) met 5. The duration to diagnosis was significantly shorter in the patients with eruption developing within 7 days since the first symptoms than those without (35.2 vs 74.3 days, p=0.03)
Conclusions: The mean duration from the first symptom to the diagnosis of AOSD was approximately 50 days, and only a half of the patients met Yamaguchi criteria at 28 days after first symptom. The time of eruption emergence affected the early diagnosis.

THU0561 CLINICAL PRACTICE GUIDELINE FOR DIAGNOSIS AND MANAGEMENT OF CATASTROPHIC ANTIPHOSPHOLIPID SYNDROME

K. Legault[1], C. Hillis[1], C. Yeung[1], A. Iorio[1], M. Crowther[1], E. Akl[2], M. Carrier[3], R. Cervera[4], F. Dentali[5], D. Erkan[6], G. Espinosa[7], M. Khamashta[8], J. Meerpohl[9], K. Moffat[10], S. O'Brien[11], V. Pengo[12], J. Rand[13], I. Rodriguez Pinto[7], L. Thom[14], H. Schunemann[1]. *[1]McMaster University, Hamilton, Canada; [2]American University of Beirut, Beirut, Lebanon; [3]University of Ottawa, Ottawa, Canada; [4]University of Barcelona, Barcelona, Spain; [5]Insubria University, Insubria, Italy; [6]Weill Medical College of Cornell University, New York, United States; [7]Barcelona Hospital Clinic, Barcelona, Spain; [8]King's College London, London, United Kingdom; [9]University of Freiburg, Freiburg, Germany; [10]Hamilton Health Sciences, Hamilton, Canada; [11]Nationwide Children's, Columbus, United States; [12]University of Padova, Padua, Italy; [13]NY Presbyterian Hospital, New York, United States; [14]None, Oxford, United Kingdom*

Background: Catastrophic antiphospholipid syndrome (CAPS) is characterized by the rapid onset of widespread or multifocal large and/or small vessel thrombosis associated with multi-organ failure in patients meeting the serological criteria for antiphospholipid syndrome [1]. Mortality in CAPS approaches 50% [2].
Objectives: The RARE-BestPractices project group identified CAPS as a rare disease condition of interest in which to develop a clinical practice guideline. The project was run in partnership with McMaster University, and used the GIN-McMaster Guideline Development checklist and Grading of Recommendations Assessment, Development and Evaluation (GRADE) methodology to develop guidelines on rare diseases [3].
Methods: The CAPS guideline was coordinated by a steering committee including representatives from RARE-BP and methodologists from McMaster University. The CAPS guideline panel consisted of 19 international members, including patient representation. The panel used the GradePro software to brainstorm and prioritize potential questions and outcomes. Systematic reviews were performed for each question. To supplement the published evidence, we compiled raw data for mortality from the CAPS Registry, and systematically elicited expert opinion from the panel members using a systematic observation form. For each question an evidence profile and evidence to decision table was generated and shared.
Results: The question prioritization step generated 47 questions, which were ranked to identify the top priorities. The top 10 questions were chosen for guideline development, yielding 7 therapy and 3 diagnostic questions. The outcome generation step yielded 7 outcomes.
The questions were addressed during an in-person panel meeting, held on April 27, 2016 in Barcelona, Spain, with follow-up via webinar on June 3, 2016, and with web-based voting completed July 31, 2016.
Recommendations were developed for all questions and will be discussed in detail.
Conclusions: Ten recommendations were issued by the CAPS Guideline Panel to assist clinicians in diagnosis and management of suspected CAPS patients. Future research is needed to improve evidence quality in rare diseases such as CAPS. The GIN-McMaster Guideline Development Checklist and the GRADE methodology were effective in producing a rigorous guideline in this rare disease.

THU0562 INFLAMMATORY JOINT DISEASE TRIGGERED BY IMMUNE CHECKPOINT INHIBITORS

L. Tucker, S. Sacks, H. Al-Mossawi. *Rheumatology, Oxford University Hospitals NHS Foundation Trust, OXFORD, United Kingdom*

Background: Immune checkpoint modulation has changed the cancer therapy landscape in recent years [1]. Randomised controlled trials now demonstrate superiority to standard chemotherapy in squamous cell lung cancer, renal cell cancer [2], squamous cell head and neck cancer [3] and malignant melanoma [4]. However, blockade of these checkpoints results in a multitude of autoimmune sequelae including joint disease. As these therapies become first-line in oncology, they will likely place a significant burden on rheumatology services.
Objectives: To establish the prevalence of rheumatological manifestations of checkpoint blockade in a non-trial standard care setting.
Methods: All patients treated with Nivolumab or Ipilimumab (as single agent or in combination) in a standard care setting within a single centre were included and the number of suspected cases with rheumatological manifestations identified from the case records.
Results: 75 patients have been treated with Nivolumab single agent and 12 with combination Nivolumab plus Ipilimumab in Oxford over the last 15 months. Within that cohort, there were 7 suspected cases of joint disease giving a potential prevalence of 8%. Of those 7, 2 had confirmed disease requiring therapy, both had received Nivolumab/Ipilimumab combination. Both cases were rheumatoid factor and CCP negative. One case responded to prednisolone only, while the second case was refractory to steroids, methotrexate and infliximab but responded to IL-6 blockade with Tocilizumab.
Conclusions: We observed an approximate 8% prevalence of checkpoint mediated autoimmune joint disease within a relatively short follow up period of 15 months. The longer-term prevalence may be higher. Both patients requiring therapy had been exposed to Ipilimumab suggesting the inflammatory joint toxicity with this agent may be higher than that caused by Nivolumab.
Checkpoint immunotherapy is set to become the first-line standard of care in a number of cancers. This will lead to an increased demand for rheumatology services. The rheumatology community needs to develop strategies and trials in order to classify and treat these patients appropriately.

THU0563 THE IMMUNOMODULATION EFFECT OF BM-MSCS ON THE INFLAMMATORY CHEMOKINES OF RATS WITH COLLAGEN TYPE II INDUCED ARTHRITIS

J. Fan, L. Zhang, D. Ma, G. Zhang, K. Xu, J. Gao. *Rheumatology, Shanxi DaYi Hospital, Shanxi Academy of Medical Sciences, Taiyuan, China*

Background: Rheumatoid arthritis (RA) is an autoimunme disease.The DMARDs is mian treatment but side effects are very high. Bone marrow mesenchymal stem cells (MSCs) have immunoregulatory function so it can be used to treat RA. This study was designed to investigate the effect of BMSCs on chemokines in CIA rats.
Objectives: To observe the immunomodulation effects of BM-MSCs on the Inflammatory Chemokines of rats with collagen-induced arthritis (CIA).
Methods: Rats MSCs were isolated and expanded from bone marrow cells by density gradient centrifugation and adhering to the culture plastic bottle, and the phenotypes were assessed by flow cytometry. We established collagen induced arthritis rats model. A total of six groups. The MSCs treatment groups contain the early and advanced stages. Meanwhile, there are normal control and CIA control group,The latter also contains the early and advanced stages. Also,there is the positive control group of MTX, by intraperitoneal injection of a small dose of MTX (0.9mg/kg/w), for six weeks. $1x10^6$ /kg BM-MSCs were implanted through tail vein to MSCs treatment groups, model control groups with equal amounts of saline served as controls.At forty two day,stream multi-factor detection technique were used to detect the level of RANTES, MCP-1 and IP-10 in serum of CIA rats.
Results: The level of RANTES, AMCP-1, AIP-10 was higher in CIA control group than normal group ($P<0.05$); After MTX treatment, these factors level were significantly difference than the CIA control group ($P<0.05$). These factors level were lower in early BMSCs treatment groups than early CIA control groups ($P<0.05$), while the late MSCs treatment group versus the later CIA control group showed no statistically significant difference ($P>0.05$). The early and late MSCs treatment group versus the MTX treatment group showed no statistically significant difference ($P>0.05$).
Conclusions: In this study MSCs has shown significant immune modulatory effects. It down regulates the level of Inflammatory Chemokines in CIA rats. The early treatment group is more effective than the late treatment group.

THU0564 IGG4-RELATED DISEASE IN THE MALTESE POPULATION

S. Chetcuti Zammit[1], M. Rogers[2], P. Ellul[1]. *[1]Gastroenterology; [2]Rheumatology, Mater Dei Hospital, Msida, Malta*

Background: IgG4-related disease (IgG4-RD) is an increasingly recognised immune-mediated fibro-inflammatory condition, most commonly affecting the pancreas.
Objectives: The aim of our study was to determine the incidence, organ involvement and outcome of IgG4-RD in the Maltese population.
Methods: The case notes of all patients who had their IgG4 level checked between 2008 and 2015 at Mater Dei Hospital were reviewed. Patients who had their IgG4 level checked inappropriately were excluded. Patients were then stratified according to the "Comprehensive diagnostic criteria for IgG4-related disease" [1].
Results: 25 patients were included in this retrospective, observational study. 60% (n=15) of patients were males and mean age was 70 years (SD±64.8). The mean IgG4 level was 0.7159 g/L (SD±0.851) (normal range 0.052–1.250g/L).
Organs involved included: pancreas (n=15), biliary tree (n=3), salivary glands (n=1), lymph nodes (n=8), lungs (n=4), thyroid gland (n=2), bone (n=1), heart (n=1), sinuses (n=2). 36% (9 patients) had involvement of more than one organ.
Blood tests at time of diagnosis demonstrated a raised mean ESR (65.7mm1st Hr; SD±36.1) and a raised mean CRP (143 mg/L SD± 112). White cell count was mostly normal (mean $11.7x10^9$/L SD±4.91).
92% of patients (n=23) had organ swelling on radiological testing. 32% (n=8) of patients had raised IgG4 levels. A histological diagnosis was obtained in 8% (n=2) of patients presenting with cervical lymphadenopathy and sinusitis respectively.
According to the "Comprehensive diagnostic criteria for IgG4-RD"[1], the diagnosis was definite in 4% (n=1), possible in 28% (n=7) and probable in 4% (n=1) of patients. 64% (n=16) only had organ swelling on imaging studies, satisfying 1 criterion.
One patient was diagnosed with malignancy during the course of disease. Patients with hepatobiliary and pancreatic involvement underwent ERCP and stenting. Patients who developed pancreatic pseudocyst as a complication of pancreatitis underwent drainage. One patient (4%) developed pancreatic insufficiency and 32% (n=8) experienced recurrent pancreatitis requiring hospital admission. Four patients (16%) passed away.
Conclusions: In concordance with current literature, our study has shown that IgG4-RD in the Maltese population is a rare disorder affecting mainly elderly males. The commonest organs involved were the pancreas and lymph nodes. The inflammatory markers ESR and CRP were always raised, thus acting as possible biomarkers for monitoring of disease activity.

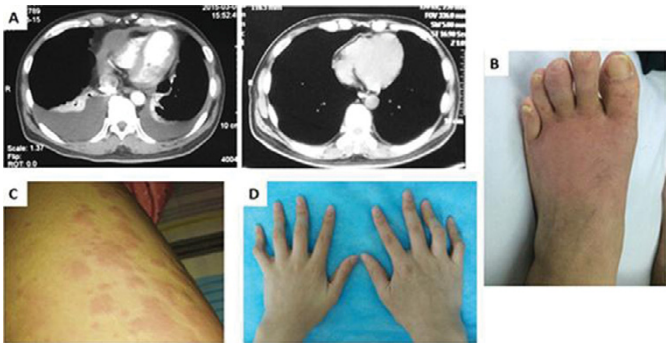
THU0565 MACROPHAGE ACTIVATION SYNDROME IN ADULTS WITH INFLAMMATORY RHEUMATIC DISEASES



M. Olejárová[1,2], K. Jarošová[2]. *[1]Clinic of Rheumatology, 1st Medical Faculty, Charles University; [2]Institute of Rheumatology, Praha 2, Czech Republic*

Background: Macrophage activation syndrome (MAS) is a rare hyperinflammatory condition characterised by macrophage activation and infiltration resulting in a multi organ damage. MAS is considered to be a type of secondary hemophagocytic lymphohistiocytosis. It is a life threatening complication of various autoimmune or autoinflammatory rheumatic diseases, particularly systemic juvenile idiopathic arthritis (sJIA). Clinical manifestations include hepatosplenomegaly, increase of liver function tests, pancytopeny, neurolological manifestations etc. High doses of glucocorticosteroids (GC), cyclosporine A (CyA) and etoposide are a treatments of choice. In refractory cases biologicals may be an option, too.
Objectives: To point out this very rare but severe complication may occur also in adult patients with rheumatic diseases.
Methods: We report 4 successfully treated cases of adult MAS in rheumatic patients seen in our clinic during the years 2009 – 2016. A review of the literature regarding the efficacy of biologics in MAS treatment is also presented.
Results: We have observed four patients with MAS, two with adult onset Still disease (AOSD), one with rheumatoid arthritis (RA) and one with sJIA. All of the patients were young (20 -33 years, mean age 27,0±5,61 years) with the duration of the primary disease ranging from 9 months to 11 years (mean 4,18±4,01 years). Three patients were in remission of the primary diseases prior to MAS manifestation, only in the last and most severe patient (AOSD) the activity of the underlying disease was not controlled. A demographic and clinical characteristic of the patients is summarized in the table.
All 4 patients were successfully treated, one with high doses of glucocorticosteroids (GC), two with combination GC plus CyA. The last and most severe one had MAS refractory to the combination GC + CyA and must have been added biological therapy (tocilizumab). We reviewed also another cases of MAS treated with biologics which have been published.
Conclusions: Our cases illustrate that MAS may develop also in adult patient with various rheumatic diseases (JIA, AOSD, RA) despite the low activity or remission. It occurs particularly in younger subjects. As the MAS symptoms may overlap with the symptoms of the primary disease (JIA, AODS) the diagnosis may be difficult. MAS must be suspected in inflammatory rheumatic diseases patients with sudden increase of CRP, extreme increase of ferritin, liver function tests and decrease of platelets. An immediate treatment with GC, CyA and etoposide is essential; biologicals (anakinra, canakinumab or tocilizumab) may be benefitial in refractory cases.

THU0566 CLINICAL AND GENETIC PHENOTYPES OF CHINESE PATIENTS WITH ADULT AUTOINFLAMMATORY DISEASES: REPORT FROM AN ADULT REFERENCE CENTER

M. Shen, D. Wu, X. Zeng. *Peking Union Medical College Hospital, Beijing, China*

Background: Autoinflammatory diseases (AUID) is a group of disorders characterized by dysfunction of innate immunity which caused by gene mutations leading to coded proteins changes, finally causing uncontrolled systemic inflammation. AUID are usually diagnosed during pediatric age. However, adult-onset disease or diagnosis during adulthood has been occasionally described. Moreover, AUID have been hardly reported in the Chinese population.
Objectives: We aimed to characterize the clinical and genetic phenotypes of Chinese adult patients with AUID.
Methods: We prospectively evaluated clinical and genetic features of adult patients (≥16 years) suspected monogenic AUID in the period April 2015 to May 2016, at the adult AUID center, Department of Rheumatology, Peking Union Medical College Hospital. The definite diagnosis of each disease was deemed to be present if both clinical phenotypes and genetic confirmation were met.
Results: During the study period, a total of 37 adult patients with clinical phenotypes suspicious of monogenic AUID requested for a genetic study. A final diagnosis of monogenic AUID was achieved in 16 patients (43.2% of patients tested). Two additional patients were diagnosed with periodic fever, aphthous stomatitis, pharyngitis and adenitis (PFAPA) syndrome. Finally, a total of 18 patients with AUID were diagnosed and follow-up in our center, including 7 (38.9%) familial Mediterranean fever (FMF), 2 (11.1%) tumor necrosis factor-receptor associated periodic syndrome (TRAPS), 3 (16.7%) cryopyrin-associated periodic syndrome (CAPS), 3 (16.7%) NLRP12-autoinflammtory disease (NLRP12-AD), 1 (5.6%) Blau syndrome (BS), and 2 (11.1%) PFAPA. Disease onset during adulthood was observed in 15 (83.3%) patients, and the final diagnosis was delayed with a mean time of 10 years. Adult AUID patients usually carried low-penetrance mutations and gene variants were presented as heterozygosis or compound heterozygosis.

Conclusions: Adult AUID is not uncommon. FMF, CAPS, and NLRP12-AD are relatively common monogenic AUID in Chinese adult patients. Adult-onset AUID may be related to the presence of low-penetrance mutations, being characterized by nonspecific, incomplete or atypical disease patterns, leading to a delay of diagnosis. The interpretation of gene analysis in adult suspected AUID should be performed with caution, and if possible, should be referred to expert physicians in the field in adult AUID center.

THU0567 RAPID IMPROVEMENT WITH TOCILIZUMAB IN REFRACTORY AND SEVERE UVEITIC CYSTOID MACULAR EDEMA

N. Vegas-Revenga[1], V. Calvo-Río[1], N. Palmou-Fontana[1], M. Mesquida[2], A. Adan[2], M. Hernández[2], E. Beltrán[3], E. Valls[4], D. Díaz-Valle[5], G. Díaz-Soriano[6], M. Hernández-Grafella[7], L. Martínez-Costa[7], I. Calvo[8], A. Atanes[9], L. Linares[10], C. Modesto[11], E. Aurrecoechea[12], M. Cordero[13], L. Domínguez-Casas[1], C. Fernández-Díaz[1], J. Hernández[1], M. González-Gay[1], R. Blanco[1]. *[1]HUMV, Santander; [2]H Clinic, Barcelona; [3]H Valencia; [4]H, Valencia; [5]H S Carlos, Madrid; [6]H, Málaga; [7]H Peset; [8]H Fe, Valencia; [9]HUAC, A Coruña; [10]H Arrixaca, Murcia; [11]H V d'Hebron, Barcelona; [12]H Sierrallana, Torrelavega; [13]H, León, Spain*

Background: In uveitis, remission-inducing therapy with even more vigor than does rheumatology is mandatory. Since the eye is so much less forgiving of chronic inflammation than is the joint, with profound life-altering consequences. Cystoid macular edema (CME) is the leading cause of blindness in uveitis.
Objectives: To evaluate the rapid efficacy of Tocilizumab (TCZ) in refractory CME.
Methods: Multicentre study of 25 patients with CME due to non-infectious uveitis who had inadequate response to traditional treatment with corticosteroids and at least one conventional immunosuppressive drug including in most cases biological therapy (n=22). CME was defined as OCT >300 μm.
The outcome variables were the degree of inflammation, visual acuity, macular thickness. The results are expressed as mean±SD for normally distributed variables, or as median [IQR] when are not. Comparison of continuous variables was performed using the Wilcoxon test.
Results: 25 patients (17 women/8 men), mean age 33.6±18.9 years were studied. The associated diseases were: juvenile idiopathic arthritis (9), Behçet's (7), Birdshot (4), idiopathic (4), sarcoidosis (1). The ocular pattern was: panuveitis (9), anterior uveitis (7), posterior uveitis (5) and intermediate uveitis (4). Most patients had bilateral involvement (24). Prior to TCZ they received: intraocular corticosteroids (22), iv. methylprednisolone (7), methotrexate (MTX) (19), cyclosporine A (CSA) (17), mycophenolate (4), azathioprine (2), leflunomide (2), cyclophosphamide (1), sulfasalazine (1), acetazolamide (1) and thalidomide (1). The biological used before TCZ were infliximab (8), adalimumab (19),

Abstract THU0565 – Table 1

Patient	Age (years)	Primary disease			Clinical manifestations of MAS	Treatment
		Dg.	Duration	Treatment prior to MAS		
L.H., female	23	JIA	11 years	MTX	hepatosplenomegaly, increase of ALT, AST, pancytopenia, serositis	GC high doses (i.v. pulses), cyclosporine
P.V., male	20	RA	2 years	MTX, SAS	fever, pancytopenia, hepatosplenomegaly, increase of ALT, AST, pericarditis	GC high doses (oral), cyclosporine
P.D., male	32	AODS	3 years	MTX	fever, hepatosplenomegaly, increase of ALT, AST, pancytopenia,	GC high doses (oral)
V.N., female	33	AODS	9 months	MP, AZA	fever, pancytopenia, hepatosplenomegaly, increase of ALT, AST, alveolar hemorrhage	GC high doses (i.v. pulses), cyclosporine, tocilizumab

	Baseline	1st week	2nd week	1st month
OCT (microns), mean±SD	415.7±177.15	413.3±162.9*	388.06±158.1*	330.8±104.2*
Visual acuity, mean±SD	0.39±0.31	0.4±0.31	0.45±0.3*	0.51±0.3*
Anterior chamber cells, median [IQR]	1 [0–1]*	0.5 [0–1]*	0 [0–1]*	0 [0–0]*
Vitritis, median [IQR]	1 [0–2]	1 [0–1.5]	0 [0–1]*	0 [0–0.5]*

*$p<0.05$ compared with basal data.

etanercept (2), golimumab (2), rituximab (2), abatacept (3), anakinra (1) and daclizumab (1).

TCZ administration schedule was 8 mg/kg/4 weeks iv. (n=23), every 2 weeks (1) and subcutaneously 162 mg/2 weeks (1). TCZ was used in monotherapy (13) or combined with conventional immunosuppressive drugs (12). Most of intraocular inflammation parameters showed a rapid improvement after TCZ onset (Table), with corticosteroid-sparing effect (15.9±13.6 to 8.5±5.17 mg; p=0.001). Remission was achieved in 8 patients and improvement in 17. After one month of therapy, no side effects were observed.

Conclusions: TCZ seems a rapid effective treatment in refractory uveitic CME.

THU0568 PREVALENCE AND AUTOIMMUNE RHEUMATIC DISEASE IN PATIENTS WITH AUTOIMMUNE/INFLAMMATORY SYNDROME INDUCED BY ADJUVANTS ASSOCIATED TO SILICONE BREAST IMPLANT

O. Vera Lastra, N.E. Torres-Oliva, G. Medrano-Rodriguez, M.D.P. Cruz-Dominguez, J. Sepulveda Delgado, L.J. Jara, G. Medina. *Internal Medicine, Hospital Especialidades CMN la Raza. Instituto Mexicano Seguro Social, Mexico City, Mexico*

Background: Autoimmune/inflammatory syndrome induced by adjuvants (ASIA) has been associated with previous exposure to various agents such as silicone implants, which elicit chronic stimulation of the immune system against the prosthetic material and clinical manifestation of autoimmune disease. This is particularly the case in genetically susceptible hosts.

Objectives: The aim is to describe de prevalence, family background and main autoimmune rheumatic disease (ARD) associated to silicone breast implant (SBI).

Methods:

We study a cohort of 150 patients with diagnosis of ASIA associated injection of mineral oil and silicone breast implant (SBI) in a tertiary Hospital, from 2011 to 2016. All patients were evaluated for the fulfilment of ASIA criteria. We only included patients with ASIA criteria associated with SBI plus criteria for an autoimmune rheumatic disease according to The American College of Rheumatology or EULAR. We excluded patient with ASIA and without ARD.

Results: There were 17 women patients with mean age 42.4±15.3 years, mean disease duration of disease 8±3. The clinical manifestation post SBI appeared 8±2 years later.

The ARD were systemic sclerosis (SSc) 5, systemic lupus erythematosus (SLE) 3, rheumatoid arthritis (AR) 3, overlap syndrome 2 (SSc plus SS and SLE plus SSc, Sjogren syndrome 1, Takayasu arteritis 1, Still disease 1, antiphospholipid syndrome 1, and 3 patients also had secondary fibromyalgia. Five Patients had more than 2 autoantibodies, 4 patients had relatives with an ARD. All patients are being treated according to the ARD (steroids plus immunosuppressive 8 patients, immunosuppressive 7, and only steroids 2), in 4 patients the prosthesis were withdrawn with improvement of clinical manifestations.

Conclusions: We found a prevalence of ASIA associated to SBI of 11%. The main ARD were SSc, SLE and RA. In these cases of ASIA associated with SBI some had genetic predisposition to ARD. The use of SBI is not recommended in women who have a family history of ARD.

THU0569 TREATMENTS OF UVEITIS IN A REFERRAL MULTIDISCIPLINARY UNIT IN NORTHERN SPAIN

P. Fanlo[1], H. Heras[2], O. Terry[1], G. Espinosa[3], A. Adan[4]. *[1]Autoimmune Sistemic Disease Unit; [2]Ophthalmology, Complejo Hospitalario de Navarra, Pamplona; [3]Autoimmune Sistemic Disease Unit; [4]Ophthalmology, Hospital Clinic, Barcelona, Spain*

Background: Intraocular inflammation is one of the leading causes of visual impairment and blindness. Early and appropiate treatment is mandatory for avoiding complications.

Objectives: To describe the treatments prescribed in a cohort of patients with uveitis in a referral multidisciplinary unit from northern Spain.

Methods: Retrospective analysis of clinical records of patients evaluated in the Uveitis Multidisciplinary Unit of the Complejo Hospitalario of Navarra since January 2010 until March 2015. We analyzed the demographic characteristics and treatments received in the following 3 months after first visit.

Results: We identified 500 patients, 50% women with a mean age of 47.9 +/- 16.4 years. The most frequent type of uveitis was anterior uveitis (65,4%), followed by posterior uveitis (17,6%), panuveitis (15,2%), and intermediate uveitis (1,8%). Considering the etiology, 31.2% were unclassifiable, followed by non-infectious systemic disease in 29.2%.During the 3-month follow-up, 904 treatments were prescribed. The most frequent treatment was ocular topical (39%), followed by immunosuppressive treatment (27%), antimicrobial (14%), other treatments (10%) and less biological (3%), surgical (3%) and finally periocular (2%) and intravitreal (2%) treatment.Topical ocular treatment: 350 patients received topical ocular treatment, which accounts for 70% of patients. Among topical ocular treatments, 15% of the samples were treated with topical steroids, 54% were topical steroids associated with another topical treatment, 2% were topical antiglaucomatous, 2% received other topical treatments and 27% of the sample did not receive topical treatment.Immunosuppressive treatment: 249 immunosuppressive treatments were prescribed. 50% of the patients received immunosuppressive treatment. Among the immunosuppressive treatments, 25% of the patients received oral steroids, 6% salazopyrine, 4% methotrexate, 5% azathioprine, 2% mycophenolate mofetil, 5% oral steroids associated with another immunosuppressant, 15% salazopyrine associated with another immunosuppressant, 1% other immunosuppressive treatment and 49% of patients did not receive any immunosuppressive treatment.Biological Treatments: 25 patients in the cohort received biological treatment, this represents 5% of patients. The biological treatment types were distributed as follows: 3% of the patients received adalimumab treatment, 1% received infliximab, 1% received other biological treatments, and 95% of the patients did not receive biological treatments.The number of treatments received per patient was analyzed and 50 patients (10%) received no treatment, 152 patients (30%) received 1 treatment, 189 patients (38%) received 2 treatments, 75 patients (15%) Had received 3 treatments, 23 patients (5%) had received 4 treatments, 9 patients (2%) had received 5 treatments and lastly 2 patients had received 6 treatments.

Conclusions: The majority of patients received the combination of two treatments. Topical steroids and oral steroids were the most frequent treatments used.

THU0570 ANAKINRA AS A SUCCESSFUL TREATMENT OF IDIOPATHIC RECURRENT PERICARDITIS: TAPER OR NOT TO TAPER? CASE SERIES AT THE UNIVERSITY OF SOUTHERN CALIFORNIA

P.S. Chhibar, G. Ehresmann. *Rheumatology, University of Southern California, Los Angeles, United States*

Background: Idiopathic Recurrent Pericarditis can be challenging to treat in patients unresponsive to NSAIDs, aspirin, colchicine and immunosuppressive drugs. Patients become steroid dependent and tapering precipitates recurrences.

Objectives: Report 2 adult cases of idiopathic recurrent pericarditis treated successfully with Anakinra.

Methods: Chart review of 2 patients with idiopathic recurrent pericarditis treated with anakinra at the Keck Medical Center of USC. Literature review on treatment of idiopathic recurrent pericarditis with anakinra.

Results: Case 1: 60-year-old Caucasian male had five episodes of idiopathic pericarditis in 2011. Serologic workup including ANA, anti-dsDNA, malignant and infectious workup was negative. Initially, patient responded to prednisone 0.4 mg/kg/day. Adding colchicine, azathioprine and methotrexate failed to prevent recurrence. Pericarditis developed whenever prednisone was tapered below 20 mg/day with bursts of CRP to 78 mg/dl. In 2012, Anakinra 100 mg sq daily resulted in immediate clinical response and normalization of CRP (1mg/dl). Prednisone and methotrexate were tapered with no recurrence. Gradually Anakinra was tapered to 3 times/week, then once a week, with no recurrence. Case 2: 37-year-old African American male had four episodes of recurrent pericarditis. He had positive ANA 1:320, but negative anti-dsDNA, anti-smith, negative infectious and malignancy workup. Initially, patient responded to prednisone 0.6 mg/kg/day and colchicine. Tapering steroids below 40 mg/day resulted in recurrent pericarditis. Sequential addition of hydroxychloroquine, methotrexate, mycophenolate mofetil, and azathioprine failed to prevent recurrence. Anakinra 100 mg sq daily resulted in prompt resolution of symptoms, normalization of acute phase reactants and allowed successful tapering of steroids. Anakinra is being slowly tapered over the past year, with no recurrence.

Conclusions: Idiopathic recurrent pericarditis, which requires chronic corticosteroids, should be treated by adding another immunosuppressive agent. European Society of Cardiology guidelines recommend azathioprine, cyclophosphamide, methotrexate, hydroxychloroquine, cyclosporine or mycophenolate mofetil. Anakinra has demonstrated success in treating autoinflammatory and autoimmune diseases including FMF, TNF receptor associated periodic syndrome, rheumatoid arthritis and in patients with TRAPS mutation TNFRSF1A. This represented the possibility to decrease inflammation by blocking interleukin-1. Using this rationale we treated our patients. Picco et al reported three pediatric cases treated with anakinra, where its discontinuation resulted in recurrence.

Vassilopoulos et al reported three adult cases, where two were not treated with immunosuppressive drugs before anakinra and one had recurrence after anakinra was tapered. The Double Blind Placebo Controlled Clinical Trial AIRTRIP, shows efficacy of anakinra in treating 11 patients with recurrent pericarditis over 14 months. It is unclear from this study if anakinra should be tapered or not. We suggest that once steroids and immunosuppressive drugs have been discontinued, anakinra should be gradually tapered over months, to avoid relapse. These experiences warrant further long term controlled trials in order to determine the efficacy and appropriate treatment regimen of anakinra for recurrent pericarditis.

THU0571 THE CLINICAL FEATURES OF 223 BEHCET'S DISEASE PATIENTS IN JAPAN

R. Saito[1], K. Nishimura[1], H. Mukoyama[1], Y. Nakamura[1], T. Nagamoto[1], K. Akashi[2], A. Onishi[2], Y. Kogata[2], J. Saegusa[2], A. Morinobu[2], T. Yokota[1]. *[1]Department of Endocrinology and Rheumatology, Kurashiki Central Hospital, Kurashiki; [2]Department of Rheumatology and Clinical Immunology, Kobe University Graduate School of Medicine, Kobe, Japan*

Background: Behcet's disease is a systemic vasculitis disease with oral and genital aphthous ulcers, ocular involvements, skin manifestations, arthritis, gastrointestinal manifestations, neurogenic diseases and vascular involvements. Patients with Behcet's disease are known to distribute along the ancient Silk Road, including Japan.
Objectives: We evaluate the clinical features of Behcet's disease in Japan.
Methods: We retrospectively investigated 223 patients (108 males and 115 females) who fulfilled the International Criteria for Behcet's Disease (ICBD) from January, 2006 until May, 2015.We examined sex, onset age, disease type, clinical symptoms, laboratory data and medications.
Results:
Median age at diagnosis was 36.0±12.8 years old. Oral ulcers were the most common manifestation (98.2%), followed by genital ulcers (62.4%), ocular involvements (53.2%), erythema nodosum (53.2%), acneiform lesions (51.8%), arthritis (38.6%), gastrointestinal manifestations (25.1%), neurogenic diseases (9.0%), and vascular involvements (8.1%). The relationship of HLA and disease manifestations was studied in 123 patients (41.5% with HLA-B51 and 24.1% with HLA-A26). The frequency of acneiform lesions, ocular involvements and HLA-B51 was significantly higher in male, while genital ulcers and arthritis were significantly higher in female. Patients with ocular involvements showed a higher assosiation rate with neurogenic diseases and HLA-B51, and lower wih gastrointestinal manifestations. TNFα inhibitor (infliximab or adalimumab) were used for 66 cases (30%), and it could be continued for 1 year in 91%, and for 2 years in 83%.

Table 1

	Total (n=223)	Male (n=108)	Female (n=115)	p value
Oral ulcers	218/222 (98.2%)	105/107 (98.1%)	113/115 (98.3%)	0.94
Skin manifestations	190/220 (86.4%)	90/107 (84.1%)	100/113 (88.5%)	0.34
Erythema nodosum	116/218 (53.2%)	49/105 (46.7%)	67/113 (59.3%)	0.06
Acneiform lesions	113/218 (51.8%)	65/105 (61.9%)	48/113 (42.5%)	0.004
Thrombophlebitis	11/218 (5.0%)	5/105 (4.8%)	6/113 (5.3%)	0.85
Ocular involvements	118/222 (53.2%)	68/108 (63.0%)	50/114 (43.9%)	0.004
Genital ulcers	138/221 (62.4%)	58/107 (54.2%)	80/114 (70.2%)	0.01
Artiritis	86/223 (38.6%)	33/108 (30.6%)	53/115 (46.1%)	0.02
Gastrointestinal manifestations	56/223 (25.1%)	23/108 (21.3%)	33/115 (28.7%)	0.20
Neurogenic diseases	20/223 (9.0%)	12/108 (11.1%)	8/115 (7.0%)	0.28
Vascular involvements	18/223 (8.1%)	6/108 (5.6%)	12/115 (10.4%)	0.18
HLA-B51 positive	51/123 (41.5%)	32/62 (51.6%)	19/61 (31.1%)	0.02
HLA-A26 positive	28/116 (24.1%)	14/56 (25.0%)	14/60 (23.3%)	0.91

Table 2

	Total (n=223)	With ocular involvements (n=118)	Without ocular involvements (n=104)	p value
Gastrointestinal manifestations	56/223 (25.1%)	17/118 (14.4%)	39/104 (37.5%)	<0.001
Neurogenic diseases	20/223 (9.0%)	19/118 (16.1%)	1/104 (1.0%)	<0.001
Vascular involvements	18/223 (8.1%)	7/118 (5.9%)	11/104 (10.6%)	0.21
HLA-B51 positive	51/123 (41.5%)	36/69 (52.2%)	15/54 (27.8%)	0.006
HLA-A26 positive	28/116 (24.1%)	19/65 (29.2%)	9/51 (17.6%)	0.15

Conclusions: A higher incidence of gastrointestinal manifestations was observed in patients with Behcet's disease in Japan. Patients with ocular involvements showed a higher assosiation rate with neurogenic diseases, and lower wih gastrointestinal manifestation. Most patients could continue TNFα inhibitor safety and effectively.

THU0572 ASSOCIATION BETWEEN RETROPERITONEAL FIBROSIS AND MALIGNANCY: A POSSIBLE PARANEOPLASTIC SYNDROME

S.J. Lee[1], J.S. Eun[1], E.Y. Lee[2], G.B. Bae[1], E.J. Nam[1], Y.W. Song[2], Y.M. Kang[1]. *[1]Internal Medicine, Division of Rheumatology, Kyungpook National University Hospital, Daegu; [2]Internal Medicine, Division of Rheumatology, Seoul National University Hospital, Seoul, Korea, Republic Of*

Background: Retroperitoneal fibrosis (RPF) are associated with malignancies. However it is unclear what is the incidence of malignancies and whether particular malignancies are more prevalent in RPF.
Objectives: The objective of this study was to examine standardized incidence ratios (SIRs) of cancers in patients with retroperitoneal fibrosis (RPF) compared with age- and sex-matched general population.
Methods: Medical records of 111 patients diagnosed as having RPF by computed tomography, positron emission tomography and/or histological evaluation were reviewed. Forty one cases of cancers, which were confirmed by biopsies, were identified in 35 patients with RPF. SIRs were calculated for cancers, cancer types, and age at cancer diagnosis and stratified according to RPF-cancer intervals compared with general population in Korea.
Results: The mean ± SD age at RPF diagnosis was 59.1±14.9 years, and 69.4% of the patients were male. The cancer SIR (95% confidence intervals) in patients with RPF relative to age- and sex-matched individuals in the general population was 3.18 (2.23 - 4.41) [2.65 (1.7 - 3.94) in men; 5.34 (2.76 - 9.32) in women]. The most frequent cancer was unspecified urinary organ cancers with SIR of 733.41 (238.14 – 1711.53). SIRs of multiple myeloma [27.58 (3.34 – 99.64)], renal cell cancers [9.53, (1.15 - 34.42)] and unspecified cancers [16.92, (2.05 - 61.12)] were also significantly higher than in general population. Whereas cancers were most frequently developed in the eighth decade of life, the peak SIR was observed in the fifth decade (8.41, 2.29 – 21.53). When stratified by RPF-cancer intervals, SIR was 6.85 (4.55 - 9.90) within 2 years of RPF diagnosis, while no significant increase in SIR was found out of 2 years. Malignancies (n=28) within 2 year of RPF diagnosis included unspecified urinary organ cancer (n=4), stomach cancer (n=4), lung cancer (n=4), colon cancer (n=3), renal cell cancer (n=2), pancreatic cancer (n=2), unspecified cancer (n=2), rectal cancer (n=1), gallbladder cancer (n=1), non-Hodgkin lymphoma (n=1), multiple myeloma (n=1), prostate cancer (n=1), thyroid cancer (n=1) and gastrointestinal stromal tumor (n=1). Predominant origin of these malignancies were epithelial cell types [transitional cell carcinomas (n=4), adenocarcinoma (n=16)].

Conclusions: RPF was strongly associated with cancers, particularly within 2 years of RPF diagnosis. Our results indicate that cancer screening in patients with RPF should may be performed regularly up to 2 years after RPF diagnosis.

THU0573 CONCOMITANT AUTOIMMUNE DISEASES IN PATIENTS WITH SARCOIDOSIS

S. Kobak[1], F. Sever[2], H. Semiz[3], M. Orman[4]. *[1]Rheumatology, Istinye University Faculty of Medicine, LIV Hospital, Istanbul; [2]Chest Diseases, Medicalpark Hospital; [3]Internal Medicine; [4]Statistics, Ege University Faculty of Medicine, Izmir, Turkey*

Background: Sarcoidosis is a chronic granulomatous disease characterized by non-caseating granuloma formation. It can mimic many rheumatic diseases and/or may be coexist with them. There are limited data in the literature about the association of sarcoidosis with autoimmune diseases.
Objectives: The purpose of this study is to determine the frequency and characteristics of autoimmune diseases associated with patients with sarcoidosis.
Methods: One hundred and thirty-one sarcoidosis patients folowed-up in single rheumatology center were included in the study. Demographic, clinical, laboratory and radiological data of these cases were evaluated retrospectively. The

characteristics of autoimmune diseases associated with sarcoidosis (sarcoidosis-overlap group) patients and isolated sarcoidosis (isolated sarcoidosis group) were analyzed and compared.

Results: Autoimmune disease was detected in 15 (11.5%) of 131 patients with sarcoidosis (1Sjögren syndrome, 3rheumatoid arthritis, 1Still disease, 1scleroderma, 4ankylosing spondylitis, 1familial Mediterranean fever, 1gut arthritis, 1immune trombocytopenic purpura, 1Hashimoto thyroiditis and 1Graves disease). Most of these diseases occurred before (such as RA, AS, Still, FMF) and others after sarcoidosis diagnosis. Among 15 sarcoidosis patients with autoimmune disease 10 were female and 5 were male, the mean age was 50.8 years and mean disease duration was 3 months (1–30 months). When compared with isolated sarcoidosis patients, more hand finger joint involvement, RF positivity, higher ESR and less NSAIDs usage were found in patients with sarcoidosis-overlap group (p=0.035, p=0.049, p=0.015, p=0.018 respectively). There was no statistically significant differences between the two groups when evaluated for demographic, clinical parameters and other treatment modalities.

Conclusions: Concomitant autoimmune diseases in patients with sarcoidosis may be often seen. This patients are characterized with more hand finger joint involvement, RF positivity, higher ESR and less NSAIDs usage. Therefore, in patients with a diagnosis of sarcoidosis, it is necessary for the physician to be careful and to make a wider differential diagnosis in terms of the presence of another underlying autoimmune disease. Multicenter, prospective studies involving large numbers of patients are needed to understand whether the association of sarcoidosis-autoimmune diseases is based only on coincidence or on a common etiopathogenesis.

THU0574 CLASSICAL IMMUNOSUPPRESSION AND DAMAGE PROGRESSION IN A GROUP OF PATIENTS DIAGNOSED WITH BEHCET'S DISEASE

S. Daia-Iliescu, C. Buzatu, A. Borangiu, I. Saulescu, L. Groseanu, V. Bojinca, A. Balanescu, D. Predeteanu, R. Ionescu, D. Opris-Belinski. *Internal Medicine and Rheumatology, Sf. Maria Clinical Hospital, Bucharest, Romania*

Background: Behcet's Disease is a rare type of vasculitis that involves both arterial and venous blood vessels of all sizes. The type of organ involvement and overall disease activity evaluated in the clinical practice determine the course of treatment and the decision to initiate immunosuppression. Activity scores such as Birmingham Vasculitis Activity score (BVASv3), Behcet's Disease Current Activity Form2006 (BDCAF), or damage indices like Vasculitis Damage Index (VDI) have been developed in this respect.

Objectives: To evaluate the ability of classical immunosuppressant therapy to prevent damage progression. To find the correlation between disease activity scores: BVASv3, BDCAF, long term treatment, immunosuppressant use and damage after remission, as calculated by VDI.

Methods: A study on a cohort of patients diagnosed with Behcet's Disease from an Internal Medicine and Rheumatology Clinic was performed. Activity and damage scores,BVASv3,BDCAF and VDI after obtained remission, were calculated. The documented cases were diagnosed according to the International Criteria for Behçet's Disease (ICBD).Windows Excel/SPSS20.0 (Spearman's correlation)were used to analyse the data.

Results: The study included 16 patients treated with long term cortisone and immunosuppressive therapy. The mean age at the time of the diagnosis was 32.3years with a male predominance 62% (10 patients). Severe systemic involvement was present in 10 cases (Ophthalmological involvement-6cases, recurrent venous thrombosis-6cases, pulmonary vasculitis-1 case, severe cardiac involvement-1case, central nervous system involvement-3cases) and all patients received classical immunosuppression (cyclophosphamide, azathioprine).The mean scores for BVASv3 and BDCAF at the time of the diagnosis were 9 and 4.12.A strong correlation was identified between BVASv3 and BDCAF (r=0.830, p<0,001). The use of immunosuppressive therapy due to severe organ involvement and long-term immunosuppression correlated stronger with BVASv3 (r=0.718) than with BDCAF (r=0.533). Vasculitis damage index (VDI) calculated after remission was obtained. There was an important correlation between disease activity scores and damage (BVASv3-VDI r=0,687,p<0,001, BDCAF-VDI r=0,676, p<0,001). Types of treatment were evaluated, a comparison was made between long-term cortisone therapy and immunosuppression.There was a stronger correlation between long term cortisone use and VDI (r=0,600) than between immunosuppression duration and damage (r=0,472).

Conclusions: Damage progression is influenced by disease activity, as calculated by activity scores (BVASv3 and BDCAF). Classical immunosuppression is used for severe organ involvement and for limiting new organ lesions once started. There was a stronger correlation between long-term cortisone use and VDI than between immunosuppression duration and damage. The damage index increased by irreversible organ damage due to disease activity and long term cortisone use, but not due to the immunosuppressive therapy.

THU0575 EFFICACY OF RITUXIMAB IN RESISTANT PALINDROMIC RHEUMATISM:FIRST REPORT IN LITERATURE

S. Sreenath[1], S. Cherian[1], G. Antony[1], U. Mony[2], P. Shenoy[1]. *[1]Centre for Arthritis and Rheumatism (CARE); [2]Molecular Medicine, AIMS, Cochin, India*

Background: Palindromic rheumatism (PR) although often considered as a benign disease can be severe and resistant to DMARDs in some patients. In these patients it can result in almost daily attacks, migrating from joint to joint resulting in poor quality of life. Rituximab has been proven to be effective in treatment of seropositive RA.

Objectives: To determine the efficacy and safety of Rituximab in patients with seropositive PR who had an inadequate response to CsDMARDs

Methods: PR was diagnosed based on criteria proposed by Hannonen P et al. Seropositive (ACPA±RF positivity) PR patients who had active disease despite being treated with two Cs DMARDs for >3 months, were treated with Rituximab. Active disease was defined as >4 attacks per month requiring intake of NSAIDS. All the patients were started on 500mg of rituximab after baseline work up. If complete control of palindromic attacks was not achieved and B cells were detectable in the peripheral blood by flow cytometry another 500 mg infusion was given after 2 weeks. Patients were continued on maximum tolerable dose of DMARDS. Patients were given repeat infusion of Rituximab once the patient developed clinical relapses as evidenced by recurrence of palindromic attacks.

Results: Twenty three patients with a mean age of 44.60±13.51 yrs and mean disease duration of 5.47±3.25 yrs were included. All patients were positive for ACPA while 17 patients were positive for RF. These patients were on a background of minimum of 2 DMARDs. Despite the maximum tolerable dose of DMARDs they had mean attack rate of 5.30±2.38 attacks per month. During a mean follow up of 14.17±8.62 months seven patients required two infusions and three patients required three infusions. Of the 33 infusions 500 mg was effective in controlling the attacks majority (88%) of the times. Seven patients required another 500 mg infusion after 2 weeks as initial 500 mg dose failed to achieve complete control of disease and B cell were not depleted in the peripheral blood. At one month follow up all patients achieved complete control of disease. Remission lasted for 10.33±5.75 months. When symptoms recurred patients were treated with rituximab again and all regained complete control of the symptoms. None of the patients evolved into RA during the study period. No serious adverse events were observed. Five patients experienced minor allergic reactions during infusion which were managed according to the standard protocol.

Conclusions: This case series indicates in patients of PR resistant to Cs DMARDs rituximab not only achieves disease control but also prevents progression to RA. To best of our knowledge this is the first report regarding efficacy of rituximab in PR. Although it needs to be proved in a larger blinded RCT this early data indicates that Rituximab may be a therapeutic option to prevent development of RA in seropositive patients.

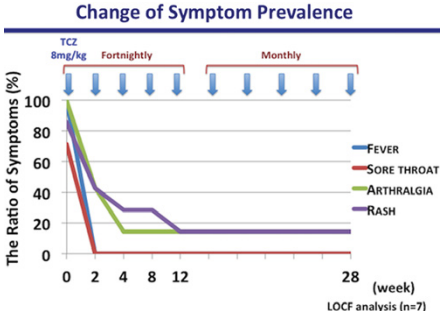
THU0576 THERAPEUTIC OPTIONS FOR PATIENTS WITH RARE RHEUMATIC DISEASES: A SYSTEMATIC REVIEW AND META-ANALYSIS

T.T.A. Bender[1], M. Mücke[1,2,3], J. Leyens[1], C. Stieber[1,4], D. Kravchenko[5], M.F. Seidel[6,7]. *[1]Center for Rare Diseases Bonn (ZSEB); [2]Institute of General Practice and Family Medicine; [3]Department of Palliative Medicine; [4]Institute of Human Genetics; [5]University Hospital Bonn, Bonn, Germany; [6]Department of Oncology, Hematology and Rheumatology, University Hospital Bonn, Bonn, Germany; [7]Schmerzklinik Basel, Basel, Switzerland*

Background: Rare rheumatic diseases are challenging for both patients and clinicians. This problem is further propelled by the scarce number of approved treatment regimens. Therapy is often limited to immunosuppression with corticosteroids or off-label use of drugs for common rheumatic diseases.

Objectives: We have recently described a set of 82 classified rare diseases in rheumatology [1]. In this systematic review, we analysed the evidence for therapeutic regimens from randomized clinical trials of rare rheumatic diseases.

Methods: For this systematic review and meta-analysis, we searched the Cochrane Central Register of Controlled Trials (CENTRAL), MEDLINE, PUBMED and SCOPUS, up to 20th of October 2016. To validate the search strategy, we selected sentinel references.



We included randomized controlled trials regarding rare rheumatic diseases and put a focus on pharmacological treatment compared with placebo, application of

two drugs, or standard therapy. The term "rare" was defined by the European Union as a condition that occurs in no more than 1 in 2,000 individuals.
Two review authors independently assessed trial quality and extracted the data. We screened the search results and included studies if they met the selection criteria. If we identified two or more trials that investigated the same rare disease and used the same assessment tools we performed a meta-analysis.
Results: 135 studies were screened, of which 34 met the inclusion criteria. In total, we analysed data on 11 different orphan diseases, encompassing 2,324 participants. There was a high degree of statistical and clinical heterogeneity in these trials. Several sources of potential bias were identified in the included studies, for example, a lack of description of the blinding methods and allocation concealment, as well as the small size of the study populations. We included studies such as rituximab against cyclophosphamide in ANCA-associated vasculitis. These studies demonstrated a non-inferiority of rituximab. The meta-analysis resulted a combined odds ratio (OR) of 1.42 in favour of rituximab (95% CI). Further meta-analyses were possible for another 22 studies involving, among others, Behçet's disease, systemic sclerosis, cryopyrin-associated periodic syndromes, and giant cell arteritis. Compounds studied were immunosuppressants like corticosteroids, methotrexate and azathioprine, or biologicals such as rilonacept, infliximab, and canakinumab.
Conclusions: A high degree of evidence is hampered by the limited number of study participants in each trial. On the other hand, diseases such as systemic sclerosis, ANCA-associated vasculitides, or Behçet's disease had more high quality trials available. The amount of data for most other rare disease remains unsatisfactory.

THU0577 TOCILIZUMAB MONOTHERAPY FOR ADULT ONSET STILL'S DISEASE – RESULTS OF 52-WEEK TREATMENT OF A PROSPECTIVE, SINGLE-CENTER, SINGLE-ARM, OPEN TRIAL

T. Kondo, Y. Okada, A. Shibata, K. Chino, T. Kurasawa, A. Okuyama, H. Takei, K. Amano. *Department of Rheumatology and Clinical Immunology, Saitama Medical Center, Saitama Medical University, Kawagoe, Saitama, Japan*

Background: Adult-onset Still's disease (AOSD) is a systemic inflammatory disease of unknown etiology. Corticosteroids still provide mainstay AOSD therapy despite various adverse effects. Recently, AOSD patients have been successfully treated with anti-cytokine therapies such as with TNF-α blocking agents, an IL-1 receptor antagonist, and an anti-IL-6 receptor monoclonal antibody. Among these case reports, TCZ seems to be highly effective for treating patients refractory to TNF antagonists and IL-1 antagonist.
Objectives: To assess the efficacy and safety of tocilizumab (TCZ) monotherapy for the induction therapy of adult onset Still's disease (AOSD) in a prospective single-arm, single-center, cohort, pilot study.
Methods: Seven AOSD patients (male 2, female 5) who had agreed with our prospective trial since April 2010 till May 2015 were enrolled. Our study protocol is that patients received 8 mg/kg of intravenous TCZ fortnightly for the first two months (five courses), then monthly for the next 5 months and after that they stop TCZ therapy and we monitor symptoms about AOSD relapses. In this report, we evaluated the efficacy and safety in 52 week. Efficacy was evaluated by serum markers (WBC, CRP and serum ferritin), clinical symptoms and ratio of patients who required additional therapy, and safety was evaluated by adverse events for 52 week.
Results: The mean age was 41.4. The ratio of fever, arthralgia, rash and sore throat are 100% (n=7/7), 100% (n=7/7), 85.7% (n=6/7) and 71.4% (n=5/7) respectively. LOCF analysis revealed that WBC, CRP and serum ferritin level decreased significantly from 14757±4667/μl to 6985±2903/μl, from 13.4±7.1mg/dl to 0.3±0.6mg/dl and from 6927±5376ng/ml to 2416±5589ng/ml at month 7 (TCZ final infusion) respectively (each, $P<0.01$). The improvement rate of fever, arthralgia and eruption were 100% (n=7/7), 85.7% (n=6/7) and 85.7% (n=6/7) respectively at month 7. One patient couldn't continue TCZ therapies because of lack of efficacy (14.3%, n=1) and required additional therapy (prednisolone) at week 2. Another patient also abandoned this trial due to adverse event (14.3%, n=1, urinary tract infection). The other 5 patients could complete the 7-month course of the study and had no symptoms at month 7. Four of five patients had no flare-up signs until month 5 after stopping TCZ. One patient had relapse symptoms such as rash and arthralgia and increased serum level of CRP and serum ferritin at month 2 after final TCZ infusion. There were no serious adverse events during the course of the trial.

Conclusions: TCZ monotherapy can be an alternative treatment strategy for AOSD in some patients.

THU0578 SPECTRUM OF THE DISEASES WITH ORBITAL INVOLVEMENT IN RHEUMATOLOGY: SINGLE-CENTER STUDY

V. Vasilyev [1], V. Gorodetskiy [1], T. Safonova [2], N. Probatova [3], N. Kokosadze [3], A. Pavlovskaya [3], A. Kovrigina [4], I. Gaiduk [5]. *[1] Nasonova Research Institute of Rheumatology; [2] Research Institute of Ophthalmic diseases; [3] N.N. Blochin Russian Cancer Research Center; [4] Hematology Research Center; [5] A.I. Evdokimov Moscow State Dental University, Moscow, Russian Federation*

Background: It is assumed that in ophthalmological clinical practice lymphoproliferative disorders in patients with affection of different orbital organs and tissues constitute 25–55% and 21% of patients have IgG4-related ophthalmic disease [1,2].
Objectives: To evaluate the most common conditions affecting the orbit in rheumatologic clinical practice.
Methods: During 2004 – 2016 years 138 patients (male – 33, female - 105) with eyelid edema and/or tumefactive lesions in the orbit were examined in Nasonova Research Institute of Rheumatology. In all patients full clinical, ophthalmological, serological (rheumatoid factor, C-reactive protein, IgG, IgG4, IgM, IgA, ANA, anti-Ro/La, C3/C4 complement) examination was carried. In all cases diagnosis was verified pathomorphologicaly with immunohystochemical staining (anti-CD 138, CD 68, IgG, IgG4, κ-chain, λ-chain). Diagnosis was established on the basis of pathomorphological examination of different tissues: orbit – 79 patients, parotid salivary gland – 40, submandibular salivary gland – 14, nasal – 4, lymph nodes – 3 and other – 6. In 79 cases (54%) the diagnosis was established on the results of orbital biopsy.
Results: Different non-neoplastic diseases were diagnosed in 108 patients (78.5%) and 30 had different conditions of hematological spectrum, including malignant conditions in 25 (18.2%) patients (see table 1). Some patients at baseline had simultaneous involvement of the major salivary glands (23 patients with IgG4-related disease, 35 with sarcoidosis, 12 with non-Hodgkin lymphomas and 2 with AL-amyloidosis). The most rare conditions affecting the orbit were Cogan's syndrome, relapsing polychondritis, Erdheim-Chester disease, NK/T-cell nasal lymphoma and calcifying aponeurotic fibroma.

Table 1. Spectrum of the diseases with orbital involvement in rheumatologic practice (n=138)

	N, pts	N, %		N, pts	N, %
Non-neoplastic conditions	**108**	**78.5**	**Hematologic conditions**	**30**	**21.5**
• IgG4-related disease	48	35.0	• non-Hodgkin lymphomas	20	14.5
• Granulematous lesions (sarcoidosis, granulematosis with polyangiitis, necrosing sarcoidal granulematosis)	41	29	• Erdheim-Chester disease	1	0.7
• Autoimmune dacryoadenitis (non-differentiated)	7	5	• AL-amyloidosis	3	2.1
• Idiopathic orbital inflammation	7	5	• NK/T-cell nasal lymphoma	1	0.7
• Endocrin ophthalmopathy	2	1.4	• Histiocytosis	4	2.9
• Cogan's syndrome	1	0.7	• Calcifying aponeurotic fibroma	1	0.7
• Relapsing polychondritis	1	0.7			

Conclusions: In rheumatologic practice in 78.5% of patients with orbital involvement different non-neoplastic conditions are diagnosed: IgG4-related ophthalmic disease (35.0%), granulematous lesions (29%). The most common hematological disorders in rheumatologic clinic are non-Hodgkin lymphomas (17.5%) and histiocytosis (3.5%).

THU0579 HYPOCOMPLEMENTEMIA IS RELATED TO ELEVATED SERUM LEVELS OF IGG SUBCLASSES OTHER THAN IGG4 IN IGG4-RELATED KIDNEY DISEASE

Y. Fujisawa, I. Mizushima, S. Tsuge, S. Hara, F. Suzuki, K. Ito, H. Fuji, K. Yamada, M. Kawano. *Division of Rheumatology, Department of Cardiovascular and Internal Medicine, Kanazawa City, Japan*

Background: IgG4-related kidney disease (IgG4-RKD) is a comprehensive term for renal lesions associated with IgG4-related disease [1]. IgG4-RKD is frequently complicated by hypocomplementemia [1, 2, 3], but its clinical significance and mechanisms have not been clarified.
Objectives: This study aimed to investigate clinical features of IgG4-RKD patients with hypocomplementemia compared with those without it, leading to clarification of the clinical significance and mechanisms of hypocomplementemia.
Methods: We extracted 25 patients with IgG4-RKD between September 2005 and December 2016 in our hospital. Based on the presence/absence of hypocomplementemia at diagnosis, we divided them into a hypocomplementemia group (n=11) and normal complement group (n=14), and retrospectively analyzed various clinical features (age, sex, serum IgG levels, serum IgG4 levels, gaps between serum IgG and IgG4 level, ratio of serum IgG to serum IgG4, serum IgG subclasses, serum IgE levels, serum creatinine levels, urinary protein and urinary occult blood, urinary β2-microglobulin, urinary N-acetyl-β-D-glucosaminidase, initial dose of prednisolone, serum IL-2R levels, multiple organ lesion) during the clinical course in the two groups.
Results: The patients comprised 18 men and 7 women with an average age of 67.5 years (range, 44 to 81 years). Serum IgG levels (3971±729 mg/dL vs. 2157±598 mg/dL; $p<0.001$), gaps between serum IgG and IgG4 level (2992±770 mg/dL vs. 1482±444 mg/dL; $p<0.001$), serum IgG1 levels (2043±1025 mg/dL vs. 891±209 mg/dL; p=0.017), and the number of involved organs (4.1±1.1 vs 2.9±1.1; p=0.018) were significantly different between the two groups, while serum IgG4 levels (979±477 mg/dL vs. 791±575 mg/dL; p=0.298) and serum creatinine levels (1.96±1.89 mg/dL vs. 1.09±0.48 mg/dL; p=0.298) were not. At relapse of renal lesions, although both groups showed serum IgG4 re-elevation, the hypocomplementemia group showed exacerbation of hypocomplementemia and re-expansion of gaps between serum IgG and IgG4 level, while the normal complement group did not.
Conclusions: Hypocomplementemia may be associated with multiple organ involvement and elevation of IgG subclasses other than IgG4 including IgG1 in IgG4-RKD. In patients who initially show hypocomplementemia, a decline in serum complement levels implies renal lesion relapse.

Education

THU0580 WHAT ARE THE PATIENTS' ISSUES AND NEEDS RELATED TO THEIR BIOLOGICS (BDMARDS) AND METHOTREXATE (MTX) TREATMENT IN DAILY LIFE: A QUANTITATIVE CROSS-SECTIONAL SURVEY AMONG 344 PATIENTS TO DEVELOP AN EDUCATIONAL SMARTPHONE APP

C. Beauvais[1], S. Tropé[2], A. Lafourcade[3], D. Carnet[4], L. Grange[5], L. Carton[6], D. Lafarge[7], G. Montagu[8], T. Pham[9], F. Tubach[10], J. Sellam[11] on behalf of Therapeutic education section of the French Society of Rheumatology and Club Rhumatismes Inflammation. *[1]Rheumatology, Saint Antoine Hospital. APHP, Paris; [2]Association ANDAR, Montpellier; [3]Biostatistics, AP-HP Hôpital Pitié-Salpétrière, Paris; [4]ANDAR, Montpellier; [5]Rheumatology, Echirolles; [6]Association AFLAR; [7]Association AFS; [8]Unknowns, Strategic and Innovation Consulting, Paris; [9]Rheumatology, Hôpital Sainte-Marguerite, AP-HM, Marseille; [10]Biostatistics, Public Health, and Medical Information, AP-HP Hôpital Pitié-Salpétrière; [11]Reumatology, AP-HP St-Antoine, Univ Paris 06, Paris, France*

Background: MTX and bDMARDs are the core treatments of chronic inflammatory arthritis (IA). We lack information on the patients' problems and needs in daily life, particularly on safety issues.
Objectives: 1-collect the most frequent issues 2-explore the patients' perceptions on a dedicated smartphone application (SP App) 3) determine the profile of the patients interested.
Methods: The survey was conducted on line. The questionnaire was designed by rheumatologists, methodologists, anthropologists, members of patients association (AP) and included 1-a non-exhaustive list of potential issues in daily life (fever, vaccines, ...) and practical aspects 2-a list of potential use of the App 3-free opinions 4- Two self-administrated questionnaire to test patients' knowledge on bDMARDs [1] and MTX [2].
Results: The survey was carried out from June to August 2016 on the websites of the PA. Non-associative patients were recruited by 3 rheumatologists who provided the Internet link. 344 patients responded, 331 analyzed, 83% female, 50% had rheumatoid arthritis, 40% had spondyloarthritis, mean age 53 years, 60% were AP; 67% were treated with MTX, 70% had bDMARDs, 34% had MTX-bDMARDs combotherapy.
66% of patients reported problems; 67% had needed help or advice. The main issues were infections (27%), vaccines (13%), surgery (10%), dental care (7%), self-administration (6%), conservation/travelling (9%) and skipped doses (5%).
Among the 76% patients who have a SP, 80% use Apps and 32% Apps for their health. Among users, 87% patients would find an App useful to manage their treatment (36% rather agree and 51% strongly agree), 82% for symptoms requiring to stop their treatment, 93% for situations related to safety, 80% as a reminder of their treatment, 80% to know what to do in case of a skipped dose, 77% to have a safety checklist before treatment administration, 66% to recall the modalities of self-injections. Patients interested in the App are younger ($p<0.05$) non-associative ($p<0.05$) and live in medium-sized cities ($p<0.01$). No correlation was found with other sociodemographic characteristics, level of education, type/duration of arthritis or knowledge.
Conclusions: Two-third of patients with arthritis face issues related to their treatment especially in case of infections, vaccination, surgery and travelling. A dedicated App is considered useful by 87% patients who already have a SP. The potential use of the App may improve safety, adherence and self-management in daily life.

THU0581 WHAT WE SEE, WHAT WE LEARN, AND THE PREVALENCE OF RHEUMATIC DISEASES IN OUR POPULATION: A DIAGNOSIS CORRELATION STUDY

D. Vega-Morales[1], J.A. Esquivel-Valerio[1], R. Ortiz-Lopez[2], A.C. Arana-Guajardo[1], M.A. Garza-Elizondo[1]. *[1]Rheumatology Service; [2]Rheumatology, Hospital Universitario Dr. José Eleuterio González, Monterrey, Mexico*

Background: The postgraduate program in rheumatology aims learning of musculoskeletal and autoimmune disorders. In México, objectively-structured clinical examination (OSCE) is applied in postgraduate certification processes by the Mexican Board of Rheumatology annually [1]. Peláez-Ballestas et al. described an epidemiological study (COPCORD, Community Oriented Program for the Control of Rheumatic Diseases) of 19,213 individuals in 5 regions in our country where they found a prevalence of musculoskeletal pain in 25.5%, osteoarthritis in 10.5%, back pain in 5.8%, rheumatic regional pain syndromes in 3.8%, rheumatoid arthritis (RA) in 1.6%, and fibromyalgia in 0.7% [2].
Objectives: The aim of the study is to describe the student training in rheumatic diseases and correlate them with OSCE assessment and the prevalence of rheumatic diseases in our population.
Methods: An observational and analytical study was made between March 2014 to March 2015 in a single rheumatology training center at University Hospital. Student training was defined according to the times they evaluated patients with a determined diagnosis, this information was obtained by medical records. We categorize OSCE questions according to the rheumatic diagnosis. Finally, the two results were compared with prevalence of the rheumatic diagnosis according to COPCORD, which were registered according a score pain >4. We made descriptive statistics and a Spearman's Rho to evaluate the correlations of the diagnosis frequencies by each category.
Results: We reviewed 6279 medical records, 854 (13.6%) were of first-time evaluation. We had 5,400 (86.4%) women, with a mean age of 47.9 (SD 15.45) years.
Descriptive statistics are in Table 1 and Figure 1, which included: medical consultations, OSCE assessment and a column with rheumatologic diagnosis according to COPCORD.
The Spearman correlation coefficients of the 32 different diagnoses were: student training vs OSCE 0.492 (p=0.004), student training vs COPCORD 0.597 (p=0.01) and OSCE vs COPCORD 0.624 (p=0.01).
Conclusions: Although the most common musculoskeletal disease in our community did not obtain the frequency observed by students or evaluated in

Table 1

THU0582 2-YEAR ADHERENCE TO THE TREATMENT OF OSTEOPOROSIS FOLLOWING A THERAPEUTIC PATIENT EDUCATION PROGRAM

D. Poivret[1], C. Wilcke[2], V. Noirez[1], C. Goetz[1,3]. *[1]Chr Metz Thionville; [2]URPS Grand Est; [3]PARC, Chr Metz Thionville, Metz, France*

Background: The management of osteoporosis requires drug treatment and changes in lifestyle. Adherence to medication does not exceed 50% at one year. Changes in lifestyle are rarely explored. Therapeutic requires a relay to continue the follow-up over several years

Objectives: To improve the follow-up of the patient, we have created cooperation between the attending physician and the pharmacy pharmacist initiated by the patient himself

Methods: We proposed a therapeutic patient education for patients treated for osteoporosis to participate in two half-day ETP sessions a year apart. Educational objectives are: The treatment of osteoporosis requires at least 5 years of treatment, and must be associated with the absorption of three dairy products per day, maintaining physical activity and preventing falls. Each patient participating in a therapeutic education session receives a follow-up notebook containing six doctor questionnaires and six pharmacist questionnaires. The patient remains the owner of the notebook. We were able to study the results of the 2-year questionnaires for 72 patients included in 2013 and 2014.

Results: 53/72 patients continue their treatment at 2 years. 4 patients died, 1 had an atypical fracture of the femoral shaft, 6 stopped treatment due to dental treatment, 3 had contraindications to any anti-osteoporotic treatment, 1 decided to discontinue treatment due to d Multiple Sclerosis, 11 decided to leave the program. 3 patients were lost to follow-up, ie 14/72 patients of whom we no longer have any news. Of the 53 patients who continued treatment, 24 sent back a doctor and pharmacist questionnaire to 2 years. 4 doctors and 2 pharmacists refused to complete the questionnaires. The study of pharmacist questionnaires received at 2 years shows that 83% of patients continue to consume 3 dairy products per day compared to 73% at 6 months, 65% maintained physical activity, 17% improved it, 9% decreased. The ground balance was satisfactory for 78% of patients compared with 71% at 6 months. 71% never forget their treatment, compared with 69% at 6 months. 8% wanted to stop their treatment, stable figure compared to questionnaires received at 6 months. All patients knew what their treatment was for at one year and 96% met the conditions for taking the medication. 69% do not forget it at two years against 86% at one year, thanks to the intervention of the pharmacist. Only 6% wanted to stop the treatment at two years due to side effects, 17% to 1 year, but did not stop after consultation with the doctor and/or pharmacist.

During the two-year follow-up, all patients were phone called at least once by a secretary, mostly several times. The notebook is driven by the patient himself, many oh them report to the nurse that it give them an active role which afoord them to continue the treatment

Conclusions: 58% of the patients enrolled continue treatment at two years, 15% have stopped the treatment as a side effect. An active role given to the patient and a collaboration between physicians and pharmacists thus promote adherence to treatment and also changes in lifestyle

THU0583 EFFECT OF AN ONLINE EDUCATIONAL INTERVENTION IN THE KNOWLEDGE OF PATIENT REGISTRIES AND PATIENT-REPORTED OUTCOMES AMONG RHEUMATOLOGISTS

E. Jackson[1], E. McCardell[1], J.R. Curtis[2]. *[1]Medscape Education, New York; [2]Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, United States*

Background: Patient-reported outcomes (PROs) have evolved into an essential element in managing rheumatoid arthritis (RA), working in concert with physician-based tools to assess disease activity and health-related quality of life [1].

Objectives: A study was conducted to determine whether an online educational intervention could effectively address a knowledge gap and an underlying educational need in applying data from patient registries including PROs in the management of patients with RA.

Methods: An online educational intervention focusing on advances in RA patient registries was developed and made available online. The intervention consisted of a 30-minute video-based roundtable discussion between 3 experts in treatment of RA. The intended audience was rheumatologists who treat patients with RA. The educational impact was assessed by comparing participants' responses to 4 identical paired pre- and post-assessment questions. Data representing a statistical sampling of the overall learner population was collected from 5/29/2015 through 8/13/2015. Statistical analysis comprised a paired (within-physician) 2-tailed t-test comparing mean pre-intervention and post-intervention scores, McNemar's $\chi 2$ statistic for measuring changes in responses to individual. Cramer's *V* determined the overall effect of the intervention.

Results: Analysis of pre- versus post-activity responses by rheumatologists (n=36) demonstrated a significant improvement ($P<0.05$) in overall knowledge with a robust effect size ($V=0.339$). This activity resulted in increased knowledge surrounding several specific areas of RA management, such as drug safety, alternative means of collecting PRO data, and issues surrounding pregnancy in women with RA. The absolute percentage increases in correct individual responses to these topics (all $P<0.05$ except where noted), included:

- 33% increase (36% vs. 69%) in rheumatologists who recognized the results from pooled registries in Europe – 11 registries from 9 countries – regarding the safety of tumor necrosis factor-alpha inhibitor therapy,
- 28% increase (36% vs 64%) in rheumatologists who recognized that biosensor-based devices can provide passive data regarding patient outcomes,
- 14% increase (47% vs 61%, $P=.237$) in rheumatologists who identified the connected CORRONA-OTIS registries that provide information on patients with RA who become pregnant,
- 62% increase (19% vs 81%) in rheumatologists who identified that patient registry data can be used to support a risk mitigation strategy for prescribing a specific DMARD in patients who may become pregnant during therapy.

Conclusions: An online educational intervention was associated with significant improvement in knowledge levels of rheumatologists in several important aspects of RA management, including interpretation of data from patient registries and adverse effect profiles of approved therapies. Future directions for education include additional reinforcement regarding the roles for PROs in patient management, and assessing the impact of improved rheumatologists' knowledge on care delivery and patient outcomes.

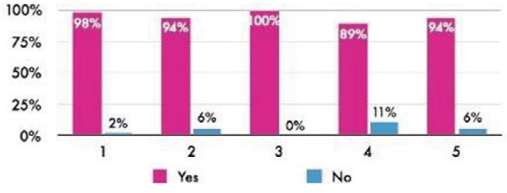
THU0584 FIVE YEARS OF EXPERIENCE WITH THE LUPUS ACADEMY: AN EFFECTIVE MODEL FOR BUILDING A ROBUST COMMUNITY OF PRACTICE FOR GEOGRAPHICALLY DIVERSE LEARNERS

R. Cervera[1], R.A. Furie[2], Z. Amoura[3], A. Jacobson[4], E. Pozniak[4]. *[1]Hospital Clinic, Barcelona, Spain; [2]Hofstra North Shore-LIJ School of Medicine, New York, United States; [3]Pitie-salpetriere Hospital, Paris, France; [4]Siyemi Learning, Manchester, United Kingdom*



Background: Systemic lupus erythematosus (SLE) is a complex yet low prevalence disease. Without a community of lupus specialists to establish consensus and guide best practices, rheumatologists have limited opportunities to develop skills and maintain competence in SLE care.

Objectives: The objectives of this initiative were to 1) create an independent community of physicians interested in the pathogenesis, diagnosis, and management of patients with SLE and related conditions; 2) share insights and practical guidance for implementing evidence-based care; 3) develop needs-driven contin-

uing medical education (CME) relevant to different levels of clinical expertise; 4) promote collaboration models with publishers to create space for dialogue and community building; and 5) involve patient advocacy groups to steer physician education and incorporate the patient voice into educational activities.
Methods: The Lupus Academy (http://lupus-academy.org) was established in 2011 as an independent CME initiative led by a Steering Committee of international experts in SLE.[1] Educational activities are designed around unmet clinical needs identified by the Steering Committee, learner survey data, and feedback from patient advocacy groups (including Lupus Europe).
Results: As of February 2017, the Lupus Academy has grown to a global community of >2,500 committed learners with an interest in SLE. The Steering Committee has guided the development and delivery of 5 2.5-day annual meetings; 4 1-day regional meetings; a meeting toolkit for learner-advocates to host meetings in their home regions; and 3 e-learning courses, with 2 additional courses in production. The 5th Annual Meeting of the Lupus Academy (6–8 May 2016) hosted 101 attendees from Europe, North and South America, and Asia. Learners reported that the learning objectives of the meeting were met (Figure). An assessment of educational effectiveness demonstrated improvements in clinical knowledge and competence (Moore's Outcomes Levels 3/4) as a result of meeting participation: 67% of learners reported a commitment to implementing changes in clinical practice, 11% reported that the educational content reinforced their current practice, and 20% reported a willingness to modify their current practice with additional training.
The most recent regional meeting, the Lupus Academy Middle East Summit Conference (9–10 December 2016), hosted 153 attendees from 13 countries representing diverse specialities: rheumatology (53%), internal medicine (13%), nephrology (11%), clinical immunology (5%), and other (18%). The majority of learners agreed or strongly agreed that the meeting provided an effective platform for the discussion of new ideas in SLE (96%) and challenged the current thinking around lupus care (96%).

Having attended this meeting, I am better able to:

1. Apply novel developments in scientific research around SLE in their clinical practice
2. Implement optimal diagnostic methods and optimal disease management of refractory lupus nephritis patients and of those patients with both SLE and rheumatoid arthritis
3. Increase competence in identifying difficult clinical cases from the broad spectrum of lupus patients and effectively manage them - including patients displaying manifestations involving lungs, GI, liver and CNS, as well as paediatric and pregnant patients
4. Implement new therapeutic options inherited from other therapeutic specialities
5. Apply learnings from other disease areas to achieve optimal treatments outcomes in patients with SLE

Conclusions: The Lupus Academy serves as an effective model for building a consortium-led, evidence-based educational resource and community of practice for rheumatologists, other physicians with an interest in SLE, and patient advocacy groups.

THU0585 THE PATIENT'S UNIVERSITY - AN INNOVATIVE CONCEPT IN THE EDUCATION OF PATIENTS WITH RHEUMATOID ARTHRITIS

F. Rodriguez[1], L. Villarreal[2], P. Santos-Moreno[3], M. Cabrera[4], D. Buitrago-Garcia[5], C. Caicedo[6]. *[1]Patient Program; [2]Psychology and processes; [3]Rheumatology; [4]Engineer and processes; [5]Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota; [6]Public Health, Universidad Nacional de Colombia, Bogota, Colombia*

Background: Rheumatoid arthritis (RA) is a chronic, inflammatory autoimmune disease of unknown etiology, it is a long term condition that causes pain, disability and affects the quality of life (1). In another countries has been demonstrated how patient education can empower the individual giving as a result a better decision making between the practitioner and patient in order to obtain better health care outcomes compared to patients that are not involved in educational activities (1).
Objectives: The objective of this work is to show how through a progressive program of patient education we reach the concept of the "expert patient" and the "patients' university".
Methods: We performed a systematic review of the literature in global and regional databases (Pubmed, Medline, Scopus, Lilacs), in order to search for information on this research question-hypothesis. Subsequently and under a Delphi-modified methodology and consensus of experts lay the conceptual bases on this particular subject – patient's education in rheumatic disease. As a result of the above was defined a proposal for the constitution and development of the program of patient's education in a RA specialized center under the concept of the "expert patient" (EP) and the "patients' university"(PU).
Results: From conceptual point of view specific themes regarding patient's education were developed by a coordinator who, after a review of the literature, presented a specific proposal on the particular topic that was discussed with the panel members and then voted on and finally implemented within the EP y PU concepts. In a specialized RA center in Bogotá Colombia during 2016 we started a patient and caregiver oriented program to support the clinical treatment in patients with RA. The structure of the program was an educational-recreational strategy where we integrated health education (disease activity, pharmacovigilance, psychology and nutrition) and recreational activities such as crafts, yoga, aerobics and dance lessons with a periodicity of two times per week. We called the program "Gest-Art". As a result of this pilot program we obtained a positive impact and perception among patients and care takers; we had the participation of 600 people during the whole year. The next phase is to develop a step-by-step program to initially train and then specialize patient focus groups (expert patient); and later develop a model of continuous improvement (updating) that we will call the university of patients.
Conclusions: From this experience we can conclude that the implementation of this educational program opened the opportunity to empower and motivate our patients and caregivers to be actively participative with the disease management and health care, also the program has been a space for the patients to share their experiences and to propose new strategies to improve the program.

THU0586 SAFETY OF BIOLOGICS AND CONVENTIONAL DMARDS: AN ETHNOGRAPHIC STUDY INVESTIGATING PATIENTS' DECISIONS AND PRACTICES TO DEVELOP AN EDUCATIONAL SMARTPHONE APP

G. Montagu[1], C. Beauvais[2], F. Madrisotti[1], T. Pham[3], S. Tropé[4], F. Tubach[5], J. Sellam[6] on behalf of Therapeutic education section of the French Society of Rheumatology and Club Rhumatismes Inflammation. *[1]Sociology and research, Unknowns, Strategic and Innovation Consulting; [2]Rheumatology, AP-HP St-Antoine hospital, Paris; [3]Rheumatology, Hôpital Sainte-Marguerite, AP-HM, Marseille; [4]Association Nationale de Défense contre L'Arthrite Rhumatoïde (ANDAR), ANDAR; [5]Biostatistics, Public Health, and Medical Information, AP-HP Hôpital Pitié-Salpétrière; [6]Rheumatology, AP-HP St-Antoine, Univ Paris 06, Paris, France*

Background: Safety and adherence to DMARDs are critical for patients with rheumatoid arthritis (RA) or spondyloarthritis (SpA). Few digital tools exist to help patients on these issues.
Objectives: We aimed to decipher the mechanisms of patients' decisions and practices with their DMARDs to develop an educational smartphone application (SP App).
Methods: An ethnographic study was designed by 3 rheumatologists, 1 methodologist, patient associations and by 2 anthropologists who conducted the interviews. The study involved 21 patients (enough to reach saturation), recruited by diversity of clinical and sociological profiles. The panel included 16 women and 5 men, median age 46 years-old (extremes 26–70), 12 with RA and 9 with SpA (median disease duration 13 years, extremes 2–38). Nine patients were treated by biologic DMARDs monotherapy, 7 by conventional DMARDs monotherapy and 5 by bDMARD-cDMARD combotherapy. Interviews were conducted using in-depth semi directive and biographic methods. The interview guide was constructed around 3 fields: 1 the organization of the patients' everyday life with their disease, 2 treatment practices, 3 the impact of arthritis on their social and professional activities and relationships. Interviews were recorded and transcribed for analysis.
Results: Patients play an active role in the management of their disease. They have to learn to live with it in order to control its impact and course. This learning progressively occurs throughout a non-linear 4-stages career: 1) from 1st symptoms to diagnosis, 2) search for the right treatment and the right dosage, 3) stabilization of the disease and the treatment, 4) dealing with a complication or an unexpected event. Back and forth between stages 2, 3 and 4 are frequent.
This learning implies a partnership-based doctor-patient relationship, and the development of specific skills around safety: dealing with health care system

(i.e. knowing which healthcare professionals they need), dealing with information (i.e. knowing how to identify relevant sources). Patients do lots of experiments (changing their DMARD dosage on their own initiative, trying alternative medicine or food exclusions...) and ritualizing their DMARDs administration. Such rituals represent a reflexive moment for the patients dedicated to themselves and their disease.

During the stage of stabilized disease and treatment, rituals tend to improve observance but also increase safety problems because of habits, over-confidence, and forgetting of risky situations. Patients renew interest about safety concerns in case of an unexpected complication.

Conclusions: Starting from the patients' point of view, this ethnographic study emphasizes a tension between observance and safety. Practices by which patients appropriate their treatment create habits that improve observance but also increase safety problems. It seems necessary to support the patients in updating their safety skills. A SP App could contribute to this goal only if its use finds its place in the patients' ritual.

THU0587 PUBLIC AWARENESS OF RHEUMATIC DISEASES IN CYPRUS - NEED FOR IMPROVEMENT

J. Joseph[1,2], I. Armata[1], A. Antoniadou[1], P. Maini[1]. [1]*St. George's University of London Programme, University of Nicosia Medical School;* [2]*Rheumatology, Aretaeion Hospital, Nicosia, Cyprus*

Background: Public awareness regarding rheumatic diseases is a constant aim of patient societies and health care professionals in rheumatology. A high level of awareness will help identification and early treatment, it would avoid unnecessary investigations and costs and more importantly, it would assist functioning of patients with such conditions in society, with the understanding and support they deserve.

Objectives: The aim was to study public awareness regarding rheumatic conditions. Specifically, what constitutes a rheumatic condition, which doctor deals with these, what is their frequency and what age groups are affected.

Methods: During the rheumatic diseases awareness week in May 2016, doctors, medical students and members of the Cyprus League against Rheumatism, walked the streets of major cities and invited passers-by to answer a few simple questions. This was optional and at the end of the questions, information was provided, based on the answers and on any additional queries raised by people.

Results: 400 people provided answers. There were slightly more women than men and ages ranged from 13 to 86 years. Almost 50% did not know what a rheumatologist does. Only 11% could name 3 rheumatic conditions. Although the majority stated that rheumatic diseases occur in the elderly, 2/3 were unaware that they can affect children. Most people correctly identified which specialists should deal with asthma or eczema, but a huge majority did not know who should be consulted for back pain, tendon problems or osteoporosis. Although 75% had heard of rheumatoid and osteoarthritis, 75% of people had never heard of ankylosing spondylitis or fibromyalgia and only about half had heard of psoriatic arthritis or lupus. Most people stated that rheumatic conditions in general, affect 10–20% of people.

Conclusions: There was significant lack of awareness as to what rheumatologists do, what constitutes a rheumatic disease, the fact that it affects young people and the link between rheumatology and back pain, tendon problems and osteoporosis. All these points need to be included in public education. Of the major rheumatic diseases, the next awareness campaign needs to include ankylosing spondylitis, fibromyalgia, psoriatic arthritis and lupus.

THU0588 ARE RHEUMATOID ARTHRITIS PATIENTS WILLING TO USE AN E-HEALTH INTERACTIVE SELF-ASSESSMENT WEBSITE? ANALYSES OF 159 PATIENTS FROM A RANDOMISED CONTROLLED TRIAL OVER 12 MONTHS

L. Gossec[1], A. Cantagrel[1], M. Soubrier[1], J.M. Joubert[2], W. Czarlewski[2], B. Combe[1], J.M. Berthelot[1], D. Wendling[1], E. Dernis[1], L. Grange[1], C. Beauvais[1], A. Perdriger[1], H. Nataf[1], M. Dougados[1], H. Servy[1]. [1]*CarNET Study Group, Paris;* [2]*UCB Pharma, Colombes, France*

Background: Interactive, online electronic (e)-health services with patient-reported outcome measure (PROM)-based instruments may be helpful for patients (pts). Sanoïa is a secure, independent e- and mobile (m)-health platform developed to allow pt self-assessment, storage of questions to ask physicians, and self-monitoring of disease status. The platform offers a dedicated set of scores, PROMs and information about different diseases, including rheumatoid arthritis (RA).

Objectives: To characterise pts with RA who chose to access e-health services regularly over a 12-month (mo) period.

Methods: Post-hoc analysis of CarNET (NCT02200068): a French, multicentre, 12-mo randomised controlled trial. Pts with RA were randomised to: access to Sanoïa (30-min training via the telephone with no further incentive to access the platform) or usual care (normal internet use without access to Sanoïa). The Sanoïa group pts used a home-based e-Case Report Form to record frequency of Sanoïa access, satisfaction with the platform (0–10 scale; 0=completely satisfied, 10=not satisfied), and barriers to use (from a pre-specified list). Baseline pt characteristics associated with more frequent use (above the median) were analysed by univariate and multivariate logistic regression.

Results: 159 RA pts were randomised to the Sanoïa arm: mean±SD age was 56.1±13.1 years, disease duration was 15.0±11.5 years and 132 (83.0%) of pts were female. Mean DAS28 was 2.7±1.2 with 57.2% of pts in remission; 115 (72.3%) were taking a biologic; 23.3% had attended therapeutic education sessions; 15.7% were members of pt associations; and 53.5% had participated in university-level studies. Overall, 41 pts (25.7%) never accessed Sanoïa and 81 (50.9%) accessed the platform at least twice; median=2, mean±SD=4.4±11.3 connections/pt over the 12 mos. 54 pts (34.0%) used Sanoïa for $\geq$2 mos with a noticeable investigator effect (0.3±0.2, 0–1 scale). Mean satisfaction with the platform was very high (1.5±1.5), with 90% scoring satisfaction $\leq$3. One barrier was expressed in 11.8% of cases: "the platform is not useful for me since I am in remission". In multivariate analysis, the only variable associated with greater usage of Sanoïa was being a member of a pt association: odds ratio [95% CI]=1.44 [1.17–1.77].

Conclusions: A quarter of pts who participated in this trial to assess e-health did not access the platform whereas half accessed the platform at least twice. Pts expressed high satisfaction and the only barrier was lower usefulness when in remission. e-Health is a promising tool for self-management in RA. The impact of offering additional services should also be explored in a further study.

THU0589 PATIENT-PERCEIVED COPING WAS ASSOCIATED WITH PATIENT-PERCEIVED QUALITY OF PATIENT-PHYSICIAN INTERACTIONS IN 320 PATIENTS WITH RHEUMATOID ARTHRITIS

L. Gossec[1], C. Desthieux[1], A. Cantagrel[1], M. Soubrier[1], J.M. Berthelot[1], J.M. Joubert[2], B. Combe[1], W. Czarlewski[2], D. Wendling[1], E. Dernis[1], L. Grange[1], C. Beauvais[1], A. Perdriger[1], H. Nataf[1], M. Dougados[1], H. Servy[1]. [1]*CarNET Study Group, Paris;* [2]*UCB Pharma, Colombes, France*

Background: There has been growing emphasis on the importance of shared decision-making in rheumatoid arthritis (RA).[1,2] Patient-physician (pt-phy) shared decision-making necessitates open and thorough discussions and good interactions.

Objectives: This analysis explored pt-perceived quality levels of pt-phy interactions and characteristics of pts when these interactions are described as very good by pts.

Methods: CarNET (NCT02200068) was a French, 12-month, multicentre randomised controlled trial to assess access to an e-health platform (Sanoïa) allowing self-assessment of disease.[1,2] This was a post-hoc analysis, using baseline data only. Pts had confirmed RA and were enrolled by their treating rheumatologist. Pt-perceived pt-phy interactions were assessed through the pt-reported questionnaire Perceived Efficacy in Patient-Physician Interactions (PEPPI-5)[3] which consists of 5 items, each starting with "How confident are you in your ability to ..." (eg. "... know what questions to ask a doctor?"). Pts rated each item on an 11-point scale; 0=not at all confident, 10=very confident. Total PEPPI-5 scores range from 0–50; higher scores represent higher perceived self-efficacy in pt-phy interactions. Factors associated with a higher PEPPI-5 (ie. >median) were analysed by univariate and multivariate logistic regression (factors included pt demographics, phy demographics, disease characteristics and activity including pt-perceived coping [scored 0–10 in the Rheumatoid Arthritis Impact of Disease (RAID) questionnaire; lower scores indicate better coping]).

Results: Of 320 RA pts (159 vs 161; Sanoïa vs usual care), mean±SD age was 57.0±12.7 years, disease duration was 14.6±11.1 years and 253 (79.1%) were female. Mean DAS28 was 2.7±1.2, 54.1% were in DAS28 remission (<2.6); 216 (67.5%) were taking a biologic; 21.9% had previous therapeutic education sessions; 15.3% were members of pt associations; and 51.9% had followed university-level studies. The mean±SD PEPPI-5 score was 39.2±7.8 and the

median was 40. In univariate analyses, associations with $p<0.05$ were observed between pt-perceived coping (p=0.0008), erosive disease (p=0.03) and DAS28 remission (p=0.05) and a high PEPPI-5; associations with $p<0.2$ were observed for older age (p=0.07) and HAQ-DI $\leq$0.5 (p=0.12). In multivariate analyses, the only factor associated with high PEPPI-5 was pt-perceived coping (odds ratio [95% CI]=0.85 [0.76–0.96]; p=0.007).

Conclusions: Among RA pts whose disease was well controlled, pt-perceived pt-phy interactions were good. Pt-perceived coping was associated with better pt-perceived pt-phy interactions, indicating that perhaps pts who felt in control were more at ease with their phy, or vice-versa. The data did not allow us to attribute causality. These elements are important in the shared decision-making process.

THU0590 THE USE OF A PORTFOLIO AMONG YOUNG RHEUMATOLOGISTS: RESULTS OF AN EMEUNET SURVEY

M. Van Onna[1], F. Sivera[2], V. Navarro-Compán[3], E. Nikiphorou[4], A. Moltó[5], S. Ramiro[6] on behalf of the EMEUNET Working Group. *[1]Department of Internal Medicine, division of Rheumatology, Maastricht University Medical Center +, Maastricht, Netherlands; [2]Rheumatology, Hospital General Universitario de Elda, Alicante; [3]Rheumatology, la Paz University Hospital, Madrid, Spain; [4]Rheumatology, Whittington Hospital, London, United Kingdom; [5]Rheumatology, Cochin Hospital, René Descartes University, Paris, France; [6]Rheumatology, Leiden University Medical Center, Leiden, Netherlands*

Background: Portfolios are increasingly used in medical education. A portfolio may stimulate deep learning, deliver summative assessment and encourage reflection on clinical practice. A portfolio is seen as the key connection between learning at the organizational and the individual level.

Objectives: To (1) explore the perceptions of young rheumatologists about the use of a portfolio and to (2) study the barriers and facilitators when implementing a portfolio at a national and international level.

Methods: A survey was sent by email to all EMEUNET (Emerging EULAR Network) members. EMEUNET is a group of young rheumatologists and researchers within EULAR-member countries. Descriptive statistics were used to analyse initial data collected (Nov-Dec 2016). Weighted averages were calculated (i.e. mean in which each item being averaged is multiplied by a number (weight) based on the item's relative importance).

Results: 132 participants responded (64% female; mean age 33.5 years (SD 4.3 years); 34 countries). In total, 56.3% of participants were working as rheumatologists; 32.8% were rheumatologists in training. 49.6% of the participants indicated that a portfolio was already used by rheumatology fellows working at their institution; in 71.9% of these cases, this portfolio was also used at a national level. 50.4% of participants did not use a portfolio during their training; of these, 86.7% (strongly) agreed that a portfolio might be a useful tool.

Several barriers for successful implementation of a portfolio were identified by the participants. The main barrier was that a portfolio was not developed at a national level, and if developed at a national level, there were often no incentives to use it (Table 1). According to participants, the top 3 competencies that should be collected and reflected upon in the portfolio were (weighted average; importance 0 (not important) – 10 (extremely important)): practical skills (e.g. ultrasound) (8.2); correct use of diagnostics and therapeutic armamentarium (7.9); clinical skills (e.g. history taking) (7.8). The skills chosen as the least important to be included in a portfolio were: information on management tasks (6.5); promoting hospital-based care (e.g. writing a protocol) (6.6); theoretical and clinical knowledge (6.7).

Table 1. Perceived barriers with regard to the implementation of a portfolio.

Barrier	Response* (n = 122)
Participants who work/ed with a portfolio (n= 58)	
No incentives to use it	50.0%
Limited time	46.6%
Lack of clarity about how and when to use it	31.0%
Lack of interest by stake holders	29.3%
Difficult to access the required forms	12.1%
Participants who did not work/ed with a portfolio (n=64)	
Portfolio not developed on national level	51.6%
No added value recognized to it	21.9%
Initiatives, but lack of clarity about how and when to use it	12.5%
Initiatives, but no incentives to use it	9.4%

*More than one answer allowed. 10 (7.6%) participants did not answer the question.

Conclusions: A portfolio is generally considered a valuable tool and half of the participants already work with it. However, several barriers may prevent optimal implementation. Developing a core set of rheumatology-oriented competencies and a template for a portfolio to be used across institutions and eventually countries could promote implementation and harmonize training.

THU0591 ASSESSING THE READABILITY AND PATIENT COMPREHENSION OF MEDICINE INFORMATION SHEETS PROVIDED TO PATIENTS BY AUSTRALIAN RHEUMATOLOGISTS

M. Oliffe[1], J. Johnston[2], D. Freeman[1], H. Bagga[1], P.K. Wong[3]. *[1]Mid-North Coast Arthritis Clinic, MNCAC; [2]Faculty of Education, Southern Cross University; [3]Mid-North Coast Arthritis Clinic, UNSW Rural Clinical School, Coffs Harbour, Australia*

Background: Literacy is "the ability to read and use written information and to write appropriately in a range of contexts".[1] Low literacy is associated with poorer health outcomes, including increased mortality.[2] Those accessing the healthcare system require adequate literacy to understand written instructions regarding medication, appointments and medication doses. We have previously shown in >200 rural and urban Rheumatology patients that <15% of patients had low health literacy and <1/3 of patients incorrectly followed dosing instructions for common Rheumatology drugs.[3] Up to 24% of US Rheumatology patients had a reading level of $\leq$8th grade.[4] These findings are concerning, as Rheumatologists often use medications such as MTX or bDMARDS with severe side effects. Rheumatologists often provide written information regarding these medications to patients.

Objectives: To assess i) the readability of Patient Medicine Information Sheets (PMIS) regarding medications provided to patients by Australian Rheumatologists, and ii) patient comprehension of these documents.

Methods: Thirty-one English-language PMIS from the Australian Rheumatology Association (ARA) website were assessed for readability using Readability Studio™ (Oleander Software). This software uses the number of sentences, words, syllables and characters in a sample of writing to estimate the required grade level and reading age of the target population using several readability scales (eg Flesch scale, Gunning Fog and Simple Measure of Gobbledygook, or SMOG).

To assess comprehension, a random sample of 100 patients from MNCAC was asked to read an ARA PMIS about one of the following medications: MTX, NSAIDS, Adalimumab, Abatacept or prednisone. He/she then answered five multiple choice questions about the content. A time limit of 15 minutes for reading the PMIS and answering the questions was allowed.Approval was obtained from the local HREC as a low/negligible risk project. Results are expressed as mean ± sem.

Results: The mean Flesch scale value (range 0–100, 0=very confusing; 100=very easy) of the 31 PMIS assessed was 51.1±0.6 (fairly difficult). The mean FORCAST grade level and reader age was 11±0 and 16–17 years, respectively. The mean Gunning Fog grade level was 11.4±0.1 with a reader age of 16–17 years. The mean SMOG grade level was 11.8±0.1 with a mean reader age of 16–17 years. At time of writing, comprehension was assessed in 7 of the planned 100 patients. So far, the mean number of correct answers was 3.2±0.5 (max. score of 5).

Conclusions: The ARA PMIS are suitable for readers who have completed a grade level $\geq$11 with a reading age $\geq$16 years. A low literacy population (< grade 8) will probably struggle to understand the content. These findings need to be extended to the PMIS used in other countries and has implications for the design of better patient information material.

THU0592 DO JUNIOR DOCTORS PRESCRIBE DISEASE MODIFYING ANTI RHEUMATIC DRUGS SAFELY?

M.K. Nisar[1], H. Weller[2]. *[1]Rheumatology, Luton & Dunstable University Hospital; [2]Rheumatology, Luton, Luton, United Kingdom*

Background: Patients with rheumatic diseases occupy over 50,000 bed days annually in the National Health Service. Adverse drug events are major causes of harm to patients in hospitals and are associated with prolonged length of stay with higher costs. National Patient Safety Agency has issued several alerts regarding DMARDs and Methotrexate overdose remains a "never event". Prescribing medications, including DMARDs for rheumatology patients, is one of the chief responsibilities of junior doctors.
Objectives: We undertook a pilot survey of junior doctors and medical students to understand their level of prescribing confidence with an aim to develop a teaching program.
Methods: Following a focus group discussion based on NPSA safety alerts and BSR DMARD monitoring guidelines, ten items were unanimously identified as core knowledge required for safe prescribing. A questionnaire was created based on these elements. Junior doctors and final year medical students were surveyed at our academic institution. Replies were compiled to ascertain their understanding of safe prescribing and troubleshooting DMARD related issues.
Results: 41 junior doctors of all grades and nine medical students contributed to the survey. Only 6/50 (12%) felt confident in prescribing whereas 16/50 (32%) had borderline confidence and remaining 56% felt it was beyond their expertise. Of the 41 junior doctors, 19 (46%) had never even prescribed DMARD despite encountering such patients on the wards. Principal reasons for this included lack of confidence (40%), paucity of knowledge (15%) and no formal education (32%). Questions pertaining to safe prescribing were confidently answered by only 4/50 (8%) participants.
Conclusions: To our knowledge, this is the first survey to demonstrate that there are serious shortcomings in junior doctors' understanding of safe DMARD prescribing. Inadequate training and hence poor confidence among front line medical staff remains the main cause of this issue. Despite consistent evidence suggesting that rheumatology teaching in medical schools has historically been poor and active measures taken in recent past to identify better ways to address the issues, this study highlights major knowledge gaps among everyday and future prescribers. Focused strategy and better training of junior doctors, both during and after graduation, are pivotal to providing better care for patients prescribed DMARDs during inpatient hospital stay.

THU0593 QUALITATIVE ASSESSMENT OF US-GUIDED INJECTION VIDEOS PUBLISHED ON VIDEO SHARING PLATFORMS

S.H. Bourdaim, C. Darrieutort-Laffite, Y. Maugars, B. Le Goff. *Rheumatology, University Hospital of Nantes, Nantes, France*

Background: Ultrasound (US) guided injections are becoming widespread in the treatment of rheumatic articular disorders. US allows a real time assessment of the needle progression and increase the accuracy of the injection. Video sharing platforms can be sources of information and learning material for healthcare professionals as for patients.
Objectives: We conducted this cross-sectional study to assess the quality of educational resources on US-guided articular and periarticular injections published on video sharing platforms.
Methods: YouTube, Dailymotion and Vimeo were searched using predefined keywords on US-guided shoulder, elbow, wrist, hand, hip, knee, ankle, and foot injections. The videos were classified according to their source. We determined the injection site and the explanations shown for each site. We collected information on patient positioning, equipment, needle, ultrasound settings and teaching material used by the author. When demonstration was performed live in patient, the compliance with the rules of asepsis and the accuracy of the injection were evaluated. Overall, videos were evaluated for quality on a 5-point ordinal global quality scale (GQS) (from 1 = poor quality to 5 = excellent quality). Results are given as median (min-max).
Results: We found 69979 results with the keywords. We screened 2802 videos by titles and included 153 videos (10.05 hours). Most of videos were published on Youtube (92.2%) and 82.4% included oral explanation. 53.6% videos were published by medical advertisement or profit companies and only 9.2% videos by university, professional organization or physician group. Among the 41.2% videos showing live demonstration of injection on the patient only 25.4% followed the strict rules of asepsis. When the videos included US cineloops of injection, 10.4% of them were outside the target. Very few videos gave details about information on the pathophysiology of the disease (6.5%), the risk (0.7%), the benefice (11.2%) or the products used for the injection (58.2%). Overall, 3.3% of the videos were classified as "Excellent quality" on the GQS, 24.2% as "Good quality", 23.5% as "Moderate quality", 34.6% as "Generally poor quality" and 14,4% "Poor quality". We compared the characteristics of the good quality videos (GQS score $\geq$4) versus the one rated $\leq$3. Better quality videos were longer (1.3 min ((0.07–1.05) versus 3.62 (0.32–40.43) min), had oral explanation (95% versus 77%; p=0.008). They more frequently showed the clinical and US site of injection and accurately reached their target (90% versus 68%). They were significantly more viewed (m2719 (13–80195) versus 856 (11–60174); p=0.026) and more liked (1 (0–80) versus 7 (0–58) (p=0.002)). However, some poor quality videos had more than 60000 views. Quality of the video created by medical advertisement or profit companies were not different from those coming from university but significantly better than those from individual physician or with unknown origin (p=0.011).
Conclusions: Our study reveals a generally a low quality of US guided learning videos available on the most popular video sharing platforms. We observed a lack of information on the treatment, its risks and benefits. Strict aseptic techniques are rarely followed and the injection can be outside the target. Finally, we identified characteristics associated with the quality of the video that can be used to improve their educational impact in the future.

THU0594 DEVELOPING THE KOREAN LEEDS SATISFACTION QUESTIONNAIRE (KOREAN-LSQ) IN RHEUMATOID ARTHRITIS: A CROSS-CULTURAL VALIDATION USING RASCH ANALYSIS

S.-K. Cho[1], D. Kim[1], S.J. Cha[1], D. Yoo[1], S.-H. Kim[2], J. Hill[3], M. Ndosi[4], Y.-K. Sung[1]. *[1]Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul; [2]Department of Measurement and Evaluation of Physical Education, Chungbuk National University, Cheongju, Korea, Republic Of; [3]Harrogate, Harrogate; [4]Centre for Health and Clinical Research, University of the West of England, Bristol, United Kingdom*

Background: The Leeds Satisfaction Questionnaire (LSQ)[1] is a patient-completed questionnaire designed to measure satisfaction among patients attending a rheumatology outpatient clinic. It was originally developed in the UK and it comprises 45 items grouped into 6 subscales: general satisfaction, information, empathy, technical competence, attitude, access and continuity.
Objectives: To undertake cross-cultural adaptation and validation of the LSQ in RA for use in Korea.
Methods: The adaptation of the LSQ from English into Korean was established according to guideline of cross-cultural adaptation of self-report measures.[2] Patients with RA were then recruited from an outpatient clinic of a university hospital in South Korea and Cross-cultural validation of the Korean-LSQ was carried out by Rasch analysis using the WINSTEPS program. Model data fit was determined by Infit and Outfit statistics ($\geq$0.50 and $\leq$1.50). If the values of the Infit and Outfit are 1.00, the observed score perfectly fit the expected model. The unidimensionality of the scale was determined by separation index (SI $\geq$2.00) and reliability (RI $\geq$0.80).
Results: An adequate conceptual equivalence was achieved following the adaptation process. The dataset for validation comprised 125 patients, 103 (82.4%) of whom were female, mean (SD) age =47.2 (12.5) and disease duration =52.8 (69.4) months. Forty-item of the 45 items had acceptable fit statistics (individual item data not shown). The individual items overall had good separation index and reliability (SI =5.98 and RI =0.97). Analysis of the 6 subscales of the Korean-LSQ resulted in good fit to the Rasch model (Table 1), high internal consistency and unidimensionality (Person SI =2.31 and RI =0.84; item SI =5.44 and RI =0.97).

Table 1. Fit statistics for testlets

LSQ subscales (testlets)	Infit		Outfit		Point-biserical correlation
	MNSQ	ZSTD	MNSQ	ZSTD	PTMEA CORR.
LSQ_general	1.12	0.90	1.12	0.70	0.80
LSQ_information	1.05	0.40	1.05	0.30	0.64
LSQ_empathy	0.64	-3.30	0.59	-2.80	0.79
LSQ_technical competence	1.06	0.40	1.05	0.30	0.77
LSQ_attitude	1.06	0.50	0.91	-0.40	0.74
LSQ_access&continuity	1.05	0.50	1.08	0.60	0.76

MNSQ = mean-square; For model fit: MNSQ lie within $\geq$0.50 and $\leq$1.50).

Conclusions: Fit to the Rasch model confirmed that the construct validity, reliability, and unidimensionality of the Korean-LSQ were preserved after the adaptation process. The Korean LSQ is a valid and reliable tool for measuring satisfaction with care among patients with RA in South Korea.

THU0595 THE VIEWS AND PERCEPTIONS OF NON-SPECIALIST, HOSPITAL JUNIOR DOCTORS ON JOINT ASPIRATION OF THE ACUTE HOT-SWOLLEN-JOINT, AND THEIR TRAINING IN THIS CLINICAL SKILL

Z. Farah. *Rheumatology, Imperial Healthcare Trust, London, United Kingdom*

Background: BSR guidance on managing hot-swollen-joints recommends early joint aspiration (arthrocentesis) to rule out septic arthritis and avoid morbidity and mortality. In such patients, the initial assessment is often performed by junior doctors prior to specialist review. Previous audit suggests poor adherence to recommended guidance. Our previous quantitative survey in 2 hospitals found low self-reported confidence at managing hot-swollen-joints in 72 of 140 (52%) respondents; 58 (42%) participants reported inadequate exposure, and 43 (31%) inadequate training. There is limited research exploring the reasons behind poor uptake of arthrocentesis by junior doctors.
Objectives: To determine the perceptions of junior doctors about joint aspirations, their training to perform this important skill and how training could be improved
Methods: The focus group included two foundation doctors, two senior house-officers and two registrars. Focus group questions were developed from themes that emerged from our previous quantitative survey. The session was recorded using an iPhone, then anonymously transcribed verbatim. The transcript was analysed using an emergent coding technique drawn from grounded theory approach. The data was coded over three passes.
Results: Decision to aspirate a joint appeared to be influenced by internal and external factors. Internal factors included their previous experience, which was variable with one who *"did 7 aspirations"* and another who *"[had] not had any experience at all."* Other factors like anatomical knowledge, level of seniority and prior training were presented. Negative emotions emerged with participants using words like *"weary"*, *"anxious"* and *"scary"*, particularly *"fear of serious consequences"* when describing joint aspiration.
External factors included procedure-related factors like technical difficulty, and the type of joint to be aspirated. Consensus suggested that all joints except the knee should be left to the specialist. Context-related factors included time constraints. The group emphasised the importance of recurrent exposure and opportunity to practice aspirations. Availability of supervision influenced the decision to aspirate, particularly if by the rheumatologist.
Training in arthrocentesis appeared to be inconsistent. Positive comments included succinct dedicated training experiences by an expert using simulation, immediate feedback followed by practice. Negative comments emerged such as training was inconsistent and of poor timing, or trainees lacked the opportunity to subsequently practice. Participants then proposed methods of how to improve training in arthrocentesis.
Conclusions: The decision to aspirate is a complex interaction between internal and external factors combining knowledge, attitudes and emotions with circumstances and context. The participants emphasise training in knee aspirations, but not other joints due to lack of exposure. Immediate feedback during training in arthrocentesis is key. Inability to continue regularly practicing the procedure in real patients may be a barrier to retaining the skill. A review of training in joint aspiration may be required in order to improve uptake of this skill in practice.

THU0596 RHEUMATOLOGY SPECIALTY TRAINING IN EUROPEAN UNION COUNTRIES

N. Cikes[1], J. Dudler[2], F. Lioté[3], D.E. Bax[4], N.D.S. Bax[4] on behalf of UEMS Rheumatology Section and Board Union Européenne des Médecins Spécialistes, Avenue de la Couronne 20, Bruxelles 1050. *[1]University of Zagreb School of Medicine, Zagreb, Croatia; [2]Department of Rheumatology, HFR Fribourg – Hôpital Cantonal, Fribourg, Switzerland; [3]Rheumatology Department, Univ Paris Diderot, Inserm UMR 1132, Hospital Lariboisière, Paris, France; [4]The Medical School, University of Sheffield, Beech Hill Road, Sheffield, United Kingdom*

Background: The Union of European Medical Specialists (UEMS) seeks through its speciality Sections and Boards (S&B) to enhance the training of its doctors and to encourage and support the movement of doctors between countries. The Rheumatology S&B has delegates from all EU countries and has developed a document (European Training Requirements (ETR) – at uemsrheumatology.eu) that provides guidance about the rheumatology curriculum.
Objectives: To determine:
1. The extent of use of the Rheumatology ETR by EU countries
2. The extent of use of logbooks in recording the progress of a trainee
3. If training centres are accredited
4. If national assessment programmes exist for trainees
5. If a country has quality assurance and enhancement processes in rheumatology training

Methods: A questionnaire was sent to all S&B members asking questions in relation to all of the objectives with one follow-up questionnaire to non-responders. Verification of responses as well as obtaining responses from continuing non-responders occurred in December 2016.
Results: Nineteen countries responded. Most (18/19) have developed and implemented their own curriculum, often with the influence of the ETR, and also are using a logbook to record the progress of trainees. Training Centres are required to undergo accreditation in 15/19 countries. Another three countries are planning to introduce this. One country does not have an accreditation programme. After accreditation only 8 countries have quality assurance (QA) and enhancement (QE) programmes. In one of these countries the QA and QE processes are variable. Two other countries are either discussing or developing such processes. In 14 countries trainees are assessed to determine their suitability to become specialists. In one of these countries the approach is variable. Two other countries are planning to introduce assessments. Three countries do not assess their trainees.
Conclusions: Most EU countries have implemented their own, and varied, curricula for rheumatology training. All countries either use or are planning to use a portfolio, again variable in nature, to record trainees' progress. Thus, it appears that at present any pan-European standardised curriculum or logbook will be of limited utility.
Most countries require training centres to undergo accreditation. However, less than half of the countries have a continuation of quality assurance or quality enhancement processes after accreditation with some countries it seems having no plans to do so.
At present, a specialist in one European country is required by European law to be recognised as such in another. This study did not determine the nature of the assessments undertaken in different countries but this is not of current relevance within Europe as regards the possible movement of a doctor from one country to another for professional reasons.

THU0597 FLIPPED LEARNING: CAN RHEUMATOLOGY LEAD THE SHIFT IN MEDICAL EDUCATION?

Y. El Miedany[1,1], M. El Gaafary[2], N. El Arousi[3], S.S. Youssef[3]. *[1]Rheumatology, Darent Valley Hospital, Dartford, United Kingdom; [2]Community and Public health; [3]Rheumatology and Rehabilitation, Ain Shams University, Cairo, Egypt*

Background: Flipped Classroom is a model that is quickly gaining recognition as a novel teaching approach among health science. Flipped learning turns the usual teaching model on its head. The idea is that students learn new content outside the classroom (usually online) and then tackle assignments in lessons, giving tutors more time to help them with aspects they don't understand.
Objectives: 1. to implement a flipped classroom teaching for rheumatology topics for both under and postgraduate education. 2. to evaluate outcomes of teaching using a post-flipped classroom assessment and a student perceived effectiveness and satisfaction questionnaire.
Methods: Ten online videos on topics of how to take rheumatology history, individual joint examination, handling cases of monoarthritis and polyarthritis, and metabolic bone disease were made available for the students. 39 undergraduate 35 postgraduate trainees were included in this educational activity. The students were exposed to online lecture content prior to the class-time active learning session. The teaching session adopted an interactive learning environment and the course instructor served as a facilitator rather than a dominator for the instructional process, provided in-class applied learning opportunities and offered timely feedback/guidance to students. Evaluation of the teaching session was assessed using a scenario based learning and an evaluation check list. The students were asked to complete a questionnaire based on a 5-point Likert scale: 1 (strongly disagree) to 5 (strongly agree) to assess for their perceived effectiveness and satisfaction. The outcomes of the evaluation sheet and students' questionnaire, were compared to 40 undergraduate and 34 postgraduate trainees who were taught in the last year on the same topics in a lecture-based model using the standard teaching protocols, followed by scenario based learning sessions, student evaluation and satisfaction survey.
Results: There was no significant difference regarding socio-demographics between the 2 students' groups included in this study. Outcomes of the flipped learning revealed that 94% of the students viewed the videos prior to the class session, and 96% attended the education sessions in comparison to 86% attendance in the traditional teaching group. Students reported an increase in knowledge, a positive learning experiences and perceptions of the flipped classroom model. Students' perceived effectiveness and satisfaction scores were significantly higher among the flipped learning in contrast to the traditional teaching comparative group (4.9 vs 4.3, $p<0.05$). Similarly, analysis of the students' assessment scores after the scenario based learning sessions was higher in the flipped learning group compared to the students taught by traditional methods ($p<0.01$).
Conclusions: Implementation of the flipped learning for the rheumatology topics demonstrated a successful and promising platform for using technology to make better use of the students' time, and for increasing their satisfaction with the necessary didactic learning. Active learning increases student engagement and can lead to improved retention of knowledge.

THU0598 CAN YOU HEAR THE JOINTS CRYING? MUSCULOSKELETAL EXAMINATION IN JUNIOR DOCTORS' MEDICAL ADMISSION CLERKINGS

F.Y.H. Kwok, L.H. Lee, A. Gupta. *Nottingham University Hospitals NHS Trust, Nottingham, United Kingdom*

Background: Physical examination is an indispensable skill in the art of medicine which, together with history taking, enables physicians to achieve a clinical diagnosis. Previous studies have consistently shown wide variations in the documentation of physical examination findings on systemic review (1,2). In particular, musculoskeletal examination was found to be frequently omitted.
Objectives: The aim of this study was to evaluate the quality of junior doctors' medical admission clerking, with a focus on clinical examination.
Methods: Fifty acute medical admission clerking entries by junior doctors in a university hospital were reviewed. Case notes were assessed for clinical details and physical examination performed.
Results: Mean age was 69. The commonest presenting complaint was fall or collapse. Musculoskeletal examination was only documented in 24% of admitted patients. There was disparity in the quality of documentation, ranging from complete omission to comments such as "valgus deformity", "erythema", "limited abduction" and "unable to SLR". Overall, the documentation of cranial nerves examination, limb neurological examination, abbreviated mental test and Glasgow coma scale was less robust (40%, 52%, 48% and 66% respectively). The documentation of musculoskeletal and neurological examination contrasts markedly with other systems: respiratory system 100%, cardiovascular system 98% and abdominal system 98%.
Conclusions: The omission of musculoskeletal examination may reflect a general apathy towards musculoskeletal health. Despite fall or collapse being the most common reason for medical admission in this study, musculoskeletal examination was only documented in a minority of patients. With an aging patient population, it is vital for physicians to address musculoskeletal disorders which are likely to be more prevalent on the acute medical take. Junior doctors' lack of confidence in performing musculoskeletal examination may also be another contributing factor. It is important that junior doctors are provided feedback on their clinical assessment by senior doctors when essential components of examination are omitted. National training programmes should consider including these areas in postgraduate curriculum to ensure competency is achieved.

THU0599 BENEFIT RISK RATIO FOR BIOLOGICAL AGENTS IN JUVENILE IDIOPATHIC ARTHRITIS, A META-ANALYSIS OF RANDOMIZED CLINICAL TRIALS

N. Cabrera[1], P. Janiaud[1], A. Belot[2], B. Kassai[1,3], J.-C. Lega[1]. *[1]UMR 5558 CRNS Lyon; [2]University of Lyon 1; [3]Clinical Investigation Center/CIC 1407, INSERM, Lyon, France*

Background: The biological agents (BAs) have revolutionized the care and have improved the prognosis of juvenile idiopathic arthritis (JIA). Effectiveness and short-term tolerance was well established in randomized clinical trials (RCTs), initially in JIA. However, there is an insufficient evidence for the long-term tolerance[1]. The serious adverse events (SAEs) include infections, malignancies and drug induced auto-immune diseases (e.g. uveitis).
Objectives: To assess the benefit/risk balance of BAs assessed by RCTs vs placebo or vs standard treatment in JIA, using meta-analysis (MA) technique.
Methods: All RCTs in JIA comparing BAs to placebo or standard treatment (e.g. methotrexate) published between 1950 and February 2016 were eligible. Data source: Cochrane, Medline, ClinicalTrial.gov register. The ILAR classification for JIA[2] was used and the clinical efficacy of treatment was measured by the ACR pediatric score[3]. Efficacy was analyzed considering the design of study. Effectiveness (ACRpedi30) was estimated as the measure of the benefit of the BAs and SAEs as a measure of risk by random effect models. The benefit/risk balance was analyzed using the net efficacy adjusted for risk (NEAR)[4]. An OR >1 indicates that the treatment has a beneficial effect and OR <1 a deleterious effect. Subgroups analyses were made to account the heterogeneity of JIA. We explored potential heterogeneity by subgroups analysis according with BAs and JIA subtypes.
Results: We included 20 RCTs conducted in JIA encompassing 1533 children. The disease duration, at the inclusion of RCTs, varies between 2 and 6 years for most studies. The maintenance of the therapeutic effect was estimated in the studies using withdrawal design in 6 studies. The maintenance of clinical response showed a large heterogeneity. Sub-groups analyses showed that the heterogeneity is marked in the systemic JIA[5]. The global NEAR OR was in favor of BAs in parallel (OR 3.83, CI 1.49–9.82) and withdrawal (OR 2.75, CI 1.51–5.01) trials. The efficacy of BAs in JIA was superior to the placebo in parallel (OR 5.46, CI 2.26–13.21) and withdrawal (OR 3.52, CI 2.15–5.77) trials. In RCTs (parallel and withdrawal design), SAEs did not differ between BAs and control (OR 1.18, CI 0.73–1.9). No death occurred at follow-up.
Conclusions: This is the first MA assessing all BAs used in all JIA categories combined. This MA in patients with JIA shows that the benefit/risk ratio of BAs in JIA is favorable.

THU0600 CUMULATIVE ADVERSE CHILDHOOD EXPERIENCES ARE ASSOCIATED WITH POOR OUTCOMES IN ADULTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

K. DeQuattro[1], L. Trupin[1], P.P. Katz[1], C. Lanata[1], E.H. Yelin[1], L.A. Criswell[1], C.G. Helmick[2], M. Dall'Era[1], J. Yazdany[1]. *[1]Division of Rheumatology, University of California San Francisco, San Francisco; [2]Division of Rheumatology, Centers for Disease Control and Prevention, Atlanta, United States*

Background: Adverse childhood experiences (ACE) such as abuse, neglect and household challenges are associated with poorer adult health status and onset of rheumatic diseases. There has been no research associating ACE with outcomes among adults with systemic lupus erythematosus (SLE).
Objectives: To characterize relationships of ACE and health outcomes of disease activity, damage, quality of life and depression in SLE patients.
Methods: Data were derived from the California Lupus Epidemiology Study (CLUES), a population based, multi-ethnic cohort of patients with SLE. Participants completed self-report measures of SLE activity (Systemic Lupus Activity Questionnaire; SLAQ), damage (Brief Index of Lupus Damage; BILD), quality of life (SF-36), depression (Patient Health Questionnaire; PHQ8) and sociodemographics. They completed the Adverse Childhood Experiences (ACE) survey, a validated 10-item scale covering 3 domains (abuse, neglect and household challenges prior to age 18). We compared demographics and SLE outcomes by ACE score and domains using ANOVA.
Results: The 166 CLUES participants were mostly women (89%) and were racially/ethnically diverse (31% non-Hispanic White, 22% Hispanic, 15% African American, 31% Asian American). Mean age was 44±14; mean age at diagnosis 28±12. The median ACE score was 1; 30 (18%) had a score of 4 or higher. ACE scores $\geq$4 were more common in Hispanic (27%) and African American (32%) participants (p=0.01) compared to other races/ethnic groups, and in participants with poverty level incomes (61% vs 13%, p$<$0.001); but did not differ by education or age at study entry or diagnosis. Higher overall ACE scores were associated with greater SLE activity and damage, poorer quality of life, and higher levels of depressive symptoms. For each ACE domain, increasing scores were generally associated with worse outcomes, but did not always reach statistical significance (Table).

Table 1. SLE Outcomes by Adverse Childhood Event (ACE) Scores and Domains

	Score	n	Outcomes [mean (sd)]			
			SLAQ	BILD	SF36PCS	PHQ8
Total ACE score	0	66	6.0 (6.2)	1.7 (2.0)	46.0 (10.5)	4.3 (4.1)
	1	31	6.9 (5.4)	1.4 (1.5)	44.3 (8.5)	4.8 (4.0)
	2–3	39	11.2 (7.6)	1.7 (2.1)	41.0 (10.5)	7.8 (5.6)
	4+	30	11.8 (8.0)	3.0 (2.9)	38.1 (11.1)	7.3 (4.6)
		p-value	$<$0.001	0.02	$<$0.001	0.003
Household Challenges	0*	66	6.0 (6.2)	1.7 (2.0)	46.0 (10.5)	4.3 (4.1)
	1	33	9.1 (6.6)	1.8 (2.2)	42.3 (8.8)	6.3 (5.7)
	2+	24	11.5 (8.0)	2.4 (2.2)	40.3 (10.6)	7.6 (5.1)
		p-value	0.002	0.35	0.04	0.01
Neglect	0*	66	6.0 (6.2)	1.7 (2.0)	46.0 (10.5)	4.3 (4.1)
	1	33	11.6 (7.0)	2.4 (2.7)	37.7 (9.9)	8.1 (4.8)
	2+	24	9.8 (7.4)	1.6 (0.9)	42.2 (5.2)	6.4 (2.6)
		p-value	$<$0.001	0.33	0.001	$<$0.001
Abuse	0*	66	6.0 (6.2)	1.7 (2.0)	46.0 (10.5)	4.3 (4.1)
	1	26	10.1 (6.3)	1.7 (1.9)	38.8 (10.4)	8.1 (4.5)
	2+	26	13.9 (7.6)	3.0 (3.2)	37.5 (10.6)	6.9 (4.5)
		p-value	$<$0.001	0.04	$<$0.001	$<$0.001

*Zero-level excludes respondents with scores in other ACE domains.

Conclusions: Adverse childhood experiences are reported frequently in individuals with SLE; accumulation of adverse experiences is associated with poor SLE outcomes. Higher scores in each domain, especially childhood neglect or abuse, were associated with poorer health measures in adulthood. Further research regarding ACE patterns and SLE outcomes is warranted.

THU0601 CARDIOVASCULAR SCREENING AMONG PATIENTS WITH INFLAMMATORY ARTHRITIS: TO WHAT EXTENT DO PATIENTS FOLLOW RECOMMENDATIONS?

A.H. Kjeldgaard[1], K. Hørslev-Petersen[1], R.D. Christensen[2], J. Søndergaard[2], J. Primdahl[3]. *[1]King Christian X's Hospital for Rheumatic Diseases, Graasten; [2]Research Unit for General Practice, University of Southern Denmark, Odense; [3]King Christian X's Hospital for Rheumatic Disease, Graasten, Denmark*

Background: Patients with inflammatory arthritis (IA) have a substantially increased risk for cardiovascular (CV) disease and consequently regular screening is recommended (1).
Objectives: To investigate whether patients with known IA and high CV risk follow the recommendation, given in a nurse-led CV risk screening consultation, to consult General Practice in order to reduce their CV risk. Furthermore to investigate the influence of socioeconomic position and gender.
Methods: A register-based cohort study comprising outpatients at King Christian X's Hospital for Rheumatic Diseases, Graasten, Denmark, diagnosed with rheumatoid arthritis (RA), psoriatic arthritis (PsA) or spondylo arthritis (SpA), who had participated in at least one screening consultation based on the EULAR recommendations (1) between 1st of July 2012 and 1st of July 2015. The primary outcome was a consultation with their GP and at least one intervention of relevance for CV risk within 3 months after the screening consultation.
Results: 1266 patients, 18–85 years of age, were included; 72.5% with RA and 27.5% with SpA or PsA. Of the 447 (35%) with high risk of CV disease, 60% consulted GP after the screening visit compared to 55% for the 819 patients with low risk of CV disease. Of the 60% of patients with high risk who consulted their GP, 41% had at least one relevant intervention. Education $\geq$10 years increased the odds for non-compliance (Odds Ratio [Confidence interval]) (0.72 [0.56;0.92], p=0.01) and age above 65 years increased the odds for compliance (1.50 [1.15;1.95], p=0.03). Income, diagnosis, gender, Low Density Lipoprotein level and systolic blood pressure did not significantly influence the odds to consult their GP after the screening consultation. Among high risk patients, 7.4% had their blood glucose checked at a GP consultation and 6.3% had their blood-pressure measured with at-home equipment after the screening consultation as opposed to 4.8% and 1% among low risk patients.
Conclusions: After a screening consultation, 40% of the patients with high risk of CV disease did not consult their GP at all in the following 3 months. At least 33% of the patients with high risk followed the recommendations to consult their GP and 27% consulted their GP for reasons not possible to clarify in this study. Only age and higher education had a significant influence on the outcome.

THU0602 WORKER PRODUCTIVITY LOSS REMAINS A MAJOR ISSUE FOR PATIENTS WITH INFLAMMATORY ARTHRITIS AND OSTEOARTHRITIS: RESULTS FROM THE INTERNATIONAL EULAR-PRO WORKER PRODUCTIVITY STUDY

S. Leggett[1], A. Bosworth[2], C. Hoffstetter[3], A. Boonen[4], D. Lacaille[5], C. Mihai[6], C. Talli[7], S. Hagel[8], G. Crepaldi[9], S. Ramiro[10], S. Dadoun[11], S. Verstappen[12,13] on behalf of EULAR-PRO at-work productivity co-investigators. *[1]Arthritis Research UK Centre for Epidemiology, University of Manchester, Manchester; [2]NRAS, Maidenhead, United Kingdom; [3]OMERACT, Ontario, Canada; [4]Division of Rheumatology, Maastricht University Medical Centre, Maastricht, Netherlands; [5]Arthritis Research Centre of Canada, University of British Columbia, Vancouver, Canada; [6]Internal Medicine and Rheumatology Clinic, Dr. Ion Cantacuzino Hospital, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [7]Rheumatology, East Tallinn Central Hospital, Tallin, Estonia; [8]Department of Clinical Sciences Lund, Section of Rheumatology, Lund University and Skane University hospital, Lund, Sweden; [9]Division of Rheumatology, IRCCS Policlinico San Matteo Foundation, Pavia, Italy; [10]Leiden University Medical Centre, Leiden, Netherlands; [11]APHP Pitie-Salpetriere Hospital, Department of Rheumatology, Paris, France; [12]Arthritis Research UK Centre for Epidemiology, University of Manchester; [13]NIHR Manchester Musculoskeletal BRU, Central Manchester Univ. Hospitals NHS Foundation Trust, Manchester, United Kingdom*

Background: Rheumatic and Musculoskeletal Diseases such as Inflammatory arthritis (IA) and osteoarthritis (OA) are one of the biggest causes of disability and worker productivity loss which has recently been recognized by European policy makers and the World Health Organization (WHO). However, limited information is available about job characteristics and the level of both presenteeism and absenteeism in employed persons with IA or OA across countries.
Objectives: To describe job characteristics and worker productivity loss in patients with IA and OA in Europe and Canada.
Methods: Patients with IA or OA in paid employment from seven countries within Europe and from Canada were recruited to the EULAR-PRO Worker productivity study. Patients completed a questionnaire including questions about their job, job characteristics and the Work Productivity and Activity Impairment Questionnaire (WPAI) measuring percent hours absent and the percentage their disease affected productivity while working (0–100%=disease completely prevented work). Patients also completed several health-related patient reported outcome measures, including: the Health Assessment Questionnaire (HAQ), Visual Analogue Scale (VAS) general well-being, and EuroQol-5D (EQ-5D).
Results: 503 patients were included in this large international study. Mean (SD) age was 47 (10) years, median [IQR] disease duration 12 [5, 21] years and 94% had IA. 42% had a predominately mentally demanding job, 10% physically demanding job, and 48% a combination; with overall 34% reporting their job being very demanding (see table for country specific results). Respectively 12% and 5% of patients were able to often or always postpone work tasks if need be, whilst, respectively 19% and 51% never or sometimes received help from colleagues which may depend on job/employment type and company size. Twenty-one% of patients reported that they missed time off work due to ill-health in the past week (median [IQR] % time missed due to ill-health 20% [9–50]). Interestingly, a total of 11% were unsatisfied with their current job; and 23% of patients did not disclose their disease to their employer.

# WPAI (0= condition no effect on work – 10=condition completely prevented work) * 100%.

Conclusions: This is one of the largest international studies investigating worker productivity loss in patients with IA and OA. It highlights the burden of the disease across countries and the importance of increasing awareness of rheumatological conditions in order to prevent presenteeism and long-term sick leave by providing the best available intervention to the individual patient in paid employment.

THU0603 DISEASE BURDEN OF KNEE OSTEOARTHRITIS PATIENTS UNDERGOING JOINT REPLACEMENT COMPARED TO MATCHED CONTROLS: A POPULATION-BASED ANALYSIS OF A DUTCH MEDICAL CLAIMS DATABASE

J.T.H. Nielen[1,2,3], A. Boonen[4], P.C. Dagnelie[1], B. van den Bemt[5,6], P. Emans[7], F. Lafeber[8], W.E. van Spil[8], F. de Vries[2,3], P. Welsing[8,9]. *[1]Epidemiology, Maastricht University; [2]Clinical Pharmacy & Toxicology, Maastricht University Medical Center, Maastricht; [3]Pharmacoepidemiology & Clinical Pharmacology, Utrecht University, Utrecht; [4]Rheumatology, Maastricht University Medical Center, Maastricht; [5]Pharmacy, Sint Maartenskliniek; [6]Pharmacy, Radboud University Medical Center, Nijmegen; [7]Orthopaedics, Maastricht University Medical Center, Maastricht; [8]Rheumatology & Clnical Immunology; [9]Julius Center, Utrecht University Medical Center, Utrecht, Netherlands*

Background: Knee osteoarthritis (OA) is a progressive joint disease generally associated with increasing pain. In severe symptomatic knee OA, knee prosthesis

(KP) can improve health-related quality of life. In the Netherlands, the incidence of KPs and KP revisions has increased, but health care costs related to these procedures over time and their determinants are unknown.[1]

Objectives: To provide estimates of age and sex-specific incidence of KPs, revision KPs, and prosthesis complications in patients with knee OA. To determine average annual health care costs of patients undergoing KP compared with matched controls in the Netherlands, and to understand drivers of costs.

Methods: All KPs in knee OA patients in the Achmea Health Database were identified and matched by age, sex, and region to a maximum of four controls. Incidence rates of KPs, KP revisions, and their complications (/1000 persons) from 2006–2013 were determined. Annual health care cost and excess costs compared to matched controls, preceding, during and after surgery were calculated and associated factors evaluated using longitudinal regression analysis.

Results: The incidence of KPs, KP revisions, and complications increased between 2006 and 2013. This increase was strongest in younger age categories and in men (Table 1). Annual health care costs slightly increased up to the year of surgery, with highest costs in the year of surgery. Post-surgery costs remained slightly higher than pre-surgery costs. High post-surgery costs were mainly associated with subsequent KPs. Other factors associated with high excess costs were younger age, female gender, and complications.

Table 1. Sex-specific incidence rates (per 1,000 person years) of all KPs, KP revisions, and complications associated with knee OA

	2006 IR	2007 IR	2008 IR	2009 IR	2010 IR	2011 IR	2012 IR	2013 IR

THU0604 THE ASSESSMENT OF THE DUTCH QUALITY REGISTRY RHEUMATOID ARTHRITIS QUALITY INDICATORS IN THREE PILOT HOSPITALS

S. Mahmood[1], L. van Tuyl[1], P. van Riel[2], S. Rongen[2], D. van Schaardenburg[1], C. Allaart[3], R. van den Berg[3,4], H. Moens[5], R. Landewé[1]. *[1]Amsterdam Rheumatology and immunology Center, Amsterdam; [2]Bernhoven, Uden; [3]LUMC, Leiden; [4]Erasmus MC, Rotterdam; [5]Ziekenhuis Groep Twente, Almelo, Netherlands*

Background: While practical guidelines and recommendations play an important role in the treatment of RA, rheumatologists often tend to deviate from these guidelines (1). This may result in disparity of quality of care among individual doctors and hospitals. To establish the best possible care, quality measures are needed. These aim to quantify the quality of the delivered care and will form the foundation of quality registries. Standardization of care processes in combination with public reporting of performance (by means of a quality registry) has been suggested to improve quality of care (2).

Objectives: To develop feasible quality indicators (QIs), endorsed by the different stakeholders of the Dutch Quality registry Rheumatoid Arthritis (DQRA).

Methods: An expert group of 8 rheumatologists, 2 patient representatives and 1 healthcare insurer representative developed a minimal set of QIs via a Delphi-like procedure (3), endorsed by the Dutch Society for Rheumatology. Since October 2015, these QIs have been registered by rheumatologists and rheumatology nurses, once a year in 26 hospitals, along with a patient evaluation questionnaire regarding the received care. To determine whether it is feasible to collect these QIs in daily practice, retrospective data from three hospitals was obtained (hospital A (university), B and C (non-academic)).

Feasibility was determined by evaluation of:

1. Completeness of registered data (figure 1)
2. Possibility to calculate disease activity categories (remission, low-high disease activity)
3. Possibility to calculate changes over time in disease activity categories
4. Extraction of data regarding (b)DMARD use

Results: Selected QIs are:

1. Percentage of patients in a certain disease activity category
2. Percentage of patients using a certain (b)DMARD
3. Patient reported experience with received care

Hospital B provided only data from one year (2014) and was not able to extract data on medication from their electronic record system.

Table 1. Assessment of feasibility of the DQRA QIs

Disease activity category				
Indicator (DAS28)	Hospital A (n=791)	Hospital B (n=1395)	Hospital C (n=822)	Mean
Remission	43.6%	45.1%	63.6%	50.8%
Low disease activity	16.3%	15.2%	14.1%	15.2%
Moderate disease activity	32.8%	30.1%	19.1%	27.3%
High disease activity	7.3%	9.6%	3.2%	6.7%
Changes over time in disease activity categories (2014–2015)				
Indicator (DAS28)	Hospital A (n=415)	Hospital B	Hospital C (n=653)	Mean
Stable over time	48.7%	N.A.	58.8%	53.8%
Decreased in disease activity category	24.8%	N.A.	17.9%	21.4%
Increased in disease activity category	26.5%	N.A.	23.3%	24.9%
DMARD use				
Indicator	Hospital A (n=1081)	Hospital B	Hospital C (n=1105)	Mean
sDMARD monotherapy	41.2%	N.A.	51.6%	46.4%
sDMARD combination therapy	29.4%	N.A.	27.8%	28.6%
bDMARD	29.4%	N.A.	16.0%	22.7%
No DMARDs	0%	N.A.	4.7%	0%

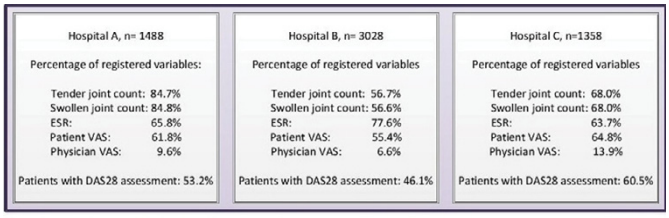

Figure 1: completeness of registered data

Conclusions: The DQRA is the first to incorporate perspectives from three stakeholders (patients, physicians and healthcare insurers) and successfully formed a limited set of QI. Collection of these indicators was feasible in two out of the three participating hospitals and offers insight in differences in provided and perceived care for RA patients.

THU0605 IMPACT OF NON-PERSISTENCE TO SUBCUTANEOUS TNF-ALPHA INHIBITORS ON MEDICAL RESOURCE UTILIZATION AND COSTS

M. Belhassen[1], F. Tubach[2], C. Hudry[3], M.-C. Woronoff[4], L. Levy-Bachelot[5], L. Lamezec[5], E. Van Ganse[1], B. Fautrel[6]. *[1]Hesper 7425, Health Services and Performance Research, University Claude Bernard Lyon 1, PELyon, Pharmacoepidemiologie Lyon, Lyon; [2]APHP, Hôpital Pitié-Salpêtrière, Département de Biostatistiques, Santé publique et Information médicale, APHP, Centre de Pharmacoépidémiologie (Cephepi); INSERM, UMR 1123 ECEVE; Université Pierre et Marie Curie Paris 6, Sorbonne Universités; [3]AP-HP Hôpital Cochin, Paris; [4]CHU Besançon, Université Franche-Comté, Comue Ubfc, UMR INSERM 1098, Besançon; [5]Merck Sharp & Dohme, Paris, France; [6]Sorbonne Universités, UPMC Univ Paris 06; AP-HP, Rheumatology Department, Pitié Salpétrière University Hospital, Paris, France., Paris, France*

Background: Biotherapies such as subcutaneous tumour necrosis factor-alpha inhibitors (SC-TNFis) have transformed the management of rheumatoid diseases. The assessment of SC-TNFis non-persistence and its impact on medical resource utilization and costs are needed.

Objectives: The objective was to assess the impact of non-persistence to subcutaneous TNF-alpha inhibitors on medical resource utilization and costs, for patients initiating treatment with an SC-TNFi in France.

Methods: The Système National d'Information Inter-régime [French national health insurance scheme information-sharing system] (SNIIRAM) database lists all outpatient and inpatient healthcare consumption for individuals covered by the general health insurance scheme. Using French claims data, conditions were diagnosed using Long Term Disease status and hospital admission, based on ICD-10 codes of rheumatoid arthritis, psoriatic arthritis and ankylosing spondylitis. Patients were then identified through first-line prescription filled for adalimumab (ADA), etanercept (ETA), certolizumab pegol (CZP) and golimumab (GLM) between 2012/07/01 and 2012/12/31. 12-months persistence status was

Abstract THU0605 – Table 1. Comparison of overall costs between persistent and non-persistent patients (n=1,575)

	Mean cost/patient (SD)			P-value
	Persistent	Non-persistent	Difference (persistent – Non persistent)	
Drugs costs	10,726.29 (6,285.74)	7,443.47 (10,199.31)	3,282.82 (-3,913.57)	<0.0001
Biotherapies	9,520.45 (3,601.16)	3,807.88 (4,887.48)	5,712.57 (-1,286.32)	<0.0001
Others	1,205.84 (5,596.59)	3,635.59 (9,818.49)	-2,429.75 (-4,221.89)	<0.0001
Non-drugs costs	3,066.42 (4,765.38)	4,658.24 (6,330.43)	-1,591.81 (-1,565.04)	<0.0001
Including sick leave compensations	525.00 (2,029.22)	1,162.55 (3,309.37)	-637.55 (-1,280.15)	<0.0001
Hospital admissions	1,234.64 (3,957.32)	3,712.15 (7,124.84)	-2,477.50 (-3,167.52)	<0.0001
Total cost	15,027.36 (10,268.24)	15,813.86 (16,976.21)	-786.50 (-6,707.97)	0.0495

estimated with Kaplan Meier analysis. A patient was considered as non-persistent in the event of a prolonged interruption of the therapy during 91 days or more. Persistent and non-persistent patients were compared, after a 1:1 propensity score matching, in term of medical resource utilization and costs (from a National Health Service perspective) in the subsequent 12-month period.

Results: Among 3,804 patients initiating treatment with an SC-TNFi in France between 2012/07/01 and 2012/12/31, 2,133 were classified as persistent at 12 months and 1,671 as non-persistent. After the 1:1 propensity score matching, 1,575 patients were studied in each group. Persistent patients had a lower overall cost than non-persistent patients (-787€): persistent patients had higher costs for drugs (+3,283€), due to the cost of biotherapies, but had lower costs associated to non-drugs (-1,592€) and hospital admissions (-2,478€).

Conclusions: The results indicate that persistence to treatment with SC-TNFi may be associated with cost offsets in terms of non-biologic costs, particularly for hospital admissions. However, as always the case with observational data, residual confounding factors could explain part of the results (e.g. disease severity).

THU0606 COGNITIVE DYSFUNCTION IN CONNECTIVE TISSUE DISEASES

A. Dima [1], L. Groseanu [1,2], A. Balanescu [1,2], D. Predeteanu [1,2], D. Opris-Belinski [1,2], A. Borangiu [1,2], D. Mazilu [1,2], V. Bojinca [1,2], R. Ionescu [1,2]. *[1] Internal Medicine and Rheumatology, Sf Maria Clinical Hospital; [2] Department 5 - Internal Medicine, University of Medicine and Pharmacy Carol Davila, Bucharest, Romania*

Background: Several studies documented the presence of cognitive dysfunction in different rheumatologic autoimmune diseases, but the absence of standard criteria of diagnostic and of an index with patients in which this dysfunction occurs, makes the mentioned studies often lead to divergent conclusions.

Objectives: To evaluate the impact of four autoimmune diseases:Systemic Lupus Erythematosus (SLE), Rheumatoid Arthritis (RA), Systemic Sclerosis (SSc) and Ankylosing Spondylitis (AS) on patient cognition and to identify potential factors which lead to cognitive dysfunction occurrence in this diseases.

Methods: This is a case-control study that included randomly selected patients with SLE, RA, SSc and AS from a University hospital and a matched control group. Data collected included: demographics, patients' education and specific data related to disease (duration, activity scores: DAS284v for RA patients, BASDAI in patients with AS, SLICC/SLEDAI for SLE patients and EUSTAR score/Rodnan score for SSc patients, damage indexes, organ involvement, treatment) and comorbidities. Cognition was assesed using MoCA Test (Montreal Cognitive Assessment The Test). The data were then processed using SPSS 23 version software.

Results: The study group included 255 patients: 58 RA patients, 52 SLE, 70 SSc and 25 AS patients and 50 healthy matched controls.

In all groups of patients, cognitive dysfunction prevalence was higher than control group (RA-64.98%, SLE -57.69%, SS -44.29%, AS -35.72% vs. 24% in the control group).

The differences were statistically significant for the RA group (p=0.00), the SLE group (p=0.001), and the SS group (p=0.001).

For the RA group none of the items analyzed (demographics, disease characteristic, patient' education) showed a significant correlation with cognitive dyfunction.

The same lack of correlation was also noted in AS and SSc patients. For the SLE group the only variable analyzed with a significant impact statistically was the SLEDAI score over 12 (p=0.002).

Also, this study did not find a significant statistically association between the presence of antiphospholipid syndrome.

Cognitive dysfunction seems to be more frequent and severe in RA and SLE patients compared to AS patients (p=0.014, respectively p=0.05).

Conclusions: The results obtained in this study show that, indeed, cognitive dysfunction is an issue to be watched very carefully in patients with autoimmune diseases. The appearance of cognitive dysfunction has a negative impact on life quality of these patients, the pathophysiological mechanisms that contribute to it's appearance are intricate and difficult to isolate.

THU0607 RISK FACTORS FOR EARLY RETIREMENT IN SYSTEMIC SCLEROSIS

A.M. Gheorghiu [1,2], C. Vrancianu [1,2], C. Draganescu [1,2], R. Oneata [1,2], L. Macovei [1,2], M. Sasu [1,2], M. Milicescu [1,2], O. Olteanu [1,3], M. Speriatu [1,2], M. Bojincă [1,2], V. Stoica [1,2], C. Mihai [1,2]. *[1] Carol Davila University of Medicine and Pharmacy; [2] Internal Medicine and Rheumatology; [3] Cantacuzino Hospital, Bucharest, Romania*

Background: Systemic sclerosis (SSc) is a connective tissue disease characterized by skin and internal organs fibrosis, microvascular impairment and frequently by disability and early retirement.

Objectives: To assess employment status, risk factors for early retirement (ER) and the associations of ER with disease characteristics and with patients' health-related questionnaires (Scleroderma Health Assessment Questionnaire (SHAQ)) and hand function (Duruoz hand index (DHI)).

Methods: This study included patients with SSc according to the 2013 ACR/EULAR classification criteria, examined in our EUSTAR center from 11.2011 to 11.2016, who were under the legal age of retirement of in our country (62 years). Patients completed a work assessment questionnaire, the DHI and the SHAQ, as well as a full assessment as per the recommendations of EUSTAR.

Logistic regression was used to investigate the associations between employment status (outcome) and potential predictors (including socio-economic status, education, disease characteristics and health-related questionnaires).

Results: There were 66 patients (8 males, mean±SD age 49.1±9.3 years, 19 with diffuse cutaneous SSc (dcSSc), 46 with history of digital ulcers (DUs) and 23 with joint contractures) included. Forty-two patients lived in urban environments and 42 had higher education (high school or above).

Twenty patients were active professionally, whereas 46 were retired, of which 32 retired because of SSc. Of those active professionally, 8 had to do manual labor, 7 had to spend many hours at work standing and 3 had a cold or moist work environment.

Using logistic regression adjusted for age and gender, higher education was found to be highly associated with employment (OR (95% CI) 9.0 (1.5, 52.4)), whereas labor conditions (manual labor, stress) had no significant influence on employment status in our cohort. No association was found between employment status and disease characteristics or SHAQ and DHI questionnaires.

Conclusions: SSc is associated with substantial work disability and unemployment. Completing less education than high school was associated with early retirement.

THU0608 ASSOCIATION BETWEEN ALLOPURINOL DOSE-TITRATION AND SERUM URIC ACID LEVELS IN GOUT PATIENTS: US ELECTRONIC HEALTH RECORD DATA

A.-C. Fu [1], D.C. Taylor [2], D.S. Reasner [2]. *[1] Ironwood Pharmaceuticals, Inc., Cambridge, Ashmore and Cartier Islands; [2] Ironwood Pharmaceuticals, Inc., Cambridge, United States*

Background: Allopurinol is a first-line urate lowering therapy for patients with gout. The American College of Rheumatology guidelines recommend allopurinol dose-titration to maintain serum uric acid (sUA) levels <6 mg/dl.

Objectives: To understand allopurinol dose-titration relative to sUA levels.
Methods: This retrospective study used the de-identified Humedica electronic medical record database. The study included all sUA and allopurinol records among gout patients (ICD-9-CM: 274.xx) ≥18 years old with first gout diagnosis in 2007 – 2015. An episode was defined as an allopurinol initial dose (ID) prior to (closest) and titrated dose (TD) after (within 30 days) an sUA test. Dose-titration was categorized as an episode with a dose-change (up-titration: ID < TD; down-titration: ID > TD), or no-dose-change (ID = TD). For multiple different doses recorded on the same prescription date, the sum of doses was taken as daily dosage. Episodes were considered uncontrolled when sUA ≥6 mg/dl. Descriptive episode-level analyses were performed.
Results: Within 64,609 episodes, 57% of episodes were uncontrolled (sUA: 6 to <8 mg/dl: 38%; 8 to <10 mg/dl: 15%; ≥10mg/dl: 4%). Seventy-one percent of uncontrolled episodes were no-dose-change, 21% were up-titrated, and 7% were down-titrated. Within no-dose-change episodes, 51% were uncontrolled and lower doses corresponded to higher percentages of uncontrolled episodes (<100mg/day: 88%; 100mg/day: 70%; >100, <300 mg/day: 49%; 300mg/day: 38%; >300mg/day: 36%). Seventy-eight percent of dose-change episodes were uncontrolled, of which 100 to 300 mg/day (39%) was the most frequent dose titration. Overall, the most frequent TD was 300 mg/day (52%) followed by 100mg/day (36%), >100 – <300mg/day (8%), >300mg/day (3%), and <100mg/day (<1%).
Conclusions: Allopurinol dose is not generally titrated regardless of sUA control. This pattern suggests a need for active management of patients with gout with uncontrolled sUA including consideration of new treatment options in addition to allopurinol.

THU0609 REGIONAL DIFFERENCES IN HEALTH CARE UTILIZATION IN THE KHOALA COHORT, A FRENCH POPULATION BASED COHORT OF SYMPTOMATIC KNEE AND/OR HIP OA PATIENTS

A.-.-C. Rat[1,2], J.-H. Salmon[3], A. Saraux[4], C. Gard[5], F. Guillemin[1,6], B. Fautrel[7]. *[1]Ea 4360 Apemac, Lorraine Université; [2]Rheumatology, CHRU Nancy, Nancy; [3]Rheumatology, CHU Reims, Reims; [4]Rheumatology, la Cavale blanche University, hospital and université de Bretagne occidentale, Brest; [5]Pharmacy, Pitié Salpetrière hospital, Paris; [6]CIC 1433 Epidémiologie clinique, Inserm, CHRU, Université de Lorraine, Nancy; [7]Rheumatology, Université Pierre et Marie Curie (UPMC)-Paris 6 GRC-UMPC 08 (EMOIS), Paris, France*

Background: In hip and knee OA, one of the leading causes of global disability, recent population-based data of health care practices and utilization are scarce. Describing patterns of care of patients is important to adapt health care practices and guide interventions to optimize patients' use of health care services.
Objectives: The aim of the project was to describe health care utilization and associated factors of a representative sample of patients with knee or hip symptomatic OA.
Methods: The KHOALA cohort is a French population-based multicenter cohort of patients with symptomatic knee and/or hip OA, aged between 40 and 75 years old recruited between 2007 and 2009. The representativity of the cohort allows for generalizing the results
Results: Among the 878 patients, 609 (69%) were women, 222 (25%) have hip OA, 607 (69%) knee OA and 49 (6%) both hip and knee OA. Groll comorbidity index (0–18) was 3.1 (1.6). Radiographic K&L grades 2, 3 and 4 were 69.8%, 26.1% and 4.1% for hip OA respectively and 44.5%, 30.3%, and 25.2% for knee OA.
In multivariate analyses, increased pain was independently associated with increased number of patients using pain killers (non-opioids and weak opioids), symptomatic slow-acting drugs or steroid injections but not NSAIDs. Increased age or being retired was associated with increased use of non-opioid drugs or decreased prescription of NSAIDs but not with opioid drugs. Weak opioid drugs were more frequently used by patients with low than high education and by those consulting a rheumatologist. The geographical effect was important, independently of the symptoms, with OR=0.3 (95% CI 0.2–0.7) and OR=0.5 (95% CI 0.2–0.9) for south vs north/east and west vs north/east respectively for weak opioids use with the same trend for non-opioids use. On the opposite, physiotherapy was more frequently prescribed in the south than in the north OR=2.1 (95% CI 1.3–3.5). More patients consulted a rheumatologist in large (>50,000) than small cities (<2,000) OR=2.8 (95% CI 1.6–5.1) but this was not the case for orthopedic surgeons consultations. Pain was not independently associated with consultations with the different health care professionals. Instead the number of patients consulting different health care professionals increased with functional impairment. Consulting an orthopedic surgeon was less frequent for patients with more comorbidities, retired, with decreased vitality or who also did not consult a rheumatologist.
Conclusions: Even if symptoms and patients characteristics are strongly associated with treatments use and health care professional consultations, regional or rural vs cities differences are important independently of pain, function or other quality of life domains. Whether these differences are due to health care professional prescriptions or patients life style and behaviors are still to be explored.

THU0610 RHEUMA SPACE: STANDARD PRACTICE AIMING CLINICAL EXCELLENCE IN RHEUMATOLOGY

C. Macieira[1], L. Cunha-Miranda[2], P. Nero[3], P. Lucas[4], J. Eurico da Fonseca[1,5], J. Canas da Silva[6] on behalf of Rheuma Space study group. *[1]Department of Rheumatology, Centro Hospitalar Lisboa Norte; [2]Department of Rheumatology, Instituto Português de Reumatologia; [3]Department of Rheumatology, Hospital CUF Descobertas, Lisbon; [4]QuintiliesIMS, Porto Salvo; [5]Faculdade de Medicina da Universidade de Lisboa, Lisbon; [6]Department of Rheumatology, Hospital Garcia de Orta, Almada, Portugal*

Background: The quality of medical care and the implementation of measures to improve it are crucial steps for the development of Rheumatology in Europe. Quality indicators were obtained through a four-step rand-modified Delphi methodology. A final set of 26 quality indicators was defined within Donabedian framework dimensions: 9 "structure", 11 "processes" and 6 "outcomes" indicators. Herein we describe the second implementation phase of a national program, Rheuma Space (RS), aiming at quality improvement in Rheumatology.
Objectives: To develop a quality improvement plan for care provided by Rheumatology Departments (RD). In this second phase we present the results of the RD evaluation.
Methods: A measurement scale on quality/excellence thresholds was developed for each of the 26 criteria. Eight RD participated in the project and each one set up an Investigation Team of 2–3 members for field criteria measurement and evaluation that required the use of different data sources and focused on the period: 2014 – 1st semester of 2015. After data analysis an individual report was delivered and discussed with each of the 8 RD. Afterwards public presentation and discussion of the results took place.
Results: "Structure" was evaluated in terms of personal, training, facilities, equipment and budgeting:
- RD lack Rheumatology specialists and need fully dedicated nurses
- Training plans exist in all RD, but physicians allocate few time to research
- Equipment is appropriate, nonetheless microscopes and computers could be updated
- Internal contracting is well established and professionals are committed to targets

"Processes" were evaluated in terms of access and medical care, clinical records, physician-patient communication and multidisciplinary patient management:
- Triage criteria for first appointments should be standardized, despite compliance for "High Priority" patients
- Follow up could be more frequent, but direct access in emergencies is guaranteed
- Reuma.pt registry is mainly used for patients under biologics and data completion could improve
- Multidisciplinary care is provided, but patient coverage and specialty diversity can increase.

"Outcomes" were evaluated in terms of clinical outcomes, patient and personal satisfaction:
- Average working absence is <15days/patient/year, but is much higher in more affected patients
- Almost 1/3 of patients requested early retirement at a median age >50years
- Patients are satisfied with provided care and physicians' attitude, but less with RD facilities
- Professionals are satisfied with working environment, however criticize career related aspects.

Conclusions: The 26 quality indicators set the basis of this quality management tool that was applied to 8 Portuguese RD. Strengths and weakness were identified and an individual Department report was elaborated and discussed. Interventions are now being planned based on these results in order to ensure quality standards of structure and process criteria for a patient oriented clinical practice, favouring desirable continuous quality improvement on health outcomes.
Acknowledgements: Investigation Teams from the eight Rheumatology Departments that participated in the Rheuma Space Project.

Olivieri[7], G. Paolazzi[12], R. Perricone[5], N. Romeo[20], A. Ruffatti[8], M.G. Sabbadini[4], C. Salvarani[11], C. Selmi[4], L. Sinigaglia[4], A. Tincani[1]. *[1]-, Brescia, Italy; [2]-, Coimbra, Portugal; [3]-, Perugia; [4]-, Milano; [5]-, Roma; [6]-, Foggia; [7]-, Matera-Potenza; [8]-, Padova; [9]-, Genova; [10]-, Ferrara; [11]-, Reggio Emilia; [12]-, Trento; [13]-, Pavia; [14]-, Pisa; [15]-, Bologna; [16]-, Bolzano; [17]-, Catania; [18]-, Ancona; [19]-, Bergamo; [20]-, Cuneo, Italy*

Background: Rheumatic diseases (RD) affect women during reproductive age. Children's outcome is a major topic for counselling on family planning, but no large studies are available.
Objectives: We aimed at assessing the long-term health conditions of children born to mothers with RD through a self-reported questionnaire.
Methods: 24 Rheumatology Centers distributed the questionnaire (65 multiple choice and 12 open-answer questions) to consecutive women with RD attending their outpatient clinic during September 2015. Data were compared according to maternal diagnosis (MD) -chronic arthritis (CA) or connective tissue disease (CTD)- and to the timing of pregnancy (before or after MD of RD).
Results: The survey yielded data about 269 children born to 184 mothers (63 CA, 121 CTD). According to MD, children had a mean age of 17.1 (±9.6 SD) and 14.4 (±9.0 SD) years at the time of interview, and male children were 52/93 (56%) and 91/176 (52%), respectively. Twenty-nine children in the CA group (31.2%) and 64 in the CTDs group (36.4%) were born after MD of RD. Pre-term delivery (before 37 weeks) was observed in 48 cases (17.8%), mostly children born to mothers with CTD (37/48, 77%).
Regarding school performance, 12 children (4.5%) repeated one year of school, in 7 cases for indolence, in 3 for learning disabilities (LD)/health problems (HP), in 2 for family problems. Eleven of these children were born before MD. Overall, 9 children (3.3%) were diagnosed with a LD and 53 children were affected by HP requiring either hospitalization or evaluation by a Specialist (Table). Three children (1%) were affected by autoimmune disease.

269 children born to mothers with RDs	Children born to women with CA (n=93)	Children born to women with CTDs (n=176)
LEARNING DISABILITIES AND NEURODEVELOPMENTAL DISORDERS n=9/269 (3.3%)		
BEFORE maternal diagnosis	1/64 (1.6%) 1 "slow learner" (1 SGA female)	4/112 (3.6%) 2 LD; 1 ADHD; 1 Autism Spectrum Disorder
AFTER maternal diagnosis *In utero* exposure: - to drugs - to maternal autoantibodies	0/29 (0%)	4/64 (6.3%) 3 LD; 1 ADHD n=3 (3 low dose prednisone; 1 azathioprine) n=4 (3 ANA, 2 anti-dsDNA, 2 anti-Ro/SSA, 2 aCL IgG)
HEALTH PROBLEMS (ACUTE AND CHRONIC DISEASES) n=53/269 (19.7%)		
BEFORE maternal diagnosis	12/64 (18.8%) 1 Juvenile Rheumatoid Arthritis; 1 Diabetes Mellitus type 1; 8 AD; 2 Pneumonitis	23/112 (20.5%) 1 Chronic Autoimmune Thyroiditis; 1 Early infantile epileptic encephalopathy; 1 perinatal death (respiratory distress); 3 CD; 5 AD; 4 acute disease*; 4 chronic disease*; 4 surgery
AFTER maternal diagnosis	3/29 (10.3%) 1 Trisomy 21; 1 Enterovirus meningitis; 1 CD+AD	15/64 (23.4%) 1 FUO; 3 CD; 5 AD; 1 acute disease*; 2 chronic disease*; 3 surgery

aCL: anti-cardiolipin antibodies; AD: Atopic Dermatitis; ADHD: Attention Deficit and Hyperactivity Disorder; ANA: anti-nuclear antibodies; anti-dsDNA: anti-double stranded DNA antibodies; CD: Celiac Disease; FUO: Fever of Unknown Origin; LD: Learning Disabilities (dyslexia, dyscalculia, dysgraphia); SGA: small for gestational age; *non-neurological, non-immunological, non-infectious conditions.

Conclusions: The long-term follow-up of children born to women with RD is reassuring of an outcome similar to that of the general pediatric population (GPP). Autoimmune diseases are not frequent. Problems seem to cluster in children born to CTD, especially after MD, with a higher frequency of LD (6.3% vs 2.5–3.5% of GPP), but no particular pattern of exposure to maternal autoantibodies nor drugs was observed.

THU0612 PROVIDING HEALTHCARE FOR THE POOREST IN EAST INDIA – A REPORT FROM A CHARITY INITIATIVE, SHAKUNTALA HOSPITAL

C.H. Brahe, U. Rydholm, M. Pikwer, K. Schreiber, C. Ståhl-Hallengren, B. Bylander, R. Dash. *The Indo-Swedish Rheumatology Foundation (ISRF), Malmø, Sweden*

Background: The region of Odisha in India has a population of over 40 million people and 45% are living in poverty. Approximately one percent of the population is affected by inflammatory rheumatoid diseases. In order to provide early diagnosis and adequate treatment initiation to prevent long term disability, patients require easily accessible basic health care and rheumatologists.
Accessible and affordable health care for patients with inflammatory diseases may not only improve disease diagnosis and management, but also improve their quality of life significantly
Objectives: The aim of our abstract is:
1) To raise awareness of the need of support for common rheumatoid diseases in the developing world
2) To present Shakuntala Hospital as an example of a successful charity initiative
Methods: The Indo-Swedish Rheumatology Foundation (ISRF) is an association of physicians whose main aim is to raise awareness, fundraise and to provide health care for patients suffering from inflammatory arthropathies. In order to bridge the gap between our advanced level of knowledge and treatment options in the western world and patients suffering from rheumatologic diseases in the Indian state Odisha we have established this unique association. ISRF, including Shakuntala Hospital, was founded in 2013 and has so far not only provided health care through diagnostic and treatment support, but also ensured patient education and physiotherapy. Health camps are organized in the peripheral communities in order to screen, diagnose and initiate first line treatment and refer these patients for follow-up care to Shakuntala Hospital for further treatments with disease modifying antirheumatic drugs (DMARD), disease monitoring and physiotherapy. Shakuntala Hospital is an example of a non-profit hospital with the aim to provide health care amongst the poorest areas in India.
Results: We have so far registered over 2,000 patients under our care, which includes patients registered in Shakuntala Hospital and in our peripheral care health camps. So far we have established outpatient care for patients with inflammatory arthritis in the districts of Balasore, Maurbhanja, Bhddark, Keonjhar, Jajpur districts of Odisa and Mednapur district of West Bengal and raised more than 32.000 Euro by ISRF from fundraising initiatives.
Inspired by a Swedish model our osteoarthritis (OA) school was founded in October 2016 providing 6 week training courses with the main focusing on patients with knee OA.
Furthermore, ISRF has increased awareness of skeletal fluorosis and provide a comprehensive focus with cleaning of drink water in co-operation with the Royal Technical High School in Stockholm.

Conclusions: Shakuntala Hospital is an example of a successful charity initiative in order to provide healthcare for the poorest patients in East India. Awareness needs to be risen in order to further foster future support for Shakuntala Hospital.

THU0613 EXPLORING THE IMPACT OF HEALTH STATUS AND WELL-BEING OF PEOPLE WITH INFLAMMATORY ARTHRITIS ON PRESENTEEISM IN THE WORKPLACE: A QUALITATIVE STUDY

C.J. Jones[1], K. Payne[1], B. Gannon[2], S. Verstappen[3]. *[1]Manchester Centre for Health Economics, The University of Manchester, Manchester, United Kingdom; [2]Mater Research Institute Chair in Health Economics, Centre for Business and Economics of Health, Brisbane, Australia; [3]Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, Manchester, United Kingdom*

Background: Presenteeism can be defined as the reduction in work performance due to ill-health at the workplace. Musculoskeletal conditions, including

inflammatory arthritis (IA), are one of the most common causes for presenteeism. There are no "gold standard" methods to identify, measure, or value the impact of presenteeism. Some evidence suggests the impact of presenteeism can be indirectly estimated using measures of health status and well-being.

Objectives: To explore whether selected measures of health status and well-being, commonly used in economic evaluations are conceptually useful to capture those aspects of IA that are associated with presenteeism.

Methods: A sample of individuals, aged 18 years and above, working in the UK with rheumatoid arthritis (RA), ankylosing spondylitis (AS), or psoriatic arthritis (PsA), was recruited via patient support groups. Semi-structured telephone interviews were designed to understand if, and how, RA, AS or PsA affects an individual's ability to work. Framework Analysis Methods were used and coding involved deductive and inductive approaches. A deductive approach was used to derive potential themes from measures of health status [EuroQol-5 Dimension-5 level (EQ5D-5L) and Short Form 6 Dimension (SF6D)], and well-being [(ICEpop CAPability measure for Adults (ICECAP-A)]. An inductive approach was used to generate other themes not captured by these measures.

Results: Twenty-two employed individuals with RA (n=10), AS (n=9) or PsA (n=3) were interviewed; 82% were female and, of the 22 patients, 23% had a manual job. The majority of interviewees explained that symptoms of the conditions increase levels of presenteeism, including: pain; stiffness; fatigue; emotional mental health; mental clarity. These symptoms make completing activities at work difficult, which, in turn, affects an individual's capability to maintain a successful career. The ICECAP-A was found to be a useful measure to capture the overall impact of presenteeism resulting from RA, AS or PsA. The SF6D and EQ5D were more specific measures capturing particular symptoms and activities that increase levels of presenteeism (see Table 1).

Table 1

	Measure		
Theme	ICECAP-A	SF6D	EQ5D
Achievement /Progress	x		
Decisions	x		
Energy	x	x	
Independence	x		
Mental Health	x	x	x
Mobility	x	x	x
Pain	x	x	x
Self-care	x	x	x
Settled /Secure	x		
Social Interaction	x		
Support	x		
Usual Activities	x	x	x
Vigorous Activities	x	x	

Two further themes were identified using inductive methods: mental clarity and feeling understood. The effect of mental clarity or feeling understood is not captured by any of the domains in EQ-5D-5l or SF6D. The ICECAP-A is potentially able to capture the impact of these themes in the respective domains ability to achieve and progress and ability to gain support.

Conclusions: This study suggests that three existing measures (EQ5D, SF6D, and ICECAP-A) were successful, in different degrees, to capture the impact of presenteeism that result from the aspects and symptoms of IA. Potentially, these measures may be used in economic evaluations to capture the impact of presenteeism.

THU0614 FIDELITY OF AN INTERVENTION TO INCREASE PHYSICAL ACTIVITY IN OLDER ADULTS WITH CHRONIC PAIN: ANALYSIS OF AUDIO-RECORDED CONSULTATIONS FROM THE IPOPP PILOT TRIAL

C. Jinks [1], J. Proctor [1], E.L. Healey [1], J. McBeth [2], C.A. Chew Graham [1] on behalf of iPOPP team. *[1]Research Institute for Primary Care & Health Sciences, Keele University, Keele; [2]Arthritis Research UK Centre for Epidemiology, University of Manchester, Manchester, United Kingdom*

Background: Physical activity levels are low in people >65 years and those with chronic musculoskeletal pain, yet increased physical activity can lead to reduced pain. Walking is acceptable to older people with pain, but interventions to increase walking in this population are untested. The iPOPP pilot trial investigated feasibility and acceptability of a walking intervention delivered by trained Health Care Assistants (HCAs) in 4 general practices in an individually randomised three arm trial (usual primary care, pedometer only and iPOPP, n=50 each arm). The iPOPP intervention comprised two consultations (1 week apart) and 8 weekly follow-up prompts (postcard, email or text).

Objectives: To investigate fidelity of the iPOPP intervention to inform design of a full-scale randomised controlled trial.

Methods: HCAs were asked to record 6 consultations (3 participants, first and second consultation). A fidelity checklist was developed (aligned to HCA training) and included activities expected (pedometer, user guide, walking diary, pain toolkit given; discussion of walking behaviour and barriers; action planning to develop walking goals; review of progress; positive feedback; revision of goals; relapse prevention strategies; and, preference for weekly prompts). Activities were scored as "Yes" (completed as intended), "partial" (some evidence), "No" (no evidence) or "NA" (not applicable). The checklist was applied to one recording (JP, CCG, CJ). Minor amendments clarified interpretation of checklist headings before application to 3 more recordings (JP, CCG). JP then scored remaining recordings (n=14).

Results: 3 HCAs recorded 18 consultations (9 first, 9 second). Most first consultations did not use the allocated 30 minutes (average 14 minutes). The pedometer, user guide, walking diary and pain toolkit were all given but there was a lack of explanation of the pain toolkit. Evidence of the benefits of walking on pain was well delivered (N=8), motivators to walk and goals were discussed in all 9, with goals set in 7. Barriers to walking were not always discussed (N=4) exploration of maintenance strategies lacking, especially with those patients who perceived themselves as already physically active. All HCAs arranged a second consultation within one week which were brief (average 6.5 minutes) and focused mainly on use of the pedometer. Patient goals were partially re-visited (N=7) and barriers to walking partially addressed (N=5). Maintenance strategies were not discussed (N=8).

Conclusions: Core iPOPP intervention components were well delivered. However we have identified areas to optimise ahead of a full-scale trial (how to discuss barriers to walking and maintenance strategies, development of motivational interviewing skills to support revision of goals, HCA knowledge of local activities). These findings will be triangulated with data from interviews with HCAs and participants to provide further evidence of the feasibility and acceptability of the iPOPP intervention.

THU0615 PARTICIPANTS' EXPERIENCE OF THE MAKING IT WORK PROGRAM, AN ONLINE PROGRAM TO HELP PEOPLE WITH INFLAMMATORY ARTHRITIS REMAIN EMPLOYED

A. Li [1], C. Backman [1,2], B. van As [1], P. Rogers [1], M. Gignac [3,4], L. Li [1,2], J. Esdaile [1,2], D. Lacaille [1,2]. *[1]Arthritis Research Canada, Richmond; [2]University of British Columbia, Vancouver; [3]University of Toronto; [4]Institute of Work and Health, Toronto, Canada*

Objectives: Health services addressing employment needs for people with arthritis are lacking. To address this need, we developed the Making it Work (MiW) program, an online self-management program aimed at helping people with inflammatory arthritis (IA) deal with employment issues. As part of a randomized controlled trial evaluating program effectiveness, this study reports on participants' experiences with various aspects of the program.

Methods: All participants in the MiW program between Jan20 and Dec7 2016 were included. Participants were recruited from rheumatologist practices, outpatient arthritis programs, a national consumer organization (Arthritis Consumer Experts), and community advertisements in BC, Alberta and Ontario. Eligibility criteria included: having IA; being currently employed; age 18–59 yrs; concern about their ability to work; and access to a computer. The program consisted of 5 online self-learning modules, 5 online group meetings facilitated by a vocational counsellor, an individual ergonomic assessment by an occupational therapist and an online session with a vocational counsellor. Feedback questionnaires were administered online after participants completed the program. Descriptive analyses were performed.

Results: The sample included 69 participants [80% female; mean (SD) age: 45.3 (10.5) yrs; 83% Caucasian; 91% with post-secondary education; 52% with RA, AS: 19%, SLE: 17%; PsA: 12%]. Overall, participants expressed satisfaction with the program with 94.2% agreeing (69.6% strongly and 24.6% somewhat) they would recommend this program to someone they know. When asked to rate program components on a scale of 0–10 where 0=not useful at all and 10=very useful, participants rated all components favourably: median [25Q;75Q] for online modules: 8 [7;10], with highest ratings for the fatigue module (rated 10 by 42%); online group meetings: 9 [7.5;10]; ergonomic and VRC assessments: 8 [7;10] each. Although participants had 2 weeks between meetings to complete the module, 55% did the module the week of, and 42% the day before, the group meeting. Median time to complete each module was 60 min. 81% enjoyed being able to listen to the information (somewhat or strongly agreed), although 35% stated they would have preferred to read the information than listen to a narrator. 74% expect to use the online modules again in the future. Participants were also satisfied with the online group meetings: 93% were very or somewhat satisfied with the group facilitation; 87% satisfied with the group dynamic; 84% comfortable with the online format. When asked to rate their online group meeting experience on a scale of 1 to 10, median [25Q;75Q] ratings for: ability to follow group discussion was 10 [9;10]; getting to know other participants: 7 [7;10]; feeling listened to and understood 9 [8;10]; feeling that group was supportive 9 [7;10]. 20% said it was difficult for them to attend group meetings.

Conclusions: In general, participants were highly satisfied with all aspects of the

MiW program. Our study demonstrates that self-management programs, including group meetings, can be successfully delivered using an online format, which facilitates wider dissemination, with greater convenience to patients, and at lower costs.

THU0616 PATIENTS' PERCEPTION ON DISEASE PROGRESSION AND ADHERENCE TO BIOLOGIC THERAPY

E. Cefai, D. Balzan, C. Mercieca, A.A. Borg. *Rheumatology, Mater Dei Hospital, Msida, Malta*

Background: Adherence to medication depends on several factors such as medication beliefs, psychosocial factors, illness beliefs and concerns. The consequences of non-adherence are not insignificant, both from the clinical and health economic aspects.
Objectives: To assess medication adherence of patients taking biologics who are in remission or who have low disease activity and patients' perception of disease progression.
Methods: Forty-four consecutive patients attending a dedicated biologic clinic and treated with TNF inhibitors were interviewed following their visit. Patients were asked about adherence to treatment, adverse effects, concerns about biologics and their perception of disease progression. Demographic and disease activity data were recorded.
Results: Forty-four patients (23 females, 21 males) participated in the survey (21 suffered from rheumatoid arthritis, 17 from ankylosing spondylitis and 6 from psoriatic arthritis). The mean age was 55.1 (SD 12.62) years. The mean DAS28 was 2.26 (SD 1.03) and the mean BASDAI was 4.21 (SD 2.1). Minimal or no pain was reported by 75%, mild or no fatigue by 78% and 77% had no restriction of activities of daily living. Medication adherence was reported as high by 68% and moderate by 32%. There were no patients who had a low level of adherence. 5% of patients admitted to be unaware of the need to omit their biologic when ill and 40% when requiring surgery.
One out of 4 patients reported to have experienced adverse events, most commonly infections. 19% claimed to be moderately or very concerned about the adverse effects. On further questioning about the severity of potential adverse effects, 45% were unsure as to what the severity might be. When asked about duration of therapy, 29% replied more than 10 years; whilst 71% were unsure on when, if ever, the biologic is going to be stopped. Patients were also asked whether they believed that the biologic had successfully stopped further joint damage and 68% replied yes, 9% replied no, whilst 23% were unsure. Of those who replied yes, this perception was based on the absence or reduction of symptoms.
Conclusions: In this cohort of patients with low disease activity or remission, a third of patients still reported sub-optimal adherence to TNF inhibitor use. The benefits of adherence to biologic therapies need to be reinforced at every visit and factors leading to non-adherence addressed. Adverse effects remain a major concern that needs to be addressed, even in patients who have been on biologics for many years and have sustained remission or low disease activity. A quarter of patients were unsure whether biologics have stopped joint damage. Patients' perception of joint damage progression needs to be explored to find ways of making it more understandable to patients.

THU0617 INFORMATION ON DISEASE AND TREATMENT OF PATIENTS WITH RHEUMATIC DISEASES TREATED WITH SUBCUTANEOUS BIOLOGICALS: SOURCES AND SATISFACTION. RHEU-LIFE SURVEY

F. de Toro[1], E. Batlle[2], C. González[3], M. Calvo[4], M. Arteaga[4], L. Cea-Calvo[4]. *[1]INBIC, A Coruña; [2]D.Salud Sant Joan, Alicante; [3]H.G.U.Gregorio Marañón; [4]Medical Affairs, Merck Sharp & Dohme, Madrid, Spain*

Objectives: To know the sources by which patients with rheumatic diseases treated with subcutaneous (SC) biological drugs obtain information on their treatment, their satisfaction with the information received from the hospital staff and their perception of the degree of information they have.
Methods: RHEU-LIFE was a survey handed by 50 rheumatologists from Spanish outpatients hospital offices to patients on SC biological drugs. They completed the survey anonymously at home and returned it by pre-paid post-mail. They selected from a list their sources of information (being able to mark all their sources), their satisfaction with the information received from the hospital staff and whether they had sought additional information in other sources.
Results: The survey was handed to 1000 patients and 592 returned it (59.2%, mean age 51.7 years, 57.6% women). The source of information most frequently mentioned was the rheumatologist (table) and, infrequently, the nurse or the hospital pharmacist. 46.1% had received information on the SC biological only orally, 6.0% written and 45.2% in both ways. The percentages quite or very satisfied with the information received were 42.6% and 44.5% respectively, 10.6% felt "neither satisfied nor dissatisfied" and 2.1% and 0.2% dissatisfied or very dissatisfied. The % quite/very satisfied was higher when the information came from the rheumatologist (89.6% vs 59.6% when the rheumatologist was not mentioned as source of information, $p<0.001$), and also when information was given both oral and written (92.8% vs 86.1% if only oral information was given, $p=0.0125$). Some 45.2% had sought information on the SC biological in sources different to the hospital staff, the % being higher among younger patients (<43 years: 65.2%: 43–52 years: 51.4%, 53–61 years: 39.1%, >61 years: 20.6%, $p<0.001$) those with higher education level (without studies: 14.3%, primary: 31.6%, secondary: 55.6%, vocational: 59.5%, university or higher degrees: 64.9%, $p<0.001$), and in those treated with a first biological SC drug (49.9%, vs. 37.7% and 37.2% with a second or third or further, $p=0.014$).

Sources from which patients received information on the different treatments and on the biological drug (patients could mark more than one option)

	General information	Information on the SC biological
Rheumatologist	91.9%	91.0%
Nurse	10.2%	17.9%
Hospital pharmacist	3.2%	11.5%
Other	5.3%	3.6%
Do not remember	1.2%	0.8%
Did not receive any information	0.8%	1.7%

Conclusions: Patients with rheumatic diseases mention the rheumatologist as their main source of information. The % who mentioned nurses or pharmacists was low, although the latter are very frequently visited for dispensing the drug. Satisfaction with the information received was high, but clearly lower when the rheumatologist did not inform the patient. Nearly half reported having sought information in sources other than the hospital staff.

THU0618 THE FACTORS AFFECTING WORKPLACE AND HOUSEHOLD LIFE IN ANKYLOSING SPONDYLITIS: A MULTI-DIMENSIONAL STUDY

B. Taser[1], F.F. Ayhan[1,2], P. Borman[1,3], A. Karagöz[1]. *[1]Physical medicine & rehabilitation, Ankara Training and Research Hospital, Ankara; [2]Physical therapy & rehabilitation, Uşak University, School of Health Sciences, Uşak; [3]Physical medicine & rehabilitation, Hacettepe Medical School, Ankara, Turkey*

Background: Work disability (WD) is the final stage of work problems and may be prevented by effective treatment and ergonomic interventions in earlier stage of work productivity loss and work instability. Contextual factors, disease related factors and local social security systems may also affect WD.
Objectives: We aimed to determine the predictive factors of work productivity and work stability in Turkish patients with ankylosing spondylitis
Methods: One-hundred patients with ankylosing spondylitis (31 females and 69 males) were included into this study. Demographics, working state, Bath scores of disease activity, functional and radiologic state, quality of life, cardiopulmonary functions (echocardiography, exercise stress test and pulmonary function test) and general work impairments (work productivity impairment and work instability) were recorded. WPAI and AS-WIS were selected as work outcomes. The most predictive factors were analyzed in work productivity and work instability. SPSS 14.0 statistics (descriptives, pearson correlation, and stepwise regressions were used for statistical analyses.
Results: Thirty-two patients (mean age: 42,6±11.7) were unemployed. Unemployed patients showed more female, less educated, low disease activity, and low fitness profile. The percentages of absenteeism (WPAI-1), presenteeism (WPAI-2), regular activity impairment (WPAI-3) and overall work impairment (WPAI-4) were determined as 8, 44, % 47, and % 37, respectively, in employee group. When affecting factors assessed with multiple stepwise linear regression analysed; the only determinant for absenteeism (WPAI-1) was the working day loss due to ilness at last year. Chest mobility, annual income level, AS quality of life (ASQoL), work change and co-morbid diseases were the determinants of presenteeism (WPAI-2), regular activity impairment (WPAI-3) and overall work impairment (WPAI-4). The score of mean work instability (AS-WIS) was 11.5±5.8, and 42.6% of patients had low and 57,4% of patients had moderate-high work instability. Multiple stepwise linear regression analysis showed that most predictive factors for work instability were regular activity impairment (WPAI-3) and AS-QoL. The factors affecting non-work status were older age, female sex and low annual income level in stepwise logistic regression.
Conclusions: The common predictive factor of work productivity and work stability was quality of life. For evaluation of work productivity; socioeconomic factors such as annual income level and frequent work change were determinative as well as clinical datas (chest expansion and comorbid diseases). We suggested both pharmacologic and nonpharmacologic interventions to improve quality of life should be enabled in early period to improve work productivity.

THU0619 PREVALENCE OF PNEUMOCOCCAL VACCINATION IN RHEUMATOLOGIC PATIENTS WITH COMMUNITY ACQUIRED PNEUMONIA. BIOBADASAR REGISTRY

G. Gómez, A. Brigante, A. Benitez, O. Cerda, S. Retamozo, I. Gandino, A. Quinteros, I. Exeni, B. Barrios, P. Astesana, C. Sanchez Andia, M.V. Collado, A. Granel, A.M. Cappuccio, R. Quintana, E. Mussano, A. Smichowski, M. de la Sota, K. Kirmayr, E. Velozo, M.S. Larroude, A. Bertoli, S. Agüero, C. Battagliotti, S. Soaures de Souza, E. Cavillon, A. Bohr, O. Rillo, L. Carlevaris, E. Bedoya, E. Kerzberg, B. Kisluk, I. Petkovic, D. Pereira, J.C. Barreira, L. Somma, C. Costi, F. Melo, B. Virasoro, S. Paira, L. Roa Perez, G. Casado, D.L.V. María Celina.
Sociedad Argentina de Reumatologia, Buenos Aires, Argentina

Background: Biobadasar is a registry that monitors adverse events in patients who use biological treatments in rheumatologic diseases conducted by the Argentine Society of Rheumatology. As in others international registries the community acquired pneumonia (CAP) has been detected as one of the most frequent infectological adverse events. Although all immunosuppressed patients should be vaccinated against streptococcus pneumoniae, there is a proportion of patients who are not.
Objectives: Evaluate the prevalence of pneumococcal vaccination in patients with CAP within the Biobadasar database. Assess factors associated with Severe CAP in these patients.
Methods: A cross-sectional, multicentric study was made in BIOBADASAR database from 2010 to2016.
In patients who reported CAP data of demographics, comorbidities and state of pneumococcal immunization was collected. Microbiological data, treatment and outcome of the event were considered. The severity of CAP was assessed according to the opinion of the attending physician, hospitalization, risk of life and/or death. Values are expressed as mean ± standard deviation, median (ranges) and frequencies (percentages), as appropriate. We performed bivariate and multivariate logistic regression analysis to identify variables associated with the event.
Results: Of the 4029 patients enrolled in the registry, the cumulative incidence of CAP was 4.2% (n 170), 72.4% (n 123) were women. The mean age was 57 (SD +/- 14.5). Biological treatment was found in 81.8% (n 139). Patient s that have received the pneumococcal vaccine were 40.6% (n=69). Severe CAP was detected in 7.1%. Streptococco Pneumoniae was the main pathogen isolated in 13% of the cases. Overall mortality was 4.1%. In the univariate analysis for severe CAP we found statistical significance for Smoking OR 3.88, CI95 1.063–14.22, p= 0.029 and chronic kidney disease (CKD) OR 31, CI95 2.6–376, p= 0.007. When performing a multiple logistic regression model, only renal failure OR 7.39 CI95 0.003–0.38 p= 0.007 was a predictor of severe CAP. Not significative association with immunosuppressive treatment (p: 0.09), age (p: 0.464), or vaccination (p: 0.937)
Conclusions: The annual incidence of CAP in Argentina varies between 0.5 - 1.1% while in our cohort it was four times higher. The prevalence of pneumococcal vaccination was less than 50%, showing that, although the literature and guidelines establish the need for vaccination, this is not so in the real world. In the multivariate analysis, only CKD was related to severe CAP. Although in the univariate analysis the CKD and the smoking habit represented factors associated with severity. We must emphasize the medical education in following the international vaccination guidelines.

THU0620 PERSISTENCE WITH BIOLOGICAL DISEASE-MODIFYING ANTIRHEUMATIC DRUGS – A RETROSPECTIVE DATABASE STUDY IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS

J. Mahlich [1], H. Kameda [2], R. Sruamsiri [1]. [1] *Health Economics, Janssen Pharmaceutical KK, Tokyo, Japan;* [2] *Toho University Ohashi Medical Center, Tokyo, Japan*

Background: Persistence rate is one of the key benefits of biological disease-modifying antirheumatic drugs (bDMARDs) in the treatment of rheumatoid arthritis (RA). Limited evidence of persistence has been found in Japan and the results are not transferrable across countries and cultures (1–3). In addition, the impact of persistence on healthcare cost is still questionable.
Objectives: To assess persistence rates of bDMARDs for the treatment of RA in Japan and compared resource utilization and treatment costs between persistence and non-persistence groups.
Methods: Data was extracted from a Japanese claims database that included 4,400,000 patients between 2009 and 2015. RA patients who initiated bDMARD treatment (bDMARD-naïve patients) were identified and included in the final analysis. Survival analysis was used to estimated 6-, 12-, and 18- month persistence rates for current bDMARDs. Propensity score matching was applied to control for potential treatment selection bias. Resource utilization and health care costs of treatments were calculated 12 months before and after initiation of bDMARDs treatment and compared between persistence and non-persistence groups.
Results: A total of 6,153 bDMARD-naïve patients were included in the final analysis. The overall 1-year persistence rate was 85% (95% CI, 84–86). Persistence of patients treated with golimumab was higher [92% (95% CI, 89–94)] than that with other bDMARDs. Overall, 1-year outpatient visits increased from 10 at baseline to 16 after bDMARD treatment, while the number of hospital admissions declined from 3.3 to 1.6. Hospital days decreased from 17 at baseline to 12 following treatment. The non-persistence group had a larger increase in outpatient visits after bDMARD initiation compared with the persistence group (8 to 16 vs. 10 to 16, respectively) and a smaller decrease in hospital admissions (3.1 to 1.9 vs. 3.5 to 1.4, respectively). Compared to non-persistence group, persistence was associated with a reduction in total healthcare costs of 760 USD.
Conclusions: Japanese bDMARD-naïve patients with RA have a high persistence rate of bDMARDs. The reduction in medication costs in non-persistent patients is offset by higher hospitalization costs, making non-persistence more expensive.

THU0621 COMPARISON OF THE EFFECT OF ANTI-TNF THERAPY ON WORK DISABILITY BETWEEN PATIENTS WITH RHEUMATOID ARTHRITIS, ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS OVER ONE YEAR– REAL LIFE DATA FROM THE CZECH BIOLOGICS REGISTRY ATTRA

J. Zavada [1], L. Szczukova [2], J. Vencovsky [1], P. Horák [3], K. Pavelka [1] on behalf of collaborators of the ATTRA registry. [1] *Rheumatology, Institute of Rheumatology, Prague;* [2] *Institute of Biostatistics and Analyses, Faculty of Medicine, Masaryk University, Brno;* [3] *Internal Medicine, Faculty of Medicine and Dentistry, Palacký University, Olomouc, Czech Republic*

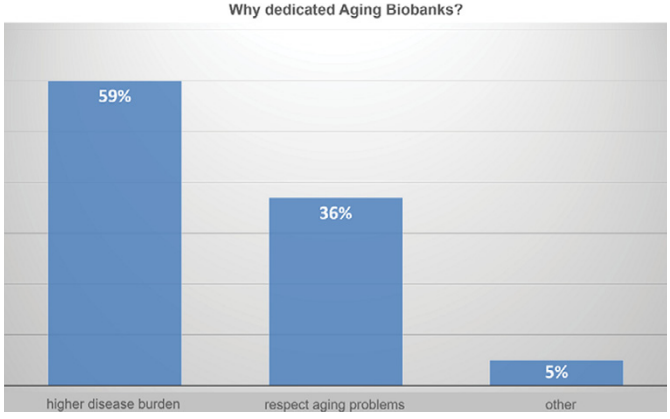
Objectives: To compare the effect of anti-TNF therapy (a-TNF-th) on Work Disability (WD) between RA, PSA and AS. In the Czech Republic (CZ), a-TNF-th is reimbursed for RA if DAS28>5.1 despite therapy with csDMARDs, for PSA if disease is not "adequately controlled" with csDMARDs, and for AS if BASDAI>4 and CRP/ESR elevated above normal. More than 95% of anti-TNF treated patients in CZ are followed up in the ATTRA registry.
Methods: Bionäive patients with RA (n=1085), AS (n=1126) and PSA (n=351) starting a-TNF-th with available baseline data on demography, disease duration and physical function, and on working status at baseline and at 12 months were included in the analysis. Patients older than 60 years, on maternity leave or students were excluded. Work status was self-reported by patients as (A) able to work = [(i) employed, or (ii) unemployed and actively seeking employment], or (B) unable to work = [(iii) on sick leave, or (iv) on disability pension]. Regression analyses were performed to examine the predictors of improvement in WD (change B→A coded as 1, B→A as -1, no change as 0) over 1 year.

Table 1. Baseline characteristics

	RA (n=1085)	AS (n=1126)	PSA (n=351)	p-value
Female	836 (77.1%)	263 (23.4%)	161 (45.9%)	**<0.001**[ABC]
Disease duration	8.2±6.6	7.5±6.9	8.2±7.2	**0.002**[A]
Age at start of anti-TNF Therapy	46.6±9.0	38.2±8.8	44.1±9.3	**<0.001**[ABC]
HAQ	1.5±0.6	1.1±0.5	1.2±0.6	**<0.001**[ABC]
Calendar year of starting anti-TNF				
before 2008	420 (38.7%)	306 (27.2%)	90 (25.6%)	**<0.001**[AB]
2009–2012	394 (36.3%)	427 (37.9%)	156 (44.4%)	
2013–2015	271 (25.0%)	393 (34.9%)	105 (29.9%)	

Post-hoc analysis (with Bonferroni correction): statistically significant difference btw groups A) RA vs. AS, B) RA vs. PSA, C) AS vs. PSA. Values or N (%) or mean (SD).

Table 2. Prediction of improvement in work disability



Independent variable	Univariate analysis		Multivariate analysis	
	OR (95% CI)	p-value	OR (95% CI)	p-value
Diagnosis				
RA	*reference*		*reference*	
AS	**1.477 (1.150; 1.898)**	**0.002**	**1.466 (1.044; 2.058)**	**0.027**
PSA	1.206 (0.840; 1.731)	0.310	1.226 (0.838; 1.792)	0.293
Female	0.821 (0.651; 1.034)	0.093	0.988 (0.754; 1.295)	0.932
Age at start of anti-TNF therapy	**0.983 (0.971; 0.994)**	**0.004**	0.987 (0.974; 1.001)	0.067
Disease duration	0.992 (0.975; 1.009)	0.341	0.998 (0.980; 1.016)	0.840
HAQ	1.024 (0.839; 1.251)	0.815	1.181 (0.949; 1.470)	0.135
Calendar year of starting anti-TNF				
before 2008	*reference*		*reference*	
2009–2012	0.843 (0.639; 1.113)	0.228	0.799 (0.601; 1.062)	0.122
2013–2015	1.075 (0.804; 1.438)	0.624	1.001 (0.741; 1.352)	0.995

Results: Baseline characteristic were significantly different between diagnoses (Table 1). In patients with RA, 60% were able to work at baseline and 61% at 12 month, with PSA 71% and 74% resp., and with AS 72% and 77% resp. The main driver of improvement of WD was a change in the sick leave (RA 6%→2%, PSA 7%→1%, AS 9%→2%). In univariate analyses, diagnosis of AS and younger age at start of a-TNF-th were predictive of improvement in WD. In multivariate analysis, only diagnosis of AS was significantly associated with improvement in WD.
Conclusions: These real life data from CZ show that for improvement of WD, a-TNF-th was most effective in patients with AS. This may be a sequel of disease specific factors or reimbursement policy.

THU0622 PATIENT-CENTERED AGING BIOBANKS - A SURVEY ON PUBLIC PERCEPTIONS AND PATIENT CHOICE AMONG RHEUMATOLOGY OUTPATIENTS

J.V. Cordeiro[1], A. Fernandes[2], C.D. Lopes[3], G. Victorino[4], P. Lobato Faria[1], M.J. Cercas[4], J.C. Branco[5], F.M. Pimentel-Santos[3,5]. *[1]Centro de Investigação em Saúde Pública (CISP), Escola Nacional de Saúde Pública; [2]CICS.NOVA – Centro Interdisciplinar de Ciências Sociais, Faculdade de Ciências Sociais e Humanas, NOVA University of Lisbon; [3]Rheumatology, CHLO, Hospital Egas Moniz; [4]NOVA Information Management School (NOVAIMS); [5]CEDOC, NOVA Medical School|Faculdade Ciências Médicas, NOVA University of Lisbon, Lisboa, Portugal*

Background: Biobanks for research (BBR) are organized repositories of biological materials and associated health information with enormous potential and value for scientific research. In consonance with increasing attention to healthy aging research, BBR specifically oriented to chronic diseases and aging populations have gathered heightened attention. Public perceptions and patient choices are key to design, develop and implement patient-centered BBR. Public awareness, education and involvement are confidence building and unequivocally lead to higher participation in scientific enterprises.
Objectives: To assess patient awareness, perception and choices regarding aging biobanking activities.
Methods: We developed and applied a standard anonymous questionnaire to rheumatology terciary outpatients, aged 50 or older, between March-October 2016. Demographic data and perceptions about biobanking were collected. Data analysis was performed using Stata 14® software.
Results: We obtained a total of 131 valid responses [age (min-max, 50–93), mean (64); sex ratio (M/F) (40/91, 44%), education years (min-max, 0–20), mean (8.5)]. 69% of respondents did not know the specific term "biobank" but 57% were aware about the possibility of donating their biological material for research purposes. Furthermore, 77% of respondents indicated they were willing to contribute with their biological material to BBR, stating they had no particular preference whether these infrastructures were of private or public nature. However, they expressed a clear preference for these to be based at scientific research institutes (50%), instead of hospitals (23%), universities (16%) or biotechnology companies (7%). Moreover, respondents highlighted diferent requirements for their participation with anonymity (31%) and confidentiality (27%) ranking as top priorities. Most importantly, a majority of respondents (70%) expressed their agreement with a biobank exclusively dedicated to the study of aging, considering that people of older ages have higher disease burdens and that such research infrastructures and practices expressed respect for the particular problems of the elderly (Figure).

Conclusions: Our study constitutes a comprehensive assessment of public perceptions and patient choices regarding biobanks for aging research purposes among rheumatology outpatients. Although awareness is still suboptimal, BBR are highly regarded health infrastructures with enormous potential for further patient-centered development.

THU0623 DECREASE IN THE TEMPORARY WORK INCAPACITY DUE TO MUSCULOSKELETIC DISEASES: UTILITY OF A PREVENTIVE PROGRAM IN VALENCIA-LA FE HEALTH AREA

J.E. Oller Rodríguez[1], M.T. Fuente Goig[2], F. Ortiz Sanjuan[1], J. Ivorra Cortés[1], E. Grau García[1], E. Vicens Bernabéu[1], E. Labrador Sánchez[1], K.R. Arévalo Ruales[1], J. Fragio Gil[1], R. González Mazario[1], C.P. Alcañiz Escandell[1], I. Cánovas Olmos[1], I. Chalmeta Verdejo[1], C.M. Feced Olmos[1], L. González Puig[1], I. Martínez Cordellat[1], C. Nájera Herranz[1], R. Negueroles Albuixech[1], J. Andani Cervera[2], J.A. Román Ivorra[1] on behalf of Rheumatology Service. *[1]Rheumatology; [2]Service of Prevention of Occupational Hazards, Hospital Universitari I Politècnic la Fe, Valencia, Spain*

Background: Musculoskeletal diseases are nowadays a frequent cause of temporary work incapacity (TWI). The implementation of specific programs for the care of these patients can be an important cornerstone in the resolution of these TWI processes.
Objectives: Our aim is to analyze the usefulness of an Early Intervention Program (EIP) in patients with TWI of musculoskeletal origin.
Methods: Case-control study, including patients from HUP La Fe area, which were referred from Primary Care since April 2012 to April 2016 to our Early intervention program (EIP) addressed to patients with TWI of musculoskeletal origin. The patients were evaluated in our consultation within a maximum of 15 days after the start of TWI. The intervention consisted in an evaluation, including complementary tests if necessary, diagnosis and treatment by the rheumatologist in consultation. The patient was followed in consultation continuously until discharge. Patients whose disabilities were of traumatic or surgical origin were excluded. A comparative study was carried out against a control group of patients with ILT of musculoskeletal origin.
Results: A total of 666 patients were recruited; 508 (76.3%) belonged to EIP group (46.1% male; 53.9% female) and 158 patients (23.7%) belonged to the control group (44.3% male; 55.7% female).
The average age was 47,6±10.5 years for the EIP ones and 46.7±10 years in the control group.
The most frequent diagnoses were low back pain (23.3%), neck pain (18%) y lumbosciatica (12.3%). In EIP group, 100% of the patients received medical treatment, a 54.5% received instructions for doings physical therapy at home, an ultrasound scan was performed to the 26,4% of the patients while the 19.9% received at least one local infiltration. The longest TWI corresponded to knee meniscopathy (203 days), painful shoulder syndrome (173 days) and lumbosciatica (170.5 days). No statistically significant differences were found between the duration of the TWI attending to sex, age group, labour activity or diagnose. However, a significant association was found between TWI duration and the delay since the start of the symptons to the referral from Primary Care to our consultation, specially within the firdt 10 days (p=0.04). Furthermore, TWI duration was significantly shorter in the EIP group patients than in the control group patients (137.4±132.3 days vs 194.7±143.1 days; $p<0,001$).The period before relapse was longer in the EIP group, although the differences did not reach significance. In addition, an inverse relation was found between age and time to relapse (p=0,01).
Conclusions: The establishment of an early intervention program specifically addressed to patients with temporary work incapacity of musculoskeletal origin shortens the duration of this situation, allowing the patient to rejoin his work activity, with the resulting cost savings related to work incapacity.

THU0624 ASESSMENT OF PSYCHIC EXPERIENCES IN PATIENTS WITH RHEUMATIC DISEASES

J.L. Prados-Ojeda[1], J.L. Garrido-Castro[2], R. Segura-Ruiz[1], C. González-Navas[2], P. Font-Ugalde[2], E. Collantes-Estevez[2], A. Escudero-Contreras[1]. *[1]Reina Sofia University Hospital; [2]Maimonides Institute for Biomedical Research of Cordoba, Cordoba, Spain*

Background: There are several studies that report psychiatric comorbidity in patients with rheumatic disease, mainly the presence of mood disorders. Some of them describe non-affective psychosis related with inflammatory processes. Population with chronic inflammatory disease could present subclinical psychotic experiences that can interfere in the patient's functional status. The Community Assessment of Psychic Experiences (CAPE) scale is a validated and widely used tool for the evaluation of these experiences in the general population.
Objectives: To identify the presence of psychic experiences in different populations with a diagnosis of rheumatic disease, and to compare it with a sample of healthy subjects.
Methods: 124 subjects completed surveys including SF-12 and CAPE questionnaires, as well as other demographic and behavioral variables. Among them, 70 had Spondylarthritis (SpA) (age 44.3±13 years, 62% female), 23 rheumatoid arthritis (RA) (age 51.2±13 years, 82% female) and the rest were individuals without rheumatic diseases (47.6±12 years, 58% female).
Results: Results of the SF-12 test in their mental and physical domains, and the CAPE questionnaire in their dimensions (positive, negative, depressive and total symptoms) are shown in the table, expressed as mean value (SD) and in the graph expressed as density histograms with mean values. Significant statistical

	SF-12		CAPE			
	Physical	Mental	Positive	Negative	Depressive	Total
SpA	31.8 (13.6)**	43.8 (10.6)	1.32 (0.2)	1.81 (0.4)*	1.98 (0.5)**	1.59 (0.3)*
RA	33.1 (13.1)**	44.9 (12.7)	1.37 (0.3)	1.66 (0.4)	1.86 (0.5)*	1.55 (0.3)
Control	47.0 (16.1)	47.2 (7.5)	1.30 (0.2)	1.61 (0.4)	1.65 (0.3)	1.47 (0.2)

differences, according a t de Student test with control group is shown in both (* $p<0.05$, ** $p<0.01$).
There were no significant differences in the mental component of the SF-12. These differences appear at the physical component, since patients have impaired their mobility and function due to their disease. About the CAPE questionnaire, patients had a little bit higher score due mainly to the appearance of depressive symptoms. The values of positive symptoms of psychosis remained within the normal range for diseases analyzed.

Conclusions: In our study, we found significant differences in the dimensions, especially depressive, of the CAPE scale among patients with rheumatic diseases (especially in SpA) and healthy subjects. This gives us an idea of the importance of considering the psychological problems of patients (anxiety, depression, ...) to improve the treatment of rheumatic disease.

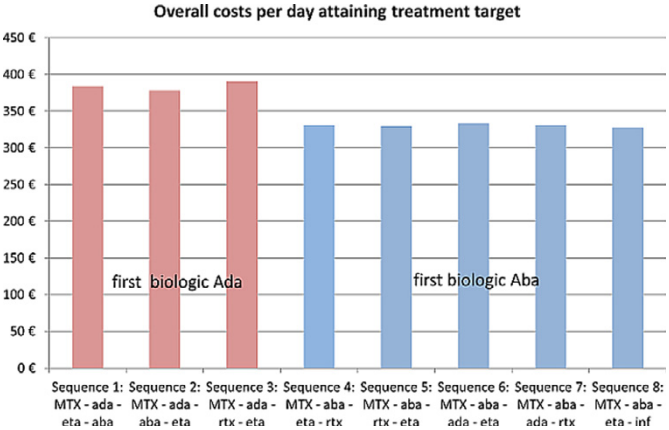
THU0625 DESIGN OF AN INFORMATION AND COMMUNICATIONS TECHNOLOGY PLATFORM TO SUPPORT COORDINATION OF CARE FOR RHEUMATOID ARTHRITIS PATIENTS WITH CARDIOVASCULAR CO-MORBIDITIES – FIRST EXPERIENCES



J.G. Richter, G. Chehab, M. Schneider on behalf of the PICASO Consortium (www.picaso-project.eu). *Policlinic & Hiller Research Unit for Rheumatology, Heinrich-Heine-University Duesseldorf, Duesseldorf, Germany*

Background: Coordination of care plans between healthcare sectors and efficient management of patients (pts) with co-morbidities is of large demand. Rheumatoid arthritis (RA) pts are at increased risk of cardiovascular diseases (CVD). Different stakeholders are potentially involved in the EULAR recommended management processes. Optimized orchestration of accumulated information is of major importance to ensure data quality, meaningful management processes and cost effectiveness. A newly developed information and communications technology (ICT) platform within the Horizon2020-funded PICASO-project (www.picaso-project.eu) will support a continuum of care from hospitals and outpatient clinics to the home.
Objectives: Explore challenges to provide an efficient ICT integrated solution across many healthcare professionals working for various organisations and potentially crossing national borders that complies to privacy and regulatory constraints allowing more efficient care management. Suitable system architecture and appropriate features require identification of target users' user requirements. PICASO platform will be developed and trialed with pts and clinician. The proposed system architecture will be evaluated for suitability for a larger scale rollout.
Methods: Projects' pre-defined clinical and technological driven work packages started. Various stakeholders (e.g. pts, local data security and IT representatives, health care insurances' representatives, clinicians) were integrated in the design phase. A PICASO ethical board including external members (e.g. Chair of the Standing Committee of PARE) addressed ethical and legal concerns.
Results: Current work-flows for the care plan management including stakeholders' hand-over procedures were elaborated. Vision scenarios (n=11) and To-Be Use Cases (n=18) addressing solutions including home monitoring were developed (1). A comprehensive list of user requirements (currently n=87) resulted. Detailed system architecture descriptions are stipulated. Ethical issues and how to handle these, in particular data-protection and -privacy challenges were pre-assigned as these affect platforms' architecture. PICASO ethical principles and guidelines were stated (2). The platform is under development. The first trial running over nine months including RA-pts will start in spring 2017. First experiences will be reported at EULAR.
Conclusions: Considering the needs of a highly valued, specialised health care system relevant To-Be Use Cases, numerous user requirements and EU-wide ethical and legal issues were gathered to serve as basis for appropriate design, development and implementation of the ICT platform. Software development will take place in iterative cycles followed by prototypes' thoroughly evaluated by real end users investigating usability and acceptance. The platform will become available for RA-pts in routine care but also for wider applicability in Rheumatology and other chronic diseases.

THU0626 COST-EFFECTIVENESS OF EARLY TREATMENT OF ACPA POSITIVE RHEUMATOID ARTHRITIS PATIENTS WITH ABATACEPT

A.S. Neubauer[1], C. Minartz[1], K.H. Herrmann[2], R. Postema[3], C. Baerwald[4]. *[1]Institute for Health Economics (IfG, IfGPh); [2]Bristol-Myers Squibb, Muenchen, Germany; [3]Bristol-Myers Squibb, London, United Kingdom; [4]Rheumatology Unit, University of Leipzig, Leipzig, Germany*

Background: Studies have reported that the presence of elevated anti-citrullinated protein antibodies (ACPA)/RF levels, together with joint erosions, is associated with higher disease burden in terms of disability, and mortality in rheumatoid arthritis (RA). Abatacept has been shown to be effective in this patient population with favorable comparative data against adalimumab.(1) However, few studies have investigated the cost effectiveness of abatacept in this population to similar treatments such as TNFs.
Objectives: The objective of the study was to compare the cost-effectiveness of abatacept to adalimumab as a first bDMARD in ACPA positive RA patients who failed treatment with methotrexate (MTX) in Germany.
Methods: A decision tree model was used to estimate the cost-effectiveness, from a payer's perspective, of different treatment sequences in RA over a two year time frame. The effectiveness criteria were defined as achieving the treatment target measured by the Disease Activity Score 28 (DAS28 (CRP)<2.6; "remission"). A treatment switch to a different biologic as 2nd line and 3rd line bDMARD was allowed -in case of not achieving remission with therapy- every 6 months over a two year time period. Effectiveness data was based on randomized controlled trials (RCT) identified by an updated previous systematic literature search by the Institute for Quality and Efficiency in Health Care (IQWiG). Costs of medication and other direct medical costs were taken from a recent publication (2) and included in the analysis. Cost-effectiveness of RA treatment was investigated in ACPA positive patients in this study and presented as overall costs per day in remission. To manage uncertainty in the model, a fully probabilistic approach was used with 10,000 runs.
Results: For ACPA positive patients, treatment strategies including early treatment with abatacept had lower total costs per clinical outcome compared to later use. Figure 1 summarizes the costs per day in remission for the treatment sequences investigated: treatment sequences starting with abatacept resulted in lower costs for reaching remission (mean 330 €/day, range 328 €-333 €/day) compared to sequences starting with adalimumab (mean 384 €/day, range 378 €-390 €/day). Choice of the second or third biologic in the treatment sequences appears to have little impact on the costs per outcome.

Conclusions: The results of this analysis suggest that in ACPA positive RA patients treatment with abatacept appears to be more cost-effective compared to treatment with adalimumab as a first bDMARD.

THU0627 TREATMENT OF RHEUMATOID ARTHRITIS: ADHERENCE TO GUIDELINES IN PRIVATE PRACTICE

L.B. Fernandes, F.A. Palacios, P.G. Lerner, C.G. Macedo, F. Omura, E.A.K. Azeka, I.M.M. Laurindo, P. Toth, R.C. Ferreira, R.A.O. Aurichio, A.P. Bazilio, J. Brudniewski, A.L. Hayata. *Private Office, São Paulo, Brazil*

Background: Guidelines and therapeutic strategies in the treatment of rheumatoid arthritis (RA) have been developed and adopted by most Societies of Rheumatology. However, the extent to which they have been supported by rheumatologists in their individual clinical practice is unclear.
Objectives: Our aim was to analyze, at private offices, adherence to guidelines and characteristics of RA patients in regular follow-up.
Methods: This was a cross-sectional study developed by a group of rheumatologists (n=13) working exclusively in private offices and hospitals in São Paulo, Brazil. It consisted of a web-based questionnaire addressing patient's demographics, social characteristics and treatment. Patients having the diagnosis of RA should be included sequentially. As Brazil's private health has no reference flowchart, patients can consult any physician from their insurance health program, or any physician at all if bearing the costs. Insurance programs can be either personal or tied to employers, in which case job changes imply in insurance and health professional changes.
Results: Data from 235 RA patients were collected, 84% were female, mean age (SD) 57.3 (13.3) yrs., disease duration 9.5 (1–54) yrs., 73% RF positive (74% of the 61 RF negative patients had an anti-CCP test and 8 were positive), The mean duration of symptoms until diagnosis was 1.7yrs (0–23), number of physicians until diagnosis 2.4 (1 – 12), including GP (102 patients), orthopedists (110 patients) and rheumatologists (129 patients). Even after diagnosis, patients switched professionals at a mean number of 2 physicians (1–6), justified by shift of health insurance (66 patients), lack of resolution (33 patients), dislike of the physician (26 patients) and cost (11 patients). Regarding treatment, 51% of patients were on biologic agents: 23% adalimumab, 15% abatacept and rituximab, 14% etanercept, 12% tocilizumab, 7.6% golimumab, 5% certolizumab and infliximab and 4% tofacitinib. Interestingly, most patients (75%) using abatacept, tofacitinib and tocilizumab were not on methotrexate (MTX), while from the 65 patients on an anti-TNF agent, 75% were also using MTX or leflunomide (LFN). Regarding traditional DMARDs, 91% of patients were on (n=94) or had used MTX (n=120); 43% were on (n=37) or had used (n=64) LFN. Concerning treatment and disease activity, 91% of patients were considered adherent to the treatment with a mean number of 4 annual visits, 82% were also deemed to be in regular monitoring. According to rheumatologist's assessment, 63% of patients had RA "under control". In fact, 72% of patients were on low disease activity (22%) or on remission (50%), according to the DAS28. However, when patients in disease activity were analyzed, few of them (0.28 CI 0.18–0.40) were on biologic or target DMARDS, pointing to a possible therapeutic transitional moment. Only 3 of these could be labeled "refractory", having previously used 3 biologic agents.
Conclusions: *Treat-to-target* strategy seems to have been adopted by most rheumatologists in their individual practice, although there is room for improvement and optimization of therapy. While treatment guidelines are roughly followed, the delay in diagnosis and changes of healthcare are particularly worrisome and need to be addressed.

THU0628 PATTERNS OF ETANERCEPT DOSE ADJUSTMENTS IN A REAL–WORLD SETTING: A CANADIAN RETROSPECTIVE COHORT STUDY

M. Khraishi[1], Y. Zhang[2], J. Ivanovic[2], B. Millson[2], E. Singh[3], J. Woolcott[4], H. Jones[3]. [1]*Faculty of Medicine, Memorial University of Newfoundland, St. Johns;* [2]*Health Access & Outcomes, QuintilesIMS, Kanata, Canada;* [3]*Inflammation and Immunology, Global Medical Affairs, Pfizer Inc., Collegeville, United States;* [4]*Health Economics and Outcomes Research, Pfizer Inc., Kirkland, Canada*

Background: Etanercept is a soluble TNF receptor (humanized protein) indicated for treatment of immune-mediated inflammatory diseases, including rheumatoid arthritis (RA), psoriatic arthritis (PsA), psoriasis (PsO), and ankylosing spondylitis (AS). Canadian monograph recommended dosing of etanercept is 50mg/week, with select indications also requiring an initial loading phase of 100mg/week for 12 weeks. Evidence suggests that real-world practices differ from monograph, with patients titrating to lower or higher weekly dosing as needed. Limited research exists on how etanercept patients are dose optimized in the real-world Canadian setting.
Objectives: To describe etanercept treatment dynamics, including dose de-escalation/escalation in the Canadian real-world setting.
Methods: A retrospective cohort study was conducted utilizing claims-level data from QuintilesIMS Private Drug Plan database, Ontario Public Drug Plan database, and Quebec Public Drug Plan database. Between 07/2013–06/2015, bio-naïve patients who initiated etanercept and who retained on therapy for 12 months were identified. Weekly dosing of each patient was calculated and analyzed for the prevalence and magnitude of dose de-escalation/escalation. Patients with at least 20% lower/higher average dose than monograph recommended dose (50mg/week) were flagged as dose de-escalators/dose escalators, respectively. The first 3 claims of etanercept were excluded from average dose calculations to exclude a possible loading phase.
Results: The study identified 3,051 etanercept patients (60% female, 77% aged between 18 and 65, 87% rheumatic diseases, and 13% PsO) across Canada in the selection period. Overall, 11% (n=332) of patients de-escalated during their first year of therapy, led by AS (15%, n=24) and RA (12%, n=286); 15% (n=449) of patients escalated, led by PsO (64%, n=262) versus 7% (n=168) in RA; 74% (n=2,270) of patients maintained a consistent dose. Average dosing across rheumatic disease patients stabilized to monograph levels by week 20 of their therapy; PsO patients' dosing was observed to be lower than monograph during the loading phase, while higher than monograph in the maintenance phase.
Conclusions: In Canadian real-world practice, the average patient utilization of etanercept remained consistent over the first year in majority of patients, with the exception of those with PsO. A notable proportion of etanercept patients with rheumatic diseases reduced their average dosing over time while on therapy, with almost twice as many patients titrating their dose downwards than upwards. However, in PsO patients, a majority of patients increased their etanercept.

THU0629 THE PERSPECTIVES OF PATIENTS, THEIR FIRST DEGREE RELATIVES, AND RHEUMATOLOGISTS AROUND PREVENTATIVE TREATMENTS FOR RHEUMATOID ARTHRITIS

L. Spooner[1], K. Milbers[2], S. Munro[1], N. Tsao[1], M. Hudson[3], C. Koehn[4], N. Bansback[1], M. Harrison[1,2]. [1]*University of British Columbia;* [2]*Centre for Health Evaluation and Outcome Sciences, Vancouver;* [3]*McGill University, Montreal;* [4]*Arthritis Consumer Experts, Vancouver, Canada*

Background: Ongoing randomized controlled trials are looking at the efficacy of preventing RA through treatment with anti-rheumatic medications. However even if these trials are successful, uncertainty around the potential benefits of preventative programs in practice will affect the uptake of a preventative treatment program. The views of rheumatologists, patients with RA and people considered at-risk of RA (potential recipients) will be important to consider.
Objectives: To identify relevant attributes for a discrete choice experiment (DCE) representing the factors that influence the preferences of patients, first-degree relatives (FDRs), and rheumatologists about preventative treatment for rheumatoid arthritis (RA).
Methods: Semi-structured focus groups were conducted with 1) RA patients in British Columbia (BC), Canada 2) FDRs of people with RA, and 3) rheumatologists from across Canada. Participants were recruited through a combination of convenience and homogenous sampling. Focus group guides were adapted from a previous study which used a DCE to represent an RA treatment decision. In the first round of focus groups, moderated discussions with RA patients, FDRs, and rheumatologists elicited open-ended responses to the interview guide questions. Findings from analysis of these discussions were reduced to a list of potential attributes for the DCE. In the second round, RA patients and FDRs provided feedback to improve the validity and representation of the potential attributes. All focus groups were audio recorded, transcribed, and analyzed using Framework Analysis.
Results: Five focus groups were conducted with 13 RA patients, 5 FDRs, and 7 rheumatologists from four Canadian provinces. Analysis of the discussions revealed that all groups considered competing risks when considering a preventative treatment decision: risks of developing RA and when it might occur; accuracy of predictive tests and the risk of a false positive; and the risks of treatment itself. For rheumatologists, the empirical evidence supporting preventative tests and preventative treatments for RA, as well as treatment side effects were of significant importance. Interestingly, some rheumatologists did not consider prevention to be part of their role. FDRs frequently mentioned the impact that a preventive treatment would have on their lifestyle, the accuracy of predictive test, and weighing the potential benefits against side effects of treatment as key factors in decisions to take a preventative treatment. The health care provider's (nurse/family physician/rheumatologist) knowledge of RA and perceived trustworthiness was also important to FDRs in considering a heath care provider's recommendation for preventative treatment.
Conclusions: Our Framework Analysis highlighted key themes in this discussion which informed the attributes to be included in a DCE. Our findings suggest there are important differences in how patients, FDRs and rheumatologists value the uncertainties surrounding the potential benefits of a preventative treatment for RA.

THU0630 OPIOID USE IN PATIENTS WITH POLYMYALGIA RHEUMATICA

M.D. Richter[1], S.J. Achenbach[2], J.A. Zamora-Legoff[3], C.S. Crowson[2], E.L. Matteson[3]. *[1]Graduate Medical Education; [2]Division of Biomedical Statistics and Informatics; [3]Division of Rheumatology, Mayo Clinic, Rochester, United States*

Background: Polymyalgia rheumatic (PMR) is a systemic rheumatic inflammatory disease characterized primarily by musculoskeletal pain and stiffness. Glucocorticoid treatment is the current standard of care however the need for additional pain management, in particular the need for opioid therapy, has not been studied.
Objectives: To examine the trends of chronic opioid use in patients with PMR over an 11 year period in Olmsted County, Minnesota, USA and compare this to subjects without the disease.
Methods: Retrospective data on opioid prescriptions were collected from 2005 to 2015 in a population-based incidence cohort of patients meeting the 2012 American College of Rheumatology classification criteria for PMR alongside comparison subjects. Poisson regression methods were used to compare opioid use between these groups.
Results: 244 patients with PMR and 211 non-PMR comparator subjects were included in the study. Rates of chronic opioid use were not significantly different between the two groups. 7.5% of patients with PMR were identified as chronic users by the end of the study period compared with 5.2% of non-PMR subjects. Any opioid use was also not significantly higher in PMR, with relative risk of 1.10 (95% CI 0.97, 1.26, p=0.14). There were higher rates of chronic use among patients over 80 years in both groups.
Conclusions: PMR does not appear to be associated with increased rates of opioid use when compared with the general population.
Acknowledgements: This study was made possible by the Rochester Epidemiology Project, which receives support from the National institute on Aging of the NIH.

THU0631 DIRECT FINANCIAL BURDEN OF RHEUMATOID ARTHRITIS ON PATIENTS' LIFE IN A DEVELOPING NATION OF PAKISTAN, ONE YEAR PROSPECTIVE STUDY

M.S. Ahmad. *Orthopedic Surgery, Fazle Omar Hospital, Chenab Nagar, Pakistan*

Background: Rheumatoid Arthritis is chronic inflammatory disease. Early diagnosis and management is necessary to ovoid joint destruction and to minimize disability. It effects 0.5 to 1 percent population. The female to male ratio is 3 to 1. Health care cost is of great concern to patients, physicians and health care policy makers. The financial impact of rheumatoid arthritis treatment like any chronic illness is of great significance in developing society like Pakistan where 30 percent population lives below poverty line and annual per capita incomes are very low. Whereas prevalence is same with high medicines prices with poorly developed health insurance system and government funded hospitals are scanty.
Most of times attention in the field of health economy is focused on direct medical in general and hospital cost in particular but however there are some social societal customs which also increases the burden of direct cost. The direct cost includes expenditures like physician visit cost, diagnostic tests, medications. There are also some hidden charges to this direct cost which are not included in studies like transport charges, food bills during hospital stay and accompany person, female are companied by males. All included puts strain on economy and major share of annual income of patient is paid on management of disease. The worst scenario is when patient stops treatment and if lucky gets support from other sources like patient welfare societies or from relatives.
Objectives: To assess the direct cost of patient's every visit to hospital outpatient department prospectively for one year and total cost of one year was summed up and percentage to annual income spend on treatment was calculated.
Methods: Study carried out from January to December 2015 at Fazle Omar Hospital Rabwah Chenab Nagar and 150 patients either newly diagnosed or already on treatment of rheumatoid Arthritis were included. Data collected for next 1 year for each visit, patients with any other disease along with rheumatoid were excluded. The estimated annual income of patient or the person bearing the expenses was recorded before start of study. Every time patient visit hospital outpatient department, prescription copy kept and cost of medicines, laboratory investigations and consultation fee is calculated and a questionnaire is filled how much it cost coming hospital and going back home and during hospital stay on any other things. The total cost of every visit was recorded for one year.
Results: The mean total per patient income after conversion from local currency was 3000 US dollars against 1474 US dollars per capita income in 2015. The annual average cost per patient including consultation fee, medicines purchased, laboratory investigations and other overhead expenses like transportation of patient and accompanied person and food bills during hospital stay was 1194 US dollars. 41% of patient gross income was spend on management of rheumatoid arthritis. Investigations cost 12%, medicines purchased 16%, consultation 2% and over head visit charges cost 10% of the total mean of per patient annual income.
Conclusions: RA management consumes large portion of patients annual income and it has significant burden on developing world economy.

THU0632 VALIDATION OF INTERNET-BASED REPORTING OF PATIENT REPORTED OUTCOMES WITHIN THE SWEDISH RHEUMATOLOGY QUALITY REGISTER

O.E. Hofstedt[1], D. Di Giuseppe[2], G.-M. Alenius[1], N. Stattin[3], H. Forsblad-d'Elia[1], L. Ljung[1]. *[1]Department of Public Health and Clinical Medicine, Umeå University, Umeå; [2]Department of Medicine Solna, Karolinska Institutet, Stockholm; [3]Swedish Rheumatism Association, Sundsvall, Sweden*

Background: Previous studies have validated the use of clinic based touch-screens for registering patient reported outcome measures (PROMs) (1–3). The Swedish Rheumatology Quality (SRQ) register has implemented an internet-based method (PER (Patientens Egen Registrering, or Patients' sElf Registration)) for collecting PROMs.
Objectives: The aim of this study was to investigate the feasibility of the internet-based method as well as the validity of reported outcomes and disease activity scores compared to the gold standard paper format.
Methods: We recruited patients (n=44, mean age =51.0, standard deviation =13.2 years, 69.6% women) included in SRQ with a diagnosis of rheumatoid arthritis, psoriatic arthritis, juvenile arthritis, spondyloarthritis or ankylosing spondylitis. Before a planned visit at the rheumatology clinic the patients registered Visual Analog Scales (VAS) for global health, pain and fatigue, both electronically by PER and on paper. Patients with axial disease also registered BASDAI and BASFI related variables (n=6). For patients with peripheral arthritis (n=38), DAS28 was calculated using both methods. The differences between the methods were compared by T-test and Intra-class correlation (ICC). Agreement was visualized using Bland-Altman plots for all VAS registrations. The patients also answered a questionnaire regarding the used device and preferred method.
Results: No differences between PER or paper based VAS scores were found for VAS Global, VAS Pain and VAS Fatigue (p=0.086, p=0.691 and p=0.197, respectively). ICC scores ranged from 0.930 to 0.971. Bland-Altman plots for VAS assessments showed good agreement and no proportional bias was detected (Fig 1). Mean difference for DAS28 was - 0.04 (p=0.177). Of the recruited patients, 78%, preferred the Internet based method. BASDAI and BASFI could not be evaluated due to a limited number of observations.

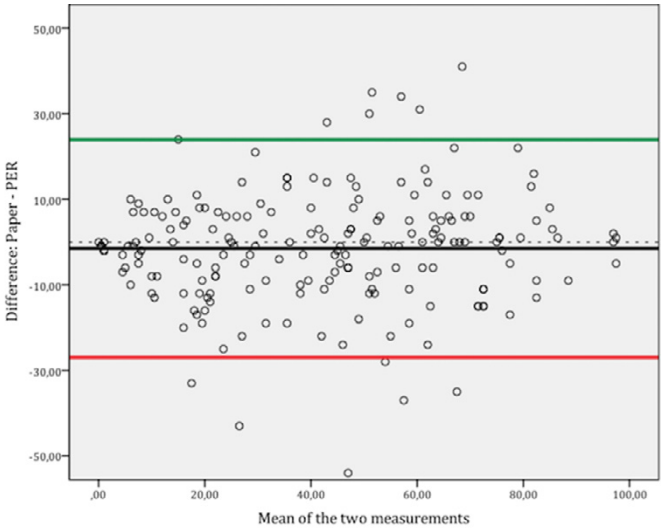

Fig. 1 Bland-Altman plot showing level of agreement of all VAS (VAS Global, VAS Pain, VAS Fatigue, VAS included in BASFI and BASDAI) between paper and PER method. BASDAI and BASFI scores multiplied by 10 for comparability.

Conclusions: Internet based reporting of PROMs supply valid VAS data. DAS28 scores from the internet-based method presents an acceptable alternative to the traditional paper formats.

THU0633 TEMPERATURE SENSITIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

P. Mandl[1], F. Alasti[1], A. Kerschbaumer[1], R. Kaltenberger[2], T. Krennert[2], G.M. Supp[1], U. Landesmann[1], J.S. Smolen[1], D. Aletaha[1]. [1]*Department of Rheumatology, Medical University of Vienna;* [2]*Central Institute for Meteorology and Geodynamics, Vienna, Austria*

Background: Studies evaluating weather sensitivity among patients with rheumatoid arthritis (RA) have yielded conflicting results.
Objectives: To evaluate whether patients with RA exhibit sensitivity to outside temperature.
Methods: We assessed correlation between mean daily temperature and self-reported pain (by visual analogue scale), and patient's global assessment of disease activity (PGA). Assessments documented in the RA database of our department as well as the average temperature obtained from the Central Institute for Meteorology and Geodynamics, were matched on a daily basis for a period of 10 years between 2005 and 2015 and analyzed using generalized estimating equation (GEE) and a mixed model analysis (MM). Patients with <5 visits in the study period, or with <1 visit/quarter or with pain=0 in ≥ 3 consecutive visits and those living outside of the catchment area were excluded. Overlap between responsiveness of pain or PGA to temperature was calculated by Cohen's kappa.
Results: A total of 399 patients with RA (average disease duration at first visit: 6.0±7.6 years, average age: 57.7±13.9 years, 82% female, mean CDAI 19.7±11.5, 59.9% rheumatoid factor positive) were analyzed. Lower temperatures correlated significantly with higher pain levels (estimate: -0.07, p=0.021) in GEE, however the effect size was very small. When we performed MM with temperature as independent variable and VAS pain or PGA as dependent variable, the majority of patients showed no sensitivity to temperature, however 22% of patients were significantly sensitive to cold temperature with an estimate of -0.29 ($p<0.0001$) for pain and -0.21 (p=0.0005) for PGA (Figure 1). When we evaluated whether patients who demonstrate temperature-sensitivity to pain also exhibit temperature-sensitivity to PGA, we found an excellent overlap between the two patient groups (kappa: 0.81).

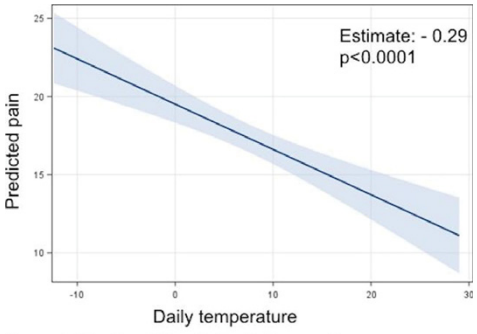

Figure 1. Mixed model analysis of influence of temperature on pain of patients demonstrating sensitivity to cold temperature

Conclusions: Our results indicate that a subgroup of patients with RA show significant sensitivity to cold temperature, and that these patients are characterized by higher pain and PGA levels at lower daily temperatures. These aspects may have to be taken into account in longitudinal analyses of disease activity of RA.

THU0634 COMPARING PREFERENCES OF PATIENTS WITH RHEUMATIC DISEASES, OF RHEUMATOLOGISTS, NURSES AND PHARMACISTS TOWARD THE TREATMENT OF RHEUMATIC DISEASES WITH BIOLOGICAL AGENTS: RESULTS FROM THE CARA STUDY

P. Sarzi-Puttini[1], P.A. Cortesi[2,3], L. Sinigaglia[4], C.M. Montecucco[5], R. Giacomelli[6], G. Lapadula[7], I. Olivieri[8], A. Giardino[9], G. DIdoni[10], L. Scalone[2,3], L.G. Mantovani[3,11], M. Mecchia[10] on behalf of CARA Working group. [1]*Rheumatology Unit, L. Sacco University Hospital, Milano;* [2]*Univeristy of Milano-Bicocca, Monza;* [3]*CHARTA Foundation;* [4]*Rheumatology Unit, G. Pini Hospital, Italy, Milano;* [5]*University of Pavia School of Medicine, IRCCS Policlinico San Matteo Foundation, Pavia;* [6]*Rheumatology Unit School of Medicine, University of L'Aquila, L'Aquila;* [7]*Rheumatology Unit, University of Bari, Bari;* [8]*San Carlo Hospital of Potenza and Madonna delle Grazie Hospital of Matera, and the Basilicata Ricerca Biomedica (BRB) Foundation, Potenza and Matera;* [9]*MSD;* [10]*MSD Italia, Roma;* [11]*University of Milano Bicocca, Monza, Italy*

Background: The management of patients with rheumatologic diseases (RDs) involves a complex interaction between different parties such as patients, physicians, pharmacists. The development of biologic therapies has created a more complex decision-making process to select the treatment option for patients. To optimize the appropriateness of the decisions, it is necessary to be informed and aware of the preferences of the interested parties.
Objectives: To estimate preferences of relevant treatment characteristics with biological agents valued by the different subjects involved in the management of patients with rheumatic diseases.
Methods: We involved patients with RDs, rheumatologists, nurses and pharmacists with experience in the treatment with/provision of biological drugs of these patients. Through a Discrete-Choice-Experiment, the participants valued 16 possible scenarios in which pairs of similarly effective treatments were described with 6 characteristics including 2–4 possible levels each: (1) frequency of administration; (2) mode and place of administration; (3) hospitality, service, efficiency and courtesy of health personnel; (4) frequency of reactions at the site of drug administration; (5) generalized undesired/allergic reactions; (6) additional cost: since the Italian NHS pays treatment costs, we included possible additional cost as monthly healthcare taxes for all the citizens, to make available the treatment to all target patients. relative importance of each characteristic was estimated through a random-effects conditional logistic regression model.
Results: 513 patients, 110 rheumatologists, 51 nurses and 46 pharmacists from 30 centres through Italy participated. Characteristics (3), (4) and (6) were the most important for every subgroup, while (1) was the least important for patients and rheumatologists, (2) the least important for the pharmacists, (2) and (5) the least important for the nurses. The four subgroups were consistent in preferences towards the specified levels of characteristics (1) and (3) to (6). However, as for characteristic (2), pharmacists preferred autonomous subcutaneous injection with syringe, nurses preferred assisted infusion at an infusional center close to patient's place, patients and rheumatologists preferred autonomous subcutaneous injection with pen.
Conclusions: Different subjects show different preferences for some treatment characteristics, which together with pure clinical aspects can play an important role in the choice and consequent success of treatments.

THU0635 PRECISE AND SIMPLE ALGORITHM TO IDENTIFY RA CASES IN ELECTRONIC MEDICAL RECORDS

R. Knevel[1,2,3,4], S. Raychaudhuri[1,2,4], K. Liao[1,2], T.W. Huizinga[3]. [1]*Rheumatology, Brigham and Women's Hospital, Boston;* [2]*Harvard Medical School, Cambridge, United States;* [3]*Rheumatology, Leids Universitair Medisch Centrum, Leiden, Netherlands;* [4]*Broad Institute, Cambridge, United States*

Background: Electronic medical records (EMR) have emerged as a large-scale data collection option for observational studies. These huge data registries create new opportunities to study the rheumatologic phenotype and the real-life implications for these diseases. EMR usage poses new questions of quality management, such as how to reliably identify patients with the disease or phenotype of interest, as well as bioinformatic tools to handle the magnitude of data.
Thusfar, the algorithms used to identify cases are often not validated and overly simplify by using one financial code, or they are well-validated but require very specific information which hampers the applicability to other datasets.
Objectives: *Aim I:* Test the accuracy of the identification of patients with rheumatoid arthritis (RA) using the financial coding system.
Aim II: Develop a simple and precise algorithm to select patients with RA that is easy to implement at other centers.
Methods: *Aim I:* Out of the 16,183 Rheumatology patients in the Leiden out-patient EMR system 400 charts were randomly selected and reviewed for the rheumatologic diagnosis. Next, the charts were reviewed for 200 randomly selected patients that were labeled as RA in the financial system.
Aim II: To enable generalizability, only codified data that was obtained at regular outpatient clinic visits was used. Lasso regression was applied to identify the most discriminative variables.
Results: *Aim I:* Since 2008, 16,183 patients were enrolled in the EMR system of the Leiden rheumatology outpatient clinic. 2,845 of these patients were classified as having RA in the financial system. 63/400 (16.3%) of the reviewed charts concerned patients with RA. The majority (n=57) were registered as having RA in the financial system. Still, 33% of the patients with the financial code RA did not have RA.
Aim II: Using Least Absolute Shrinkage and Selection Operator (LASSO) regression anti CCP, MTX prescription and number of visits were identified as the most discriminative variables. Combining these with the presence of the financial code for RA improved the algorithm from an accuracy of 67% to 90%.
Conclusions: The vast majority of patients that are classified as having RA are registered as such in the financial system. However, a substantial number of patients are registered as RA in the financial system are not classified as RA in clinical charts. Using widely available data on anti-CCP status, MTX prescription

and visit count improved the selection of RA patients from a 67% to 90% accuracy. The combination of these variables provides a widely applicable algorithm, as they are broadly registered in Rheumatology clinics.
Subsequent replications are ongoing.

THU0636 INFLUENZA AND MENINGOCOCCAL C VACCINATIONS IN A COHORT OF PATIENTS WITH AUTOIMMUNE RHEUMATIC DISEASES: ADHERENCE, SAFETY AND IMMUNOGENICITY

R. Vagelli, C. Tani, L. Maggi, E. Elefante, A. Parma, E. Cioffi, S. Talarico, C. Baldini, C. Stagnaro, A. Delle Sedie, S. Vagnani, M. Mosca. *Department of Clinical and Experimental Medicine, Rheumatology Unit, University of Pisa, Pisa, Italy*

Background: The EULAR recommendations for vaccination in adult patients with autoimmune rheumatic diseases strongly recommend inactivated influenza vaccination.Insufficient data are available about safety and efficacy of meningococcal C vaccination.In 2015–2016,after an increased incidence of meningitidis C infections in our country,the health care system has promoted a free meningococcal vaccination campaign
Objectives: To evaluate the adherence to the EULAR recommendations for influenza vaccination and to the meningococcal C vaccination campaign in a cohort of patients with autoimmune rheumatic diseases and to assess their safety.The efficacy in term of immune response to meningococcal C vaccination has been also evaluated
Methods: Consecutive in- and out-patients seen at our unit from February to December 2016 were enrolled in the study.Using a questionnaire created *ad hoc* the following data were collected:the percentage of patients who underwent influenza and/or meningococcal C vaccinations in the previous 12 months,the occurrence of adverse events and of disease flares after vaccinations,according with the report from the patients and with the rheumatologist clinical evaluation.Seroconvertion rates in patients and healthy controls were assessed using ELISA kits for human anti-meningococcal ACWY IgG antibodies.Antibody titres were expressed in U/ml and according with kit reference value were classified in absent,low,medium and high titre
Results: 286 patients (91% female) (143 SLE, 68 RA,60 Scleroderma,11 Sjögren Syndrome,3 Behcet disease and 1 Dermatomyositis) were included in the analysis.The mean age at evaluation was 52.9±16.1 years,mean disease duration was 15.3±10 years.The 53.1% of patients was taking steroids,at an average dose of 4.2 mg of 6-metilprednisolone/day,134/286 (46.9%) patients were on immunosuppressive therapies,of which 49/134 (36.6%) on biologic agents.The 19.9% (57/286) of patients underwent influenza vaccinations and the 13.3% (38/286) meningococcal C vaccination,8 patients underwent both vaccinations.No disease flares were observed after vaccination;seven patients reported non-specific adverse events after influenza (fever,discomfort,nausea,arthralgia) and 2 patients after meningococcal C vaccination (fever,rash at the injection site,discomfort).Seroconversion after meningococcal vaccination was analysed in 27 patients and 9 healthy subjects,no statistically significant differences in terms of antibody response to meningococcal vaccination were observed between these two groups.Treatment (steroids and immunosuppressive drugs) did not influence antibody titres
Conclusions: These data highlight the poor adherence to international recommendations on influenza vaccination in patients with autoimmune rheumatic disease at our Unit.The adherence to the meningococcal C vaccination campaign conducted in our country in 2015–2016 was also low.Our data confirm the safety of these vaccination and show that the immune response elicited by meningococcal C vaccination is comparable to healthy controls and is not influence by therapy

THU0637 PATIENT'S AND RHEUMATOLOGIST'S PERSPECTIVES ON THE FOLLOW-UP INTERVAL AS A TOOL FOR OPTIMIZED OUTPATIENT TREATMENT

S. Hermann, S. Fügner, E. Wiebe, T. Alexander, G.R. Burmester, F. Buttgereit. *Dept. of Rheumatology, Charite, Berlin, Germany*

Background: Scientific progress and better disease awareness constantly lead to increasing patient numbers in rheumatology which requires optimization of patient care.
Objectives: The aim of this study was to evaluate and to optimize the procedures of patient care in an university-based outpatient rheumatology setting in Berlin, Germany.
Methods: One hundred patients with rheumatoid arthritis (80 women, 20 men, mean age 61.2 years, mean disease duration 12.9 years) were independently assessed both by a rheumatologist and via patient-reported self-assessment questionnaires. Current follow-up interval (usually 3 months), patient's perspective on follow-up intervals, signs of disease activity as well as individual patient concerns were recorded. Satisfaction with follow-up intervals was grouped into three categories: too early, just right/optimal, too late.
Results: Based on the physicians perspective, 46 patients presented at the optimal time point, 51 too early, and three too late. The patients reported the category "just right" in 82 cases, too early follow-up in 10 cases and too late in 8 cases. Of note, 51% (42 individuals) of all patients with self-reported satisfactory follow-up interval were judged to visit the out-patient department too early by the expert rheumatologist. When taking into account the follow-up interval and optimal satisfactory levels, 62% of patients were concluded to visit the department too early in those revisited after 3–4 months (n=65), and in 12% of those who were seen again after 5–6 months (n=17). 82% of patients in the latter group were judged to revisit just right by the physician.
Conclusions: There was a high proportion of overlap in the views on the satisfaction with follow-up intervals between physicians and patients. Especially in patients who were seen every 3–4 months, a high proportion was deemed to could have come later to the out-patient care unit from a purely medical point of view. Here we see a way to stretch the interval to 5–6 months without risking a long-term deterioration in patient care. However, this measure should be flanked by patient education and good collaboration with the general practitioners.
Acknowledgements: We thank AbbVie for financial support in the development of measures to optimize out-patient management in patients with rheumatoid arthritis. The sponsor did not influence the scientific results.

THU0638 PREVALENCE AND DIRECT HEALTHCARE COSTS OF UPPER GASTROINTESTINAL (UGI) ADVERSE EVENTS IN ASIAN RHEUMATIC PATIENTS ON LONG-TERM NON-STEROIDAL ANTI-INFLAMMATORY DRUGS (NSAIDS)

S.L. Pok[1], F.H. Shabaruddin[2], J.Y. Teng[2], M. Dahlui[3], C.T. Ng[1], S. Sockalingam[1], M.S. Said[4], A. Rosman[5], I.S. Lau[5], L. Mohd Isa[6], H. Hussain[6], S. Mahadeva[2]. *[1]Dept. of Rheumatology; [2]Dept. of Medicine; [3]Dept. of Social & Preventive Medicine, University of Malaya; [4]Dept. of Rheumatology, National University of Malaysia, Kuala Lumpur; [5]Dept. of Rheumatology, Selayang Hospital, Selangor; [6]Dept. of Rheumatology, Putrajaya Hospital, Kuala Lumpur, Malaysia*

Background: NSAIDs are frequently used in patients with rheumatoid arthritis (RA) and osteoarthritis (OA). NSAID-induced UGI adverse events are well described in the Western population but data is lacking in Asian patients.
Objectives: To describe the prevalence and direct healthcare costs of NSAID-induced UGI adverse events in a large cohort of RA and OA patients in Malaysia.
Methods: A retrospective cohort study of RA and/or OA patients who received long-term NSAIDs (minimum 4 weeks prescription of any NSAID) between 2010 and 2013 was conducted in 4 large tertiary care centres with rheumatology units in Malaysia. Electronic clinical records and pharmacy prescriptions were reviewed. Resource use data was collected in patients who developed UGI adverse events within the 24 months follow up period. Unit costs were estimated by combining top down (general overheads for hospital services) and bottom up (activity-based costing for clinic visits, hospitalisation, diagnostic investigations, medications) approaches.
Results: 634 patients were included in the final analysis with mean age 53.4±12.5 years, 90% female, diagnosis of RA in 60%, OA in 10% and both RA and OA in 30%. 45% and 8% of patients were on concomitant prednisone and aspirin respectively. 89% of patients had no previous upper GI disease. 59% and 41% of patients were grouped under non-selective and COX-2 inhibitor respectively. 84 (13.2%) patients developed UGI adverse events (Figure 1), consisting of 78 (12.3%) patients with dyspepsia, 5 (0.79%) with peptic ulcer disease (PUD) and 1 (0.16%) with upper GI bleeding (UGIB). The total direct cost was RM37,352 (USD 11,419) with a mean cost of RM447±535 (USD 137±163) per patient (Table 1). The largest cost components were pharmacotherapy (34%), oesophagoduodenoscopies (OGD) (23%) and outpatient visits (18%). The mean cost of dyspepsia was RM409±513 (USD 125±157) per patient. The mean cost of PUD and UGIB was approximately double (RM806±579) (USD 246±177) and quadruple (RM1,602) (USD 490) of dyspepsia respectively.

Healthcare resource	Mean cost per patient in RM (USD)			
	Dyspepsia (n=78)	PUD (n=5)	UGIB (n=1)	All patients with UGI adverse events (n=84)
Outpatient visits	77 (23)	146 (45)	146 (45)	82 (25)
Emergency Dept visits	28 (9)	0	146 (45)	28 (9)
Inpatient stay	46 (14)	136 (41)	679 (207)	59 (18)
OGD	85 (26)	253 (77)	211 (65)	103 (32)
Blood tests	4 (1)	32 (10)	57 (17)	6 (2)
Radiology	8 (3)	0	0	8 (3)
Blood transfusion	4 (1)	56 (17)	280 (86)	10 (3)
Pharmacotherapy	150 (46)	183 (56)	84 (26)	151 (46)
Mean cost per patient in RM ±SD (USD)	409 ±513 (125±157)	806±579 (246±177)	1602 (490)	447±535 (137±163)

Conclusions: The low prevalence of UGI adverse events in Malaysian rheuma-

tology patients suggests judicious use of NSAIDs in tertiary care setting resulting in a low cost implication for the management of these events.

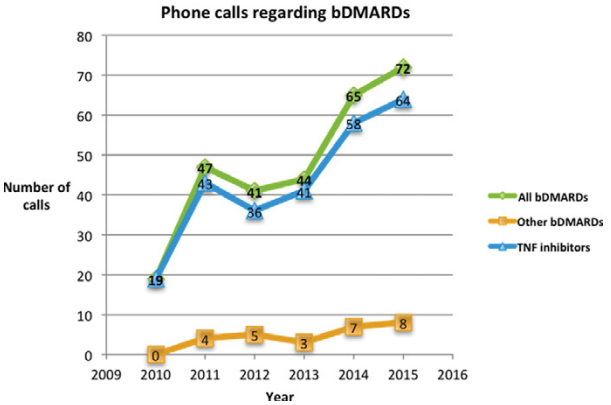
THU0639 RHEUMATOLOGICAL MEDICATION USE IN PREGNANCY, PLANNING PREGNANCY, AND BREASTFEEDING AT MOTHERSAFE DURING THE YEARS 2010 TO 2015

S.-N. Luong[1], D. Kennedy[2], J.V. Bertouch[1]. [1]*Rheumatology, Prince of Wales Hospital;* [2]*Clinical Genetics, Royal Hospital for Women, Randwick, Australia*

Background: MotherSafe is a free, statewide, phone based counselling service for the general public and healthcare professionals concerned about exposures during pregnancy, pregnancy planning and breastfeeding (1). Obstetric drug information services such as MotherSafe are important in guiding decision-making in pregnancy, breastfeeding and planning of future pregnancies, and are increasingly used worldwide by both patients and healthcare providers (1, 2). At MotherSafe, phone advice is provided by trained telephone counsellors who are generally pharmacists. Data from each phone call is entered onto an electronic document. Some patients are then referred onto the MotherSafe clinic for specialised counselling by a clinical geneticist.

Objectives: To analyse data including patient and medication characteristics and trends from phone calls made to MotherSafe regarding disease modifying antirheumatic drugs (DMARDs) and biologic DMARDs (bDMARDs) from January 2010 to December 2015 inclusive.



Methods: Retrospective study of phone calls made to MotherSafe from January 2010 to December 2015 regarding conventional DMARDs and biologic DMARDs. SPSS software facilitated statistical analysis.

Results: A total of 135,115 phone calls were made to MotherSafe from 2010–2015 with 2611 (1.93%) phone calls pertaining to DMARDs and bDMARDs.

Of these 2611 phone calls, 65.4% were made by patients and 13.5% by general practitioners. Most phone calls were made in metropolitan New South Wales (69.3%). 43% of phone calls were concerning exposures during breastfeeding, followed by exposures during pregnancy (32.9%), exposures whilst planning pregnancy (17.7%) and paternal exposures (2.9%). Where a specific diagnosis was given, inflammatory bowel disease was the most common indication (18.4%), followed by rheumatoid arthritis (8.2%). Corticosteroids were the most common medication exposure (37.3%), followed by azathioprine (18.8%), sulfasalazine (11.2%) and methotrexate (8.5%).

Most callers just received phone advice, especially if the call was just regarding breastfeeding exposures (73.4%). 383 callers (14.7%) were referred onto the MotherSafe clinic, which is run by a clinical geneticist.

bDMARDs made up 9.5% of calls with calls tending to increase over the years, but there was a slight decrease in 2012 and 2013 albeit with small numbers. TNF inhibitors still made up the majority of calls regarding bDMARDs.

Conclusions: This study evaluated the only obstetric medicine exposure information service in New South Wales, Australia. It is the first time that DMARDs and bDMARDs have been analysed for MotherSafe. There was a trend to increasing number of calls regarding bDMARDs over 2010 to 2015, which presumably reflects change in prescribing patterns. This study highlights the need for services like MotherSafe so patients and health care professionals can receive evidence based information and make choices about treatment in pregnancy.

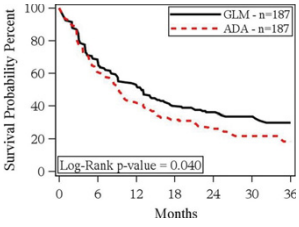
THU0640 SECOND LINE TREATMENT PERSISTENCE AND COSTS AMONG PATIENTS WITH IMMUNE-MEDIATED RHEUMATIC DISEASES TREATED WITH SUBCUTANEOUS TNF-ALPHA INHIBITORS



J. Dalén[1], A. Svedbom[1], C.M. Black[2], S. Kachroo[2]. [1]*Mapi group, Stockholm, Sweden;* [2]*Merck & Co., Inc., Kenilworth, United States*

Background: For some patients with Immune Mediated Rheumatic Disease (IMRD) discontinuing 1st line treatment with a subcutaneous Tumor Necrosis Factor-alpha inhibitor (SC-TNFi), 2nd line treatment with another SC-TNFi may be appropriate.

Objectives: The primary objective of this study was to describe treatment persistence with 2nd line SC-TNFi stratified by agent in patients with IMRD in Sweden. The secondary objective was to explore the impact of non-persistence with a second SC-TNFi on health care costs.

Methods: We conducted a retrospective study on treatment persistence and health care costs using data from health registers. Adults (≥18 years old) previously treated with one SC-TNFi and subsequently prescribed a second SC-TNFi were identified through prescriptions for adalimumab (ADA), etanercept (ETA), certolizumab pegol (CZP) and golimumab (GLM) between 5/6/2010 and 12/31/2012. Prescriber specialty and department were used to exclude patients treated for diseases other than IMRD. Persistence up to 3 years was estimated using non-parametric survival analysis. Given differences in baseline characteristics, analyses were conducted on propensity score matched (PSM) cohorts. Matching was based on age, gender, index year, diagnosis, Charlson Comorbidity Index and non-biologic DMARD use. Non-treatment health care costs were captured 12 months pre and post initiation of 2nd line SC-TNFi treatment and stratified by persistence status at 6 months.

Results: In total, 845 patients were identified (ADA: 316, ETA: 202, CZP: 140, GLM: 187). PSM cohorts were generated as GLM vs ADA, GLM vs ETA and GLM vs CZP, with 187, 164, and 113 matched pairs, respectively. GLM exhibited statistically significant higher persistence than ADA over 3 years (Figure; p=0.040) and numerically, but not statistically significant, higher persistence than ETA and CZP at 12 and 24 months. Persistent and non-persistent patients had similar mean total cost 12 months pretreatment initiation (USD 5,185 vs USD 5,064, p=0.750). During the 12 months post treatment initiation, persistent patients had lower mean total costs (USD 4,377 vs USD 6,605), corresponding to a difference in difference of USD 2,228 (p<0.001).

Conclusions: In patients previously treated with a SC-TNFi, GLM exhibited significantly better persistence than ADA and numerically higher persistence than ETA and CZP at 12 and 24 months, findings that are similar to results observed in 1st line SC-TNFi patients[1]. Given the lower healthcare costs for persistent patients, the choice of 2nd line SC-TNFi among eligible patients may merit careful consideration given its impact on patients and payers.

THU0641 THE DISEASE BURDEN OF SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS FOR PATIENTS AND CAREGIVERS: AN INTERNATIONAL HEALTH RELATED QUALITY OF LIFE SURVEY AND RETROSPECTIVE CHART REVIEW

S. Shenoi[1], G. Horneff[2], M. Cidon[3], A. Ramanan[4], Y. Kimura[5], P. Quartier[6], I. Foeldvari[7], A. Zeft[8], K.G. Lomax[9], J. Gregson[10], A. Tineke[11], S. Campbell[12], J. Weiss[13], N. Marinsek[12], D. Patel[12], N. Wulffraat[14]. *[1]Seattle Children's Hospital, Seattle, United States; [2]Asklepios Kliniken GmbH, Hamburg, Germany; [3]Stanford University, Palo Alto, United States; [4]University Hospitals Bristol, Bristol, United Kingdom; [5]Hackensack University Medical Center, New Jersey, United States; [6]Paris-Descartes University Necker-Enfants Malades Hospital, Paris, France; [7]Hamburger Zentrum für Kinder-und Jugend Rheumatologie, Hamburg, Germany; [8]Pediatrics Rheumatology, Cleveland Clinic, Cleveland; [9]Novartis Pharmaceutical Corporation, New Jersey, United States; [10]Novartis Pharma AG, Basel, Switzerland; [11]VU University Medical Centre, Amsterdam, Netherlands; [12]Navigant Consulting Inc., London, United Kingdom; [13]Navigant Consulting Inc., San Francisco, United States; [14]Wilhelmina Kinderziekenhuis, Utrect, Netherlands*

Background: Systemic juvenile idiopathic arthritis (SJIA) is a severe autoinflammatory disease characterised by systemic features including high fevers, rash and arthritis. SJIA can impose a high physical, psychosocial, behavioral and financial burden on patients (pts) and their families.
Objectives: To analyse the impact of the burden of SJIA by evaluating caregiver perspectives of disease burden utilising a SJIA-specific questionnaire combined with physician data about disease severity and treatment in an international, real-world study.
Methods: SJIA treatment centers in France, Germany, Netherlands, UK and the US participated. Pts (aged 4–18 years) with confirmed SJIA received one of the following biologic treatments for ≥2 months: anakinra (ANA), canakinumab (CAN), or tocilizumab (TOC). SJIA burden in patients on biologics was assessed using a caregiver questionnaire and retrospective chart review. Validated measures included: Child Health Questionnaire Parent-Form 50 (CHQ-PF50), 36-Item Short-Form Health Survey (SF-36v2) and Work Productivity and Activity Impairment questionnaire: Specific Health Problem (WPAI:SHP). Caregivers completed function, treatment satisfaction and resource utilization questions.
Results: Sixty-one pts enrolled from June 2015- June 2016: 12 on ANA, 25 on CAN, 24 on TOC; 46% from the US; 48% female; mean age at survey was 11.3 years. Mean age at SJIA diagnosis was 6.4 years, mean age at start of ANA, CAN, and TOC treatment was 9.9, 9.1, and 7.5 years, respectively. Caregivers were 79% female, mean age 41.2 years, and 36% reduced or stopped working due to their child's SJIA. Of the pts enrolled on CAN and TOC, 72% and 46% respectively had previously been on ANA. Baseline CHAQ, CHQ-PF50, and WPAI scores were worse in CAN and TOC than ANA pts. Mean (±SD) CHQ-PF50 physical (PhS) and psychosocial (PsS) summary scores were significantly lower in SJIA patients than a normative population (PhS: 40.0±18.2 vs. 53.0±8.8; PsS: 46.6±11.3 vs. 51.2±9.1) as was caregivers' mean SF-36v2 mental component score (46.2±10.7 vs. 50.0+10). Highest caregiver stressors were worry over long-term SJIA impact on their child (45%) and uncertainty about the future (28%).
Conclusions: Treatment sequencing and patient-reported outcome measures indicate ANA is used as 1st line for less severe SJIA while CAN and TOC are used as 2nd/3rd line for severe SJIA. Caregivers expressed stress over the long-term impact of SJIA and fear for the future and had variable treatment satisfaction and resource utilisation levels.

THU0642 THERE IS A COMMUNICATION PROBLEM BETWEEN PATIENT AND PHYSICIAN DURING PRE-CONCEPTIONAL PERIOD: HUR-BIO REAL LIFE RESULTS

O.A. Uyaroglu[1], E. Seyhoglu[1], A. Erden[2], L. Kılıç[2], B. Armagan[2], A. Sarı[2], Ö. Karadağ[2], A. Akdoğan[2], S. Apraş Bilgen[2], S. Kiraz[2], I. Ertenli[2], U. Kalyoncu[2]. *[1]İnternal Medicine; [2]Division of Rheumatology, Hacettepe University School of Medicine, Ankara, Turkey*

Background: A significant part of patients with inflammatory arthritis are at their reproductive ages. Biological drugs are one of the important treatment options for inflammatory artritis which can cause fetal morbidity and mortality. Management of arthritis during pre-conceptional period is one of the challenges in rheumatology.
Objectives: This study aims to assess whether patients under biological treatment share their conception intents with their physicians.
Methods: 1580 patients admitted to our outpatient clinic between July 2015 and July 2016 who were received biological treatment. A questionnaire was performed to 373 patients who are at their reproductive ages. Patients were asked whether they or their wifes had got pregnant after the start of biological agent. If they had got, they were asked;
1. Was the pregnancy intented?
2. Did your physician know if you were going to get pregnant while taking a biological agent?
Results: There were total of 79 patients who or whose wifes had got pregnant after the start of biological agent. 34 (%43) out of 79 were female and 45 (%57) out of were male. Mean age of patients were 35.1 (5.3). Median disease duration was 10 (IQR=9) years. 24 (30.4%) pregnancies out of 79 were not planned [15 female (44.1%), 9 male (20%), p=0.021]. In addition, 43 (54.4%) out of 79 patients did not share their pregnancy plans with their physicians [15 (44,1%) female and 28 (62,2%) male (p=0.110)]. 28 (35.4%) of all patients stated that their disease was active during pre-conceptional period [20 (58,8%) female patients, 8 (17,8%) male patients, (p<0,001)].
Conclusions: In our study group, almost one third of the patients had unplanned pregnancies particularly with in female patients. One third of the patients were in active state before conception according to patients' report. Almost half of the patients did not share their plan of pregnancy with their physicians. We suggest that in routine practise, physicians should ask plan of pregnancy in every clinical visit.

THU0643 WHAT FACTORS RELATE TO PATIENTS CONTRIBUTING LONGITUDINAL DATA USING SMARTPHONE TECHNOLOGY? FINDINGS FROM RA PATIENTS PARTICIPATING IN ARTHRITISPOWER REGISTRY

W.B. Nowell[1], H. Yun[2], J. Willig[3], J. Beaumont[4], B. Johnson[3], S. Ginsberg[5], C. Wiedmeyer[5], R. Crow-Hercher[5], B.J. Johnson[5], S. Yang[3], J.R. Curtis[3]. *[1]Global Healthy Living Foundation, Upper Nyack; [2]University of Alabama at Birmingham School of Public Health; [3]University of Alabama at Birmingham, Birmingham; [4]Northwestern University Feinberg School of Medicine, Evanston; [5]CreakyJoints, Global Healthy Living Foundation, Upper Nyack, United States*

Background: Data capture of patient reported outcomes (PROs) is gradually shifting from data collection on paper in medical office settings to use of computer or mobile based technologies between doctor visits. Concerns have been raised that patients may have limited interest in contributing data over time or that they may only record new data when there has been a change in their clinical status.
Objectives: The objective of this study was to evaluate the patterns and factors associated with longitudinal PRO data capture among participants in the PCORI-funded Patient Powered Research Network for adult rheumatologic conditions, ArthritisPower.
Methods: Patients in the registry were asked to voluntarily complete PROs including the RAPID3 and 4 PROMIS instruments plus disease-specific information via a mobile application (App) on their smartphone or computer. We evaluated the average time it took the patient to record each of the instruments and the total number of unique days that patients recorded PROs on the smartphone. Given the newness of the registry (launched late 2015), longitudinal data was defined as contributing at least 2 sets of PROs on unique calendar days. We tested the hypothesis that patients would contribute longitudinal data only when at least one of their scores exceeded a minimally important difference (MID) of any of the 5 PROs examined (generally 2–3 units for PROMIS instruments; 3.6 units for RAPID3). Demographic factors associated with multiple PRO reports were identified using logistic regression among patients who had been enrolled in the registry for at least 3 months.
Results: At the time of analysis, ArthritisPower had recruited 2,103 patients, most (approximately 68%) had RA, and 20% provided their Twitter handle. Average (SD) age was 50 (12); 87% were women. The mean assessment time for each of the PROMIS instruments ranged from a low of 16 seconds (Sleep Disturbance) to a high of 105 seconds (RAPID3). The average score for Pain Interference was 64.3 (SD: 6.3), Physical Function 37.5 (6.5), Sleep Disturbance 59.3 (8.4), Fatigue 64.2 (8.4), and RAPID3 15.7 (5.3). Of 1,946 patients who registered the Smartphone App more than 3 months prior to analysis, 20.6% never contributed any PRO information, 53.3% answered once, and 26.1% answered at least twice. Among patients with longitudinal data (≥2 assessments), the mean change score of PROs between pairwise PRO assessments was <1 point for all instruments

Table: Mean change between 1st and 2nd visit among ArthritisPower patients with longitudinal data

	Mean change from 1st to 2nd visit	Absolute mean change from 1st to 2nd visit	% of patients exceeding change > MID
PROMIS Physical Function	-0.4 (3.8)	2.7 (2.7)	34.2%
PROMIS Pain Interference	-0.4 (5.4)	3.9 (3.6)	52.3%
PROMIS Sleep Disturbance	0.2 (6.1)	4.6 (4.0)	56%
PROMIS Fatigue	-0.03 (6.6)	4.8 (4.4)	55.6%
RAPID3	0.2 (3.8)	2.8 (2.6)	29.8%
MID: Minimally important difference (using 3 points for PROMIS instruments and 3.6 for RAPID3)			

(Table). Only 23.1% of patients contributing longitudinal data had a change greater than the MID in any of the 5 PRO measures. Patients with RA (OR: 1.54, 95% CI: 1.14–2.06), biologic use (2.12, 1.43–3.15), and those with Twitter accounts (1.40, 1.08–1.82) were more likely to contribute longitudinal PRO data in the absense of regular reminders.
Conclusions: Multiple factors were associated with patients contributing longitudinal PRO data. Patients were willing to contribute longitudinal PRO data even in the absence of a change in their health state exceeding any MID. Additional efforts are needed to engage patients to contribute PRO data over time.

THU0644 PATIENT DECISIONS RELATED TO HIP AND KNEE ARTHROPLASTY AND THE FACTORS INFLUENCING THEM

W.B. Nowell[1], S. Venkatachalam[2], E. Harden[2], T. Concannon[3,4,5]. *[1]Global Healthy Living Foundation, Upper Nyack, United States; [2]CreakyJoints, Global Healthy Living Foundation, Upper Nyack; [3]Tufts Clinical and Translational Science Institute; [4]Tufts University School of Medicine; [5]The RAND Corporation, Boston, United States*

Background: Patient-engaged research can improve the safety and satisfaction outcomes of hip and knee arthroplasty (joint replacement surgery).
Objectives: The objective of this study was to identify the decisions that are most important to patients when undergoing hip or knee arthroplasty and the factors they view as important in making those decisions.
Methods: Forty-nine U.S. participants were recruited from ArthritisPower Patient-Powered Research Network and CreakyJoints arthritis patient community to participate in structured one-hour discussions held via webinar during January to April 2016 to understand patients' experiences with joint replacement. Patients described decisions that were most important to them and the factors they used to make those decisions. Discussions were transcribed and coded to identify themes; patient decisions and factors were identified and categorized and co-occurrence of decisions and factors was tabulated. Demographic and procedure-related characteristics were captured.
Results: Eight decisions emerged that were influenced by at least ten factors (Table). The most important decisions involved whether to have surgery, selection of surgery date, surgeon, facility, implant device, and ancillary health care professionals (HCPs) and services. Factors included current situation, expectations of having or not having surgery, professional and word-of-mouth familiarity with surgeon/HCP, procedure, services and device, and perceived value. Patients' current situation and health status and their expectations of surgery were most commonly used to make decisions about whether and when to have surgery. Patients' trust of and communication with doctors was the most commonly factor used when deciding on arthroplasty surgeon.

Table 1: Arthroplasty Decisions Important to Patients and the Most Common Factors Influencing Them

Decisions Important to Patients	Most Common Factors Influencing Decisions
Surgery: Whether to have partial or total hip/knee joint replacement surgery (arthroplasty)	Current life situation / health status (44%), Expectations of surgery (11%), Information provided to patient by doctor/HCP (11%), Alternatives to surgery (11%)
Timing: When to have surgery	Current life situation and health status (38%), Expectations of surgery (19%), Alternatives to surgery (19%)
Surgeon: Which surgeon will perform surgery	Trust and communication with surgeon (45%), Perceived value of surgeon's expertise (19%), Expectations of surgery (16%), Information accessed by patient (10%)
Facility: Where surgery will be performed (e.g., location, specific hospital or medical center)	Information provided to patient by doctor/HCP (28%), Trust and communication with HCP (18%), Firsthand familiarity with facility (18%), Expectations of surgery (18%), Information accessed by patient (9%), Perceived value of facility expertise (9%)
Device: Which implant device will be installed during surgery	Expectations of surgery (39%), Information provided to patient by doctor/HCP (18%), Perceived value of device (16%), Trust and communication with HCP (11%)
Approach: Specific approach to surgery (e.g., anterior vs. posterior, bilateral joint replacement)	Expectations of surgery (45%), Trust and communication with surgeon (42%), Firsthand familiarity with other HCPs (18%)
Other HCPs: Who/which other health care professionals (HCPs) besides the surgeon will be involved in care during and after surgery	Expectations of surgery (30%), Trust and communication with HCP (20%), Current life situation / health status (20%), Perceived value of / familiarity with other HCPs (20%)
Other Services: What other services will be necessary before, during or after surgery	Expectations of surgery (71%), Trust and communication with HCP (14%), Current life situation / health status (14%)

Conclusions: Arthroplasty patients are concerned about a variety of decisions. Patient-centered research should maximally address questions of importance to patients and this study is a first step in identifying and prioritizing topics that matter most to patients and the information that patients currently use to make joint replacement decisions.

THU0645 OPTIMIZING THE EFFICIENCY OF PATIENT DATA CAPTURE USING SMARTPHONE TECHNOLOGY: EVALUATION OF THE CORRELATION BETWEEN PROMIS INSTRUMENTS FOR PRO DATA CAPTURE

W.B. Nowell[1], H. Yun[2], J. Beaumont[3], S. Yang[4], J. Willig[4], S. Ginsberg[5], K.V. Clayton[5], S. Hazel[5], C. Wiedmeyer[5], J.R. Curtis[4]. *[1]Global Healthy Living Foundation, Upper Nyack; [2]University of Alabama at Birmingham School of Public Health, Birmingham; [3]Northwestern University Feinberg School of Medicine, Evanston; [4]University of Alabama at Birmingham, Birmingham; [5]CreakyJoints, Global Healthy Living Foundation, Upper Nyack, United States*

Background: Patient-reported outcomes (PROs) are key to enabling the comprehensive assessment of patient-centered benefits in comparative effectiveness research (CER). However, the relationships between different PROMIS instruments and condition-specific disease activity measures in diseases such as rheumatoid arthritis (RA) have not been well studied.
Objectives: The objectives of this analysis were to evaluate the longitudinal relationship between different PROMIS instruments and the RAPID3, a measure of self-reported patient disease activity.
Methods: Four NIH PROMIS instruments (Pain Interference, Physical Function, Sleep Disturbance and Fatigue) and the RAPID3 were administered to participants in the PCORI-funded ArthritisPower patient registry. After descriptive analytics, we estimated multiple correlations between PROMIS instruments and the RAPID3. For each PRO instrument and with each assessment used as the unit of measure, we calculated the R-squared using mixed models to evaluate how the PROs were related to each other. Using Pain Interference as an example, we evaluated R-squared for each model with additional PROs and demographic factors including enrollment age, sex, race, Twitter account, region, and visit times.
Results: A total of 1,590 unique participants who answered the survey one or more times were included in the analysis, with mean (SD) age of 49 (12) years. The mean score for Pain Interference was 63.7 (SD: 7.0), Physical Function 37.5 (8.7), Sleep Disturbance 58.4 (8.7), Fatigue 63.8 (8.8), and RAPID3 15.5 (5.7). Most PROMIS instruments were low to moderately correlated (around 0.2) with each other and the RAPID3. Using Pain Interference as an example, R-squared measures revealed a high total variance explained (R^2=49%) between Pain Interference and Physical Function (Table); those involving Pain Interference, Physical Function, Fatigue, Sleep Disturbance and RAPID3 also revealed a higher variance contribution with these additional PROs (66%). Additional adjustment for demographic factors added little variance explanation (1.4%).

Table: Total variance explained by predictors (R-Squared) with PROMIS Pain Interference as the dependent variable

Models with PROMIS Pain Interference as the dependent variable	Pain variance that could not be explained by predictors	Total variance that could be explained by predictors (R-Squared)
Baseline model: no predictors	42.6	-
Model with predictors: PROMIS Physical Function	22.6	46.9%
Model with predictors: PROMIS Physical Function, Sleep Disturbance	20.7	51.6%
Model with predictors: PROMIS Physical Function, Sleep Disturbance, Fatigue	18.7	56.1%
Model with predictors: PROMIS Physical Function, Sleep Disturbance, Fatigue, RAPID3	15.3	64.1%
Model with predictors: PROMIS Physical Function, Sleep Disturbance, Fatigue, RAPID3 and demographic predictors (age, gender, race, region, etc.)	15.1	64.7%
Model with only demographic predictors: age, gender, race, region, etc.	42.3	0.7%

Conclusions: PROMIS Pain Interference, Physical Function, Sleep Disturbance, Fatigue instruments and RAPID3 are reasonably correlated to each other. Age, gender, race and other demographic factors play little role in explaining variance in PROs. These results suggest potential efficiencies in using some measures to predict or impute the values for other measures and to optimize the frequency of patient data collection using at-home technologies including Smartphone Apps like ArthritisPower.

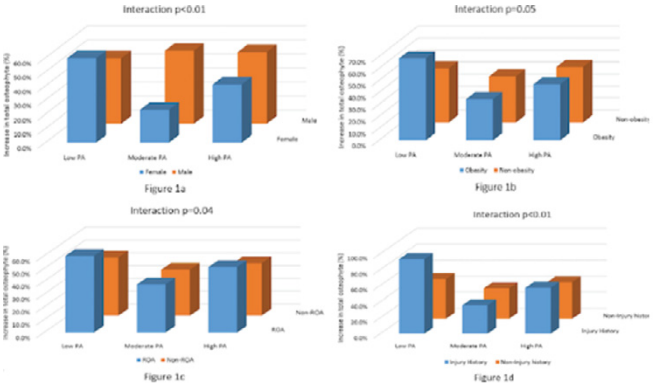
THU0646 INTERCHANGEABILITY FROM INFLIXIMAB ORIGINATOR TO INFLIXIMAB BIOSIMILAR: EFFICACY AND SAFETY IN A PROSPECTIVE OBSERVATIONAL STUDY ON 89 PATIENTS



Y. Presberg[1], V. Foltz[2], C. L'Amour[2], P. Tilleul[1], D. Zerkak[2], C. Gard[1], B. Fautrel[2,3]. [1]*Pharmacy;* [2]*Rheumatology, AP-HP pitié salpetrière hospital;* [3]*Université Pierre et Marie Curie (UPMC)-Paris 6, Paris, France*

Background: Biosimilar biologic disease modifying anti-rheumatic drug (bsDMARD) are supposed to offer a real economic advantage for these diseases for the same health benefit. While the administration of a biosimilar to a new patient is widely accepted, the switch from a biologic originator DMARD (boDMARD) to its biosimilar remains questioned.
Objectives: This study aimed to assess the safety and efficacy of switching from an IV anti-TNF boDMARD to its bsDMARD in patients with rheumatic arthritis, spondyloarthritis, psoriatic arthritis, juvenile arthrtitis and uveitis.
Methods: Prospective real-life study in the rheumatology unit of La Pitié-Salpêtrière Hospital, from February 2016 to December 2016. Patients initially treated with the boDMARD infliximab (RemicadeÒ), all switched to infliximab bsDMARD (InflectraÒ) after patient's information by a rheumatology nurse. The dose and administration schedule remained unchanged at the switch. Our primary endpoint was infliximab maintenance rate. Secondary endpoints were evolution of disease activity, as well as evolution of both infliximab trough levels and anti-drug antibody (ADA) serum levels before and after the switch. In addition, safety events were also monitored.
Results: We identified 89 patients – spondyloarthritis (61%), rheumatic arthritis (27%), psoriatic arthritis (11%), juvenile arthritis and uveitis (1%) – in rheumatology who have been switched to boDMARD infliximab to its bsDMARD. Clinical assessment was based on DAS28 (peripheral joint involvement) or BASDAI (axial involvement) scores. 93% of patients remained treated with infliximab: 6 patients (7%) stopped the treatment due to a loss of efficacy. As shown in Figure 1, there is no significant change in disease activity before and after having switched patients to infliximab biosimilar.The ADAdosage were detected in 10 patients, 7 with high titer (>200ng/mL) and 3 with moderate titer (between 50 and 200 ng/mL). It was significantly correlated with low trough levels of IFX (<0,3µg/mL). Among them, 6 (4 with high titer; 2 with moderate titer) also had a poor clinical response before switch (refractory patients). 4 ADA-positive patients (3 with high titer; 1 with moderate titer) were still good clinical responders.
Conclusions: The interchangeability of infliximab boDMARD to its bsDMARD does not rise any efficacy and safety concern in our experience. The role of drug and ADA monitoring during the switch remains to be further explored.

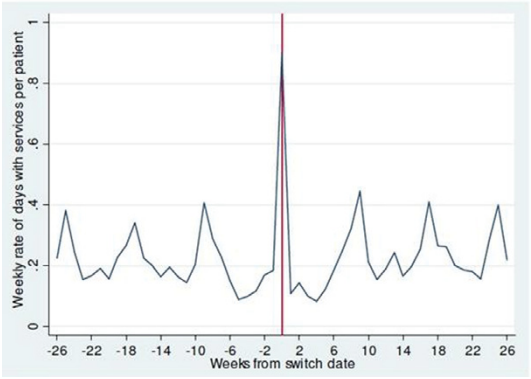
THU0647 INTERACTIONS BETWEEN STEPS PER DAY AND RISK FACTORS FOR OSTEOARTHRITIS ON MRI-DETECTED OSTEOPHYTES IN A POPULATION BASED COHORT STUDY

Z. Zhu[1,2], W. Han[1], S. Zheng[1], K. Wang[1], T. Winzenberg[1], F. Cicuttini[3], C. Ding[1], G. Jones[1] on behalf of Musculoskeletal Uni, Menzies Institute for Medical Research. [1]*Musculoskeletal Unit;* [2]*12779, Hobart;* [3]*Department of epidemiology and Preventive Medicine, Monash University, Melbourne, Australia*

Background: It is clear that exercise helps the symptoms of osteoarthritis. However, the relationship between physical activity (PA) and progression of knee osteoarthritis (OA) remains controversial. Moreover, no guideline on the amount of PA to prevent OA progression in general older population has been recommended, and it is still uncertain whether PA should be promoted among subgroups with knee OA such as female gender, obesity, radiographic osteoarthritis (ROA) and knee injury history. Osteophyte (OP) has long been viewed as a defining structural feature of knee OA. Recently, MRI-detected OPs have been shown to be more sensitive to change than radiographs.
Objectives: The aims of this study were to describe the longitudinal association between objectively-measured PA and knee MRI-detected (OPs), and to test the interactions between PA and gender, obesity, ROA or knee injury history on the increases in MRI-detected OPs.
Methods: 408 community-dwelling adults aged 51–81 were randomly selected from local community and measured at baseline and 2.6 years later. T1-weighted fat suppressed MRI was used to evaluate knee OPs at baseline and after 2.6 years. PA was assessed at baseline by pedometers (steps per day) and categorized as 3 groups: low PA (≤7499 steps per day), moderate PA (7500 to 9999 steps per day) and high PA (≥10000 steps per day). Radiographs were obtained and scored for individual features of radiographic osteoarthritis (ROA). Knee injury history was recorded by questionnaire and body mass index (BMI) was calculated. Logistic regression and log binomial regression were used in longitudinal analyses.
Results: In total study sample, doing moderate PA was associated with reduced risk of an increase in MRI-detected OPs, comparing to low PA (RR=0.73, p=0.03). There were significant interactions between PA and gender, obesity, ROA or knee injury history (all p<0.05) for an increase in MRI-detected OPs. In stratified analyses, moderate PA was protective against an increase in MRI-detected OPs in females (OR=0.23, p<0.01), obese participants (OR=0.23, p<0.01), participants with ROA (OR=0.45, p=0.02) and participants with knee injury history (OR=0.05, p=0.02). These significant associations still existed after further adjustments for age, sex, BMI, ROA and/or knee injury history (where appropriate). High PA was not associated with an increase in MRI-detected OPs in total sample or the stratified analyses but there were relatively few in this category.



Conclusions: Moderate PA is protective for change in MRI-detected OPs in older adults, especially in those with female gender, ROA, obesity and knee injury history. This implies older people with above risks of knee OA may need to aim for a range from 7500 to 9999 steps per day.

THU0648 USE OF OUTPATIENT RHEUMATOLOGIC HEALTH CARE SERVICES BEFORE AND AFTER SWITCH FROM ORIGINATOR TO BIOSIMILAR INFLIXIMAB

B. Glintborg[1], J. Sørensen[2,3], M.L. Hetland[1]. [1]*The DANBIO registry and Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Centre of Head and Orthopaedics, Glostrup;* [2]*University of Southern Denmark, Odense, Denmark;* [3]*Royal College of Surgeons in Ireland, Dublin, Ireland*

Background: According to Danish national guidelines issued in 2015, pts (pts) with inflammatory rheumatic diseases in routine care treatment with originator infliximab (INX) must switch to the cheaper biosimilar infliximab (CT-P13). This switch was done for economic reasons (CT-P13 64% cheaper than INX). Since any treatment change potentially induces additional guidance of pts and use of hospital services, it is relevant to investigate whether the switch affected use of hospital resources.
Objectives: To study difference in rates of outpatient activities and services provided 6 months before vs after the switch to CT-P13 for pts treated at rheumatologic departments which provide infliximab treatment.
Methods: The switch population and switch dates were identified in the Danish quality registry, DANBIO (1). Vital status was validated in the Central Person Registry. The Danish National Patient Registry (NPR) provided information regarding outpatient contacts and services. The use of 16 types of services relevant to the rheumatologic specialty was identified and included outpatient visits, infliximab infusion, nurse counselling, phone consultation, and rheumatologic ultrasound. Number of days with these services was counted. Services performed on the switch date were analyzed separately. Thus, for each patient the following rates were calculated 6 months before and after the switch: 1) days with at least one outpatient service provided, and 2) number of services provided. In addition, the weekly rate of days with services was calculated.
Only pts who were alive and could be followed in the NPR for 6 full months after the switch were included.
Paired t-tests were used to compare rates before and after switch. A graphical interrupted time series analysis was conducted for weekly number of services provided.
Results: Among 802 pts identified, 769 had available NPR outpatient data from hospital departments of rheumatology. The 769 pts had 1484 outpatient treatment contacts at the included rheumatology departments with a total of 9243 days with services provided (including 693 on the switch date). The mean rate of days with services provided was 5.4 before the switch and 5.7 after switch (p=0.0003). The

Figure Weekly rate of days with services per patient according to switch date

weekly rate of days with services showed no obvious differences before and after the switch but had a clear 8-week pattern (corresponding to the average infusion interval) (Figure).

The total number of services provided was 19,752 (2,019 of these on the switch date). There were significant increases in the rates before vs after switch for 6 of the 16 service categories, although the mean rates were small: telephone consultations (mean rate 1.0 before vs. 1.2 after), patient guidance (0.5 vs. 0.4), intravenous medication (0.0 vs. 0.1), clinical controls (2.1 vs. 2.3) and clinical investigations (0.3 vs. 0.5), whereas the rate of infliximab treatment decreased (3.1 vs 3.0) (all $p<0.05$, insignificant results not shown).

Conclusions: This analysis showed that there were only small differences in the rates of days with outpatient services and rates of services 6 months before and after the switch from original to biosimilar infliximab. Thus, it is unlikely that the switch is associated with substantially higher cost of health care resources.

THU0649 MANDATORY CHOICE OF FIRST BDMARD IN DENMARK – AN OPPORTUNITY TO STUDY REAL-LIFE EFFECTIVENESS? RESULTS FROM THE DANBIO REGISTRY

K.L. Grøn[1], B. Glintborg[1], M. Nørgaard[2], F. Mehnert[2], M. Østergaard[1], L. Dreyer[1], N.S. Krogh[3], M.L. Hetland[1]. *[1]DANBIO, COPECARE; [2]Department of Clinical Epidemiology, Aarhus; [3]Zitelab Aps, Copenhagen, Denmark*

Background: In Denmark, biological treatments (bDMARDs) are tax paid. Since year 2013, The Danish Council for the Use of Expensive Hospital Medicines (RADS) has issued recommendations with annual updates regarding RA patients (pts) initiating biological treatment, dictating a mandatory choice of the cheapest bDMARD (1). Furthermore, the percentage of pts expected to be treated according to the RADS recommendation per year is stated. For pts treated with concomitant methotrexate (MTX) recommendations on first line, first choice bDMARD were: Jan 1th 2013-June 30th 2014: certolizumab pegol (in 80% of pts); July 1th 2014 - June 30th 2015: abatacept (80%); July 1th 2015-June 30th 2016: biosimilar infliximab (CT-P13) (50%). The nationwide Danish DANBIO registry collect data prospectively and covers >90% of adults with rheumatological diseases treated with bDMARDs in routine care (2).

Objectives: To characterize Danish RA pts initiating first line, first choice treatment with a bDMARD in combination with MTX in the three RADS periods and to explore the degree of compliance to RADS recommendations. Furthermore, to investigate differences in baseline characteristics between those pts who were compliant to RADS guidelines and those who were not.

Methods: For each of the three RADS' periods bio-naive pts with RA were identified in DANBIO and compliance to RADS recommendations was assessed. Baseline characteristics of those who started first choice bDMARD treatment according to RADS were compared with those who started another biologic instead. Comorbidities and previous hospitalized infections were identified in the Danish National Patient Registry. Comorbidities from Charlson Comorbidity Index were summarized except category number 7, connective tissue disease.

Results: For all three RADS periods, age, gender, functional status and disease activity were typical for pts with RA. Age was median: 57 years, range 18–88 years and disease duration: 3 years, range 0–54 years. 16–22% of pts had ≥1 comorbidity and 7–9% had ≥1 hospitalized infection the previous year. In each of the three RADS periods, 71%, 66% and 60% of pts followed the RADS recommendations, respectively (Table). The table shows differences between those who started first choice bDMARD treatment according to RADS, and those who did not. Overall, pts who complied to RADS had higher DAS28 and patient VAS global. Characteristics of pts who followed RADS recommendations in the three periods appeared similar.

Conclusions: In this nationwide study of >600 RA pts, pts' clinical characteristics were more heterogeneous than in clinical trials, reflecting routine care. Overall, compliance to recommendations was good. Thus, the national guidelines in Denmark with mandatory choice of the first biological drug may provide an interesting opportunity to study effectiveness of bDMARDs in routine care. This highlights observational studies as a valuable supplement to RCTs.

Table 1: Characteristics of RA pts initiating treatment with first bDMARD in combination with MTX stratified by compliance to the recommendations of RADS or not in the three time periods.

THU0650 THE EFFECT OF ANTI-TNF THERAPY ON WORK PRODUCTIVITY AND ACTIVITY IMPAIRMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS, ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS OVER ONE YEAR – REAL LIFE DATA FROM THE CZECH BIOLOGICS REGISTRY ATTRA

J. Zavada[1], L. Szczukova[2], K. Pavelka[1], P. Horák[3], J. Vencovsky[1] on behalf of collaborators of the ATTRA registry. *[1]Rheumatology, Institute of Rheumatology, Prague; [2]Institute of Biostatistics and Analyses, Faculty of Medicine, Masaryk University, Brno; [3]Internal Medicine, Faculty of Medicine and Dentistry, Palacký University, Olomouc, Czech Republic*

Objectives: To assess the effect of anti-TNF therapy on work productivity using the Work Productivity and Activity Impairment-Specific Health Problem (WPAI-SHP) questionnaire in patients with RA, PSA and AS in the real life setting. In the Czech Republic, anti-TNF-therapy is reimbursed for RA if DAS28>5.1 despite therapy with csDMARDs, for PSA if disease is not "adequately controlled" with csDMARDs, and for AS if BASDAI>4 and CRP/ESR elevated above normal.

Methods: WPAI-SHP scores were collected for all patients enrolled in ATTRA since 2012 at baseline and after 12 months of anti-TNF exposure. Bionäive patients with RA (n=352), AS (n=442) and PSA (n=133) starting anti-TNF therapy with available baseline data on demography, disease duration and physical function, and WPAI-SHP at baseline and at 12 months were included in this analysis. Patients older than 60 years, on maternity leave or students were excluded. Only patients working for pay at baseline were assessed for WPAI-SHP summary scores: absenteeism (mean % work time missed), presenteeism (mean % productivity loss at work), overall work impairment (mean % overall work productivity loss), and activity impairment (mean % productivity loss in regular activities).

Results: Baseline characteristic were significantly different between diagnoses (Table 1). Working status changed significantly only in patients with RA (employed

Table 1

	RA (n=352)	AS (n=442)	PSA (n=133)	p-value*
Female	257 (73.0%)	104 (23.5%)	58 (43.6%)	<0.001 ABC
Disease duration	7.1±5.7	7.0±6.7	7.5±7.2	0.245
Age at start of anti-TNF therapy	47.2±8.9	39.5±8.6	44.4±9.1	<0.001 ABC
HAQ	1.5±0.5	1.2±0.5	1.2±0.6	<0.001 AB

Post-hoc analysis (with Bonferroni correction): statistically significant difference btw groups A) RA vs. AS, B) RA vs. PSA, C) AS vs. PSA. Values or N (%) or mean (SD).

Table 2

Dg.	WPAI-SHP component	Baseline	12 months	Mean change after 12 months	N†	P-value*
RA	Absenteeism	12.8 (27.9)	5.1 (18.5)	7.7 (30.3)	203	<0.001
	Presenteeism	52.1 (21.9)	27.6 (20.9)	24.5 (26.3)	183	<0.001
	Overall work impairment	53.9 (22.8)	28.7 (22.0)	25.2 (26.9)	183	<0.001
	Activity impairment	62.4 (21.4)	36.0 (23.0)	26.4 (27.7)	352	<0.001
AS	Absenteeism	10.6 (25.6)	3.5 (15.8)	7.1 (28.0)	307	<0.001
	Presenteeism	53.1 (22.2)	21.1 (18.0)	32.0 (24.9)	282	<0.001
	Overall work impairment	54.8 (22.6)	21.8 (18.8)	33.0 (25.5)	281	<0.001
	Activity impairment	60.7 (22.1)	27.3 (21.4)	33.5 (26.4)	442	<0.001
PSA	Absenteeism	5.7 (17.3)	4.2 (18.4)	1.5 (24.6)	90	0.135
	Presenteeism	43.9 (24.0)	15.3 (16.2)	28.6 (24.5)	84	<0.001
	Overall work impairment	45.2 (25.0)	15.9 (16.8)	29.3 (25.1)	84	<0.001
	Activity impairment	57.4 (24.6)	26.2 (21.3)	31.2 (26.5)	133	<0.001

†N = Number of assessed patients. Values are mean % (SD). *Wilcoxon paired test for difference between baseline and 12 months within each WPAI score.

69→64%, p=0.013), but not in AS (77→78%) or PSA (77→73%). In patients employed for pay both at baseline and after 12 months, all WPAI-SHP scores improved significantly over one year of anti-TNF therapy (Table 2).

Conclusions: In the real life setting of the Czech Republic, anti-TNF therapy effectively reduced absenteeism, presenteeism, activity impairment and work impairment over one year in employed patients with RA, AS and PSA.

Espinosa[14], C. Ramos[14], P. Lazaro[6]. *[1]Rheumatology, HU la Princesa; [2]Research Unit, SER, Madrid; [3]Rheumatology, HU Fundación Alcorcón, Alcorcón; [4]Rheumatology, HU Ramon y Cajal; [5]Rheumatology, HU la Paz; [6]Independent Health Services Researcher, Madrid; [7]Rheumatology, HU Virgen de la Nieves, Granada; [8]Rheumatology, Hospital Clínico San Carlos, Madrid; [9]Rheumatology, Hospital General Universitario, Elda; [10]Rheumatology, Hospital Virgen de la Salud, Toledo; [11]Rheumatology, Hospital Gral San Jorge, Huesca; [12]Rheumatology, HU Parc Taulí, Sabadell; [13]Rheumatology, Hospital Clinic, Barcelona; [14]Rheumatology, HU Puerta de Hierro, Majadahonda; [15]Rheumatology, HU Canarias, Sta Cruz Tenerife, Spain*

Background: Dose tapering of biological therapies (BT) in patients with rheumatoid arthritis (RA) or spondyloarthritis (SpA) is frequent in Spain. However, there is variability in BT optimization (BTO). So, Spanish Society of Rheumatology published in 2015 recommendations on how to optimize BT (1). Nevertheless, there is no solid evidence on which patient profiles BTO is appropriated.

Objectives: To develop appropriateness criteria for BTO in patients with RA, axial SpA (axSpA) or peripheral SpA (pSpA)

Methods: The RAND/UCLA appropriateness method was used. Five rheumatologists experienced in RA and/or SpA clinical research selected and defined the variables considered relevant when deciding reduction of BT in order to define patient profiles. Ten BT experienced rheumatologists anonymously rated 1 (completely inappropriate) to 9 (completely appropriate) each profile after reading evidence synthesis. Then, in a meeting, classification variables and profiles with disagreement were revised and all profiles were scored again. Profiles with a median score >6 were considered appropriate, those with a median score <3.5 were considered inappropriate and the remaining uncertain. In addition, a study of the prevalence of these profiles was performed in 9 Spanish hospitals.

Results: Combining the options of variables 2,304 different profiles were obtained for RA, 768 for axSpA, and 3,072 for pSpA. 327 (14.2%) profiles in RA, 80 (10.4%) in axSpA, and 154 (5%) in pSpA were considered appropriate for BT dose reduction. By contrast, 749 (53.3%) profiles in RA, 270 (54.4%) in axSpA, and 1243 (54.5%) in pSpA were considered inappropriate. The remaining profiles were considered uncertain. In the preliminary study to determine profiles prevalence, we collected information from 242 RA, 171 axSpA and 172 pSpA patients that underwent BTO. We found that BTO was performed appropriately in 23% RA, 67% axSpA and 61% pSpA patients. BTO was indicated in uncertain profiles in 67% RA, 23% axSpA and 37% pSpA patients. Only in RA we detected BT dose reduction in patient profiles considered inappropriate (2%).

Conclusions: Appropriateness criteria for BT dose reduction in three inflammatory conditions were developed and the preliminary prevalence study suggests that BTO was wisely applied. However, further research in this field is needed to determine the real prevalence of clinical profiles of patients undergoing BTO in daily clinical practice and validate these criteria in real life.

THU0652 ASSESSMENT OF BIOSIMILARS USING REAL WORLD DATA: THE COMPLEXITY OF CHOOSING A COMPARATOR AND UNDERSTANDING UPTAKE

D. Di Giuseppe[1], T. Frisell[1], S. Ernestam[1], H. Forsblad-d'Elia[2], E. Lindqvist[3], U. Lindström[4], C. Sjöwall[5], J. Askling[1] on behalf of the ARTIS group. *[1]Department of Medicine Solna, Karolinska Institutet, Stockholm; [2]Umeå University, Umeå; [3]Lund University and Skåne University hospital, Lund; [4]Sahlgrenska Academy, University of Gothenburg, Göteborg; [5]Linköping University, Linköping, Sweden*

Background: The introduction of biosimilars has been linked with concerns regarding how to best monitor their similarity vs. the originator product using real world data.

Methods: Data from the Swedish Rheumatology Quality register (SRQ) was used to identify all patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriatric arthritis (PsA), and other spondyloarthropathy (SpA), who started a treatment with infliximab (originator Remicade or biosimilars Remsima or Inflectra) between 1st Mar 2015 and 30th Sept 2016 or with etanercept (originator Enbrel or biosimilar Benepali) between 1st April 2016 and 30th Sept 2016.

Results: During the study period, a total of 1833 patients started an infliximab treatment and 1793 started etanercept. These patients were either bDMARD-naïve (patients without a history of any biological treatment), non-medical switchers (patients who switched from the originator product), or patients who had a history of a previous (but not the same) bDMARD (Table 1). These three groups were not evenly distributed across originators or biosimilars, and had different baseline demographic and disease characteristics.

The uptake in terms of *treatment starts* was faster for Benepali (it covered more than 90% of this part of the etanercept market after only 3 months) as compared to Remsima and Inflectra (together they accounted for 88% of this section of the infliximab market after 10 months). The uptake of biosimilars in terms of proportion of all patient *on treatment* was, at the end of September 2016, 27%

Table 1. Number of patients starting infliximab (from 1 March 2015 to 30 September 2016) or etanercept (from 1 April 2016 to 30 September 2016) originator or biosimilar, by line of treatment

	Infliximab		Etanercept	
	Originator	Biosimilars	Originator	Biosimilar
Total	570	1263	186	1607
Bio- naïve	379 (66%)	508 (40%)	89 (48%)	581 (36%)
Non-medical switchers	–	524 (42%)	–	710 (44%)
Switchers from other biologics	191 (34%)	231 (18%)	97 (52%)	316 (20%)

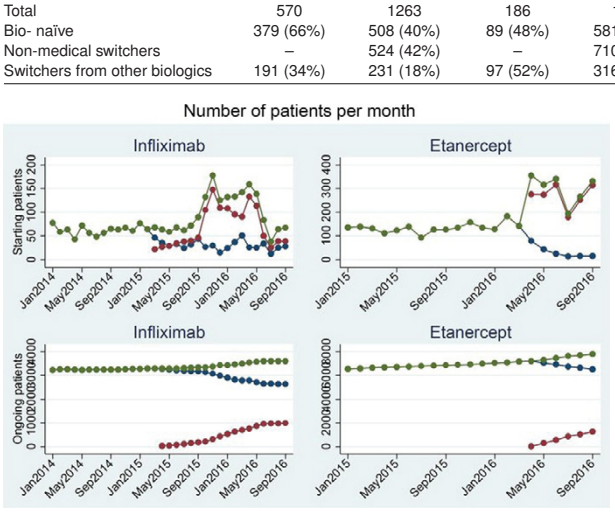

Figure 1. Number of patients *starting*, and *on*, respectively, infliximab or etanercept by month. Green: total, red: biosimilar, blue: originator.

of all infliximab (after 18 months of marketing) and 16% of etanercept (after 5 months since marketing).
In contrast to the bio-naïve group and those with a history of a previous (but not the same biologic), there was no readily available comparator group for the non-medical switcher group. To this end, we assessed three tentative definitions for a comparator; i) a historical comparison, i.e., same patients 18 months before the switch, ii) an individually matched sample of those patients still on originator treatment at the time of the switch, and iii) the total cohort of those who had not switched.
Conclusions: "Uptake" of biosimilars can be expressed both as proportion of all new starts and as proportion of ongoing treatments. Assessments of uptake, and any comparison between biosimilars and their originators, need to be based on line of therapy in order to avoid mixing up effects of channeling with true differences between originator and similar. For the same reason, any originator comparator for non-medical switchers needs to be reflective of those patients who stood the same chances of switching, but did not switch.

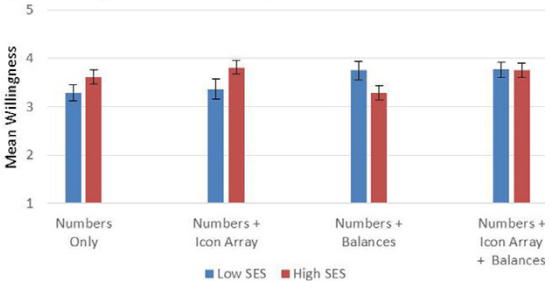
THU0653 PREVENTING RHEUMATOID ARTHRITIS: A GENERAL POPULATION PILOT STUDY ON PERSPECTIVES OF THE RISK OF DEVELOPING THE DISEASE AND POTENTIAL PREVENTATIVE INTERVENTIONS

M. Harrison[1,2], N. Bansback[1,2], L. Spooner[1], K. Milbers[2], C. Koehn[3], M. Hudson[4]. *[1]University of British Columbia; [2]Centre for Health Evaluation and Outcome Sciences; [3]Arthritis Consumer Experts, Vancouver; [4]McGill University, Montreal, Canada*



Background: Evidence suggests that treatment of people at risk of rheumatoid arthritis (RA) with anti-rheumatic drugs could prevent the onset of disease, and there are ongoing randomized controlled trials on the efficacy of preventing RA. However even if these trials are successful, there will be uncertainty around the potential benefits of these programs in practice; namely, the ability to predict those at risk of RA, exact benefits and risks, and inconvenience of treatment.
Objectives: To determine the features of a preventative treatment program that are likely to be acceptable to pre-symptomatic people at high risk of RA. Our focus is on preferences for treatment, the values and most important attributes of a preventative treatment program, and the likely uptake of preventative treatment. In this pilot study we sought general population preferences.
Methods: A discrete choice experiment was administered to a US general population sample, asking participants to choose between sets of 2 hypothetical preventative RA treatments, then between their preferred treatment and "no treatment for now". The treatment (risk of developing RA, how treatment is taken, chance of side effects, certainty in estimates, health care provider's opinion) and test attributes (chance test is wrong, who recommends treatment) were identified in focus groups with RA patients, first-degree relatives of RA patients and rheumatologists. An efficient experimental design was developed using SAS and included 2 consistency checks. Responses were analyzed using a conditional logit regression model to estimate the significance and relative importance of attributes in influencing preferences.
Results: 201 respondents completed the survey. The majority of the sample was 25–54 years old (modal age category: 30–39 years (38%)) and 50% were female. 23 members (11%) reported having a physician diagnosis of RA, and 91 (45%) had a family member or close friend with RA. All attributes' levels significantly influenced treatment preferences, but risk reduction, how treatment is taken, and health care provider preference were most influential. Respondents were most willing to trade a reduction in risk of RA for a treatment preferred by their health care professional and an oral route of administration. Respondents had a similar strength of preference for reducing uncertainty in evidence and reducing the risk of side effects. The preferred preventative treatment was chosen over no treatment in 67% of choices.
Conclusions: Our survey suggests that people value the potential benefits of treatments, but equally values how the treatment is taken and the preference of their health care provider. The degree of confidence in the estimates of a treatment's risks and benefits is as important to people as the risk of side effects. The uptake of a preventative strategy will depend on these key factors. This evidence will help policymakers understand whether different preventative treatment strategies are likely to be acceptable to people they are offered to.

THU0654 THE INFLUENCE OF RISK PRESENTATION FORMAT ON WILLINGNESS TO START A MEDICATION

R. Cozmuta[1], L. Fraenkel[2], E. Wilhelms[3], V. Reyna[4], J. Nolte[4]. *[1]Emory University, Atlanta; [2]Yale University, New Haven; [3]Vasser College, Poughkeepsie, NY; [4]Cornell University, Ithica, NY, United States*

Background: Patients with rheumatoid arthritis frequently refuse to escalate care because they overweight the probability of adverse events. Effectively communicating risk information to patients is difficult. Several approaches have been developed to facilitate comparative risks; however, recent data suggest that current approaches have a limited impact on risk perceptions and willingness to take medication.
Objectives: The objective of this study was to examine whether an icon array (IA), an illustration of the gist of how medications regulate the immune system (a series of balance beams), or both influence willingness to start a medication.
Methods: Patients with a rheumatic disease were mailed a survey in which they were asked to imagine that their symptoms had worsened and that their physician was recommending a new medication. We varied the probability of an adverse event (pneumonia requiring hospitalization): 2% or 0.2%, and the risk presentation format: numbers, numbers + IA, numbers + balance beams (BB), or numbers + both. Route of administration, benefit, and cost were held constant. Each subject responded to a single, randomly-assigned scenario. We controlled for socioeconomic status (SES), using a variable including both difficulty paying for medications as well as education, in a full-factorial model testing willingness to take the medication (measured on a 5-point scale).
Results: Of 1453 surveys, 465 patients completed the survey. Overall, the mean (SD) age was 59.0 (14.8); 79.7% were female; 83.2% White and 39.1% were classified as having low SES. There were no statistical differences in patient characteristics across the risk presentation formats. Willingness to start the medication was predicted by the interaction between the risk presentation format and SES (F =2.9, p=0.03). Willingness by SES status is described in the Figure 1. Among low SES subjects, addition of an IA did not affect willingness compared to the numbers-only format. In contrast, addition of BB (mean difference =0.47, p=0.07), or both IA and BB increased willingness (mean difference =0.48, p=0.04). Among high SES subjects, addition of an IA or BB or both did not influence willingness compared to the numbers only format. However, both formats including an IA increased willingness compared to the BB format among high SES subjects (mean difference IA vs BB = 0.53, p=0.01; mean difference IA vs IA + BB = 0.48, p=0.02).

Figure 1. Willingness across Formats by SES

Conclusions: SES affects how subjects respond to risk presentation formats. IA marginally increases willingness in high SES subjects, while BB increases willingness in low SES subjects; when both IA and BB are present, SES differences disappear. BB, when not accompanied by an IA, may decrease willingness in high SES subjects. These results demonstrate the differential effects of risk presentation formats, and highlight the need to identify mechanisms underlying their effects when implementing decision-support tools.

THU0655 DO VISUAL DECISION AIDS HELP PATIENTS CORRECTLY DIFFERENTIATE BETWEEN A 2% AND A 0.2% RISK?

R. Cozmuta[1], L. Fraenkel[2], E. Wilhelms[3], V. Reyna[4], J. Nolte[4]. *[1]Emory University, Atlanta; [2]Yale University, New Haven; [3]Vasser College, Poughkeepsie, NY; [4]Cornell University, Ithica, NY, United States*

Background: Studies have found that patients ignore probabilities when making treatment decisions.
Objectives: The objective of this study was to examine whether addition of an icon array (IA), a series of three consecutive balance-beam (BB) illustrations depicting how medications regulate the immune system, or both resulted in patients being able to better differentiate between an uncommon (2%) and rare (0.2%) adverse event (AE).
Methods: Patients currently being treated for a chronic inflammatory rheumatic disease were mailed a survey in which they were asked to imagine that their symptoms had recently worsened and that their physician was recommending a new medication. The medication was described using eight scenarios (manipulated using a 2x4 design). We varied the probability of a serious AE (pneumonia

requiring hospitalization): 2% vs 0.2% and the risk presentation format: numbers only, numbers + IA, numbers + BB, and numbers + IA + BB. Route of administration, benefit, and cost were held constant. Each subject responded to a single, randomly-assigned scenario. Dependent variables included perceived riskiness, worry, global gist related to the acceptability of the AE, and willingness to take the medication (all measured on 5-point ordinal scales). We hypothesized that the IA and BB formats would result in 1) lower perceived riskiness and worry, and 2) greater acceptability of the AE and willingness to take the medication in the 0.2% vs 2% scenarios. Socioeconomic status (SES) was defined based on difficulty paying for medication and education level.

Results: We mailed 1453 surveys. 465 patients completed and mailed the survey back (32% response rate). Overall, the mean age of responders was 58.99 (SD=14.85); 79.7% of were female; 83.2% White and 39.1% had a low SES. There were no statistical differences in demographic or clinical characteristics across the four risk presentation formats. Mean (SD) perceived riskiness, worry, global gist, and willingness to take the medication for 2% versus 0.2% chance of the AE, by SES level, are presented in the Image.

Perceived riskiness was lower for a 0.2% versus 2% risk of the AE in the numbers + IA condition in higher SES subjects. Lower SES subjects who viewed both IA and BB were more worried about the AE and found the AE to be less acceptable in the 0.2% versus 2% condition.

Risk Presentation Format		Riskiness Mean (SD)	Worry Mean (SD)	Gist Mean (SD)	Willingness Mean (SD)
Low SES					
Numbers Only					
AE probability	2%	3.12 (0.18)	3.16 (0.23)	3.12 (0.22)	3.20 (0.24)
	0.20%	3.04 (0.19)	3.38 (0.23)	3.69 (0.22)	3.38(0.25)
	p-value	0.77	0.51	0.07	0.61
Numbers + IA					
AE probability	2%	3.4 (0.24)	3.4 (0.29)	3.07 (0.28)	3.20 (0.31)
	0.20%	2.79 (0.21)	3.05 (0.26)	3.61 (0.25)	3.53 (0.28)
	p-value	0.06	0.37	0.15	0.43
Numbers + BB					
AE probability	2%	3.06 (0.23)	3.13 (0.28)	3.32 (0.27)	3.69 (0.30)
	0.20%	3.17 (0.19)	3.17 (0.23)	3.55 (0.22)	3.82 (0.25)
	p-value	0.72	0.91	0.52	0.74
Numbers + IA + BB					
AE probability	2%	2.83 (0.17)	**2.83 (0.21)**	**3.67 (0.2)**	4.03 (0.22)
	0.20%	3.20 (0.17)	**3.40 (0.21)**	**2.99 (0.2)**	3.50 (0.22)
	p-value	0.12	**0.05**	**0.02**	0.09
High SES					
Numbers Only					
AE probability	2%	2.95 (0.15)	3.03 (0.18)	3.52 (0.18)	3.50 (0.20)
	0.20%	2.77 (0.17)	2.71 (0.20)	3.83 (0.20)	3.74 (0.22)
	p-value	0.44	0.25	0.24	0.41
Numbers + IA					
AE probability	2%	**3.29 (0.16)**	3.06 (0.19)	3.61 (0.19)	3.82 (0.21)
	0.20%	**2.78 (0.15)**	2.73 (0.18)	3.82 (0.17)	3.80 (0.19)
	p-value	**0.02**	0.21	0.41	0.93
Numbers + BB					
AE probability	2%	3.25 (0.15)	3.43 (0.18)	3.48 (0.17)	3.43 (0.19)
	0.20%	3.00 (0.16)	3.28 (0.20)	3.49 (0.19)	3.14 (0.21)
	p-value	0.25	0.59	0.97	0.33
Numbers + IA + BB					
AE probability	2%	2.79 (0.15)	2.76 (0.18)	3.89 (0.18)	4.03 (0.20)
	0.20%	3.2 (0.17)	3.27 (0.21)	3.40 (0.2)	3.50 (0.22)
	p-value	0.07	0.07	0.07	0.08

Conclusions: With the exception of the IA's impact on perceived riskiness among subjects with higher SES, the risk formats used did not enable subjects to correctly differentiate between a 0.2% and a 2% risk of a serious AE. These results highlight the lack of impact of quantitative risk information on patients' risk perceptions.

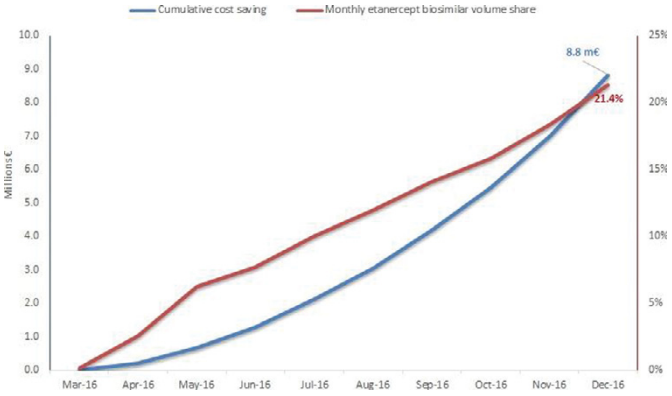
THU0656 ETANERCEPT BIOSIMILAR USAGE AND ASSOCIATED COST SAVINGS IN GERMANY

K. Thakur, A. Handrich, E. Psachoulia. *Biogen, Zug, Switzerland*

Background: The first etanercept biosimilar was approved by the European Commission in January 2016. Of the 27,000 patients* estimated to be treated with etanercept biosimilar in the Europe, 5,122 patients* are estimated to be on the etanercept biosimilar in Germany at the end of the analysis period. Its usage in Europe may support healthcare sustainability by reducing costs, thereby relieving the burden on healthcare budgets and improving patient's ability to get the right care at the right time.



Objectives: The analysis aimed to estimate the pharmacoeconomic impact of etanercept biosimilar use in Germany between March and December 2016.

Methods: The volume of etanercept biosimilar prescribed in Germany was calculated using sell-out data from retail pharmacies to patients sourced from INSIGHT Health. For this analysis, only the pre-filled syringe (PFS) and pre-filled pen (PFP) presentations of 50 mg etanercept were considered. The biosimilar volume share was calculated by dividing the total etanercept biosimilar 50 mg units prescribed by total etanercept 50 mg units prescribed. The cost savings realized through the use of the biosimilar was calculated using the INSIGHT Health volume data and the pharmacies selling price (source: Lauertaxe) of the etanercept reference product and the etanercept biosimilar. (Note: volume, volume share, patient and price data will be updated at time of presentation to reflect most current impact of etanercept biosimilars use).

Results: Based on 5,122 patients currently estimated to be treated with etanercept biosimilar (volume share of 21.4% in Dec 2016) in Germany and on the price differential between etanercept biosimilar and the reference product, a total cost saving of 8.8 million EUR was realized during the analysis period. Assuming these patients remain on etanercept biosimilar treatment, a total savings of 21.1 million EUR** can be returned annually to the healthcare system, compared to using only the reference product. This annual cost savings could be utilized to provide treatment to additional 1,208 patients with etanercept biosimilar.

Table 1. No. of 50 mg Pen/PFS etanercept prescribed: March–Dec 16

Product	Pen	PFS	Total
Reference product	318,317	580,563	898,880
Biosimilar	71,408	40,658	112,066

Conclusions: Experience with etanercept biosimilar has been growing in Germany, as reflected by the growing market share. Based on the current number of patients treated with etanercept biosimilar, savings of 21.1 million EUR are projected to be returned to the health system in Germany annually. The economic burden associated with etanercept treatment is expected to decrease further with an increase in market share for the etanercept biosimilar. These savings can have a significant impact on broadening patient access to biologic treatment in Germany.

THU0657 A TELE-HEALTH FOLLOW-UP STRATEGY FOR TIGHT CONTROL OF DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS: RESULTS OF THE NON-INFERIORITY RANDOMISED CONTROLLED TRAIL (THE TERA STUDY)

A. Thurah[1,2], K. Steengaard-Pedersen[1,2], M. Axelsen[3], U. Fredberg[3,4], L.M.V. Schougaard[5], N.H.I. Hjøllund[5,6], M. Pfeiffer-Jensen[1,2], T.B. Laurberg[1], K. Lomborg[6,7], T. Maribo[8,9]. *[1]Department of Rheumatology, Aarhus University Hospital; [2]Clinical Medicine, Aarhus University, Aarhus; [3]Diagnostic Centre, Silkeborg Regional Hospital, Silkeborg; [4]Department of Rheumatology, Odense University Hospital, Odense; [5]WestChronic, Department of Occupational Medicine, University Clinic, Health, Aarhus University, Herning; [6]Clinical Epidemiology, Aarhus University; [7]The Research Programme in Patient Involvement, Aarhus University Hospital; [8]Defactum, Central Denmark Region; [9]Department of Public Health, Section for Clinical Social Medicine and Rehabilitation, Aarhus University, Aarhus, Denmark*

Background: Despite the increased prevalence of rheumatoid arthritis (RA) in recent years, no studies have yet investigated the effect of monitoring disease activity through a standardized tele-health strategy in patients with RA (1).

Objectives: To test the effect of patient-reported outcome (PRO) based tele-health follow-up for tight control of disease activity in patients with RA, and the differences between tele-health follow-up performed by rheumatologists or rheumatology nurses.

Methods: A total of 294 patients were randomized (1:1:1) to either PRO-based tele-health follow-up carried out by a nurse (PRO-TN) or a rheumatologist (PRO-TR), or conventional out-patient follow-up by physicians. The Flare-RA (2) was used as decision aid for assessing disease activity.
The primary outcome was change in DAS28 after week 52. Secondary outcomes were: physical function, quality of life and self-efficacy. The non-inferiority margin was a DAS28 change of 0.6. Mean differences were estimated following per-protocol, intention to treat (ITT) and imputation (IMP).
Results: Overall patients had low disease activity at baseline and end follow-up. Demographics and baseline characteristics were similar between groups. Non-inferiority was established for DAS28. In the ITT analysis mean difference in DAS28 between PRO-TR vs. control were -0.10 (90% CI -0.30; 0.13) and -0.19 (-0.41; 0.02) between PRO-TN vs. control. When including one yearly visit to the outpatient clinic, patients in PRO-TN had a total of 1.72 (SD 1.03) visit/year, PRO-TR 1.75 (SD 1.03) vist/year and control 4.15 (SD 1.0) visits/year. This included extra visits due to inflammatory flare.
Overall more than 80% of the patients in all three groups answered that they were "very satisfied" with the consultation form they received and no differences were found between the three groups.
Conclusions: Among RA patients with low disease activity or remission a PRO-based tele-health follow-up for tight control of disease activity in RA can achieve similar disease control as conventional outpatient follow-up. The degree of disease control did not differ between patients seen by rheumatologists or rheumatology nurses.

Validation of outcome measures and biomarkers

THU0658 WNT/β-CATENIN PATHWAY IS AFFECTED IN PRIMARY SJÖGREN'S SYNDROME

Z. Omercikoglu[1], A. Karatas[2], O. Catak[3], B. Oz[2], F. Erman[4], K. Sahin[5], A.F. Dagli[6], N. Gozel[1], S.S. Koca[2]. *[1]Department of Internal Medicine; [2]Department of Rheumatology; [3]Department of Ophthalmology, Faculty of Medicine, Firat University; [4]Elazıg Health High School, Firat University; [5]Department of Animal Nutrition, Faculty of Veterinary Medicine, Firat University; [6]Department of Pathology, Faculty of Medicine, Firat University, Elazığ, Turkey*

Background: Sjögren's syndrome (SS) is a chronic autoimmune disease that causes salivary and lacrimal gland dysfunction, resulting in oral and ocular dryness. The pathogenesis of SS is still unknown. The Wingless (Wnt)/β-catenin pathway has been recently shown to play an important role in inflammation.
Objectives: The aim of the present study was to determine serum and salivary levels of *Dickkopf-related protein 1* (DKK1) and sclerostin those are inhibitor of Wnt/β-catenin signaling pathway and to evaluate the expression of Wnt-1 and Wnt-3a in the salivary gland, in patients with primary SS.
Methods: 30 patients with primary SS, 30 patients with systemic lupus erythematosus (SLE) and 29 healthy controls were enrolled in the study. Fasting blood and saliva samples were obtained from the participants. Serum and salivary levels of DKK1 and sclerostin were measured by enzyme-linked immunosorbent assay. Wnt-1 and Wnt-3a expression were also immunohistochemically assessed in salivary gland. EULAR SS Disease Activity Index (ESSDAI), and EULAR SS Patient Reported Index (ESSPRI) in the SS group and Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) in the SLE group were recorded.
Results: Serum DKK1 and sclerostin levels were decreased in the SS and SLE groups compared to the controls (Table 1) ($p<0.001$ for both). Salivary sclerostin levels were similar among the study groups ($p>0.05$ for all). Salivary DKK1 levels were higher in the SS group compared to the control and SLE group ($p=0.004$ and $p=0.009$, respectively). Moreover, serum DKK1 level was higher in the SS group than in the SLE group ($p=0.046$). Serum DKK1 level was positively correlated with serum sclerostin level in the SS, SLE and control groups ($r=0.677$; $p<0.001$, $r=0.783$; $p<0.001$, and $r=0.829$; $p<0.001$, respectively). ESSPRI was negatively correlated with serum DKK1 and sclerostin levels ($r=-0.363$; $p=0.049$ and $r=-0.416$; $p=0.022$, respectively) in the SS group.
Moreover, in the salivary gland tissues, the positivities of Wnt-1 (71.4% vs. 46.2%, $p=0.182$) and Wnt-3a (71.4% vs. 53.8%, $p=0.345$) were relatively higher in the SS group compared to the control group, respectively.
Conclusions: According to the best of our knowledge, this study is the first study evaluating the activity of Wnt/β-catenin pathway in the primary SS. The altered serum levels of DKK1 and sclerostin in primary SS and SLE is suggest that Wnt/β-catenin pathway is affected in these inflammatory diseases. Salivary DKK1 level is increased in primary SS in contrast to SLE. On the other hand, Wnt-1 and Wnt-3a expressions on the salivary gland are increased in primary SS. Therefore, it may be concluded that Wnt/β-catenin pathway acts pathogenic roles on the glandular inflammation.

Table 1. Demographics and clinical variables in the study groups

	HC	SLE	SS	P_1 (SLE vs. HC)	P_2 (SS vs. HC)	P_3 (SS vs. SLE)
Serum DKK1, ng/ml	49.8±14.9	27.8±11.8	35.2±8.8	<0.001	<0.001	0.046
Salivary DKK1, ng/ml	30.6±5.9	31.1±6.9	36.3±6.9	0.944	0.004	0.009
Serum Sclerostin, ng/ml	12.9±5.1	5.7±4.1	5.5±3.8	<0.001	<0.001	0.984
Salivary Sclerostin, ng/ml	16.1±3.4	15.7±2.5	15.6±3.7	0.877	0.838	0.996

THU0659 SKIN MICROVASCULAR FLOW ASSESSED BY DYNAMIC OPTICAL COHERENCE TOMOGRAPHY: FIRST NON-INVASIVE QUANTITATIVE OUTCOME MEASURE OF MICROVASCULAR DAMAGE IN SYSTEMIC SCLEROSIS

A. Daniel[1,2], G. Abignano[2,3], S. Eng[2,3], L. Green[2,3], P. Emery[2,3], F. Del Galdo[2,3]. *[1]Rheumatology Unit, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [3]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

Background: Reduction in capillaries number is the defining feature of microvascular disease in Systemic Sclerosis (SSc) and it concurs to the ischemic manifestations of the disease. Digital Ulcers (DUs) are the major complication of ischemic peripheral vasculopathy.
Dynamic optical coherence tomography (D-OCT) is a recently developed imaging technique that allows non-invasive in vivo study of the microvasculature of the skin. In addition to the skin architecture and vessels morphology, it offers information about flow status, allowing the functional and quantitative evaluation of the microcirculation.[1]
Objectives: To determine the face and content validity of D-OCT as outcome measure of the skin microvascular disease, assuming the presence of current DUs, distal to the DIP joints, as gold standard for ischemic peripheral vasculopathy in SSc.
Methods: A total of 54 patients were enrolled in this cross-sectional study, including 18 SSc patients with current DUs (DU group); 18 SSc patients without current DUs (no DU group) and 18 patients with Raynaud's phenomenon and SSc specific ANA, who did not fulfilled ACR/EULAR 2013 classification criteria (SRP group).
For each patient, we performed a D-OCT scan on both index and middle fingers, on the dorsal aspect of the second phalanx, employing *Vivosight Scanner (Michelson Diagnostics)*. The speckle variance signal of D-OCT images within the first mm of skin depth was extracted, quantified as area under the curve (AUC) and defined as Micro Vascular Flow (MVF).
MVF comparison between the groups was done using parametric or non-parametric tests as appropriate. Statistical Analysis was performed with SPSS V.22.
Results: All three groups were comparable in terms of age and gender distribution ($p>0.80$ for both) as well as disease duration and clinical subset between the two SSc groups ($p=0.839$ and $p=0.646$, resp.). With a scan time <1 minute, D-OCT allowed the visualization and quantification of capillaries within the first millimeter of skin depth (Figure 1).
The distribution of MVF was not significantly different among the four fingers within each group (DU group: $p=0.459$, no DU group: $p=0.953$ and SRP group: $p=0.616$). On the contrary, the distribution and median MVF for all fingers was significantly different among the 3 groups: DU group=0.134 (IQR 0.121–0.134), no DU group=0.153 (IQR 0.132–0.153) and SRP group=0.167 (IQR 0.148–0.167) ($p<0.0001$), as well as in the DU group vs. no DU group ($p<0.001$) or DU vs SRP group ($p<0.001$).
Further, sub analysis of the DU group showed that 10 of the total 20 DUs were on the left index finger. Within this subgroup the MVF of patients on Sildenafil (n=6) was significantly higher than the rest of the group (0.148±0.021 vs. 0.113±0.019, $p=0.03$).

Figure 1

Conclusions: MVF assessed by D-OCT is a quantitative, non-invasive surrogate outcome measure of severe peripheral ischemic vasculopathy in SSc. Longitudinal

studies assessing its sensitivity to change will inform whether MVF can be used as end point of skin microvascular involvement in SSc.

THU0660 POLYMYALGIA RHEUMATICA TREATMENT SERUM BIOMARKERS VERSUS RHEUMATOID ARTHRITIS

M.K. Meyer[1], M. Andersen[1], T.V. Stausbo[2], K.J. Elbæk[2], G.N. Andersen[1], A. Stensballe[2]. [1]*Department of Rheumatology, Nortmark Regional Hospital, Hjørring;* [2]*Department of Health Science and Technology, Aalborg University, Aalborg, Denmark*

Background: Polymyalgia rheumatica (PMR) is a systemic inflammatory disorder with unknown etiology and overlapping symptoms with giant cell arthritis and late-onset rheumatoid arthritis (RA). To date, no proteomics studies have been performed on PMR patients, and the number of biomarker studies remain limited.
Objectives: The primary aim of this study was to thoroughly investigate the corticosteroid treatment serum proteome of PMR with a focus on acute-phase reactions, complement system, and cytokines.
Methods: Filter-aided sample preparation for mass spectrometry, cell free DNA (cfDNA) assay, and 10plex cytokine assay were applied to PMR serum samples from the same patients before and after treatment, DMARD-naïve RA patients, and healthy controls.
Results: The core serum proteomes of the four groups were remarkably similar, and consisted of >200 proteins, which included acute-phase reactants, coagulation and complement proteins (figure), immunoglobulins, and apolipoproteins, and several more. Acute Phase Serum Amyloid A (SAA1) was differentially less abundant after PMR treatment, and CRP (after adjusting for two patients with low baseline CRP). cfDNA were more abundant in both groups of PMR compared to healthy controls. Complement factors were narrowly distributed and not affected by PMR treatment. The individual serum proteome of each PMR patient provided more than 100 differentially abundant proteins, and highlights the heterogeneity of patients.

Conclusions: We have established the core serum proteome of PMR in response to treatment, and compared it with RA and healthy controls. The results suggest a functional role of SSA1, and increased cfDNA in the pathogenesis of PMR indicates the activation of NETs.

THU0661 CLINICAL RELEVANCE OF DETECTING ANTI-ADALIMUMAB ANTIBODIES WITH A DRUG-TOLERANT ASSAY

A. Martinez-Feito[1], L.Y. Bravo Gallego[2], B. Hernandez-Breijo[1], C. Plasencia[1], A. Jochems[1], M.A. Gonzalez[2], I. Monjo[1], D. Peiteado[1], G. Bonilla[1], P. Nozal[2], A. Balsa[1], D. Pascual-Salcedo[1]. [1]*Immuno-Rheumatology research group;* [2]*Immunology, University Hospital la Paz, madrid, Spain*

Background: Adalimumab (Ada) has proven effective in treating rheumatoid arthritis (RA) and spondyloarthropathies (SpA), although approximately 30% of responders will present secondary clinical failure. Immunocomplex formation between antibodies to Ada (ATA) and Ada can increase drug clearance. Most of the assays to measure ATA present drug interference. Currently, different assays are available to measure total ATA (free and complexed).
Objectives: To compare the detection of ATA along Ada treatment between two assays: one drug-sensitive and another drug-tolerant assay. Study the association of ATA with the clinical status.
Methods: This is a prospective observational study with 63 patients with rheumatic diseases under Ada treatment enrolled at Biological Therapy Unit of Hospital La Paz. Serum Ada levels were measured by ELISA and serum ATA levels by two assays: an in-house two-site (bridging) ELISA (bELISA) to detect uncomplexed ATA (free ATA) and a drug-tolerant assay developed by ImmundiagnostikÒ (Bensheim, Germany) (IDK) to measure simultaneously free and complexed ATA (total ATA). Samples were evaluated at 0, 0.2, 0.5, 1, 1.5 and 2 years after Ada initiation.
Results: Out of the 63 studied patients, 12 (19%) had RA and the rest (51, 81%) had different spondyloarthropathies (24, 38%) ankylosing spondylitis, 9 (14%) psoriatic arthritis, 14 (22%) undifferentiated spondyloarthritis and 4 (6%) spondyloarthritis associated with inflammatory bowel disease).Thirty-one patients (49%) received concomitant methotrexate (26% RA patients and 74% SpA patients), 13 (21%) received another DMARDs associated to Ada and 19 (30%) were on monotherapy.Out of the 63 patients, in 27 (43%) no ATA were detected. Thirty six patients (57%), were IDK+ and 12 patients (19%) were bELISA+ (all of them IDK+).The presence of ATA by bELISA was associated with absence of serum Ada levels. However, most (78%) samples with complexed ATA had low circulating Ada levels (1.65 mg/ml in ATA+ vs 6.25 mg/ml in ATA-, $p<0.0001$). ATA appeared by IDK at earlier treatment stages than by bELISA, statistically different at all studied time points.In patients who dropped-out (30 patients, 48%) ATA detection was frequent and significant by both methods.Ten patients (33%) bELISA ATA+ dropped-out vs 2 patients bELISA ATA+ in those who continued treatment ($p<0.0001$). Twenty four patients (80%) IDK ATA+ dropped-out vs 12 patients (36%) who continued treatment ($p<0.0001$). The percentage of ATA detected by IDK was higher than by bELISA, with a tendency of more IDK ATA+ among patients with less survival (24,80% IDK positive vs 10,33% bELISA +; p=0.06)
Conclusions: ATA are detected by a drug-tolerant assay at earlier stages of treatment than by bELISA. The antibodies formed early are associated with lower levels of circulating Ada, indicating higher drug clearance. This information might be useful to implement the Therapeutic Drug Monitoring. However, the detection of early complexed ATA has not demonstrated a significant advantage over the bELISA to predict treatment survival.

THU0662 COMPARING ELECTRONIC COLLECTION OF PATIENT REPORTED OUTCOMES AT HOME VERSUS TOUCH-SCREENS IN THE WAITING AREA AMONG PATIENTS WITH ARTHRITIS IN CLINICAL PRACTICE: A RANDOMISED AGREEMENT STUDY WITH ONLINE RECRUITMENT USING DANBIO

A.E. Secher[1], B. Glintborg[1], H. Gudbergsen[2], N.S. Krogh[3], D.V. Jensen[1], I.J. Sørensen[1], R. Christensen[2], M. Skougaard[2], M.L. Hetland[1]. [1]*DANBIO registry, Glostrup;* [2]*The Parker Institute;* [3]*Zitelab Aps, Frederiksberg, Denmark*

Background: Collection of patient-reported outcomes (PROs) is an important aspect of modern treatment strategies. Electronic capture in waiting areas by touch screens is part of routine care in the Danish DANBIO registry[1]. It is not known whether this data collection can be replaced with electronic data entry from home.
Objectives: To test the feasibility of online patient recruitment via touch screens and to investigate if electronic reporting of PROs from home (ELECTOR IT-platform) is comparable to reporting completed at the hospital among patients with rheumatoid arthritis (RA) or axial spondyloarthritis (AS).
Methods: Patients with RA or AS were recruited via touch screens and randomized to one of two groups by a pre-computed list generated through DANBIO; the first group completing the PROs at home and then at the hospital-site, and vice versa for the second group. All patients completed the Health Assessment Questionnaires (HAQ), the Visual Analogue Scales (VAS) for fatigue, pain and global health and the annual visit questions. Furthermore, AS patients completed the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and the BAS Function Index (BASFI). Pearson's Chi-square test, independent samples t-test and Mann-Whitney U test were calculated. Smallest detectable differences (SDDs), 95% confidence intervals (CIs) and intra-class correlation coefficients (ICCs) were calculated.
Clinicaltrials.gov identifier: NCT02818478.
Results: A total of 952 patients received invitation, 45% accepted, 127 patients were contacted by phone, and 56 (44%) gave consent to participate. 22 patients with RA and 20 patients with AS completed the trial.
All differences between scores from home vs hospital were smaller than SDD, and all were non-significant ($p<0.05$), except for BASFI and BASDAI item 5. ICC ranged from 0.947–0.990 ($p<0.00001$). Annual visit questions showed 96% concordance between the two methods. 50% of the patients preferred from home data entry over hospital and 10% vice versa.
Conclusions: Recruitment of patients for a randomized trial via touch screens was feasible. PROs collected from patients' own devices at home generated

Table: Scores, differences, SDD and ICC for hospital and home PROs.

	Hospital, mean (SD)	Home, mean (SD)	Difference, mean (95% CI)*	SDD	ICC (95% CI)
Rheumatoid arthritis (RA)					
HAQ (0-3)	0.580 (0.499)	0.619 (0.531)	-0.040 (-0.283, 0.204)	0.244	0.984 (0.962, 0.994)
VAS pain, mm	25.5 (24.2)	24.2 (23.8)	1.3 (-15.3, 17.7)	16.4	0.969 (0.927, 0.987)
VAS fatigue, mm	35.6 (30.4)	33.1 (30.3)	2.4 (-15.8, 20.7)	18.2	0.975 (0.942, 0.990)
VAS global, mm	34.0 (29.8)	34.8 (30.7)	-0.81 (-18.3, 15.4)	16.1	0.982 (0.955, 0.993)
Spondyloarthritis (AS)					
HAQ (0-3)	0.356 (0.307)	0.319 (0.276)	0.038 (-0.215, 0.290)	0.253	0.947 (0.868, 0.979)

THU0663 SERUM GALECTIN-3 BINDING PROTEIN IS A NOVEL PREDICTOR OF VENOUS THROMBOEMBOLISM IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

A.S.R. Peretz[1], N.S. Rasmussen[2], N.H.H. Heegaard[3], S. Jacobsen[2], C. Sjöwall[4], C.T. Nielsen[2]. *[1]Centre for Rheumatology and Spine Diseases, Gentofte, Copenhagen University Hospital, Denmark., Gentofte; [2]Copenhagen Lupus and Vasculitis Clinic, Centre for Rheumatology and Spine Diseases, Rigshospitalet; [3]Department of Autoimmunology and Biomarkers, Statens Serum Institut, Copenhagen, Denmark; [4]Rheumatology/AIR, Department of Clinical and Experimental Medicine, Linköping University, Linköping, Sweden*

Background: SLE patients have a marked increased risk of venous (VTE) and arterial (AT) thrombosis, which is not fully explained by traditional risk factors or the presence of anti-phospholipid antibodies. Thrombosis is a major cause of damage accrual, morbidity, and mortality in SLE. A better understanding of the pathogenesis and development of new biomarkers to identify patients at risk are needed. Recent studies link leptin and tumor necrosis factor-like weak inducer of apoptosis (TWEAK) to subclinical atherosclerosis and galectin-3-binding protein (G3BP) to type I interferon activation and a pro-thrombotic environment.

Objectives: To explore G3BP, interferon gamma-induced protein 10 (IP-10), soluble CD163 (sCD163), TWEAK, and leptin serum levels as predictors of venous and arterial thrombotic events, damage accrual, and all-cause mortality during long-term follow-up in a large cohort of Swedish SLE patients.

Methods: Baseline clinical and paraclinical data including disease activity and damage scores (SLICC) were available from 167 SLE patients. VTE (deep vein thrombosis and/or pulmonary embolism) and AT (myocardial infarction and/or cerebrovascular incident) data were available with a median follow-up period of six years. Baseline serum G3BP, IP-10, sCD163, TWEAK, and leptin were quantified using ELISA. Univariate and multivariate analyses were conducted to asses associations between the serum biomarkers and the occurrence of VTE/AT, damage accrual, and death.

Results: In the follow-up period 11 (7%) VTE and 12 (7%) AT events occurred. SLICC-scores increased in 79 (47%) patients, and 19 (11%) patients died. In the univariate Cox regression analysis G3BP levels were significantly associated with an increased risk of VTE (hazard ratio (HR) 1.10, 95% confidence interval (CI): 1.01–1.2, *P*=0.03). This persisted in the multivariate cox regression analyses when adjusting for age, gender, diabetes, antiphospholipid syndrome, and treatment with warfarin (HR 1.16, 95% CI: 1.04–1.31, *P*=0.01). None of the other serum biomarkers were associated with AT and VTE. No significant associations were observed between the biomarkers and changes in SLICC-scores or all-cause mortality.

Conclusions: Our study identifies serum G3BP as a novel independent predictor of VTE in SLE. This may improve our understanding of VTE pathogenesis in SLE and aid future VTE risk stratification and prophylaxis. Further studies are needed to translate this into clinical practice.

THU0664 TRANSLATION, CULTURAL ADAPTATION AND VALIDATION OF THE SYSTEMIC LUPUS ACTIVITY QUESTIONNAIRE (SLAQ) IN A COHORT OF ITALIAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

C. Tani[1], R. Vagelli[2], L. Carli[2], C. Stagnaro[1], F. Drago[1], V. Lorenzoni[3], G. Turchetti[3], M. Mosca[1]. *[1]Rheumatology Unit, University of Pisa, Pisa, Italy; [2]Via Roma 67, Pisa, Rheumatology Unit, University of Pisa; [3]Institute of Management, Scuola Superiore Sant'Anna, Pisa, Italy*

Background: Evaluation of disease activity is one of the most important assessments in SLE; several instruments have been developed based on clinical and laboratory information recorded by the physician. Patient-administered questionnaires provide useful information with significant time and cost saving. Indeed, patient-reported outcomes are gaining a central role as outcome measures.SLAQ is a patient-reported instrument for the assessment of disease activity in SLE. It consists of three scores: Patient Global Assessment question (PGA) about presence and severity of lupus activity over the past month, questions on 24 symptoms (SLAQscore) and a single Numerical Rating Scale (NRS) for disease activity (0 – 10).

Objectives: The aim of the study was to translate and to validate the SLAQ in Italian.

Methods: The process of translation and cultural adaptation followed published guidelines (1). The final version of the questionnaire (SLAQit) was pretested in a group of 35 SLE patients to assess acceptability, comprehension and feasibility. The validity of the SLAQit was evaluated by its administering to consecutive SLE patients attending the outpatient's clinic or the inpatients wards. Internal consistency between the three components of the score was evaluated by Chronbach's alpha; the external validity was tested toward validated activity indices (SLEDAI and ECLAM) scored by a physician blinded to the SLAQ results. In a subgroup of 30 patients the questionnaire was administered twice at 2 weeks' interval to assess its reliability.

Results: 137 patients were enrolled (92% female, mean age 43.1 years, mean disease duration 15.3 years). At enrollment, the median SLEDAI score was 2 (range 1–18) and 45% of patients had at least one organ damage (median 2, 1–8). The pilot test provided a good acceptability (99.9% of response rate) and feasibility (mean of 4.6±2.3 minutes to be completed, 1–10); moreover, the 100% of patients declared to comprehend the scope of the SLAQ and 67.5% declared no content comprehension problems. Internal consistency was very good between (NRS vs PGA vs SLAQscore (α=0.79). NRS and PGA showed a linear correlation with both ECLAM and SLEDAI scores (ρ=0.24, p=0.004 and ρ=0.45, p<0.001 respectively), while the correlation with the SLAQscore didn't reach the statistical significance. SLAQit showed a very high reliability by comparing the test-retest results (α>0.8 for NRS, PGA and SLAQscore). SLAQit scores resulted directly related to the patients age (p=0.002) and the SLICC score (p=0.003) while no correlation with disease duration was observed.

Conclusions: SLAQit demonstrated to be acceptable, comprehensible and feasible in our routine clinical setting; it also showed good internal consistency; correlation with physician's driven instruments is weaker and the SLAQit was influenced by epidemiological and disease-related factors (i.e. damage), thus confirming that the disease perception from the patient's perspective can be different from physicians and influenced by several factors. The SLAQit can be considered a useful screening tool for the first assessment of the disease activity before the standard visit.

THU0665 CAN ONE GIVE UP BASDAI IN FAVOR OF ASDAS IN MONITORING SPONDYLOARTHRITIS PATIENTS ON BIOLOGICS?

C. Cobilinschi, D. Opris-Belinski, R. Ionescu. *Sfanta Maria Clinical Hospital, Bucharest, Romania*

Background: Disease activity in SpA is widely evaluated through BASDAI or ASDAS with no proven superiority between the two, in spite the more objective evaluation of ASDAS through the inflammatory markers.

Objectives: The aim of this study was to evaluate the clinical quality and discriminating power between the above indices when subdividing patients with anti-TNF therapy according to their disease status indicated by BASDAI, ASDAS or PtGA.

Methods: This prospective, observational study included 100 patients with definite SpA on biological therapy.Demographic, clinical and laboratory data was collected. Statistical analysis was performed with SPSS 20.0.

Results: When used as an external criterion PtGA showed that 12% of patients had active disease with a PtGA of over 5 while 88% were classified as low disease activity.Mean ASDAS-CRP and ASDAS-ESR in the active group were 3.39 and 3.24.Mean BASDAI score in the high activity group according to PtGA was 5.66.We showed that both ASDAS scores had good discriminating capacities, with similar values when using the SMD (2.0034 [95% CI 1.29–2.71]).Based on PtGA,BASDAI outperformed ASDAS scores with a SMD of 3.3391 [95% CI 2.5334–4.1447]. ROC curves of the disease activity scores by using the PtGA $\geq$5

as variable of high disease activity state showed the following: for ASDAS-CRP, ASDAS-ESR and BASDAI the AUCs (*area under curve*) were 0.89 (P=0.05; 95% CI 0.80–0.99), 0.88 (P<0.001; 95% CI 0.77–0.99), and 0.99 (P=0.009; 95% CI 0.97–1.00).For CRP and ESR the AUCs were 0.81 and 0.79. This shows the high accuracy of the three scores in assessing SpA activity,but with a lower fidelity of the inflammatory markers alone.When dividing patients according to BASDAI score,14% showed a more active disease than the rest of 86% who had low disease activity.Mean ASDAS-CRP scores in the first group was 3.31.When correlating disease activity scores for the entire study group we observed that BASDAI correlated to both ASDAS scores (r=0.65 and 0.71, P<0.001) and that PtGA showed a stronger correlation to BASDAI (r=0.912, P<0.01) than ASDAS and to acute phase reactants.

Conclusions: This study shows that disease activity scores have good discriminatory powers. BASDAI surpassed ASDAS scores when relating to the PtGA. According to Van der Heijde et al.(1), the only situation in which BASDAI can outperform ASDAS is when assessing the PASS (*patient acceptable symptom state*). However, ASDAS-CRP had better discriminatory power than ASDAS-ESR or acute phase reactants. This demonstrates that ASDAS-CRP is a more objective evaluation that can better differentiate patients with high or low disease activity.

THU0666 PATIENT GLOBAL ASSESSMENT IS MORE SENSITIVE TO CHANGE THAN HEALTH-RELATED QUALITY OF LIFE INSTRUMENTS IN EARLY AXIAL SPONDYLOARTHRITIS OVER 3 YEARS: DATA FROM THE DESIR COHORT

D. Puyraimond-Zemmour[1,2], C. Desthieux[1,2], A. Ruyssen-Witrand[3], B. Fautrel[1,2], L. Gossec[1,2]. *[1]Pitie Salpetriere Hospital; [2]Paris 06 university, Pierre and Marie Curie, Paris; [3]CHU de Toulouse, Hôpital Pierre-Paul Riquet, Toulouse, France*

Background: Several questionnaires assess similar constructs of global patient-reported state or Health-Related Quality of Life (HRQoL).

Objectives: To evaluate sensitivity to change (ie, discriminance) of several questionnaires in early axial spondyloarthritis (axSpA) over 3 years of follow up: the SF36, axial spondyloarthritis quality of life (ASQoL), axial spondyloarthritis health assessment questionnaire (AS-HAQ) and patient global assessment (PGA).

Methods: DESIR is an ongoing prospective, multicenter, longitudinal, observational French cohort (1). Patients had inflammatory back pain of more than 3 months and less than 3 years suggestive of axSpA. For our analysis, only patients with no missing data for MCS and PCS SF36 values during the first 3 years were included. A global construct of patient global state was assessed by the SF36 questionnaire and its 2 subscales (scored 0–100 with higher scores indicating better status): the physical composite score (PCS) and the mental composite score (MCS), AsQoL, a disease-specific HRQoL scale, PGA and AS-HAQ. ASDAS-CRP was used as comparator. Each outcome was assessed at baseline, 6 months, 12 months, 24 months and 36 months. Standardized mean differences (SMD) were calculated using Cohen's effect size with confidence intervals, between each time point for each outcome. A SMD <0.5 is usually considered small, between 0.5 and 0.8 moderate and >0.8 as important.

Results: In all, 442 patients were analyzed: at baseline, mean age was 34.2±8.6 years; mean disease duration was 18.6±10.7 months; 239 (54%) were females, 274 (62%) had HLAB27 and 124 (28%) had radiological sacroiliitis. At baseline, patients were not in an optimal state; improvement was clear up to month 6 then minimal (at the group level): Table. Sensitivity to change was greatest for PGA, then ASQoL whereas AS-HAQ, MCS and PCS appeared the least discriminant measure (Table).

Conclusions: PGA was more sensitive to change than HRQoL measures in early axSpA. ASDAS appeared also sensitive to change. Changes in all the measures were very small at the group level after 6 months of follow-up indicating the concepts convered may be as much patient- as disease-related.

THU0667 A QUALITATIVE AND QUANTITATIVE COMPARISON OF SYNOVIAL BIOPSY TECHNIQUES DURING CLINICAL TRIALS OF INFLAMMATORY ARTHRITIS

F. Humby[1], S. Bugatti[2], A. Filer[3], S. Kelly[4], A. Manzo[2], E. Souza[5], V. Romao[5], V. Rocher[1], R. Hands[1], M. Wechalekar[6], J. Fonseca[5], C. Montecucco[2], C. Pitzalis[1]. *[1]Experimental Medicine and Rheumatology, Barts and the London School of Medicine and Dentistry, London, United Kingdom; [2]Division of Rheumatology, University of Pavia, Pavia, Italy; [3]Institute of Inflammation and Ageing, University of Birmingham, Birmingham; [4]Department of Rheumatology, Barts Health NHS Trust, London, United Kingdom; [5]Department of Rheumatology, Lisbon Academic Medical Centre, Lisbon, Portugal; [6]Rheumatology Unit, Repatriation General Hospital, Adelaide, Australia*

Background: Synovial tissue is an attractive area of research for biomarkers of disease outcome in RA. Currently acquisition of synovial tissue using an arthroscopic approach in clinical trials is recommended though two US-guided techniques have been described, a portal and forceps (P&F) approach and an adaptation using a quick core needle (NB). However before US-guided biopsy techniques are widely adopted into clinical trials validation of performance against arthroscopy is required.

Objectives: To evaluate whether there were significant differences in synovial sampling quality and quantity between arthroscopic, US-P&F and US-NB procedures within the context of clinical trials.

Methods: This was a multicentre retrospective analysis of inflammatory arthritis patients recruited to clinical trials utilizing US-guided NB (Barts Health NHS Trust), US-guided P&F (ICRSS Policlinico San Matteo and University Hospital Birmingham) and arthroscopic biopsy (Repatriation General Hospital).

Paraffin embedded synovial sections from each procedure underwent H&E staining and sections examined for intact cell lining layer (graded sections). Biopsy procedures were segregated into large (knee) and small joint procedures (wrist/MCP) for analysis. Proportion of samples yielding graded tissue per procedure was recorded. Using CellSens Dimensions software the mean area of synovial tissue obtained per procedure was determined. In addition the degree of synovitis was assessed using semi-quantitiative scoring (0–9).

Results: 78 patient procedures were evaluated, 22 on small joints (11 US-NB, 11 US P&F) and 56 on large joints (11 US-NB, 35 US-P&F, 10 arthroscopic). 47 patients had RA, 11 undifferentiated arthritis and 10 psoriatic arthritis. Arthroscopic sampling resulted in a significantly higher area of tissue retrieved per procedure than US P&F or US-NB. There were no significant differences in proportion of graded samples per procedure suggesting quality of synovial tissue was preserved between techniques. Finally no significant differences in degree of histological synovitis were demonstrated between sampling techniques.

Conclusions: The results suggest that US-guided biopsy provides a reliable method for sampling synovial tissue of comparable quality to that obtained from arthroscopy. However when sampling large joints arthroscopic techniques, and when sampling small joints US-P&F yield a significantly higher quantity, though not quality, of tissue per procedure than US-NB. These results may influence choice of biopsy technique when designing clinical trial protocols in inflammatory arthritis.

THU0668 RELIABILITY OF PATIENT GLOBAL ASSESSMENT IN RHEUMATOID ARTHRITIS PATIENTS

G. Kageyama[1], A. Onishi[2], Y. Ueda[2], J. Saegusa[2], A. Morinobu[2]. *[1]Department of Rheumatology, Hyogo Prefectural Amagasaki General Medical Center, Amagasaki; [2]Department of Rheumatology, Kobe University Hospital, Kobe, Japan*

Background: Patient's global assessment (PtGA) is one of the most widely used patient reported outcomes in rheumatoid arthritis (RA) that reflects both disease activity and other factors. PtGA is onymous and obtained at hospital, which may cause a conscious or unconscious bias, whereas PtGA obtained anonymously may be free from any bias. The credibility of PtGA to report RA patient outcomes has been usually investigated by assessing test-retest reliability. There has been no study comparing routine PtGA and PtGA where patients answered anonymously.

Objectives: The aim of this study was to compare routinely obtained in-hospital PtGA before clinical examination with those answered anonymously at home. Additionally, physician's global assessment (PhyGA) was compared with routine PtGA and anonymized PtGA

Methods: We asked RA patients (n=389) to answer and mail the PtGA test anonymously, Clinical data regarding disease duration, stage, class, swollen joint counts, tender joint counts, pain visual analog scale (VAS), PhyGA, Health Assessment Questionnaire (HAQ), EuroQOL five dimensions questionnaire (EQ5D), Kessler 6 scale (anxiety/ depression), treatment data, laboratory data, and socioeconomic factors were collected simultaneously. We compared the PtGA that is routinely surveyed at hospital before clinical examination with those surveyed anonymously at home. We calculated a discrepancy score by subtracting anonymized PtGA from routine in-hospital PtGA. We defined (1) positive discrepancy when routine PtGA was over-rated relative to the anonymized PtGA; (2) negative discrepancy when routine in-hospital PtGA was under-rated relative to the anonymized PtGA.

Results: The anonymized PtGA score was higher than routinely evaluated in-hospital PtGA ($p<0.0001$). The anonymized PtGA poorly correlated with routine in-hospital PtGA ($r=0.426$, $p<0.0001$). We compared patients who had discordance between in-hospital PtGA and anonymized PtGA. We used 3 models in which the discordance between both PtGAs was set at 10 mm, 20 mm, or 30 mm. If we adopted 30 mm as discordance, the pain scale remained to be a risk factor of positive discrepancy (higher in-hospital PtGA than anonymized PtGA). If we adopted 20 mm or 10 mm as discordance, the pain scale remained to be a risk factor of positive discrepancy and remaining low quality of life (QOL) negative discrepancy (lower in-hospital PtGA than anonymized PtGA) after multivariate analysis. The discordance between PhyGA and routine PtGA are associated with high pain VAS. The discordance between PhyGA and anonymized PtGA is associated with tender joint counts, swollen joint counts, and low QOL.

Discordance Model	Difference between in-hospital PtGA and anonymized PtGA		
	30mm	20mm	10mm
Household income	-0.074 ± 0.18	0.14 ± 0.14	0.09 ± 0.082
Married (yes)	1.0 ± 1.2	1.3 ± 1.0	-0.057 ± 0.06
Tender Joint Counts	-0.3 ± 0.3	-0.12 ± 0.18	0.011 ± 0.14
Swollen Joint Counts	0.5 ± 0.66	0.32 ± 0.37	0.2 ± 0.18
CRP (mg/dl)	-0.42 ± 0.51	-0.26 ± 0.40	-0.18 ± 0.26
Pain VAS	0.11 ± 0.035 **	0.12 ± 0.026 ***	0.081 ± 0.013 ***
Physician's Global Assessment	0.028 ± 0.066	-0.017 ± 0.045	-0.0089 ± 0.026
EQ5D	0.093 ± 0.056	0.093 ± 0.037 *	0.043 ± 0.018 *
K6 scale(Anxiety/Depression)	-0.15 ± 0.14	0.0027 ± 0.091	0.56 ± 0.59

Value are expressed as Estimate ± Standard Error. * p<0.05, *** p<0.0001

Conclusions: Discrepancy exists between routine in-hospital PtGA and anonymized PtGA.

The high pain VAS scale and low QOL are risk factors that could make the difference between routine PtGA from anonymized PtGA. There is a possibility that high pain VAS score and low QOL influence the reliability of PtGA.

THU0669 THE ASSOCIATION BETWEEN HARRIS HIP SCORE AND DISEASE ACTIVITY OR HIP MRI FEATURES IN ANKYLOSING SPONDYLITIS

Z. Wu[1], L. He[2], M. Yang[3], Y. Liu[4], D. He[5], Y. Zhang[6], C. Wang[7], H. Xu[8]. *[1]Department of Rheumatology, Xijing Hospital; [2]Department of Rheumatology, The First Affiliated Hospital of Xi'An JiaoTong University Hospital, Xi'An; [3]Department of Rheumatology, Nanfang Hospital, Guangzhou; [4]Department of Rheumatology, West China Hospital, Sichuang; [5]Department of Rheumatology, GuangHua Hospital, Shanghai; [6]Department of Rheumatology, Tangdu Hospital; [7]Medical Affairs, Xian-Janssen Pharmaceutical Ltd, Xi'An; [8]Department of Rheumatology and Immunology, Shanghai Changzheng Hospital, Shanghai, China*

Background: Hip involvement is a common clinical feature observed in ankylosing spondylitis (AS) patients and it often leads to substantial restriction of the body functions.[1] Hip involvement in AS is mainly assessed by radiographic changes, clinical symptoms or MRI. The Harris hip score (HHS) is a valuable assessment tool to measure health status of AS patients. However, the relationship between HHS and other clinical indices is unknown.

Objectives: To evaluate relationship between HHS and other commonly used clinical indices.

Methods: In this multicentre, observational study, AS patients with hip clinical manifestation are enrolled and randomly assigned to infliximab treatment (group I, with/without DMARDs and/or NSAIDs) or conventional therapy (group II, DMARDs and/or NSAIDs). Primary endpoint: to compare functional improvement of hip joint (HHS) between two treatment groups (infliximab and conventional therapy) at week 30. Secondary endpoint: to compare disease activity and functional improvement of AS and radiologic progression of hip joint between two treatment groups at week 30 and 52. Association between baseline HHS and disease activity measures such as Bath ankylosing spondylitis (BAS)-functional index (BASFI), BAS disease activity index (BASDAI), AS disease activity score (ASDAS), CRP and ESR was analysed using Pearson correlation coefficient. BAS metrology index (BASMI) and hip imaging functions (MRI of hip, BAS radiology hip index [BASRI-h]) were analysed using independent two-sample t-test or ANOVA based on data characteristics.

Results: Study is ongoing; currently, only baseline information is analyzed. Baseline demographics and disease characteristics did not show any significant difference between groups. Almost all baseline disease activity measures showed significant Pearson correlation (high correlation in BASFI=0.646) with HHS, except for BASDAI (table 1). Significant association between HHS and three MRI scores (articular cartilage stripping, bone destruction under joint surface, femoral head bone marrow cavity edema) and BASRI-h was shown (table 2). Also, significant correlation was shown between BASMI and HHS (F value [degree of freedom]=4.70 [4]; p=0.0022).

Table 1. Association between HHS and disease activity measures at baseline

	Mean (SD)	Pearson correlation-HHS	P Value
ASDAS	2.81 (0.904)	-0.449	0.0004
BASDAI	4.60 (1.109)	-0.169	0.1691
BASFI	3.79 (2.050)	-0.646	<0.0001
CRP	12.270 (19.4810)	-0.348	0.0074
ESR	22.1 (24.06)	-0.386	0.0023

Table 2. Association between HHS and hip imaging functions at baseline

		N	HHS, mean (SD)	T-test (degree of freedom)	P value
Articular cartilage stripping	No	29	62.5 (9.13)	2.27 (54.97)	0.0271
	Yes	32	55.9 (13.39)		
Bone destruction under joint surface	No	22	63.8 (4.66)	3.08 (49.29)	0.0034
	Yes	38	56.2 (14.02)		
Femoral head bone marrow cavity edema	No	29	62.4 (9.37)	2.18 (58.00)	0.0332
	Yes	31	55.8 (13.46)		
BASRI-h (at least one Hip ≥1)	_	29	54.7 (14.01)	-3.00 (37.55)	0.0048

Conclusions: The baseline results of HHS were found to be well associated with disease activity scores like BASFI, ASDAS and BASMI and four hip imaging features in AS patients with hip involvement.

THU0670 DETECTION OF SERUM ANTI-DNASE I ANTIBODIES IN SYSTEMIC LUPUS ERYTHEMATOSUS USING IMPROVED IMMUNOSORBENT ASSAY

A.S. Trofimenko[1,2], I.P. Gontar[1], I.A. Zborovskaya[1], L.N. Shilova[2], E.G. Korenskaya[2]. *[1]Research Institute for Clinical and Experimental Rheumatology; [2]Volgograd State Medical University, Volgograd, Russian Federation*

Background: Diagnosis of systemic lupus erythematosus (SLE) is a sophisticated problem in most of the disease cases. The reasons of this include common diagnostic markers of SLE (ANA, anti-dsDNA, anti-Sm), that are insufficiently reliable itself as well. One of possible ways to overcome these difficulties is searching for new SLE markers. These emerging diagnostic tools are not only to be valuable for diagnosis establishment, but also to provide economical efficiency and facility in common use.

Objectives: To compare diagnostic efficiency of anti-DNase I antibodies measured by conventional ELISA and by originally modified enzyme immunosorbent assay using magnetic polyacrylamide beads as an antigen carrier.

Methods: The research was carried out in agreement with the WMA Declaration of Helsinki principles, it was approved by the Regional Committee on Medical Ethics. All the patients signed the informed consent. We have enrolled 54 in-hospital adult patients with SLE, verified by the ACR criteria (1997). Control group (n=52) was comprised of patients with rheumatoid arthritis, systemic sclerosis, systemic vasculitides, dermatomyositis, and Sjogren's disease. Serum

anti-DNase I concentrations were evaluated by conventional ELISA, as described elsewhere [1]. The beads were synthesized using original technique [2], modified ELISA and recovery of the beads for repeating use was performed according to the previously published protocols [2]. Antibody concentrations were expressed as relative optical density units (ODU). The cutoff values for conventional and modified ELISA were 0.061 and 0.057 ODU, respectively. All the means and operation characteristics were expressed as values (95% confidence intervals). Differences were considered significant when $p<0.05$.

Results: Mean anti-DNase I concentrations in SLE patients (negative and positive together) were 0.088 (0.031–0.145) and 0.079 (0.033–0.125) ODU for conventional and modified ELISA, respectively; in the control group they were 0.068 (0.020–0.116) and 0.063 (0.019–0.107) ODU, respectively. Differences within these couples were not significant. Diagnostic sensivity and specificity of modified ELISA were 64.74 (53.09–76.39) and 85.01 (72.95–97.07)%, coinciding with those for conventional ELISA. LOQ for the modified ELISA was slightly lower than for the conventional one. Accuracy and repeatability of modified ELISA were also insignificantly higher than those for conventional approach. There was no substantial change in all the parameters of modified ELISA after single recovery of beads.

Conclusions: The newly developed ELISA for anti-DNase I antibodies was demonstrated to have equivalence or advantage in some analytical parameters over conventional ELISA. Considering some economic and maintenance benefits, our innovation can be an alternative tool to improve SLE diagnostics.

THU0671 CAN AN INNER DISPOSABLE GLOVE BE USED UNDER AN ELECTROGONIOMETRIC GLOVE FOR MEASURING FINGER MOVEMENT WITHOUT LOSS OF ACCURACY?

J. Connolly[1], P. Gardiner[2], J. Condell[3], K. Curran[3], D. Small[2]. *[1]Computing, Letterkenny Institute of Technology, Letterkenny, Ireland; [2]Rheumatology, Altnagelvin hospital; [3]Computing, Ulster University, Londonderry, United Kingdom*

Background: Improving joint mobility is an important outcome for patients with arthritis, but finger joint range of motion is rarely measured in clinic. Electronic gloves with movement sensors have been developed to measure joint movement accurately and it is now possible to assess dynamic mobility of the finger joints. However these gloves are expensive and it is likely that when carrying out measurements in the patient population they would be used with inner disposable gloves to avoid nonsocomical infection. Establishing accuracy and usability of electronic gloves whilst wearing disposable inner gloves is therefore an important pre-requisite for studies in patients with arthritis.

Objectives: To establish the accuracy and repeatability of measurements of finger movement obtained using two different electrogoniometric gloves worn with and without an inner disposable glove.

Methods: We used two different types of electrogoniometric glove for the purpose of this study. One is the commercially available 5DT dataglove 14 Ultra (5DT, 2011) and the other was produced to our specifications by Tyndall National Institute, University College Cork. We called this the “IMU glove”. We developed a graphical interface for both devices to facilitate detailed evaluation of joint movement in each finger. Both gloves were tested using a protocol adapted from Dipietro, Sabatini, & Dario, (2003).

Results: Table 1 displays comparison of Coefficient of Variation (CV) readings for both data gloves. Figure shows this information graphically.

Sensor	No surgical glove		Surgical glove underneath	
	5DT	IMU	5DT	IMU

Ring PIP	5.38	9.95	5.00	11.03
Little PIP	9.11	3.71	10.07	5.46

Results show no significant change for 5DT angular readings with and without a surgical glove worn underneath the data glove. Results for PIP sensors show an improvement in repeatability with a surgical glove. CV variance was smaller for MCP sensors with a surgical glove worn underneath the data glove compared with no surgical glove.

CV for the IMU data glove show negligible changes in MCP readings when a surgical glove is worn underneath. PIP readings show small changes when using a surgical glove.

Conclusions: Inner disposable gloves can be worn when using electrogoniometric gloves for testing finger movement without loss of accuracy or any significant discomfort in patients with arthritis.

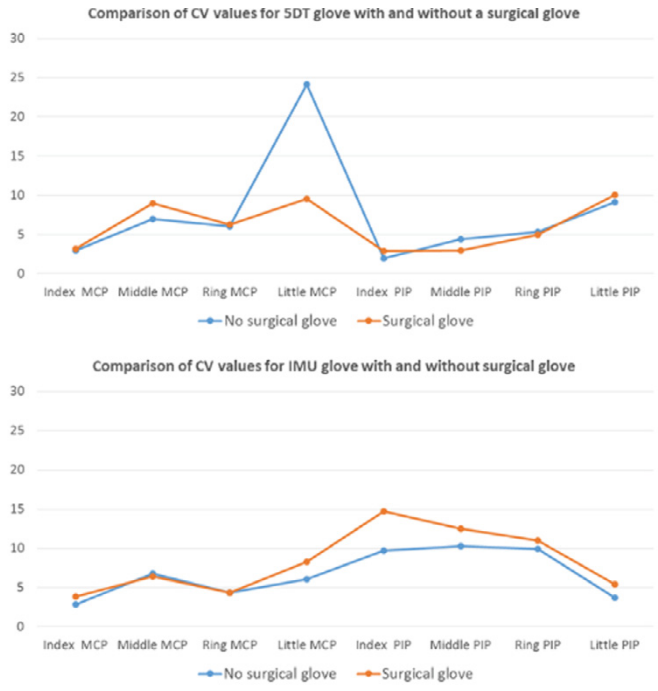

Figure 1: Comparison of Coefficient of Variation (CV) values for mean angular readings for both data gloves, with and without a surgical glove worn underneath.

THU0672 REAL WORLD EVIDENCE COMPARING THE PATIENT REPORTED OUTCOMES MEASUREMENT INFORMATION SYSTEM TO THE CDAI IN RHEUMATOID ARTHRITIS PATIENTS

J.R. Curtis[1], S. Kafka[2], D. Parenti[2], S. Black[2], S. Xu[3], Y. Wang[3], C.O. Bingham III[4]. *[1]University of Alabama at Birmingham, Birmingham; [2]Janssen Scientific Affairs, LLC, Horsham; [3]Janssen Research & Development, LLC, Springhouse; [4]Johns Hopkins University, Baltimore, United States*

Background: Patient (Pt) reported outcomes (PROs) play a role in overall disease evaluation, therapeutic response assessment and care of rheumatoid arthritis (RA) patients (Pts). The Pt Reported Outcomes Measurement Information System (PROMIS [P]) questionnaires developed by the NIH have been validated and are a feasible assessment tool in RA (Bartlett 2015).

Objectives: AWARE (Comparative and Pragmatic Study of Golimumab Intravenous (IV) Versus Infliximab in RA) is a real-world study of golimumab IV (G-IV) vs. infliximab (IFX) in RA and will assess infusion reactions, disease activity and multiple PROs as outcomes measures.

Methods: AWARE is a prospective, noninterventional, ongoing US-based study in which 1,200 adult Pts will be enrolled on initiation of treatment with G-IV or IFX. Objectives include PRO assessments of Pt response to treatment using the PROMIS-29 Profile v2.0 (P29v2), P Pain Interference Short Form-6b (PISF) and P Fatigue Short Form-7a (FSF), 36-Item Short Form Health Survey (SF-36v2) and the Clinical Disease Activity Index (CDAI). We report an interim analysis from the first 353 Pts of baseline PROMIS questionnaire and CDAI scores, and their inter-relationships. PROMIS questionnaire results are scored on a 0 to 100 scale, normed to the US population and reported as a “T-score” (mean of 50 and standard deviation (SD) of 10). PROMIS T scores were compared across CDAI disease activity (DA) categories.

Results: Baseline mean (SD) CDAI score was 33.46 (±15.79), with 73.4% of pts with high DA (HDA), 22.1% with moderate disease activity (MDA), 3.7% with low disease activity (LDA) and 0.8% pts in remission. PROMIS scores are shown below. All P29v2 domains, PISF and FSF scores were significantly worse in pts with CDAI>22 vs. CDAI≤22 ($p<0.05$). The same was true for SF-36 domains (data not shown). PROMIS scores are shown below for all pts, and also based on CDAI DA category. PROMIS T scores across all domains (P29v2 domains, PISF and FSF) were compared to CDAI disease activity category (below). As shown, PROMIS T scores correlated with CDAI disease category, with HDA Pt T scores significantly (*, $p<0.05$) greater than those of MDA, LDA and Remission pts (excepting the Sleep Disturbance domain).

Mean PROMIS T Score of All Patients in Interim Analysis Dataset and a Comparison of T Scores of PROMIS-29 Domains, Fatigue Short Form and Pain Interference Short Form to CDAI Disease Activity Category

	All Patients (n=353)	Remission CDAI</=2.8 (n=3)	LDA 2.8<CDAI</=10 (n=13)	MDA 10<CDAI</=22 (n=78)	HDA CDAI>22 (n=259)
P29-Physical Function	37.5 ± 6.4	50.1 ± 6.07	43.5 ± 7.37	39.7 ± 6.83	36.4 ± 5.66*
P29-Anxiety	54.5 ± 10.3	44.8 ± 7.74	50.4 ± 9.12	51.6 ± 10.0	55.7 ± 10.24*
P29-Depression	52.7 ± 10.1	43.7 ± 4.62	46.2 ± 7.25	49.8 ± 10.18	54.0 ± 9.91*
P29-Fatigue	59.9 ± 9.6	41.8 ± 7.53	51.1 ± 9.57	56.9 ± 9.55	61.5 ± 9.04*
P29-Sleep Disturbance	56.0 ± 8.3	52.8 ± 14.36	52.3 ± 6.41	54.1 ± 8.48	56.8 ± 8.17
P-29 Ability to participate in Social Roles and Activities	42.3 ± 8.2	56.2 ± 9.18	49.9 ± 8.43	44.5 ± 8.84	41.2 ± 7.50*
P29-Pain Interference	64.0 ± 7.5	45.7 ± 7.1	54.3 ± 7.81	61.0 ± 8.10	65.5 ± 6.35*
Fatigue SF 7a	60.3 ± 8.3	43.0 ± 10.19	54.3 ± 7.65	57.5 ± 7.22	61.7 ± 8.02*
Pain Interference SF 6b	63.0 ± 7.7	43.5 ± 4.33	54.6 ± 9.29	59.9 ± 8.03	64.5 ± 6.62*
P29 Pain Intensity (scored 0-10 scale)	6.2 ± 2.2	2.0 ± 3.46	3.5 ± 1.71	5.4 ± 2.32	6.6 ± 1.91*

T scores > 50 indicate worsening of the domain relative to the general population, except "Physical Function" and "Ability to participate in Social Roles and Activities", where T-scores < 50 indicate worsening of these domains relative to the general population. * = p<0.05 vs respective scores in MDA, LDA and remission DA categories

Conclusions: These interim data further support the viability of using PROMIS questionnaires to evaluate RA pts, and indicate in this predominantly HDA population of RA pts correlations between PROMIS and CDAI disease activity category. Confirmation of the baseline interim analysis findings with the fully enrolled AWARE study, as well as inclusion of longitudinal and subset analyses based on disease activity levels, will further define the role of PROMIS relative to CDAI in RA patients in a real world setting.

THU0673 THE EUROPEAN CONSENSUS FINDING STUDY GROUP (ECFSG) HELPS CHARACTERIZING NEW TENTATIVE REFERENCE STANDARDS FOR AUTOANTIBODY MEASUREMENT

J. Rönnelid[1], C. Dahle[2], M. Blüthner[3], E. Feist[4], C. Dolman[5], S.J. Thorpe[5], E. Monogioudi[6], I. Zegers[6], P.L. Meroni[7], D. Hamann[8] on behalf of ECFSG.
[1]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala; [2]Department of Clinical Immunology and Transfusion Medicine, Linköping University Hospital, Linköping, Sweden; [3]MVZ Laboratory PD Dr. Volkmann & colleagues, Department of autoimmune diagnostics, Karlsruhe; [4]Department of Rheumatology and Clinical Immunology, Charité-Universitätsmedizin, Berlin, Germany; [5]National Institute for Biological Standards and Control, Biotherapeutics Group, Potters Bar, Herts, United Kingdom; [6]Joint Research Centre, European Commission, Geel, Belgium; [7]Department of Clinical Sciences & Community Health, University of Milan, Milan, Italy; [8]Department of Immunopathology and Blood Coagulation, Sanquin Diagnostic Services, Amsterdam, Netherlands

Background: Since 1988, the European Consensus Finding Study Group on autoantibodies in rheumatic diseases (ECFSG), also known as the EULAR autoantibody study group, has been distributing sera with unspecified antibodies to European laboratories (presently n=43) for evaluation of different autoantibody measurement techniques in a clinical context. Use of reference materials helps to align test results by adopting internationally used measurement units, but reference materials are missing for many autoantibody specificities.

Objectives: Recently the scope for ECFSG was expanded to also include unbiased autoantibody characterization of serum/plasma specimens planned to constitute raw material for production of future autoantibody reference materials.

Methods: Four samples were included to be evaluated as future tentative international reference materials for four different autoantibody specificities: double stranded/native DNA (dsDNA, evaluated in 2013/14), IgG anti-b2GP1, proteinase 3 (PR3) and myeloperoxidase (MPO, evaluated in 2015/16). The samples were included "blind", and evaluated broadly for multiple autoantibody specificities by participating laboratories.

Results: All or almost all participating laboratories detected the target specificities, and all four samples showed restricted autoantibody specificities related to the target specificity. Anti-dsDNA was detected by all laboratories using *Crithidia luciliae*, ELISA/EIA, FARR assay or ALBIA and all labs reported a homogenous ANA pattern. Other specificities were restricted to histones, nucleosomes and anti-Ku. All laboratories but one detected IgG anti-b2GP1 and IgG anti-cardiolipin, mostly in high levels, in the tentative IgG anti-b2GP1 reference standard, whereas corresponding IgA and IgM antibodies were absent. All laboratories detected anti-MPO, mostly monospecific and in high levels together with P-ANCA pattern in the anti-MPO reagent. Anti-PR3 and C-ANCA pattern, mostly in high levels/titers were detected by all laboratories in the tentative anti-PR3 reagent, irrespective of method used.

Conclusions: The expanded scope of ECFSG has enabled broad characterization of new tentative autoantibody reference standards. The anti-dsDNA specimen has been processed by the National Institute for Biological Standards and Control (NIBSC) for consideration as the 2nd WHO anti-dsDNA reference standard. The other materials are basis for certified reference material for IgG anti-myeloperoxidase (ERM-DA476/IFCC), and the candidate reference materials for IgG anti-proteinase 3 (in certification) and for IgG anti-b2PG1 (in evaluation) from the Joint Research Centre.

THU0674 ANTI-DFS70 ANTIBODY – A BIOMARKER THAT AID IN THE EXCLUSION OF ANA ASSOCIATED RHEUMATIC DISEASES

K. Conrad[1], N. Röber[1], M. Achtleitner[1], M. Aringer[2], S. Rudolph[3], L. Unger[4], A. Gräßler[5], K. Lüthke[6], M. Mahler[7]. *[1]Medical Faculty of the TU Dresden, Institute of Immunology; [2]University Hospital Carl Gustav Carus, Department of Internal Medicine and Rheumatology, Dresden; [3]Admedia MVZ, Immune Center Chemnitz, Chemnitz; [4]Municipal Hospital Dresden-Friedrichstadt, Department of Medicine I, Dresden; [5]Medical Practice, Pirna; [6]Medical Practice of Rheumatology, Dresden, Germany; [7]Inova Diagnostics, San Diego, United States*

Background: Positive ANA may lead to additional testing and potentially even inappropriate treatment in patients with rheumatic symptoms not caused by ANA associated rheumatic diseases (AARD).

Objectives: It has been shown that autoantibodies directed against lens epithelial derived growth factor (LEDGF), also named DFS70 according to the staining pattern (dense fine speckled) and molecular weight of the target antigen (70 kDa), are common among ANA positive individuals with no evidence of AARD [1,2]. The aim of our study was to evaluate if autoantibodies directed against DFS70 can be used to exclude AARD in ANA positive patients.

Methods: Anti-DFS70 antibody were determined by chemoluminescence assay (CIA) in sera of 352 apparently healthy controls (AHI), 1048 patients of an ANA positive routine cohort, 579 patients with AARD (300 SLE, 76 idiopathic inflammatory myopathies, 167 systemic sclerosis, 36 Sjögren's syndrome), 56 patients with undifferentiated connective tissue disease (UCTD), and 660 non-AARD patients (302 rheumatoid arthritis, 94 ANCA-associated vasculitis, 87 atopic rhinitis, 135 pediatric patients with celiac disease, and 42 autoimmune liver diseases).

Results: In AHI and in the non-AARD cohort, anti-DFS70 antibodies occur with a prevalence of 5.1% and 2%, respectively. Of the 1048 selected routine sera, 205 (19.6%) were positive for anti-DFS70 antibodies. Up to now, clinical reports are available for 116 of anti-DFS70 positive patients in this group. The diagnoses were widely scattered (nonspecific rheumatic symptoms, arthritis, thyreoiditis, asthma, psoriasis, tumor, infections, inflammatory bowel disease), but no definite AARD could be diagnosed. In the AARD group, only 6 of 579 patients (1.2%) were positive for anti-DFS70 antibodies, all of them also show disease specific autoantibodies (two anti-Scl70 antibody positive SSc, one anti-RNAPIII antibody positive SSc, one Ro-52 positive SSc, one anti-Mi-2 antibody positive IIM, one SLE patient with multiple autoantibodies including dsDNA antibodies). In patients with UCTD, 6 (10.7%) were anti-DFS70 antibody positive in the absence of disease specific autoantibodies. Up to now, no development of an AARD was observed in these patients.

Conclusions: Anti-DFS70 antibodies are frequently observed in sera with chromatin binding antibodies in the absence of disease specific autoantibodies. If anti-DFS70 antibodies are positive in the absence of AARD specific autoantibodies, an AARD can be excluded with high certainty.

THU0675 DEVELOPMENT AND PSYCHOMETRIC VALIDATION OF A TOOL TO ASSESS THE FEARS OF PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES: THE FAIR SCALE

L. Gossec[1,2], P. Chauvin[3], C. Hudry[4], G. Cukierman[5], V. Saulot[6], F. Russo-Marie[6], T. de Chalus[5], J.M. Joubert[5], A. Saraux[7], F. Berenbaum[8]. *[1]UPMC Univ Paris 06; [2]AP-HP, Hôpital Pitié Salpêtrière; [3]INSERM, UPMC Univ Paris 06; [4]AP-HP, Hôpital Cochin, Paris; [5]UCB Pharma, Colombes; [6]Arthritis Fondation Courtin, Neuilly-sur-Seine; [7]CHU la Cavale Blanche and Université de Bretagne Occidentale, Brest; [8]UPMC Univ Paris 06, AP-HP, Hôpital Saint-Antoine, Paris, France*

Background: Patients (pts) with chronic inflammatory rheumatic diseases (CIRDs) such as rheumatoid arthritis (RA) and axial spondyloarthritis (axSpA) have fears related to their disease that can negatively impact health-related quality of life and compromise treatment adherence.

Objectives: To develop and validate a patient-reported outcome (PRO) ques-

tionnaire to explore fears related to CIRDs using the Fears Assessment in Inflammatory Rheumatic Diseases (FAIR) Scale.

Methods: The preliminary questionnaire included 44 items (23 related to fears) most frequently cited by pts in a qualitative study of 50 French pts.[1] Each item was formulated as an affirmative sentence and scored from 0 (completely disagree) to 10 (totally agree). Item scores were summed to provide a total score. The questionnaire was finalised and validated. Pts diagnosed with RA (EULAR/ACR criteria) or axSpA (ASAS criteria), recruited during routine visits by 100 participating rheumatologists across France, completed the preliminary questionnaire, HAD (Hospital Anxiety and Depression) and AHI (Arthritis Helplessness Index) scores. Redundant items (inter-item correlation coefficient >0.65) were eliminated. For the others, internal consistency (Cronbach alpha) and the factorial structure of the scale (principal component analysis) were assessed. Pts were classified according to their level of fears (cluster analysis) and corresponding score thresholds were determined (ROC analysis). The final questionnaire was independently translated into English and back into French twice, with reconciliation of the translated texts.

Results: 672 pts were included: 432 RA pts (mean±SD disease duration was 13.1±11.4 years, DAS28[ESR] was 2.6±1.2, 77.3% were taking biologics) and 240 axSpA pts (disease duration was 13.8±10.6 years, BASDAI was 3.3±2.2, 72.7% were taking biologics). The final FAIR Scale included 10 questions (Table) with total scores ranging 0–100. Mean±SD scores were 51.2±25.4 in RA and 60.5±22.9 in axSpA. Three pt groups were identified, characterised by high, moderate and low level of fears (17.2%, 41.1% and 41.7% of the population, respectively). The corresponding thresholds of the total score were 77 and 51, respectively. Fear scores were correlated with HAD scores for anxiety (r=0.47) and depression (r=0.40) and with the AHI (r=0.50).

Table: FAIR Scale – 10 items [a]

Fears about the progression and consequences of the disease:
B-7: I am afraid of suffering like I did in the past.
D-3: I am afraid that my disease is rapidly getting worse.
D-5: I am afraid that my spinal column or some of my bones will fuse.
D-7: I am afraid of not having anyone to help me if I lose my autonomy.
E-1: I am afraid that I will no longer be able to carry out my daily activities.
E-5: I am afraid that people will think of me as disabled.
C-6: I am afraid that at some point there will be no more effective treatments for my disease.
Fears about treatments:
C-2: I am afraid of the side effects of treatments for my disease.
C-3: I am afraid that the treatments of my disease may cause cancer.
C-4: I am afraid that the treatments of my disease will become less effective.

[a] Each item is scored between 0 (strongly disagree) and 10 (strongly agree); total score of 100.

Conclusions: The FAIR Scale is a 10-question PRO to evaluate disease-related fears in CIRD pts. In this pt population, 17.2% had high fear scores, contrasting with a disease that is often well-controlled. The FAIR Scale was associated with psychological distress. This psychometrically-validated and easy to use questionnaire could be used to improve pt-physician dialogue in CIRDs and also be of value in clinical studies. Further validation in other populations is needed.

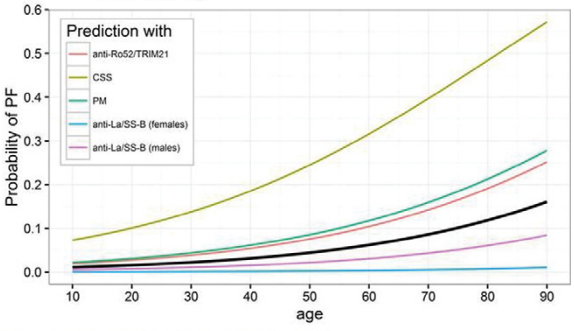
THU0676 ANTI-RO/SS-A 52-KDA ANTIBODIES: A MARKER FOR LUNG FIBROSIS IN RHEUMATIC DISEASES

L. Garcia Montoya, C.N. Sáenz-Tenorio, R.D. González-Benítez, M. Correyero-Plaza, J.C. Nieto, I. Janta, J.G. Ovalles-Bonilla, J. Martínez-Barrio, B. Serrano, L. Valor, D. Hernández-Flórez, C.M. González, I. Monteagudo, F.J. López-Longo. *Rheumatology, Hospital General Universitario Gregorio Marañon, Madrid, Spain*

Background: Lung fibrosis (LF) is a type of interstitial disease that leads to lung scarring, respiratory failure and later on, death. There are 2 main types of LF: idiopathic and secondary; and the prognosis is very different. LF becomes relevant in connective tissue diseases (CTD) and some studies have suggested that there could be an association between anti-Ro/TRIM21 antibodies and the development of interstitial lung disease in these patients.

Objectives: The aim of this study was to assess if the presence of anti-Ro52/TRIM21 antibodies is an independent risk factor for developing CTD-associated LF. We also aimed to evaluate the initial manifestations of systemic diseases and clinical characteristics linked to certain antibodies.



Methods: It is a prospective, observational, longitudinal, single-center study conducted among unselected patients with CTD (rheumatoid arthritis, systemic lupus erythematosus (SLE), systemic sclerosis (SSc), polymyositis (PM), overlap CTD syndrome (OCTD), MCTD, primary Sjögren's sd (PSS), primary antiphospholipid sd, systemic vasculitis, and undifferentiated connective tissue disease).

We analysed data from 1,432 caucasian patients included in the "Systemic Autoimmune Diseases (SAD) Registry" from 1988 to 2014. They were all checked at least biannually and blood samples were taken according to clinical practice. Exclusion criteria were LF as the initial manifestation of the SAD, LF already diagnosed at the first visit and also LF secondary to drugs or a specific environment.

Results: 10% of patients included in the study developed LF. The OR for LF in patients with anti-Ro52/TRIM21 antibodies was 1.757 (95%*CI*=1.1–2.7). The OR for LF increased with every year of age (*OR*=1.03, 95%*CI*=1.02–1.04). Only 9 out of 146 patients with LF were positive for Anti-La/SS-B antibodies, and the OR for males was 8.6 compared to women (95%*CI*=1.8–39.5). Patients with SSc and PM showed a higher OR for the development of LF (6.9 95%*CI*=4.6–10.4 and 2.0, 95% CI=1.2–2.8 respectively) compared to those diagnosed with other CTD. The time passed from the first symptoms to the diagnosis of LF was inversely related to the age of onset (r=-.230; p=0.013). The average time was 60 months for patients with anti-Ro52/TRIM21 antibodies (29 patients) and 138 months for patients without them.

	LF				p	OR	OR 95% CI
	Yes (*n*=146)		No (*n*=1286)

Figure 1. **Multiple logistic regression predictions (the black line represents the base prediction)**

CSS: cutaneous systemic sclerosis; PM: polymyositis

Conclusions: Anti-Ro52/TRIM21 antibodies have been proved to be a risk factor for developing LF. The earlier the age of onset, the slower the progression to fibrosis. However, patients with anti-Ro52/TRIM21 antibodies tend to have a faster development, independent of the age of onset. Anti-La-SS-B antibodies seem to be a protective factor for the development of LF in both genders; but the association is stronger in women.

THU0677 OUTCOME MEASUREMENT INSTRUMENTS FOR SAFETY IN RHEUMATOLOGY: A SCOPING REVIEW OF AVAILABLE INSTRUMENTS TO INFORM THE OMERACT SAFETY WORKING GROUP

L. Klokker[1], T. Woodworth[2], D.E. Furst[2], P. Tugwell[3], D. Devoe[4], P. Williamson[5], C.B. Terwee[6], M.E. Suarez-Almazor[7], V. Strand[8], A.L. Leong[9], N. Goel[10], M. Boers[11], P.M. Brooks[12], L.S. Simon[13], R. Christensen[1] on behalf of OMERACT working group. *[1]The Parker Institute, Bispebjerg & Frederiksberg Hospital, Copenhagen, Denmark; [2]David Geffen School of Med., Division Rheumatology, UCLA, Los Angeles, United States; [3]Dept of Medicine, School of Epidemiology, Public Health and Community Medicine, University of Ottawa, Ottawa; [4]Department of Medicine, University of Calgary, Cumming School of Medicine, Calgary, Canada; [5]Institute of translational medicine, University of Liverpool, Liverpool, United Kingdom; [6]Department of Epidemiology and Biostatistics, the EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, Netherlands; [7]Section of Rheumatology and Clinical Immunology, University of Texas MD Anderson Cancer Center, Houston; [8]Div Imm/Rheum, Sanford University, San Fransisco; [9]Healthy Motivation, Global Alliance for Musculoskeletal Health, Bone and Joint Decade, Santa Barbara; [10]Advisory Services, Strategic Drug Development, Quintiles IMS, Morrisville NC, United States; [11]Department of Epidemiology and Biostatistics, Amsterdam Rheumatology and immunology Center, VU University Medical Center, Amsterdam, Netherlands; [12]Centre for Health Policy Melbourne School of Population, Global Health University of Melbourne, Melbourne, Australia; [13]SDG LLC Cambridge, Cambridge MA, United States*

Background: International scientific networks have raised concerns about inadequate reporting of safety outcomes in randomised trials and systematic reviews. Outcome Measures in Rheumatology (OMERACT) has previously developed an adaptation of the US National Cancer Institute (US NCI) Common Terminology Criteria for Adverse Events (CTCAE), the RCTC (Rheumatology Common Toxicity Criteria) to collect adverse events in rheumatology clinical trials. To respond to the need to also report safety outcomes from the patient perspective, the Safety Working Group is developing a core outcome set, followed by a core outcome measurement set. A scoping review of available instruments for measuring safety outcomes is needed to inform this work.

Objectives: To identify candidate measurement instruments for safety outcomes in rheumatology clinical trials.

Methods: A systematic search was performed in the MEDLINE database (via PubMed) in January 2017 using MeSH terms covering synonyms for adverse events, rheumatology and measurement instruments and the Boolean operator AND to combine them. Full-text articles about the development or evaluation of instruments for measuring safety in rheumatology were eligible. One reviewer (LK) screened for eligibility based on title and abstracts. Two reviewers (LK and RC) screened the full text articles.

Results: Of 434 unique references identified, 19 were read in full-text, and 8 were included (see figure). The instruments identified were: Glucocorticoid Toxicity Index (GTI), Patient Reported Experiences and Outcomes of Safety in Primary Care (PREOS-PC), Safety of Estrogens in Lupus Erythematosus National Assessment (SELENA)-SLEDAI flare index (cSFI), the BioSecure questionnaire, Rheumatology Common Toxicity Criteria (RCTC), OMERACT 3x3, and the Stanford Toxicity Index (STI). These instruments were specific for substance (GTI, BioSecure questionnaire), setting (PREOS-PC), condition (cSFI), or not fully validated (RCTC, OMERACT 3x3, STI).

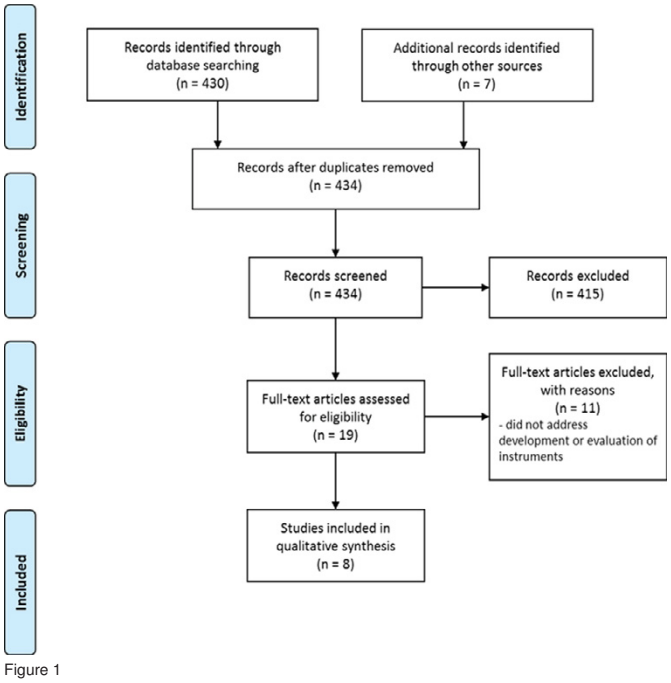

Figure 1

Conclusions: The instruments identified are either too specific, or require further development/evaluation, for the purpose of standardizing measurement of safety in rheumatology clinical trials. Thus, we will proceed to gain consensus on the domains that must be measured to develop a core outcome set.

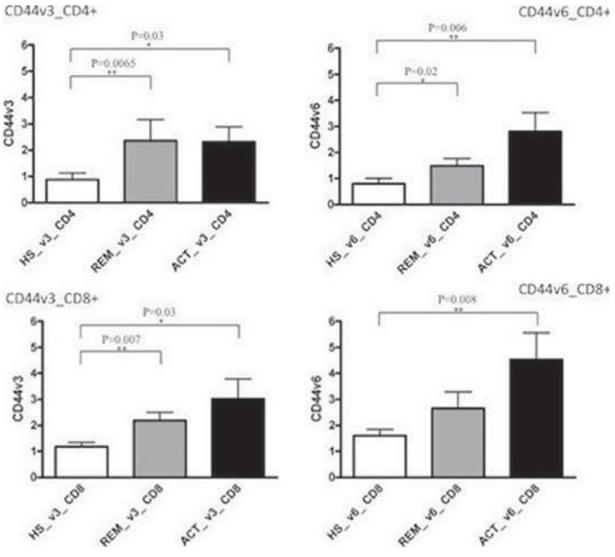
THU0678 EXPRESSION OF ADHESION MOLECULES CD44V3 AND CD44V6 ON T CELLS IN SLE PATIENTS: CORRELATION WITH CLINICAL PHENOTYPE AND DISEASE ACTIVITY

L. Novelli[1], C. Barbati[1], F. Ceccarelli[1], C. Perricone[1], F.R. Spinelli[1], C. Alessandri[1], G. Valesini[1], R. Perricone[2], F. Conti[1]. *[1]Lupus Clinic, Sapienza University of Rome, Italy; [2]Rheumatology, Allergology and Clinical Immunology, Tor Vergata University, Rome, Italy*



Background: Adhesion molecule CD44 enables T lymphocytes' adhesion to endothelium. During inflammation, increased expression of CD44 contributes to T cell migration into target organs. Infiltration of peripheral tissues is crucial in the development of SLE organ damage and the different isoforms of CD44 seem to be involved in this process. Both CD44v3 and CD44v6 isoforms have been found in kidney biopsies of SLE patients, and CD44v3 in the skin only[1,2]. A higher expression of CD44v3 and v6 has been identified on T cells from SLE patients compared to healthy subjects (HS) and the expression levels seem to correlate with disease activity[3].

Objectives: The aim of this study was to investigate the expression of the CD44v3/v6 isoforms on T cells of SLE patients and their correlation with disease activity and clinical phenotype.

Methods: We enrolled 23 patients (23F, mean age±SD 45.7±13 years, mean disease duration±SD 13±8years) affected by SLE according to the 1997 ACR criteria, and 14 HS (14F, mean age±SD 34.28±12.7 years). Disease activity was measured by SLEDAI-2K. 10 patients were in remission (SLEDAI-2K=0) and 13 patients had an active disease (SLEDAI-2K≥4). Expression of CD44v3 and v6 on T cells was determined by flow cytometry analysis.

Results: Expression of CD44v3 and v6 was significantly higher in active and remission patients compared to HS on CD4+ and CD8+ T cells. SLE patients with active disease showed a trend of major expression of CD44v3 and v6 on CD4+ and CD8+ cells compared to patients in remission (Fig.1). CD44v3/CD44v6 expression ratio on CD4+ and CD8+ T cells was shifted towards isoform v3 on CD4+ cells and towards isoform v6 on CD8+ cells in SLE patients in remission and HS. In active disease this ratio was shifted towards isoform v6 on both T cells populations (Table 1). By using a ROC curve analysis, CD44v6 on CD4+ T cells resulted the most sensitive and specific one (sensitivity 82.6%, specificity 78.6%). Finally, we observed a significant correlation between CD44v3 on CD4+ cells and skin involvement (P=0.027, r=0.632).

Ratio	CD4 CD44v3/CD4 CD44v6	CD8 CD44v3/CD8 CD44v6
Healthy subjects	1.14	0.74
SLE SLEDAI-2k=0	1.58	0.82
SLE SLEDAI-2k≥4	0.82	0.67

Conclusions: Our study confirms previous evidences suggesting a higher expression of CD44v3 and v6 on T cells from SLE patients compared to HS. Higher expression of CD44v3 and v6 on patients with active disease suggests their possible use as biomarkers of disease activity. The good specificity and sensitivity of CD44v6 on CD4+ T cells, and the shift of the ratio towards this

isoform in active patients, suggest a stronger value of this isoform as a biomarker of disease activity.

THU0679 CAN THE USE OF NEW TECHNOLOGIES IMPROVE THE USE OF PATIENT REPORTED OUTCOMES (PROS) AND PATIENT PARTICIPATION IN A NATIONAL REGISTRY?

L. Cunha-Miranda[1], H. Santos[1], F. Barcelos[1], N. Madeira[1], S. Fernandes[1], J. Borges[1], R. Marques[1], C. Silva[1], C. Miguel[1], A. Cardoso[2], R. Trinca[3], A. Faustino[1]. *[1]Rheumatology; [2]Nutrition; [3]Nurse Day Hospital, Instituto Português de Reumatologia, Lisboa, Portugal*

Background: PROs are especially useful in the management of rheumatic diseases in complement to physician evaluation. However they are time consuming and used in a limited manner in the daily clinical practice.
Reuma.pt is the Portuguese national rheumatic diseases register and one of the few registries in Europe that allows the patient to do at home the PROs before the appointment. In our institute we have complemented that with the creation of a paper free day hospital with the use of touch screen computers that also allows the patient to do the PROs before the clinical evaluation by the rheumatologist.
Objectives: to compare the impact of the use off Reuma.pt at home PROs completion platform before and after the utilization of touch screen computers in the day hospital.
Methods: We determined the number of patients and appointments with the use at home of the PROs platform one year prior to the introduction of the touch screen computer at our day hospital (October 2014 –October 2015) and one year after the paper free day hospital was installed (November 2015-November 2016). To determine any change of pattern of the use at home of the platform and the relations between that and patients characteristics.
Results:

Table 1. Diferences between previous use of touchscreen computers in the use at home PROs

	T0 October 2014 to October 2015	T1 November 2015 to November de 2016
Number of appointments with PROs done at home/total of appointments with completed PROs/percentage	93/419 /22.1%	216/448/48,2%
Number of patients with PROs done at home	57	106
Age	45.19±10.33	49.82±11.54
Sex	40F + 17M	75F + 31M
Mean school years	11.79±3.96 (N=29)	10.35±4.3 (N=68)
Under biologics	53 appointments (56.99%)	162 appointments (75%)
Diagnosis	43 AS, 11 RA e 3 PsA	61 AS, 33 RA e 12 PsA

When we analyse the available variables between the patients that performed the PROs at home we found for both periods considered that they were younger (45,2/49,8 vs 53,4/55,1 $p<0.001$) they have more education (11.8/10.35 vs 8.2/7,9) no differences were found regarding gender. There is a tendency that with the continuous use of touchscreen computers at the day hospital less educated (T0 -11.8, T1–10.35 school years) and older patients (T0- 45,2/ T1 -49,8 years) are using more at home platform of Reuma.pt.
Conclusions: The use of technology could have a consider impact on the way we collected data from our patients. With the use of a touchscreen computer we have improved not only the overall completion of PROs but also increased the familiarity of patient to the online questionnaires. Number of appoitments with previous at home completion of the questionnaires more than double. This has a clear impact on patient participation, quality of data in the registry but even more impact on time and human resources at a day hospital.

THU0680 VALIDATION OF EQ-5D, RAPID-3 AND HADS QUESTIONNAIRES FOR THE ASSESSMENT OF THERAPY EFFICACY IN PANNICULITIS PATIENTS

N. Savushkina, V. Amirdjanova, O. Egorova, B. Belov. *V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Pn is a group of heterogeneous inflammatory diseases characterized by involvement of the subcutaneous fat (SF), locomotor system and viscera, *and* the number of panniculitis (Pn) cases is increasing in everyday practice of a rheumatologists. There are no specific scales available to assess efficacy of Pn therapy. EQ-5D, RAPID-3 and HADS validity, sensitivity and specificity were proven for some rheumatic diseases. Thus, evaluation of EQ-5D, RAPID-3 and HADS psychometric properties in Pn patients has become the objective of this study.
Objectives: Evaluate psychometric properties of questionnaires EQ-5D, RAPID-3 and HADS in Pn patients.
Methods: The study group included 83 Pn pts (80 females, 3males) aged 43,4±13,9 years with median disease duration of 5 [2;24] months who were at the record of V. A. Nasonova Research Institute of Rheumatology during 2009–2015 yy. All patients filled in EQ-5D, RAPID-3 and HADS questionnaires during the first and the control visits at 12 months. Questionnaires' sensitivity was assessed by comparing patient's answers and objective response to therapy measured by achievement of complete regression of the nodules on the control visit. The construct validity was measured based on correlation with "external criteria", including presence of arthritis and arthralgias, tenderness of nodules at palpation measured by VAS, ESR and CRP values.
Results: Positive dynamics (nodule regression) correlated with improved EQ-5D (EQ-5D-scale - p=0,005, EQ-5D-VAS - p=0,004) and RAPID-3 (p=0,0011). Median Δ EQ-5D and HADS-depression after therapy were 0,27 [0,12; 0,45] (p=0,005), and 2 [1;5] (p=0,13) scores, respectively, while average decline in RAPID-3 and HADS-anxiety scores after therapy was 9,2±5,2 (p=0,0011) and 4±3 (p=0,15), respectively. EQ-5D showed the greatest power in Pn patients' quality of life assessment. EQ-5D-scale and VAS-"thermometer" showed moderate correlation with nodule tenderness at baseline (r= -0,23, p=0,036) & (r= -0,45, p=0,0003), and control visits (12 months) (r= -0,38, p=0,0002) & (r= -0,41, p=0,0002); EQ-5D-scale showed moderate correlation with ESR and CRP values at the control visit (r= -0,23, p=0,03) & (r= -0,25, p=0,005), and EQ-VAS – with CRP value at 12 months (r= -0,33, p=0,002), demonstrating clear correlation with patient's objective health status and lab parameters values. Moderate correlation between functional RAPID-3 values and nodule tenderness at baseline (r=0,34, p=0,0015) and after 12 months (r=0,5, $p<0,0001$) are also indicative of close links between the questionnaire data and pts' objective health status. As for the HADS scale, moderate correlation was found only between HADS-depression and nodule tenderness at baseline (r= -0,24, p=0,026) and 12 months (r=0,28, p=0,014) visits. There were no other significant correlations identified.
Conclusions: EQ-5D and RAPID-3 questionnaires should be considered as valid and sensitive instruments for the assessment of the quality of life and efficacy of therapy in Pn pts.

Objectives: To characterize and quantify systemic involvement at diagnosis in a large international cohort of patients with primary Sjögren's syndrome (SS).
Methods: The Big Data Sjögren Project was formed in 2014 to take a "high-definition" picture of primary SS at diagnosis by merging international databases (9302 consecutive patients from 21 countries of the 5 continents). The main features (including ESSDAI/DAS) at diagnosis were analysed.
Results: Baseline ESSDAI was available in 8061 patients (93% female, mean age 53yrs). The mean ESSDAI score at diagnosis of the entire cohort was 6.4±7.9. In 1498 patients (19%), score at diagnosis was 0, while 681 (8%) presented with high activity in at least one domain. The main systemic features at diagnosis were

biological (51%), articular (38%), haematological (24%) and glandular (22%). Low DAS was reported in 4480 (56%) patients, moderate DAS in 2483 (31%) and high DAS in 1098 (14%) patients. The mean baseline ESSDAI was higher the younger the patient was ($p<0.001$), higher in White patients (6.9 vs 5.1, $p<0.001$), males (8.4 vs 6.2, $p<0.001$), those with positive ocular (6.7 vs 4.9, $p<0.001$) or oral (6.8 vs 6.2, $p=0.016$) tests, and those with ANA (6.9 vs 4.5, $p<0.001$), RF (7.5 vs 5.8, $p<0.001$) and anti-Ro/La antibodies (7.2 vs 4.4, $p<0.001$). Logistic regression identified as independent variables White ethnicity (OR 3.07), abnormal ocular tests (OR 2.14), ANA (OR 1.67) and Ro/La autoantibodies (OR 2.78).

Conclusions: This is the largest series of patients with primary SS in whom the ESSDAI score has been evaluated. Primary SS is undeniably a systemic disease even at the time of diagnosis, with nearly 80% of patients showing an ESSDAI score >0.

THU0682 POPGEN-OSSA: DEVELOPMENT OF AN ORGAN SPECIFIC SELF ASSESSMENT (OSSA) FOR INTERDISCIPLINARY DOCUMENTATION OF PATIENT REPORTED CLINICAL OUTCOMES

R. Zeuner[1], U. Gsell[2], M. Hübenthal[3], S. Schreiber[4], A. Franke[3], M. Laudes[4], J.O. Schröder[1]. *[1]Section of Rheumatology, Clinic for Internal Medicine I, University Hospital Schleswig-Holstein, Campus Kiel, Kiel; [2]Klinik Eichstätt, Eichstätt; [3]Institute of Clinical Molecular Biology; [4]Clinic for Internal Medicine I, University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany*

Background: Patient reported outcome measures are comprised of either sets of questionnaires or patient global assessment based on visual analogue scale (VAS). These patient-reported outcome measures lack accuracy and/or clinical feasibility when comparing heterogeneous patient groups with different diseases, or when characterizing patients with systemic disease involving different organ systems.

Objectives: Developing a clinical feasible patient-reported outcome measure based VAS assessment of different organ systems.

Methods: Patients were asked to rate their health status in a 10cm VAS (0–100%) concerning their global health as well as of different organ systems, namely heart, lung, muscle and joints, gastro-intestinal, metabolic, uro-genital, skin, neuro-psychiatric, eyes and ears. All VA-scales were "anchored". Patients were advised to rate their health status below 75% if they felt "medical action is needed", they should rate the health status <50% in case of a "strong need for medical action" and <25% in case of a "medical emergency".

336 patients from different outpatient clinics (cardiologic, pneumologic, gastro-intestinal, nephrologic, neurologic, dermatologic, rheumatologic, ophthalmologic and obesity outpatient clinic) as well as patients from internal emergency clinics and a general practitioner clinic were evaluated. Both, patients and the attending physicians completed the Popgen-OSSA. In addition the attending physician was asked to document ranking of the 5 most important diagnoses of the patient.

Statistical analysis was carried out using non-parametric testing. Furthermore, to predict main diagnoses based on patients's as well as physician's OSSA state-of-the-art machine learning tools, namely support vector machines (SVMs), were applied. To assess model performance multi-class AUC (area under the ROC curve) according to Hand and Till (2001) was estimated based on repeated cross validation (10 folds, 5 repeats), optimizing the SVM's hyperparamters using grid search.

Results: The test showed a good reproducibility. With a mean percentage of 74±0.98 SE and 66±1.17 SE, respectively, the physicians OSSA rating was significantly higher than the rating of the patients ($p_{wilcoxon}<0.001$). Models predicting main diagnoses were constructed and estimated to perform with multi-class AUCs of 63.5% and 73.4% based on patient's and physician's OSSA, respectively.

Conclusions: In this preliminary trial with low sample size the Popgen-OSSA showed a good reproducibility and allowed a correct allocation of the patient's clinical problem to involved organ system by SVM analysis with multi-class AUC of up to 73.4%. These data merit further investigation and development of the Popgen-OSSA on larger patient cohorts.

THU0683 RAPID DETERMINATION OF THE INFLAMMATION MARKER CALPROTECTIN IN SERUM FROM PATIENTS WITH INFLAMMATORY ARTHRITIS AT THE POINT OF CARE

N. Ryter[1], A. Szentpetery[2], S.R. Pennington[3], R. Cotti[1], O. FitzGerald[2], J.M. Weber[1]. *[1]BÜHLMANN Laboratories AG, Schoenenbuch, Switzerland; [2]St Vincent's University Hospital; [3]University College, Dublin, Ireland*

Background: A Treat-to-Target (T2T) strategy for inflammatory arthritis, targeting remission or minimal disease activity, is the recommended treatment approach by EULAR and ACR. This strategy relies on "tight monitoring" which necessitates regular clinical examination and measuring acute-phase reactants such as C-reactive protein. Calprotectin (MRP8/14; S100A8/A9), a relatively novel inflammation and disease activity marker in the arthritis field, exhibits several features which fit the "theranostic needs" for accurate therapy monitoring. Those features include discrimination between responders and non-responders [1], detection of subclinical disease activity [2] and prediction of relapse or radiographic progression [3]. The classical method to determine calprotectin in serum (sCAL) is ELISA which is used in service or central laboratories. A rapid and simple determination of sCAL at the point of care is a substantial step forward in supporting clinicians to deliver an efficient T2T strategy. Here, we report on the validation of a quantitative, rapid test which can measure sCAL within 15 minutes.

Objectives: (1) To demonstrate the performance evaluation of a quantitative lateral flow assay combined with a dedicated test reading device for the rapid quantification of calprotectin in serum; and (2) to compare results to a well-established laboratory reference method using patient samples.

Methods: The Quantum Blue® sCAL sandwich lateral flow immunoassay uses two highly specific monoclonal antibodies immobilized on the test membrane and on the gold label. 10μL of serum was diluted in 90μL of chase buffer, 60μL of this mixture was applied onto the lateral flow test cassette, which was incubated for 12 minutes at ambient temperature and then measured with the BÜHLMANN Quantum Blue® Reader. Performance evaluation (sensitivity, linearity, high-dose hook effect, interferences) was carried out according to CLSI guidelines. A method comparison based on 178 serum samples from RA and PsA patients was performed against the BÜHLMANN sCAL (MRP8/14) reference ELISA.

Results: The linearity study over the complete measuring range together with the observed limit of quantification (LoQ) of <0.5 μg/mL allowed a quantitative measurement in the clinically relevant range from 0.5 to 10.0 μg/mL calprotectin. No high dose hook effect was observed up to a concentration of 200 μg/mL. Moreover, no interferences were detected with triglycerides (37mmol/L), conjugated bilirubin (342μmol/L), unconjugated bilirubin (342μmol/L), and hemoglobin (200mg/dL). The Quantum Blue® sCAL lateral flow assay showed an excellent linear correlation (r=0.94, slope=1.05) to the BÜHLMANN sCAL (MRP8/14) reference ELISA. There was a negligible bias of -3.1% by Bland-Altman difference plot between the sCAL lateral flow assay and ELISA.

Conclusions: Rapid quantification of serum calprotectin using the Quantum Blue® sCAL assay represents a fast and reliable method for the determination of inflammation and the disease activity of a patient with inflammatory arthritis at the point of care. This rapid test shows excellent agreement to a corresponding laboratory reference method.

THU0684 WORK IMPACT IN AXIAL SPONDYLOARTHRITIS: THE AS-WIS QUESTIONNAIRE PREDICTS THE RISK OF WORK IMPACT: A LONGITUDINAL STUDY OF 101 PATIENTS

S. Dadoun[1], C. Jacquemin[1], S. Kreis[1], S. Fabre[1], C. Rein[1], C. Hudry[2], E. Pertuiset[1], B. Fautrel[1], L. Gossec[1]. *[1]Rheumatology, Pitié Salpétrière Hospital; [2]Rheumatology, Cochin Hospital, Paris, France*

Background: Axial spondyloarthritis (axSpA) mainly affects the working-age subject and can have a moderate (short-term sick leave) or significant (long-term sick leave, disability status, unemployment) work impact.

Objectives: To evaluate the value of a simple and short (2 minutes) questionnaire, the AS-Work instability scale (AS-WIS) to predict the work impact of axSpA after 1–2 years.

Methods: Longitudinal study in 3 centers in Paris, France. Patients with axSpA according to the rheumatologist and the ASAS criteria were included. Patients were asked twice (1 to 2 year interval) to answer questionnaires evaluating: disease activity, demographic characteristics, impact on work (short-term and long-term sick leave, disability, unemployment), and the ASWIS questionnaire (1): a 20 item, simple screening tool for Work Instability (the consequences of a mis-match between an individual's functional ability and their work tasks). The risk of disability is assessed as low if the score is <11, medium between 11–18 and high>18. Only patients who answered both questionnaires were included for analyses. Statistical analyses included descriptive analyses and univariate/ multivariate

analyses to search for baseline factors of work impact at 1–2 years (including a medium/high ASWIS score, gender, age, schooling level, BASDAI, BASFI).
Results: Among the 188 patients who answered the first questionnaire, 144 were currently working and were asked to answer the second questionnaire. A total of 101 patients answered both questionnaires. Mean age at inclusion was 45 (SD 9) years, 52% were male, disease duration was 14 (SD 8) years and 62% had an education level equivalent to more than high school. The BASDAI and the BASFI were respectively 34 (SD 21) and 23 (SD 23). At baseline, median ASWIS was 10, a low-risk score was found in 55 patients (54%), and a medium/high risk score in 46 (46%).
1 -2 years later, 37 patients (36%) had work impact: 25 patients (25%) a short-term sick leave, and 12 patients (12%) a significant work impact (long-term disability or unemployment due to Ax-SpA).
Among patients with a low ASWIS score at baseline (n=55), only 13 (24%) had a work impact (including only 2 with a significant impact). Among patients with a medium/high ASWIS score (n=46), 24 (52%) had a work impact (including 10 patients of a significant impact).
In univariate analysis, baseline factors associated with work impact (moderate or significant) were a medium/high ASWIS score, a high BASFI and a shorter disease duration. In multivariate analysis, medium/high ASWIS (odds ratio, OR 2.71 (1.04–7.22)) and a lower disease duration (0.94 (0.89–0.99)) were independent predictive factors of work impact.
Conclusions: In patients with axSpA, a medium/high ASWIS score was followed by a work impact in 50% of cases within 2 years in this well-controlled population. This short questionnaire can be helpful to screen for future difficulties at work, whatever the stage of disease.

THU0685 ASAS HEALTH INDEX FOR PATIENTS WITH SPONDYLOARTHRITIS: TRANSLATION INTO PORTUGUESE, VALIDATION, AND RELIABILITY

S. Rodrigues Manica[1,2], E. Cruz[3], S. Ramiro[4], S. Sousa[5], R. Aguiar[6], A. Sepriano[1,4], P.M. Machado[7], U. Kiltz[8], J.C. Branco[1,2], F.M. Pimentel-Santos[1,2]. *[1]CEDOC - NOVA Medical School | Faculdade de Ciências Médicas, NOVA University of Lisbon; [2]Rheumatology Department, Hospital Egas Moniz, Centro Hospitalar de Lisboa Ocidental, Lisbon, Lisbon; [3]Escola Superior de Saúde de Setúbal, Instituto Politecnico de Setúbal, Setúbal, Portugal; [4]Rheumatology, Leiden University Medical Center, Leiden, Netherlands; [5]Hospital Garcia de Orta, Almada; [6]Centro Hospitalar Baixo Vouga, Hospital de Aveiro, Aveiro, Portugal; [7]Centre for Rheumatology Research & MRC Centre for Neuromuscular Diseases, University College London, London, United Kingdom; [8]Rheumazentrum Ruhrgebiet, Herne, Germany*

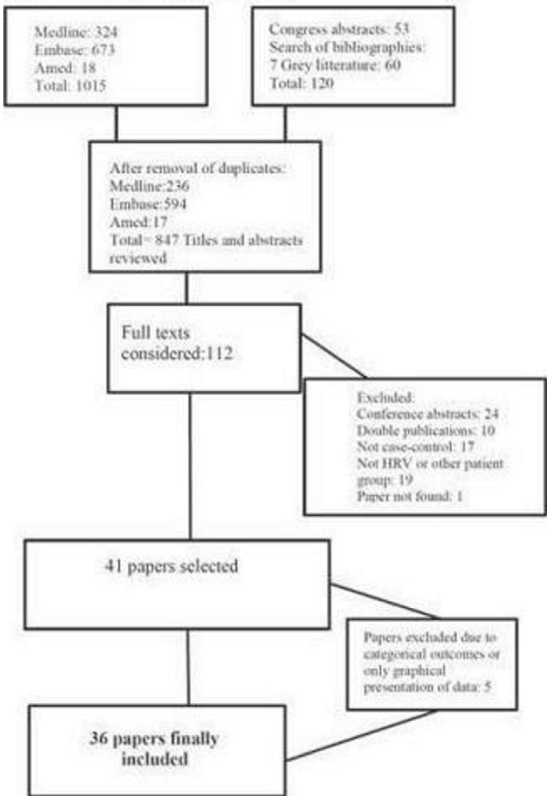
Background: The Assessment of SpondyloArthritis international Society Health Index (ASAS HI), is a unidimensional questionnaire, that includes 17 items, measuring functioning and health in patients with spondyloarthritis (SpA) (1). At the beginning of this project, only an English version of the instrument existed.
Objectives: The aim of this study was to conduct the cross-cultural adaptation of the ASAS-HI into European Portuguese language and investigate its reliability and validity in a sample of Portuguese patients with SpA.
Methods: The ASAS-HI has a range from 0 (best health state) to 17 (worst health state). The questionnaire was first translated and then back translated following published guidelines. Patients fulfilling ASAS classification criteria for either axial (axSpA) or peripheral SpA (pSpA) were included. Reliability was assessed through internal consistency coefficient, and internal consistency was assessed using Cronbach's alpha. Construct validity was assessed through Spearman's correlation analyses between the ASAS-HI and the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), Ankylosing Spondylitis Disease Activity Score-CRP (ASDAS-CRP), and the Short Form (36) Health Survey (SF-36) (physical) SF-36 (physical) for convergent validity and between the ASAS-HI and the HAD-S Anxiety/Depression, and SF-36 (mental) for divergent validity. Discriminative validity was tested comparing the ASAS-HI across ASDAS-CRP disease activity states using the Kruskal–Wallis test.
Results: In total, 86 patients were included: 65% male, mean (SD) age 47.1 (12.9) years, symptom duration 11.4 (11.0) years, BASDAI 3.1 (2.1), BASFI 2.2 (2.6), ASDAS-CRP 2.2 (0.8). The diagnosis of axSpA was established in 58 patients (AS =45, nr-axSpA =13) and of pSpA in 28 patients. The forward backward translation was successful and qualitative interviews raised no further comments of the patients. The total mean score of the ASAS-HI was 4.6 (3.8). The ASAS- HI showed an excellent test-retest reliability (n=72) (ICC=0.93: 95% CI=0.89;0.96, $p<0.001$) and a good internal consistency (Cronbachs-α of 0.87). According to the predefined hypothesis, the ASAS-HI correlated strongly with the BASDAI (0.76, $p<0.001$), SF-36 (physical) (-0.75, $p<0.001$), moderately well with the HAD-S Anxiety (0.41, $p<0.001$), and SF-36 (mental) (-0.44, $p<0.001$) (Table 1), and showed a good discriminatory capacity across the different levels of disease activity ($p<0.001$) (Table 2).

Table1 – Correlation between ASAS-HI at baseline and other health outcomes

Characteristics		R	P value
BASDAI	(0-10)	0.76	<0.001
BASFI	(0-10)	0.63	<0.001
ASDAS-CRP		0.64	<0.001
SF-36 (physical)	(0-100)	-0.75	<0.001
SF-36 (mental)	(0-100)	-0.44	<0.001
HAD-S Anxiety		0.41	<0.001
HAD-S Depression		-0.05	0.660

Table 2 - Discriminant ability of ASAS-HI (at baseline) stratified by disease activity (mean±SD)

	ASDAS-CRP				
	Inactive (N=9)	Moderate (N=30)	High (N=32)	Very high (N=6)	p-value
ASAS-HI	1.6 (1.5)	2.3 (2.0)	6.2 (4.1)	8.1 (3.3)	<0.001



Conclusions: The findings of this study showed that the Portuguese version of the ASAS –HI is a comprehensible questionnaire that is reliable and valid. Therefore, its use can be recommended, both for clinical practice and research purposes, to assess the state of health and functioning in Portuguese SpA patients. Future research is needed to evaluate the responsiveness of the ASAS-HI in SpA patients.

THU0686 HEART RATE VARIABILITY IN INFLAMMATORY JOINT DISEASE. A META-ANALYSIS

S.A. Provan[1], D.S. Olstad[2], E.E. Solberg[3], G. Smedslund[2], H. Dagfinrud[2]. *[1]Rheumatology, Diakonhjemmet Hospital; [2]Rheumatology, National Resource Centre for Rehabilitation in Rheumatology, Diakonhjemmet Hospital; [3]Medicine, Diakonhjemmet Hospital, Oslo, Norway*

Background: Autonomic dysfunction is an established predictor of all-cause mortality and post-myocardial infarction mortality. It has been suggested to be a pathogenic factor for the development of cardiovascular disease (CVD) in the general population, possibly acting through the impact of the autonomic nervous system on inflammation [1]. Heart rate variability (HRV) is a marker of cardiac autonomic function and is increased in many conditions including chronic widespread pain. HRV is responsive to physical exercise. Inflammatory joint diseases (IJD) are characterised by joint inflammation and symptoms include pain, functional decline and restricted movement. Patients with IJD have an increased risk of premature death due to CVD.
Objectives: To compare HRV between adult patients with IJD and healthy controls, using the "Preferred Reporting Items for Systematic Reviews and Meta-Analyses" (PRISMA) methodology, and to describe the associations between IJD disease activity, pain and physical activity, and HRV.

Figure 1 Flow chart literature search

Methods: A research librarian conducted systematic searches in Medline, Embase and Amed from earliest date until August 2016. Inclusion criteria were adult human case-control studies published in English or a Scandinavian language, presenting data on HRV in patients with IJD (Rheumatoid Arthritis (RA) or Spondyloarthritis (SpA)). Included under the SpA diagnosis were patients with psoriatic arthritis or ankylosing spondylitis. Six established measures of HRV were selected: the Square root of mean squared difference of successive R-R interval (rMSSD), high frequency (HF), total power (TP), Ewing protocol standing (E-S), breathing (E-B) and Valsalva (E-V). Patients with RA, SpA and healthy controls were compared separately using random-effects meta-analyses of standardized mean differences (SMD).
Results: 847 titles and abstracts were reviewed, 36 papers were eligible for inclusion (Figure 1). For rMSSD the pooled SMD (95% CI) RA vs. controls was -0.90 (-1.35 to -0.44), for SpA vs. controls; -0.34 (-0.73 to 0.06). For HF, the pooled SMD RA vs. controls was -0.78 (-0.99 to -0.57), for SpA vs. controls; -0.04 (-0.22 to 0.13). For TP the pooled SMD RA vs. controls was -0.60 (-1.26 to 0.06), SpA vs. controls; -0.27 (-0.51 to -0.03). All pooled Ewing parameters were significantly lower in cases compared to controls, except for E-V which was comparable between cases and controls in patients with RA. 18/36 papers examined the relationship of IJD disease activity to HRV, of which the majority, 13, describe an inverse association between the parameters. The impact of pain on HRV was not explored in any study, and only one study explored the impact of physical activity on HRV, finding no cross-sectional association.
Conclusions: Patients with IJD have lower cardiac parasympathetic modulation compared to healthy controls and this may be a risk factor for CVD. There is an inverse relationship between IJD disease activity and HRV. The relationship between pain, physical activity and HRV should be further explored.

THU0687 FEASIBILITY AND VALIDITY OF PROMIS® GLOBAL HEALTH SHORT FORM (PROMIS10) IN OUTPATIENTS WITH SLE

S. Kasturi[1], J. Szymonifka[1], J. Burket[2], J. Berman[1], K. Kirou[1], A. Levine[1], L. Sammaritano[1], L.A. Mandl[1]. *[1]Medicine; [2]Healthcare Research Institute, Hospital for Special Surgery, New York, United States*

Background: Routine measurement of patient reported outcomes (PROs) is a priority for improving quality of care and outcomes in chronic rheumatic conditions including systemic lupus erythematosus (SLE). Measuring PROs at the point of care requires validated instruments with minimal responder burden. PROMIS10 is a 10 question universal (non-disease specific) PRO instrument measuring physical and mental health domains with T-scores normalized to the general population (mean score =50). The feasibility and validity of PROMIS10 have not been demonstrated in SLE.
Objectives: To evaluate: 1) feasibility and 2) validity of PROMIS10 in outpatients with SLE.
Methods: Adults meeting 1997 ACR SLE classification criteria were recruited from an SLE Center of Excellence. Subjects completed SF-36, LupusQoL-US, selected PROMIS Computerized Adaptive Tests (CATs), and PROMIS10. Construct validity was evaluated using Spearman's correlations comparing PROMIS10 physical and mental health scores with PROMIS CATs and legacy instruments. Test-retest reliability was evaluated in subjects reporting stable SLE activity at 2 assessments a week apart with intraclass correlation coefficients (ICCs). Focus groups of participants evaluated the relevance and utility of PROMIS10.

Table 1. Spearman's Correlations of PROMIS10 with PROMIS CATs, SF-36, and LupusQOL

	PROMIS10 Physical Health (n=199)	PROMIS10 Mental Health (n=187)
PROMIS CAT- Physical Function	**0.77**	0.54
PROMIS CAT- Pain Interference	**-0.80**	-0.59
PROMIS CAT- Fatigue	-0.65	-0.60
PROMIS CAT- Anxiety	-0.41	-0.61
PROMIS CAT- Depression	-0.48	**-0.73**
PROMIS CAT- Ability to Participate in Social Roles	**0.74**	0.65
SF-36- Physical Function	**0.76**	0.47
SF-36- Role Physical	0.60	0.46
SF-36- Physical Component Summary	**0.77**	0.41
SF-36- Mental Health	0.42	**0.72**
SF-36- Role Emotional	0.49	0.61
SF-36- Mental Component Summary	0.41	0.72
SF-36- Bodily Pain	**0.79**	0.56
SF-36- Social Function	**0.70**	0.66
LupusQoL-US- Physical Health	**0.77**	0.59
LupusQoL-US- Emotional Health	0.52	**0.70**
LupusQoL-US- Pain	**0.74**	0.56
LupusQoL-US- Fatigue	0.62	0.62
LupusQoL-US- Planning	0.69	0.62

$p<0.01$.

Results: 204 (86%) of 238 patients approached, enrolled. There were no statistically significant differences in demographic characteristics between participants and non-participants. SLE patients scored worse than the general population in PROMIS10 physical health (mean T-score 41.6 +/- SD 8.8; range 19.9 - 67.7) and mental health (mean T-score 43.7 +/- SD 8.7; range 25.1 - 67.6). PROMIS10 physical health scores correlated strongly with physical function, pain, and social health domains in PROMIS CATs, SF-36, and LupusQoL, while PROMIS10 mental health scores correlated strongly with PROMIS depression CAT and SF-36 and LupusQoL mental health domains (Table 1). Test-retest reliability for both PROMIS10 physical and mental health scores was high with ICCs of 0.89 and 0.85 respectively. Median time to complete PROMIS10 was <2 minutes. Focus group participants found PROMIS10 relevant and useful.
Conclusions: PROMIS10 is feasible to administer to outpatients with SLE and valid compared to legacy instruments. PROMIS10 can be used to quickly, accurately, and reliably screen for impaired physical function, pain, and depression and could be an important tool in the measurement of patient centered outcomes and improvement of quality of care in SLE.

THU0688 DISEASE FLARES, DAMAGE ACCRUAL AND SURVIVAL IN ANCA-ASSOCIATED VASCULITIS

S. Paramalingam[1], G. Dogra[2], A. Mclean-Tooke[3], J. Nossent[1,4]. *[1]Rheumatology; [2]Renal Medicine; [3]Immunology, Sir Charles Gairdner Hospital; [4]School of Medicine, University of Western Australia, Perth, Australia*

Background: ANCA- associated vasculitis (AAV) is a potentially life threatening condition requiring careful monitoring and balancing of treatment options to minimize morbidity and mortality.
Objectives: To investigate the influence of baseline disease characteristics and induction therapy on the disease course and outcome in ANCA- associated vasculitis.
Methods: Single centre longitudinal cohort study of all adult patients with an EMEA algorithm based diagnosis of AAV followed up to August 2016. Clinical data including disease activity (BVAS), ANCA type and level, treatment, relapses (BVAS >3) and organ damage (VDI) and other complications (e.g. infections) during the disease course were recorded. Predictors for ESRD, death, cancer and damage accrual were analysed by multivariate logistic regression presented as Odds Ratios (OR).
Results: A total of 63 patients (59% male) (mean age at diagnosis 57 years, 59% with GPA, 24% MPA and 16% EGPA) were included. Fluorescence ANCA was positive in 92%, while 47% had MPO-ANCA and 43% PR3-ANCA. Induction therapy included corticosteroids (92%), Cyclophosphamide (57%), Rituximab (35%) and Plasmapheresis (6%). During 46 months of follow-up 34 patients (54%) experienced 71 relapses (rate 2.5/100 months) and 55 serious complications occurred (rate 2/100 months). Mean VDI at last follow-up was 2.1 with only 11 patients (17.4%) not developing organ damage. Averaged BVAS correlated with last VDI scores (Rs 0.25,p=0.012). Overall, 4 patients (6.3%) died, 19 (27%) developed renal insufficiency of which 2 (3.1%) required chronic dialysis, while 6 (9.5%) developed a new cancer. Age was an independent predictor (OR 1.09, p=0.05) for patient survival (95% and 91% at 1 and 5 years), but no effect was seen for baseline BVAS, gender, AAV or ANCA subtype (all $p>0.1$).
Conclusions: While current treatment reduces the risk of death, AAV is still associated with a high rate of disease relapse, organ damage accrual and serious complications.

THU0689 MODERATE TO GOOD CONSTRUCT VALIDITY OF GLOBAL PRESENTEEISM MEASURES WITH MULTI-ITEM PRESENTEEISM MEASURE AND PATIENT REPORTED HEALTH OUTCOMES: EULAR-PRO WORKER PRODUCTIVITY STUDY

S. Leggett[1], A. Boonen[2], D. Lacaille[3], S. Talli[4], M. Bojinca[5], J. Karlson[6], D. Beaton[7], B. Fautrel[8], J. Canas da Silva[9], C. Hoffstetter[10], S. Verstappen[1,11] on behalf of EULAR-PRO at-work productivity co-investigators. *[1]Arthritis Research UK Centre for Epidemiology, University of Manchester, Manchester, United Kingdom; [2]Department of Internal Medicine, Division of Rheumatology, Maastricht University Medical Centre, and Caphri Research Institute, Maastricht University, Maastricht, Netherlands; [3]Arthritis Research Centre of Canada, University of British Columbia, Vancouver, Canada; [4]Rheumatology, East Tallinn Central Hospital, Tallinn, Estonia; [5]Internal Medicine and Rheumatology Clinic, Dr. Ion Cantacuzino Hospital, Bucharest, Romania; [6]Section of Rheumatology, Lund University and Skane University hospital, Lund, Sweden; [7]St. Michael's Hospital, Mobility Program Clinical Research Unit, Toronto, Canada; [8]All - APHP Pitie-Salpetriere Hospital, Department of Rheumatology, Paris, France; [9]Hospital Garcia de Orta, Almada, Portugal; [10]OMERACT, Toronto, Canada; [11]NIHR Manchester Musculoskeletal BRU, Central Manchester Univ. Hospitals NHS Foundation Trust, Manchester, United Kingdom*

Background: Inflammatory arthritis (IA) and osteoarthritis (OA) often impact on

the worker's performance whilst at work due to ill health (i.e. presenteeism). A number of global measures have been developed to assess presenteeism in clinical studies. However, limited information is available on the correlation between these measures and the construct validity of these measures.

Objectives: To i) determine the correlation between four global measures of presenteeism and ii) to evaluate the construct validity of these measures.

Methods: The main aim of this international observational study (7 countries in Europe and Canada), recruiting patients with IA (RA, PsA or AS) or OA in paid employment, was to investigate content and construct validity of global presenteeism measures. Patients completed 4 global measures (Work Productivity Scale – Arthritis (WPS-A), Work Productivity and Activity Impairment Questionnaire (WPAI), Work Ability Index (WAI), and both the Quality and Quantity scales of the QQ questionnaire) (see table legend for descriptions individual scales). Spearman correlations were applied to test the correlation between individual presenteeism scales and to test construct validity with the 11-item Workplace Activity Limitation presenteeism Scale (WALS) and several health related patient reported outcome measures. Interpretation of correlation coefficients: (very) weak (r_{range}=0.0–0.39), moderate (r_{range}=0.40–0.59) to strong (r_{range}=0.60–1.0).

Results: 468 patients with a median disease duration of 10 [IQR 5–18] yrs were included; 62% were female. Median [IQR] presenteeism scores were, respectively: 2 [0–5] for WPS-A, 3 [1–5] for WPAI, 8 [6–9] for WAI, 81 [49–100] QQ-total, with WAI and QQ having reversed scales (Legend table). Correlations between the 4 global measures were moderate to strong, ranging from -0.49 for the correlation between WPS-RA and QQ-Quality to 0.83 between WPAI and WPS-RA. The multi-item presenteeism scale WALS, measuring difficulty at work, strongly correlated with both WPAI (r=0.65, $p<0.05$) and WPS-RA (r=0.64, $p<0.05$), both measures capturing the affect and interference of arthritis on work productivity. Moderate correlations were achieved between all six global presenteeism measures and health outcomes ($r_{range\ irrespective\ direction}$: $|r_{presenteeism\text{-}VAS\ Well\text{-}being}|$ =0.36 to 0.54; $|r_{presenteeism\text{-}EQ\text{-}5D}|$ =0.37 to 0.54; and $|r_{presenteeism\text{-}HAQ}|$ =0.40 to 0.58).

		WPAI	WPS-RA	WAI	QQ-Quantity	QQ-Quality	QQ-Total
Global presenteeism scales	WPAI	1.0					
	WPS-RA	0.83	1.0				
	WAI	-0.65	-0.62	1.0			
	QQ-Quantity	-0.58	-0.53	0.60	1.0		
	QQ-Quality	-0.52	-0.49	0.58	0.75	1.0	
	QQ-Total	-0.60	-0.56	0.63	0.95	0.88	1
Multi-item presenteeism scale	WALS	0.65	0.64	-0.55	-0.50	-0.49	-0.54
Health related patients reported outcomes	VAS Well being	0.54	0.51	-0.43	-0.39	-0.36	-0.42
	EQ-5D	-0.54	-0.54	0.48	0.37	0.39	0.42
	HAQ	0.57	0.58	-0.52	-0.40	-0.41	-0.45

WPAI (0= condition no effect on work – 10=condition completely prevented work); WPS-IA/OA (0=no interference – 10=complete interference; WAI (0=completely unable to work – 10=work ability at its best); QQ-Quantity/Quality (0=normal quantity/good quality – 10=normal quantity/good quality); QQ-Total=$Q_{quantity} * Q_{quality}$; VAS well-being = Visual Analogue Scale general Well being; EQ-5D=EuroQol 5D measurement; HAQ= health assessment questionnaire.

Conclusions: Global measures of presenteeism show good to moderate construct validity, with the WPAI and WPS-IA/OA showing slightly better construct validity compared to the WAI and QQ. The information obtained in this study will further inform research on instrument use for a standardized approach to estimate presenteeism in future clinical studies.

THU0690 SERUM AMYLOID A LEVELS AS A POTENTIAL BIOMARKER TO MONITOR PSORIATIC ARTHRITIS PATIENTS ON BIOLOGICS – A RETROSPECTIVE OBSERVATIONAL STUDY

T. Martins Rocha, R. Fonseca, D. Rosa-Goncalves, F. Aguiar, R. Ferreira, A. Bernardo, M. Bernardes, L. Costa. *Rheumatology, Centro Hospitalar de São João, Porto, Portugal*

Background: According to previous studies, serum amyloid A (SAA) is involved in the pathophysiology of several conditions including inflammatory arthritis and psoriasis. Recent evidence suggests its valuable role in monitoring disease activity in Rheumatoid Arthritis, but its role is yet to be determined in Psoriatic Arthritis (PsA).

Objectives: To study the association between SAA levels and its variation with other biomarkers and disease activity/functional parameters in a cohort of PsA patients under biologic therapy.

Methods: Observational retrospective study was conducted including PsA patients (according to CASPAR criteria) followed at our Rheumatology department with at least one measurement of SAA levels from January 2015 until December 2016. Demographic and clinical data were obtained by consulting the national database (Reuma.pt). The disease activity/functional scores from at least one visit and corresponding measurements of SAA, ESR and CRP levels were collected. The difference (Δ) between 2 evaluations separated by a median time of 6 months [6–18] was calculated for all variables. Agreement between dichotomized biomarkers was calculated using kappa coefficients. Correlations were studied using Pearson and Spearman coefficient analysis. Significance level was set as 0.05.

Results: 53 PsA patients were included. 31 (59%) patients were females with a mean (SD) age of 50 (11.2) years and a median disease duration of 9 years [1–43]. 28% had axial involvement, 34% peripheral involvement and 38% had both types. All patients were under biologic DMARD. 100 SAA measurements were collected. Median SAA and ESR levels were significantly superior in female patients (23 vs 6mm/1sth and 8.6 vs 4.4mg/L, respectively, $p<0.05$) and only ESR levels correlated with age (r=0.20, p=0.05). The three biomarkers showed a weak association with serum creatinine levels, with greater correlation for SAA (r=0.46, $p<0.001$). SAA levels had a stronger correlation with CRP (r=0.75, $p<0.001$) than with ESR levels (r=0.26, $p<0.01$). SAA and CRP (dichotomized as negative/positive) had a greater level of agreement (κ=0.40) compared to ESR (κ=0.26 and κ=0.32, respectively). No significant correlations were found between the biomarkers and the tender/swollen joint count or the pain/global disease activity VAS. SAA levels correlated with ASDAS CRP (r=0.43, $p<0.001$) and weakly with ASDAS ESR and DAS28 CRP (r=0.20 and r=0.24, respectively, $p<0.05$). Only ESR had a significant weak correlations with BASDAI, MASES and SPARCC scores (r=0.25, r=0.21, r=0.35; $p<0.05$). All the biomarkers had weak correlations with BASFI and HAQ scores. ΔSAA levels had a weak correlation with ΔCRP (r=0.32, p=0.03; n=47) and no significant association was found with ΔESR. ΔSAA correlated significantly with ΔASDAS CRP and ΔBASMI (r=0.32, r=0.39; $p<0.05$).

Conclusions: This study showed that SAA levels and its variation had a significant correlation with CRP levels and its variation, respectively. Significant association with ASDAS CRP variations suggests that serial measurements of SAA may represent an additional marker for monitoring disease activity over time in PsA patients.

THU0691 IS SERUM AMYLOID A PROTEIN AN USEFUL BIOMARKER TO MONITOR TREATMENT WITH ANTI-TUMOUR NECROSIS FACTOR-ALPHA AGENTS IN SPONDYLOARTHRITIS PATIENTS?

F. Aguiar, D. Rosa-Gonçalves, T. Martins-Rocha, R.M. Ferreira, A. Bernardo, I. Brito, M. Bernardes. *Rheumatology, Centro Hospitalar São João, Oporto, Portugal*

Background: Quantitating the degree of inflammation has become essential to tailor the treatment strategy of various rheumatic diseases. Traditionally used measures to assess disease activity and treatment response in spondyloarthritis (SpA) are ESR, CRP and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score (ASDAS). Serum amyloid A (SAA) is an acute-phase reactant predominantly synthesized in the liver by hepatocytes in response to proinflammatory cytokines. Some studies have shown that SAA can be a valuable indicator of disease activity, damage and functional impairment, however it has not been extensively used in clinical practice.

Objectives: To investigate if SAA levels have better correlation with conventional assessments used to monitor anti–tumor necrosis factorα (anti-TNF) treatment in SpA than CRP and ESR.

Methods: Prospective study, including SpA patients under anti-TNFα treatment at a Rheumatology Department of a Portuguese Universitary Hospital. The following parameters were collected and registered in two different evaluations 6 months apart from each other: SAA, CRP and ESR levels, BASDAI, ASDAS-PCR, ASDAS-VS, BASFI, BASMI, swollen and tender joints counts (SJC and TJC), MASES, SPARCC, and patient global assessment (PtGA), physician global assessment (PGA), total back pain (TBP), nocturnal back pain (NBP) measured in a visual analogue scale (VAS). The variation of each parameter was calculated as the difference between the levels registered at each evaluation (baseline and 6 months) and presented as Δ(parameter). We compared the correlation between ΔSAA, ΔCRP and ΔESR levels with ΔBASDAI, ΔASDAS-PCR, ΔASDAS-VS, ΔBASFI, ΔBASMI, ΔSJC, ΔTJC, ΔMASES, ΔSPARCC, ΔPtGA-VAS, ΔPGA-VAS, ΔTBP-VAS, ΔNBP-VAS. The statistical analysis was performed using SPSS 21.0 software, and *$p<0.05$* was taken to indicate statistical significance. Correlation was calculated using the Spearman rank correlation (r).

Results: 89 patients were included, 58.4% (n=52) were male. On baseline the median age was 44.0 years (range 21.0–74.6) and median disease duration was 18.8 years (2- 51.6). ΔSAA was moderately correlated with ΔCRP (r=0.65,

p<0.001) and had lower correlation with ΔESR (r=0.28, p=0.009). ΔSAA correlated with ΔNBP-VAS (r=0.260, p=0.016), but ESR and CRP did not correlate with this parameter. We also found statistically significant correlation between ΔSAA and ΔASDAS-VS (r=0.257, p=0.017), ΔASDAS-CRP (r=0.387, p<0.001), ΔBASFI (r=0.301, p=0.005). ΔCRP also showed significant correlation with ΔBASFI, but it was weaker than that observed with ΔSAA (r=0.230, p=0.033). There was no statistically significant correlation between ΔSAA levels and ΔMASES, although ΔCRP had a weak correlation (r=0.217, p=0.041). There was no significant correlation between neither ΔSAA, ΔCRP or ΔESR and the following parameters: ΔTBP-VAS, ΔPtGA-VAS, ΔPGA-VAS ΔBASDAI, ΔBASMI, ΔSPARCC, ΔTJC or ΔSJC.

Conclusions: This study suggests that SAA can be an useful tool in monitoring treatment with anti-TNFα and that could be introduced in clinical practice. However more studies, with larger sample sizes, should be undertaken to better assess this subject.

THU0692 THE TURKISH VALIDATION AND RELIABILITY OF DISEASE-SPECIFIC, PATIENT REPORTED OUTCOME MEASURE IN RHEUMATOID ARTHRITIS: TR AIMS2-SF

T. Duruoz[1], C. Unal Ertekin[2], C. Sanal Top[2]. [1]*PM&R Department, Rheumatology Division;* [2]*PM&R Department, Marmara University, School of Medicine, Istanbul, Turkey*

Background: Rheumatoid arthritis (RA) can have a major impact on health related quality of life (HRQoL). The revised AIMS-2 is the main outcome measure that has been used for measuring HRQoL in patients with rheumatic diseases. Guillemin et al. developed a short form of AIMS-2 (AIMS-2 SF) (1) which is more practical and less time consuming compared to AIMS-2.

Objectives: The purpose of this study was to investigate validity and reliability of the Turkish version of AIMS2-SF (TR AIMS-2 SF).

Methods: Turkish AIMS2-SF was developed after translation and back-translation method. Culturally adapted version preserved 5 component-structure (upper limb function, lower limb function, affect, pain and social interaction) with 26 items according to the original article (1). Subjects fulfilling ACR/EULAR 2010 classification criteria for RA were consecutively enrolled into the study. Patients with malignancy, fibromyalgia syndrome and other systemic inflammatory diseases were excluded. Demographic data, the body mass index (BMI), severity of pain (VAS), disease duration (month) and other clinical features was evaluated. Reliability was investigated with test-retest reliability (intraclass correlation coefficient-ICC) and internal consistency (Cronbach's alpha). Spearman's rank correlation coefficient was used to evaluate the relation between quantitative parameters and the validity. Construct validity was assessed by the correlation of TR AIMS2-SF with other clinical parameters (age, disease duration, VAS pain, DAS-28) and functional parameters such as Nottingham Health Profile (NHP), Health Assessment Questionnaire (HAQ), Beck Depression Inventory (BDI), Duruoz Hand Index (DHI). Statistical analyses were performed with SPSS version 20 and a value of p<0.05 was considered as statistically significant.

Results: Sixty patients (6 males) were recruited into the study. The mean ± standart deviation (SD) of age (years) and disease duration (months) were 51.8±12.5 and 71.4±69.3, respectively. Mean scores of TR AIMS2-SF were; upper limb function 7.3±6.9, lower limb function 7.7±4.7, affect 7.4±3.2, pain 6±3.1, social interaction 4±2.3 and total score 35.5±16.6. The floor and ceiling effects of TR AIMS2-SF were 1.6 and 3.3, respectively. Both Cronbach's alpha and ICC were 0.83 indicating good reliability. There was significant correlation (rho, p value) with parameters that were directly related to HRQoL which were NHP subscales (energy level: 0.46, pain: 0.63, emotional reaction: 0.55, sleep 0.33, social interaction: 0.60, physical activity: 0.63; p<0.0001), HAQ (0.70, p<0.0001), BDI (0.54, p<0.0001), DHI (0.60, p<0.0001). Poor or not significant correlation was found with parameters that were not directly related to HRQoL such as age (-0.004, p=0.97), disease duration (0.21, p=0.09), vas pain (0.37, p<0.05); on the other hand, disease activity (DAS-28) correlated moderate (0.49, p<0.0001).

Conclusions: Turkish version of AIMS2-SF is a reliable and valid tool that can be used to evaluate the quality of life in RA. This is a feasible measure that can be used in daily practice easily.

THU0693 FEASIBILITY AND RELIABILITY OF THE SPONDYLOARTHRITIS RESEARCH CONSORTIUM OF CANADA SACROILIAC JOINT INFLAMMATION SCORE FOR CHILDREN WITH SPONDYLOARTHRITIS

N.A. Chauvin[1], W.P. Maksymowych[2], R.G. Lambert[3], J.L. Jaremko[3], D.M. Biko[1], J. Paschke[4], T.G. Brandon[5], P.F. Weiss[5]. [1]*Radiology, Children's Hospital of Philadelphia, Philadelphia, United States;* [2]*Rheumatology;* [3]*Radiology, University of Alberta;* [4]*Care Arthritis, Alberta, Canada;* [5]*Rheumatology, Children's Hospital of Philadelphia, Philadelphia, United States*

Background: Clinical trials in children with pediatric spondyloarthritis and axial disease are lacking. In order to assess the effectiveness of medications we need an objective measure to quantify severity of inflammation in the pediatric sacroiliac joint.

Objectives: We evaluated the reliability and construct validity of the Spondyloarthritis Research Consortium of Canada (SPARCC) sacroiliac joint inflammation score (SIS) in children with suspected or confirmed juvenile spondyloarthritis (SpA).

Methods: The SIS divides the joint into quadrants and scores the presence, depth, and intensity of bone marrow edema (BME) on short tau inversion recovery (STIR) magnetic resonance imaging (MRI). Six consecutive semicoronal slices through the cartilaginous portion of the joint are scored for BME (total score 0–72). We developed a pediatric training module that included scoring instructions and examples of bright subchondral signal on STIR scans easily confused with inflammation (Figure). After reviewing the module, 6 readers (1 adult and 3 pediatric radiologists, 1 adult rheumatologist, and 1 pediatric rheumatologist), blinded to clinical details except age, scored 30 studies that included semicoronal T1-weighted and STIR sequences. Pain was recorded on a visual analogue scale (0–10). Disease activity was evaluated using the juvenile SpA disease activity (JSpADA) index (range 0–8). Inter-observer reliability was assessed using intraclass correlation (ICC). Correlation (convergent validity) of the mean SPARCC SIS developers' score with disease activity was tested using Spearman correlation. Discrimination was tested by comparing the mean SPARCC SIS developers' score between children with and without inflammatory back pain using the Mann-Whitney test.

Results: The SIS had face validity and was feasible to score in the 30 pediatric cases. 21 (70%) were male. Median age at the time of imaging was 15.5 years (IQR: 12.7–16.8). Median pain score and JSpADA index were 2 (IQR 0.5–6) and 2 (IQR: 0.5–3), respectively. Of the 180 scores submitted by 6 readers, 140 (78%) of the studies had a SIS ≥2. Median SIS was 14 (IQR: 3–29). ICCs for all readers (N=6), SPARCC developers (N=2), rheumatologists (N=2), and pediatric radiologists (N=3) were 0.63 (95% CI: 0.45–0.78), 0.89 (95% CI: 0.75–0.95), 0.43 (95% CI: -0.02–0.71), and 0.85 (95% CI: 0.72–0.92), respectively. SIS had low correlation with disease activity as measured by the JSpADA (r=-0.08) and C-reactive protein (r=0.14). SIS score did not discriminate between those with and without inflammatory back pain (p=0.16).

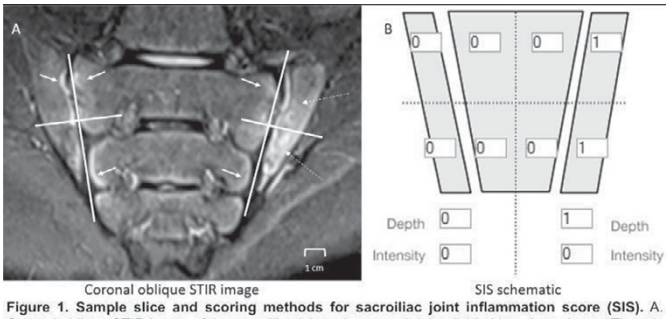

Figure 1. Sample slice and scoring methods for sacroiliac joint inflammation score (SIS). A. Coronal oblique STIR image of the sacroiliac joints shows each joint divided into 4 quadrants. There is normal bright subchondral signal along both sides of the right sacroiliac joint and along the periarticular region of the left sacrum (solid arrows) in this skeletally immature patient. On the left, there is abnormal signal consistent with bone marrow edema within periarticular region of the left ilium in both the upper and lower quadrants (dashed arrows). B. Scoring schematic demonstrates a "1" within the left iliac bone in both the upper and lower quadrants representing bone marrow edema. An additional score of "1" is given as the depth of the bone marrow edema extends >1cm from the articular surface. The patient received a total score of "3" for this image slice.

Conclusions: The SIS was feasible to score and had near excellent reliability, even with limited calibration. SIS did not have convergent validity with clinical measures of disease activity, highlighting that imaging and clinical evaluations provide complimentary but non-overlapping information. Responsiveness of the SIS should be evaluated in a prospective cohort of children who start biologic therapy.

THU0694 EFFECTS OF ANTI-TNF THERAPY ON SOLUBILE UROKINASE PLASMINOGEN ACTIVATOR RECEPTOR (SUPAR) LEVELS IN ARTHRITIS

A. Pusztai, E. Végh, Á. Horváth, A. Hamar, S. Szántó, Z. Szekanecz, G. Szücs. *Department of Rheumatology, University of Debrecen, Faculty of Medicine, Debrecen, Hungary*

Background: The urokinase plasminogen activator receptor (uPAR) is expressed mainly on immune cells, smooth muscle cells and endothelial cells, favoring extracellular matrix degradation, cell adhesion, cell proliferation and regulates cell migration. The suPAR is the soluble form of the cell membrane-bound protein

uPAR, elevated levels may reflect increased activation of immune system which observed in the autoimmune diseases.
Objectives: The aim of this study was to assess the effects of anti-TNF therapy on uPAR production in rheumatoid arthritis (RA) and ankylosing spondylitis (AS). We also wished to correlate suPAR levels with various autoimmune-inflammatory biomarkers.
Methods: Altogether 33 arthritis patients including 22 RA patients treated with either etanercept (ETN) or certolizumab pegol (CZP) and 11 AS patients treated with ETN were included in a 12- month follow-up study. Circulating suPAR levels were assessed by suPARnostic Quick Test Reader. In addition,disease activity (DAS28 or BASDAI), CRP, IgM rheumatoid factor, anti-CCP were also assessed. Assessment were performed at baseline, as well as 6 and 12 months after treatment initation.
Results: Anti-TNF treatment was highly effective in both disease, as the mean DAS28 decreased in RA, mean BASDAI decresead in AS. There were no significant change in the suPAR levels after 12 months of anti-TNF therapy, although resulted non-significant decrease ($p<0,18$) in RA patients with critical suPAR levels (>9ng/ml). Baseline suPAR levels positively correlated with anti-CCP ($p<0,001$) and rheumatoid factor (p=0,024) in RA patients. Circulating suPAR levels did not correlate with DAS28, BASDAI or CRP.
Conclusions: In a mixed cohort of RA and AS patients, anti-TNF therapy did not affect the suPAR levels after 12 months. suPAR levels correlated with rheumatoid factor and anti-CCP. Based on these results suPAR may be a marker of autoimmunity rather than that of disease activity.

THU0695 THE RA FLARE QUESTIONNAIRE (RA-FQ) IS RESPONSIVE TO CHANGE IN RA SYMPTOMS AND IMPACTS IN CLINICAL AND OBSERVATIONAL TRIALS

S.J. Bartlett[1,2], V.P. Bykerk[3], B. Fautrel[4], F. Guillemin[5], A. den Broeder[6], R. Alten[7], R. Christensen[8], E. Choy[9], D. Furst[10], S. Hewlett[11], A. Leong[12], L. March[13], T. Woodworth[10], B.I.O. Clifton[1] on behalf of CATCH, STPR, & DRESS Investigators. *[1]Johns Hopkins, Baltimore, United States; [2]McGill University, Montreal, Canada; [3]HSS, New York, United States; [4]Pierre & Marie Curie Universite, Paris; [5]Universite de Lorraine, Nancy, France; [6]Maartens Kliniek, Nijmegen, Netherlands; [7]Schlosspark Klinik, Berlin, Germany; [8]Parker Institute, Copenhagen, Denmark; [9]Cardiff University, Cardiff, United Kingdom; [10]UCLA, Los Angeles, United States; [11]University of the West of England, Bristol, United Kingdom; [12]Healthy Motivation, Santa Barbara, United States; [13]University of Sydney, Sydney, Australia*

Background: The RA-FQ is a new tool to measure RA flares. We have previously provided evidence of construct validity and reliability.1
Objectives: We evaluated sensitivity to change of the RA-FQ in clinical trials and observational studies of RA patients with low disease activity.
Methods: RA patients in observational studies [CATCH-Canada (n=896) and STPR-France (n=138)], and an RCT (DRESS-Netherlands; n=178) completed 5 items asking whether they were in flare (yes/no), and if so, the severity and duration. We selected patients who said they were not in flare and had a DAS28 <3.2 at thefirst visit (V1). Flare at the next study visit (V2) was defined three ways: 1) patient report (yes/no); 2) patient report-stringent (Boolean: patient report yes AND severity ≥4/10 AND duration >7 days [to increase this reflected increased inflammatory disease activity]; and c) DAS definition often used in studies (DAS28<3.2 at V2 required increase of 1.2; DAS≥3.2 at V2 required increase of 0.6). We compared RA-FQ scores with other PROs and disease activity indicators between flaring and non-flaring patients at V2. Effect size was estimatedusing Cohen's SMD. We hypothesized that at V2, RA-FQ scores would be similar in patients not flaring at both visits, and would be significantly higher in those flaring at V2.
Results: The mean difference in RA-FQ scores at V2 ranged from 7.3 (95% CI 1.4, 13.2) in STPR (DAS def) to 19.6 (95% CI 16.7, 22.6) in CATCH (patient report-stringent). The standardized mean difference effect sizes (SMDES) ranged from 0.82–1.95, and were largest for patient report-stringent in 2 studies. SMDE were strong (range 0.84–2.42) for patient global, MD global, HAQ, DAS28, and other clinical indicators except ESR.
The mean difference in RA-FQ scores at V2 ranged from 7.3 (95% CI 1.4, 13.2) in STPR (DAS def) to19.6 (95% CI 16.7, 22.6) in CATCH (patient report-stringent). The standardized mean difference effect sizes (SMDES) ranged from 0.82–1.95, and were largest for patient report-stringent in 2 studies. SMDE were strong (range 0.84–2.42) for patient global, MD global, HAQ, DAS28, and other clinical indicators except ESR.
Conclusions: Data from clinical and observational studies support the responsiveness of the RA-FQ in detecting change over time. The robust psychometric properties of the RA-FQ suggest it reliably detects clinically relevant worsening of RA symptoms consistent with increased disease activity and support its use in research and clinical care.

THU0696 ANTI-CARBAMYLATED PROTEINS ANTIBODIES IN SLE PATIENTS WITH JOINT INVOLVEMENT: A POSSIBLE NEW BIOMARKER FOR EROSIVE DAMAGE

F. Ceccarelli[1], C. Perricone[2], L. Massaro[1], T. Colasanti[1], E. Cipriano[1], M. Pendolino[1], F. Natalucci[1], G. Capalbo[1], R. Mancini[1], F.R. Spinelli[1], C. Alessandri[1], G. Valesini[1], F. Conti[1]. *[1]Lupus Clinic, Reumatologia, Dipartimento di Medicina Interna e Specialità Mediche, Sapienza Università di Roma, Roma; [2]Lupus Clinic, Reumatologia, Dipartimento di Medicina Interna e Specialità Mediche, Sapienza Università di Roma, Rome, Italy*

Background: The traditional concept of non-erosive arthritis in Systemic Lupus Erythematosus (SLE) patients changed during the last years, thanks to the use of more sensitive imaging techniques, such as ultrasonography (US). The predictive role of Rheumatoid Arthritis (RA)-specific autoantibodies for bone loss in SLE patients has been investigated. In particular, anti-citrullinated peptide antibodies (ACPA) have been identified in about 50% of SLE patients with x-Ray detected erosive arthritis. More recently, anti-carbamylated proteins (anti-CarP) antibodies have been demonstrated in seronegative RA patients, with a prevalence of about 16% and a significant association with erosive damage.
Objectives: In the present cross-sectional study, we aimed at assessing the association between anti-CarP antibodies and erosive damage in a large cohort of SLE patients with joint involvement.
Methods: For this purpose, we evaluated 152 SLE patients (1997 ACR criteria; M/F 11/141, mean±SD age 46.4±11.3 years, mean±SD disease duration 144.9±110.5 months) with joint involvement (arthralgia/arthritis). The clinical and laboratory data were collected in a standardized computerized electronically filled form. All patients underwent blood draws to detect Rheumatoid Factor (RF) and ACPA, by using commercial ELISA kits according to the manufacturer's instructions, and anti-CarP antibodies by home-made ELISA (results were expressed in arbitrary units (AU)/ml and values above 340 IU/ml were considered positive). US was performed to assess the bone surfaces of metacarpophalangeal and proximal interphalangeal. At each joint, according with OMERACT definition, the presence of erosions was registered with a dichotomous value (0/1), allowing the possibility to obtain a total score, ranging from 0 to 20.
Results: The prevalence of anti-CarP antibodies was 28.3%, similar to RF (27.6%) and significantly higher to ACPA (11.2%, p=0.003). The mean±SD titer of anti-CarP antibodies was 890.5±794.9 IU/ml. Thirty-nine patients (25.6%) showed erosive arthritis: all the patients referred the occurrence of at least one episode of clinical synovitis. Erosive arthritis was significantly associated with anti-CarP antibodies (p=0.004) and ACPA (p=0.0008). Moreover, a significant correlation between anti-CarP antibody titer and US-erosive score was observed (r=0.2, p=0.01). Of note, anti-CarP antibodies were identified in 24.5% of double negative (ACPA-/RF-) patients, with erosive damage in 25% of them. Interestingly, anti-CarP antibodies resulted significantly associated with the presence of anti-dsDNA (P=0.01).
Conclusions: In the present study, for the first time, we identified a significant association between anti-CarP antibodies and erosive damage in SLE-related arthritis, in terms of frequency and severity. We found these antibodies in about 25% of $ACPA^-/RF^-$ SLE patients, a prevalence higher than that described in seronegative RA patients. Taken together, our results suggest that anti-CarP antibodies could be considered as a candidate biomarker of severity in SLE patients with joint involvement.

THU0697 FEASIBILITY AND RELIABILITY OF THE SPARCC SACROILIAC JOINT STRUCTURAL SCORE FOR CHILDREN WITH SPONDYLOARTHRITIS

N.A. Chauvin[1], W.P. Maksymowych[2], R.G. Lambert[3], J.L. Jaremko[3], D.M. Biko[1], J. Paschke[4], T.G. Brandon[5], P.F. Weiss[5]. *[1]Radiology, Children's Hospital of Philadelphia, Philadelphia, United States; [2]Rheumatology; [3]Radiology, University of Alberta; [4]CARE Arthritis, Alberta, Canada; [5]Rheumatology, Children's Hospital of Philadelphia, Philadelphia, United States*

Background: Clinical trials in juvenile spondyloarthritis (JSpA) and axial disease are lacking. To assess the effectiveness of medications, we need measures to evaluate structural progression in the pediatric sacroiliac joint (SIJ).
Objectives: To evaluate the reliability of the SPARCC sacroiliac joint structural score (SSS) in children with suspected or confirmed JSpA.
Methods: The SSS assesses a spectrum of structural lesions of the SIJ on MRI including fat metaplasia, erosion, backfill, and ankylosis on 5 consecutive slices through the cartilaginous part of the joint. These components are scored 0–20 (backfill and ankylosis) or 0–40 (fat metaplasia, erosion). We developed a pediatric training module that included a detailed description of each SSS component plus sclerosis (0–40), scoring methodology, and numerous examples. After reviewing the module, 6 readers (mix of adult and pediatric radiologists and rheumatologists) scored 30 studies (Exercise 1). All readers then reviewed a second training module based on DICOM images and scored an additional 29 studies (Exercise 2). Inter-observer reliability was assessed using intraclass correlation (ICC).
Results: The SSS had face validity and was feasible to score in the 59 pediatric cases. 35 (59%) were male and median age was 15 years (IQR 12–16). The ICCs for the SSS components from both calibration exercises are shown in the Table. In the 1st exercise, fat metaplasia and sclerosis had good reliability ($\geq$0.4) while reliability for erosion, backfill, and ankylosis were low. During the first exercise, 31 (17%), 131 (73%), 56 (31%), 100 (56%), and 21 (12%) of the 180 ratings from 6 readers had a score$>$0 for fat metaplasia, erosion, backfill, sclerosis, and ankylosis, respectively. In the second exercise, the ICC for erosion, backfill, and sclerosis improved and had good reliability. Of the 174 ratings from 6 readers, 91 (52%), 18 (10%), and 49 (28%) of scores were $>$0 for erosion, backfill, or sclerosis in exercise 2, respectively. Reliability for fat metaplasia and ankylosis were not calculated due to low frequency of lesions (8 (5%) and 3 (2%), respectively).

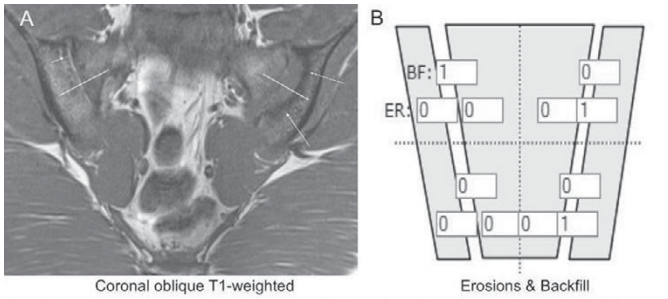

Figure 1. Sample slice and scoring methods for the sacroiliac joint structural score. A. Coronal oblique T1-weighted image of the sacroiliac joints shows each joint divided into 4 quadrants. There is backfill along the superior aspect of the right sacroiliac joint, as demonstrated by increased T1 signal in the joint space (short arrow). There is an extended erosion of the left iliac cortex affecting both upper and lower quadrants of the left iliac bone (long arrows). No sclerosis, ankylosis or fat metaplasia. B. Scoring schematic demonstrates a "1" for backfill (BF) within the R upper SIJ quadrant and "1" in both the upper and lower quadrants of the left SIJ representing erosions (ER).

Conclusions: The SSS was feasible to score and had acceptable reliability for pediatric SIJ MRI evaluation. ICC improved with additional calibration exercises based on DICOM, even for readers with limited experience.

THU0698 MEASUREMENT PROPERTIES OF PRESENTEEISM MEASURES WITH DUAL ANSWER KEYS IN INFLAMMATORY ARTHRITIS

M. Donaldson[1], A. Kobza[1], D.E. Beaton[2], M.A. Gignac[2], D. Lacaille[1,3]. *[1]Arthritis Research Canada, Richmond; [2]Institute for Work and Health, Toronto; [3]University of British Columbia, Vancouver, Canada*

Background: Employment studies in arthritis have emphasised the importance of decreased productivity at work, or presenteeism. Yet, how to best measure presenteeism remains challenging. The "Work Limitations Questionnaire" (WLQ) is frequently used. A drawback is that it measures the amount of time people are limited, but not the degree to which they are limited. In contrast, the "Workplace Activity Limitations Scale" (WALS) measures the degree of limitation, but not the time. We modified the response keys to the WALS and WLQ to measure both degree of difficulty and amount of time with difficulty.
Objectives: Our objective was to evaluate measurement properties, i.e. internal consistency and construct validity, of the WALS and WLQ with combined scores from dual answer keys.
Methods: A cross-sectional study used baseline data from the RCT of an employment intervention, the "Making It Work" Program. Participants were recruited from BC, Alberta and Ontario. Inclusion criteria included: having inflammatory arthritis, currently employed, age 19–59, and having concerns about arthritis affecting ability to work. 364 participants were included (RA:195, PsA:54, SLE:46, AS:69; 77% female, mean (SD) age: 45.9 (9.8) yrs). Combined scores were obtained by i) multiplying, and ii) adding, the scores of difficulty and time answer keys at the item level. No significant differences were observed between the additive and multiplicative models. Hence, we report on the multiplicative model, which reflects consumers' preference. Internal consistency was analyzed using Cronbach's alphas; construct validity by measuring correlation (Spearman coefficients) between WALS or WLQ subscales and constructs such as work productivity activity impairment (WPAI), risk of impending work loss (work instability, RA-WIS), disease measures, and job characteristics.
Results: Analyses at the item level revealed a strong floor effect (WALS: 16% to 56%; WLQ: 27% to 81% of answers for all items except one) but no ceiling effect, likely reflecting the relatively low limitation expected in a working sample. High (i.e. $\geq$0.7) internal consistency (α 0.70–0.82) was found for WALS and all WLQ subscales except WLQ Physical Demands (0.67). As a priori hypothesized, moderate correlation was observed between the time (0.33–0.57), or combined (0.44–0.61), scores of WLQ subscales and WPAI, or WIS; and correlation was consistently higher for combined than time scores. Moderate correlation was also observed between degree of difficulty (0.70–0.77), or combined (0.60–0.69), scores of the WALS and WPAI, or WIS. Contrary to our hypothesis, the WALS combined score did not have a higher correlation with WPAI, or WIS, than degree of difficulty score. Correlations with disease (fatigue, pain, physical function, depression) and job characteristics (job demand, autonomy, social support at work, commuting difficulty) with time, difficulty, or combined scores of the WALS and WLQ met the a priori hypothesized correlation levels.
Conclusions: Our previous research confirmed the value of measuring both degree of difficulty and amount of time, showing they measure different concepts, which can serve different purposes and are both important to patients. This research demonstrates that applying a dual answer key to two validated instruments shows good initial indicators of internal consistency and construct validity.

THU0699 CHARACTERIZING AND VALIDATING THE PHENOTYPE OF KNEE PAIN: A LATENT CLASS ANALYSIS

F. Pan[1], J. Tian[2], D. Aitken[1], F. Cicuttini[3], C. Ding[1], G. Jones[1]. *[1]Musculoskeletal Unit; [2]Public Health, Menzies Institute for Medical Research, University of Tasmania; [3]Department of Epidemiology and Preventive Medicine, Monash University Medical School, Hobart, Australia*

Background: Pain in osteoarthritis (OA) is very common and often involves multiple joints. It is multifactorial and individualised with multiple factors involved in the genesis and pain experience, such as structural pathology, psychological factors and pain coping strategies. Thus it may be possible to group people together based on specific factors which are linked to experiencing pain.
Objectives: To identify and validate the phenotype of knee pain over 10.7 years.
Methods: 1099 participants (mean age 63 years; range 51–81 years) from the population-based Tasmanian Older Adult Cohort study were recruited at baseline. 875, 768 and 563 participants attended years 2.6, 5.1 and 10.7 follow-up, respectively. Demographic, psychological, lifestyle and comorbidities data were obtained at baseline. T1-weighted or T2-weighted fat saturated MRI of the right knee was performed to measure knee structural pathology–cartilage defects, bone marrow lesions (BMLs) and effusion-synovitis at baseline. Knee pain was assessed using Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) at each time-point. Presence of pain (yes/no) at the neck, back, hands, shoulders, hips, knees and feet was also assessed by questionnaire at each time-point. Latent class analysis, which can identify unmeasured class membership

Legend: ICC$<$0.40 is poor, 0.40$\leq$ICC$<$0.75 is good, ICC$\geq$0.75 is excellent.

among participants using observed variables, was used to differentiate "pain phenotypes" considering sex, body mass index (BMI), emotional problems, comorbidities, number of painful sites and knee structural damage on MRI.

Results: Three pain phenotypes were identified: Class 1: high levels of emotional problems and low levels of structural damage (24%); Class 2: high levels of structural damage and low levels of emotional problems (20%); Class 3: relatively low levels of emotional problems and low levels of structural damage (56%). People within Class 1 were more likely to be female, had greater BMI, lower education level, more comorbidities, more severe knee pain and more painful sites as compared to Class 2 and Class 3. Furthermore, WOMAC pain scores and number of painful sites were consistently greater at baseline, 2.6, 5.1 and 10.7 years in Class 1 than Class 2 and Class 3 (all $P<0.05$).

Conclusions: Psychological and structural factors interact with each other to influence pain perception.

THU0700 IMMUNOGENICITY IN PATIENTS SWITCHING FROM STABLE ORIGINATOR INFLIXIMAB TREATMENT TO CT-P13: ANALYSES ACROSS SIX DISEASES FROM THE 52-WEEK RANDOMIZED NOR-SWITCH STUDY

G.L. Goll[1], I.C. Olsen[1], K.E.A. Lundin[2], K.K. Jørgensen[3], M. Lorentzen[4], R.A. Klaasen[5], D.J. Warren[5], C. Mørk[6], J. Jahnsen[3], E.A. Haavardsholm[1], T.K. Kvien[1], N. Bolstad[5] on behalf of The NOR-SWITCH study group. *[1]Dept of Rheumatology, Diakonhjemmet Hospital; [2]Gastroenterology, Oslo University Hospital, Oslo; [3]Gastroenterology, Akershus University Hospital, Lørenskog; [4]Dermatology; [5]Biochemistry DNR, Oslo University Hospital, Oslo; [6]Dermatology, St Olav University Hospital, Trondheim, Norway*

Background: TNF-inhibitors (TNFi) have improved treatment of Crohn's disease (CD), ulcerative colitis (UC), spondyloarthritis (SpA), rheumatoid arthritis (RA), psoriatic arthritis (PsA) and chronic plaque psoriasis (Ps). The NOR-SWITCH study was funded by the Norwegian government to investigate if switching from originator infliximab (Remicade®, INX) to biosimilar CT-P13 (Remsima®), is safe. Previously, the primary analyses of the pooled indications have been published[1]. Immunogenicity is associated with treatment failure and has been of particular concern in switching [2].

Objectives: The NOR-SWITCH study aimed to assess if immunogenicity to infliximab differed between patients treated with continous INX vs patients switched to CT-P13.

Methods: The study was designed as a 52-week randomized, double-blind, non-inferiority, phase IV trial. Adult patients with a diagnosis of CD, UC, SpA, RA, PsA or Ps on stable treatment with the originator infliximab were eligible. Patients were randomized 1:1 to either continued INX or switch to CT-P13 treatment, using unchanged dosing regimen. Trough drug levels and neutralizing anti-drug antibodies (ADAb) measurements were done prior to every infusion, but results were not reported during the study. Assays for drug serum levels and ADAb are fully automated on the AutoDELFIA® (PerkinElmer, Waltham, MA) immunoassay platform.

Results: Twenty patients entered the study with detectable ADAb (9 in INX arm, 11 in CT-P13 arm). 36 additional patients developed detectable incident ADAb during the 52-week study period (17 in INX arm, 19 in CT-P13 arm). Incident ADAb in each disease are shown in the table. Patients with detectable ADAb at any time during the study period were more likely to discontinue study drug treatment (7/26 (26.9%) in INX arm, 5/30 (16.7%) in CT-P13 arm) than patients without detectable ADAb (17/214 (7.9%) in INX arm, 13/210 (6.2%) in CT-P13 arm) (p=0.001).

Incident ADAb during study period (total number of patients), Full Analysis Set

	INX	CT-P13
All patients in study	17 (241) 7.1%	19 (240) 7.9%
RA patients	6 (39) 15.4%	2 (38) 5.3%
SPA patients	2 (45) 4.4%	5 (46) 10.9%
PSA patients	1 (14) 7.1%	0 (16)
UC patients	5 (47) 10.6%	8 (46) 17.4%
CD patients	3 (75) 3.9%	4 (77) 5.2%
Ps patients	0 (18)	0 (17)

Conclusions: The NOR-SWITCH study demonstrated similar immunogenicity in patients switched to CT-P13 vs those who continued INX treatment, supporting that switch does not influence ADAb formation. Presence of ADAb was associated with termination of study treatment.

THU0701 THE EFFECTS OF STRUCTURAL DAMAGE ON FUNCTIONAL DISABILITY IN PSORIATIC ARTHRITIS

A. Kerschbaumer, F. Alasti, J.S. Smolen, D. Aletaha. *Department of Medicine III (Chairman: Prof. Josef Smolen, MD), Medical University of Vienna, Vienna, Austria*

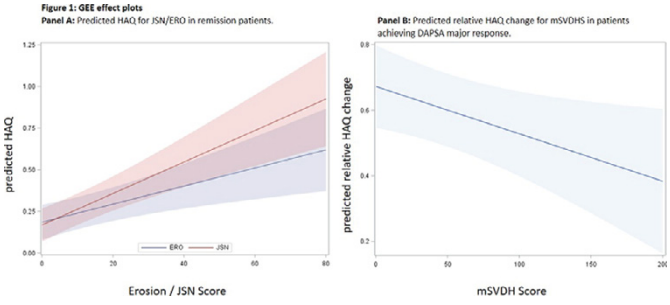
Background: Functional outcomes are central in patients with chronic inflammatory musculoskeletal diseases. It has been shown in rheumatoid arthritis that functional outcomes are impaired in the presence of structural damage, a finding that has not yet been investigated in psoriatic arthritis (PsA), which has a more complex phenotype than rheumatoid arthritis (RA).

Objectives: To quantify the association of radiographic damage with physical function in PsA patients.

Methods: We analysed patients enrolled in the GO-REVEAL study[1] who had received golimumab. We obtained modified Sharp-van-der-Heijde scores (mSvDHS) from X-rays, performed at week 0, 24, 52 and week 104 (n=262). In longitudinal data analysis, we then used generalized estimating equations (GEE) on all patients in DAPSA remission (n=96), utilising all their remission visits, whereby the health assessment questionnaire (HAQ) disability index of each patients visit was used as dependent variable and mSvDHS, joint space narrowing (JSN) and erosion (ERO) scores, respectively, were used as independent variables in separate models.

To analyse effects of structural damage on changeability of functional limitations, we identified a subgroup of patients who had functional limitations at baseline (HAQ$\geq$1) and who showed a major response of DAPSA (improvement of $\geq$85% from baseline). In this model we assess the effect of mSvDHS on changes in HAQ, while adjusting for HAQ at baseline (n=54).

As validation cohort, we analysed a routine clinic PsA cohort with complete cDAPSA (the clinical version of the DAPSA without CRP) and mSvDHS (n=99). A cDAPSA cutoff of $\leq$4 was used to define the remission cohort in an analogous way as decribed above (n=32).



Results: As shown in table 1 and visualised in figure 1A, for patients in DAPSA remission, significant effects were seen for mSvDHS, JSN and ERO. These results could be confirmed in the validation cohort with patients achieving cDAPSA remission and showed a significant association of HAQ and mSvDHS (Estimate=0.0044, p=0.0176) as well as JSN (Estimate=0.0078, p=0.0165).

In the second analysis, looking at patients achieving DAPSA major response, again, results were significant for the association total mSVDHS and JSN. Additionally, higher estimates of JSN, compared to mSvDHS could be observed, with relative HAQ change as outcome parameter (see table 1 and figure 1B).

Table 1. Association of radiographic damage and HAQ in separate GEE models

Dependent variable	DAPSA remission (n=96) HAQ		DAPSA Major Response (n=54) relative HAQ change*	
Independent variable	Estimate	p	Estimate	p
mSVDHS	0.0037 (0.0018 to 0.0055)	**<0.001**	-0.0014 (-0.0027 to -0.0002)	**0.024**
Erosion	0.0054 (0.0021 to 0.0088)	**0.001**	-0.0021 (-0.0043 to 0.0002)	0.075
JSN	0.0095 (0.0057 to 0.013)	**<0.001**	-0.0039 (-0.0067 to -0.0012)	**0.005**

*Adjusted for HAQ at baseline.

Conclusions: Our results suggest that in JSN is functionally more important than

erosions. Functional outcomes have an irreversible component that is strongly related to the amount of structural damage. This needs to be considered when targeting functional outcomes in clinical practice.

THU0702 ARE MRI-DETECTED EROSIONS SPECIFIC FOR RA? A LARGE EXPLORATIVE CROSS-SECTIONAL STUDY

D. Boeters[1], W. Nieuwenhuis[1], H. van Steenbergen[1], R. Landewé[2], M. Reijnierse[3], A. van der Helm-van Mil[1]. *[1]Department of Rheumatology, LUMC, Leiden; [2]Department of Clinical Rheumatology and Immunology, AMC and Atrium MC, Amsterdam and Heerlen; [3]Department of Radiology, LUMC, Leiden, Netherlands*

Background: Magnetic resonance imaging (MRI) is recommended in the diagnostic process of rheumatoid arthritis (RA), as it can detect damage at an earlier time point than conventional radiographs. However, MRI-detected erosions as defined by EULAR and included in RAMRIS are also observed in symptom-free controls, especially at older age. It is unclear how RA-specific erosions on MRI can be distinguished from physiological erosions in symptom-free individuals. Therefore this study compared MRI-detected erosions between RA-patients and healthy controls, including evaluation of the effect of age.
Objectives: To compare characteristics of MRI-detected erosions (total erosion score, location and severity of erosions and simultaneous presence of MRI-detected inflammation) in metacarpophalangeal (MCP) and metatarsophalangeal (MTP) joints between RA-patients and healthy controls.
Methods: 422 subjects (229 newly presenting patients with a clinical diagnosis of RA and fulfilling the 2010-criteria and 193 symptom-free controls) underwent contrast enhanced 1.5T MRI of unilateral MCP and MTP joints. The readers were blind to the clinical information. Total erosion score according to the RAMRIS method (hence a combination of number and severity), location and severity of erosions and simultaneous presence of MRI-detected inflammation (synovitis and/or bone marrow edema) were compared between groups, also in relation to age.
Results: First total erosion scores were analyzed. Both in RA-patients and in controls this score was associated with age ($p<0.001$ in both groups). In addition, at all ages and on group level, RA-patients had 1.2 (95% CI 1.1–1.3) times higher erosion scores than controls. Despite this difference, total erosion scores could not differentiate RA-patients from controls on the individual level, as there was large overlap (Figure). Next different characteristics of erosions were explored within age groups (<40, 40–59, ≥60) to search for RA-specific features. With respect to location, erosions found in MTP5 were specific for RA (spec 90–98% for different age groups). Erosions found in MTP1 were specific for RA if subjects were aged <40 (spec 98%), but specificity decreased by increasing age (spec 86% if aged 40–59 and 63% if aged ≥60). Evaluating the severity revealed that "severe erosions" (scores ≥2) were infrequent in all subjects, but almost exclusively present in RA (spec 98–100%). Finally the simultaneous presence of erosions with inflammation was studied. In the age group <40 years, the simultaneous presence was exclusively observed in RA-patients (specificity 100%); but specificity decreased by age since the combined presence was also seen in symptom-free controls (spec 91% if aged 40–59 and 71% if aged ≥60 years).

Conclusions: Whilst the group of RA-patients at disease presentation had significantly higher erosion-scores than healthy controls, scores of individual subjects were largely overlapping. Some erosion characteristics were specific for RA, but these were present in only a minority of all RA-patients (22%).

THU0703 SYSTEMATIC REVIEW OF RHEUMATOID ARTHRITIS CLINICAL STUDIES: SUBOPTIMAL STATISTICAL ANALYSIS OF RADIOLOGICAL DATA

S. Mahmood[1,1], L. van Tuyl[1], L. Schoonmade[2], R. Landewé[1], D. van der Heijde[3], J. Twisk[2], M. Boers[1]. *[1]Amsterdam Rheumatology and immunology Center; [2]VUmc, Amsterdam; [3]LUMC, Leiden, Netherlands*

Background: Radiography is an inexpensive, reliable and reproducible method to detect and quantify progression of damage, an important outcome in rheumatoid arthritis (RA) trials and observational studies. However, the distribution of progression scores is skewed with many low or zero scores. Analysis of such data is challenging, and the choice of analysis technique may influence the result. Current analysis practice is unknown.
Objectives: We systematically searched the literature to identify current practice for the analysis of radiographic progression in clinical trials and observational studies of RA.
Methods: PubMed Embase and Cochrane databases were searched (2006–2016) to identify studies that described analysis techniques to compare radiographic progression in at least two groups. Studies in animals, children as well as conference abstracts and studies not written in English were excluded. Titles and abstracts were screened by one researcher (SM); a second investigator (LvT) evaluated the included cases, doubtful cases and a random sample of the excluded cases.
Information on study design, sample size, assessment methods and analysis technique was extracted by one researcher (SM), in consultation with 3 others (LvT; MB and JT).
Results: Of 5980 identified papers, 252 were eligible. 226 of these reports were on a single study while 26 were on multiple studies in one paper.
Of the 226 studies, 75 studies used parametric techniques, such as t-tests, ANOVA or linear regression to analyze the data. Of these only 12% took the skewed distribution into account. In 78 studies, the continuous data was categorized into two or more groups and analyzed with binomial or ordinal methods, such a chi-square tests or logistic regression analyses. 4 studies treated the outcome as a "count" outcome variable (2 studies applied a Poisson regression, 1 a negative binomial regression and 1 a zero-inflated binomial regression).
43% compared more than two groups. Median (IQR) sample size was 351 (range 163–608). 30% had one reader, 57% two readers, and 2% more than two; in 10% the number of readers was not recorded. Order of reading was random in 43%, sequential in 31%, and unknown in 26%. Most applied the Sharp van der Heijde scoring method (75%); 9% the Genant modification, and 16% other methods.
Conclusions: There is large heterogeneity in the analysis strategy of radiographic progression in recent RA clinical trials and observational studies: a large number of studies apply simple, suboptimal or inappropriate methods. In addition, key information (i.e. number of readers and order of readings) is poorly documented.

THU0704 EVALUATION OF THE ACCURACY OF HAND AND FOOT MRI IN THE EARLY IDENTIFICATION OF RA: USING THE PREVALENCE OF LOW-GRADED INFLAMMATION IN THE SYMPTOM-FREE POPULATION AS REFERENCE REDUCES FALSE-POSITIVE MRI RESULTS

A.C. Boer[1], L.E. Burgers[1], L. Mangnus[1], R.M. Ten Brinck[1], W.P. Nieuwenhuis[1], H.W. Van Steenbergen[1], M. Reijnierse[2], T.W. Huizinga[1], A.H. van der Helm van Mil[1]. *[1]Rheumatology; [2]Radiology, LUMC, Leiden, Netherlands*

Background: Early identification of rheumatoid arthritis (RA) is important, because it allows early treatment initiation and is associated with better disease outcomes. In this perspective, the use of hand and foot MRI in the diagnostic process of rheumatoid arthritis (RA) has been advocated. Recent studies showed that MRI is helpful in predicting progression from clinically suspect arthralgia (CSA) to clinical arthritis, and from undifferentiated arthritis (UA) to RA. However, the diagnostic value of MRI is still undetermined. Most studies focussed on the sensitivity rather than the specificity of inflammation detected on MRI. It is known that symptom-free persons can also show inflammation on MRI. Consequently, it has been questioned if MRI-findings in symptom-free volunteers are relevant to consider as a reference when defining a "positive MRI".
Objectives: To determine the value of considering MRI-findings in a control group for the predictive accuracy of MRI when defining a positive MRI.
Methods: 225 patients with CSA and 201 patients with UA underwent MRI of MCP-, wrist- and MTP-joints at baseline and were followed for 1 year on progression to arthritis and RA respectively. MRI was considered positive either if ≥1 joint showed inflammation (called "uncorrected definition"), or if ≥1 joint had inflammation that was present in <5% of persons of the same age-category at the same location in a symptom free reference population (called "5% corrected definition"). MRI scans were scored according to RAMRIS method. Test characteristics were compared for both definitions, hence with and without the incorporation of a reference population when defining a "positive MRI".
Results: By using MRI-data of symptom-free volunteers as reference, the

specificity of MRI-detected inflammation increased from 22% to 56% in CSA-patients, and from 10% to 36% in UA-patients. The sensitivity was not affected; it was 88% and 85% in CSA-patients and 93% and 93% in UA-patients. The accuracy also increased, from 32% to 60% in CSA-patients and 22% to 44% in UA-patients.

Conclusions: The use of a reference population resulted in a substantial reduction of false-positive results, without affecting the sensitivity. This is of high importance because of the potential risks of false-positive MRI-results, for example in the setting of UA as a positive MRI-result may influence the decision to initiate disease modifying medication. Although a reference population is generally used in medicine for other tests to derive a definition of a positive test result, this is the first study demonstrating the value of a reference population to define a "positive MRI".

Rehabilitation

THU0705 EXPERIMENTAL USE OF 3D PRINTING TECHNOLOGY FOR THE CONSTRUCTION OF DEVICES AS INTEGRATION OF OCCUPATIONAL THERAPY INTERVENTION WITH RHEUMATOID ARTHRITIS PATIENTS (RA)

G. Sandri[1], A. Bottini[2], F. Franchi[3], M.T. Mascia[2]. *[1]Department of Clinical, Diagnostic and Public Health, Service of Rheumatology; [2]Department of Clinical, Diagnostic and Public Health, Occupational Therapy Unit; [3]Orthopedic, Hand Rehabilitation, Modena, Italy*

Background: RA is a chronic inflammatory disease that can interfere with the ability to perform activities of daily living. The adoption of aid devices allows to maintain and/or improve employment performance, reducing the pain preventing further joint damage. However, it is known that the abandonment rate of such devices is quite high, resulting in failure of the rehabilitation project, and waste of resources. The reasons people give for abandoning support technology are that they have not been involved in the process of provision, and that the devices do not have the intended effect (1).

Objectives: technology may allow customization of 3D printing devices agreed together with patients, utilizing materials which are cheap, fast and easily adjustable.

Methods: The study was organized into the following phases: recruitment of RA patients for the "joint protection laboratories"; sessions of the "joint protection laboratories"; recruitment of patients for the identification of needs for customized aid devices; co-design of customized aid devices; printing of customized aid devices; delivery of customized aid devices; detection using customized aid devices.

We have collected a list of needs to be able to develop such customized aid devices at the end of a course to educate on joint protection covering: ergonomic gestures, management of fatigue and pain, environmental adaptations and aid devices.

18 patients (17 women and 1 man), age between 30 and 75 years old, were organized into small groups for the "joint protection laboratories". 9 patients expressed their specific needs regarding the aid devices and therefore subsequent meetings were organized that have allowed us to produce and deliver customized objects.

Autodesk® Fusion360 for object modeling; Ultimaker Care for slicing; 3D printing DeltaWASP 20 40. For the collection of the design features we used the PA board (product analysis) of the USERfit tool. For the psycho-social impact assessment of the assistance, the PIADS (Psychosocial Impact of Assistive Devices Scale – scale -3+3) was used, and for the evaluation of the patient's satisfaction with respect to the aid device, QUEST (Quebec User Evaluation of Satisfaction with Technical Aids, scale 1–5) was used.

Results: 6 aid devices were customized: hand grip holder for chalk, toothbrush, ignition key, tablespoon, iron, as well as a handle to open the moka coffee machine.

The psychosocial assessment of 6 delivered aid devices, collected through PIADS, showed an overall positive outcome (mean competence +1.488; adaptability: +1.690; self-esteem: +1.375). The assessment of patient satisfaction through QUEST, was good overall (scale 1–5: satisfaction aid: 4.75; service satisfaction: 4.68).

Conclusions: This work also demonstrated, over a range of small numbers, that the path of co-design and production of customized aid devices via rapid manufacturing with 3D printing technology is feasible and fulfilling.

THU0706 LOW DISEASE ACTIVITY AFTER A SHORT COURSE OF DRUG THERAPY AND REHABILITATION IS ASSOCIATED TO A GREATER IMPROVEMENT IN FUNCTIONAL CAPACITY IN RHEUMATOID ARTHRITIS

B. Cunha, B. Ferreira, L. Moreira, C. Barros, A. Gushikem, J. Kauer, T. Ferreira on behalf of SARAR 2 cohort. *Rheumatology, SARAH Network of Rehabilitation Hospitals, Brasíia, Brazil*

Background: Patients with rheumatoid arthritis (RA) have lower funcional capacity than general population (1). Studies have shown that patients are able to improve their functional capacity after adequate treatment with disease-modifying antirheumatic drugs (DMARDs) (1–2), but it is unclear which other factors are involved in rehabilitation settings.

Objectives: To investigate which clinical factors are associated to improvement in funcional capacity in patients with RA in the context of DMARD therapy and rehabilitation.

Methods: It was a case-control study. Patients with RA admitted between june 2014 and july 2016 were included. Assessments were carried out just before and after completion of rehabilitation program. Functional capacity was assessed with Health Assessment Questionnaire-Disability Index (HAQ-DI). Disease activity was evaluated with Clinical Disease Activity Index (CDAI). It was allowed to change DMARD treatment or dose during the follow-up period. Interventions were carried out at the discretion of the rehabilitation team and could include joint injections, exercises, orthoses, insoles, educational interventions and assistive devices. Patients that were operated in the follow-up period were excluded.

An improvement in HAQ-DI was defined as a difference of -0,22. Patients that improved after treatment were compared with those who did not, regarding clinical caracteristics and modalities of treatment that were employed. Chi-square or Fisher exact test analyses were employed.

Results: Forty-six women and two men were included, with average age of 56 (11) years old and 10,8 years of diagnosis, Rheumatoid factor was positive in 58% (mean title 242,3 U/L); anti-CCP was positive in 48% (mean title 283,8 U/L). Patients were followed for 6–12 months.

HAQ-DI improved 0,51 (0,3–0,71; $p<0,001$) and CDAI improved 12,8 (7,6–17,9). Patients who were able to improve HAQ-DI had a better average CDAI in the second assessment (16 vs. 7, p=0,011). There was no association between improvement of HAQ-DI and other clinical and laboratorial variables, including drug and rehabilitation modalities.

Conclusions: Low disease activity after a short course of drug therapy and rehabilitation is related to a greater improvement of functional capacity in patients with RA. Therefore, patients with RA may have better outcomes in rehabilitation if disease activity is controlled.

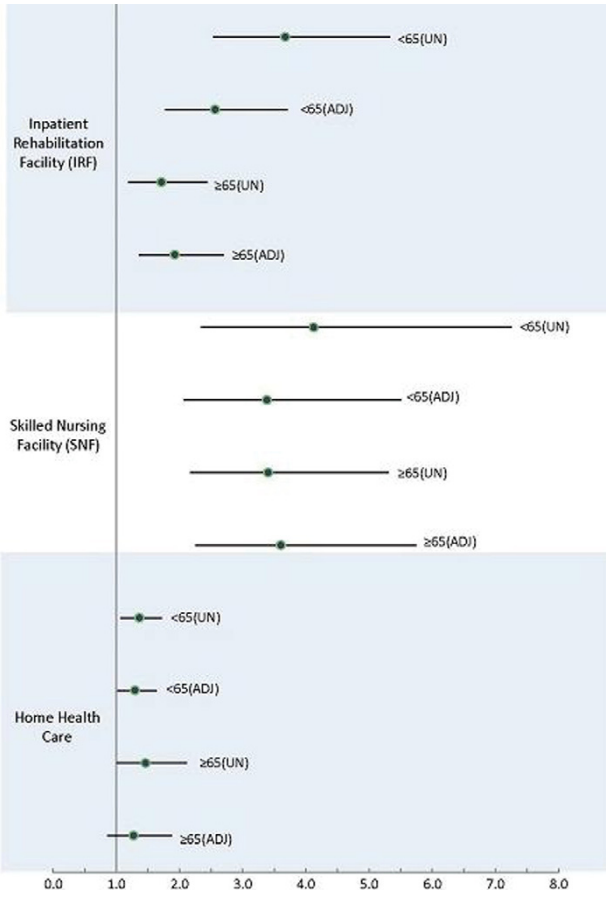
THU0707 RACE & REHABILITATION DESTINATION AFTER TOTAL HIP REPLACEMENT

E.R. Vina[1], M. Kallan[2], A. Collier[2], C. Nelson[2], S. Ibrahim[2]. *[1]University of Arizona, Tucson; [2]University of Pennsylvania, Philadelphia, United States*



Background: There are marked racial/ethnic disparities in the utilization of hip joint replacement in the US. Differences in post-surgical rehabilitation care may influence this disparity. There is relatively little research on racial variations in post-hip joint replacement surgery care processes.

Objectives: The main objective of this analysis was to examine racial differences in where patients go for post-acute care rehabilitation after elective hip replacement surgery. We also assessed whether or not where patients go for post-surgery rehabilitation care impacts quality of care markers such as 90-day hospital readmission.

Methods: A retrospective, large regional dataset analysis using the Pennsylvania Health Care Cost Containment Council database was performed. Patients who underwent elective hip replacement surgery and discharged from Pennsylvania hospitals between fiscal years 2008–2012 were selected. Post-surgery rehabilitation destinations options included: home with self-care, home with home health (HH) care; skilled nursing facility (SNF) and in-patient rehab facility (IRF).

We used multinomial logistic regression models to estimate unadjusted and adjusted relative risk ratios (aRRRs) of being discharged home with HH care, to a SNF or to an IRF (vs. home with self-care) after surgery, comparing African-American (AA) to white patients. Multivariable models adjusted for patient-level and facility-level variables associated ($p<0.10$) with post-surgical discharge destination based on bivariate analyses. Unadjusted and adjusted odds ratios (aORs) of 90-day hospital readmission were estimated using binary logistic regression models. Multivariable models adjusted for patient-level and facility-level variables associated

(p<0.10) with 90-day hospital readmission. In all models, patients were stratified by age group (<65 and ≥65 years) to account for differences in Medicare eligibility.
Results: Among all patients analyzed, 4,391 self-identified as AA and 63,625 self-identified as white. Among those <65 years of age, AAs, in comparison to whites, were less likely to have private insurance (52.5% vs. 82.7%) and more likely to rely on Medicare or Medicaid (47.5% vs. 17.3%) (both p<0.001). For those age ≥65, ~90% of both AAs and whites relied on Medicare. Co-morbidities such as hypertension, diabetes and renal failure were more common among AAs than whites (p<0.001, all comparisons, both age groups).
The Figure summarizes the unadjusted (UN) and adjusted (ADJ) RRRs of referral to an IRF, SNF and HH care (vs. home self-care) in AAs (vs. whites) by age group. Among patients <65 years of age, compared to whites, AAs had higher risk of discharge to an IRF (aRRR 2.56, 95% CI, 1.77–3.71) and a SNF (aRRR 3.37, 95% CI, 2.07–5.49). Among those ≥65 years of age, AA patients also had higher risk of discharge to an IRF (aRRR 1.96, 95% CI, 1.39–2.76) and a SNF (aRRR 3.66, 95% CI, 2.29–5.84). Discharge to either IRF (<65 years: aOR 4.06, 95% CI, 3.49–4.74; ≥65 years: aOR 4.32, 95% CI, 3.67–5.09) or SNF (<65 years: aOR 2.05, 95% CI, 1.70–2.46; aOR 1.74, 95% CI, 1.46–2.07), instead of home with self-care, was significantly associated with higher odds of hospital readmission within 90 days.

Conclusions: Compared to whites, AA patients who underwent hip replacement were more likely to be discharged to an IRF or SNF. Furthermore, discharge to either IRF or SNF was associated with higher risk of hospital readmission.

THU0708 LONG-TERM OUTCOME AND RISK FOR TOTAL ARTHROPLASTY OF KNEE OSTEOARTHRITIS AFTER COMPREHENSIVE REHABILITATION

F. Angst[1,1], T. Benz[1], A. Aeschlimann[1], S. Lehmann[1], B. Winteler[2], M.L. Verra[2]. *[1]Research, Rehabilitation Clinic "REHACLINIC", Bad Zurzach; [2]Physiotherapy, Bern University Hospital, Bern, Switzerland*

Background: Knee osteoarthritis affects mobility leading to substantial loss of perceived health and quality of life. Our previous study showed that aged persons with various comorbidities may profit from comprehensive rehabilitation in the short-term by corrected effect sizes up to 0.62 in pain, 0.51 in physical function, and 0.32 in psychosocial health (1).
Objectives: To follow-up those patients to 5 years by 1) quantifying observed effects in pain, function, and psychosocial health and 2) associating risk factors to total knee arthroplasty during the observation period.
Methods: Prospective cohort study with assessments at baseline (start of rehabilitation) and 1, 2, 3, 4, 5 years after. Comprehensive rehabilitation lasted 2–3 weeks for inpatients and 6 weeks for outpatients. Changes between baseline and the follow-ups were measured by the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and the Short Form 36 Health Survey (SF-36). They were expressed as effect sizes (ES) according to Kazis (2). Multivariate logistic regression included various sociodemographic and disease-modifying confounders and provided adjusted odds rations (OR) for the risk of getting total knee arthroplasty.
Results: At baseline, n=205 knee osteoarthritis patients were included: 77.1% women, mean age 65.7 years (sd=10.3y), 81.5% having 3 or more comorbidities. Up to the 5 year follow-up, n=83 (40.5%) remained with complete data, 48 (23.4%) received arthroplasty. At 5 years, ES were 0.13 to 0.79 for pain, –0.12 (worsening) to 0.42 (improvement) for function, and –0.25 to 0.21 for psychosocial health. At the last follow-up before surgery, WOMAC pain had worsened by ES=–0.42 (p=0.001) and WOMAC function by ES=–0.54 (p=0.002) in the total knee arthroplasty group. Getting total knee arthroplasty was statistically significantly associated with female sex (OR=3.30), educated at university (OR=3.54), minus 1 comorbidity less (OR=1.41), and 10 (of 100 possible) points worsening on the WOMAC factor ascending/descending (OR=1.60).
Conclusions: Moderate to small improvements on pain, function, and psychosocial health were observed up to 5 years after comprehensive rehabilitation of knee osteoarthritis. Nevertheless, almost one quarter of the participants were referred to total knee arthroplasty suffering from significant deterioration in pain and function. The WOMAC seems to be sensitive to predict the need for arthroplasty. Highly educated women with low number of comorbidities and high disability to manage stairs were more likely to receive total knee arthroplasty (3).

THU0709 DOES THE USE OF ANALGESIC CURRENT THERAPIES INCREASE THE EFFECTIVENESS OF NECK STABILIZATION EXERCISES FOR IMPROVING PAIN, DISABILITY, MOOD, AND QUALITY OF LIFE IN CHRONIC NECK PAIN? A RANDOMIZED, CONTROLLED, SINGLE-BLIND STUDY (A PILOT STUDY)

H. Yesil[1], S. Hepguler[2], U. Dundar[1], S. Taravati[2], B. Isleten[3]. *[1]Physical Medicine and Rehabilitation, Afyon Kocatepe University, Faculty of Medicine, Afyonkarahisar; [2]Physical Medicine and Rehabilitation, Ege University, Faculty of Medicine, Izmir; [3]Physical Medicine and Rehabilitation, Yalova Aktif Hastanesi, Yalova, Turkey*

Background: Analgesic therapies; such as interferential current (IFC) and transcutaneous electrical nerve stimulation (TENS) have been applied solo or combined with exercise for management of neck pain (NP), however, the efficacy of these combinations are unclear.
Objectives: To determine if TENS or IFC increase the effectiveness of neck stabilization exercises on pain, disability, mood, and quality of life for chronic NP.
Methods: 60 patients with chronic NP were included in the study. Patients were randomly assigned into 3 groups; Group I: neck stabilization exercise, Group II: TENS+ neck stabilization exercise and Group III: IFC+ neck stabilization exercise. Patients' pain levels (visual analogue scale (VAS)), quality of life (short form-36), mood (Beck depression inventory (BDI)), levels of disability (Neck Pain and Disability Index) and the need for analgesics were evaluated prior to treatment, at 6th and 12th week follow-up. All participants had group exercise accompanied by a physiotherapist for 3 weeks and an additional 3 weeks of home exercise program.
Results: All three groups had statistically significant improvement regarding their VAS, neck disability index and most sub-scores of short form-36 (p<0,05). At 12th- week follow-up, no difference was found between groups regarding pain, disability, and quality of life (p>0,05). On the other hand, analyses indicated significantly lower scores of neck disability index (p=0.004) and less need for paracetamol (p=0.036) in TENS group 6th-week follow-up when compared to exercise and IFC groups.
Conclusions: All treatment modalities improved pain, disability, mood and quality of life in patients with chronic NP. Besides, results suggest TENS enhanced the efficacy of exercise therapy on pain, disability and need for analgesics in acute phase but not in long term, since there was no difference at 12th week follow-up. To conclude, we think exercise protocols can be of choice since they are inexpensive, easy and effective in the management of chronic NP.

THU0710 VALIDATION OF NEW WEIGHTED SCORING SYSTEM TO PREDICT MODIFIED HEALTH ASSESSMENT QUESTIONNAIRE SCORES IN PATIENTS WITH RHEUMATOID ARTHRITIS USING NATIONAL DATABASE OF RHEUMATIC DISEASES IN JAPAN DURING 2009 AND 2014

K. Ono[1], S. Ohashi[2], Y. Kadono[3], H. Oka[4], J. Hirose[5], T. Matsumoto[5], N. Izawa[5], M. Naito[5], J. Nishino[5], S. Tanaka[5], S. Tohma[6]. *[1]Joint Surgery, Research Hospital, The institute of Medical Science, The university of Tokyo, Tokyo; [2]Orthopaedic sugery, Satamihara Hospital, National Hospital Organization, Kanagawa; [3]Orthopaedic sugery, Saitama medical university, Saitama; [4]22nd century Medical and Research center; [5]Orthopaedic sugery, Faculty of medicine, The university of Tokyo, Tokyo; [6]Clinical Research center for allergy and rhuematology, Satamihara Hospital, National Hospital Organization, Kanagawa, Japan*

Background: We reported the impact of joint diseases on modified health assessment questionnaire (MHAQ) scores determined using 2011 data from NinJa (National Database of Rheumatic Diseases by iR-net in Japan). The MHAQ score was significantly associated with disease in almost all joints and physical ability tended to become aggravated. We also developed a joint-weighted scoring system from odds ratios. Respective integer scores assigned to disease in bilateral and unilateral joints comprised shoulder, 4 and 2; elbow, 3 and 2; wrist, 2 and 2; hip, 0 and 3; knee, 3 and 2; ankle, 2 and 2; finger, 1 and 1. Statistical analyses indicated a cut-off at 3 points using this system (Ono K, et al., Modern Rheumatology, 2016).
Objectives: To validate the weighted scoring system using NinJa data from 2009 and 2014.
Methods: We analyzed data from 7,189 and 13,459 patients listed in the NinJa database during 2009 and 2014. The presence or absence of disease in each joint (swelling and/or tenderness were considered to indicate active disease) and whether the disease was bilateral or unilateral were investigated. We calculated joint scores for each patient using a weighted scoring system and then created ROC curves for each patient based on total scores.
Results: Patients in the 2009 and 2014 groups were aged 62.4±12.6 and 64.1±12.8 years, median DAS28 CRP values were 2.9 and 2.4, and total joint scores were 3.4 and 2.4 with a significant difference ($p<0.05$; Wilcoxon signed-rank test) between the two groups. Analyses of ROC curves generated from scores derived using the new system and MHAQ revealed a cut-off of 3 points (same as 2011); AUC, 0.72, 0.68 (Table 1).

Variable	2009 (n=7,189)	2014 (n=13,459)	P value
Age (mean ± SE, years)	62.4±12.6	64.1±12.8	<0.05
Duration of disease (mean ± SE, years)	12.7±10.7	13.0±12.9	0.68
MHAQ score (median)	0.25	0.13	<0.05
DAS28 CRP (median)	2.9	2.4	<0.05
DAS28 ESR (median)	3.6	3.0	<0.05
Total joint score (median)	3.4	2.4	<0.05
Joint score: ROC analysis' cut-off value	3.0	3.0	
AUC	0.72	0.68	

Conclusions: Disease activity changed from moderate to low in the NinJa cohorts and the scoring system was validated for the years 2009 and 2014. The weighted scoring system appears useful to predict functional disability in a simpler way by examining each joint rather than changes in disease activity among patients with RA.

THU0711 IMPACT OF SPORTS PRACTICE IN PATIENTS WITH ANKYLOSING SPONDYLITIS: A SYSTEMATIC REVIEW OF RANDOMIZED CONTROLLED STUDIES

L. Bouleau[1,2,3], C. Palazzo[4,5], M. Kerzoncuf[1,3], T. Pham[2,3]. *[1]Physical Medicine and Rehabilitation Department, la Timone Hospital, AP-HM; [2]Rheumatology Department, Sainte-Marguerite Hospital, AP-HM; [3]Aix-Marseille University, Marseille; [4]Service de rééducation et de réadaptation de l'appareil locomoteur et des pathologies du rachis, Cochin Hospital, AP-HP; [5]ECaMO, INSERM U1153, Paris, France*

Background: The recent update of the ASAS-EULAR management recommendations for axial spondyloarthritis highlights effectiveness of home exercises and physical therapy. However, the adherence rates to these structured exercises are low, what could limit their long-term effectiveness. An option could be to replace or to complete the practice of specific exercises with the regular practice of a recreational sport activity. Data concerning the effectiveness and tolerance of sports in ankylosing spondylitis (AS) are scarce.
Objectives: To assess the tolerance and effectiveness of recreational sports practice on function, spinal mobility, disease activity, pain and quality of life in patients with AS.
Methods: A systematic review was performed according the PRISMA guidelines, using the following search engines: MEDLINE (Pubmed), COCHRANE Library, Google Scholar and Physiotherapy Evidence Database (PEDro), completed by a manual research. We included randomized controlled trials (RCTs) from 1984 to September 2016, with participants with AS fulfilling the New York modified criteria, and interventions involving sports practice. We defined "sports" according to the MeSH definition as "Activities or games, usually involving physical effort or skill [with purpose of] pleasure, competition, and/or financial reward." Exercise therapy and physiotherapy were not included in the research. The outcomes measured were the followings: stiffness/spinal mobility, function, disease activity, quality of life, pain, side effects. Methodological quality was assessed using the PEDro scale.
Results: From the 40 studies identified after screening, only 5 articles were selected for eligibility. One study was excluded (poor quality). The 4 RCTs concerned a total of 187 AS patients. Interventions were Pilates, Tai Chi, swimming, walking, and exergames. Control groups received either no specific intervention or standard exercise therapy. The studies were too heterogeneous to be pooled but the comparisons inter and intra-groups in each study tended to show significant effectiveness of sports practice on function, activity and spinal mobility. Data on tolerance were scarce, but no significant side effect was reported.
Conclusions: Recreational sports practice may improve function, activity and spinal mobility in patients with AS. However, there are very few studies available, and evidence-level is low. More controlled randomized clinical trials should be conducted in the future to confirm the effectiveness and safety of sports in AS.

THU0712 DUTCH NORM SCORES FOR FOUR DUTCH-FLEMISH PROMIS ITEM BANKS IMPORTANT FOR PATIENTS WITH RHEUMATOID ARTHRITIS

M.H. Crins[1], L.D. Roorda[1], H.C. de Vet[2], R. Westhovens[3,4], M. Boers[2,5], J. Dekker[6], C.B. Terwee[2]. *[1]Amsterdam Rehabilitation Research Center, Reade; [2]Department of Epidemiology and Biostatistics, The EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, Netherlands; [3]Rheumatology, University Hospitals; [4]Department of Development and Regeneration, Skeletal Biology and Engineering Research Center, KU Leuven, Leuven, Belgium; [5]Amsterdam Rheumatology and immunology center; [6]Department of Rehabilitation Medicine and Department of Psychiatry, VU University Medical Center, Amsterdam, Netherlands*

Background: In the assessment of patients with rheumatoid arthritis (RA) it is important to measure physical function, fatigue, pain behavior and pain interference. The Patient-Reported Outcomes Measurement Information System (PROMIS) initiative developed item banks for measuring these concepts. These item banks were translated into Dutch-Flemish language.
Objectives: To facilitate interpretation and implementation of PROMIS in the Netherlands, we aimed to calibrate and validate the Dutch-Flemish PROMIS Physical Function (DF-PROMIS-PF), Fatigue (DF-PROMIS-FA), Pain Behavior (DF-PROMISPB) and Pain Interference (DF-PROMIS-PI) Item Banks in the general Dutch population, to obtain Dutch norm scores for these item banks.
Methods: 3365 persons of the general Dutch population completed a web-based survey, of which 1309 persons completed the full DF-PROMIS-PF (121 items), 1007 persons completed the full DF-PROMIS-FA (95 items), and 1049 persons completed the full DF-PROMIS-PB (39 items) and the full DF-PROMIS-PI (40 items). The sample was stratified for gender, age, education, and ethnicity according to the distribution of the 2015 census of the general Dutch population. A one-factor confirmatory factor analysis (CFA) was performed per item bank to assess unidimensionality. A graded item response model (GRM) was fitted per item bank to evaluate the item characteristics of the item banks and to facilitate future development of computer adaptive tests (CATs). Ordinal regression models were used to evaluate Differential Item Functioning (DIF) for language (Dutch vs. English) as a measure of cross-cultural validity.
Results: All four item banks showed good fit to the GRM: they showed good fit indices for CFA and high percentages of explained variance by first factor. The item banks showed only little local dependency and the scalability coefficients suggested strong scalability for all four item banks. The item characteristics

showed good coverage across the range of the four concepts. DIF analyses are in progress.
Conclusions: The item banks exhibited good psychometric properties in the general Dutch population. The four Dutch-Flemish PROMIS item banks can be used to develop CATs for measuring physical function, fatigue, pain behavior and pain interference in the Netherlands. Dutch norm scores are presented.

THU0713 HOW THE VARIATION IN THE LUMBOPELVIC PATTERNS OF MOVEMENT AFFECTS THE NEUROMOTOR CONTROL OF THE BICEPS FEMORIS DURING TRUNK FORWARD BENDING

M. Sarti[1], R. Expositor-Rodríguez[2], R. Borona-Carvajal[1], M. Ybañez-García[3], M. Fuster-Ortí[4]. *[1]Human Anatomy and Embryology, Universidad de Valencia (UVEG); [2]Inst, for Research on Musculoskeletal Disorders, Catholic University of Valencia; [3]Rheumatology Section, Pesset Hospital; [4]Department of Statistics and Operations Research, Universidad de Valencia (UVEG), Valencia, Spain*

Background: Trunk forward bending is one of the most common activities in daily living; it is a two-part movement involving the lumbar spine flexion and pelvis rotation at hip joint. The pattern of movement during forward bending was defined as the relative contribution of the lumbar spine to pelvis motion, and was expressed as the ratio between the ranges of lumbar spine motion to pelvis motion (L/P), which, calculated at certain degrees of trunk flexion during the entire movement, provides the lumbo-pelvic rhythm. This is associated with a specific pattern of activation for back and hip extensor muscles which was coined as flexion relaxation phenomenon, observed either in the erector spinae and biceps femoris (BF). It has been shown that in healthy people lumbopelvic pattern of movement for entire flexion varies, showing both lumbar spine dominant and pelvis dominant-patterns of movement.
Objectives: To find out whether the variation in the lumbopelvic pattern of movement (lumbar spine or pelvis dominant) affects the appearance of the relaxation of the BF during trunk forward bending.
Methods: Surface electrodes were applied to the skin on right BF, midway between ischial tuberosity and head of fibula to record EMG during a trunk flexion movement from the upright position. The EMG signal was full-wave rectified and averaged (40ms) to produce a linear envelope. An electrogoniometer measured the differential lumbar spine - pelvis sagittal angular displacement during trunk flexion in asymptomatic subjects. Both signals (EMG and degrees) were synchronously and continuously captured during the movement. Ranges of flexion (ROF) for the lumbar spine, pelvis and trunk motion were calculated for the entire movement. The subjects (both sexes) were assigned to group-L (n=11) and group-P (n=15) according to exhibiting lumbar spine and pelvis dominant patterns of movement (average age,24.5±3.3years).The myoelectric relaxation (MR) appearance was defined in terms of degrees of flexion where the electrical activity of the BF was less than that in upright posture (EMG basal), at this point the degrees of flexion for the pelvis and spine were determined; and their respective "range of motion" (ROM) was calculated and normalized to range of trunk flexion. One-way MANOVA was used to determine differences in range of flexion at the appearance of the myoelectric relaxation between groups.
Results: ROF for MR of the BF was significantly greater in group-P (77,3%±3,4%) ($p<0.01$) than in group-L (47,8%±2,4%) for the pelvis, whereas ROF for the lumbar spine was significantly greater in group-L 95%±1,2% ($p<0.01$) than in group-P 40,41%±1,7%.
Conclusions: In healthy subjects, differences in lumbopelvic patterns of movement during trunk flexion vary the appearance of the relaxation of the biceps femoris in the range of flexion. Present results show that the variance of the lumbar spine and pelvis Kinematics is associated with the neuromotor control of the biceps femoris.

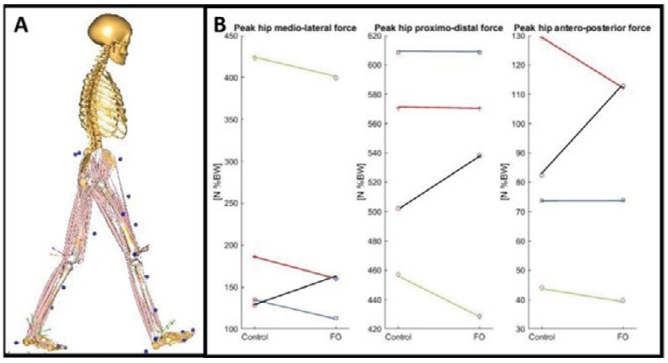
THU0714 INVESTIGATING THE EFFECTS OF HYPERMOBILITY ON BALANCE VARIABLES

M. Selmani[1], A. Elvan[1], B. Akcay[1], G. Kenar[2], A.M. Birlik[2], S. Angin[1], I.E. Simsek[1]. *[1]School of Physical Therapy and Rehabilitation, Dokuz Eylul University Institute of Health Sciences; [2]Department of Internal Medicine, Dokuz Eylul University Faculty of Medicine, Izmir, Turkey*

Background: Hypermobility syndrome (HMS) is a clinical syndrome in which the range of motion of the joint is observed above normal ranges without being associated with a rheumatic disease. Excessive joint motion in HMS reduces joint stability and joint position sense and also can cause pain. Decreased muscle tone and tensile forces of the tendons cause decreased locomotor system stiffness and impairment of proprioception mechanisms. These problems in proprioceptive mechanisms can lead to balance-related disorders in individuals with hypermobility syndrome
Objectives: The aim of this study was to investigate the possible effects of hypermobility on balance variables.
Methods: 50 hypermobile (5 males and 45 females) volunteers diagnosed with Brighton Scale and 50 healthy (21 males and 29 females) volunteers were included in this cross sectional study. Participants with a score of 4 or over according to the Beighton scale were referred to a rheumatologist and were administered Brighton scale. Participants who were diagnosed by the physician were included in the hypermobile group. The objective balance evaluation was conducted using a balance platform. Evaluation variables were; static balance on single foot, static balance on both feet, limits of stability test and tandem walking. analysis was performed using independent samples t-test.
Results: The mean age was found 21,69±2,13 years old for the control group and 20,09±2,65 years old for the HMS group. Body Mass Index was found 22,13±3,54 kg/m^2 in the control group and 21,54±3,50 kg/m^2 in the HMS group. HMS group showed significant wider step width in tandem walking (p=0,001), significantly longer reaction time (p=0,23, p=0.030), significantly higher end-point excursion (p=0.003, p=0,026, p=0,049), significant higher mean maximum excursions (p=0.018) (Table 1).

Table 1. Comparison of Groups About Balance Variables

	HMS Group (Mean ± SD)	Control Group (Mean ± SD)	p
Tandem Walking			
Step-Width (cm)	6,52±0,89	7,20±1.10	0.001*
Limits Of Stability			
Reaction Time 2 (sec)	0,91±0.44	0,72±0.37	0.023*
Reaction Time 6 (sec)	0,78±0,36	0,64±0,25	0.030*
End-Point Excursion 1 (°/sec)	86,69±17,73	73,19±26,17	0.003*
End-Point Excursion 4 (°/sec)	76,56±17,36	83,92±14,91	0.026*
Maximum Excursion 5 (°/sec)	76,54±18,31	82,69±11,50	0.049*
Mean Maximum Excursion (°/sec)	94,56±6,51	97,25±4,29	0.018*



*$p<0.05$.

Conclusions: In this study it was found that hypermobility has significant effects on the stability limits test and tandem walking. In previous studies it was found that hypermobility affects the static balance assessment variables (1, 2), but in this study dynamic balance assessment variables were affected.

THU0715 ESTIMATION OF THE EFFECT OF FOOT ORTHOTICS ON HIP JOINT LOADING FOR RHEUMATOID ARTHRITIS PATIENTS USING MRI-BASED MUSCULOSKELETAL MODELS: A PILOT STUDY

M.B. Simonsen[1], K. Næsborg-Andersen[2], M.R. Kowalski[3], K. Hørslev-Petersen[4], M.S. Andersen[1]. *[1]Department of Mechanical and Manufacturing Engineering, Aalborg University, Aalborg; [2]Bandagist-Centret A/S, Haderslev; [3]Department of Rheumatology, Hjørring Hospital, Hjørring; [4]King Christian 10th Hospital for Rheumatic Diseases, Gråsten, Denmark*

Background: Over 85% of rheumatoid arthritis (RA) patients experience feet and ankle problems during the course of the disease. Persistent foot and ankle problems still occur even after clinical remission is reached [1]. In RA, synovitis, effusion, and eventually erosive arthritis are thought to cause clinically recognizable planovalgus or valgus heel [1]. With the intention to stabilize and align the foot, patient-specific foot orthotics (FO) are commonly prescribed to this patient group. A limitation of the previous literature on FO to treat RA and related diseases is that it has focused exclusively on clinical outcomes of FO such as pain and physical function, while overlooking the biomechanical principles on which the rationales for FO is based [2].
Objectives: The aim of this study was to investigate the effect of patient-specific FO on hip loading during gait. This was accomplished by developing patient-specific (PS) musculoskeletal models (MS) capable of estimating joint mechanics with and without the FO.
Methods: Four early stage RA patients were recruited for this study. A pair of FO was developed for each patient using a weight bearing casting technique. PS bone geometry was obtained from magnetic resonance imaging (MRI) images and segmented in an image analysis package (Mimics 19, Materialse, Belgium). Motion capture was performed with an eight-camera setup (Qualysis, Sweden) with reflective markers together with three force plates (AMTI, USA) sampling at 100 and 1000 Hz, respectively. The gait trials consisted of two conditions: one with the PS FO and one with a control insole (C). PS MS models of each patient were developed using the AnyBody Modeling System (AnyBody Technology, Denmark), Figure 1A. Muscle attachments were made PS based on the Twente Lower Extremity Model version 2.0 dataset using advanced morphing to customize a generic cadaver-based model with respect to PS morphology

acquired from MRI [3]. Accurate joint centers and axes were calculated with analytical surface fits to the segmented MRI bones for the hip, knee and ankle.
Results: Peak hip force for medio-lateral (ML) proximo-distal (PD) and antereo-posterior (AP) is presented in Figure 1B for the C and FO with values for each subject.
Conclusions: The results of this study indicate that FO can change the load distribution in the hip joint. A reduction or similar values for ML, DP and AP force was found for all but one participant. These changes may potentially contribute to the reduction in pain. Further studies are needed to investigate if there is a relationship between changed loading and pain for RA patients. This knowledge can potential be used for design of better FO and clinical guidelines for use of FO.

THU0716 LONGITUDINAL OUTCOME OF AEROBIC FITNESS IN ADOLESCENTS AND YOUNG ADULTS WITH JIA

P.V. Pelt[1,2], T. Takken[3], M.V. Brussel[4], R. Dolhain[1], J. Hazes[1], J. Bijlsma[5], N. Wulffraat[6], A. Kruize[5]. *[1]Department of Rheumatology, Erasmus MC, University Medical Center Rotterdam, Rotterdam; [2]Department of Pediatric Immunology, Wilhelmina Children's Hospital, University Medical Center Utrecht; [3]Child Development and Exercise Center, Wilhelmina Children's Hospital, University Medical Center Utrecht; [4]Child Development and Exercise Center, Wilhelmina Children's Hospital, University Medical Center Utrecht; [5]Department of Rheumatology and Immunology, University Medical Center Utrecht; [6]Department of Pediatric Immunology, Wilhelmina Children's Hospital, University Medical Center Utrecht, Utrecht, Netherlands*

Background: Aerobic fitness may serve as an important health-related outcome measure in JIA. A reduced aerobic fitness is associated with cardiovascular morbidity, mortality and osteoporosis in adult patients with chronic diseases. However, in adolescents and young adults, long-term outcome data of aerobic fitness are unknown. Reduced aerobic fitness was described in cross-sectional studies in children and adolescents with JIA, and was more impaired in active disease
Objectives: Our objectives are to describe course of the aerobic fitness in a longitudinal cohort of adolescents and young adult JIA-patients who are intensively treated including the possibility of biologics and to identify the association of clinical variables with aerobic fitness.
Methods: In a longitudinal cohort, all consecutive JIA patients aged 10–24 years were included after informed consent. Annual examinations were obtained from demographic and disease-related items. At baseline and end of the study, aerobic fitness (VO2peak) was assessed using a graded cardiopulmonary exercise test (CPET) to volitional exhaustion performed on an electronically braked cycle ergometer. Absolute and relative VO2-peak values were measured and related to healthy controls (Z-scores), using one-sample T-tests. Non-parametric tests were used to evaluate results
Results: Paired Z-scores were available from 27 patients. 44% were male, median age at baseline was 13,0yrs (IQR 4,3), disease duration 7,6yrs (6,7), JADAS27 4,0 (5,9), DAS28 2,2 (1,2). 76% of the patients were in DAS28-remission. 11% had systemic JIA, 7% persistent oligoarticular and 82% had a polyarticular course. Baseline and end Z-scores were reduced compared to healthy controls (ZAbs_base -0,68, IQR2,3 p=0,01; Zrel_base -1,33, IQR 2,0, p<0,01; Zabs_end -0,23, IQR 1,7, p=0,06; Zrel_end -0,87, IQR 2,2, p=0,01) and did not change significantly over time (change Zabs_change 0,45, p=0,34; Zrel_change 0,46, p=0,31). At baseline, MTX-use (p=0,04) and a higher DAS28 (p=0,015) and ESR (p=0,013) are associated with a worse outcome of aerobic fitness. The greatest improvement of aerobic fitness over time was seen in patients with a higher ESR (p<0,01) and thrombocytes (p<0,01) at baseline. Multivariate analysis showed that a higher DAS28 and male gender were the most important variables for worse aerobic fitness at baseline, a higher ESR at baseline was the most important predictor for improving aerobic fitness over time
Conclusions: Aerobic fitness is significantly reduced in adolescents and young adults with JIA and does not improve over time, despite intensive treatment. Be aware of a reduced quality of life due to a persistent reduced aerobic fitness during disease course of JIA, despite low disease activity

THU0717 MIRROR VISUAL FEEDBACK THERAPY IMPROVES CLINICAL OUTCOMES AND THE ACTIVITY OF DAILY LIVING TO PATIENTS WITH HAND COMPLEX REGIONAL PAIN SYNDROME

S. Patru[1], I.R. Marcu[2], D. Matei[1], A.M. Bumbea[1], A.C. Bighea[1]. *[1]Physical Medicine and Rehabilitation; [2]University of Medicine and Pharmacy of Craiova, Craiova, Romania*

Background: Wrist osteoporotic fractures may be as disabling as vertebral or hip fractures and the functional decline attributed to them is similar to that seen for arthritis and diabetes mellitus. Sometimes these fractures will lead to a painful, debilitating condition with sensory and motor disturbances, changes in vascular tone, temperature and edema- complex regional pain syndrome (CRPS). We found some clinical trials and case reports which conclude that mirror visual feedback therapy (MVFT) improves clinical outcomes and the activity of daily living to patients with hand neurological disorders, including CRPS.
Objectives: In this controlled randomized clinical study we tried to investigate the effects of (MVFT) in CRPS type I following osteoporosis wrist fracture.
Methods: We included 21 subjects with osteoporotic wrist fracture and early CRPS (duration of 3–4 weeks), with a single hand affected by allodynia, stiffness and vasomotor disturbances, from Physical Medicine and Rehabilitation outpatient clinic. They are randomly assigned into two groups: MVFT group (n=11, simply place a mirror between their two hands and train the patient by asking them to move both hands while watching the reflection of the non-affected hand in the mirror, 10 minutes for each session, four times a day) and Control group (n=10, moved both hands separated by an opaque partition between the arms). All subjects also received conventional therapy. On presentation and after 4 weeks of rehabilitation programme we assessed the wrist flexion and extension with a goniometer and the Patient-Rated Wrist Evaluation (PRWE) a 15-items questionnaire designed to measure wrist pain and disability in activities of daily living.
Results: Subjects in the mirror therapy group showed significant improvement in range of motion: extension increased with 50.4% vs. 41.7% and for flexion MVFT achieved 33.2% and Control group 16.8% ($P<.001$). The rehabilitation programme also increased hand function with better results to 4 weeks PRWE for MVFT group (40.4 vs. 51.8, $P=0.003$).
Conclusions: MVF is a simple, inexpensive, without adverse events treatment option that significantly reduces pain and stiffness and improves hand mobility in early CRPS after osteoporosis wrist fracture.

THU0718 DIFFERENCES IN THE COURSE OF ITALIAN- AND GERMAN-SPEAKING PATIENTS' OUTCOME AFTER INTERDISCIPLINARY PAIN PROGRAM

T. Benz[1,2], S. Lehmann[2], R. Brioschi[2], A. Elfering[1], A. Aeschlimann[2], F. Angst[2]. *[1]Institute of Psychology, University of Bern, Bern; [2]Research Department, RehaClinic, Bad Zurzach, Switzerland*

Background: Available evidence shows that the experience and perception of pain varies among different populations. Further, inequalities are reported in pain treatment across various types of pain and in different settings (1). In particular, it is unknown how much immigrants in Western European countries profit from pain management programs.
Objectives: The aim of this study was to detect differences in the course of Italian- and German-speaking patient's state of health and quality of life after a 4-week standardized interdisciplinary pain management program in German or in Italian.
Methods: The prospective cohort study with 61 Italian-speaking and 63 German-speaking patients with fibromyalgia or chronic back pain measured health-related quality of life, pain, anxiety and depression comparing at baseline, after 4 weeks of pain program and at 1 year follow-up. Differences between the two groups

were tested on significance by generalized estimation equations (GEE) (2). This method modeled changes of health by multivariate logistic regression adjusting for sex, education, number of comorbidities and the baseline score over both follow-ups for each scale.

Results: Italian-speaking patients (n=61) showed higher proportions of males, lower educated and less burdened by comorbidities than German-speaking patients (n=63). At baseline, physical and psychosocial health, depression and anxiety of the Italian-speaking patients were worse than German-speaking patients, with the exception of less pain in the Italian-speaking patients on the SF-36. Changes of health showed more improvement in German- than in Italian-speaking patients on all scales and at both follow-ups. In GEE, the highest differences were observed in SF-36 physical functioning (p=0.035), HADS anxiety (p=0.038) and HADS depression (p=0.023). On SF-36 bodily pain, the difference was not significant (p=0.166).

Conclusions: This study detected that short- and midterm outcome of Italian-speaking patients was worse than that of German-speaking patients, even after adjustment for baseline differences. The reasons for this study's results remain unclear, but may have consequences for future management of Italian-speaking patients in interdisciplinary pain management programs. Considering language as a proxy for acculturation, this supports the hypothesis that patients with lower level of acculturation may have special needs in therapeutic management. A cultural sensitive approach in a multidisciplinary pain program might enhance the positive outcome in the short- and mid-term (3).

THU0719 LONG-TERM COURSE OF HEALTH AND WORKING CAPACITY AFTER A REHABILITATION PROGRAM FOR WHIPLASH INJURY

T. Benz[1], P. Haiduk[1], S. Lehmann[1], F. Gysi-Klaus[1], B.A. Michel[2], A. Aeschlimann[1], F. Angst[1]. *[1]Research Department, RehaClinic, Bad Zurzach; [2]Clinic of Rheumatology, University Hospital of Zurich, Zurich, Switzerland*

Background: Persistent pain and disability of whiplash injury associated disorders (WAD) cause high burden for the individual and costs for healthcare.

Objectives: The aim of this study was to determine state and change of health and working-capacity five years after a standardized inpatient pain management program of four weeks.

Methods: This prospective cohort study quantified health and quality of life by the generic Short Form 36 (SF-36, 100=best), the neck-specific Northern American Spine Society (NASS) form, and the Coping Strategies Questionnaire (CSQ). SF-36 data were compared to age-, sex-, and comorbidity-specific German population norms (1). Changes of health were determined using effect sizes (ES) at the 6 month and the 60 month follow-up. Changes of health were determined using effect sizes (ES) (2).

Results: The 59 participants had mean age of 40.3 years (sd=12.3), 83% were women, and 37% had one or more comorbidites. At 5 years, health was worse on all SF-36 scales when compared to the norms ($p<0.001$), varying from mean 41.5, norm 82.3 on role physical to mean 65.7, norm 71.0 on mental health (all $p<0.001$).

Table 1

Effect sizes (ES)	Entry to 60 months	6 months to 60 months
SF-36 Physical functioning	0.99	0.16
SF-36 Role physical	2.22	0.83
SF-36 Bodily pain	1.61	0.78
SF-36 Vitality	0.89	0.32
SF-36 Social functioning	0.71	0.47
SF-36 Mental health	0.61	0.30
NASS Pain	1.12	0.56
NASS Function	0.78	0.26
CSQ Catastrophizing	1.03	0.62

Median working capacity improved from 0 at entry to 21 at 6 months and to 30 hours/week at 5 years.

Conclusions: Moderate to large long-term effects were observed. Substantial improvements still occurred between 6 and 60 months after start of the pain program, especially in pain, catastrophizing, and physical role performance. Improvements observed after the inpatient pain program can be maintained and expanded in the long-term at home (3).

Cartilage, synovium and osteoimmunology

FRI0001 ALL STAGES OF SYNOVIAL MESENCHYMAL STEM CELL ACTIVITY INCLUDING ADHESION, PROLIFERATION, MIGRATION AND CHONDROGENIC DIFFERENTIATION ARE SUPPORTED BY HUMAN PLATELET LYSATE- IMPLICATIONS FOR NOVEL ONE STAGE JOINT REGENERATIVE PROCEDURES

A. Altaie, T.G. Baboolal, E. Jones, O. Wall, D. McGonagle. *Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom*

Background: Both synovial and related synovial fluid-derived mesenchymal stem cells (SF-MSC) are highly proliferative and chondrogenic and have direct access to superficial cartilage injuries [1]. Human platelet lysate (PL) is being increasingly used for joint regenerative approaches [2,3] but the biological basis for in vivo effect, if any is lacking.
Objectives: The study evaluated the effect of PL on adhesion, proliferation, migration and trilineage differentiation of synovial cavity derived MSCs in comparison to "gold standard" foetal calf serum (FCS) based stem cell media.
Methods: MSCs were derived from joint cavity washout in patients undergoing anterior cruciate ligament reconstruction or meniscal repairs. Cells were plated in StemMACS (FCS media) or with DMEM Supplemented with 10% Stemulate (PL media, Cook Regentec). Standard MSC proliferation, trilineage differentiation assays, and transwell migration assays were performed for both conditions.
Results: PL enhanced MSC colonies sizes (CFU-F) by 2.5 folds compared to FCS (p=0.0023, n=5). PL shortened MSC doubling times (p=0.0411, n=6). However, PL had no impact on CFU-F numbers (p=0.5973, n=5). In transwell migration assays, MSC migration was significantly increased toward 10%PL compared to 10%FCS (p=0.0286, n=6). Under standard chondrogenic induction conditions, PL-expanded MSC showed 30% more sulphated GAG (sGAG) production compared to FCS-expanded cells (n=4). In osteogenic and adipogenic induction, Alizarin red staining Ca++ assay and Nile Red showed no significant difference compared to FCS expanded cells (p=0.3429, n=4). Interestingly, replacing TGFβ with 20% PL was as good as standard chondrogenic media and with increasing PL percentage sGAG production increased (n=4). In same time using PL with high glucose media in 1:1 ratio was efficient to produced sGAG as compared to negative control (media only) (p=0.0286, n=4, figure 1). Moreover, substituting FCS with PL in the osteogenic media resulted in increased Ca++ deposition in both PL and FCS expanded cells by 90% and 100% compared standard osteogenic media.

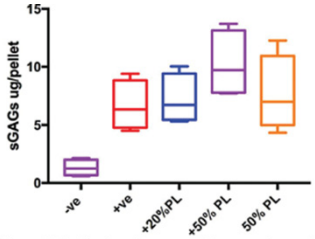

Figure 1: Evaluation the use of PL as an alternative TGFBeta in chondrogenic media. A: sGAGS activity of SF-MSC in different chondrogenic media; -ve: high glucoase+10% FCS, +ve: complete chondrogenic media, +20%PL: complete media with no TGFBeta and with 20%PL, +50%PL: complete media with nc TGFBeta and with 50%PL, 50%PL: high glucose DMEM with 50%PL. (N=4), Mann-Whitney test.

Conclusions: This is the first study that assessed joint cavity MSC responses to PL. All aspects of joint cavity derived MSC biology towards cartilage repair were augmented in vitro with PL based media over "gold standard" MSC media. This work provides biological plausibility for the combination of PL with joint resident MSC towards endogenous joint repair strategies.

FRI0002 DEVELOPMENT OF AN IN VITRO MULTI-COMPONENT 3D JOINT MODEL TO SIMULATE THE PATHOGENESIS OF ARTHRITIS

A. Damerau[1], A. Lang[1,2,3], M. Pfeiffenberger[1], F. Buttgereit[1,2], T. Gaber[1,2]. *[1]Department of Rheumatology and Clinical Immunology, Charité-Universitätsmedizin Berlin; [2]German Arthritis Research Center; [3]Berlin-Brandenburg School of Regenerative Therapies, Charité-Universitätsmedizin Berlin, Berlin, Germany*

Background: Our ultimate goal is to develop a valid *in vitro* 3D model to simulate the immune mediated pathogenesis of arthritis in order to present an alternative experimental setup for the traditional animal models. Therefore, we work to establish an *in vitro* simulation of a healthy joint, followed by the depiction of an inflamed arthritic joint to finally study the efficacy of drug treatment. The *in vitro* 3D joint model consists of different components including an (1) osteogenic and (2) chondrogenic part, (3) the joint space with synovial fluid and (4) the synovial membrane. The model is suggested to include all involved cell types and thus, to allow interactions between cells by cell contacts and signaling molecules. To our knowledge, there is currently no valid 3D model which is able to mimic an inflamed arthritic joint.
Objectives: Here, we aim to mimic the (1) osteogenic and (2) chondrogenic part of the joint for our *in vitro* multi-component 3D joint model.
Methods: We used β-tricalcium phosphate (TCP) particles as a mineralized 3D bone scaffold and human bone marrow derived mesenchymal stem cells (hMSCs), non- and pre-differentiated towards osteoblastic lineage. Both were cultured up to 21 days on β-TCP. Osteogenic differentiation was performed in the presence of osteogenic supplements under normoxic conditions (37 °C, 18% O2). Adhesion and proliferation of hMSCs on β-TCP were evaluated by immunofluorescence and histological analysis. To confirm cell attachment and biocompatibility of β-TCP particles cellular release of LDH was assessed. Osteogenic differentiation was analyzed on gene expression level using qRT-PCR. The chondrogenic model, a scaffold-free 3D cartilage construct (fzmb GmbH) was generated using hMSCs. Chondrogenic differentiation was performed under hypoxia (37 °C, 1% O2) with intermittent mechanical stimulation and analyzed by histology.
Results: We developed an *in vitro* 3D trabecular bone model by seeding hMSCs on β-TCP scaffold after pre-incubation for 24 hours. The analysis of cell viability via LDH detection showed no toxic effects on the cells seeded as compared to the corresponding control. Furthermore, we assessed cell attachment and proliferation by measurement of LDH activity after scaffold crushing. As a result, samples showed higher LDH activity compared to the controls. Histological and immunofluorescence analysis based on DNA and actin staining demonstrated cell attachment until day 21. After 21 days, cells were located more inside the scaffold compared to day 1. qRT-PCR expression of bone-related genes such as RUNX2, SPP1 and COL1A1 confirmed the phenotypic change during osteogenic differentiation on the scaffold. Furthermore, the scaffold-free 3D chondrogenic structure was confirmed by HE staining representing the different zones. Cartilage phenotype was confirmed by the reduced expression of Col1a1, an abundant expression of Col2a1 and Aggrecan.
Conclusions: The initial results from our *in vitro* 3D osteogenic and chondrogenic model confirm good cell vitality which indicates successful progression. To confirm the exchange of β-TCP through cellular matrix, we will now extend the assay co-cultivation time for up to 6 weeks. This 3D multi-component joint model should enable us to simulate arthritis and to study the efficacy of drug treatment *in vitro.*

FRI0003 MODULATION OF ARTICULAR JOINT TISSUE TURNOVER IN BOVINE EXPLANT MODELS OF CARTILAGE AND SYNOVIAL MEMBRANE: DEVELOPMENT OF NOVEL DRUG DEVELOPMENT TOOLS

A.S. Siebuhr, C.A. Cabanes, S. Dahab, M.A. Karsdal, A.-C. Bay-Jensen, C.S. Thudium. *Biomarkers and Research, Nordic Bioscience, Herlev, Denmark*

Background: There is currently a lack of disease modifying OA drugs approved by the drug administration agencies. One of the obstacles in the development of DMOADs that can effectively halt or reverse cartilage degradation is the lack of robust and reproducible model systems for early drug testing.
Objectives: To develop inducable anabolic bovine ex vivo models of 1) synovial membrane explants and 2) synovial membrane explants in co-culture with cartilage explants.
Methods: Synovium (bSME) from healthy bovine (<24months old) hind knees were isolated and cut into explants of 30±5 mg. Bovine cartilage (BEX) was cut into equally sized explants using a 6mm diameter biopsy puncher. bSME and BEX were cultured together (bCC) or alone for 14–35 days in DMEM-GlutaMAX™ with or without continuous stimuli in 4 replicates per treatment: Oncostatin M [10 ng/mL] + TNF-α [20 ng/mL] (O+T), O+T + GM6001 [1uM], IGF-1 [100ng/mL] or TGFβ-1 [50–0.5 ng/mL]. Media were changed 3 times a week and the viability was assessed with Alamar Blue every week. The reversibility of synovial membrane degradation was investigated by 10 days incubation with O+T followed by 21 days of TGFβ-1 [50–0.5 ng/mL] treatment. The following biomarkers were assessed in the conditioned media by competitive ELISA: Type I, II and III collagen degradation (C1M, C2M and C3M), formation of type I and II collagen (P1NP

and PRO-C2), aggrecanase degraded aggrecan (AGNxI) and MMP degraded aggrecan (exFFGV). C1M and C3M are synovial membrane biomarkers and C2M, AGNxI and exFFGV are cartilage biomarkers.

Results: Explants were viable throughout the experiments, albeit the bSME lost some viability with time. bSME treated with O+T showed increased C1M and C3M (>400% and >200%) from day 10, compared to w/o, whereas in bCC O+T increased C1M from day 21 and C3M from day 14 (>800%, >1900%). O+T treatment increased C2M was increased from day 21 (>400% and >1000%) in both BEX and bCC. The release was blocked by the generic MMP inhibitor GM6001 which also decreased the C1M and C3M compared to w/o. O+T treatment increased AGNxI at day 7 and 10 (>600%) and exFFGV from day 21 (>650%) in both BEX and bCC. In bSME, TGF-b1 continuously and dose-dependently increased P1NP from day 7 compared to w/o (250%). O+T pre-treatment for 10 days followed by TGF-b1 stimulation increased P1NP after 7 days of TNF-b1 treatment (150%, figure). IGF-1 did not affect the P1NP level at any time point in bSME. In bCC both TGF-b1 (dose-dependently) and IGF-1 sustained the PRO-C2 level at the level of baseline throughout the study periods (figure), whereas O+T decreased PRO-C2 compared to with w/o. The PRO-C2 level in BEX with TGF-b1 was unaltered compared to w/o.

Conclusions: We here show that bovine synovium can be anaobolic and catabolic stimulated, both alone and in co-culture with cartilage. Anabolic stimulation was achieved with TGF-b1 in both bSME and bCC, while IGF-1 only showed an anabolic effect in the bCC. Previous human explant models using human tissuehave lacked the anabolic capacity. These translational explants models may be applied in the early development of anabolic drugs for cartilage degenerative diseases.

FRI0004 14-3-3ETA AS A NOVEL INVADOSOME REGULATORY MOLECULE IN RHEUMATOID ARTHRITIS

C. Lalanne[1], R.R. Lavoie[1], M. Charbonneau[1], J. Savill[2], A. Marotta[2], C. Dubois[1]. *[1]University of Sherbrooke, Sherbrooke; [2]Augurex Life Sciences Corp, Vancouver, Canada*

Background: Progressive cartilage destruction, mostly mediated by invasive fibroblast-like synoviocytes (FLS), is a central feature in the pathogenesis of rheumatoid arthritis (RA). We have reported that the ability of arthritic FLS to degrade the extracellular matrix depends on the formation of actin-rich plasma membrane invadosomal structures detected in cells strategically located at the cartilage-synovial membrane interface. Interference with the formation of invadosomes in RA FLS impeded matrix degradation in vitro and cartilage degradation in a model of collagen-induced arthritis, suggesting that invadosomes are important physiological structures involved in cartilage destruction.

The chaperonin molecule 14–3-3η has been detected in the joints of patients with early and established RA and that its concentration in both serum and synovial fluid correlated with elevated expression of extracellular matrix (ECM) degrading enzymes and erosive damage. Extracellular 14–3-3η has therefore been proposed to be a novel biomarker for joint damage and a potential drug target for the personalized treatment of connective tissue-associated diseases but the direct relationship between 14–3-3η and joint damage remains a key area of research.

Objectives: To evaluate the role of 14–3-3η in the ability of synoviocytes to degrade the ECM.

Methods: mRNA from primary synoviocytes of healthy individuals (N=3) and RA patients (N=5) was extracted and the relative level of 14–3-3 isoforms and MMP gene expression was determined by qPCR. The ability of the synovial cell lines to degrade ECM was assessed by in situ invadosome assays using fluorescent cross-linked gelatine. Confocal microscopy was used to determine the cellular localization of 14–3-3η.

Results: We found a significant increase in 14–3-3η, MMP1 and MMP3 mRNA levels in synoviocytes from rheumatoid arthritis patients compared to cells from non-arthritis individuals. A strong correlation between 14–3-3η expression levels and the ability of synoviocyte cell lines to form invadosomes was observed (r2=0.8299). Knockdown of 14–3-3η decreased the ability of arthritic synoviocytes to form invadosomes indicating a role of 14–3-3η in extracellular matrix degrading ability. Confocal microscopy revealed that 14–3-3η staining was mostly found as small punctated structures in the cytoplasm and at the cell periphery of arthritic synoviocytes where they colocalized with leading edge F-actin and discrete patches of the exocyst component, Exo70.

Conclusions: The finding of the role of 14–3-3η in invadosome formation points to a previously unappreciated facet of how 14–3-3η influences joint ECM remodelling and reinforces its role as a marker of RA progression and joint damage. How 14–3-3η is involved in the regulation of MMP production/secretion and the possible role it plays in remodelling of actin-rich subcellular structures is the subject of ongoing studies.

FRI0005 TARGETING CARTILAGE AGING AS OSTEOARTHRITIS THERAPEUTICS BY DRUG REPURPOSING

B. Carames[1], U. Nogueira-Recalde[1], M.I. Loza[2], F.J. Blanco[1], E. Dominguez[2]. *[1]Rheumatology Division. Cartilage Biology Group, The Institute of Biomedical Research of A Coruña (INIBIC), A coruña; [2]Biofarma Research Group, Center for Research in Molecular Medicine and Chronic Diseases (CIMUS), University of Santiago de Compostela, Santiago de Compostela, Spain*

Background: Effective treatments for Osteoarthritis (OA) are not available. In aging-related diseases, including OA, failure of cellular homeostasis mechanisms, such as autophagy can cause extracellular matrix destruction and cell death (1). With aging, chondrocyte function is diminished, contributing to a cellular senescence phenotype often observed in OA chondrocytes. In addition, a defect in autophagy is observed in both aging and cartilage degeneration (2,3).

Objectives: The objective of this study was to identify anti-senescence and pro-autophagy molecules by a cell-based high-throughput screening (HTS) in human chondrocytes.

Methods: To induce cellular senescence or reduced autophagy, immortalized human chondrocytes (TC28a2) were seeded (2500 cells/well) in 384 well plates, and treated with IL-6 (20 ng/ml) for 72 or 18 hours, respectively. Then, chondrocytes were incubated with Prestwick Chemical Library (1120 approved drugs with chemical and pharmacological diversity, as well as bioavailability and safety in humans) at 10 μM for 72 hours. To identify anti-senescence hits, nuclei was stained with Hoechst 33342 (2,5μg/ml), while β–galactosidase subcellular structures was stained by using Imagene Green C12FDG substrate (30 μM). To evaluate autophagic flux, a reporter cell line was generated by retrovirus transfection of pBABE-mCherry-EGFP-LC3 plasmid in TC28a2 chondrocytes. Plates were imaged by using Operetta® High Content Screening (HCS) system in non-confocal mode using the 20x WD objective. For each well, 4 fields and 4 planes of bright field, Hoechst and fluorescein channels were obtained. Relative intensity of C12FDG in cytoplasm and number of autophagosomes/autolysosomes per area of cytoplasm were determined to quantitate β–galactosidase activity and autophagy flux respectively. Compound validation was performed in TC28a2 chondrocytes and in primary human chondrocytes by evaluating cell senescence, autophagy pathway and cell death by apoptosis.

Results: A primary screening was performed to identify anti-senescence compounds by measurement of senescence-associated β-galactosidase activity. 283 compounds with anti-senescence effects were identified. The anti-senescence hits were analyzed by monitorizing autophagic flux. 29 compounds with both anti-senescence and pro-autophagy effects were selected. Then, one compound was selected for further validation. The compound reduced chondrocyte senescence, increased autophagy ($p<0.0001$) and protected against inflammation and cell death by apoptosis in human chondrocytes ($p<0.05$) in response to IL-6. Interestingly, this protective effect was partially mediated by mTOR inhibition, a proposed mechanism to prevent cartilage aging.

Conclusions: Our screening methodology provides a unique opportunity to repurpose drugs and mechanisms to prevent cartilage aging. Autophagy activation and protection against senescence in chondrocytes may provide benefits for delaying cartilage degeneration.

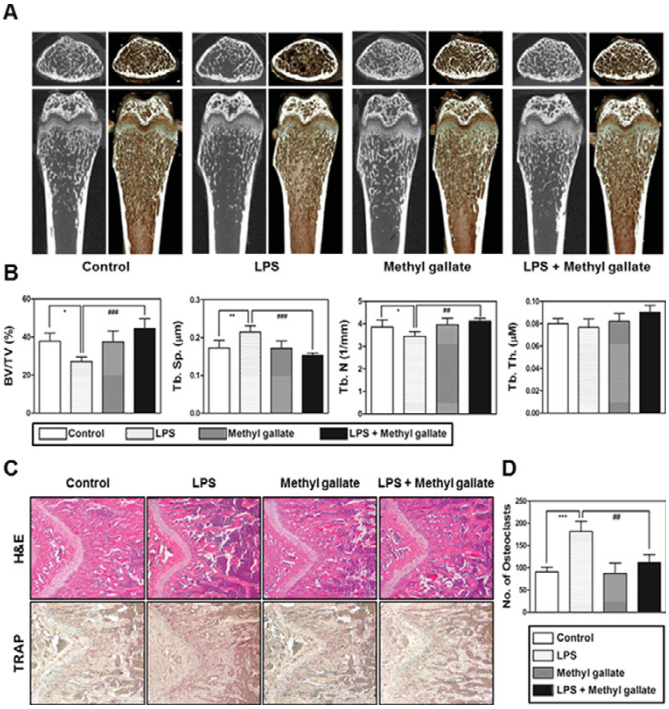
FRI0006 PROTEIN CITRULLINATIONS BY PAD ENZYMES PROMOTE DENDRITIC CELL TRANSDIFFERENTIATION INTO OSTEOCLAST AND GENERATE TARGETS FOR RA-SPECIFIC ANTIBODIES



B. Réthi[1], A. Krishnamurthy[1], J. Ytterberg[1], M. Sun[1], V. Joshua[1], H. Wähämaa[1], N. Tarasova[2], J. Steen[1], V. Malmström[1], A.I. Catrina[1].

Background: Immature dendritic cells (DCs) are able to trans-differentiate into osteoclasts (OCs) although the mechanisms regulating this process are little understood. We have recently described an important role for protein citrulliantion and peptidylarginine deiminase (PAD) enzyme activity in the regulation of OC development (1).
Objectives: We studied the molecular bases of DC-OC trans-differentiation and aimed at understanding the role of protein citrullination in this process.
Methods: Monocyte-derived DCs and peripheral blood CD1c+ DCs were cultured in the presence of osteoclastogenic cytokines. Polyclonal ACPAs were isolated from the serum of RA patients and applied in OC cultures. DC and OC differentiation was analyzed *in vitro* using gene expression analyses, flow cytometry-based methods, DC-T cell co-culture experiments, tartrate-resistant acid phosphatase stainings and osteolysis assays. Protein citrullination was monitored with the help of mass spectrometry. PAD activity was measured by ELISA.
Results: Different DC types showed different capacities to develop into OCs. OC-prone DCs were characterized by little immunogenicity and their development was potentiated by the increase of lactic acid, a side product of glycolytic metabolism. The more immunogenic DC types, characterized by prominent ability to migrate towards secondary lymphoid tissues and trigger T cell activation, showed a limited capacity to develop into OCs (2). The differentiation switch towards the OC lineage was associated with increased activity of the Protein Arginine Deiminase (PAD) enzymes and with higher level of protein citrullination in DCs. The PAD inhibitor Cl-Amidine efficiently interfered with OC development form DC precursors. In addition, the deposition of citrullinated proteins on the cell surface made the cells sensitive for anti-citrullinated protein autoantibodies, which could further stimulate DC-OC trans-differentiation through inducing the cytokine IL-8.
Conclusions: Our results indicated that DCs are heterogenic in their ability to form OCs and lineages for immunostimulatory and OC-prone DCs might separate early during DC differentiation. Plasticity towards OC differentiation might be influenced by the metabolic environment and the upregulation of PAD activity in DCs.

FRI0007 METHYL GALLATE INHIBITS OSTEOCLAST FORMATION AND FUNCTION THROUGH SUPPRESSING THE AKT AND BTK-PLCγ2-CA2+ SIGNALING, AND PREVENTS LPS-INDUCED BONE LOSS

M.-S. Lee[1], J.M. Baek[2], J.-Y. Kim[2], W.-H. Yoo[3], S.-J. Hong[4], C.-H. Lee[1].
[1]Internal Medicine, Wonkwang University Hospital; [2]Anatomy, School of Medicine, Wonkwang University, Iksan; [3]Internal Medicine, Chonbuk National University Medical School, Jeonju; [4]Internal Medicine, Kyung Hee University School of Medicine, Seoul, Korea, Republic Of

Background: Methyl gallate, a plant-derived phenolic constituent has been known to possess numerous pharmacological features against inflammation, oxidation, and cancer. But so far, there have been no evidences to describe relationship between methyl gallate and bone metabolism.
Objectives: In order to propose a promising candidate for osteoporosis, we performed experiments in this study by using methyl gallate.
Methods: we performed screening of methyl gallate utilizing TRAP staining and revealed intracellular mechanisms responsible for methyl gallate-mediated regulation of osteoclastogenesis through western blotting and quantitative RT-PCR. Also, we assessed the role of methyl gallate on characteristics of mature osteoclasts. we used LPS-induced bone loss mice as a model of osteoporosis and analyzed using micro-CT system and the right femurs were stained with TRAP and H&E.
Results: we observed that methyl gallate significantly suppressed osteoclast formation through Akt and Btk-PLCγ2-Ca^{2+} signaling. The blockade of these pathways was reconfirmed through transduction of CA-Akt retrovirus and evaluation of Ca^{2+} influx intensity stained with Fluo-3/AM. Indeed, methyl gallate down-regulated the formation of actin ring-positive osteoclasts and resorption pit areas. In agreement with in vitro results, we found that the administration of methyl gallate restored osteoporotic phenotype stimulated by acute systemic injection of LPS in vivo through micro-CT and histology.

Conclusions: Consequently, the overall data strongly indicated that methyl gallate could be a useful substance for development of plant-based anti-osteoporotic agent.

FRI0008 EFFECTS OF THE HUMAN IL4-10 FUSION PROTEIN IN THE CANINE GROOVE MODEL OF OSTEOARTHRITIS

E.M. Van Helvoort[1], J. Popov-Celeketic[1], K. Coeleveld[1], M.A. Tryfonidou[2], F.P. Lafeber[1], S.C. Mastbergen[1]. *[1]Rheumatology and Clinical Immunology, University Medical Centre Utrecht; [2]Clinical Sciences of Companion Animals, Faculty of Veterinary Medicine, University Utrecht, Utrecht, Netherlands*

Background: Ideally a disease modifying osteoarthritis drug (DMOAD) combines treatment for pain, tissue damage and inflammation, all in one molecule. Intra-articular application of a DMOAD brings additional value to treatment for two reasons, (i) lower risk of systemic side effects and (ii) higher drug concentration and potentially improved penetration of non-vascularized articular cartilage. Interleukin-4 (IL-4) and Interleukin-10 (IL-10) have been shown to prevent joint degeneration and can work synergistically[1].
Objectives: This study evaluates the DMOAD activity of repetitive intra-articular injections with a human fusion protein of IL-4 and IL-10 (hIL4–10FP) in the canine Groove model of osteoarthritis (OA).
Methods: In 8 dogs joint degeneration was induced according to the Groove model. Six weeks after surgery dogs were treated with ten weekly intra-articular injections of either hIL4–10FP (n=4) or PBS (n=4). Subsequently, dogs were euthanized and cartilage and synovium were harvested. Cartilage damage and synovial inflammation were macroscopically evaluated. Proteoglycan release and content were determined ex vivo by staining of glycosaminoglycans (GAGs) with Alcian Blue. Proteoglycan synthesis was measured by $^{35}SO_4^{2-}$ incorporation and precipitation with cetylpyridium chloride and liquid scintillation analysis of $^{35}SO_4^{2-}$-labeled GAGs. Potential antibody formation against hIL4–10FP was evaluated with ELISA and a cell based assay. Immunohistochemistry of CD79α and CD10 was used to evaluate the presence of B-cells in synovium.
Results: Affected knees of PBS treated dogs showed enhanced macroscopic cartilage damage compared to their controls (0.31 vs 2.44, p=0.068). Also differences in proteoglycan release, content and synthesis indicated a degenerative state in the affected knees.
Unexpectedly, enhanced synovial inflammation was observed in hIL4–10FP treated joints compared to PBS treated joints, demonstrated by enhanced macroscopic (3.5 vs 2.3 out of 5) and histologic (2.5 vs 1.8 out of 6) scores. CD79α and CD10 showed enhanced expression in synovium of the hIL4–10FP group compared to the PBS group, although not statistically significant (fig 1). Additional analyzes showed that hIL4–10FP was immunogenic in dogs after multiple injections. Formation of neutralizing antibodies was shown in a cell based assay where the activity of hIL4–10FP was inhibited in the presence of serum of hIL4–10FP treated dogs (fig 2). Despite the enhanced inflammatory response

in hIL4–10FP group there was no enhanced cartilage degeneration detected compared to the PBS group (fig 3).

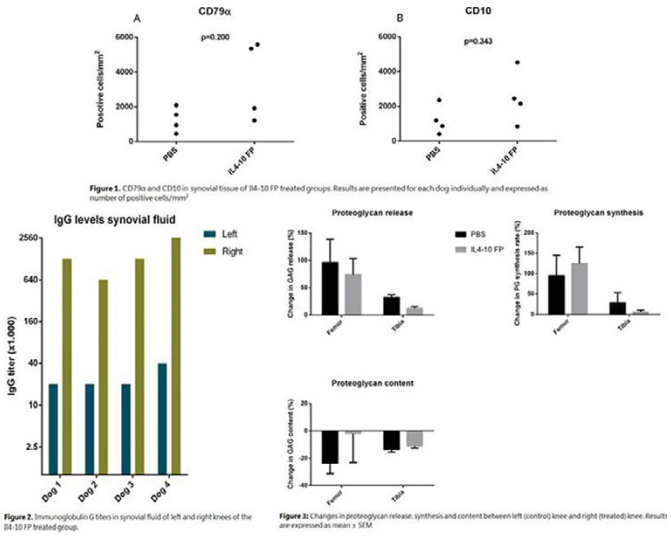

Figure 1. CD79α and CD10 in synovial tissue of Il4-10 FP treated groups. Results are presented for each dog individually and expressed as number of positive cells/mm²

Figure 2. Immunoglobulin G titers in synovial fluid of left and right knees of the Il4-10 FP treated group.

Figure 3: Changes in proteoglycan release, synthesis and content between left (control) knee and right (treated) knee. Results are expressed as mean ± SEM

Conclusions: Repetitive intra-articular injection of human IL4–10FP led to antibody formation in a non-inflammatory canine model of OA. Despite the immune response, proteoglycan turnover parameters were comparable between the two treatment groups, suggesting a beneficial effect of hIL4–10FP. This study also shows that it is not evident to use a human protein in a (canine) animal model, although this is often done. Instead, a species specific protein is warranted. Therefore a canine version of IL4–10FP will be developed to study its DMOAD activity in this model.

FRI0009 ACCELERATED DEVELOPMENT OF AGING-ASSOCIATED AND INSTABILITY-INDUCED OSTEOARTHRITIS IN 12/15-LIPOXYGENASE DEFICIENT MICE

L. Habouri, F. El Mansouri, Y. Ouhaddi, J.-P. Pelletier, J. Martel-Pelletier, M. Benderdour, H. Fahmi. *Medicine, CRCHUM, Montreal, Canada*

Background: 12/15-Lipoxygenase (12/15-LOX) catalyzes the generation of various anti-inflammatory lipid mediators, and has been implicated in several inflammatory and degenerative diseases. However, there is currently no evidence that 12/15-LOX has a role in osteoarthritis (OA).

Objectives: The aim of this study was to investigate the role of 12/15-LOX in the pathogenesis of OA

Methods: The development of aging-associated and destabilization of the medial meniscus (DMM)-induced OA were compared in 12/15-LOX-deficient (12/15-LOX-/-) and wild-type (WT) mice. The extent of cartilage damage was evaluated by histology. The expression of OA markers was evaluated by immunohistochemistry and RT-PCR. Cartilage explants were stimulated with IL-1α in the absence or presence of the 12/15-LOX metabolites, 15-HETE, 13-HODE or LXA4, and the levels of MMP-13, NO and PGE_2 were determined. The effect of LXA4 on the progression of OA was evaluated in WT mice.

Results: The expression of 12/15-LOX in cartilage increased during the progression of DMM-induced OA and with aging in WT mice. Cartilage degeneration was more severe in 12/15-LOX-/- mice compared to WT mice in both models of OA, and this was associated with increased expression of MMP-13, ADAMTS5, iNOS, and mPGES-1. Treatment of cartilage explants with 12/15-LOX metabolites, suppressed IL-1α-induced production of MMP-13, NO and PGE_2, with LXA4 being the most potent. Intra-peritoneal injection of LXA4 reduced the severity of DMM-induced cartilage degradation.

Conclusions: These data demonstrate an important role of 12/15-LOX in OA and suggest that activation of this pathway may provide a novel strategy for prevention and treatment of OA.

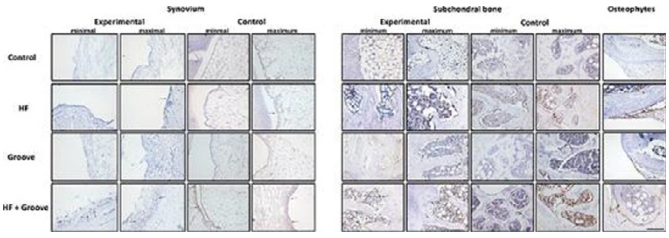
FRI0010 METABOLIC DYSREGULATION ACCELERATES JOINT DEGENERATION UPON MECHANICALLY INDUCED CARTILAGE DAMAGE, DRIVEN BY LOCAL INFLAMMATION; AN IN VIVO RAT STUDY



H.D. Visser[1,2], S. Mastbergen[2], A. Kozijn[2], K. Coeleveld[2], M.V. Rijen[1], H. Weinans[1,2,3], F. Lafeber[2]. *[1]Orthopaedics; [2]Reumatology & Clinical Immunology, UMC Utrecht, Utrecht; [3]Biomechanical Engineering, Delft University of Technology, Delft, Netherlands*

Background: Obesity is a well-known and important risk factor for osteoarthritis (OA). Moreover, obesity is highly associated with the metabolic syndrome (MetS)[1]. Growing evidence indicates that both OA and MetS are low-grade inflammatory conditions with elevation in systemic inflammatory markers. Nonetheless, it is unclear whether MetS low-grade inflammation induces OA, or contributes to the disease.

Objectives: To determine the contribution of metabolic alterations, induced by a High-Fat Diet (HFD), on the onset or progression of OA in a rat model of local cartilage damage.

Methods: Forty Wistar rats (12 weeks old, male), were randomly divided over two groups: twenty rats were fed a HFD (60% of the kcal contained fat:D12492i, Research Diets Inc.) while the other animals received a standard diet. After 12 weeks, local articular cartilage damage was induced on the femoral condyles, in one knee joint according to the groove model in 14 rats of each diet group. Remaining animals served as a control group in each arm. At week 24, serum was collected, subchondral bone was assessed by μCT scan (Quantum FX, PerkinElmar,USA), OA severity was evaluated by rat OARSI histopathology score and macrophage presence with CD68 immunostaining from histological sections was assessed.

Results: HFD feeding resulted in metabolic dysregulation as indicated by significantly increased metabolic parameters (weight, fasting insulin and total cholesterol) compared to the standard fed rats. HFD feeding alone resulted in mild cartilage degeneration (2±1.1 vs 0.58 ±0.7; p=0.06) and synovial membrane inflammation (1.0±0.6 vs 0.3±0.5; p=0.075) both subscores of the rat OARSI histopathology score. However, when HFD feeding is combined with the surgical model of applied local cartilage damage, OA severity is statistically significant increased compared to the local cartilage damage group on a standard diet (6.2±2.1 vs 3.4±1.4; p=0.001). Synovial membrane inflammation (1.3±0.9vs 0.5±0.5; p=0.011) and multiple large osteophyte formation, demonstrated by histology (0.9±1 vs 0.2±0.4; p=0.04) and quantified on μCT (328±349 μm^3 vs 7±14 μm^3; p=0.0001), contributes most to this increased OA severity. Immunohistochemical CD68 expression as observed on both the synovial membrane as well as in the subchondral bone and around the formed osteophytes can explain the increase in selected inflammatory parameters when groove surgery is combined with a HFD (Figure 1).

Conclusions: This study shows that a HFD induces metabolic alterations and increases the inflammatory state of the joint. This by itself does not result in severe OA. However, when adding a HFD to a mild cartilage damage model of OA, joint degeneration is significantly increased. This progression of joint degeneration appears to be driven mainly by inflammatory responses as demonstrated by an increased CD68 expression in both the subchondral bone and synovium membrane with increased osteophytosis. Hence, our findings indicate that systemic metabolic and subsequent inflammatory factors need an additional trigger to contribute to the progression of the OA.

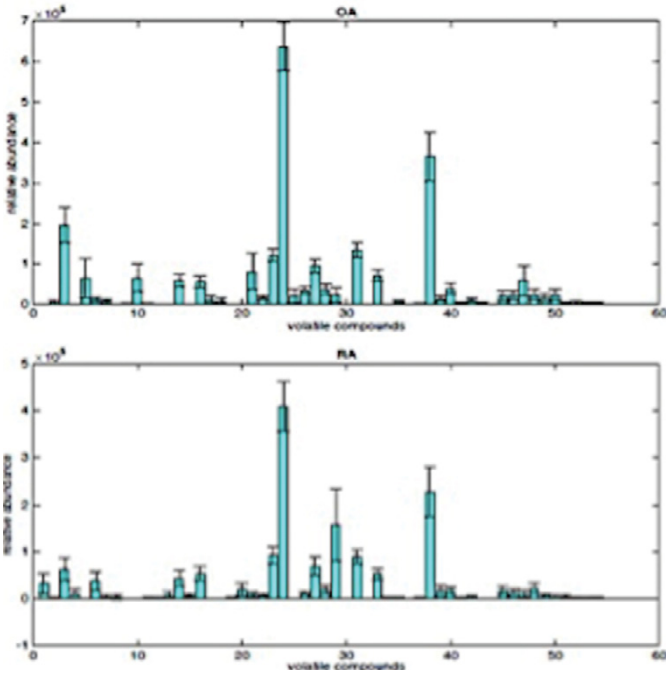
FRI0011 TARGETING NEUTROPHIL MICROVESICLES TO DAMAGED CARTILAGE USING ANTIBODIES TO POST TRANSLATIONALLY MODIFIED COLLAGEN II

L.M. Topping, H. Rhys, L. Norling, A. Nissim. *Biochemical Pharmacology, William Harvey Research Institute, Queen Mary University of London, London, United Kingdom*

Background: Microvesicles (MV) are double membrane-bound extracellular vesicles released from the plasma membrane of cells. MV derived from polymorphonuclear neutrophils (PMN) promote tissue protection, and have been demonstrated to penetrate cartilage during inflammatory arthritis and provide protection to the tissue [1].



Collagen type II (CII) is the most abundant protein found in cartilage. We have produced a single chain variable fragment (scFv) antibodies specific to CII modified by reactive oxygen species (ROS), namely anti-ROS-CII_{scFv}. Previously, we have demonstrated the ability of anti-ROS-CII_{scFv} to localise exclusively and deliver payload drugs to the arthritic joint in mice models of rheumatoid arthritis[2].
Objectives: To test our hypothesis that anti-ROS-CII association with MV might i) target delivery of MV to inflamed joint and/or ii) enhance the avidity of the scFv (several scFv can be loaded in each MV) and may thus increase localisation and enhance therapeutic efficacy.
Methods: Cy5.5 labeled Anti-ROS-CII_{scFv} were loaded on fluorescently labelled human PMN MV by aqueous energy dissemination using a sonic dismembrator [3–4]. Anti-ROS-CII_{scFv} MV incorporation was confirmed by Imagestream^X analysis. Anti-ROS-CII_{scFv} MV were tested by ELISA to assess the retention of antibody binding capabilities.
Results: Positive incorporation of Anti-ROS-CII_{scFv} upon MV was observed by flow cytometric analysis. ELISA demonstrated the ability of the anti-ROS-CII loaded MV to bind strongly to ROS-CII following incorporation into MV.
Conclusions: In this study, we have demonstrated a simple, efficient and cost effective way of antibody targeting that retains antibody function. Such technology has the potential to increase efficacy of existing therapies by ensuring specific targeting. Future *in vivo* studies will assess the ability of the Anti-ROS-CII_{scFv} MV to localise to arthritic joints.

FRI0012 ROLE OF VOLATILE COMPOUNDS RELEASED BY SYNOVIAL FLUID IN THE DIAGNOSIS OF OSTEOARTHRITIS AND RHEUMATOID ARTHRITIS OF THE KNEE JOINT

R. Capuano[1], M.S. Chimenti[2], F. Dini[1], A.C. Domakoski[3], E. Martinelli[1], P. Conigliaro[2], R. Paolesse[3], C. Di Natale[1], R. Perricone[2], A. Bergamini[2]. *[1]Department of Electronic Engineering; [2]Department of system medicine, Rheumatology, Allergology and Clinical Immunology; [3]Department of Chemical Science and Technology, University of Rome Tor Vergata, Rome, Italy*

Background: Synovial fluid (SF) receives protein contribution from the tissue around: cartilages, synovial membranes and bones. The presence of inflammation and oxidative stress alters the its chemical composition. In particular, inflammation modulates the release of volatile organic compounds (VOCs) that are the product of reactive oxygen species and free radicals excreted by mithocondria during oxydative stress (1). Articular inflammation plays a major role both in Osteoarthritis (OA) and Rheumatoid arthritis (RA), thus, the identification of specifics VOCs associated with inflammation in the SF may represent a suitable procedure to facilitate a diagnosis and a better characterization of these diseases. E-noses are versatile instruments based on arrays of partially selective gas sensors system that do not provide specific information about the individual molecules but can detect a large spectrum of VOCs to provide a discrimination among samples classified according to their chemical composition (VOC pattern) (2).
Objectives: Aim of this study was to prospectively investigate whether analysis of volatile compounds (VOCs) emitted from knee synovial fluid can identify differences between osteoarthritis (OA) and rheumatoid arthritis (RA).
Methods: VOCs Profile emitted by knee synovial fluid of 10 OA patients was compared with that of 25 RA patients using gas chromatography and mass spectrometry (GC-MS) and a gas sensor array (electronic nose) made by an ensemble of metalloporphyrins coated quartz microbalances. Patients' data are summarized in Table 1. Data were analyzed by principal component analysis (PCA), partial least squares discriminant analysis (PLSDA). Permutation analysis and area under curve (AUROC) of receiver operating characteristics (ROC) curves were used to characterize the classifier performance.
Results: GC-MS analysis identified 55 VOCs in the headspace of synovial fluids. The ANOVA analysis of the relative abundance indicated five VOCs significantly different between OA and RA. The abundance of five compounds allowed to identify OA with respect to RA with an accuracy of 82% (sensitivity: 0.90, specificity: 0.80, AUROC=0.92, 99.7% CI). The signals of the electronic nose sensors allowed to classify the studied subjects in OA or RA. In particular, OA patients could be distinguished from that of RA patients with an accuracy of 100% (sensitivity: 1, specificity: 1, AUROC=1, 99.9% CI).) (Figure 1). However, no single VOC was specific for OA or RA.

Figure 1. Mean and standard deviation of relative abundance of the 54 compounds.

Conclusions: This study shows that OA and RA patients exhibit qualitative and quantitative differences in the chemical compositions of knee synovial fluid. These differences may be attributed to five volatile compounds and can be detected by an electronic nose which may represent a suitable diagnostic tool for diagnosis and characterization of OA vs. RA.

FRI0013 ACPA-INDUCED MOBILITY OF PRIMED SYNOVIAL FIBROBLASTS: THE MISSING LINK BETWEEN ACPA-INDUCED BONE LOSS AND SYNOVIAL CHANGES

M. Sun[1], V. Joshua[1], A. Krishnamurthy[1], A.H. Hensvold[1], Y. Liu[2], S.B. Catrina[3], C. Ospelt[4], V. Malmström[1], J. Steen[1], M. Engström[1], H. Wähämaa[1], B. Rethi[1], A.I. Catrina[1]. *[1]Rheumatology unit, Department of Medicine, Karolinska Institute, Stockholm, Sweden; [2]Department of Rheumatology and Immunology, Peking University People's Hospital, Beijing, China; [3]Department of Molecular Medicine and Surgery, Diabetes Center Karolinska, Karolinska Institute, Stockholm, Sweden; [4]Centre of Experimental Rheumatology, Department of Rheumatology, University Hospital Zürich, Zurich, Swaziland*

Background: Anti-citrullinated proteins antibodies (ACPAs) injected in mice induce IL-8 dependent bone loss and arthralgia, but no synovial changes. We hypothesized that additional stimulus, sensitizing the synovial compartment to ACPA effects, is needed for the transition from bone to synovial pathology.
Methods: Synovial fibroblasts (SFs) were isolated from synovial tissue of RA patients by enzymatic digestion. Polyclonal ACPA and other non-ACPA IgGs were separated from peripheral blood of RA patients by affinity purification on a cyclic citrullinated peptide (CCP)-2 column. SF migration capacity was tested by scratch-assays in starved and non-starved cultures treated with ACPAs, with or without presence of IL-8. The results were evaluated by NIH ImageJ software. SF adhesion was analyzed by xCELLigence System Real-Time Cell Analyzer (ACEA bioscience). Peptidylarginine deiminases (PAD) expression and protein citrullination were evaluated by immunohistochemistry. The role of signaling pathways in the ACPA-mediated SF modulation was analyzed by using specific signal inhibitors and by monitoring protein phosphorylations using western blot.
Results: Serum starvation of SF increased citrullinated proteins and PAD expression. Starved but not non-starved SF showed an increased mobility index following polyclonal ACPA stimulation to a mean±SD fold increase of 2.6±0.5. This effect was abolished by PAD inhibition as well as ACPA blocking with citrullinated but not native fibrinogen. Exogenous pro-inflamamatory cytokines (IL-8 and TNF) synergistically increased SF mobility when added together with ACPA. Phosphorylation and inhibition studies of intracellular signalling pathways

in starved SF indicated an important role for PI3K-mediated signals in the ACPA-induced increase of SF mobility.
Conclusions: We demonstrated that additional stimuli (such as stress-induced citrullination and cytokine priming) were needed for SF to react upon ACPA stimulation. This is an indirect proof supporting the idea that a synovial insult that will normally resolve unobserved, might be essential for the transition towards chronic synovial changes in the presence of ACPA.

FRI0014 ANTIOXIDANT ROLE OF MICROVESICLES FROM ADIPOSE TISSUE-DERIVED MESENCHYMAL STEM CELLS IN HUMAN OSTEOARTHRITIC CHONDROCYTES

M. Tofiño-Vian[1], I. Guillen[1,2], M.D. Perez del Caz[3], A. Silvestre[4], M.J. Alcaraz[1]. *[1]Pharmacology and IDM, University of Valencia, Burjasot, Valencia; [2]Dpt. Pharmacy, CEU-Cardenal Herrera; [3]Department of Burn and Plastic Surgery, la Fe University Hospital; [4]Orthopaedic Surgery and Traumatology, Clinical University Hospital, Valencia, Spain*

Background: Oxidative stress results in the disruption of normal physiologic signaling leading to inflammatory changes, cartilage degradation and osteoarthritis (OA) progression (1). Recent advances have revealed the role of cell-derived microvesicles (MV) as a new mechanism of cell-to-cell communication with potential therapeutic applications. We have shown previously the antiinflammatory effects of human adipose tissue-derived mesenchymal stem cells (AD-MSC) conditioned medium in OA chondrocytes (2).
Objectives: We have isolated the MV fraction from the secretome of AD-MSC to investigate its activity on oxidative stress and inflammation in OA chondrocytes stimulated with interleukin (IL)-1β. Furthermore, we have characterized the MV protein content by proteomic analysis.
Methods: AD-MSC were isolated from fat of patients who undergone abdominoplasty (without obesity). MV were isolated from AD-MSC conditioned medium by differential centrifugation with size filtration. MV size and concentration were determined by resistive pulse sensing. Proteomic analysis was performed by LC-MS/MS, with ProteinPilot and PeakView software and the bioinformatic tools UNIPROT and PANTHER. OA chondrocytes were isolated from knee specimens of advanced OA patients, stimulated with IL-1β (10 ng/mL) and treated with MV ($3.6x10^7$ particles/mL) for 24h. Accumulation of 4-hydroxy-2-nonenal (HNE)-modified proteins and cytokines were measured by ELISA, NO production and MMP activity by fluorometry. Expression of specific proteins was evaluated by confocal microscopy or immunostaining. The data were analysed by ANOVA followed by Dunnett's test.
Results: MV reduced the accumulation of HNE-modified proteins, a biomarker of oxidative stress–induced lipid peroxidation, in OA chondrocytes stimulated with IL-1 β. The production of NO, IL-6 and TNFα, as well as MMP activity were also significantly reduced by MV treatment, whereas IL-10 and collagen II were enhanced. Proteomic analysis of MV showed high levels (5.89-fold upregulation) of peroxiredoxin 6 (Prdx6), a member of the peroxiredoxin family of antioxidant proteins which is downregulated in OA cartilage (3). MV treatment increased the expression of Prdx6 in OA chondrocytes suggesting a protective role against oxidative stress in these cells.
Conclusions: MV from AD-MSC downregulate the production of oxidative stress and inflammatory mediators in OA chondrocytes. Prdx6, an antioxidant enzyme, may contribute to the protective effects of MV. Our data support the interest of these MV to develop new therapeutic approaches.

FRI0015 MODELLING THE INITIAL PHASE OF FRACTURE HEALING IN VITRO – 3D BONE-LIKE MODELS OF ENDOCHONDRAL OSSIFICATION

M. Pfeiffenberger[1], A. Lang[1], I. Ponomarev[2], D. Barnewitz[2], F. Buttgereit[1], T. Gaber[1]. *[1]Charité University Hospital, Berlin, Germany, Berlin; [2]Research Center of Medical Technology and Biotechnology, Bad Langensalza, Germany*

Background: Immunosuppressed patients with ongoing inflammation experience more often difficulties in the process of fracture healing. Hereby amongst others immunomodulated activation of osteoclasts leads to augmented osteolysis. Most notably numerous cytokines and invading lymphocytes provide an inflammatory environment within the fracture gap, utmost during the first phase of fracture healing. Nowadays researchers, whilst investigating fracture healing, use small rodent models, facing the problem of translation towards the human system. Hence, there is a lack of valid *in vitro* models to examine the first phase of fracture healing. To test new therapeutic strategies, we develop a valid 3D-model using human cells to mimic the first phase of fracture healing *in vitro* which is characterized by the formation of a fracture hematoma, a hypoxic microenvironment as well as inflammation that initiate the healing cascade and the process of endochondral ossification.
Objectives: To develop 3D bone-like models displaying endochondral ossification.
Methods: As a first step, we focus on establishing 3D bone-like, matrix-free models consisting of human mesenchymal stromal cells (hMSC). MSC were isolated from bone-marrow samples of patients undergoing total hip replacement and characterized with regard to their typical surface markers as well as their differentiation potential towards osteogenic, adipogenic and chondrogenic lineage. 3D bone-like models were generated from micro-mass culture of hMSC (Research Center of Medical Technology and Biotechnology, Bad Langensalza). After initial maturation, 3D bone-like models were cultured under hypoxic conditions (37°C, 1% O2) in osteogenic medium for up to 3 months. *In vitro* μCT analyses were performed at day 0, after one and two months focusing on the total volume (TV) and bone volume (BV). Additionally osteogenic-relevant genes/factors (Runx2, SPP1, Dlx5, ALP, RANKL, SPI1) as well as exclusion markers (SOX9, PPARg2) were investigated after 3 months of cultivation using qRT-PCR. Finally, we implemented histological/immunohistochemical methods (van Kossa, ALP, Col1 staining).
Results: The 3D bone-like models achieved diameters between 0.5 and 0.7 and a thickness of 0.3 cm. *In vitro* μCt analysis revealed a high amount of mineralized tissue at day 0 and substantial increase in the bone volume (BV/TV) after cultivation. At day 0 *in vitro* μ Ct analysis implied mineralization mostly at the margin but penetrated the tissue within further cultivation. These results are also supported by positive van Kossa staining. Additionally, qRT-PCR results yielded higher expressions of *RUNX2, SPP1, SPI1, RANKL* and *DLx5*. Furthermore, immunohistochemistry showed high ALP-activity and CoII-expression.
Conclusions: Preliminary results of our study focusing at developing a 3D bone-like model displayed a promising trend towards modelling endochondral ossification *in vitro* by increased mineralization (*in vitro* μCt analysis and van Kossa staining), and upregulation of osteogenic-relevant *RUNX2* and *SPP1* expression as well as ALP-activity and CoII-expression. High expression of *SPI1* and *RANKL* could refer to osteoclast-like activities, which will be in the focus of further investigations. Finally, the complete 3D model will leave us the opportunity for studying the first phase of fracture healing under *in vitro* conditions.

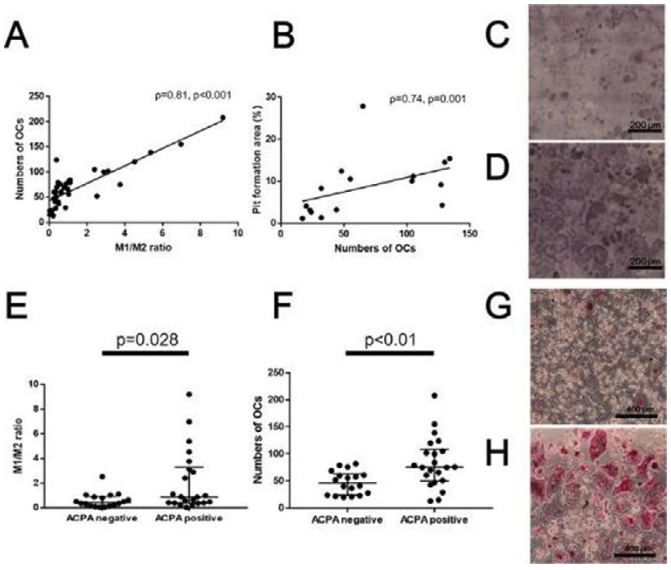
FRI0016 INVOLVEMENT OF RUNX-2 AND β-CATENIN SIGNALING IN THE PRODUCTION OF ADAMTS-7 AND ADAMTS-12 IN OSTEOARTHRITIC SYNOVIAL FIBROBLASTS

S. Pérez-García[1], I. Gutiérrez-Cañas[1], R. Villanueva-Romero[1], J. Leceta[1], J. Fernández[2], I. González-Álvaro[3], Y. Juarranz[1], R.P. Gomariz[1]. *[1]Cell Biology, Faculty of Biology, Complutense University of Madrid; [2]Traumatology Service; [3]Rheumatology Service, la Princesa University Hospital, Princesa Medical Research Institute, Madrid, Spain*



Background: Proteinases released from synovial membrane of osteoarthritis (OA) patients contribute to cartilage damage. We recently reported in synovial fibroblasts (SF) the expression of ADAMTS (a disintegrin and metalloproteinase domain with thrombospondin motifs)-7 and -12, involved in the destruction of the cartilage oligomeric matrix protein (COMP) (1). Signaling pathways regulating these ADAMTS are poorly understood. As Runx2 and β-catenin are two transcription factors involved in chondrocytes metabolism and OA pathology (2–5), we studied whether these factors are implicated in the production of ADAMTS-7 and 12 in SF. Moreover, we analyzed the induction by two inflammatory mediators present in OA joints: interleukin-1β (IL-1β), and fibronectin fragments (Fn-fs), previously described in ADAMTS expression (1).
Objectives: To elucidate the signaling pathways involved in the production of ADAMTS-7 and -12 in healthy donors (HD) - and OA-SF.
Methods: ADAMTS-7 and -12 were detected in HD- and OA-SF protein extracts by Western blot. Blockade experiments were performed after stimulation with IL-1β or 45-kDa Fn-fs. We used inhibitors for two mitogen-activated protein kinases (MAPKs), ERK and p38, implicated in the activation of Runx2, PD98059 and SB203580, respectively. We also used an inhibitor of Wnt/β-catenin signaling, DDK-1. Levels of ADAMTS-7 and -12 were analyzed by quantitative RT-PCR and ELISA in SF culture supernatants.
Results: Intracellular presence of ADAMTS-7 and -12 was confirmed in HD- and OA-SF, with higher levels of ADAMTS-7 in OA. After IL-1β or Fn-Fs stimulation, DDK-1 decreased ADAMTS-7 transcript in HD and OA-SF that was translated to a protein reduction in OA. Besides, ERK inhibitor decreased ADAMTS-12 mRNA and protein exclusively in OA-SF.
Conclusions: We reported that ADAMTS-7 protein expression is higher in OA-SF compared to HD confirming previous data at mRNA level (1). As DKK decreased ADAMTS-7, Wnt-β-catenin signaling seems to be implicated in its expression. By contrast, the expression of ADAMTS-12 is regulated by ERK, pointing to a possible implication of ERK-Runx2 axis, exclusively in OA-SF.

FRI0017 A NOVEL CONCEPT OF M1 AND M2 MONOCYTES IN RHEUMATOID ARTHRITIS: PRO-INFLAMMATORY MONOCYTE POLARIZATION IMBALANCE, ANTI-CITRULLINATED PROTEIN ANTIBODY AND OSTEOCLASTOGENESIS

S. Fukui[1], N. Iwamoto[1], R. Masuyama[2], K. Kosai[3], K. Yanagihara[3], A. Kawakami[1]. *[1]Immunology and Rheumatology; [2]Molecular Bone Biology; [3]Laboratory Medicine, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan*

Background: Monocytes can differentiate into either proinflammatory, microbicidal M1 macrophage or anti-inflammatory M2 macrophage subtypes. In addition to macrophages, regarding monocyte subsets, M1 monocytes and M2 monocytes mirroring the M1/M2 macrophage polarization concept were suggested.
Little is known regarding the relationships between osteoclastogenesis and M1/M2 monocyte subsets.
Objectives: We investigated the relationships among M1 monocytes, M2 monocytes, osteoclast differentiation ability and clinical characteristics in patients with rheumatoid arthritis (RA).
Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from RA patients and healthy donors, and we then investigated the number of M1 monocytes or M2 monocytes by fluorescence-activated cell sorting. We defined positive CD14, CD68 and CCR2 monocytes as M1 monocytes, and in separate tubes, we defined positive CD14, CX3CR1 and CD163 or CD206 monocytes as M2 monocytes.
We also obtained and cultured CD14-positive cells from PBMCs from RA patients and healthy donors to investigate osteoclast differentiation in vitro. We defined osteoclasts as tartrate-resistant acid phosphatase (TRAP) staining-positive cells with >3 nuclei. We counted the osteoclasts in the whole wells of a 96-well dish. Pit formation assays were performed to evaluate function of osteoclasts.
Results: Forty RA patients and 20 healthy donors were included. Twenty-two patients (55%) were ACPA-positive.
The median M1/M2 ratio was 0.59 (0.31–1.11, IQR). There were no significant differences between the RA patients and healthy donors.
There was a positive correlation between the M1/M2 ratio and the differentiated osteoclast number in vitro in RA patients (ρ=0.81, p<0.01) (A). The numbers of osteoclasts in vitro were significantly correlated with the area percentage of the pit formation area (ρ=0.74, p=0.001) (B).We demonstrated that the RA patients who had lower M1/M2 ratio and fewer osteoclasts (C) had smaller resorbed areas compared to the RA patients who had higher M1/2 ratio and greater numbers of osteoclasts (D).
The ACPA-positive patients had significantly higher M1/M2 ratio in vivo (p=0.028) (E) and significantly greater numbers of osteoclasts in vitro (p<0.01) (F) than the ACPA-negative patients. We show an ACPA-negative patient's osteoclasts in vitro (G) and those of an ACPA-positive patient (H).

Multivariable regression analysis revealed that the M1/M2 ratio was the sole significant contribution factor to in vitro osteoclastogenesis (β-coefficient 16.3, p<0.0001).
RA patients with M1/M2 ratio >1 (having relatively more M1 monocytes) had higher erythrocyte sedimentation rates (p=0.011) and C-reactive protein (p=0.032) than RA patients with M1/M2 ratio ≤1.
M1-dominant monocytes in vitro produced higher concentrations of IL-6 upon stimulation with lipopolysaccharide than M2 monocytes (p=0.032).
Conclusions: The M1/M2 ratio is strongly correlated with the in vitro differentiation of osteoclasts in patients with RA. The RA patients with positive ACPA had higher M1/M2 ratio and higher numbers of osteoclasts.
M1 and M2 monocyte subsets may become a new target of treatments for RA.

FRI0018 TARGETED INHIBITION OF JANUS KINASES ABATES IFN-GAMMA-INDUCED INVASIVE BEHAVIOR OF FIBROBLAST-LIKE SYNOVIOCYTES

T. Karonitsch[1], D. Beckmann[2], K. Dalwigk[1], R. Byrne[1], B. Niederreiter[1], J. Holinka[3], F. Sevelda[3], A. Korb-Pap[4], G. Steiner[1], J. Smolen[1], T. Pap[2], H. Kiener[1]. *[1]Division of Rheumatology, Medical Universitiy of Vienna, Vienna, Austria; [2]Institute of Experimental Musculoskeletal Medicine, University Hospital Muenster, Muenster, Germany; [3]Department of Orthopaedics, Medical Universitiy of Vienna, Vienna, Austria; [4]University Hospital Muenster, Muenster, Germany*

Background: Emerging evidence suggests that fibroblast-like synoviocytes (FLS) are key effector cells in rheumatoid arthritis (RA) and research into the mechanisms defining FLS activity in RA indicate that cytokines secreted by leukocytes play a crucial role. Nevertheless, the contribution of IFNγ, which is increased in rheumatoid synovitis, to the inflammatory synovial tissue reaction is not known.
Objectives: To explore the function of the T-cell cytokine IFNγ for mesenchymal tissue remodeling in RA, and to determine whether IFNγ-signaling controls the invasive potential of FLS.
Methods: To assess architectural responses, FLS were cultured in three-dimensional micromasses. FLS motility was analyzed in migration-, spreading- and invasion assays. Signaling events relevant to cellular motility were defined by western blots. Baricitinb and siRNA pools were used to suppress Janus Kinase (JAK) functions.
Results: Histological analyses of micromasses revealed unique effects of IFNγ on FLS shape and tissue organization. This was consistent with accelerated migration, pronounced actin and focal adhesion (FA) re-organization upon IFNγ stimulation. Since actin and FA dynamics and, thus, cell motility are integrated by the focal adhesion kinase (FAK), we next analyzed its activity. Indeed, IFNγ stimulation induced the phosphorylation of FAK-Y925, a phosphosite implicated in FAK-mediated cell migration. siRNA knockdown of JAK2, but not JAK1, abrogated FAK activation by IFNγ. Correspondingly, IFNγ-inudced FAK activation and invasion of FLS was abrogated by the JAK-inhibitor baricitinib.
Conclusions: Our study contributes insight into the synovial response to IFNγ and reveals JAK2 as a potential therapeutic target for FLS-mediated joint destruction in arthritis, especially in RA.

FRI0019 HUMAN MESENCHYMAL STROMAL CELLS REDUCE TNFα SECRETION OF ACTIVATED PBMC VIA CTLA-4

T. Gaber[1,2], K. Schönbeck[3], C.L. Tran[2], C. Strehl[1,2], E. Röhner[4], G. Matziolis[4], G.-R. Burmester[1], F. Buttgereit[1,2], P. Hoff[1,2]. *[1]Department of Rheumatology and Clinical Immunology, Charité – Universitätsmedizin Berlin; [2]German Rheumatism Research Center (DRFZ); [3]Department of Pediatric Oncology and Hematology, Charité – Universitätsmedizin Berlin, Berlin; [4]Department of Orthopaedics, Friedrich-Schiller-University, Jena, Germany*

Background: The inhibitory costimulatory molecule Cytotoxic T-Lymphocyte Antigen-4 (CTLA-4) plays a crucial role in conveying immune tolerance in both inflammatory disorders and regenerative processes such as bone healing. During regenerative processes, mesenchymal stromal cells (MSC) provide the building bricks for reestablishing structural integrity but do also control inflammation by their immunomodulatory activities under restrictive microenvironmental conditions such as hypoxia. Here, we hypothesize these cells to support the control of inflammation via CTLA-4 in order to facilitate tissue regeneration such as bone fracture healing.
Objectives: Therefore, we analyzed expression of CTLA-4 by human MSC and their ability to convey immune suppression.
Methods: MSC were isolated from bone marrow of patients undergoing total hip replacement and characterized (i) by surface marker staining using flow cytometry and (ii) via assessing their osteogenic and adipogenic differentiation potential. MSC were cultured under normoxic (~18% O_2) and hypoxic (<1.5% O_2) con-

ditions, respectively. CTLA-4 expression in MSC was analyzed on protein and on transcriptional levels by flow cytometry, immunoblotting, ELISA and by quantitative PCR, respectively. To assess the functionality of CTLA-4 expression, MSC were co-cultured with peripheral blood mononuclear cells (PMBC) isolated by density gradient centrifugation from venous blood of healthy donors. The cells were stimulated for 48h with PHA (5μg/ml) or left untreated and challenged using either CTLA-4-Ig or anti-CTLA-4-antibody, incubated under normoxic (~18% O_2) or hypoxic (<1.5% O_2) conditions and analyzed for TNFα secretion by suspension assay.
Results: The MSC phenotype of bone-marrow derived cells could be verified according to their surface marker expression and their osteogenic and adipogenic differentiation capacity. On transcriptional level, MSC express both the full-length and - to a higher extent - the soluble CTLA-4 isoforms with a higher mRNA abundance under normoxic as compared to hypoxic conditions. Extra- and intracellular analysis of CTLA-4 expression on protein level, demonstrated a significant shift of the whole MSC population ($p<0,01$). CTLA-4 expression and secretion by MSC was confirmed using immunoblot and ELISA, respectively. Co-culture of MSC with PHA-activated PBMC significantly reduced the amount of secreted TNFα ($p<0,05$) which could be reversed by anti-CTLA-4-antibody ($p<0,05$), under both normoxic and compared to hypoxic conditions, respectively.
Conclusions: We clearly demonstrate the existence of CTLA-4 on hMSC and its functionality with regard to the inhibition of PHA-induced TNFα secretion by PBMC. We also demonstrate that the expression of CTLA-4 (i) contributes to the immunomodulatory capacity of hMSC and (ii) supports the '*immune privileged*' status of these cells.

FRI0020 ALTERED BIOENERGETICS, MITOCHONDRIAL FUNCTION AND PRO-INFLAMMATORY PATHWAYS IN RA SYNOVIUM IN RESPONSE TO TOFACITINIB

C. Orr[1], T. Mcgarry[2], S. Wade[3], M. Biniecka[4], S. Wade[5], D.J. Veale[4], U. Fearon[5]. *[1]Translational Rheumatology, St. Vincent's University Hospital; [2]Clinical Medicine, Trinity Biomedical Sciences Institute; [3]Molecular Rheumatology, Trinity Biomedical Sciences Centre; [4]Center for Arthritis and Rheumatic Diseases, St Vincent's University Hospital; [5]Molecular Rheumatology, Trinity Biomedical Sciences Center, Dublin, Ireland*

Background: Rheumatoid arthritis (RA) is a chronic joint disease, characterised by synovial inflammation and a shift in the metabolic profile of cells to a more destructive phenotype. The JAK-STAT signalling pathway is implicated in the pathogenesis of RA.
Objectives: To examine the effect of tofacitinib, a selective JAK inhibitor, on synovial cellular bioenergetics, mitochondrial function and subsequent pro-inflammatory mechanisms in RA.
Methods: *Ex-vivo* RA whole tissue synovial explants and primary RA synovial fibroblasts (RASFC) and were cultured with tofacitinib (1μM) for 24–72hrs. RASFC metabolism was assessed by the XF24-Flux-analyser and mitochondrial mutagenesis was quantified using a mitochondrial random mutation capture assay. Mitochondrial function was assessed for reactive oxygen species (ROS), mitochondrial membrane potential (MMP) and mitochondrial mass (MM) using the specific cell fluorescent probes and differential gene expression by mitochondrial gene arrays or RT-PCR. Mitochondrial structural morphology was assessed by transmission electron microscopy. Lipid peroxidation (4HNE) was measured by specific ELISA. Dual staining of pSTAT3 and mitochondrial marker Cox-IV was demonstrated by confocal microscopy. The effect of tofacitinib (1μM) in RA synovial explant on markers of cellular bioenergetics and pro-inflammatory mediators, including cytokines and growth factors were quantified by ELISA, MSD multiplex assays and Real-time PCR.
Results: An initial screen demonstrated alterations in 18 key genes involved in mitochondrial function in RA synovial tissue in response to tofacitinib. Supporting this, tofacitinib inhibited ROS production, decreased the MMP and MM (all $p<0.05$), coupled with altered mitochondrial morphology. No effect observed for mtDNA mutations or 4HNE levels. Tofacitinib significantly inhibited the expression of glycolytic genes HIF1α, HK2, LDHA, GSK3A and PDK1 (all $p<0.05$) suggesting altered energy metabolism. This was paralleled by inhibition of baseline ECAR (glycolysis) with a concomitant increase in baseline OCR (oxidative phosphorylation), ATP production, maximal respiratory capacity and in the respiratory reserve in RASFC, confirming a bioenergetic switch in synovial cells in response to tofacitinib. Furthermore, we demonstrated co-localisation of pSTAT3 with Cox-IV in RASFC, suggested that in addition to nuclear transcription, pSTAT3 may also act as a mitoTF, regulating mitochondrial function directly. Finally, in RA whole tissue explants, tofacitinib significantly inhibited glycolytic genes HK2, GSK3A and PDK1 which was paralleled by a significant decrease in the spontaneous secretion of inflammatory mediators IL-6, IL-8, IL-1β, ICAM-1, VEGF, Tie2 and MMP1 (all $p<0.05$).
Conclusions: In this study, we describe a potential mechanism of action for tofacitinib, through reversing mitochondrial dysfunction and subsequent switch in cellular bioenergetics, in favour of a less glycolytic microenvironment leading to the reduction of inflammatory mediators. Thus, we have demonstrated that pathological cellular metabolism may be reversed by therapeutic treatment with tofacitinib.

FRI0021 INTRAVENOUS INFUSION OF FUCOSYLATED BONE MARROW MESENCHYME CELLS IN PATIENTS WITH OSTEOPOROSIS. PRECLINICAL STUDY IN A MURINE MODEL

N. Lozano-Rivas[1], V. Cabañas-Perianes[2], L. Linares-Ferrando[1], C. Marras Fernández-Cid[1], M.D. Lucas López[2], F.A. Martínez-Angosto[1], M. Blanquer[2], J. Martínez Ferrín[1], A. García Hernández[2], R. Sackstein[3], J.M. Moraleda[2]. *[1]Rheumatology; [2]Hematology, University Hospital Virgen de la Arrixaca, Murcia, Spain; [3]Harvard Medical School, Cambridge, United States*

Background: Osteoporosis is a skeletal disease characterized by systemic bone loss with an increased risk to bone fractures, associated with high morbidity and mortality[1]. Mesenchymal stem cells (MSC) from bone marrow (BM) are ideal candidates for the treatment of osteoporosis because they are able to differentiate to osteoblasts although its osteotropism is low[2]. Ex vivo fucosylation (adding a fucose residue) in α1–3 position of the CD44 antigen by use of the enzyme fucosyltransferase VI (FTVI) yields Hematopoietic cell E and L-selectin ligand (HCELL) in MSC increasing the affinity for E-selectin and osteotropism.
Objectives: To describe the safety and efficacy of human fucosylated MSC infused in an immunocompromised mice model (NOD/SCID).
Methods: 31 NOD/SCID mice were randomized to by tail vein injection: $1x10^6$ fucosylated MSC (n=13), $1x10^6$ MSC (n=14) or saline (n=4). Toxicities were evaluated by a clinical score, weight and histological assessment (heart, lung, liver, spleen, kidney, gonads, brain, bone and BM). RT-PCR array-based evaluation of the expression of human β-actin and β2-microglobulin genes was performed to study biodistribution of MSC. The maintenance of genetic integrity was evaluated during in vitro culture by karyotype. Additional samples of tibia and calota were to immunostained with a polyclonal Rabbit anti-human osteocalcina to demonstrate efficacy. Osteocalcin-positive cells were identified by a dark-brown cytoplasmic precipitate.
Results: There was no unexpected death and none of the mices had any acute toxicity. The histology of heart, liver, kidney, spleen, gonads, brain, bone and bone marrow was normal in all mice. There were localized areas of lung inflammation in 15%, 42% and 25% of mice infused with fucosylated MSC, MSC, and saline, respectively without significance differences (p=0.28). Biodistribution was normal with except one mice (infused with MSC non-fucosylated) showed an expression of human RNA β-actin and β2-microglobulin in the lung sample taken after 12 weeks of intravenous infusion. Osteoblasts were seen in 100% of mices infused with fucosylated MSC, in 62.5%% of animals infused with MSC alone, and none in saline group (p=0.01). NOD/SCID mice infused with fucosylated MSC presented a higher number of osteoblasts positive for osteocalcin in 10 high-power fields (400x) of tibia and calvarium sections that non-fucosylated (32 vs 5.5) (p=0.0082). Human osteoblasts were detected inside the bone from the fifth to the twelfth week after infusion.
Conclusions: Intravenous infusion of human fucosylated MSC is safe and effective in guiding the cells to bone with a higher potential to ossification in NOD/SCID mices that non-fucosylated MSC. These results are allowing to start a human clinical trial with intravenous fucosylated MSC as treatment in patients with osteoporosis.

Rheumatoid arthritis - etiology, pathogenesis and animal models

FRI0022 GLUTAMINE METABOLISM PLAYS A KEY ROLE IN THE CELL GROWTH OF FIBROBLAST-LIKE SYNOVIOCYTES IN RHEUMATOID ARTHRITIS

S. Takahashi, J. Saegusa, H. Yamada, Y. Ichise, I. Naka, T. Okano, K. Akashi, S. Sendo, Y. Ueda, A. Onishi, A. Morinobu. *Rheumatology and Clinical Immunology, Kobe University Graduate School of Medicine, Kobe, Japan*

Background: Many signaling pathways activated under inflammatory and hypoxic conditions have profound effects on intracellular metabolism to support cell growth and survival. The recent findings of cancer-specific metabolic changes, including increased glucose and glutamine consumption, has provided new therapeutic targets for consideration. The microenvironment in inflamed joints in RA is also characterized by hypoxia and low concentration of nutrients, and fibroblast-like synoviocytes from RA patients (RA-FLS) is known to have several tumor-like characteristics. However, the role of glucose and glutamine metabolism in the aberrant proliferation of these cells is unclear.

Objectives: We evaluated the role of these metabolic pathways in RA-FLS proliferation and in autoimmune arthritis in SKG mice.
Methods: The expression of glycolysis- or glutaminolysis-related enzymes was evaluated by real-time PCR and Western blotting, and the intracellular metabolites were evaluated by metabolomic analyses. The effects of glucose or glutamine on RA-FLS cell growth were investigated using glucose- or glutamine-free medium. Glutaminase 1 (GLS1) siRNA and the GLS1 inhibitor compound 968 were used to inhibit GLS1 in RA-FLS. Arthritis was induced in SKG mice by zymosan A injection. Compound 968 was used to study the effect of GLS1 inhibition on Zymosan A-injected SKG mice. Ki-67-positive cells were analyzed by immunohistochemistry.
Results: GLS1 expression was increased in RA-FLS, and metabolomic analyses revealed that glutamine and glutamate consumption were increased in RA-FLS. RA-FLS proliferation was reduced under glutamine-deprived, but not glucose-deprived conditions. Cell growth of RA-FLS was inhibited by GLS1 siRNA transfection or GLS1 inhibitor treatment. Silencing of GLS1 in RA-FLS did not affect IL-6 or MMP-3 production in supernatants. GLS1 expression in RA-FLS was not affected by pro-inflammatory cytokine stimulation. Compound 968 ameliorated the autoimmune arthritis and decreased the number of Ki-67-positive synovial cells in SKG mice.

Conclusions: Our findings suggested that glutamine metabolism plays an important role in regulating RA-FLS proliferation, without being affected by pro-inflammatory cytokine stimulation or affecting cytokine production, and may be a novel therapeutic target for RA.

FRI0023 ARTESUNATE CAN INHIBIT MIGRATION AND INVASION OF FIBROBLAST-LIKE SYNOVIOCYTES VIA SUPPRESSION OF MATRIX METALLOPROTEINASE 9 IN RHEUMATOID ARTHRITIS PATIENTS

J. Jing[1], T. Yan[2], J.-D. Ma[1], Y.-Q. Mo[1], L. Dai[1]. [1]*Rheumatology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University;* [2]*Zhongshan School of Medicine, Sun Yat-Sen University, Guangzhou, China*

Background: Evidences show that antimalarial agents of artemisinin and its derivatives such as artesunate may inhibit proinflammatory cytokines secretion from human rheumatoid arthritis (RA) fibroblast-like synoviocytes (FLS) in vitro. It has also been demonstrated that artesunate may ameliorate the symptoms of arthritis and prevent joint damage in collagen induced arthritis rat, which suggests that artesunate may be used for RA treatment. Recent studies show that RA-FLS is critical for joint destruction in RA because it can migrate and attach to cartilage and bone, and then invade them by secreting proteases such as matrix metalloproteinases (MMP) 9 in RA. However, effects of artesunate on migration and invasion of RA-FLS are poorly understood.
Objectives: To investigated the effects of artesunate on migration and invasion of RA-FLS and its underlying mechanism.
Methods: Synovial tissues were obtained from active RA patients as well as osteoarthritis (OA) and noninflammatory orthopedic arthropathies (Orth.A) patients and immumohistochemical (IHC) staining were performed for MMP9 expression. FLS isolated from these patients were analyzed for MMP9 exprssion by western blot (WB) and incubated with artesunate at different concentrations (0μM, 20μM, 40μM and 60μM), methotrexate (MTX, 10nM) or hydroxychloroquine (HCQ, 20μM) for 24 hours. Effects of artesunate on migration and invasion capacity were detected by transwell and wound healing assays. MMP9 and PI3K/Akt signal transduction protein expression after artesunate treatment was measured by WB.
Results: (1) IHC staining showed that synovial MMP9 expressed in lining and sublining area with intense nuclear and endochylema staining in RA synovium and the percentage of MMP9+ cells was significantly higher in RA (n=32) than that in OA (n=6) or Orth.A (n=6, Figure 1A, B).
(2) Migration and wound healing assays for 12 hours and invasion assay for 24 hours showed that RA-FLS possessed stronger capacity in migration and invasion than OA-FLS or Orth.A-FLS (Figure 1E, F). Artesunate inhabits the migration and invasion capacity of RA-FLS in a dose-dependent manner. MTX also has an inhibition effect on the migration and invasion of RA-FLS, but not HCQ (Figure 2A).
(3) MMP9 expression in RA-FLS was significantly higher than that in OA-FLS or Orth.A-FLS (Figure 1C, D). 40μM or 60μM artesunate markedly inhibited the expression of MMP9 in RA-FLS by WB (Figure 2B).
(4) WB analysis showed artesunate suppressed generation of phophso-Akt in a dose-dependent manner which indicated that Akt activity (phophso-Akt/Akt) in 40μM and 60μM artesunate treatment groups were significantly lower than that in untreated group (Figure 2C).

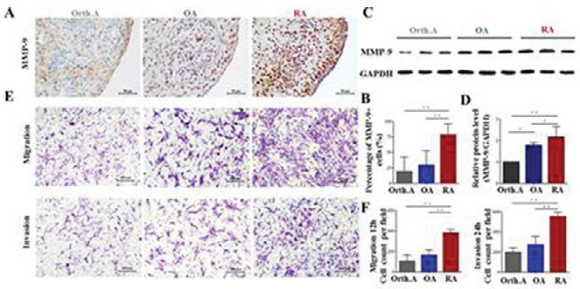

Figure 1 Expression of MMP9 in synovium and FLS and migration and invasion capacity of FLS. **(A and B)** IHC analysis showed that expression of MMP9 from RA patients was significantly higher than OA and Orth.A patients. Data are representative as means ± SD **P<0.01, ***P<0.001. **(C and D)** WB analysis showed that expression of MMP9 from RA-FLS was significantly higher than Orth.A-FLS or OA-FLS. Data were representative as means ± SD, *P<0.05, **P<0.01. **(E and F)** Transwell assays showed that RA-FLS possess stronger capacity of migration and invasion than OA-FLS or Orth.A-FLS. Data were representative as means ± SD, **P<0.01.

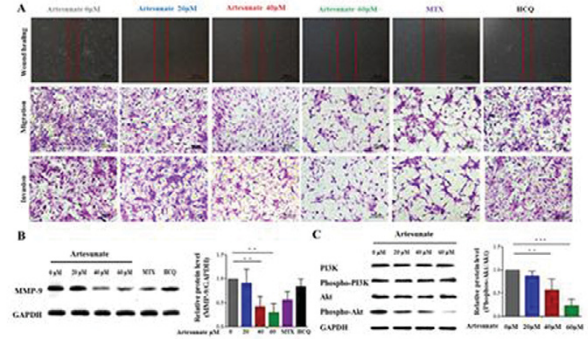

Figure 2 Effects of artesunate on the migration and invasion capacity and MMP9, PI3k/Akt pathway expression. (A) Artesunate inhabits the migration and invasion capacity of RA-FLS in a dose-dependent manner. **(B)** WB analysis of RA-FLS showed that MMP9 expression was siginificantly inhibited with treatment with 40 μM and 60 μM artesunate. **(C)** WB analysis showed that artesunate suppressed the expression of phophso-Akt in a dose-dependent manner. Bar are representative as means ± SD, **P<0.01, ***P<0.001.

Conclusions: Artesunate could inhibit the migration and invasion capacity of RA-FLS and the expression of MMP9 through suppressing Akt activity.

FRI0024 MICRORNA-146A CONTROLS LOCAL BONE DESTRUCTION BY REGULATING FIBROBLAST INDUCED OSTEOCLASTOGENESIS IN INFLAMMATORY ARTHRITIS

V. Saferding[1], A. Puchner[1], E. Goncalves-Alves[1], M. Hofmann[1], M. Bonelli[1], S. Hayer[1], H.P. Kiener[1], P. Georgel[2], M.I. Koenders[3], G. Steiner[1], J.S. Smolen[1], K. Redlich[1], S. Blueml[1]. [1]*Medical University of Vienna, Vienna, Austria;* [2]*Université de Strasbourg, Strasbourg, France;* [3]*Radboud University Nijmegen, Nijmegen, Netherlands*

Background: MicroRNA (MiR-) 146a plays an important role in the regulation of the innate immune response and has also been shown to suppress cancer development in myeloid cells. Although in late stages of arthritis elevated expression of miR-146a in synovial tissue of rheumatoid arthritis patients was detected, the level of this miRNA was found to be down regulated in early disease, but its role in the development of inflammatory arthritis is still elusive.
Objectives: The objective of this study is to analyse the role of miR-146a in arthritis by the use of a chronic arthritis disease model. We aim to investigate the regulatory function of this miRNA in the pathogenic stroma, therefore in fibroblasts but also in immune cells.
Methods: To induce arthritis we used the chronic inflammatory hTNFtg disease model, therefore we crossed miR-146a deficient into hTNFtg mice. Disease severity was assessed clinically and histologically. Blood of arthritis animals was analysed by flow cytometry. Serum cytokine levels were measured by Elisa. Synovial fibroblasts were isolated from metatarsal bones and their proliferation

was analysed histologically and by ^{3}[H]thymidine incorporation. RNA expression levels were measured by qPCR.
Results: When we crossed miR-146a$^{-/-}$ into hTNFtg mice, histological examination revealed a significant increase in synovial inflammation and even more striking a more than twofold increase in local bone destruction, due to increased generation of osteoclasts in the tarsal joints of miR-146a$^{-/-}$/hTNFtg mice compared to hTNFtg mice. Interestingly, systemic bone loss was comparable in hTNFtg compared to miR-146a$^{-/-}$/hTNFtg mice, suggesting an important local role of miR-146a. Indeed, we detected increased levels of IL-1β, TRAF6, a major target of miR-146a and RANKL, in addition the expression level of OPG was decreased locally in the paws of miR-146a$^{-/-}$/hTNFtg compared to hTNFtg mice. By performing bone marrow transplants we could indeed show a pivotal role for miR-146a in mesenchymal cells in controlling local osteoclast generation and bone destruction. Analysis of important mesenchymal cells in arthritis, the synovial fibroblasts exhibited enhanced proliferation if miR-146a is missing, *in vitro* and *in vivo*. Moreover stimulation of these cells with IL-1β, a prominent cytokine in arthritis which was also shown to be negatively regulated by miR-146a, led to increased expression of RANKL and TRAF6 in miR-146a deficient synovial fibroblasts.
Conclusions: These data demonstrate an important mitigating role of the miR-146a in inflammatory arthritis, most importantly in local bone destruction, by controlling mesenchymal expression of osteoclastogenic factors. This shows an important anti-inflammatory role of miR-146a, which might possibly be exploited for therapeutic purposes.

FRI0025 THE TAM RECEPTORS AXL AND MER PLAY A PROTECTIVE ROLE IN A TEMPORAL AND SPATIAL MANNER IN INFLAMMATORY ARTHRITIS

C.E.J. Waterborg[1], P.G. Través[2], S. Beermann[1], M.I. Koenders[1], P.L.E.M. van Lent[1], F. den Hoogen[1], P.M. van der Kraan[1], F.A.J. van de Loo[1]. *[1]Experimental Rheumatology, Radboudumc, Nijmegen, Netherlands; [2]Molecular Neurobiology Laboratory, The Salk Institute for Biological Studies, la Jolla, CA, United States*

Background: Rheumatoid arthritis (RA) is a chronic autoimmune disease characterized by an inflammatory response in synovial joints. One family of tyrosine kinase receptors that mediates a natural anti-inflammatory feedback mechanism are Tyro3, Axl and Mer (gene *Mertk*; TAM). The two principal TAM receptor protein ligands are Growth Arrest-Specific 6 (Gas6) and Protein S (Pros1). Targeting the TAM receptors by adenoviral overexpression of their ligands alleviates experimental arthritis pathology. Notably, Gas6 is a ligand for all three receptors but with the highest affinity for Axl. In contrast, Pros1 can only activate Tyro3 and Mer but not Axl. The role of the separate TAM receptors in RA has not been elucidated.
Objectives: To reveal the individual role of the TAM receptors Axl and Mer in an experimental inflammatory model of RA.
Methods: The KRN serum transfer model of arthritis was induced by two intraperitoneal injections of arthritic K/BxN serum in *Axl*$^{-/-}$, *Mertk*$^{-/-}$, *Axl*$^{-/-}$*Mertk*$^{-/-}$ and wild-type (WT) mice. Ankle joints were macroscopically scored for 7 days. At day 0, 2 and 7, ankle and knee joints were isolated for histology and immunohistochemistry.
Results: The course of arthritis was studied macroscopically and *Mertk*$^{-/-}$ mice had increased macroscopic ankle scores until day 4, compared to WT. Thereafter, *Axl*$^{-/-}$ mice developed more severe arthritis as compared to WT with enhanced macroscopic scores from day 4 until day 7. Histology of ankle joints showed significantly more inflammation in *Mertk*$^{-/-}$ mice at day 2 and increased arthritis pathology in *Axl*$^{-/-}$ mice at day 7, reflecting the macroscopic ankle scores. Histological analysis of ankle joints of *Axl*$^{-/-}$*Mertk*$^{-/-}$ mice at day 7 showed enhanced pathology compared to both *Axl*$^{-/-}$ and WT mice, indicating an additive effect of Axl and Mer deficiency. In contrast to the ankle joints at day 7, enhanced macroscopic scores and arthritis pathology in knee joints of *Mertk*$^{-/-}$ mice, compared to WT mice, was observed at both day 2 and day 7. *Axl*$^{-/-}$ mice had comparable knee joint pathology compared to WT. To explain the discrepancy of Axl involvement between ankle and knee at day 7, we examined Axl expression in synovium before the onset of arthritis. The cells in the lining layer of ankle synovium were strikingly Axl positive whereas the synovium of the knee joints was Axl negative.
Conclusions: The Mer receptor plays a protective role at the onset of arthritis whereas the Axl receptor takes over this role in established disease in ankle joints. In the knee joints, however, Mer but not Axl, plays a prominent protective role, likely due to the lack of Axl in naïve knee joints. These findings identify the TAM receptors Axl and Mer as protective in arthritis, dependent on the distinct anatomic location. It is tempting to speculate that these differences in topographically distinct synovial joints could, at least in part, explain the differential joint involvement in RA.

FRI0026 IDENTIFICATION OF MICRORNAS CANDIDATES SPECIFICALLY EXPRESSED IN MONOCYTES OF UNDIFFERENTIATED ARTHRITIS PATIENTS WHO PROGRESSED TO RHEUMATOID ARTHRITIS

W. Kurowska[1], E. Kuca-Warnawin[1], A. Radzikowska[1], M. Ciechomska[1], U. Skalska[1], M. Jakubaszek[2], B. Kwiatkowska[2], W. Maslinski[1]. *[1]Department of Pathophysiology and Immunology; [2]Early Arthritis Clinic, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland*

Background: Monocytes are central to the initiation of inflammation and bone erosion in rheumatoid arthritis (RA). Therefore, understanding of molecular pathways regulation in monocytes, especially at the early stages of RA development, is of crucial importance as it may help to predict the progression to the full-blown disease. However, mechanisms of gene regulation in monocytes, particularly the pattern of microRNA molecules (miRNAs) expression which can be involved in regulation of several cellular inflammatory pathways, in early phases of RA (i.e. at undifferentiated arthritis-UA stage) are not fully characterized.
Objectives: To investigate the pattern of miRNAs expression in monocytes that could serve as new biomarkers for RA development.
Methods: Magnetically sorted monocytes from peripheral blood of 19 patients with UA served for total RNA isolation. Total RNA from both sample and reference was labelled with Hy3 and Hy5 fluorescent label, respectively, using the miRCURY LNA microRNA Hi-Power Labeling Kit (Exiqon, Denmark). Fluorescent labelled samples and a reference RNA sample were hybridized to the miRCURY LNA microRNA Array 7th Gen (Exiqon), followed by scanning by Microarray Scanner System (Agilent Technologies, USA). The image analysis was carried out using ImaGene 9 Software (Exiqon).
Results: Out of 19 patients with UA enrolled in the study, 12 were verified for diagnosis after 4 years of follow-up (7 patients did not respond to the call for re-evaluation). Four patients developed full-blown RA (UA→RA patients), 6 patients remained still in UA phase (UA→UA patients), 1 patient was diagnosed as having Sjögren's Syndrome, and 1 undifferentiated connective tissue disease. Baseline characteristics of UA→RA *vs* UA→UA patients were as follows: age (median: 50.5, range 37–59 years *vs* 52.5, range 32–63 years), CRP (median: 9.0, range 1–22 mg/l *vs* 8.0, range 1–21 mg/l), ESR (median: 37.0, range 4–47 mm/h *vs* 34.0, range 15–44 mm/h) and swollen joins count (median: 3.0, range 1–9 *vs* 2.5, range 1–4). Following computational unsupervised analysis we identified 50 miRNAs in monocytes that have the largest variation across all patients samples. From these 50 miRNAs we selected several specific miRNA candidates on the basis of significantly changed expression in monocytes of UA→RA *vs* UA→UA patients. Predicted specific miRNAs targeting inflammatory genes in monocytes of UA→RA patients are: miR-483–3p (2.7-fold increased, p=0.009), miR-378d (4.1-fold decreased, p=0.0059), miR-371b-5p (52.8-fold increased, p=0.0381) miR-642b-5p (13.7-fold increased, p=0.0380), and miR-25–3p (1.8-fold decreased, p=0.0317). Additional validation of selected miRNAs candidates will be further performed using qPCR analysis.
Conclusions: Our results indicate new miRNA candidates differentially expressed in peripheral blood monocytes from patients with UA who subsequently developed RA, in comparison to patients with UA who did not progress to RA after 4 years follow-up.

FRI0027 TNF EXPRESSION ON MICROPARTICLES FROM RHEUMATOID ARTHRITIS PATIENTS MEDIATES ENDOTHELIAL CELL FATE IN VITRO

C. Barbati, M. Vomero, T. Colasanti, L. Novelli, F.R. Spinelli, F. Miranda, F. Ceccarelli, A. Finucci, C. Perricone, R. Scrivo, F. Conti, G. Valesini, C. Alessandri. *Department of Internal Medicine and Medical Specialties, Arthritis Center, Sapienza University of Rome, Rome, Italy, roma, Italy*

Background: Microparticles (MPs) are small membrane vesicles released by many cell types under physiological conditions or pathological situations. Increased levels of MPs have been reported in patients with autoimmune diseases, such as Rheumatoid Arthritis (RA) (1) which is characterized by an accelerated atherosclerosis. TNF, a key cytokine involved in the pathogenesis of RA, has been associated to RA atherosclerosis (2). Moreover, MPs could also have a role in endothelial dysfunction contributing to atherosclerosis in RA patients.
Objectives: The aim of this study was: 1) to evaluate TNF expression on RA-MPs. 2) to estimate the effects of serum RA-MPs on endothelial apoptosis and autophagy before and after in *vivo* and in *vitro* treatment with Etanercept.
Methods: 15 RA patients were recruited from the Department of Rheumatology Sapienza University of Rome at baseline (T0) and after three months of therapy (T3) with Etanercept. A fasting blood sample was collected and centrifuged two times to obtain platelet-poor plasma rich in MPs. The resulting plasma was stained with Ab anti-TNF and analized by flow cytometry. In *vitro* effects of serum RA-MPs on endothelium were evaluated using human umbilical vein cell line *EA.hy926*. Cells were treated with RA-MPs purified at T0 and T3 and with RA-MPs in *vitro* treated with Etanercept. At the end of experiments apoptosis and autophagy were evaluated. Apoptosis was analyzed by flow cytometry using a FITC-conjugated

annexin V and propidium iodide apoptosis detection kit; autophagy was analyzed by western blot for the expression level of the autophagic marker LC3-II.
Results: Our results showed that MPs purified from RA patients at T0 expressed TNF on their surface and this expression decreased after three months of treatment with Etanercept (p=0.04). Moreover, serum RA-MPs at T0 significantly increased, in a dose-dependent manner, both apoptosis and autophagy levels in the human umbilical vein cell line *EA. hy926* (p=0.005 and p=0.02, respectively *versus* untreated cells). After three months of treatment with Etanercept, RA-MPs were not able to significantly change these parameters.Finally, in *vitro* studies showed that RA-MPs treated with Etanercept significantly decreased surface expression of TNF and were no longer able to modulate apoptosis and autophagy in *EA.hy926* cells.
Conclusions: Our data demonstrate that serum RA-MPs express TNF on their surface. Moreover, both in *vivo* and in *vitro* treatment with Etanercept interfere with the ability of MPs to significantly modulate apoptosis and autophagy of endothelial cells by decreasing surface expression of TNF.

FRI0028 IN VITRO INHIBITORY EFFECT OF ETANERCEPT ON AUTOPHAGY: A NEW MECHANISM OF ACTION OF TNF INHIBITORS IN RHEUMATOID ARTHRITIS

M. Vomero[1], A. Capozzi[2], C. Barbati[1], T. Colasanti[1], V. Manganelli[2], F. Ceccarelli[1], F.R. Spinelli[1], F. Conti[1], C. Perricone[1], A. Finucci[1], M. Pendolino[1], R. Scrivo[1], R. Misasi[2], M. Sorice[2], G. Valesini[1], C. Alessandri[1]. *[1]Department of Internal Medicine and Medical Specialties, Arthritis Center, Sapienza University of Rome; [2]Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy*

Background: Autophagy has emerged as a key mechanism in the development, survival and function of immune cells and dysregulation of autophagic pathway has been implicated in the pathogenesis of several autoimmune diseases including Rheumatoid Arthritis (RA) (1). In fact, autophagy seems to be involved in the generation of citrullinated peptides, with consequent breakage of tolerance in RA (2). Moreover, increased autophagy levels and a reduction of apoptosis-related molecules have been found in RA synovial tissues and a role of TNF-induced autophagy in RA development has been proposed (3).
Objectives: The aim of the study was to analysed the effect of TNF and anti-TNF inhibitor etanercept on autophagy and apoptosis in cells involved in RA pathogenesis.
Methods: Peripheral blood mononuclear cells (PBMCs) and fibroblast-like synoviocytes (FLS) isolated from RA patients were cultured in presence of TNF and in serum deprivation state (starvation) for 4 hours and then etanercept, at concentration of 15 ug/mL, were added to the culture. After 24h cells were analyzed for levels of autophagy marker LC3-II by western blot and for percentage of annexin V-positive apoptotic cells by flow cytometry.
Results: As expected, TNF and starvation induced autophagy on RA PBMC and FLS in dose-dependent manner after 24h of culture ($p<0.05$ in all experimental conditions). Moreover, the adding of etanercept caused a significant reduction of LC3-II levels (p=0.004) and an increase of apoptosis rate (p=0.002) after both pro-autophagic stimuli ($p<0.05$).
Conclusions: We demonstrated for the first time an inhibitory effect of etanercept on autophagy activation of cells involved in RA pathogenesis. In addition, our findings suggest a crucial role of autophagy in RA cells survival.

FRI0029 THE OXYGEN SENSOR PHD1 IS AN INDISPENSABLE REGULATOR OF ARTHRITIS DEVELOPMENT

K. De Wilde[1,2], D. Gaublomme[1,2], J. Coudenys[1,2], F. Windels[1,2], S. Van Welden[3], A. De Muynck[4], D. Elewaut[1,2]. *[1]Department of Rheumatology, Department of Internal Medicine, Ghent University; [2]Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center; [3]Department of Gastroenterology; [4]Department of Physics and Astronomy, Ghent University, Ghent, Belgium*

Background: Oxygen supply is a fundamental requirement for all living tissues. Some tissues such as articular joints are characterized by a physiological state of hypoxia. Interestingly, under conditions of inflammation such as in arthritic disease, this level of hypoxia is even further enhanced. However, the functional significance of these observations and the molecular mechanisms involved remain poorly characterized to date. Our goal was therefore to examine the role of 3 known oxygen sensors, prolyl hydroxylase domain (PHD) proteins: PHD1, PHD2 and PHD3. They are enzymes whose function is essentially controlled by oxygen. Their expression pattern varies between either of them and all of them have been ascribed specific roles in a myriad of biological processes. [1]
Objectives: Our goal was to examine the role of oxygen sensors PHD1, PHD2 and PHD3 in preclinical models of rheumatoid arthritis, and to delineate the cellular source involved.
Methods: We subjected the collagen antibody induced arthritis (CAIA) model (resembling rheumatoid arthritis) to hypoxic (10% O_2) and normoxic conditions (21% O_2), respectively. Furthermore, the CAIA-model was induced in mice with germline deficiency of the specific PHD's and in mice with a myeloid cell-specific PHD1 deficiency versus controls. Arthritis development was assessed by clinical scoring of paw swelling, histopathology of knee joints and μCT.
Results: Mice kept in hypoxic conditions during CAIA experiments showed markedly less arthritis (both by clinical and histopathological assessment) compared to mice in normoxic conditions. Furthermore, we demonstrated that PHD1 knock-out (KO) mice had significantly less joint inflammation compared to wildtype mice. PHD1 KO mice were also protected against inflammation induced bone loss as evidenced by μCT. By contrast, no differences were found between PHD2 heterozygous (PHD2 KO mice are not viable) or PHD3 KO mice and littermate controls. Because myeloid cells are considered critical effector cells upon passive transfer of arthritogenic antibodies in the CAIA model we also generated myeloid cell specific ko mice ($PHD1^{myelKO}$). Of interest, $PHD1^{myelKO}$ mice developed less arthritis compared to wildtype mice and were protected against inflammation induced bone loss.
Conclusions: Our data are consistent with a new paradigm that the oxygen sensor PHD1 is a critical regulator of myeloid cell function in arthritic disease. Overall, the data suggest that PHD1 is a potential target in the treatment of arthritis.

FRI0030 SYNOVIAL MAST CELLS IDENTIFY PATIENTS WITH A SEVERE PHENOTYPE IN A COHORT OF DMARD NAÏVE PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

F. Rivellese[1], F. Humby[1], A. Nerviani[1], S. Pagani[1], D. Mauro[1], A. de Paulis[2], G. Marone[2], C. Pitzalis[1]. *[1]Centre for Experimental Medicine & Rheumatology, William Harvey Research Institute, Barts and the London School of Medicine & Dentistry, London, United Kingdom; [2]Department of Translational Medical Sciences (DiSMeT) and Center for Basic and Clinical Immunology Research (CISI), University of Naples Federico II, Naples, Italy*

Background: Mast cells (MCs) are among the immune cells participating to the inflammatory response in Rheumatoid Arthritis (RA), but their exact contribution to disease development and progression is unclear.
Objectives: To evaluate the presence of MCs in the synovia of patients with early RA naïve to treatment and their correlation with baseline clinical phenotype, response to DMARDs and disease progression.
Methods: DMARD-naïve patients with early (<12 months) RA (n=99) fulfilling the 2010 ACR/EULAR criteria were recruited as part of the Pathobiology of Early Arthritis Cohort at Barts Health NHS Trust. Sections of paraffin embedded synovial tissue obtained by ultrasound-guided synovial biopsy were stained by immunohistochemistry for CD117 (c-kit) and patients were classified into MC+ and MC- groups. Differences in clinical parameters at baseline and 6 months and progression in radiographic damage at 12 months were evaluated. The expression of Receptor Activator of Nuclear factor Kappa-B Ligand (RANKL) by human primary MCs was assessed by western blot and immunofluorescence.
Results: The presence of synovial CD117+ MCs was significantly associated with highly active disease (DAS28, ESR, CRP, tender and swollen joint counts, $p<0.05$). At the 6 months follow-up, there were no differences in terms of response to treatment with synthetic DMARDs (e.g. DAS28 remission 38.8% in MC+ vs 42.9% in MC-, p=0.725). Nonetheless, MC+ patients showed a significantly higher prevalence of radiographic progression at 12 months (progressors/non progressors 13/38 in MC+ vs 0/28 in MC-, p=0.003, n=79). When progressors were compared with non progressors, there were no differences in clinical parameters at baseline (inflammatory markers, DAS28, ACPA or RF positivity). Because of the observed association of MCs with radiographic progression, we looked for mechanisms that could link MCs to bone erosions, and we found that human primary MCs express the osteoclast activator RANKL.
Conclusions: We show that synovial MCs identify patients with a severe clinical phenotype in a DMARD-naïve early RA cohort. In particular, despite a similar rate of response to DMARDs at 6 months, the presence of synovial MCs at baseline was significantly associated with radiographic progression at 12 months. As clinical parameters at baseline showed no association with radiographic

progression, our work suggests that the analysis of synovial MCs could help to identify patients at high risk of progression in radiographic damage, warranting further investigations to confirm the association of MCs with the development of joint damage and their direct contribution to bone erosion, possibly via a RANKL-mediated activation of osteoclasts.

FRI0031 DNA OXIDASE ENZYME TET3 EXACERBATES SYNOVIAL INFLAMMATION AND BONE DESTRUCTION

A. Kawabe[1], K. Naknao[1], K. Sakata[1,2], K. Yamagata[1], S. Nakayamada[1], Y. Tanaka[1]. [1]*The First Department of Internal Medicine, University of Occupational and Environmental Health, Japan, Kitakyushu;* [2]*Mitsubishi Tanabe Pharma, Yokohama, Japan*

Background: In rheumatoid arthritis (RA), fibroblast-like synoviocytes (FLSs) play an important role in joint destruction. We have shown a disease-specific DNA methylation pattern in RA patient-derived FLSs (RA FLSs). In 2009, active demethylation enzymes, Ten-Eleven translocation (TET) 1/2/3, were demonstrated. However, little is known about the role of the TET protein family in RA FLSs

Objectives: The aim of this study was to examine the role of the TET protein family in the pathological process of RA from an *in vivo* perspective with a mouse model, and from an *in vitro* perspective using human synovial tissue.

Methods: K/BxN serum-induced arthritis was induced in *Wild-type* (*WT*) and TET3 heterozygous-deficient (*TET3*$^{+/-}$) C57BL/6 mice. Synovial tissues were obtained from patients with RA and Osteoarthritis (OA) who had received joint replacement surgery. FLSs were transfected with siRNA and knocked down (KD). Gene expression was determined by qPCR and protein expression by western blot and immunostaining. 5-hydroxymethylcytosine (5hmC) was determined by dot blot and hMeDIP assay. Cell migration were assessed using a scratch assay.

Results: TET3 was expressed in particularly infiltrative synovial areas in K/BxN-*WT* mice. The arthritis score of K/BxN-*TET3*$^{+/-}$ was not increased after day 8. Histologically, synovial inflammation and proliferation, and bone destruction were significantly suppressed in the K/BxN-*TET3*$^{+/-}$ mice. In the RA synovial membrane, TET3 was more highly expressed in RA than in OA. In cultured FLSs, the expression of *TET3* mRNA tended to be slightly higher in RA than in OA. After 2 h of stimulation with various cytokines, the expression level of *TET3* mRNA was increased by stimulation with TNFα, interleukin (IL)-1, or IL-17. Assessment of the protein expression of TET3 after stimulation by TNFα using extracted intranuclear proteins of FLSs showed an increase in the expression level of TET3 protein over time. Similarly, the expression level of 5hmC was increased after stimulation by TNFα. Next, the function of TET3 in the FLSs was examined using TNF stimulation follwoing TET3-KD. A scratch assay of cell migration and invasion demonstrated that the TNFα-dependent migration and invasion of FLSs was completely inhibited by TET3-KD. The protein levels of CCL2 were strongly induced by TNFα stimulation, and inhibited by TET3-KD. In addition, flow cytometry of the expression of intercellular adhesion molecule-1 (ICAM-1) revealed that the expression of ICAM-1 was TNFα-dependent and was inhibited by TET3-KD. Assessment of gene expression changes showed that the induction of TNFα-dependent *CCL2* and *ICAM-1* mRNA expression was significantly inhibited by TET3-KD. Subsequently, although 5hmC level on the *ICAM-1* promoter was increased by TNF stimulation, it was strongly inhibited by TET3-KD.

Conclusions: *In vivo*, the arthritis and bone erosion were significantly decreased in the *TET3*$^{+/-}$ mice. *In vitro*, TET3 was induced by inflammatory cytokine stimulation, and TET3 knockdown inhibited the cytokine-induced expression of CCL2 and ICAM-1 in RA FLSs. In addition, hydroxymethylation of the ICAM-1 promoter region was dependent on TET3. These results suggest that continuous exposure to inflammatory cytokines results in leaving an inflammatory memory in FLS in a TET3-dependent manner, thereby promoting pannus formation and increasing the probability of joint destruction.

FRI0032 CURATIVE EFFECT OF CAMELLIA SINENSIS (CS) AGAINST OPPORTUNISTIC INFECTION IN VULNERABLE ANIMAL MODEL OF RHEUMATOID ARTHRITIS

A. Tanwar[1,2], R. Chawla[2], M. Basu[2], R. Arora[3], H.A. Khan[1]. [1]*Heavy metal and Clinical Toxicology Laboratory, Department of Medical Elementology and Toxicology, Jamia Hamdard, New Delhi;* [2]*Division of CBRN Defence, Institute of Nuclear Medicine and Allied Sciences (INMAS);* [3]*Office of DG (LS), Defence Research and Development Organisation, DRDO Bhawan, Delhi, India*

Background: Rheumatoid arthritis (RA) is an autoimmune disease characterised by chronic inflammation of pro-inflammatory cytokines. Opportunistic infection plays a significant role in loss of tolerance to citrullinated proteins along with inflammatory progression of RA. Due to the immunosuppressive property of anti-rheumatic drugs, the patients of RA become highly vulnerable to microbial infections [1]. Thus, the present study employed an *in vivo* animal model to explore the holistic remedies for the effective treatment of RA.

Objectives: To study the immunomodulatory effect of *Camellia sinensis (Cs)* against inflammatory disorder

Methods: Study utilized collagen induced arthritis (CIA) rat model with *Salmonella typhimurium* (10^8 CFU/ml, p.o) as an opportunistic infectious agent which was introduced to enhance disease severity (on 21st day)[2]. Treatment with Cs at oral dose 400 mg/kg/body wt. (p.o) was started from 21st day for 14 days to explore its curative, anti-edematogenic effect and quantitation of oxidative stress markers. To validate biochemical changes, the histopathologiy and level of cytokines were also studied in joint tissue followed by 7 Tesla Magnetic Resonance Imaging (7T MRI).

Results: Treatment groups significantly restored the level of oxidative stress markers (Table-1). Furthermore, there was significant reduction in the number of bacterial colonies in blood and fecal matter in the treatment group as compared to infected group, while pro-inflammatory cytokine level of TNF-α, IL-1, IL-6 was significantly lower in joint tissue. Histological & 7T-MRI changes in the treatment group included significant reduction of cartilage erosion & pannus formation and there were no signs of inflammation in the small intestine as compared to arthritic and infected group (Figure 1).

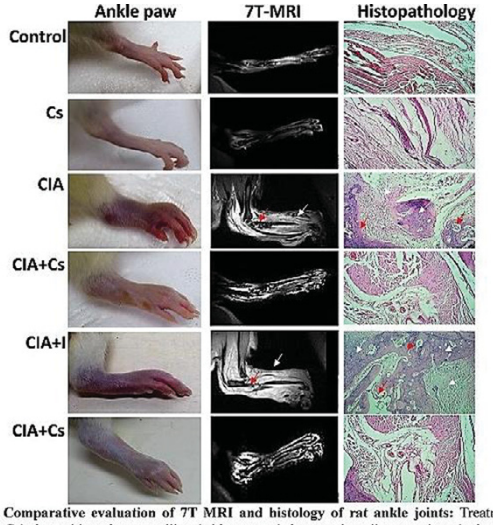

Fig 1: Comparative evaluation of 7T MRI and histology of rat ankle joints: Treatment group (CIA+Cs, CIA+I+Cs) showed less tissue swelling (white arrows), bone and cartilage erosions (red arrows) as compared to infected groups (CIA , CIA+I) and there was no significant change in between control and Cs only groups.

Conclusions: The present study demonstrated that Cs has anti-inflammatory effect and could also be used as potent immunomodulator to manage RA.

FRI0033 IMPORTANT ROLE OF CD11C+ DENDRITIC CELLS IN INFLAMMATORY ARTHRITIS

A. Puchner[1], V. Saferding[1], M. Bonelli[1], H. Leiss[1], R. Pfeifle[2], G. Kroenke[2], M. Koenders[3], J. Smolen[1], K. Redlich[1], S. Blüml[1]. *[1]Medizinische Universität Wien, Wien, Austria; [2]University Hospital Erlangen, Erlangen, Germany; [3]Radboud University Nijmegen Medical Center, Nijmegen, Netherlands*

Background: Dendritic cells (DCs) are important antigen presenting cells (APCs) and therefore they play an important role in bridging the innate and the adaptive immune response. DCs can be divided in different subsets with specific functions. As powerful APCs, DCs are thought to play an important role in the induction of autoimmune diseases such as rheumatoid arthritis. However, the active role of DCs in joint inflammation is not known yet.
Methods: We analyzed histological sections of K/BxN serum transfer arthritis as well as hTNFtg arthritis for the presence of $CD11c^+$ cells by immunohistochemistry. We also performed synovial biopsies and analyzed the cellular composition of the inflammatory infiltrate with respect to DCs. We used CD11c-diphteria toxin receptor (DTR) transgenic mice, which express the human diphtheria-toxin receptor under the CD11c promoter, allowing for specific depletion of $CD11c^+$ cells by administration of diphtheria toxin (DT). K/BxN serum transfer arthritis was induced, and mice were given either DT or PBS or in wt and BARF3 deficient mice. In addition CD11c DTR mice were crossed into hTNFtg animals and also received either DT or PBS. The severity of arthritis was determined clinically and histologically.
Results: We show that $Cd11c^+$ cells are present in significant numbers in the synovia of K/BxN and TNF driven arthritis. Both $CD8^+CD11c^+$ and $CD11b^+CD11c^+$, can be found in synovial tissue. Upon depletion of CD11c+ cells clinical signs of K/BxN serum transfer arthritis were significantly reduced. Histological analysis found reduced synovial inflammation after the depletion of $CD11c^+$ cells in K/BxN arthritis. In addition, local bone destruction and the number of osteoclasts was also significantly reduced. Analysis of K/BxN arthritis in wt mice and $BATF3^{-/-}$ mice, which lack a subset of DCs, namely $CD8^+CD11^+$ DCs, revealed no difference in arthritis severity between the two groups. In addition to K/BxN arthritis, we found that also in TNF-driven arthritis depletion of $CD11c^+$ cells led to a striking reduction of synovial inflammation and a complete depletion of osteoclasts.
Conclusions: These data show that in addition to initiating an adaptive immune response, $CD11c^+$ dendritic cells, are also involved in innate effector mechanisms of inflammatory arthritis. Especially $CD11b^+CD11c^+$ and monocyte derived inflammatory seem to play a role in inflammatory arthritis, suggesting that they could be an important therapeutic target for patients suffering from inflammatory arthritis.

FRI0034 ADALIMUMAB REDUCES CXCR4 EXPRESSION DURING INFLAMMATORY ARTHRITIS AND IN FIBROBLAST-LIKE SYNOVIOCYTES AND OSTEOCLASTS UNDER CHRONIC TNF EXPOSURE

B.P. Harvey[1], L. Li[2], M. Konrad[2], H. Knight[3], S. Westmoreland[3], M. Ruzek[2], Z. Kaymakcalan[1]. *[1]Biologics; [2]Translational Research; [3]Immunology Pharmacology, Abbvie Bioresearch Center, Worcester, United States*

Background: The CXCL12/CXCR4 chemokine axis has been implicated in the pathogenesis of RA. The expression of this chemokine and receptor has been shown to be increased in RA synovium, and moreover, CXCR4 levels in synovium have been correlated with joint destruction in RA patients.
Objectives: Given that high levels of CXCR4 are associated with RA pathogenesis, we sought to determine whether CXCR4 levels are altered by adalimumab (ADA) both *in vivo* in RA patients and in the human TNF transgenic mouse model (huTNF Tg197) of arthritis, as well as *in vitro* with RA fibroblast-like synoviocytes (RA-FLS) and human osteoclast precursors (OCP) following TNF exposure. In addition, we investigated the role of CXCR4 in human osteoclastogenesis (OCgenesis) under chronic TNF exposure.
Methods: Public DNA microarray data of synovial tissue from ADA treated RA patients was analyzed for changes in the expression level of various chemokines and their cognate receptors. PBMC populations from ADA treated RA patients taken at baseline, wks. 4 & 12 were assessed by CyTOF for CXCR4. IHC staining was performed on formalin paw sections from wk. 13 placebo control and ADA treated (1 mg/kg i.p.) huTNF Tg197 mice to evaluate CXCR4 expression in various pannus-associated cells. To assess the role of TNF and concomitant ADA treatment on human cultures *in vitro*, CXCR4 RNA expression was evaluated in RA-FLS treated with conditioned media from PBMCs +/-ADA for 6 hrs., and CXCR4 protein on OCP by flow cytometry in response to 72 hr. M-CSF+RANKL+/-TNF+/-ADA. To demonstrate the role of CXCR4 in OCgenesis, OCP were cultured for 6 d. in M-CSF+RANKL+/-TNF following 30 min. pretreatment with CXCR4 neutralizing antibody. OC maturation and activity were assessed by measuring TRAcP 5b activity and CTX-I release, respectively.
Results: Preliminary microarray data analysis of RA synovial tissue demonstrated that active RA patients over-expressed CXCR4 while CXCR4 was significantly normalized (two-fold reduction) in the responders to ADA therapy. In addition, CyTOF analysis of PBMC from ADA treated RA patients indicated a significant 2-fold reduction from baseline in CXCR4 expression on B cells with a modest trend of reduction on CD4+ T cells by wk. 4. In huTNF Tg197 mice, CXCR4 expression in the inflamed pannus (most notably in FLS, lymphocytes and OC) was also decreased by ADA therapy. *In vitro* human cultures of similar cell types including RA-FLS and OCP were subjected to conditioned media or TNF, respectively, and found to express higher levels of CXCR4 that was reduced with concomitant ADA treatment. Finally, antibody-mediated blockade of CXCR4 on human OCP decreased both TNF-enhanced OC maturation and activity.
Conclusions: Our findings demonstrate that ADA therapy reduces CXCR4 expression *in vivo* both in RA patient PBMCs and in the pannus of huTNF Tg mice with inflammatory arthritis especially in lymphocytes, FLS and OC. Similar results were also observed with our *in vitro* human cultures of equivalent cell types. More importantly, we've shown that inhibition of CXCR4 can reduce TNF-enhanced OCgenesis *in vitro*, suggesting that CXCR4 may be a contributing factor to TNF-mediated osteolysis in RA.

FRI0035 SPECIFIC MONOCYTE SUBSETS IN PATIENTS WITH RHEUMATOID ARTHRITIS ARE ASSOCIATED WITH THE PROGRESSION OF THE DISEASE ALONG WITH THEIR AUTOIMMUNE AND PRO-ATHEROTHROMBOTIC PROFILE

N. Barbarroja[1], P. Ruiz-Limon[1], C. Pérez-Sánchez[1], Y. Jimenez-Gomez[1], M.C. Abalos[1], P. Segui[2], R. Ortega[1], E. Collantes[1], A. Escudero[1], M. Alarcon-Riquelme[3], L. Lelann[4], C. Jamin[4], J.O. Pers[4], C. Lopez-Pedrera[1] on behalf of PRECISESADS Clinical Consortium. *[1]GC-5/Rheumatology; [2]Radiology, IMIBIC/Reina Sofia Hospital/University of Cordoba, Cordoba; [3]Genetic, Centro de Genomica e Investigación Oncológica (GENYO), Granada, Spain; [4]Université de Brest, Brest, France*

Background: Circulating monocytes play a key role in the pathogenesis of cardiovascular disease (CVD). Three monocyte subsets have been described based on their CD14 and CD16 expression profiles, with different actions in vascular pathology. The distribution of these monocyte subsets and their inflammatory profile associated with CVD in rheumatoid arthritis (RA) remain unknown.
Objectives: This study, developed within the Innovative Medicines Initiative Joint Undertaking (IMI JU) project PRECISESADS framework, aimed at: 1) determine which of the two CD16+ monocyte subpopulations is expanded in RA patients and to investigate their possible role in disease pathogenesis. 2) Functionally characterize the CD16+ monocyte subsets in RA patients and analyze their role in the pro-atherothrombotic profile associated to RA.
Methods: The frequencies of monocyte subpopulations in the peripheral blood of 50 healthy donors and 50 RA patients included in the PRECISESADS study were determined by flow cytometry. A second cohort of 30 RA patients was included, of which CD16+ monocyte subpopulation was isolated using immuno-magnetic selection. Proinflammatory circulating cytokines, as well as peroxide levels and cellular activation markers were analyzed. The expression of 84 genes related to atherosclerosis was analyzed by PCR-array. Endothelial function was measured through post occlusive hyperaemia using Laser-Doppler. Carotid intima media thickness (CIMT) was evaluated as atherosclerosis marker.
Results: CD14highCD16+ monocyte subset was expanded in RA patients belonging to the PRECISESADS study. Their frequency correlated with the evolution of the disease as well as with the positivity for RF and anti-CCP autoantibodies. Correlation studies further indicated a link between the increased frequency of these monocytes and increased levels of circulating cytokines such as IL-17F and IL-10.
CD14highCD16+ monocytes were also significantly extended in RA patients of the second cohort. Those patients had impaired endothelial function, with a reduced perfusion value after ischemia. Increased CD14highCD16+ monocyte proportions were associated with both endothelial dysfunction and the presence of a pathologic CIMT. CD16+ monocyte subsets showed increased protein and gene expression of proinflammatory cytokines, markers of atherosclerosis and peroxide levels.
Conclusions: RA patients exhibit an increased number of CD14highCD16+ monocytes, which display a specific atherogenic and inflammatory pattern directly associated to the autoimmune profile, the progression of the disease and the altered microvascular function. That data suggest that CD16+ subpopulation might play a key role in the CVD pathogenesis associated with RA.

FRI0036 ASSOCIATION BETWEEN THE 18FDG-PET IMAGING AND THE PATHOLOGICAL FINDINGS OF RHEUMATOID SYNOVITIS

C. Okura, Y. Yonemoto, K. Okamura, T. Suto, M. Tachibana, H. Chikuda. *Orthopaedic Surgery, Gunma University Graduate School of Medicine, Maebashi, Japan*

Background: It has been reported that 18FDG-PET (PET) is useful in the evaluation of RA and for monitoring the effects of treatment on the disease activity, so its utility for the evaluation of arthritis is expected. However, the mechanism underlying the uptake of FDG into the inflamed joint is still unclear.
Objectives: The aim of this study was to investigate the associations among the amount of FDG uptake in RA joints, the inflammatory findings with regard to the pathology of the synovium and the clinical findings.
Methods: We performed PET in 18 RA patients who underwent Total Knee Arthroplasty surgery in our hospital just prior to surgery. We calculated the FDG uptake as the standardized uptake value (SUV)max and scored it using the Rooney score, with the degree of inflammation of the synovial tissues used for the pathological evaluation. We evaluated the associations among the SUVmax, Rooney score, CRP level, ESR and MMP-3 level just before surgery.
Results: The subjects were 18 cases with 20 joints, which were in four females and 14 males. At the time of surgery, the average age of the patients was 66.7±7.9 years old, and the mean disease duration was 20.8±14.0 years. Significant correlation was not observed between SUVmax and total Rooney score (r =0.056, p=0.814). But there were strong correlations between SUVmax and some of the individual items in Rooney score, including the "Synoviocyte hyperplasia", and also between SUV max and "Diffuse infiltrates of lymphocytes" (r=0.512, p=0.021 and r=0.581, p=0.007, respectively).
Conclusions: The accumulation of FDG was associated with the extent of "synoviocyte hyperplasia" and "diffuse infiltrates of lymphocytes". It is estimated that accumulation of FDG is associated with relatively early stage of active inflammation of RA.

FRI0037 MER-MEDIATED EFFEROCYTOSIS TEMPERS ARTHRITIS BY PREVENTING NEUTROPHILS TO GO INTO SECONDARY NECROSIS AND SPILL THEIR INFLAMMATORY CONTENT IN THE JOINT

C.E.J. Waterborg, S. Beermann, M.B. Bennink, M.I. Koenders, P.L.E.M. van Lent, F. van den Hoogen, P.M. van der Kraan, F.A.J. van de Loo. *Experimental Rheumatology, Radboudumc, Nijmegen, Netherlands*

Background: Rheumatoid arthritis is characterized by an inflammatory response in synovial joints, showing a predominant influx of neutrophils. These cells are cytotoxic and contribute to matrix degradation. In addition, they are implicated as a source of citrullinated auto-antigens, leading to the production of anti-citrullinated protein antibodies. Neutrophils have a relative short life span and many of them undergo apoptosis. If they are not cleared, they undergo secondary necrosis and release their cell content. A key mediator in the resolution of inflammation and the uptake of apoptotic cells, or efferocytosis, is the receptor tyrosine kinase Mer.
Objectives: To elucidate the local role of Mer during gonarthritis.
Methods: Macrophages were transduced by adenoviruses encoding the Mer ligand *Pros1* or *Luciferase*. One day after the collagen booster injection in mice, Mer-specific antibodies or IgG antibodies, or adenoviruses overexpressing *Pros1* or *Luciferase* were injected intravenously. Mice were euthanized at day 30 or 36, respectively. The KRN serum transfer arthritis model was induced by two intraperitoneal injections of arthritic K/BxN serum in either Mer-deficient or wild-type (WT) mice, or in mice that overexpress *Pros1* or *Luciferase* in their knee joints. Mice were euthanized at day 7 or day 14, respectively. From all mice, serum was taken for cytokine profiling and knee joints were isolated for either synovial gene expression or histology and immunohistochemistry.
Results: Adenoviral overexpression of the Mer ligand *Pros1* resulted in reduced production of pro-inflammatory cytokines and chemokines by macrophages, compared to *Luciferase*. In addition, local *Pros1* overexpression resulted in reduced expression of pro-inflammatory and pro-destructive mediators by synovial cells of arthritic mice. Systemic and local *Pros1* overexpression diminished joint pathology, reduced the number of cleaved Caspase 3-positive apoptotic cells and secondary necrotic neutrophils. Conversely, inhibiting Mer-mediated efferocytosis by either Mer-specific antibodies or *Mertk* gene ablation resulted in aggravation of arthritis compared to controls, as evidenced by increased inflammation and tissue destruction. Additionally, Mer-inhibited mice had increased numbers of apoptotic cells in their knee joints, and higher serum levels of IL-16C, a cytokine released by secondary necrotic neutrophils.
Conclusions: Together, these results demonstrate that Mer locally plays a unique protective role in knee joint disease by enhancing resolution of arthritis. Our data suggest that promoting and/or restoring Mer-mediated uptake of apoptotic cells in the arthritic joint might be therapeutically beneficial.

FRI0038 RELEASE OF PEPTIDYLARGININE DEIMINIASE 2 FROM ACTIVATED NEUTROPHILS

M.A. Steffensen, D. Damgaard, M. Bassi, C.H. Nielsen. *Institute for Inflammation Research, Rigshospitalet, Copenhagen University Hospital, Copenhagen, Denmark*

Background: Extracellular citrullination catalyzed by peptidylarginine deiminase (PAD) is thought to play a central role in the pathogenesis of rheumatoid arthritis. Neutrophils are a major reservoir of PAD2 and PAD4. Cellular release of PAD2 and PAD4 is usually considered a consequence of cell death.
Objectives: We aimed to determine if PAD2 can be released from live, activated neutrophils as an active process.
Methods: Whole blood cells were purified from healthy blood were stimulated with phorbol 12-myristate 13-acetate (PMA). To capture PAD2 released from neutrophils and detect it by flow cytometry, we used biotinylated anti-CD15 and anti-PAD2 (mAb DN6) mAbs linked by streptavidin, and a different PE-labelled anti-PAD2 amtibody (mAb DN2). In addition, intracellular PAD2 was quantified by intracellular staining with PE-anti-PAD2. PAD2 released from leukocytes and subcellular fractions of human granulocytes were assessed for content of PAD2 using an in-house luminex-based assay.
Results: On incubation of whole blood cells with PMA, PAD2 was detectable in the supernatants after 30 minutes, and levels increased thereafter in parallel with increasing cell death. However, using PAD2 catch reagent, we found that live neutrophils released PAD2 in the 30 minutes after stimulation. Intracellular staining for PAD2 showed that the content of PAD2 in live neutrophils decreased correspondingly. Upon subcellular fractioning of granulocytes, the majority of PAD2 was found in cytosol and, in 25 times lower quantities, in the fraction containing plasma membranes and secretory vesicles. Sparse amounts of PAD2 were also observed in gelatinase granules.

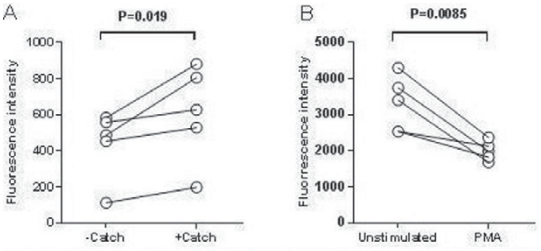

Figure 1: Release of PAD2 by live neutrophils following activation. (A) Whole blood cells were stimulated with PMA for 30 minutes in presence of a catch reagent consisting of co-conjugated anti-CD15 and anti-PAD2 antibodies, and PAD2 caught on the surface of CD15- granulocytes was detected by flow cytometry using PE-conjugated anti-PAD2 antibody (+Catch). Cells not exposed to catch reagent (-Catch) were included as controls. (B) Whole blood cells were incubated with or without PMA for 30 minutes, and the content of PAD2 in granulocytes was assessed using flow cytometry with a PE-conjugated anti-PAD2 antibody (DN2). In both A and B, granulocytes were gated on the basis of forward and side light scatter characteristics, and dead cells staining positive for a near-IR dead-cell stain were excluded.

Conclusions: In conclusion, PAD2 can be released from live, activated neutrophils, which may contribute to extracellular citrullination and thereby play a role in driving inflammatory processes in RA patients with immune responses to citrullinated proteins.

FRI0039 ENDOTHELIAL DYSFUNCTION IN RHEUMATOID ARTHRITIS: WHICH EFFECT OF METHOTREXATE? A STUDY IN ADJUVANT INDUCED ARTHRITIS MODEL

R. Bordy [1], P. Totoson [1], F. Verhoeven [2], C. Prati [1,2], J. Moretto [1], M. Tournier-Nappey [1], C. Demougeot [1]. *[1]Pepite Ea4267, Université de Franche-Comté; [2]Rhumatologie, CHRU Besançon, Besançon, France*

Background: Rheumatoid arthritis (RA) is associated with increased cardiovascular (CV) risk [1] secondary to endothelial dysfunction (ED) [2]. There is accumulating evidence that methotrexate (MTX), first intention DMARD, reduces CV risk in RA [3], but the mechanisms involved are still unknown.
Objectives: The aim of this study was to determine the effect of MTX on endothelial function in arthritis and to investigate its effect on endothelial pathways.
Methods: Experiments were conducted in the adjuvant-induced arthritis (AIA) model in Lewis rat. At onset of arthritis, rats were treated by a sub-cutaneous injection of MTX (1 mg/kg/week) or phosphate buffer saline (vehicle) for 3 weeks. Arthritis score was daily monitored. At the end of treatment, thoracic aorta was harvested to measure the relaxation to acetylcholine on pre-constricted aortic rings in the presence or not of inhibitor of nitric oxide (NO) synthase (L-NAME), arginase (nor-NOHA), EDHF (Apamin/Charybdotoxin), or a superoxide dismutase analog (Tempol). The effect of norepinephrine (NE) and sodium nitroprusside

(SNP) was studied on endothelium-denuded aortic rings. The effect of MTX on hind paw radiographic score, serum lipids and plasma pro-inflammatory cytokines (TNFα and IL-1β) levels was measured.

Results: As compared to Vehicle rats, MTX significantly reduced arthritis score ($p<0.01$) but did not change radiographic score. It reduced plasma cytokines levels ($p=0.02$) but not total cholesterol and triglycerides levels. MTX did not change Ach-induced relaxation as compared to Vehicle. As regards endothelial pathways, MTX increased vascular NOS activity ($p<0.0001$) and decreased superoxide anions production but did change neither COX-2 and arginase activities nor EDHF production. Vascular smooth muscle reactivity to NE and SNP was unchanged by the treatment.

Conclusions: Despite a reduction of clinical and biological inflammation, MTX did not improve endothelial function in AIA rats. The study of endothelial mechanisms highlights the role of COX and arginase as seminal targets for reducing ED in RA. This study suggests that other mechanisms than improvement of endothelial function are involved in the CV benefits of MTX in RA that remain to be elucidated. Our data also suggest that the adjunction of drugs targeting endothelial function to MTX in RA patients might improve their CV prognostic.

FRI0040 CHARACTERIZATION OF ANTI-CARBAMYLATED SYNOVIAL PROTEIN ANTIBODIES (ANTI-CARPS) IN RHEUMATOID ARTHRITIS PATIENTS

C. Regueiro[1], A. Montes[1], M.D. Boveda[2], S. Amhaz-Escanlar[3], E. Perez-Pampin[4], A. Mera-Varela[4], A. Gonzalez[1]. *[1]Experimental and observational Rheumatology; [2]Unit of Diagnosis and Treatment of Congenital Metabolic Diseases; [3]Orthopedic Surgery and Traumatology; [4]Rheumatology Unit, Instituto Investigacion Sanitaria- H. Clinico Universitario de Santiago, Santiago de Compostela, Spain*

Background: Anti-carbamylated protein antibodies (anti-CarP) are a new type of autoantibodies specific of patients with RA. Reactivity has generally been tested with *in vitro* carbamylated proteins from fetal calf serum (FCS) as anti-CarPF. It is likely that other sources of antigens could be more suitable than FCS unless the reactivity of the autoantibodies is directed primarily against the carbamylated residues independently of the protein.

Objectives: To evaluate the anti-CarP antibodies against *in vitro* carbamylated synovial tissue proteins (anti-CarPS) and to compare them with anti-CarPF antibodies.

Methods: A pool of sinovial tissue proteins from 3 osteoarthritis patients was *in vitro* carbamylated and used as antigen for ELISA. Anti-CarPS antibodies were determined in 520 sera from patients with RA and 278 healthy controls, which have been previously tested for anti-CarPF antibodies (1). Logistic regression analysis was used to evaluate the association of the antibodies with SE alelles, *PTPN22,* smoking and erosions. Relationship between antibodies titers was analyzed with Spearman rank correlation (r_s) and concordance between positivity of the different antibodies was analyzed with the Goodman and Kruskal γ.

Results: Similar percentages of patients were positive for anti-CarPS (31.7%) and for anti-CarPF antibodies (29.4%). However, many patients were discordant (28.9%). Notably, the concordance between anti-CarPS and anti-CCP antibodies was higher than the concordance between anti-CarPS and anti-CarPF antibodies (γ =0.73, 95% CI: 0.60–0.86 *vs.* γ =0.60, 95% CI: 0.47–0.73, respectively). Moreover, titers of anti-CarPS antibodies were more correlated with anti-CCP than with anti-CarPF antibodies (r_s =0.41, 95% CI: 0.33–0.48 *vs.* r_s=0.29, 95% CI: 0.21–0.37, respectively). Accordingly, presence of anti-CarPS antibodies showed a clearer trend to be associated with the genetic and environmental RA risk factors than anti-CarPF antibodies, although only the association with smoking was significant (smoking OR=2.0, p=0.02 *vs.* OR=1.1, p=0.8, respectively; OR=1.3 *vs.* OR=1.1 for HLA-SE and OR=1.3 *vs.* OR=0.9 for PTPN22). There were no differences in the association with erosions, which was significant for both antibodies analyzed separately (OR=2.3, $p=6.8 \times 10^{-4}$ for anti-CarPS and OR=2.4 $p=2.0 \times 10^{-4}$ for anti-CarPF) and together (OR=1.8, p=0.02 and OR=2.0, p=0.005, respectively).

Conclusions: Our results indicate that the proteins used as antigens in the determination of anti-CarP antibodies are relevant for the obtained positivity and titer. The differences could affect the pattern of characteristics associated with these antibodies, making it necessary to identify the specific carbamylated autoantigens targeted by them *in vivo*.

FRI0041 IN VIVO MONITORING OF ANTI-FOLATE THERAPY IN ARTHRITIC RATS USING [18F]FLUORO-PEG-FOLATE AND PET

D.M.S.H. Chandrupatla[1], C.J. van der Laken[1], R. Vos[2], M. Verlaan[2], R. van Kooij[2], A.D. Windhorst[2], Q. Chen[3], P.S. Low[3], A.A. Lammertsma[2], G. Jansen[1], C.F.M. Molthoff[2]. *[1]Amsterdam Rheumatology and immunology Centre – location VUmc; [2]Radiology and Nuclear Medicine, VU University Medical Center, Amsterdam, Netherlands; [3]Department of Chemistry, Purdue University, West Lafayette, United States*

Background: Macrophages play a key role in the pathophysiology of rheumatoid arthritis (RA). The folate receptor β (FR-β) is expressed on these macrophages [1] and [^{18}F]fluoro-PEG-folate positron emission tomography ([^{18}F]fluoro-PEG-folate PET) can be used to visualize arthritis *in vivo* [2]. In addition, [^{18}F]fluoro-PEG-folate PET could be a highly interesting tool for therapeutic monitoring of MTX therapy, the corner stone for RA therapy.

Objectives: To study the potential of [^{18}F]fluoro-PEG-folate PET for monitoring response to MTX in a rat model of RA.

Methods: Arthritic rats [3] (n=3–6 per group) received interventions with either MTX [i.p., 1mg/kg; 2 times (group A) or 4 times (group B)] or PBS (control group)] with a time interval of 3–4 days. Healthy rats didn't receive any arthritic induction or MTX therapy. [^{18}F]fluoro-PEG-folate PET-CT were acquired for one hour after tracer injection [2]. Scans were analysed using the region of interest method and standardized uptake values (SUVs) were determined (50–60 min time frame). Sixty minutes after the PET scan, *ex-vivo* tissue distribution was performed and the amount of radioactivity measured in a gamma counter (expressed as percentage of the injected dose/gram tissue (%ID/g)) [2]. For histopathology (Haematoxylin-Eosin (HE) and immunohistochemistry with macrophage specific antibodies ED1 (∼CD68) and ED2 (∼CD163) were applied. Synovial macrophages were counted in predefined areas of the knees [3].

Results: PET scans clearly visualized significantly lower SUVs (1.5-fold, $p<0.01$) in arthritic knees of both MTX-treated groups, approximating the levels observed in healthy rats. Corroborating [^{18}F]fluoro-PEG-folate PET, *ex vivo* tissue distribution [^{18}F]fluoro-PEG-folate demonstrating a 2- and 4-fold decrease (group A and B, respectively) in tracer uptake in arthritic knees after MTX therapy (0.12 and 0.06 for groups A and B, and 0.22%ID/g for controls, respectively) (Figure). This reduction in uptake of [^{18}F]fluoro-PEG-folate in arthritic knees was also associated with a significant decrease in ED1 and ED2 positive synovial macrophages in arthritic knees (∼4 fold) for both treated groups compared with control rats knees ($p<0.01$).

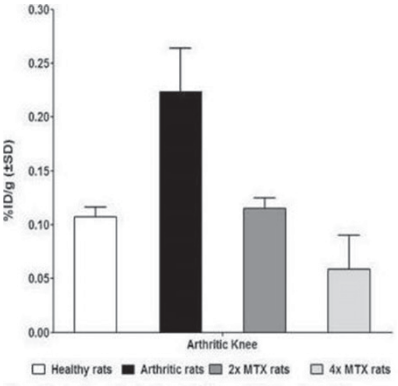

Figure. Ex vivo tissue distribution of [^{18}F]fluoro-PEG-folate in arthritic knee of healthy (white bars) (n=3), arthritic (black bars) (n=3), 2x-MTX (dark grey) (n=4) and 4x-MTX (light grey) (n=4) treated rats at 60 min post tracer injection. Results are expressed as mean percentage injected dose per gram (%ID/g ± SD).

Conclusions: This study in arthritic rats underscores the potential and usefulness of [^{18}F]fluoro-PEG-folate PET as tool to monitor of MTX therapy and potentially other anti-folate treatments of RA.

FRI0042 BAFF-R EXPRESSION IN NAÏVE CD5+IGM+ B CELLS IN RHEUMATOID ARTHRITIS PATIENTS REPOPULATING AFTER RITUXIMAB

E. Becerra[1,2], I. de la Torre[2], M.J. Leandro[2], G. Cambridge[2]. *[1]Rheumatology, Hospital universitario de Torrevieja, Alicante, Spain; [2]Rheumatology, University College London, London, United Kingdom*

Background: Serum levels of B cell activating factor (BAFF) rise following Rituximab (RTX) therapy in patients with Rheumatoid arthritis (RA). CD5+IgM+B cells are present within transitional and naïve B cell subsets and their increased production or accumulation is associated with some autoimmune diseases. Previous studies have shown that BAFF does not enhance their survival compared with CD5- naïve B cells, suggesting that signalling pathways are important in promoting their survival.
Objectives: To determine serum BAFF levels and BAFF-receptor (BAFF-R) expression in CD5+IgM+B cells in healthy controls (HC), RTX-naïve RA patients (pre-RTX), and relapsing at different time points after peripheral B cell repopulation post-RTX treatment, divided into 2 groups: early relapsers (0–3 months post-B cell return) and later relapsers (>4 months post-B cell return).
Methods: Immunophenotyping of peripheral blood mononuclear cells was used to determine %CD5+IgM+B cells and BAFF-R (% and expression, mean fluorescence intensity (MFI)) in 5 HC, 13 pre-RTX and 12 post-RTX RA patients. Results were analyzed with respect to timing of relapse after peripheral B cell return (≥5 B cells/μL) and serum BAFF levels.
Results: %CD5+IgM+B cells, but not absolute numbers, were significantly higher in post-RTX early relapsers compared to HC ($p<0.01$), pre-RTX patients ($p<0.001$) and post-RTX later relapsers ($p<0.01$). There was a strong inverse correlation between %CD5+IgM+B cells and time after B cell return ($r^2=0.88$, $p<0.0001$). BAFF-R+ expression was significantly lower in both post-RTX groups compared to HC and pre-RTX patients; early relapsers showed the lowest % and MFI BAFF-R+ expression, compared with later relapsers ($p<0.01$). BAFF-R+ expression increased with time after B cell return, both % ($r^2=0.47$, $p<0.002$) and MFI ($r^2=0.76$, $p<0.0004$). BAFF levels were significantly higher in both post-RTX groups compared to HC and pre-RTX patients, with the highest BAFF levels in early relapsers ($p<0.05$ compared to later relapsers). There was a significant inverse correlation between BAFF levels and % ($r^2=0.51$, $p<0.01$) and MFI ($r^2=0.4$, $p<0.05$) BAFF-R+ expression.
Conclusions: Early relapsers show increased %CD5+IgM+ naïve B cells, and decreased BAFF-R expression, similar to ontogeny and what is seen in cord blood B cells. Whether the increased numbers of CD5+ naïve cells were contributing to relapse was not determined but they have the capacity to rapidly mature into autoantibody producing plasma cells, independent of the BAFF/BAFFR system. BAFF-R expression was found to increase with time after B cell return, again mirroring ontogeny with a later relapse showing more normalized BAFF/BAFF-R levels, suggesting their mechanism of relapse may follow a more conventional B cell differentiation pathway.

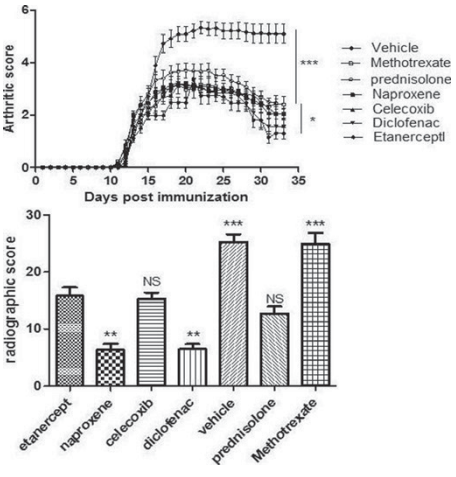
FRI0043 PEPTIDES HIGHLY SPECIFIC TO THE VARIABLE REGION OF TNF-ALFA-SPECIFIC REFERENCES LICENSED (RL) MONOCLONAL ANTIBODIES (MAB), AS POTENTIAL TOOL TO EFFECTIVELY ASSESS SIMILARITY BETWEEN BIOSIMILARS AND THE CORRESPONDIG RL MAB



E. Favoino, C. Ionescu, F. Perosa. *Department of Biomedical Sciences and Human Oncology, Systemic Rheumatic and Autoimmune Disease Unit, University of Bari Medical School, Bari, Italy*

Background: Monoclonal antibodies (mAb) have greatly facilitated the development of highly specific immunotherapy, with a significant improvement of clinical outcome in certain rheumatologic diseases. However, the approaching of many references licensed mAb (RLM) to the end of their licensing period, have stimulated a tremendous interest in the synthesis of a new generation of low-cost mAb referred to as biosimilars (BS) mAb (BSM), because of their similarity to the RLM. An essential requirement imposed by Regulatory Agencies for a mAb to be considered BS is that its variable region (VR) primary sequence must be highly similar to that of RLM. However, epitope recognition and affinity of a mAb very much depends on its VR conformational structure, which may differ even between two mAb bearing highly similar (but not identical) VR. The availability of reagents highly specific to the RLM VR may offer an unique opportunity to define whether a mAb can or cannot be considered BS to a given RLM.
Objectives: To isolate and characterize phage clone-expressing peptide (pc) which are highly specific for the VR of two anti-TNF-α RLP namely mAb Infliximab (Inf) and Golimumab (Gol).
Methods: Cross-inhibition ELISA on recombinant TNF-α (rTNF-α) was performed to define the spatial relationship among the epitopes detected by mAb. mAb-specific phage clones expressing peptide (pc) were obtained by the panning of a phage peptide display library with TNF-a specific mAb. Characterization of pc-specificity and of the spatial relationship between pc- and the TNF-a-binding site on the variable region of mAb was assessed by binding and inhibition assay.
Results: mAb Inf and Gol specifically and dose-dependently cross-inhibited each to the other in the binding to rTNF-a, indicating the recognition by these 2 mAb of the same or two distinct spatially related epitopes on TNF-a. The panning of mAb Inf and Gol with a phage peptide display library resulted in the isolation of one Inf-specific pc (pcInf) and three Gol-specific pc (pcGol1 to 3). Binding assay showed that pcInf and the three pcGol specifically reacted with the corresponding mAb. Furthermore, pcInf and pcGol3 specifically and dose-dependently inhibited the binding of the corresponding mAb to rTNF-α, suggesting the recognition by the pc of the corresponding mAb antigen-combining site. Finally, pcInf and all three pcGol did not react with two additional TNF-a antagonists, suggesting that they are highly specific for mAb Inf and Gol respectively.
Conclusions: The highly specificity of the pc described indicates that they can be eventually employed to predict similarity between a newly synthesized BSM and the claimed RLM, based on the BSM reactivity (or the lack of reactivity) with RLM-specific pc.

FRI0044 NON-STEROIDAL ANTI-INFLAMMATORY DRUGS ARE MORE BENEFICIAL THAN ANTI-TNFα DRUGS ON THE RADIOGRAPHIC DAMAGE IN ARTHRITIS: A STUDY IN ADJUVANT INDUCED ARTHRITIS

F. Verhoeven[1], C. Prati[2], P. Totoson[3], R. Bordy[3], D. Wendling[1], C. Demougeot[3]. *[1]Rhumatologie; [2]CHRU de Besançon; [3]Ea 4267 "Pepite", université de Bourgogne Franche Comté, Besançon, France*

Background: The management of the chronic inflammatory rheumatisms has dramatically evolved in the last decade with a concept of "treat to target". The theory of a window of opportunity with more beneficial effects of an early intensive treatment is supported by several evidences. The positive impact of an early treatment with a TNFα blocker is expected but the place and the interest of non-steroidal anti-inflammatory treatments (NSAIDs) and glucocorticoids is not clear.
Objectives: The aim of this study was to evaluate the radiological outcomes after an early treatment during 21 days by Etanercept, or Naproxene, or Celecoxib, or Prednisone, or Diclofenac or Methotrexate in adjuvant induced arthritis in rats.
Methods: Adjuvant-induced arthritis (AIA) was induced in 6 weeks old male Lewis rats by injection of *Mycobacterium butyricum* in adjuvant at the basis of the tail. At the onset of arthritis, rats were daily treated with Naproxene (10 mg/kg/d i.p), or Diclofenac (5mg/kg i.p twice a day), or Celecoxib (3 mg/kg/d i.p) or Prednisone (10 mg/kg/d i.p), or Etanercept (10 mg/kg/3 days, s.c.), or Methotrexate (1mg/kg/3 days, s.c.), or saline solution (Vehicle), for 21 days. Arthritic score was daily monitored. At the end of treatment, paws' radiological exam was performed with a BMA High Resolution Digital X Ray (40mV, 10mA). A score of 0 to 20 was determined for each paw using a grading scale modified from Ackerman *et al (1979)*.

Abstract FRI0042 – Table 1

	%CD5+IgM+ (median;range)	%BAFF-R+ve	BAFF-R+ve (MFI)	BAFF levels (ng/ml) (median;range)
HC	18.5 (9.1–26.8)	98.7 (97.9–99.5)	62.5 (50.5–82.4)	1.1 (0.9–1.2)
Pre-RTX	5.4 (1.9–21.4)	97.3 (85.8–100)	58 (34.2–139)	1.4 (0.9–1.7)
Post-RTX early relapse	44.4 (39.6–55.8) **###$$	60.6 (12.9–71.2)**###$$	15.6 (11.8–17.5)**###$$	2.4 (2–6.4)**###$
Post-RTX late relapse	12.7 (2.3–27.9)$$	93.1 (81.5–97.9)**$$	30.2 (19.9–36)**##$$	1.7 (1.3–2.4)**#$

*p<0.05; **p<0.01; ***p<0.001 compared with NC; #p<0.05; ##p<0.01; ###p<0.001 compared with pre-RTX; $p<0.05; $$p<0.01; $$$p<0.001 for comparisons between post-RTX groups.

Results: Compared to the Vehicle, all treatments significantly reduced ($p<0.001$) arthritic score with a reduction of the arthritic score evaluated between 40% (for methotrexate) and 70% (for diclofenac) (figure 1. Compared to the vehicle, the radiographic score was improved by Naproxene, Diclofenac, Celecoxib, Glucocorticoids, Etanercept ($p<0.001$) but not by methotrexate. Compared to Etanercept, Naproxene and diclofenac showed less radiological structural changes ($p<0.01$) (figure 2).
Conclusions: Our study demonstrates for the first time that an early treatment with NSAIDs, excluding COX2 selective inhibitor, is more beneficial than Etanercept on the radiological damages in adjuvant induced arthritis. The close efficacy of all drugs on the arthritis score suggests that the beneficial impact of NSAID is not only driven by their impact on the systemic inflammation. NSAIDs should be used during the window of opportunity.

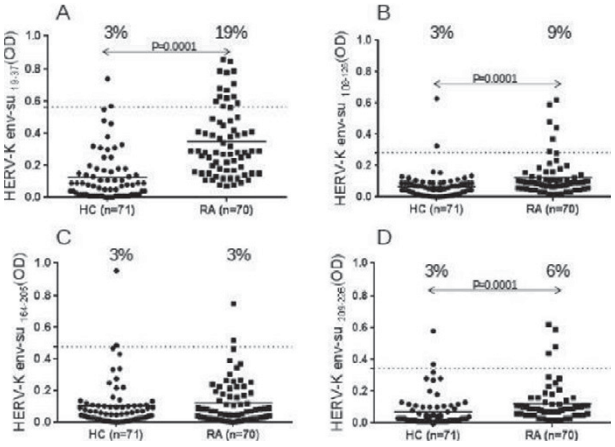
FRI0045 ORAL MICROBIOME PROFILE IN RHEUMATOID ARTHRITIS PATIENTS: ASSOCIATION BETWEEN TONGUE BIOFILM PORPHYROMONAS GINGIVALIS AMOUNT AND DISEASE ACTIVITY



F. Ceccarelli[1], G. Orrù[2], A. Pilloni[3], I. Bartosiewicz[4], C. Perricone[4], E. Martino[5], R. Lucchetti[6], S. Fais[2], M. Vomero[4], M. Olivieri[4], M. Di Franco[4], R. Priori[4], V. Riccieri[4], A. Sili Scavalli[4], R. Scrivo[4], C. Alessandri[4], F. Conti[4], A. Polimeni[4], G. Valesini[4]. *[1]Reumatologia, Dipartimento di Medicina Interna e Specialità Mediche, Sapienza Università di Roma, Rome; [2]Molecular Biology Service, University of Cagliari "Ospedale S. Giovanni di Dio", Cagliari; [3]Odontoiatria, Dipartimento di Scienze Odontostomatologiche e Maxillo Facciali, Sapienza Università di Roma, Rome; [4]Reumatologia, Dipartimento di Medicina Interna e Specialità Medica; [5]Odontoiatria, Dipartimento di Scienze Odontostomatologiche e Maxillo Facciali, Sapienza Università di Roma; [6]Reumatologia, Dipartimento di Medicina Interna e Specialità Medica, Sapienza, Università di Roma, Roma, Italy*

Background: *P. gingivalis* is a Gram-negative anaerobic bacterium usually located in the oral cavity, as component of microbiome. Next to the established association with oral cavity diseases, such as periodontitis and halitosis, in the last years a growing interest has been addressed to its implication in the development of autoimmune diseases, such as Rheumatoid Arthritis (RA). The ability of *P. gingivalis* to citrullinate peptides is the most relevant link with RA. Indeed, this bacterium has several virulence factors directly contributing to its chronic inflammation regardless of citrullination. Data from the literature demonstrated the ability of *P. gingivalis* in inducing the production of several inflammatory cytokines, such as TNF, IL6 and IL17, through the TLR signaling pathways.
Objectives: In the present case-control study, we aimed at analysing tongue microbiome in a large RA cohort, focusing on the evaluation of *P. gingivalis* presence and quantification.
Methods: We enrolled 143 RA patients (1987 ACR criteria; M/F 32/111, mean±SD age 57.5±19.8 years, mean±SD disease duration 155.9±114.7 months); 36 periodontitis (M/F 11/25, mean±SD age 56±9.9 years, mean±SD disease duration 25.5±20.9 months); 57 (M/F 12/45, mean ±SD age 61.4±10.9 years, mean ±SD disease duration 62.3±66.9 months) affected by knee osteoarthritis or fibromyalgia (control subjects – CS). All subjects underwent a clinical evaluation in order to assess disease activity by DAS28. Blood serum samples were obtained to evaluate the presence of ACPA by a commercial ELISA kit. Finally, a standard cytologic swab to collect tongue biofilm samples was performed and the presence of *P. gingivalis* was evaluated by PCR method.
Results: The prevalence of *P. gingivalis* resulted significantly higher in RA and PD patients in comparison with CS (P=0.01 and P=0.003, respectively). No correlation between bacterium presence and ACPA was found. When evaluating the percentage of *P. gingivalis* on the total tongue biofilm, we observed a significant correlation between this measure and DAS28 values (r=0.4, P=0.01). Furthermore, RA patients in DAS28 remission showed a significantly lower prevalence of *P. gingivalis* in comparison with non-remission patients (P=0.02).
Conclusions: In the present study, for the first time we assessed the prevalence of *P. gingivalis*, i.e. its percentage on the total tongue biofilm, in a large RA cohort. A significant correlation between the amount of *P. gingivalis* on total tongue biofilm and disease activity was observed. There was no association with ACPA, suggesting that this bacterium, beyond citrullination, could be implicated in triggering a pro-inflammatory state in RA.

FRI0046 IDENTIFICATION OF HERV-K ENV SURFACE PEPTIDES HIGHLY RECOGNIZED IN RA PATIENTS

G.L. Erre[1], G. Mameli[2], D. Cossu[2], S. Mura[3], A. Piras[3], M.L. Cadoni[1], G. Buscetta[3], N. Mundula[3], E. Colombo[3], M.G. Longu[1], L.A. Sechi[2], G. Passiu[3]. *[1]UOC Reumatologia, Dipartimento di Medicina Clinica e Sperimentale, Azienda Ospedaliero-Universitaria di Sassari; [2]Scienze Biomediche, Istituto di Microbiologia; [3]UOC Reumatologia, Dipartimento di Medicina Clinica e Sperimentale, Università degli Studi di Sassari, Sassari, Italy*

Background: Endogenous Retroviruses (HERV) are believed to be pathogenic in several autoimmune diseases. Among them, HERV-K viruses have been recently reported to be involved in the pathogenesis of rheumatoid arthritis (RA).
Objectives: In this study we have explored the role of humoral immune response against HERV-K as a potential pathogenetic mechanism in RA.
Methods: Four different peptides from the extracellular portion of the *env* protein of HERV-K (env-su $_{19–37}$, env-su $_{109–26}$, env-su $_{164–205}$, env-su $_{209–226}$) were selected by bioinformatic analysis on the basis of their putative immunogenicity. Indirect ELISA was then carried out to quantify antibodies against those peptides on blood samples from RA patients and healthy controls (HC). Differences between the two groups were analysed using the Mann-Whitney rank-sum and chi-square tests. Potential correlations between RA laboratory, clinical descriptors and IgGs levels were explored by bivariate regression analysis.
Results: Seventy consecutive RA patients and seventy-one HC crossed by age and sex were enrolled in the study. Serum autoantibodies against three out of the four tested peptides, anti HERV-Ksu$_{19–37}$, HERV-K env-su$_{109–126}$ and HERV-K env-su$_{205–226}$, were significantly more prevalent in RA than in HC (19% vs 3%,p=0.0001;9% vs 3%, p=0.0001; and 6% vs 3%, p=0.0001 respectively) (See Fig. 1)
Subgroup analysis showed no association between anti-HERV-K peptide humoral response and clinical, serological and clinimetric RA disease descriptors.

Conclusions: Serum from RA patients in our series significantly reacted against different HERV-K peptides in comparison to the general population suggesting a role for the HERV-K related, secondary antigenic driven immune response in the pathogenesis of RA. Further studies are needed to confirm these results and to explore the role of HERV-K surface peptides as potential therapeutic targets.

FRI0047 ELEVATED 14-3-3ETA LEVELS PREDICT WORSE RADIOGRAPHIC OUTCOMES IN PATIENTS WITH RECENT-ONSET INFLAMMATORY ARTHRITIS IN CLINICAL REMISSION

N. Carrier[1], M.-P. Garant[2], A. Marotta[3], A.J. De Brum Fernandes[4], P. Liang[4], A. Masetto[4], Y. Gui[5], J. Savill[5], S. Michienzi[5], W.P. Maksymowych[6], G. Boire[4]. *[1]Division of Rheumatology, CIUSSS de l'Estrie-CHUS; [2]Biostatistics, Centre de recherche du CHUS, Sherbrooke; [3]Auguex Life Sciences Crop., Vancouver; [4]Medicine, Division of Rheumatology, Université de Sherbrooke, Sherbrooke; [5]Augurex Life Sciences Corp., Vancouver; [6]Medicine, University of Alberta, Edmonton, Canada*

Background: 14–3-3η is a joint-derived serum protein that up-regulates pro-inflammatory factors. We have previously reported that baseline 14–3-3η levels ≥0.50 ng/ml (HIGH 14–3-3η) were predictive of radiographic progression over 5 years.
Objectives: Our objective was to verify if the persistence of HIGH 14–3-3η at 18 months in recent-onset polyarthritis patients in REMISSION predicts more rapid radiographic progression over the following years, up to 42 months.
Methods: Serum 14–3-3η titres were assessed at baseline and at 18 months into disease, a median of 14 months after diagnosis and initiation of treatment. Three definitions of "clinical remission" at 18 months were used: Swollen Joint Count (SJC) =0; SJC + Tender Joint Count (TJC) =0; ACR/EULAR Boolean definition. The progression of radiographic damage (Erosion and Total Sharp/van der Heijde (SvH) scores) in patients with LOW (<0.50 ng/ml) or HIGH (≥0.50 ng/ml) 14–3-3η were compared using the Mann-Whitney test. P values <0.05 were considered significant.
Results: Out of 331 patients, 36.0% of which had HIGH 14–3-3η at Baseline, 308 had complete data up to 5 years. Median age was 60 years, 62% women. Depending on the stringency of the definition used, variable numbers of patients reached remission at 18 months: 162 (53%) had SJC=0; 108 (35%) SJC+TJC=0; and 56 (18%) Boolean.
Remission at 18 months was negatively associated with persistence of HIGH

14–3-3η since HIGH 14–3-3η were then present in 32/162 (19.7%) SJC=0 patients; 22/108 (20.4%) SJC+TJC=0 and 13/56 (23.2%) Boolean.
Compared to patients in remission with LOW 14–3-3η, patients in remission with HIGH 14–3-3η at 18 months had numerically faster subsequent progression with all definitions. For example, in patients with Boolean remission, mean (SD) erosion progression over 42 months was 7.2±13.1 vs 1.5±3.3 and mean (SD) progression of Total score 9.2±14.5 vs 2.8±4.4 units (Figure).
However, due to low numbers and limited power, differences in progression were statistically significant only for the less strict definitions of remission and only over the following year: Erosions (SJC=0, p=0.0042, SJC+TJC=0, p=0.0236), Total score (SJC=0, p=0.0146; with a trend for SJC+TJC=0, p=0.077).
None of the comparisons over 42 months or of those involving Boolean reached significance.

Figure. Progression of Erosion Sharp/van der Heijde score in patients in Boolean remission at 18 months.
A. 14-3-3η <0.50 ng/ml at 18 months. **B.**14-3-3η ≥0.50 ng/ml at 18 months.

Conclusions: The persistence of 14–3-3η levels ≥0.50 ng/ml appears to be associated with a lower probability of reaching remission in polyarthritis patients. 14–3-3η levels ≥0.50 ng/ml in patients in clinical remission appear to be associated with more rapid radiographic (especially erosive) progression over the following year. A larger study is required to validate these findings, especially with the most stringent criterion of Boolean remission.

Background: Rituximab (RTX) has been shown to be successful in the treatment of rheumatoid arthritis (RA), indicating that B cells have an important role in this disease.
Objectives: The present study was undertaken to investigate the mechanisms of action of RTX on the immune and endothelial cells (EC) of the vascular system in the setting of RA.
Methods: Purified lymphocytes from five RA patients with high disease activity were treated with RTX (1ug/mL) for 24 hours. Then, the depletion of B cells was assessed by flow cytometry, and the changes occurred in the inflammatory profile of T-lymphocytes was analysed by RT-PCR. In a second set of experiments, to evaluate the influence of B-cell depletion on the inflammatory/prothrombotic profile of cells belonging to the vascular system, supernatants from cultured lymphocytes of RA patients in the presence or in the absence of RTX were added to isolated monocytes from AR patients and to cultured endothelial cells. The response to RTX was then examined.
Results: As expected, RTX promoted a significant depletion of B-cells. In parallel, the inflammatory profile of T lymphocytes from RA patients was downregulated, as shown by a significant drop of IL-1, IL-6, IL-17, IFN and TNF expression levels, thus suggesting that the anti-inflammatory effects of RTX might be related to B cell depletion. Supernatants from RTX-treated lymphocytes further abridged the prothrombotic profile of RA-monocytes, promoting a significant inhibition of TF, MCP-1, IL-8, IL-1 and VEGF-A gene expression. Moreover, endothelial cells, activated after treatment with supernatants from cultured RA-lymphocytes, showed reduced expression of cell-adhesion molecules (i.e. V-CAM, I-CAM, E-Selectin) and pro-thrombotic factors (i.e. TF, VEGF, IL-8) after treatment with supernatants from cultured RA-lymphocytes in the presence of RTX.
Conclusions: Overall, these results reveal that depletion of B-cells by RTX in RA influences the inflammatory profile of T lymphocytes, as well as their interaction with monocytes and ECs, thus modulating the inflammatory and prothrombotic shape of vascular cells in the setting of RA.

FRI0049 FC GAMMA RECEPTOR IV ENHANCES BONE EROSION IN EXPERIMENTAL ARTHRITIS BY PROMOTING INFLUX OF PMNS

I. Di Ceglie[1], G. Ascone[1], M. van den Bosch[1], J.S. Verbeek[2], P. van der Kraan[1], P. van Lent[1]. *[1]Experimental Rheumatology, Radboud University Medical Center, Nijmegen; [2]Leiden University Medical Center, Leiden, Netherlands*

Background: FcγRs are involved in regulation of synovial activation and bone destruction during immune complex (IC)-mediated arthritis. The balance between activating FcγRs (FcγRI,III and IV) and inhibiting FcγRII determines synovial activation. Here we investigated the particular role of activating FcγRIV in bone erosion in IC-mediated antigen induced arthritis (AIA) by comparing FcγRI,II,III,IV$^{-/-}$ mice, FcγRI,II,III$^{-/-}$ mice and wild type controls (WT).
Objectives: To investigate the role of FcγRIV in bone erosion during experimental arthritis.
Methods: AIA was induced by injection of mBSA into knee joints of mice previously immunized with mBSA/CFA. Joint inflammation, bone destruction, number of TRAP^{+} osteoclasts and S100A8/A9 positive cells was determined using histology and immunohistochemistry. *In vitro* osteoclastogenesis was assessed using TRAP staining.
Results: Seven days after induction of AIA, we observed decreased inflammation and bone erosion in the knee joints of FcγRI,II,III,IV$^{-/-}$ mice compared to WT. The ability of bone marrow cells of FcγRI,II,III,IV$^{-/-}$ mice to differentiate into osteoclasts *in vitro* was comparable to the one of WT controls. Moreover, we observed comparable numbers of TRAP^{+} osteoclasts on the bone surface of FcγRI/II/III/IV$^{-/-}$ and WT arthritic mice, suggesting that the observed decrease in bone erosion is mainly caused by a reduced osteoclast activity, rather than decreased osteoclast number. However, in contrast to FcγRI/II/III/IV$^{-/-}$, AIA induction in knee joints of FcγRI/II/III $^{-/-}$ resulted in increased bone erosion and inflammation compared to WT, highlighting the possible crucial role of FcγRIV in the pathology. Interestingly, the number of PMNs infiltrated in the knee joint of FcγRI/II/III$^{-/-}$ resulted increased, whereas it was decreased in the knee joints of FcγRI/II/III/IV$^{-/-}$ compared to their WT controls. This observation suggests that particularly FcγRIV is involved in regulating influx of PMNs. PMNs are potent producers of alarmins S100A8/A9 which are described to promote osteoclast activity. In line the number of S100A8/A9 positive cells in synovium was increased in FcγRI/II/III$^{-/-}$ while decreased in FcγRI/II/III/IV$^{-/-}$, compared to their WT control.
Conclusions: FcγRIV promotes bone erosion in AIA by enhancing influx of PMNs within the synovium. PMNs are potent producers of S100A8/A9 which has been described to induce osteoclast activity.

FRI0050 TYPE II COLLAGEN SECRETED FROM ARTICULAR CHONDROCYTES IS MAINLY DESTROYED BY CATHEPSIN S IN RA MICE

J. Zhao, Q. Huang, H. Ren, M. Yang. *Department of Rheumatology, Nanfang Hospital, Southern Medical University, Guangzhou, China*

Background: Mast cells have long been recognized to increase strikingly in number in the synovial membrane of rheumatoid arthritis (RA), accounting for 5% of the surface synovial membrane cells. Type II collagen has the longest half-life in cartilage matrix. The main cells which might affect articular cartilage in RA are synovial fibroblasts, synovial macrophages and mast cells. The latter two could express cathepsin S.
Objectives: We aimed to find the cells which have the biggest influence on type II collagen secreted from articular chondrocytes and the possible mechanisms in RA mice.
Methods: Four types of cells from collagen-induced arthritis model-established C57BL/6 mice were primary cultured, including synovial fibroblasts, peritoneal

macrophages, bone marrow-derived mast cells and articular chondrocytes. The first three were co-cultured with articular chondrocytes separately. LHVS, a specific inhibitor of cathepsin S, and E64, a broad-spectrum inhibitor of cysteine protease, were added into the cocultures of macrophages and articular chondrocytes separately. Also, C48/80, an activator of mast cells, LHVS, and E64 were added into the cocultures of mast cells and articular chondrocytes separately. The culture supernatant fluid was collected. The concentration of cathepsin S and type II collagen were measured by ELISA. The expression of type II collagen mRNA in each group was detected with RTPCR.

Results: Macrophages and mast cells expressed cathepsin S, while synovial fibroblasts did not express cathepsin S. Synovial fibroblasts had little effect on the expression of type II collagen from articular chondrocytes. When articular chondrocytes were co-cultured with macrophages, the expression of type II collagen decreased (8.79±2.79ng/ml),compared with the control group (17.75±7.84ng/ml). The secretion of type II collagen could return to normal by the inhibitors of cathepsin S, both LHVS (16.15±8.05 ng/ml) and E64 (12.55±6.64 ng/ml). When articular chondrocytes were co-cultured with mast cells, the type II collagen could be restrained by C48/80 (9.82±0.42ng/ml), compared with the control group (26.09±9.34ng/ml). Similarly, the secretion of type II collagen could return to normal by LHVS and E64 (16.15±8.05 ng/ml, 12.55±6.64 ng/ml, respectively). There was no significant difference in the expression of type II collagen mRNA between different groups. It showed that the type II collagen was not suppressed at the transcription level, but was mainly destroyed by cathepsin S after secretion.

Conclusions: Macrophages and mast cells are the major sources of cathepsin S, which might be the main factor that destroys type II collagen secreted from articular chondrocytes in RA mice.

FRI0051 EARLY ARTHRITIS INDUCES DISTURBANCES AT BONE NANOSTRUCTURAL LEVEL REFLECTED IN DECREASED TISSUE HARDNESS

B. Vidal[1], R. Cascão[1], M. Finnilä[2,3], I. Lopes[1], S. Saarakkala[2,4,5], P. Zioupos[6], H. Canhão[7], J. Fonseca[1,8]. *[1]Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Lisboa, Portugal; [2]Research Unit of Medical Imaging, Physics and Technology, Faculty of Medicine, University of Oulu, Oulo; [3]Department of Applied Physics, University of Eastern Finland, Kuopio; [4]Medical Research Center Oulo, Oulu University; [5]Department of Diagnostic Radiology, Oulu University Hospital, Oulo, Finland; [6]Biomechanics Labs, Cranfield Forensic Institute, Cranfield University, Swindon, United Kingdom; [7]EpiDoC Unit, CEDOC, NOVA Medical School, NOVA University; [8]Rheumatology Department, Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria, Lisbon Academic Medical Centre, Lisboa, Portugal*

Background: Arthritis induces joint erosions and skeletal bone fragility.

Objectives: The main goal of this work was to analyze the early arthritis induced events at bone tissue level.

Methods: Eighty-eight Wistar rats were randomly housed in experimental groups, as follows: adjuvant induced arthritis (N=47) and a control healthy group (N=41). Rats were monitored during 22 days for the inflammatory score, ankle perimeter and body weight and sacrificed at different time points (11 and 22 days post disease induction). Bone samples were collected for histology, micro-CT, 3-point bending, nanoindentation and Fourier transformed infrared spectroscopy (FTIR) analysis. Blood samples were also collected for bone turnover markers and systemic cytokine quantification.

Results: At bone tissue level, measured by FTIR analysis and nanoindentation, there was a reduction of the mineral and collagen content and of hardness in the arthritic group, associated with an increase of the ratio of bone concentric to parallel lamellae and of the area of the osteocyte lacuna. In addition, increased bone turnover and changes in the microstructure and mechanical properties were observed in arthritic animals, since the early phase of arthritis, when compared with healthy controls.

Conclusions: Arthritis induces very early changes at bone tissue level characterized by decreased tissue hardness and of collagen and mineral content. These observations highlight the pertinence of immediate control of inflammation in the initial stages of arthritis.

FRI0052 SALIVARY PEPTIDYL-ARGININE DEIMINASE AND TANNERELLA FORSYTHIA ARE ASSOCIATED WITH CLINICAL ACTIVITY OF RHEUMATOID ARTHRITIS

D.-X. Xibillé-Friedmann[1], J.-I. Martínez-Rivera[2], M.-A. De la Garza-Ramos[3], J. González-Christen[4], S.-M. Carrillo-Vázquez[5], J.-L. Montiel-Hernandez[4]. *[1]SEIC, Servicios de Salud de Morelos; [2]CISEI, Instituto Nacional de Salud Pública, Cuernavaca; [3]CIDICS/Facultad de Odontología, Universidad Autonoma de Nuevo Leon, Monterrey; [4]Facultad de Farmacia, Universidad Autonoma del Estado de Morelos, Cuernavaca; [5]Hospital Regional 1o. Octubre, ISSSTE, Mexico city, Mexico*

Background: Although the expression of bacterial Peptidyl-Arginine Deiminase (PAD) derived from *P. gingivalis* seems critical in explaining the potential effects of severe periodontitis in the development of Rheumatoid arthritis (RA), the association with the presence of the bacteria or anti-P. gingivalis/anti-PPAD antibodies is not always evident suggesting that other bacteria could be involved in the link between oral microbiota and citrullination of host proteins.

Objectives: To confirm the association between RA disease activity in a homogeneous population (aCCP+ RA patients), oral PAD activity and the prevalence of other bacterial strains such as *T. forsythia*.

Methods: RA patients fulfilling ACR/EULAR 2010 criteria were evaluated from a periodontal (Periodontal Screening Recoding Index) and rheumatologic standpoint. Patients with Sjögren's syndrome or sicca symptons were excluded. Disease activity was measured using DAS28 (ESR). Oral PAD activity was measured by colorimetric assay and presence of *Porphyromonas gingivalis, Tannerella forsythia* and *Prevotella intermedia* was evaluated by PCR. Autoantibody levels were determined by ELISA. Multivariate analysis adjusted for gender, age, time since onset of disease, RF and ESR. Comparisons between groups were performed by Mann-Whitney U testing or Kruskal–Wallis testing per the t variables. Spearman correlation testing was employed to correlate PAD activity and DAS28. Statistical significance was set at 0.05%.

Results: 132 patients were included. After a multivariate analysis an association was observed between severe periodontitis/dental mobility with moderate/high RA disease activity (OR: 4.4 (1.8–14.0), p=0.04 and 3.4 (1.1–13.4), p=0.03, respectively). Additionally, presence of *P. gingivalis* and *T. forsythia*, but not *P. intermedia*, was significantly associated with moderate/high RA disease activity (3.4 (1.1–10.5), $p<0.05$ and 4.4 (1.2–10.9), $p<0.05$). Comparing PAD activity in saliva samples of RA patients we found significant differences between the low (2.3±0.5), moderate (3.4±0.8) and high (4.3±0.3) disease activity subgroups ($p<0.01$%), whereas patients in remission demonstrated a PAD activity similar to the low disease activity group (1.9±0.39). Additionally, we found a significant correlation between oral PAD activity and RA activity, but not with autoantibody titers.

Conclusions: These results show that RA activity is associated with severe periodontitis, high oral PAD activity and the presence of *T. forsythia* and *P. gingivalis*, suggesting that both bacteria equally participate in PAD activity present in the oral microenvironment.

FRI0053 ANTIBODIES TO A SUBSET OF CITRULLINATED PEPTIDE ANTIGENS CORRELATE WITH NEUTROPHIL EXTRACELLULAR TRAP LEVELS IN THE SPUTUM OF SUBJECTS AT-RISK FOR FUTURE RA

K.D. Deane[1], M. Purmalek[2], N.L. Seto[2], E. Bowers[1], J.M. Norris[3], V.M. Holers[1], W. Robinson[4], M. Kaplan[2], M.K. Demoruelle[1]. *[1]Division of Rheumatology, University of Colorado Denver, Aurora; [2]Systemic Autoimmunity Branch, National Institutes of Health/NIAMS, Bethesda; [3]Epidemiology, Colorado School of Public Health, Aurora; [4]Division of Immunology and Rheumatology, Stanford University, Palo Alto, United States*

Background: Prior data suggest that anti-citrullinated protein/peptide antibodies (ACPA) may originate in the lung prior to the onset of synovitis in rheumatoid arthritis (RA) (1). Neutrophil extracellular trap (NET) formation is one potential mechanism that could trigger or be associated with local ACPA generation because NETs externalize citrullinated proteins and release peptidylarginine deiminase that could citrullinate nearby proteins (2–4).

Objectives: Using induced sputum, we recently identified a significant correlation between NETs and anti-cyclic citrullinated peptide (CCP) antibodies in subjects at-risk for future RA. Herein, we sought to explore associations of individual ACPAs and NETs in these subjects.

Methods: From the Studies of the Etiology of RA (SERA) cohort, we included 24 RA-free subjects At-Risk for future RA based on familial (i.e. first-degree relative of RA patient) or serologic (i.e. serum anti-CCP positive identified at health fairs) risk. Induced sputum was tested using a bead-based ACPA array for IgG reactivity to 29 individual citrullinated proteins/peptides. Levels of NET complexes in sputum were measured using a deoxyribonucleic acid (DNA)-myeloperoxidase (MPO) and DNA-neutrophil elastase (NE) sandwich ELISA. Analyses included Spearman's correlation and linear regression. Using Bonferonni's correction, results were considered significant if both DNA-MPO and DNA-NE assays had a $p<0.002$.

Results: Subjects had a median age of 51 years, were 67% female and 38% ever-smokers. Increasing sputum NET levels significantly correlated with increasing ACPA levels for 27/29 ACPAs, including proteins/peptides of cit-vimentin, cit-fibrinogen, cit-fibronectin, cit-apoliporoteins and cit-alpha-enolase. After adjusting for ever-smoking, sputum NET levels remained significantly associated with 17/29 ACPAs. The strongest associations ($p\leq0.001$ for both NET assays) were cit-H2A/a2$_{1–20}$, cit-vimentin$_{58–77\ \text{cyclic}}$, cit-alpha-enolase$_{5–21}$, cit-fibrinogen$_{27–43}$, cit-fibrinogen$_{211–230\ \text{cyclic}}$, cit-fibrinogen$_{616–635\ \text{cyclic}}$, cit-fibrinogenB$_{54–72}$, and cit-apolipoprotein E$_{277–269\ \text{cyclic}}$.

Conclusions: In subjects At-Risk for future RA, we identified a strong corre-

lation between sputum NET complexes and multiple sputum ACPAs that was independent of smoking exposure. These data suggest that in the lung, NET formation may be associated with the production of multiple ACPA reactivities locally. Additional studies are needed to determine if NET-associated cit-proteins are an initial trigger or a self-perpetuating stimulus of sputum ACPA generation as well as contributions of other local mechanisms of citrullination.

FRI0054 A NOVEL PHARMACOLOGICAL ACTION OF MTX THROUGH CIRCADIAN CLOCK GENES IN RA FIBROBLAST-LIKE SYNOVIAL CELLS

K. Suzuki[1], K. Yoshida[1], T. Hashimoto[2], K. Kaneshiro[1], A. Nakai[1], N. Hashimoto[1], Y. Kawasaki[3], N. Shibanuma[4], N. Nakagawa[5], Y. Sakai[6], A. Hashiramoto[1]. *[1]Biophysics, Kobe University Graduate School of Health Sciences; [2]Rheumatology; [3]Kobe Kaisei Hospital, Kobe, Japan; [4]Orthopaedic Surgery, Kobe Kaisei Hospital, Kobe; [5]KonanKakogawa Hospital, Kakogawa; [6]Kobe University Graduate School of Medicine, Kobe, Japan*

Background: Methotrexate inhibits the proliferation of RA fibroblast-like synovial cells (RA-FLS) by folate anti-metabolism. We previously reported that disruptions of circadian clock genes were involved in the pathogenesis of inflammatory arthritis (1,2).
Objectives: To explore pharmacological effects of MTX on circadian clock genes of RA-FLS.
Methods: Under treatments of MTX on RA-FLS, cell viabilities were determined by WST-8 assay, expressions of circadian clock genes (*Clock, Bmal1, Cry1* and *Per2*), circadian transcriptional factor PAR bZip (*Dbp, Tef* and *Hlf*), and pro-apoptotic Bcl-2 interacting killer (*BIK*) were examined by real time PCR, and expressions of PER2 and CYTOCHROME C were examined by western blotting. The expressions of PER2, BIK, CYTOCHROME C and morphological changes of the nucleus were observed by fluorescent immunostaining. RA-FLS were transfected with *Per2* and *BIK* siRNAs and successively treated with MTX to determine cell viabilities by WST-8 assay.
Results: MTX (1,10 nM) treatment significantly decreased the cell viabilities. MTX (10nM) have increased mRNA expression of *Per2, Dbp, Tef, Hlf*, and *BIK*, and protein expressions of PER2 and CYTOCHROME C, as well. In fluorescent observations, PER2, BIK, and CYTOCHROME C were increased in apoptotic cells. Cytotoxicity of MTX was attenuated by knockdowns of *Per2* or *BIK* in RA-FLS.
Conclusions: The transcriptional factor PAR bZip binds to the D-box elements of *Per2* and *BIK* promoters (3,4). Here, we propose a novel action of MTX that up-regulates the expressions of *Per2* and *BIK* via PAR bZip to induce apoptosis in RA-FLS.

FRI0055 HISTONE DEACETYLASE 1 (HDAC1): A NOVEL THERAPEUTIC TARGET IN RHEUMATOID ARTHRITIS

L. Göschl[1], M. Bonelli[1], V. Saferding[1], T. Preglej[2], C. Seiser[3], S. Knapp[4], J. Backlund[5], C. Bock[6], P. Mathias[7], K. Hirahara[8], C. Scheinecker[9], G. Steiner[1], W. Ellmeier[10]. *[1]Division of Rheumatology, Medical University of Vienna; [2]Division of Immunobiology, Medical University of Vienna; [3]Department of Medical Biochemistry, Medical University of Vienna; [4]Research Center for Molecular Medicine (CeMM), Austrian Academy of Sciences, Vienna, Austria; [5]Department of Medical Biochemistry and Biophysics, Karolinska Institutet, Stockholm, Sweden; [6]Research Center for Molecular Medicine (CeMM), Austrian Academy of Sciences, Wien, Austria; [7]Friedrich Miescher Institute for Biomedical Research, Basel, Switzerland; [8]Department for Cell Biology, Chiba University, Chiba, Japan; [9]Internal Medicine III, Division of Rheumatology; [10]Division of Immunobiology, Medical University of Vienna, Vienna, Austria*

Background: Autoreactive T cells have been shown to play a major role in Rheumatoid Arthritis, which drive the inflammatory process leading to an irreversible destruction of the joints. Gene transcription and regulation of proinflammatory cytokine production in T cells is regulated by epigenetic mechanisms. Histone deacetylases (HDACs) modify the epigenetic landscape by removing acetyl groups of lysine residues of histones, resulting in chromatin condensation and repression of transcription. The application of pan-HDAC inhibitors has been shown to be a potential therapeutic strategy. However, major side effects limited the clinical use and underline the need of more specific HDAC inhibitors.
Objectives: Our aim was to to investigate whether HDAC1 is linked with the development of autoimmune diseases. Therefore we were using the collagen-induced arthritis model (CIA) and the experimental autoimmune encephalomyelitis model (EAE).
Methods: Mice with a T cell specific deletion of HDAC1 (HDAC1cKO) were generated by using the CD4Cre/LoxP system. The clinical and the histological phenotype were assessed in the CIA and the EAE. Anti-collagen antibody levels were determined by ELISA. Qualitative and quantitative analysis of T cell subsets of the spleen and draining LN were assessed using flow cytometry. Additionally comparative RNA-sequencing of $CD4^+$ T cells from wild type (WT) and HDAC1cKO mice was performed.
Results: To address whether HDAC1 is involved in the pathogenesis of autoimmune diseases we induced the CIA and the EAE in WT and HDAC1cKO mice. Unexpectedly, HDAC1cKO mice did not develop any clinical or histological signs of inflammation, despite the presence of serum anti-CII antibodies. A similar protection against disease development was also observed in the context of EAE. A molecular analysis of HDAC1cKO $CD4^+$ T cells revealed increased STAT1 phosphorylation in activated HDAC1cKO $CD4^+$ T cells in comparison to WT cells. This was accompanied with an impaired expression of CCR6 in activated HDAC1cKO $CD4^+$ T cells, which is an essential chemokine receptor for the development of arthritis and EAE. In line with this finding we observed increased expression of CCR6 in $STAT1^{-/-}$ $CD4^+$ T cells. This indicates a negative role of STAT1 in the regulation of CCR6 expression.
Conclusions: Our data show the importance of HDAC1 as a key immune regulator in the pathogenesis of collagen induced arthritis. Therefore it might be considered as an interesting novel therapeutic target in RA.

FRI0056 INCREASED EXPRESSION OF THE COLLAGEN INTERNALIZATION RECEPTOR ENDO180 IN FIBROBLAST-LIKE SYNOVIOCYTES OF PATIENTS WITH RHEUMATOID ARTHRITIS

L. Yan, Y. Wen. *Department of Rheumatology, Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Background: Hyperproliferative and invasion are the characteristics of fibroblast-like synoviocytes in rheumatoid arthritis (RA-FLSs), which contribute mainly to RA disease progression and ultimately to joint destruction. Endo180 is a recycling endocytic receptor that has functions to regulate cell migration and bind and internalize collagens. However, the expression of Endo180 in RA-FLSs and its underlying mechanisms remain unclear.
Objectives: To examine the expression of Endo180 in RA-FLSs and the role it played in RA.
Methods: Tissues were collected from RA patients with joint replacement surgery or arthroscopy and RA-FLSs were obtained by tissue culture; Westren blot was used to measure the expression of Endo180 in RA-FLSs. Chemically synthesized small interference RNA (siRNA) specifically targeting Endo180 gene was transfected into RA-FLSs by cationic liposome; The interference efficiency of Endo180-siRNA on the production of Endo180 mRNA and protein was determined by RT-qPCR and Western blot respectly; The proliferative inhibition rate was examined by CCK8 assay and the migration of RA-FLSs were examined by Transwell assay.
Results: Expression of Endo180 was obviously higher in fibroblast-like synoviocytes in RA than OA and the traumatic patients. And its expression level has positive correlation with disease activity. The proliferative inhibition rate was obviously higher in the Endo180-siRNA group than the control groups ($P<0.05$) after transfection for 48h (8.31%±1.17%), 72h (15.93%±2.12)%), 96h (18.01%±2.78%). Transwell migration assay demonstrated the RA-FLSs through the transwell membrane in Endo180-siRNA group (21.27±6.35) were lesser than the NC-siRNA group (80.20±11.12) ($P<0.05$)and the blank control group (82.17±10.36) ($P<0.05$).
Conclusions: Endo180 may play a role in the regulation of proliferation and migration of RA-FLSs, which may provide beneficial therapeutic effects in RA.

FRI0057 EVALUATION OF THE IMMUNODOMINANCE OF A HISTONE H4 PEPTIDE IN ANTI-CCP ANTIBODIES FROM RHEUMATOID ARTHRITIS PATIENTS

L. Rodriguez-Martinez[1], C. Regueiro[1], A. Montes[1], E. Perez-Pampin[2], A. Mera-Varela[2], A. Gonzalez[1]. *[1]Experimental and Observational Rheumatology; [2]Rheumatology Unit, Instituto Investigacion Sanitaria- H. Clinico Universitario de Santiago, Santiago de Compostela, Spain*

Background: The anti-CCP assay identifies antibodies against endogenous citrullinated proteins that are not completely characterized. The histone H4 seems to be a prominent one according to a recent study (1), which found this protein specifically in the immune complexes from synovial fluid of anti-CCP positive RA patients. Only vimentin, among the previously proposed autoantigens, was present in those immune complexes, but its abundance was much lower than that of histone H4. In addition, a citrullinated H4-derived peptide, H4-c39/40, showed marked immunodominance since antibodies directed against this peptide were present in 100% of synovial fluid samples and in 92–94% of anti-CCP positive sera. These frequencies are much larger than the reported with other autoantigens.
Objectives: To confirm the immunodominance of the H4-c39/40 peptide in anti-CCP antibodies from RA patients by direct comparison with citrullinated peptides of two other potential autoantigens.
Methods: Five hundred and thirteen patients with established RA and 273 healthy controls were included. Antibodies against H4-c39/40, cFibB36–52 and cVim60–75 were evaluated using indirect ELISA. Concordance between positives and negatives was analyzed with the Goodman and Kruskal's gamma coefficient (γ). In addition, Spearman's rank correlation (r_s) was used to analyze the correlation between levels of antibody titers.
Results: In contrast to the previous report (1), only 68.5% of the anti-CCP positive patients carried anti-H4-c39/40 antibodies. However, this frequency was higher than the observed with the other two peptides, 50.5% of anti-cFibB36–52 and 28.8% of anti-cVim60–75 positive patients. Consequently, a high concordance was found between anti-CCP and anti-H4-c39–40 antibodies (γ =0.95), which was moderately larger than that observed between anti-CCP and anti-cFibB36–52 antibodies (γ =0.86). In addition, anti-H4-c39/40 antibody titers were correlated with anti-CCP titers, but this correlation was similar to the observed between anti-cFibB36–52 and anti-CCP titers (r_s =0.34 and 0.33, respectively). The anti-cVim60–75 antibodies, in turn, showed notably low concordance and low correlation with the anti-CCP antibodies.
Conclusions: Our results confirm that anti-H4-c39/40 antibodies are a significant component of the antibodies detected with the anti-CCP assay. However, immunodominance of this peptide was not as marked in our patients as the described in the original study.

FRI0058 EFFECT OF MIF GENE HAPLOTYPES ON RHTNF-A AND RHMIF RESPONSE IN PERIPHERAL BLOOD MONONUCLEAR CELLS OF RHEUMATOID ARTHRITIS PATIENTS

L.A. Hernandez-Palma[1], S. Garcia-Arellano[1], S. Cerpa-Cruz[2], J.F. Muñoz-Valle[1]. *[1]Research Institute in Biomedical Sciences, University of Guadalajara; [2]Division of Rheumatology, Guadalajara Civil Hospital "Fray Antonio Alcalde", Guadalajara, Mexico*

Background: Macrophage migration inhibitory factor (MIF) is a pro-inflammatory cytokine that plays important role in the development and pathogenesis of rheumatoid arthritis (RA). MIF promotes the expression of cytokines related to RA development, as tumor necrosis factor alpha (TNF-α), interleukin (IL)-6 and IL-17. Two polymorphisms in the promoter of the *MIF* gene have been associated with increased production of protein and it has been shown that TNF-α is involved in the regulation of *MIF* mRNA expression and protein secretion in a dose-dependent manner.
Objectives: To evaluate the effect of *MIF* gene haplotypes on rhTNF-α and rhMIF response in peripheral blood mononuclear cells (PBMC) of RA patients
Methods: Genotyping was performed for *MIF* gene haplotypes in 230 RA patients. Cell culture of PBMC from two patients per homozygous haplotype (5G, 6G and 7C) was performed and stimulated with rhTNF-α and rhMIF. Cytokine levels were analyzed by a microsphere-based ELISA method (Bio-Plex® MAGPIX™).
Results: rhTNF-α and rhMIF-induced IL-6, IL-17A and IL-17F secretion in PBMC of RA patients. We observed that PBMC extracted from patients with MIF 7C haplotypes stimulated with rhTNF showed higher secretion of IL-17A and IL-17F than patients with 5G and 6G haplotypes. IL-6 production with rhMIF stimulation was more pronounced in the 5G haplotype group than 6G or 7C haplotype groups.
Conclusions: rhTNF-α and rhMIF promote differential secretion of IL-6, IL-17A and IL-17F according to *MIF* haplotypes presence. IL-17A and IL-17F secretion of stimulated PBMC with rhTNF-α are higher in patients with 7C haplotype than non-7C haplotypes. Furthermore, IL-6 levels are higher in PBMC from patients with 5G haplotype stimulated with MIF than non-5G haplotypes.

FRI0059 CARDIAC, PULMONARY AND PERIODONTAL DISEASE AS COMORBIDITIES IN TNF-DRIVEN MODELS OF CHRONIC POLYARTHRITIS

M.C. Denis[1], L. Ntari[2], M. Sakkou[2], P. Chouvardas[2], A. Prados[2], G.M.C. Consortium[3], H. Fuchs[3], V. Gailus-Durner[3], M. Hrabě de Angelis[3], B. Simic[4], M. Crucet[4], T.F. Lüscher[4], K. Mitchell[5], C. Schwarzwald[5], N. Karagianni[1], G. Kollias[2,6]. *[1]Biomedcode Hellas SA; [2]Department of Immunology, Biomedical Sciences Research Center (BSRC), "Alexander Fleming", Vari, Greece; [3]German Mouse Clinic, Institute of Experimental Genetics, Helmholtz Zentrum München, German Research Center for Environmental Health (GmbH), Neuherberg, Germany; [4]Center for Molecular Cardiology; [5]Clinic for Equine Internal Medicine, Equine Department Vetsuisse Faculty, University of Zurich, Zurich, Switzerland; [6]Department of Physiology, School of Medicine, National Kapodistrian University, Athens, Greece*

Background: Patients with RA exhibit an increased risk of developing multiple extraarticular pathologies. The link between co-manifested pathologies and RA at the level of common molecular and cellular mechanisms remains to be further elucidated.
Objectives: We aimed to identify comorbidities developing in models of TNF-driven chronic polyarthritis and further explore their aetiopathogenesis.
Methods: Through detailed phenotyping, clinical, histopathological and functional analysis we investigated the development of comorbidities in the Tg197 and $Tnf^{\Delta ARE/+}$ mouse models that overexpress respectively human and mouse TNF and develop spontaneous chronic polyarthritis with the concomitant development of Crohn's-like IBD in the case of the $Tnf^{\Delta ARE/+}$ animals. Targeting mesenchymal origin cells, *ex vivo* cellular analyses and RNA sequencing expression profiling allowed us to further explore the key cellular instigators of RA related comorbidities.
Results: Histopathological evaluation and echocardiography assessment of both arthritis models showed thickening of the aortic valve and cardiac dysfunction characterized by mild decreased fractional shortening, decreased heart rate and increased velocities in ascending aorta hinting towards aortic valve disease. The aortic valve pathology, similarly to arthritis, was ameliorated with anti-TNF treatment. The thickening of the aortic valve leaflets was due to fibrosis which consisted almost entirely of mesenchymal origin Valve Interstitial Cells (VICs). VICs from mutant mice expressed high levels of TNF and exhibited a proliferative and migratory phenotype resembling the activated phenotype of pathogenic Synovial Fibroblasts (SFs) isolated from the joints of the same mice. RNA-seq analysis further supported a significant correlation between pathogenic SFs and VICs highlighting a common cellular mechanism linking RA and aortic valve pathology. Furthermore, we show that TNF deregulation leads to additional RA related comorbidities, as described in human disease, including periodontitis with early onset alveolar bone loss and pulmonary inflammation with mild to severe bronchus-associated lymphoid tissue (BALT).
Conclusions: Similarly to human RA patients, TNF-driven arthritis models develop multiple RA-associated comorbidities, offering novel insights into potential molecular and cellular mechanisms commonly underlying these complex pathologies.

FRI0060 MONOCYTE-DERIVED MICROPARTICLES IN CIRCULATION OF PATIENTS WITH RHEUMATOID ARTHRITIS: A NOVEL BIOMARKER FOR THE DISEASE ACTIVITY

M. Koseki, H. Yasuoka, K. Sakata, K. Yoshimoto, K. Yamaoka, T. Takeuchi.
Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan

Background: Rheumatoid arthritis (RA) is a systemic connective tissue disease and characterized by inflammation of synovium of multiple joints, however, its pathogenesis is still unclear (1). Physiologically, microparticle (MP) is categorized as a membrane microvesicle which contains various humoral factors such as cytokines or growth factors and 0.1–1 μm in size (2). And MPs can distribute systemically through circulation. MP is released from almost all cell types and induced by stimulation, stress or apoptosis (3). Thus, we hypothesized that MPs derived from various cells can distribute to the lesion of RA and be associated with systemic disease process of RA.
Objectives: To clarify the source of MPs in circulation of RA and elucidate their role in the pathogenesis and the possibility for application as a novel disease marker.
Methods: Twenty patients with RA and 13 healthy controls were involved. Using gradient centrifugation, platelet-rich plasma was isolated from whole blood and applied to flow cytometry. MP is defined as a vesicle less than 1 mm in diameter and Megamix® was used to set a gating condition to detect microparticles (4). Sources of MP (MP subsets) were identified by the expression of cell-specific markers using flow cytometry with fluorescence-conjugated antibodies as follows; platelets MP: $CD41^+CD31^+$ MP, endothelial cell MP: $CD41^-CD31^+$ MP, immune cell MP: $CD45^+CD41^-$ MP, MP derived other cells: $CD41^-CD31^-CD45^-$ MP. Correlation between clinical information and proportion of MP subsets was also analyzed. Comparisons between two groups were examined by Mann-Whitney U-test with Bonferroni correction. Significant difference was defined as corrected *p* value (*Pc*) <0.05.
Results: Mean age of 20 patients with RA was 56±14 years, 95% was female, disease duration was 8.5±8.0 years, and DAS28-ESR was 2.0±1.1. Methotrexate was administered to 75% and average dose was 8.0±2.4 mg/week. Platelet-derived MP covered the largest proportion in all groups. Interestingly, proportion of immune-cell-derived MP was higher ($Pc<0.006$) in patients with RA compared to controls. Proportion of immune-cell-derived MP was positively correlated with inflammatory markers such as CRP and composite disease markers such as DAS28-ESR. Furthermore, when stratified by monocyte fraction and non-monocyte fraction based on CD14 expression, proportion of monocyte-derived MP showed higher ($Pc<0.01$) in patients with RA compared to controls, but non-monocytes MP did not, and that of monocyte-derived MPs was also correlated with disease markers for activity of RA.
Conclusions: Proportion of circulating immune-cell-derived MPs, especially monocyte-derived MPs, increased in RA and correlate with disease activity. These results suggest that monocyte-derived MPs can be measured as a novel biomarker and involved in the disease process of RA.

FRI0061 IDENTIFICATION OF CITRULLINATION SITES SPECIFIC FOR PEPTIDYLARGININE DEIMINASE 2 (PAD2) AND PAD4 IN FIBRINOGEN FROM SYNOVIAL FLUID OF PATIENTS WITH RHEUMATOID ARTHRITIS

M. Sharma[1], D. Damgaard[2], L. Senolt[3], B. Svensson[1], A.C.B. Jensen[4], C.H. Nielsen[2], P. Hägglund[1]. *[1]Department of Biotechnology and Biomedicine, Technical University of Denmark; [2]Center for Rheumatology and Spine Diseases, Copenhagen University Hospital, Rigshospitalet, Institute for Inflammation Research, Copenhagen, Denmark; [3]Department of Rheumatology and Faculty of Medicine, Charles University, Institute of Rheumatology and Department of Rheumatology, Prague, Czech Republic; [4]Rheumatology, Biomarkers and Research, Nordic Biosciences, Copenhagen, Denmark*

Background: Protein citrullination, i.e. conversion of arginine residues into citrulline residues, is a post-translational modification catalyzed by PAD, and is an important pathophysiological determinant in conditions such as Rheumatoid arthritis (RA). Identification of citrullination sites on putative autoantigens is likely to enhance our understanding of PAD's substrate specificity.
Objectives: Citrullinated fibrinogen is an autoantigen linked to the pathophysiology of RA.We have applied a novel MS-based proteomics approach to estimate the degree of citrullination in synovial fluid (SF) from RA patients, and compare to fibrinogen citrullinated *in vitro* by PAD2/4, the most important PAD isoforms involved in RA. The estimated degree of citrullination induced by the two isoforms is also compared to evaluate their relative impact.
Methods: Fibrinogen was citrullinated *in vitro* by PAD2/4 and citrullination sites were identified by LC-MS/MS on a Q-exactive orbitrap following proteolytic digestion with Lys-C. These *in vitro* citrullination profiles were compared to those observed in SF fibrinogen of four RA patients with varying DAS28 scores, CRP levels and leukocyte counts. DAS28 scores >5.1 and ≤ 2.4 correspond to moderate to severe and low activity of disease respectively. Patients with high inflammatory activity gave high CRP level and leukocyte count values.
Results: A total of 52 citrullination sites were identified. Overall, PAD2 generated higher number of identified sites and higher degree of citrulline occupancy at given sites than PAD4. In fibrinogen from SF, 38 citrullination sites were identified, of which 23 have not been previously reported. Several of these sites were identified in more than one patient, and were regarded as hotspots. Fibrinogen from patients with high DAS28 levels contained markedly more citrullination sites and higher citrulline occupancy.
Conclusions: Study suggests that PAD2 citrullinates fibrinogen more efficiently than PAD4 and citrullination of certain sites in fibrinogen from SF reflects disease activity. Identification of such sites may have diagnostic or prognostic value in RA and other inflammatory disorders.

FRI0062 SYNOVIAL FLUID TREG CELLS SECRETE IL-17 AND AT THE SAME TIME ARE POTENT SUPPRESSORS OF TRESP CELL PROLIFERATION, TNF ALPHA AND IFN GAMMA PRODUCTION

M. Benito-Miguel[1,2], A. Villalba[1], M.-G. Bonilla-Hernán[1], D. Peiteado[1], A. Balsa[1], P. Aguado[1], P. Sánchez-Mateos[3], A. Puig-Kröger[3], E. Martin-Mola[1], M.E. Miranda Carus[1]. *[1]Rheumatology, HOSPITAL LA PAZ - IdiPAZ; [2]Biochemistry, Centro de Ciencias de la Salud San Rafael. Universidad Antonio de Nebrija; [3]Immunology, Hospital Gregorio Marañon, Madrid, Spain*

Background: IL-17-expressing FoxP3 regulatory T cells have been described, and their suppressive capacity has been questioned. An inflammatory environment seems to favor IL-17 secretion by regulatory CD4+CD25+FoxP3+ T cells.
Objectives: To assess the suppressive function and IL-17 producing capacity of CD4+CD25+CD127-FoxP3+ T cells in the synovial fluid of RA patients (RASFd).
Methods: Synovial fluid was drawn from 35 patients with established RA who were receiving methotrexate and low-dose oral prednisone. The frequency of CD4+CD25+CD127-FoxP3+ T cells was assessed by flow cytometry. Total CD4+ T cells, CD4+CD25+CD127- T reg cells and CD4+CD25- Tresp cells were isolated by Ficoll-Hypaque gradient, followed by sorting. After isolation, cells were stimulated for 5 hours with PMA+ionomycin or cultured for 5 days in flat-bottom 96-well plates coated with an anti-CD3 monoclonal antibody. Treg cell function was assessed using two different approaches: A.The regulatory function of natural proportions of Tregs was inferred by comparing the proliferative and cytokine responses of total CD4+ T cells (TCD4T) versus CD25+ depleted CD4+ T cells (CD4+CD25-T cells or Tresp cells); B. The per cell suppressor potency of Tregs was assessed in cocultures of isolated Tregs with Tresp, established at different Treg/Tresp ratios. Proliferation was determined by 3Hthymidine incorporation and CFSE dilution; cytokine secretion was measured by ELISA of culture supernatants.
Results: A high proportion of CD4+CD25+CD127- T cells was present in RASFd (mean ± SD, 21.1%±6.2), which is significantly higher than reported frequencies of this cell population in the peripheral blood of both RA and healthy subjects. These RASFd CD4+CD25+CD127- T cells expressed FoxP3 but did not express CD69. The proliferation rate, TNFα and IFNγ secretion were significantly higher for isolated Tresp as compared with TCD4T cells, indicating that natural proportions of Treg cells present in the synovial fluid of RA are funcionally suppressive. Surprisingly, TCD4T cells secreted higher amounts of IL-17 as compared with Tresp cells, although the difference did not reach statistical significance. On a per cell basis, RAPB Tregs were potent suppressors of Tresp proliferation, TNFα and IFNγ but not of IL-17 secretion; in fact IL-17 secretion did not decrease but was enhanced in the presence of increasing proportions of Treg cells. Isolated Treg cells did not proliferate or produce cytokines when cultured alone in anti-CD3 coated plates. However, in the presence of plate-bound anti-CD3 plus anti-CD28 and recombinant human IL-2, isolated Treg cells secreted significant amounts of IL-17 whereas no TNFα or IFNγ could be detected in supernatants.
Conclusions: CD4+CD27+CD127- FoxP3+ Treg cells present in the synovial fluid of RA patients are potent suppressors of Tresp proliferation, TNFα and IFNγ secretion, and at the same time produce significant amounts of IL-17.

FRI0063 RESVERATROL ATTENUATES SYNOVIAL HYPERPLASIA IN AN ACUTE ANTIGEN-INDUCED ARTHRITIS MODEL BY AUGMENTING AUTOPHAGY AND DECREASING ANGIOGENESIS

M. Almonte-Becerril[1], J.A. Fernandez-Rodriguez[1], J.A. Fernandez-Rodriguez[1], O. Ramil-Gomez[1], R.R. Riveiro-Naveira[1], L. Hermida-Carballo[1], A. Concha[2], A. Vela-Anero[3], S. Viñas[1], F.J. Blanco[4], M.J. Lopez-Armada[1]. *[1]Aging and Inflammatory Research Lab; [2]Servicio de Patología; [3]Terapia Celular y Medicina Regenerativa; [4]Laboratorio de Investigacion Osteoarticular y Envejecimiento, SERGAS, A Coruña, Spain*

Background: Previously, we have demonstrated that dietary supplementation with resveratrol lowers synovial hyperplasia, inflammatory markers and oxidative damage in an acute antigen-induced arthritis (AIA) model.
Objectives: In this work, we investigated whether resveratrol can also regulate this abnormal proliferation of synovial tissue in an acute AIA model by inducing cell death pathways and by modifying the angiogenesis in the synovial membrane.
Methods: Animals were randomly divided into 3 groups: control, AIA, and resveratrol-treated AIA group. Resveratrol (12,5 mg/kg/day) was given orally 8 weeks before AIA induction until sacrifice day (48 h after intra-articular injection). Control and AIA animals were administered 100 μl of water. Resveratrol effects on autophagy and apoptosis were evaluated by LC3 and active caspase-3 expression (confocal and immunohistochemistry, respectively). Angiopoietin 1 (Ang-1), vascular endothelial growth factor (VEGF), and the nuclear factor NF-*kappa*-B p65 subunit (p65) were also determined by immunohistochemistry and cartilage degradation with Safranin-O.
Results: Resveratrol significantly reduced the histological score of synovial tissue. Results showed a significant higher expression of LC3 signals in the AIA synovial membranes, compared with control samples, in which the presence of vesicles was easily observed. Interestingly, the synovial tissues from the resveratrol group showed a significantly ($p \leq 0.001$) higher signal for LC3, compared with the AIA samples. Active caspase-3 expression was up-regulated at the same level in the synovial membranes of AIA group than in resveratrol-treated AIA group; however, in resveratrol-treated AIA group active caspase-3 signal was mainly located in the inflammatory cells. Resveratrol consumption significantly attenuated Ang-1 signal, whereas expression of VEGF showed a non significant reduction. Resveratrol administration also mitigated, even not significantly, p65 expression that was significantly higher in the AIA animals than those from the control animals. In addition, resveratrol decreased articular cartilage degradation.
Conclusions: These data suggest that resveratrol is able to modulate synovial hyperplasia by increasing autophagic cell death and limiting angiogenic response in an acute AIA model, which could also modulate the inflammatory and destructive processes for rheumatoid arthritis.

FRI0064 CHEMOKINE RECEPTOR 6 MODULATES ARTHRITIS IN A T CELL DEPENDENT MANNER

M. Bonelli, A. Puchner, L. Goeschl, S. Hayer, B. Niederreiter, J.S. Smolen, C. Scheinecker, S. Blueml. *Devision of Rheumatology, Medical University of Vienna, Vienna, Austria*

Background: Rheumatoid arthritis (RA) is an inflammatory autoimmune disease, characterized by synovial infiltration of various cells. Chemokines are involved in the recruitment of different cell types into the synovial membrane. Accumulation of CCR6 expressing mononuclear cells can be found in joints of RA patients. CCR6 expression has also been reported on $CD4^+$ T cells, in particular regulatory as well as Th17 cells. In addition, a subset of regulatory T cells, namely $CD25^-Foxp3^+$ T cells, can upregulate CCR6 and RANKL and thereby can promote osteoclastogenesis.
Objectives: In this study, we investigated the role of CCR6 in the pathogenesis of arthritis using different arthritis models.
Methods: Clinical as well as histological signs of arthritis were investigated in the collagen-induced arthritis (CIA), K/BxN serum transfer arthritis and in the human tumor necrosis factor (hTNFtg) arthritis model, comparing *wt* and *CCR6-/-* mice. We analyzed the phenotype of lymph node cells by flow cytometry and cytokine concentrations in serum. Anti-collagen antibodies and cytokines were measured by enzyme-linked immunosorbent assay.
Results: The K/BxN serum transfer arthritis and hTNFtg arthritis model are known to be T cell independent. Since CCR6 is an important component of the innate immune system we compared the development of arthritis in both models. We did not detect any significant differences in clinical signs of inflammation or histological severity of arthritis between *wt* and *CCR6-/-* mice. In addition, bone volume was similar between *wt* and *CCR6-/-* mice. To investigate the role of CCR6 as part of the adaptive immune system in the development of arthritis we induced CIA in *wt* and *CCR6-/-* mice, which is known to be T cell dependent. *CCR6-/-* mice were almost completely protected from CIA. Indeed, analyses of T cell subsets by flow cytometry revealed a significant reduction of $CD25^-Foxp3^+$ T cells.
Conclusions: CCR6 is necessary for the generation of pathogenic $CD25^-Foxp3^+$ T cells in CIA, suggesting an important function of CCR6 on T cells in the development of autoimmune arthritis.

FRI0065 HELMINTHES BASED NOVEL COMPOUND, TUFTSIN-PHOSPHORYLCHOLINE (TPC) AMELIORATES ESTABLISHED MURINE ARTHRITIS

T. Bashi[1], J. Lachnish[1], M. Fridkin[2], Y. Shoenfeld[3], M. Blank[1]. *[1]Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Ramat Gan; [2]Organic Chemistry, Weizmann, Rehovot; [3]Zabludowicz Center for Autoimmune Diseases, Sheba.health.gov.il, Ramat Gan, Israel*

Background: In areas where helminthes infections are common, autoimmune diseases are rare. Treatment with helminthes or their ova, improved clinical findings of several autoimmune diseases. Based on the helminthes biological activity, a novel chimeric be-specific molecule was synthetized of tuftsin-phosphoryl-choline (PC)-TPC.
Objectives: To study TPC treatment in established collagen induced arthritis (CIA) mice, and the mechanism of activity.
Methods: Arthritis was induced in DBA male mice by immunization with collagen emulsified in TB-mycobacteria at the tail base. Boost was given 3 weeks later. Treatment with TPC started when the clinical score was 2. Cytokines were measure in culture-fluid of splenocytes in-vitro. T regulatory cells and B regulatory cells were measured by FACS. TPC effect on TLR4 expression was studied using HEKTM-mTLR4 cells system and its inhibitor. M1 shift to M2 was performed in RAW macrophages differentiated to M1 by PMA followed by LPS. TPC was added and IL-6, TNFalpha, IL-10 were tested by ELISA.
Results: Starting TPC treatment of CIA mice after disease establishment, had a significant lower arthritis score in comparison with control vehicle subjected mice (i.e. TPC-6.8±0.8 vs vehicle-13.8±0.45; $p<0.0001$). Joints staining revealed normal joint structure in TPC treated mice, whereas, control mice treated with PBS, PC or tuftsin had severe inflamed joints. Likewise, TPC enhanced anti-inflammatory response by enhanced IL-10 secretion, reduced pro-inflammatory cytokines secretion (IL-1β, IL-17, IL-6, and TNF-α) ($p<0.001$). Furthermore, TPC induced expansion of splenic CD4+CD25+FOXP3+ T regulatory cells (Tregs) and IL-10+CD5+CD1d+ B regulatory cells (Bregs). The mechanism underling the TPC related immunomodulatory activity was attributed to its bi-specific activity: a) Shift of Raw cells macrophages from pro-inflammatory macrophages M1 to anti-inflammatory M2 secreting anti- IL-10 ($p<0.001$), through the tuftsin part of TPC. b) TPC inhibited significantly TLR4 expression by HEKTM-mTLR4 cells ($p<0.02$) *via* the phosphorylcholine end. Our data indicated that TPC significantly ameliorated established CIA by anti-inflammatory immunomodulatory activity.
Conclusions: Our data may lead to a novel bi-specific self small molecule for therapy of patients with advanced RA.

FRI0066 GASTRIN-RELEASING PEPTIDE AND ITS RECEPTOR INCREASE ARTHRITIS FIBROBLAST-LIKE SYNOVIOCYTE INVASIVENESS OVER THE PI3K/AKT PATHWAY

M. Farinon[1,2], V.S. Clarimundo[1], R.T. Pedó[1,2], V.O.N. Teixeira[1], C. Nör[3], P.S. Gulko[4], R.M. Xavier[1,2], P.G. Oliveira[1,2]. *[1]Hospital de Clínicas de Porto Alegre; [2]Universidade Federal do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil; [3]Peter Gilgan Centre for Research and Learning, Toronto, Ontario, Canada; [4]Icahn School of Medicine at Mount Sinai, New York, United States*

Background: Rheumatoid arthritis (RA) is an autoimmune disease where the chronic inflammation and subsequent cartilage and bone erosion lead to joint destruction. The fibroblast-like synoviocytes (FLS) have a central role in disease pathogenesis and *in vitro* FLS invasiveness correlates with articular damage in RA patients. Gastrin-releasing peptide (GRP) plays an important role in the immune and inflammatory response. GRP is found in synovial fluid of RA patients and its receptor (GRPR) is found in synovial membrane of murine arthritis. RC-3095 in an antagonist of GRPR.
Objectives: To evaluate the role of GRP and GRPR on invasive behavior of mice FLS and to evaluate the GRP-induced signaling on PI3K/AKT pathway.
Methods: FLS were isolated from joints of DBA/1J mice with collagen-induced arthritis. Expression of GRPR in FLS was investigated by immunocytochemistry and western blot (WB). Proliferation of FLS treated with GRP (0.1 μM – 10 μM)

(n=3) and RC-3095 (0.05 μM – 10 μM) (n=4) was assessed by Sulforhodamine B assay in 24h, 48h and 72h. Invasion assay with FLS was performed using a Matrigel-coated transwell system over 24h in two different experimental arms: first, FLS were treated with GRP (10 μM), RC-3095 (1 μM) or GRP+RC-3095 (GRP 10 μM and RC-3095 1 μM) (n=6) and after, FLS were treated with GRP (10 μM), Ly294002 (10 μM), or GRP+Ly294002 (GRP 10 μM and Ly294002 10 μM) (n=4). Akt phosphorylation was assessed by WB.

Results: GRPR protein was detected in FLS both by immunocytochemistry and WB. GRP and RC-3095 treatments did not affect FLS proliferation. Exposure to GRP increased FLS invasion (5356±1027) by nearly two-fold compared with untreated cells (2845±532) ($p<0.02$), while the treatment with RC-3095 reduced FLS invasion (1723±271) compared with untreated cells. Treatment with GRP+RC-3095 (2670±499) reversed the invasiveness effect of GRP ($p<0.0001$). GRP also increased phosphorylated AKT expression in FLS by 30% ($p<0.001$). When Ly294002 was added with GRP (7772±1200), it prevented the GRP-induced increased cell invasiveness (11036±953.6) ($p<0.001$) (Figure 1).

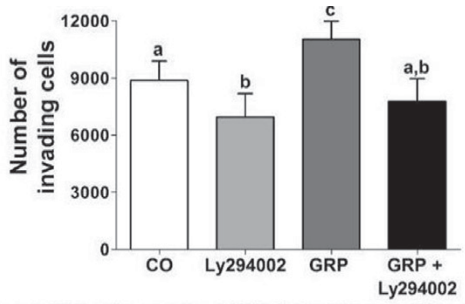

Figure 1. FLS invasion assay (n = 4). GRP significantly increased FLS invasion compared with untreated cells, whereas Ly294002 present opposite effect. Bars represent mean ± SEM. Data were analyzed by generalized estimating equation (GEE) followed by Bonferroni. a) p<0.008 versus Ly294002; p<0.026 versus GRP; b) p<0.001 versus GRP; c) p<0.001 versus GRP+Ly294002.

Conclusions: Our group demonstrated for the first time GRPR expression in FLS and that GRP are able to activate FLS invasion through AKT pathway. Finally, our results suggest that GRP/GRPR pathway could be relevant in the development of FLS-targeted therapy for RA.

FRI0067 MICRORNA PROFILING OF MTX-TREATED FIBROBLAST-LIKE SYNOVIAL CELLS IN RHEUMATOID ARTHRITIS REVEALED A POSSIBILITY OF MICRORNA-887-3P AS NOVEL THERAPEUTIC TARGET OF RA

N. Iwamoto, S. Fukui, T. Koga, S.-Y. Kawashiri, K. Ichinose, M. Tamai, H. Nakamura, T. Origuchu, A. Kawakami. *Department of Immunology and Rheumatology, Unit of Advanced Preventive Medical Sciences, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Nagasaki, Japan*

Background: The hallmarks of rheumatoid arthritis (RA) is the expansive of fibroblast-like synovial cells (FLS) in affected joints, causing joint destruction. FLSs are resistant to programmed cell death resulting in aggressive, invasive phenotype like a cancer invades and the hyperplastic synovial tissue destroys cartilage and bone. Therefore inhibition of FLS proliferation and is one of the therapeutic targets of RA. MicroRNAs (miRNAs), a group of small non-coding RNAs, have been shown to regulate cell differentiation through regulation of gene expression post-transcriptionally. Recently, several studies reported anti-cancer drugs modulate miRNA expression and that have been considered as one of important mechanism of cellular action to drug[1,2].

Objectives: To investigate the changes in microRNA expression profiles in response to MTX.

Methods: RA-FLS was treated with MTX with 1nM 48 hours, that could inhibit IL-6 production from RA-FLS. To investigate differentially expressed miRNAs in response to MTX, we performed miRNA array analysis. Expression of miR-887–3p in response to MTX of RA-FLS was analyzed by quantitative real-time PCR. To investigate the functional role of miR-887–3p, RA-FLS was transfected with synthetic precursor miRNA (pre-miR)/inhibitors of miRNA (anti-miR) of miR-887–3p using Lipofectamine and then gene expression microarray was performed. The cytokine/ chemokine production was screened by Multiplex cytokine/chemokine bead assays and confirmed by ELISA. Finally, we analysed migratory activities of RA-FLS by scratch assay.

Results: After 48 h of treatment with MTX, 7 miRNAs were up-regulated and 6 miRNAs were down-regulated as compared with that of untreated control. Among them quantitative real-time PCR with additional samples confirmed that miR-887–3p was up-regulated in response to MTX treatment of RA-FLS (1.79±0.46 -fold, $p<0.05$, n=7). To elucidate the functional consequence of the deregulation of miR-887–3p of RA-FLS, we performed gain-and-loss of function assays with miR-887–3p. Microarray analysis with gene ontology analysis revealed several genes correlated with cell signalling was modulated by miR-887–3p. Multiplex bead assay showed that overexpression of miR-887–3p decreased cytokine/chemokine production of RA-FLS such as TNF-a, GM-CSF, CCL4. Among these candidates, the secretion of GM-CSF was consistently and strongly decreased from RA-FLS transfected with pre-miR-887–3p. Furthermore overexpression of miR-887–3p reduced migratory activity of RA-FLS in scratch assay.

Conclusions: Our result showed that MTX altered micro RNA expression profiles in RA-FLS. MiR-887–3p might be downstream effector of MTX in suppression of its cytokine production and invasive phenotype. This knowledge may also be useful for the development of novel therapeutic strategies for RA based on other treatments able to boost the cellular reservoir of miR-877–3p.

FRI0068 REDUCTION OF PROLIFERATION, MIGRATION AND INVASION OF RHEUMATOID SYNOVIOCYTES BY ALL-TRANS RETINOIC ACID

N. Mosquera[1], Á. Rodríguez-Trillo[1], S.B. Bravo[2], A. Mera[1], C. Conde[1]. *[1]Experimental and Observational Rheumatology; [2]Proteomic Unit, IDIS, CHUS, Santiago de Compostela, Spain*

Background: Fibroblast-like synoviocytes (FLS) are pivotal in inflammation and joint damage of rheumatoid arthritis (RA). These cells proliferate, become resistant to apoptosis, migrate and invade, contributing to perpetuate synovial inflammation and destruction of cartilage and bone. Current treatments of RA are focused against inflammatory factors and immune cells, however, a significant percentage of patients do not successfully respond. Combined treatments with drugs that control inflammation and with others that reverse the pathogenic phenotype of FLS could improve the prognosis of these patients. An unexplored area includes vitamin A and its metabolites. These compounds modulate differentiation, development, apoptosis and proliferation. Indeed, retinoids are being successfully used in the treatment of several cancers for their anti-proliferative and pro-differentiative actions. In addition, several studies have shown a notable reduction of cell migration and invasion in different cell types after treatment with all-trans retinoic acid (ATRA). However, it is not known if ATRA could modify the migratory and invasive ability of rheumatoid synoviocytes.

Objectives: To analyse the effect of treatment with the retinoid all-trans retinoic acid in proliferation, migration and invasion of rheumatoid synoviocytes.

Methods: FLS were obtained from 8 RA patients. Cellular proliferation was determined using the CellTiter-Glo luminescent viability assay (Promega). Migration was analysed by wound healing assay, using Ibidi inserts. Percentage of migrating cells was determined by Image J. Invasion was tested by the Boyden chamber method using inserts (Millicell) coated with Matrigel (BD Biosciences). Invasion was determined by quantification of Giemsa stained cells on the bottom side of the inserts under the microscope. Proteomic analysis was performed using LC-MALDI-TOF/TOF and 1-DE and 2-DE gels. MS and MS/MS data was searched against the UniProt/Swiss-Prot database of protein sequences.

Results: We analysed the effect of ATRA in the spontaneous proliferation of FLS from 8 RA patients. ATRA treatment significantly reduced proliferation at 48, 72 and 96 h (p=0,005; p=0,002; p=0,04; respectively). Next, we analysed the effect of ATRA on RA FLS migration and invasion. Migration of RA FLS treated with ATRA for 96 h was reduced by 46% when compared with cells treated with vehicle control (p=0,002). In addition, RA FLS invasion was also impaired after ATRA treatment, as the invaded area was 31% lower than in controls (p=0,018). To elucidate the mechanisms underlying the effects of ATRA on RA FLS a proteomic analysis was performed. We compared the proteome of FLS from 5 RA patients treated with ATRA or with vehicle using LC-MALDI analysis. The differentially identified proteins in ATRA-treated FLS *vs* control FLS were Septin, Rho GTPase activating protein (ARHGAP1) and actin related protein 2 (ARP2). Validation experiments using 1-DE and 2-DE gels were performed.

Conclusions: Overall these results reveal that retinoid treatment reduces the proliferative, migratory and invasive capacity of RA FLS, indicating that this treatment could decrease joint damage and loss of function in RA patients.

FRI0069 **NEUTROPHILS PLAY A KEY ROLE IN THE REGULATION OF THE CHRONIC INFLAMMATION ASSOCIATED WITH RHEUMATOID ARTHRITIS THROUGH EPIGENETIC MECHANISMS MODULATED BY ANTI-CCPS ANTIBODIES AND REVERSED BY BIOLOGIC THERAPIES**

P. Ruiz-Limon, I. Arias de la Rosa, M.C. Abalos, C. Perez-Sanchez, Y. Jimenez-Gomez, M. Caracuel, J. Calvo, R. Ortega, M. Castro, E. Collantes, A. Escudero, C. Lopez-Pedrera, N. Barbarroja. *Rheumatology Service, IMIBIC/Reina Sofia Hospital/University of Cordoba, Cordoba, Spain*

Background: MicroRNAs (miRNA) are as a new class of modulators of gene expression, regulating inflammation, degradation of extracellular matrix and invasive behavior of the resident cells in rheumatoid arthritis (RA).
Objectives: 1) To investigate the miRNA expression profile in synovial and blood neutrophils in RA and its role in the pathogenesis of this disorder. 2) To study the effects of biological therapies on the miRNA profile in neutrophils.
Methods: Neutrophils were isolated from peripheral blood (PB) of 25 healthy donors (HD) and 25 RA patients. Neutrophils were isolated from paired synovial fluid (SF) of 15 RA patients. nCounter microRNA Assay was used to detect 800 human microRNAs simultaneously. Altered miRNAs were analyzed for potential mRNA targets using Ingenuity pathways analysis (IPA) software. mRNA targets and genes involved in miRNA biogenesis were evaluated. RA neutrophils were treated in vitro with tocilizumab and infliximab.Healthy neutrophils were treated in vitro with anti-CCPs isolated from RA patients alone or combined with tocilizumab or infliximab. RA neutrophils were cotransfected with the pre-miRNAs 126 and 148.
Results: 94 miRNAs were downregulated and 3 upregulated in PB neutrophils from RA patients compared to HD.Among the miRNAs deregulated in blood, 34 miRNAs were even more significantly reduced in SF neutrophils. Accordingly, RA neutrophils showed a downregulation of the proteins participating in miRNA biogenesis and upregulation of its mRNA targets. Altered miRNAs were mainly involved in immunological disease and inflammatory response, suggesting the abnormal activation of this cell subtype in RA. In vitro treatment of RA neutrophils with infliximab reversed the expression of miRNAs, genes involved in their biogenesis and reduced the inflammatory profile in these cells.In addition, treatment of healthy neutrophils with IgGs anti-CCPs isolated from RA patients decreased the expression of the miRNAs, proteins involved in the biogenesis machinery and increase its inflammatory targets. Finally, cotransfection of RA neutrophils with the pre-miRNAs 126 and 148 reduced the levels of their target proteins.
Conclusions: 1)RA neutrophils exhibit a defect in the miRNAs processing, showed by a decrease in most of the detected miRNAs and the downregulationof proteins involved in their biogenesis. This defect seems to be modulatedby anti-CCPs antibodies.2)miRNA downregulation is even more pronounced in synovial fluid neutrophils, which may contribute to the high inflammatory profile of these cells in the joint. 3) Infliximab reverses the altered miRNA profile and the defect in the biogenesis machinery, reducing the proinflammatory pattern in these cells. 4)miRNAs 126 and 148 regulate the expression of numerous inflammatory proteins in RA neutrophils.In sum, this study shows that the neutrophils play a key role in the regulation of the chronic inflammation link to RA. The effect, associated to epigenetic mechanisms, seems to be mediated by the anti-CCPs and is reversed by biologic therapies.

FRI0070 **ANGIOTENSIN II TYPE 2 RECEPTOR (AT2R) IS OVEREXPRESSED IN RHEUMATOID ARTHRITIS AND OSTEOARTHRITIS SYNOVIUM AND INCREASES STEADILY WITH INFLAMMATORY STIMULI: A POTENTIAL NEW TARGET FOR PAIN AND ANTI-INFLAMMATORY THERAPIES**

R. Terenzi[1], M. Manetti[2], I. Rosa[2], E. Romano[1], F. Galluccio[1], S. Guiducci[1], L. Ibba-Manneschi[2], M. Matucci-Cerinic[1]. *[1]Department of Medicine, Division of Rheumatology; [2]Department of Anatomy, Università degli Studi di Firenze, Firenze, Italy*

Background: Despite increasing evidence suggesting that angiotensin II type 2 receptor (AT2R) antagonism might be a feasible strategy for the treatment of chronic inflammation and pain, no study has yet analyzed the synovial expression of AT2R.
Objectives: To investigate the expression of AT2R in rheumatoid arthritis (RA) and osteoarthritis (OA) synovium and its possible modulation in fibroblast-like synoviocytes (FLS) by proinflammatory stimuli.
Methods: The expression of AT2R in RA and OA synovium was investigated by immunohistochemistry. AT2R expression in synovial T cells, B cells, macrophages and FLS was assessed by double immunofluorescence. FLS were isolated from healthy (H), OA and RA synovium and treated with tumor necrosis factor (TNF)-α and interleukin (IL)-1β, alone or in combination. Immunocytochemistry and Western blotting were performed to study AT2R expression in cultured FLS.
Results: RA synovium showed stronger AT2R immunostaining than OA synovium in the lining and sublining layers. In RA synovium, AT2R was strongly expressed in CD3+ T cells, CD20+ B cells, CD68+ macrophages and vimentin+ FLS. High levels of AT2R were found in OA-FLS and RA-FLS at baseline, while AT2R expression was negligible in basal H-FLS. AT2R expression was higher in RA-FLS than OA-FLS. Treatment with TNF-α and IL-1β was able to foster the expression of AT2R not only in OA-FLS and RA-FLS, but also in H-FLS.
Conclusions: AT2R is strongly expressed in different cell types of the inflamed synovium and proinflammatory stimuli may foster the expression of AT2R in FLS. AT2R might represent a novel potential therapeutic target in chronic arthritides.

FRI0071 **TOFACITINIB RESTORES THE INHIBITION OF REVERSE CHOLESTEROL TRANSPORT INDUCED BY INFLAMMATION: UNDERSTANDING THE LIPID PARADOX ASSOCIATED WITH RHEUMATOID ARTHRITIS**

S. Pérez Baos, J.I. Barrasa, P. Gratal, A. Larrañaga-Vera, I. Prieto-Potin, G. Herrero-Beaumont, R. Largo. *Bone and Joint Research Unit, Rheumatology Dept., IIS-Fundación Jiménez Díaz UAM, Madrid, Spain*

Background: Patients with active rheumatoid arthritis (RA) have increased cardiovascular mortality, paradoxically associated with reduced serum lipid levels. In fact, an inverse relationship between C-reactive protein (CRP) and circulating lipid levels has been observed [1,2]. The Jak inhibitor tofacitinib ameliorates systemic and joint inflammation in RA with a concomitant increase in serum lipids [3].
Objectives: Our aim was to analyze the effect of tofacitinib on the lipid and inflammatory profile of hyperlipidemic rabbits with chronic arthritis (CA), and on the regulation of reverse cholesterol transport (RCT) during chronic inflammation.
Methods: New Zealand male rabbits were randomly assigned to three groups: control group (*n*=6), chronic arthritic rabbits (CA, *n*=9) and CA rabbits receiving tofacitinib (CA+TOFA, *n*=9). All animals were fed *ad libitum* with a high-fat diet (0.5% cholesterol, 4% peanut oil). CA was induced in previously immunized rabbits by administering four intra-articular injections of ovalbumin. A group of rabbits received tofacitinib (10mg/kg/day) for two weeks. All animals were euthanized 6 weeks after challenge, when synovial and serum samples were collected. For *in vitro* studies, vehicle and ABCA1 siRNA-treated THP-1-derived macrophages were exposed to high lipid concentrations, and then stimulated with interferon gamma (IFNγ) in the presence or absence of tofacitinib, in order to assess their cholesterol efflux capacity and the involved mediators.
Results: CA rabbits showed lower levels of serum TC and LDL-C compared to controls (p=0.001, p=0.012), while TC/HDL-C ratio was higher in CA+TOFA rabbits when compared to CA animals (150±15 vs 231±17, p=0.004). Synovial inflammation and CRP levels were increased in CA animals, and a significant reduction was shown in CA+TOFA rabbits in both parameters. We also observed an inverse correlation between serum TC and CRP (R=-0.454, p=0.029). Tofacitinib was able to reduce the lipid content within synovial macrophages up to a 58% (p=0.041), although it did not modify synovial macrophage density. In foam macrophages in culture, an inflammatory milieu induced by IFNγ further stimulated the intracellular lipid accumulation (p=0.041) along with a decrease in the protein levels of the nuclear factor LXRα (liver X receptor α) and the cholesterol transporter ABCA1 (ATP-binding cassette transporter 1) (p=0.002 and p=0.0047, respectively). Tofacitinib prevented the lipid accumulation within macrophages (p=0.029) by increasing LXRα (p=0.047) and ABCA1 synthesis (p=0.004) in a Jak/STAT-dependent manner, while it was unable to reduce lipid accumulation in ABCA1 silenced macrophages.
Conclusions: Our results suggest that active inflammation could be associated with lipid accumulation within macrophages – in the synovium and probably in other tissues – thus inducing a decrease in serum lipid levels. Tofacitinib may prevent this phenomenon, at least partially, by increasing RCT pathways in macrophages. Taken together, these findings further explain how serum lipid levels are diminished in RA and partially justify the effect of tofacitinib on the lipid profile in RA patients.

FRI0072 **ALTERATION OF THE INTESTINAL MICROBIOME IN THE PRECLINICAL PHASE OF EXPERIMENTAL ARTHRITIS AND THE EFFICACY OF MICROBIOTA MODULATION IN ESTABLISHED ARTHRITIS IN MICE**

R. Rogier[1], H. Evans-Marin[2], P. van der Kraan[1], W. van den Berg[1], M. Koenders[1], J. Scher[2], S. Abdollahi-Roodsaz[1,2]. *[1]Rheumatology, Radboud University Medical Center, Nijmegen, Netherlands; [2]Medicine, New York University School of Medicine, New York, United States*

Background: The composition of intestinal microbiota is perturbed in patients with new-onset rheumatoid arthritis (RA) and those with chronic RA. However, it is not known whether the changes in the intestinal microbiome precede

the development of arthritis or are rather a consequence of the inflammatory processes. Furthermore, while both germ-free condition and administration of oral antibiotics prevent arthritis in mice, it is unclear whether modulation of the intestinal microbiota after the onset of arthritis may still suppress the disease.
Objectives: We aimed to assess potential alterations of the intestinal microbiome in the preclinical phase of inflammatory arthritis, and to determine the efficacy of microbiota modulations in the treatment of established disease in mice.
Methods: We sequenced fecal bacterial 16S rRNA to define the intestinal microbiome in mice before immunization with collagen and 21 days later before the booster injection for the induction of collagen-induced arthritis (CIA). To assess the efficacy of microbiota modulation during arthritis, mice with ongoing CIA were treated orally by a broad-spectrum antibiotic cocktail for one week to partially eliminate the intestinal microbiota. T cell differentiation and production of cytokines in intestinal lamina propria and joint-draining lymph nodes were assessed by flow cytometry and Luminex. Arthritis was assessed macroscopically and by histology. Serum-transfer arthritis induced by intraperitoneal injections of arthritogenic K/BxN mouse serum was used as a control, T cell-independent, model.
Results: The preclinical phase of inflammatory arthritis in mice was characterized by marked changes in the intestinal microbiome, represented by a significant increase of the phylum *Bacteroidetes* and a decrease of *Firmicutes* and *Proteobacteria*. Among the most abundant bacterial families, S24–7 and *Staphylococcaceae* were expanded, whereas *Lachnospiraceae* were reduced during the immune priming phase of CIA. Several operational taxonomic units associated with S24–7 family increased, while those assigned to *Lachnospiraceae* and *Ruminococcaceae* decreased in the intestinal microbiota before the clinical onset of arthritis. The abundance of intestinal lamina propria Th17 cells significantly correlated with the severity of CIA; however, intestinal Th1 cells were not correlated with the disease. Elimination of intestinal microbiota in mice with ongoing CIA specifically suppressed intestinal Th17 cell differentiation without affecting Th1 and Treg cells. Importantly, elimination of intestinal microbiota suppressed Th17 cell differentiation and IL-17 production in joint-draining lymph nodes, and reduced the severity of established CIA. In contrast, the T cell-independent serum-transfer arthritis was not affected by this strategy.
Conclusions: These observations suggest that perturbations of the intestinal microbiome may precede the development of inflammatory arthritis. Similar studies are warranted in human pre-RA or at-risk individuals to shed light on the functional role of the microbiome in the development of RA. Our studies also suggest that modulation of the intestinal microbiota after the onset arthritis may still provide opportunities to treat inflammatory arthritis.

FRI0073 RAGE ACTIVITY INFLUENCES CO-DEVELOPMENT OF JOINT AND VASCULAR DISEASE IN RA

S. Yu[1], L.-S. Tam[2]. *[1]Rheumatology, The Second Affiliated Hospital of Guangzhou Medical University, Guangzhou, China; [2]Rheumatology, Medicine & Therapeutics, Hong Kong, Hong Kong*

Background: RAGE is expressed by many cells in blood and joints of RA and interacts with a variety of pro-inflammatory ligands, especially HMGB1 that are enriched in inflamed joint. The RAGE-ligand interaction leads to a sustained inflammatory response. Soluble RAGE (sRAGE) lacks the transmembrane and cytoplasmic domain of the cell surface full-length RAGE (flRAGE) and function as a decoy for RAGE ligand. Relatively little is known about factors that regulate sRAGE levels in human subjects and whether circulating levels reflect tissue RAGE expression and activity is unclear. The relationship between the up-regulation of flRAGE/HMGB1 and the level of "protective" sRAGE levels in RA is of obvious clinical interest.
Objectives: To elucidate the balance between the expression of flRAGE on peripheral blood monocyte and dendritic cell (DC), and the plasma concentration of sRAGE and HMGB1 in patients with active RA compare to controls; To ascertain whether flRAGE expression profiles, plasma sRAGE and HMGB1 level correlated with disease activity or inflammatory markers in RA patients.
Methods: 40 consecutive patients attending the rheumatology clinic at Prince of Wales Hospital, who fulfilled the 2010 ACR/RULAR classification criteria with active RA (28 joint disease activity score 28–4 [CRP] (DAS28)$>$3.2) and 40 age- and sex-matched healthy volunteers were recruited for this cross-sectional study. The expression profile of cellular transmembrane RAGE on peripheral blood monocyte ($ILT3^+CD123^-$), total DC ($ILT3^+CD14^-CD16^-$), myeloid DC ($ILT3^+CD14^-CD16^-CD123^-$) and plasmacytoid DC ($ILT3^+CD14^-CD16^-CD123^+$), plasma levels of HMGB1 and soluble RAGE in all RA patients and healthy controls were measured at baseline using flow cytometry and ELISA. In RA patients, associations with disease activity and severity variables were analyzed by simple and multiple linear regressions.
Results: Protein expression of flRAGE on peripheral blood monocytes ($ILT3^+CD123^-$), total DCs ($ILT3^+CD14^-CD16^-$) and myeloid DCs ($ILT3^+CD14^-CD16^-CD123^-$) were significant increased in RA patients with active disese compared with control subjects (all $p<0.01$) (no enough cells for flRAGE detection on plasmacytoid $ILT3^+CD14^-CD16^-CD123^+$ DCs). Also, the flRAGE was more common in patients with cardiac affection. There was no statistically significant difference of the plasma level of HMGB1 from active RA patients as compared healthy controls ($p>0.05$). The plasma sRAGE level was significantly lower in patients compared to healthy controls ($p<0.001$), which correlated negatively with serum levels of CRP, ESR, DAS28 and high-density lipoprotein (HDL) (all $p<0.05$). Linear regrssion analysis detected CRP as significant predictors for sRAGE level.
Conclusions: Autoimmunity-mediated inflammation might induce aberrant expression and activation of flRAGE while decreasing the plasma level of sRAGE in RA patients, subsequently leading to the augmented inflammatory response. Moreover, membrance flRAGE and sRAGE were associated not just with RA inflammation and autoantibody protein, but also with classical vascular risk factors for end-organ damage. These data suggest that RAGE activity influences co-development of joint and vascular disease in RA patients.

FRI0074 ANTI-INFLAMMATORY EFFECT OF RESVERATROL IN VITRO; POTENTIAL ROLE IN MANAGING LOW DISEASE ACTIVITY IN ARTHRITIS?

S. Lomholt[1], A. Mellemkjaer[2], M.B. Iversen[2], S.B. Pedersen[3], T.W. Kragstrup[4]. *[1]Aarhus University, Aarhus C, Denmark; [2]Department of Biomedicine, Aarhus University; [3]Department of Endocrinology and Internal Medicine; [4]Department of Rheumatology, Aarhus University Hospital, Aarhus C, Denmark*

Background: Resveratrol (RSV), a non-toxic polyphenol found in grapes, certain nuts, roots etc., have received increased attention in the last decade due to its anti-inflammatory modulation of a number of pathways, including cyclooxygenase-1/-2, nuclear factor kappa-beta and cytokine production. In vitro, RSV has been shown to reduce production of interleukin 1-beta and tumor necrosis factor alpha in monocytes and inhibit T-cell activation and synoviocyte proliferation. In vivo, intra-articular injections of RSV have demonstrated anti-inflammatory and pannus inhibiting effects in rats with induced arthritis.
Objectives: Here, we tested whether the anti-inflammatory effect of RSV in arthritis patients depends on the degree of systemic inflammation and the cellular composition of extracted synovial fluid. Furthermore, we evaluated the anti-inflammatory effect of RSV in combination with methotrexate (MTX) and adalimumab.
Methods: Synovial fluid mononuclear cells (SFMCs) from patient with rheumatoid arthritis (n=7) and spondyloarthritis (n=7) were cultured in monoculture for 48 hours (in vivo activated lymphocytes and monocytes) or 21 days (spontaneous generation of osteoclasts). Cultures were either left untreated or treated with RSV (25 μM), methotrexate (0.5 μg/ml), adalimumab (5 μ g/ml) or in combination. Supernatants were analysed for the production of monocyte chemoattractant protein-1 (MCP-1) and matrix metalloproteinase 3 (MMP3). Osteoclast differentiation was analysed with a tartrate resistant acidic phosphatase (TRAP) enzymatic assay.
Results: In the SFMC cultures, RSV reduced MCP-1 production by 25% compared with untreated cells (P=0.032). When grouping results by c-reactive protein (CRP), i.e. $<$ median vs. $\geq$ median, the inhibitory effect of RSV was primarily seen in cultures from patients with CRP $<$21 mg/l. In this group, RSV reduced MCP-1 production by 63%. Combining MTX and RSV reduced MCP-1 production compared to MTX alone, but only in the group of patients with CRP $<$21 mg/l (P=0.002). Combining adalimumab and RSV seemed to reduce MCP-1 in the group of patients with CRP $<$21 mg/l, but increase production in patients with CRP $\geq$21 mg/l (P=0.03). Similar grouping based on lymphocyte count showed RSV, MTX and adalimumab, alone or in combination, all reduced MCP-1 significantly compared to untreated cells in cultures from patients with $\geq$62% lymphocytes in the synovial fluid. RSV, MTX and adalimumab did not affect MMP3 production in the SFMC cultures. In the osteoclast cultures, RSV alone did not affect MCP-1 or TRAP. However, the combination of RSV and MTX reduced MCP-1 compared to no treatment (P=0.004). Adalimumab alone or combined with RSV reduced TRAP compared with untreated cultures ($P<0.027$).
Conclusions: RSV exhibits an anti-inflammatory effect on SFMCs. Interestingly; our data suggest that this effect is most pronounced in patients with relatively low CRP. Further, RSV produces an additive anti-inflammatory response in combination with MTX in the group of patients with low CRP and a synovial fluid dominated by lymphocytes. Together, this suggests that RSV may possess an additive potential when added to MTX treatment of arthritis patients with low disease activity.

FRI0075 RHEUMATOID ARTHRITIS PATIENTS RECEIVING GLUCOCORTICOID EXHIBITS SIGNIFICANT BONE QUALITY ABNORMALITIES, LEADING TO SEVERE BONE FRAGILITY REGARDLESS OF BISPHOSPHONATE TREATMENT

T. Shimizu[1,2], M. Takahata[1], H. Hamano[1], M. Ota[1], S. Hiratsuka[1], N. Iwasaki[1]. *[1]Department of Orthopeadic Surgery, Hokkaido University School of Medicine, Sapporo, Japan; [2]Department of Radiology & Biomedical Imaging, Musculoskeletal Quantitative Imaging Research, University of California San Francisco, San Francisco, United States*

Background: Patients with rheumatoid arthritis (RA) receiving glucocorticoids

develop particularly severe bone fragility accompanied with high risk factors for fragility fractures[1,2]. Although bisphosphonate is recommended for treatment of osteoporosis related RA and glucocorticoid-induced-osteoporosis[3], there are more frequently fractures than expected from bone mineral density based prediction even after used bisphosphonate.

Objectives: To clarify the pathological mechanisms of bone fragility of these RA patients, we investigated bone biopsy samples obtained from RA and normal postmenopausal patients.

Methods: We examined 10 female postmenopausal RA patients receiving glucocorticoid and bisphosphonate therapy (RA group) and 10 age-matched female patients with postmenopausal osteoporosis (Ctl group) selected from patients who required autologous iliac bone grafts. Analyses of clinical data, bone mineral density, serum metabolic markers, bone quality and material mechanical property of biopsy sample were performed.

Results: Although bone mineral density didn't show significant differences, RA group had significantly higher score of fracture risk assessment tool (FRAX), number and severity of existing vertebral fractures.

	Control	RA	p
FRAX score (%)			
Major osteoporosis fx.	10.7±4.8	33.4±8.0	<0.001
Femoral neck fx.	2.8±2.4	9.9±6.1	0.002
Clinical fragility fx.			
Number	4	16	
Severity (# x grade)	4	29	
Mechanical strength (N/mm)	218.8±24.6	164.9±36.5	0.001

RA group exhibited significant bone quality abnormalities including deterioration of the bone microstructure, decreased calcification of the bone matrix, increased osteocyte atrophy and empty lacunae (Figure), and an impairment bone material strength properties.

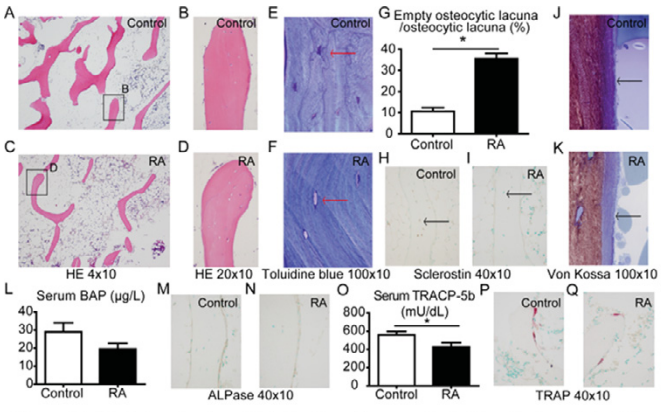

Figure: Histological mechanism of deterioration of bone quality in RA patients receiving GCs. (A-D) Representative photomicrographs of HE stained sections of the specimen. Images show sections from Control (A, C) and RA groups (B, D). Boxed areas in B and D are shown at higher magnification in the indicated images. (E, F) Representative micrographs focused on osteocytes of Control (E) and RA groups (F) with toluidine blue staining. Osteocytic lacunas (red arrows) are out of shape and emptiness in RA patients. (G) Comparison of ratio of empty osteocytic lacuna is shown. (H, I) Representative micrographs of Control (H) and RA groups (I) with immunostaining of sclerostin (black arrow). (J, K) Representative micrographs of Control (J) and RA group (K) with von Kossa staining. Black arrows show the cement lines. (L) Comparison of serum BAP is shown. (M, N) Representative micrographs of Control (M) and RA groups (N) with immunostaining of sclerostin ALP ase. (O) Comparison of serum TRACP-5b is shown. (P, Q) Representative micrographs of Control (P) and RA group (Q) with TRAP staining. Osteoclasts are stained red. Values shown are means ± SD (* p<0.05).

Conclusions: Our findings showed that RA patients receiving glucocorticoid treatment have severe bone fragility regardless of increased bone quantity by using bisphosphonate. The functional deteriorations of the osteocyte system and the abnormalities of bone quality might induce bone fragility fracture. Therefore, management of osteoporosis associated with RA should be targeted about bone quality as well as bone quantity.

FRI0076 LACTATE/SLC5A12-INDUCED METABOLIC SIGNALLING NETWORK: A NEW TARGET IN RHEUMATOID ARTHRITIS

V. Pucino[1,2], J. Smith[1], D. Cucchi[1], K. Blighe[3], M. Bombardieri[2], C. Pitzalis[2], C. Mauro[1]. *[1]Centre of Biochemical Pharmacology; [2]Centre for Experimental Medicine and Rheumatology, William Harvey Research Institute, Barts and The London SMD, Queen Mary University of London, London, United Kingdom; [3]Channing Division of Network Medicine, Brigham and Women's Hospital and Harvard Medical School, Boston, United States*

Background: RA is a systemic-autoimmune-disease characterized by chronic inflammation of the synovial-joints. Up to 30–40% of patients do not respond to treatment and current biomarkers are largely insensitive at predicting disease progression and response to treatment. It is well recognised that RA-synovitis is a heterogeneous pathology with different histological phenotypes i.e. lymphoid-(L), myeloid-(M) and fibroid-(F). As a result of inflammation the RA synovial microenvironment is hypoxic and acidic partly due to the accumulation of lactate, the end product of anaerobic glycolysis. Exposure of $CD4^+$ T cells to lactate inhibits their migratory capabilities and induces their shift toward a Th17 phenotype[1,2]. These effects are mediated via the interaction of lactate with its transporter SLC5A12, which is expressed on the $CD4^+$ T cell surface[1,2].

Objectives: To characterize whether the newly identified lactate/SLC5A12-induced metabolic signalling pathway can be harnessed in the stratification of RA patients in the different histological phenotypes and to modulate inflammatory responses *in vitro* and *in vivo*.

Methods: RA peripheral blood cells, RA synovial tissues (ST, 21 lymphoid and 8 myeloid) and mononuclear cells from tonsil of patients undergoing tonsillectomy were included in the analysis. RNA sequencing of RA-ST was performed and data analysed for the expression of metabolic genes. SLC5A12 expression and IL17 production was performed by flow-cytometry. Cytokines and transcription factors mRNA relative expression was evaluated by RT-PCR. Seahorse and western blot analysis was performed for the evaluation of metabolic pathways. Transwell plates were used for migration assays. Human-glucose-6-phosphate-isomerase (hG6PI) induced arthritis model was used to evaluate the impact of anti-SLC5A12 on the clinical and histological score.

Results: We showed that: i) the expression of SLC5A12 is up-regulated by $CD4^+$ T cells upon inflammation; ii) SLC5A12 is up-regulated in anti-CD3 stimulated RA $CD4^+$ T cells cultured in autologous synovial fluid; iii) the lactate/SLC5A12 induced metabolic pathway is differentially activated in RA patients with distinctive synovial "pathotypes"; iv) SLC5A12 antibody reduces lactate-induced pro-inflammatory cytokines, limits Th17 and follicular helper T cell differentiation, reverses lactate impaired $CD4^+$ T cell migration and restores lactate-mediated inhibition of glycolysis *in vitro*; v) antibody-mediated blockade of SLC5A12 ameliorates the clinical course in human-glucose-6-phosphate-isomerase (hG6PI)-induced arthritis.

Conclusions: Targeting lactate/SLC5A12-induced metabolic signalling pathway may provide a novel therapeutic strategy to reduce inflammation in RA patients.

FRI0077 GUT COMMENSALS MODULATE INFLAMMATION VIA T REGULATORY CELLS

V. Taneja. *Mayo Clinic, Rochester, United States*

Background: Role of environmental factors in predisposition to develop rheumatoid arthritis (RA) have gained interest due, in part, to the studies showing an association of gut microbiota with immune homeostasis. Although the etiology of RA is unknown, recent studies on the role of gut microbiota in inflammatory adaptive immune response have led to the concept that interaction between the host microbiome and genetic factors influences autoimmunity. We have recently shown an association of Collinsella aerofaciens with RA

Objectives: In this study, we aimed to determine how human gut commensals modulate arthritis phenotype in humanized mice expressing RA-susceptible HLA-DQ8.

Methods: DQ8 mice following immunization with type II collagen develop arthritis and antigen-specific cellular and humoral response. DQ8 mice orally gavaged with RA-associated Collinsella aerofaciens and non-associated Prevotella histicola on alternate days for one week and were induced for arthritis. Gavage with microbes continued for 4 weeks. Mice were monitored for onset and progression of arthritis. Th17 regulatory network and cells involved in regulation were analyzed. DQ8 mice were gavaged with fecal homogenates supernatants from arthritis-resistant mice, induced for arthritis and monitored for disease.

Results: Mice gavaged with C. aerofaciens enhanced disease severity while P. histicola protected mice from arthritis. While treatment with *P. histicola* reduced intestinal permeability by increasing expression of tight junction proteins, C.

aerofaciens had a complete opposite effect. Suppression of arthritis by P histicola was dependent on an increase in the numbers of CD103+ dendritic cells, myeloid suppressors, CD11b+Gr-1, and T regulatory cells, CD4+CD25+FoxP3+, in the gut as well as systemically. This led to reduction in TH17 response while increasing IL-10. On the other hand, C. aerofaciens gavage increased expression of IL-17 and regulatory chemokines as compared to controls. DQ8 mice gavaged with intestinal microbes of arthritis-resistant mice developed arthritis with lower incidence and had skewed Th17/Th2 response.

Conclusions: Our studies suggest that gut commensals influence immune response in and away from the gut. Commensals and their products may provide novel targets for therapeutic strategies in arthritis.

FRI0078 ADENOSINMONOFOSFAT-AKTIVACTIVATING PROTEIN KINASE (AMFK) – THE BIOPOWER REGULATOR OF AN AUTOPHAGY IN RHEUMATOID ARTHRITIS (PA)

V.I. Shihkin, G.V. Kudriavtseva, V.V. Shishkin, Y.A. Malenkov. *Saint Petersburg state University, Saint Petersburg, Russian Federation*

Background: Rheumatoid arthritis is an autoimmune disease characterized by altered cellular homeostasis. A great role of an autophagy is expected in the pathogenesis of these changes.

Objectives: To assess the functional activity of AMFK as a strategic biopower regulator of an autophagy and specific indicator of red-ox potential of cells in the sinovial fluid (SF) of patients with rheumatoid arthritis (RA).

Methods: SF of knee joints of 7 RA patients with active synovitis and 5 donors were investigated. Activity of enzymes was measured in cytosol of SF cells after ultracentrifugation. Activity of AMFK was estimated with the Western blotting method. The consumption speed of oxygen by SF cells was recorded polarographycally using as the substrate glutamic acid (5 μ mol/ml in incubation fluid). Registration of the active forms of oxygen was carried out by EPR (electronic paramagnetic resonance). Levels of adenylic nucleotides were determined chromatographically.

Results: In RA SF we noted activation of AMFK (on average by 2,5 times) at the considerable increase of the AMP level and decrease in ADP and ATP.

Conclusions: These data demonstrate transition of cells of SF in RA to the energy saving mode of functioning that is followed by strengthening of oxidizing processes, deep dissociation of respiration with oxidizing phosphorylation and sharp increase of oxigen consumption speed by SF cells in vitro against the background of the progressing hypoxia of synovial cells and chondrocytes in vivo. Destabilization of mitochondrial and lysosomal membranes of SF cells appears against the background of shift of pH in RA in more acidic zone. It leads to the reinforced formation of the active forms of oxygen (short-lived toxiferous hydroxyl radicals), shift of red-ox potential of cells, activation of lysosomal hydrolyzing enzymes that forms biochemical mechanisms of development of an autophagy in RA.

FRI0079 TAS5315, A NOVEL BRUTON'S TYROSINE KINASE INHIBITOR, IMPROVE BONE MINERAL DENSITY (BMD) AND BONE EROSION VIA INHIBITION OF OSTEOCLAST ACTIVATION IN MURINE MODEL FOR RHEUMATOID ARTHRITIS

Y. Yoshiga, F. Hosoi, S. Iguchi, R. Kaneko, Y. Nakachi, D. Akasaka, K. Tanaka, K. Yonekura, T. Utsugi, E. Sasaki, Y. Iwasawa. *Taiho Pharmaceutical, Ibaraki, Japan*

Background: The erosions of bone and cartilage are a cardinal feature of rheumatoid arthritis (RA) and associated with disease severity and poor functional outcome[1]. Although several anti-inflammatory drugs improve symptoms of articular inflammation, they are less effective against bone erosion. The bone erosions in RA are associated with aberrant activations of osteoclasts induced by pro-inflammatory cytokines and receptor activator of nuclear factor κB ligand (RANKL)[2]. Bruton's tyrosine kinase (BTK), which is expressed in immune cells and mature osteoclast, is reported to be a key molecule in inflammatory response and bone resorption[3,4]. Thus, targeting BTK may be efficacious against not only inflammation but also bone erosion through direct regulation of activation of effector cells such as B cells, macrophages and osteoclasts in RA.

Objectives: In this study, we evaluated the effect of TAS5315, a novel BTK inhibitor, on *in vitro* osteoclasts activation and bone erosion in mouse collagen-induced arthritis.

Methods: Kinase selectivity of TAS5315 was assessed by available kinase assay panels. The effects of TAS5315 on macrophages and osteoclasts were assessed by examining phosphorylation of BTK, cytokine productions, osteoclast differentiation and bone resorptions. The effects of TAS5315 were investigated in mouse collagen-induced arthritis (CIA). Disease severity was evaluated by clinical score of paw swelling. Changes in bone mineral density (BMD) and bone erosion were assessed using microCT. TNF blocker was used as a control drug.

Results: TAS5315 selectively inhibited the enzyme activity of BTK and had less off target inhibition against other kinases. TAS5315 dose-dependently inhibited cytokine productions by macrophages, phosphorylation of BTK, osteoclastogenesis and bone resorbing activity in osteoclasts. In established mouse CIA, TAS5315 significantly ameliorated paw swelling in a dose dependent manner and the anti-inflammatory effect of TAS5315 (0.3 mg/kg, once daily) was comparable to that of TNF blocker. Most importantly, improvement of BMD and bone erosion were observed in TAS5315 treated mice at a doses of higher than 0.1 mg/kg within 13 days from treatment initiation, but not in TNF blocker-treated mice. The onset of action of TAS5315 on BMD and bone erosion was earlier and stronger compared with that of TNF blocker. These data suggest that TAS5315 had direct effect against osteoclasts function and led to improvement of bone erosion in murine model for RA.

Conclusions: Our study demonstrates that TAS5315, a novel BTK inhibitor, would be an ideal RA therapeutic agent that could inhibit bone destruction as well as inflammation.

FRI0080 CD11B+GR1DIM TOLEROGENIC DENDRITIC CELL-LIKE CELLS ARE EXPANDED IN INTERSTITIAL LUNG DISEASE IN SKG MICE

S. Sendo, J. Saegusa, Y. Ichise, H. Yamada, I. Naka, T. Okano, S. Takahashi, Y. Ueda, K. Akashi, A. Onishi, A. Morinobu. *Department of Rheumatology and Clinical Immunology, Kobe University Graduate School of Medicine, Kobe City, Japan*

Background: SKG mice develop interstitial lung disease (ILD) resembling human rheumatoid arthritis (RA)–associated ILD. We identified a unique cell population of $CD11b^{+}Gr1^{dim}$ cells in the severely inflamed lungs in SKG mice.

Objectives: The aims of this study are to clarify the mechanism behind the lung pathology, and to elucidate the phenotype and function of $CD11b^{+}Gr1^{dim}$ cells in ILD-induced SKG mice.

Methods: We assessed the severity of zymosan A-induced ILD in SKG mice histologically, and examined lung-infiltrating cells by Giemsa stain and flow cytometry. Total lung cells and isolated monocytic myeloid-derived suppressor cells (M-MDSCs) were cultured in vitro with GM-CSF (and IL-4). The proliferation of CSFE-labeled naïve T cells co-cultured with isolated $CD11b^{+}Gr1^{dim}$ cells and MDSCs was evaluated by flow cytometry.

Results: MDSCs, Th17 cells, and group 1 and 3 innate lymphoid cells (ILC1s and ILC3s) were increased in the lungs; the proportion of these cells varied with ILD severity. In this process, we found that a unique cell population, $CD11b^{+}Gr1^{dim}$ cells, were expanded in the severely inflamed lungs (Figure). About half of the $CD11b^{+}Gr1^{dim}$ cells expressed CD11c and Giemsa stain revealed that they were morphologically dendritic cell (DC)-like. The $CD11b^{+}Gr1^{dim}$ cells were induced from M-MDSCs with GM-CSF in vitro and were considered tolerogenic because they expressed high levels of PD-L1 and suppressed T-cell proliferation. The $CD11b^{+}Gr1^{dim}$ cells have never described previously and termed $CD11b^{+}Gr1^{dim}$ tolerogenic DC-like cells ($CD11b^{+}Gr1^{dim}$tolDC-LCs). Th17 cells, ILC1s and ILC3s in the inflamed lung produced GM-CSF, which in turn could induce $CD11b^{+}Gr1^{dim}$tolDC-LCs to reduce inflammation.

Conclusions: We identified a unique cell population, termed $CD11b^{+}Gr1^{dim}$tolDC-LCs, in ILD-induced lungs in SKG mice.

FRI0081 A MACAQUE MODEL OF RHEUMATOID ARTHRITIS BY IMMUNIZATION WITH CITRULLINATED PEPTIDES: LESSONS FOR THE HUMAN DISEASE

S. Bitoun[1], P. Roques[2], T. Larcher[3], G. Nocturne[1], C. Serguera[4], P. Chretien[5], G. Serre[6], R. Le Grand[7], X. Mariette[1]. *[1]Université Paris-Sud, Hôpitaux Universitaires Paris-Sud, INSERM U1184, le Kremlin Bicêtre; [2]Immunology of viral infections and autoimmune diseases, CEA, Fontenay aux Roses; [3]INRA UMR703 Veterinary School of Nantes, Nantes; [4]MIRCEN, CEA/INSERM, Fontenay aux Roses; [5]AP-HP, Hôpitaux Universitaires Paris-Sud, le Kremlin Bicêtre; [6]INSERM U1056 - Université de Toulouse Paul, Toulouse; [7]CEA - Université Paris Sud 11 - INSERM U1184, Fontenay aux Roses, France*

Background: Recent evolution in the understanding of rheumatoid arthritis (RA) mechanisms is the role of antibodies directed against citrullinated (cit) proteins (ACPAs). The shared epitope (SE) on the MHC class II is the main genetic risk factor of RA and favors presence of ACPAs. Mouse models dependent on cit peptides immunization require transgenic expression of the SE and are controversial. Non-human primates are ideal to study the interaction between ACPA and RA since 8% carry, similarly to humans, the SE called the H6 haplotype.
Objectives: The goal of this study was to develop a new animal model of RA based on immunization of genetically predisposed macaques against cit peptides to generate an ACPA-mediated model of arthritis.
Methods: Six macaques were intra dermally (ID) immunized with 4 peptides: vimentin (59–71) and (66–78), α fibrinogen (79–91) and aggrecan (89–103). H6 animals were immunized with either cit (n=2) or arginine (arg) (n=2) containing peptides. Two non H6 animals were immunized with cit peptides. These peptides are known to induce a T cell response in RA patients carrying the SE. T-cell response was assessed with Interferon γ ELISPOT and B-cell response by ELISA. An intra articular (IA) boost was done 30 weeks after initial immunization with either incomplete Freud's adjuvant (IFA) alone, IFA and cit peptides and IFA plus non relevant peptides.
Results: In the macaques, the T-cell response was specific to cit or arg peptides (depending on the peptides used for immunization). Surprisingly, the presence of the H6 epitope did not influence the response. Conversely the antibodies generated in response to the peptides were cross-reactive between the cit and arg peptides. Since no clinical response was observed, an IA boost was performed with the same 4 cit peptides and IFA adjuvant. This led to a prolonged neutrophil-rich mono-arthritis preferentially in H6 animals (Figure). Conversely, animals boosted with IFA alone only or with IFA plus myelin oligodendrocyte glycoprotein (MOG) peptides and previously immunized with MOG peptides presented with a transient mono-arthritis. Histological analysis revealed a local mononuclear infiltrate in one of the two animals that had prolonged knee monoarthritis. There was no clinical polyarthritis but 2 animals displayed synovial proliferation in 1 MCP and 1 MTP, respectively.
Conclusions: Immunization of macaques with cit peptides, then IA boost with the same cit peptides plus IFA, induced a prolonged monoarthritis. Shared epitope bearing did not restrict the T-cell response but seemed to favor the prolonged swelling after the IA boost. Neutrophil infiltration of the joint occurred similarly to what is seen in RA. Further use of neutrophil chemo-attractant might lead to a poly-articular disease. This macaque model of RA appears unique to study the events occurring during the pre-clinical phase of RA.

FRI0082 RAS SIGNALING INHIBITORS ATTENUATE ARTHRITIS IN ANIMAL MODELS OF RHEUMATOID ARTHRITIS BY DOWN MODULATING THE PATHOGENIC TH17 CELL RESPONSE

M. Zayoud[1,2], E. Vax[1], G. Elad Sfadia[3], V. Marcu-Malina[1], Y. Kloog[3], I. Goldstein[1,2,4]. *[1]Immunology Core Laboratory, Chaim Sheba Academic Medical Center, Ramat Gan; [2]Medicine, Sackler Faculty of Medicine, Tel Aviv University; [3]Faculty of Life Sciences, Tel Aviv University, Tel Aviv; [4]Rheumatology, Chaim Sheba Academic Medical Center, Ramat Gan, Israel*

Background: Ras-GTPases are vital for normal T cell activation, and downstream effectors of Ras include the MEK/ERK, PI3-kinase/AKT, mTOR/p70S6-kinase, and NF-kB pathways. Somatic mutations in *NRAS* cause an autoimmune lymphoproliferative disorder and T cells from Rheumatoid Arthritis (RA) patients exhibit perturbation of the Ras/MEK/ERK pathway. The small molecule Farnesylthiosalicylic acid (FTS) inhibits the interaction between Ras-GTPases and prenyl-binding chaperones vital for proper plasma membrane localization and downstream signaling [1]. Previous pre-clinical studies suggest that FTS has an immunomodulatory effect in various animal models of autoimmunity [2].
Objectives: To test in the Lewis rat adjuvant induced arthritis (AIA) and in the DBA/1 mouse collagen type-II induced arthritis (CIA) models the therapeutic immunomodulatory effect of FTS alone or combined with methotrexate (MTX).
Methods: Arthritis was induced in 8–12 week old male Lewis rats by complete Freund's adjuvant (CFA) injection and in male DBA/1 mice by collagen type-II (CII) immunization. Animals were treated prophylactically with once daily oral FTS (100 mg/kg); weekly i.p injection of MTX (0.5 mg/kg), oral FTS combined with MTX, or daily oral vehicle solution (0.5% carboxy methyl cellulose; CMC). Arthritis severity was scored daily from disease onset until study termination. In addition, we measured multiple disease- and drug-related immunological/molecular biomarkers.
Results: AIA severity was significantly reduced by FTS treatment compared to CMC controls (Figure 1A, $P<0.001$). Combining FTS and low dose MTX significantly increased its therapeutic efficacy compared to each drug alone (Figure 1A, $P<0.05$). FTS or FTS+MTX treatment also suppressed the upsurge in serum IL-17 and CRP compared to ailing controls. Global gene expression analysis of relevant splenic CD4+ T cells revealed that FTS is a potent inhibitor of pro-inflammatory and TH17 related gene networks. Next, our data from the mouse CIA model show that the therapeutic efficacy of FTS was non-inferior to MTX and it significantly reduced arthritis severity compared to controls (Figure 2, $P<0.001$). Importantly, FTS significantly inhibited the production of pathogenic anti-CII autoantibodies and upregulation of serum IL-6 and IL-17A compared to control arthritic mice. The in depth, multiplex, analysis of the effect of FTS on the T cell cytokine response to CII, revealed strong suppression of IL-22, IL-17, IL-9, GM-CSF and TNF production. Noteworthy, FTS therapy positively correlated with reduced Ras-GTP, p-ERK and p-AKT levels in splenic lymphocytes (drug related biomarkers).

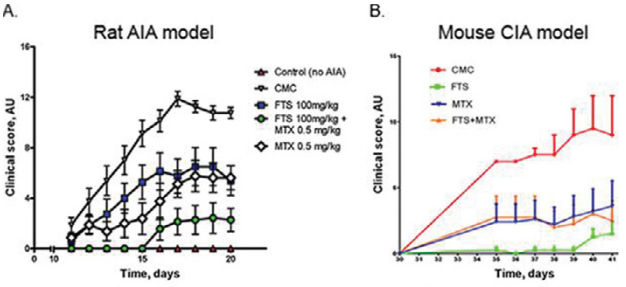

Figure 1. FTS attenuates arthritis severity in the (A) rat AIA and (B) mouse CIA models

Conclusions: FTS, a first-in-class oral selective Ras-GTPases inhibitor, exhibits a potent immunomodulatory effect in two classical murine model of arthritis, coupled with the inhibition of the TH17 response to relevant arthritogenic-antigens. Thus, Ras-signaling-blockade is a promising novel therapeutic approach for RA.

FRI0083 REDUCED INCREASE OF ACPA IGG-FC GALACTOSYLATION DURING PREGNANCY IN COMPARISON TO TOTAL IGG: AN EXPLANATION WHY AUTOANTIBODY POSITIVE RA-PATIENTS IMPROVE LESS DURING PREGNANCY?

A. Bondt[1,2,3], L. Hafkenscheid[3], D. Falck[2], T.M. Kuijper[1], Y. Rombouts[3], J.M. Hazes[1], M. Wuhrer[2], R.J. Dolhain[1]. *[1]Rheumatology, Erasmus University Medical Center, Rotterdam; [2]Center for Proteomics and Metabolomics; [3]Rheumatology, Leiden University Medical Center, Leiden, Netherlands*

Background: Rheumatoid arthritis (RA) disease activity (DAS28-CRP) improves less during pregnancy in autoantibody positive patients.[1] The most specific autoantibodies for RA are anti-citrullinated protein antibodies (ACPAs), which mainly occur as the immunoglobulin (Ig) G isotype. An association with DAS28-CRP and the pregnancy-associated improvement is well established for the Fc glycosylation of total IgG, in particular for galactosylation (Gal) and sialylation (SA).[2] The Fc glycosylation of ACPAs – mainly present as IgG – has been reported to be different from the total IgG Fc glycosylation.[3]
Objectives: We sought to determine whether the change in ACPA IgG glycosylation during pregnancy is different from that of total IgG, and whether this relates to the improvement of RA during pregnancy.
Methods: ACPA positive patient sera (*n*=152) were obtained within the framework of the PARA cohort, a prospective study designed to investigate pregnancy-associated improvement of RA. ACPA IgG was isolated using microscale affinity chromatography. Trypsin digested ACPA IgG was measured using nano-liquid chromatography mass spectrometry, and compared to total IgG.
Results: Pregnancy-associated changes in the levels of glycosylation were observed for all ACPA IgG subclasses. Pregnancy-associated glycosylation changes were less pronounced during pregnancy and after delivery in ACPA IgG (Gal +5%; SA +0.5%) compared to total IgG (Gal +11%; SA +2.5%; Figure 1), but – for total IgG – not different between ACPA+ and ACPA- patients. No association of the change in DAS28-CRP with the change in ACPA IgG or total IgG galactosylation was observed for ACPA+ patients, whereas a strong association of total IgG galactosylation was observed for ACPA- patients.

Conclusions: During pregnancy the increase in galactosylation of ACPA IgG was less pronounced than that of total IgG, whereas the increase in the galactosylation of total IgG was not different between ACPA+ and ACPA- patients. Since it is known that changes in IgG galactosylation are associated with improvement of RA during pregnancy and since ACPA is thought to be of pathogenic significance in RA, our data might provide an explanation why ACPA+ RA patients are less likely to improve during pregnancy.

FRI0084 THE TONSIL MICROBIOME IS INVOLVED IN RHEUMATOID ARTHRITIS

J. Li[1], J. He[1], K. Deng[2], J. Qin[2], Y. Jin[1], J. Chen[1], Z. Li[1]. *[1]Department of Rheumatology and Immunology, Peking University People's Hospital, Beijing; [2]Digital Microbiota Technology Co. Ltd., Shenzhen, China*

Background: Rheumatoid arthritis (RA) is a prevalent systemic autoimmune disease characterized by the production of autoantibodies[1]. The tonsil has been demonstrated to be a site of citrullination, and tonsillectomy has been reported to be a potential treatment of RA, suggesting the possibility that the tonsil could be a site of autoimmunity generation in RA[2,3]. The dysbiosis of gut microbiome and the associated host immune response has been implicated in the initiation and progression of RA[4–6]. However, there is no in-depth studies on the role of tonsil microbiota in RA. Thus, studies of the characteristics of tonsil microbiome in RA patients, the underlying mechanisms, as well as specific markers for the diagnosis and therapeutic evaluation for RA, are critical for the early diagnosis and prevention of RA.
Objectives: Therefore, we aimed to define the association of RA with tonsil microbiome as well as a microbial and metabolite profile that could predict disease status.
Methods: 16S rRNA gene sequencing was utilized on 220 tonsil swab samples (121 RA patients and 99 healthy controls) as well as 78 fecal samples (68 RA and 10 controls). Analysis of microbial taxa and metabolic pathway were performed to characterise and compare the tonsil microbiome of RA patients and healthy subjects
Results: Results showed that the tonsil harbored a unique microbiome relative to that present in the fecal samples. Patients with RA exhibited different tonsil microbiome from controls. A taxon-level analysis suggested that the relative abundance of 26 microbial clades were significantly altered, with 7 taxa increased and 19 taxa decreased in RA samples. Noticeably, we observed an expansion of rare microbial lineages as well as an alteration in microbial cladogenesis within RA patients. RA tonsil microbiota was associated with smoke, anti-peripheral factor, rheumatoid factors, disease duration and activity. Furthermore, we identified that 86 genes associated with bacterial metabolic pathway were enriched in RA tonsil microbiome.
Conclusions: Our results demonstrated that the RA tonsil microbiome differs from that of healthy controls, which correlates with systemic autoimmune changes and may potentially drives initiation of RA.

Rheumatoid arthritis - prognosis, predictors and outcome

FRI0085 NUMBER OF PEPTIDE-SPECIFIC ANTI-CITRULLINATED PEPTIDE ANTIBODIES IN SYNOVIAL FLUID AND IN SYNOVIAL FLUID IMMUNE COMPLEXES ASSOCIATE WITH DEGREE OF RADIOLOGICAL DESTRUCTION AND RESPONSE TO TRIAMCINOLONE HEXACETONIDE FOR KNEE SYNOVITIS IN RHEUMATOID ARTHRITIS

A. Sohrabian[1], L. Mathsson Alm[1,2], M. Hansson[3], J. Lysholm[4], M. Cornillet[5], A. Knight[6], K. Skriner[7], G. Serre[5], A. Larsson[8], T. Weitoft[9], J. Rönnelid[1]. *[1]Department of Immunology, Genetics and Pathology, Uppsala university; [2]ImmunoDiagnostic Division, Thermo Fisher Scientific, Uppsala; [3]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm; [4]Clinic of Rheumatology, Falun Hospital, Falun, Sweden; [5]Epithelial Differentiation and Rheumatoid Autoimmunity, U 1056 Inserm Toulouse University, Toulouse, France; [6]Rheumatology, Department of Medical Sciences, Uppsala university, Uppsala, Sweden; [7]Department of Medicine, Charité University Hospital, Berlin, Germany; [8]Section of Clinical Chemistry, Department of Medical Sciences, Uppsala university, Uppsala; [9]Section of Rheumatology, Center for Research and Development, Uppsala university, Gävle, Sweden*

Background: We have described a planar microarray for the determination

of antibodies against individual citrullinated peptides (ACPA; Hansson M et al. Arthritis Res Ther 2012;14:R201). We have also developed a method for the quantification of autoantibodies in immune complexes (IC; Sohrabian et al. Ann Rheum Dis 2015;74(Suppl 1):A74). Here we have combined these techniques to determine ACPA profiles in RA IC.

Objectives: To investigate if measurement of specific ACPA in synovial fluids (SF) and in IC from sera and SF can provide more prognostic information than conventional measurement of total ACPA and rheumatoid factor (RF) in serum.

Methods: Seventy-seven RA patients with knee synovitis were treated with intra-articular triamcinolone hexacetonide, and followed until relapse. DAS28 and radiographic joint damage according to Larson-Dale were recorded. Anti-CCP2, IgM and IgA RF and circulating C1q-binding immune complexes (CIC) were determined in paired sera and SF. IC were purified from sera and SF by binding to C1q-coated beads, and thereafter eluted with a procedure developed in our laboratory. Antibodies against 19 citrullinated peptides were investigated with a custom-made microarray assay based on the ImmunoCAP ISAC system (Phadia AB, Sweden) in sera and SF as well as in IC from sera and SF. The target peptides were filaggrin 307–324 (CCP1), vimentin peptides 60–75 and 2–17, fibrinogen peptides α36–50„ α563–583, α580–600, α621–635, β36–52, β60–74, β62–81 (with citrullination in positions 72 and 74, respectively), α-enolase 5–21 (CEP-1), peptides 1, 5, Z1, Z2 and Bla26 from hnRNP, and histone 4 peptides 14–34 and 31–50. Cutoffs were established in relation to healthy controls. Backward stepwise regression was used to investigate what factors determined Larsen Dale index, DAS28, and duration of remission after steroid treatment. Independent factors were anti-CCP2, IgM RF, IgA RF, CIC, number of ACPA peptide reactivities, and number of ACPA reactivities in IC, all measured both in serum and paired SF.

Results: A considerable proportion of anti-CCP2 negative patients had multiple ACPA in SF, and in IC fractions. High DAS28 associated with reactivity against 7/19 peptides in serum and 9/19 in SF. High Larsen score associated with number of specific ACPA in SF IC and with CIC in SF. DAS28 levels associated with IgM RF in SF and with CIC in SF, and steroid response duration with number of specific ACPA in serum and in SF IC.

Conclusions: We found ACPA in SF, and especially in the IC fraction of SF, in a sizeable fraction of anti-CCP2 negative patients. Number of peptide-specific ACPA (but not anti-CCP2 levels) associated with radiological destruction and length of remission after intra-articular steroid therapy. Our data do not support a role for any unique ACPA specificity in RA pathogenesis. Instead, the number of individual ACPA specificities may be important.

FRI0086 EFFICACY AND SAFETY DATA BASED ON HISTORICAL OR PRE-EXISTING CONDITIONS AT BASELINE FOR PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS WHO WERE TREATED WITH BARICITINIB

B. Combe[1], A. Balsa[2], P. Sarzi-Puttini[3], H.-P. Tony[4], I. de Torre[5], V. Rogai[5], F. Durand[6], A. Jahangir[5], S. Witt[5], J. Zhong[7], M. Dougados[8]. *[1]Hopital Lapeyronie, Montpellier, France; [2]Hospital Universitario la Paz, Madrid, Spain; [3]Sacco Hospital, Milano, Italy; [4]University Hospital of Würzburg, Würzburg, Germany; [5]Eli Lilly and Company, Indianapolis; [6]Eli Lilly and Company, Madrid; [7]QuintilesIMS, Morrisville, United States; [8]Rene Descartes Univ/ Cochin Hospital, Paris, France*

Background: Patients (pts) with rheumatoid arthritis (RA) often experience comorbidities that may affect efficacy and safety when treated with different drugs.[1] Baricitinib (BARI) is a selective inhibitor of Janus kinase[2,3] 1 and 2 that improves disease activity in pts with RA with an acceptable safety profile.[4–6]

Objectives: To investigate the effect of selected comorbidities on safety and efficacy outcomes in pts treated with BARI.

Methods: Pts were selected for this post hoc analysis on the basis of historical or ongoing conditions defined by Medical Dictionary for Regulatory Activities and divided by the following comorbidity subgroups: depression, osteoporosis, hepatic disorders, and previous cardiovascular events. Efficacy outcomes included 20% and 50% improvement in American College of Rheumatology 20 Response (ACR20) and American College of Rheumatology 50 Response (ACR50) criteria, respectively; the proportion of pts who achieved a Disease Activity Score for 28-joint count using high-sensitivity C-reactive protein (DAS28-hsCRP) score ≤3.2; and change from baseline in Health Assessment Questionnaire-Disability Index (HAQ-DI) at week 12. Pts who had an inadequate response (IR) to conventional disease-modifying antirheumatic drugs (cDMARDS) from 5 studies with BARI 4 mg and placebo (PBO) were included in efficacy analyses (N=1684) and safety analyses (N=1683). The interaction of comorbidity by treatment was analysed using logistic regression or analysis of variance modelling. Interaction tests were performed within each comorbidity subgroup, and the effect size in pts with and without the comorbidity was analysed.

Results: Pts in the efficacy set had similar baseline demographic and disease-activity characteristics across treatments within each comorbidity subgroup. The presence of a comorbid condition did not affect the incidence of treatment-emergent adverse events (TEAEs), serious adverse events (AE), discontinuations, or deaths caused by AEs for BARI 4 mg vs PBO (Table 1). The most common TEAEs across the subgroups for BARI and PBO were nasopharyngitis and upper respiratory tract infection. For cDMARD-IR pts, change from baseline for each comorbidity subgroup for ACR20, ACR50, DAS28-hsCRP ≤3.2 response, and HAQ-DI was higher for BARI 4 mg compared with PBO. Within each comorbidity subgroup, BARI responses compared with PBO were similar (interaction $P > 0.1$) (Table 2).

Table 1: Adverse Events Reported by Selected Comorbidity up to Week 16

Baricitinib 4 mg n (%)	Depression (N=64)	Osteoporosis (N=113)	CV Event (N=350)	Hepatic Event (N=222)	Overall (N=802)

Placebo	(N=69)	(N=134)	(N=381)	(N=202)	(N=881)
ACR20, NRI, n (%)	22 (31.9)	43 (32.1)	155 (40.7)	75 (37.1)	345 (39.2)
ACR50, NRI, n (%)	6 (8.7)	16 (11.9)	55 (14.4)	23 (11.4)	127 (14.4)
DAS28-hsCRP ≤3.2, mLOCF, n (%)	9 (13.0)	17 (12.7)	60 (15.7)	26 (12.9)	146 (18.2)
ΔHAQ-DI, mLOCF* N-Obs, LSM (SE)	68, -0.20 (0.13)	131, -0.08 (0.07)	374 -0.27 (0.04)	201, -0.28 (0.08)	868, -0.25 (0.03)

Abbreviations: ACR20 = 20% improvement in American College of Rheumatology 20 Response criteria; ACR50 = 50% improvement in American College of Rheumatology 50 Response criteria; CV = cardiovascular; DAS28-hsCRP = Disease Activity Score for 28-joint count using high-sensitivity C-reactive protein; HAQ-DI = Health Assessment Questionnaire-Disability Index (patient-reported questionnaire with 24 questions in 8 domains: dressing/grooming, arising, eating, walking, hygiene, reach, grip, and activities); LSM = least squares mean; mLOCF = modified last observation carried forward; N-obs = number of patients in the analysis; NRI = nonresponder imputation; SE = standard error
*LSM and SE were calculated using analysis of variance model.

Conclusions: Treatment with BARI 4 mg showed similar effect in selected comorbidity subgroups with depression, osteoporosis, cardiovascular events, and hepatic impairment for efficacy and safety. No trends were noted for pts in each comorbidity subgroup for increased risk of events after treatment with BARI 4 mg compared with PBO.

FRI0087 LOW RATES OF RADIOGRAPHIC PROGRESSION OF STRUCTURAL JOINT DAMAGE OVER 2 YEARS OF BARICITINIB TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

D. van der Heijde[1], M. Schiff[2], Y. Tanaka[3], R. Klar[4], L. Xie[5], G. Meszaros[5], T. Ishii[5], M. Casillas[5], R. Ortmann[5], P. Emery[6]. *[1]Leiden University Medical Center, Leiden, Netherlands; [2]University of Colorado, Denver, United States; [3]School of Medicine, Kitakyushu, Japan; [4]Quintiles IMS Holdings, Inc, Durham; [5]Eli Lilly and Company, Indianapolis, United States; [6]University of Leeds, Leeds, United Kingdom*

Background: In ph3 studies, baricitinib (bari) inhibited progression of radiographic joint damage for up to 1 year in patients (pts) with active rheumatoid arthritis (RA) who were DMARD-naïve or who had an inadequate response to conventional synthetic DMARDs (csDMARD-IR).

Objectives: To evaluate radiographic progression of structural joint damage in pts with RA over 2 years of treatment.

Methods: Upon completion of a bari ph 3 study, pts could enter a long-term extension (LTE) study, in which they continued to receive the same bari dose as in the original ph3 study. At 52 wks, DMARD-naïve pts receiving methotrexate (MTX) or combination therapy (bari 4mg + MTX) were switched to bari 4mg monotherapy; MTX-IR pts receiving adalimumab (ADA) were switched to bari

4mg on background MTX. At 24 wks, csDMARD-IR pts receiving placebo (PBO) were switched to 4mg on background csDMARD. Radiographs at baseline, year 1 and year 2 were scored using the van der Heijde modified total sharp score (mTSS). Data are least squares mean change from baseline using mixed model repeated measures on observed data.

Results: Of all pts randomised, 82.5% entered the LTE, and 87.6% of those could be entered in this analysis. At year 2, progression was significantly lower with initial bari (including monotherapy) vs. initial MTX in DMARD-naïve pts. In MTX/csDMARD-IR pts, progression with initial bari was significantly lower than initial PBO, and similar to initial ADA.

	1 year (52 weeks)			2 years (100 weeks)

FRI0088 SYNOVIAL PATHOBIOLOGY CORRELATES WITH DIAGNOSTIC SUBGROUPS IN EARLY INFLAMMATORY ARTHRITIS: RESULTS FROM THE PATHOBIOLOGY OF EARLY ARTHRITIS COHORT (PEAC)

G. Lliso-Ribera[1], F. Humby[1], S. Kelly[1], M. Bombardieri[1], M. Lewis[1], R. Hands[1], V. Rocher[1], F. Bene[1], A. Nerviani[1], C. Buckely[2], P. Taylor[3], I. McInnes[4], C. Pitzalis[1]. *[1]Experimental Medicine and Rheumatology, Queen Mary University London, London; [2]Centre for Translational Inflammation Research, University of Birmingham, Birmingham; [3]Kennedy Institute of Rheumatology, University of Oxford, Oxford; [4]Experimental Medicine and Rheumatology, University of Glasgow, Glasgow, United Kingdom*

Background: Application of the 2010 ACR/EULAR Criteria for RA to early inflammatory arthritis cohorts permits an enhanced sensitivity for diagnosis compared to the historic 1987 ACR criteria but risks loss of diagnostic specificity. Heterogeneity in RA synovial pathobiology is well recognised with differences in qualitative and quantitative degree of immune cell infiltration, whether such heterogeneity correlates with classification criteria in early inflammatory arthritis is unknown, offering the potential to refine early diagnostic criteria.

Objectives: The aim of this study was to examine in a cohort of therapy naïve, early inflammatory arthritis patients whether synovial immune cell infiltration differed significantly between diagnostic categories of early inflammatory arthritis (ACR/EULAR 2010 vs ACR 1987 vs undifferentiated).

Methods: A total of 200 consecutive DMARD naïve early arthritis patients (disease duration <1 year) recruited as part of the multicentre PEAC study at Barts Health NHS Trust were categorised according to the following criteria: i. RA 1987 ACR, ii. RA 2010 ACR/EULAR, and iii. Undifferentiated Arthritis (UA). All patients underwent a baseline synovial biopsy of a clinically active joint along with collection of demographic data. Following H&E staining, degree of synovitis was assessed. Sections underwent immumohistochemical staining and semi-quantitative scoring (0–4) to determine the degree of CD20+Bcells, CD3+T cells, CD68+ lining (l) and sublining (sl) macrophage and CD138+ plasma cell infiltration. Sections were categorised into three pathotypes: (i) Fibroid: (CD68 SL<2 and or CD3, CD20, CD138<1), (ii) Myeloid: (CD68SL>2, CD20<1 and or CD3>1) and (iii) Lymphoid: (grade 2–3 CD20+ aggregates, CD20>2).

Results: 166/200 samples were suitable for analysis. 115 patients were classified as RA1987, 16 patients as RA 2010 ACR/EULAR and 35 as UA. 80% of synovial samples were collected from small joints (wrist, MCP, PIP). Although there were no significant differences in disease duration between diagnostic subgroups, patients classified as RA1987 criteria had significantly higher levels of CRP, tender and swollen joints, DAS28 and sero positivity for ACPA and RF. When patients were stratified into pathotypes, a numerically higher proportion of patients within the RA1987 group were categorised as lymphoid. Further, patients within the RA 1987 group had a significantly higher synovitis score and degree of immune cell infiltration.

N=166	RA1987 (115)	RA2010 (16)	UA (35)	P value
Fibroid 47 (%)	27 (23.5%)	6 (37.5%)	14 (40%)	
Myeloid 57 (%)	38 (33%)	5 (31.2%)	14 (40%)	0.10
Lymphoid 62 (%)	50 (43.5%)	5 (31.2%)	7 (20%)	
CD3 T cells	3.19	1.21	0.60	<0.001
CD20 B cells	2.88	0.80	0.75	<0.05
CD68L macrophages	3.60	1.86	1.34	<0.001
CD68SL macrophages	3.60	2.18	1.79	<0.05
CD138 Plasma Cells	2.85	1.06	0.73	<0.05
Synovitis Score	6.17	3.26	3.24	<0.001

Conclusions: Stratifying patients according to baseline clinical diagnosis translates into differences in synovial pathobiology. The capacity to refine early clinical classification criteria through application of synovial pathobiological markers offers the potential to predict disease outcome and stratify therapeutic intervention.

FRI0089 EFFECT OF STARTING DOSE OF BARICITINIB IN ACHIEVING SUSTAINED LOW DISEASE ACTIVITY

J.R. Curtis[1], A. Kavanaugh[2], D. van der Heijde[3], D. Muram[4], J. Alam[4], S. Beattie[4], J.S. Smolen[5]. *[1]Univ of Alabama at Birmingham, Birmingham; [2]UC San Diego School of Medicine, la Jolla, United States; [3]Leiden University Medical Centre, Leiden, Netherlands; [4]Eli Lilly and Company, Indianapolis, United States; [5]Medical University of Vienna, Vienna, Austria*

Background: In Phase 3 studies, baricitinib (bari) treatment with 2 different doses (2 mg and 4 mg once daily) demonstrated significant improvements across multiple measures of disease activity in patients (pts) with active RA and an inadequate response (IR) to conventional synthetic (cs) DMARDs (RA-BUILD[1]) or biologic (b) DMARDs (RA-BEACON[2]).

Objectives: To determine the effect of starting dose of bari on achieving and sustaining low disease activity (LDA).

Methods: RA-BUILD and RA-BEACON trials were 24 week (wk), placebo (PBO) controlled studies. Pts completing the studies on bari treatment could enter a long-term extension (LTE) study, RA-BEYOND, continuing blinded treatment with the same dose, while pts on PBO switched to bari 4 mg. This post hoc analysis assessed disease activity in pts who achieved CDAI ≤10 at ≥1 visit (LDA) or at ≥2 consecutive visits (sustained LDA) within the originating study (24 wks) and continued into the LTE. The length of time required by pts to achieve LDA was determined by the incidence rate (percent pts responding per month) for each group.

Results: Treatment with bari 2 mg and 4 mg, when compared to PBO, resulted in higher rates of LDA and sustained LDA, as well as higher incidence rates (shorter time to achieve LDA/sustained LDA) within 24 wks of each originating study. Across studies, treatment with bari 4 mg demonstrated higher incidence rates when compared to bari 2 mg, both in achieving LDA and sustained LDA, indicating that these pts reached the desired LDA state faster. Incidence rates were lower in all treatment groups in bDMARD-IR pts compared with csDMARD-IR pts.

Conclusions: The most robust benefit in terms of achieving LDA and sustained LDA was observed with bari 4 mg treatment, which required shorter time to response, than treatment with 2 mg. This was observed in both the short (24 wks) and in the long-term in pts with IR to csDMARDs or bDMARDs.

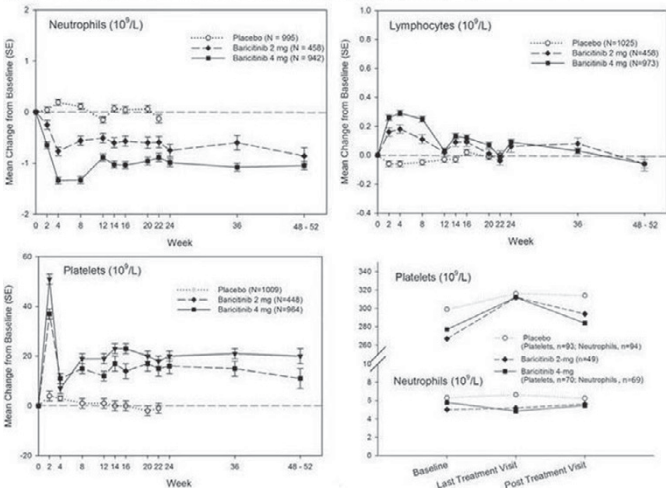
FRI0090 ANALYSIS OF NEUTROPHILS, LYMPHOCYTES, AND PLATELETS IN POOLED PHASE 2 AND PHASE 3 STUDIES OF BARICITINIB FOR RHEUMATOID ARTHRITIS

J. Kremer[1], T.W.J. Huizinga[2], L. Chen[3], C.G. Saifan[3], M. Issa[3], S.L. Witt[3], C.D. Walls[3], I. de la Torre[3]. *[1]Albany Medical College, New York, United States; [2]Leiden University Medical Center, Leiden, Netherlands; [3]Eli Lilly and Company, Indianapolis, United States*

Background: Rheumatoid arthritis (RA) is associated with increased neutrophil levels[1] and platelet[2] counts and decreased lymphocyte levels.[1,3] Baricitinib (bari) is a selective and reversible Janus kinase (JAK)1/JAK2 inhibitor in development for patients (pts) with moderate to severe RA.[4]



Objectives: To characterize changes in absolute neutrophil counts (ANC), absolute leukocyte counts (ALC), and platelet counts following once daily oral administration of bari.

Methods: Data were pooled from 6 placebo-controlled phase 2 and 3 studies of bari (2 and 4 mg). Changes in ANC, ALC, and platelets were evaluated for up to 52 weeks (wks) including data from a long-term extension study. Reversibility was evaluated in a subgroup of pts who discontinued treatment by wk 24.

Results: Mean ANC decreased within 1 month of administration of bari, followed by stabilization and an increase to baseline after treatment discontinuation (Figure 1). ANC <1000 cells/mm^3 were reported in <1% of pts, and 2 bari-treated pts (0.1%) reported permanent discontinuation of study drug due to neutropenia. Incidence of neutropenia was not associated with higher risk of overall or serious infections (Table 1).

Mean ALC increased within 1 month of bari administration and then decreased to baseline level in wks 12 to 24 (Figure 1). Lymphopenia appeared to be associated with slightly higher rate of overall infections (Table 1).

Figure 1: Longitudinal Profiles of Neutrophils, Lymphocytes, and Platelets

Mean platelet counts increased to peak at wk 2, returned towards baseline, stabilized over time, and returned to baseline after treatment discontinuation (Figure 1). Permanent study drug discontinuations from thrombocytosis occurred in 2 bari-treated pts (0.1%). No clear association between platelet increase and thromboembolic events was observed.

Conclusions: Treatment with bari was associated with a decrease in ANC and an increase in ALC and platelets, which stabilized over time and returned to baseline with prolonged treatment (ALC) or treatment discontinuation (ANC and platelets). No associations between ANC decrease and infections or between thrombocytosis and thromboembolic events were observed.

FRI0091 PATIENT-PROVIDER DISCORDANCE MAY BE ASSOCIATED WITH INCREASED RISK OF SUBSEQUENT FLARES IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Myasoedova, C.S. Crowson, K. McCarthy-Fruin, E.L. Matteson, J.M. Davis III. *Rheumatology, Mayo Clinic College of Medicine and Science, Rochester, MN, United States*

Background: Patient-provider discordance in assessment of disease status has been linked to lower patient satisfaction with potential implications on patient compliance and outcomes of care. Global assessment (GA) of disease activity in rheumatoid arthritis (RA) is discordant between patient and provider in about one third of cases. Prospective studies evaluating the implications of patient-provider discordance on RA disease course are lacking.

Abstract FRI0090 – Table 1. Infection by Worst Neutropenia and Lymphopenia CTCAE Grade in Placebo-Controlled Period up to Week 24

	Placebo			Baricitinib 4-mg		
	Total Pts	Pts (%) with Overall Infection	Pts (%) with Serious Infection	Total Pts	Pts (%) with Overall Infection	Pts (%) with Serious Infection

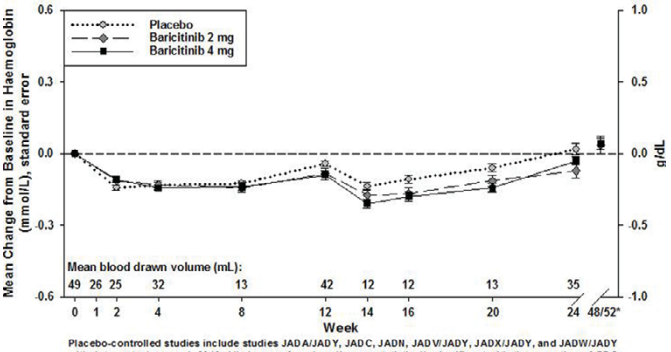
CTCAE=common terminology criteria for adverse events; pts = patients. [1]Upper respiratory tract; [2]Pharyngitis.

Objectives: We aimed to assess the occurrence and severity of patient-reported flares of RA in patients who had discordant estimates of RA disease activity with their provider at baseline compared to those who had concordant estimates.
Methods: Patients with RA (age≥18 years; 2010 ACR criteria) participating in an ongoing prospective study underwent clinical evaluation by a rheumatology provider (MD/NP/PA) at baseline with assessment of tender (TJC28) and swollen joint counts (SJC28), C-reactive protein (CRP), patient and provider GA of RA disease activity, disease activity score (DAS28-CRP), clinical disease activity index (CDAI), completion of Health Assessment Questionnaire-II (HAQ-II), visual analogue scales (0–100 mm) for pain (VAS-pain) and the flare-assessment in RA (FLARE) questionnaire. Patient-provider discordance was defined as ≥25 mm difference in GA between the patient and provider. Occurrence of patient-reported RA flares was compared between patients with and without discordance in GA. Flare was defined based on patient report when answered "Yes" to the question "Are you having a flare of your RA at this time?" or a predefined cut-off ≥2.5 on FLARE questionnaire (1,2).
Results: The study included 55 patients with RA (mean age 60.7 years; 65% female), of whom 40 had GA concordant with their provider and 15 had higher GA than their provider. Table 1 summarizes patient characteristics depending on GA discordance at baseline. Patients with discordance were similar in age, sex, duration of follow-up, had similar TJC28 and SJC28, but had significantly higher HAQ-II, VAS-pain, CRP, DAS28, CDAI, provider GA and FLARE scores at baseline vs patients with concordant GA. During the follow up, patients with discordance had significantly higher numbers and rates of flares, and tended to have more visits with discordant GAs compared to patients who had concordant GA with their provider at baseline.

Table. Characteristics of patients with rheumatoid arthritis (RA) depending on the presence of discordance in general assessment of RA disease activity

Characteristics*	Patients with concordant baseline GA (n=40)	Patients with discordantly high baseline GA (n=15)	p-value
Age	59.5 (10.3)	64.0 (7.4)	0.22
Sex, female	26 (65%)	10 (67%)	0.91
Duration of follow up, months	6.5 (4.0)	8.2 (5.8)	0.37
TJC28, baseline	2.0 (4.2)	2.6 (6.2)	0.91
SJC28, baseline	0.6 (1.5)	1.1 (2.4)	0.92
HAQ-II, baseline	0.5 (0.5)	1.0 (0.5)	0.001
VAS pain, baseline	26 (27)	54 (14)	<0.001
CRP, mg/L	7.0 (12.8)	10.5 (10.6)	0.020
DAS-28 CRP, baseline	2.3 (1.2)	3.0 (1.0)	0.006
CDAI, baseline	6.2 (9.0)	10.9 (8.5)	0.002
Patient GA, baseline	20.7 (23.1)	56.5 (12.6)	<0.001
Provider GA, baseline	15.0 (22.5)	17.0 (11.3)	0.044
Patient-reported flare, baseline	6 (15%)	5 (33%)	0.13
Number of patient-reported flares during the follow up	0.6 (0.9)	2.0 (2.9)	0.010
Flare rate based on patient-reported flares (% of subsequent months with flare)	8.4 (15.1%)	25.4 (29.3%)	0.009
FLARE score, baseline			
- Overall FLARE	1.9 (2.6)	4.4 (2.6)	0.002
- Systemic subscale	1.6 (2.5)	4.3 (2.9)	0.001
- Joint subscale	2.3 (2.8)	4.5 (2.7)	0.006
Number of FLARE questionnaire reports scoring ≥2.5 during the follow up			
- Overall FLARE	0.7 (1.2)	3.2 (3.6)	0.001
- Systemic subscale	0.6 (1.0)	2.5 (3.3)	0.002
- Joint subscale	1.1 (1.5)	3.4 (3.5)	0.007
Number of visits with discordant GA during the follow up	0.1 (0.2)	0.3 (0.6)	0.076
Rate of discordance (% of subsequent months with discordance)	0.5 (2.5%)	2.9 (6.2%)	0.070

*All measures are shown as mean (standard deviation) or as number (%)



Conclusions: Patients with patient-provider discordance at baseline were more likely to report flares of RA during follow-up. Patient-provider discordance tended to persist at follow-up visits. Disease activity assessments with patient-reported component (i.e., HAQ-II, VAS-pain, DAS28, CDAI, FLARE score), as well as CRP and provider GA, but not joint counts, were higher at baseline in patients with discordance. Consideration of the results of clinical and laboratory assessment in combination with patient-reported measures of RA disease activity may be important to inform future risk of flares in patients with RA and help improve patient-provider communication and shared decision making.

FRI0092 EFFECTS OF BARICITINIB ON HAEMOGLOBIN AND RELATED LABORATORY PARAMETERS IN RHEUMATOID ARTHRITIS PATIENTS

J. Kay[1], M. Harigai[2], J. Rancourt[3], C. Dickson[3], Y. Isaka[3], L. Chen[3], T. Carmack[3], D. Hyslop[3], D. Muram[3], W. Macias[3], J. Bradley[3], E. Keystone[4].
[1]Division of Rheumatology, U Mass Memorial Med Ctr and Med School, Worcester, United States; [2]Tokyo Women's Medical Univ., Tokyo, Japan; [3]Eli Lilly and Company, Indianapolis, United States; [4]Mt. Sinai Hospital, Ontario, Canada

Background: Baricitinib (bari), a selective, transient and reversible inhibitor of Janus kinase (JAK)1 and JAK2, improved signs and symptoms of active rheumatoid arthritis (RA) in multiple phase 3 studies. Since erythropoietin (EPO) stimulates erythrocyte production via the JAK2 signaling pathway, haemoglobin (Hgb) and other haematologic parameters were thoroughly evaluated in the bari RA clinical development program.
Objectives: To evaluate baseline and subsequent changes in Hgb and related laboratory parameters in RA patients (pts) treated with bari (2 or 4 mg once daily), placebo (PBO), or active comparator (methotrexate [MTX] or adalimumab [ADA]).
Methods: Blood samples were analyzed at baseline and at each study visit for complete blood count, with more extensive phlebotomy at baseline (Wk 0) and Wks 12, 24, and 52 (Figure 1). Data were aggregated from completed Phase 2 and 3 RA studies and one ongoing long-term extension study. EPO and reticulocyte (RET) data were collected from a Phase 2 RA study in Japan.
Results: Hgb levels below the gender-adjusted lower limit of normal (LLN) were often observed at baseline (25%). Small declines in Hgb were observed at Wk 2 and again at Wk 14 in bari (2 and 4 mg) and PBO-treated RA pts consistent with the volume and frequency of phlebotomy (Figure 1). Initial decreases in Hgb were accompanied by declines in RET counts in bari-treated RA pts. Subsequent increases in Hgb were associated with increases in RET after Wk 8 and statistically significant dose-dependent increases vs. PBO in total iron (Fe), total iron binding capacity (TIBC) and EPO. Treatment-emergent (TE) shifts in Hgb from normal to <LLN were very common in all groups without differences across groups except for ADA, which was associated with a lower incidence of TE low Hgb. TE Common Terminology Criteria for Adverse Events (CTCAE) shifts in Hgb from <grade 3 to ≥grade 3 (<4.9 and ≥4.0 mmol/L; <8.0g/dL and ≥6.5g/dL) were uncommon and occurred in similar proportions of RA pts across groups (Table 1). Permanent discontinuation of study drug due to CTCAE ≥grade 3 Hgb shifts was uncommon (0.2%).

Figure 1. Mean Change from Baseline in Haemoglobin Over 52 Weeks in Placebo-Controlled Studies

Placebo-controlled studies include studies JADA/JADY, JADC, JADN, JADV/JADY, JADX/JADY, and JADW/JADY with data up to January 1, 2016. All changes from baseline are statistically significant with the exception of PBO and BARI 4-mg at Week 24 and BARI 2-mg and 4-mg at Week 52.
*Last blood draw prior to Week 48/52 data was up to 12 weeks prior.

Table 1. Summary of Treatment-Emergent Changes in Haemoglobin

	Treatment-emergent abnormally low, n/NAR (%)	Shift from <grade 3 to ≥grade 3[a], n/NAR (%)
RA bari PBO-controlled studies through Week 24[b]		
PBO (N=1070) [PYE=393.8]	193/747 (25.8)	2/1059 (0.2)
Bari 4 mg (N=997) [PYE=409.4]	204/696 (29.3)	1/988 (0.1)
RA bari studies containing 2- and 4-mg doses[c,d]		
Bari 2 mg (N=479) [PYE=434.8]	106/343 (30.9)	3/478 (0.6)
BARI 4 mg (N=479) [PYE=477.7]	126/360 (35.0)	1/474 (0.2)
All RA bari studies[d]		
N=3464 [PYE=4214.1]	829/2451 (33.8)	16/3407 (0.5)

Abbreviations Bari=baricitinib; NAR=number at risk; PYE=patient years of exposure; RA=rheumatoid arthritis.
[a]Grade 3 is <4.9 and ≥4 mmol/L (<8.0 and ≥6.5 g/dL).
[b]Includes Studies JADA, JADC, JADN, JADV, JADW and JADX.
[c]Includes Studies JADA/JADY, JADN, JADW/JADY and JADX/JADY.
[d]Includes data up to August 10, 2015.

Conclusions: The proportions of RA pts with TE abnormally low Hgb did not differ significantly between bari and PBO. Reductions in Hgb, including to ≥grade 3, were generally not associated with adverse outcomes. Despite concerns about the impact of JAK2 inhibition on EPO signaling, following initial declines incident to phlebotomy, dose-dependent increases in EPO, Fe, and TIBC with return to baseline in RET and Hgb were observed with bari. This suggests that homeostatic mechanisms counterbalance the pharmacologic effect of JAK inhibition on EPO signaling and that bari treatment enhances iron utilisation markers associated with anaemia of chronic disease.

FRI0093 CAROTID ATHEROSCLEROSIS IS ASSOCIATED WITH DISEASE ACTIVITY AND BONE MINERAL DENSITY IN RHEUMATOID ARTHRITIS

J.W. Kang, E.S. Lee, J.S. Eun, J.H. Kim, J.Y. Kang, G.B. Bae, N.R. Kim, S.J. Lee, E.J. Nam, Y.M. Kang. *Kyungpook National University School of Medicine, Daegu, Korea, Republic Of*

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease which causes juxta-articular and generalized bone loss. Several studies revealed that bone mineral density (BMD) is associated with atherosclerosis.
Objectives: In the present study, we investigated the association between BMD and RA disease activity and the carotid atherosclerosis in RA patients based Kyungpook National University Hospital Atherosclerosis Risk in Rheumatoid Arthritis (KARRA) cohort study.
Methods: A total of 323 patients with RA, who performed dual-photon x-ray absorptiometry and carotid ultrasound, were included. We assessed RA disease activity, risk factors for atherosclerosis including hypertension, diabetes mellitus and dyslipidemia, presence of carotid plaque, carotid intima-media thickness (IMT), and BMD. BMD was measured at the lumbar spine (L-spine, L1-L4), femur neck (total femur neck) and distal forearm (total radius), and low BMD was defined as a T score of -1.0 or less.
Results: The BMD in the L-spine, femur, and radius was significantly lower in patients with carotid plaques (n=152), compared to patients without plaques (n=171) (1.014 g/cm^2 ± 0.21 vs. 1.066 g/cm^2 ± 0.18, p=0.016 for L-spine; 0.816 g/cm^2 ± 0.16 vs. 0.863 g/cm^2 ± 0.13, p<0.001 for femur; 0.542 g/cm^2 ± 0.13 vs. 0.603 g/cm^2 ± 0.12, p<0.001 for radius). The frequency of low BMD in these areas was also higher in patients with carotid plaques, compared to patients without plaques (52.7% vs. 47.5%, p=0.045 for L-spine; 56.0% vs. 44.0%, p=0.001 for femur; 60.6% vs. 39.4%, p<0.001 for radius). Carotid IMT showed a significant difference between patients with low BMD and those with normal BMD (0.84 mm ± 0.14 vs. 0.80 mm ± 0.19, p=0.025 for L-spine; 0.83 mm ± 0.15 vs. 0.80 mm ± 0.18, p=0.045 for femur; 0.85 mm ± 0.15 vs. 0.77 mm ± 0.18, p <0.001 for radius). In subgroup analysis, patients with the highest IMT quartile had a significantly lower BMD in all the regions than those with the lowest IMT quartile (61.2% vs. 37.7%, p=0.004 for L-spine; 59.5% vs. 35.1%, p=0.003 for femur; and 71.4% vs. 28.6%, p<0.001 for radius). Multivariate logistic regression analysis demonstrated that BMD at radius (OR 4.995, 95% CI [1.067–10.276], p<0.001), DAS28-ESR (OR 1.906, 95% CI [1.042–3.046], p=0.036), and dyslipidemia (OR 2.334, 95% CI [1.164–3.156], p=0.02) were risk factors for presence of carotid plaques.

Conclusions: The present study showed that carotid atherosclerosis was influenced by both disease activity and impaired bone health.

FRI0094 TIME TO AND FACTORS ASSOCIATED WITH INITIATION OF BIOLOGICAL THERAPY WITH DISEASE-MODIFYING ANTIRHEUMATIC DRUGS IN PATIENTS WITH RHEUMATOID ARTHRITIS IN COLOMBIA

J.E. Machado-Alba, L.F. Calvo-Torres, A.M. Bañol-Giraldo, S. Garcia-Betancurt on behalf of Grupo de Investigación en Farmacoepidemiología y Farmacovigilancia. Universidad Tecnológica de Pereira- Audifarma S.A. *Grupo de Investigación en Farmacoepidemiología y Farmacovigilancia, Universidad Tecnológica de Pereira-Audifarma S.A, Pereira, Colombia*

Background: Rheumatoid arthritis (RA) treatment is usually done with non-biological disease-modifying antirheumatic drugs (DMARDs), but the addition of a biological DMARD can be necessary. Biological drug therapy is usually prescribed following failure to achieve remission of the morbidity with one or more non-biological DMARDs. However, there is the possibility of using them as a first line in the initial phase, which there is the possibility of potentially altering its course or even reverting it to normality.
Objectives: To determine the time Colombian patients with rheumatoid arthritis (RA) are treated with non-biological disease-modifying antirheumatic drugs (DMARDs) before changing to biological therapy.
Methods: A retrospective cohort study that collected information about the start of antirheumatic treatment in patients of all ages with a diagnosis of RA until the change to biological DMARD therapy. Survival analysis using Kaplan–Meier curves, from 1 January 2007 until 31 December 2013 by SPSS 23.0 for Windows, was made.
Results: A total of 3880 patients (75.3% women) with a mean age of 51.3 years started non-biological DMARDs. After 5 years, 234 patients (6.0%) initiated biological DMARD therapy in 17.5±13.9 months. Differences in the socio demographic and pharmacological characteristics between the two groups of treatment are shown in the table 1. The use of glucocorticoids was associated with a greater risk of biological DMARD initiation (OR: 2.49; 95% CI: 1.658–3.732; p<0.001), while the use of methotrexate (OR: 0.04; 95% CI: 0.014–0.108; p<0.001) and chloroquine (OR: 0.13; 95% CI: 0.092–0.187; p<0.001) reduced the risk of initiation.

Variables	Non biological DMARDs (n: 3646)	%	Biological DMARDs (n: 234)	%
Sociodemographic				
Aged (mean ± SD)	52.2± 14.8		51.2± 16.2	
Sex (Male/Female, %)	74/160	31.6/68.4	884/2762	24.3/75.7
Women > 55 años	1364	37.4	79	33.8
Men > 45 años	580	15.9	46	19.6
Initial therapy				
Chloroquine	1485	40.7	44	18.8
Sulfasalazine	945	25.9	0	0
Methotrexate	493	13.5	4	1.7
Azatriopine	300	8.2	21	9.0
Cyclophosphamide	117	3.2	9	3.8
Cyclosporine	112	3.1	8	3.4
Others	59	1.6	4	1.7
Comedication				
Glucocorticoids	2183	59.9	199	85.0
Antihypertensives	582	16.0	52	22.2
Diuretics	281	7.7	19	8.1
Hipolipemiants	414	11.3	33	14.1
Antiplatelets	298	8.2	20	8.5
Antidiabetics	170	4.7	11	4.7
Nonsteroidal anti-inflammatory drugs	298	8.2	34	14.5
Antiulcer drugs	623	17.1	91	38.9
Thyroid hormone	200	5.5	21	9.0
Vitamin D and Calcium	283	7.8	43	18.4

Conclusions: After 5 years of non-biological DMARD therapy, 6.0% of people with RA started biological DMARDs. Receiving glucocorticoids, having any comedication, being treated in Bogota City or cities of the Colombian Atlantic coast affected the probability of switching to biological therapy in these patients.

FRI0095 PILOT STUDY OF THE EARLY RHEUMATOID ARTHRITIS DIAGNOSIS PROGRAM WITH A STRUCTURED REFERRAL FORMAT

J. Jaimes-Hernandez[1], P. Aranda-Pereira[2], C.I. Melendez-Mercado[2], A. Mendoza-Fuentes[2], I. Guzman-Sanchez[2], R.M. Rodriguez-Romo[3].
[1]Rheumatology Department, ISSEMYM Toluca Medical Center, Toluca, State of Mexico; [2]Rheumatology Department, ISSEMYM, Toluca; [3]Rheumatology, Mexican College of Rheumatology, Mexico City, Mexico

Background: The delay in referral of patients with suspicion of Undifferentiated Inflammatory Arthritis (UIA), especially the Rheumatoid Arthritis (RA), from the primary care physician (PCP) to the Rheumatologist prevents diagnosing and treatment in a timely manner. Early diagnosis and treatment decreases progression and permanent joint damage. Several strategies have been proposed to improve the time to referral of patients with UIA, however there is none for early RA in specific.
Objectives: We present a pilot study for the use of a weighted construct format for the improvement of the time to referral of patients with suspicion of early RA.
Methods: Since June 2005, in clinics and hospitals, PCPs were trained for the use of the weighted construct format tool. Adult patients with less than 1year of symptoms were considered for the referral. The criteria for reference of suspicion of early RA are shown in Table 1. The patient referral was made through the counter-reference system, including the complete format and laboratory results. The patient's appointment was given within 15 business days. Once the patients were evaluated and studied in the Department of Rheumatology, they were classified with RA according to 2010 ACR/EULAR criteria when was available this criteria classification. For the demographic variables, we used descriptive and inferential statistics and for the format validation we verified the reliability, and validity of the construct and criterion tool.
Results: Between July 2005 and July 2015, 298 patients were referred to our clinic. The average referral time in the first year (2005–2006) was 34.3±20.4 days, maintaining an average of 32.1±16.8 days until 2015. There was a reduction of 74% of referral time compared to a historical reference (mean time of referral was 127.4±51.8 days, in 122 patients). 182 (62%) patients filled out the 2010 ACR/EULAR criteria. The referral format for early RA had a Cronbach alpha of 0.49, Sensitivity 85.1%, Specificity 93.5% and PPV 92.2%. The correlation between patients with early RA and the 2010 ACR/EULAR criteria was 0.765 with a $p<0.000$.
Conclusions: In this pilot study, we observed that the construct had a suitable sensitivity, specificity and PPV for a referral format. Therefore, on suspicion of early RA the referral format could be useful as a simple clinical tool for the timely referral to the Rheumatologist. On the other hand, the program implementation allowed the reduction in the referral time substantially. To implement the use of this tool in the daily clinical practice it needs to be validated with an open population and an adequate sample size

Table 1

	Criteria	Score	Total
Clinical	Polyarticular arthritis: >5 joints Small joints: proximal interphalangeal joints, metacarpophalangeal joints, metatarsophalangeal or wrist joints+ any large joint (shoulders, elbows, knees or ankles)	4	
	Morning stiffness greater than 30 minutes (>30').	3	
	Oligoarticular arthritis: < 5 joints (small and large joints).	0	
Laboratory	Rheumatoid factor (+): dilution > 1:160 or 20 IU for nephelometry or turbidimetry.	4	
	Erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP): positive (> than normal reference parameter).	3	
	Anemia: hemoglobin (Hb) ≤12.5g/dl or thrombocytosis>40x10 ^{3}/µl platelets.	1	
	Total	15	

≤ 5points low suspect, between ≥6 and ≤10 suspect, and ≥11 points highly suspect.
Clinical criteria: obtained through complete clinical history (morning stiffness: time it takes to mobilize a joint after waking up). Musculoskeletal examination should show joint swelling (swelling, tenderness, temperature increase and difficulty to mobilize).
Laboratory: obtained within the protocol that caused the patient's visit (no > 2 weeks) results must be attached.

FRI0096 DURABILITY AND MAINTENANCE OF EFFICACY FOLLOWING PROLONGED TREATMENT WITH BARICITINIB

J.S. Smolen[1], Z. Li[2], R. Klar[3], L. Xie[4], D. Walker[4], A. Ghizdavescu[4], R. Ortmann[4], M. Dougados[5]. *[1]Medical University of Vienna, Vienna, Austria; [2]Peking University People's Hospital, Beijing, China; [3]Quintiles IMS Holdings, Inc., Durham; [4]Eli Lilly and Company, Indianapolis, United States; [5]Hôpital Cochin, Paris Descartes University, Paris, France*

Background: Baricitinib (bari) demonstrated clinical efficacy in Ph3 trials in RA patients (pts) naïve to DMARDs (RA-BEGIN[1]); and in RA pts with inadequate response to conventional synthetic DMARDs (RA-BEAM[2] and RA-BUILD[3]) or biologic DMARDs (RA-BEACON[4]).
Objectives: To evaluate durability and maintenance of efficacy over an additional 96 weeks (wks) of bari treatment.
Methods: Pts included were those randomised to bari in an originating study (OS), completed that study without rescue (52 wks in RA-BEGIN or RA-BEAM; 24 wks in RA-BUILD or RA-BEACON), and entered the long-term extension (LTE) study ≥96 wks prior to data cut-off. Durability of response was evaluated as pts achieving low disease activity (LDA) of SDAI ≤11 and minimal clinically important difference (MCID) of HAQ-DI improvement ≥0.22. Maintenance of response was evaluated as proportion of pts who had responded to bari at entry into LTE and maintained response at wk 96. Data are also provided for pts who had not responded to bari at entry into LTE who achieved response.
Results: Approximately half the pts in the durability analyses were categorised as LDA by wk 24 and the proportion of pts in the LDA category were similar or higher at wk 96. Three quarters of pts across groups demonstrated HAQ-DI improvement by wk 12 and more than half achieved MCID at wk 96. Most responders at entry into LTE maintained their response through wk 96. More than 25% of SDAI and HAQ-DI nonresponders at entry into LTE achieved response after 96 wks of treatment.
Conclusions: These data provide further evidence of the effectiveness of bari treatment in achievement of meaningful clinical control of disease activity long term.

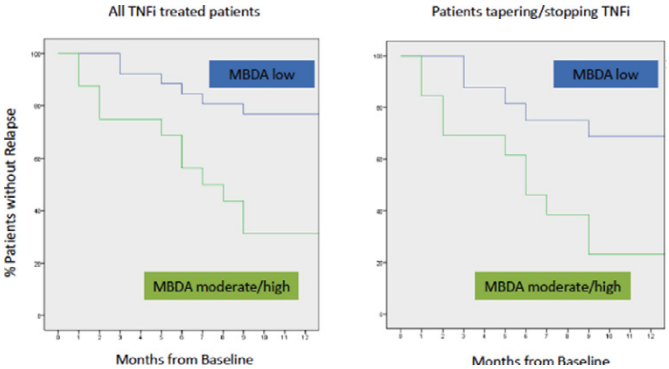
FRI0097 REPAIR OF JOINT DAMAGE IN NEWLY DIAGNOSED RHEUMATOID ARTHRITIS PATIENTS OCCURS BUT DOES NOT RELATE TO PREVIOUS SUPPRESSION OF INFLAMMATION; AN 8-YEARS SUB ANALYSIS IN THE BEST-COHORT

J.A. van der Pol[1], G. Akdemir[1], M. van den Broek[1], L. Dirven[1], P. Kerstens[2], W.F. Lems[3], I.M. Markusse[1], T.W. Huizinga[1], C.F. Allaart[1]. *[1]Department of Rheumatology, Leiden University Medical Center, Leiden; [2]Department of Rheumatology, Westfries Gasthuis, Hoorn; [3]Department of Rheumatology, VU Medical Center, Amsterdam, Netherlands*

Background: Joint damage in rheumatoid arthritis (RA) is thought to be irreparable. We hypothesized that in patients where inflammation is well suppressed for a long time, repair may be possible.
Objectives: To investigate whether reversal of erosions and joint space narrowing (JSN) in RA occurs and whether clinical variables predict repair.
Methods: In the BeSt study, patients with active early RA (ACR 1987 criteria, arthritis symptoms <2 years) were randomized to 4 treatment strategies, each with the aim to ensure and maintain suppression of disease activity by adjusting medication based on three-monthly calculations of the 44-joint Disease Activity Score (DAS), target ≤2.4. Radiographic joint damage was assessed yearly, using the Sharp/van der Heijde score (SHS). In this analysis, 8-years data of the study were used. Repair of erosions or JSN was defined at the individual joint level as a reduction of ≥1 SHS point compared to the previous available X-ray, present in ≥2 consecutive visits and with ≥3 out of 4 independent scorers agreeing. Radiographs were scored in random order per patient, blind for patient identity and treatment arm. Multiple logistic regressions were applied at the patient level for associations between achieving repair and maximum duration of previous remission, mean DAS until repair, previous prednisone use, previous infliximab use, anti-citrullinated protein antibody (ACPA), gender, age and randomization arm. All models were adjusted for mean joint damage over time in the group with repair. In the group without repair, the models were corrected for mean damage over time until mean time point of repair in the group with repair.
Results: Seven out of 508 patients did not have any X-ray images taken in the study. Of the remaining 501 patients, 320 had damage in at least 1 joint and thus could potentially show repair. In total, 2395 X-rays were available, on average 7.5 per patient (range 2–9). Median SHS after 8 years in these patients was 10 (IQR 4–21, range 0–234), and mean (SD) DAS from month 3 was 2.00 (0.67). Repair was seen in 17 patients, 3.3%; 10 had reduction of JSN, 6 of erosions, 1 had repair of both JSN and erosions. In 14 patients repair was seen in 1 joint, in 3 patients repair was seen in 2 joints (same time point). Mean (SD) time to repair was 44.1 (20.1) months. Ten of 17 patients (59%) had previously achieved DAS-remission, compared to 100% of the patients who at a matching time point showed no repair. Adjusted for mean SHS until repair, we found no associations with repair for duration of remission, mean DAS until repair, gender, age, presence of ACPA, or previous exposure to prednisone or infliximab (table 1). Apart from a trend towards fewer patients with repair in the initial infliximab study arm, there were no differences in any of the groups in any of the regression analyses.

Table 1. Results of multiple logistic regression models to investigate associations with repair (n=17)

	OR	95% CI	P
Duration of previous remission*	-	-	-
Mean DAS from month 3 to time of repair	1.39	0.77 - 2.51	0.270
Previous prednisone	1.09	0.385 - 3.09	0.871
Previous infliximab	0.599	0.206 - 1.74	0.347
ACPA	1.51	0.413 - 5.53	0.533
Gender	1.13	0.401 - 3.16	0.822
Baseline age	1.01	0.975 - 1.05	0.548
Randomization arm			
Sequential monotherapy	ref	-	-
Step-up combination therapy	0.797	0.231 - 2.75	0.721
Initial combination with prednisone	0.597	0.158 - 2.26	0.448
Initial combination with infliximab	0.147	0.0173 - 1.25	0.080



All models were adjusted for mean Sharp/van der Heijde score until repair
DAS: disease activity score, ACPA: anti-citrullinated peptide antibody
*No results due to 100% remission in non-repair comparator group

Conclusions: In this early RA cohort, during 8 years treated to target DAS ≤2.4, repair of JSN and erosions was seen in 17 patients (3.3%), which supports that repair occurs in early RA. However, repair is a rare phenomenon, and does not seem to relate to previous inflammation or other predictors in this cohort.

FRI0098 ELEVATED MULTI-BIOMARKER DISEASE ACTIVITY (MBDA) PREDICTS RELAPSES IN RA PATIENTS IN SUSTAINED REMISSION TAPERING TUMOUR NECROSIS FACTOR INHIBITOR THERAPY- RESULTS FROM THE RANDOMIZED CONTROLLED RETRO STUDY

Kleinert[6], J. Wendler[6], F. Schuch[6], M. Ronneberger[6], M. Feuchtenberger[7], M. Fleck[8], K. Manger[9], W. Ochs[10], M. Schmitt-Haendle[10], H.-M. Lorenz[11], H. Nuesslein[12], R. Alten[13], J. Henes[14], K. Krueger[15], G. Schett[1]. *[1]University of Erlangen-Nuremberg, Erlangen, Germany; [2]St.Vincent Hospital, Vinforce Study Group, Medical University of Vienna, Vienna, Austria; [3]Institutio de Rheumatologia, Sao Paolo, Brazil; [4]University of Wuerzburg, Internal Medicine 2, Wuerzburg; [5]University Medical Center Freiburg, Rheumatology and Clinical Immunology, Freiburg; [6]Rheumatology Clinical Practice Erlangen, Erlangen; [7]Rheumatology Practice and Department of Internal medicine 2, Clinic Burghausen, Burghausen; [8]Asklepios Medical Center, Department of Rheumatology and clinical Immunology, Bad Abbach; [9]Rheumatology Practice Bamberg, Bamberg; [10]Rheumatology Practice Bayreuth, Bayreuth; [11]University of Heidelberg, Medicine 5, Heidelberg; [12]Rheumatology Practice Nuremberg, Nuremberg; [13]Schlosspark Klinik, Internal Medicine/Rheumatology, Berlin; [14]University of Tuebingen, Centre for Interdisciplinary Clinical Immunolog, Tuebingen; [15]Praxiszentrum St.Bonifatius, Munich, Germany*

Background: Tumor necrosis factor inhibitors (TNFi) are the most frequently used bDMARDs in RA patients. TNFi induces remission in a substantial numbers of patients. Once remission, particularly sustained remission is achieved the question arises whether TNFi can be successfully tapered. To date biomarkers, which can help to predict if TNFi can be tapered or stopped, remain to be developed.
Objectives: To test whether residual subclinical inflammation assessed by multi-biomarker disease activity (MBDA) predicts the risk of disease relapse after tapering or stopping TNFi treatment in RA patients in sustained remission.
Methods: Sub-analysis of TNFi treated patients of the RETRO study, a randomized-controlled study in RA patients in sustained (>6 month) DAS28 remission comparing 3 different DMARD treatment strategies (continuation of full dose, 50% dose tapering, stopping after 50% dose tapering). Patients were followed over one year for the occurrence of relapses as defined by leaving DAS28-ESR remission (>2.6 units) (1). Vectra-DA tests were done in the baseline samples of all patients included into the RETRO study. MBDA score was calculated according to previously defined algorithms with low MBDA score defined as <30 units and moderate to high scores as ≥30 units (2).
Results: Of the 151 patients included in the RETRO study, 42 received TNFi treatment (mean age: 56 ys, 25 (60%) females, 78% concomitant csDMARDs; 69% ACPA/RF positive. Baseline demographic and disease specific characteristics of these patients were comparable to the non-TNFi treated patients of the RETRO study. 26/42 patients (62%) had low MBDA scores at baseline, while 16/42 (38%) had moderate/high scores. Relapse rates were significantly (chi square p=0.016) lower in RA patients with low MBDA scores (N=8 of 26; 31%) than in those with moderate/high scores (N=11 of 16; 69%) (Figure; left graph). When separately analyzing only patients tapering TNFi (N=29), relapse rates were moderate in

RA patients with low MBDA scores (N=6 of 16; 37%) but high in those with moderate/high scores (N=10 of 13; 77%) (chi square p=0.015) (Figure; right graph).

Conclusions: These data show that the majority of RA patients in sustained clinical remission with low MBDA scores can successfully taper TNFi. In contrast tapering cannot be recommended in patients with moderate to high MBDA scores, as relapse rates are high in these patients.

FRI0099 PAIN REDUCTION IS ASSOCIATED WITH IMPROVED WORK PRODUCTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Michaud[1,2], B. Zhu[3], C. Gaich[3], A.M. DeLozier[3], V. Arora[3], C. Dickson[3], J.S. Smolen[4]. *[1]University of Nebraska Medical Center, Omaha; [2]NE & National Data Bank for Rheumatic Diseases, Wichita; [3]Eli Lilly and Company, Indianapolis, United States; [4]Division of Rheumatology, Medical University of Vienna, Vienna, Austria*

Background: Patients with rheumatoid arthritis (RA) indicate pain is an important aspect of disease burden and may persist despite control of disease. In a randomized, double-blind phase 3 clinical trial of baricitinib (RA-BEAM),[1] baricitinib provided significant improvement in pain reduction. It is not clear, however, how much reductions in pain impacted other aspects of life, such as work productivity.

Objectives: To assess the relationship between pain reduction and improvements, regardless of treatment, in daily activity and work productivity in patients with RA.

Methods: In this post-hoc analysis of RA-BEAM[1], pain for the intention-to-treat patients was assessed using the patient's assessment of pain (0–100 mm visual analogue scale). The Work Productivity and Activity Impairment Questionnaire-RA (WPAI-RA) instrument was used to evaluate the percentage of activity impairment due to RA (impairment in regular daily activities, N=1302), percentage of work-time missed due to RA (absenteeism, N=521), percentage of impairment while working due to RA (presenteeism, N=490), and percentage of overall work impairment due to RA (impairment in work productivity, N=490). Pain was divided into pain reduction groups (<30%, 30% – <50%, ≥50% at Weeks 12 and 24; ≥30% [Y/N] and ≥50% [Y/N] at Weeks 1 and 2). Pairwise comparisons on improvement in WPAI-RA scores between pain reduction groups at Weeks 12 and 24 were assessed by ANCOVA adjusting for region, baseline joint erosion status, and baseline values of outcome variables. Missing values were imputed using the modified last-observation carried forward method.

Results: At baseline across treatment groups, the mean values ranged from 56–58 for daily activity impairment, 12–13 for absenteeism, 42–46 for presenteeism, and 45–49 for work productivity impairment. A ≥30% reduction in pain as early as Week 1 was associated with significantly greater (p<0.001) improvement than <30% pain reduction in regular daily activity (-22.8 vs -16.0), presenteeism (-17.5 vs. -12.1), and work productivity (-16.8 vs. -11.6) at Week 12. Greater improvement was observed in most WPAI-RA scores in patients who had more pain reduction at Weeks 12 and 24; with a reduction of ≥50% in pain from baseline, the WPAI-RA scores were substantially improved at Weeks 12 or 24 for daily activity, presenteeism, and work productivity (Table).

	Pain (VAS) % reduction from baseline at Week 12			Pain (VAS) % reduction from baseline at Week 24		
Mean (SD)%	**<30%**	**30% - <50%**	**≥50%**	**<30%**	**30% - <50%**	**≥50%**
Improvement in WPAI-RA	**WPAI-RA at Week 12**			**WPAI-RA at Week 24**		
Impairment in Regular Daily Activity	-5.6 (22.2)	-17.8 (21.8)[c]	-30.1 (25.4)[cd]	-3.5 (23.6)	-17.1 (22.4)[c]	-33.2 (25.3)[cd]
Absenteeism	0.7 (28.0)	-5.2 (29.7)[b]	-3.0 (18.2)[c]	-1.8 (28.5)	-2.1 (36.1)	-2.5 (21.8)
Presenteeism	-2.8 (24.6)	-12.9 (21.1)[c]	-23.4 (24.6)[cd]	-0.2 (25.1)	-7.7 (23.1)[a]	-26.0 (25.1)[cd]
Impairment in Work Productivity	-2.3 (24.4)	-11.3 (23.5)[c]	-23.1 (26.5)[cd]	0.5 (25.6)	-5.7 (26.2)	-25.2 (28.1)[cd]

[a]p≤0.05; [b]p≤0.01; [c]p≤0.001 vs. pain reduction <30%; [d]p<0.001 vs. pain reduction 30-<50%

Conclusions: Regardless of treatment, pain reduction was associated with improved regular daily activity and work productivity in patients with RA, with larger levels of reduction related to more improvement.

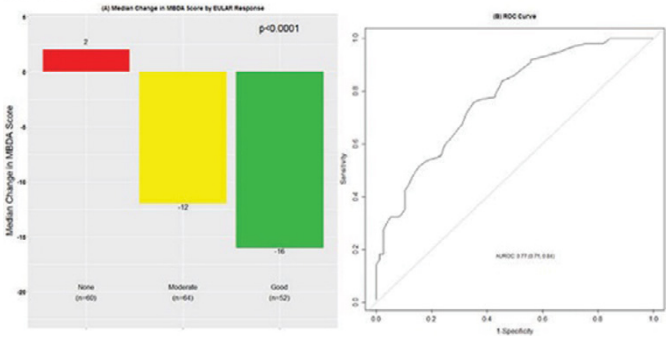
FRI0100 DETERMINING MINIMUM CLINICALLY IMPORTANT CHANGE IN MULTI BIOMARKER DISEASE ACTIVITY SCORE ASSOCIATED WITH CLINICAL IMPROVEMENT IN METHOTREXATE NAÏVE PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

K. Chatzidionysiou[1], A.H. Hensvold[1], S. Saevarsdottir[1], R.J. Bolce[2], D. Chernoff[2], C.C. Hwang[2], X. Wang[2], A.I. Catrina[1]. *[1]Karolinska University and Institutet, Stockholm, Sweden; [2]Crescendo Bioscience Inc., South San Francisco, United States*

Background: The Multi-Biomarker Disease Activity (MBDA) score is a validated tool that quantifies 12 biomarkers to assess disease activity in rheumatoid arthritis (RA) patients. Many studies have demonstrated usefulness of the score for assessing RA disease activity.

Objectives: To determine minimum clinically important change in MBDA score (ΔMBDA) from baseline (BL) to Month 3 (M3) associated with clinical improvement (decrease in DAS-ESR >1.2) in early RA patients after initiating methotrexate (MTX).

Methods: We evaluated the MBDA test in patients from one of the sites participating in the Solna Epidemiological Investigation of RA (EIRA) cohort. EIRA patients were eligible if they were ≥18 years; RA diagnosis within 12 months of symptom duration; had serum and clinical assessments at BL and M3; and clinical follow-up data in the Swedish Rheumatology Quality Register. Patients naïve to disease modifying anti-rheumatic drugs who received MTX were included. Kruskal-Wallis was used to test the null hypothesis that medians of ΔMBDA scores of 3 EULAR response groups are equal. Receiver operating characteristic (ROC) analysis was performed. The optimal threshold of ΔMBDA associated with DAS28-ESR improvement (decrease in DAS-ESR >1.2 at M3) was determined by Youden criterion maximizing sum of sensitivity and specificity.



Results: 176 patients were included: 72% women, mean age 51 (SD: 11.7) years, mean DAS28-ESR score 5.6 (SD: 0.99); 51% had ESR <28 mm/hr, 66% were anti-CCP2+, and 22% received prednisone. Mean BL MBDA score was 56.8 (SD: 14.7) with 8 (5%) patients in low (<30), 29 (16%) patients in moderate (30–44) and 139 (79%) patients in high MBDA disease activity categories. Median MBDA scores for patients with no EULAR response worsened by 2 points and for patients with moderate and good response improved by 12 and 16 points, respectively (p<0.0001 across groups, Fig 1A). Median MBDA scores improved by 10 points for all patients and 15 points in patients with a DAS28-ESR decrease >1.2. The best combination of sensitivity and specificity to achieve a DAS28-ESR decrease >1.2 was provided by a ≥8 point MBDA score improvement (Fig 1B). A similar result was obtained using the bootstrap method. AUROC was 0.77 (95% CI: 0.71, 0.84). 125 patients (71%) had concordance between DAS28-ESR improvement and ΔMBDA improvement at the optimal threshold (Table 1).

Table 1. Performance Measures (95% CI) Based on Optimal Threshold of ΔMBDA Score from BL to M3 Associated with DAS28-ESR Improvement

Improvement		DAS28-ESR (decrease >1.2)		
		Yes	No	Total
MBDA (optimal threshold: improvement ≥8 points)	Yes	75	27	102
	No	24	50	74
	Total	99	77	176

Sensitivity: 0.76 (0.66, 0.83); Positive predictive value: 0.74 (0.64, 0.81); Specificity: 0.65 (0.54, 0.75); Negative predictive value: 0.68 (0.56, 0.77).r Concordance rate: 71%.

Figure A) Median Change in MBDA Score by EULAR Response; B) Receiver Operating Curve (ROC) to Determine the Optimal Threshold of Change in the MBDA Score Associated with Clinical Improvement (ΔDAS28-ESR Decrease >1.2)

Conclusions: The optimal threshold of ΔMBDA score associated with a clinically relevant decrease of DAS28 was 8 points. Using this threshold, the MBDA test is informative to detect clinical improvement. Thus, based on these results improvement in MBDA score ≥8 points at M3 after initiating MTX is indicative of meaningful clinical improvement.

FRI0101 RA IN MALE CARPENTERS: OCCUPATIONAL WOOD DUST EXPOSURE INCREASES ACPA AND RF SEROPOSITIVITY AND SIGNIFICANTLY RAISES RF TITRES

K. Bellis[1], M. Whallett[2], D. Murphy[1,2], D. Hutchinson[1,2]. [1]*Rheumatology, Royal Cornwall Hospital;* [2]*University of Exeter Medical School, Cornwall Campus, Truro, Cornwall, United Kingdom*

Background: Wood dust has been hypothesised as a trigger in RA. Exposure may activate peptidyl arginine deaminase through exposure to silica and carbon nanoparticles,[1] stimulating RF autoantibody production.[2] Though non-silica dusts have shown increased RA risk in construction workers, wood dust exposed individuals were excluded from analysis in a recent large registry study.[3]
Objectives: To analyse the autoantibody status of male RA wood workers in Cornwall, UK, compared to matched RA controls with no occupational dust or fume exposure.
Methods: All male RA patients were sent an occupational questionnaire, detailing current occupation, last occupation (if retired) and other occupations for >1 year. Telephone follow up was completed to minimise missing data. 41/720 (6%) patients died during the study period (22 months). 39/720 (5%) were excluded due to incomplete data. 147/640 (23%) had exposure to wood dust including other dust co-exposures, with 44/147 (30%) indentifying wood dust as their primary occupational exposure as carpenters, approximately seven times higher than expected given UK employment census data. This cohort was matched to 102 RA controls with no dust or fume exposure for age +/- 5 years, sex and index of multiple deprivation (IMD) +/- 1 decile. RF titres were compared via 2 tailed Mann Whitney U test, and ACPA seropositivity was compared using a Z test of 2 proportions.
Results: No significant differences were seen in median age between woodworker cases (median 59 years IQR 50–63), and controls (median 58 years IQR 48–65). Woodworker never smokers demonstrated significantly higher seropositivity rates for both RF and ACPA than respective controls, and RF titres were significantly higher amongst woodworkers irrespective of smoking (Table 1). Median smoking rates were not significantly different between cohorts: woodworkers median pack years 23.5 (IQR 14.75–36), control median pack years 20.5 (IQR 10.25–32.75).

Table 1. Seropositivity rates and RF levels for woodworkers vs. controls

	Median RF (IQR)	ACPA+ (%)
Control never smokers (n=40)	16 (IQR 6.7–47.2)*	19/40 (48%)***
Control ever smokers (n=62)	68.9 (IQR 20.65–167.58)**	46/62 (74%)****
Wood worker never smokers (n=8)	86.4 (IQR 19.5–230.3)*	7/8 (88%)***
Wood worker ever smokers (n=36)	156.1 (IQR 54–321.1)**	29/36 (81%)****

*p<0.04; **p<0.01; ***p<0.04; ****p= not sig.

Conclusions: Wood dust exposed RA patients are more likely to be seropositive. Sequential environmental insults of smoking and wood dust exposure have an additive effect on rheumatoid factor levels, conferring increased disease severity. Further studies are needed to determine if occupational wood dust exposure causes RA.

FRI0102 ULTRASOUND AND MRI DURING FLARES OF PALINDROMIC RHEUMATISM REVEAL A DISTINCT PHENOTYPE EVEN IN IMMINENT RA

K. Mankia[1], M.-A. D'Agostino[1], R. Wakefield[1], G. Eugenio[1], L. Horton[1], J. Nam[1], A. Grainger[2], P. Emery[1]. [1]*Leeds Institute of Rheumatic and Musculoskeletal Medicine and Nihr Leeds Musculoskeletal Biomedical Research Unit;* [2]*Radiology, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

Background: Palindromic rheumatism (PR) is a recurrent, self-abortive arthritis and/or peri-arthritis which progresses to RA in up to 50% of patients, especially those that are anti-CCP positive (1). Whether PR is truly a prodrome of RA or a distinct syndrome is unclear; the pathological phenotype of PR flare, and whether this changes when RA is imminent, remains unknown
Objectives: To describe the clinical and imaging (US and MRI) phenotype during PR flares and to determine whether this changes in PR patients with imminent RA. We hypothesised PR patients with imminent RA would have a RA phenotype during flare
Methods: Patients were recruited from a prospective PR cohort. PR flares were defined as ≥2 of pain, swelling, erythema in or around ≥1 joint, that later normalised. Clinical details were recorded during flares. Blinded US assessment (wrists, MCPs, PIPs, elbows, knees, MTPs, ECUs and 2nd-5th finger flexor tendons) was performed during and between flares. Synovitis, tenosynovitis, subcutaneous oedema, peri-articular inflammation and peri-tendinous oedema were reported at each joint. Where possible, MRI was also performed on the most symptomatic region during flare. Patients were followed for progression to RA
Results: US was performed in 22 patients during flare. 19 patients also had non-flare US. Mean age was 49 yrs. 16/22 (73%) were anti-CCP+ and 6/22 (27%) anti-CCP-. Six (27%) patients developed RA (mean 23 weeks post flare); these patients had higher frequency of flares and absence of flare trigger (figure) but no difference in distribution of flaring joints. *The flare US* showed grey scale (GS) synovitis in 13/22 (59%) patients, power Doppler (PD) synovitis in 4/22 (18%) and no erosions. 12/22 (55%) patients had peri-articular inflammation and/or subcutaneous oedema; in 6 patients this was without synovitis/tenosynovitis. Tenosynovitis and/or peri-tendinous oedema were present in 6/22 (27%) patients. Non-flare US demonstrated fewer abnormalities with improvement post flare. In 5 patients multiple flares were imaged with variable US abnormalities identified. The US flare phenotype did not differ (from non-progressors) in patients who progressed to RA, with PD synovitis present in only 17% (table 1) contrasting with our early RA cohort where PD synovitis occurred in 73% of patients (2). MRI was performed on 8 patients (2 flares imaged in 1 patient) and detected more pathology than US. Bone marrow oedema (BME) was found in only 1 patient. No erosions were seen.

Table 1

US abnormality	Progressed to RA (n=6)	Not progressed to RA (n=16)
PD synovitis	1 (17%)	3 (19%)
GS synovitis	2 (33%)	10 (63%)
Tenosynovitis	1 (17%)	4 (25%)
Peri-tendinous oedema	0 (0%)	2 (13%)
Peri-articular inflammation	1 (17%)	7 (44%)
Subcutaneous oedema	3 (50%)	6 (38%)

		Progressed to RA (n=6)	Not progressed to RA (n=16)
Anti-CCP positive		5 (83%)	11 (69%)
Disease duration (yrs), median (IQR)		2.6 (1.8-9.2)	3.1 (1.1-7.4)
Frequency of flares (per yr), median (IQR)		25 (12-50)	9 (5-23)
Flare Trigger identifiable?		0 (0%)	7 (44%)
	Mechanical	0 (0%)	4 (57%)
	Emotional Stress	0 (0%)	3 (43%)
Flare symptoms			
	Joint pain	6 (100%)	15 (94%)
	Joint swelling	5 (83%)	15 (94%)
	Skin colour change	6 (100%)	14 (88%)
Number of joints involved in the flare, median (IQR)		2 (1-5)	2 (1-4)
CRP (mg/L), median (IQR)		10.8 (6.0-31)	9.0 (2.2-41.3)

Conclusions: PR flares have a distinct imaging phenotype characterised by peri-articular inflammation and subcutaneous oedema, often without synovitis. The low prevalence of PD synovitis, BME and erosions distinguishes PR from RA. PR patients with imminent RA have no triggers and more frequent flares, but retain the distinct PR phenotype. This suggests distinct pathological mechanisms in PR and should be of value for potential therapeutic interventions.

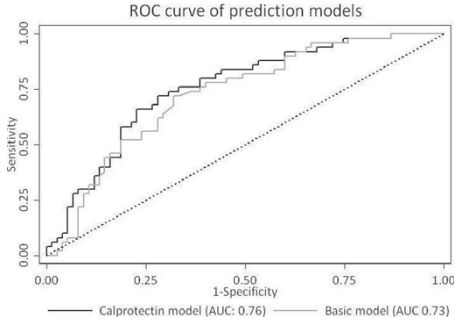
FRI0103 CONTRIBUTION OF SUBJECTIVE DISEASE ACTIVITY SCORE 28 (DAS28) COMPONENTS TO THE RESPONSE TO TREATMENT OF RHEUMATOID ARTHRITIS

K.M. Son[1], S.Y. Lee[2], Y.I. Seo[2], J.-E. Choi[3], H.A. Kim[2]. [1]*Hallym University Dongtan Sacred Heart Hospital;* [2]*Hallym University Sacred Heart Hospital, Gyeonggi-Do;* [3]*Ewha womans University, Seoul, Korea, Republic Of*



Background: Some patients with rheumatoid arthritis (RA) do not respond adequately to treatment.
Objectives: We investigated the contributions made by the subjective components of the disease activity score 28 (DAS28) to the treatment response of RA. In addition, factors associated with poor response to treatment at 6 months, despite normalization of objective measures, were examined.

Methods: A total of 426 newly diagnosed RA patients treated from August 2011 to December 2014 were included. The DAS28-P score (the subjective components of the DAS28 relative to the total components) was calculated as DAS28-P = 0.56*sqrt(TJC28) + 0.014*(VAS-GH) / 0.56*sqrt(TJC28) + 0.28*sqrt(SJC28) + 0.78ln(ESR) + 0.014*(VAS-GH). The EULAR response was assessed after 6 months of treatment. Of those who failed to attain good EULAR responses, those for whom the objective measures (the ESR, the CRP level, and swollen joints) were normalized were defined as having failed treatment because of subjective measures.
Results: The mean age of all patients was 54 years and 79% were female. The median (IQR) DAS28 score at baseline was 4.8 (4.04–5.49) and that after 6 months of treatment 3.21 (2.41–3.95). Good responders (according to the EULAR criteria) numbered 180 (38.9%), moderate responders 150 (32.4%), and non-responders 96 (20.7%). The DAS28-P score fell significantly from baseline to 6 months in good (0.43 versus 0.28, $p<0.001$) and moderate responders (0.44 versus 0.4, $p=0.003$), but not in non-responders (0.43 versus 0.45, $p=0.727$). Younger age, a lower DAS28 score, and a lower DAS28-P score at baseline were related to a good EULAR response. Subjects who failed to respond because of subjective measures tended to have higher DAS28-P scores at baseline.
Conclusions: We found that RA patients with high DAS28-P scores, reflecting subjective measures, were less likely to achieve good EULAR responses 6 months after treatment initiation and tended not to be classified as good responders despite normalization of objective measures.

FRI0104 NO ADDED PREDICTIVE VALUE OF SERUM CALPROTECTIN FOR TREATMENT RESPONSE TO ADALIMUMAB OR ETANERCEPT IN RA PATIENTS

L. Tweehuysen[1], N. den Broeder[1], L.A.B. Joosten[2], T. Vogl[3], F.H.J. van den Hoogen[1,4], R.M. Thurlings[4], A.A. den Broeder[1,4]. *[1]Rheumatology, Sint Maartenskliniek; [2]Internal Medicine, Radboudumc, Nijmegen, Netherlands; [3]Immunology, University of Münster, Münster, Germany; [4]Rheumatology, Radboudumc, Nijmegen, Netherlands*

Background: Approximately 60% of RA patients do not achieve good clinical response after 6 months of treatment with a TNF inhibitor (TNFi).[1] To date, no clinically useful baseline biomarkers have been found to predict response.[2] Calprotectin (a heterodimer of S100A8/S100A9) was shown to be modestly predictive for treatment response to adalimumab (ADA) (area under the curve (AUC): 0.69) while no difference in calprotectin levels was found between responders and non-responders in RA patients treated with etanercept (ETN) and methotrexate.[3,4]
Objectives: To assess the added predictive value of serum calprotectin for clinical response after 6 months treatment with ADA or ETN in RA patients.
Methods: RA patients starting treatment with ADA or ETN in the BIO-TOP study (a prospective cohort study) were included. Patients who discontinued TNFi treatment within 2 months were excluded from analysis. Serum calprotectin was measured at baseline using ELISA. EULAR response was measured at 6 months (good versus moderate/no response). Discontinuation of TNFi before 6 months was regarded as non-response (in case of lack of effect) and clinical response at 3 months was carried forward (when stopped for other reasons). First calprotectin levels were correlated cross-sectionally with several clinical baseline markers. Thereafter receiver-operator-characteristic (ROC) curves were created for ADA and ETN separately. Finally logistic prediction models (basic model and calprotectin added model) were created using backward selection, including baseline characteristics and calprotectin levels to examine the added predictive value of calprotectin.
Results: Data on calprotectin levels and EULAR response were available for 125 patients (ADA (n=50), ETN (n=75)) with 40% of patients achieving EULAR good response. Responders showed significantly higher calprotectin levels at baseline: 985 ng/mL (p25-p75: 558–1417) versus 645 ng/mL (p25-p75: 415–973) (p=0.04). Calprotectin levels were significantly correlated to DAS28-CRP (Spearman $\rho=0.32$, $p<0.01$) and C-reactive protein (CRP) levels (Spearman $\rho=0.57$, $p<0.01$) and significantly higher in rheumatoid factor positive patients (p=0.03). No significant correlation was found between calprotectin and age, gender or ACPA positivity. The AUC for serum calprotectin in the ADA and ETN group were 0.68 (95% CI: 0.49–0.88) and 0.49 (95% CI: 0.35–0.63), respectively. The basic model (backward selected variables: baseline DAS28-CRP and medication used (ADA versus ETN)) showed an AUC of 0.73 (95% CI: 0.64–0.82). The calprotectin added model performed similarly with an AUC of 0.76 (95% CI: 0.67–0.84) (p=0.27).

Conclusions: Serum calprotectin is modestly predictive for EULAR good response to ADA but not ETN treatment after 6 months in RA patients. However, calprotectin does not provide additional predictive value over a basic clinical prediction model.

FRI0105 FLUCTUATING, UNPREDICTABLE AND CHALLENGING: HOW PAIN, FATIGUE AND SLEEP DISTURBANCE IMPACT QUALITY OF LIFE IN PEOPLE WITH RHEUMATOID ARTHRITIS

V. Short[1], J. McBeth[1], K.L. Druce[1], S. Moore[2], W. Dixon[1], S. Kyle[3], M. Lunt[1], L. Cordingley[4]. *[1]Arthritis Research UK Centre for Epidemiology, University of Manchester; [2]Research User Group, NIHR Manchester Musculoskeletal Biomedical Research Unit, Central Manchester University Hospitals NHS Foundation Trust, Manchester; [3]Sleep & Circadian Neuroscience Institute, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford; [4]Division of Musculoskeletal and Dermatological Sciences, University of Manchester, Manchester, United Kingdom*

Background: Qualitative studies of patient experiences have provided useful insights into how rheumatoid arthritis (RA) affects quality of life (QoL). RA threatens self-image and feelings of independence, reduces personal control, and is associated with difficulty in juggling self-management alongside pre-existing demands of work, home and family life. Pain, fatigue, sleep problems and low mood are commonly reported by patients and perceived as particularly troublesome aspects of RA. We wanted to know whether these symptoms of RA were viewed as the key drivers of reported changes to QoL.
Objectives: To explore RA patients' perceptions of RA-related pain, fatigue, sleep problems and mood, and their impact on QoL.
Methods: Participants, recruited through RA charities across England, were purposively sampled to include a broad range of current ages and ages at onset of RA. Eleven individuals with RA were interviewed either in a group interview (three participants) or individual semi-structured interviews (eight participants). The interview topic guide was developed in consultation with patient representatives. Interviews were audio-recorded and transcribed in full. Interview data were analysed using inductive latent thematic analysis.
Results: All participants were female, aged 36–75 years. Disease duration ranged from five months to 31 years.
Pain, fatigue, poor sleep and low mood were all attributed to RA, and viewed as having wide-ranging impacts on QoL. Participants saw the bidirectional nature of relationships between these four symptoms as particularly challenging. For example, reduced sleep led to increased pain and vice versa.
Themes included: "*Fluctuating symptoms*" referring to the impact of the significant changes in mood, fatigue or pain which can occur within a single 24 hour period during "an RA flare"; "*The unpredictability of symptoms*" was viewed as emotionally draining, anxiety-provoking and undermined both short and long-term plans; "*Challenging*" described both the symptoms and the need to anticipate potential daily challenges in the context of current levels of symptoms.
Most were able to articulate the attitudinal, practical and emotional strategies which could facilitate adaptation to living with RA such as the need to maintain optimism, a focus on what could realistically be achieved, day-to-day cognitive flexibility and practical support.
Pain, fatigue and changes to sleep patterns were viewed as affecting the following aspects of QoL; ability to work effectively, family and social relationships, self-worth, ability to feel "in control", threats to future plans and appearance. The appearance theme included a desire not to be viewed as ill or "disabled", weight-gain and self-consciousness.
Conclusions: Daily and hourly variations in pain, fatigue and low mood are challenging for individuals with RA. The unpredictable nature of RA often was associated with anticipatory anxiety and mood fluctuations within the day. However, despite this the importance of positivity and acceptance were identified as mitigating some of the impact RA was having on QoL.

FRI0106 RESULTS OF A SYSTEMATIC LITERATURE REVIEW OF PROGNOSTIC FACTORS IN RHEUMATOID ARTHRITIS AS A BASIS FOR A PROSPECTIVE RHEUMATOLOGISTS SURVEY

L. Carmona[1], T. Otón[1], A. Royo[2], J.L. Baquero[3], S. Luján[2], S. Muñoz-Fernández[4]. *[1]Instituto de Salud Musculoesquelética; [2]Medical Dpt., Bristol-Myers Squibb; [3]Departamento Científico, Scientia Salus; [4]Rheumatology, Hospital Universitario Infanta Sofía, Universidad Europea, Madrid, Spain*

Background: Selecting the most appropriate therapy for each patient with rheumatoid arthritis (RA) is crucial in order to prevent joint damage, particularly in patients with rapidly progressing disease. The literature on prognostic factors is tremendous, being practical to summarize which factors are most strongly associated with a particular outcome and what is the utility that rheumatologists assign to these factors.
Objectives: To identify well established factors predicting long-term outcomes in RA, as the basis for a survey.
Methods: The identification of the factors was performed via an overview of systematic reviews studying prognostic factors in RA, followed by scoping reviews for individual factors. All searches were conducted in PubMed. In order to be included in the overview, the study had to be a systematic review of prognostic factors of any of the following outcomes: disability, mortality, remission, response to treatment, or radiological damage. All factors identified, in positive or negative association with the selected outcomes, were compiled in a matrix of factors * outcomes. Subsequent scoping literature reviews were performed for each combination of the matrix.
Results: The overview of systematic reviews allowed the identification of 36 prognostic factors (see Table 1).

Table 1. Prognostic factors identified in the overview of systematic reviews

Outcomes	Prognostic factors	
Disability	Genetic markers	Genetic polymorphisms
	Quality of life index	HAQ
Mortality	Genetic markers	Shared epitope
	Medical history	Lung disease
No remission	Medical history	Clinical Presentation
		Advanced age
		Age at disease onset
		Duration of disease
		Tobacco
		Obesity
		Comorbidities
		Disease activity
		Monotherapy
		Biological treatment
		Response to treatment
	Biomarkers	RF
		ACPA
		RFA
		IL2
		RANKL
		Vitamin D
	Radiological data	Residual synovitis by US
		Scintigraphy
		MRI
	Treatment	Treat to target
		Remission
No response to treatment	Biomarkers	Calprotectin
		RF
	Treatment	Treatment Failure
Structural damage	Genetic markers	Shared epitope
		Polymorphisms
	Radiological data	Erosions
	Biomarkers	Calprotectin
		RF
		ACPA
		Composite activity indices
	Treatment	Minimum treatment
		Combination Therapy Effect
		Recruitment time in clinical trials

After a round of discussions, we decided to remove all factors depending on treatment or study methodology for the scoping reviews, considering that they could not properly be considered prognostic factors but modifiers. Following the scoping reviews, we obtained a list of studies of prognostic factors, with methodological characteristics and 27 reviews of specific prognostic factors and outcomes. With this information, a survey addressed to practicing rheumatologists was developed to test how often they use the various factors to make long-term predictions, and how strong they think the association with outcome is.
Conclusions: We have analyzed and compiled a summary of prognostic factors published in RA and their predictability of long-term outcomes. This may act as a reference for cross-factor comparison and evidence-based risk assimilation and serve as a basis of surveying the value of such factors.

FRI0107 DEVELOPMENT OF A PREDICTIVE MODEL FOR RHEUMATOID ARTHRITIS MORTALITY USING RANDOM SURVIVAL FOREST

L. Rodriguez-Rodriguez[1,2], J.M. Lezcano[3], E. Soudah[4], J.Á. Jover[1], I. González-Álvarez[5,6], F. Salazar[4], L. Abásolo[1,2]. *[1]Rheumatology, Hospital Clínico San Carlos; [2]San Carlos Health Research Institute, Madrid, Spain; [3]Rheumatology, San Carlos Health Research Institute; [4]CIMNE-Madrid; [5]La Princesa Health Research Institute; [6]Rheumatology, Hospital de la Princesa, Madrid, Spain*

Background: Different machine learning methods have been used to develop predictive models of high quality and precision [1]. Among them, Random Survival Forests (RSF) has been proposed as an alternative to traditional survival models [2], being able to overcome most of the limitation of traditional survival techniques, such as Cox proportional hazards models.
Objectives: Our objective was to develop and internally validate a predictive model for rheumatoid arthritis (RA) mortality using Random Survival Forests (RSF).
Methods: Retrospective longitudinal study involving 1,461 patients diagnosed with RA between January 1994 and August 2011, and followed at the outpatient clinic of the Rheumatology Department of the Hospital Clínico San Carlos (Madrid, Spain) until death or September 2013. Demographic and clinical-related variables collected during the first two years after disease diagnosis were used. RSF models were developed, based on 1,000 trees. 100 iterations of each model were performed to measure the mean and standard deviation (SD) of the predictive error and the integrated Brier score (IBS). Missing values were imputed using the function implemented by the *randomForestSRC* package [3]. The predictive capacity of the variables was assessed using the "variable importance" (VIMP). Two models were constructed using the log-rank (M_{LG}) or log-rank score (M_{LGS}) splitting rules. The model with the lowest prediction error was selected. Next, those variables with negative VIMP were excluded and a final model developed.
Results: 148 patients died (10.1%). M_{LG} showed the lowest prediction error. All variables exhibited a positive VIMP. Final model showed a mean (SD) prediction error and IBS of 0.187 (0.002) and 0.150 (0.003) respectively. The most important predictor variables were age at diagnosis, median erythrocyte sedimentation rate and number of hospital admissions in the first 2 years after RA diagnosis.
Conclusions: We developed an accurate and precise model for RA mortality using RSF. Age and disease activity showed the highest influence in mortality.

FRI0108 TIME TO FIRST TREATMENT IS ASSOCIATED WITH A REFRACTORY COURSE OF RHEUMATOID ARTHRITIS

M. Bécède[1], F. Alasti[1], L. Haupt[2], A. Kerschbaumer[1], U. Landesmann[1], G. Supp[1], J. Smolen[1], D. Aletaha[1]. *[1]Department of Internal Medicine 3, Division of Rheumatology, Medical University of Vienna; [2]Hietzing Hospital, Vienna, Austria*

Background: It is an ongoing matter of research, whether the natural course of rheumatoid arthritis (RA) can be altered by an early intervention, a concept historically referred to as the "window of opportunity" (1). So far, only short-term disease activity outcomes have been investigated (e.g. "remission off drugs"), which are, however, inherently affected by the unknown rate of underlying rate self-limiting disease. It is unclear, whether among those, who eventually develop RA, the disease course is really affected by the timing of their initial treatment.
Objectives: To explore whether the long-term course of RA is different according to the delay of initial treatment.
Methods: Based on a longitudinal observational dataset, we initially identified a group of patients with an observed refractory disease, we defined presenting with ongoing moderate or high disease activity (by the Simplified Disease Activity Index, SDAI), despite at least three courses of DMARDs, of which at least on course was a biological compound. To ensure that sufficient time had been allowed for the previous treatments to be exert their non-effects, we also required these patients to have total treatment time of at least 18 months in accordance with treat to target strategy (3 x 6 months).
We identified 399 patients with a treatment time of at least 18 months. 48 patients were excluded despite fulfilling the disease activity criteria, because they haven't experienced enough treatment courses, or had received a biological compound yet, to claim refractory disease as per our criteria above. We could include 69 refractory and 282 non-refractory patients in our analyses and then performed

logistic regression analysis to assess the effects of different characteristics at baseline, including disease duration, on becoming refractory.

Results: By comparing patient characteristics (Table 1), more of the patients, who later will become refractory, are female (94.2% Vs 73.4%, p>0.001), have higher baseline disease activity (SDAI of 25.5 vs 17.7, p<0.001), and longer delay of the initial treatment from symptom onset (3.17 Vs 1.34 years, p=0.001).

The multivariable logistic regression model confirmed that a longer delay of first treatment is independently afflicted with a higher probability of a refractory disease course at a later stage. This model was adjusted for disease activity at baseline and gender (p<0.001, Figure 1). With increasing treatment delay, the chance of a dire disease course rises by approximately 1% every 6 months.

Table 1. Baseline characteristics in refractory and non-refractory patients

Baseline Descriptive	ReRA (n=69)	non-ReRA (n=282)	Sig.
% Female	94.2	73.4	<0.001
% RF +	56.5	62.1	0.398
% ACPA +	60.9	61.0	0.985
Time to Treatment*	3.17 (4.10)	1.34 (2.70)	0.001
SDAI	25.54 (12.24)	17.70 (12.17)	<0.001
CRP†	2.02 (2.30)	1.80 (2.02)	0.435
SJC 28	6.42 (5.35)	4.64 (4.72)	0.009
TJC 28	9.22 (6.98)	4.35 (5.40)	<0.001
EGA‡	37.78 (20.49)	28.77 (21.40)	0.002
PGA‡	55.19 (26.67)	41.42 (26.67)	<0.001

*years; †mg/dl; ‡100mm VAS scale.

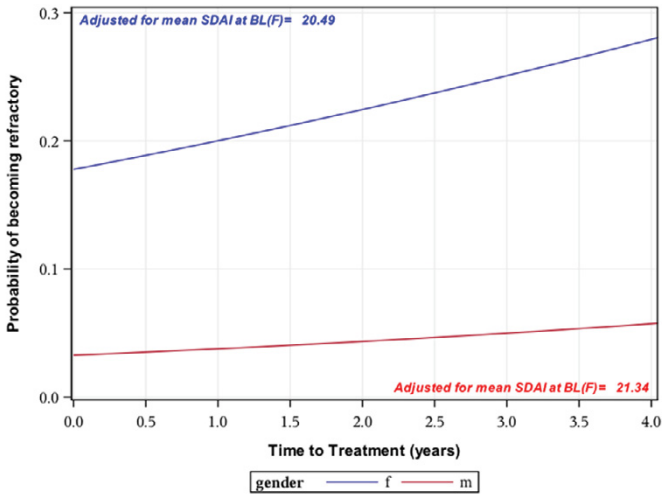

Figure 1: Predicted probabilities for becoming refractory depending on time to first treatment adjusted for baseline disease activity levels and gender.

Conclusions: Our data suggest that delay to initial treatment in RA affects the long-term course of RA. Earlier treatment initiation thus may change the severity of RA.

FRI0109 SHORT-TERM MONITORING OF SONOGRAPHIC CHANGES INDUCED BY A CORTICOSTEROID INJECTION IN METACARPOPHALANGEAL JOINT OF RHEUMATOID ARTHRITIS PATIENTS: A PILOT STUDY

M. Di Carlo, D. Roia, A. Di Matteo, F. Salaffi, E. Filippucci, W. Grassi.
Rheumatology Department, Università Politecnica delle Marche, Jesi, Italy

Background: Intra-articular corticosteroid injection is a well-established procedure in the daily practice since many decades [1]. High-resolution ultrasound (US), considered as *in vivo* microscopy, has the potential to help to understand how drugs develop their anti-inflammatory properties inside the articular space [2].

Objectives: To provide a very tight sonographic monitoring of the changes in a single metacarpophalangeal (MCP) joint in rheumatoid arthritis (RA) patients after the administration of intra-articular corticosteroid.

Methods: In this study we consecutively enrolled RA patients with active disease (Composite Disease Activity Index - CDAI >10), at least one tender and swollen MCP joint, and without contraindication to intra-articular corticosteroid injection (e.g. poor controlled diabetes). After the clinical evaluation that established the most clinically involved MCP joint to inject, patients underwent an US examination of the joint by an experienced sonographer. Synovitis was scored in grey scale (GS) in terms of joint space enlargement (measured at the level where the distance between the bone diaphysis and the joint capsule was greater), and power Doppler (PD) signal (scored by a semiquantitative method: 0 = no intra-articular flow, 1 = single vessel signal, 2 = confluent vessels, and 3 = vessel signal in more than 50% of the intra-articular area). After the baseline US assessment (T0), the MCP joints were injected with 20 mg triamcinolone acetonide under sonographic guidance. Sonographic follow-up was performed in five timepoints: two hours (T1) after the injection, four hours (T2), eight hours (T3), 24 hours (T4), and 48 hours after the injection (T5).

Results: Fifteen patients (13 women), with a mean age of 62.5 years, completed the follow-up. The mean CDAI was 28.9, anti-citrullinated protein antibodies were present in 9 patients. At T5, in all the patients was detectable a global reduction of joint space enlargement, of intra-articular PD signal, and of the numerical rating scale (NRS) of pain at the joint injected (Table). However, in majority of the patients (n: 13), the joint space enlargement showed an increase in the T1 and T2 US examinations, and in four patients PD signal, compared to T0, increased within the eight hours after the injection. No major adverse events were registered.

	Power Doppler grade (0–3)			Joint space enlargement (mm)			NRS pain (0–10)		
Case ID	First	Last	Maximum	First	Last	Maximum	First	Last	Maximum
1	2	1	3	3,4	2,4	4,2	3	1	5
2	2	0	2	4,4	3,7	5,7	8	1	8
3	2	0	2	2,1	1,3	3	7	2	7
4	3	1	3	2,1	1,8	2,9	9	0	9
5	3	2	3	4	4	4,9	10	0	10
6	3	1	3	6,5	2,7	6,5	2	1	2
7	2	0	2	3,5	1,2	3,6	6	0	6
8	1	1	3	4,6	3,3	4,6	3	0	3
9	3	0	3	2,5	2,1	3,6	2	0	2
10	2	1	3	4,3	3,9	5,6	7	3	7
11	3	1	3	5,3	3,3	5,7	8	3	8
12	3	1	3	3,3	2,6	3,3	7	3	7
13	2	1	2	2,6	2,3	3	7	2	7
14	3	1	3	3,1	2,2	4	7	2	7
15	2	1	3	4,5	3,7	4,5	7	0	7

Conclusions: A single intra-articular corticosteroid injection, performed under US guidance, is a very fast treatment to reduce synovitis of the injected joint. In the hours next to the injection is common to reveal a rise of joint space enlargement together with that of PD signal score.

FRI0110 METHOTREXATE MONOTHERAPY IN REAL LIFE: A DRUG SURVIVAL ANALYSIS. COMPARISON BETWEEN VERY EARLY ARTHRITIS AND EARLY ARTHRITIS COHORTS

M.G. Anelli[1], C. Rotondo[2], G. Righetti[2], A. Rinaldi[2], S. Perniola[2], M. Nivuori[2], S. Lopriore[2], G. Lopalco[2], G. Laselva[2], C. Scioscia[1], F. Cacciapaglia[2], G. Lapadula[2], F. Iannone[2]. *[1]DIM; [2]DETO, Unit of Rheumatology, Bari, Italy*

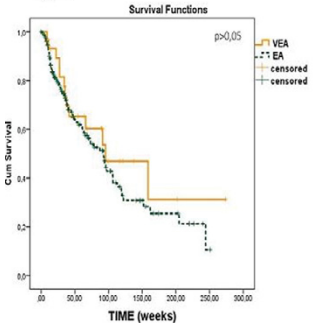
Background: Methotrexate (MTX) is the first line drug suggested in the ACR/EULAR guidelines to treat the rheumatoid arthritis (RA) (1) and spondylarthritis (SpA). Although MTX efficacy is demonstrated by high levels of evidences, maximum benefit might require interventions even earlier. For this reason, it is suggested to identify the patients (pts) with symptom onset of less than 12 weeks, that is very early arthritis, to obtain better outcomes. Few data are available by the clinical practice on MTX monotherapy (MTXm) survival in very early or early arthritis pts.

Objectives: We aim to evaluate the presence of different outcomes in MTXm drug survival and MTX efficacy between Very Early arthritis (VEA) pts (less than 12 weeks from symptom onset) and Early arthritis (EA) pts (12–52 weeks from symptom onset), and between early RA pts and early SpA pts.

Methods: On 305 pts, we selected 219 pts (30 pts diagnosed as VEA (4,2 (4) weeks from symptom onset) and 155 pts as EA (25,7 (25) wks from symptom onset) in which MTXm could be started. The RA pts were 93 and SpA pts were 126. To assess the MTXm persistency the Kaplan-Meier survival curves analysis was performed and Cox regression analysis was used to assess clinical predictors of MTXm suspension. The results are expressed as mean±standard deviation or median (interquartile range). A p≤0.05 was set for statistically significant.

Results: No difference in MTXm survival was found between VEA pts 95,5 (36) wks and EA 92,5 (10) wks (p=0,38) (Fig.1a). We observed a significant difference in drug survival between early RA pts 63 (16) wks) and early SpA pts 112,7 (15,8) wks (p=0,001) (Fig.1b). In 55% early RA pts and in 45% early SpA pts the biotechnology drug needs to be added because of disease flare. In the remaining pts a low disease activity (DAS≤3,2) was observed. No adverse events were recorded in follow-up period. In early RA pts predictors of shorter MTXm survival were younger age at diagnosis (p=0,004), lower dose of MTX (p=0,032),

Fig. 1a



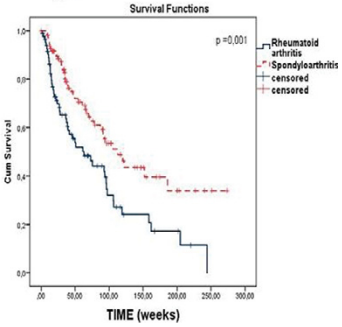


Fig. 1b

earlier diagnosis from symptom onset (p=0,0001), higher titer of rheumatoid factor (p=0,037) and female gender (p=0,019). In early SpA pts the only predictor of shorter MTXm survival was younger age at diagnosis (p=0,0,37). Smoking, disease activity at diagnosis and BMI were not predictors of MTXm survival.

Conclusions: The MTXm survival is not influenced by VEA or EA diagnosis. The RA seems to be less responder to MTXm than SpA. It might be due to the difficult to capture the earliest phase of disease, as circulating antibodies might appear years before the onset of symptoms in RA, and biomarkers reflecting bone destruction are elevated before arthritis is present, as described in previous studies. In particular, might be pay attention to younger pts, female gender and pts with higher titer of rheumatoid factor as they seem to present a more resistant RA disease. A high dose of MTX and earlier interventions are suggested in RA to improve the clinical outcome of patients and the MTXm survival.

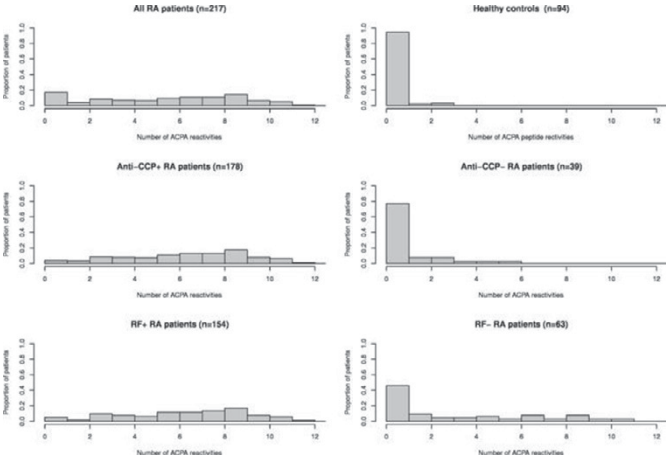
FRI0111 ANTI-CITRULLINATED PROTEIN ANTIBODY REACTIVITIES IN TREATMENT NAÏVE EARLY RHEUMATOID ARTHRITIS

M.K. Jonsson[1,2], A.H. Hensvold[3], M. Hansson[3], L. Mathsson-Alm[4], A.-B. Aga[2], J. Sexton[2], B.-T.S. Fevang[1,5], S. Lillegraven[2], A.I. Catrina[3], E.A. Haavardsholm[2,6]. *[1]Haukeland University Hospital, Bergen; [2]Diakonhjemmet Hospital, Oslo, Norway; [3]Karolinska Institute, Stockholm; [4]Thermo Fisher Scientific, Uppsala, Sweden; [5]University of Bergen, Bergen; [6]University of Oslo, Oslo, Norway*

Background: An increase in the number of anti-citrullinated protein antibodies (ACPA) reactivities precede RA onset, and may be involved in the pathogenesis of the disease. The presence of ACPA is associated with radiographic progression in RA, and it has been suggested that ACPAs with different reactivities may be associated with different phenotypes of RA.



Objectives: To assess the prevalence of baseline ACPA reactivities in an inception cohort of early RA patients, including subgroups based on anti-CCP/RF status, and to compare the findings to healthy controls.

Methods: 217 DMARD-naïve early RA patients from the ARCTIC trial (1) were analysed. Radiographs were scored according to van der Heijde Sharp (vdHS) score. Anti-CCP status was analysed by FEIA (pos. if ≥10 IU/mL) and RF by ELISA (pos. if ≥25 IU/mL). ACPA titres (AU/ml) were considered pos. if above the 98-perc. of values in 619 non-RA subjects. Analysis of 13 ACPA reactivities targeting citrullinated peptides from fibrinogen, alpha-1 enolase, vimentin, fillagrin and histone was performed at baseline in patients and 94 controls (blood donors matched for age/gender/smoking), using a multiplex chip-based assay (2).

[1]Mean (SD), [2]n (%), [3]Median [IQR], [4]ACPA reactivity, n positive (%).

Results: Baseline characteristics are presented in the table. The figure shows the prevalence of ACPA reactivities in the subgroups, with median [IQR] number of antibody reactivities in all patients 7 [3,10], compared to 0 [0,0] in controls (p<0.001). The corresponding numbers were 8 [5,10] and 0 [0,1] for the anti-CCP+ vs. anti-CCP- patients (p<0.001), and 8 [5,10] and 2 [0,7.5] for the RF+ vs. RF- patients (p<0.001). Positivity for ACPA reactivities was seen mainly in the anti-CCP+ and RF+ patients, but also occurred more frequently in RF- and anti-CCP- patients (table) than in controls (anti-CCP- vs controls p=0.037, RF- vs controls p<0.001).

Conclusions: Prevalence of ACPA reactivities differed in subgroups of DMARD-naïve early RA patients according to anti-CCP and RF status. All RA subgroups, including RF- and anti-CCP- patients, had higher prevalence of ACPA reactivities compared to healthy controls.

FRI0112 SERUM LEVELS OF IL-33 AND SST2 ARE ASSOCIATED WITH FUNCTIONAL DISABILITY IN RHEUMATOID ARTHRITIS

M.R. Pinto[1], A. Kakehasi[2], M.V. Andrade[3]. *[1]Rheumatology, Hospital das Clínicas da UFMG; [2]Aparelho Locomotor; [3]Faculdade de Medicina, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil*

Background: Interleukin 33 (IL-33) is a cytokine related to amplification of the articular inflammation in rheumatoid arthritis (RA) animal models. Elevated IL-33 serum levels have been described in RA patients, suggesting a possible participation of this cytokine in the physiopathology of the disease.[1,2] IL-33 soluble receptor (sST2) is a decoy receptor that functions as an inhibitor of the interaction of the transmembrane receptor with IL-33.[3]

Objectives: To identify the association between serum levels of IL-33 and its soluble receptor (sST2) with clinical and laboratory characteristics of RA.

Methods: Cross-sectional observational study in which RA patients were submitted to clinical and laboratorial evaluation. IL-33 and sST2 serum levels were measured by ELISA (R&D System Inc, Minneapolis, MN, USA).

Results: 102 RA patients were included, 92,5% women, mean age of 55,5±10 years and mean disease duration of 17,6±9,5 years. Eighty-four (82,4%) patients had seropositive RA. The median (interquartile range) IL-33 serum level was 69.1 pg/ml (31.6 - 114.5). Higher scores on the visual analogue scale (VAS) of disease activity assessed by the examiner were associated with higher IL-33 values (CI95%: 0.01–0.05). In the group of patients with high titres of rheumatoid factor (RF), IL-33 levels were higher, compared to the group with negative RF (95% CI: 0.55 - 2.34). In 34 (33.3%) patients, IL-33 was undetectable and the presence of metabolic syndrome[4] represented a 63% lower chance (OR =0.37, 95% CI: 0.15–0.90) of having IL-33 detected. In addition, 1-unit increase in HAQ-DI increased by 2.43 times the chance of detecting IL-33 (95% CI: 1.23 - 4.80). The median sST2 serum level was 469.8 pg/ml (336.3–651). sST2 was associated with worse functional capacity by the classification of Steinbroker[5] (IC95%: 0.09 - 0.5), use (current or in the past) of tobacco (95% CI: 0.02 - 0.53) and use of leflunomide (95% CI: 0.05 - 0.53). There was no correlation between IL-33 and sST2 levels.

Conclusions: These findings may suggest that both IL-33 and its soluble receptor play a role as a marker of RA severity and functional disability. The negative association of IL-33 with metabolic syndrome is in agreement with the possible protective role of this cytokine in relation to lipid metabolism.[6]

FRI0113 VALIDATION AND RESULTS OF THE SYMPTOMS IN PERSONS AT RISK OF RHEUMATOID ARTHRITIS (SPARRA) QUESTIONNAIRE

M.V. Beers-Tas[1], M. Ter Wee[2], B. Maat[1], W. Hoogland[1], A. Hensvold[3], A. Catrina[3], E. Mosor[4], A. Finckh[5], D. Courvoisier[6], K. Raza[7], D.V. Schaardenburg[1]. *[1]Amsterdam Rheumatology and immunology Center, Reade; [2]Amsterdam Rheumatology and immunology Center, VUMC, Amsterdam, Netherlands; [3]Rheumatology, Karolinska university, Stockholm, Sweden; [4]Rheumatology, Section for Outcomes Research, CeMSIIS, Medical University of Vienna, Vienna, Austria; [5]Rheumatology; [6]University hospital of Geneva, Geneva, Switzerland; [7]Rheumatology, Institute of Inflammation and Ageing, Birmingham, United Kingdom*

Background: A range of symptoms can be present in persons at risk of rheumatoid arthritis (RA). However, information on the nature, location, timing, severity and predictive value of these symptoms is largely lacking. The Symptoms in Persons At Risk of Rheumatoid Arthritis (SPARRA) questionnaire has been developed with support from EULAR, informed by data from a qualitative study[1] and with input from patient research partners.
Objectives: To test the psychometric properties of the SPARRA questionnaire in an international group of arthralgia patients at risk of RA and to quantify these symptoms.
Methods: The SPARRA questionnaire contains questions about presence, severity, impact and location of 13 symptoms. 240 individuals (69% rheumatoid factor and/or ACPA positive, 23% seronegative with clinically suspect arthralgia and 8% first degree family members of patients with RA) completed the questionnaire in the Netherlands (N=125), United Kingdom (N=70), Sweden (N=15), Austria (N=11) and Switzerland (N=19). Individuals had no history or presence of clinically diagnosed arthritis at the time of first physical examination. Reliability (test-retest) and validity (face, content and construct validity) were tested.
Results: Face validity was tested by a group of experts on the at-risk phase of RA and feedback on the questionnaire was asked and received from 30 arthralgia patients, leading to only minor comments. The test-retest within 7–14 days (N=51) showed moderate to good agreement (kappa mean 0.565, range 0.309–1; agreement mean 71%, range 59–100%). The content validity was high, in line with the fact that the items were derived from a qualitative study in seropositive arthralgia patients. In contrast, the construct validity (relation to visual analog scale scores (VAS) for pain and well-being) was low (R-square 0.040–0.199), suggesting that the questions measure different elements in different time frames and grasp symptom content not captured with regular VAS pain/well-being. Most symptoms were present in a high percentage of individuals, with pain, stiffness and fatigue as the most common ones. When a symptom was present, it was usually experienced as moderate to severe, and with moderate impact. ACPA positive individuals reported lower presence of symptoms then ACPA negative individuals (mean 47% for ACPA-positive (N=118), 41% for only RF positives (N=53) and 59% in seronegative individuals (N=69)), but functional impact was higher in ACPA positive individuals (51%, versus 42% in seronegatives, NS). Note that the inclusion criteria for the seronegative individuals was presence of symptoms.
Conclusions: This study provides evidence of good psychometric properties of the SPARRA questionnaire, except for low construct validity. This means the questionnaire adds information to currently available clinical measures in persons at risk of RA. Future studies are needed to evaluate whether SPARRA data can help to improve the prediction of RA.

FRI0114 ALLOGRAFT INFLAMMATORY FACTOR 1 (AIF1) POLYMORPHISMS RS4711274 (G/A) AND RS2269475 (C/T) MAY PREDICT ETANERCEPT PLUS METHOTREXATE RESPONSE IN FRENCH CAUCASIAN PATIENTS WITH RHEUMATOID ARTHRITIS

D.F. Azzouz[1], M. El Haddad[1], S. Kanaan[1], N. Balandraud[1,2], M. Martin[1], C. Picard[3], J. Roudier[1,2], I. Auger[1], N.C. Lambert[1]. *[1]INSERM UMRs1097; [2]Rheumatology, AP-HM; [3]HLA Laboratory, Etablissement Français du Sang, Marseille, France*

Background: Several risk loci for Rheumatoid Arthritis (RA) have been identified by Genome Wide Association Studies (GWAS), but they do not include Allograft Inflammatory Factor 1 (AIF1). Nevertheless, a few studies have shown that AIF1 rs2269475 (C/T) is associated with RA[1,2].
Objectives: We propose 1) To examine associations in French Caucasian patients with RA, of the seven most described AIF1 SNPs; 2) To study their linkage disequilibrium with HLA-DRB1 alleles; 3) To evaluate whether AIF1 single nucleotide polymorphisms (SNPs) could predict first line treatment responses in RA.
Methods: We amplified the AIF1 gene region containing the 7 SNPs and sequenced PCR products on a total of 469 individuals, including 95 Anti-Citrullinated Protein Antibody (ACPA) positive RA patients, 146, patients with scleroderma, 132 healthy controls and 96 additional healthy controls selected from a large database of volunteer bone marrow donors (VBMD) for carrying at least one RA-associated allele. Patients and controls were HLA-DRB1 genotyped. Patients with RA were divided into 2 groups, a first group called "*non responders*" was defined as patients who did not respond to first-line methotrexate (MTX) combined with Etanercept and a second group called "*good responders*" was defined as patients who did respond to methotrexate combined with Etanercept.
Results: Two SNPs were associated with RA: *rs4711274 (G/A)* and *rs2269475 (C/T)*. The frequency of minor allele carriers was respectively 37% (A) and 36% (T) in patients with RA versus 18% among controls (p=0.0014 and p=0.001). Furthermore, patients with RA-associated HLA-DRB1 alleles carried more often minor alleles for both SNPs (p=0.0005). Preliminary clinical data show that 56% of non-responders (N=16) carried the minor alleles of both rs4711274 and rs2269475 compared to only 21% of good responders (N=24, p=0.02).
Conclusions: AIF is an inflammation-responsive protein encoded within the HLA class III region on chromosome 6 (6p21.3). As already described in British and Polish Caucasians, we found a significant AIF1 Rs2269475 association with RA. We also found an association with Rs4711274 in linkage disequilibrium with the former. The increased frequency of minor AIF1 alleles in RA was not associated with a particular HLA-DRB1 allele, but to any HLA-DRB1 allele carrying the shared epitope.
Finally, patients who failed to respond to Etanercept and MTX carried more often minor alleles of the 2 described AIF1 SNPs.
Further analysis on a larger groups of patients is required to confirm whether AIF1 SNPs can predict response to therapy with Etanercept and Methotrexate.

FRI0115 EVER-SMOKING IS ASSOCIATED WITH DISEASE SEVERITY AND OPIOID USE IN RHEUMATOID ARTHRITIS

A. Karellis[1], E. Rampakakis[1,2], J.S. Sampalis[1,2], M. Cohen[3], M. Starr[3], P. Ste-Marie[4], Y. Shir[4], M. Ware[4], M.-A. Fitzcharles[3,4]. *[1]JSS Medical Research, St-Laurent; [2]Jewish General Hospital; [3]Rheumatology; [4]Alan Edwards Pain Management Unit, McGill University Health Centre, Montreal, Canada*

Background: Cigarette smoking, both current and past, is a risk for incident rheumatoid arthritis (RA), even for those with low exposure rates of 1–10 pack years. Current smoking is also associated with severity of disease and poorer response to treatments. It is however not known whether any exposure to cigarettes impacts disease expression, especially for those who have discontinued smoking.
Objectives: To assess the disease severity in RA according to smoking status (ever-, past-, current-, non-smoker).
Methods: As part of a study to examine cigarette and marijuana smoking in rheumatic disease patients, consecutively attending rheumatology patients completed an anonymous self-administered questionnaire including: pain severity on visual analog scale (VAS), patient global assessment (PtGA) and cigarette or marijuana smoking status. Concomitant physician recorded information included: sociodemographics, co-morbidities, treatments for RA, physician global assessment (PGA). Patients were categorized according to smoking status. Categorical variables were compared between groups with the Chi-Square test and continuous variables with the Student's t-test. Variables showing a statistical trend ($p<0.15$) in univariate analysis were considered in multivariate logistic regression.

Results: Over a 2-month period (April-May 2014), there were 248 (25%) RA attendees of 1000 participants. Significant differences were observed between current, past and non-smokers in regard to age [mean (SD): 59.5 (10.0) vs. 65.2 (10.6) vs. 61.0 (18.2) years; p=0.034], gender (male: 23.9% vs. 30.3% vs. 14.6%; p=0.027), unemployment due to disability (13.3% vs. 3.1% vs. 4.9%; p=0.044), number of RA medications [mean (SD): 2.3 (1.1) vs. 2.1 (1.1) vs. 1.8 (1.1); p=0.019], DMARD use (78.3% vs. 82.8% vs. 64.1%; p=0.008), opioid use (19.6% vs. 10.1% vs. 3.9%; p=0.009), pain [mean (SD): 5.0 (3.3) vs. 4.0 (2.9) vs. 3.7 (2.6) cm; p=0.040] and PGA [mean (SD): 3.8 (2.8) vs. 3.1 (2.8) vs. 3.0 (2.4); p=0.039]. Recreational marijuana was used by 3 non cigarette smokers only, with 1 also reporting medicinal marijuana use. Ever smokers vs. non-smokers used a greater number of RA medications [mean (SD): 4.3 (3.0) vs. 3.7 (2.6); p=0.081], were more likely to use DMARDs (81.4% vs. 64.1%; p=0.003) and opioids (13.1% vs. 3.9%; p=0.014), and showed a trend towards more pain [mean (SD): 4.3 (3.0) vs. 3.7 (2.6); p=0.081]. In multivariate analysis, male gender (OR=2.193; p=0.025) and DMARD use (OR=2.376; p=0.010) were significantly associated with ever smoking while opioid use (OR=2.784, p=0.103 for ever smoking; OR=3.561, p=0.074 for current smoking) showed a statistical trend.
Conclusions: Current, but also ever cigarette use, was associated with worse RA disease as indicated by the use of more drug categories, and more likely use of DMARDs to treat RA, and a trend to more pain and opioids. The combination of opioids and cigarettes may be a manifestation of a patient "chemical coping" strategy in RA patients.

FRI0116 A HIGH LEVEL OF CLINICAL RESPONSE BASED ON COMPOSITE INDICES IS ASSOCIATED WITH IMPROVED HEALTH-RELATED QUALITY OF LIFE: ANALYSES FROM A PHASE 3 CLINICAL TRIAL IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Dougados[1], B. Zhu[2], A.C. Tang[2], A. Quebe[2], I. Stoykov[2], Z. Cai[2], M. Ishida[2], C. Gaich[2]. *[1]Hopital Cochin, Paris, France; [2]Eli Lilly and Company, Indianapolis, United States*

Background: Rheumatoid arthritis (RA) is a chronic disease associated with inflammatory activity and joint damage that result in disability, pain, and other impairments. The current recommendation is to assess disease activity based on composite indices with objective signs of inflammation (e.g. synovitis, acute phase reactants) and patient's assessment of disease activity. The patient's perception of disease impact and its treatment also facilitate shared decision-making about treatment.
Objectives: To compare patient-reported outcomes (PROs) for RA patients who achieved low disease activity (LDA) or remission based upon the DAS28-ESR compared to those with moderate and high disease activity (MDA and HDA) in this post-hoc analysis of a randomized, double-blind phase 3 clinical trial, RA-BEAM[1].
Methods: 1305 patients were randomized to placebo (N=488), adalimumab (N=330) or baricitinib 4 mg (N=487). Patients with observed DAS28-ESR values at Week 24 (N=1,010) were divided into 4 disease activity groups: HDA (DAS28-ESR>5.1), MDA (3.2<DAS28-ESR≤5.1), LDA (2.6≤DAS28-ESR≤3.2), or remission (DAS28-ESR<2.6). Change from baseline to Week 24 were assessed for the pain visual analogue scale (VAS, 0–100 mm), Health Assessment Questionnaire-Disability Index (HAQ-DI) and SF-36 physical and mental component score (PCS and MCS) for the intent-to-treat (ITT) patients.
Results: Patients with HDA and MDA at Week 24 had greater baseline pain and HAQ-DI scores and lower PCS and MCS scores than patients achieving LDA or remission at Week 24. Lower disease activity at Week 24 was associated with improvement in pain, HAQ-DI, SF-36 PCS and MCS at Week 24. Among patients who achieved remission, residual pain was observed, with close to 40% still experiencing some level of pain and 20% of patients in remission at Week 24 had a residual pain score>20. Sensitivity analyses using other clinical measures (DAS28-CRP, SDAI, CDAI) to define disease activity confirmed the findings.
Conclusions: Improving patient disease activity is associated with improved health-related quality of life. Patients who achieved remission had greater improvement in PROs but residual pain remained. Further research is needed to understand the treatment differences in the association between disease activity and PROs among different therapies.

Table 1. Improvement in disease activity is associated with improved PROs.

PRO Measures	Outcomes at Week 24	Disease Activity at Week 24			
		HDA DAS28-ESR>5.1 N=210	MDA 3.2<DAS28-ESR≤5.1 N=490	LDA 2.6≤DAS-28-ESR≤3.2 N=142	Remission DAS28-ESR<2.6 N=168

FRI0117 CHRONOLOGICAL CHANGES IN ACHIEVING J-HAQ REMISSION IN PATIENTS WITH EARLY-STAGE RHEUMATOID ARTHRITIS IN THE IORRA COHORT

M. Ochiai[1], E. Tanaka[1], E. Inoue[1,2], R. Yamaguchi[1], Y. Shimizu[1], N. Sugimoto[1], K. Ikari[1], A. Nakajima[1], A. Taniguchi[1], H. Yamanaka[1]. *[1]Rheumatology, Institute of Rheumatology Tokyo Women's Medical University; [2]Center for Clinical Research for Development, National Center for Child Health and Development, Tokyo, Japan*

Background: With the introduction of biologic disease-modifying antirheumatic drugs (DMARDs) and the increase in the approved maximum dose of methotrexate in our country, the treatment of rheumatoid arthritis (RA) has advanced dramatically in the past 2 decades. Consequently, many patients were able to achieve clinical remission and low radiographic progression rates[1–3]. In view of these dramatic changes in RA treatment, we investigated whether the Japanese version of the Health Assessment Questionnaire (J-HAQ) improved chronologically due to improved treatment over time.
Objectives: To investigate chronological changes in achieving J-HAQ remission and the factors related to J-HAQ remission in Japanese patients with an early stage of RA.
Methods: RA patients who enrolled in the IORRA cohort for the first time between 2000–2002 (Term 1), 2005–2007 (Term 2), and 2010–2012 (Term 3) and were within 2 years of disease onset were examined. For each patient in Term 3, one patient was extracted from Term 1 and Term 2 by matching the sex, age, and J-HAQ score. Among them, patients with J-HAQ >0.5 at study entry (baseline) were selected; the time to achieve J-HAQ remission (J-HAQ ≦0.5) and the J-HAQ remission rate at 3 years were analyzed. Multivariate analysis was performed to assess factors related to achieving J-HAQ remission.
Results: In each term, 348 RA patients were extracted. At baseline, the average J-HAQ of all 1,044 patients was 0.52. Baseline characteristics of 408 patients with baseline J-HAQ >0.5 were as follows: female, 89.0%; mean age, 56.3 years; anti-cyclic citrullinated peptide (anti-CCP) antibody positivity, 78.0%; mean Disease Activity Score with 28-joint count (DAS28), 4.37; and mean J-HAQ, 1.11. The mean time from baseline to achieving J-HAQ remission became significantly shorter chronologically (Term 1: 2.2 years; Term 2: 1.8 years; Term 3: 1.7 years; p<0.005, Fig.1). J-HAQ remission rates significantly increased in both Term 2 (55.2%) and Term 3 (57.4%) compared with Term 1 (37.5%; p<0.005). The factors significantly related to achieving J-HAQ remission at 3 years were younger age (OR 1.02; 95% CI 1.00–1.04) and enrollment in Term 2 (OR 2.0; 95% CI 1.2–3.5) or Term 3 (OR 2.3; 95% CI 1.3–4.1) compared with enrollment in Term 1.

Conclusions: Along with the improvement in RA treatment, patients were able to achieve J-HAQ remission more frequently and more quickly.

FRI0118 CLINICAL UTILITY OF AREA-UNDER-CURVE (AUC) OF PATIENT-DERIVED DISEASE ACTIVITY SCORE (PDAS2) BETWEEN CLINIC VISITS ON REMISSION, FLARE UP AND RHEUMATOLOGIST'S DECISION TO ESCALATE ANTI-RHEUMATIC DRUGS

M.-H.A. Leung [1], E. Choy [2], C.S. Lau [3]. *[1]Department of Medicine, Queen Elizabeth Hospital, Kowloon, Hong Kong; [2]Arthritis Research UK, Health and Care Research Wales CREATE Centre, Institute of Infection and Immunity, Cardiff University, Cardiff, United Kingdom; [3]Department of Medicine, LKS Faculty of Medicine, University of Hong Kong, Hong Kong, Hong Kong*

Background: The standard of care in RA is treat-to-target of remission or low disease activity state (LDAS). Integral to this is the regular assessment of disease activity. Patient-derived Disease Activity Score 2 (PDAS2) was developed to allow RA patients to self-assess. Validation, corresponding disease activity statuses cut-points and response criteria had been published. PDAS2 scores <3.8, 3.8–4.5, 4.6–5.0, >5.0 correspond to remission, LDAS, moderate and high disease activities respectively. PDAS2 can be recorded by patients in-between clinic visits.
Objectives: To explore the clinical utility of PDAS2 on remission, flare and need of drug adjustment
Methods: A cohort of 100 consecutive RA patients was recruited to complete PDAS2 score at home fortnightly in between two consecutive rheumatology clinics. Patients would return the forms when they attended the second clinic. Rheumatologists adjusted treatment according to disease activity while blinded to the scores of PDAS2 recorded at home. AUC of PDAS2 was calculated from the mean of (PDAS2 score multiplied by the time interval between scores). They were compared with disease activity at the first and second visits. The change of PDAS2 score for those patients having SDAI flare-up (from remission/LDAS to moderate/high disease activity) was compared to those didn't flare-up using unpaired T-test. Receiver Operator Characteristic curve was used to determine the cut-point for AUC-PDAS2 increment to predict flare-up and the cut-point of PDAS2 score for rheumatologists to escalate anti-rheumatic drugs.
Results: Mean age of the cohort was 60 years, mean RA duration 14 years, 90% female, 71% sero-positive and 48% in remission/low disease activity. 89 patients (89%) returned written questionnaires which were done 7.8±3.5 times (mean±standard deviation) (range 1–16) for a follow-up interval of 17.5±9.4 weeks (range 3.9–60.3). Disease activities in first and second visits are shown in Table. *Remission:* For the 14 patients in SDAI remission in both visits, 13/14 were in AUC-PDAS2 remission, and 1/14 in LDAS. There were 47, 45 and 37 out of 89 patients in SDAI, CDAI and DAS28 remission/LDAS respectively – they were all in AUC-PDAS2 remission/LDAS. *Flare-up:* There were 10/89 patients in SDAI remission/LDAS in first visit and moderate/high activity in second visit. Their AUC-PDAS2 score rose by 0.33±0.35 points compared to 0.01±0.32 who had no flare-up (p=0.002). ROC curve AUC was 0.80 (95% CI: 0.64, 0.95) (p=0.002), with optimal cut-point at increment of AUC-PDAS2 score by 0.11 to predict flare, sensitivity and specificity both being 80%. Moreover, rheumatologists decided to *escalate anti-rheumatic drugs* in 15/89 patients. ROC curve AUC was 0.71 (95% CI: 0.56, 0.86) (p=0.01), with optimal cut-point at PDAS2 score 4.33 to predict the need of escalating anti-rheumatic drugs, sensitivity being 60% and specificity 77%.

		First visit		*Second visit*	
		N (%)	AUC-PDAS2 (SD)	N (%)	AUC-PDAS2 (SD)
SDAI	Remission	22 (24.7%)	3.23(0.40)	22 (24.7%)	3.22(0.43)
	LDAS	36 (40.4%)	3.72(0.52)	35 (39.5%)	3.80(0.55)
	Moderate	29 (32.6%)	4.50(0.60)	30 (33.7%)	4.40(0.66)
	High	2 (2.2%)	5.26(1.08)	2 (2.2%)	5.21(1.15)

Table. Simplified Disease Activity Index (SDAI) disease activities of RA patients (N=89) in first and second visits, and corresponding mean area-under-curve of Patient Disease Activity Score 2 (AUC-PDAS2)

Conclusions: PDAS2 scoring by patients in-between follow-up is feasible and useful in reassuring RA patients kept in remission/LDAS, informing a potential flare from previous remission/LDAS state, and predicting rheumatologists' decision to escalate anti-rheumatic drugs. AUC-PDAS2 concept is useful in development of smartphone application for patient use.

FRI0119 A PROPOSAL FOR A SDAI, CDAI, AND RAPID3-BASED DEFINITION OF MINIMAL DISEASE ACTIVITY FOR USE IN ROUTINE CARE OF RHEUMATOID ARTHRITIS: RESULTS FROM A JAPANESE NATIONAL DATABASE

N. Yokogawa [1], A. Komiya [2], K. Shimada [1], S. Sugii [1], J. Nishino [3], S. Tohma [4]. *[1]Department of Rheumatic Diseases, Tokyo Metropolitan Tama Medical Center, Tokyo; [2]Department of Clinical Laboratory, Sagamihara National Hospital, National Hospital Organization, Kanagawa; [3]Department of Orthopaedic Surgery and Spinal Surgery, he University of Tokyo, Tokyo; [4]Clinical Research Center for Allergy and Rheumatology, Sagamihara National Hospital, National Hospital Organization, Kanagawa, Japan*

Background: The OMERACT group proposed minimal disease activity (MDA) as a treatment target, given the current treatment possibilities and limitations. Whereas a Disease Activity Score 28 (DAS28)-based definition of MDA has been proposed[1], definitions based on the Simplified Disease Activity Index (SDAI), Clinical Disease Activity Index (CDAI), and Routine Assessment of Patient Index Data 3 (RAPID3) have not, despite the increasing use of these indices.
Objectives: To define SDAI, CDAI, and RAPID3-based definition of MDA for use in routine care.
Methods: We analyzed 15,101 patients registered in the Japanese National Database (NinJa 2015). As the OMERACT group proposed, patients with tender joint count (TJC) of 0, swollen joint count (SJC) of 0, and erythrocyte sedimentation rate (ESR) $\leq$10 mm/hour or patients with five of the following seven criteria, namely, pain $\leq$2, SJC $\leq$1, TJC $\leq$1, HAQ $\leq$0.5, physician's global $\leq$1.5, patient's global $\leq$2, and ESR $\leq$20, were considered to be in MDA.[1] The ROC curve was used to obtain the best cut-off points for the SDAI, CDAI, and RAPID3-based definitions of MDA, which emerged as good predictors of MDA as defined by the core dataset. To compare the usefulness of the indices, the interclass correlation of MDA in DAS28, SDAI/CDAI, and RAPID3 was compared to that of low disease activity (LDA).
Results: 57.6% of patients (5,629/9,767) were categorized as having MDA, and 29% of patients (4,003/13,781) were categorized as Boolean remissions. In the ROC analysis, the area under the curve for DAS28, SDAI, CDAI, and RAPID3 was 0.911, 0.955, 0.953, and 0.930, respectively. Based on the Youden index, SDAI $\leq$5.3, CDAI $\leq$4.8, and RAPID3 $\leq$5 were defined as SDAI, CDAI, and RAPID3-based MDA, respectively. The sensitivity and specificity of the DAS28, SDAI, CDAI, and RAPID3-based definitions were higher than those of the DAS28-based definition, with a sensitivity of 81.5%, 89.2%, 88.8%, and 90.0%, respectively, and a specificity of 83.5%, 89.4%, 89.9%, and 88.4%, respectively. Each index-based definition of MDA showed better interclass correlation than that of LDA; DAS28 vs CDAI/SDAI: MDA of 0.643/0.662 and LDA of 0.540/0.540; DAS28 vs RAPID3: MDA of 0.541 and LDA of 0.482; CDAI/SDAI vs RAPID3: MDA of 0.677/0.671 and LDA of 0.433/0.425.
Conclusions: SDAI $\leq$5.3, CDAI $\leq$4.8, and RAPID3 $\leq$5, values two points higher than each remission criterion, may provide a more stringent therapeutic goal than LDA in clinical practice.

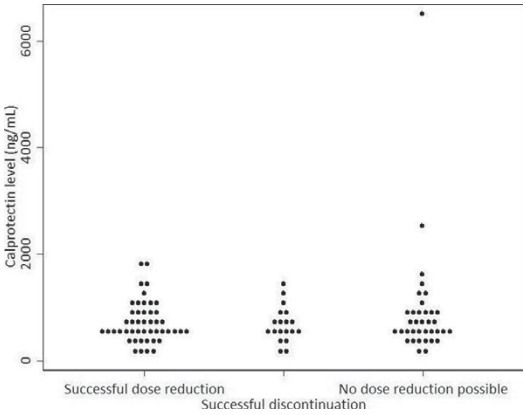
FRI0120 SERUM CALPROTECTIN IS NOT PREDICTIVE FOR SUCCESSFUL DOSE REDUCTION OR DISCONTINUATION OF TNF INHIBITORS IN RA PATIENTS WITH LOW DISEASE ACTIVITY



N. Den Broeder[1], L. Tweehuysen[1], T. Vogl[2], N. van Herwaarden[1], F.H.J. van den Hoogen[1,3], R.M. Thurlings[3], A.A. den Broeder[1]. *[1]Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands; [2]University of Münster, Münster, Germany; [3]Rheumatology, Radboudumc, Nijmegen, Netherlands*

Background: Dose reduction and discontinuation of TNF inhibitors (TNFi) have been shown feasible in a large proportion of RA patients with low disease activity.[1] However, to date, no predictors for successful dose reduction or discontinuation have been identified.[2] Calprotectin (a heterodimer of S100A8/S100A9) might be a promising biomarker in this context, as preliminary data showed this pro-inflammatory marker to be associated with disease activity and radiographic progression in RA and to be predictive for response in RA patients starting treatment with a TNFi.[3,4]

Objectives: To investigate the predictive value of baseline serum calprotectin for successful TNFi dose reduction or discontinuation in RA patients with low disease activity.

Methods: Data was derived from the intervention arm of the DRESS (Dose REduction Strategies of Subcutaneous TNFi) study, which showed non-inferiority of a dose reduction strategy of adalimumab or etanercept compared to usual care.[1] TNFi dose interval was reduced stepwise every 3 months until flare (DAS28-CRP increase >1.2 or >0.6 if current DAS28-CRP ≥ 3.2) or discontinuation. Patients were classified at 18 months as being successfully dose reduced, discontinued or not able to reduce the TNFi dose. At baseline, quantification of calprotectin was carried out on serum samples using ELISA. To assess the predictive value, calprotectin levels were compared between each group and receiver-operator-characteristic (ROC) curves were created. In addition, calprotectin was correlated cross-sectionally with several clinical markers for disease activity.

Results: Calprotectin levels were available for 102 of 121 patients randomised to the intervention group; 61% were women, 63% received etanercept and 37% received adalimumab. Overall, 46% of patients successfully reduced their TNFi dose, 19% of patients successfully discontinued their TNFi and 35% of patients could not reduce their TNFi dose. In these groups, median calprotectin levels were 599 ng/ml (p25-p75: 473–965), 629 ng/mL (p25-p75: 453–896) and 624 ng/mL (p25-p75: 514–931) (p=0.801) (Figure 1). The area under the ROC-curve was 0.52 (95% CI: 0.40–0.63) for predicting successful TNFi dose reduction, 0.53 (95% CI: 0.38–0.67) for successful TNFi discontinuation and 0.54 (95% CI: 0.42–0.66) for no dose reduction possible. Calprotectin levels were significantly but weakly correlated with C-reactive protein (CRP) levels with a Spearman ρ of 0.21 (p=0.03). No significant correlation was found between calprotectin and age, gender, DAS28-CRP, rheumatoid factor or ACPA positivity.

Conclusions: Serum calprotectin is not predictive for successful TNFi dose reduction or discontinuation in the context of RA patients with low disease activity, and calprotectin was only weakly correlated to CRP levels. These results might be caused by the lack of variability in calprotectin levels at baseline as all patients were in low disease activity state.

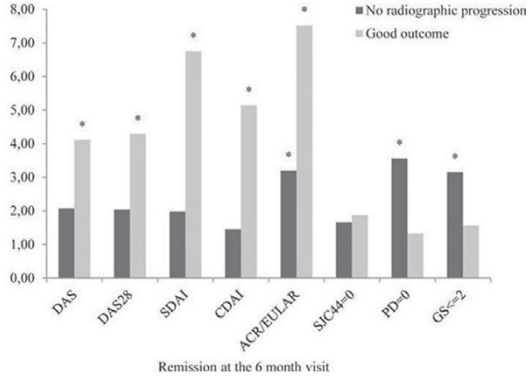
FRI0121 REMISSION AT 6 MONTHS AND IDENTIFICATION OF FUTURE GOOD RADIOGRAPHIC AND PHYSICAL OUTCOME IN EARLY RHEUMATOID ARTHRITIS

N.P. Sundlisater[1], A.-B. Aga[1], I.C. Olsen[1], H.B. Hammer[1], T. Uhlig[1], D. van der Heijde[2], T.K. Kvien[1], S. Lillegraven[1], E.A. Haavardsholm[1] on behalf of the ARCTIC study group. *[1]Diakonhjemmet Hospital, Oslo, Oslo, Norway; [2]Leiden University Medical Center, Leiden, Netherlands*



Background: Treat-to-target strategies with achievement of clinical remission within 6 months minimize radiographic progression and physical impairment in RA.(1) The preferred target, ACR/EULAR Boolean remission criteria, was developed to optimize a combination of radiographic and functional outcome.(2) However, clinical remission does not exclude subclinical inflammation, associated with progression of radiographic damage.(3)

Objectives: Our aim was to assess the association between definitions of remission at six months, including absence of ultrasound inflammation, and future absence of joint damage and physical disability.

Methods: DMARD-naïve RA patients with <2 years since first swollen joint and indication for DMARD treatment were included in the treat-to-target ARCTIC trial.(4) Patients followed with ultrasound (treatment target DAS <1.6 + SJC44=0 + no PD signal in 32 joints) were analyzed. We assessed remission at 6 months according to the following criteria: DAS-ESR, DAS28-ESR, SDAI, CDAI, ACR/EULAR Boolean remission (based on 44 joints), no swollen joints (SJC44), no ultrasound PD signal in any joint (0–96), and minimal greyscale (GS) score (GS ≤ 2, 0–96). Radiographs were scored by two readers using van der Heijde-Sharp score, with no radiographic progression defined as <1 unit change between 12–24 months based on the average score of the readers. We defined good outcome as a combination of no radiographic progression and physical function (PROMIS) $\geq$ median of the general population.(2) Odds ratios of reaching both outcomes were calculated according to various remission states at 6 months.

Results: Of the 103 patients included, 74% were female, mean [SD] age 51.4 [12.9], disease duration 6.7 [5.3] months, DAS 3.5 [1.1] and PROMIS 39 [8]. Median [25th, 75th percentile] radiographic progression 12–24 months was 0.49 [0.0, 1.03], and 71% had no progression. DAS remission was achieved by 59% at the 6-month visit, while 42% were in ACR/EULAR Boolean remission. Patients in ACR/EULAR Boolean remission had significantly higher odds ratio of no radiographic progression from 12–24 month than patients not in Boolean remission, as had patients with no PD signal or minimal GS findings (fig). Being in remission at six months according to each composite score separately or ACR/EULAR Boolean remission (OR 7.52, CI 3.06 –18.49) predicted a good outcome, while criteria based on ultrasound or no swollen joints did not (fig). No statistically significant association was found between remission according to composite scores and radiographic progression (Fig).

Figure: OR of no radiographic progression at 12-24 months compared to OR of a good outcome (no radiographic progression + physical function ≥ median in the general population) at 12-24 months. P-values ≤0.05 marked with an asterix.

Conclusions: Our data show that being in ACR/EULAR Boolean remission after six months of treat-to-target therapy increases both the odds of no radiographic progression and good physical function, supporting current recommendations stating that ACR/EULAR remission should be the preferred treatment target in early RA.(1) Additionally, our analyses support that absence of ultrasound inflammation is associated with no future radiographic progression.

FRI0122 PREDICTING FACTORS FOR DISAPPEARANCE OF ANTI-MUTATED CITRULLINATED VIMENTIN ANTIBODIES IN SERA FROM PATIENTS WITH RHEUMATOID ARTHRITIS

N. Ishigooka[1], T. Fujii[1,2], S. Kondo-Ishikawa[1], M. Hashimoto[3], M. Furu[3], M. Tanaka[3], H. Ito[4], R. Nakashima[1], K. Murakami[1], Y. Imura[1], H. Yoshifuji[1], K. Ohmura[1], T. Mimori[1]. *[1]Department of Rheumatology and Clinical Immunology, Kyoto University Graduate School of medicine, Kyoto; [2]Department of Rheumatology and Clinical Immunology, Wakayama Medical University, Wakayama; [3]Department of the Control for Rheumatic Diseases; [4]Department of Orthopaedic Surgery, Kyoto University Graduate School of medicine, Kyoto, Japan*

Background: Mutated citrullinated vimentin (MCV) is one of the important targets of anti-citrullinated protein/peptide antibodies (ACPA) and is found in synovial fluid in patients with rheumatoid arthritis (RA). Serum anti-MCV antibody (anti-MCV) titer may be better correlated with RA disease activity and radiographic progression than anti-cyclic citrullinated peptide antibody (anti-CCP) titer.
Objectives: In the present study, we tried to determine the predicting factor of anti-MCV disappearance in sera from RA patients.
Methods: Both anti-MCV (ORGENTEC Diagnostika, Germany) and anti-CCP (MESACUP^{TM}-2 test CCP, MBL, Japan) in sera from 280 RA patients who met 2010 ACR/EULAR classification criteria in Kyoto University RA Management Alliance (KURAMA) cohort 2013 and 2014 were measured by ELISA. Then, we determined retrospectively the predicting factors of anti-MCV disappearance using multivariate logistic analysis.
Results: In 2013 cohort, anti-MCV and anti-CCP positivities were 64.6 and 84.6%, respectively. The majority (97.8%) of anti-MCV-positive patients was also anti-CCP-positive and there was significant correlation between anti-MCV and anti-CCP titers (r=0.63, $p<0.001$). In 2013 baseline, there was no difference in patients' age, gender and disease duration between anti-MCV-positive (n=181, 64.6%) and -negative (n=99, 35.4%) groups. DAS28, however, was higher in anti-MCV-positive group than in -negative group (3.08±1.22 vs. 2.68±1.07, p=0.011), while anti-CCP-positive (n=237, 84.6%) and -negative (n=43,15.4%) groups had no significant difference of DAS28. Of note, whereas anti-CCP positivity rate did not change during 2013 and 2014, anti-MCV changed to positive and to negative were recognized in 20 (=7.2%) and 41 (=14.6%, disappeared group) patients. So we next compared anti-MCV disappeared and sustained-positive groups (n=140, 50.0%). There was no difference in patients' age, gender, disease duration and DAS28 in 2013. While decrease of DAS28 from 2013 to 2014 (=ΔDAS28) in disappeared group was more apparent than that in sustained-positive group (-0.58±1.1 vs. +0.02±0.34, p=0.028). Methotorexate monotherapy was rarer in disappeared group than in sustained-positive group (26.5% vs. 53.8%, p=0.015), while continuous use of biological disease modifying antirheumatic drug (bDMARD) was more frequent in disappeared than sustained-positive group (64.7% vs. 25.2%, $p<0.0001$). Also serum levels of KL-6, a serum marker of interstitial lung disease, were lower in disappeared than in sustained-positive group (255±146 vs. 315±183, p=0.006). To clear the most effective factor in anti-MCV disappearance, we choose variables including anti-MCV titers in baseline, KL-6 levels, ΔDAS28 and bDMARD use, and performed multivariable analysis. Analysis showed that anti-MCV titers and bDMARD use, especially TNF inhibitor (Odds Ratio =7.2, $p<0.001$) were observed as the predicting factors of anti-MCV disappearance. On the other hand, no predicting factor for newly anti-MCV appearance was recognized in our cohort.
Conclusions: Anti-MCV, but not anti-CCP, can be disappeared in a year by continuous bDMARD use regardless of disease activity.

FRI0123 DOES THE BODY MASS INDEX HAVE ANY INFLUENCE IN THE CHARACTERISTICS OF EARLY ARTHRITIS PATIENTS?

P. Moreno Fresneda, L. Martínez-Quintanilla, A.M. Ortiz, E. Tomero, R. García Vicuña, I. González Álvaro. *Rheumatology Deparment, Hospital Universitario de la Princesa, Madrid (Madrid), Spain*

Background: Obesity has been proposed as a risk factor to develop rheumatoid arthritis (RA) and it has been associated with a worse response to several disease modifying anti-rheumatic drugs (DMARDs).
Objectives: To study the differences in baseline characteristics according to the body mass index (BMI) of patients in the PEARL (Princesa Early Arthritis Register Longitudinal) study.
Methods: A total of 432 patients (69.1% female) of the PEARL cohort were included for this study. The register protocol comprises the collection of sociodemographic, disease-related and treatment data in five visits (baseline, 6, 12, 24 and 60 months). The local ethics and clinical research committee approved the protocol and all patients sign an informed consent prior to their inclusion. For this study it was analyzed the baseline visit data from the 304 (70.37%) patients that met ACR 1987 criteria for RA after 2 years of follow-up, as well as those considered undifferentiated arthritis (UA) since other diagnoses were excluded. The WHO definition for low, normal weight, overweight and obesity (BMI $<$18.5, 18.5–25, 25–30 or $\geq$30 kg/m^2 respectively) was applied. ACPA (anticitrullinated peptide antibodies) were assessed by enzyme immunoassay (CCP2 Eurodiagnostica). HLA-DRB1 genotype was determined in 219 patients using specific HLADRB1 typing kits (Dynal RELI SSO). The presence of shared epitope (SE) was determined based on this genotyping. The statistical analysis was performed by using Stata 12.1. Chi-Square and Kruskal-Wallis tests were used for the bivariate analysis. A multivariate logistic regression was performed to determine which factors may be related to ACPA positivity, including BMI, age, sex, smoking habit, number of SE alleles and study level as independent variables.
Results: Patients were 54.9 years old [44.2–67.5] (median [p25-p75]); disease duration was 5.3 months [3–8.4]. Table 1 shows the main variables significantly associated to BMI. In addition, we observed less ACPA positivity with increasing BMI (57% low weight vs. 43% in obese [p =0.08]), as well as a lower frequency of SE in patients with a higher BMI. The multivariate analysis confirmed that being smoker (ever or current) and carrying SE alleles is associated with the presence of ACPA. Adjusted by these variables, overweight and obesity were associated with lower probability of suffering an ACPA positive disease (OR 0.49, p=0.027 and OR 0.39, p=0.019 respectively).

Table 1. Variables significantly different according to BMI

BMI	Age (years)	Sex (W/M)	Level of studies (N/P/Se/U; %)	HAQ	VAS pain	TJC28
Low weight	52.3 [22.2–64]	7/0	0/14.3/42.9/42.9	1.25 [0.9–2.2]	50 [26–75]	7 [2–19]
Normal weight	50 [38.6–64]	145/24	1.2/21.4/35.1/42.3	0.87 [0.4–1.4]	41 [20–61]	3 [0–7]
Overweight	57.9 [47–69.6]	120/45	8.5/35.4/32.9/23.2	0.87 [0.5–1.6]	49 [20–62]	3 [0–9]
Obesity	59 [50.7–69.8]	68/23	12/38.5/26.5/22.9	1.3 [0.7–1.9]	50 [36–65]	5 [2–12]
	p$\leq$0.001	p=0.01	p$\leq$0.001	p=0.0018	p=0.031	p=0.047

*HAQ: Health Assessment Questionnaire; VAS: visual analogic scale (mm); TJC28: tender joints count (28 joints); W: women; M: men; N: no studies; P: primary studies; Se: secondary studies; U: universitary studies.

Conclusions: In our early arthritis register, patients with a higher BMI have predominantly ACPA negative disease, a more intense perception of pain and higher disability. These findings should be validated in other populations.

FRI0124 TEMPORARY INTERRUPTIONS OF STUDY DRUG DURING THE BARICITINIB PHASE 3 RHEUMATOID ARTHRITIS PROGRAM

P. Emery[1], Y. Tanaka[2], T.E. Cardillo[3], D.E. Schlichting[3], S. Beattie[3], L. Chen[3], T.P. Rooney[3], J.S. Smolen[4]. *[1]Leeds MSK Biomed/Chapel Allerton Hosp, Leeds, United Kingdom; [2]University of Occupational & Environmental Health, Kitakyushu, Japan; [3]Eli Lilly and Company, Indianapolis, United States; [4]Medical University of Vienna, Vienna, Austria*

Background: Temporary interruption of RA therapy is common in clinical practice; therefore, rapid clearance and low immunogenicity may be useful DMARD attributes. Baricitinib (bari) is a non-biologic Janus kinase (JAK) 1 /JAK2 selective inhibitor with a pharmacokinetic half-life in RA patients of approximately 13 hours. It has demonstrated improved clinical efficacy compared to MTX, adalimumab and placebo (pbo) with a satisfactory safety profile when administered once daily to RA patients in 4 completed Phase 3 studies.
Objectives: These analyses aimed to characterize temporary interruptions of study drug during these studies and explore the kinetics of RA symptoms during and following interruption.
Methods: During bari Phase 3 studies, investigators were required to document temporary interruptions of study drug, including timing, reason and duration, using electronic case report forms. In 2 studies, patients recorded RA symptoms (duration and severity of morning joint stiffness, worst tiredness and worst joint pain) daily for 12 weeks. Post hoc analyses investigated changes in these scores among patients randomized at least 7 days prior to interruption, having an interruption that lasted at least 3 days, and retreated.
Results: Across the 3 pbo-controlled studies, interruptions occurred in a larger proportion of patients with bari than pbo only in the biologic DMARD-inadequate responder (IR) study RA-BEACON. In the 2 active comparator-controlled studies, the lowest rates of interruption were in the bari monotherapy arm of the DMARD-naïve MTX-controlled RA-BEGIN study, and proportions were similar for bari and adalimumab in the MTX-IR study, RA-BEAM (Table 1). Adverse events (predominantly non-serious, mild or moderate infections, most commonly of the respiratory tract) were the most frequent reason for interruption. Few patients interrupted for the reason of abnormal laboratory results. Most interruptions lasted for 2 weeks or less; in RA-BEAM, interruptions appeared shorter in duration for bari than for adalimumab. Diary measures indicated modest symptom increases during interruption compared to the last pre-interruption value, with a return to pre-interruption values or better after resumption of study drug (Table 2).
Conclusions: Consistent with its pharmacologic properties, brief temporary interruptions of bari during Phase 3 studies were associated with minor increases in RA symptoms, which resolved following resumption of therapy. A small molecule with a short half-life may offer advantages over injectable biologic therapies with respect to drug interruption for clinical cause in RA patients.

FRI0125 RHEUMATOID ARTHRITIS PATIENTS WITH ANTI-ACETYLATED PEPTIDE ANTIBODIES STARTING THEIR FIRST TUMOR-NECROSE-FACTOR-INHIBITOR TREATMENT SHOW GREATER RESPONSE

P. Studenic[1], S. Blüml[1], H. Bang[2], D. Sieghart[1], D. Aletaha[1], H. Haslacher[3], T. Perkmann[3], J.S. Smolen[1,4], G. Steiner[1]. *[1]Internal Medicine 3, Division of Rheumatology, Medical University Vienna, Vienna, Austria; [2]Orgentec Diagnostika, Mainz, Germany; [3]Department of Laboratory Medicine, Medical University Vienna; [4]Internal Medicine 2, Hietzing Hospital, Vienna, Austria*

Background: Anti-acetylated-peptide antibodies (AAPA) have recently been described in rheumatoid arthritis (RA) patients.[1] Patients that show multiple autoantibody positivity have a higher likelihood to flare when stopping biological treatment. The role of AAPA antibodies for response to Tumor-Necrose-Factor-inhibitor treatment (TNFi) has not been explored.
Objectives: To determine the prevalence and serological overlap of AAPA to rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) in a cohort of RA patients starting their TNF-inhibitor, and to assess their relation of autoantibody status to response to therapy.
Methods: We measured AAPA by ELISA using two acetylated peptides derived from vimentin, as well as RF and ACPA. We evaluated the prevalence of autoantibodies, baseline characteristics of autoantibody positive and negative patients, and their association with a 50% response by the Simplified disease activity index (SDAI50), and with achieving of SDAI low disease activity or remission at 6 months after starting the first TNFi. Likelihood ratios were calculated from logistic regression analyses. To better determine differences in SDAI change over time General Estimated Equation analyses (GEE) was used.
Results: Among our 93 patients starting treatment on a TNFi (85% female, mean disease duration: 7.7±7 years mean SDAI20±13), 50% were positive for AAPA, 57% for ACPA and 61% for RF (for overlap of antibodies see figure). There were no significant differences in baseline characteristics found between AAPA positive and negative patients. 61% of patients reached LDA or REM and 33% achieved an SDAI50 response after 6 months of TNFi treatment. AAPA positive patients showed a likelihood ratio (LR+) of 5.3 (p=0.022) to achieve an SDAI50 response and 3.9 (p=0.048) to reach LDA/REM. In contrast, being RF or ACPA positive did not coincide with a higher likelihood of achieving SDAI50 (LR+ of 0.08; p=0.773 and 1.09; p=0.297, respectively) or LDA/REM (LR+ of 1.83; p=0.177 and 1.55; p=0.213). Relative changes upon treatment with TNFi in composite scores were neither different between RF+ vs. RF- patients, nor between ACPA+ vs ACPA-patients; however AAPA+ showed significantly higher relative changes in SDAI (p=0.021), CDAI (p=0.025) and DAS (p=0.022) compared to AAPA- patients. Of note, relative changes in CRP were similar between the groups.
GEE on up to 230 days of TNFi treatment or until change of treatment, showed no significant difference in SDAI courses comparing RF+ vs RF- or ACPA+ vs ACPA-

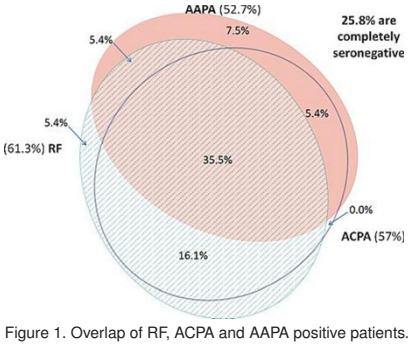

Figure 1. Overlap of RF, ACPA and AAPA positive patients.

patients; but for AAPA+ vs. AAPA- patients the difference in change in SDAI was significant (p=0.045) over time.
Conclusions: AAPA positivity, in contrast to RF and ACPA positivity, appears to have a tighter association with greater levels of response in patients who are initiating TNFi-treatment. Therefore, AAPA might add additional information to estimate the chances of RA patients for responding to TNF-inhibitors.

FRI0126 AIMING FOR REMISSION ACCORDING TO ANY OF THE RHEUMATOID ARTHRITIS DISEASE ACTIVITY INDICES IS MORE IMPORTANT FOR PHYSICAL FUNCTION THAN THE ACTUAL CHOICE OF INDEX: A LONGITUDINAL ANALYSIS IN A CLINICAL PRACTICE SETTING (METEOR COHORT)

P.D. Carvalho[1], R. Ferreira[1], R. Landewé[2], D. Vega-Morales[3], K. Salomon-Escoto[4], D.J. Veale[5], J. da Silva[1], P.M. Machado[6]. *[1]CHUC, Coimbra, Portugal; [2]ARC, Amsterdam, Netherlands; [3]HU/UANL, Monterrey, Mexico; [4]UMass, Massachusetts, United States; [5]DAMC, Dublin, Ireland; [6]UCL, London, United Kingdom*

Background: The association between remission and disability in patients with rheumatoid arthritis (RA) has been established mainly in clinical trial cohorts and not in "real-life" patients. Moreover, only a limited number of remission definitions have been tested.
Objectives: To compare the association between different remission criteria and physical function in patients with RA followed in clinical practice.
Methods: Longitudinal data from the METEOR database were used. Fifteen definitions of remission were tested: ACR-EULAR boolean-based; Simplified Disease Activity Index (SDAI); Clinical Disease Activity Index (CDAI); Disease Activity Score (DAS) and 28-joint count DAS (DAS28), both with ESR/CRP, with 3/4 variables (3v/4v), and various cut-offs tested. Disability was measured by the Health Assessment Questionnaire (HAQ) and HAQ≤0.5 was defined as a good outcome. Associations were investigated using generalised estimating equations (GEE), using HAQ≤0.5 as dependent variable and the various remission criteria as independent variables. Potential confounding factors (age, body mass index, gender, rheumatoid factor positivity, erosions and biologic treatment) were also tested. Sensitivity analyses were performed using first visits only and using patients with no missing data for all definitions of remission.
Results: Data from 32,915 patients and 157,899 visits were available. The most stringent definition of remission (table 1) was the ACR-EULAR boolean definition (4.5%). The proportion of patients with HAQ≤0.5 among patients in remission

Table 1. Remission rates (%) and association with HAQ≤0.5

Remission definition		Remission rate	HAQ≤0.5 (%)		Adjusted OR (95%CI) for HAQ≤0.5 (GEE)
			Among patients in remission	Among patients in non-remission	
ACR-EULAR boolean		4.5	87.0	34.1	2.6 (2.3-2.9)
CDAI≤2.8		13.4	78.5	27.4	3.2 (2.9-3.5)
SDAI≤3.3		17.1	78.1	25.7	3.4 (3.0-3.7)
DAS-CRP<1.6	4v	38.6	59.1	19.3	3.2 (2.9-3.5)
	3v	39.1	56.4	20.7	2.8 (2.6-3.0)
DAS-ESR<1.6	4v	31.7	63.2	22.6	3.0 (2.7-3.2)
	3v	30.4	60.4	24.3	2.6 (2.4-2.8)
DAS28-CRP<2.6	4v	34.8	62.8	20.2	3.3 (3.0-3.6)
	3v	37.5	57.7	21.3	2.8 (2.6-3.0)
DAS28-ESR<2.6	4v	25.2	68.1	26.5	2.8 (2.6-3.1)
	3v	24.4	62.5	28.7	2.3 (2.2-2.5)

	3v	21.7	64.5	27.4	2.3 (2.2-2.5)
DAS28-ESR≤2.2*	4v	18.4	71.3	29.9	2.6 (2.4-2.8)
	3v	17.3	64.4	31.8	2.1 (1.9-2.2)

*Fleischmann 2015 (PMID: 25143522)

was higher for the most stringent definitions. However, this also meant that, for the most stringent criteria, many patients in non-remission had HAQ≤0.5. The strongest degree of association between remission and HAQ≤0.5 was observed for the SDAI. However, only minor differences were noted between definitions (table 1). Sensitivity analyses yield similar results (not shown).
Conclusions: The various remission definitions confirmed their validity in terms of physical function in a large international clinical practice setting. However, many patients in non-remission will still have good functional status and being in clinical remission does not equate to having HAQ≤0.5. A multidimensional approach should be taken to help patients achieve this functional goal. Achievement of remission according to any of the indices is more important than the use of a specific index.

FRI0127 OUTCOMES OF DISEASE ACTIVITY IN A 5-YEAR LARGE COHORT OF RHEUMATOID ARTHRITIS PATIENTS TREATED UNDER TREAT TO TARGET RECOMMENDATIONS AND A MULTIDISCIPLINARY CARE MODEL – A REAL-LIFE EXPERIENCE

P. Santos-Moreno[1], D. Gomez[1], E. Castillo[1], R. Giraldo[1], G. Ballesteros[1], L. Villarreal[2], J. Bello[3], D. Buitrago-Garcia[3]. *[1]Rheumatology; [2]Psychology and processes; [3]Epidemiology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia*

Background: Treat to Target (T2T) strategy becomes from the need to develop therapeutic targets and tools to achieve defined outcomes in rheumatoid arthritis (RA), this strategy has become recognized as a standard of good practice embodying the principle that rapid attainment of remission, or low disease activity, can halt joint damage and maintain good quality of life.
Objectives: The aim of this study was to describe global change in Disease Activity Score 28 (DAS28) using T2T strategy for a 60 month period in a large cohort of patients from a Colombian specialized in RA center.
Methods: A descriptive cohort study was conducted. Medical records of patients from specialized in RA center were reviewed; those patients were followed-up under T2T standards and a multidisciplinary approach. Each patient had a minimum of 6 follow-up visits. Clinical follow-up was designed by the authors according to DAS28 as follows: every 3–5 weeks (DAS28 >5.1), every 7–9 weeks (DAS28 ≥3.1 and ≤5.1), and every 11–13 weeks (DAS28 <3.1). Tender joint count (TJC), swollen joint count (SJC) and DAS28 were measured on each visit. Therapy had to be adjusted with DAS28 >3.2 unless patient's conditions don't permit it; we considered this follow-up type as implementation of a T2T strategy in patients with RA. We divided patients in four groups: remission (REM), low disease activity (LDA), moderate disease activity (MDA) and severe disease activity (SDA) patients and the aim of the study was to look at what percentage of patients who were in moderate or severe disease activity reached a low disease activity or remission. Descriptive epidemiology was done, percentages and averages were calculated; the median of each variable was analyzed using t-Student assuming normality for DAS28 distribution and the level activity disease was analyzed using Pearson's statistics.
Results: 3618 patients meet the inclusion criteria. 72% were receiving conventional DMARDs therapy and 28% were receiving biological therapy. 83% were woman and 17% were men. Mean age was 61 years ±11. Mean DAS28 at beginning was 3.3±1.3 and at the end of five year period was 2.8±0.7. The difference of medians for DAS28 at begging and at the end showed improvement with statistical significance (p<0.00). It was found a global increase in the percentage of patients in remission and LDA and decrease in moderate and severe disease activity groups (from 31% to 19% and from 12% to 2% respectively) with statistical significance.

ACTIVITY LEVEL	TIME 0 n(%)	2011-2012 n(%)	2013-2014 (%)	2015-2016 (%)
REM	1512 (42)	1548 (43)	1751 (48)	1826 (50)
LDA	536 (15)	955 (26)	969 (27)	1033 (29)
MDA	1128 (31)	875 (24)	809 (22)	694 (19)
SDA	442 (12)	240 (7)	89 (2)	65 (2)

Conclusions: This study show evidence of an improvement in DAS28 and level of disease activity in a cohort of RA patients from a specialized center in Colombia treated under recommendations of T2T strategy; it was found a global increase in the percentage of patients in remission (REM) and decrease in moderate and severe disease activity groups. This revision shows the importance of T2T follow-up and a multidisciplinary treatment for the management or RA.

FRI0128 PRISM – PICTORIAL REPRESENTATION OF ILLNESS AND SELF MEASURE: THE USE OF A SIMPLE NON-VERBAL TOOL AS A PATIENT-CENTRED OUTCOME MEASURE IN EARLY RHEUMATOID ARTHRITIS COHORTS

P.C. Taylor[1], R. Alten[2], B. Haraoui[3], B. Amess[1], J. Macdonald[1], M. Truchon[4], C. Pohl[2], C. Swales[1], Y. Kaneko[5], T. Sensky[6]. *[1]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom; [2]Schlosspark-Klinik Charité, University Medicine Berlin, Berlin, Germany; [3]Université de Montréal, Montreal; [4]l'institut de Rhumatologie de Montréal, Montréal, Canada; [5]Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan; [6]Centre for Mental Health, Imperial College London, London, United Kingdom*

Background: Treatment recommendations in early RA advocate a treat to target approach with the ideal goal of remission. But not all patients attain this goal. There is a need for outcome measures that are meaningful to patients and inform management of which alleviation of suffering is a key aim. PRISM[1] is a novel, validated, brief method of measuring suffering consistent with Cassell's seminal conceptualisation[2].
Objectives: To understand the relationships between a patient's perception of the totality of the impact of RA and commonly used clinical assessments of disease activity, depression and illness intrusiveness.
Methods: Basic sociodemographic and clinical data were collected from 182 RA patients from 3 international centres, assigned to one of four cohorts (two early RA and two established RA), at baseline, weeks 12 and 24. The two early RA cohorts (diagnosis <2 yr) comprised Group 1 on stable treatment (n=37) and Group 2 requiring csDMARD adjustment (n=34). Using the iPRISM App on a tablet, all patients were asked to complete the basic PRISM task to measure self-illness separation (SIS). The smaller the SIS, the greater the person's perceived suffering. In the PRISM+ task, patients were asked to identify two valued aspects of their life at the moment (X and Y) which bring pleasure, satisfaction, a sense of achievement, or a sense of purpose. The iPRISM App automatically records the distance between the centres of each of these disks and the Self disk to measure patients' perceptions of the intrusiveness of their illness on two personally valued aspects of their lives.
For both groups, direction of change in SIS and the PRISM+ measures were compared with direction of change in disease activity measures and patient global disease activity (ptGbl), assessed at wks 12 and 24, using the sign test.
Results: PRISM was easy to use and most patients understood the simple instructions. Of 182 patients at baseline, SIS showed significant correlations with ptGbl (r_s=-0.48, p<0.0001), pain VAS (r_s=-0.45, p<0.0001), PHQ9 (r_s=-0.45, p<0.0001) and illness intrusiveness scale (r_s=-0.51, p<0.0001). Suffering was inversely correlated with the perceived controllability of the symptoms of RA; for Group 1, r_s=0.41, p<0.0001, for Group 2, r_s=0.32, p<0.0001.
In Group 2, SIS and DAS28-ESR showed small trends to improvement by wk 12 (DAS28-ESR Δ=-0.11, p=0.557; SIS Δ=1.7, p=0.296) with significant improvement by wk 24 (DAS28-ESR Δ=-0.82, p=0.002; SIS Δ=3.85, p=0.029). However, there was no significant improvement in the intrusiveness of the illness on the valued aspects of life over this time period (Actual X, Δ=-0.25, p=0.557; Actual Y, Δ=1.89, p=0.169).
Conclusions: PRISM is a novel PRO that quantifies factors salient to each individual with respect to the impact of RA and its treatment while allowing for incorporation of a wide range of such influences. It may have utility as an adjunct to disease activity measures in setting agreed personalised therapeutic targets.

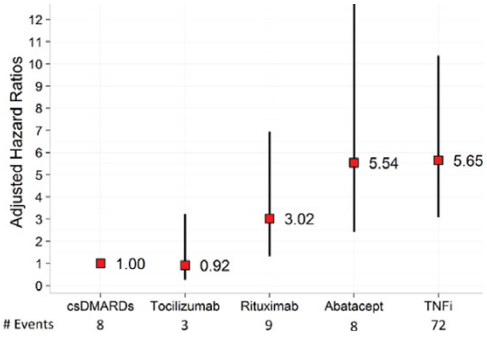
Rheumatoid arthritis - comorbidity and clinical aspects

FRI0129 COMPARATIVE SAFETY OF BIOLOGIC DMARD INITIATION IN RA: A POPULATION-BASED OBSERVATIONAL STUDY OF MALIGNANCY RISK

S. Suissa[1], S. Dell'Aniello[1], T. Simon[2]. *[1]McGill University, Montreal, Canada; [2]Bristol-Myers Squibb, Princeton, United States*



Background: Patients (pts) with RA are at increased risk for some malignancies and the use of biologic (b)DMARDs has been reported to further increase this risk.[1] Abatacept (ABA), the first selective T-cell co-stimulation modulator for RA treatment, is now often prescribed as a first-line bDMARD, but long-term effects are unknown.

Objectives: To assess in a real-world, observational study whether treatment with ABA had a similar malignancy risk as other biologics, with or without MTX, when used as the initial bDMARD for RA.
Methods: The Truven MarketScan® Commercial and Supplemental Medicare databases were used to identify adult pts diagnosed with RA who initiated bDMARD treatment with ABA or another bDMARD between Jan 2007 and Dec 2014. Other bDMARDs included adalimumab, anakinra, certolizumab, etanercept, golimumab, infliximab, rituximab and tocilizumab. Pts were required to have ≥6 months (M) of continuous health plan enrolment before bDMARD initiation (index date) and deemed to have initiated a treatment if there was no claim for any bDMARD in the limited 6M period before bDMARD initiation. Pts who had a malignancy in the baseline 6M period were excluded. Pts were followed up from the date of the first bDMARD prescription initiation, either ABA or another bDMARD, until occurrence of a malignancy (identified by ICD-9 diagnosis code), end of enrolment in the database or end of data collection, whichever occurred first. A 6M latency period was included. Propensity scores of ABA initiation were estimated from the baseline covariates using a logistic regression model, and trimmed to include only pts with ranges common to both ABA-exposed and comparator bDMARD cohorts. The Cox proportional hazard regression model was used to provide an estimate of the hazard ratio (HR) of malignancy associated with ABA initiation compared with initiation of another bDMARD, adjusted for age and deciles of the propensity score after trimming.
Results: A total of 5391 pts were identified as above as having initiated bDMARD therapy with ABA and 74,315 initiated with another bDMARD, with follow-up of <8 yrs (mean 2.1 yrs). Pts who initiated ABA vs other bDMARDs were older (mean 55 vs 52 yrs), had more co-morbidity, used less MTX (49 vs 57%) and more other non-bDMARD (41 vs 36%) at baseline. After trimming on propensity scores, 565 pts developed a malignancy after ABA (incidence rate 5.0 per 100/yr) compared with 5750 after another bDMARD (incidence rate 3.6 per 100/yr). The adjusted HR (95% CI) of any malignancy with ABA initiation relative to other bDMARDs was 1.18 (1.06, 1.30), while for any malignancy excluding non-melanoma skin cancer it was 1.17 (1.02, 1.34). The risk (HR; 95% CI) was not significantly elevated for lung cancer (1.11; 0.70, 1.76), female breast cancer (1.21; 0.91, 1.62) and lymphoma (1.21; 0.77, 1.90).
Conclusions: In this large, real-world study of pts treated for RA, the incidence of the most common malignancies of breast, lung and lymphoma were not significantly increased in pts using abatacept as first-line bDMARD treatment compared with other bDMARDs, though the confidence intervals were wide. The slight increase in the risk of overall malignancy with abatacept needs further investigation, particularly to assess the potential for residual confounding and the impact of the short baseline period.

FRI0130 RATES AND RISK FACTORS OF NEW-ONSET PSORIASIS UNDER DIFFERENT BIOLOGIC AGENTS AND CONVENTIONAL SYNTHETIC DMARD TREATMENT

A. Strangfeld[1], L. Baganz[1], A. Richter[1], B. Manger[2], G.-R. Burmester[3], C. Eisterhues[4], S. Wassenberg[5], A. Zink[1,3], J. Listing[1]. *[1]German Rheumatism Research Center, Berlin; [2]Scientific Advisory Board, Erlangen; [3]Charité University Medicine, Berlin; [4]Rheumatologist, Braunschweig; [5]Rheumatologist, Ratingen, Germany*

Background: Psoriatic skin disease is a burdensome, sometimes painful, dermatologic condition which was reported to occur as an adverse event (AE) during TNF-inhibitor (TNFi) treatment of rheumatoid arthritis (RA). Single case reports revealed the occurrence of psoriasis also during treatment with non-TNFi, but the magnitude under those agents remains unclear.
Objectives: To compare incidence rates of psoriasis in RA under treatment with different biologic and conventional synthetic (b/cs)DMARDs and to investigate risk factors.
Methods: We used data of 12,722 patients (53,585 patient years (py)) enrolled with the start of a b/csDMARD in the German biologics register RABBIT. Patients were required to have no psoriasis at baseline and at least one follow-up. All psoriatic events (PsE) reported until 30 April 2016 were selected and assigned to treatments administered within 3 months prior to the event. Crude incidence rates (IR) of PsE were calculated per 1,000py. Cox regression was applied to investigate risk factors for the occurrence of PsE with and without inverse probability weights (IPW) to adjust for confounding by indication.
Results: 96 PsE were reported, with only 6 of them categorized as being serious. The median time between enrollment in the cohort and onset of psoriasis was 19 months (IQR:11–45 months). 21 of all PsE (22%) were palmoplantar manifestations of which 9 were reported as pustular type.
Compared to csDMARD treatment with a crude IR of 0.44/1,000py (95% CI 0.2;0.9), the IRs found under TNFi (IR 2.99 (95% CI 2.3;3.8)) and abatacept (IR 3.99 (95% CI 1.7;7.9)) were significantly higher. In patients treated with rituximab (IR 1.8 (95% CI 0.8;3.4)) or tocilizumab (IR 0.7 (95% CI 0.1; 2.0)) IRs for PsE were not significantly different from csDMARD patients. Across TNFi, the IR varied insignificantly.
Adjusted regression analysis showed higher risk for PsE with TNFi, abatacept and rituximab (graph). Female sex (adjusted hazard ratio (HR) 1.8 (1.0;3.3)) and being rheumatoid factor negative (HR 1.6 (1.0;2.6)) were additional significant risk factors. Smoking (HR 1.6 (1.0; 2.5)), age (HR 1.0 (0.98;1.01)), glucocorticoids per 5 mg/d increase (HR 1.1 (1.0;1.2)), and prior (≤6months) skin infections (HR 2.2 (0.5;9.7)) were not significantly associated. Replacing glucocorticoids with DAS28 did not show differing results. Adjustment with IPW attenuated the effect of rheumatoid factor (p=0.4) but smoking was significantly associated with a higher risk (p<0.01).

Conclusions: This is the first analysis comparing the incidence of psoriasis under biologics with different modes of action within one cohort. Our results confirmed a higher risk for TNFi [1] and showed a similar result for abatacept. A lower but still significant increased risk was found for rituximab, whereas there was no difference for tocilizumab compared to csDMARDs. New onset psoriasis is a rare and most often non-serious event. The number needed to harm is 334 patients treated with TNFi for one year to observe one PsE.

FRI0131 THE 2010 ACR/EULAR CRITERIA ARE INSUFFICIENTLY ACCURATE IN THE EARLY IDENTIFICATION OF AUTOANTIBODY-NEGATIVE RHEUMATOID ARTHRITIS: RESULTS FROM THE LEIDEN-EAC AND ESPOIR COHORTS

D. Boeters[1], C. Gaujoux-Viala[2], A. Constantin[3], A. van der Helm-van Mil[1]. *[1]Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands; [2]Department of Rheumatology, Nîmes University Hospital; EA2415, Montpellier University, Nîmes; [3]Department of Rheumatology, Centre Hospitalier Universitaire de Toulouse, Hôpital Purpan, Toulouse, France*

Background: The 2010-ACR/EULAR criteria were derived to classify RA earlier in time. Previous studies indeed observed that the 2010-criteria were fulfilled earlier than the 1987-criteria. This study determined whether the 2010-criteria perform equally in the early detection of autoantibody-positive and autoantibody-negative RA.
Objectives: To compare the performance of the 2010-criteria between autoantibody-positive and autoantibody-negative RA within two different early arthritis cohorts.
Methods: From the total Leiden-EAC (n=3448) and ESPOIR (n=813) RA-patients who fulfilled the 1987-RA criteria at 1-year but not at presentation were selected (n=515 and n=53, respectively). These RA-patients were studied on the presence of ACPA and RF, and on fulfilling the 2010-criteria at baseline, as 2010-positivity indicated that these RA-patients were earlier identified.
Results: In the EAC, 67% of the selected RA-patients did already fulfil the 2010-criteria at baseline. In ESPOIR this was 57%, indeed demonstrating early classification with the 2010-criteria. Among the selected autoantibody-positive RA-patients of the EAC, 85% was identified at baseline already with the 2010-criteria. Within autoantibody-negative RA this was 45% (p<0.001). Similarly within autoantibody-positive RA-patients in ESPOIR 92% was 2010-positive at baseline, whereas this was only 25% within autoantibody-negative RA (p<0.001).
Conclusions: The 2010-criteria perform well in the early identification of autoantibody-positive RA, but autoantibody-negative RA-patients are still frequently missed with these criteria. As it has been demonstrated that early

treatment initiation is beneficial for the outcome of ACPA-negative RA as well, other diagnostics are required for the early identification of ACPA-negative RA.

FRI0132 HIGH DISEASE ACTIVITY IS A PREDICTOR OF DEPRESSION AND PERSISTENT DEPRESSION IN EARLY RHEUMATOID ARTHRITIS: RESULTS FROM THE ONTARIO BEST PRACTICES RESEARCH INITIATIVE (OBRI)

R. Joshi[1], M. Movahedi[2,3], E. Rampakakis[2], A. Cesta[3], X. Li[3], S. Couto[3], J. Sampalis[2], C. Bombardier[3,4,5], B. Kuriya[6] on behalf of OBRI investigators. *[1]Department of Rheumatology, Brampton Civic Hospital, William Osler Health System, Brampton; [2]JSS Medical Research, Montreal; [3]Ontario Best Practices Research Initiative, Toronto General Hospital, University Health Network; [4]Division of Rheumatology, Mount Sinai Hospital; [5]Department of Medicine (DOM) and Institute of Health Policy, Management, and Evaluation (IHPME); [6]Sinai Health System, University of Toronto, Toronto, Canada*

Background: The prevalence of depression among individuals with rheumatoid arthritis (RA) may be as high as 40% but persistence of depression over time is relatively unknown. Uncontrolled inflammation may drive severe disease and, in turn, inflammation and high disease activity are hypothesized to mediate depressive symptoms.
Objectives: The aims of this analysis were to: (1) describe the prevalence of depression at baseline and determine how often depression persists over time; (2) determine whether there is an association between changes in disease activity and depression over time among individuals with early RA (ERA).
Methods: ERA patients enrolled in the Ontario Best Practices Research Initiative (OBRI) with ERA ($\leq$1 year disease duration) and $\geq$2 years of follow-up were included. Persistent depression was defined as self-reported depression at baseline and at >50% of visits over the first 2 years. The association between baseline disease activity, measured by the Clinical Disease Activity Index (CDAI), and depression at baseline or persistent depression was evaluated with multivariate logistic regression. The General Estimation Equation was also used to explore the association between changes in CDAI disease activity over time and risk of depression.
Results: 469 patients with ERA (72.9% female) were included with a mean (SD) age of 56.8 (13.6) years. Mean (SD) disease parameters were: CDAI: 22.9 (14.1); DAS28: 4.6 (1.5); and HAQ disability Index: 1.1 (0.75). At baseline, the prevalence of depression was 26%, and 23% reported persistent depression. Persistent depression was significantly higher in patients with moderate CDAI (19%) and high CDAI (29%) compared to those in CDAI low disease activity (LDA) or remission (16%, p=0.02). After adjusting for potential confounders (sex, rheumatoid factor status, prior use of csDMARDs, current use of bDMARDs, HAQ disability index, number of comorbidities), increased CDAI at baseline was significantly associated with both baseline depression and persistent depression (OR: 1.04; 95% CI: 1.01–1.06, p=0.002). Female gender (OR: 3.17; 95% CI: 1.50–6.68 p=0.002) and greater number of comorbidities at baseline (OR: 1.68; 95% CI: 1.47–1.93, p<0.001) were also associated with persistent depression. Over the course of follow-up, the risk of depression was significantly higher among patients with moderate disease activity compared to those in CDAI LDA or remission (OR: 1.16; 95% CI: 1.04–1.29, p=0.006). The risk of depression was substantially greater for those with high disease activity (OR: 1.32; 95% CI: 1.15–1.52) over time compared to those achieving LDA or remission states.
Conclusions: Depression in ERA is common and initial high disease activity increases the risk of depression as well as its persistence. High CDAI during the early years of follow-up was also an independent predictor of depression. This highlights the importance of intervening during the "window of opportunity" to control disease activity and the potential to mitigate adverse health outcomes, including depression.

FRI0133 IS THERE INCREMENTAL MENTAL HEALTH BURDEN ASSOCIATED WITH RHEUMATOID ARTHRITIS?

V. Strand[1], M. Kosinski[2], R. Rendas-Baum[2], D. Brooks[3], R. Ganguly[3]. *[1]Stanford University, Palo Alto, CA; [2]Optum, Inc., Eden Prairie, MN; [3]GlaxoSmithKline, Collegeville, PA, United States*

Background: Rheumatoid arthritis (RA) patients are more likely to experience depression.[1] This comorbidity is associated with increased disability, use of healthcare services, and mortality risk.[2,3] The association between RA and other mental health disorders has received limited attention and there remains a need to further demonstrate and understand the impact of RA on mental health.
Objectives: Evaluate the mental health burden of RA patients based on the analysis of Short Form-36v2 Health Survey (SF-36v2) mental health (MH) and role emotional (RE) domain scores from two independent general population databases in the US and Europe.
Methods: The mental health burden associated with RA was analyzed by comparing mean SF-36v2 MH and RE scores of individuals self-reporting RA (with or without depression) and the scores from 2 benchmark samples (individuals without RA, individuals with depression and no RA) in two large cross-sectional survey studies (QualityMetric's 2009 General US Population Norming Study of the SF-36v2 and the 2014 European National Health and Wellness Survey). Multivariate regression methods were used to adjust each benchmark sample to the distribution of the RA sample in terms of age and gender. Differences between samples were interpreted with respect to minimally important differences: 3 points for MH; 4 points for RE.
Results: The US (2009) and European (2014) samples included 4,042 and 81,366 individuals, respectively. Compared with individuals without RA or depression, mean RE scores were significantly (P<0.001) lower for RA patients without depression in the US (-7.75 points) and Europe (-5.31 points). Likewise, mean MH scores were significantly (P<0.001) lower among RA patients without depression in the US (-4.85 points) and Europe (-5.03 points) compared with individuals without RA or depression. Compared to individuals with depression and no RA, mean RE and MH scores were 5 to 10 points higher (P<0.001) for RA patients without depression in both the US and Europe. Comparisons of RE and MH scores between RA patients with and without comorbid depression showed that comorbid depression was associated with 2 to 6 points lower scores (P<0.01) in RE and MH domains, in both the US and Europe.
Conclusions: RA is associated with significant and clinically meaningful mental health burden as measured by SF-36v2 MH and RE domains. Results comparing scores between RA patients with and without comorbid depression suggest that there is an incremental mental health burden associated with RA, often exceeding minimally important differences among US patients.

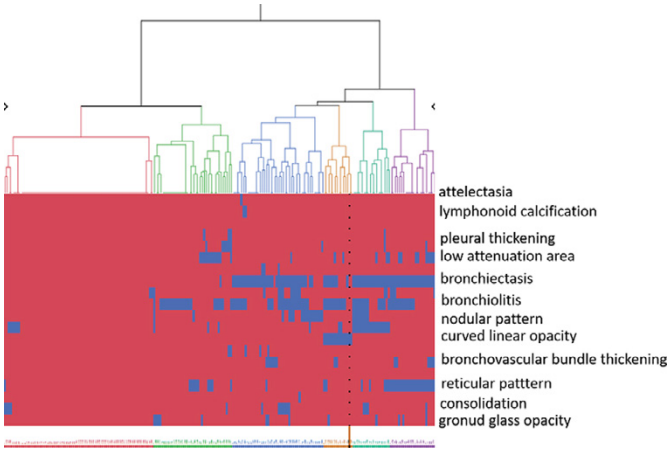
FRI0134 CLUSTER ANALYSIS OF PULMONARY LESIONS IN RHEUMATOID ARTHRITIS (RA); AIRWAY DISEASE IS SHARED AND CRITICAL PULMONARY ABNORMALITY IN RA



A. Tanaka, Y. Namiki, R. Yamazaki, H. Okada, S. Arai, T. Owada, R. Maezawa, M. Arima, K. Kurasawa. *Departoment of Rheumatology, Dokkyo Medical University, Shimotuga-Gun, Japan*

Background: Rheumatoid arthritis (RA) is a systemic inflammatory disease that affects joints and various organs including the lung. The pulmonary involvement is critical for prognosis of the patients and decision of the treatment. Moreover, the pulmonary involvement showed various abnormalities such as interstitial pneumonia (ILD) and airway disease (AD). Importantly, a pulmonary abnormality coexists with other ones in RA patients. There have been large numbers of studies on the prevalence of pulmonary abnormalities and clinical features of patients with these lesions. However, it remains to be elucidated what existence pattern of pulmonary abnormalities RA patients have.
Objectives: To reveal the existence pattern of the pulmonary abnormalities in RA patients using cluster analysis, and to clarify the clinical features of patients with multiple pulmonary abnormalities.
Methods: Subjects were consecutive 208 RA patients who were treated with bDMARDs as the first one from Feb. 2004 to Sep. 2015 in our department and received HRCT scan before and after the therapy. Pulmonary abnormalities were classified into 4 categories (ILD, nodular lesions, AD and other) and 20 lesions such as ground-glass opacity, reticular pattern, bronchiolitis and bronchiectasis and were examined their existence and distribution. Cluster analysis was conducted according to the existence of the lesions by Ward method. Clinical features were analyzed through reviewing medical records.
Results: Subjects were 208 RA cases (M/F; 64/144, mean age 59.2 year-old,

disease duration 13.1 years). Pulmonary lesions were found in 146 (70.2%) of RA patients before treatment Imaging findings were 81of ILD (39%),45 of nodular lesion (21.6%) and 115 of AD (55%). Cluster analysis showed 6 clustered (Fig.), 1; no pulmonary lesions, 2; AD without bronchoectasia, 3; AD with bronchoectasia, 4; AD with curved linear opacities, 5; AD with nodular lesions, and 6; reticular pattern with AD.

AD was common abnormalities and coexisted with other pulmonary lesions in RA. AD was found in 79%, 78% and 71% of patients with pulmonary abnormalities, ILD and nodular lesions, respectively. AD alone, AD with ILD, and AD with nodular pattern were found in 16.3%, 8.6% and 28.9%, respectively, while patients without pulmonary lesions were 29.8% in RA. AD was frequently associated with ILD and nodule compare to non-AD.

No differences were found in gender, smoking history, disease duration and disease activity between patients with and without AD. New emergence or exacerbation of pulmonary abnormalities developed in AD patients compared to those without pulmonary abnormalities or AD. No significant differences were found in clinical features, among AD alone, AD with ILD and AD with nodules.

Conclusions: Pulmonary abnormalities were found in 70% in RA. AD was found in 55% of RA patients and coexisted with other pulmonary lesions such as ILD and nodular lesions. Patients with AD frequently showed newly emerging or worsening pulmonary lesions, regardless of the coexistence of other pulmonary lesions. Thus, AD is shared and critical pulmonary abnormality in RA.

FRI0135 TREATMENT OF JAPANESE EARLY RHEUMATOID ARTHRITIS PATIENTS WITH LOW-DOSE PREDNISOLONE FOR MAXIMUM 1 YEAR LEADS TO EARLIER IMPROVEMENT OF DISEASE ACTIVITY AND DOES NOT WORSEN BONE METABOLISM STATUS AND RATES OF NEW COMPLICATIONS

E. Torikai, M. Suzuki, Y. Matsuyama. *Orthopaedic Surgery, Hamamatsu University School of Medicine, Hamamatsu, Japan*

Background: Glucocorticoid (GC) therapy for rheumatoid arthritis patients improves joint inflammation and destruction; however, it is associated with risk of complications such as osteoporosis, diabetes (DM), and cardiovascular (CV) disease. Although EULAR recommends that low-dose GC should be administered for up to 6 months, the ideal dose and duration of GC use remain unresolved.

Objectives: To investigate the efficacy and safety of low-dose GC therapy in addition to other disease-modifying antirheumatic drugs (DMARDs) for maximum 1 year in Japanese early RA patients.

Methods: Ninety-six Japanese RA patients with disease duration of <2 years were included. Patients were treated with a T2T strategy; if disease activity did not improve within 3 months, their DMARDs were replaced with alternatives or additional DMARDs were added. We excluded patients with a history of prior complications, including CV disease, DM, or vertebral fracture. We classified patients into two groups, one was group treated with DMARDs alone (N group; 35 females and 10 males) and the other with maximum 5 mg of GC for maximum 1 year along with DMARDs (GC group; 40 females and 11 males). The mean ages of the N and GC groups were 56.3 and 60.9 years, respectively. Thirty-four percent of patients were treated with MTX monotherapy, 20.9% were treated with combined conventional synthetic DMARD with MTX, and 31.3% were treated with a biological agent. Regarding MTX or biological agent use rates, no significant statistical differences were observed between the groups. We evaluated the change of DAS28-CRP scores for 3 years, bone metabolism makers [urine type I collagen cross-linked N-telopeptide (NTX), serum tartrate-resistant acid phosphatase 5b (TRACP5b), serum bone-specific alkaline phosphatase (BAP), and serum osteocalcin (OC)], bone mineral density (BMD) of lumber spine (L-spine) and femoral neck (FN) and the rate of new complications. Comparisons of BMD and the rate of new complications were made at baseline and 3 years after initiating GC treatment.

Results: There were no significant differences in DAS28-CRP scores at baseline. In the GC group, the mean GC dose was 2.46 mg/day. At 1 month after treatment, there was a significant difference in the improvement rate of DAS28-CRP scores in the GC group compared with the N group. However, no significant difference was observed between the two groups at 3 months or more post-treatment (Fig.1). None of the bone metabolism makers and BMD deteriorated in the GC group and there were no statistical differences between both groups (Table.1, Fig.2). New complications occurred in four cases in the N group (one, vertebra fracture; one, CVD; and two, high HbA1c levels) and four cases in the GC group (two, vertebrae fractures and two, high HbA1c levels). There were no significant differences in the rate of new complications between both groups.

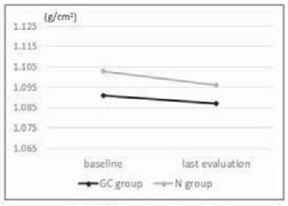

Fig.2(a) BMD of L-spine

(GC group)	baseline	1 year	3 year
NTX (nmolBCE/mmolCr)	45.9± 24.5	48.3± 25.1	46.5± 23.9
TRCP5b (mU/dL)	376± 181	388± 176	369± 169
BAP (μg/L)	17.1± 6.5	16.1± 6.0	17.6± 6.4
OC (ng/mL)	13.4± 6.5	12.6± 6.4	13.9± 6.9
(N group)	**baseline**	**1 year**	**3 year**
NTX (nmolBCE/mmolCr)	44.1± 22.9	44.7± 23.5	44.0± 23.0
TRCP5b (mU/dL)	359± 172	364± 165	365± 164
BAP (μg/L)	17.9± 6.5	17.4± 6.0	17.0± 6.4
OC (ng/mL)	13.7± 6.1	13.6± 6.2	14.1± 6.5

Table. bone metabolism makers

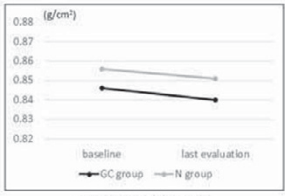

Fig.2(b) BMD of FN

Conclusions: The treatment of early rheumatoid arthritis by low-dose GC for maximum one year enables earlier improvement of disease activity and does not worsen bone metabolism status or the rate of new complications. The therapy does not pose a problem in the middle term. This study confirms that use of GC in RA patients leads to patient satisfaction.

FRI0136 OVARIAN RESERVE, AS ASSESSED BY MEASURING SERUM ANTI-MÜLLERIAN HORMONE LEVELS, DECLINES MORE RAPIDLY OVER TIME IN RHEUMATOID ARTHRITIS PATIENTS COMPARED TO CONTROLS

J. Brouwer[1,2], J.S. Laven[1], J.M. Hazes[2], N.S. Erler[3], J.A. Visser[4], R.J. Dolhain[2]. *[1]Division of Reproductive Medicine - Department of Obstetrics and Gynaecology; [2]Department of Rheumatology; [3]Department of Biostatistics; [4]Department of Internal Medicine, Erasmus MC University Medical Center Rotterdam, Rotterdam, Netherlands*

Background: The ovarian reserve in women with rheumatoid arthritis (RA) may be compromised, based on a reduced fertility[1] and a younger age at menopause[2]. Serum anti-Müllerian hormone (AMH) levels are a proxy for the ovarian follicle pool, and are the most reliable predictor of the age at which menopause sets in.

Objectives: Our objectives were to study the intra-individual change in AMH levels in female RA patients, and to study the effect of RA-related factors on the decline of AMH levels over time.

Methods: Female RA patients from a nationwide prospective cohort study (PARA study) in 2002–2008, were re-assessed in 2015–2016. Serum AMH levels were measured using the pico AMH assay (provided by Ansh Labs, Texas, USA) and compared to healthy controls (Lie Fong, 2012)[3]. A linear mixed model was built to assess the effect of RA-related clinical factors on the decline of serum AMH levels over time.

Results: 128 women were re-assessed at a mean age of 42.6±4.4 years, with a median disease duration of 15.8 (IQR 12.7–21.5) years. The participants appeared a more fertile selection of the original PARA cohort. The mean time between the first and the follow-up assessments was 10.7±1.8 years. At follow-up, more patients had AMH levels below the 10th percentile of controls (39%; 95% CI 31 – 48%), than at baseline (16%; 95% CI 9.3–22%). The linear mixed model showed only a significant effect of age, and no significant effect of RA-related factors on the decline of serum AMH levels over time.

Conclusions: This is the first longitudinal study on AMH levels in women with RA, and is showing that AMH levels in RA patients decline more rapidly over time compared to healthy controls. This indicates that the disease process of RA has a negative impact on the ovarian reserve of young pre-menopausal RA women.

FRI0137 PRESENCE OF THYROID DISEASE IN RHEUMATOID ARTHRITIS PATIENTS IS PREDICTOR OF WORSE INITIAL TREATMENT RESPONSE: AN OBSERVATIONAL, COHORT STUDY

A. Emamifar[1], R. Hviid Larsen[2], R. Asmussen Andreasen[1], I.M. Jensen Hansen[1,3]. *[1]Rheumatology; [2]Medicine, Svendborg Hospital, Odense University Hospital, Svendborg; [3]DANBIO, Copenhagen, Denmark*

Background: Rheumatoid Arthritis (RA) should be treated instantly to prevent further joint destruction. The first few months after treatment initiation are critical for long-term treatment outcome.[1]Patients with RA are at increased risk of thyroid disease with direct effect on initial treatment response.[2]

Objectives: To define the prevalence of thyroid disease among RA patients as well as to evaluate the correlation between presence of thyroid disease in RA patients and initial treatment response.

Methods: All RA patients who were registered in the local part of Danish Danbio registry were included in this study. Patients' demographic data, serology results including rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibody (anti-ccp) as well as disease activity score in 28 joints-C-reactive protein (DAS28-CRP) at the time of diagnosis and after 4 months (±1–2 months) of treatment initiation were extracted. ∆DAS28 was calculated as follows: DAS28 at the time of diagnosis – DAS28 after 4 months (±1–2 months) of treatment initiation. Patients' electronic hospital records including laboratory results were reviewed to reveal if they had been diagnosed with thyroid disease.

Results: 1035 patients were included in the study (Table 1). Prevalence of thyroid disease was 11.8% (122/1035). Multiple linear regression analysis showed a negative correlation between ∆DAS28 and presence of thyroid disease adjusted for age, gender, disease duration, RF, anti-ccp and DAS28 at the time of diagnosis (Regression coefficient (95% Confidence Interval): -0,157 (-0.312 to -0.002), P=0.047) (Table 2). RA patients with thyroid disease had significantly poorer initial response to RA treatment compared to patients with isolated RA after 4 months of treatment (P=0.002).

Table 1. Demographic and disease characteristics of the included (N=1035) patients

Age (years), Mean ± SD:	67,1±14,5
Gender (%) Female	656 (63.4%)
DAS28 at time of diagnosis, Mean ± SD:	4.5±0.9
DAS28 after 4 months of treatment, Mean ± SD:	3.1±0.8
∆DAS28, Mean ± SD:	1.4±1.0
IgM Rheumatoid Factor (%) Positive	607 (58.6%)
Anti-ccp (%) Positive	532 (51.4%)

Table 2. Results of Multiple linear regression analysis

Variables	Coefficient	t-stat	Confidence Interval		P value
			Lower 95%	Upper 95%	
Age	0,002	1.427	-0.001	0.006	0.154
Male gender	0,056	1.051	-0.049	0.161	0.293
disease duration	-0,003	-1.093	-0.009	0.002	0.275
Rheumatoid Factor positivity	0,010	0.159	-0.118	0.139	0.873
Anti-ccp positivity	-0,030	-0.456	-0.158	0.098	0.649
DAS28 at diagnosis	0,717	26.173	0.664	0.771	>0.001
Presence of Thyroid Disease	-0,157	-1.988	-0.312	-0.002	0.047

Conclusions: Presence of thyroid disease in RA patients worsens initial treatment response and is suggestive of poor long-term prognosis. The authors propose routine measurement of serum thyroid stimulating hormone (TSH) in all RA patients at the time of diagnosis and with yearly interval.

FRI0138 LUNG INVOLVEMENT IN RHEUMATOID ARTHRITIS – A PORTUGUESE REALITY

A.C. Duarte, S. Sousa, A. Cordeiro, M.J. Santos, J. Canas da Silva. *Rheumatology, Hospital Garcia de Orta, Almada, Portugal*

Background: Rheumatoid arthritis (RA) is associated with a wide range of extra-articular manifestations. Non-cardiac thoracic manifestations occur in approximately 5–20% and can affect the pleura, pulmonary parenchyma, airways and vasculature[1]. Besides, patients can also experience drug-induced pulmonary disease related to RA medication[2].

Objectives: To characterize lung involvement and factors associated with lung disease in a cohort of RA patients.

Methods: Retrospective analysis of RA patients followed in our Rheumatology department. Lung involvement was defined by the presence of imagiological/histopathological alterations described in the spectrum of rheumatoid arthritis-associated lung disease in either symptomatic or asymptomatic patients. Logistic regression analysis was used to evaluate demographic and clinical features independently associated with lung disease.

Results: In total, 532 RA patients were analysed, 400 females, mean age of 63.6 (±13.8) years and mean disease duration of 11.8 (±9.5) years. Rheumatoid factor (RF) was positive in 69% and anti-cyclic citrullinated peptide antibodies (ACPA) in 60%; 8.8% were current smokers and 7.5% past smokers. Methotrexate (MTX) was the most prescribed synthetic DMARD (85.9%) and biologics were used in 32.3% of patients.

Lung involvement was documented in 38 patients (7.1%; 95% CI 5.2%>9.7%). The specific types of lung disease are presented in figure 1. The mean interval between articular and pulmonary symptoms was 6.1 (±6.4) years, with only 1 patient having lung involvement diagnosed prior to joint manifestations. Most patients were female (73.7%), 78.9% RF positive, 68.4% ACPA positive and 29% current/previous smokers. Secondary Sjögren's Syndrome was present in 5 patients. Eighteen (47%) patients were medicated with MTX, 16 of them initiated therapy before developing respiratory symptoms and 10 (26.5%) with biologics (4 with TNF antagonists, 3 with tocilizumab, 2 with rituximab and 1 with abatacept). Most patients (92.1%) had abnormal chest x-rays, but only 47.4% were symptomatic. Pulmonary function tests (PFT) were abnormal in 31.6% of patients and 47.4% had diffusing capacity for carbon monoxide (DLCO) less than 75% predicted (7 had no DLCO estimated). Respiratory insufficiency was present in 7 (18.4%) patients. In multivariate logistic regression analysis, current MTX use (OR: 2.1 [1.02–4.33]), RF positivity (OR: 3.48 [1.18–10.25]) and older age (OR: 1.03 [1.00–1.06)] were independently associated with lung involvement.

Type of lung involvement	**UIP** (n=10)	**NSIP** (n=8)	**Bronchiectasis** (n=16)	**Follicular bronchiolitis** (n=1)	**Pleural involvement** (n=3)
Female	7	6	14	1	0
RF positive	8	7 (1 missing)	12 (1 missing)	1	2 (1 missing)
Smoking	4 (1 missing)	3	3	0	1
PFT	4 normal	5 normal	9 normal	1 normal	3 normal
	3 restrictive	1 restrictive	4 restrictive		
	1 obstructive	1 restrictive + obstructive	2 obstructive		
DLCO < 75%	7	3 (2 missing)	7 (3 missing)	0	2

UIP – usual interstitial pneumonia; NSIP – nonspecific interstitial pneumonia

Figure 1 – Specific types of lung involvement and its characteristics

Conclusions: Lung involvement was present in 7.3% of our cohort and was diagnosed in average 6.1 years after the first joint manifestations. RF positivity, older age and current MTX use are associated with lung disease.

As most patients remain asymptomatic, lung involvement is probably under-diagnosed in RA patients. Besides, in clinical practice exams that can detect preclinical disease, such as high-resolution chest computed tomography, are usually reserved for symptomatic patients or with an abnormal chest x-ray.

FRI0139 PREVALENCE OF HYPERPARATHYROIDISM IS HIGHER AMONG RHEUMATOID ARTHRITIS PATIENTS COMPARED TO THE GENERAL POPULATION: AN OBSERVATIONAL, COHORT STUDY

A. Emamifar[1], L. Stilgren[2], R. Hviid Larsen[3], R. Asmussen Andreasen[1], I.M. Jensen Hansen[1,4]. *[1]Rheumatology; [2]Endocrinology; [3]Medicine, Svendborg Hospital, Odense University Hospital, Svendborg; [4]DANBIO, Copenhagen, Denmark*

Background: Patients with Rheumatoid Arthritis (RA) are at increased risk of different comorbidities which may affect long-term prognosis.[1] Primary hyperparathyroidism (PHP) is a metabolic disorder of one or more of the parathyroid glands with a prevalence of 1–7 per 1000 adults.[2]

Objectives: To define the prevalence of PHP in patients with RA.
Methods: All RA patients who were registered in the local part of Danish Danbio registry were included in this study. Patients'demographic data and serology results (rheumatoid factor (RF) and anti-cyclic citrullinated peptide antibody (anti-ccp)) were extracted from Danbio. Patients' electronic hospital records including laboratory results (Parathyroid hormone (PTH) and calcium levels) were reviewed to reveal if they had been diagnosed with PHP as well.
Results: 1035 RA patients were included in this study [table 1]. Prevalence of PHP was 2.8% (29/1035). RA Patients with PHP had significant longer disease duration compared to patients with isolated RA (p=0.003). There was no significant difference between RA patients with and without PHP with respect to age, gender, RF and anti-ccp positivity (Table 1).

Table 1. Association of PHP with age, gender, disease duration, Rheumatoid Factor and Anti-ccp in RA patients

Variables:	RA patients with PHP N=29	RA patients without PHP N=1006	P value
Age	69.9±10.6	67.0±14.6	0.170
Gender, Female	23 (79.3%)	633 (62.9%)	0.107
Disease Duration	15.2±9.5	9.4±9.6	0.003
Rheumatoid Factor, Positive	20 (69%)	587 (58.3%)	0.393
Anti-ccp, Positive	19 (65.6%)	513 (51%)	0.241

RA: Rheumatoid Arthritis, PHP: Primary Hyperparathyroidism.

Conclusions: Clinicians should pay special attention to higher prevalence of PHP among RA patients compared to the general population. Presence of PHP in RA patients may aggravate the effect of RA on bones and joints by means of interaction with cytokines and inflammatory markers involved in RA. Concurrent PHP can be diagnosed at early stage by testing PTH and calcium levels which minimize the future morbidities e.g. fracture due to osteoporosis.

FRI0140 COMORBIDITY AND SURGERY HISTORY OF RHEUMATOID ARTHRITIS PATIENTS WHO ARE RECEIVING BIOLOGICAL AGENT

B. Armagan[1], A. Sari[1], A. Erden[1], L. Kilic[1], E.C. Erdat[2], O. Karadag[1], A. Akdogan[1], S. Apras Bilgen[1], U. Kalyoncu[1], I. Ertenli[1], S. Kiraz[1]. *[1]Hacettepe University, Department of Internal Medicine, Division of Rheumatology; [2]Department of Internal Medicine, Hacettepe University, Ankara, Turkey*

Background: Rheumatoid artritis (RA) is a chronic and autoimmune disorder that primarily affects middle and older ages. Comorbidities are important during RA treatment.
Objectives: We aim to determine the frequency of comorbidites and surgical history in the RA patients who receive biological agents.
Methods: Hacettepe University Biologic Registry (HUR-BIO) includes demographic and clinical data of patients treated with biological agent since 2005. By August 2016, 1235 RA patients were recorded in the database. Age, gender, smoking habits, disease duration, rheumatoid factor, anti citrullinated peptide (CCP), C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), current and previous treatments, comorbidites and surgical history of patients were analyzed. Comorbidites and surgery history were determined by patients medical records. Disease activity was estimated by the 28-joint activity calculator- C reactive protein (DAS28-CRP). Functional assessment was evaluated by the Health Assessment Questionnaire (HAQ).
Results: Mean age (SD) of the patients (79,8% women) was 53,1 (12,6) and the mean disease duration was 11,0 (7,7) years. Of patients, 166 (16,6%) were older than 65 years. A total of 630 (63%) patients education level were less than high school, 197 (19,7%) of the patients were graduated from university. Smoking habitus of patients was as follows, 599 (59,9%) never smoked, 189 (18,9%) current smoker and 212 (21,2%) ex-smoker. At least one cardiovascular risk factor was detected in 699 (69,9%) patients. Comorbidities and surgical history of patients were shown in the table below. Patients with at least one comorbidity had less frequently female (77.3% vs 84.5%, p=0.007), high seropositivitly of RF (66% vs 57.1%, p=0.004), high patient global assessment (4.4±2.5 vs 3.9±3.9, p=0.007), high fatique score (4.6±3 vs 3.9±3.1, p=0.001), high pain score (4.8±2.5 vs 4.0±2.8, p=0.009), DAS-28 (3.43±1.39 vs 3.17±1.48, p=0,009) and high HAQ score (0.72±0.59 vs 0.58±0.54, p=0.001) than patients without comorbidities.
Conclusions: Comorbidities and past surgical history should be considered in RA patients when biological therapy is indicated. Comorbidities is one of the important conditions for physicians to manage patients. Cardiovascular, chronic viral infection such as hepatitis B and C, tuberculosis and cancer have to be investigated to start biological treatments. Surgical history such as cataracts, ortopedic surgery were also important for clinicians. HURBIO data demonstrated that patients with at least one comorbidities reflects more negative patient outcome measures.

Table: Comorbidity and surgery details in RA patients

FRI0141 LEFT VENTRICULAR CONCENTRIC REMODELING IS MORE PREVALENT IN RHEUMATOID ARTHRITIS: A CASE-CONTROL STUDY

D.Á. Galarza-Delgado[1], J.R. Azpiri-López[2], I.J. Colunga-Pedraza[1], F.J. Torres-Quintanilla[2], R.E. Ramos-Cázares[1], A. Valdovinos-Bañuelos[1], A. Martínez-Moreno[3], R.I. Arvizu-Rivera[3], R. Vera-Pineda[3], J.A. Cárdenas-de la Garza[3], M.A. Garza-Elizondo[1], M.A. Benavides-González[2], J.A. Silva-Ortiz[2]. *[1]Rheumatology; [2]Cardiology; [3]Internal Medicine, Hospital Universitario "Dr. José Eleuterio González", UANL, Monterrey, Mexico*

Background: Patients with rheumatoid arthritis (RA) have a higher risk to develop cardiovascular complications than general population (1), leading to a decrease in life expectancy of 3 to 10 years (2). RA is associated to increased left ventricle mass, pericardial effusion and diastolic dysfunction (3).
Objectives: The aim of this study was to assess the structure and function of the left ventricle in patients with RA and compare the results with matched controls.
Methods: We designed an observational cross-section case-control study. Patients diagnosed with RA according to the 1987 ACR and/or 2010 ACR/EULAR classification criteria, 40–75 years old, with no overlap syndromes, atherosclerotic cardiovascular disease or hypertension were included. Subjects for the control group were matched by sex, age and comorbidities. A board-certified cardiologist performed a transthoracic echocardiogram.
Results: We included a total of 44 RA-patients and 26 control subjects. Table 1 summarizes the demographic characteristics for each group. Left ventricular concentric remodeling (LVCR), defined as a relative wall thickness (RWT) >0.42 cm and a left ventricular mass index (LVMI) ≤ 95 gm/m^2 in women and ≤ 115 gm/m^2 in men, was found in 14 patients (32.6%) of the RA-group and 2 subjects (8%) of the control group; this difference was statistically significant (p=0.021).
When we analyzed general abnormalities of left ventricle (either LVCR or left ventricular concentric hypertrophy [RWT >0.42 cm and LVMI >95 gm/m^2 in women, >115 gm/m^2 in men]) we found 15 RA patients (34.1%) with abnormalities and 3 subjects in the control group (11.5%) (p=0.037). There were no statistically significant differences among the groups in LVMI, diastolic dysfunction, global longitudinal strain or ejection fraction.

Table 1. Demographic characteristics

	RA group (n=44)	Control group (n=26)	*p*
Age, mean ± SD	52.35±7.34	53.94±6.81	0.371
Disease duration (years), mean ± SD	10.682±8.3321	–	–
DAS-28 CRP, mean ± SD	3.36±1.42	–	–
Women, n (%)	43 (97.7)	24 (92.3)	0.279
Body Mass Index, mean ± SD	26.98±6.13	28.3±4.12	0.956
Active smoking, n (%)	4 (9.1)	0 (0)	0.113
Type 2 Diabetes mellitus, n (%)	2 (4.5)	2 (7.7)	0.584

DAS-28 CRP - Disease activity score 28 using C-reactive protein.

Conclusions: Left ventricle concentric remodeling is more prevalent in RA-patients when compared to controls. Further research is needed to determine the impact of these findings in the clinical prognosis of RA-patients.

FRI0142 NEUTROPENIA IN RHEUMATOID ARTHRITIS. INCIDENCE, PROGNOSTIC FACTORS, NATURAL HISTORY AND OUTCOME

G.E. Fragoulis[1], I.B. McInnes[1], D. Porter[2], S. Siebert[1] on behalf of SERA collaborators. *[1]Institute of Infection, Immunity and Inflammation, University of Glasgow; [2]Rheumatology, NHS Greater Glasgow and Clyde, Glasgow, United Kingdom*

Background: Neutropenia is an uncommon finding in the context of rheumatoid arthritis (RA). The incidence and association with RA features is not yet well-defined.
Objectives: To determine the incidence and severity of neutropenia in an early RA inception cohort, explore possible association with RA features and describe its impact on patient's management.
Methods: The Scottish Early Rheumatoid Arthritis (SERA) inception cohort prospectively recruited newly diagnosed RA patients (ACR-EULAR 2010 criteria), who were followed-up every 6 months. Patients who developed at least one episode of neutropenia (grade 1: <2000/μL, grade 2: <1500/μL, grade 3: <1000/μL, grade 4: <500/μL) were compared with patients who never developed neutropenia. Binominal logistic regression was performed, exploiting the enter model and using the occurrence of neutropenia as dependent variable.
Results: 77 episodes of neutropenia were observed in 60 (8.6%) out of 698 RA patients, who were followed up for a median (range) time of 18 (6–48) months. Neutropenia occured in 12 (0–120) [median (range)] months after RA diagnosis. The majority had mild neutropenia (grade 1: n=49, grade 2: n=9, grade 3: n=0, grade 4: n=2) and the mean ± SD number of neutrophils/μL was 1.68±0.35. Of the 77 neutropenic episodes recorded, coexistent lymphopenia was found in 13.0%, leukopenia in 70.1%, thrombocytopenia in 1.3% and anaemia in 32.5%. At the time of the neutropenia, most of the patients were in remission (DAS28<2.6: 53%, DAS28<3.2: 15.5%, DAS28≤5.1: 22.4%, DAS28>5.1: 8.6%). Neutropenia was a single episode in the majority (76.7%) of the patients and led to treatment discontinuation in 11.7% of them.
Patients who subsequently developed neutropenia, were more likely females (p=0.03) and non-smokers (p=0.0009) (Table 1). Treatment received for RA was comparable between the two groups. Binominal regression analysis confirmed female gender [p=0.017, Exp(B): 2.587] and not smoking [p=0.032, Exp(B): 2.880] as predictors of neutropenia development.
During total follow-up time, patients who had at least one episode of neutropenia they also manifested more commonly anaemia (p=0.04) and lymphopenia (p=0.03). The rate of infections/1000 person-months did not differ between patients who developed neutropenia and those who did not [5.75 (2.47–11.33) vs 4.1 (3.13–5.47), p=0.399].

Table 1. Baseline patients characteristics

	Neutropenia	No Neutropenia	p value
Patients characteristics	N=60	N=638	
Age, mean (mean±SD)	58.7±14.5	58.7±13.2	0.978
Female gender, No (%)	50 (83.3%)	414 (64.9%)	0.03
Total follow-up (months), median (range)	18 (6–48)	18 (6–48)	0.173
Smoking, No (%)	5 (8.3)	172 (27.0)	0.0009
Smoking (present/past/never)	5/23/32	172/240/225	0.002
Anaemia[a], No (%)	8/57 (14.0)	133/631 (21.1)	0.235
Thrombocytopenia[b], No (%)	0/57 (0.0)	0/631 (0.0)	1.000
Leukopenia[c], No (%)	1/57 (1.7)	3/631 (0.4)	0.293
Lymphopenia[d], No (%)	4 (7.0)	34/631 (5.4)	0.545
RF positive, No (%)	28/36 (77.8)	295/401 (73.5)	0.693
Anti-CCP positive, No (%)	34/48 (70.8)	410/527 (77.8)	0.282
Baseline DAS28 (mean±SD)	4.8±1.6	5.02±1.42	0.408

[a]Hb<120 g/L, [b]platelets <100000/μl, [c]white blood cells: $<4x10^9$/L, [d]lymphocytes: $<1x10^9$/L.

Conclusions: Neutropenia was observed in about 9% of patients in this early RA cohort. It was usually mild, transient and not associated with increased infection rates. Interestingly, not-smoking and female gender were associated with neutropenia.

FRI0143 PREVALENCE AND DETERMINANTS OF PERIPHERAL ENDOTHELIAL DYSFUNCTION IN A COHORT OF RHEUMATOID ARTHRITIS PATIENTS: PRELIMINARY RESULTS FROM A MULTICENTER CROSS-SECTIONAL STUDY

G.L. Erre[1,1], M. Piga[2], A.L. Fedele[3], M.L. Cadoni[1], G. Di Sante[3], I. Cangemi[2], A. Piras[4], M. Dessì[2], S. Mura[4], B. Tolusso[3], M.G. Longu[1], P.S. Saba[5], E. Gremese[3], A. Cauli[2], G. Ferraccioli[3], A. Mathieu[2], G. Passiu[4]. *[1]UOC Reumatologia, Dipartimento di Medicina Clinica e Sperimentale, Azienda Ospedaliero-Universitaria di Sassari, Sassari; [2]UOC Reumatologia, Azienda Ospedaliero-Universitaria di Cagliari, Cagliari; [3]UOC Reumatologia, Policlinico Gemelli, Roma; [4]UOC Reumatologia, Dipartimento di Medicina Clinica e Sperimentale, Università degli Studi di Sassari; [5]UO Cardiologia, Azienda Ospedaliero-Universitaria di Sassari, Sassari, Italy*

Background: RA patients suffer of a life expectancy significantly reduced with respect to the general population mainly due to cardiovascular (CV) disease. Endothelial dysfunction (ED), the early step in atherosclerotic process, is more evident in RA than in the general population. Peripheral arterial tonometry (PAT), a simple, rapid, and objective tool for evaluation of ED, measures small digital artery reactive hyperaemia after an ischemic stimulus in forearm. PAT shows high grade of correlation with coronary ED and predicts future CV events in the general population.
Objectives: To define prevalence and determinants of peripheral ED in RA.
Methods: Data from 633 RA patients free of previous CV events prospectively enrolled in the EDRA study* (ClinicalTrials.gov: NCT02341066) were analysed. Reactive hyperemia index (LnRHI) was evaluated by PAT using the EndoPAT2000 device: ED was defined by LnRHI <0.51. Linear and logistic regression analysis were performed to define independent predictors of ED in RA patients. A p-value <0.05 was considered statistically significant.
Results: Peripheral ED was documented in 212 out of 633 RA patients (33.3%). A linear regression for multiple variables (stepwise method) performed including into the models variables showing significant association with LnRHI at the univariate regression analysis (systolic blood pressure, HDL cholesterol levels, triglycerides levels, smoking habit and ACPA positivity; Age and gender were forced) showed that only higher levels of triglycerides [B coefficient (95%IC) = -0,001 (-0,001–0,00); $p<0.05$] negativity for ACPA [B coefficient (95%IC) = -0,070 (-0,135–0,005); $p<0.05$] and smoking habit [B coefficient (95%IC) =0,01 (0,043–0,156); $p<0.05$] were independently related to lower values of LnRHI. No significant correlation between peripheral ED and RA activity (DAS-28, CDAI, SDAI, HAQ), burden of systemic inflammation (CRP, ESR) and type of immunosuppressive treatment (steroids, NSAIDs, DMARDs and bDMARDs) was found. At logistic regression analysis ACPA negativity [OR ((95%IC) = 1.57 (1.04–2.21); $p<0.05$] and smoking habit [OR ((95%IC) = 1.64 (1.06–2.53); $p<0.05$] indipendently conferred a major risk of peripheral ED.
Conclusions: This study demonstrates for the first time a very high prevalence of peripheral ED in patient with RA free of previous CV events. Triglycerides levels and smoking habit, among traditional cardiovascular risk factor, showed a significant correlation with lower peripheral ED. Surprisingly ACPA negativity confers an increased risk for ED in RA population. Moreover, other than expected, systemic inflammation does not appear to influence peripheral ED in RA population. In conclusion our data further support the notion that atherogenesis in RA is only partially driven by traditional CV factors. The negative association between ACPA and ED warrants further investigation.

FRI0144 EVALUATION OF FACTORS AFFECTING FATIGUE IN PATIENTS WITH RHEUMATOID ARTHRITIS

G. Kilinc Kamaci[1], S. Unsal Delialioglu[1], S. Ozel[1], F. Yurdakul[2], H. Bodur[2]. *[1]Ankara Physical Therapy and Rehabilitation Training and Research Hospital; [2]Ankara Numune Training and Research Hospital, Ankara, Turkey*

Background: Fatigue is a common and disturbing symptom in patients with Rheumatoid arthritis (RA) (1,2). Measuring fatigue, understanding its contributory factors, and treating it lead to better patient outcome (3).
Objectives: The aim of this study is to investigate the relation between fatigue and pain, functional status, disease activity in patients with RA and to determine the effect of fatigue on the quality of life of patients with RA.

Methods: A total of 141 patients (103 female, 38 male) who were diagnosed RA according to ACR (American College of Rheumatology) diagnostic criteria were included in the study. Fatigue Symptom Inventory (FSI) was used for evaluation of fatigue. While the disease activity was determined using the Disease Activity Score-28 (DAS28), the Health Assessment Questionnaire (HAQ) was used to determine the functional status. The pain intensity was determined using 10 cm Visual Analogue Scale-Pain (VAS-pain).
Results: The mean age of the patients is 54.67±10.70 years and the mean duration of illness is 14.31±10.89 years. When the relationship between fatigue and other factors was examined, a statistically significant relationship was found between FSI fatigue severity scores (maximum, minimum, mean, current), FSI duration scores (number of days felt tired, amount of time felt tired), FSI interference score and HAQ, number of swollen joints, number of tender joints, VAS rest and VAS motion values ($p<0.05$). There was a statistically significant lower correlation between FSI fatigue severity scores (at least, mean) and DAS28 (r: 0.216, r: 0.181, respectively). There was no significant relationship between FSI scores and age, duration of illness, steroid use
Conclusions: Fatigue affects patients independently of disease duration in patients with RA. Fatigue is associated with disease activity, functional status, and pain. For this reason, fatigue in RA patients should be considered as an important symptom that should not be overlooked and should be struggled.

FRI0145 DOES PAIN HAVE INFLUENCE ON HEALTH ASSESSMENT QUESTIONNAIRE DISABILITY INDEX (HAQ-DI) IN RHEUMATOID ARTHRITIS PATIENT? AN ATTEMPT TO EVALUATE EFFECTIVENESS OF PAIN VAS (PS-VAS) ON HAQ-DI IN REAL CLINICAL PRACTICE –

I. Yoshii[1], T. Chijiwa[2]. [1]*Rheumatology, Yoshii Hospital, Shimanto City;* [2]*Rheumatology, Kochi Memorial Hospital, Kochi, Japan*

Background: Health Assessment Questionnaire Disability Index (HAQ-DI) is the most important index in treatment for rheumatoid arthritis (RA) patient. HAQ-DI expresses patient's disability in daily life (ADL), and this is influenced by disease activity (ACT-HAQ) and joint structural damage (DAM-HAQ), and aging when patient gets older in senectitude (AGE-HAQ) (1–3). One more factor that possibly makes influence on HAQ-DI is patient's pain. However, this problem is not discussed at all.
Objectives: We have investigate patient's pain and its effect on HAQ-DI in our clinical data in order to evaluate whether pain influences on HAQ-DI, and to make assessment existence of pain related HAQ-DI (PAIN-HAQ)
Methods: RA patients who have been treated continuously for more than five years, who had visited later than October 31th, 2016, were picked up in this study. Patients average 28-joints disease activity score with C-reactive protein (DAS28-CRP), modified HAQ (mHAQ), Sharp/van der Heijde Score (SvdHS), age, and pain score calculated by visual analogue scale (PS-VAS) were calculated in fifth treatment year. Average values of these parameters have been calculated. Relationships among these factors have been investigated statistically using multiple linear regression analysis (MLR). After evaluation of relationship of each pairs of these factors, the relationship between HAQ-DI and the other factors had been evaluated from modified data of these patients in minimize the effect of parameters other than PS-VAS and data that minimized effectiveness of PS-VAS with MLR.
Results: 382 patients had been picked up. Their sex distribution was 87 for male and 295 for female, and their average values and standard deviations of age, DAS28-CRP, HAQ-DI, SvdHS, and PS-VAS were 68.99 and 13.47, 1.91 and 0.54, 0.43 and 0.55, 54.97 and 67.30, and 22.96 and 17.85, respectively. HAQ-DI demonstrated significant regression with all of DAS28-CRP, SvdH, age, and PS-VAS (<0.01). DAS28-CRP demonstrated positive correlation with PS-VAS, HAQ-DI, and SvdHS, but negatively correlated significantly with age (<0.01). PS-VAS demonstrated positive correlation with HAQ-DI and DAS28-CRP, but negatively correlated with SvdHS significantly (<0.01), while no significant correlation demonstrated with age. SvdHS demonstrated positive correlation with DAS28-CRP and HAQ-DI, but negative correlation with PS-VAS significantly (<0.01), while no significant correlation demonstrated with SvdHS. Age demonstrated positive correlation with HAQ-DI, but negatively correlated with DAS28-CRP (<0.01), while no significant correlation demonstrated with PS-VAS and SvdHS (Figure 1).
After minimizing the data effectiveness of DAS28-CRP, Age, and SvdHS on HAQ-DI, HAQ-DI demonstrated significant regression only with PS-VAS. When the effectiveness of PS-VAS was minimized, HAQ-DI demonstrated significant regression with parameters other than PS-VAS. Threshold of PS-VAS was 15mm.

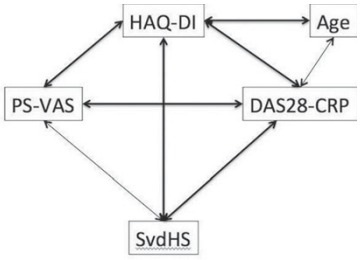

Figure 1: Schematic relationship among HAQ-DI, DAS28-CRP, SvdHS, Age, and PS-VAS. Thick lines demonstrate significant positive correlations, and thin lines demonstrate significant negative correlations.

Conclusions: These results suggested that HAQ-DI is influenced PS-VAS when it is no less than 15mm. Therefore, we conclude that HAQ-DI consists with PAIN-HAQ in adding with ACT-HAQ, DAM-HAQ, and AGE-HAQ.

FRI0146 ANTI-ELASTIN AND ANTI-ELASTASE AUTOANTIBODIES: POTENTIAL CLINICAL AND DIAGNOSTIC IMPLICATIONS IN RHEUMATOID ARTHRITIS

N.V. Nenasheva[1], A.S. Trofimenko[1,2], I.P. Gontar[1], L.A. Maslakova[1], O.A. Rusanova[1], O.V. Paramonova[2]. [1]*Research Institute for Clinical and Experimental Rheumatology;* [2]*Volgograd State Medical University, Volgograd, Russian Federation*

Background: Elastin is an ubiquitous molecule, presented in connective tissue matrix, including skin, ligaments, lungs, and blood vessels. Elastase is a characteristic protease, considerably presented in neutrophils and in pancreas. Autoantibodies (Ab) to elastin and to elastase are promising candidate biomarkers in rheumatoid arthritis (RA).
Objectives: To explore potential clinical and diagnostic utility of anti-elastin and anti-elastase Ab in RA.
Methods: The research was carried out in agreement with the WMA Declaration of Helsinki principles and was approved by Volgograd Regional Committee on Medical Ethics. All the patients signed the informed consent. We enrolled 106 adult patients with definite RA in Volgograd Municipal Hospital #25, the diagnosis have been established using ACR-EULAR criteria (2010). For ROC analysis calculations we used mixed control group consisted of 19 patients with ankylosing spondylitis, 32 with gout, 11 with psoriatic arthritis, and 22 with reactive arthritis. Serum anti-elastin and anti-elastase Ab concentrations were evaluated by ELISA, using antigens immobilized on magnetic polyacrylamide beads, which were previously described by our group [1]. Antibody concentrations were expressed as relative optical density units (ODU). The cutoff values for anti-elastin and anti-elastase Ab presence were 0.104 and 0.113 ODU, respectively; the calculations were performed using 34 healthy control sera. All the means and operation characteristics were expressed as values (95% confidence intervals). Differences were considered significant when $p<0.05$.
Results: In RA anti-elastin Ab were found in 37 (34.9%) patients, and the mean concentration was 0.128 (0.118–0.138) ODU. There was no significant correlation between DAS28 and anti-elastin concentrations, but the least marker was increased in patients with heart and kidney involvement, as well as in vasculitis patients, comparing to those who have no such manifestations (p=0.017, 0.046, and 0.009, respectively). We detected 58 (54.72%) anti-elastase positive RA patients, with the mean concentration 0.137 (0.103–0.171) ODU. Anti-elastase positive patients had significantly increased frequencies of anemia (p=0.025) and vasculitis (p=0.017) comparing to the negative subgroup. The prevalence of anti-elastase Ab was also increased along with RA activity. Concentrations of these two Ab were positively correlated (r=0.866, $p<0.001$).For anti-elastin Ab assay (cutoff point 0.112 ODU) diagnostic sensivity in RA patients was 72 (62–87)%, specificity 50 (41–64)%, AUC of ROC curve 0.703 (0.590–0.797). For anti-elastase Ab assay (cutoff point 0.115 ODU) the respective values were 77 (62–87)%, 81 (59–91)%, and 0.822 (0.675–0.923).
Conclusions: Anti-elastin and, increasingly, anti-elastase antibodies are valuable candidate markers to improve diagnosis of RA and, particularly, rheumatoid vasculitis and heart involvement. Further investigations are needed to assess sensivity and specificity of these markers being included in the comprehensive diagnostic algorithms.

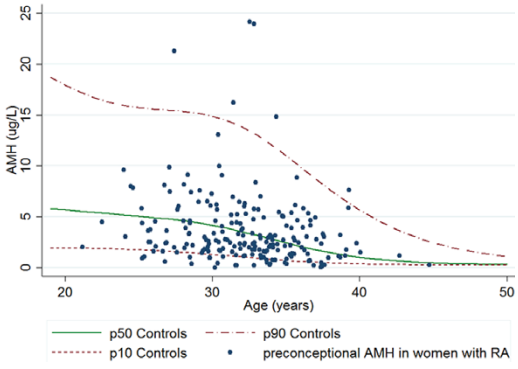
FRI0147 ANTI-MÜLLERIAN HORMONE LEVELS IN FEMALE RHEUMATOID ARTHRITIS PATIENTS TRYING TO CONCEIVE – THE ROLE OF OVARIAN FUNCTION IN TIME TO PREGNANCY IN A NATIONWIDE COHORT STUDY

J. Brouwer[1,2], J.S. Laven[1], J.M. Hazes[2], J.A. Visser[3], R.J. Dolhain[2]. *[1]Division of Reproductive Medicine - Department of Obstetrics & Gynaecology; [2]Department of Rheumatology; [3]Department of Internal Medicine, Erasmus MC University Medical Center Rotterdam, Rotterdam, Netherlands*



Background: Subfertility, a time to pregnancy (TTP) >12 months, is present in 40% of women with rheumatoid arthritis (RA) actively trying to conceive.[1] Since RA patients appear to reach menopause at a younger age[2], the reduced fertility may be caused by a lower ovarian reserve (OR). Serum anti-Müllerian hormone (AMH) levels are currently the most reliable way to measure the OR.

Objectives: Our objective was to study preconception AMH levels and their association with TTP in women with RA.

Methods: A post-hoc analysis was performed in patients of the Pregnancy-induced Amelioration of RA (PARA) cohort who were visited preconceptionally. Serum AMH levels were measured using the pico AMH ELISA assay (Ansh Labs, Texas, USA), and compared to converted[3] AMH values from a cohort of 554 healthy adult controls[4].

Results: Preconception serum was available in 209 women aged 32.1±3.9 years, of whom 45% were subfertile. The median AMH level was 2.5 ug/L (IQR 1.5–4.6). AMH levels were significantly lower compared to healthy controls ($p<0.001$), with 17.2% (95% CI 10.7 – 23.8%) of patients having levels below the age-specific 10th percentile.

Log-transformed AMH levels were negatively associated with age (-0.070 (95% CI -0.11;-0.031), p=0.001), and with the presence of anti-citrullinated protein antibodies (ACPA) (-0.38 (95% CI -0.71;-0.056), p=0.022). The associations remained significant in the multivariable analyses. AMH levels showed no significant association with TTP (HR 1.09 (95% CI 0.94;1.27), p=0.26).

Conclusions: Women with RA have lower AMH levels than healthy controls. Reduced AMH levels were more pronounced in ACPA positive patients, suggesting that the OR may be compromised more strongly in patients with a more severe disease. However, since preconception AMH levels were not associated with TTP, the reduced levels do not explain the reduced fertility in women with RA.

FRI0148 THE EFFECT OF TNF INHIBITORS, METHOTREXATE (MTX), AND THE OTHER DMARDS THERAPIES ON DIABETIC CONTROL IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA): TREATMENT WITH MTX ALONE IMPROVED DIABETES CONTROL MORE THAN TNF INHIBITORS PLUS MTX

K. Fujioka, M. Tangiku, M. Fuwa, I. Mori, T. Ishizuka. *Center of General Internal Medicine and Rheumatology, Gifu Municipal Hospital, Gifu City, Japan*

Background: It has been shown that inflammation directly influences insulin and glucose metabolism through cytokines such as TNFα and IL-6. It has also been reported that certain RA drugs such as TNF inhibitors, hydroxychloroquine, and MTX were associated with lower diabetes risk among people with RA, but it is still clinically unknown. On the other hand, it has been shown that MTX is involved in activation of intracellular AMP-kinase and promotes glucose uptake in skeletal muscle (Diabetes, 2015).

Objectives: We examined medical records of patients with new RA patients complicated with glucose intolerance to measure in HbA1c, body weight, and DAS28-ESR for 6 and 12 months treated with TNF inhibitors, MTX, and the other DMARDs.

Methods: Newly registered 20 RA patients complicated with glucose intolerance (HbA1c ≥5.6%) at our hospital from May 2013 to December 2015, have treated with as follows; Treatment with infliximab (1 case), golimumab (3 cases), and etanercept (2 cases) in combination with 4–12mg/week of MTX (group A: 6 cases, TNF inhibitors + MTX), MTX (4–10 mg/week) alone (group B: 8 cases MTX alone). The other DMARDs (group C: 6 cases, the other DMARDs including bucillamine (BCL) + salazosulfapyridine (SASP) + tacrolimus (TAC); 1case, BCL+SASP; 1case, BCL alone; 2 cases and SASP alone; 2 cases) had been registered. We have compared the changes of HbA1c levels, body weight, DAS 28-ESR from the beginning of the treatments and 6 and 12 months later. RA patients treated with glucocorticoid were excluded. Diabetic treatment were diet and exercise in all cases, but metformin (500 mg) and DPP4 inhibitor were used in 4 cases (Group A and C). However, each patient in Group B did not use antidiabetic agents. We analyzed these results with paired and unpaired *t* test using JMP12.2.0.

Results: These registered RA patients with female were 60.0%. The mean age were 62.1, 53.5 and 63.8 for group A, B, and C, respectively. There were significant changes in DAS28-ESR after treatment for 6 months in group A and B, respectively ($p<0.01$ in group A and $p<0.05$ in group B).

Groups A and B showed significant improvement of DAS 28-ESR after treatment with 12 months ($P<0.0001$ in group A, $p<0.01$ in group B), but no significant difference of DAS28-ESR in group C was observed. The mean reduction in HbA1c showed a significantly decreases only in the group B ($P<0.01$). There were no significant differences in body weight between the each group, but slightly an increase in body weight was observed in group B. There were no significant correlations between body weight and DAS28-ESR and its changes.

Conclusions: In this study, MTX was thought to contribute not only to suppress chronic inflammation but also to improve the glucose tolerance as compared with TNF inhibitors plus MTX and the other DMARDs. Further studies concerns about the interrelationship between glucose tolerance and RA treatments may require.

FRI0149 DOES THYROXIN SUBSTITUTION PREDICT NON-RESPONSE TO METHOTREXATE IN EARLY RA?

K. Waldenlind[1], S. Saevarsdottir[1], C. Bengtsson[2], J. Askling[1]. *[1]Rheumatology Unit, Department of Medicine, Solna, Karolinska Institute; [2]Institute of Environmental Medicine, Karolinska Institute, Stockholm, Sweden*

Background: Response to treatment varies widely between RA-patients. Our means to predict disease course and treatment response is limited, leading to substantial over- as well as under- treatment. Whereas female gender and smoking have been identified as predictors of non-response, the impact of autoimmune co-morbidities remains largely unknown. Autoimmune thyroid disease (AITD) is one of the most frequent autoimmune diseases in the population. AITD is more prevalent in RA-patients and has also been identified as a risk factor for RA. AITD can be readily identified via thyroxin substitution. We aimed at assessing the impact of prevalent AITD in relation to 3- and 6-month EULAR response to methotrexate in early RA.

Objectives: To investigate whether thyroxin substitution impacts response to methotrexate as the first-line therapy in RA.

Methods: We identified patients with incident RA (symptom duration <1 year), included in the Swedish Rheumatology Quality Register, July 2006 through 2015 (n=7009). All patients starting treatment with methotrexate and who had a follow-up visit at 3 months (n=4364) and/or at 6 months (n=3148) were included. Prevalent AITD was defined as prescription of thyroxin substitution before RA-diagnosis (n=347), based on linkage to the Swedish Prescribed Drug register,

and excluding participants with prescriptions for iodine-containing drugs or history of thyroid cancer (e.g. non-autoimmune cause of thyroxin use). We used a case-control design with thyroxin substitution as exposure, cases defined as EULAR DAS28 3- and 6-month non-responders, and controls defined as moderate/good responders at these time-points. Odds Ratios (OR) were calculated adjusted for sex, age, and HAQ.

Results: At 3 months, the proportion of thyroxin users did not differ between responders and non-responders 12% vs. 11%, (OR non-response =1.1, 95% CI 0.9–1.4). At 6 months, the corresponding figures were 13% vs. 11%, respectively, (OR non-response =1.3, 95% CI 1.0–1.7). However, a significant difference was observed in RF and/or ACPA positive patients at 6 months, where 15% of non-responders and 10% of responders used thyroxin (OR non-response=1.6, 95% CI 1.1–2.1), while no such difference was observed for seronegative RA. When stratified for gender, thyroxin substitution was significantly associated with non-response in men but not in women.

Table 1. Relative risk of prevalent AITD before RA-diagnosis in *non-responders* compared to *moderate and good responders* according to EULAR response criteria, at the 6 month follow-up visit among 3148 RA-patients starting methotrexate as first ever DMARD

	No of AITD in non-responders (718)/ moderate and good responders (887+1543)	Adj. OR (95% CI)
Overall	93 (13%)/254 (11%)	1.28 (0.98–1.66)
Sex		
Women	81 (16%)/231 (14%)	1.19 (0.89–1.57)
Men	12 (5.6%)/23 (2.8%)	2.20 (1.05–4.60)
Serostatus		
RF and/or ACPA positive	73 (15%)/163 (10%)	1.57 (1.14–2.14)
RF and ACPA Negative	20 (8.9%)/80 (11%)	0.82 (0.48–1.42)
Serostatus unspecified	0/11	NA

Values are the number. RA = rheumatoid arthritis; AITD = autoimmune thyroid disease; OR = odds ratio; 95% CI = 95% confidence interval.

Conclusions: This large real-life study of response to methotrexate in early RA suggests that AITD, measured as thyroxin replacement therapy, may be linked to treatment response in seropositive patients (and among males). Exploratory by nature, these findings call for replication.

FRI0150 EPIDEMIOLOGICAL DESCRIPTION OF PSYCHOLOGICAL, SEXUAL AND SLEEP DISORDERS IN PATIENTS WITH RHEUMATOID ARTHRITIS AND CORRELATION BETWEEN THEM AND DISEASE ACTIVITY

L. Villarreal[1], S. Henao[2], D. Buitrago-Garcia[3], P. Santos-Moreno[4]. *[1]Psychology and processes; [2]Patient service; [3]Epidemiology; [4]Rheumatology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia*

Background: Rheumatoid arthritis (RA) is the prevalent autoimmune inflammatory arthritis found in adults, with the worldwide prevalence ranging from 0.4% to 1.3%. Psychological disorders can be underestimated in this population; on the other hand studies had shown that the daily experience with RA can lead to sleep, psychological and sleep disorders.

Objectives: To characterize a population with RA and to describe the psychological, sexual and sleep disorders in a specialized rheumatology center in Bogotá Colombia.

Methods: We perform a cross-sectional study of patients attending to our psychology consultation the information was collected through semi-structured interviews, also using classificatory criteria of pathologies described in CIE 10 diagnostic manual, applying descriptive epidemiology for continuous variables, measure of central tendency and dispersion for qualitative and categorical variables through percentages and averages.

Results: We included 1398 patients attending to our psychology consultation. Mean age was 55 years ± 8; 80% were female and 20% male. Mean DAS28 was 2.6±1.3, mean HAQ was 1.6±1.6; patients had the disease for an average of 12 years ± 8; 41% of patients had comorbidities associated with non-autoimmune disease, 14% comorbidities related to autoimmune disease; 35% of our patients did not report other comorbidities. Most of patients were married 60%, followed by divorced 19%, single 14% and widowed 7%. Regarding occupation 33% were employees, 25% were housekeepers or retired due to age, 12% were retired due to disabilities, and 3% unemployed. Of the total population 45% had elementary school, 32% high school, 8% college education, 7% graduate education and 7% were illiterate. 17% of patients lived alone. Regarding psychological factors 25% had any mood disorders, 13% sleep disorders, 12% somatomorphic disorders, 6% sexual dysfunction, 2% dementia, 4% eating disorders and 38% reported no to have any of the above. Concerning sexual disorders, 38% reported no to have any sexual activity, 32% reported to have a satisfactory sexual life, 11% dyspareunia, 9% had an unsatisfactory sexual life, 5% loss of desire, 3% premature ejaculation and 2% orgasmic decrease. When the psychologist asked about sleep disorders 69% reported no to have any, 25% primary insomnia, 1% hypersomnia, 3% OSAS and 2% alterations on the circadian rhythm. There was a statistical association between psychological and sexual disorders, sleep and sexual disorders and, psychological and sleep disorders. Disease activity was associated only with sleep disorders.

Conclusions: Not only DMARDs disease management should be a priority for RA patients, factors such as sleep, sexual and psychological are important because one third of patients have it; on the other hand there is a interdependence between them and disease activity. Thus, it is important to have a multidisciplinary care team for the patient with RA, including a psychologist that can manage this kind of conditions and if necessary refer to a psychiatrist consultation.

FRI0151 DISEASE COURSE IN SERONEGATIVE RA PATIENTS CLASSIFIED ACCORDING TO THE 2010 ACR/EULAR CRITERIA

L.B. Nordberg[1], S. Lillegraven[1], A.-B. Aga[1], I.C. Olsen[1], E. Lie[1], H.B. Hammer[1], T. Uhlig[1], D. van der Heijde[2], T.K. Kvien[1], E.A. Haavardsholm[1] on behalf of the ARCTIC study group. *[1]Diakonhjemmet Hospital, oslo, Norway; [2]Leiden University medical center, Leiden, Netherlands*

Background: The development of the 2010 classification criteria for rheumatoid arthritis (RA) has led to a redefinition of the patient population, including classification of seropositive versus seronegative patients. In our recently published study of DMARD naïve early RA patients fulfilling the 2010 ACR/EULAR criteria, we found seronegative patients to have markedly higher disease activity at time of diagnosis, compared to seropositive patients.[1] There is very limited information about the disease course of seronegative patients classified according to the new criteria.

Objectives: Our aim was to examine the disease course of seronegative early RA patients fulfilling the 2010 ACR/EULAR criteria.

Methods: In the treat-to-target ARCTIC trial, DMARD-naive RA patients classified according to the 2010 EULAR/ACR criteria were randomised 1:1 to follow-up with or without ultrasound. Patients in both arms were treated according to the same DMARD escalation strategy. Patients were assessed at 13 visits during two years of follow-up.[2] We stratified the patients as seropositive (rheumatoid factor (RF)+, anti-citrullinated peptide antibody (ACPA)+, or both) or seronegative (RF- and ACPA-). At 24-month follow-up, measures of disease activity were compared across the groups using independent samples t-test, Mann-Whitney U test or chi square test as appropriate.

Results: A total of 230 patients were included, the mean (SD) age was 51.4 (13.7) years and 61.3% were female; 34 patients (14.8%) were seronegative. The mean age (SD) was 55.4 (2.7)/ 50.8 (0.9) years (p=0.07), mean (SD) disease duration was 7.7 (6.8)/7.0 (5.1) months (p=0.46), and 56/62% were females (p=0.48) in the seronegative/seropositive groups. At 24-month follow-up, measures of disease activity were similar between groups (table). There was a tendency towards more radiographic damage in the seronegative patients. Seronegative patients had a significantly greater reduction (0–24 months) in disease activity measures in terms of DAS, number of swollen joints, physician global and ultrasonography scores (table).

Table: Measures of disease severity at follow-up compared across serology status

Variable	Baseline			State at 24 months			p-value Δ0-24 months
	Seronegative N=34	Seropositive N=196	p-value	Seronegative N=34	Seropositive N=196	p-value

Values are median (25-75 percentiles) if not otherwise indicated. *Mean(SD).

Conclusions: In this study of early RA patients, seronegative patients had more inflammatory activity at baseline and a tendency to more radiographic damage, but disease activity after two years of treat-to-target therapy was similar to the seropositive patients. Our findings suggest that seronegative patients classified according to the new criteria respond to modern treatment strategies, with similar rates of patients reaching remission compared to seropositive patients.

FRI0152 RHEUMATOLOGISTS' EXPERIENCES AND VIEWPOINTS TOWARDS MANAGING RHEUMATOID ARTHRITIS IN ELDERLY PATIENTS: A QUALITATIVE STUDY

J. Nawrot[1], A. Boonen[1,2], R. Peeters[3], M. Starmans[3], M. Van Onna[1,2].
[1]Department of Internal Medicine, division of Rheumatology, Maastricht University Medical Center +; [2]School for Public Health and Primary Care, Maastricht University, Maastricht; [3]Rheumatology, Zuyderland Hospital, Heerlen, Netherlands

Background: The number of elderly individuals with rheumatoid arthritis (RA) is expanding in Europe, mainly due to an increase in life expectancy. As a result, management of these patients, e.g. the application of the treat-to-target and tight control principles, shall have to account for frailty and comorbidity. However, knowledge about how rheumatologists perceive and manage RA in the elderly patient population is limited.
Objectives: To explore the viewpoints of rheumatologists on management goals in elderly RA patients and the influence of factors such as age, frailty and comorbidity on these goals. Furthermore, experiences of rheumatologists with regard to outcome instruments to guide management in elderly patients were assessed.
Methods: A qualitative study involving semi-structured interviews with rheumatologists was conducted. Two readers independently annotated the transcripts of the interviews. Important concepts were taxonomically categorized and later combined in overarching themes by using NVivo 11.
Results: Seventeen rheumatologists were purposively sampled from nine medical centres (mean age: 44.8 years (SD 7.7 years); 29% male). High levels of frailty and comorbidity frequently influenced management goals of rheumatologists: in these cases, preserving an acceptable functional status prevailed over the treat-to-target and tight control principles. For instance, most rheumatologists accepted the presence of tender and swollen joints when overall functioning and social participation were not or only minimally impaired. In patients ≥80 years, age instead of frailty and comorbidity was the most prominent factor that steered management. On that line, almost all rheumatologists admitted that their management strategy is less driven by the result of the Disease Activity Score-28 (DAS28), since comorbidity (e.g. osteoarthritis) and an age-related physiological Erythrocyte Sedimentation Rate (ESR)-elevation might distort the DAS28 value. Instead, before adapting anti-rheumatic therapy, rheumatologists weighted the frailty and comorbidity levels of a patient and the functional consequences of these factors such as cognitive and physical decline, dependency and polypharmacy (quote 1, Table 1). This frequently resulted in a less future-oriented management approach that was not aimed at the maximal prevention of joint erosions and deformities (quote 2, Table 1). Rheumatologists reported that a lack of time to evaluate all comorbid conditions, as well as contradictory advices of other medical specialists often complicated the management of elderly RA patients.

Table 1. Illustrative quotes made by rheumatologists.

Quote	
1	'I sometimes ask my patients: what physical complaint bothers you the most? The RA, the heart failure or something else? Treat what actually limits an elderly patient.'
2	'I wonder if low-dosage prednisone for the rest of their lives is considerably worse than to initiate biological therapy and cause a life-threatening infection?'

Conclusions: Commonly accepted RA treatment paradigms such as treat-to-target and tight control are not automatically adopted in the elderly patient population. Maintaining a patient acceptable functional status prevails. Future RA management recommendations for elderly RA patients are needed and should account for factors such as frailty and comorbidity.

FRI0153 COMPARISON OF CARDIOVASCULAR RISK IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH BIOLOGICS VERSUS METHOTREXATE: RESULTS AT 24-MONTHS OF FOLLOW-UP

M. Khraishi[1], M. Stutz[2], A. Lewis[3], C. Molta[4], E. Rampakakis[2]. *[1]Rheumatology, Memorial University of Newfounbdland, St. John's; [2]JSS Medical Research, St-Laurent; [3]Epidemiology, Memorial University of Newfoundland, St.John's, Canada; [4]Rheumatology, MainLine Rheumatology Lankenau Medical Center, Philadelphia, United States*

Background: Rheumatoid arthritis (RA) is associated with increased risk of atherosclerotic cardiovascular (CV) disease. Treatment with conventional systemic disease modifying drugs (csDMARDs) such as methotrexate (MTX), as well as biological DMARDs (bDMARDs), has been shown to decrease CV risk. Although bDMARDs specifically target inflammation common to RA and atherosclerosis, whether or not cardioprotective effects associated with bDMARD use is superior to csDMARDs, remains to be determined.
Objectives: To investigate 10 year-CV risk, and incidence of new myocardial infarctions (MI), in RA patients treated with either MTX or bDMARD mono/combination therapy, in a Canadian routine clinical care setting
Methods: RA patients were prospectively followed between January 2011-March 2014. Parameters collected were patient demographics, RA disease activity parameters, traditional CV risk factors, lipid parameters, and 10-year CV risk, assessed using the Framingham Risk Score (FRS). Between-group differences in change from baseline to month 24 in FRS, disease activity, and lipid parameters were assessed with the two sample t-test or the Chi-Square statistic; within-group differences were assessed with the paired-samples t-test or the McNemar-Bowker test. Adjusted change in FRS was ascertained using general linear models, and logistic regression identified predictors of MI.
Results: A total of 517 RA patients receiving bDMARDs (n=313) or MTX (n=199), were included. Mean (SD) age was comparable between cohorts [57.57 (12.11) years vs. 59.58 (12.60), p=0.11; bDMARD vs. MTX, respectively], as was female gender (76.7% vs. 73.9%, p=0.268). Patients receiving bDMARDs had significantly ($p<0.05$) longer mean (SD) RA duration [12.63 (9.95) vs. 7.88 (6.94) years] and higher total comorbidities [3.96 (2.53) vs. 3.38 (2.32)]. Mean (SD) baseline FRS was 11.84 (9.38) vs. 12.36 (9.19) percent (p=0.564; bDMARDs vs. MTX, respectively), and patient distribution across low (62.3% vs. 54.8%), intermediate (9.9% vs. 12.2%) and high (27.8% vs. 33.2%) FRS risk categories was comparable (p=0.239).
At month 24, FRS category remained stable in bDMARD patients (low: 58.8%; intermediate: 14.2%; high: 27.0%; p=0.380), whereas a shift in FRS category was observed in MTX patients (low: 69.6%; intermediate: 10.1%; high: 27.0%, p=0.006). Within-group changes in FRS were significant for both MTX ($p<0.001$) and bDMARD patients (p=0.016). Adjusted mean change (SE) in FRS was higher in MTX patients [-1.37 (0.30) vs. -0.72 (0.25)], although not statistically different (p=0.098). Incidence of new MI was similar between groups (MTX: 3.8% vs. dDMARD: 3.0%; p=0.421), and predictors [OR (95% CI)] identified were: higher total comorbidities [1.45 (1.24, 2.20), $p<0.001$], age [1.07 (1.00, 1.13), p=0.037], and male gender [4.00 (1.38, 11.57), p=0.011].
Conclusions: Significant improvement in CV risk at 24 months was observed during treatment with both MTX and bDMARDs. As predictors of MI did not include several established CV risk factors, longer studies, as well as the development of an RA-specific tool, may permit better assessment of CV risk in RA patients.

FRI0154 THE TOLERABILITY OF VACCINATION AGAINST PNEUMOCOCCUS IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

M. Soloshenko[1], E. Alexeeva[1,2], T. Bzarova[1,2], S. Valieva[1], R. Denisova[1], O. Lomakina[1], K. Isaeva[1], E. Kashchenko[1], A. Karaseva[1]. *[1]Federal State Autonomous Institution "National Scientific and Practical Center of Children's Health"; [2]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*

Background: Children with chronic rheumatic diseases, including juvenile idiopathic artritis, are at high risk of bacterial and viral infections. The risk of complications and severity of infectious diseases are increased in immunosuppressive therapy due to given the long-term use.
Objectives: To evaluate the safety and tolerability of vaccination against pneumococcus in children with juvenile idiopathic arthritis.
Methods: The analysis included 39 patients with juvenile idiopathic arthritis who were in remission. Patients were divided into two groups, depending on the type of immunosuppressive therapy. Group 1 (n=24) consisted of patients receiving etanercept, mean age 5,4±2,5, observed 48 patient-years; Group 2 (n=15), patients who received methotrexate mean age 6,8±3,2, observed 30 patient-years. All patients had been vaccinated by 13-valent pneumococcal polysaccharide conjugate vaccine (13PPV). Recorded the incidence of infection diseases (such as pneumonia, tonsillitis, otitis media, etc.) in the 12 months prior to vaccination and 12 months after vaccination. All patients monitored the development of adverse events against the background of vaccination.
Results: The study showed a decrease in the incidence ofinfection diseases after vaccination in the first group from 5,4±1,66 to 1,7±0,77, in second group from 4,4±1,05 to 1,6±0 73, ($p<0.05$). Adverse events related to vaccination are presented in the table. Results of the study showed no relapse of the underlying disease following immunization. Adverse events related to vaccination are presented in the table.
Conclusions: The results showed a good tolerability of the vaccine, no relapse of the underlying disease following immunization, as well as a statistically significant ($p<0.05$) reduction in the incidence following immunization.

FRI0155 PREVALENCE OF HBV INFECTION AND RISK OF REACTIVATION ON BIOLOGIC TREATMENT: A POPULATION-BASED OBSERVATIONAL STUDY OF RHEUMATOID ARTHRITIS SUBJECTS IN A NORTHERN ITALY AREA

M. Meroni [1,2], L. Sangiovanni [3], E. Lupi [1], S. Fagiuoli [3], M. Limonta [1]. *[1] Rheumatology Unit, ASST Papa Giovanni XXIII, Bergamo; [2] Research Laboratory and Academic Division of Clinical Rheumatology, Internal Medicine Dept., University of Genova, Genova; [3] Gastroenterology and Transplant Hepatology Unit, ASST Papa Giovanni XXIII, Bergamo, Italy*

Background: The introduction of biologic agent's treatment in rheumatic diseases dramatically changed their outcome, but raised some concerns about infections recrudescence. Due to the prevalence of hepatitis B virus (HBV) among Italian general population (2–6%), the possibility of a disease reactivation in case of an immunosuppressive treatment has to be considered.
Objectives: Aim of this prospective, population-based observational study was to assess the prevalence of HBV (both in chronic carriers and recativated) rheumatoid arthritis (RA) patients in our setting; to verify if these findings were in line to the Italian and European-reported data; finally, to evaluate the final outcome of HBV RA subjects.
Methods: We enrolled the totality of RA patients treated by biologics and, therefore, consulting our Unit at least every 12 weeks, from December 2015 to January 2017. According to the current (ACR/EULAR and AASLD) guidelines, every subject was screened for HBV before starting biologic treatment. Descriptive statistics was performed. Acute infection; previous (resolved) infection; inactive and active carrier; and vaccine-immunized subjects were defined according to Tab. I.
Results: A totality of 265 RA patients (female 56.3%; male 43.7%; mean age 36+/-20 years) underwent biologic treatment after succeeding the screening (HBsAg+ subjects were excluded). The huge majority of them (82%) was treated by TNF-alpha inhibitors (TNFi), since the remaining received biologic agents with different mechanisms of action. We overall detected 33 (12.5%) inactive carriers, for whom HBsAg and HBV DNA periodical monitoring was suggested; in 3 of them (1.1% of the study population), HBV DNA became detectable, with a low viral load (<2000 UI/ml): they prosecute the biologic therapy after the introduction of the standard prophylaxis (lamivudine 100 mg daily) and a more strictly (periodic liver enzymes and liver ETG evaluation) monitoring.
In occasion of the screening, we observed 6 (2.3%) HBV-immunized (due to vaccine) and 6 (2.3%) previously infected (HBcAb+) patients: for the first ones no action is required, since the latter were put on standard prophylaxis before undergoing biologic agent and monitored. One of them (0.38%) developed, after 6 months of treatment, HBV reactivation with high-level (>2000 UI/ml) detectable DNA and liver enzymes elevation (>normality x3). She was therefore stopped from receiving biologic agent and put on entecavir 1 mg daily.

Interpretation of HBV serologic test results

	HBsAg	HBsAb	HBcAb IgM	HBcAb IgG	HBeAg	HBV DNA
Acute infection	POS	neg	POS	neg	POS	POS
Past infection (resolved)	neg	POS	neg	POS	neg	neg
Inactive carrier	POS	neg	neg	POS/neg	neg	neg
Active carrier	POS	neg	neg	POS	POS/neg	POS
Vaccine induced immunity	neg	POS	neg	neg	neg	neg

POS: positive; neg: negative; HBsAg: hepatitis B surface antigen; HBsAb: hepatitis B surface antibody;
HBcAb: hepatitis B core antibody; HBeAg: hepatitis B envelope antigen.

Conclusions: Our prospective, population-based observational study, performed in a first-level referring Hospital in a highly populated area, suggests some considerations. In a way, our data reported a significantly higher prevalence of HBV infection "contact" among our RA population, in comparison to the general one ($p<0.05$). This issue has previously been reported and could be justified but the generally higher HBV diffusion in certain area (i.e., Italy); by the age/ethnicity of the sample; and, finally, by the bias consisting in an extensive screening of these patients. On the other hand, our experience suggests that a tight monitoring of parameters predicting infectious flare should lead to a prompt diagnosis and a lower number of complications for these peculiar patients, as observed in our population.

FRI0156 DO CHANGES IN ADIPOCYTOKINES CORRELATE WITH CHANGES TO DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS? FINDINGS FROM THE TOMORROW STUDY

M. Tada [1], K. Inui [2], Y. Sugioka [3], T. Okano [2], K. Mamoto [2], T. Koike [3], H. Nakamura [2]. *[1] Orthopaedic Surgery, Osaka City General Hospital; [2] Orthopaedic Surgery; [3] Center of Senile Degenerative Disorders, Osaka City University Graduate School of Medicine, Osaka, Japan*

Background: Cytokines released from mast cells evoke inflammation and correlate with arteriosclerotic lesions and autoimmune disease[1]. The relationship between disease activity and lipid metabolism is a notable in research surrounding rheumatoid arthritis (RA). RA patients without disease control reportedly show high titers of leptin or adiponectin as adipocytokines[2].
Objectives: We analyzed the interaction between changes in disease activity and adipocytokines using data from the TOMORROW (TOtal Management Of Risk factors in Rheumatoid arthritis patients to lOWer morbidity and mortality clinical trial) study, a 10-year prospective study (registration number, UMIN000003876).
Methods: We analyzed data collected from the cohort of the TOMORROW study including 193 patients with RA and age- and sex-matched 194 healthy individuals (controls). We compared changes in leptin and adiponectin (Δleptin and Δadiponectin) in both groups between baseline and after 3 years. Correlations with the change in disease activity (ΔDAS28ESR) during 3 years and changes in Δleptin and Δadiponectin in RA were investigated by univariate analysis.
Results: Leptin levels increased in both groups. No significant differences in Δleptin were seen between RA (0.21 ng/ml) and controls (0.18 ng/ml; p=0.37). On the other hand, adiponectin was significantly decreased in controls (-3.3 μg/ml) compared to RA (-1.8 μg/ml; p=0.01). Negative correlations between Δleptin and Δadiponectin were detected in the RA group ($r=-0.29$, $p<0.01$). The correlation between adiponectin and DAS28ESR was positive both at baseline ($r=0.22$, p=0.01) and after 3 years ($r=0.18$, p=0.01). However, no such tendencies were seen for leptin. Table 1 shows details of the correlations with changes in adipocytokine. In terms of the relationship with ΔDAS28ESR, no correlation was seen with Δleptin ($r=0.07$, p=0.31) or Δadiponectin ($r=-0.01$, p=0.91). Changes in lipid metabolic markers and fat percentages were detected as predictive factors for Δadipocytokines.

Table 1. Correlations with changes in adipocytokine by univariate analysis

	R	*P*
ΔAdiponectin		
Baseline age	-0.199	0.006
ΔHigh-density lipoprotein	0.265	0.001
ΔFat percentage	-0.144	0.046
ΔDAS28ESR	-0.009	0.906
ΔLeptin		
Baseline age	0.258	0.001
ΔLow-density lipoprotein	0.347	0.001
Δfat percentage	0.554	0.001
Fall	-0.145	0.045
ΔDAS28ESR	0.074	0.311

Conclusions: Leptin increased and adiponectin decreased over the course of 3 years. Correlations between Δadipocytokines and ΔDAS28ESR were not detected. RA patients with high disease activity show higher adiponectin titers.

FRI0157 FERTILITY IN WOMEN WITH RHEUMATOID ARTHRITIS COMPARED TO HEALTHY CONTROLS

M.E.B. Clowse, G. McDaniel, A.M. Eudy. *Rheumatology, Duke University Medical Center, Durham, United States*

Background: Data suggest infertility is increased in women with rheumatoid arthritis (RA) compared to healthy women. Therefore, it is possible that diminished ovarian reserve and ovulatory dysfunction may be more common among women with RA.
Objectives: To compare differences in ovarian reserve and ovulatory frequency, as well as in self-reported infertility, between women with and without RA.
Methods: Women with RA aged 20–40 seen in a university clinic without a history of ovarian surgery or prior exposure to possible ovary-toxic medications were invited to participate in a cross-sectional survey. Healthy controls were women aged 20–40 without an autoimmune disease, matched for age and current use of hormonal contraceptives. Infertility was defined as a patient reporting physician-diagnosed infertility or being unable to get pregnant after 12 months of trying. Ovarian reserve was assessed by measuring anti-Müllerian hormone (AMH). In women who were not taking hormonal contraceptives, progesterone level was measured from a serum sample drawn between days 21 and 23 of the menstrual cycle. Anovulation was defined as a progesterone level <3 ng/mL. In

descriptive comparisons, differences in proportions were determined by Fisher's exact test, and ANOVA determined differences in means for continuous variables. Multivariate linear models estimated the effect of RA on AMH. In women with RA, the effect of RA medication use on AMH and anovulation was explored.

Results: There were 75 RA patients (83% Caucasian, 4% Hispanic, 77% with at least a college education) and 75 controls (64% Caucasian, 5% Hispanic, 88% with at least a college education). The majority of RA patients were married (60%), compared to 31% of controls. The mean age of both RA patients and controls was 32 years. Mean AMH in RA patients was 3.0 (SD: 2.6) compared to 3.9 (SD: 3.9) in controls (p-value: 0.1). In linear regression models adjusted for age, hormonal contraceptives and race (nonwhite vs. white), RA patients had a lower AMH than healthy controls (β: -1.05; 95% CI: -2.09, -0.005; p=0.05). There was no observed difference in the proportion of RA patients and controls with anovulation (19% in RA and 21% in controls). Infertility was reported by 12% of RA patients and 7% of controls (p=0.4).

Among RA patients, 81% reported having ever used methotrexate (MTX). The mean AMH for MTX users was 2.8 (SD: 2.4) compared to 4.0 (SD: 3.1) in never users (p=0.1). In linear regression models adjusted for age, hormonal contraceptives and race, RA patients who had ever taken MTX had a lower AMH than those who had never taken MTX (β: -1.49; 95% CI: -2.83, -0.15; p=0.03). However, when the cumulative dose of MTX was analyzed, there was no effect of cumulative MTX and AMH. Ever use of prednisone or NSAIDs did not appear to affect AMH levels in RA patients. Methotrexate, prednisone, and NSAIDs use did not have an observed effect on anovulation.

Conclusions: In this cross-sectional study, women with RA appeared to have a lower AMH level than healthy controls, suggesting ovarian reserve may be lower in these patients. In RA patients, previous use of methotrexate was associated with lower AMH, although no dose response of cumulative methotrexate exposure was observed. We did not observe a difference in anovulation between RA patients and controls. This suggests women with RA may have reduced fertility for reasons other than anovulation.

FRI0158 CAROTID ENLARGEMENT, BRACHIAL ARTERY FLOW-MEDIATED VASODILATATION AND SERUM LEVELS OF VON WILLEBRAND FACTOR IN RHEUMATOID ARTHRITIS

M. Veselinovic, A. Tomic-Lucic, V. Grbovic, V. Jakovljevic. *KC Kragujevac, Kragujevac, Serbia*

Background:

In rheumatoid arthritis (RA), higher mortality is mainly due to cardiovascular disease, as a consequence of accelerated atherosclerosis found in this diseases (1). Finding methods for assessing vascular dysfunction during the early stages of the disease is important, particularly in patient groups at high CV risk (2).

The use of noninvasive imaging techniques may help identify high-risk individuals who may benefit from active therapy to prevent clinical disease. Two of them, brachial ultrasonography to determine the presence of endothelial dysfunction and carotid ultrasonography to assess carotid intima-media wall thickness (IMT) have been found to be useful in the assessment of the cardiovascular risk of patients with RA (3). Prothrombotic markers have been shown to be able to predict cardiovascular risk in patients with RA (4).

Objectives: The first aim of the study was to investigate whether early signs of atherosclerosis and endothelial dysfunction, as measured by IMT and brachial artery flow-mediated (FMD) vasodilatation, were present in patients with RA compared with controls. The second aim was to analyze correlation between serum levels of vWf and IMT and FMD in patients with RA.

Methods: Fifty-two patients with RA and 30 matched healthy controls without clinically evident CV disease were studied. Brachial and carotid ultrasonography was performed to determine FMD and IMT, respectively. We also assayed immunological, inflammatory and metabolic laboratory markers.

Results: IMT was significantly higher in RA patients (1.00±0.16 mm) patients than in controls (0.89±0.13 mm) (P=0.001). FMD% was significantly lower in RA (9.16±7.03) as compared to controls (12.60±5.49) (p=0.005). It showed statistically higher values of vWF in the RA patients compared to the control group (p=0.01).

Patients with RA is divided into two groups according to the value of the IMT, below 9mm and 0.9mm and above. vWFact is statistical significantly higher in the group with thicker IMT (p=0.046), as well as the percentage of men (p=0.030). Other parameters did not show statistical significance in relation to the value of the IMT.

Conclusions: In patients with RA, increased serum levels of vWF and impaired FMD and IMT, indicating endothelial dysfunction and accelerated atherosclerosis. IMT measurement is the first candidate to evaluate against conventional evaluation of cardiovascular risk in prospective studies.

FRI0159 INFECTION AND MALIGNANCY ARE NOW THE MAJOR CAUSES OF DEATH IN AGGRESSIVELY TREATED RHEUMATOID ARTHRITIS PATIENTS

N. Chaplin[1], J. McNally[2], J. Kitchen[2]. *[1]St George's University of London, London; [2]Rheumatology, Royal Berkshire NHS Foundation Trust, Reading, UK*

Background: Patients with rheumatoid arthritis (RA) have an increased mortality compared to the general population. Previous studies have shown that this is attributable to cardiovascular and respiratory disease. Over recent years earlier and more aggressive treatment with higher dosage of methotrexate and the earlier use of biologic drugs has improved disease outcomes. The effect on cause of death is unknown. In this retrospective cohort study we found the major cause of death was infection followed by malignancy and found no correlation with seropositivity or gender.

Objectives: To analyse the causes of death in RA patients treated with aggressive disease modifying anti rheumatic drugs (DMARD) and Biologic therapies in Berkshire, UK.

Methods: Patients with RA who died between 2010 and 2016 were identified using the DAWN software DMARD monitoring database. A cohort of 3106 patients with RA are monitored using DAWN software in Berkshire, UK. The causes of death were identified from medical records, general practice records or the local coroners office.

Results: 198 patients on DAWN monitoring died during the 6 year study period. Treatment details and cause of death was identified for 131 RA patients. 71% were seropositive for rheumatoid factor and 61% were female.

91 patients (69%) were treated with methotrexate, 28 hydroxychloroquine (21%), 14 sulphasalazine (21%) and 7 with leflunomide (5%). The majority of patients (81) were on monotherapy (61%), 32 were on 2 DMARDS (24%) and only one was on triple therapy.

4 patients with RA who died were on biologic monotherapy, 10 were treated with biologic and combination DMARD. The most commonly prescribed biologics were etanercept (35%) and rituximab (35%).

The leading causes of death in this cohort were pneumonia (39 patients 29%), cerebrovascular disease (16 patients 12%), septicaemia (11 patients 8%) and lung cancer (6 patients 4%).

Infection accounted for 57 patients' deaths (43%) followed by malignancy in 24 patients (18%). Cerebrovascular disease (20 patients, 15%) and cardiovascular disease (13 patients, 9%) were less frequent causes of death in our cohort.

Comorbidity data for the cohort was recorded premortem. 49 patients (37%) had cardiovascular disease of any kind. 25% had respiratory disease and 23% had an endocrine comorbidity (predominantly diabetes).

Conclusions: In our large cohort of aggressively treated RA patients, infection followed by malignancy and not cardiovascular disease, was the leading cause of death. Larger prospective studies will be required to see if cumulative drug toxicity of more aggressive early treatment improves outcome from RA but changes mortality from comorbidities over time.

FRI0160 EVALUATION OF INFLAMMATORY CARDIOVASCULAR (CV) RISK FACTORS IN PRE- AND POST-MENOPAUSAL FEMALE PATIENTS WITH RHEUMATOID ARTHRITIS (RA)

O.O. Garmish, V. Levchenko, V. Kovalenko. *NSC "Institute of Cardiology named by M.D.Strazhesko NAMS of Ukraine", Kiev, Ukraine*

Objectives: To assess inflammatory factors and peripheral vessels involvement as markers of cardiovascular risk in female patients with RA

Methods: 105 female patients who fulfill ACR/EULAR 2010 criteria were examined. Laboratory assessments consisted of biochemistry and hematology analysis, measuring of CRP level, rheumatoid factor, anti-CCP level, total cholesterol, HDL, LDL, thyroglobulin, apoliprotein, A1, apoliprotein B, uric acid, HbA1c, microalbuminuria. DAS28 was used in characterizing RA activity. CV risk was defined per mSCORE. Tibial artery and carotid artery ultrasonography examination included the measurement of cIMT in 3 points, detection of focal plaques in the extracranial carotid tree, blood flow velocity and morphology of the intima was performed

Results: 83.3% reproductive age patients were without CV risk, 11.1% experienced middle level and 5.6% low level of CV risk on mSCOR. In 96.1% postmenopausal patients moderate, high and very high CV risk was detected. According to multiple logistic regression analysis we identified CV risk factors:

high CRP and DAS28, swollen joint count, LDL cholesterol level, menopause, thickness of cIMT and tibial artery. Were identify a significant correlation between tibial artery thickness and age, BMI, RA duration, systolic and diastolic blood pressure, cholesterol, menopause ($p<0.01$, $\chi2=26.18$). Also, we identified a significant relationship between tibial artery thickness and changes of the intima morphology ($\chi2=31,64$; $p<0,01$), carotid plaques ($\chi2=26,179$; $p<0,01$), sclerosis of the heart valves ($\chi2=25,78$; $p<0,01$). A less significant relationship was between cIMT ($\chi2=8,507$; $p<0,01$). The DAS28, age ($p<0.001$), thickness of cIMT and tibial artery ($p<0.001$) are predictive factors for the development of carotid plaques. The predictive factors for tibial artery thickness in female patients <45 age are: high CRP ($p<0.004$) and DAS28 ($p<0.03$), anti-CCP positivity ($p<0.04$), Vps internal carotid artery ($p<0.04$)

Conclusions: The results of our study indicate that high CRP and DAS28 score, swollen joint count, LDL cholesterol level, menopause, thickness of cIMT and tibial artery associated with the increased cardiovascular risk. Tibial artery thickness and Vps internal carotid artery may be assessed like the new predictive factors of CV diseases in RA female patient

FRI0161 NON-INVASIVE ASSESSMENT OF MYOCARDIAL PERFUSION IN PATIENTS WITH RHEUMATOID ARTHRITIS

P. Anyfanti [1], N. Koletsos [1], A. Triantafyllou [1], S. Chatzimichailidou [2], G. Triantafyllou [1], P. Panagopoulos [1], E. Gkaliagkousi [1], S. Aslanidis [2], S. Douma [1]. *[1]3rd Department of Internal Medicine, Papageorgiou Hospital; [2]2nd Propedeutic Department of Internal Medicine, Hippokration Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece*

Background: Cardiac involvement among patients with rheumatoid arthritis (RA) is common, potentially life-threatening, but often underdiagnosed at presymptomatic stages. Subendocardial viability ratio (SEVR) reflects microvascular coronary perfusion, as it correlates with the ratio of subepicardial to subendocardial blood flow, that can be non-invasively estimated by applanation tonometry. Although it has been studied as a surrogate measure of myocardial perfusion in high-cardiovascular risk populations, it remains unclear whether it is affected in RA patients.

Objectives: The purpose of the study was to compare SEVR between RA patients and healthy controls. We additionally sought predictors of SEVR in RA among a wide range of disease-related parameters, hemodynamic factors, and markers of atherosclerosis, arteriosclerosis, and endothelial dysfunction.

Methods: Consecutive patients with RA and healthy, nontreated volunteers were recruited. SEVR was estimated from applanation tonometry with the Sphygmocor device (AtCor Medical, Sydney, Australia), which was also used to evaluate arterial stiffness (aortic index, AIx; pulse wave velocity, PWV). In the RA group, carotid atherosclerosis was additionally evaluated by ultrasound (carotid intima-media thickness, cIMT); cardiac and hemodynamic parameters by impedance cardiography, and endothelial dysfunction by measurement of asymmetric dimethylarginine (ADMA) in serum samples.

Results: A total of 122 participants, 91 RA patients and 31 controls, were studied. SEVR was significantly lower among RA patients compared to controls (141.4±21.9 vs 153.1±18.7%, p=0.005), and the same was observed when the subgroup of RA patients without cardiovascular comorbidities (n=29) was studied separately (139.7±21.7 vs 153.1±18.7%, p=0.013). In the univariate analysis, SEVR significantly correlated with cardiac and hemodynamic parameters, but not with PWV, AIx, cIMT, ADMA, or disease-related parameters. In the linear regression analysis accounting for sex, statin use, markers of atherosclerosis, cardiac, and hemodynamic parameters, female gender (p=0.007), blood pressure (p=0.028), heart rate (p=0.025), cholesterol levels (p=0.008), cardiac index ($p<0.001$), and left ventricular ejection time (p=0.004) were identified as independent predictors of SEVR among patients with RA.

Conclusions: Patients with RA exhibit lower values of SEVR compared to healthy individuals, suggesting a disturbed balance between oxygen supply and demand that might provide an additional pathophysiological link for the increased cardiovascular burden in RA. Cardiac and hemodynamic parameters, rather than markers of atherosclerosis, arteriosclerosis, and endothelial dysfunction, may be useful as predictors of impaired myocardial perfusion in RA.

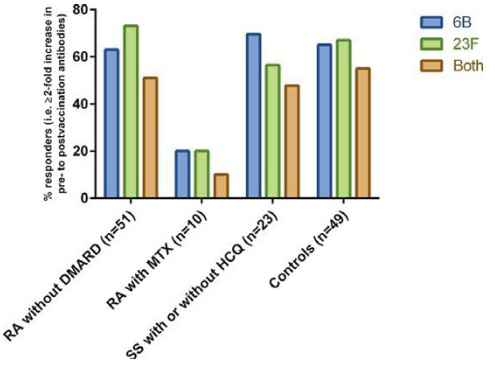
FRI0162 ANTIBODY RESPONSE TO 13-VALENT PNEUMOCOCCAL CONJUGATE VACCINE IS NOT IMPAIRED IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA) OR SJOGRENS SYNDROME WITHOUT DMARD TREATMENT COMPARED TO CONTROLS



P. Nived [1,2], J. Nagel [1], T. Saxne [1], P. Geborek [1], T. Mandl [3], L. Skattum [4,5], M.C. Kapetanovic [1]. *[1]Department of Clinical Sciences Lund, Section of Rheumatology, Skåne University Hospital, Lund University, Lund; [2]Clinic for Infectious Diseases, KRYH, Kristianstad; [3]Department of Clinical Sciences Malmö, Section of Rheumatology, Skåne University Hospital, Lund University, Malmö; [4]Clinical Immunology and Transfusion Medicine, Region Skåne; [5]Department of Laboratory Medicine, Section of Microbiology, Immunology and Glycobiology, Lund University, Lund, Sweden*

Objectives: To investigate if antibody response and functionality of antibodies following immunization with 13-valent pneumococcal conjugate vaccine (PCV13) is impaired in patients with rheumatoid arthritis (RA) and primary Sjogrens syndrome (pSS) without treatment, with methotrexate (MTX) or hydroxychloroquine (HCQ), compared to healthy controls.

Methods: In total, 61 patients with RA (51 without DMARD and 10 on MTX), 23 patients with pSS (18 without DMARD and 5 on HCQ) and 49 controls were vaccinated with a single dose (0.5 ml) PCV13 intramuscularly. Pre- and postvaccination serotype-specific antibody concentrations for pneumococcal serotypes 6B and 23F and functionality of antibodies (23F) were determined in serum samples taken immediately before and 4–6 weeks after vaccination using ELISA and opsonophagocytic activity (OPA) assay, respectively. Proportions of individuals with positive antibody response (i.e. ≥2-fold increase from prevaccination concentrations) for both serotypes were calculated and groups were compared using Chi2 test. Percentage change (pre- to postvaccination) in OPA was calculated and groups were compared using Mann-Whitney U test.

Results: Pre- to postvaccination antibody concentrations (Table) increased significantly for both serotypes and in both patient and control groups ($p<0.001$). Antibody response to serotypes 6B and 23F was decreased in patients with RA on MTX treatment (both $p<0.01$), but not in RA without DMARD or pSS with or without HCQ, compared to controls (Figure). Proportions of antibody responders to both serotypes did not differ significantly between groups RA without DMARD (51%), pSS (48%) and controls (55%). After vaccination, OPA increased in groups RA without DMARD ($p<0.001$), pSS without DMARD ($p=0.01$) and controls ($p<0.001$), but did not change significantly in patients with RA on MTX and pSS on HCQ. The mean percentage change in OPA was lower in RA on MTX (1.8%, $p=0.01$), RA without DMARD (8.9%, $p<0.01$) and pSS on HCQ (-1.5%, $p=0.01$), but not in pSS without DMARD (11.0%), compared to controls (17.9%).

Figure. Antibody response to vaccination.

Conclusions: Pneumococcal conjugate vaccine is immunogenic in patients with RA and pSS without DMARD treatment. Both antibody response and functionality of antibodies is impaired in patients with RA on MTX.

FRI0163 INVESTIGATION OF THE PERIODONTAL CONDITION AMONG RHEUMATOID ARTHRITIS (RA) PATIENTS AND ANALYSIS OF INFLAMMATORY MEDIATOR IN THEIR SERUM AND GINGIVAL CREVICULAR FLUID (GCF)

F. Xiao, P. Zhang, X. Li, Y. Mou, H. Chen, Z. Chen. *The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

Background: Rheumatoid arthritis (RA) and periodontitis (PD) are common chronic inflammatory diseases with remarkable pathological and clinical similarities.A lot of similarities exist between RA and PD at cellular and molecular levels.
Objectives: To analyse the PD incidence among RA patients, measure the level of tumor necrosis factor-alpha (TNF-α), Interleukin-1β(IL-1β) and Interleukin-6 (IL-6)in their serum and gingival crevicular fluid (GCF), and to investigate their relationship.
Methods: The experimental group was composed of 350 patients with RA and the control group consisted of 426 age and gender matched healthy individuals,check and record periodontal condition by dentist,analyse the PD incidence of the two groups,then select 64 PD patients without systematic diseases and 47 PD patients with a stable condition of RA,Detect and compare their periodontal status and the level s of TNF-α, IL-1β and IL-6 in their serum and GCF.
Results: The percentage of PD was 67.7%,which was statistically significant higher than control group (43.6%) ($P<0.001$). The periodontal disease index (PDI),Probing depth (PD)and Clinical attachment loss (CAL) in patients with PD and RA are all significantly higher than those with simple PD ($P<0.05$). But the bleeding on probing (BOP) in the two groups was not statistically significant ($P>0.05$). Meanwhile, the level of TNF-α, IL-1β and IL-6 in serum and GCF are significantly higher in all PD patients than oral healthy individuals ($P<0.01$).Although those inflammatory mediators in serum are much higher in patients with PD and RA than in those with simple PD ($P<0.01$), there is no difference in the two group about those inflammatory mediators in GCF. The serum level of TNF-α,IL-1β and IL-6 in patients with PD and RA are positively correlated with the corresponding inflammatory mediators in their GCF (r value was 0.531,0.422 and 0.770 respectively,$p<0.01$).
Conclusions: Individuals with RA are more likely to experience periodontitis compares to healthy subjects, and the periodontitis is much more serious in patients with RA and PD than those with simple PD. the serum and GCF inflammatory factors' level increased significantly in patients with RA and PD,even during their RA stable period. The serum level of inflammatory factors in patients with PD and RA are positively correlated with the corresponding inflammatory mediators in their GCF. There is correlation between periodontitis and RA,and they may be the risk factors for eachother, the improvement of the periodontal status in patients with RA and PD may help to control systemic inflammation level and to make comprehensive treatment measure for RA patients.

FRI0164 DIFFERENCES BETWEEN RA PATIENTS WITH AND WITHOUT ILD FROM A UNITED STATES TERTIARY REFERRAL CENTER

R. Meehan[1], J. Solomon[1], J. Crooks[1], D. Muram[2], E. Hoffman[1], P. Zelarney[1]. [1]*National Jewish Health, Denver;* [2]*Eli Lilly and Company, Indianapolis, United States*

Objectives: To describe the characteristics of RA patients with and without ILD and to determine if medication use constitutes a risk factor for the development of ILD.
Methods: The medical records of RA patients with and without ILD treated at one academic center between 2008 and 2016 were analyzed. Data extracted include: patient demographics, serology, medication use (prednisone, DMARDs, biologics or small molecule drugs), and self-reported disease activity as MDHAQ and RAPID 3 scores. The subtype of ILD was based upon HRCT imaging, and some patients through histology. Differences between RA-ILD patients and RA patients without ILD were determined by Fishers exact test, and t-tests with a $p<0.05$ were considered statistically significant.
Results: The demographics and clinical data of 1,024 RA non-ILD patients and 96 RA-ILD patients indicate ILD patients were older males, had a higher mortality and were less likely to have been never smokers (Table 1). At the onset of ILD diagnosis, 31% were on no medication, 56% on monotherapy (MTX 16%, prednisone 13%, Etanercept 7%, adalimumab or LEF 5%, Rituximab 4%, HCQ 3%, and <1% on infliximab, SSZ or tofacitinib) and 11% received combination therapy. Twenty five percent of the RA-ILD patients developed ILD preceding or coinciding with the diagnosis of RA. After the onset of ILD those patients were more likely to receive prednisone and less likely to receive MTX than those without ILD ($p<0.05$). The predominant types of ILD were as follows: UIP 27%, NSIP 15%, NSIP vs UIP 14%, and unclassifiable 9%.

Table 1

	RA-ILD	RA-without ILD	P values
Total number of patients	96	1,024	
Gender (Male)	48 (50%)	238 (23%)	<0.001
Age >65	57 (59%)	337 (33%)	<0.001
Never smoker	33 (34%)	504 (50%)	<0.001
Fatalities	15 (16%)	38 (4%)	<0.001
BMI (>25)	64 (67%)	671 (66%)	NS
RF+ (>14 units)	67 (74%)	678 (69%)	NS
CCP+ (>20 units)	62 (65%)	617 (61%)	NS
MDHAQ	0.7	0.7	NS
Rapid3	10.6	12.0	NS

Conclusions: RA-ILD patients differed from RA patients without ILD in demographic characteristics, but not in self-reported measures of disease activity or serology. Thirty one percent of RA-ILD patients were not on any immunomodulatory medications at the time of ILD diagnosis, and 25% of RA-ILD patients developed ILD preceding, or coinciding with, the onset of active RA. Our results did not identify a specific drug class or biologic agent as a risk factor for developing ILD in RA patients.

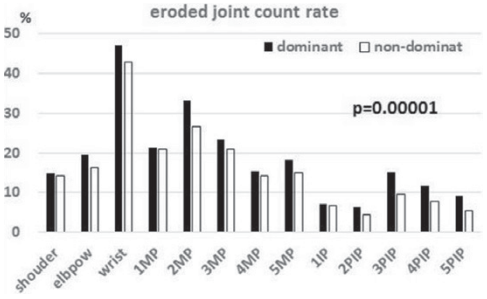
FRI0165 SERUM FREE LIGHT CHAINS OF IMMUNOGLOBULINS IN RHEUMATOID ARTHRITIS: CORRELATION WITH INTERSTITIAL LUNG DISEASE

S. Belghali[1], S. Lataoui[1], S. Ferchichi[2], K. Baccouche[1], N. Elamri[1], K. Limam[2], H. Zeglaoui[1], E. Bouajina[1]. [1]*Rheumatology Department;* [2]*Laboratory of Biochemistry, Farhat Hached Hospital, Sousse, Tunisia*



Background: Lungs in Rheumatoid arthritis (RA) seem to play an important role, not only as an extra-articular manifestation but also as a site of initiation of the disease and activation for the immune response. B lymphocytes are thought to be involved in the pathophysiology of RA and interstitial lung disease (ILD). The encouraging results of the use of Anti-CD20 treatments to stabilize articular symptoms and lung involvement reinforce this theory. Serum Free immunoglobulin Light Chains (FLC) might represent, in this context, an interesting marker of B lymphocytes activation during this disease.
Objectives: To determine the serum FLC levels in RA patients with and without ILD and to study their possible association with disease characteristics and activity.
Methods: Fifteen RA patients with clinically symptomatic interstitial lung disease, confirmed by computed tomography (RA-ILD) (53.3% females; mean age 61,27±6,48 years) and age matched RA patients (66.7% females) with no clinically evident interstitial disease (non-ILD) were studied. Clinical and immunological inflammatory characteristics were assessed for all the patients. FLC levels were quantified by turbidimetry (Freelite TM Kappa and Lambda Kits, The Binding Site, UK).
Results: The mean serum FLC-κ levels (RA-ILD: 40,74±16,94 ng/ml *vs* non-ILD 24,88±8,87 ng/ml, p=0,003) and FLC-λ levels (RA-ILD: 37,34±16,56 ng/ml *vs* non-ILD 26,28±7,22 ng/ml, p=0,028) were significantly higher in patients with ILD compared to non-ILD, while the serum FLC-ratioκ/λ (RA-ILD: 1,15±0,38 *vs* non-ILD 1,00±0,43, p=0,304) were comparable.
There was no significant difference for the DAS28 disease activity score between both groups (RA-ILD: 4,6±1,5 vs non-ILD 4,38±1,46, p=0,69). No significant correlations were found between the DAS28-score and FLCκ, FLCλ and FLC-ratioκ/λ ($p>0,05$). FLC-κ levels correlated significantly with ESR and CRP levels ($p<0.001$), FLC-λ levels with CRP (p=0,005) but not with ESR (p=0,247) and FLC-ratioκ/λ did not correlate with both ESR and CRP levels.
Conclusions: High levels of serum FLC are associated with RA-ILD and with a higher degree of inflammation, supporting the role of B cell activation in the pathophysiology of RA with ILD.

FRI0166 RADIOGRAPHIC STRUCTURAL DAMAGE IS WORSE IN THE DOMINANT THAN THE NON-DOMINANT UPPER EXTREMITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Nakazaki[1], T. Murayama[1], S. Kato[2]. [1]*Rheumatology, Johoku Hospital;* [2]*Rheumatology, Kamiaraya Clinic, Kanazawa, Japan*

Background: The relationship between mechanical stress and radiographic damage in rheumatoid arthritis (RA) has been detected in patients with hemiplegia[1)] or poliomyelitis[2)]. In patients without neurological disorder, Koh reported that radiographic damage was worse and progressed faster in the dominant hand in

individuals with early RA[3]. However, few studies have detected the radiographic damage in the whole upper extremity on the mechanical stress.
Objectives: To examine the relationship between mechanical stress and radiographic damage in RA, we evaluated the joint destruction of the dominant and non-dominant upper extremity.
Methods: The joint destruction of the upper extremity (shoulder, elbow, wrist, metacarpo-phalangeal, interphalangeal, proximal interphalangeal) in 295 patients with RA, who were from 25 years to 91 years (mean age 64 years, mean disease duration 183 months, 86% females and 97% right-handed), was assessed according to the eroded joint, which was defined as ≥2 by Larsen scores for radiographic damage. These were divided into the dominant and non-dominant upper extremity. The Wilcoxon signed-rank test was used to examine the difference between the eroded joint count (EJC) in the dominant and the non-dominant upper extremity.
Results: The mean EJC in the dominant and the non-dominant upper extremity was 2.4 and 2.05 respectively. The EJC was significantly more in the dominant than the non-dominant upper extremity. And, in regards to every joint of upper extremity, the eroded joint rate was higher in the dominant than the non-dominant

Conclusions: The eroded joint count of the upper extremity was significantly more in the dominant than the non-dominant one, therefore it was suggested that the mechanical stress influenced the radiographic damage in patients with RA

FRI0167 COMPARATIVE CARDIOVASCULAR SAFETY OF ABATACEPT AND TUMOR NECROSIS FACTOR INHIBITORS IN RHEUMATOID ARTHRITIS PATIENTS WITH AND WITHOUT CARDIOVASCULAR DISEASE: A POPULATION-BASED COHORT STUDY

Y. Jin[1], E.H. Kang[1,2], G. Brill[1], R.J. Desai[1], S.C. Kim[1,3]. *[1]Division of Pharmacoepidemiology and Pharmacoeconomics, Brigham and Women's Hospital, Harvard Medical School, Boston, United States; [2]Division of Rheumatology Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of; [3]Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, United States*

Background: Rheumatoid arthritis (RA) patients have an increased risk of cardiovascular disease (CVD). Recent studies suggested that treatment of RA with tumor necrosis inhibitors (TNFi) can reduce the risk of cardiovascular events. However, it is unclear how abatacept, a selective costimulation modulator, affects cardiovascular risk among RA patients compared with TNFi.
Objectives: To evaluate the comparative cardiovascular safety of abatacept versus TNFi in RA patients with and without underlying CVD.
Methods: We identified RA patients aged ≥18 with ≥2 RA ICD-9 codes (714.xx) separated by ≥7 days but <365 days, from two large insurance claims data across the U.S.: Medicare (2008–2013) and Truven MarketScan (2006–2015). Only new users of abatacept or TNFi (adalimumab, etanercept, certolizumab, golimumab, and infliximab) were included. The primary outcome of interest was a composite endpoint of CVD including myocardial infarction (MI), stroke/transient ischemic stroke, or coronary revascularization. Secondary outcomes were each component of the primary outcome, incident heart failure (HF), and venous thromboembolism (VTE). 1:1 propensity score (PS) matching was performed separately in each database and each subgroups (with or without baseline CVD). Then the PS-matched subgroups were aggregated to form the overall matched cohort. Cox regression model was used to estimate the hazard ratio (HR) and 95% confidence interval (CI) of risk of each outcome. Estimates from two different databases were combined through an inverse variance-weighted fixed-effects model.
Results: After 1:1 PS matching, there were 6,102 patient pairs from Medicare and 6,934 pairs from MarketScan. Among them, patients with baseline CVD were 35.3% in Medicare and 14.0% in MarketScan. Baseline characteristics were well balanced between two treatment groups after matching (standardized mean difference <0.1). In Medicare cohort, abatacept consistently showed a decreased risk of composite CVD compared with TNFi in overall and each subgroup (Figure). However, in MarketScan cohort, where the population was younger than Medicare cohort, there was no association between abatacept and CVD compared to TNFi. After combining the two databases, abatacept was significantly associated with reduced risk of composite CVD outcome vs. TNFi in overall cohort (HR =0.79, 95% CI=0.67–0.92) and baseline CVD subgroup (HR =0.79, 95% CI=0.64–0.98). We also observed similar trend for secondary outcomes, where abatacept had decreased risk than TNFi.

Figure. Risk of composite CVD outcome in Abatacept initiators versus TNF inhibitors: PS-matched analysis

Subgroup	Database	Exposure	Total N	Number of event	IR per 100 person-years	HR (95% CI)
	Medicare	Abatacept	6102	185	2.38	0.67 (0.55, 0.81)
		TNFi	6102	248	3.58	Ref
Overall	MarketScan	Abatacept	6934	114	1.38	1.08 (0.83, 1.41)
		TNFi	6934	113	1.27	Ref
	Pooled					**0.79 (0.67, 0.92)**
	Medicare	Abatacept	2156	107	4.18	0.71 (0.55, 0.92)
With		TNFi	2156	134	5.92	Ref
baseline	MarketScan	Abatacept	968	49	4.6	1.02 (0.68, 1.51)
CVD		TNFi	968	49	4.35	Ref
	Pooled					**0.79 (0.64, 0.98)**
	Medicare	Abatacept	3946	78	1.5	0.61 (0.46, 0.82)
Without		TNFi	3946	114	2.44	Ref
baseline	MarketScan	Abatacept	5966	65	0.91	1.10 (0.77, 1.57)
CVD		TNFi	5966	64	0.82	Ref
	Pooled					**1.04 (0.74, 1.46)**

Conclusions: In this large multi-database population-based study of RA patients, abatacept treatment was associated with reduced risk of CVD compared to TNFi, especially among older population and patients with prior CVD conditions.

FRI0168 RESTORATION OF DECREASED LYMPHOCYTES, CD8+T CELL SUBSETS WITH TH1 SKEWED PHENOTYPE ASSOCIATE WITH SPONTANEOUS REGRESSION OF LYMPHO-PROLIFERATIVE DISORDERS IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH METHOTREXATE

S. Saito[1], K. Suzuki[1], K. Yamaoka[1], K. Amano[2], M. Tokuhira[3], T. Takeuchi[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo; [2]Division of Rheumatology, Saitama Medical Center, Saitama Medical University; [3]Division of Hematology, Saitama Medical Center, Saitama Medical University, Saitama, Japan*

Background: Lympho-proliferative disorder (LPD) is known as a relatively rare but life-threatening complication in RA patients under MTX administration. Spontaneous regression of LPD after MTX withdrawal is regarded as a distinct character of LPD under MTX administration. Previous study from our institution [1] and others [2] reported the link between decreased lymphocyte counts at LPD diagnosis and restoration after MTX cessation and the regression of LPD.
Objectives: To investigate the immunological factors including lymphocyte subsets which involved in spontaneous regression of LPD following MTX withdrawal.
Methods: We studied 35 RA patients complicated with LPD under MTX administration in our institution. Age, sex, RA disease duration matched control MTX-treated patients (N=35) were selected. LPD patients were divided into two groups regarding to the status of LPD after MTX cessation; regressive group (N=22) and persistent group (N=13). Clinical features were compared among 3 groups. Flowcytometric analysis of the whole blood sample and measurement of cytokine concentration in ELISA were conducted in a part of the LPD patients (N=10, 7 regressive, and 3 persistent LPD) and controls (N=10). The time of MTX cessation, which was simultaneous with LPD diagnosis, was defined as week 0, and blood sample was collected at week 0, 4 and 12.
Results: At week 0, number of peripheral lymphocytes was significantly decreased in regressive group, compared to persistent group and control group. Flowcytometric analysis revealed significant decrease in proportion of effector memory CD8+ T cells (EMCD8+T), Epstein Barr Virus specific CD8+ T cells (EBV specific CD8+) and T helper 1 cells (Th1 cells) subset in regressive group compared to control group. Following MTX cessation, significant increase in proportion and absolute number of these subsets were observed only in the regressive group, but not in persistent group. Expansion of Th1 cells and EMCD8+ T cells significantly correlated with increase of serum IFN-γ, and expansion of EMCD8+ T cells inversely correlated with change of serum IL-15.
Conclusions: Restoration in proportion and absolute number of Th1 cells, EMCD8+T cells and EBV specific CD8+ T cells coincided with increase of IFN-γ, and associated with regression of LPD developed under MTX administration. Since changes of those immunological factors were not observed in persistent LPD, this study would be the first report to demonstrate the difference of

immune status between regressive and persistent LPDs developed under MTX administration.

FRI0169 GLOMERULAR FILTRATION RATE IS LOW IN RHEUMATOID ARTHRITIS COMPARED TO HEALTHY POPULATION: ESSENTIAL ROLE OF INFLAMMATION

S. Hannawi[1], I. AlSalmi[2]. [1]*Rheumatology, Ministry of Health and Prevention of UAE, Dubai, United Arab Emirates;* [2]*Nephrology, Royal Hospital, Muscat, Oman*

Background: Rheumatoid Arthritis is associated with subclinical renal impairment which contributes to increase mortality and morbidity. The role of inflammation on kidney function in inflammatory arthritis is not well studied.

Objectives: To investigate the associations between estimated glomerular filtration rates (eGFR), traditional cardiovascular risk factors, and markers of inflammation in rheumatoid arthritis compared to healthy controls.

Methods: RA patient were recruited through a specialized rheumatology clinic at the Ministry of Health and Prevention of UAE, from January 2013 to January 2016. Healthy subjects recruited from the community through brochure advertisement. The Modification of Diet in Renal Disease Study (MDRD) formula was used to calculate the eGFR. ttest was used to compare the laboratory values and renal function parameters between two groups. Linear regression analysis used to look for the correlation between the eGFR and each of the traditional cardiovascular risk factors and inflammatory markers

Results: 98 RA patients and 82 controls were recruited. None of the patients has history of diabetes, atherosclerosis or renal impairment. The mean age for the total participants was 49±13 years (Min16 –Max 82). The mean eGFR of the inflammatory arthritis patients was 118±30 ml/min (range 60–227) and 128±37 ml/min (range 62–286) for the controls. Patients and control had no significant difference in Systolic and diastolic blood pressure.

Inflammatory arthritis patients had lower GFR, albumin ($P<0.001$), and total protein (p=0.03) levels, and had higher Erythrocyte Sedimentation Rate (ESR) ($P<0.001$), C-reactive protein (CRP) ($P<0.001$), and uric acid level (p=0.01),

Negative linear relationships were found as follows:

Among RA patients and controls: There was a negative linear relationship between GFR and each of the age of the participants; ($p<0.001$, CI: -1.24, -0.40 for the patients and p=0.01, CI: -1.82, -0.26 for the controls), and the systolic blood pressure; (p=0.04, CI: -0.61 for the patients and, -.00 and p=0.022, CI: -0.61, -0.05 for the controls).

Among RA patiens: The GFR had a negative linear relationship with the age of the participants, age at RA onset (p=0.002, CI: -1.18, -0.29), diastolic blood pressure (p=-2.14, CI: -1.24, -0.05), ESR level (p=0.04, CI: -0.24,-0.01), C-reactive protein; CRP level (p=0.02, CI: -0.47, -0.04), uric acid level ($p<0.001$, CI -0.18, -0.05), and total protein (p=0.01, CI: -0.91, -0.16). There was a positive linear relationship between eGFR and albumin level (p=0.03, p=0.14, 2.35),

Conclusions: In RA non-traditional cardiovascular risk factors such as inflammatory markers are associated with sub-clinical presence of renal injury. Our data indicate that in RA, inflammation is involved in the early stages of impaired kidney function. Whether anti-inflammatory therapies are effective in slowing down the deterioration of kidney function in the arthritis diseases remain to be established.

FRI0170 CARDIOVASCULAR RISK FACTORS AND DISEASE CHARACTERISTICS ARE CONSISTENTLY ASSOCIATED WITH ARTERIAL STIFFNESS IN RHEUMATOID ARTHRITIS

S. Gunter[1], C. Robinson[1], G. Norton[1], A. Woodiwiss[1], L. Tsang[1], A. Millen[1], P. Dessein[1,2]. [1]*Cardiovascular Pathophysiology and Genomics Research Unit, University of Witwatersrand, Johannesburg, South Africa;* [2]*Rheumatology Division, Universitair Hospital Brussels, Brussels, Belgium*

Background: In the non-rheumatoid arthritis (RA) population, arterial stiffness contributes to cardiovascular disease risk beyond brachial blood pressure and other established cardiovascular risk factors. The increased cardiovascular disease risk in RA is now well documented. In this regard, how RA impacts on arterial stiffness remains uncertain.

Objectives: The aim of the present study was to identify potential determinants of comprehensively assessed arterial stiffness in a relatively large group of ethnically diverse patients with RA.

Methods: Relationships of traditional cardiovascular risk factors and RA characteristics with 9 arterial stiffness markers including central systolic and pulse pressure, pulse wave velocity, augmentation index, forward and reflected wave pressure, reflection magnitude, brachial-to-aortic pulse pressure amplification (a marker of reduced wave reflection) and peripheral pulse pressure were identified in multivariable backward regression models among 177 (118 white, 32 Asian, 22 black, 5 mixed ancestry) patients without established cardiovascular disease.

Results: Recorded characteristics explained 37% (pulse wave velocity) to 71% (reflected wave pressure) of the variability in arterial stiffness. RA duration (partial r=0.17, p=0.04), rheumatoid factor status (partial r=-0.19 to 0.20, p=0.01 to 0.03), leukocyte counts (partial r=0.16 to 0.19, p=0.02 to 0.05) and total cholesterol (-0.18 to 0.26, p=0.00 to 0.03) were associated with enhanced central systolic blood pressure or/and wave reflection markers. C-reactive protein (partial r=-0.24, -0.17 and -0.20, respectively, $p\leq0.05$) was paradoxically related to reduced central pulse pressure, pulse wave velocity and forward wave pressure, and body mass index (partial r=-0.39 to 0.42, p=0.00 to 0.02) and insulin resistance (partial r=-0.21 to -0.20, p=0.00 to 0.01) to reduced wave reflection and peripheral pulse pressure. Exercise (partial r=0.19, p=0.02) and alcohol (partial r=-0.27, p=0.00) consumption were associated with increased pulse pressure amplification and decreased peripheral pulse pressure, respectively. Tumour necrosis factor-α inhibition (partial r=-0.25, p=0.00) was related to reduced pulse wave velocity and tetracycline use (partial r=-0.20, p=0.02) to reduced peripheral pulse pressure.

Conclusions: Traditional cardiovascular risk factors and disease characteristics are consistently associated with vascular hemodynamic alterations in RA. The role of arterial stiffness in cardiovascular disease risk in RA needs further study.

FRI0171 OBESITY CONTRIBUTES TO SUBOPTIMAL PHYSICAL FUNCTION IN RHEUMATOID ARTHRITIS

A. Sirois[1], N. Chiarlitti[1], M. Inceer[1], M. Jones[2], C.O. Bingham III[2], S.J. Bartlett[1]. [1]*McGill University, Montreal, Canada;* [2]*Johns Hopkins, Baltimore, United States*

Background: Aggressive, early treatment of RA with new therapeutic agents has dramatically improved the management of RA. However, many studies have failed to show greater improvements in function or disability reduction between targeted control vs. less-aggressive care. The prevalence of obesity is increasing dramatically globally, and may be even higher in RA patients.[1]

Objectives: Because obesity is also a risk factor for disability, we evaluated the extent to which excess weight may independently contribute to poorer physical function (PF) in RA.

Methods: RA patients enrolled in an observational study at an academic Inflammatory Arthritis Clinic in Baltimore USA completed the patient global, pain VAS, and PROMIS measures assessing PF, pain, fatigue, sleep, and depression. RA clinical indicators were also collected at the visit. Outcomes were compared in obese and non-obese patients using t-tests and chi-square. Multiple regression was used to evaluate the effects of pain, fatigue, and BMI on PF, after controlling for age and disease activity.

Results: Participants were mostly female (82%) and white (83%) with mean (SD) age of 55 (13) years; 24% had $\leq$ high school; RA duration 12 (9). Mean CDAI was 8.1 (8.1). Most were in CDAI remission (n=57; 32%) or LDA (n=64; 36%); 40 (23%) were in MDA and 16 (9%) in HDA. 49 (28%) were classified as normal weight (BMI 18.5–24.9), 46 (26%) were overweight (BMI 25–29.9), and 82 (46%) were obese (BMI$\geq$30). Men had a significantly higher mean BMI than women (33.6 [8.4] vs. 29.5 [7.2], p=0.006).

As compared to non-obese participants, obese participants had a significantly ($p<.05$) higher CDAI (6.1 [6.9] vs. 10.4 [8.9]; p=.000, respectively) and worse PF, pain, fatigue, sleep, and depression (mean differences -5.0, -4.6, 4.6, 3.8, 2.9, 3.6, and -4.7, respectively). In regression analyses, pain, fatigue, and BMI (but not sleep or depression) were inversely related to PF, after controlling for age and disease activity. In the final model, pain, fatigue and BMI were significantly and inversely related to PF (β=-.39, -.24, and -.153, respectively) after controlling for age and disease activity ($F(5, 170) = 55.5$, p=.000, adjusted r^2=.61).

Table. Independent Contributors of Function in RA.

	Coefficient		Std		Collinearity	
	B	SE	Beta	Sig.	Tol	VIF
Pain	-.386	.064	-.405	.000	.500	2.001
Fatigue	-.240	.060	-.266	.000	.509	1.965
BMI	-.153	.058	-.128	.010	.932	1.073
Adjusted for age and CDAI.						

Conclusions: Our results suggest that excess weight also contributes to poorer PF in addition to pain and fatigue. As the prevalence of obesity continues to

escalate in RA populations, weight loss may be increasingly important to improve not only physical health, disease activity, and response to treatment, but also pain, fatigue, and PF.

FRI0172 PREVALENCE AND FEATURES OF THE "MASKED" ARTERIAL HYPERTENSION IN WOMEN WITH RHEUMATOID ARTHRITIS WITHOUT CARDIOVASCULAR DISEASES BASED TO AMBULATORY BLOOD PRESSURE MONITORING

T.A. Romanova, N.M. Nikitina, A.P. Rebrov. *Hospital Therapy Department, State Medical University of Saratov, Saratov, Russian Federation*

Background: Cardiovascular (CV) events are the main reason of increased mortality at patients with rheumatoid arthritis (RA). Arterial hypertension (AH) takes a leading position among CV risk factors in RA. Ambulatory blood pressure monitoring (ABPM) has to be executed for persons with high cardiovascular risk and can be used for evaluation of "masked" arterial hypertension (MAH), according to the current recommendations.
Objectives: to estimate the frequency of identification and peculiarities of the MAH according to ambulatory blood pressure monitoring in women with RA without CV diseases.
Methods: The study included 36 women with RA (ACR 1987 and/or EULAR/ACR 2010 criteria) without CV diseases and AH (according to the anamnesis and 3-fold "office" blood pressure (BP) measurement). Mean age of RA patients was 55±7.15 years; mean duration of RA was 10 [3; 17] years, mean DAS 28 – 5.25 [4.6; 5.7]. As controls were involved 39 women with RA and AH (mean age- 58.3±6.08 years; mean duration of RA - 8 [4;14] years, mean DAS 28- 5.08 [4.04; 5.85]) and 30 women with AH without inflammatory joint diseases (mean age 55.9±6.2). Exclusion criteria were smoking, diabetes mellitus, symptomatic AH (except controls), cardiovascular diseases.
ABPM was measured using the BPlab with the program VASOTENSE (Russian). Criteria for MAH were out-of-office BP $\geq$135/85 mmHg and/or average daily out-of-office BP $\geq$130/80 mmHg according to ABPM and considering optimal office BP.
The anamnesis, laboratory and instrumental methods of inspection were considered. Statistical analyze was performed with STATISTICA 7.0 (State Soft, USA).
Results: According to ABPM 24 of the 36 (66.6%) RA patients had optimal BP, 12 (33.3%) patients had the MAH phenomenon.
The patients with RA + AH and AH patients had the comparable levels of a daily BP [132.1/80.7 and 126.9/78.0 mmHg respectively, $p>0.05$].
The RA patients with MAH had statistically significant differences of BP in day and night hours [137.58/87 mmHg and 137/84 mmHg, respectively] compared to the RA + AH patients [132.1/80.7 mmHg and 128.3/73.8 mmHg, respectively, p=0.004] and AH patients [126.9/78 and 118/68.5 mmHg, respectively, p=0.001], what it is can be bound to absence of anti-hypertensive therapy at RA patients with MAH.
Nocturnal systolic BP correlated with ESR (Spearmen's r=0.64, $p<0.05$). Daily diastolic BP interrelated with SCORE/EULAR (r=0.86, $p<0.05$) and arterial stiffness index (r=0.86, $p<0.05$) in RA patients with MAH; nocturnal systolic BP correlated with C-reactive protein (r=0.36, $p<0.05$) in RA+AH patients.
More than 60% of the RA+AH patients and RA+MAH had high variability of BP. High variability of nocturnal systolic BP occurred at 34.3% and 44.4% of RA+AH and RA+MAH patients, respectively.
In RA patients were found correlations between indices of a BP variability, duration of RA (r=0.33, $p<0.05$); C-reactive protein (r=0.36, $p<0.05$); daily diastolic BP (r=0.35, $p<0.05$); pulse BP (r=0.31, $p<0.05$); and frequency of non-steroidal anti-inflammatory drugs intake (r=0.42, $p<0.05$).
Conclusions: In RA patients AH can proceed subclinically. Activity of RA and increased arterial stiffness can predict the masked arterial hypertension's development in RA patients.
ABPM measurement can be use full in early evaluation of AH and optimization of RA treatment.

FRI0173 CORRELATION BETWEEN ASSYMETRIC DIMETHYLARGININE AND HOMOCYSTEINE LEVELS IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. Dimitroulas[1,2], J. Hodson[3], A. Sandoo[4], K. Douglas[1], J. Smith[1], G. Kitas[5]. *[1]Department of Rheumatology, Dudley Group of Hospitals NHS Trust, Russells Hall Hospital, Dudley, United Kingdom; [2]4th Department of Internal Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece; [3]Wolfson Computer Laboratory, University Hospital Birmingham NHS Foundation Trust, Queen Elizabeth Hospital Birmingham, Mindelsohn Way, Birmingham; [4]School of Sport, Health and Exercise Sciences, Bangor University, George Building, Bangor; [5]Arthritis Research UK Epidemiology Unit, University of Manchester, Manchester, United Kingdom*

Background: Rheumatoid Arthritis is a chronic inflammatory condition associated with increased cardiovascular disease (CVD) morbidity and mortality due to high coronary and cerebral atherosclerotic burden. Assymetric dimethylarginine (ADMA) – the most potent endogenous inhibitor of nitric oxide synthase - is an emerging marker of endothelial dysfunction and CVD in several conditions such as coronary artery disease and diabetes mellitus. ADMA levels are higher in RA patients compared to controls suggesting a role in the development of atherosclerosis. In addition ADMA is involved in the metabolism of honocysteine (Hcy) which is considered a novel, non-traditional CVD risk factor contributing to excess CVD risk in this population.
Objectives: The aim of our study was to determine whether asymmetric dimethylarginine (ADMA) levels are associated with Hcy and methylenetetrahydrofolate reductase (MTHFR) C677T (rs1801133) gene variants in patients with RA.
Methods: Serum ADMA and Hcy levels were measured in 201 RA individuals [155 (77.1%) females, median age 67 years (interquartile range 59–73)]. The MTHFR C677T polymorphism was assessed by using the LightCyclerTM System. Initially, ADMA was compared across the categories of MTHFR using a one-way analysis of variance (ANOVA), followed by a multivariate model, which accounted for Hcy, age, erythrocyte sedimentation rate (ESR), and homeostatic model assessment (HOMA).
Results: In univariable analysis, ADMA differed significantly across the categories of MTHFR (p=0.037). Patients with the MTHFR 677TT genotype had the highest ADMA levels, with a mean of 0.62 (SE =0.03), significantly higher than either those patients carrying the MTHFR 677CT (0.55, SE =0.01) or the MTHFR 677CC (0.55, SE=0.01) genotype (p=0.042) in both cases. In the multivariable model, Hcy (p=0.022) and ESR ($p<0.001$) were found to have significant positive associations with ADMA but the relationship between MTHFR gene variants and ADMA was found to be non-significant (p=0.102).
Conclusions: The results of our study indicate an association between ADMA and Hcy in patients with RA without any genetic background as no relationship was established between ADMA and MTHFR gene variants. Abnormal metabolism of Hcy and dimethylarginines may interfere with each other resulting in endothelial dysfunction and accelerated atherosclerosis in RA individuals.

FRI0174 A POPULATION BASED COHORT STUDY OF RHEUMATOID ARTHRITIS-ASSOCIATED INTERSTITIAL LUNG DISEASE: COMORBIDITY AND MORTALITY

C. Hyldgaard[1], O. Hilberg[2], A.B. Pedersen[3], S.P. Ulrichsen[3], A. Løkke[1], E. Bendstrup[1], T. Ellingsen[4]. *[1]Department of Respiratory Diseases, Aarhus University Hospital, Aarhus C; [2]Department of Medicine, Vejle Hospital, Vejle; [3]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus; [4]Department of Rheumatology, Odense University Hospital, Odense, Denmark*

Background: Interstitial lung disease (ILD) is an important reason for excess mortality among patients with rheumatoid arthritis.
Objectives: The aim of this study was to compare mortality risks in patients with rheumatoid arthritis-associated interstitial lung disease (RA-ILD) and patients with RA without ILD.
Methods: The study was conducted in Denmark, using nationwide, prospectively collected data from the national medical registries. Among patients with RA, diagnosed between 2004 and 2016, 679 patients with RA-ILD were matched for age, gender, and age at RA diagnosis with 11,722 patients with RA but without ILD. Mortality risks were assessed using Kaplan-Meier survival curves, and hazard rate ratios (HRR) for death were estimated using Cox proportional hazards regression models.
Results: The number of prevalent RA patients more than doubled from 15,352 to 35,362 individuals during the study period. RA-ILD was seen in 2.2% of incident RA patients. 34.0% of RA-ILD cases were diagnosed within one year prior to and one year after the RA diagnosis. One-year mortality was 13.9% in RA-ILD and 3.8% in non-ILD RA, three-year mortality was 28.0% and 10.9%, and five-year mortality was 39.0% and 18.2%, respectively. The HRRs for death were two to 10 times increased for RA-ILD compared with non-ILD RA, irrespective of follow-up period. Stratified analysis showed that the HRR for death was highest in the first months after the diagnosis of RA-ILD was made, especially in patients diagnosed with RA before diagnosis of ILD. HRR was higher in males and in patients without comorbidity as assessed by the Charlson Comorbidity Index.

Conclusions: ILD is a serious complication in RA with a significantly increased mortality compared with a large matched cohort of RA comparisons without ILD.

FRI0175 USING SMARTPHONES TO IMPROVE REMOTE MONITORING OF RHEUMATOID ARTHRITIS: COMPLETENESS OF PATIENTS' SYMPTOM REPORTS

S. Van Der Veer[1], L. Austin[1,2], C. Sanders[2], W. Dixon[1]. [1]*Arthritis UK Centre for Epidemiology, Centre for Musculoskeletal Research, Faculty of Biology, Medicine and Health, Manchester Academic Health Science Centre, University of Manchester;* [2]*Centre for Primary Care, Faculty of Biology, Medicine and Health, Manchester Academic Health Science Centre, University of Manchester, Manchester, United Kingdom*

Background: Clinical decisions about management of rheumatoid arthritis (RA) happen at intermittent clinic visits. In the absence of objective measures of disease severity between visits, understanding fluctuating disease severity largely relies on patients' symptom reports, and thus on patients' recall, eloquence, stoicism and willingness to discuss symptoms.
The Remote Monitoring of Rheumatoid Arthritis (REMORA) study aims to improve monitoring of disease severity in RA. Patients, clinicians and researchers co-designed a smartphone app to enable RA patients to report daily symptoms in between clinic visits with data integrated into the electronic health record. The data presented here were collected as part of the REMORA feasibility evaluation.
Objectives: To evaluate the completeness of patient-reported symptom data submitted through the REMORA smartphone app over three months.
Methods: We invited 23 RA patients treated at the outpatient clinic of Salford Royal Foundation Trust (UK) to record their symptoms for three months using the REMORA smartphone app. Participants received notifications to record: daily scores for the seven items of the RA Impact of Disease score, as well as morning stiffness on a scale from 0 to 10; weekly scores for thirteen items on 28 tender and swollen joint self-assessments, global assessment, impact on work and activity, and flare occurrence; and monthly scores for the Health Assessment Questionnaire (HAQ) 20-item disability scale. We calculated the time that participants were in the study as the number of days between the first and last day of submitting daily scores. We then explored patterns of data entry, as well as entry completeness.
Results: Twenty patients accepted the invitation to participate. Eight (40%) were male, all but one were white British, and their mean age was 56.9±11.1 years. The median number of days in the study was 82 (interquartile range [IQR], 80 to 82). While being in the study, participants submitted daily scores on almost all days (median, 91% of days; IQR, 78 to 95), with four doing this on <60% of study days. Across participants, almost all of 1325 daily entries were complete, with only nine (<1%) having missing values for up to two individual items. Participants submitted weekly scores for a medium of 11 out of 13 weeks (IQR, 10 to 12). Of all 213 weekly entries, fifteen (7%) had missing values, but never more than two. Lastly, 8/20 participants provided monthly HAQ scores only once, while a further 9/20 and 3/20 participants did this for two and all three months, respectively. No monthly entries had any missing values.
Conclusions: Our feasibility study showed that smartphones have the potential to support collection of daily patient reports of symptoms with high levels of completeness over three months. Lengthier monthly question sets were less likely to be completed compared to briefer daily and weekly ones. Future steps include exploring methods for adapting data entry frequency to (fluctuations in) disease severity in order to support sustained symptom reports over longer time periods and in a wider group of patients.

Background: Rheumatoid arthritis (RA) patients can cause joint swelling and tenderness, and affect the patient's mental health. Previous studies showed that 13–47% of RA patients suffered from anxiety and/or depression. Hospital anxiety and depression scale (HADS) is usually used to evaluate patients' mental health, which consists of 14 items divided into an anxiety subscale (HADS-A) and a depression subscale (HADS-D). Disease activity score in 28 joints (DAS28) is one of the most used tool to assess RA patients' disease activity. Both HADS and DAS28 assessments were commonly led by health professionals with paper questionaire. This study applies the mobile platform of Smart System of Disease Management (SSDM) for evaluating DAS28 and HADS by RA patients.
Objectives: The purpose of this study is to describe the morbidity of mental comorbidity in Chinese patients with RA and analyze the potential association among DAS28 and HADS.
Methods: SSDM is a mobile application includes physicians' and patients' interfaces. The patient's terminal system includes self-assessment (DAS28, HADS), lab test results and medication management. After data entry, patients can synchronize data to the mobile terminal of their authorized rheumatologist. A cohort study was conducted with patients who were diagnosed with RA in tertiary hospital across China. All participants self-assessed both DAS28 and HADS with SSDM at least one time. Descriptive statistics were performed for patient and disease characteristics, assuming normality for DAS28 distribution and the level of disease activity was analyzed using Pearson's statistics. One-way analysis of variance was employed to explore for difference between sub-groups. Bivariate correlation and linear logistic analysis were employed to explore for potential correlation between DAS28 and HADS.
Results: From June 2016 to January 2017, 230 patients (male 66, female 164) from 12 hospitals performed 311 times HADS and 517 times DAS28 self-assessment. The mean (±SD) age was 34.17±13.11 (11–71) years, with the median disease duration of 24.70 (0–572) months. As the standard of HADS score higher than 10, 31% and 37% patients could be diagnosed as anxiety and depression respectively. According to the DAS28 assessment results, the proportion of patients with remission, low disease activity, moderate activity and high activity were 18%, 19%, 46% and 18% respectively. Bivariate correlation showed that DAS28 was positively correlated with HADS, $p<0.001$. Both HADS-A and HADS-D showed linear regression association with DAS28 score, the regression equation as "HADS-A = 5.962 + 0.435*DAS28" and "HADS-D = 6.379 + 0.694*DAS28" respectively, $p<0.001$.
Conclusions: DAS28 was positively correlated with HADS. SSDM is an effective mobile interface to serve for RA patients performing self-management of both disease activity and mental health as well as to supply physicians with valuable data.

FRI0177 THE UNDERRATED PREVALENCE OF DEPRESSION IN PATIENTS WITH RHEUMATOID ARTHRITIS

R. Sruamsiri[1], Y. Kaneko[2], J. Mahlich[1]. [1]*Health Economics, Janssen Pharmaceutical KK, Tokyo, Japan;* [2]*Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan*

Background: Significant evidence in the scholarly literature suggests that depression is a common comorbidity among patients with rheumatoid arthritis (RA) (1) Comorbid depression in RA patients is especially troublesome because it often goes unrecognized and untreated (2) often because rheumatologists and their patients seldom communicate about depression (3). In addition, evidence of depression in RA patients is limited in Asia studies.
Objectives: To determine the prevalence of depression among patients with RA and explore the relationships between depression and an array of variables.
Methods: Cross-sectional online survey (n=500) of RA patients including the Patient Health Questionnaire [PHQ-9] (4) to measure the presence and severity of depressive symptoms were performed. The survey contained patient demographic, clinical characteristics such as functional impairment as assessed using the Japanese version of the Stanford Health Assessment Questionnaire (J-HAQ score), and the participant's current medical treatment. Ordered logistic regression was used to identify the determinants of depression conditions among survey respondents.
Results: The mean age of the 500 patients with RA was 54.3 years old and 67% were female. While only 25 (5%) of the population studied had been officially diagnosed with depression, 176 (35%) had PHQ-9 scores indicating depression was present. Comorbidity conditions, except for migraine and heart conditions, were not different between patients with depression and those without. Logistic regression analysis revealed a negative correlation between the prevalence of depression and younger age with odds ratio (OR) of 0.96 (95% confidence interval (CI); 0.93–0.98), higher education (OR, 0.60; 95% CI, 0.36–0.98 for a bachelor's degree or higher) and an income level of 0.8–1.6 million yen (OR, 0.45; 95% CI, 0.22–0.91). Positive correlations with depression was found in RA patients with high J-HAQ score (OR, 1.99; 95% CI, 1.47–2.71). Patients treated with biologic monotherapy were significantly less likely to have depression compared to those treated with non-biologic anti-rheumatic drugs (OR, 0.36; 95% CI, 0.17–0.75)
Conclusions: It is a potential risk of under-diagnosis and under-reporting of Depression in patients with RARA patients are more likely to experience depression if they are younger, have greater functional impairment, or whose treatment regimen includes pain medications without biologic drugs.

FRIDAY, 16 JUNE 2017

Rheumatoid arthritis - anti-TNF therapy

FRI0178 RITUXIMAB IS EFFECTIVE IN THE TREATMENT OF RHEUMATOID ARTHRITIS REGARDLESS OF BODY MASS INDEX

D.H. Yoo[1], W. Park[2], C.H. Suh[3], S.C. Shim[4], S.J. Lee[5], Y.J. Bae[5], C. Park[5], J.H. Koo[5]. *[1]Hanyang University Hospital for Rheumatic Diseases, Seoul; [2]IN-HA University, School of Medicine, Incheon; [3]Ajou University School of Medicine, Suwon; [4]Chungnam National University Hospital, Daejeon; [5]Celltrion Inc., Incheon, Korea, Republic Of*

Background: High body mass index (BMI) is known to be associated with inadequate clinical response to anti-TNF agents in rheumatoid arthritis (RA) patients.[1] However, there are limited data on the effect of high BMI on the response to rituximab in RA patients, who showed an inadequate response or intolerance to anti-TNF agents.
Objectives: To investigate the impact of BMI on clinical response in the post-hoc analysis of randomized controlled trial that demonstrated clinical equivalence between a biosimilar of rituximab, CT-P10 and innovator rituximab, RTX[2] (NCT02149121).
Methods: A total of 332 patients who received two courses of either CT-P10 or RTX were included in this analysis. Patients were classified into 3 groups; normal weight (<25kg/m^2), overweight (≥25 kg/m^2 ~<30 kg/m^2) and obesity (≥30 kg/m^2) as per WHO BMI category. Improvement in disease activity by the Disease Activity Score using C-reactive protein (DAS28-CRP), remission (≤2.6), low disease activity rate (LDA, ≤3.2) and ACR response at Week 24 (Week 24 of 1st course) and Week 48 (Week 24 of 2nd course) and duration of sustained LDA (from the first LDA observed to the last LDA observed up to Week 48) were analysed by BMI categories in the each and combined group of CT-P10 and RTX.
Results: In the pooled group of CT-P10 and RTX, the mean weights were 59 kg in normal weight, 73kg in overweight and 91kg in obesity. All other baseline characteristics were comparable among BMI groups including baseline disease activity based on DAS28; Moderate disease activity, 22.3% vs. 22.8% vs. 25.7%, respectively; High disease activity, 77.7% vs. 77.2% vs. 74.3%, respectively. There was no statistical difference among BMI groups in terms of DAS28 change from baseline and ACR 20/50/70 response (Table). No particular trend was observed in remission and LDA rate by DAS28 at Week 24 and Week 48 among BMI groups (Figure). Mean duration of sustained LDA (months) were also comparable among the groups (4.5 vs. 4.7 vs. 5.0, respectively). Additionally, similar trends in all analyses were observed in each treatment group; CT-P10 and RTX.
Conclusions: The BMI does not affect the clinical response in RA patients with rituximab treatment. Therefore, this result supports that rituximab could be a reasonable therapeutic option for obese RA patients with inadequate response to anti-TNF agents.

Table 1. DAS28, ACR responses by BMI subgroups

Parameter	Visit	Normal (N=148)	Over weight (N=114)	Obesity (N=70)
DAS28, mean (SD)	Baseline	5.88 (0.95)	5.81 (0.89)	5.69 (0.78)
	Week 24*	-2.43 (1.12)	-2.13 (1.19)	-2.39 (0.99)
	Week 48*	-2.76 (1.31)	-2.47 (1.32)	-2.74 (1.01)
ACR20, n (%)	Week 24	122 (82.4%)	86 (75.4%)	56 (80.0%)
	Week 48	119 (80.4%)	88 (77.2%)	60 (85.7%)

FRI0179 MINIMAL TO NO TRANSFER OF CERTOLIZUMAB PEGOL INTO BREAST MILK: RESULTS FROM CRADLE, A PROSPECTIVE, POSTMARKETING, MULTICENTER, PHARMACOKINETIC STUDY

M.E.B. Clowse[1], F. Förger[2], C. Hwang[3], J. Thorp[4], R.J.E.M. Dolhain[5], A. van Tubergen[6], L. Shaughnessy[7], J. Simpson[7], M. Teil[8], N. Toublanc[9], M. Wang[7], T.W. Hale[10]. *[1]Duke University Medical Center, Durham, United States; [2]Inselspital, University of Bern, Bern, Switzerland; [3]Keck Hospital of USC, Los Angeles; [4]University of North Carolina at Chapel Hill, Chapel Hill, United States; [5]University Medical Centre Rotterdam, Rotterdam; [6]Maastricht University Medical Center, Maastricht, Netherlands; [7]UCB Pharma, Raleigh, United States; [8]UCB Pharma, Slough, United Kingdom; [9]UCB Pharma, Brussels, Belgium; [10]Texas Tech University School of Medicine, Amarillo, United States*

Background: Women with active chronic rheumatic inflammatory conditions (RA, PsA, AxSpA) often face uncertainty regarding the safety of the use of biologics during breastfeeding.[1] Limited and non-validated data exist on the potential transfer of anti-TNFs into breast milk.[2] CRADLE (NCT02154425) was the first sponsored study to evaluate certolizumab pegol (CZP) concentrations in breast milk, and to estimate the Average Daily Infant Dose (ADID) of maternal CZP.
Objectives: To determine the concentration of CZP in breast milk and calculate the ADID of maternal CZP.
Methods: CRADLE was a pharmacokinetic study of lactating mothers (≥6 weeks postpartum) receiving commercial CZP. Decision to treat with CZP and breastfeed was independent of study participation. At steady state (≥3 CZP doses), breast milk samples were collected on Days 0, 2, 4, 6, 8, 10, 12, 14 (±28) from each mother across 1 dosing period. CZP was detected using a highly sensitive, CZP-specific electrochemiluminescence immunoassay validated in milk (lower limit of quantification [LLOQ]=0.032 μg/mL; 10-fold lower than previous assays). CZP stability in milk was confirmed.
Results: 18 CZP-treated mothers were screened: 17 entered the sampling period; 16 on CZP 200 mg Q2W; 1 on CZP 400 mg Q4W (7 RA; 5 SpA; 5 CD; Table A). Samples from 4/17 mothers had no measurable CZP in breast milk; 13/17 had quantifiable levels for at least 1 time point (highest concentration: 0.076 μg/mL; Table B). Estimated ADID ranged 0–0.0104 mg/kg/day; median Relative Infant Dose (RID; calculated post hoc[3]): 0.15%. Infants of CZP-exposed mothers had a

Less than 3×LLOQ (<0.096 μg/mL)
Less than 2×LLOQ (<0.064 μg/mL)
BLQ (<0.032 μg/mL)
CZP plasma C_{trough} from the RAPID2 study: 15.7 μg/mL

BLQ: below the lower limit of quantification; LLOQ: lower limit of quantification.

safety profile consisting of events occurring in unexposed infants of similar age.
Conclusions: CZP was below the lower limit of quantification in 56% of the milk samples. When detectable, CZP concentrations were less than 3x LLOQ (<1% of expected plasma concentration of a therapeutic dose[4]), indicating no to minimal transfer of CZP from plasma to breast milk. RID was below 0.5% of maternal dose; <10% is unlikely to be of clinical concern.[3] CZP absorption via breast milk is unlikely, due to low bioavailability and its Fc-free molecular structure. These findings support continuation of CZP treatment during breastfeeding.

FRI0180 MULTIPLE SCLEROSIS RISK-ALLELES STUDY IN PATIENTS WITH DEMYELINATING SIDE EFFECTS ON ANTI TNF ALPHA THERAPY

S. Bitoun[1], C. Verstuyft[2], C. Miceli-Richard[1], J.-M. Berthelot[3], C. Richez[4], C. Cauquil[5], C. Sordet[6], S. Melac-Ducamp[7], L. Gossec[8], B. Beatrice[9], E. Dernis[10], E. Houvenagel[11], M.-A. Boutry-Bacle[12], X. Mariette[1], R. Seror[1]. *[1]Université Paris-Sud, Hôpitaux Universitaires Paris-Sud, INSERM U1184, le Kremlin Bicètre; [2]Department of Pharmacogenetics, Hôpitaux Universitaires Paris-Sud, le Kremlin Bicêtre; [3]C.H.U. Hôtel Dieu, Nantes; [4]C.H.U Pellegrin, Bordeau; [5]Hôpitaux Universitaires Paris-Sud, le Kremlin Bicètre; [6]Hôpitaux Universitaires Strasbourg, Strasbourg; [7]C.H.I, Nevers; [8]Pitie-Salpétrière Hospital, Paris; [9]CHU, Angers; [10]Centre Hospitalier du Mans, le Mans; [11]Hôpital Saint Philibert, Lomme; [12]C.H., Abbeville, France*

Background: Tumor Necrosis Factor alpha (TNFα) is a key cytokine in inflammatory rheumatic diseases. TNF inhibitors (TNFi) has revolutionized treatment of rheumatic diseases, but may cause flares of multiple sclerosis (MS). Two Single Nucleotide Polymorphisms, (SNPs) *rs1800693* and *rs4149584*, located within *TNF receptor superfamilly 1* (*TNFRSF1A*) locus have been shown to increase the risk of developing MS [1]. The rs1800693*G allele leads to a dysfunctional TNFα soluble receptor that inhibits TNFα signaling while *rs4149584* is involved in TNF receptor associated periodic syndrome.
Objectives: The aim of this study was to look for a possible the association between *TNFRSF1A* polymorphisms and demyelinating complications occurring during TNFi therapy.
Methods: Patients who presented with a demyelinating disorder (central or peripheral involvement) while treated with TNFi (cases), were recruited between March 2013 and December 2015, through the physicians involved in the CRI ("Club Rhumatismes et Inflammation") a nationwide network of the French Society of Rheumatology. Rheumatoid arthritis patients treated with TNFi, from the French ReAct cohort, and who did not develop demyelinating complication constituted the control population (n=294). The frequency of *rs1800693* and *rs4149584* TNFRSF1A SNPs were compared between cases and controls.
Results: Twenty-four cases with demyelinating disorders, recruited from 11 centers with a median age of 39.7 years (range 30.4–75.8); of which 16 (67%) were females were included in the study. Neurological symptoms occurred after a median of 18.3 (1–66) months of anti TNFi; 15 (62.5%) had central neurologic involvement and 9 (37.5%) had peripheral involvement. The median follow-up was 26 (4–54) Months. No significant difference in the frequency of the *rs1800693* MS risk-alleles (39,5% for cases vs 38,6% for controls) was observed. Similarly no difference was observed between cases (2%) and controls (4%) for *rs4149584.*
Conclusions: This study was unable to show an association between MS-associated SNPs within *TNFRSF1A* locus and the occurrence of demyelination while taking TNFi, suggesting that demyelination might be linked to other genetic factors or other pathways.

FRI0181 TAPERING OR CESSATION OF ANTIVIRAL AGENT IN HEPATITIS B VIRUS-INFECTED PATIENTS CONCOMITANTLY TREATED WITH BIOLOGIC AGENTS

B. Ghang[1], D.-H. Lim[2], W.J. Seo[3], Y.-G. Kim[1], B. Yoo[1]. *[1]Rheumatology, Asan Medical Center, Seoul; [2]Rheumatology, Ulsan University Hospital, Ulsan; [3]Rheumatology, Seoul Veterans Hospital, Seoul, Korea, Republic Of*

Background: Clinicians generally prescribe antiviral agents to patients with chronic hepatitis B (CHB) or to inactive carriers of the virus until 6–12 months after the cessation of biologic agents. However, the current antiviral prophylaxis regimen, in addition to biological therapy, is expensive and poses an economic burden to both patients and societies. We have had patients in our medical center quit or reduce antiviral prophylaxis due to economic reasons.
Objectives: To assess the outcome of tapering or discontinuation of antiviral agents in patients who were infected with hepatitis B virus (HBV) during biologic therapy.
Methods: We identified 45 patients who were infected with HBV and treated with biologic agents concomitantly from January 2005 to December 2016. They were diagnosed with rheumatoid arthritis (n=20), Crohn's disease (n=13), ankylosing spondylitis (n=8), ulcerative colitis (n=3), and psoriatic arthritis (n=1). The criteria of HBV reactivation was a 10-fold rise in HBV DNA compared with previous HBV DNA titers, resulting in HBV DNA of greater than 20,000 IU/ml (HBeAg-positive patients) or 2,000 IU/ml (HBeAg-negative patients), and an increase in AST or ALT to more than twice the upper normal limit (40 IU/l).
Results: Sixteen CHB patients and 29 inactive carriers were treated with biologic agent for 4.1±2.7 years. No reactivation case was observed in 23 patients (10 of CHB and 13 of inactive carrier) who maintained antiviral prophylaxis for 4.0±2.3 years. Among them, 4 patients (3 treated with infliximab and 1 with adalimumab) taking antiviral prophylaxis regimen on alternate days did not experience HBV reactivation for 28–42 months of follow-up period. In the discontinuation group (n=9), no reactivation case was observed in all inactive carrier patients (2 treated with etanercept, 1 with infliximab, and 1 with rituximab) after discontinuation of antiviral prophylaxis for 6–33 months of follow-up period. In contrast, 3 patients (2 treated with etanercept and 1 with adalimumab) among the 5 patients with CHB experienced reactivation after discontinuation of antiviral prophylaxis for 3–29 months of follow-up period.
Conclusions: During biologic therapy, HBV reactivations were frequently found in CHB patients who ceased to take antiviral prophylaxis. However, no reactivation after the cessation of prophylaxis was found in inactive carrier patients who were previously treated with prophylaxis. Based on our experience, tapering or discontinuation of antiviral agent in inactive carriers with economic problem undergoing concomitant biologic agent therapy could be considered viable, albeit with caution.

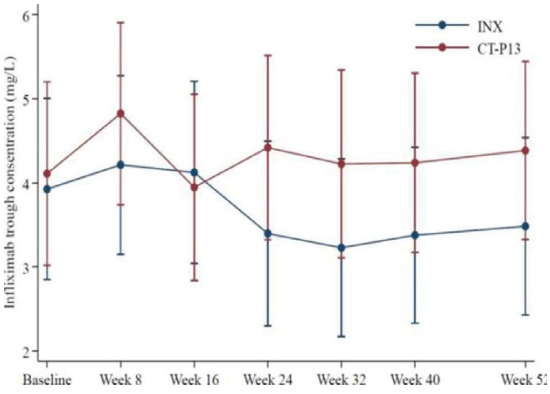
FRI0182 DISEASE WORSENING AND SAFETY IN PATIENTS SWITCHING FROM ORIGINATOR INFLIXIMAB TO BIOSIMILAR INFLIXIMAB (CT-P13) IN THE NOR-SWITCH STUDY: EXPLORATIVE ANALYSIS OF RA PATIENTS

G.L. Goll[1], I.C. Olsen[1], N. Bolstad[2], K.K. Jørgensen[3], M. Lorentzen[4], C. Mørk[5], J. Jahnsen[3], E.A. Haavardsholm[1], T.K. Kvien[1] on behalf of The NOR-SWITCH study group. *[1]Dept of Rheumatology, Diakonhjemmet Hospital; [2]Biochemistry DNR, Oslo University Hospital, Oslo; [3]Gastroenterology, Akershus University Hospital, Lørenskog; [4]Dermatology, Oslo University Hospital, Oslo; [5]Dermatology, St Olav University Hospital, Trondheim, Norway*

Background: The NOR-SWITCH study was a 52-week randomized, double-blind, non-inferiority, phase IV switch trial in patients with Crohn's disease (CD), ulcerative colitis (UC), spondyloarthritis (SpA), rheumatoid arthritis (RA), psoriatic arthritis (PsA) and plaque psoriasis (Ps) on stable treatment with originator infliximab (Remicade®, INX) and was funded by the Norwegian government. Previously, the primary analyses of the pooled indications have been published[1].
Objectives: To investigate efficacy, safety and immunogenicity in RA patients treated with continous INX vs patients switched to CT-P13 (biosimilar infliximab, Remsima®) in the NOR-SWITCH study (explorative analyses).
Methods: Patients were randomized 1:1 to continued INX or switch to CT-P13. Serum drug levels were analysed in automated in-house assay. The primary



Abstract FRI0182 – Table 1. Demographic and baseline characteristics (FAS), percentage of RA patients with disease worsening and change in disease measures during 52 weeks follow-up (PPS)

Demographics and baseline characteristics	INX	CT-P13	
Total number of RA patients PPS/FAS	30/39	30/38	
Age (years) mean (SD)	59.9 (11.5)	60.4 (11.4)	
Females	31 (79%)	25 (66%)	
Duration of ongoing infliximab treatment (years) mean (SD)	8.2 (3.7)	9.9 (3.4)	
Concomitant immunosuppressive medication	27 (69%)	34 (89%)	
ACPA pos	25 (83%)	20 (74%)	
Disease worsening			95% CI of group difference after 52 weeks
All study patients	53 (26.2%)	61 (29.6%)	-12.7–3.9%
RA	11 (36.7%)	9 (30.0%)	-20.3–29.3%
Change in disease measures from baseline			
Physician Global Assessment of Disease Activity (0–10)	-0.1 (1.3)	0.1 (1.4)	-0.58–0.68
Patient Global Assessment of Disease Activity (0–10)	1.1 (1.4)	0.4 (1.9)	0.21–1.91
Log_{10} erythrocyte sedimentation rate (mm/h)	0.0 (0.3)	0.0 (0.3)	-0.08–0.16
Log_{10} C-reactive protein (mg/L)	0.1 (0.3)	0.0 (0.5)	-0.11–0.22
DAS28	0.2 (0.9)	0.2 (0.9)	-0.30–0.50
TEAE (FAS)	94	62	

Data are n (%), mean (SD) or median (25–75 percentiles). 95% CI, 95% confidence interval of the adjusted treatment difference. DAS28, Disease Activity Score in 28 joints. FAS, Full Analysis Set. PPS, Per Protocol Set. TEAE, treatment emergent adverse events.

endpoint was disease worsening according to disease-specific composite measures and/or consensus between investigator/patient leading to major treatment change. Exploratory subgroup analyses examined disease worsening and safety in RA. The primary endpoint was analysed using logistic regression, adjusted for diagnosis and disease duration.

Results: Demographics, occurence of disease worsening, change in disease measures and treatment-emergent adverse events (TEAE) were similar (Table). Serum drug levels for INX and CT-P13 were similar throughout the study (Figure)

Conclusions: Explorative analyses in the NOR-SWITCH study showed similar efficacy, serum drug levels and safety in RA patients switched to CT-P13 as those on continuous INX. The study was not powered to show non-inferiority within each diagnosis.

FRI0183 ASSESSING ADHERENCE OF RA PATIENTS TREATED WITH ETANERCEPT USING ETANERCEPT SERUM TROUGH CONCENTRATIONS AND PATIENT SELF-REPORT

E. Vogelzang[1], R. Hebing[2], M. Nurmohamed[1], M. L'Ami[1], C. Krieckaert[1], G. Wolbink[1,3]. *[1]Rheumatology; [2]Rheumatology, Pharmacy, Amsterdam Rheumatology and immunology Center | Reade; [3]Immunopathology, Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands*

Background: The EULAR recommendations for the management of rheumatoid arthritis (RA) update 2013 contained the following research question: "How good is patient adherence to biological agents and can lack of adherence be related to loss of efficacy?" [1]. Limited studies are published in which adherence of RA patients treated with biological disease-modifying anti rheumatic drugs (bDMARDs) has been assessed. Previous studies regarding adherence of RA patients treated with etanercept did not take into account that patients are instructed to temporarily discontinue bDMARDs therapy during e.g. a serious infection. In addition, etanercept concentrations have never been utilized in determining adherence to etanercept in RA patients.

Objectives: The aim of our study was to determine the percentage of non-adherent RA patients treated with etanercept, using etanercept concentrations and patient self-report, and to assess the relationship between adherence and clinical outcome during 52 weeks.

Methods: Non-adherence was defined as an etanercept trough concentration <0.1ug/mL at least once and no valid/medical reason to miss an etanercept dose. In this retrospective cohort study patients visited our clinic at baseline and 4, 16, 28, 40 and 52 weeks after initiation of etanercept treatment. At baseline and following visits disease activity score of 28 joints (DAS28) was calculated and blood was drawn to measure etanercept concentrations. During each visit patients were asked if they missed an etanercept dose, at which date and for which reason. Remission was defined as DAS28 <2.6 at least for two consecutive visits. Low disease activity (LDA) was defined as DAS28 <3.2 during a minimal of two consecutive visits.

Results: In total 292 patients were included. Mean age was 53 years (SD 12.7), 82% was women and median disease duration was 8 years (IQR 3–16). In total 24 patients had an etanercept concentration <0.1ug/mL. Most patients had a medical reason to miss an etanercept dose, see table 1.

Table 1. Reasons for patients to miss an etanercept dose

Reason	Number of patients
Medical	10
Did not start	3
Logistical problem	1
Stopped due to inefficacy	1
Unknown	9

Only ten patients (3.4%) were non-adherent during the follow-up of 52 weeks. Of the adherent patients 82 out of 282 (29%) reached LDA versus 1 out of 10 non-adherent patients. A total of 127 of 282 (45%) adherent patients achieved MDA versus 3 out of 10 non-adherent patients.

Conclusions: Most patients had a medical reason to miss an etanercept dose. The percentage of patients who are non-adherent to etanercept therapy is very low (3.4%).

Objectives: To describe profiles of rheumatoid arthritis (RA) patients according to their beliefs in their subcutaneous biological medication (SC).

Abstract FRI0184 – Table 1

		Accepting (n=116)	Ambivalent (n=182)	Indifferent (n=16)	Skeptical (n=7)	p
Mean age (SD)		55.5 (12.6)	54.2 (12.5)	58.8 (13.2)	53.6 (10.2)	0.459
		%	%	%	%	
Sex	Men	19.0	23.1	43.8	43.9	0.090
	Women	81.0	76.9	56.2	57.1	
RA duration	> median	51.8	50.3	43.8	28.6	0.651
	≤ median	48.2	49.7	56.2	71.4	
Satisfaction						
Symptoms control	Very/quite satisfied	93.1	82.9	68.8	85.7	0.009
	Indifferent, quite/very unsatisfied	6.9	17.1	31.2	14.3	
Tolerance/side effects	Very/quite satisfied	79.7	57.0	50.0	57.1	<0.001
	Indifferent, quite/very unsatisfied	20.3	43.0	50.0	42.9	
Expectations						
Effect of the drug on symptoms	Much/quite greater than expected	69.6	53.3	75.0	57.1	0.031
	+/– As expected	23.5	39.0	12.5	28.6	
	Quite/lower than expected	7.0	7.7	12.5	14.3	
Side effects/discomfort	Much/quite greater than expected	7.0	17.0	12.5	0.0	0.004
	+/– As expected	27.0	39.6	25.0	57.1	
	Quite/lower than expected, or no side effects/discomfort	66.0	43.4	62.5	42.9	

Methods: ARCO was a study carried out on RA Spanish patients who initiated a SC biological drug 11–18 months prior to the study visit. Patients completed the Beliefs About Medication Questionnaire (BMQ). According to the scores obtained in the necessity (N) and concerns (C) sub-scales, patients were classified into 4 groups: accepting (high N [>3]/low C [≤3]), ambivalent (N>3/C>3), indifferent (N≤3/C≤3) and skeptical (low N [≤3]/high C [>3]). We studied demographic characteristics, expectations and satisfaction with the treatment by group.
Results: 321 patients (77% women) completed the BMQ, 92.8% scored N>3 and 58.9% C>3. A higher % of men than women scored N≤3 (13.5% vs. 5.2%, p=0.031). The % who scored C>3 was higher in those with low satisfaction with symptom control (71.1% vs. 56.7% in satisfied/very satisfied, p=0.098), or side effects (72.1% vs. 52.0%, p<0.001), and in those with lower fulfillment of expectations of efficacy and tolerance (p=0.006 and p<0.001). The combination of N and C scores identified 116 accepting (36.1%), 182 ambivalent (56.7%), 16 indifferent (5.0%) and 7 skeptical patients (2.2%). There were no differences in age, gender, or RA duration among the groups, but differences were seen in the satisfaction with the treatment and in the fulfillment of the expectations (table). Ambivalent patients showed less satisfaction and lower fulfillment of expectations with the treatment received than accepting patients.
Conclusions: Patients with RA have strong beliefs about the need of their biological SC medication, but a high % also expresses concerns. Beliefs, and especially concerns, seem to relate to the satisfaction and fulfillment of expectations of efficacy and tolerability or the drug, rather than to demographics or RA characteristics. Discussing expectations may be important when initiating a biological treatment.

FRI0185 A SYSTEMATIC REVIEW AND BIVARIATE META-ANALYSIS OF STUDIES THAT MEASURED ADALIMUMAB DRUG LEVELS BY ELISA TO DETECT TREATMENT RESPONSE IN RHEUMATOID ARTHRITIS

S. Gavan[1,2], K. Payne[1], A. Barton[2,3]. *[1]Manchester Centre for Health Economics, The University of Manchester; [2]National Institute for Health Research Manchester Musculoskeletal Biomedical Research Unit at Central Manchester University Hospitals NHS Foundation Trust; [3]Centre for Musculoskeletal Research, The University of Manchester, Manchester, United Kingdom*

Background: Previous research has demonstrated an association between circulating drug levels and treatment response in patients with rheumatoid arthritis that received the anti-TNF therapy adalimumab. Commercial ELISA assays are now available for use in routine practice to monitor anti-TNF drug levels at regular intervals. However, the ability to detect treatment response by measuring adalimumab drug levels using an ELISA is uncertain.
Objectives: The objectives of this research were to identify and synthesise all published studies that investigated the accuracy of measuring adalimumab drug levels by ELISA to detect treatment response in patients with rheumatoid arthritis.
Methods: A systematic review identified all published studies that performed a receiver operating characteristic (ROC) analysis to detect treatment response in patients with rheumatoid arthritis by measuring adalimumab drug levels using an ELISA. Medline and Embase were searched electronically from inception to August 2016. Two researchers independently identified studies for the review using a pre-defined inclusion criteria. Assay results were classified as positive if adalimumab drug levels exceeded the cut-point reported in each study. Study design characteristics, sample characteristics, and test outcomes from 2x2 tables (true-positive; false-positive; true-negative; false-negative) were extracted from each study. The quality of each study was assessed using the QUADAS-2. A hierarchical bivariate meta-analysis synthesised the findings of the ROC analyses to account for between-study heterogeneity and correlation between assay sensitivity and specificity.
Results: The search strategy identified 4,006 abstracts and four studies met the inclusion criteria of the systematic review. Patients received 40mg adalimumab every two weeks in all studies. Studies varied in their design and sample characteristics, but had low risk of bias and low concern of applicability to the research objective. The hierarchical bivariate meta-analysis estimated that measuring high adalimumab drug levels by ELISA detected treatment response with an average sensitivity of 0.95 (95% CI: 0.85–0.98) and specificity of 0.68 (95% CI: 0.28–0.92).
Conclusions: Measuring high adalimumab drug levels by ELISA in patients with rheumatoid arthritis appeared to be predictive of treatment response. However, the measurement of low adalimumab drug levels was less predictive of no response to treatment. In practice, test accuracy may be improved by measuring anti-drug antibodies alongside adalimumab drug levels. Given the imperfect accuracy of ELISA assays, the relative cost-effectiveness of drug level monitoring should be evaluated before being recommended for use in routine practice.

FRI0186 INFLUENCE OF IMMUNOGENICITY TO THE FIRST TNF-I THERAPY ON RESPONSE TO THE SECOND BIOLOGIC AGENT IN RA PATIENTS

P. Bogas[1], C. Plasencia[1], D. Pascual-Salcedo[2], G. Bonilla[1], E. Moral[1], C. Tornero[1], L. Nuño[1], A. Villalba[1], D. Peiteado[1], A. Martinez[2], B. Hernandez[2], A. Balsa[1]. *[1]Rheumatology; [2]Immunology, Hospital Universitario la Paz, Madrid, Spain*

Background: There is currently no consensus on selecting a therapeutic target in patients (pts) non-responsive to their first TNF-inhibitors (TNF-i). The development of anti-drug antibodies (ADA) is a frequent cause of secondary inefficacy in our pts with TNF-i and there is evidence that those who develop ADA at their 1st TNF-i achieve a higher degree of response to the second one, compared to ADA- pts. Thus ADA measurement can help in choosing a therapeutic target in pts who failed to respond to their 1st TNF-i
Objectives: To assess if development of ADA to the 1st TNF-i determines better response when switching to a 2nd TNF-i versus a nonTNF-i. As secondary objective, analyze whether the presence or absence of ADA to a 1st TNF-i influences the efficacy of a 2nd TNF-i
Methods: Of a total of 144 pts that switched from infliximab or Adalimumab to a 2nd biologic agent (Etanercept, Rituximab, Tocilizumab, Adalimumab, Abatacept, Certolizumab and Infliximab), only 60, who had measured drug levels (DL)/ADA at discontinuation of the 1st TNF-I, were included. Clinical response was evaluated with DAS28, Delta-DAS28 (ΔDAS28) and EULAR response (E-resp) at 6 (v-6) and 12 (v-12) months after initiating 2nd biologic agent and at the last visit prior to drug discontinuation or ending of the study for those who did not interrupt the biological therapy (v-end). DL/ADA levels were measured by ELISA. Statistical analysis was performed using SPSS version 20.0
Results: Within the 60 pts who had measured DL/ADA at suspension of the 1st TNF-i, 26 (43%) were ADA- (i.e. DL +). In this ADA- subpopulation, 50% changed to a 2nd TNF-i; at v-6 there were no differences between switchers to a 2nd TNF-i and switchers to a nonTNF-i in DAS28 (3.7±2.1 TNF-i vs 4.2±1.1 nonTNF-i, p=0.286), ΔDAS28 (1,4±2 TNF-i, 1±1,2 nonTNF-i, p=0,374) and resp-E (75% good/moderate resp in TNF-I, 40% in nonTNF-i, p=0,064). At v-12, switchers to a 2nd TNF-i showed a lower DAS28 (2.5±0.6 TNF-i, 3.9±0.9 nonTNF-i, p=0.009) and a higher good E-resp rate with a marginally significant difference (80% in TNF-i, 22% in nonTNF-i, p=0.071). However, at v-end, pts with a 2nd nonTNF-i had better response (DAS28 >5,1 in 50% of TNF-i pts, 0% of nonTNF-i, p=0.044). Likewise ΔDAS28 at v-end was higher in the nonTNF-i group with trend to significance (0,7±1,7 TNF-i, 1,7±0,8 nonTNF-i, p=0,06). Along these lines, the

good/moderate E-resp rate was higher in switchers to a nonTNF-i (70% in TNF-i, 8.3% in nonTNF-i, p=0.006). In ADA+ subpopulation (n=34), no differences were found in clinical response at v-end in DAS28 (3.7±1.2 TNF-i, 3.9±1.1 non-TNF-i, p=0.64), ΔDAS28 (0,63±1,6 in TNF-i, 1,4±1,4 in nonTNF-i, p=0,35) and good/moderate E-resp rate (30% in TNF-i, 91% in nonTNF-i, p=0,703). In pts who changed to a 2nd TNF-i, those with ADA to 1st TNF-i had a higher good response rate than ADA- pts (65% in ADA +, 30% in ADA-, p=0.07)

Demographic characteristics	ADA+ subpopulation	ADA- Subpopulation	p
Age (years)	62,3±14,6	65,7±14,9	0,203
Sex (female)	28 (82%)	23 (88%)	0,719
Smokers	7 (20,6%)	4 (26%)	0,537
BMI	26,9±8,9	23,9±4,2	0,39
Disease duration (years)	19,3±8,05	24,1±8,2	0,844
RF +	32 (94%)	20 (77%)	0,067
Anti-CCP +	32 (94%)	22 (88%)	0,641
Basal CPR	15,1±18,2	20,4±21,7	0,46
Basal ESR	41±27,9	38±20	0,28
Basal DAS	5,31±1,4	5,51±1,3	0,18

Conclusions: The development of ADA to the first TNF-i entails a better response when switching to a 2nd TNF-i, with a similar efficacy to the pts who switched to a nonTNF-i. In those pts who did not develop immunogenicity to the 1st TNF-I, there is a better response when changing therapeutic target. The ADA measurement can help to select the pts who can benefit from a 2nd TNF-i

FRI0187 RADIOGRAPHIC PROGRESSION BY DISEASE ACTIVITY STATES IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH SB2 OR REFERENCE INFLIXIMAB

J.S. Smolen[1], J.-Y. Choe[2], E. Keystone[3], Y.H. Rho[4], Y. Lee[4], S. Lee[4]. *[1]Medical University of Vienna, Vienna, Austria; [2]Daegu Catholic University Medical Center, Daegu, Korea, Republic Of; [3]Mount Sinai Hospital, University of Toronto, Toronto, Canada; [4]Samsung Bioepis Co., Ltd., Incheon, Korea, Republic Of*

Background: Based on the totality of evidence, SB2 has shown to be similar with reference infliximab (INF) and has been approved as a biosimilar by the European Medical Agency. It is, however, hitherto unknown, if SB2 also shares similar structural efficacy in the different disease activity states when compared with INF.

Objectives: To evaluate the disease activity by simplified disease activity index (SDAI) and clinical disease activity index (CDAI) at weeks 14, 30 and 54 in patients with rheumatoid arthritis (RA) treated with SB2 or INF from a phase III study and to assess the radiographic progression at week 54 in patients by disease activity states (remission, low disease activity [LDA], moderate disease activity [MDA], or high disease activity [HDA]).

Methods: Patients with RA were randomised to receive either SB2 or INF 3 mg/kg at weeks 0, 2, 6, and then every 8 weeks thereafter until week 46 with background methotrexate. Dose increments were allowed after week 30 by 1.5 mg/kg up to a maximum dose of 7.5 mg/kg. Disease activities by SDAI, and CDAI were compared at weeks 14, 30, and 54. The radiographic progression was measured by modified Total Sharp Score (mTSS) at weeks 0 and 54.

Results: Up to week 54, comparable proportions of patients achieved ACR-EULAR-index remission between SB2 and INF (by SDAI: 13/279 [4.7%] vs. 13/283 [4.6%] at week 14; 24/250 [9.6%] vs. 29/263 [11.0%] at week 30; 34/226 [15.0%] vs. 24/224 [10.7%] at week 54; by CDAI: 12/279 [4.3%] vs. 12/283 [4.2%] at week 14; 22/253 [8.7%] vs. 31/265 [11.7%] at week 30; 33/227 [14.5%] vs. 24/225 [10.7%] at week 54 in SB2 and INF, respectively). The proportions of radiographic non-progressors (defined as change in mTSS ≤0) by disease activity were comparable between SB2 and INF at week 14, 30 and 54 (Table 1). Patients treated with SB2 as well as INF also exhibited the lowest progression of radiographic damage in remission and the largest progression in HDA, but also very small increases in mTSS in LDA and MDA, in line with previous findings on INF.

Table 1. The proportion of radiographic non-progressors (mTSS progression ≤ 0) and mean change from baseline in mTSS at week 54 by disease activity states at weeks 14, 30, and 54

Disease activity state at each visit		CDAI				SDAI			
		SB2		INF		SB2		INF	
		Radiographic non-progressors	Mean change	Radiographic non-progressors	Mean change	Radiographic non-progressors	Mean change	Radiographic non-progressors	Mean change

	LDA	55/74 (74.3)	0.40	52/67 (77.6)	-0.10	56/74 (75.7)	0.42	54/69 (78.3)	-0.23
	Remission	16/20 (80.0)	0.05	22/24 (91.7)	-0.13	17/21 (81.0)	0.07	20/22 (90.9)	0.07
Week 54	HDA	31/43 (72.1)	0.39	25/42 (59.5)	1.59	25/36 (69.4)	0.65	23/36 (63.9)	1.71
	MDA	47/69 (68.1)	0.69	46/66 (69.7)	0.30	50/73 (68.5)	0.57	44/68 (64.7)	0.35
	LDA	51/67 (76.1)	0.20	62/78 (79.5)	0.29	54/69 (78.3)	0.18	66/82 (80.5)	0.24
	Remission	28/33 (84.8)	-0.11	23/23 (100.0)	-1.39	27/33 (81.8)	-0.08	23/23 (100.0)	-1.22

Disease activity was defined as following:
by CDAI: remission, CDAI ≤ 2.8; LDA, 2.8 < CDAI ≤ 10.0; MDA, 10 < CDAI ≤ 22.0; HDA, 22.0 < CDAI
by SDAI: remission, SDAI ≤ 3.3; LDA, 3.3 < SDAI ≤ 11.0; MDA, 11 < SDAI ≤ 26.0; HDA, 26.0 < SDAI
Patients with available mTSS at both baseline and week 54 were included.

Conclusions: The proportion of patients achieving remission or LDA was comparable up to week 54 upon treatment with both SB2 and INF. Inhibition of radiographic progression was also comparable in each disease activity state. The proportion of radiographic non-progressors was also similarly high in patients achieving remission, and overall very low radiographic progression rates were seen even in LDA and MDA in both treatment arms. These data further confirm the comparability of SB2 and INF.

FRI0188 EFFECTIVENESS OF ADALIMUMAB COMBINATION THERAPY WITH METHOTREXATE AND NON-METHOTREXATE CSDMARDS: RESULTS FROM THE CORRONA RHEUMATOID ARTHRITIS REGISTRY

D. Pappas[1,2], J. Griffith[3], C.A. Schlacher[3], J.L. Subotcki[3], R.W. Harrison[2], Y. Shan[2], C. Karki[2], J.M. Kremer[4]. *[1]Columbia University, New York; [2]Corrona, LLC, Southborough; [3]AbbVie, Inc., Abbott Park; [4]Albany School of Medicine, Albany, United States*

Background: Combination therapy of methotrexate (MTX) with biologics results in superior outcomes vs. monotherapy. However, little is known on the effectiveness of adalimumab (ADA) combination therapy with non-MTX conventional synthetic disease modifying anti-rheumatic drugs (csDMARD).

Objectives: To evaluate whether ADA in combination with non-MTX csDMARD has similar effectiveness as MTX combination therapy on clinical and patient report outcomes (PROs).

Methods: Adult RA patients, naïve to other monoclonal antibodies, who initiated standard dose ADA (40mg q2w) in combination with MTX or ≥1 non-MTX csDMARD between 2003–2016 and had a 6 month follow-up visit were included. The primary outcomes were mean change in clinical disease activity index (CDAI) and mean change in PROs (mHAQ, pain, fatigue, morning stiffness) from baseline to 6 months. Secondary outcomes included achievement of remission (CDAI≤2.8)/low disease activity (LDA: CDAI≤10). Outcomes were evaluated adjusting for covariates that differed at the time of initiation using mixed model linear regression. Kaplan-Meier survival analysis was used to examine the persistency of ADA between the two groups.

Results: A total of 754 patients were included: N=519 ADA+MTX and N=235 ADA+non-MTX csDMARD. Patients on ADA+MTX were slightly younger (mean age: 54.5 vs 57.4 years), with shorter disease duration (median: 3 vs 5 years), more likely to be biologic naïve (77% vs 69%) compared to patients on ADA+nonMTX csDMARD (all p<0.05). Disease activity and PROs were comparable in both groups at the time of initiation (mean CDAI: 20.4 vs 22.8; mean pain: 45.3 vs 45.9; mean fatigue: 46.3 vs 47.8; mean patient global assessment: 42.8 vs 42.9 (on a VAS 0–100) in ADA+MTX and ADA+nonMTX csDMARD group respectively. Adjusted analysis showed that patients on ADA+MTX had significantly lower mean CDAI at 6 months and higher change in CDAI vs patients in the ADA+non-MTX csDMARD group (p<0.05). In addition, patients on ADA+MTX were more likely to achieve LDA compared to the ADA+non-MTX csDMARD group (Table). Change in PROs and persistency of ADA was comparable in both groups.

Table: Outcomes at 6 months among ADA+MTX and ADA+nonMTX csDMARD therapy

	ADA +MTX	ADA + nonMTX csDMARD[a]	Unadjusted[b]	Adjusted[b,c]
6 month outcomes	Mean (SD)	Mean (SD)	β (95% CI)	β (95% CI)
Mean CDAI at 6 months	11.9 (11.5)	15.7 (13.1)	4.07 (2.09 to 6.04)	3.15 (1.11 to 5.18)
Change in CDAI	-8.8 (13.4)	-7.4 (13.4)	1.72 (-0.85 to 4.29)	3.15 (1.11 to 5.18)
Change in mHAQ	-0.11 (0.39)	-0.1 (0.4)	0.01 (-0.07 to 0.08)	0.01 (-0.07 to 0.08)
Change in pain	-10.1 (26.5)	-9.7 (30.7)	0.68 (-4.51 to 5.88)	1.61 (-3.58 to 6.80)
Change in fatigue	-2.7 (25.9)	-5.3 (25.1)	-2.64 (-9.13 to 3.84)	-2.58 (-9.22 to 4.07)
	Response rate n (%)	Response rate n (%)	Odds Ratio[†] (95% CI)	Odds Ratio[††] (95% CI)
Achievement of Remission (CDAI≤2.8)	46 (15.5%)	13 (8.6%)	0.52 (0.26, 1.06)	0.58 (0.27, 1.26)
Achievement of LDA (CDAI≤10)	136 (45.9%)	47 (31.1%)	0.51 (0.32, 0.80)	0.59 (0.37, 0.96)

mHAQ: modified Health Assessment Questionnaire; LDA: Low Disease Activity; nonMTX csDMARD: non-methotrexate conventional synthetic disease modifying anti-rheumatic drug. [a] Includes leflunomide, sulfasalazine, and hydroxychloroquine. [b] Compared with MTX combination therapy as a reference; [c]Adjusted for age, duration of RA, work status (part-time, full-time, disabled, retired, other), insurance status (none, private, Medicare), prior biologic count, MTX continuation, baseline CDAI, baseline patient pain.

Conclusions: In this real world study, patients on ADA+MTX had significantly greater improvements in disease activity compared to patients on ADA+nonMTX

csDMARD therapy but had comparable improvements in PROs at 6 months from initiation.

FRI0189 SIMILAR EFFICACY AND SAFETY OF BIOSIMILAR CANDIDATE BI 695501 AND ADALIMUMAB ORIGINATOR REFERENCE PRODUCT IN PATIENTS WITH MODERATE TO SEVERE ACTIVE RHEUMATOID ARTHRITIS: 24 WEEK RESULTS FROM A PHASE III CLINICAL STUDY (VOLTAIRE®-RA)

S. Cohen[1], A. Alonso-Ruiz[2], P.A. Klimiuk[3], E. Lee[4], N. Peter[5], I. Sonderegger[5], D. Assudani[5]. *[1]Metroplex Clinical Research Center, Dallas, United States; [2]Hospital de Cruces, Barakaldo, Spain; [3]Medical University of Bialystok and Gabinet Internistyczno-Reumatologiczny, Bialystok, Poland; [4]Inland Rheumatology, Upland, United States; [5]Boehringer Ingelheim, Ingelheim a.R., Germany*

Background: PK bioequivalence of BI 695501, a biosimilar candidate, and the adalimumab originator was demonstrated previously (VOLTAIRE®-PK: Wynne et al., Expert Opin Investig Drugs 2016;25:1361–70) and led to further clinical development.

Objectives: To demonstrate clinical equivalence of BI 695501 with the adalimumab originator by comparing efficacy, safety and immunogenicity using a clinical model sensitive to detect potential differences between the two biologics.

Methods: In this 58-week, multi-national, multicentre, randomised, double-blind, parallel arm Phase III study (NCT02137226), 645 pts (18–80 years) with moderate to severe active RA on stable treatment with methotrexate were randomised to receive US-licensed SC adalimumab originator or BI 695501 40mg Q2W for 24 weeks. At Wk 24, pts on adalimumab originator were re-randomised to continue the adalimumab originator or switch to BI 695501 until Wk 48. Pts on BI 695501 were dummy re-randomised. Co-primary end points were proportion of pts achieving ACR20 at Wks 12 and 24. Equivalence between BI 695501 and the adalimumab originator was demonstrated if the relevant confidence intervals (CI) for differences in ACR20 response rate at Wks 12 and 24 were within the predefined margins (Wk 12: 90% CI –12%, 15%; Wk 24: 95% CI –15%, 15%). The secondary efficacy end point was change from baseline in DAS28-ESR at Wks 12 and 24. Safety and immunogenicity were exploratory objectives. Wk 48/58 data will be reported later.

Results: The co-primary end points of ACR20 response at Wks 12 and 24 were within the pre-defined criteria for equivalence, demonstrating clinical equivalence between BI 695501 and the adalimumab originator (Table 1).

The proportion of pts with treatment-emergent adverse events (TEAE) was similar between the BI 695501 and the adalimumab originator treatment groups (Table 2).

Table 1. Response at Weeks 12 and 24

ACR, %	Week 12		Week 24	
	BI 695501 n=321	Adalimumab originator n=318	BI 695501 n=321	Adalimumab originator n=318
ACR20*	67.0	61.1	69.0	64.5
ACR50	29.3	31.0	36.8	36.8
ACR70	10.1	11.1	13.6	18.2
DAS28-ESR#, mean change from baseline (95% CI)	–2.1 (–2.28, –2.01)	–2.0 (–2.18, –1.91)	–2.4 (–2.51, –2.21)	–2.4 (–2.54, –2.24)

*Week 12 risk difference (RD) and 90% CI for BI 695501-adalimumab originator are 5.9% and 90% CI (–0.9%, 12.7%); #Week 24: RD and 95% CI are 4.5% and (–3.4%, 12.5%).

Table 2. Overview of TEAEs up to Week 24

Pts, n (%)	BI 695501 (n=324)	Adalimumab originator (n=321)
≥1 TEAE	138 (42.6)	148 (46.1)
≥1 TEAE related to trial drug	36 (11.1)	44 (13.7)
≥1 Non-serious TEAE	135 (41.7)	141 (43.9)
≥1 serious TEAE	12 (3.7)	18 (5.6)
≥1 serious TEAE related to trial drug	1 (0.3)	5 (1.6)
A TEAE leading to trial drug discontinuation	8 (2.5)	11 (3.4)
A TEAE leading to death	0 (0.0)	0 (0.0)

Rates of serious AEs and discontinuation due to TEAEs were similar across the groups. No deaths were reported during the study. Similar frequencies of pts tested positive for anti-drug antibodies (BI 695501 43.2%; adalimumab originator 47.8%), and neutralising antibodies (BI 695501 16.0%; adalimumab originator 20.6%) in both groups at Week 24.

Conclusions: This study in pts with RA demonstrated that BI 695501 and the adalimumab originator are highly similar in terms of efficacy, safety and immunogenicity.

FRI0190 CLINICAL OUTCOMES FROM A NATIONWIDE NON-MEDICAL SWITCH FROM ORIGINATOR TO BIOSIMILAR ETANERCEPT IN PATIENTS WITH INFLAMMATORY ARTHRITIS AFTER 5 MONTHS FOLLOW-UP. RESULTS FROM THE DANBIO REGISTRY

B. Glintborg, I.J. Sørensen, A.G. Loft, J. Esbesen, H. Lindegaard, D.V. Jensen, K. Danebod, S. Dieperink, O. Hendricks, I.M.J. Hansen, A. Linauskas, S. Kristensen, L.S. Andersen, M. Hossein, H. Nordin, B.L. Andersen, S. Chrysidis, J.L. Raun, N. Manilo, J. Grydehøj, E.B. Dalgaard, D.D. Pedersen, N.S. Krogh, M.L. Hetland. *The DANBIO registry and the Danish Departments of Rheumatology, Copenhagen, Denmark*

Background: In Denmark, biological drugs are provided free by the hospitals to the patients via a tax-based system. In 2015 a non-medical switch from originator infliximab to CT-P13 was conducted (1). According to national guidelines in April 2016, a non-medical switch from originator (ETA, Enbrel® 50 mg/week) to biosimilar etanercept (SB4, Benepali®) was dictated when SB4 was marketed, including patients with inflammatory rheumatic diseases treated in routine care.

Objectives: To investigate 3 months' disease activity and 5 months' treatment withdrawal in ETA-treated patients (pts) with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthrits (SpA), who were switched to SB4 and monitored prospectively in the DANBIO registry.

Methods: Pts with RA/PsA/SpA followed in DANBIO since start of first bDMARD were included. Disease activity at 3 months before switch (pre-switch), at the switch and after 3 months (post-switch) and changes over time (∆pre-switch and ∆post-switch) were calculated. Disease flare was defined as ∆DAS28≥1.2 (RA/PsA) or ∆ASDAS≥1.3 (SpA). Factors associated with withdrawal (gender/age/diagnosis/bDMARD-treatment-no/comedication methotrexate/baseline CRP/patient's global score) were explored by multivariable Cox regression analysis.

Results: In total, 1548 switch pts were identified (891 RA, 335 PsA, 322 SpA). 60% were women, age (median (IQR) 56 (44–65) yrs)). Prior ETA treatment duration was 5.2 (3.2–8.0) yrs. ETA was the first biological treatment in 49%, and the second in 33% of pts. Concomitant MTX was given in 60% (RA)/49% (PsA)/15% (SpA). Median follow-up time was 154 (110–178) days.

Disease activity remained largely unchanged 3 months prior to vs. after the switch (Table). The proportion of patients with disease flare pre-/post switch was 8%/13% (RA), 9%/13% (PsA), 5%/5% (SpA).

Overall, 129 pts (9%) stopped SB4 treatment during 5 months' follow-up (Table). Prior ETA treatment duration in these patients was 4.5 (2.7–7.1) years.

Higher patient's global score (HR 1.12/cm, 95% CI (1.05–1.21), p=0.002) and no concomitant methotrexate (HR 2.28 (1.48–3.52), p<0.001) at baseline were associated with withdrawal.

Table Disease activity 3 months pre/post-switch and changes in patients switched from originator to biosimilar etanercept. Reasons for withdrawal after 5 months' follow-up are also shown

	Disease activity, median(IQR)			Changes, median(IQR)		P*
	pre-switch	switch	post-switch	Δpre-switch	Δpost-switch	
RA, n=891						
DAS28	2.1 (1.7-2.9)	2.1 (1.6-2.9)	2.2 (1.6-3.1)	0.0 (-0.4-0.5)	0.0 (-0.4-0.5)	0.2

BASDAI, mm	33 (15-51)	27 (12-48)	29 (16-47)	-1 (-7-5)	1 (-5-8)	0.03
CRP, mg/l	3 (1-6)	3 (1-5)	3 (1-5)	0 (-2-1)	0 (-1-1)	0.4
VAS global, mm	34 (16-59)	30 (12-53)	31 (15-53)	-1 (-12-6)	2 (-6-14)	0.04
ASDAS	2.0 (1.3-2.8)	1.9 (1.2-2.7)	1.9 (1.3-2.7)	-0.1 (-0.4-0.2)	0.1 (-0.4-0.5)	0.1
Reasons for withdrawal during ≈ 5 months follow-up (n= 129)						
Lack of effect 59, Adverse event 42 (rash 5, diarrhea 3, unspecific/other 34), remission 2, cancer 4, death 1, other/unknown 21						
*Delta values for disease activity pre-switch vs. post-switch, Wilcoxon matched-pair signed rank test						

Conclusions: In 1548 patients with inflammatory rheumatic diseases treated with ETA for >5 years, disease activity was largely unaffected in the majority of patients 3 months after non-medical switch to SB4 and comparable to the fluctuations observed in the 3 months prior to the switch. Several patients (≈9%)

stopped treatment during 5 months follow-up. Higher patient's global score and no use of methotrexate were associated with withdrawal. Longer follow-up will offer additional understanding of the potential efficacy and safety consequences of the non-medical switch.

FRI0191 INCIDENCE OF DISEASE WORSENING IN INFLAMMATORY ARTHRITIS PATIENTS ON LONG-TERM INNOVATOR INFLIXIMAB THERAPY

A.M. Marrache[1], E. Psaradellis[2], J. Vaillancourt[2], E. Rampakakis[2], F. Nantel[1]. *[1]Medical Affairs, Janssen Inc., Toronto; [2]JSS Medical Research, Montreal, Canada*

Background: A recent randomized controlled study in a single country reported rates of disease worsening over a one-year follow-up period for innovator infliximab (REMICADE®, IFX) and a comparator in various diseases including AS and RA. After a mean duration of treatment of 6.7 years of innovator IFX, rates for disease worsening post-one year follow-up were 39.5% in AS and 36.7% in RA[1]. Other such data reporting disease worsening rates are rare.

Objectives: Using data from a longitudinal database, the objective was to determine the incidence of disease worsening in AS and RA patients on long-term therapy with innovator IFX. PsA patients were not included in this study due to low numbers (n=49).

Methods: BioTRAC is an ongoing, prospective registry of inflammatory arthritis patients initiating treatment with infliximab, golimumab or ustekinumab that has been ongoing since 2002 in Canada. We included AS and RA patients who had been on innovator IFX therapy for at least two, four or six years. Disease worsening endpoint was defined as follows: for AS patients; an increase in ASDAS $\geq$1.1 from baseline and a minimum score of 2.1. For RA patients; an increase in DAS28 $\geq$1.2 from baseline and a minimum score of 3.2.

Results: This analysis included a total of 196 AS and 425 RA patients. Among AS patients, 36.1% were female, 90.8% were bio-naïve at IFX initiation and 50% were on concomitant NSAID(s) at the 2-year index. The mean (SD) ASDAS score was 2.17 (1.05). As for the RA patients, 75% were female, 88.5% were bio-naïve, and 93% were on concomitant DMARD(s) while 35% were on corticosteroids at the 2-year index. The mean (SD) DAS28 ESR and DAS 28 CRP were 3.37 (1.40) and 3.00 (1.24), respectively.

As shown in table 1, the incidence of disease worsening in AS and RA patients on stable IFX for 2–6 years was low and varied from 2.7% to 11.5% at the subsequent 12 and 24 months visit.

Table 1. Incidence of disease worsening in AS and RA patients at the 2, 4, and 6-year index

Disease	Outcome	Index date post IFX initiation	Disease worsening at subsequent visits, n/N (%)	
			12 months	24 months
AS	ASDAS	2 years	9/79 (11.4%)	6/59 (10.2%)
		4 years	2/42 (4.8%)	1/37 (2.7%)
		6 years	1/25 (4.0%)	2/18 (11.1%)
RA	DAS28 ESR	2 years	20/184 (10.9%)	17/148 (11.5%)
		4 years	9/121 (7.4%)	7/106 (6.7%)
		6 years	8/73 (11.0%)	5/47 (10.6%)
	DAS28 CRP	2 years	16/160 (10.0%)	11/124 (8.9%)
		4 years	8/115 (7.0%)	6/104 (5.9%)
		6 years	6/80 (7.5%)	4/54 (7.4%)

Conclusions: In this prospective longitudinal cohort, patients on long-term innovator IFX therapy show low rates of disease worsening of 2.7% to 11.5% at 1 and 2 years in AS and RA. Additional studies may elucidate the true rate of and reasons for disease worsening in rheumatologic populations.

FRI0192 CLINICAL PRACTICE GUIDE FOR THE TREATMENT OF PATIENTS WITH RHEUMATOID ARTHRITIS (RA). SYSTEMATIC REVIEW: IN PATIENTS WITH RA, WHICH IS THE SAFEST THERAPY FOR PATIENTS WITH PREVIOUS CANCER?

M.B. Nishishinya[1], C.A. Pereda[2], P. Diaz del Campo[3], A. Balsa[4] on behalf of GUIPCAR, Evidence based Rheumatology Working Group (SER) and GUIPCAR Working Group. *[1]Traumatology Institute Quirón, Barcelona; [2]Rheumatology, Hospital Mediterraneo, Almeria; [3]Investigation Unit, Spanish Rheumatology Society; [4]Rheumatology, Hospital Universitario la Paz, Madrid, Spain*

Background: Anti TNF therapy, has been used for the treatment of RA patients for several years. Yet, cancer and infections are among the most serious adverse effects described. Unfortunately, little is known about the effect of anti TNF therapy amongst patients with RA and previous cancer, mainly when synthetic DMARds treatment fails.

Objectives: To review the evidence on the safety of biological therapy in RA patients with previous neoplasia.

Methods: we performed a systematic review through Medline, Cochrane Library, and EMBASE databases. Studies written in English, French and Spanish were considered. Patients 18 years or older, with RA diagnosis (ACR 1987 o ACR/EULAR 2010 criteria), and cancer diagnosis before starting biologic therapy were included. While Systematic reviews, clinical trials and or observational studies with a minimal follow –up of 6 months were considered; case reports or narrative reviews were excluded.

Results: 1077 studies were potentially identified, and 6 cohort studies were finally included, (Aaltonen 2015, Dixon 2010, Phillips 2015, Raaschou 2015, Silva-Fernández 2016, Stranfeld 2010). Studies were based on registries of patients with RA treated with DMARds and biological therapy. Registries evaluated between 3.762 and 14.168 patients. The number of patients with documented previous cancer was around 122 to 425 as a whole. Biological therapies evaluated were: IFX, ETN, ADA, RTX, certolizumab pegol, Golimumab, ANAKinRA and synthetic DMARDs. Studies results were organized as anti TNF vs. DMARDs. All studies assessed were cohort trials, SIGN 2+ (Quality Scale). They included solid tumours as breast cancer, lymphoproliferative tumours, skin cancer, neck and brain tumours, as well as in situ uterus cancer.

There was no increment in the risk of incidence of previous cancer in patients treated both with synthetic DMARDs and with anti TNF therapy in all studies assessed.

We point out, that 1 SR (LaForest Divonne 2016) evaluated biological therapy safety in patients with RA. It included 124 trials, while in 27 metanalysis was performed. From these 27, only 3 (Dixon 2010, Mercer 2013 and Strangfeld 2010) where the only studies which assessed risk of recurrence of previous cancer in patients with RA. The RR 0, 77 (IC 95% 0, 29–2,03), did not exhibit an increment in the risk of cancer in these patients.

Conclusions: - Studies showed no differences in the incidence of previous cancer in patients treated either with synthetic DMARds or with anti TNF. However, we suggest precaution in the use of these therapies, as the real risk in this population is still unknown.

- The final decision of treating or not treating these patients (risk factors, limitations etc.) needs to be performed in accordance with oncologists.
- There is no strong evidence that could identify the real risk of anti TNF therapies in RA patients, with previous cancer.
- The Individual impact risk of different anti-TNF therapies in this population could not be performed due to incomplete data. Yet, there is not real time schedule considering time since previous cancer and the start of anti TNF therapy.

Well design studies with long follow-up periods are needed to answer these questions

FRI0193 EFFECT OF VALENCY OF ANTI-TNFS ON ELIMINATION MEDIATED BY ANTI-DRUG ANTIBODIES

J. Silva, A. Nesbitt. *UCB Pharma, Slough, United Kingdom*

Background: There are five different anti-TNF biologics: three are bivalent full length (FL) antibodies (adalimumab, golimumab, and infliximab), one a bivalent fusion protein (etanercept), and one a univalent PEGylated Fab' (PF) (certolizumab pegol [CZP]). Administration of such protein biologics can induce anti-drug antibodies (ADAbs), of which the majority are anti-idiotypic antibodies (anti-ID).[1] The potential cross-linking of bivalent anti-IDs with bivalent biologics can result in the formation of large immune complexes (ICs), which are subsequently cleared by mechanisms using the multiple Fc domains, thereby resulting in a decrease in the efficacy of the biologic. Since univalent biologics, such as CZP, only have one binding Fab' arm, such large cross-linked anti-ID-mediated ICs are unlikely to form. Therefore, anti-IDs may have a different effect on the elimination and bioavailability of univalent and bivalent biologics *in vivo*.

Objectives: To determine if the valency of a biologic will affect the *in vitro* size and *in vivo* elimination from the plasma of ICs formed with an anti-ID following intravenous (IV) administration to BALB/c mice.

Methods: An anti-ID antibody to CZP was generated and used for subsequent studies to mimic an ADAb response. Univalent PF CZP was reengineered as a bivalent FL humanized IgG1 antibody (similar to adalimumab) to directly

compare the effect of valency on IC-mediated clearance. This FL antibody showed very similar TNF neutralization compared to the conventional PF molecule in a bioassay. To generate ICs, the anti-ID was incubated overnight with either PF or FL CZP, and the size of the resultant ICs determined by analytical ultracentrifugation (AU). The anti-ID complexes and PF and FL CZP alone were then administered IV to the mice, and the elimination of the anti-TNFs from the circulation was monitored by quantitative liquid chromatography-mass spectrometry (LC-MS) in serial plasma samples.

Results: AU analysis of the immune complexes formed between PF CZP and the anti-ID showed the presence of one peak corresponding in size to one anti-ID molecule bound to two PF molecules (~$3.5x10^5$ Da). In contrast, the FL CZP/anti-ID mixture showed ICs of various sizes up to very large molecular weights (>$1x10^6$ Da), with the predominant species corresponding to a complex of two anti-IDs bound to two FL CZP molecules (~$6x10^5$ Da). The *in vivo* studies showed that the FL CZP/anti-ID ICs were eliminated much faster ($t_{1/2}$=0.3 hours) than the FL CZP alone ($t_{1/2}$=44.5 hours), whereas the PF CZP/anti-ID ICs were eliminated more slowly ($t_{1/2}$=60.5 hours) than the PF CZP alone ($t_{1/2}$=19.7 hours).

Conclusions: The FL CZP molecule formed large ICs with the anti-ID, which led to much faster elimination than the FL molecule alone. This result suggests that an ADAb response to a FL antibody could lead to rapid elimination and loss of efficacy of the drug in patients. In contrast, the PF CZP/anti-ID complex had a longer half-life than the PF CZP alone, presumably because this molecule was not seen as an IC due to the presence of only one Fc. These results showed that an ADAb to a univalent biological reagent may not lead to elimination and instead, may actually increase the *in vivo* half-life of the molecule.

FRI0194 USE OF GLORESPONSETM NF-κB-RE-LUC2P HEK293 CELLS TO MONITOR DRUG AND ANTI-DRUG ANTIBODY LEVELS IN SERUM

B. Hernandez-Breijo[1], L.Y. Bravo Gallego[2], A. Martinez-Feito[1], A. Jochems[1], E. Olariaga[1], J. Cheng[3], L. Delaurière[4], F. Fan[3], T. Schagat[3], C. Plasencia[1], A. Mezcua[2], P. Nozal[2], A. Balsa[1], D. Pascual-Salcedo[1].

Background: Rheumatoid Arthritis (RA) is often treated with anti-TNFα such as infliximab (Ifx) which in a long-term treatment can lead to the development of anti-Ifx antibodies (ATI), resulting in an interference with the drug activity. The investigation of the bioactivity of the circulating drug and antibodies present in patients sera with inflammatory diseases will allow to harmonize the different published data using both bioassays as well as immunoassays.

Objectives: To evaluate the ability of the Promega bioassay in the quantification of both Ifx and ATI in serum from RA patients.

To compare the bioassay performance between capture- and bridging-ELISA.

Methods: Serum Ifx-trough levels were determined in 50 samples from patients with RA. To measure Ifx, the *bioassay* uses GloResponse™ NF-κB-RE-luc2P HEK293 cell line, which responses to TNFα resulting in modulation of NF-κB activity (Promega Corp., Madison, USA). This is an ease on performing reporter assay (add-mix-read) that detects the serum Ifx by inhibition of the luminiscent signal due to TNFα. The inhibition of the Ifx-driven luminescent signal is reverted by the presence of ATI in the serum. ATI concentration is determined using a standard curve obtained with a serial dilution of a serum sample known to have ATI. A relative luminescent unit (RLU) is arbitrarily defined. The *immunoassay* for Ifx (ELISA) captures recombinant TNFα, via a monoclonal antibody that does not interfere with the serum Ifx binding to TNFα. The reaction is developed with a biotinylated anti-idiotype antibody[1] (Cut-off for Ifx: 0.050 μg/ml). The ELISA to detect ATI takes advantage of the bivalency of most IgG subclasses, allowing the antibodies present in serum to bridge between Ifx-coated onto the plate with biotinylated Ifx in fluid phase[1] (Cut-off for ATI 50 AU/ml).

Results: Addition of TNFα on GloResponse cells induces the production of luciferase resulting in an increase of the luminescent signal in a dose-response. Addition of Ifx on GloResponse cells +TNFα decreases the production of luciferase and therefore the luminescent signal falls (r^2=0.99). Addition of anti-Ifx (in relative units) on GloResponse cells +TNFα + Ifx restore the production of luciferase resulting in an increase of the luminescent signal (r^2=0.98).

Serum Ifx concentrations were sorted into 3 groups (low, medium and high following ELISA levels). Similar number of positive Ifx results was found (30 samples, 55% by ELISA vs 28 samples, 52% by bioassay; κ=0.92; p=0.56) along with a significant Pearson correlation (r=0.8) between methods. The bioassay to measure ATI activity showed lower sensitivity than ELISA (9/31, 29% by ELISA vs 4/31, 13% by bioassay, κ=0.53, p=0.22) with a slightly less correlation for ATI levels by both methods (r=0.26).

Conclusions: Bioassay using GloResponse NF-κB cell line can be performed to monitor therapeutic drug of TNFα blocker and are useful to detect the presence of anti-drug antibody in serum samples treated with anti-TNFα antibodies. Comparison with ELISA method shows in most of the case the same data.

FRI0195 POINT-OF-CARE MONITORING OF ANTI-INFLIXIMAB ANTIBODIES IN PATIENTS TREATED WITH THE REFERENCE INFLIXIMAB OR CT-P13 IN ROUTINE CLINICAL PRACTICE

A. Ametzazurra[1], N. Rivera[2], A. Balsa[3], M.P. Arreba[4], E. Ruiz[2], C. Plasencia[3], J. Ortiz[4], D. Pascual-Salcedo[5], M.C. Muñoz[4], C. De Aysa[3], M.J. Allande[2], N. Torres[1], A.M. Hernández[1], X. Recalde[1], A. Martínez[1], D. Nagore[1]. *[1]R&D, Progenika-Grifols, Derio; [2]Rheumatology, Basurto University Hospital, Bilbao; [3]Rheumatology, la Paz University Hospital, Madrid; [4]Gastroenterology, Basurto University Hospital, Bilbao; [5]Immunology, la Paz University Hospital, Madrid, Spain*

Background: Loss of clinical response and infusion reactions to infliximab (IFX) are associated to the development of antibodies to IFX (ATI). ATI detection is a key step of patient management. However, current techniques may require additional patient appointments for sample collection, processing and batching in centralised facilities. Test reporting usually takes several days or weeks impairing effective decision making.

Objectives: To clinically validate the use of a new rapid test to detect ATI in capillary blood in a real-life point-of-care (POC) setting where patients attend the infusion center for the reference IFX (Remicade®, RMC) or CT-P13 (Inflectra®, IFT, or Remsima®) infusions.

Methods: PQ-EF1 and PQ-EF2 are prospective, observational studies designed to evaluate and compare the performance of a rapid POC test (CE-marked Promonitor® Quick Anti-IFX, Progenika, Spain) to detect ATI in routine clinical practice in rheumatic and gastroenterology patients treated with the reference IFX or the biosimilar CT-P13 attending the infusion center with the ELISA technique as a reference. The POC test is a qualitative immunochromatographic assay based on lateral flow technology to detect ATI (including biosimilar CT-P13) in either fingerprick or serum or venous whole blood. Consecutive patients (initiating or under maintenance therapy) were recruited and tested in La Paz and Basurto University hospitals with the rapid test in capillary and venous whole blood specimens immediately before the infusion. ATI test results were read visually with the POC test in 30 min, just before the patient started the infusion. Trough sera were also collected for subsequent analysis with the rapid test and benchmarked with Promonitor®-Anti-IFX ELISA (Progenika, Spain). Follow-up time was 6 months. ELISA quantitative results were categorized as positive and negative to allow comparisons with the qualitative rapid test.

Results: Ninety consecutive patients were recruited (a total of 137 visits in the 6 months follow-up) accounting for a total of 137 sera, 137 fingerpricks and 71 venous whole blood samples. Overall, 8 (8.9%) patients developed ATI (5 ankylosing spondylitis, 1 Crohn's disease, 1 ulcerative colitis and 1 juvenile idiopathic arthritis). ATI were detected in 5 patients treated with Remicade® and 3 treated with Inflectra®. Overall agreements between fingerprick vs venous whole blood and fingerprick vs serum measured with the rapid POC test were 100% and 99%, respectively. Positive (PPA) and negative (NPA) agreements between the POC test and ELISA were 91% and 99%, respectively. PPA and NPA between the ELISA and the POC test in serum was 100% and 99%, respectively.

Conclusions: ATI can be reliably detected in either venous or capillary circulation. Results show an almost perfect agreement between specimens and with the reference ELISA technique. ATI measurement with the POC test allows the clinician to detect ATI in a quick and fully decentralised mode facilitating immediate POC decision making.

FRI0196 BIOSIMILARS IN THE UK: EARLY REAL WORLD DATA FROM THE BRITISH SOCIETY FOR RHEUMATOLOGY BIOLOGICS REGISTERS FOR RHEUMATOID ARTHRITIS

D. De Cock[1], K. Watson[1], K.L. Hyrich[1,2] on behalf of BSRBR-RA Control Centre Consortium. *[1]Arthritis Research UK Centre for Epidemiology, University of Manchester; [2]National Institute of Health Research Manchester Musculoskeletal Biomedical Research Unit, Central Manchester NHS Foundation Trust, Manchester Academic Health Science, Manchester, United Kingdom*

Background: Biosimilars, biopharmaceuticals assessed by regulatory agencies

to have efficacy and safety similar to their reference products, were introduced to the UK market in February 2015 for rheumatoid arthritis (RA). Most research on RA biosimilars has been done in the context of clinical trials, but real world data are lacking. No national mandate exists in the UK to switch all patients from originator to biosimilars, but there are regional variations.

Objectives: This analysis aims to describe the characteristics of the first UK patients starting RA biosimilars registered with the British Society for Rheumatology Biologics Register for RA (BSRBR-RA).

Methods: Since 03/08/2015, the BSRBR-RA has captured data on patients starting biosimilars available in the UK: infliximab (Inflectra and Remsima) and etanercept (Benepali). At biosimilar start, information is captured from the hospital including demographic and clinical data, previous biologic exposure and if switching therapies, the reason for switch (as a tick box and free text). Follow-up data, including disease activity, occurrence of adverse events and changes to treatment is captured 6-monthly for 3 years and annually thereafter. Descriptive data are presented.

Results: To 15/12/2016, 417 RA patients were recruited to the BSRBR-RA at point of starting a biosimilar for whom data were available for analysis on 414 participants: 47 (11%) Inflectra, 78 (19%) Remsima and 289 (70%) Benepali. Of these, 138 started a biosimilar as first biologic, 242 switched directly from the originator product and 34 switched from an alternative biologic (Table). Patients switching from the originator did so after a median (IQR) of 6.7 (3.0–9.5) years and the majority had low disease activity (median DAS28 2.7 (IQR 2.0–3.9)). The switch reason was reported in 33% of patients, with cost listed as the main reason and "trust policy" included in 63% of 30 free text comments. Six-month follow-up data were available in 41 patients. Three patients on Remsima and 1 patient on Inflectra reported drug hypersensitivity reactions (rash, pruritus, hyperpigmentation), and 18% (6/34) of patients experienced a deterioration in their DAS28 of >1.2 after 6 months.

Table

	Biological naive	Switched from reference product	Not switched from reference product
Number	138	242	34
Biosimilar, n (%)			
Inflectra	3 (2%)	40 (16%)	4 (12%)
Remsima	9 (6.5%)	65 (27%)	4 (12%)
Benepali	126 (91%)	137 (57%)	26 (76%)
Women, n (%)	108 (78%)	181 (75%)	28 (82%)
Age (years)	56.0 (48.0-64.5)	67.0 (57.0-72.0)	59.5 (44.5-68.0)
Disease Duration (years)	4.0 (1.0-10.0)	17.0 (10.0-24.0)	9.5 (6.0-14.0)
DAS28(CRP)	5.9 (5.3-6.5)	2.7 (2.0-3.9)	5.1 (3.5-6.2)
Comorbidities			
0	52 (38%)	84 (35%)	12 (35%)
1	47 (34%)	84 (35%)	11 (32%)
2	32 (23%)	32 (13%)	5 (14%)
3+	7 (5%)	42 (17%)	6 (19%)
Previous biological on n (%)			
Enbrel	-	137 (57%)	1 (3%)
Remicade	-	105 (43%)	4 (12%)
Kineret	-	-	1 (3%)
Humira	-	-	7 (21%)
Mabthera	-	-	1 (3%)
Orencia	-	-	4 (12%)
Simponi	-	-	4 (12%)
RoActemra	-	-	6 (18%)
Cimzia	-	-	6 (18%)
Reasons to switch, n (%)			
Cost factors	6 (86%)	107 (86%)	2 (50%)
Clinical indication	-	5 (4%)	1 (25%)
Patient choice	-	1 (1%)	1 (50%)
Other	1 (11%)	11 (9%)	-
Follow-up data available, n	5	35	1
DAS28 at 6 months	3.9 (3.1-7.1)	2.8 (2.2-3.9)	5.3

All data presented are numbers (percentages) or median (IQR).

Conclusions: This preliminary study gives an early review of biosimilar use in the UK, showing that these drugs are used in patients with active disease as both first-line and subsequent-line biologics. Many patients with low disease activity are also being switched from originators primarily for cost reasons. Outcome data are limited but data capture will continue and updated reports from the BSRBR-RA will continue to be presented.

FRI0197 ADHERENCE, SATISFACTION AND FULFILLMENT OF EXPECTATIONS OF PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH SUBCUTANEOUS BIOLOGICALS. ARCO STUDY

J. Calvo-Alén[1], C. Marras[2], I. Monteagudo[3], G. Salvador[4], T. Vázquez-Rodríguez[5], J. Tovar[6], P. Vela[7], F. Maceiras[8], M. Bustabad[9], E. Peiró[10], J. Rosas[11], M. Arteaga[12], S. Fernández[12], L. Cea-Calvo[12], Y. Mestre[12], E. Raya[13]. *[1]H Txagorritxu, Vitoria; [2]HUV Arrixaca, Murcia; [3]HGU Gregorio Marañón, Madrid; [4]HU Mútua Terrasa, Barcelona; [5]HU Lucus Augusti, Lugo; [6]HGU, Elche; [7]HGU, Alicante; [8]CHU, Vigo; [9]HU, Tenerife; [10]HU Marqués de Valdecilla, Santander; [11]H Marina Baixa, Alicante; [12]Medical Affairs, Merck Sharp & Dohme, Madrid; [13]HU San Cecilio, Granada, Spain*

Background: In patients with rheumatoid arthritis (RA), we previously described that adherence to the subcutaneous (SC) biological treatment is better with monthly administration.

Objectives: We further assessed if there are differences in patients expectations and satisfaction with efficacy and tolerance that could contribute to explain such finding.

Methods: ARCO was a retrospective study on RA patients who had been prescribed a SC biological 11–18 months prior to the study. Adherence was calculated with the medication possession ratio (MPR). Satisfaction and expectations were assessed with the Spanish validated Carbonell questionnaire [1].

Results: We included 364 patients (age 54.9 years [SD 12.5], 77.5% women, median duration of RA 7.8 years, period studied for the SC biological 14.8 months). Non-adherence (MPR ≤80%) was lower in patients with monthly (6.4%) than with weekly (17.4%, p=0.034) or every 2 weeks administration (14.4%, p=0.102). The % of satisfied patients (quite/very satisfied) was 86.2% for efficacy and 64.4% for side effects or tolerance. Non-adherence was similar in satisfied with efficacy and in neutral/unsatisfied patients (14.7% vs. 8.3%, p=0.399), or in patients satisfied/not satisfied with side effects (13.1% vs. 15.4%, p=0.504). The fulfillment of expectations is shown in the table. With regard to expectations on the effect, non-adherence was 15.5% (higher than expected), 12.6% (as expected) and 10.7% (lower than expected) (p=0.677), and with regard to discomfort/side effects, it was 15.6% (greater than expected), 18.5% (as expected) and 11.1% (lower than expected, or no side effect) (p=0.189). Fulfilment of expectation on efficacy was similar for the 3 dosing schemes, but the % reporting lower than expected discomfort or no discomfort was greater with fewer SC injections (table). In particular, the % reporting no discomfort/side effects with the administration were 17.8% (weekly), 29.3% (every 2 weeks), and 35.0% (monthly) (p=0.013).

	All %	Weekly %	Every 2 weeks %	Monthly %	p
Effect of the treatment					
Much/quite higher than expected	59.9	59.2	57.2	66.7	0.573
More or less as expected	32.1	33.6	33.8	25.0	
Quite/much lower than expected	8.0	7.4	9.0	8.3	
Discomfort					
Much/quite higher than expected	13.0	15.8	11.5	10.1	0.048
More or less as expected	34.4	38.2	35.3	23.3	
Quite/much lower than expected or there were no discomfort	52.5	46.0	53.2	66.6	

Conclusions: RA patients on SC biological therapy show high satisfaction and fulfillment of expectations on efficacy, although both aspects lower for tolerance. Dosing regimen with lower number of SC injections seems to be associated with better fulfillment of expectations of tolerance. This finding, added to the lower number of injections itself, might explain the better adherence observed with monthly administration.

FRI0198 USABILITY AND SAFETY OF SB5 (AN ADALIMUMAB BIOSIMILAR) PRE-FILLED SYRINGE AND PRE-FILLED PEN IN PATIENTS WITH RHEUMATOID ARTHRITIS

J. Ghil[1], J. Niebrzydowski[2], A. Zielińska[3], Y. Lee[1]. *[1]Samsung Bioepis Co., Ltd., Incheon, Korea, Republic Of; [2]Medica Pro Familia Sp. z o.o. S.K.A., Gdynia; [3]Medica pro Familia Sp z o.o. S.K.A, Warszawa, Poland*

Background: SB5 is developed as a biosimilar of the reference adalimumab (ADL). Equivalence in pharmacokinetics (PK) and efficacy between SB5-pre-filled syringe (PFS) and ADL-PFS has been demonstrated in a phase I and phase III study.[1,2] The PK equivalence between SB5-PFS and SB5-pre-filled pen (PFP) in healthy subjects has been reported previously.[3]

Objectives: To compare the usability and safety of SB5-PFS and SB5-PFP from a phase II study.

Methods: This was an open-label, single-arm study in patients with rheumatoid arthritis (RA). Patients with RA self-administered a total of 6 injections of 40 mg SB5 every other week; the first two injections were through PFS and the following four injections were through PFP. The primary objective of this study was to demonstrate comparability between PFS (at week 2) and PFP (at week 6) in terms of injection site pain score. Patients completed a pain evaluation questionnaire using an 11-point numeric rating scale at two time points (immediately and 15–30 minutes post-injection) after the first four injections. Equivalence between PFS and PFP was concluded if the 97.5% confidence interval (CI) of the difference in the injection site pain score was contained within the equivalence margin of ±5. Other usability (overall impression and patient preference) and safety endpoints were also measured.

Results: A total of 49 patients were enrolled and 48 patients completed the study. The mean injection site pain score was 2.3 in PFS vs. 2.0 in PFP immediately post-injection and 0.8 in PFS vs. 0.7 in PFP at 15–30 minutes post-injection. At both time points the score was equivalent between PFS and PFP: the 97.5% CI was (–0.99, 0.30) and (–0.47, 0.25) immediately and 15–30 minutes post-injection, respectively.
The overall impression was also comparable between PFS and PFP. There were no patients who had an overall impression of extremely unfavorable and the proportion of patients who had a favorable impression was higher than that of unfavorable impression in both PFS and PFP. The overall preference for PFP (56.5%) was higher than PFS (30.4%) as presented in the Table.
Both PFS and PFP were well tolerated and there were no serious treatment-emergent adverse events. Only one patient after administration of PFS experienced injection site reaction.

Table. Preference between Pre-filled Syringe and Pre-filled Pen

Preference	Pre-filled Syringe n/n' (%)	Pre-filled Pen n/n' (%)	No Preference n/n' (%)
Overall preference	14/46 (30.4)	26/46 (56.5)	6/46 (13.0)
Preference categories			
Ease to use	10/46 (21.7)	33/46 (71.7)	3/46 (6.5)
Convenience	6/46 (13.0)	35/46 (76.1)	5/46 (10.9)
Time to administration injection	9/46 (19.6)	30/46 (65.2)	7/46 (15.2)
Safety	6/46 (13.0)	31/46 (67.4)	9/46 (19.6)
Less pain	17/46 (37.0)	21/46 (45.7)	8/46 (17.4)

Conclusions: The injection site pain score of PFS and PFP was comparable with overall preference rate higher for PFP. Both PFS and PFP were well tolerated with similar safety profiles.

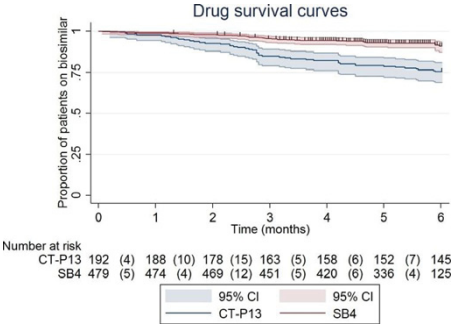
FRI0199 SYSTEMATIC REVIEW AND META-ANALYSIS ON CERTOLIZUMAB PEGOL FOR RHEUMATOID ARTHRITIS IN ADULTS



J.A. Bernal[1], P. Vela[1], V. Ruiz García[2], A. Burls[3], J.B. Cabello[4], S. Bort-Martí[5]. *[1]Rheumatology, Hospital General Universitario de Alicante, Alicante; [2]Hospital at Home Unit, la Fe University Hospital, Valencia, Spain; [3]School of Health Sciences, University of London, London, United Kingdom; [4]Cardiology & CASP Spain, Hospital General Universitario de Alicante, Alicante; [5]Acella Incubator, Paterna, Valencia, Spain*

Background: The appearance of tumor necrosis factor-alpha (TNFalpha) inhibitors dramatically changed the prognosis of rheumatoid arthritis. Certolizumab pegol (CZP) is a human Fab fragment of anti-TNFalpha monoclonal antibody which is approved for the treatment of rheumatoid arthritis. We performed a systematic review and meta-analysis, with Cochrane methodology, of the effects of CZP in rheumatoid arthritis.
Objectives: To assess the clinical benefits and harms of CZP in patients with rheumatoid arthritis.
Methods: We performed a search of electronic database (Cochrane Database, MEDLINE, EMBASE, Web of Knowledge and clinicaltrials.gov) until 26th September 2016. We searched for randomized controlled trials of CZP in rheumatoid arthritis compared to any other agent including placebo.
Results: 14 trials were included for the meta-analysis, 12 (5422 patients) in the pooled analysis for benefits and 14 (5499 patients) in the pooled analysis for safety. The overall possibility of bias seemed to be low but the quality of the evidence was low due to the risk of attrition bias.
With the approved dose - CZP 200 mg subcutaneous every other week with the first three doses of 400 mg - CZP showed statistically significant improvements at 24 weeks compared to placebo in: ACR50 absolute improvement 27% (95% CI 20% to 33%), RR 3.8 (95% CI 2.42 to 5.95) and NNT=4 (95% CI 3 to 8); DAS28 $<$2.6 - original definition of remission - with RR 3.79 (95% CI 1.90 to 7.56); HAQ with -12% absolute improvement (95% CI -9% to -14%); and erosion score with -0.29% (95% CI -0.42% to -0.17%). There are also data available at 12 weeks with RR of 1.99 (95% CI 1.44 to 2.76) of achieving DAS28$<$2.6 with CZP 200 mg dose. The proportion of patients achieving DAS28$<$2.6 was still higher with CZP at 52 weeks with RR of 1.83 (95% CI 1.53 to 2.18).
Serious adverse events were more frequent for CZP 200 mg dose with a RR of 1.47 (95% CI 1.13 to 1.91) and NNH of 32. There have been eight adverse events leading to death in CZP 200 mg group versus two in the control group (not statistically significant) and 10 patients developing tuberculosis versus two in the control group (not statistically significant).
Conclusions: There is low level evidence from randomized controlled trials that CZP as monotherapy or combined with methotrexate improved ACR50, DAS28, HAQ and joint damaged on x-ray. Adverse events were more frequent with active treatment.

FRI0200 HIGHER ACCEPTANCE AND PERSISTENCE RATES AFTER BIOSIMILAR TRANSITIONING IN PATIENTS WITH A RHEUMATIC DISEASE AFTER EMPLOYING AN ENHANCED COMMUNICATION STRATEGY

L. Tweehuysen[1], V.J.B. Huiskes[2], B.J.F. van den Bemt[2,3], F.H.J. van den Hoogen[1,4], A.A. den Broeder[1,4]. *[1]Rheumatology; [2]Pharmacy, Sint Maartenskliniek; [3]Pharmacy; [4]Rheumatology, Radboudumc, Nijmegen, Netherlands*

Background: In blinded trials, transitioning from an innovator to a biosimilar has shown to be equivalent to maintenance on innovator biologic treatment in rheumatic diseases. However, data on open label transitioning to a biosimilar are scarce. Recently, we sequentially implemented two biosimilar transition projects (from innovator infliximab (REM) to biosimilar infliximab (CT-P13) and from innovator etanercept (ENB) to biosimilar etanercept (SB4)) in patients with a rheumatic disease using different communication strategies.
Objectives: To investigate the impact of different communication strategies on the acceptance and persistence rates after transitioning from ENB to SB4 in 2016 and transitioning from REM to CT-P13 in 2015.
Methods: Adult patients treated with REM or ENB were informed by letter about the request to transition to a biosimilar. Subsequently, patients were approached by telephone to ask whether they agreed. After the transition of REM to CT-P13 had finished, communication was enhanced for the transition of ENB to SB4 by 1) informing all patients at the same time directly followed by a national media item, 2) reporting that lower costs and fewer injection site reactions (demonstrated in a previous trial) were the reason for transitioning, 3) providing a "soft skills" training for rheumatology and pharmacy staff about how to assuage patient concerns regarding a biosimilar and how to act if a patient has objective or subjective health complaints (discuss possible nocebo response and incorrect causal attribution). Also, group think effects did not play a role during SB4 treatment (individual subcutaneous versus group intravenous administration). Transitioning patients were eligible for inclusion in the BIO-SWITCH study (switch REM to CT-P13) and BIO-SPAN study (switch ENB to SB4)[1]. Demographic, disease and treatment specific characteristics at baseline and disease activity and adverse events (AEs) during 6 months follow-up were collected.
Results: 196 of 222 (88%) REM-treated patients and 636 of 643 (99%) ENB-treated patients transitioned to respectively CT-P13 and SB4 (delta 11%, 95% CI 7% to 16%). Until January 1st 2017, 479 of 636 (75%) patients gave informed consent for the BIO-SPAN study. Baseline characteristics were similar, except for disease duration and innovator treatment duration (both shorter in the BIO-SPAN cohort; p$<$0.01). Drug survival of patients on SB4 was adjusted for confounders greater than patients on CT-P13 (Figure 1; adjusted Hazard Rate 0.21, 95% CI 0.13 to 0.34). During 84 person-years of follow-up 47 patients discontinued CT-P13 (56/100 person-years; 26% due to inefficacy, 74% due to AEs). In contrast, 36 patients discontinued SB4 during 230 person-years of follow-up (16/100 person-years; 53% due to inefficacy, 42% due to AEs and 5% due to remission).

Conclusions: Use of an enhanced communication strategy, together with more experience and absence of group think effects, resulted in much higher acceptance and persistence rates after open label shared decision making biosimilar transitioning in patients with a rheumatic disease.

FRI0201 ETANERCEPT RETENTION PATTERNS AND FACTORS ASSOCIATED WITH TREATMENT DISCONTINUATION: A RETROSPECTIVE COHORT STUDY USING CANADIAN CLAIMS-LEVEL DATA

M. Khraishi[1], Y. Zhang[2], J. Ivanovic[2], B. Millson[2], M.-J. Brabant[2], K. Charland[2], E. Singh[3], J. Woolcott[4], H. Jones[3]. [1]*Faculty of Medicine, Memorial University of Newfoundland, St. Johns;* [2]*Health Access & Outcomes, QuintilesIMS, Kanata, Canada;* [3]*Inflammation and Immunology, Global Medical Affairs, Pfizer Inc., Collegeville, United States;* [4]*Health Economics and Outcomes Research, Pfizer Inc., Kirkland, Canada*

Background: Etanercept is a soluble TNF receptor (humanized protein) indicated for the treatment of immune-mediated inflammatory diseases such as rheumatoid arthritis (RA), psoriatic arthritis (PsA), ankylosing spondylitis (AS), and psoriasis (PsO). Limited information exists on the factors associated with long-term retention and use of etanercept in Canada in a real-world setting.
Objectives: To evaluate the 6-year retention rates of etanercept patients in Canada, and to identify factors associated with discontinuation.
Methods: A retrospective cohort study was conducted using longitudinal prescription drug claims data from QuintilesIMS Private Drug Plan database (PDP), Ontario Public Drug Plan database (OPDP), and Quebec Public Drug Plan database (RAMQ). Between 07/2008 and 06/2010, bio-naïve patients who initiated etanercept were identified and followed for 72 months. 12-month retention rates were evaluated in 1-year increments for all patients retained on therapy at years 1, 2, 3, 4 and 5 and compared to retention rates in the first year. The covariates associated with time to discontinuation over the entire 72 month period were identified using a Cox proportional hazards regression model.
Results: The study identified 4,528 etanercept patients (61% female, 85% rheumatic diseases, and 15% PsO) across Canada who started their therapy during the selection period. Overall, 12-month retention rates on etanercept increased significantly for patients following their first year on therapy ($p<.0001$), with 66% of patients retained at year 1 vs. 12- month retention rates of 79%, 82%, 84%, 83% and 79% at year 2, 3, 4, 5 and 6, respectively. A total of 17.1% (n=771) of patients were retained for the entire 72 month study. Regression analysis showed PsO patients were less likely to be retained on therapy than other indications (HR 1.199; $p<.0001$), older patients (65+) were more likely to be retained than younger patients (HR 0.802; $p<.0001$), and public plan patients (ODB HR 0.735, RAMQ HR 0.55; $p<.0001$) were more likely to be retained than private plan patients.
Conclusions: Etanercept patient retention likelihood increased the more years a patient was retained on therapy. This pattern was consistent across therapeutic areas, sex, age, and payers. Age, indication, and payer were found to have a significant impact in determining etanercept patients' time to therapy discontinuation. With better understanding of factors associated with retention, patient support programs can be designed to address the specific needs of at-risk groups while supporting patients stable on therapy.

FRI0202 THE DIFFERENT EFFECT OF TNFα BLOCKERS AND SDMARDS ON LIPOPROTEIN SUBCLASSES IN RA PATIENTS. A PERSPECTIVE CONTROLLED LONGITUDINAL STUDY

M. Zakalka[1], M. Karakota[2], G. Koliakos[3], L. Settas[1]. [1]*Division of Clinical Immunology/Rheumatology, 1st Internal Medicine Department, AHEPA University Hospital, Medical School, Aristotle University;* [2]*Laboratory of Biological Chemistry;* [3]*Laboratory of Biological Chemistry, Aristotle University, Thessaloniki, Greece*

Background: The different antirheumatic drugs reduce inflammation in RA patients, causing alterations in cholesterol levels (mainly decreasing LDL and increasing HDL cholesterol levels), but HDL and LDL structure and function predict cardiovascular disease better than LDL and HDL cholesterol levels.
Objectives: The investigation of the qualitative changes of LDL and HDL lipoprotein subclasses in RA patients who are good responders, depending on the anti-inflammatory treatment (sDMARDs vs anti-TNFa+sDMARDs) and their in between associations.
Methods: 85 patients ((89%) 76females) with established RA (mean disease duration ≥5 yrs), mean age 57 yrs (SD: 12yrs), without known cardiovascular disease, D/M and thyroid disorders, on sDMARD (MTX, LEF, SSZ, low dose prednisolone or combination) and naïve to biologic treatment, were divided into two groups: the 1st one of 43 patients who had $DAS_{28}>3.2$ and were given in addition a TNFα inhibitor (23 patients had golimumab and 20 patients had certolizumab-pegol) for at least 54weeks (mean treatment duration 18 months) with good clinical response according to Eular and the 2nd group of 42 patients (disease control group) with $DAS_{28}\leq3.2$,who continued on sDMARDs and followed closely the same time period so as to ensure, as well, good clinical response without biologic therapy. Plasma electrophoresis was performed in two time points, before and after anti-TNFα administration and on the same time for the control group, with non-denaturing polyacrylamide gel (ND-PAGE) for size-based separation of lipoprotein subclasses, a standard laboratory technique that indentify various HDL subspecies separable on the basis of average diameter/size into 6 distinct subclasses (HDL-1, HDL2a, HDL2b, HDL3a, HDL3b, HDL3c), as well as LDL lipoprotein into 2 subfractions (LDL-B, LDL-A.)
Results: The RA patients on DMARDs had a percent reduction of LDL-B subfraction by 11.9% (p=0.014), but a significant increase of HDL-3c subclass by 2.38% (p=0.049). In a multivariate model of stepwise logistic regression the after (treatment)-LDL-B subfraction in these patients was found to have significant positive association only with pro-LDL-B subfraction (odds ratio: 10.95, %CI (1.59–62.79)). In the RA patients who took TNFα inhibitors was observed a prominent percent decrease of the more lipoprotein subclasses: LDL-B by 2.33% (p=0.005), LDL-A by 2.33% (p=0.0001), HDL3a by 11.63% (p=0.072) and HDLc by 4.65% (p=0.035). Accordingly, in stepwise logistic regression the after-(treatment) LDL-B subfraction had a significant positive association only with pro-LDL-B subfraction (odds ratio: 12.91,95% CI (2.2–75.83)), as well as, after-LDL-A with pro-LDL-A subfraction (odds ratio:36.16, 95% CI (5.05–258.89)), whereas the reduced after (treatment)-HDL3c subclass was significantly positively associated with pro-HDL3a subclass (odds ratio:8.15, 95% CI (1.04–63.65)) and after-HDLa subclass (odds ratio:22.09, 95% CI (3.56–137.18)).
Conclusions: The discrepancy of qualitative modification of lipoprotein subclasses (LDL and HDL) after treatment with different antirheumatic drugs (sDMARDs, anti-TNFa+sDMARDs) demonstrate their different effect on RA dyslipidemia and their subsequent antiatherogenic prospective.

FRI0203 GOLIMUMAB IN BIOLOGIC-NAÏVE PATIENTS WITH ESTABLISHED RHEUMATOID ARTHRITIS (RA), PSORIATIC ARTHRITIS (PSA) OR ANKYLOSING SPONDYLITIS (AS) - SUBANALYSIS FROM THE NON-INTERVENTIONAL EVALUATION GO-NICE

K. Krüger[1], G.R. Burmester[2], S. Wassenberg[3], M. Bohl-Bühler[4], M.H. Thomas[5]. [1]*Rheumatologisches Praxiszentrum, München;* [2]*Department of Rheumatology and Clinical Immunology, Charité-Universitätsmedizin, Berlin;* [3]*Rheumazentrum Ratingen, Ratingen;* [4]*Rheumahaus Potsdam GbR, Potsdam;* [5]*Medical Affairs, MSD Sharp & Dohme GmbH, Haar, Germany*

Background: Golimumab (GLM) has demonstrated efficacy and safety in several randomized clinical trials with biologic-naïve patients. However, data from effectiveness and patient-reported outcomes (PROs) parameters in daily clinical practice in Germany are still lacking
Objectives: The aim of this subanalysis is to assess Golimumab on the effectiveness, and PROs in biologic-naïve patients with established RA, PsA or AS
Methods: This is a subanalysis of the non-interventional, prospective, 24-month study GO-NICE. Biologic-naïve patients with established RA, PsA or AS starting with GLM 50mg SC once monthly in a real life setting in Germany. Endpoint measures: disease activity DAS28, PsARC and BASDAI. PROs included QoL (EQ-5D-3L), functionality (FFbH), fatigue (FACIT-F). Safety data were also collected
Results: *RA patients* (n=265): Mean age 54.5 yr, 82.1% of the patients were female, 77.3% (n=204) were rheumatoid factor (RF) positive, and 76.4% (n=201) had anti-ccp antibodies at BL.
The DAS28 score at BL was 5.0 and dropped significantly to 2.9 within 24 months ($p<0.0001$ v. BL). After 3 months of treatment, 45.2% of patients had LDA (DAS28 ≤3.2), which increased to 50.8% after 6 month and 64.9% after 24 months.
PsA patients (n=247): Mean age 49.7 yr, 53.8% of the patients were female, 42.1% (n=104) had a nail involvement, 25.5% (n=63) dactylitis and 13.8% (n=34) enthesitis at BL. The proportion of patients achieving a response (mod PsARC) was 64%, 72.2% and 77.7% at 3, 6 and 24 months, respectively.
AS patients (n=246): Mean age 41.9 yr, 70.7% of the patients were male, 80.5% (n=198) were HLA-B27 positiv. Most common extraarticular manifestations were: enthesitis (12.6%), iritis (12.2%), IBD (3.7%), and dactylitis (2.8%) at BL.
The BASDAI at BL was 5.0 and dropped significantly to 2.0 within 24 months ($p<0.0001$ vs. BL). The proportion of patients achieving a response (BASDAI 50) was 62.2%, 66.9% and 76.9% at 3, 6 and 24 months, respectively.
An improvement of quality of life (QoL) by EQ-5D-3L was seen after 6 months and was maintained over 24 months. The patients' health state today (EQ VAS) improved from 52.3 at BL to 64.9 (RA), from 49.0 to 66.3 (PsA) and from 49.2 to 70.6 (AS). The functional ability (FFbH) improved significantly ($p<0.0001$ vs. BL) from 73.1 to 80.4 points (RA), from 73.0 to 82.2 (PsA) and from 72.8 to 81.2 (AS). The mean Fatigue score (FACIT-F) increased from BL: 33.3 to 39.5 points (RA), from 31.6 to 38.4 points (PsA), and from 31.6 to 40.2 points (AS) (each $p<0.001$ vs BL) within 24 months.
No new safety signals were detected.
Conclusions: GLM SC once-monthly showed after 3 months remarkable improvements in clinical effectiveness, patient-reported quality of life, functionality, and fatigue parameters and were maintained over 24 months in biologic-naive patients with established RA, PsA or AS.
At month 24, 64.9% of RA patients achieved LDA status, 77.7% of PsA achieved positive PsARC response and 76.9% of AS patients achieved BASDAI 50.
No new safety signals were detected.

FRI0204 COMPARISON THE LONG-TERM CLINICAL OUTCOMES BETWEEN NONTNF-INHIBITORS VERSUS TNF-I IN RA PATIENTS WHO FAILED TO A FIRST TNF-I

P. Bogas[1], C. Plasencia[1], D. Pascual-Salcedo[2], G. Bonilla[1], E. Moral[1], C. Tornero[1], L. Nuño[1], A. Villalba[1], D. Peiteado[1], A. Martinez[2], B. Hernandez[2], A. Balsa[1]. *[1]Rheumatology; [2]Immunology, Hospital Universitario la Paz, Madrid, Spain*

Background: There are many biological therapies for Rheumatoid Arthritis (RA) with different mechanisms of action and good efficacy rate; however, up to 40% of patients (pts) fail to respond to the 1st biologic agent, and it is still not clear what strategy to follow after showing inadequate response to tumor necrosis factor α inhibitors (TNF-i)
Objectives: To assess the clinical response and survival (SVV), in our cohort of RA pts that discontinued the 1st TNF-i, of a 2nd TNF-i vs a nonTNF-i, both in the global cohort and in the subpopulation that dropped out the 1st TNF-I due to inefficacy
Methods: This observational study included 110 pts in the RA-Paz cohort who previously suspended Ifx (68%) or Ada (32%) between 1999–2016. Two groups were established as they switched to a TNF-i or nonTNF-i. Clinical response was evaluated by DAS28, Delta-DAS28 (∆DAS28) and EULAR response (E-resp). The assessments were performed at 6 (v-6) and 12 months (v-12) since initiating 2nd biological agent and during the last visit prior to drug discontinuation or ending of the study for those who did not interrupt the drug (v-end). Statistical analysis was performed using SPSS version 20.0
Results: Of the 110 pts who had stopped Ifx or Ada as 1st TNF-i, 65% changed to a 2nd TNF-i. The 84% of the overall pts were women. The mean age was 64±14 years and the mean time of 2nd biologic drug was 3.71±3.51 years. 61% associated methotrexate at the beginning of 2nd biologic agent and 56% at the v-end, without differences between those who switched to TNF-i and those who did to nonTNF-i. At v-6 and v-12, there was no difference in ∆DAS28 [at v-6:1.3±1.4 in TNF-i and 1.2±1.2 in nonTNF-i (p=0.919), at v-12: 1.3±1.5 in TNF-I and 1.2±1.1 in nonTNF-i (p=0.852)]. In contrast, at v-end, pts with nonTNF-i showed a higher clinical improvement (∆DAS28: 0.68±1.7 in TNF-i, 1.8±1.1 in nonTNF-i, p=0.002). At v-6, the TNF-i group achieved higher good E-resp rate (41% vs 18%, p=0.035), but there was no difference at v-12 (36% in TNF-I vs 23% in nonTNF-i, p=0.435). However, at v-end, the nonTNF-I group achieved better E-resp (good resp: 38% in nonTNF-i vs 25% in TNF-I, no resp 18% in nonTNF-i vs 50% in TNF-i, p=0.01). Likewise, 100% (n=7) of the pts that finished 2nd biologic agent by remission, had changed to a nonTNF-i (p<0.00001). There were no differences regarding 2nd biologic drug SVV (mean SVV time of 5.7±0.66 in TNF-I, 4.3±0.59 in nonTNF-i, p=0.797). When analyzing the cohort that discontinued 1st TNF-I because of inefficacy, at v-6 and v-12 there were no differences between switchers to TNF-I and nonTNF-i in ∆DAS28 [v-6: 1.4±1.4 vs 0.9±1 p=0.164); v-12: 1.5±1.4 vs 1±1, p=0.192)], but at v-end, the nonTNF-i group reached a higher ∆DAS28 (0.9±1.5 in TNF-i, 1.6±1 in nonTNF-i, p=0.031)

Demographic characteristics	
Age (years)	64±13,9
Sex (female)	92 (84%)
Smokers	18 (16%)
BMI	26,6±7,7
Disease duration (years)	16,7±8,04
RF +	94 (85%)
Anti-CCP +	96 (89%)
Duration of treatment 1st biological (years)	3,2±3,1
Basal DMARDs (2º biological)	99 (90%)
Basal MTX (2º biological)	67 (61%)
v-Final FAMEs (2º biological)	93 (86%)
v-Final MTX (2º biological)	60 (56%)
Basal CPR (2º biological)	15,2±18,7
Basal ESR (2º biological)	42±24,1
Basal DAS (2º biological)	5,55±1,3

Conclusions: In our sample of RA patients who suspended Ifx/Ada as 1st TNF-i, switching to a 2nd biologic agent did not show relevant clinical differences between a TNF-i and a nonTNF-i within the 1st year of treatment. However, in the long-term, switching to a nonTNF-i shows enhanced clinical benefits with no impact on survival vis-à-vis a 2nd TNF-i. Despite the efficacy of TNF-i, new therapeutic targets are needed for those who fail to respond to these biological agents

FRI0205 CORRELATION OF PATIENT PREFERENCES TO TREATMENT OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA) TREATED WITH ANTI-TNF AGENTS IN GREECE. THE PANORAMA STUDY

P. Sidiropoulos[1], A. Bounas[2], P. Athanassiou[3], A. Andrianakos[4], E. Petrikkou[5], A. Drosos[6], D. Vassilopoulos[7]. *[1]Department of Rheumatology, Clinical Immunology and Allergy, University of Crete, Heraklion; [2]Private practice, Patras; [3]Rheumatology Division, General Hospital of Thessaloniki St. Paul, Thessaloniki; [4]IASO General Hospital; [5]Medical Affairs, MSD, Athens; [6]Rheumatology Clinic, University of Ioannina, Ioannina; [7]Joint Rheumatology Program, Clinical Immunology-Rheumatology Unit, 2nd Department of Medicine and Laboratory, National and Kapodistrian University of Athens, Athens, Greece*

Background: Route and frequency of administration of treatment options may be an important differentiator between drugs that are used to treat RA and patient preferences may influence adherence to and outcomes of therapy.
Objectives: The objective of this study was to assess the correlation between the fulfillment of patient preferences and clinical and patient reported outcomes.
Methods: PANORAMA was a non-interventional, prospective, multicenter, cohort study. Patients were either biologic naïve or experienced who initiated/switched to anti-TNF at enrollment. Post physician's anti-TNF choice, patients completed a preferences questionnaire over attributes related to anti-TNF treatment. Satisfaction with treatment was assessed with the TSQM questionnaire and compliance (proportion of full doses/planned) was recorded via the use of a patient diary. Persistence was defined as the time period between first and last anti-TNF administration. The observational period was 12 months, with study visits every 3 months.
Results: A total of 254 patients were enrolled in the study. The mean patient age was 58.3±13.4 years, 82.7% were female, 65.4% were biologic naïve and 66.1% had severe disease (DAS-28 ESR>5.1).The mean DAS-28 and HAQ-DI scores at enrollment were 5.5±1.1 and 1.4±0.6 respectively, while mean disease duration was 6.7±6.2 years with 53.2% of patients being seropositive (RF (+):49.2%, Anti-CCP (+): 40.5%). A monthly administration was most preferred by patients (65.7% vs. 20.1% for twice per month, 11.8% for once per week and 3.9% for twice per week), and the large majority of patients (75.2%) preferred the subcutaneous mode of administration. The mean compliance and 12-month persistence rates were 97.0% and 72.3% respectively. At 12 months, good EULAR response rate was achieved by 56.5% of patients and 40.8% were in DAS-28 remission. Univariate analysis demonstrated that fulfillment of patient preferences was correlated to good EULAR response (p<0.001), increased probability of being persistent (p=0.019) and satisfaction with treatment (p=0.063). Multivariate logistic regression analysis revealed that a good EULAR response was associated with satisfaction of patient preferences (OR 5.560, p<0.001), good patient knowledge of the disease (OR 1.327, p=0.006), absence of history of comorbidities (OR 2.42, p=0.014) and lower SJC (OR 1.10, p=0.021), whereas anti-TNF persistence at 12 months was associated (Cox regression analysis) with seropositivity (HR 0.566, p=0.047) and a high baseline ESR (>35 mm/h (HR 0.587, p=0.071)).
Conclusions: In anti-TNF treated RA patients, fulfillment of expressed treatment preferences was independently associated with a good EULAR response and correlated with drug persistence at 12 months, emphasizing the importance of patient preferences in treatment outcomes.

FRI0206 CORRELATION BETWEEN THE SERUM ETANERCEPT LEVEL AND RESPONSE TO ETANERCEPT TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

S.M. Zivojinovic[1], M. Sefik-Bukilica[2], N.S. Damjanov[3]. *[1]Clinical IV; [2]Laboratory department; [3]Head of Institute of rheumatology, Institute of Rheumatology, Belgrade, Serbia*

Background: It is well documented that the blockade of TNF-α significantly reduces disease activity in patients with rheumatoid arthritis (RA). However, at least one third of patients receiving etanercept either do not respond to treatment, or lose initial responsiveness [1]. Recent findings indicate that lack of clinical response may be related with lowering the serum drug levels.
Objectives: To investigate the relationship between serum etanercept levels and response to etanercept treatment in patients with RA.
Methods: The study population consisted of fifty eight patients with rheumatoid arthritis (RA), all treated with etanercept. Disease activity was assessed according to the 28-joint count *Disease Activity* Score (*DAS28*) at baseline and 6 months of

therapy. Clinical response was assessed using the European League Rheumatism (EULAR) response criteria [2]. Serum etanercept levels were measured by sandwich ELISA based on the ability of etanercept to bind TNF. Antibodies against etanercept were measured by bridging ELISA (Promonitor).

Results: The 47 female and 11 male were of a mean age 52.1±11.2 years (22–87) and have been living with RA for a mean of 13.2±8.2 years (2–24). At baseline the DAS28-$_{ESR}$ mean score was 6.1±1.0. After six months of etanercept treatment, 20 (34.5%) patients were in remission, 20 (34.5%) were in low disease activity and 18 (31%) were in moderate disease activity. The serum etanercept levels were significantly higher in patients in remission compared with patients in moderate disease activity (p=0.05). According to the EULAR response criteria, RA patients were divided into responders (52pts, 89.7%) and non-responders (6 pts, 10.3%). Median etanercept levels in all patients were 3.937mcg/ml. There were no statistical differences in etanercept levels between responders and non-responders patients (p=0.41). In addition, we stratified all patients into quartiles according to height of the etanercept level. The percentage of EULAR good responders was significantly different between the highest and the lowest quartiles ($p<0.05$).

Anti-etanercept antibodies were not found in any of the studied patients (0/58).

Conclusions: Patients with RA who did not respond to etanercept treatment achieved lower etanercept levels compared with responding patients. Higher concentrations of the drug were associated with a better response to treatment. Further studies are needed to provide evidence for this approach.

Background: Rheumatoid arthritis is a chronic form of inflammatory arthritis that is thought to have an early stage or reversibility with effective therapy ("window of opportunity").

Objectives: In the present study, we explored the effects of induction therapy with anti-TNFα antibody infliximab (IFX) plus methotrexate (MTX) compared with MTX alone and with placebo (PL) in patients with very early inflammatory arthritis.

Methods: In an investigator-initiated, double-blind, randomized, placebo-controlled, multi-center trial, patients with synovitis of 12–16 weeks duration in at least 2 joints underwent one year of treatment with IFX in combination with MTX, MTX monotherapy or PL randomized in a 2:2:1 ratio. The primary endpoint was clinical remission after 1 year (sustained for at least two consecutive visits 8 weeks apart including week 54) with remission defined as no swollen joints, 0 - 2 tender joints and a C-reactive protein (CRP) level within the normal range (<0.5 mg/dl) or a normal ESR (<25 mm/h). Further, sustainability of remission was assessed during the second year of the study, during which patients received no treatment. The trial was registered at www.isrctn.com (ISRCTN21272423).

Results: See Table 1.

Table 1. Number of patients in clinical remission at 6 months, one year and two years

	1: IFX+MTX (N=38)	2: MTX (N=36)	3: PL (N=16)
6 Mo	10 (26%)	6 (17%)	0
1 Year*	12 (32%)	5 (14%)	0
2 Years*	9 (24%)	1 (3%)	3 (19%)

*$p<0.05$ across the three groups.

90 patients participated in the present study. At week 54 (primary endpoint), 32% of the patients in the IFX+MTX group achieved sustained remission compared with 14% on MTX alone and 0% on PL (Table). This difference was statistically significant for all three groups ($p<0.05$) and for IFX+MTX vs PL ($p<0.05$) separately, but not for IFX+MTX vs MTX (p=0.10), nor for MTX vs PL (p=0.31). Remission was maintained during the second year on no therapy in 75% of the IFX+MTX patients but was lost in 80% of the MTX-only-patients (Table). The analysis of radiographic progression did not reveal significant differences between the three treatment groups. The number needed to treat (NNT) to achieve one additional sustained remission at 52 weeks with IFX+MTX was 3 compared to placebo; the NNT for MTX alone versus placebo was 7 (NNT=6 for IFX+MTX vs MTX alone).

Conclusions: These results indicate that patients with early arthritis can benefit from induction therapy with anti-TNF plus MTX compared to MTX alone, suggesting the existence of a window of opportunity where intensive treatment can alter the disease evolution

Background: Infliximab (IFX) was one of the first genetically engineered biologics successfully applied for medical use in patients with active RA and patients with AS. Previous preclinical studies showed that BCD-055 is highly similar to innovator IFX.

Objectives: This abstract presents results from three clinical trials of infliximab biosimilar, BCD-055, including comparative data on pharmacokinetics (PK), efficacy and safety in a variety of patient populations.
Methods: All three studies were conducted as international multicenter randomized double-blind studies in direct comparison with innovator IFX. ASART-1 study (Phase 1, PK study) and ASART-2 study (Phase 3, efficacy and safety study) were conducted in patients with AS. After the screening patients were stratified by CRP and BASDAI score, randomized (1:1 ratio in ASART-1; 2:1 ratio in ASART-2) into 2 arms and received BCD-055 or innovator IFX at a dose 5 mg/kg IV on day 1 wk 0, 2, 6 and then every 8 wks (up to wk 54). LIRA study (Phase 3 study) was conducted in patients with active RA who were stratified by age and DAS28 score, randomized (2:1) into 2 arms and received BCD-055 or innovator IFX at a dose 3 mg/kg IV on day 1 wk 0, 2, 6 and then every 8 wks (up to wk 54).
Results: A total of 91 patients were enrolled in ASART-1 study, 198 patients - in ASART-2 study and 195 patients - in LIRA study in Russia and Belarus.
PK characteristics were equivalent for BCD-055 and innovator IFX. After the single administration 90%CI for the ratio of geometric means for $AUC_{0–336}$ was 86.40% – 110.09%, for C_{max} – 82.70% – 109.83%. After multiple-dose administration 90%CI for the ratio of geometric means for $AUC_{0\text{-}tau}$ was 81.35% – 121.13%, for $C_{max,ss}$ – 90.16% – 117.32%.
Efficacy: BCD-055 is non-inferior to innovator IFX both in RA and AS patients: ACR20 at wk 14 was reached by 75.83% of patients in BCD-055 group and 74.19% in innovator IFX group (p=0.951, 95% CI for difference in proportion [-12.90%; 16.18%], margin -20%), ASAS20 at wk 30 - by 81.30% and 67.74% respectively (p=0.061, 95% CI for difference in proportion [-1.18%; 28.28%], margin -17.5%).
Safety: BCD-055 and innovator IFX showed highly similar safety profiles in all three studies without cases of unexpected toxicity. The rates of AEs were equivalent for both drugs and varied from 47% in patients with AS to 53% in patients with RA. Immunogenicity assessment didn't find any significant difference between BCD-055 and innovator IFX, anti-drug antibodies occurred at the same rate irrespectively to the group.
Conclusions: BCD-055 is highly similar to innovator IFX in patients with active RA and in patients with AS in terms of efficacy, safety and PK.

FRI0209 REAL-LIFE SAFETY PROFILE OF BIOSIMILAR ADALIMUMAB IN PATIENTS WITH INFLAMMATORY ARTHRITIC CONDITIONS

V. Kaushik, S. Apparao. *Arthritis & Rheumatism Centre, Chennai, Chennai, India*

Background: Biologic therapies have dawned a new era in the management of patients with chronic inflammatory arthritis by nudging the goal post from control to induction of remission. Adalimumab, a TNF-α inhibitor, has proven to be safe and effective in improving the disease activity and quality of life in patients with conditions like rheumatoid arthritis (RA) and ankylosing spondylitis (AS).[1,2] A biosimilar adalimumab (developed by *Cadila Healthcare Ltd., India*) has been approved for clinical use in 2014 in India. While the initial biosimilarity has been established for physicochemical, functional as well as clinical efficacy and safety aspects;[3,4] ongoing evaluation of safety in real-life patients is crucial for such biosimilar therapies.
Objectives: We share our experience on the real-life safety profile of biosimilar adalimumab following its clinical use in patients with RA and AS.
Methods: Patients with RA or AS treated with biosimilar adalimumab in our outpatient clinic at Arthritis and Rheumatism Centre during the period of 17 Dec 2014 to 30 Mar 2016 were considered for this analysis. The patients were prescribed biosimilar adalimumab 40 mg subcutaneously every fortnight for a minimum of 6 months. The patients were followed up till the end of the treatment, and any safety signals or adverse events reported were collected and analysed.
Results: A total of 200 patients - 119 patients with AS and 81 patients with RA - who received biosimilar adalimumab therapy for a period of 6 months were included. The median age for the group was 36 (17–68 years); and 138 patients were males. The mean BMI was 25.74±3.83; and the median duration of disease for the entire group was 4.54 (0.5–13.5) years - 4.54 (0.5–9.58) years for the patients with AS, and 4.58 (2.5–13.5) years for the patients with RA. About 90% (181 out of 200 patients) received concomitant therapy with methotrexate. Biosimilar adalimumab therapy was well tolerated by all patients, with no serious adverse events. Adverse events were noted in only 2 patients - one patient had developed pulmonary tuberculosis in the 4th month of treatment, biosimilar adalimumab was discontinued and AKT treatment was started; while another patient experienced rise in transaminases for which, the dose of methotrexate was reduced. Overall assessment of tolerability as "Excellent" was 65.5% by the treating physician and 82% by patients.
Conclusions: To the best of our knowledge, this is the first report on "real-life" use of biosimilar adalimumab in such a large number of patients. The analysis reveals a safety and tolerability profile of biosimilar adalimumab comparable to that of the innovator product.

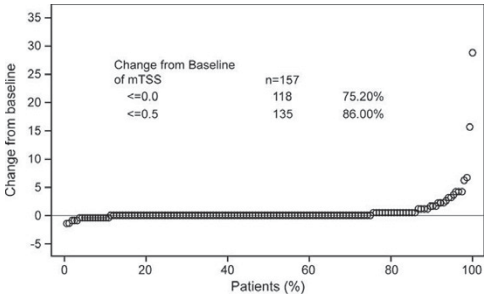
FRI0210 REAL-WORLD HAWK STUDY: LONG-TERM SAFETY AND EFFECTIVENESS OF ADALIMUMAB WITH HIGHER-DOSE METHOTREXATE IN JAPANESE PATIENTS WITH EARLY RHEUMATOID ARTHRITIS



Y. Tanaka[1], T. Mimori[2], H. Yamanaka[3], R. Nakajima[4], K. Morita[4], J. Kimura[4], T. Takeuchi[5]. *[1]The First Department of Internal Medicine, School of Medicine, University of Occupational and Environmental Health, Kitakyushu; [2]Department of Rheumatology and Clinical Immunology, Graduate School of Medicine, Kyoto University, Kyoto; [3]Institute of Rheumatology, Tokyo Women's Medical University; [4]AbbVie GK; [5]Division of Rheumatology, Department of Internal Medicine, School of Medicine, Keio University, Tokyo, Japan*

Background: TNF inhibitors are first-line biologic therapy used in combination with MTX for treatment of RA. However, in Japan, limited real-world data exist on this combination with relatively higher doses of MTX (>8 to ≤16 mg/week).
Objectives: The HAWK study was designed to assess real-world, long-term safety and effectiveness of the TNF inhibitor ADA with MTX (≥12 mg/week) in Japan. Week 52 results are presented.
Methods: This multicenter, prospective, observational study, enrolled biologic-naïve, early (≤2 years) RA patients with DAS28-CRP>3.2 despite MTX therapy for ≥3 months. Eligible patients received ADA + MTX (≥12 mg/week at beginning of ADA) for 104 weeks. Primary endpoint was DAS28-CRP <2.6 at week 52. Secondary endpoints included CDAI, SDAI, HAQ-DI and inhibition of structural joint damage using the mTSS. ADRs and dosage of ADA and MTX were recorded.
Results: As of April 15, 2016, 346 patients were enrolled (safety set 301; effectiveness set 293). Effectiveness set comprised 73% women; mean (±SD) age, 54.3 (13.9) years; duration of RA, 12.1 (6.2) months; MTX dosage, 13.4 (1.8) mg/week; DAS28-CRP, 4.5 (0.9); and mTSS, 7.7 (10.0) at baseline. At week 52, DAS28-CRP <2.6 and low disease activity (<3.2) were achieved in 77% and 92% patients, respectively. Remission rates in CDAI (≤2.8), SDAI (≤3.3), and HAQ-DI (≤0.5) were 49%, 51%, and 82%, respectively. Although average MTX dosage was decreased (≤2 mg/week), unchanged, and increased (≥2 mg/week) from baseline in 19.6%, 78.9%, and 1.4% patients over 52 weeks, respectively, there was no significant difference in disease activity improvement across these MTX dosage groups at week 52 (p=0.350). Structural remission rate at week 52 was 86% (ΔmTSS ≤0.5) (Figure). A total 110 ADRs occurred in 80 (26.6%) patients, 23 were serious in 21 (7.0%) patients (Table).

	All (N=301)		Serious (N=301)	
ADR				
Total	80	26.6%	21	7.0%
ADRs by SOC				
Infections and infestations	29	9.6%	9	3.0%
Investigations	16	5.3%	1	0.3%
Respiratory, thoracic and mediastinal disorders	13	4.3%	3	1.0%
Hepatobiliary disorders	9	3.0%	0	
ADRs of particular interest				
Tuberculosis	0		0	
Pneumocystis jirovecii pneumonia	4	1.3%	4	1.3%
Pneumonia bacterial*	6	2.0%	4	1.3%
Herpes zoster	4	1.3%	0	
Malignancy (1)	4	1.3%	4	1.3%
Interstitial lung disease	2	0.7%	2	0.7%
Sepsis	0		0	
Pancytopenia	0		0	
Reactivation of hepatitis B	0		0	

*Pneumonia, Pneumonia bacterial, Pneumonia pneumococcal, Pneumonia legionella, Pneumonia streptococcal. (1) Colon cancer, diffuse large B-cell lymphoma, ovarian cancer metastatic, lung neoplasm malignant.

Conclusions: Results show that ADA with MTX (≥12 mg/week at the beginning) displayed a consistent safety profile and was effective with a DAS28-CRP remission rate of 77% in routine clinical practice. The ADR rate of 26% was similar to a previous, short-term (28 weeks) postmarketing surveillance report (1).

FRI0211 **A DESCRIPTIVE ANALYSIS OF REAL-WORLD TREATMENT PATTERNS OF INNOVATOR INFLIXIMAB (REMICADE) AND BIOSIMILAR INFLIXIMAB IN A TREATMENT NAÏVE TURKISH RHEUMATOLOGIC DISEASE POPULATION**

Y. Yazici[1], L. Xie[2], A. Ogbomo[2], D. Parenti[3], K. Goyal[3], A. Teeple[3], L. Ellis[3], I. Simsek[4]. *[1]NYU Hospital for Joint Diseases, New York; [2]STATinMED Research Inc, Ann Arbor; [3]Janssen Scientific Affairs, LLC, Horsham, United States; [4]Guven Hospital, Ankara, Turkey*

Objectives: This retrospective healthcare claims analysis examined treatment patterns of innovator infliximab (IFX) and biosimilar infliximab (CT-P13) in a Turkish rheumatologic disease population after CT-P13 availability in July, 2014.
Methods: Adult patients (pts) with ≥1 diagnosis code (ICD-10-CM) for rheumatoid arthritis (RA) were identified in a national Turkish healthcare database during the study period (01DEC2010–01DEC2015). Eligible pts had continuous medical/pharmacy enrollment ≥12 months before and ≥6 months after IFX or CT-P13 initiation (index date). Patients were naïve to IFX or CT-P13 (i.e. had no IFX or CT-P13 within 12 months before the index date). Demographics, concomitant diseases and medications, and treatment patterns, eg., dose, interval, discontinuation, and switch were summarized. Confirmed discontinuation was defined as a switch to another biologic medication or the absence of an index biologic claim for ≥120 days without censoring.
Results: Key results are shown in the Table. A total of 1044 patients initiated either medication. The majority (80%; n=831) initiated IFX. The IFX cohort had a mean age of 42 years; 56% were women and mean follow up was 12 months. The CT-P13 cohort consisted of 213 pts with mean age of 43 years; 58% women; and mean follow up of 9 months. Approximately one-third of pts in each cohort had a concomitant diagnosis of ankylosing spondylitis (AS; TABLE). Other concomitant diseases and medications appeared balanced between cohorts. Pts in the IFX cohort had an average of 5.2 infusions and mean dose of 4.7 vials per infusion approximately every 8 weeks. Pts in the CT-P13 cohort had an average of 3.6 doses and mean dose of 5.8 vials per dispensing approximately 9 weeks apart.
A confirmed discontinuation occurred in 55% of the IFX cohort; driven in part by switching. 24% of IFX pts had ≥1 biologic switch with 8% initially switching to CT-P13. Time to any discontinuation or censoring of IFX is shown in the Table.
In the CT-P13 cohort, a confirmed discontinuation was observed in 63%; 31% switched to another biologic therapy; and 20% initially switched to IFX. Time to any discontinuation or censoring of CT-P13 is shown in the Table.
Conclusions: These findings in a single country indicate that real world utilization patterns may differ between innovator IFX and CT-P13, with predominantly more patients initiating IFX; greater overall CT-P13 discontinuation and a higher proportion of patients switching from CT-P13 to IFX. Further studies are needed to understand the reasons for these observed differences.

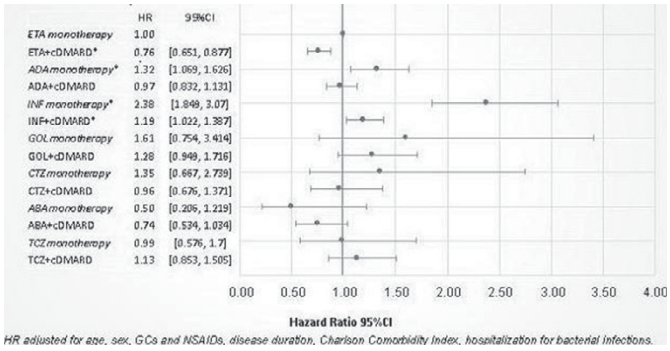
Rheumatoid arthritis - other biologic treatment



FRI0212 **COMPARATIVE EFFECTIVENESS OF FIRST-LINE BIOLOGIC MONOTHERAPY IN RHEUMATOID ARTHRITIS**

E. Silvagni[1], A. Bortoluzzi[1], G. Carrara[2], M. Govoni[1], C. Scirè[1,3]. *[1]1Department of Medical Science, Rheumatology Unit, University of Ferrara and Azienda Ospedaliero-Universitaria Sant'anna, Cona (Ferrara), ITALY, Ferrara (FE); [2]Epidemiology Unit, Italian Society for Rheumatology; [3]Epidemiology Unit, Italian Society for Rheumatology, Milan, Italy*

Background: Non-Biological disease modifying antirheumatic drugs (csDMARDs) are recommended in association to biologics (bDMARDS) in the treatment of Rheumatoid Arthritis (RA) and combination therapy is superior than bDMARD monotherapy with a better drug survival. Limited data are available in literature about the best biological treatment choice when a monotherapy is necessary in biologic-naïve patients.
Objectives: To assess comparative effectiveness (drug survival) of different first-line bDMARDs when administered in monotherapy in a large population-based sample of RA deriving from the administrative health database of the Lombardy region in Italy.
Methods: Data were obtained from health database of the Lombardy Region between 1/1/2004 and 31/12/2013. Patients with RA, diagnosed by a rheumatologist, with a certified diagnosis (exemption code 006.714.0) and treated with first-line approved bDMARDs (Abatacept [ABA], Adalimumab [ADA], Certolizumab [CTZ], Etanercept [ETA], Golimumab [GOL], Infliximab [INF] and Tocilizumab [TCZ]) were included; the presence of a combination therapy of any duration with a concomitant csDMARD (Methotrexate, Leflunomide, Sulfasalazine, Cyclosporine and Hydroxychloroquine) was compared to monotherapy. Clinical characteristics recorded were age, sex, disease duration, Charlson Comorbidity Index, hospitalization for bacterial infections, use of concomitant glucocorticoid (GCs) or Nonsteroidal Anti-Inflammatory Drugs (NSAIDs). Propensity to treatment with monotherapy was assessed by logistic models and results were presented as odds ratios and 95%confidence intervals (CI) Effectiveness was evaluated as drug survival using Cox proportional hazard models.
Results are presented as hazard ratios (HR) and CI, crude and adjusted for pre-specified confounders.
Results: 4478 RA patients who started a first-line bDMARD were included; 840 (18.8%) in monotherapy and 3638 (81.2%) in association to at least one csDMARD. Among biologic-naïve monotherapy patients, N.398 (47.4%) received ETA, N.215 (25.6%) ADA, N.92 (10.9%) INF, N.48 (5.7%) TCZ, N.35 (4,2%) ABA, N.30 (3,6%) CTZ, N.22 (2,6%) GOL. Median survival on treatment was 19.9 months (7.9–45.1).
Monotherapy was associated with a lower age, longer disease duration, a consistently higher Charlson Comorbidity Index (in particular hepatic or renal disease), lower GCs and NSAIDs intake.

Compared to monotherapy, combination therapy was associated with a lower drug failure (crude HR 0.75 [95% CI 0.68–0.82]; adjusted HR 0.78 [95% CI 0.70–0.86]; $p<0.0001$).

In patients in monotherapy, considering ETA as reference and adjusting for the above mentioned clinical characteristics, the HR for bDMARD failure was 1.32 for ADA (95% CI 1.07–1.63) and 2.38 for INF (95% CI 1.85–3.07).

HR adjusted for age, sex, GCs and NSAIDs, disease duration, Charlson Comorbidity Index, hospitalization for bacterial infections.

Conclusions: Monotherapy with bDMARDs is consistenly associated with lower retention rate in first-line therapy for anti-TNF drugs. Comparing bDMARDs administered in monotherapy, INF and ADA show a higher risk of withdrawal than ETA. Real life data support the currently recommended use of bDMARDs in association to csDMARDs.

FRI0213 COMPARATIVE EFFECTIVENESS OF ABATACEPT, RITUXIMAB, TOCILIZUMAB AND ANTI-TNF BIOLOGICAL DMARDS IN RA: RESULTS FROM THE NATIONWIDE SWEDISH REGISTER

T. Frisell[1], M. Dehlin[2], D. Di Giuseppe[1], N. Feltelius[3], A. Kastbom[4], C. Turesson[5], J. Askling[1] on behalf of the ARTIS Study Group. *[1]Karolinska Institutet, Stockholm; [2]Sahlgrenska Academy, University of Gothenburg, Göteborg; [3]Medical Products Agency, Uppsala; [4]Rheumatology/AIR, Linköping; [5]Rheumatology, Department of Clinical Sciences, Malmö, Lund University, Malmö, Sweden*

Background: Many current guidelines rank abatacept (ABA), rituximab (RTX), tocilizumab (TOC), and the TNFi bDMARDs as equal in effectiveness for the treatment of RA, at least as second line therapies. This is mainly based on evidence from separate RCTs, with few direct comparisons and limited comparative effectiveness data from clinical practice.
Objectives: To describe outcomes in clinical practice among RA patients starting different bDMARDs as first bDMARD, and after switch from initial TNFi.
Methods: The Swedish Rheumatology Register was linked to nationwide registers with data on demographics and medical history. We included all patients with RA starting a first ever bDMARD, or switching to a new bDMARD after a TNFi as first bDMARD, in 2010 - 2014, with follow-up through 2015. Effectiveness was assessed at 1 year (±90 days) after starting therapy, and measured as 1) the proportion remaining on therapy, or the proportion remaining on therapy and with 2) Good EULAR response, 3) HAQ improvement >0.2, 4) no swollen or tender joints. Relative response was estimated with log-binomial regression adjusting for potential confounders.
Results: Patients starting non-TNFi were older than those starting a TNFi, had lower socioeconomic status, and more often a history of diseases including malignancy, serious infections, and diabetes. After switch from TNFi, those starting non-TNFi also had higher disease activity.
Non-TNFi were associated with better drug survival and higher proportion reaching response outcomes compared to TNFi as first bDMARD. After switch from TNFi, RTX and TOC, but not ABA, were associated with significantly better drug survival and response. Differences remained after adjusting for identified potential confounders.
Conclusions: Despite channeling of older and sicker individuals to non-TNFi-bDMARDs, treatment outcomes were in general better in these groups, particularly for TOC and RTX. In interpreting this, the risk of residual confounding should be remembered, and that we did not include safety or long term outcomes.

FRI0214 LONG-TERM EFFICACY AND SAFETY OF SIRUKUMAB IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS DESPITE ANTI-TUMOR NECROSIS FACTOR THERAPY: RESULTS OF THE RANDOMIZED, PHASE 3 SIRROUND-T STUDY

Y. Tanaka[1], D. Aletaha[2], P. Agarwal[3], R. Kurrasch[4], P.P. Tak[5], S. Popik[3]. *[1]Department of Internal Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan; [2]Division of Rheumatology, Medical University of Vienna, Vienna, Austria; [3]Janssen Research & Development, LLC, Spring House, PA; [4]GlaxoSmithKline, Collegeville, PA, United States; [5]GlaxoSmithKline, Stevenage, United Kingdom*

Background: Sirukumab, a selective, high-affinity human monoclonal antibody to the interleukin-6 (IL-6) cytokine, is under development for rheumatoid arthritis (RA) and other diseases.
Objectives: To evaluate long-term efficacy and safety of sirukumab in patients (pts) with RA refractory or intolerant to anti-tumor necrosis factor (TNF) agents.
Methods: This phase 3 study included pts ≥18 years with moderate to severe active RA, and a lack of benefit to ≥1 anti-TNF or intolerance to ≥2 anti-TNFs. Eligible pts were initially randomized 1:1:1 to sirukumab subcutaneous (SC) 50mg q4w, sirukumab SC 100mg q2w, or placebo SC q2w for 24 wks. Placebo-treated pts with <20% improvement in tender and swollen joints at Wk 18 (early escape [EE]) and those remaining on placebo at Wk 24 (crossover) were re-randomized to sirukumab through Wk 52. Efficacy endpoints included ACR response, HAQ-DI scores, DAS28 (CRP) remission rates, and SF-36 scores. Results are presented for these key endpoints at Week 52.
Results: 878 pts were initially randomized to placebo (n=294), sirukumab 50 mg q4w (n=292), or sirukumab 100 mg q2w (n=292). Of placebo-treated pts, 94 met EE criteria at Wk 18 and 158 crossed over at Wk 24 and were re-randomized to sirukumab. 60% of pts had received ≥2 prior biologics, including non-TNF–targeted biologics. RA signs and symptoms and patient-reported outcomes (PROs [SF-36 scores]) improved significantly with sirukumab versus placebo through Wk 24. Improvements were maintained through Wk 52 with no dose response (Table 1). Through Wk 52 in the combined sirukumab 50mg q4w and 100mg q2w groups, respectively, an adverse event (AE) was reported for 79.6% and 81.3% of pts and a serious AE was reported for 14.2% and 13.2% of pts; injection-site reactions and alanine aminotransferase increases were the most commonly reported AEs.
Conclusions: In this population intolerant or refractory to anti-TNFs/other biologics, sirukumab SC 50mg q4w and 100mg q2w were well tolerated and reduced signs and symptoms of RA and improved PROs through 52 wks of treatment, also among pts who switched from placebo to sirukumab.

FRI0215 COMPARATIVE EFFICACY AND RETENTION RATE OF TOCILIZUMAB AND TNF INHIBITORS USED IN COMBINATION WITH METHOTREXATE AS FIRST-LINE BIOLOGIC THERAPY IN RHEUMATOID ARTHRITIS: DATA FROM A MULTICENTRE OBSERVATIONAL REGISTRY

E.G. Favalli[1], M. Biggioggero[1], P. Sarzi Puttini[2], F. Atzeni[2], E. Fusaro[3], V. Grosso[4], R. Pellerito[5], R. Gorla[6], C. Bazzani[6], A. Marchesoni[1], R. Caporali[4]. *[1]Department of Rheumatology, Gaetano Pini Institute; [2]Rheumatology Unit, University Hospital L. Sacco, Milano; [3]Rheumatology, Azienda Ospedaliera Universitaria Città; della Salute e della Scienza, Torino; [4]Rheumatology, University of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia; [5]Rheumatology, Ospedale Mauriziano, Torino; [6]Rheumatology Unit, Spedali Civili, Brescia, Italy*

Background: Despite a demonstrated superiority of interleukin-6 over tumour necrosis factor (TNF) blockade when used as monotherapy, the choice of the first biologic agent (bDMARD) for treating rheumatoid arthritis (RA) in combination with methotrexate (MTX) is still a challenge for rheumatologist.
Objectives: To retrospectively evaluate in a multicentre observational cohort of Northern Italy (the LORHEN registry) the 6- and 12-month comparative drug survival and remission rate of tocilizumab (TCZ) and TNF inhibitors (TNFis) used as first bDMARD in combination with MTX.
Methods: All RA patients treated with TCZ or a TNFi as first-line bDMARD with at least 12-month follow-up were selected from the LORHEN registry. The analysis was limited to the period from January 2009 to May 2016 and to patients receiving either TCZ or TNFi in combination with MTX, excluding bDMARD monotherapy. Six- and 12-month clinical remission rate was defined as achievement of disease activity score 28 calculated by using erythrosedimentation rate (DAS28-ESR) <2.6. Drug persistence was calculated by Kaplan-Meier method. The comparison between treatment subgroups was performed by a chi-square test for remission data and by a log-rank test for drug survival. Moreover, DAS28-ESR remission rate has been corrected for drug discontinuation by using the LUNDEX formula [(1)].
Results: The overall study population included 591 patients (female 77.3%, mean age [± standard deviation, SD] 54.2±13.2 years, mean disease duration [±SD] 7.4±7.7 years, positive rheumatoid factor 67.5%, positive anti-citrullinated peptide antibodies 77.6%, mean baseline DAS28-ESR 5.1±1.2) treated with TCZ (n=61) or TNFis (n=530; infliximab 43, adalimumab 163, etanercept 195, golimumab 60, certolizumab pegol 69). Baseline characteristics were similar in the two groups, with the exception of mean age (TCZ 58.2 vs TNFis 53.7 years; p=0.021). No significant differences (p=0.361) emerged in the 6- (TCZ 88% vs TNFis 84.3%; p=0.752) and 12-month (TCZ 76.4% vs TNFis 71.5%;) retention rate. Clinical remission was achieved in overall 35.7% patients at 6 months (TCZ 59% vs TNFis 33%; p<0.001) and in 36.8% patients at 12 months (TCZ 58.8% vs TNFis 34.5%; p<0.001). Similar trends were observed after correction by LUNDEX formula at 6 (TCZ 51.9% vs TNFis 27.8%) and 12 months (TCZ 44.9% vs TNFis 24.6%).
Conclusions: Despite a similar 1-year retention rate, the proportion of patients achieving DAS28-ESR remission was significantly higher in TCZ+MTX treated group compared with TNFis+MTX, suggesting a deeper clinical response in patients receiving IL6 blockade.

FRI0216 RESULTS OF A LONGITUDINAL REVIEW OF PULMONARY FUNCTION AND SAFETY DATA IN A PHASE IIB CLINICAL PROGRAMME TESTING GRANULOCYTE-MACROPHAGE COLONY-STIMULATING FACTOR (GM–CSF) RECEPTOR ANTAGONIST MAVRILIMUMAB FOR TREATMENT OF RHEUMATOID ARTHRITIS (RA)

G. Burmester[1], M.A. Michaels[2], D. Close[3], A. Godwood[3], K. Middleton[3], P. Miranda[4], J. Vencovský[5], J. Kremer[6], I.B. McInnes[7], M. Albulescu^[3], M. Weinblatt^[8]. *[1]Charité – University Medicine Berlin, Berlin, Germany; [2]MedImmune, Gaithersburg, United States; [3]MedImmune, Cambridge, United Kingdom; [4]Centro de Estudios Reumatológicos, Santiago, Chile; [5]Institute of Rheumatology, Prague, Czech Republic; [6]The Albany Medical College, Albany, United States; [7]University of Glasgow, Glasgow, United Kingdom; [8]Brigham and Women's Hospital, Boston, United States*

Background: RA is associated with pulmonary comorbidity and lung function decline over time, but longitudinal assessment of pulmonary abnormalities in the context of RA treatment needs further characterisation. Mavrilimumab, an investigational human monoclonal antibody, inhibits GM-CSF by binding to the GM-CSF receptor α subunit.
Objectives: To investigate the pulmonary safety of mavrilimumab because of the theoretical risk of inhibiting alveolar macrophage function and causing pulmonary alveolar proteinosis (PAP).
Methods: Pulmonary monitoring included standardised serial pulmonary function testing (spirometry and diffusing capacity of lung carbon monoxide [DLCO]), chest X-rays, assessments of dyspnoea and pulmonary adverse events (AEs) in two randomised, double-blind studies (NCT01706926; NCT01715896) where patients (pts) with moderate to severe RA received mavrilimumab 30, 100 or 150 mg every other week (eow), or placebo and mavrilimumab 100 mg eow or golimumab 50 mg every 4 weeks, respectively. Eligible pts transferred to the open-label extension study (NCT01712399) and received mavrilimumab 100 mg eow. All studies excluded pts with clinically significant uncontrolled pulmonary disease. An Independent Pulmonary Evaluation Committee (IPEC), blinded to treatment, adjudicated pulmonary AEs and lung function abnormalities.
Results: Mavrilimumab was received by 442 pts with cumulative safety data exposure of approximately 900 pt-yrs and a median (range) exposure time of 2.5 (0.1–3.3) yrs. Baseline (BL) characteristics are shown (Table). Mean dyspnoea (Table), forced expiratory volume in 1 second (FEV_1), forced vital capacity (FVC) and DLCO were mostly maintained within 5% of BL values for pts treated with mavrilimumab during the clinical programme. Clinically relevant decreases in predicted FEV_1 and FVC (>20% from BL and <80% predicted) were demonstrated by ≤6.2% of pts at any visit (Table); decreases were mostly transient with no apparent trends. Overall, 83 pts (9.24/100 pt-yrs) reported ≥1 pulmonary AE; bronchitis was reported most frequently (34 pts [3.78/100 pt-yrs]); one AE was considered serious and treatment-related (acute bronchitis). The reported pulmonary AE rate was generally stable over time. No suspected or confirmed PAP cases were found by IPEC and no pulmonary-related deaths were reported.
Conclusions: We believe this is the most comprehensive longitudinal study of pulmonary function in a clinical RA programme. The BL pulmonary function profile indicates that this is not a normal population from a pulmonary health perspective. Mavrilimumab was not associated with substantial decline in pulmonary function or PAP in pts treated up to 3.3 years; its acceptable safety profile advocates initiation of Phase III studies with mavrilimumab. Further studies are now required to fully characterise pulmonary function over time in RA.

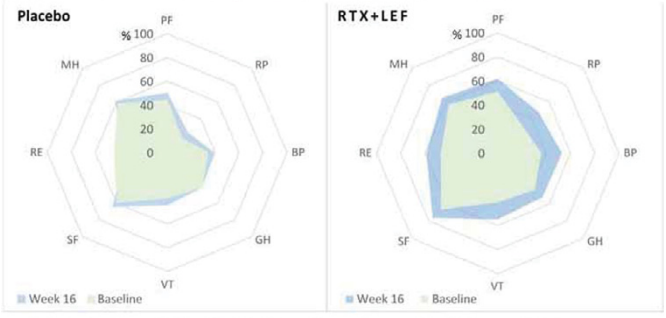
FRI0217 IMPACT OF RITUXIMAB IN COMBINATION WITH LEFLUNOMIDE AND RITUXIMAB RETREATMENT WITH TWO DIFFERENT DOSAGES ON PATIENT-REPORTED OUTCOMES: RESULTS FROM A MULTICENTER RANDOMIZED PLACEBO CONTROLLED INVESTIGATOR INITIATED CLINICAL TRIAL IN ACTIVE RHEUMATOID ARTHRITIS (AMARA-STUDY)

M. Köhm[1,2], T. Rossmanith[2], S. Dauth[2], R. Alten[3], M. Aringer[4], M. Backhaus[5], G. Burmester[6], E. Feist[6], H. Kellner[7], K. Krüger[8], U. Müller-Ladner[9], A. Rubbert-Roth[10], H.-P. Tony[11], S. Wassenberg[12], H. Burkhardt[1,2], F. Behrens[1,2] on behalf of AMARA study group. *[1]Rheumatology, Goethe-University Frankfurt/Main, Frankurt/Main; [2]Clinical Research, Fraunhofer IME-TMP, Frankfurt; [3]Rheumatology, Schlosspark-Klinik, Berlin; [4]Medizinische Klinik und Poliklinik III, Universitätsklinik, Dresden; [5]Rheumatologie, Park-Klinik Weißensee; [6]Rheumatologie, Charité Universitätsmedizin, Berlin; [7]Rheumatologische Fachpraxis; [8]Praxiszentrum St. Bonifatius, München; [9]Abteilung Rheumatologie und klinische Immunologie, Kerckhoff-Klinik, Bad Nauheim; [10]Rheumatologie, Universitätsklinik, Köln; [11]Abteilung Rheumatologie/Immunologie, Universitätsklinik, Würzburg; [12]Rheumazentrum, Ratingen, Germany*



Background: Use of biologicals such as Rituximab (RTX) in Rheumatoid Arthritis (RA) is effective and often only licensed in combination with Methotrexate (MTX). In cases of contraindications to or intolerances of MTX other cDMARDs are frequently used without robust data from RCTs. In addition, different strategies of retreatment of RTX are available.

Objectives: To demonstrate efficacy on patient-reported outcomes (PROs) of RTX in combination with leflunomide (LEF) in a multicenter investigator-initiated placebo (PLA)-controlled RCT in Germany.

Methods: A total of 189 patients with active RA (DAS28>3.2 and at least 3 SJC and 3 TJC) despite stable LEF treatment were screened for a 52-weeks double-blind placebo controlled RCT. Patients were randomized to receive either two-times 1000mg RTX i.v. followed by a retreatment at week 24 with two-times 1000 (RTX-RTXhigh) or 500mg (RTX-RTXlow) or two times PLA at baseline, followed by a retreatment of RTX of either two-times 1000 (PLA-RTXhigh) or 500mg (PLA-RTXlow) at week 24. Adult patients who had inadequate response to more than one antiTNF or failed more than three cDMARDs were excluded. PROs (HAQ, FACIT-F, SF36) were measured at each visit until week 52. Treatment effects on PROs were determined by differences from baseline to week 16, 24 and week52.

Results: Of 189 screened patients 148 were randomized (mean age 56 years; mean proportion of RF-and antiCCP-positivity 58.4% and 55.7% in the RTX-group; 74% female). DAS28 at baseline was 5.55 for RTX and 5.53 in the PLA-group. All baseline-characteristics were well balanced between treatment groups. An improvement in HAQ from baseline to week 16 was seen with a mean delta of -0.23 in the RTX-group (MCID) vs. -0.11 for PLA. In the RTX-group, retreatment until week 52 resulted in stable HAQ-values compared to week24 independent from its dosage. FACIT-F values increased in the RTX-group from baseline to weeks 16, 24 and 52 by 11.87, 12.3 and 14.25, respectively. All physical and mental domains of the SF36 showed a pronounced increase of levels at week 16 compared to baseline in the RTX-group (Figure 1). A total of 372 adverse events (AE) were observed during the one-year studyperiod, only 14 classified as severe (10 in RTX and 4 in PLA). 43 serious adverse events were reported, 28 of them in the RTX-group during the placebo-controlled period.

Figure 1: SF36 domains at baseline and week 16 after placebo or RTX+LEF treatment

PF: physical functioning; RP: physical role limitations; BP: pain; GH: general health; VT: energy/vitality; SF: social functioning; RE: emotional role limitations; MH: mental health

Conclusions: Efficacy of LEF plus RTX was demonstrated not only by measurements of disease activity (as presented previously) but also by measurements of PROs (HAQ, FACIT-F, SF36). This treatment regime showed equal effect sizes compared to the combinational therapy of MTX plus RTX. The treatment with LEF plus RTX illustrated an acceptable safety profile.

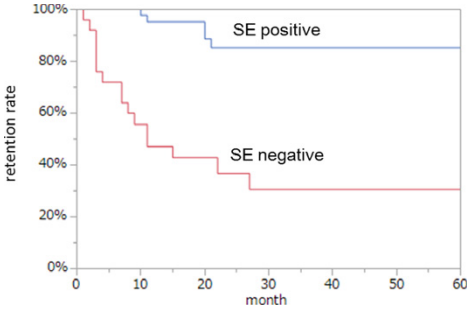
FRI0218 SHARED EPITOPE POSITIVITY IS RELATED TO EFFICACY OF ABATACEPT IN RHEUMATOID ARTHRITIS



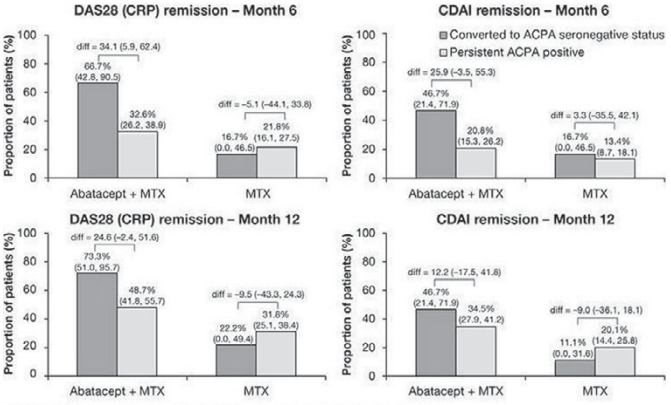
K. Oryoji, K. Yoshida, S.-I. Mizuki. *Matsuyama Red Cross Hospital, JAPAN, Matsuyama-Shi, Japan*

Background: Abatacept, a soluble fusion protein composed of the extracellular domain of CTLA-4 molecule and the Fc portion of human IgG1, is approved therapy for RA by the mechanism of binding to CD80/86 (B7–1/B7–2) on antigen presenting cell (APC), and blocking the B7:CD28 interaction. Meanwhile, it is suggested that HLA-DRB1 shared epitope (SE) associates with the production of ACPA through MHC molecule-based antigen presentation. Moreover, the association between the efficacy of abatacept and the positivity for anti-cyclic citrullinated peptide antibody (ACPA) was reported. Thus, we speculated that there may be correlation between the efficacy of abatacept and patients' HLA-DRB1 SE positivity, so we investigated correlation between the clinical efficacy of abatacept in RA patients and their HLA-DRB1 genotype.

Objectives: To identify the relation between the efficacy of abatacept on patients with rheumatoid arthritis (RA) and their HLA-DRB1 phenotype including whether having shared epitope (SE).

Methods: HLA-DRB1 phenotype of 72 patients treated with abatacept was identified, and divided into 2 group, SE (HLA-DRB1 0101, 0401, 0404, 0405,

0408, 1001) positive and SE negative. To overcome potential bias, multivariate logistic regression analysis was done in this retrospective cohort.
Results: They were divided into 47 SE positive patients (65.3%) and 25 SE negative patients (34.7%). The retention rate of abatacept treatment at week 52 were 95.3%/47.1% (SE positive/SE negative, p<0.0001, log-rank test), respectively. Adjusted hazard ratio for abatacept discontinuation due to lack of efficacy was 8.94 (95% CI: 2.95–34.1, p<0.0001, Multivariable Cox proportional hazards regression model) in SE negative group compared to SE positive group. The EULAR good response rate at week 24 were 74.5%/20.0% (SE positive/SE negative, p<0.0001, Fisher's exact test), respectively. Simplified Disease Activity Index (SDAI) remission rate at week 24 were 55.3%/20.0% (SE positive/SE negative, p=0.004, Fisher's exact test), respectively. Multivariate logistic regression revealed the odds ratio of EULAR good response and SDAI remission achievement in SE positive patients was 23.2 and 6.73 (95% CI: 5.10–152.0, p<0.0001 and 1.70–32.3, p=0.006), respectively.



Conclusions: Abatacept is strictly effective to SE positive RA patients.

FRI0219 ASSOCIATION BETWEEN CONVERSION TO ACPA/RF SERONEGATIVE STATUS AND CLINICAL OUTCOMES FOLLOWING TREATMENT WITH ABATACEPT IN COMBINATION WITH METHOTREXATE COMPARED WITH METHOTREXATE ALONE IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS AND POOR PROGNOSTIC INDICATORS

D. Jansen[1], P. Emery[2], J. Smolen[3], R. Westhovens[4], M. Le Bars[5], S. Connolly[6], J. Ye[6], R. Toes[1], T. Huizinga[1]. *[1]Leiden University Medical Center, Leiden, Netherlands; [2]University of Leeds and Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom; [3]Medical University of Vienna, Vienna, Austria; [4]UZ Gasthuisberg, Leuven, Belgium; [5]Bristol-Myers Squibb, Rueil-Malmaison, France; [6]Bristol-Myers Squibb, Princeton, United States*

Background: RA is characterized by the production of autoantibodies, including anti-citrullinated protein antibodies (ACPA) and RF, which are associated with poor prognosis in RA.[1–3] More data on the clinical significance of ACPA/RF seroconversion in response to treatment are needed. Evidence suggests a role for T cells in ACPA production.[2,3]
Objectives: This *post hoc* analysis investigated the effect of the T-cell co-stimulation modulator abatacept (ABA) in combination with MTX vs MTX alone on conversion of ACPA positive (+) and RF+ patients (pts) to seronegative status, and the relationship between conversion to seronegative status and clinical response.
Methods: Data from a double-blind, randomized, Phase III study (AGREE; NCT00122382) conducted in MTX-naïve pts with early RA (≤2 years) and poor prognostic factors (ACPA+ and/or RF+ with evidence of erosions) were included.[4] Pts were randomized to ABA (~10 mg/kg IV according to weight)+MTX or placebo+MTX (MTX alone) in a 12-month (M) double-blind phase followed by 12M of open-label ABA+MTX. Autoantibody titres were assessed at baseline and 6M and 12M of the double-blind phase by ELISA. Pts with titres below the threshold for positivity (ACPA 5 AU/mL; RF [IgM] 15 IU/mL) at M6 or M12 were considered to have converted to seronegative status. The relationship between conversion to ACPA seronegative status and clinical response at M6 and M12 was determined. All analyses were descriptive and based on pts with available DAS28 (CRP) and CDAI data at baseline and M6 and M12.
Results: A total of 435 and 461 pts, respectively, were ACPA+ or RF+ at baseline and had known serostatus at M6 and M12. At 6M, 6.6% (15/227) and 17.0% (39/230) of ABA+MTX pts were ACPA and RF negative, respectively, vs 2.9% (6/208) and 9.5% (22/231) of MTX pts. At 12M, 7.1% (15/212) and 18.5% (41/222) of ABA + MTX pts were ACPA and RF negative, respectively, vs 4.5% (9/198) and 14.6% (32/219) of MTX pts. A higher proportion of pts receiving ABA + MTX who converted to ACPA seronegative status achieved remission (DAS28 [CRP] <2.6 or CDAI ≤2.8) compared with ABA + MTX-treated pts who remained ACPA+ or with pts treated with MTX alone regardless of whether they converted to seronegative status or not (Figure). Pts receiving ABA + MTX who converted to ACPA seronegative status also had a numerically higher cumulative probability of achieving sustained remission (DAS28 [CRP] <2.6) and lower radiographic progression than pts receiving MTX who converted to seronegative status or pts in either treatment group who remained ACPA+ (data not shown).

Figure. Proportion of Patients Achieving Remission, According to DAS28 (CRP)-Defined or CDAI Criteria, by ACPA Seronegative/Seropositive Status

Baseline to Month 6 and baseline to Month 12 were carried out as separate analyses.

Conclusions: Compared with MTX alone, treatment with abatacept + MTX was more likely to result in conversion to ACPA/RF seronegative status in pts with early erosive RA. Conversion to ACPA seronegative status was associated with better clinical and radiographic outcomes.

FRI0220 ALLOGENEIC MESENCHYMAL PRECURSOR CELLS (MPCS): A NOVEL APPROACH TO TREATING BIOLOGIC REFRACTORY RHEUMATOID ARTHRITIS

S. Kafaja[1], K.R. Segal[2], D. Skerrett[3], S. Itescu[4], D.E. Furst[5]. *[1]Division of Rheumatology, David Geffen School of Rheumatology, University of California Los Angeles, Los Angeles; [2]Mesoblast, Inc; [3]Mesoblast, Inc, New York, United States; [4]Mesoblast, Inc, Melbourne, Australia; [5]Arthritis Associates of Southern California, Los Angeles, United States*

Background: Allogeneic STRO-3 immunoselected mesenchymal precursor cells (MPCs) derived from bone marrow of healthy donors are a potent, homogeneous cell population which can be activated by pro-inflammatory cytokines to release factors which polarize pro-inflammatory monocytes and T cells to an anti-inflammatory state. This is the first in human trial to assess MPC therapy in biologic refractory RA, a disease driven by monocyte and T cell activation.
Objectives: To assess the safety and tolerability and to explore the clinical efficacy of MPC therapy in RA.
Methods: MSB-RA001 is a phase 1B/2A randomized, double-blind, placebo-controlled, sequential, dose-escalation trial to assess the safety and explore efficacy of a single intravenous (IV) infusion of MPCs in patients with active RA who had failed to respond to at least one biologic. Efficacy endpoints included ACR 20,50,70, ACR core components, HAQ and DAS28. Patients were randomized to receive one IV infusion of MPC 1 million cells/kg (n=16), 2 million cells/kg (n=16), or placebo (n=16) in 2 sequential dose cohorts. The primary study period was 12 weeks.
Results: Patients in all 3 treatment groups (N=16 per group) were comparable in mean age (55 y), gender (73% women), duration of RA (14 years) and

prior biologic exposures. Importantly, MPC infusions were well-tolerated with no adverse infusion reactions or serious adverse events (SAE) noted over 12 weeks. At 4 and 8 weeks, both MPC groups achieved higher ACR20 levels than placebo, with the placebo group reaching similar levels by 12 weeks. Notably, at 12 weeks both ACR50 rates (31, 27, 19%) and ACR70 rates (27, 20, 0%) were higher for the 2M/kg and 1M/kg MPC groups than placebo (Figure 1); p=0.04 for ACR70 in 2M/kg vs. placebo. The MPC groups showed dose-related greater improvement in pain, patient global assessment (PGA) of disease and physical function vs. placebo with greater efficacy in the 2M/kg group (Table 1). At 12 weeks PGA and Pain were significantly reduced in 2M/kg MPC group vs. placebo (both p=0.04). MPC treatment was associated with significantly improved health-related physical function by the HAQ. Minimal clinically important difference in HAQ defined as reduction of at least -0.22 points was achieved in 93% of 2M/kg MPC vs. 25% of placebo at 12 weeks (p=0.003).

Figure 1. ACR20/50/70 Over 12 Weeks

*P values vs. Placebo by Fisher's exact test

Table 1 Summary of Week 12 Efficacy Assessments

	Placebo	MPC 1M/kg	MPC 2M/kg
	N=16	N=16	N=16
ACR20 (%)	50%	47%	50%
ACR50 (%)	19%	27%	31%
ACR70 (%)	0%	20%	27%*
DAS-28 CRP (%)			
Response: ≤3.2	19%	27%	36%
Remission: <2.6	13%	20%	21%
HAQ Change from baseline ≤-0.22 (%)	37.5%	53%	93%**
ACR Core Components [Change (SE) from baseline]			
Tender joints	-9.8 (1.9)	-5.8 (1.9)	-11.2 (1.9)
Swollen joints	-7.7 (1.6)	-6.1 (1.6)	-10.1 (1.6)
Investigator global assessment	-21.6 (6.5)	-32.6 (6.5)	-35.6 (6.6)
Patient global assessment	-6.7 (6.5)	-17.5 (6.5)	-25.7 (6.5)*
Patient pain	-8.4 (6.6)	-16.2 (6.6)	-28.6 (6.7)*

*P<0.05; **P<0.005

Conclusions: A single infusion of MPCs was well-tolerated in RA patients. While the efficacy results are encouraging, further assessment including dose optimization is needed. The current trial is a unique early phase trial that shows promise of a future role for MPCs as a therapeutic option in biologic-refractory RA patients, a subset of the RA population with substantial remaining medical need.

FRI0221 DOES SEROPOSITIVITY INFLUENCE DIFFERENTIALLY DRUG DISCONTINUATION OF BIOLOGIC ANTIRHEUMATIC AGENTS WITH NON-ANTI-TNF MODE OF ACTION?

A. Finckh[1], D. Courvoisier[1], J.-E. Gottenberg[2], X. Mariette[3], J. Morel[4], S.A. Bergstra[5], V. Hernandez[6], C. Codreanu[7], T.K. Kvien[8], M.J. Santos[9], K. Pavelka[10], M. Hetland[11], K. Chatzidionysiou[12], J. Askling[12], C. Turesson[13], C. Gabay[1], R. Van Vollenhoven[14]. *[1]HUG, Geneva, Switzerland; [2]CHU, Strassbourg; [3]Paris-S University, le Kremlin-Bicêtre; [4]CHU, Montpellier, France; [5]University Medical Center, Leiden, Netherlands; [6]Hospital Clinic, Barcelona, Spain; [7]Univ of Medicine and Pharmacy, Bucharest, Romania; [8]Diakonhjemmet Hospital, Oslo, Norway; [9]Rheuma.PT, Lisbon, Portugal; [10]Institute of Rheumatology, Prague, Czech Republic; [11]Glostrup Hospital, Glostrup, Denmark; [12]Karolinska Institute, Stockholm; [13]Lund University, Lund, Sweden; [14]AMC, Amsterdam, Netherlands*

Background: Rheumatoid factor (RF) and anti-citrulinated protein antibodies (ACPA) are used as diagnostic tools, but may also be used as prognostic factors or as predictors of response to therapy, as these biomarkers have been associated with better clinical responses to some bDMARDs.
Objectives: To examine whether seropositivity has a similar impact on drug discontinuation of different bDMARDs with a non-anti-TNF mode of action (non-aTNF bDMARDs).
Methods: This is a pooled analysis of 10 observational European RA registries (FR, CZ, DK, NO, PT, RO, ES, SE, CH, NL). Inclusion criteria were a diagnosis of RA, initiation of treatment with abatacept (ABA), rituximab (RTX) or tocilizumab (TCZ) and available information on RF and/or ACPA status. The exposure of interest was seropositivity, which was defined as positive if RF or ACPA was positive and negative if both were negative. The primary endpoint was overall drug discontinuation, defined as the period between treatment initiation and treatment discontinuation. Because national differences may constitute a potential confounder, we only included national registries with information for all 3 bDMARD and pooled data across registries only after excluding significant effect modification by country. Drug discontinuation was analyzed using a Cox proportional hazard model, including drug, seropositivity, and their interaction, adjusting for age, gender, disease duration, baseline DAS28, concomitant synthetic DMARD (sDMARDs), number of previous sDMARDs and bDMARDs, and stratifying by country and calendar year.
Results: We found no effect modification by country, allowing us to pool data from 12040 patients (Table). In crude analyses, seropositivity was associated with a lower drug discontinuation with all 3 bDMARD (*p*-value interaction 0.22), with a hazard ratio for seropositive vs. seronegative (HR) 0.89 (95% CI: 0.82–0.97). In adjusted analyses, seropositivity remained associated with a lower drug discontinuation, but the effect differed by drug (*p* interaction 0.01): ABA: HR for seropositive vs. seronegative: 0.76 (95% CI 0.66–0.88), RTX: 0.88, (95% CI: 0.70–1.10), and TCZ: 1.08, (95% CI: 0.89–1.31). Two-by-two drug to drug comparisons showed that the effect of seropositivity differed between ABA and TCZ (*p*=0.004), but not between ABA and RTX (*p*=0.29), or between TCZ and RTX (*p*=0.16). Other factors associated with discontinuation were higher baseline disease activity and more previous bDMARD.

Table 1: Baseline demographic and treatment characteristics

	ABA N=3089	RTX N=5539	TCZ N=3412
Seropositivity, N (%)	2602 (84.2%)	5176 (93.4%)	2920 (85.6%)
• RF+	2234 (73.0%)	4655 (84.1%)	2682 (79.3%)
• ACPA+	1861 (68.5%)	3703 (85.0%)	1826 (73.7%)
Female sex, N (%)	2463 (79.7%)	4543 (82.0%)	2692 (78.9%)
Age [yr], mean (SD)	56.8 (13.2)	58.9 (12.1)	55.9 (12.8)
Disease duration [yr], mean (SD)	11.8 (9.3)	12.5 (9.3)	11.2 (9.6)
DAS28 at baseline, mean (SD)	4.9 (1.5)	5.2 (1.5)	4.7 (1.4)
N previous sDMARD, N (%)			
≤1	917 (32.3%)	1988 (40.1%)	1245 (39.2%)
≥2	1925 (67.7%)	2972 (59.9%)	1928 (60.8%)
N previous bDMARD, N (%)			
≤1	1903 (62.1%)	3818 (69.2%)	1733 (52.5%)
≥2	1163 (37.9%)	1699 (30.8%)	1569 (47.5%)
Concomitant sDMARD, N (%)	1657 (53.6%)	3899 (70.5%)	2251 (66.1%)
Median follow-up time [yrs]	0.96	2.00	1.12
Calendar year of treatment initiation, 10th - 90th percentile	2008-2014	2006-2012	2009-2015

Conclusions: Data from this pooled european registry analysis suggests that seropositivity is associated with lower drug discontinuation of non-aTNF bDMARDs. This effect differed between drugs and was significant for ABA, but not for TCZ or RTX. The impact of seropositivity on other measures of effectiveness still needs to be investigated.

FRI0222 SUSTAINED RESPONSE FOLLOWING DISCONTINUATION OF METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH SUBCUTANEOUS TOCILIZUMAB: RESULTS FROM A RANDOMIZED CONTROLLED TRIAL (COMP-ACT)

J. Kremer[1], W. Rigby[2], N. Singer[3], C. Birchwood[4], D. Gill[4], W. Reiss[4], J. Pei[4], M. Michalska[4]. *[1]Albany Medical College and The Center for Rheumatology, Albany, NY; [2]Geisel School of Medicine, Dartmouth College, Lebanon, NH; [3]School of Medicine, MetroHealth System, Case Western Reserve University, Cleveland, OH; [4]Genentech, Inc., South San Francisco, CA, United States*

Background: Methotrexate (MTX) is frequently administered in combination with biologics for the treatment of rheumatoid arthritis (RA). MTX may be subsequently discontinued due to intolerance or nonadherence, and/or to reduce medication burden once disease control is achieved. Previous studies have established the efficacy of tocilizumab (TCZ) initiated as monotherapy (MONO), but the impact

of MTX withdrawal in patients achieving good clinical response to TCZ+MTX (COMBO) has not been evaluated.

Objectives: To evaluate whether TCZ-MONO is non-inferior to TCZ-COMBO in maintaining clinical response in patients who achieve low disease activity with TCZ-COMBO.

Methods: US patients with RA who were inadequate responders to MTX were enrolled: initial combination therapy included MTX (15 mg/week orally) plus TCZ 162 mg subcutaneous (SC) either weekly (qw; for patients ≥100 kg) or every 2 weeks (q2w; for patients <100 kg). Dose escalation from q2w to qw was allowed at week 12 in patients who had not achieved low disease activity (DAS28 ≤3.2). If patients achieved DAS28-ESR ≤3.2 at week 24, they were randomized (double-blind) 1:1 to receive either TCZ-MONO or continue TCZ-COMBO until week 52. Patients who did not achieve DAS28 ≤3.2 were assigned to an open-label arm and continued TCZ-COMBO until week 52. The primary outcome measured was the comparison of mean change in DAS28-ESR score in the randomized cohort between weeks 24 and 40, between the TCZ-MONO or TCZ-COMBO arms (noninferiority margin of 0.6). Secondary outcomes included the proportion of patients achieving DAS28 <2.6, DAS28 ≤3.2 and American College of Rheumatology 20%/50%/70% (ACR20/50/70) responses at weeks 40 and 52, and safety. Trial registration number: NCT01855789.

Results: Of 718 patients enrolled, 296 were randomized at week 24 (TCZ-MONO, n=148; TCZ-COMBO, n=148). Early discontinuation in the randomized cohort occurred in 12.2% of patients in the TCZ-MONO group and 10.2% in the TCZ-COMBO group. Baseline characteristics were balanced between treatment groups (mean age 55.5 years; 74.8% female; mean RA duration 6.8 years; mean DAS28-ESR 6.3). At week 24, DAS28 scores were similar in both groups, but ACR responses were ~8–11% lower in the TCZ-MONO group prior to MTX withdrawal (randomization). The mean change in DAS28 was similar between the randomized treatment groups (Table 1). For the primary efficacy analysis, the mean changes in DAS28 from week 24 to week 40 were 0.46 and 0.14 in the TCZ-MONO and TCZ-COMBO groups, respectively (95% CI: 0.045–0.592). This study met the primary endpoint by demonstrating that discontinuing MTX in TCZ responders was noninferior to continuing MTX. The safety of TCZ-SC in this study was consistent with the known safety profile with no new safety signals observed (Table 2). The most common SAE was infection, occurring in 4.1% of patients. TCZ-COMBO had greater frequency of AEs, SAEs and serious infections than TCZ-MONO.

Table 1. Efficacy of TCZ as Monotherapy and in Combination With MTX

	TCZ-MONO n = 147	TCZ-COMBO n = 147	Difference (95% CI) (TCZ-MONO minus TCZ-COMBO)
ΔDAS28-ESR, Mean (SEM)*			
Week 24 to week 40	0.46 (0.123)	0.14 (0.126)	0.318 (0.045, 0.592)
Week 24 to week 52	0.43 (0.136)	0.20 (0.139)	0.232 (−0.068, 0.532)
Response at Week 40, n (%)			
DAS28 ≤ 3.2	94 (63.9)	113 (76.9)	−12.9 (−23.3, −2.6)
DAS28 < 2.6	74 (50.3)	87 (59.2)	−8.8 (−20.2, 2.5)

FRI0223 ANTI-CCP IS AN INDEPENDENT PREDICTOR OF 12-MONTH EULAR RESPONSE IN PATIENTS WITH RA TREATED WITH ABATACEPT

A. den Broeder[1], T. Kerstens[2], J. Fransen[2], C. van den Ende[1], L. Tweehuysen[3], R. Postema[4], E. Alemao[5], F. van den Hoogen[2]. *[1]Sint Maartenskliniek and Radboud UMC; [2]Radboud UMC; [3]Sint Maartenskliniek, Nijmegen, Netherlands; [4]Bristol-Myers Squibb, Uxbridge, United Kingdom; [5]Bristol-Myers Squibb, Princeton, United States*

Background: Although anti-cyclic citrullinated peptide (anti-CCP) positivity is regarded as a strong prognostic factor for untreated RA outcome, the benefit of anti-CCP tests for personalized medicine is controversial.[1] Illustratively, anti-CCP was not predictive for response to anti-TNF in RA, as shown in meta-analyses, although some predictive value was shown for rituximab.[2–4] There are, however, indications that better response to abatacept (ABA) is predicted by anti-CCP positivity.[5–7]

Objectives: To test whether anti-CCP level at baseline (BL) is an independent predictor for treatment response (DAS28 [CRP]-based EULAR response criteria) at 12 months (M) in patients (pts) with RA treated with ABA.

Methods: Consenting pts with RA from Radboud UMC and Sint Maartenskliniek were consecutively included if they started treatment with ABA (BL). The anti-CCP values closest before BL were used. DAS28 (CRP) was assessed at BL and at 12M by trained rheumatology nurses or rheumatologists. Demographic and disease-related variables, treatment history and co-morbidity were also assessed. Primary outcome was response to treatment based on DAS28 (CRP) EULAR response criteria at M12. Therapy cessation was regarded as non-response. Multiple imputation with 20 repetitions was used to replace missing predictors. Multivariate logistic regression was used to examine whether anti-CCP positivity was an independent predictor for treatment response, taking confounding BL covariates (Table variables) into account.

Results: Data were available for 200 pts with RA starting ABA. Mean (SD) age was 58 (13) years, 165 (83%) were female and median (p25–p75) disease duration was 12 (7–19) years (Table). Overall, 121 (61%) pts were anti-CCP positive at BL. At 12M, 86 (43%) pts remained on ABA. In the univariate model, anti-CCP was a predictor for treatment response (odds ratio 2.51; 95% CI 1.1, 6.0; p=0.038). No relevant confounding was present.

Table 1. Baseline Characteristics

	Abatacept (n=200)
Age, years, mean (SD)	58 (13)
Female, n (%)	165 (83)
RF+, n (%)	128 (64)
Anti-CCP+, n (%)	121 (61)
No. of previous bDMARDs*	3 (3–4)
No. of previous csDMARDs*	3 (2–4)
Oral glucocorticoids, n (%)	79 (40)
Disease duration, years*	12 (7–19)
Treatment duration, months*	8 (4–28)
NSAID, n (%)	117 (59)
Concomitant DMARD, n (%)	117 (59)
Overweight (BMI >25.0 kg/m^2), n (%)	98 (48)

*Median (p25–p75). RF+: IgM-Rheumatoid factor positivity. b/csDMARD=biologic/conventional synthetic DMARD.

Conclusions: Anti-CCP positivity was confirmed as an independent predictor for treatment response at 12M in pts with RA treated with abatacept. As indicated by meta-analysis and systematic reviews, anti-CCP is not predictive for the response to anti-TNFs.[2–4] Additional studies are needed to evaluate whether abatacept could be a preferable treatment in anti-CCP-positive pts.

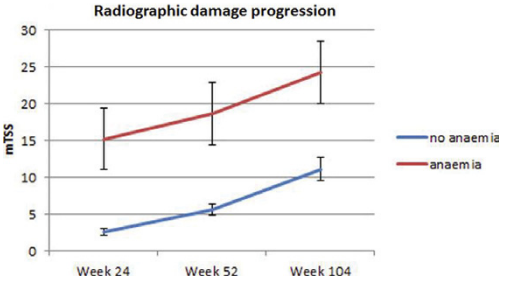
FRI0224 RITUXIMAB SELECTIVELY REDUCES IGG4 LEVELS IN RHEUMATOID ARTHRITIS PATIENTS



A. Sarantopoulos, I. Gkougkourelas, M. Mytilinaiou, P. Klonizakis, A. Georgiadou, P. Boura. *Clinical Immunology Unit, 2nd Dpt of Internal Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece*

Background: Rituximab has been applied as a therapeutic strategy in a variety of diseases, including Rheumatoid Arthritis (RA) and IgG4-Related Disease (IgG4-RD)[1]. On IgG4-RD, it has been shown that apart from B-cell depletion, rituximab induces remission by reducing IgG4 levels[2].
Objectives: On this regard, we investigated weather B-cell depletion in RA is also associated with a selective reduction of any IgG subclass, especially IgG4.
Methods: 31 RA patients, 25/6 female/male, median age 59 years (34–73), duration of disease 9,5 years (1–30) on standard of care DMARD treatment and rituximab administration every 6 months for 2 years were investigated for alterations on disease activity along with Igs' and IgG subclasses levels. All parameters were assessed at enrollment (T0), and after 6, 12 and 24 months. On this 2-year period all patients had been periodically receiving rituximab every 6 months.
Results: After 2 years of rituximab administration, patients achieved a good response to treatment (EULAR criteria). Igs' levels were not statistically altered, though all of them declined (data for IgM and IgA not shown). Furthermore, from IgG subclasses, only IgG4 levels statistically declined.
Conclusions: This is the first time that IgG4 variations are investigated in a non-IgG4RD after rituximab administration. Our results imply that IgG4 may be actively implicated in RA pathophysiology, since disease remission is accompanied by only IgG4 level reduction among all classes and subclasses of Igs'. Furthermore, in RA patients, rituximab may exert its therapeutic results not only via B-cell depletion, but also via IgG4 levels reduction.

FRI0225 ANEMIA IS A BETTER PREDICTOR FOR RADIOGRAPHIC DAMAGE IN RHEUMATOID ARTHRITIS THAN DAS28 WHEN DETERMINED BEFORE START OF TOCILIZUMAB-TREATMENT – A SECONDARY ANALYSIS FROM THE ACT-RAY TRIAL

B. Möller[1], G. Scholz[1], M. Dougados[2], T. Huizinga[3], P.M. Villiger[1], A. Finckh[4]. *[1]Rheumatology, Immunology & Allergology, Inselspital - Bern University Hospital, Bern, Switzerland; [2]Rheumatology, Hôpital Cochin, Paris, France; [3]Rheumatology, Leiden University Medical Center, Leiden, Netherlands; [4]Rheumatology, University Hospital Geneva, Geneva, Switzerland*

Background: Clinical remission, or at least low disease activity, as measured by DAS28 or alternative compound indices is currently the goal of RA treatment. Anemia in the context of RA is mainly driven by tumor necrosis factor alpha (TNF-α) and interleukin-six (IL-6), and may serve as a simple biological marker of inflammation. Anemia was recently discovered as a largely DAS28-independent parameter to predict radiographic damage progression in RA, both with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) or with anti-TNF agents.
Objectives: To study the predictive value of anemia in relation to DAS28 for radiographically detectable joint damage progression in patients treated with IL-6R inhibitor tocilizumab (TCZ) plus conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) when used in a treat to target concept.
Methods: In the ACT-RAY trial, all patients were methotrexate (MTX) inadequate responders and randomized to receive either TCZ plus MTX (add-on) or TCZ plus placebo (switch strategy) for at least one year. After week 24, open-label csDMARDs other than MTX could be added according to a treat-to-target approach in patients with moderate or high disease activity (DAS28≥3.2). After week 52, patients in sustained clinical remission (DAS28<2.6) could discontinue TCZ before stopping csDMARDs, and finally MTX/Placebo. The exposure of interest was anemia, defined using the WHO definition or the more liberal NHANES definition, both at baseline and over time. The primary outcome was the rate of joint damage progression measured by the change in the modified total Sharp score (ΔmTSS). We used longitudinal multivariate mixed effects models to test the impact of anemia on ΔmTSS. To examine the association of anemia to ΔmTSS independently from RA disease activity, the models were run with and without DAS28 at baseline and DAS28 over time.
Results: Of 556 randomised patients, complete datasets for fully adjusted models were available from 285 patients. Overall radiographic progression was regarded to be minimal, with insignificant differences in favor of the add-on strategy. Median annual ΔmTSS before inclusion was 2.9 (IQR 1.5 to 6.4) in patients without and 5.5 (IQR 2.7 to 11.1) in patients with baseline anemia, but evolved subsequently similar when being on TCZ. Anemia at baseline was a strong predictor of mTSS (per WHO definition: coefficient 14.8, 95% CI 7.6–21.9, p<0.001; per NHANES definition: coefficient 14.6 95% CI 7.6–21.5 p<0.001), as well as baseline DAS28 (coefficient 3.9, 95% CI 0.7–7.0, p=0.016). Mean DAS28 over time (p<0.001), in contrast to anemia data over time when obtained in patients already on TCZ, was significantly associated with subsequent ΔmTSS. Baseline anemia in contrast to baseline DAS28 remained a significant predictor of mTSS for up to two years on TCZ in fully adjusted multivariate analyses (p<0.05), including time-variant DAS28.

Conclusions: Anemia may be a strong and DAS28-independent long-term predictor of radiographic joint damage progression. Present data from patients on IL-6R blockade, a potent target-specific RA treatment with major impact also on erythropoiesis, add importantly to the growing body of evidence for the studied association.

FRI0226 RITUXIMAB IN RHEUMATOID ARTHRITIS WITH INTERSTITIAL LUNG DISEASE: A MULTICENTER STUDY

C. Fernández-Díaz[1], M. Martin-Lopez[2], M. Carrasco-Cubero[3], D. Reina-Sanz[4], P. Rubio-Muñoz[5], A. Urruticoechea-Arana[6], J. Miranda-Filloy[7], N. Vegas-Revenga[1], L. Dominguez-Casas[1], M. Gonzalez-Gay[1], R. Blanco[1]. *[1]Rheumatology, Hospital Universitario Marques de Valdecilla, Santander; [2]Rheumatology, Hospital Universitario 12 de Octubre, Madrid; [3]Rheumatology, Hospital Infanta Cristina, Badajoz; [4]Rheumatology, Hospital Sant Joan Despi Moises Boggi; [5]Rheumatology, Hospital Universitario Germans Trias i Pujol, Barcelona; [6]Rheumatology, Hospital Can Misses, Ibiza; [7]Rheumatology, Hospital Universitario Lucus Augusti, Lugo, Spain*

Background: Anti-TNFα drugs and several conventional disease-modifying anti-rheumatic drugs (DMARDs) such as methotrexate (MTX) have been involved in the development of Interstitial Lung Disease (ILD).
Objectives: Our aim was to assess the efficacy and safety of Rituximab (RTX) in RA patients with ILD.
Methods: Multicenter study of RA patients with ILD treated with RTX. ILD was diagnosed by high-resolution computed tomography (HRCT). RTX was used at standard dose (1 gx2 and premedication with iv Methylprednisolone for a six month interval. We assess the the following variables: a) 1-point change in the degree of dyspnea according to the Modified Medical Research Council (MMRC); b) FVC improvement ≥10%; and improvement ≥10% in DLCO; c) radiological changes in HRCT scan, and d) changes in the joint assessment measured by DAS28 score.
Results: We studied 18 patients (13 women /5 men) with ILD associated to RA. The mean age±SD was 62.8±11.0 years. The median [IQR] to progression of RA was 5.25 [2–12.8] years. They had received the following DMARDs previously; MTX (n=11), Leflunomide (LFN) (n=9) mycophenolate (MMF) (n=1) sulfasalazine (SSZ) (n=5), hydroxichloroquine (HCQ) (n=4), azathioprine (AZA) (n=1), gold salts (n=1), D-penicillamine (n=1), cyclophosphamide (n=1). 7 patients had previously received biological drugs. RA was seropositive in 16 cases (89%). Besides HRCT, the diagnosis of ILD was confirmed by biopsy in 4 patients. In 2 patients ILD was drug-related: MTX (n=2). RTX was prescribed as monotherapy (n=7) and combined with DMARDs (11. The DMARDs prescribed were: LFD (4), SSZ (2),

Abstract FRI0224 – Table 1. DAS28 and IgG class and subclasses variations. Because of non-normal distribution of our sample, the results were expressed as median and range and statistical analysis was performed by using the Kruskal Wallis tests

	DAS28	IgG	IgG1	IgG2	IgG3	IgG4
T0	4,46 (2,06–6) *	12,2 (5,1–23,1)	7,7 (3,59–12,4)	2,7 (0,844–5,21)	0,573 (0,079–1,85)	0,451 (0,032–2,1)*
T6	3,8 (2,2–6,44)	11,1 (5,78–15)	7,28 (3,38–11,2)	2,7 (1,23–5,36)	0,445 (0,086–1,58)	0,35 (0,044–1,06)

FRI0227 SARILUMAB SIGNIFICANTLY SUPPRESSES CIRCULATING BIOMARKERS OF BONE RESORPTION AND CARDIOVASCULAR RISK COMPARED WITH ADALIMUMAB: BIOMARKER ANALYSIS FROM THE PHASE 3 MONARCH STUDY

C. Gabay[1], J. Msihid[2], C. Paccard[2], M. Zilberstein[3], N.M. Graham[4], A. Boyapati[4]. *[1]University Hospitals of Geneva, Geneva, Switzerland; [2]Sanofi R&D, Chilly-Mazarin, France; [3]Sanofi R&D, Bridgewater; [4]Regeneron Pharmaceuticals, Inc, Tarrytown, United States*

Background: MONARCH (NCT02332590) was a randomized, active-controlled, double-blind, double-dummy, phase 3 superiority trial comparing sarilumab monotherapy with adalimumab monotherapy. Exploratory biomarkers associated with inflammation, bone erosion, and cardiovascular (CV) risk were evaluated in this study.
Objectives: To compare the effects of sarilumab monotherapy vs adalimumab monotherapy on circulating biomarkers associated with acute-phase response (CRP, serum amyloid A [SAA]), bone resorption (RANKL and osteoprotegerin [OPG]), and CV risk (lipoprotein (a) [Lp(a)]) in patients from MONARCH.
Methods: Sera were analyzed at baseline and posttreatment through wk 24 from patients who consented to biomarker analyses and received SC sarilumab 200 mg q2w (N=153) or adalimumab 40 mg q2w (N=154). Biomarkers were assessed using validated ELISAs. Nonparametric methods were used to evaluate differences in the percent change from baseline in biomarker levels between treatments at each time point. Percent change from baseline in biomarkers at wk 24 was also compared, separately by treatment group, between ACR50 responders and nonresponders at wk 24. The Benjamini-Hochberg procedure was used to correct *P* values for multiplicity and control false discovery rate. Significance level was $P<0.05$.
Results: A significant difference in RANKL was observed at wks 2 and 24 between sarilumab and adalimumab groups ($P<0.0001$; Table). Numerically, RANKL decreased after sarilumab and increased after adalimumab treatment. Significantly greater reductions in Lp(a), SAA, and CRP were observed at wks 12 and 24 after treatment with sarilumab vs adalimumab. The difference in OPG between groups was significant at wk 2 only.

Table 1. Median Percent Change From Baseline in Serum Concentrations of Circulating Biomarkers

		Sarilumab 200 mg q2w (N=153)	Adalimumab 40 mg q2w (N=154)
CRP	Wk 12	-94.2†	-29.7
	Wk 24	-94.0†	-24.0
SAA	Wk 12	-79.9†	-32.2
	Wk 24	-83.2†	-17.4
RANKL	Wk 2	-2.5†	4.4
	Wk 24	-18.3†	10.5
OPG	Wk 2	0.9*	-4.0
	Wk 24	2.2	3.3
Lp(a)	Wk 12	-35.0†	-0.4
	Wk 24	-41.0†	-2.8

*Adjusted $P<0.01$ vs adalimumab. †Adjusted $P<0.0001$ vs adalimumab.

At wk 24, change in OPG, RANKL, and Lp(a) did not differ between ACR50 responders and nonresponders at wk 24 in either treatment group. Responders in both groups demonstrated greater reductions vs nonresponders in CRP (sarilumab, -95.8% vs -87.3%; adalimumab, -47.6% vs -6.4%; all $P<0.01$); a trend was observed for SAA (sarilumab, -92.3% vs -73.2%; adalimumab, -33.0% vs 0.0%; unadjusted $P<0.05$, not significant after adjustment).
Conclusions: Sarilumab monotherapy significantly suppressed bone-resorptive and CV risk markers to a greater degree than adalimumab monotherapy. Reductions in CRP were significantly different in ACR50 responders vs nonresponders after either treatment. Analyses to assess predictive and prognostic effects of biomarkers (including markers of myeloid and lymphoid synovial phenotypes) are ongoing.

FRI0228 UGT1A1 GENETIC VARIANTS ARE ASSOCIATED WITH INCREASES IN BILIRUBIN LEVELS IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH SARILUMAB

A. Damask[1], A. Boyapati[1], J.D. Hamilton[1], S. Hamon[1], C. Paccard[2], J. Parrino[1], J. van Adelsberg[1], N.M. Graham[1], J. Penn[1], A. Lopez[1], J. Reid[1], J. Overton[1], A. Baras[1], A.R. Shuldiner[1], C. Paulding[1]. *[1]Regeneron Pharmaceuticals, Inc, Tarrytown, United States; [2]Sanofi R&D, Chilly-Mazarin, France*

Background: Sarilumab is a human mAb that blocks IL-6 from binding to both membrane-bound and soluble IL-6Rα. Variants in the *UGT1A1* gene have been shown to be strongly associated with increased unconjugated bilirubin levels in patients treated with tocilizumab, another IL-6Rα inhibitor.[1,2] *UGT1A1* encodes the enzyme responsible for the glucuronidation of bilirubin and variation in this gene is also responsible for Gilbert's syndrome, a mild benign condition characterized by elevations in unconjugated bilirubin and jaundice. The underlying main genetic variation responsible for Gilbert's syndrome has been identified as a TA repeat located in the promoter of *UGT1A1* (UGT1A1*28 allele), which is in linkage disequilibrium with a single nucleotide polymorphism, rs6742078, previously associated with higher bilirubin levels after tocilizumab treatment.[1]
Objectives: To test for an association between rs6742078 and bilirubin levels in RA patients treated with sarilumab.
Methods: DNA was collected from patients enrolled in MOBILITY (NCT01061736), which evaluated the efficacy and safety of sarilumab + methotrexate (MTX) in RA patients with inadequate response to MTX. The pharmacogenetic analysis was conducted in 599 Caucasian patients treated with MTX + sarilumab (150 or 200 mg q2w) or placebo. Log-transformed unconjugated and total bilirubin levels were analyzed at baseline and over the treatment period (using maximum bilirubin).
Results: There was a strong association between the rs6742078 TT genotype and higher unconjugated bilirubin levels. The least squares mean (SE) for patients at baseline with the TT genotype was 0.48 (0.02) mg/dL vs 0.25 (0.009) and 0.21 (0.009) mg/dL for those with GT and GG genotypes, respectively ($p=1.02\times10^{-21}$). After sarilumab treatment, the difference between genotype groups increased over the course of the study ($p=4.3\times10^{-10}$; Figure). In the binary analysis of maximum total bilirubin in sarilumab-treated patients, the TT genotype was significantly associated with mild bilirubin elevations (OR =34.7; $p=1.2\times10^{-8}$; Table).

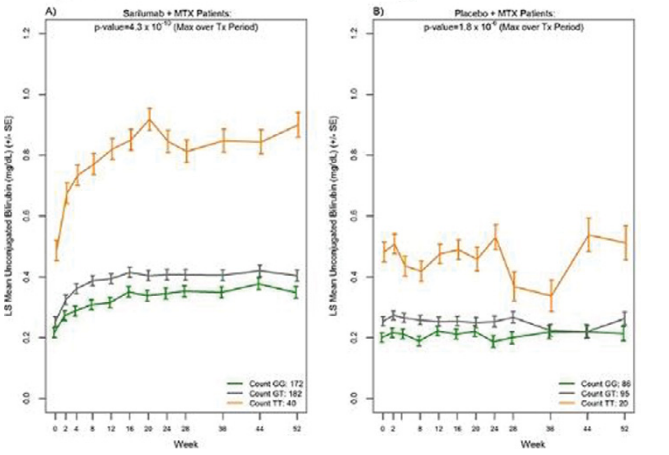

Table 1. Maximum Total Bilirubin in Sarilumab-Treated Patients by rs6742078 Genotype

	Maximum total bilirubin, n (%)		
Genotype, n (%)	≤1.5×ULN	>1.5×ULN	Total
GG/GT	352 (92)	4 (27)	356 (90)
TT	29 (8)	11 (73)[a]	40 (10)
	381	15	396

OR=34.7[b]; $p=1.2\times10^{-8}$. [a]Elevations remained ≤2×ULN. [b]Logistic regression with recessive genetic model, adjusting for ancestry covariates.

Conclusions: The association observed between the rs6742078 TT genotype in *UGT1A1* and unconjugated bilirubin elevations in sarilumab-treated patients is consistent with previous observations in tocilizumab-treated patients. These findings suggest that sarilumab-related increases in bilirubin levels are likely benign and caused by common genetic variation in *UGT1A1* and are not due to underlying liver injury.

FRI0229 SURVEY ON TRANSPORTATION AND STORAGE OF BIOLOGICAL THERAPIES BY PATIENTS

M. Arias Saavedra, C. Aimo, J.J. Astudillo Andrade, D. Alvarez, G. Sequeira, E.M. Kerzberg. *Servicio de Reumatologia, Hospital J. M. Ramos Mejia, Buenos Aires, Argentina*

Background: in order to ensure the pharmacological action of thermolabile drugs, it is mandatory to keep the cold chain unbroken from manufacturing to administration since lack of observance of these rules may compromise their efficacy. (1,2)
Objectives: to ascertain key aspects of transportation and storage of Biological Therapy (BT) on the part of the patients.
Methods: survey among outpatients who either were treated in the centre or attended the centre for the administration of a BT. Inclusion criteria encompassed patients of over 18 years of age, who were receiving a BT (at least one dose over the last 12 months) whose patient information leaflet indicated, "... must be refrigerated at 2℃ to 8℃ (36℉ to 46℉). Do not freeze." The survey comprised 31 questions about transportation and storage of the BT from the moment of collection from the pharmacy to its administration. This study was approved by the Bioethics Committee. Every patient signed an informed consent form.
Results: Eighty-three patients were interviewed (76% female and 24% males), their average age was 53 years old, 60% had Rheumatoid Arthritis, 24% Psoriatic Arthritis, and 16% sustained other conditions. Sixty-four percent were undergoing BT for the first time. Forty-eight percent were enrolled in a patient assistance programme.
Had patients been fully informed of the importance of proper transportation and storage of the drug? No, 20% acknowledged that the first time they dealt with a BT, they had not been made aware of the relevance of its correct preservation.
Are patients administered the BT immediately after collecting it from the pharmacy? No, 77% collected the drug at least 7 days before administration and though they received the BT in a cooler with ice packs (except in 5 cases) 71% was uninformed of how long it could be kept in this condition.
Is the BT duly stored in the patient's refrigerator? No, 28% misplaced the drug (65% in the freezer), and 90% did not know the temperature range at which it should be kept in the fridge. Only 1 patient used a thermometer to control the appliance temperature.
Is there another crucial point as to BT storage at home? Yes, 53% of the 83 patients had experienced frequent power cuts in summer; out of these, 59% on a weekly basis. Forty percent of the 83 patients had power cuts of over 12 hours, 28% of over 24 hours, and 22% of over 48 hours. Out of the 83 patients, 37% took the BT to another house to avoid wasting it, and 4 had to dispose of it due to a protracted power cut. Five patients were away from home for over 48 hours during which the BT was in the fridge and they had not assigned another person to take care of the drug during their absence.
Is the BT removed from the fridge only for its immediate administration? No, 46% of the respondents travelled to a centre, half of them for over an hour, carrying the BT.
Conclusions: before administering a BT, it is imperative to brief patients on suitable transportation and storage methods. Thus, treatment failure should prompt a thorough assessment of transportation and storage conditions.

FRI0230 RETENTION RATES OF TNF INHIBITORS AND ABATACEPT USED AS A FIRST BIOLOGIC DMARD IN THE TREATMENT OF RHEUMATOID ARTHRITIS: 8 YEARS OF EXPERIENCE FROM THE RHUMADATA® REGISTRY

D. Choquette[1], L. Bessette[2], E. Alemao[3], B. Haraoui[1], F. Massicotte[1], M. Mtibaa[4], E. Muratti[4], J.-P. Pelletier[1], R. Postema[5], J.-P. Raynauld[1], M.-A. Rémillard[1], D. Sauvageau[1], A. Turcotte[2], É. Villeneuve[1], L. Coupal[1]. *[1]Rheumatology, Institut de recherche en rhumatologie de Montréal (IRRM), Montréal; [2]Rheumatology, Centre d'ostéoporose et de rhumatologie de Québec (CORQ), Québec, Canada; [3]Bristol-Myers Squibb, Princeton, United States; [4]Bristol-Myers Squibb, Montréal, Canada; [5]Bristol-Myers Squibb, Uxbridge, United Kingdom*

Background: Sustainability of treatment is important to consider when selecting a therapy for chronic conditions such as RA. Sustainability is a useful clinical marker for both long-term efficacy and safety. A recently published randomized controlled trial has demonstrated similar efficacy and safety profiles between abatacept (ABA) and adalimumab over 2 years.[1,2]
Objectives: To assess the long-term sustainability of ABA and anti-TNFs following treatment failure with a conventional synthetic DMARD (csDMARD) in comparable cohorts of patients (pts) with RA.
Methods: Data from pts with RA seen at two tertiary centres and prescribed either ABA or a TNF inhibitor (adalimumab, certolizumab, etanercept, golimumab or infliximab) as their first biologic (b)DMARD after 1 January 2006 were extracted from the RHUMADATA® registry. The choice of therapy was a joint decision between the pt and the treating physician. Pts were followed until either they discontinued treatment, were lost to follow-up or the cut-off date of 9 January 2017. Pt baseline characteristics were compared using descriptive statistics and the cumulative incidence of biologic agent discontinuation using Kaplan-Meier methods. Overall differences in the discontinuation rates of biologic agents were tested using the log-rank test.
Results: Overall, 641 pts met study criteria; 82 pts received ABA and 559 TNF inhibitors (adalimumab=136, certolizumab=52, etanercept=226, golimumab=88 and infliximab=57) as first-line treatment following inadequate response to csDMARDs. No clinically significant differences in baseline characteristics were noted between treatment groups. Most pts were diagnosed after January 2000 (72.5%) and were women (77.5%). Average age at diagnosis was 47.1 (SD=13.4) years, with a mean disease duration of 7.2 (7.8) years, and a mean CDAI of 43.1 (32.5) at baseline. No significant differences in retention rates were observed in the ABA and anti-TNF groups (Table, Figure). On average, pts treated with anti-TNFs and ABA maintained their treatment for 1.59 (1.91) and 1.90 (2.08) years, respectively. Lack of efficacy (47.6%) and adverse effects (22.0%) were the most commonly cited reasons for treatment discontinuation.

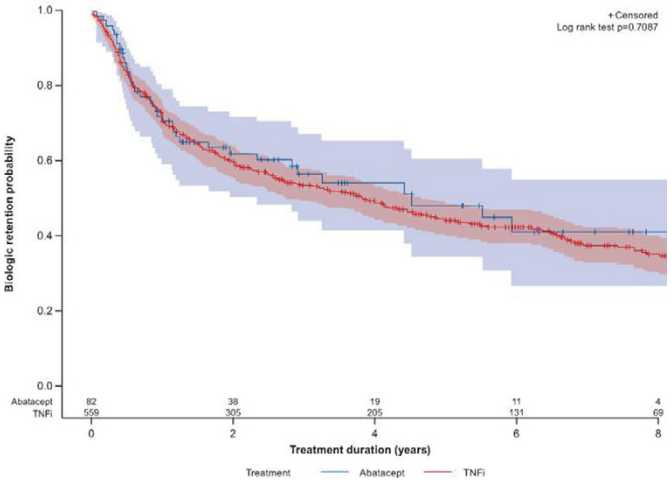

Table 1. Retention of the first bDMARD

	TNFi	Abatacept
Biologic retention probability at*:		
12 Months	71.66% (1.92%)	70.71% (5.15%)
24 Months	59.85% (2.11%)	62.16% (5.60%)
60 Months	44.28% (2.26%)	48.37% (6.75%)
96 Months	35.29% (2.46%)	41.17% (7.43%)
bDMARD retention time (years)		
Mean (SE)	4.83 (0.18)	4.71 (0.45)
Lower quartile, (95% CI)	0.86 (0.72–1.00)	0.86 (0.50–1.24)
Median, (95% CI)	3.83 (2.87–4.67)	4.53 (2.34-++)

*% (% standard error) survival.

Conclusions: Abatacept and TNF inhibitors demonstrate similar sustainability at 8-year, supporting studies[1,2] that demonstrate that abatacept used after csDMARDs inadequate response is as safe and effective as a TNF targeting agents in the long term.

Figure. Retention Rates of Abatacept and TNFi Groups

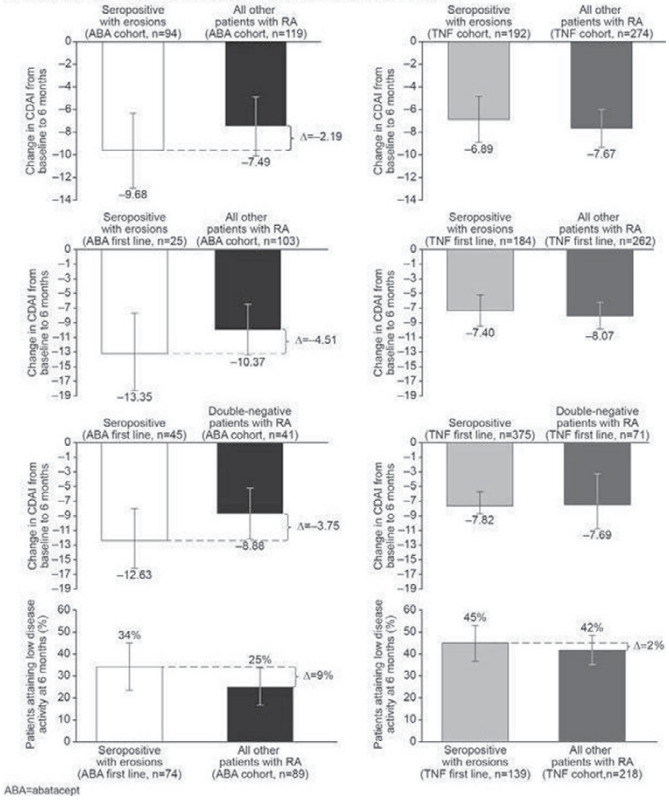
FRI0231 THE FIRST REPORT OF SIGNIFICANT INCREASE OF BODY MASS INDEX IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH TOFACITINIB DURING 12-MONTH FOLLOW-UP

D. Novikova, I. Kirillova, E. Luchikhina, E. Markelova, H. Udachkina, N. Demidova, A. Misiyuk, T. Popkova, A. Volkov, L. Denisov, D. Karateev.
V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation



Objectives: to evaluate the effects of tofacitinib (TOFA) on cardiovascular risk factors (CVRF) in rheumatoid arthritis (RA) patients (pts).
Methods: After 12-m follow-up the CVRF dynamic was assessed in 28 RA pts treated with TOFA (22 women, median age 54 [40; 62] years, disease duration 39.5 [16.5; 60.0] m, moderate to high activity (DAS28 - 5.1 [4.6; 6.0], SDAI – 26 [21; 34]), positive for ACCP (75%)/RF (79%), who were non-responders to MTX at least 15 mg/week and/or other synthetic DMARDs and biologic DMARDs. TOFA therapy was started in all pts with dose 5 mg BID per os followed by the dose escalation to 10 mg BID in 8 (29%) pts. TOFA used in combination with MTX in 27 (96%) pts, leflunomide in 1 (4%). Low-dose oral corticosteroids (<10 mg/day prednisone or equivalent) were received by 9 (35%) pts. Remission or low disease activity was achieved in 55% pts (DAS28), 77% (SDAI). At baseline the most of pts had multiple CVRF and subclinical organ damage. Cardioprotective therapy received 16 (57%) pts (beta-blockers – 7, angiotensin II receptor type 2/ACE inhibitors – 11, statins – 11, dihydropyridine calcium channel blockers – 7).
Results: The incidence rate of arterial hypertension (67% vs 70%), overweight (57% vs 72%), abdominal obesity (61% vs 68%), physical inactivity (64% vs 47%), smokers/ex-smokers (25%/21% vs 21%/25%), menopausal status (59% vs 59%), DM type 2 (7% vs 7%), mSCORE≥5% (21% vs 28%), subclinical carotid atherosclerosis (64% vs 64%), cardiac heart failure with preserved ejection fraction (7% vs 7%) did not change significantly. Blood pressure remained stable over time except 1 pt. An increase in body mass index (BMI) was observed from 26.2 [22.9; 28.9] to 26.7 [24.0; 30.1], p<0.001, waist circumference from 86 [76;97] to 91 [80; 103], p=0,001. The increase of BMI <5% was observed in 11 (39%) pts, 5% - 10% - 7 (25%), >10% - 6 (21%). The normal BMI remained in 7 (25%) pts, overweight – 9 (32%), obese class I – 3 (11%), the rest of pts passed to a higher category of BMI (from normal BMI to overweight – 4 (14%), from overweight to obese class I – 1 (4%), from obese class I to obese class II – 1 (4%)) and only 1 pt went from underweight to normal BMI (4%). The change in BMI correlated negatively with DAS 28, SDAI at baseline (r=-0.6, p<0.001). BMI dynamic was independent of TOFA dose, achieving RA activity, dynamic of DAS 28, SDAI, use of cardioprotective therapy. Dynamic of lipid levels depended on statins treatment. An increase in HDL-C level from 1.35 [0.88; 1.91] to 1.90 [1.64; 2.17], p<0.05, a decrease in LDL-C level from 3.75 [3.11; 4.40] to 2.60 [2.55; 2.93], p<0.03 was observed in pts treated with statins (n=11). An increase in total cholesterol level from 4.60 [4.14; 6.41] to 5.45 [4.56; 6.64], p=0,001 was observed in pts who didn't receive statins (n=17). The change in HDL-C level correlated negatively with dynamic of DAS 28, SDAI (r=-0.4, p<0.05).
Conclusions: TOFA therapy of RA pts contributes to dramatical increase of BMI. Greater BMI dynamic associated with higher disease activity at baseline. BMI dynamic was independent of achieving RA activity and dynamic of DAS 28, SDAI. Co-administration TOFA and statins resulted in significant favorable changes of LDL-and HDL-cholesterol levels.

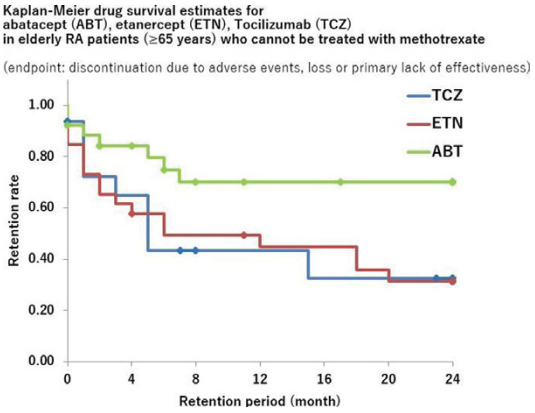
FRI0232 TREATMENT EFFECTS OF ABATACEPT AND ANTI-TNF IN PATIENTS WITH RA WITH POOR PROGNOSTIC FACTORS: DATA FROM COMMUNITY RHEUMATOLOGY CLINICS

E. Alemao[1], K. Knapp[2], V. Anupindi[3], S. Annamalai[4], G. Craig[5]. *[1]Bristol-Myers Squibb, Princeton; [2]Discus Analytics, Spokane; [3]Mu Sigma, Princeton, United States; [4]Mu Sigma, Bangalore, India; [5]Arthritis Northwest, Spokane, United States*

Background: Poor prognostic factors (PPFs; e.g. elevated anti-citrullinated protein antibody/RF levels and erosions) are associated with higher disability and mortality in RA.[1–2] In addition, high seropositivity or CRP/ESR levels are correlated with erosive disease.[3]
Objectives: To evaluate if the presence of specific PPFs of seropositivity with erosions (PPF+) in patients (pts) with RA have an effect on treatment with abatacept (ABA) and anti-TNFs.
Methods: This retrospective study was based on electronic medical record data. This database includes >6500 pts with RA from 50+ rheumatologists. At each visit, data on diagnosis, medications and test results were collected. A homunculus was used to record joint tenderness, swelling, deformity or decreased range of motion. Disease activity was measured by DAS28 (ESR/CRP), SDAI, CDAI, RAPID3 and Vectra DA blood tests. For this analysis, pts aged ≥18 yrs with an RA diagnosis from 1 Jan 2009 to 3 Mar 2016 were followed until lost to follow-up, death or end of study period. Date of first ABA/anti-TNF prescription was designated as index date, preceded by the baseline (BL) period. The ABA cohort comprised pts with a record of ABA in the study period, while the anti-TNF cohort comprised pts with a record of anti-TNF and no record of ABA in the study period. Primary outcome was change (Δ) in CDAI at 6 months (M); other outcomes were SDAI, DAS28 (CRP), pain, RAPID3 and Patient Global Assessment. Descriptive statistics were used for BL characteristics. Univariate and multivariate regression analyses were

Figure. Changes in CDAI in Base Case Abatacept and TNF Cohorts and in Subgroups



used to evaluate ΔCDAI. Subgroup analyses were conducted by line of therapy, after excluding switch pts.
Results: Overall, 3959 pts met inclusion criteria and 2045 had data on PPF; 344 and 814 pts received ABA and anti-TNF. Mean (SD) age of ABA pts was 60.3 (12.5) yrs and median (interquartile range; IQR) CDAI was 25.5 (18.1). Mean (SD) age of anti-TNF pts was 56.4 (13.3) yrs and median CDAI (IQR) was 19.8 (18.1). PPF+ pts treated with ABA (vs all other ABA pts) had a better CDAI outcome at 6M (–9.7 [16.1] vs –7.5 [14.4]). In sensitivity analyses, the difference persisted (–10.4 vs –8.4; Fig). PPF+ pts treated with ABA as first-line therapy (vs all other ABA pts) had a better CDAI outcome (–13.4 vs –10.3). Similar trends were not observed in the anti-TNF cohort (Fig). Adjusted mean (SE) ΔCDAI in PPF+ vs PPF– pts treated with ABA was –12.1 (2.01) vs –9.5 (0.79); covariates included in the model were age, sex and BL CDAI (p=0.24). During follow-up, more PPF+ pts treated with ABA changed from high/medium to LDA or remission vs all other pts (34% vs 25%), while this was not seen in anti-TNF pts (45 vs 42%).
Conclusions: Pts with RA treated with abatacept had higher disease activity at BL and a greater reduction in disease activity was observed in seropositive pts with RA and erosions compared with all other abatacept pts. Similar trends were not observed in anti-TNF pts. No direct comparisons between treatments were conducted in these cohorts.

FRI0233 THE RETENTION RATES OF ABATACEPT IN ELDERLY RA PATIENTS (65 YEARS AND ABOVE) WHO CANNOT BE TREATED WITH METHOTREXATE: COMPARISON WITH ETANERCEPT AND TOCILIZUMAB; A SINGLE-CENTER, RETROSPECTIVE, CASE-CONTROL STUDY

E. Kikuchi, N. Aoki, T. Yoshioka, T. Okai. *Center for Rheumatology and Joint Surgery, Kawakita General Hospital, Tokyo, Japan*

Background: There are many elderly rheumatoid arthritis (RA) patients who cannot be treated with methotrexate (MTX) for many reasons, but data about the therapeutic strategies by biologic agents for the patients are insufficient.
Objectives: To analyze the retention rate of abatacept in elderly patients with RA who cannot be treated with MTX.
Methods: Data were retrospectively collected from the medical records of patients with rheumatoid arthritis at our center. Abatacept (ABT), etanercept (ETN), or tocilizumab (TCZ) was administered to 68 elderly RA patients who could not be treated with MTX. We analyzed the retention rate of each group by Kaplan–Meier curves and the log-rank test. The primary end point was the 24-month retention rate of the biologics without discontinuation due to adverse events, loss or primary lack of effectiveness.
Results: In the ABT group (26 cases: a mean age of 77.8±6.3 years, ACPA positive 92.3%, oral steroid use 34.6%), the cumulative retention rates for both 12 and 24 months were 0.699. In the ETN group (26 cases: a mean age of 75.8±5.1 years, ACPA positive 92.0%, oral steroid use 73.1%), the cumulative retention rates for 12 and 24 months were 0.450 and 0.315, respectively. In the TCZ group (16 cases: a mean age of 73.7±5.6 years, ACPA positive 87.5%, oral steroid use 56.3%), the cumulative retention rates for 12 and 24 months were 0.433 and 0.325, respectively.
There was a significant difference in the retention rates between ABT groups and the other two groups [log-rank test, *p*=0.018 (ABT vs. ETN), 0.047 (ABT vs. TCZ)]. There are no significant retention rates between ETN groups and TCZ groups.
Three cases (11.5%) in the ABT group were discontinued the biologic agents by hospitalization for severe infection within 24 months. Five cases (19.2%) in the ETN group, six cases (37.5%) in TCZ group were hospitalized for severe infection, respectively.
Conclusions: Our data suggested that abatacept can be used for a period longer than etanercept or tocilizumab for elderly RA patients who cannot be treated with methotrexate.

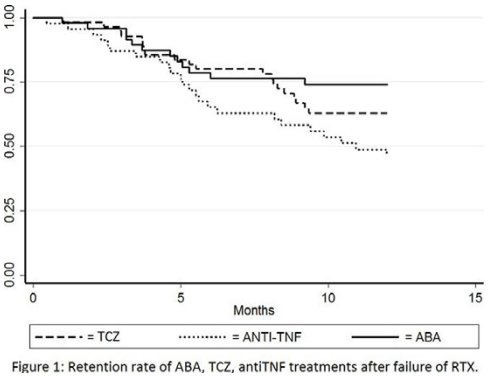
FRI0234 CHOICE OF BIOLOGIC THERAPY FOLLOWING RITUXIMAB: INFLUENCING FACTORS IN A FRENCH MULTICENTER COHORT OF RHEUMATOID ARTHRITIS

G. Vial[1], A. De Pouilly[2], L. Scouppe[3], B. Pereira[4], C. Lukas[5], C. Daien[5], A. Ruyssen-Witrand[6], P. Vergne-Salle[2], A. Tournadre[1], C. Richez[3].
[1]Rheumatology, CHU, Clermont Ferrand; [2]Rheumatology, CHU, LIMOGES; [3]Rheumatology, CHU, Bordeaux; [4]DRCI, CHU, Clermont Ferrand; [5]Rheumatology, CHU, Montpellier; [6]Rheumatology, CHU, Toulouse, France

Background: In rheumatoid arthritis (RA), the long lasting effect of rituximab (RTX) on B lymphocyte depletion may influence the choice of biologic after RTX failure but there is currently no specific recommendation about the optimal strategy.
Objectives: We assessed factors which may have influenced the choice of biologic following failure to RTX in RA patients and analysed the effectiveness of these biologics.
Methods: A retrospective study of RA patients, who had started a new biologic during the year after RTX discontinuation, was conducted between 2009 and 2016 in 5 French rheumatology centers. We collected at baseline (at the time the biologic was introduced after RTX) and during follow-up (3, 6 and 12 months), data about patients and disease. Characteristics of the patients receiving tocilizumab (TCZ), abatacept (ABA) or anti-TNF following RTX, the EULAR response and retention rate were compared using univariate and multivariate analyses.
Results: 152 RA patients (117 women, mean age 56.9±13 years) were analysed. RA duration was 14.3 years [IQR 7.8–19.8], mean DAS28 ESR at baseline 4.8±1.3. 57 patients (37.5%) received TCZ, 47 (31%) anti-TNF and 48 (31.2%) ABA following RTX. 87% had received anti-TNF prior to RTX. No significant difference in the biologics prescription profile was noted across centers. At baseline, sex, disease characteristics and activity, use of concomitant DMARDs or prednisone were not different between the 3 groups. There was no difference in the number of cycles or dose of RTX received and the number of previous anti-TNF treatment. Patients receiving ABA were slightly older (59.8 years vs 54 years for TCZ and 57.8 years for anti-TNF, p=0.06). Multimorbidity index (MMI) assessing the number of comorbidities was higher in the group ABA but not significantly (MMI count 2±1.7 for ABA, 1.6±1.5 for TCZ, 1.7±1.4 for anti-TNF, p=0.5). At 3, 6 and 12 months, DAS28ESR was lower in patients with TCZ as compared to those with anti-TNF or ABA (Table) but tender and swollen joint counts did not differ. The EULAR good-or-moderate response rates were similar across groups (Table). After adjustment on age, sex, disease duration, MMI count,

Table 1. Change in DAS28-ESR score and EULAR response at 3, 6, 12 months according to the biologic following RTX treatment

	TCZ (n=57)	Anti TNF (n=47)	ABA (n=48)	p
DAS28 ESR (mean±SD)				
M3	2,7±1,2	3,5±1,7	3,7±1,3	0.002
M6	2,6±1,5	3,5±1,7	3,5±1,2	0.01
M12	2,5±1,2	3,1±1,7	3,3±1,3	0.04
EULAR Good-Moderate response n (%)				
M3	29 (76)	12 (63)	17 (52)	0.09
M6	22 (79)	8 (57)	19 (73)	0.34
M12	21 (75)	7 (70)	16 (73)	0.95



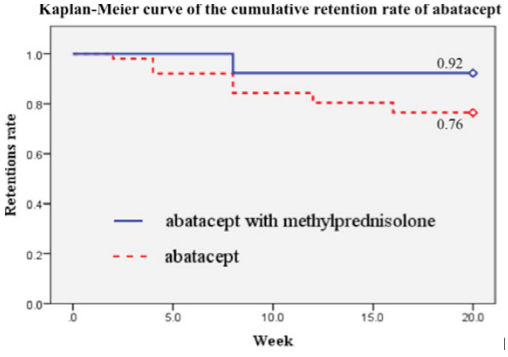


Figure 1: Retention rate of ABA, TCZ, antiTNF treatments after failure of RTX.

number of previous anti-TNF, use of concomitant DMARDs and prednisone, drug retention rate at 1 year was significantly better for ABA compared to anti-TNF (p=0.02) and for TCZ compared to anti-TNF (p=0.04), but no difference was found between TCZ and ABA (p=0.62) (Figure).
Conclusions: Patients who received ABA following failure of RTX, seem to be older and with more comorbidities. Similar rate of good-or-moderate EULAR response was observed between patients receiving TCZ, ABA or anti-TNF. However, drug retention rate was better with TCZ and ABA compared to anti-TNF after RTX discontinuation.

FRI0235 CNCOMITANT USE OF INTRAVENOUS METHYLPREDNISOLONE TO OBTAIN HIGHER RETENTION RATE OF ABATACEPT IN RHEUMATOID ARTHRITIS

H. Sawada, M. Suda, M. Kishimoto, M. Okada. *Immuno-Rheumatology Center, St Luke's International Hospital, Tokyo, Japan*

Background: Abatacept (ABT) is a widely used biologic for treating rheumatoid arthritis (RA).
Objectives: Concomitant use of intravenous corticosteroids with ABT infusion may contribute to achieve earlier remission and higher retention rates.
Methods: We conducted a retrospective cohort study at St. Luke's International Hospital, Tokyo, Japan, from January 2010 to June 2016. Patients who met the 2010 ACR/EULAR classification criteria for RA and treated with ABT were included in the study. We excluded patients who use two or more biologics prior to initiation of ABT. Our primary outcome was treatment retention rates of ABT at week 24. Secondary outcomes were changes in C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) during follow-up (week 0 vs. week 8). We compared these outcomes between the patients receiving concomitant intravenous methylprednisolone (mPSL) with first 3 consecutive doses of ABT and those not receiving it. Log-rank analysis and Fisher's exact test were applied for statistical analysis.
Results: 64 RA patients were included in the study. Mean age was 67.3 (± 14.2) and 55 (85.9%) were female. Among them, 13 (20.3%) received concomitant ABT with mPSL. The dosage of mPSL ranged from 30mg to 250mg (median dosage was 40mg). At week 24, the cumulative retention rates of the patients receiving mPSL (mPSL group) and those not receiving it (non-mPSL group) were 92.3% and 76.5%, respectively. There was no significant difference in the retention rates between the two groups (log-rank test, p=0.21) (figure). Changes in CRP between week 0 vs. week 8 were -1.56 mg/dl (± 2.92) in mPSL group and -1.08 mg/dl (± 2.17) in non-mPSL group (p=0.22), and those in ESR were -8.23 mm/h (± 18.40) in mPSL group and -6.61 mm/h (± 17.93) in non-mPSL group (p=0.75), respectively.

Conclusions: This is the first real world study to investigate whether ABT administrated with intravenous mPSL maintain higher retention rates in rheumatoid arthritis. Though there was no statistically significant difference, the retention rates of ABT at 24 weeks were higher among patients receiving ABT and mPSL concomitantly, compared with ABT mono-therapy group. It may reflect rapid improvement of the disease activity.

FRI0236 AFTER DISCONTINUATION OF THE 1ST TUMOR NECROSIS FACTOR INHIBITOR (TNFI), NON-TNFI BIOLOGIC AGENTS HAVE SIMILAR RESPONSES BUT HIGHER SURVIVAL COMPARED TO A 2ND COURSE OF A DIFFERENT TNFI: LONG-TERM PROSPECTIVE OBSERVATIONAL STUDY OF PATIENTS WITH RHEUMATOID ARTHRITIS IN A TERTIARY HOSPITAL OF GREECE

I.D. Flouri[1], A. Repa[1], N. Avgoustidis[1], N. Kougas[1], A. Fanouriakis[1], I. Papalopoulos[1], C. Adamichou[1], P. Kyfonidou[1], E. Kampouraki[1], M. Terizaki[1], D.T. Boumpas[2], G. Bertsias[1], P. Sidiropoulos[1]. *[1]Rheumatology, Clinical Immunology and Allergy, Faculty of Medicine-University of Crete, Heraklion, Crete; [2]4th Internal Medicine Department, Attikon University Hospital, Athens, Greece*

Background: For rheumatoid arthritis (RA) patients who discontinue the first biologic agent (bDMARD), most commonly being a TNF inhibitor (TNFi), there is little evidence supporting the next best choice between a second TNFi course or a non-TNFi bDMARD in clinical practice.
Objectives: To compare the effectiveness and the adherence to therapy with non-TNFi versus TNFi administered as the second-line bDMARD in RA patients with one prior TNFi use.
Methods: All patients starting a bDMARD in the Rheumatology Department of the University Hospital of Heraklion, Crete, are included in a prospective observational study after their written informed consent. Data concerning disease activity at pre-specified time-points, drugs, comorbidities and any adverse events are recorded. For the present study we analyzed patients with RA starting their second course of a bDMARD after discontinuation of a TNFi. We compared DAS28 difference at 6 and 12 months using linear regression analysis and treatment retention using Kaplan-Meier survival curves with log-rank test.
Results: A total of 384 patients started a 2nd (different) TNFi [N=213 (Infliximab: 26, Adalimumab: 77, Etanercept: 89, Golimumab: 13 and Certolizumab: 8)] or a non-TNFi [N=171 (Rituximab:71, Abatacept:66, Tocilizumab:34)]. Patients' characteristics at baseline are described in the Table.
Two-year drug survival was higher for non-TNFi (64% vs. 39%, log rank $p<0.001$) due to lower frequency of discontinuations for primary failure ($p<0.001$) and adverse events (p=0.019).
δDAS28 was comparable between non-TNFi and TNFi patient groups both at 6 [mean (SD): -1.16 (1.29) and -1.07 (1.55) respectively, p=0.296] and at 12 months [-1.41 (1.29) and -1.39 (1.26) respectively, p=0.670]. In patients who did not receive co-therapy with methotrexate, significantly greater δDAS28 was observed with a non-TNFi (-1.25 (1.29) vs.-0.68 (1.61), p=0.006). When the first TNFi was discontinued due to primary failure, we observed a trend for greater δDAS28 in the non-TNFi patient group compared to the 2nd TNFi group (-1.4 vs. -1.0, p=0.12) while the opposite was observed in patients who have experienced secondary failure to the 1st TNFi (-0.81 vs -1.48, p=0.18), but this did not reach statistical significance, probably due to the low number of available patients.
Conclusions: In RA patients who need a 2nd bDMARD after discontinuation of a TNFi, administration of a non-TNFi results in similar clinical responses but higher treatment adherence compared to a second TNFi agent. In patients who do not receive methotrexate, responses are better with a non-TNFi bDMARD.

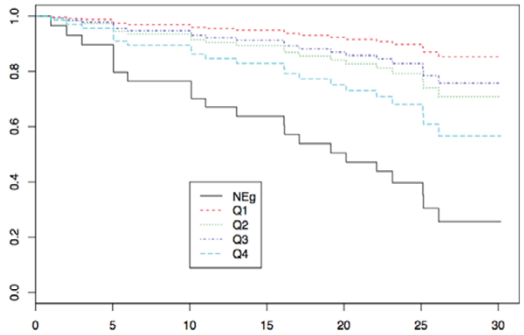
FRI0237 SAFETY OF BIOSIMILAR INFLIXIMAB USE IN A MEDICAL DAY HOSPITAL: A CASE-SERIES

J.M. Lopez Suarez[1], J.M. Lopez Chozas[2], E. Rubio Romero[3]. *[1]Family Doctor, CS Olivar de Quinto; [2]Interne Medicine; [3]Rheumatology, HU Virgen del Rocio, Sevilla, Spain*

Background: The first biosimilar anti-NTF (infliximab) approved by the EMA (European Medicines Agency) began to be used throughout Europe in 2015. Since then, it has been widely used throughout the world, even replacing the original treatment approved in 1999 Remicade® with Remsima®, a biosimilar drug. This medicine is currently approved to treat people who have been diagnosed with rheumatoid arthritis, ankylosing spondylitis or psoriatic arthritis in the field of reheumatology, in addition to ulcerative colitis (UC) or Crohn's disease (EC) in gastroenterology. However, safety data of the use of Remsima® infliximab in a medical day hospital (MDH) are lacking.
Objectives: To report intrainfusion and postinfusion adverse events related to intravenous Remsima® use in a medical day hospital. Besides, we will describe the rehospitalizations and continuity of treatment in the follow up.
Methods: We designed a prospective uncontrolled case-series study. Patients referred from March 2015 to October 2016 to our MDH to receive intravenous Remsima® were consecutively enrolled. Demographic data were collected, and a harmonised active monitoring strategy was applied. We recorded the indication for treatment, the doses administered and the number and symptoms of acute transfusion reactions (ATR) occurring both in the infusion period and during the 3 hour postinfusion observation interval
Results: 2828 doses were administered, 0.67% presented ATR, all of them during the infusion and reported to the Regional Pharmacovigilance Center. 53% of those ATR were women and they were on average 35.78 years (SD 14.71). The mean dose used was 4,809 mg/kg (SD 0.47). The indications for treatment in patients suffering ATR were: EC (47%), CU (26%), Spondylitis (21%) and Psoriasis (5%). As a predominant symptom during ATR we found: shortness of breath (36.89%), pruritus (15.75%), flushing sensation (15.75%), urticaria (10.4%), alopecia (5.2%), chest pain (5.2%), paresthesia (5.2%) and nausea (5.2%). 95% of ATR showed complete recovery of the symptoms, 47% disappeared with the pause of infusion. However, they had prolonged in MDH stay, the infusion was stopped for 30 minutes and restarted at a lower rate according to the protocol. 21% of patients presenting ATR dropped out because of the symptomatology, which represents 0.14% of the total infusions.
Conclusions: Biosimilar Inflximab seems to be safe in a MDH setting, given the



low rate of adverse transfusion reactions during the 18 months analyzed. The most frequent adverse reaction was shortness of breath.

FRI0238 EFFECT OF BASELINE ANTI-CYCLIC CITRULLINATED PEPTIDE 3 ANTIBODY TITRE ON LONG-TERM DRUG SURVIVAL OF SUBCUTANEOUS ABATACEPT IN RHEUMATOID ARTHRITIS: A PROSPECTIVE COHORT STUDY

J.C. Sarmiento-Monroy[1,2], N. Molano-González[2], M. Rodríguez-Jiménez[2], R.D. Mantilla[1,2]. *[1]Rheumatology, Center of Dermatology and Rheumatology (FUNINDERMA); [2]Center for Autoimmune Diseases Research (CREA), Universidad del Rosario, Bogotá, Colombia*

Background: Clinical response to biologics varies widely between individuals with rheumatoid arthritis (RA). To date, there are few, and in some cases, conflicting results in the personalized approach of patients with RA treated with abatacept. Only the seropositive subphenotype (anti-cyclic citrullinated peptide, CCP) was validated in several populations, including a real-life registry (ORA) [1], and non-inferiority trial (AMPLE) [2].
Objectives: To assess whether baseline anti-CCP3 antibody status and concentration correlated with drug survival of subcutaneous (SC) abatacept among patients with RA in a real-world setting.
Methods: This was a prospective study in which well-characterized patients with RA (by 1987 ACR criteria) were included from April 2014 to December 2016. Patients were evaluated at a single rheumatology outpatient center in Bogotá, Colombia. Baseline anti-CCP3 antibody status (positive/negative) and concentration were determined using an anti-CCP3 IgG ELISA (INOVA Diagnostics). Patients with a baseline anti-CCP3 IgG concentration of ≥20 U were considered to be positive and were further divided into equal quartiles according to concentration [Q1–Q4 (highest concentration)]. The Cox proportional hazards regression model was used to test if there were any differences in drug survival curves according to baseline anti-CCP3 antibody status and concentration. The test was performed by the coxph function of the "survival" R package [3].
Results: A total of 129 patients were included. Baseline characteristics: female gender 86%, mean age 52±13 years, median disease duration 10 (IQR 11) years, and erosions 35%. Treatment background was as follows: biologic-naïve (n=54), switched from IV to SC abatacept administration (n=24), and inadequate response to at least 1 biologic disease-modifying antirheumatic drug (n=51). Forty-three patients (33%) discontinued treatment. The most frequent reasons for drug suspension were loss of efficacy. Rheumatoid Factor and anti-CCP3 was positive in 94%, and 89%, respectively. Median titre of anti-CCP3 was 248 U (IQR 352), and number of patients in each quartile group were Q1 (22–122)=21; Q2 (123–248)=20; Q3 (249–475)=19; Q4 (476–1544)=19. According to Cox proportional hazards regression model (Fig.1), there were significant differences between survival curves for Q1 (HR 0.1; 0.02–0.60 95% IC; p=0.011), Q2 (HR 0.2; 0.06–0.94 95% IC; p=0.041), and Q3 (HR 0.2; 0.04–0.85 95% IC; p=0.030), compared to negative group at month 32.

Figure 1. Subcutaneous abatacept survival by anti-CCP3 antibody status.

Antibody-positive patients were divided into equal quartiles (Q1-Q4), representing increasing antibody concentrations. The duration of follow-up was 32 months.

Conclusions: Baseline anti-CCP3 positivity was associated with a better response for SC abatacept in a real-world setting. Patients with lowest baseline anti-CCP3 antibody concentrations had better drug survival than patients with higher concentrations. Our results highlight the importance of identification of factors associated with response to biologics in order to optimize treatment and reduce costs.

FRI0239 RESULTS OF A PHASE 2B STUDY OF VOBARILIZUMAB, AN ANTI-INTERLEUKIN-6 RECEPTOR NANOBODY, AS MONOTHERAPY IN PATIENTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS

T. Dörner[1], M. Weinblatt[2], K. Van Beneden[3], E.J. Dombrecht[3], K. De Beuf[3], P. Schoen[3], R.K. Zeldin[3]. *[1]Rheumatology and Clinical Immunology, Charité University Hospitals, Berlin, Germany; [2]Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, United States; [3]Ablynx Nv, Zwijnaarde, Belgium*

Background: Vobarilizumab is a Nanobody® consisting of an anti-IL6 receptor domain and an anti-human serum albumin domain in development for treatment of RA.
Objectives: To assess the efficacy and safety of several dose regimens of vobarilizumab monotherapy administered subcutaneously to patients with active RA.
Methods: Patients with active RA who were intolerant to methotrexate (MTX) or for whom continued MTX treatment was inappropriate were randomized in a 1:1:1:1 ratio to 1 of the 3 blinded dose groups of vobarilizumab or to open-label tocilizumab (TCZ), all of which were given subcutaneously. Efficacy was evaluated descriptively at Week 12 using a number of widely accepted clinical endpoints. Adverse events and routine safety parameters including laboratory assessments were recorded. TCZ administered weekly or biweekly according to local labeling was included to obtain parallel descriptive information.
Results: The study enrolled 251 patients in Europe, Latin America and the United States. Baseline demographics and disease characteristics were well balanced across groups with mean $DAS28_{CRP}$ between 5.9 and 6.2.

Week 12 (% of patients)	Vobarilizumab 150mg q4w (N=62)	Vobarilizumab 150mg q2w (N=62)	Vobarilizumab (N=63) 225mg q2w (N=63)	Tocilizumab 162mg q1w (N=60) q2w (N=4)
ACR20	73	77	81	78
ACR50	44	37	49	45
ACR70	16	24	21	23
HAQ-DI score decrease ≥0.25	65	68	71	72
$DAS28_{ESR}$ <2.6	34	21	40	25
$DAS28_{CRP}$ <2.6	26	27	41	27
SDAI remission	8	5	8	11
CDAI remission	10	5	6	9

At Week 12, 73% to 81% of the patients assigned to one of the vobarilizumab groups achieved an ACR20 response, while ACR50 and ACR70 response rates between 37 - 49% and 16 - 24%, respectively, were observed (see table). At the end of the 12-week treatment period, clinically meaningful improvement in HAQ-DI scores and remission based on $DAS28_{CRP}$ and $DAS28_{ESR}$ was observed in a substantial number of patients treated with vobarilizumab, either q4w or biweekly. Between 5% and 10% of the patients achieved remission defined by the more stringent CDAI or SDAI criteria. In total, 94% of patients randomized to open-label TCZ received drug weekly. In spite of this disparity in dosing frequency similar efficacy results were obtained in the vobarilizumab and TCZ groups.
One vobarilizumab treated patient (225mg q2w treatment group, 1.6%) experienced a SAE during the treatment period as did 2 patients in the TCZ group (3.1%). Frequencies of treatment-emergent adverse events were similar across the groups. Of the vobarilizumab treated patients, 2.1% discontinued study drug due to TEAEs compared with 6% in the TCZ group. One case of severe hypersensitivity, not considered serious, was reported in the 225mg q2w treatment group. Liver function abnormalities were infrequent across all study groups. Grade 3 neutrophil toxicities were less commonly observed with vobarilizumab (1.1%) than with TCZ (4.3%).
Conclusions: In patients with active RA, treatment with vobarilizumab monotherapy had a positive impact on disease activity with no unexpected safety findings.

FRI0240 RHEUMATOID ARTHRITIS (RA) IMPACT FOLLOWING TREATMENT WITH SARILUMAB: PATIENT REPORTED OUTCOMES USING THE RAID SCALE FROM TWO RANDOMIZED PHASE III TRIALS

L. Gossec[1], V. Strand[2], C. Proudfoot[3], C. Chen[4], S. Guillonneau[5], T. Kimura[4], H. van Hoogstraten[6], E. Mangan[4], M. Reaney[3]. *[1]Université Pierre et Marie Curie and Hôpital Pitié-Salpêtrière, Paris, France; [2]Stanford University, Palo Alto, United States; [3]Sanofi, Guildford, United Kingdom; [4]Regeneron Pharmaceuticals, Inc, Tarrytown, United States; [5]Sanofi, Paris, France; [6]Sanofi, Bridgewater, United States*

Background: Patients with RA experience a variety of signs and symptoms and report significant physical and psychological impairment. The RA Impact of Disease (RAID) scale is a disease-specific measure of the impact of RA on patients' lives. RAID was assessed in two Phase 3 randomized trials of sarilumab,

a human monoclonal antibody directed against the IL-6 receptor-α (TARGET [NCT01709578]; MONARCH [NCT02332590]).

Objectives: To evaluate patient-perceived impact of sarilumab on RA using the RAID scale vs either placebo + conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) or adalimumab.

Methods: TARGET assessed sarilumab 150mg and 200mg added to csDMARDs vs placebo in patients with RA intolerant of or not responding to anti-TNF therapy. MONARCH assessed sarilumab 200mg monotherapy vs adalimumab 40mg monotherapy in patients with RA either intolerant of, inadequate responders to, or considered inappropriate candidates for continued treatment with methotrexate. Treatments were administered subcutaneously every 2 weeks. RAID has 7 single-item domains, each rated by patients on an 11-point numeric rating scale from 0 (absence) to 10 (extreme). A total score from 0 to 10 (with lower scores indicative of less impact of disease) is calculated by weighting responses for each item based on patient assessment of the relative importance of the item. RAID was assessed at baseline (BL), Weeks 12 and 24. Least square mean (LSM) changes from BL in total score (Weeks 12 and 24) and domains (Week 24 only) were analysed with a mixed model for repeated measures, including treatment, region, visit, and treatment-by-visit interaction (and prior csDMARD therapy in TARGET) as fixed effects and BL as a covariate. RAID was tested outside of trial hierarchy and statistical significance is not claimed; nominal p-values are provided. Post-hoc categorical change analyses were conducted to identify "responders" in the total score (improvements ≥ minimum clinically important difference from BL to Week 24 [absolute change of 3 or relative change of 50% in total score]). Patients discontinuing therapy/requiring rescue medication prior to endpoint were classified as non-responders.

Results: Sarilumab was superior (nominal $p<0.05$) to placebo (TARGET) and adalimumab (MONARCH) at Weeks 12 and 24 for RAID total score (Table). There was a greater proportion of responders in both sarilumab dose groups vs placebo at both time points (TARGET) and in sarilumab 200mg vs adalimumab at Week 24 (MONARCH). The effect of sarilumab was consistent across all 7 individual RAID domains (nominal $p<0.05$) at Week 24, except for sleep difficulties vs placebo in TARGET. Effects of placebo were highest on pain and effects of sarilumab were lowest on emotional well-being (TARGET) and coping (MONARCH).

Table. RAID total and individual domain scores at Week 24

		TARGET study			MONARCH study	
		Placebo + csDMARD (n=181)	Sarilumab SC 150 mg q2w + csDMARD (n=181)	Sarilumab SC 200 mg q2w + csDMARD (n=184)	Adalimumab 40 mg q2w (n=185)	Sarilumab SC 200 mg q2w (n=184)

FRI0241 THE EFFECT OF ABATACEPT ON CYTOKINE PROFILE IN PATIENTS WITH RHEUMATOID ARTHRITIS

M.A. Borisova, G.V. Lukina, Y. Sigidin, E.L. Luchihina, D.E. Karateev, A. Novikov, E. Alexandrova, E. Aronova, S. Glukhova, E. Nasonov. *Nasonova Reserch Institute of Rheumatology, MOSCOW, RUSSIA, Moscow, Russian Federation*

Background: Pathological activation of T-cells with the overproduction of pro-inflammatory cytokines is playing a major role in the pathogenesis of rheumathoid arthritis (RA). The influence of the selective co-stimulation modulator abatacept (ABA) on the dynamics of cytokine profile in patients with RA is not fully understood.

Objectives: To assess the changes in cytokine profile in patients treated with ABA.

Methods: 44 patients with RA and an inadequate response to synthetic DMARDs or biologics were enrolled in the study. Most of them were middle aged females (46,9±13,9 years) with median RA duration 2 years (1,4–3), high disease activity (DAS28=5,2±0,8), RF-positive (80%) and ACPA-positive (79,5%). 16 healthy individuals were included in the study as control. The serum levels of IL-1, IL-6, IL-17, TNF-α, VEGF, IP-10 (pg/ml) were measured by ELISA immunoassay, YKL-40 by MicroVue immunoassay at baseline and 24 weeks. Disease activity was measured by DAS28, results were assessed every 12 weeks by EULAR criteria. ABA was administered intravenously every 4 weeks.

Results: Levels of IL-6 (2.4 (1,1–6,4) vs 0.7 (0,62–1,0), p=0,0002), YKL-40 (97 (68,4–97, 9) vs. 64 (52,4–107,5), p=0,03), IP-10 (21 (12,9–49,8) vs 14 (9,2–15,2), p=0,005) were significantly higher in patients with RA compared to control. ABA significant reduced disease activity already after 12 weeks of therapy ($p<0,05$). After 24 weeks of ABA therapy good and moderate response by EULAR criteria was achieved in 86%, low disease activity by DAS28 in 52%. By the 6-th month ABA significant decreased levels of IL-6 (1,29 (0,9–2,2, p=0,0006), IP-10 (14 (7,5–28), p=0.007) as well as MMP3: before 30.1 (13–82), after 24 weeks 10 (7.4–55), p=0.0003 and RF: before 218 (9.6–187), after 24 weeks 159 (9.7–155), p=0.02. Lowering of the IL-6 (r=0,5) and IP-10 (r=0,32) levels were significantly ($p<0.05$) associated with a decrease of DAS28.

Conclusions: ABA therapy leads to a significant reduction in serum levels of IL-6, IP-10, MMP3 and RF. The serum levels of IL-6 and IP-10 correlate with decrease activity of RA.

FRI0242 ASSOCIATION BETWEEN CLINICAL AND RADIOGRAPHIC RESPONSES, AND PHYSICAL FUNCTION IN A PHASE 3 STUDY OF SARILUMAB PLUS METHOTREXATE IN PATIENTS WITH ACTIVE, MODERATE-TO-SEVERE RHEUMATOID ARTHRITIS

M.C. Genovese[1], H. van Hoogstraten[2], W. Kampman[3], S. Jayawardena[2], T.W. Huizinga[4]. *[1]Stanford University Medical Center, Palo Alto; [2]Sanofi Genzyme, Bridgewater; [3]Regeneron Pharmaceuticals, Inc., Tarrytown, United States; [4]Leiden University Medical Centre, Leiden, Netherlands*

Background: In MOBILITY (NCT01061736), SC sarilumab (150 or 200 mg q2w) + MTX demonstrated efficacy in adults with RA and inadequate response to MTX. The most common TEAEs were infections, neutropenia, injection site reactions, and increased transaminases.

Objectives: To examine association between clinical response and radiographic progression and functional response (HAQ-DI) in MOBILITY.

Methods: In this post hoc analysis, associations between HAQ-DI and clinical efficacy categories (CDAI, DAS28-CRP, SDAI, and Boolean-based ACR/EULAR remission) were tested at wk 16. Trend for change from baseline (BL) in HAQ-DI across response categories was assessed using the Jonckheere-Terpstra test.

Results: Regardless of definition, percentage achieving remission (CDAI ≤2.8, DAS28-CRP <2.6, SDAI ≤3.3) or no x-ray progression was higher with sarilumab vs Pbo ($P<0.05$). Overall, there was a significant trend between magnitude of clinical response at wk 16 and improvement in physical function (Table). This trend was also observed for radiographic progression (mTSS change from BL),

Table. Change From BL in HAQ-DI at Wk 16 by Categories of Clinical and Radiographic Efficacy

*$P<0.05$ for trend test. †$P<0.05$ vs Pbo for % with remission/no progression.

regardless of cutoff (≤0.5 and ≤0). In patients achieving remission, there was a numerically greater improvement in HAQ-DI with sarilumab vs placebo (Pbo). Even if patients did not achieve remission or LDA, the sarilumab group had generally greater numerical improvements in HAQ-DI vs Pbo.

Conclusions: Achieving LDA or remission, or absence of radiographic progression, was associated with overall greater improvement in physical function. Irrespective of whether patients achieved remission or LDA, sarilumab + MTX showed greater improvements in HAQ-DI than Pbo + MTX.

FRI0243 SIRUKUMAB TREATMENT REDUCES LEVELS OF IRON-REGULATORY PROTEINS AND AMELIORATES INFLAMMATION-ASSOCIATED ANEMIA IN RHEUMATOID ARTHRITIS PATIENTS

M. Loza[1], K. Campbell[1], K. Sweet[1], B. Hsu[1], S. Daga[2], B. Dasgupta[1].
[1]*Janssen Research & Development, LLC, Spring House, PA, United States;*
[2]*GlaxoSmithKline, Uxbridge, United Kingdom*

Background: Anemia of chronic disease, a common comorbidity of rheumatoid arthritis (RA), is detrimental to patients' (pts) quality of life, productivity, and long-term health.

Objectives: Sirukumab (SIR), a human monoclonal antibody that selectively binds to the IL-6 cytokine with high affinity, has recently demonstrated efficacy in RA. It was hypothesized that SIR, compared to placebo (pbo) and tumor necrosis factor-inhibitors (TNFi), increases hemoglobin (Hb) concentrations in RA pts by decreasing levels of iron-scavenging proteins and increasing transferrin levels, thus ameliorating anemia. This hypothesis was tested in post hoc analyses of 4 phase 3 studies of SIR in RA: SIRROUND-M (methotrexate [MTX] inadequate responders [IR]); -D (disease-modifying antirheumatic drug [DMARD] IR); -T (TNFi-IR); -H (MTX-IR, monotherapy).

Methods: Standard hematology measurements, including Hb levels, were made throughout the studies by a central laboratory. Anemia was defined as Hb levels <125 g/L (males) and <115 g/L (females). In a subset of pts, iron-regulatory proteins (hepcidin, haptoglobin, hemopexin, transferrin) were measured in serum at baseline (BL) and Wk 4 using the SomaLogic SOMAscan™ platform (for SIRROUND-M, -D, -T, and -H studies, respectively: SIR 100mg q2w, n=61, 205, 136, 0; SIR 50mg q4w, n=61, 201, 128, 100; pbo, n=0, 118, 56, 0; adalimumab [ADA], n=0, 0, 0, 98).

Results: SIR consistently reduced the prevalence of anemia to a greater extent than was observed for pbo ($p<0.05$; eg, in SIRROUND-D, anemia decreased from 25% of pts at BL to 10% at Wk 16 post-treatment with SIR 50mg q4w vs increase from 24% of pts to 28% with pbo) and ADA (SIRROUND-H). Across studies on SIR 50mg q4w, increases in Hb levels ranged from 7±10 to 10±11 g/L (mean±SD) through Wk 16; however, greater changes were seen in pts anemic at BL (13±13 to 16±12 g/L increase). Significant Hb elevations were observed by Wk 2, with comparable results for SIR 100mg q2w. Statistically significant increases in Hb levels were not observed with ADA (Fig.1) or pbo, regardless of BL anemia status. Changes in Hb levels with SIR were independent of changes in RA disease activity. Mean haptoglobin levels were modestly higher at BL in RA pts with anemia compared to pts without anemia. Across studies, both SIR doses similarly strongly decreased levels of hepcidin, haptoglobin, and hemopexin and increased transferrin levels at Wk 4, regardless of BL anemia status. The modulation of these proteins by ADA was considerably less (Fig.1) and by pbo non-significant. After SIR treatment, greater decreases in hepcidin levels were consistently observed in pts with vs without BL anemia across studies by Wk 4.

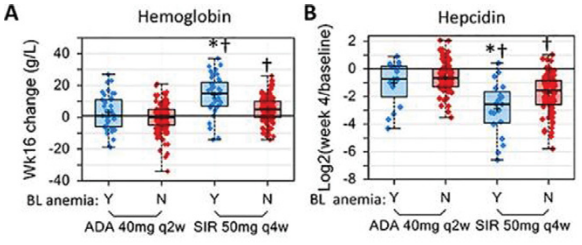

Figure 1. For the SIRROUND-H study, changes in (A) hemoglobin (week 16 change from baseline in g/L) and (B) hepcidin (log_2(week 4/baseline)) are plotted for each available patient, stratified by treatment group and baseline (BL) anemia status (Y, blue; N, red). * p<0.05 for baseline anemia Y vs. N within treatment group; † p<0.05 vs. adalimumab, within baseline anemia group. ADA, adalimumab; SIR, sirukumab.

Conclusions: SIR consistently increased Hb levels in RA pts (DMARD-IR, TNFi-IR, monotherapy), most prominently in pts with BL anemia, resulting in significant reductions in the prevalence of anemia. These effects were independent of the extent of improvement in RA disease activity, suggesting additional benefits of SIR beyond clinical response in RA. By inhibiting IL-6, SIR may decrease key iron-regulatory proteins, such as hepcidin, and shift homeostasis towards an increase in the pool of iron available for red blood cell Hb, thus ameliorating anemia of chronic inflammation associated with RA.

FRI0244 LOW DOSE OF RITUXIMAB IS EFFECTIVE FOR MAINTENANCE OF CLINICAL REMISSION OR LOW DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

N. Avgoustidis, I. Flouri, C. Adamichou, E. Kabouraki, A. Eskitzis, P. Kyfonidou, I. Papalopoulos, A. Fanouriakis, A. Repa, N. Kougkas, G. Bertsias, P. Sidiropoulos. *Department of Rheumatology, Clinical Immunology and Allergy, University Hospital of Heraklion, Crete, Greece, Heraklion, Greece*

Background: Although existing data support the effectiveness of the low dose regimen (LDR, 1gr every 6 months) of rituximab as initial treatment for active rheumatoid arthritis (RA) (2), it is unknown whether this regimen may be used to maintain the therapeutic effect in patients achieved clinical remission or low disease activity (LDA) upon treatment with conventional rituximab regimen (2gr every 6 months)

Objectives: To evaluate the effectiveness of the rituximab LDR for maintenance of clinical remission and/or LDA in patients with RA in clinical practice.

Methods: Long-term prospective study of RA patients who received rituximab in the Rheumatology Department of the University Hospital of Heraklion during 03/2005–07/2016. All patients on clinical remission [DAS 28 (ESR) <2.6] or LDA [DAS28 (ESR) <3.2] for at least 12 months were treated with the LDR after obtaining verbal consent.

Results: We analyzed 247 patients who received conventional rituximab regimen, of median age (IQR) 62 (54.3–70.4)years, females (84%), disease duration 9.6 (5.6–18.3) years,52% seropositive (RF or anti-CCP). Patients have had failed in (median) 3 (2–3) non-biologic (nbDMARDs) and 1 (1–2) biologic DMARDs (bDMARDs) before rituximab initiation. At baseline of rituximab treatment, 58.3% and 91.1% of them were on steroids and (nbDMARDs) respectively, while the disease activity was high [mean DAS28 (ESR): 5.84 (5.20–6.49)] and they had impaired physical functioning [mean HAQ: 1.0 (0.63–1.38)].

Overall, 27/247patients (11%) received the LDR. Before the initiation of LDR, the duration of rituximab treatment was 24 (18–48) months and cumulative rituximab "exposure" was 8 (6–15) gr. At the time of LDR initiation, disease activity [DAS28 (ESR)] was 2.8 (2.2–3.6) and HAQ: 0 (0–0.4), while the time needed for achieving remission or LDA was18 (8–23) months. The median duration of follow-up of patients on LDR was12 (6–20) months. 23 (85%) of patients remained in remission or LDA with median DAS28 (ESR) 2.85 (2.23–3.52) and HAQ 0 (0–0.5) at last follow-up. Only 3 (11%) of the patients experienced an increase of DAS28 (>1.2) and 2 (7%) of patients return to conventional dose.

Conclusions: In clinical practice, RA patients who achieved remission or low disease activity with conventional dose of rituximab may sustain clinical responses if treated with LDR. These preliminary findings support the use of LDR as maintenance treatment regimen and this may allow cost savings. (1)

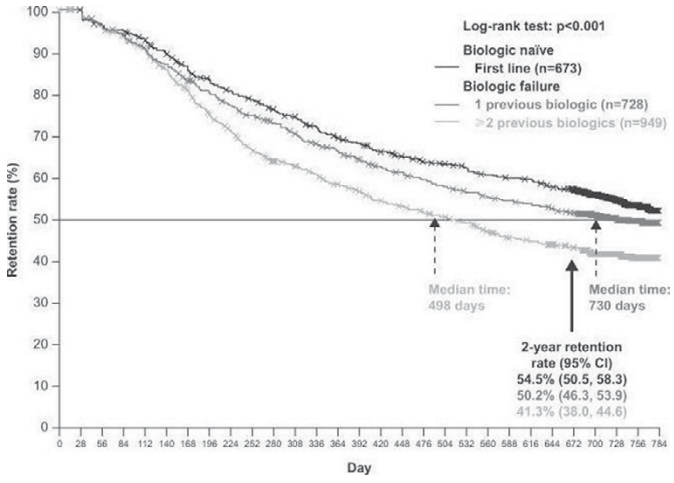
FRI0245 ABATACEPT RETENTION RATES AND PROGNOSTIC FACTORS OF RETENTION IN PATIENTS WITH RHEUMATOID ARTHRITIS: 2-YEAR RESULTS FROM THE REAL-WORLD ACTION STUDY

R. Alten[1], H.-M. Lorenz[2], X. Mariette[3], H. Nüßlein[4], M. Galeazzi[5], F. Navarro[6], M. Chartier[7], Y. Elbez[8], C. Rauch[9], M. Le Bars[7]. [1]*Schlosspark-Klinik University Medicine, Berlin;* [2]*University Hospital, Heidelberg, Germany;* [3]*Université Paris-Sud, Paris, France;* [4]*University of Erlangen-Nuremberg, Nuremberg, Germany;* [5]*University of Siena, Siena, Italy;* [6]*Hospital Universitario Virgen Macarena, Seville, Spain;* [7]*Bristol-Myers Squibb, Rueil-Malmaison;* [8]*Excelya, Boulogne-Billancourt, France;* [9]*Bristol-Myers Squibb, Munich, Germany*



Background: The ACTION (NCT02109666) study was designed to provide

prospective, real-world data on abatacept (ABA) retention in patients (pts) with RA.

Objectives: To assess the retention rate and to identify prognostic factors of ABA retention in the overall ACTION population and by treatment line over 2 yrs.

Methods: ACTION is a 2-yr, international, observational study of pts with RA who initiated IV ABA as first- or as second-/further-line biologic therapy in routine clinical practice. Biologic-naïve and biologic-failure pts were enrolled during three periods between May 2008 and December 2013. The primary endpoint was crude ABA retention rate over 2 yrs (Kaplan–Meier plot). Prognostic factors ($p \leq 0.2$) from univariate analyses with no colinearity, clinically relevant variables and known risk factors were entered into a multivariate model; factors with $p \leq 0.1$ were retained by backward selection. EULAR response was compared by Fisher's exact test.

Results: In the ACTION cohort, 2350/2364 enrolled pts were evaluable for analysis; 673 (28.6%) were biologic naïve and 1677 (71.4%) had failed biologic treatment. Most biologic-failure pts (56.6%) had previously received ≥2 biologics. Some expected differences in baseline characteristics were observed between groups; mean (SD) RA duration was shorter (7.2 [8.2] vs 12.1 [9.1] yrs; $p<0.001$), more pts had RA for ≤2 yrs (35.7 vs 9.0%; $p<0.001$) and fewer pts had radiographic erosions (58.2 vs 71.5%; $p<0.001$) for biologic-naïve vs biologic-failure pts. At Yr 2, the overall retention rate was 47.9% (95% CI 45.7, 50.0). The retention rate was higher in biologic-naïve vs biologic-failure pts (54.5 vs 45.2%; $p<0.001$) and in pts with 1 vs ≥2 previous biologics (Fig). Reasons for discontinuation were comparable between groups; main reasons were lack of efficacy (61.4 vs 67.7%) and safety (21.3 vs 21.2%). RF and anti-citrullinated protein antibody (ACPA) seropositivity were prognostic factors for higher retention in biologic-naïve (p=0.030) and biologic-failure pts (p=0.028); other positively impacting factors were diabetes mellitus (p=0.044; biologic naïve); geographic location ($p<0.001$; biologic naïve) and ABA combination therapy ($p<0.001$; biologic failure). Only Pt Global Assessment (p=0.009; biologic failure) predicted lower retention. Among pts continuing ABA, a greater proportion of biologic-naïve vs biologic-failure pts had a good/moderate EULAR response (90.7 vs 81.6%; p=0.005) and RF/ACPA seropositivity was associated with a better response (p=0.002). There were no new safety signals.

Conclusions: In this first prospective, international, non-interventional research evaluating the long-term IV abatacept retention, RF and ACPA seropositivity were predictors of 2-yr higher retention and better outcomes. Higher retention rates may be achievable with earlier vs later initiation of abatacept treatment, consistent with prior findings from a pooled analysis of EU and Canadian registries.[1]

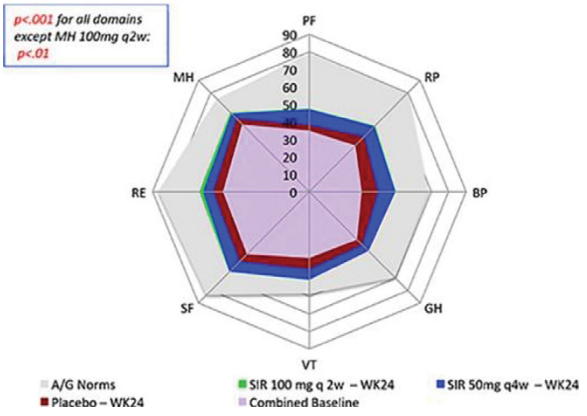
FRI0246 IMPROVEMENTS IN HEALTH-RELATED QUALITY OF LIFE WITH SIRUKUMAB ARE STATISTICALLY SIGNIFICANT, CLINICALLY MEANINGFUL, AND MEET OR EXCEED NORMATIVE VALUES IN RHEUMATOID ARTHRITIS PATIENTS WITH INADEQUATE RESPONSE TO DISEASE-MODIFYING ANTIRHEUMATIC DRUGS: POST HOC ANALYSES OF A PHASE 3 TRIAL

V. Strand[1], K. McQuarrie[2], N. Li[2], R. Ganguly[3]. [1]*Stanford University, Palo Alto, CA;* [2]*Janssen Research & Development, LLC, Spring House, PA;* [3]*GlaxoSmithKline, Collegeville, PA, United States*

Background: Rheumatoid arthritis (RA) is associated with impaired health-related quality of life (HRQoL). Sirukumab (SIR) is an anti–interleukin-6 (IL-6) monoclonal antibody.

Objectives: These post hoc analyses evaluated improvements in HRQoL compared with an age/gender-matched normative population in a phase 3 randomized, controlled trial of SIR in RA pts with inadequate response to conventional disease-modifying antirheumatic drugs (DMARD-IR; SIRROUND-D).

Methods: 1670 pts received SIR 50mg every 4 weeks (q4w), SIR 100mg every 2 weeks (q2w), or placebo (pbo) q2w. Health-related physical/emotional well-being was measured at baseline (BL) and Wk 24 by the 36-item Short Form Questionnaire (SF-36), fatigue by Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue (FACIT-F), and physical function by Health Assessment Questionnaire-Disability Index (HAQ-DI).



Results: SF-36 physical and mental component summary (PCS and MCS) mean scores at BL were comparable for pbo, SIR 50mg q4w and 100mg q2w (PCS: 33.8, 34.2, and 33.5; MCS: 40.5, 40.5, and 41.8) and indicative of substantial impairment. At Wk 24, treatment with SIR 50mg q4w and 100mg q2w resulted in significantly greater mean improvements from BL vs pbo in SF-36 PCS (5.4 and 5.9 vs 2.3) and MCS (4.9 and 4.2 vs 2.9) scores (all $P<0.001$), exceeding the minimum clinically important difference (MCID) of 2.5. Least squares mean changes in all SF-36 domain raw scores were significantly greater with both doses of SIR than pbo at Wk 24 and all >MCID of 5.0 (Table; Figure). Substantial proportions of pts treated with SIR 50mg q4w or 100mg q2w reported scores ≥normative values in SF-36 domains at Wk 24 (ranges: 20–33% and 21–36%) vs pbo (range: 10–28%). For pbo, SIR 50mg q4w, and SIR 100mg q2w, BL FACIT-F scores were 27.2, 27.1, and 27.5. Significantly greater proportions of pts reported clinically meaningful improvements in FACIT-F (MCID=4) with SIR 50mg q4w and 100mg q2w vs pbo (61.4 and 59.4% vs 43.9%; $P<0.001$). FACIT-F scores ≥normative values were reported by 33% of pts on SIR 50mg q4w and 100mg q2w vs 22% on pbo. HAQ-DI scores at BL were 1.56, 1.50, and 1.52 with pbo, SIR 50mg q4w, and 100mg q2w, with clinically meaningful improvements (MCID= -0.22) reported by 63.0 and 65.4% with SIR 50mg q4w and 100mg q2w vs 46.9% with pbo ($P<0.001$). HAQ-DI scores ≥normative values were reported by numerically more pts receiving SIR 50mg q4w (22%) and 100mg q2w (21%) vs pbo (10%).

Table 1. Improvements in SF-36 Domain Scores at Wk 24 (all $P \leq 0.006$)

Domain	LSM change SIR 50mg q4w	LSM change SIR 100mg q2w	LSM change pbo
Physical function	10.48	12.39	2.85
Role-physical	14.88	16.04	7.96
Bodily pain	19.09	18.98	9.44
General health	8.90	7.53	3.57
Vitality	11.83	11.96	6.37
Social function	13.49	13.25	7.65
Role-emotional	12.50	11.74	6.54
Mental health	9.26	7.97	5.00

LSM, least squares mean.

Figure. SF-36 domains at Wk 24 for SIR 50mg q4w and SIR 100mg q2w

Conclusions: Through 24 wks, SIR treatment resulted in greater improvements in HRQoL than pbo that were clinically meaningful and met or exceeded normative values in DMARD-IR RA pts, with similar effects observed with both doses of SIR.

FRI0247 MEDIAN TIME TO LOW DISEASE ACTIVITY IS SHORTER IN TOCILIZUMAB COMBINATION THERAPY WITH CSDMARDS AS COMPARED TO MONOTHERAPY IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AND INADEQUATE RESPONSES TO CSDMARDS AND/OR TNF INHIBITORS: SUBANALYSIS OF THE SWISS AND AUSTRIAN PATIENTS FROM THE ACT-SURE STUDY

R. Mueller[1], W. Graninger[2], P. Sidiropoulos[3], C. Goger[4], J. von Kempis[1]. *[1]Division of Rheumatology, Kantonsspital St. Gallen, St. Gallen, Switzerland; [2]Division of Rheumatology, Medical University of Graz, Graz, Australia; [3]F. Hoffmann-La Roche Ltd., South San Francisco, United States; [4]Roche Austria GmbH, Vienna, Austria*

Background: To analyze efficacy and safety of tocilizumab in patients with rheumatoid arthritis (RA) and an inadequate response to conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) and/or tumour necrosis factor (TNF) inhibitors of the Swiss and Austrian patients from the ACT-SURE study.
Objectives:
Methods: Sub-analysis of RA patients from Switzerland and Austria, who participated in the international phase IIIb, open-label, ACT-SURE study. Patients with an inadequate response to csDMARDs or TNF antagonists were included into the study receiving 8 mg/kg of IV tocilizumab every 4 weeks during a 24 week time period. Therapy with one or more csDMARDs could be continued as combination therapy with tocilizumab (Combo) or stopped, resulting in tocilizumab monotherapy (Mono), at the treating physician's discretion. These two patient groups were analyzed in separate and compared.
Results: Overall, 107 (22 on Mono vs 85 on Combo and) patients were treated with tocilizumab. The percentage of patients with at least one adverse event was significantly lower in the tocilizumab combination (58.8%) as compared to the monotherapy group (81.8%, p=0.0458). No differences in ACR20/50/70/90 response rates were observed between both treatment groups at week 24 (Mono: 63.6%, 40.9%, 22.7%, and 18.2% vs. Combo: 61.2%, 43.5%, 25.9%, and 10.6%). The median time to low disease activity (LDA) was significantly shorter in patients treated with tocilizumab combination therapy Mono: 9.1, Combo 7.9 weeks, Log Rank p=0.038).
Conclusions: In this post hoc regional sub-analysis of the ACT-SURE study no differences for disease activity were found comparing the two patient groups at week 24. However, median time to LDA was statistically shorter in patients treated with tocilizumab combination therapy as compared to tocilizumab monotherapy. Consequently, adding tocilizumab to csDMARD therapy rather than changing to tocilizumab monotherapy may be, in our opinion, the safest strategy to reach maximum effect in RA patients with active disease despite treatment with csDMARD. csDMARDs can be withdrawn either immediately due to adverse events or after at least low disease activity has been reached.

FRI0248 INCIDENCE OF MELANOMA IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH TOCILIZUMAB

S. Gale[1], J. Wang[2], J.M. Nebesky[3], A.T. Linke[1], E. Berber[1]. *[1]Genentech, South San Francisco, CA, United States; [2]Roche Products, Welwyn Garden City, United Kingdom; [3]F. Hoffmann-La Roche, Basel, Switzerland*

Background: There have been conflicting reports whether patients with rheumatoid arthritis (RA) receiving conventional or biologic immunosuppressive therapies are at increased risk of specific malignancies. Melanoma is an aggressive malignancy with risk factors including sex, age, fair skin and elevated cumulative UV exposure. Interleukin-6 (IL-6) has a role in pro- and antitumorigenic pathways. Whether tocilizumab (TCZ), a biologic that alters IL-6 signaling, increases the risk of melanoma in patients with RA is unclear.
Objectives: This age- and sex-adjusted standardized incidence ratio (SIR) analysis compared the observed reports of melanoma in patients with RA treated with TCZ in clinical trial and postmarketing settings with the expected number of cases across geographic regions.
Methods: SIRs for melanoma were calculated from the TCZ clinical trials all-exposure population. Postmarketing rates were estimated from the TCZ Global Safety Database population. Both databases were searched cumulatively from 11 April 2005 to 10 October 2015. For clinical trials, observed reports of melanoma in patients with RA treated with TCZ were compared with expected number of cases in the general population based on the 2012 US Surveillance, Epidemiology, and End Results using an age- and sex-adjusted SIR. Postmarketing regional SIRs were calculated based on the estimated commercial exposure in each region and the incidence of melanoma as reported by Globocan by age and sex (2012). Crude postmarketing rates were age- and sex-adjusted according to the clinical trial demographic profile to estimate the expected number of cases of melanoma in each region.
Results: In the clinical trial setting, 4 qualifying cases of melanoma were identified among 7093 patients with RA treated with TCZ (20,828 PY of exposure). The SIR estimate (0.71 [95% CI, 0.19–1.81]) for melanoma incidence in patients with RA treated with TCZ in clinical trials was comparable to that in the general population (Table 1). In the postmarketing setting, the number of observed reports of melanoma was comparable to the expected number of cases in Europe and Japan and fewer than expected in North America (Table 2). The exception is Australia, where SIR estimates indicated more than the expected number of cases in patients with RA receiving TCZ in Australia compared with the general population in that region (SIR 3.71 [95% CI: 2.16, 5.93]).

Table 1. Incidence of melanoma in patients with RA from TCZ clinical trials, stratified by sex

Sex	Observed cases[a]	Exposure (PY)	Expected cases[b]	SIR (95% CI)
Female	3	17,047	4.01	0.75 (0.15, 2.19)
Male	1	3781	1.66	0.60 (0.02, 3.35)
All	4	20,828	5.65	0.71 (0.19, 1.81)

[a] The age range of patients in the study cases was 50-64.
[b] Expected cases are based on Surveillance, Epidemiology, and End Results 2012 age-standardized incidence rates.

Table 2. Incidence of melanoma in patients with RA from TCZ postmarketing reports, stratified by region

Region	Observed cases	Region-Specific Exposure (PY)[c]	Expected cases[d]	SIR (95% CI)
Europe	30	126,683	26.6	1.13 (0.76, 1.61)
North America	17	131,546	36.9	0.46 (0.27, 0.74)
Japan	2	121,732	1.5	1.38 (0.17, 4.98)
Australia	17	6,480	4.6	3.71 (2.16, 5.93)

[c] Combined exposure from Europe, North America, Japan and Australia accounts for 86% of the total cumulative postmarketing exposure and for all cases of melanoma at the data lock point of 10 October 2015.
[d] Expected cases are based on region-specific incidence rates in the general population (Globocan 2012).
PY, patient years; SIR, standardized incidence ratio; TCZ, tocilizumab.

Conclusions: In clinical trials, no evidence was found to suggest there were more cases of melanoma than expected in patients with RA treated with TCZ compared with the general population. Consistent with this, no evidence was found to suggest that patients with RA treated with TCZ in Europe, North America or Japan had more cases of melanoma than expected compared with the general population in each region. In contrast, the estimated SIR of melanoma in patients with RA treated with TCZ in Australia indicated more than the expected number of cases in the general population. This finding is consistent with reports of elevated risk of melanoma in patients with RA in Australia (compared with the general population), where UV exposure is high and methotrexate is a common first-line therapy.[1,2]

FRI0249 CIRCULATING FOLLICULAR HELPER-LIKE T CELLS IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH ABATACEPT

S. Piantoni[1], M. Scarsi[2], F. Regola[1], A. Tincani[1], P. Airò[1]. *[1]Rheumatology and Clinical Immunology Unit, Spedali Civili and University of Brescia, Brescia; [2]Internal Medicine Unit, Esine-Vallecamonica Hospital, Esine, Italy*

Background: Rheumatoid arthritis (RA) is characterized by synovial inflammation and, in most cases, by autoantibodies, including rheumatoid factor (RF) and anti-cyclic citrullinated peptide antigen (ACPA), whose presence is associated to a more severe disease. The capability of producing autoantibodies is acquired by B cells with the "help" of specialized T lymphocytes, known as Follicular helper T (TFH) cells, in the germinal centers (GC) of secondary lymphoid tissues. TFH express the inducible co-stimulator (ICOS), and are characterized by a high expression of CXC-chemokine receptor 5 (CXCR5), which mediate their migration into the GC, where its ligand CXCL13 is expressed. Here, TFH promote the GC development and B cell maturation. These cells are reported to exist in greater quantities in the peripheral blood (circulating TFH-like cells) of RA patients.
Abatacept (ABA) is a fusion protein, which through its CTLA4 portion can bind to CD80 and CD86 on antigen presenting cells, thereby inhibiting CD28 costimulation. Data from animal models and phenotypic analysis of circulating T cells in RA suggest that ABA may act in the secondary lymphoid organ, and not directly on the synovium (1,2). While experimental models show that ABA can block the generation of TFH (3), little is known on the effect of ABA on circulating TFH-like cells of RA patients (4).
Objectives: To analyze the effect of the blockade of costimulation performed by

ABA on the levels of circulating TFH-like cells of RA patients.
Methods: 25 RA patients (F/M=18/7; median age (25th-75th percentile): 57 (44–63) years; ACPA+: 16 (64%); RF+: 17 (68%)), treated for at least 6 consecutive months with ABA were evaluated. Circulating TFH-like cells were identified by flow-cytometry as CD4+ICOS+CXCR5+.The response to treatment was evaluated with the EULAR Criteria.
Results: After 6 months of therapy with ABA the percentage of circulating TFH-like cells among total CD4+ T-cells tended to decrease from a median of 1.8 (0.6–3.8) to 0.8 (0.1–2.3) (p:0.07; Wilcoxon signed rank test). The percentage of circulating TFH-like cells at baseline was higher among patient who did not respond to ABA (n.8; 2.6 (2.0–3.6)) than in those who achieved a moderate or good EULAR response (n:17; 1.0 (0.5–5.4)) ($p<0.01$; Mann-Whitney test), but their trend of reduction was similar in the two groups of patients. No difference in the levels of circulating TFH-like cells was found between ACPA+ and ACPA- RA patients.
Conclusions: ABA tends to reduce the number of circulating TFH-like cells in RA patients, suggesting the relevance of costimulation via CD28 in their generation. A higher percentage of these cells is present in patients not responding to ABA. While this observation suggests their possible use as predictors of clinical response to ABA, further studies are deserved to evaluate whether it reflects different localizations of TFH, or functional variability within this T-cell subset in patients with RA.

FRI0250 SERIOUS ADVERSE EVENTS IN PATIENTS WITH RA TAKING ABATACEPT COMPARED WITH OTHER DMARDS BY LINE OF TREATMENT

S.A. Pedro[1], R. Schumacher[1], K. Michaud[1,2]. *[1]National Data Bank for Rheumatic Diseases, Wichita, KS; [2]University of Nebraska Medical Center, Omaha, NE, United States*

Background: Observational studies are critical in assessing medication safety and effectiveness in the real world. Nonrandom assignment can provide insight to how and when medications are prescribed. Since the US introduction of TNF inhibitors (TNFi) in 1998, several newer biologics with varying mechanisms of action are available to patients and physicians.
Objectives: To compare baseline characteristics and serious adverse events (serious infections (SI), malignancies) of patients who received abatacept (ABA) compared to those who received other comparison cohorts: conventional DMARDs (cD) and biologic DMARDs (bD) by line of treatment.
Methods: Participating patients from 2005–2015 with RA in the National Data Bank for Rheumatic Diseases (NDB) provided treatment and other characteristics through self-reported biannual questionnaires. Initiators of ABA were matched to patients initiating other DMARDs in a 1:3 ratio. All patient-reported outcomes were verified by medical record review. ITT (OT) analyses were performed for malignancies (SI). Incidence rates were calculated using Poisson regression (1000 patients–years (pt-yr)). Marginal structural models were used to estimate the effect of treatment on the outcome by an appropriate control for the effects of time-dependent confounders using stabilized weights and reported as hazard ratios (HR). Variables included sex, employment, smoking, education, income, BMI, insurance, comorbidity index, RA severity, and co-medications.
Results: Overall 1496 ABA patients with 2502 (4896) pt-yr of drug exposure (total follow-up time), 1520 cD treated patients with 4330 pt-yr of drug exposure (4816) and 3490 bD treated patients with 9658 pt-yr of drug exposure (11777) were studied (overall mean age 62 years (83% female)). At baseline, the distribution of first line patients in the several cohorts was: 15.2% ABA, for 23.4% bD and 33.8% cD. Switchers were more likely to have longer duration of RA (mean values (yrs): 11.4 for ABA, 8.3 cD; 14.7 bD first line vs. 17.6 ABA; 17.4 cD; 18.0 bD switchers), higher comorbidities, including prior cancer. ABA patients had worse disease compared to cD or bD, both used as first line or as switchers (mean HAQ any line for ABA 1.3 vs 1.0 (1.2) cD or 1.0 (1.3) bD as first line or as switchers).

Table 1. Incidence rates of malignancies and SI for 3 RA treatment cohorts by line of treatment

	ABA	cD	bD
All malignancies			
0	8.2 (1.7–23.9)	8.2 (4.8–13.1)	5.1 (2.8–8.5)
1	6.3 (2.3–13.7)	11.8 (4.3–25.7)	5.0 (2.2–9.8)
2+	8.3 (4.4–14.3)	4.5 (0.1–25.2)	4.7 (1.5–11.0)
SI			
0	3.0 (0.1–16.6)	15.3 (11.2–20.5)	15.1 (11.4–19.5)
1	17.9 (10.0–29.6)	27.2 (16.9–41.6)	18.6 (13.4–25.1)
2+	19.4 (12.0–29.7)	33.1 (16.5–59.2)	23.9 (16.6–33.2)

Excluding patients with prior events, incidence rates of malignancies tended to be uniform by line of treatment but SI seemed to increase with higher exposure of prior biologics, in all cohorts (Table). HR estimates by MSM did not show an increased risk for ABA in comparison with both cohorts, irrespectively of the line of treatment considered.
Conclusions: Differences in baseline characteristics revealed that channeling bias might be present when comparing ABA with other DMARDs and by line of treatment. After adjustment, no overall risk was found for increased risk of cancer and infections.

FRI0251 SIRUKUMAB, AN ANTI-IL-6 CYTOKINE MONOCLONAL ANTIBODY, LEADS TO IMPROVEMENTS IN WORK PRODUCTIVITY AND GENERAL HEALTH STATUS IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS REFRACTORY TO ANTI-TNF THERAPY: RESULTS FROM THE PHASE 3 SIRROUND-T STUDY

Y. Tanaka[1], D. Aletaha[2], S. Peterson[3], R. Ganguly[4], R. Kurrasch[4], S. Popik[3], P. Agarwal[3], N. Li[3]. *[1]University of Occupational & Environmental Health, Kitakyushu, Japan; [2]Division of Rheumatology, Medical University of Vienna, Vienna, Austria; [3]Janssen Research & Development, LLC, Spring House, PA; [4]GlaxoSmithKline, Collegeville, PA, United States*

Background: Sirukumab is an anti–interleukin-6 (IL-6) monoclonal antibody that selectively binds to the cytokine with high affinity and is in development for rheumatoid arthritis (RA) and other diseases.
Objectives: This study evaluated the effects of sirukumab on work productivity/interference and health status in patients with active RA despite treatment with anti-tumor necrosis factor (TNF) therapy.
Methods: In this randomized, double-blind, phase 3 trial, 878 eligible patients with active RA who were intolerant/refractory to anti-TNFs were randomized 1:1:1 to sirukumab subcutaneous (SC) 50mg every 4 weeks (q4w; n=292), sirukumab SC 100mg every 2 weeks (q2w; n=292), or placebo SC q2w (n=294). At Week 18, placebo patients were re-randomized to 1 of the sirukumab doses if insufficient (<20%) improvement; at Week 24, all patients remaining on placebo crossed over to sirukumab. The Work Limitations Questionnaire (WLQ) evaluated health-related job limitations and productivity loss in 4 domains (mental-interpersonal, output, physical demands, time management); the 3-level EuroQol-5 Dimension (EQ-5D) questionnaire measured 5 dimensions of health status (mobility, self-care, usual activities, pain/discomfort, anxiety/depression).
Results: At Week 24, mean total WLQ scores improved significantly from baseline for sirukumab 50mg q4w and 100mg q2w versus placebo (mean change, –2.2 and –2.3 vs 0.2, respectively; both $p<0.001$), as did all 4 mean WLQ domain scores (all $p\leq0.01$). Improvements from baseline in mean total WLQ and all 4 domain scores were maintained through Week 52 for both sirukumab doses. Mean EQ-5D index and health state visual analog scale (VAS) scores improved significantly from baseline at Week 24 for sirukumab 50mg q4w and 100mg q2w versus placebo (mean index change, 0.2 and 0.2 vs 0.0, respectively; mean VAS change, 13.9 and 15.4 vs 4.8, respectively; all $p<0.001$); improvements from baseline were maintained through Week 52 with both sirukumab doses.
Conclusions: Sirukumab treatment led to significant improvements in work-related productivity and general health status in patients with active RA despite anti-TNF therapy, consistent with demonstrated effects of sirukumab on RA disease improvement.

FRI0252 SUMMARY OF NEUTROPENIA IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH SIRUKUMAB IN THE SIRROUND PHASE 3 CLINICAL TRIALS

T. Takeuchi[1], Y. Tanaka[2], M. Schiff[3], M. Harigai[4], K. Brown[5], R. Rao[6], K. Fei[7], S. Popik[7], K. Yoshizawa[8], Q. Wang[7], B. Hsu[7]. *[1]Division of Rheumatology, Keio University School of Medicine, Tokyo; [2]University of Occupational and Environmental Health, Kitakyushu, Japan; [3]University of Colorado School of Medicine, Denver, CO, United States; [4]Tokyo Women's Medical University, Shinjuku-ku, Tokyo, Japan; [5]GlaxoSmithKline, Collegeville, PA, United States; [6]GSK Medicines Research Centre, Hertfordshire, United Kingdom; [7]Janssen Research & Development, LLC, Spring House, PA, United States; [8]Janssen Pharm KK Japan, Chiyoda-ku, Tokyo, Japan*

Background: Neutropenia has been reported with interleukin-6 (IL-6) pathway inhibitors and could potentially be associated with increased rates of infection. The reduced neutrophil counts seen with IL-6 inhibitors may be due to effects on margination of circulating neutrophils as opposed to a decrease in bone marrow production or reduced survival. Efficacy of sirukumab (SIR), a human anti-IL-6 cytokine monoclonal antibody, has recently been shown in several phase 3 trials.
Objectives: To assess incidence of neutropenia from completed and ongoing SIRROUND clinical studies.
Methods: Neutrophil counts were compared for SIR 50mg q4w and 100mg q2w doses vs placebo (pbo) in the pbo-controlled period (Wks 0–18) of 2 phase 3 trials and in long-term analysis for the 5-trial, phase 3 program.
Results: 2926 pts received SIR for up to 3.4y with a median duration of 1.46y. For the 18-wk pbo-controlled period, neutropenia was more frequent in both SIR groups compared with pbo. Across all groups, the majority of the decreases in neutrophil counts were National Cancer Institute Common Terminology Criteria for Adverse Events grade 0/1, within the normal range, and the incidence of grade 3/4 decreases was low across groups (Table). Neutropenia began at Wk 2 and persisted through the study period. In long-term analysis, the proportions of pts with grade 1, 2, or 3 neutropenia were slightly higher than in the 18-wk pbo-controlled period, suggesting the majority of events occurred early. No dose relationship was observed in the grade or frequency of neutropenia. Grade 3/4 neutropenia was mostly transient and resolved after interrupting the dose or resolved within the dosing interval such that no change in dose schedule was required. The majority of grade 4 decreases in neutrophils were not correlated with infections; 2 cases of serious infections occurred with grade 4 neutropenia. The distribution of neutropenia by grade was similar in pts who did or did not use disease-modifying antirheumatic drugs (DMARDs) at baseline.

Table 1. Neutropenia by Maximum Toxicity Grade Across Phase 3 Trials (n, %)

Neutrophil count decreased	0–18 wks			Long-term analysis	
	Pbo (N=850)	SIR 50mg q4w (N=848)	SIR 100mg q2w (N=850)	SIR 50mg q4w (N=1454)	SIR 100mg q2w (N=1461)
Grade 0 (≥LLN)	816 (96.9)	576 (68.3)	568 (67.1)	843 (58.0)	806 (55.2)
Grade 1 (3)	19 (2.3)	149 (17.7)	167 (19.7)	313 (21.5)	352 (24.1)
Grade 2 (<1,500–1,000/mm^3)	5 (0.6)	97 (11.5)	94 (11.1)	222 (15.3)	240 (16.4)
Grade 3 (<1,000–500/mm^3)	1 (0.1)	21 (2.5)	16 (1.9)	68 (4.7)	61 (4.2)
Grade 4 (<500/mm^3)	1 (0.1)	0	1 (0.1)	8 (0.6)	2 (0.1)

LLN, lower limit of normal.

Conclusions: Across phase 3 studies, there was no dose effect of SIR on neutropenia, and the use of DMARDs did not have an apparent effect on neutropenia. The majority of grade 4 neutropenia with SIR was not associated with infections.

FRI0253 PATIENT-REPORTED OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH SUBCUTANEOUS TOCILIZUMAB COMPARED WITH PLACEBO OR INTRAVENOUS TOCILIZUMAB IN COMBINATION WITH CSDMARDS

V. Strand[1], K. Lampl[2], C. Birchwood[2], J. Pei[2], K. Tuckwell[3], R. Finch[3], A. Kivitz[4], G. Burmester[5]. *[1]Stanford University School of Medicine, Palo Alto; [2]Genentech, Inc, South San Francisco, United States; [3]Roche, Welwyn Garden City, United Kingdom; [4]Altoona Center for Clinical Research, Duncansville, United States; [5]Charité-Universitätsmedizin Berlin, Free University and Humboldt University of Berlin, Berlin, Germany*

Background: Two previous randomized, controlled trials (RCTs), BREVACTA and SUMMACTA, showed subcutaneous tocilizumab (TCZ-SC) was superior to placebo (PBO) and comparable to intravenous TCZ (TCZ-IV) in combination with csDMARDs for improving RA disease activity.[1,2]
Objectives: To compare the efficacy of TCZ-SC with PBO or TCZ-IV + csDMARDs for improvement in patient-reported outcomes (PROs) in 2 RCT populations.
Methods: Both RCTs enrolled patients (pts) with inadequate responses to DMARDs; up to 20% had inadequate responses to tumor necrosis factor inhibitors. In BREVACTA, pts received blinded TCZ-SC 162 mg or PBO every 2 weeks (q2w) + csDMARDs for 24 weeks. In SUMMACTA, pts received TCZ-SC 162 mg weekly or TCZ-IV 8 mg/kg q4w + csDMARDs for the 24-week double-blind period. PROs, assessed at 12 weeks (prior to rescue) in BREVACTA and 24 weeks in SUMMACTA, included patient global assessment (PtGA; visual analog score [VAS], 0–100 mm), pain (VAS), Health Assessment Questionnaire Disability Index (HAQ-DI, 0–3) and Short Form-36 (SF-36) physical and mental component summary (PCS, MCS: 0–50) and domain (0–100) scores. The proportions of pts reporting scores ≥ minimum clinically important differences (MCID) and ≥ age/gender-matched normative values were assessed for each treatment group.
Results: Baseline PRO scores were mostly comparable between treatment groups in each study and between study populations. In BREVACTA, significantly more pts who received TCZ-SC reported scores ≥ MCID for all PROs at week 12 compared with PBO (54% to 73% vs 42% to 55%, respectively; number needed to treat [NNT], 5.2 to 13.0). Compared with 1% to 20% at baseline, 8% to 34% of pts who received TCZ-SC and 4% to 25% of PBO pts reported scores ≥ normative values in all PROs at week 12 (Table). In SUMMACTA, similar proportions of pts who received TCZ-SC and TCZ-IV reported scores ≥ MCID in all PROs at week 24 (61% to 84% vs 64% to 84%, respectively). The proportion of patients who reported scores ≥ normative values was comparable between the TCZ-SC and TCZ-IV groups across all PROs; compared with 0.2% to 23% at baseline, 14% to 41% of pts who received TCZ-SC and 15% to 42% of pts who received TCZ-IV reported scores ≥ normative values at week 24 (Table).

Table. PROs at 12 weeks in BREVACTA and 24 weeks in SUMMACTA.

LSM, least squares mean; NNT, number needed to treat; PBO, placebo; qw, weekly; q2w, every 2 weeks; q4w, every 4 weeks.
* $P < 0.05$; ** $P < 0.01$; *** $P < 0.001$.
† Analyses were performed using the intention-to-treat population in BREVACTA (TCZ SC, n = 437; PBO, n = 219) and the per-protocol population in SUMMACTA (TCZ SC, n = 558; TCZ IV, n = 537).
‡ Adjusted for region and body weight category (< 60 kg; 60 to < 100 kg; ≥ 100 kg).

Conclusions: In BREVACTA, TCZ-SC + csDMARDs resulted in significantly greater improvements across all PROs and significantly more pts reporting scores

≥ MCID at week 12 compared with PBO. Similarly, more pts receiving TCZ-SC reported scores ≥ normative values at week 12 compared with PBO, despite few pts with such scores at baseline. Responses were similar between pts treated with TCZ-SC and TCZ-IV + csDMARDs in SUMMACTA at week 24. These data show TCZ treatment resulted in clinically meaningful improvements in PROs and indicate that attainment of normative scores is a realistic goal in treatment of pts with active RA.

FRI0254 EFFICACY OF TOCILIZUMAB FOR SUPPRESSING RADIOGRAPHIC PROGRESSION OF CERVICAL LESIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS COMPARISON WITH METHOTREXATE TREATMENT; TWO YEARS OF FOLLOW-UP ～A MULTICENTER REGISTRY STUDY～

Y. Kanayama[1], T. Kojima[2], Y. Hirano[3], Y. Yabe[4], N. Takahashi[2], Y. Oishi[3], N. Ishiguro[2] on behalf of TBCR study group. *[1]Orthopedic Surgery and Rheumatology, Toyota Kosei Hospital, Toyota; [2]Orthopedic Surgery, Nagoya University Graduate School of Medicine, Nagoya; [3]Rheumatology, Toyohashi Municipal Hospital, Toyohashi; [4]Rheumatology, Japan Community Healthcare Organization Tokyo Shinjuku Medical Center, Tokyo, Japan*

Background: Cervical lesions are known to occur at high frequency as a complication of rheumatoid arthritis (RA). Treatment with biological agents are more clinically effective than the DMARDs that were in use previously, in particular, with their efficacy in suppressing joint destruction having been emphasized. We reported the efficacy of infliximab, anti-tumor necrosis factor antibodies for suppressing the radiographic progression of RA cervical lesions at ACR2009, EULAR2010, 11, 12, 13, 14 and 16. However there is still few studies of efficacy of against RA cervical lesions of Tocilizumab (TCZ), anti-interleukin 6 receptor antibody.

Objectives: To evaluate the efficacy of TCZ for suppressing the radiographic progression of RA cervical lesions comparison with MTX for 2 years.

Methods: We used TCZ or MTX for treating Japanese patients with active RA who fulfilled the ACR criteria in 1987. The final study cohort of each 38 and 71 patients received continuous TCZ and MTX treatment for at least 2 years. For evaluation of cervical lesions, the atlanto-dental interval (ADI), the space available for the spinal cord (SAC), and the Ranawat value were measured by plain lateral radiographs in the flexion position, at initiation and Year 1,2.

Results: In the patients receiving TCZ (n=38) and MTX (n=71), the number of female were each 28 (72%) and 51 (72%) cases (p=0.999). The mean age was 57.3±12.4 and 63.3±10.9 years old (p=0.011); disease duration was 7.0±7.3 and 8.8±9.7 years (p=0.929) and the mean dose of MTX was 9.0±3.4 and 8.3±2.9 mg/w (p=0.335). Clinical findings related to RA were as follows; CRP 3.8±3.1 and 1.5±2.1 mg/dl (p<0.001); ESR 52.7±25.3 and 30.0±20.8mm/h (p<0.001); MMP3 400±300 and 213±356ng/ml (p<0.001); the number of RF-positive 30 (79%) and 58 (82%) cases (p=0.801); DAS28-ESR 5.46±0.92 and 4.24±1.34 (p<0.001); ADI 2.7±1.7 and 2.6±1.6mm (p=0.917); SAC 19.3±2.8 and 20.7±2.5mm (p=0.008) and Ranawat value 15.4±1.6 and 15.9±1.5mm (p=0.073). The respective changes in cervical lesion parameters after 1 year were as follows: ADI: 0.21±0.53 and 0.25±0.44 mm (p=0.327); SAC: –0.16±0.44 and –0.17±0.38 mm (p=0.653); and Ranawat value: –0.13±0.34 and –0.11±0.32 mm (p=0.773). The respective changes in cervical lesion parameters after 2 years were as follows: ADI: 0.32±0.70 and 0.52±0.67 mm (p=0.045); SAC: –0.24±0.49 and –0.45±0.63 mm (p=0.067); and Ranawat value: −0.24±0.49 and –0.35±0.56 mm (p=0.270) in the patients receiving TCZ and MTX (Fig.1). The numbers of patients who did not showed progression in ADI, SAC and Ranawat value were each 30 (79%) and 41 (58%) cases (p=0.035); 30 (79%) and 44 (62%) cases (p=0.087) and 30 (79%) and 49 (69%) cases (p=0.367) after 2 years. Also the number who was able to suppress progression in all three parameters were each 29 cases (76%) receiving TCZ and 41 cases (58%) receiving MTX (p=0.062) after 2 years (Fig.2).

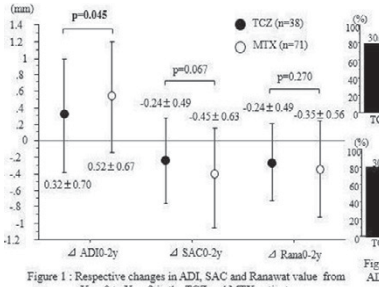

Figure 1 : Respective changes in ADI, SAC and Ranawat value from Year 0 to Year 2 in the TCZ and MTX patients

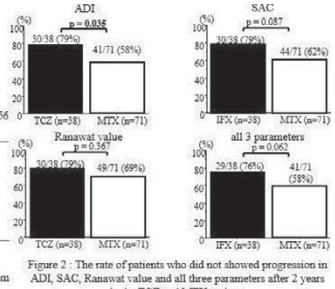

Figure 2 : The rate of patients who did not showed progression in ADI, SAC, Ranawat value and all three parameters after 2 years in the TCZ and MTX patients

Conclusions: This study suggested that TCZ treatment can be used to suppress the progression of RA cervical lesions more than MTX treatment.

SLE, Sjögren's and APS - clinical aspects (other than treatment)

FRI0255 PATTERNS OF DISEASE ACTIVITY IMPACT ON ORGAN DAMAGE IN SYSTEMIC LUPUS ERYTHEMATOSUS

A. Bortoluzzi, M. Padovan, E. Silvagni, C.A. Scirè, M. Govoni. *Department of Medical Sciences, Rheumatology Unit, University of Ferrara and Azienda Ospedaliero-Universitaria Sant'Anna, Cona (Ferrara), Italy*

Background: Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease characterized by fluctuating disease activity in which adverse long-term outcomes remain a major challenge. In the face of extreme individual unpredictability of the disease course over time, four different patterns can be defined, as elsewhere described [1], using SLEDAI-2K (Systemic Lupus Erythematosus Disease Activity Index-2K) excluding serology in order to focus on clinical activity. The patterns are clinical quiescent disease (CQD), chronic active disease (CAD), relapsing-remitting disease (RRD) and minimal disease activity (MDA).

Objectives: The aim of our study was to assess the association between different disease activity patterns and damage accrual in SLE patients.

Methods: Patients with SLE registered at our Lupus Clinic at the Rheumatology Unit, between 1 January 2013 and 1 October 2016, were included. Demographic and clinical variables included age, gender, age at SLE onset, major organ involvement. SDI (Systemic Lupus International Collaborating Clinics/American College of Rheumatology (SLICC/ACR) Damage Index) was categorized as absent (SDI=0) or present (SDI ≥1), Disease activity patterns (CQD, MDA, RRD, CAD) were retrospectively assessed. Drugs used in the treatment of SLE, including hydroxychloroquine, cumulative dose of glucocorticoid (prednisone equivalent >10 g) and other immunosuppressive drugs, were also collected.
Multivariate logistic regression analyses were performed to identify disease patterns associated with damage accrual. Results are presented as odds ratio (OR) and 95% confidence intervals (CI).

Results: A total of 473 Caucasian patients were observed, mainly female (89.4% F, 10.6% M), mean age 52.6 years (± 14.9 SD). In our cohort, the disease activity pattern distribution was as follows: 65.4% CQD (290 pts), 21.5% RRD (91 pts), 6.1% MDA (28 pts) and CAD in 19.1% of the cases (64 pts). Damage was significantly more frequent in CAD subset (81.2%, 52/64 pts) versus 54.5% in CQD (158/290 pts), 50% in MDA (14/28 pts) and 58.2% in RRD (53/91 pts). Compared to a CQD course, CAD pattern was independently associated with overall damage after controlling for factors including gender, disease duration, cumulative glucocorticoid dosage, major individual organ involvement (neuropsychiatric and renal), positive antiphospholipid antibody profile, exposures to cyclophosphamide and hydroxychloroquine (Table 1).

Table1. Logistic regression analysis of independent factors associated with damage in SLE patients

Factors	Crude odds ratio (95% CI)	*P value*	Adjusted* Odds ratio (95% CI)	*P value*
Disease Activity Pattern				
Clinical quiescent disease	**Reference category**		**Reference category**	
Minimal disease activity	0.84 (0.38 - 1.81)	0.650	0.77 (0.33 - 1.80)	0.541
Relapsing-remitting disease	1.16 (0.73 - 1.87)	0.529	1.03 (0.62 - 1.72)	0.900
Chronic active disease	**3.62 (1.86 - 7.07)**	**<0.0001**	**3.07 (1.49 - 6.34)**	**0.002**
Gender (M)	1.23 (0.68 - 2.22)	0.489	1.29 (0.68 - 2.43)	0.434
Disease duration(yr)	1.05 (1.03 - 1.07)	<0.0001	1.03 (1.01 - 1.06)	0.033
NP involvement	2.86 (1.65 - 4.94)	<0.0001	2.11 (1.17 - 3.80)	0.013
Renal involvement	1.35 (0.76 - 2.41)	0.301	0.95 (0.49 - 1.84)	0.877
aPL positivity	1.68 (1.16 - 2.44)	0.006	1.64 (1.09 - 2.47)	0.017
Cumulative dosage of CS (>10g PDN)	2.50 (1.69 - 3.71)	<0.0001	1.64 (1.03 - 2.61)	0.038
HCQ	0.37 (0.24 - 0.57)	<0.0001	0.41 (0.26 - 0.66)	<0.0001
CYC	2.46 (0.97 - 6.25)	0.058	1.89 (0.66 - 5.46)	0.236

* adjusted for: age, gender, disease duration, NP and renal involvement, cumulative dosage of CS; aPL positivity, HCQ, CYC (*NP, neuropsychiatric; aPL, antiphosphlipid; CYC, cyclophosphamide; HCQ, hydroxychloroquine; M,male; CS,corticosteroid; PDN, prednisone*)

Conclusions: Our results demonstrated that a clinically and persistent CAD triples the risk of damage compared to milder or relapsing courses, while hydroxychloroquine appeared to have a "protective" effect. Identifying the prevailing pattern of disease activity in every patient can be translated into a more effective personalized preventing strategy to reduce damage accrual and improve outcomes.

Background: Ultrasonography (US) of salivary glands (USSG) may support diagnosis and evaluation of disease activity in primary Sjögren's syndrome pSS. In order to extent the use of USSG in daily practice, consensus definitions of normal and abnormal USSG findings are needed.

Objectives: To obtain consensual definitions of normal and abnormal USSG findings using a Delphi process.

Methods: Twenty-seven experts participated in the Delphi process. A Likert scale from 1–5 was used in which 1 indicated complete disagreement and 5 complete agreement. Three core items were proposed: 1. Consensus of assessment of SG (parotid gland (PG), submandibular glands (SMG), sublingual glands SLG)). 2. Consensus for elementary lesions of PG, SMG, and SLG changes in PSS patients. 3. Consensus on grading of PG, SM, and SLG in pSS.

Results: The consensus of definitions between experts was reached after three rounds.The results (table 1) showed agreement with more than 75% of agreement in normal and abnormal definitions in SG and concluded to not evaluate SLG in pSS patients as well as to score pSS SG patients with at least two abnormal glands out of 4 (2 PG and 2 SMG) with a scoring system >2 for each abnormal gland.

Conclusions: We developed a consensual US definition of normal and abnormal USGS findings through a Delphi exercise process. This finding will be used as a basis to further proceed with the validation of USGS for clinical application.

FRI0257 URINARY ANGIOSTATIN, CXCL4 AND VCAM-1 AS BIOMARKERS FOR LUPUS NEPHRITIS

C.C. Mok[1], S. Soliman[2], L.Y. Ho[1], F. Mohamed[3], F.I. Mohammed[3], C. Mohan[2]. *[1]Medicine, Tuen Mun Hospital, HK, Hong Kong;[2]Biomedical Engineering, University of Houston, Houston, United States; [3]Rheumatology and Rehabilitation Department, Minya University, Minya, Egypt*

Background: Our preliminary proteomic analysis revealed elevated levels of urinary angiostatin, CXCL4 and VCAM-1 in patients with active lupus nephritis

Objectives: To study the performance of urinary angiostatin, CXCL4 and VCAM-1 in differentiating between active renal and non-renal SLE.

Methods: Patients who fulfilled the ACR classification for SLE with active renal disease, active non-renal disease and inactive disease were randomly recruited, together with a group of healthy controls. Stored urine samples of the participants were assayed for angiostatin, CXCL4 and VCAM-1 and compared among the different groups. ROC analysis was performed to obtain the best cut-off values to calculate the performance of these markers in differentiating among the different groups of patients. SLE disease activity was assessed by the SELENA-SLEDAI and physician's global assessment (PGA). Specificity and sensitivity of these markers in differentiating between active renal and non-renal SLE was determined by 2x2 contingency tables. In patients with active renal disease, correlation between these urinary biomarkers with clinical renal parameters was also performed.

Results: 227 SLE patients (80 inactive SLE; 67 active non-renal disease; 80 active renal disease; 94% women, age 39.2±13.8 years) and 53 controls were studied. Urinary angiostatin, CXCL4 and VCAM-1 levels normalized for creatinine were significantly higher in patients with active renal than non-renal disease (angiostatin 18.4±27.1 vs 1.6±2.91 pg/ng; $p<0.0001$; CXCL 9.11±15.7 vs 5.12±10.4 pg/ng; $p=0.003$; VCAM-1.41±1.31x10^3 vs 0.72±1.10x10^3 pg/ng; $p<0.0001$). The levels of these urinary protein markers were also significantly higher in active SLE patients than inactive SLE patients or healthy controls. Urinary angiostatin, CXCL4 and VCAM-1 correlated significantly with the renal SLEDAI (Rho 0.66, 0.45 and 0.51, respectively; $p<0.001$ in all), total SLEDAI score (Rho 0.60, 0.46 and 0.53, respectively; $p<0.001$ in all) and urine protein-to-creatinine (uPCr) ratio (Rho 0.73, 0.51, 0.59, respectively; $p<0.001$) in all the SLE patients studied. Urinary angiostatin was more specific (specificity 0.82) than elevated anti-dsDNA and low C3 (specificity 0.64 and 0.66) in differentiating active renal SLE from non-renal SLE. In a subset of patients with biopsy proven active lupus nephritis (N=68), these urinary protein markers could not differentiate between proliferative (III/IV) from non-proliferative (I/II/V) types of lupus nephritis. However, urinary CXCL4 (Rho 0.25; $p=0.049$) and VCAM-1 (Rho -0.28; $p=0.02$), but not angiostatin (Rho 0.11; $p=0.39$), correlated significantly with the histologic activity index. There was no significant association between these protein markers and the histologic chronicity index or renal SLEDAI score. On the other hand, urine angiostatin levels (Rho 0.36; $p=0.003$), but not CXCL4 (Rho 0.07; $p=0.59$) or VCAM-1 (Rho -0.11; $p=0.36$), correlated significantly with the uP/Cr ratio in this subgroup of patients.

Conclusions: Urinary angiostatin, CXCL4 and VCAM-1 are potentially useful biomarkers for SLE, in particular lupus nephritis. Further longitudinal studies are necessary to delineate the sensitivity and specificity of these two urinary protein markers in predicting renal flares and prognosis in SLE patients.

FRI0258 LONG-TERM PROGNOSISOFPATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS-ASSOCIATED PULMONARY ARTERIAL HYPERTENSION: CSTAR-PAH COHORT STUDY

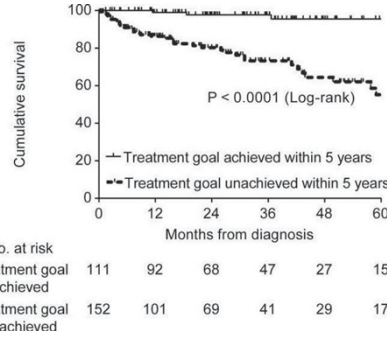
J. Qian[1], M. Li[2], X. Zhang[3], Q. Wang[2], J. Zhao[2], Z. Tian[4], X. Zeng[2] on behalf of CSTAR group. *[1]Internal Medicine; [2]Rheumatology, Peking Union Medical College Hospital, Beijing; [3]Rheumatology, The People's Hospital of Guangdong Province, Guangzhou; [4]Cardiology, Peking Union Medical College Hospital, Beijing, China*

Background: SLE-associated pulmonary arterial hypertension (PAH) is common in Asian countries, and the clinical outcome of patients with SLE-associated PAH is dramatically impaired.

Objectives: This study aimed to identify the long-term clinical outcomes and prognostic factors of patients with SLE-associated PAH confirmed by right heart catheterization (RHC).

Methods: A multicenter cohort of SLE-associated PAH was established. Baseline and follow-up records were collected. The primary endpoint was death from any

Abstract FRI0256 – Table 1



(% of agreement)	Definition of normal US findings	Procedure of scanning	Definition of abnormal US findings	SG to evaluate in pSS	Definition of scoring
Parotid glands	Uniformly echoic texture with a clear delineation from the superficial tissue. Tissue comparable to thyroid parenchyma (81%)	Longitudinal and transverse plane (90%)	Focal or diffuse an/hypoechoic areas (95%)	yes	4-grade semiquantitative scoring system (i.e. grade 0, normal parenchyma; grade 1, minimal change: grade 2, moderate: grade 3, severe: diffuse inhomogeneity occupying all the surface of the gland) (79%)
Submandibular glands	SMG are usually of finer granular echo texture compared to PG or to the normal thyroid parenchyma (89.1%)	Longitudinal and transverse plane (90%)	Idem PG (95%)	yes	Idem PG (79%)
Sublingual glands	SLG has no clear delineation from the superficial tissue because of no true fascial capsule (77%)	longitudinal and transverse plane (77%)	Idem PG (95%)	no	Not useful

cause. The secondary experimental end point was treatment goal achievement (TGA), defined as an integrated outcome.

Results: Among the 310 patients enrolled from 14 PAH centers, the median follow-up was 24.0 months. The 1-, 3- and 5-year survival rates were 92.1%, 84.8% and 72.9%, respectively. The 1-, 3- and 5-year TGA rates were 31.5%, 53.6% and 62.7%, respectively.Serositis, 6MWD >380 m and CI ≥2.5 L/min×m^2 were identified as independent prognostic factors of TGA. TGA within 5 years was identified as a factor associated with survival in patients with SLE-associated PAH (Figure 1).

Table 1. Baseline characteristics of patients with SLE-associated PAH

Characteristics	SLE-associated PAH (n=310)
Age at recruitment, yr	35.0±10.1
Female sex, %	99.4
WHO Fc I-II, %	51.7
6MWD, m	408.6±98.0
NT-proBNP, pg/ml	1660.5±2275.1
SLEDAI	6.1±5.5
mPAP, mmHg	46.5±12.1
CI, L/min × m^2	2.8±0.9
RAP, mmHg	5.8±5.6

Conclusions: TGA was associated with the long-term survival, which supports and provides evidence to the treat-to-target strategy in SLE-associated PAH. Early diagnosis, intervention and heart function preservation are priorities for better long-term outcomes.

FRI0259 LUPUS LOW DISEASE ACTIVITY STATE (LLDAS) IN PATIENTS WITH LUPUS NEPHRITIS (LN)

D.V. Monova, S. Monov, M. Ivanova, E. Peneva. *Department of Internal Medicine, Medical Institute, Sofia, Bulgaria*

Background: Lupus Low Disease Activity State (LLDAS) is a consensus-based definition of minimally acceptable disease activity in patients with Systemic lupus erythematosus (SLE).

Objectives: The aims of this study were to evaluate what proportion of patients with LN fulfils the definition of LLDAS and to evaluate the effect of LLDAS attainment on damage accrual over a period of 5 years.

Methods: This is a retrospective analysis of data prospectively collected in a longitudinal observational cohort of LN patients. The conceptual definition of LLDAS is a state, which if sustained, is associated with good long-term outcomes. The operational definition of LLDAS is fulfilled when all of the following criteria are met: (1) SLE Disease Activity Index (SLEDAI-2 K) ≤4, with no activity in major organ systems (renal, central nervous system, cardiopulmonary, vasculitis, fever) and no haemolytic anaemia or gastrointestinal activity; (2) no new features of lupus disease activity compared to the previous assessment; (3) a Safety of Estrogens in Lupus Erythematosus National Assessment (SELENA)-SLEDAI physician global assessment (PGA) (scale 0–3) ≤1; (4) a current prednisolone (or equivalent) dose ≤7,5 mg daily; and (5) well-tolerated standard maintenance doses of immunosuppressive drugs and approved biologic agents, excluding investigational drugs. The definition of LLDAS was applied to each patient for each visit; organ damage was calculated with the SLICC/DI score (SDI) at study entry and at last observation.

Results: 294 patients were eligible for the study (89.79% females, mean age at first visit 31,4±11,9 years, mean disease duration at last visit 19,8±8,7 years). At last observation 219 patients (85,37%) were on treatment with glucocorticoids (GC) and/or immunomodulators. According with all the items of the definition, at last observation LLDAS was present in 146 patients (49,65%); among these, 37 patients (20,8%) maintained a stable LLDAS during the last 5 years of follow-up (LLDAS fulfilled for all visits). 68 patients (23,12%) accrued organ damage during the follow-up; in the cohort as a whole the mean increase in SDI was 0,4±0.67 resulting in a mean final SDI of 1,2±1,8. Patients who maintained LLDAS were younger (p<0,05), had a lower disease activity score at study entry (p<0,001) and were more likely GC-free at last observation (p<0,001). Patients who maintained LLDAS accrued less organ damage but this difference did not reach statistical significance.

Conclusions: High percentage of patients fulfils the proposed definitions for LLDAS at last visit but only a minority maintained this state for all the follow-up period. A minimally acceptable disease activity state is associated with a successful GC tapering and, probably, better long-term outcomes. LLDAS was shown to be associated with protection from damage accrual.

FRI0260 ULTRASOUND STUDY OF PLEURAL PROFILE AND CHEST HIGH-RESOLUTION COMPUTED TOMOGRAPHY (HRCT): DIAGNOSTIC ROLE IN PRIMARY SJÖGREN'S SYNDROME-INDUCED LUNG INVOLVEMENT

F. Ferro [1], A. Bulleri [2], A. Delle Sedie [1], E. Elefante [1], N. Luciano [1], M. Mosca [1], C. Baldini [1]. *[1]Clinical and Experimental Medicine, Rheumatology Unit, University of Pisa; [2]Radiology Unit, University of Pisa, Pisa, Italy*

Background: Ultrasound pleural irregularity (PI-US) is a novel promising tool for non-invasive diagnosis of interstitial lung involvement (ILD) in connective tissue diseases (CTDs). Few data are available on its diagnostic usefulness in primary Sjögren's syndrome (pSS)-induced ILD.

Objectives: a) To assess the accuracy of PI-US to diagnose ILD in pSS when compared to chest tomography (HRCT) (i.e gold standard imaging technique); b) to explore PI-US diagnostic value in early preclinical phases of lung involvement.

Methods: PI-US was performed by a single operator using a MyLab-25 (Esaote), 10 MHz, 5 cm linear probe. PI was defined as the loss of the normal hyperechoic linear pleural contour (score 0–2: normal, minimal and major changes at each intercostal space). Abnormal findings at HRCT were quantified by an expert radiologist according to a semiquantitative score (0–2: absent, moderate, severe). Semi-quantitative scores assigned by PI-US and HRCT to 6 lung fields (2 for the anterior, 2 for postero-superior and 2 for postero-inferior chest surface) were compared. Total and partial scores (for each lung fields) were evaluated. For statistical analysis chi-square, Mann-Whitney test, R-Spearman, and ROC-curve analysis were used.

Results: *Validation study phase (PI-US vs HRCT):* To validate PI-US technique, we enrolled 32 pSS patients [M/F:5/27; median age (IQR): 67 yrs (51.5–71); median disease duration (IQR): 7 (4–11) yrs; anti-Ro/SSA (+) 78.1%]. To be included patients should have performed a HRCT evaluation within 6 months. Thirteen patients (41%) presented HRCT lesions suggestive for ILD. HRCT total scores and PI-US total scores were strongly correlated (r=0.744, p=0.000). Similarly, PI-US and HRCT partial scores related to the postero-inferior fields showed a strong correlation one to each other (r=0.780, p=0.000). ROC-curve analysis identified a total PI-US score of 28.5 (Youden index) as able to predict HRCT-diagnosis of ILD with a sensitivity (SE) of 84.6% and a specificity (SP) of 89.5%. Analogously, a postero-inferior PI-US score of 12.5 demonstrated a SE of 100% and a SP of 89.5% for the ILD diagnosis. *Prospective study phase exploring the usefulness of PI-US for ILD early pre-clinical diagnosis:* We included 24 consecutive pSS patients without overt respiratory symptoms [M/F:1/23; median age (IQR): 55 yrs (47–67); median disease duration (IQR): 4 yrs (1–12); anti-Ro/SSA (+) 60.9%]. Out of them, at the end of the diagnostic work -up, four new cases of HRCT-proven pSS-ILD were diagnosed. Their PI-US mean total score was significantly higher than that observed in non-ILD patients (48±18 vs 16±12, p=0.001) as well as their mean postero-inferior PI-US score (19±9 vs 6±5, p=0.003). The total PI-US and postero-inferior PI-US cut-off retrieved in the first part of the study (i.e. 28.5 and 12.5) allowed us to identify those patients with an HRCT-proven pSS-ILD with a SE of 75% and 100%, a SP of 95% and 89.5%, a PPV of 75% and 57% and a NPV of of 95% and 100%, respectively.

Conclusions: Even if preliminary, this study demonstrated a strong correlation between PI-US and HRCT in the detection of ILD-pSS also in asymptomatic patients, opening new perspectives for the early non-invasive screening of lung involvement in pSS.

FRI0261 SKIN CANCER IN A COHORT OF SYSTEMIC LUPUS ERYTHEMATOSUS

M. Taraborelli[1], C. Genitori[2], I. Cavazzana[3], M. Fredi[3], A. Tincani[4], P. Calzavara Pinton[2], F. Franceschini[3]. *[1]Internal Medicine Unit, Mellino Mellini Hospital, Chiari (Brescia); [2]Dermatology Unit and Chair, University and Spedali Civili of Brescia; [3]Rheumatology Unit, Spedali Civili of Brescia; [4]Rheumatology Unit and Chair, University and Spedali Civili of Brescia, Brescia, Italy*

Background: Conflicting results about the prevalence of skin cancer in Systemic Lupus Erythematosus (SLE) have been reported in the literature [1,2].
Objectives: The aim of this study was to retrospectively evaluate the prevalence of malignancies, with a particular focus on skin cancers, in a cohort of SLE patients followed in a single Center.
Methods: All the SLE patients classified according to the ACR and SLICC criteria, attending the Rheumatology and Clinical Immunology Unit of Spedali Civili, Brescia, were retrospectively evaluated. Clinical and laboratory data were obtained from clinical charts. Diagnoses of skin cancers (melanoma and non-melanoma: basalioma, squamous cell carcinoma) and other malignancies were recorded together with the time elapsed from diagnosis of SLE. Univariate analysis was performed to compare characteristics of patients with (K+) and without (K-) cancer. We also compared the prevalence of cancer in our population to that reported in the italian general population (from the Italian National Institute of Statistics, ISTAT, report 2014).
Results: In a cohort of 511 SLE patients (92% females,95% caucasian) regularly followed from 1972 to 2016 (mean age at diagnosis 31 years±13 and median follow-up 12 years, range 1–40) we detected 51 cases (9,9%) with a history of malignancy: melanoma was reported in 3 (0.5%), non melanoma skin cancer (NMSC) in 11 (2%) and other malignancies in 38 cases (7.4%). Table I reports the comparison between patients with and without cancer. Patients with cancer, as well as cases with NMSC and non cutaneous malignancies, showed a higher age at disease onset ($p<0.0001$; $p=0.002$ and $p<0.0001$ respectively) and higher SLE damage ($p<0.0001$; $p=0.019$ and $p<0.0001$ respectively) compared with patients without malignancies. Patients with melanoma showed the same age at SLE onset, but a higher prevalence of discoid lupus ($p<0.0001$) and oral ulcer history ($p=0.02$). No difference in serological SLE features or in disease activity were detected between groups. The prevalence of melanoma in our cohort (0.5%) was only slightly higher than the one reported in the northern Italian general population (0.2%), while the prevalence of NMSC (2%) resulted to be significantly higher than that reported in the same population (prevalence of spinocellular and basocellular cancer 0.1% and 0.5% respectively).

Table I Characteristic of Systemic Lupus Erythematosus patients with and without cancer

Variable	All n.511	K+ n. 51	K- n. 460	melanoma n.3	NMSC n. 11	Other tumors n. 38
Male sex, n (%)	40 (8)	1 (1.9)	39 (8.4)	0 (0)	0	1 (2.6)
Mean age at diagnosis (years), (SD)	31.4 (12.7)	41 (14.48)	32 (12.1)	21 (1.5)	43 (18)	43 (12.6)
Mean disease duration, years (SD)	16.31 (9.53)	18 (22)	16 (9.3)	20 (4.5)	15 (11.7)	18 (11.3)
Mean SLEDAI-2K at inclusion (SD)	11.6 (6.02)	12.18 (5.81)	11.6 (6)	17.33 (8.96)	10.3 (2)	12.2 (6)
Mean last SLICC (SD)	1.5 (1.6)	3 (1.85)	1 (1.5)	3.67 (2.8)	2 (1.5)	3 (1.85)
Discoid lupus (%)	32	3 (5.8)	29 (6.3)	3 (100)	0 (0)	3 (7.8)
Acute cutaneous lupus (%)	270 (53)	24 (47)	246 (53.4)	3 (100)	5 (45.4)	17 (44.7)
Photosensitivity (%)	246/502 (49)	21 (41.1)	225 (48.9)	1 (33.3)	5 (45.4)	16 (42.1)
Glomerulonephritis (%)	160 (31)	13 (25.4)	147 (31.9)	1 (33.3)	2 (18.1)	10 (26.3)
Arthritis (%)	298 (58)	34 (66.6)	264 (57.3)	3 (100)	9 (81.8)	23 (60.5)
Oral ulcers (%)	170 (33)	12 (23.5)	158 (34.3)	3 (100)	0 (0)	9 (23.6)
Chronic alopecia (%)	47 (9.2)	5 (9.8)	39 (8.4)	1 (33.3)	1 (9)	3 (7.8)
Pleurisy (%)	81(16)	10 (19.6)	71 (15.4)	0 (0)	4 (36.3)	6 (15.7)
Pericarditis (%)	63 (12)	5 (9.8)	58 (12.6)	0 (0)	2 (18.1)	3 (7.8)
Leucopenia (%)	134 (26)	14 (27.4)	120 (26)	3 (100)	5 (45.4)	7 (18.4)
Lymphopenia (%)	73 (14)	7 (13.7)	66 (14.3)	1 (33.3)	2 (18.1)	5 (13.1)
Thrombocytopenia (%)	91(18)	9 (17.6)	82 (17.8)	1 (33.3)	1 (9)	7 (18.4)
Deep vein thrombosis/ pulmonary embolism (%)	43 (8.4)	4 (7.8)	37 (8)	0 (0)	1 (9)	4 (10.5)
Anti-dsDNA (%)	439 (86)	43 (84.3)	396 (86)	3 (100)	10 (90.9)	31 (81.5)
Anti-ENA (%)	297 (58)	27 (52.9)	270 (58.6)	2 (66.6)	5 (45.4)	20 (52.6)
Antiphospholipid syndrome (%)	70/509 (13.7)	8 (15.6)	62 (13.4)	0 (0)	2 (18.1)	6 (15.7)
Lupus anticoagulant	115/326 (35.3)	14 (27.4)	136 (29.5)	1 (33.3)	3 (27.2)	10 (26.3)
aCL (IgG and/or IgM)	186/458 (40.6)	26 (50.9)	204 (44.3)	0 (0)	6 (54.5)	19 (50)
anti-B2GPI (IgG and/or IgM)	156/413 (37.8)	25 (49)	222 (48.2)	2 (66.6)	3 (27.2)	20 (52.6)

Conclusions: Non-melanoma was the most common skin cancer observed in our SLE cohort. Its prevalence appeared to be higher than that reported in the general poopulation. SLE patients with melanoma showed a higher frequency of cutaneous lupus history compared with other SLE patients.

FRI0262 CLINICAL, LABORATORY AND IMMUNOLOGICAL CHARACTERISTICS OF 413 PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN SOUTH KOREA: A MULTICENTER RETROSPECTIVE COHORT STUDY

E.-K. Park[1], S.-G. Lee[1], J.-H. Park[1], S.-M. Kweon[1], D.H. Sohn[2], Y. Kim[3], G.-T. Kim[3], Y.-S. Suh[4], H.-O. Kim[4], J.-W. Lee[5]. *[1]Internal Medicine, Pusan National University School of Medicine, Pusan National University Hospital, Busan; [2]Microbiology and Immunology, Pusan National University School of Medicine, Yangsan; [3]Internal Medicine, Kosin University College of Medicine, Busan; [4]Internal Medicine, Gyeongsang National University School of Medicine, Gyeongsang National University Changwon Hospital, Changwon; [5]Internal Medicine, Busan St. Mary's Hospital, Busan, Korea, Republic Of*

Background: Epidemiologic studies have described clinical characteristics of patients with systemic lupus erythematosus (SLE) in Middle Eastern Asia and Western countries and marked ethnic and geographic differences in the prevalence, severity and outcome of SLE have been reported. However, data from Northeast Asia countries including South Korea are lacking.
Objectives: To investigate demographic, clinical, laboratory and immunological characteristics and prognosis of patients with SLE in South Korea.
Methods: We retrospectively evaluated 413 SLE patients (380 female, 33 male, mean age 40.6 years) diagnosed at 3 tertiary rheumatology centers in South Korea from 1992 to 2016 by reviewing medical chart. All patients fulfilled 1997 revised American College of Rheumatology classification criteria for SLE and were ethnically Korean.
Results: The mean (±SD) age at disease diagnosis was 30.9 (±12.8) years and the median (IQR) disease duration was 108 (60–168) months. The commonest clinical manifestations in our patients were arthritis (59.1%), fever (49.9%), malar rash (48.4%), alopecia (43.8%) and oral ulcer (35.1%). The frequency of major organ involvement was as follows: biopsy-proven lupus nephritis (40.7%), neuropsychiatric involvement (19.4%), secondary anti-phospholipid antibody syndrome (6.1%) and lupus pneumonitis (1.7%). Class IV (41.1%) was the most common type of lupus nephritis followed by class V (15.5%). Regarding hematologic abnormalities, the cumulative incidence of leucopenia was 74.3%, thrombocytopenia 46.5%, lymphopenia 45.1% and hemolytic anemia 8.7%. Antinuclear antibodies were detected in 97.8%, anti-Sm in 38.4%, anti-dsDNA IgG in 56.5%, anti-cardiolipine IgG in 27.4%, anti-cardiolipine IgM 11.8%, lupus anticoagulant in 23.2%, anti-Ro in 62.3%, anti-La 30.2% and anti-RNP in 47.9%. Twenty (4.8%) patients died during median follow-up of 84 months and the 5-year and 10-year survival rates were 96.9% and 95.5%, respectively (Figure 1). The major causes of death were infection (35%) and diffuse alveolar hemorrhage (20%). In multivariable Cor regression models, male (HR=8.68, $p<0.001$), age at diagnosis ≤16 years (HR=3.33, p=0.033), serositis (HR=3.04, p=0.018) and thrombocytopenia (HR=3.23, p=0.041) were associated with poor survival, while SLE patients with hydroxychloroquine use showed better survival (HR=0.11, p=0.001).

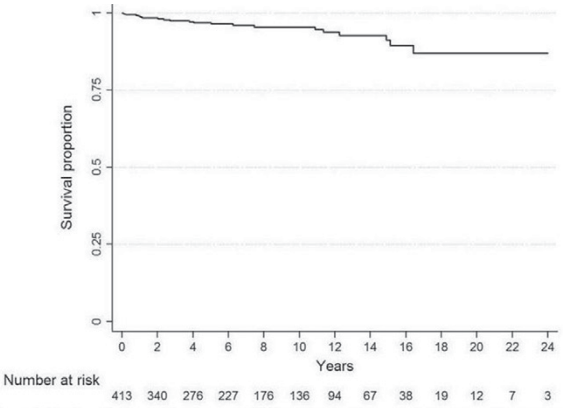

Figure 1. Kaplan-Meier survival curve of 413 patients with systemic lupus erythematosus

Conclusions: Compared with data from other countries, the higher prevalence of hematologic manifestatons and positive anti-Ro antibody were prominent feature of South Korean SLE patients. Overall survival rate in our patients was better than that in other populations.

FRI0263 SYSTEMIC DISEASE ACTIVITY PROGRESSION IN A LARGE COHORT OF PRIMARY SJÖGREN'S SYNDROME: A LONG-TERM FOLLOW-UP DATA BASED ON THE ESSDAI SCORE

L. Quartuccio, S. Zandonella Callegher, S. Gandolfo, C. Fabro, S. De Vita. *Rheumatology Clinic, Udine Hospital Santa Maria della Misericordia, Udine, Italy*

Background: Primary Sjögren's syndrome (pSS) is a chronic slowly progressive

autoimmune disease, which mainly affects the salivary and lachrymal gland function. However, it is an autoimmune systemic disease with a widespread spectrum of systemic manifestations, which are now captured by validated scores (1).

Objectives: The aim of this restrospective study is to evaluate the disease course in a long-term follow-up, by focusing on the accrual of the systemic activity of the disease over time.

Methods: 254 patients suffering from pSS were studied. Mean (standard deviation) age at diagnosis was 52 (13) years. They were 235/254 (92,5%) females. Patients' chart were reviewed in order to compare the baseline ESSDAI score, ie calculated at the diagnosis, with the total ESSDAI accrual, by verifying the new onset ESSDAI domain and/or the worsening in already active ESSDAI domains in the whole available follow-up.

Results: The observation covered 9,1 (6,9) years of follow-up from the diagnosis to the last follow-up visit. The median (range) baseline ESSDAI was 4 (0–31), while the total ESSDAI score accrual up to the last visit was 7 (0–43) ($p<0,0001$, by Wilcoxon). The onset of new ESSDAI domains and/or worsening of already active ESSDAI domains was shown in 136/254 (53,5%) patients, accounting for a total amount of 210 onsets of new domains or worsening in the already active domains [9,1 (95% CI 5,2–27,7) events/100 patients/year]. There was no difference between patients with baseline ESSDAI score <5 and patients with baseline ESSDAI score ≥ 5 (56/103, 54,4% vs 66/121, 54,5%). In only 15/135 (11,1%), the biologic domain was the sole ESSDAI domain, which was worsened or newly recorded. Finally, the ESSDAI domains, which more frequently raised or worsened in the follow-up were haematological (42/210, 20%), biological (37/210, 17,6%), articular (37/210, 17,6%), lymphadenopathy (28/210, 13,3%), and peripheral nervous system (15/210, 7,1%).

Conclusions: Primary Sjögren's syndrome is not a benign disease, a half of patients showing an increasing disease activity, and probably damage, in terms of new onset or worsening of already existing manifestations, even when the disease activity is low at the onset. Importantly, clinically relevant changes over time are much more frequently observed than only biological changes, thus suggesting the need of a careful follow-up by experts, as well as the unmet need of effective treatments, according to disease activity and damage.

FRI0264 EPIDEMIOLOGIC PROFILE OF ERECTILE DYSFUNCTION IN SLE: A MULTI-CENTER STUDY IN LATIN AMERICAN PATIENTS

J. Merayo-Chalico[1], A. Barrera-Vargas[1], S. Morales-Padilla[1], R. Reyna-De la Garza[1], R. Vázquez-Rodríguez[1], M. Sotomayor[2], D. Gómez-Martín[1], J. Alcocer-Varela[1], C. Abud-Mendoza[3], M. Martínez-Martínez[3], I. Colunga-Pedraza[4], C. Uriarte-Hernández[5], I. Acosta-Hernández[6], D. Fajardo[7], C. García-García[8], D. Padilla-Ortíz[9,10]. *[1]Immunology and Rheumatology; [2]Urology, Instituto Nacional de Ciencias Médicas y Nutrición "Salvador Zubirán", Mexico City; [3]Rheumatology, Hospital Central "Dr. Ignacio Morones Prieto", San Luis Potosí; [4]Rheumatology, Hospital Universitario "Dr José e González", Monterrey, Mexico; [5]Internal Medicine, Hospital Metropolitano "Vivian Pellas", Managua, Nicaragua; [6]Rheumatology, Instituto Salvadoreño del Seguro Social, San Salvador, El Salvador; [7]Rheumatology, Instituto Mexicano del Seguro Social, Guadalajara; [8]Departamento de Reumatología, Hospital General de México "Dr. Eduardo Liceaga", Mexico City, Mexico; [9]Internal Medicine, Hospital Universitario de la Samaritana; [10]Internal Medicine, Hospital Militar Central, Bogotá, Colombia*

Background: Although systemic lupus erythematosus (SLE) has a higher prevalence in women, the disease usually has a more aggressive course in men. Information regarding erectile function in men with SLE is quite scant.

Objectives: The aim of this study was to describe the prevalence of erectile dysfunction (ED), as well as associated demographic and clinical features, in men with SLE, by means of a systematic, standardized evaluation.

Methods: We performed a transversal study in eight tertiary care centers in Latin America. We included male patients ≥ 16 years who fulfilled ≥ 4 ACR criteria for SLE, and who had regular sexual activity in the previous 6 months. Patients with other rheumatic diseases (except for APS), chronic viral infections and late-onset SLE were excluded. All patients answered the IIEF-5 Questionnaire, which has been validated in Spanish. Other relevant demographic, clinical and serological characteristics were documented. We included two control groups: the first one was made up by healthy men and the second by men with autoimmune diseases different from SLE (non-SLE group).

Results: We included 279 subjects (174 SLE, 55 non-SLE and 50 healthy controls). The prevalence of ED in SLE group 68% (*vs* 22% in healthy group, p=0.001). The mean age of patients with ED in the SLE group was 36.1±1.03, while in patients without ED it was 32.5±1.27 (p=0.022). Whereas there was no difference regarding ED prevalence between SLE patients and the non-SLE group (68 vs 60%, p=0.25), patients with other autoimmune diseases were 10 years older (46.3±1.60 years, p=0.001).

Among SLE patients with and without ED, the presence of persistent lymphopenia ($\leq$1000cells/mcl at three consecutive times, p=0.006), the prednisone dose (9.3±1.2 vs 5.3±1.2mg, p=0.026), as well as the SLICC damage score (1.2±0.1 vs 0.8±0.1 points, p=0.026), were significantly different. Comorbidities and other demographic, serological and treatment variables were not different between those groups. Multivariate analysis showed the following independent risk factors for ED in SLE patients: persistent lymphopenia (OR 2.79 CI95% [2.79–5.70], p=0.001) and corticosteroid use (any dose) in the previous year (OR 2.15 CI95% [1.37–3.37], p=0.001). Only 7% of patients had been questioned about their sexual function in the previous three visits to the rheumatologist; also, 81% of subjects considered it would be appropriate to be asked about their sexual function.

Conclusions: Regardless of comorbidities, treatment (excluding steroids) and type of disease activity, SLE patients have a high prevalence of ED, especially considering most patients are young and sexually active. Rheumatologists should be aware of the relevance of this problem in male SLE patients and should ask about this issues in regular visits.

FRI0265 CYTOKINES AND CORRELATIONS WITH PATIENT REPORTED OUTCOMES IN SYSTEMIC LUPUS ERYTHEMATOSUS AND POPULATION CONTROLS

S. Pettersson[1,2], H. Idborg[3], S. Eketjäll[4], I. Gunnarsson[3], E. Svenungsson[3]. *[1]Rheumatology unit, Karolinska University hospital; [2]Department of Neurobiology, Care Sciences and Society, Karolinska Institutet; [3]Rheumatology unit, Department of Medicine, Karolinska Institutet and Karolinska University Hospital, Stockholm; [4]Cardiovascular and Metabolic Diseases, Innovative Medicines and Early Development Biotech Unit, AstraZeneca, Integrated Cardio Metabolic Centre (ICMC), Karolinska Institutet, Huddinge, Sweden*

Background: In open questions patients with systemic lupus erythematosus (SLE) report fatigue as the most distressing symptom. Pro-inflammatory cytokines are generally suggested to contribute to fatigue in chronic diseases, however results are contradictory (1, 2). Patient reported outcome measures (PROMs) quantify patients' experiences of qualities like fatigue and depression, which have great impact on both physical and psychological wellbeing. If PROMs are associated with pro-inflammatory cytokine activity in SLE has not yet been well investigated

Objectives: In this study we explored the relationship between a large set of cytokines and self-assessments of fatigue, anxiety, depression and quality of life in a large group of patients with SLE and in matched controls.

Methods: In a cross-sectional setting, persons with SLE and age- and gender-matched population controls responded to PROMs, assessing fatigue (Multidimensional Assessment of fatigue Scale), depression/anxiety (Hospital Anxiety and Depression Scale) and health related quality of life (Medical Short Form 36 (SF-36)). 30 cytokines were analyzed (MSD 30-plex cytokine assay). Spearman's rank correlation coefficient (r_s) between cytokines and PROMs were calculated.

Results: 423 patients, age 46.6 (±15.3) and 315 controls age 47.5 (±14.6) (p 0.43) were included. Of 30 analyzed cytokines 20 gave reliable results and were correlated to PROMs. Five of the cytokines (IL-6, TNF-alfa, IL-15, MCP-1 and MIP-1-beta) correlated best ($r_s \geq 0.37$) with investigated PROMs (table 1). Fatigue correlated with TNF-α (r_s =0.32), IL-15 (r_s =0.31), and MIP-1-beta (r_s =0.32), $p<0.01$ for all. When summarizing SF-36 results we noted a pattern of stronger correlations between investigated cytokines and the physical component than the mental component. Anxiety and depression correlated, but weakly ($r_s<0.25$).

Table 1. Correlations between cytokines and patient reported outcomes

	IL-6	TNF-α	IL-15	MCP-1	MIP-1β
Fatigue	0.28**	0.32**	0.31**	0.29**	0.32**
Anxiety	0.05	0.12**	0.12**	0.06	0.10**
Depression	0.19**	0.25**	0.21**	0.19**	0.21**
Physical Function§	-0.38**	-0.41**	-0.37**	-0.42**	-0.42**
Role Physical§	-0.29**	-0.38**	-0.32**	-0.35**	-0.34**
Bodily Pain§	-0.24**	-0.29**	-0.28**	-0.27**	-0.30**
General Health§	-0.37**	-0.45**	-0.37**	-0.40**	-0.38**
Vitality§	-0.26**	-0.34**	-0.29**	-0.29**	-0.30**
Social Function§	-0.20**	-0.27**	-0.27**	-0.25**	-0.25**
Role Emotional§	-0.12**	-0.24**	-0.18**	-0.16**	-0.16**
Mental Health§	-0.11**	-0.20**	-0.19**	-0.15**	-0.17**
Physical Component Summary score§	-0.39**	-0.43**	-0.38**	-0.42**	-0.41**
Mental Component Summary score§	-0.07	-0.16**	-0.15**	-0.10**	-0.11**

**Spearman correlation is significant at the 0.01 level (2-tailed). §From SF-36.

Conclusions: Most PROMs were positively associated with pro-inflammatory cytokines. Fatigue and PROMs reflecting physical aspect of disease correlated most convincingly, while correlations with mental aspects were weaker.

FRI0266 **COMPARISON OF CLINICAL AND SEROLOGICAL CHARACTERISTICS BETWEEN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS WITH AND WITHOUT ASSOCIATED JACCOUD ARTHROPATHY**

A. Alía Jiménez, W.A. Sifuentes Giraldo, L. Villalobos Sánchez, M.J. García Villanueva, A. Zea Mendoza. *Rheumatology, Ramon y Cajal University Hospital, Madrid, Spain*

Background: Jaccoud arthropathy (JA) is a chronic non-erosive reversible joint disorder commonly associated with systemic lupus erythematosus (SLE), and occurs in roughly 5% of all cases. Some studies suggest different profiles of clinical and immunological features between SLE patients with or without JA.
Objectives: To compare the profile of clinical and serological manifestations of patients with SLE with and without JA followed in a tertiary care hospital of Madrid.
Methods: We performed a retrospective observational study of a cohort of patients diagnosed with SLE (4 or more ACR criteria) between June 1977 and December 2015. The variables evaluated included demographics, clinical, analytical and radiological manifestations. The definition of JA was based on the presence of clinical criteria (reversible joint deformities) and absence of radiographic erosions typical of rheumatoid arthritis. Statistical analysis was performed using SPSS software version 21.0.
Results: We included 108 patients representing a sample of 24% of the total number of patients with SLE treated at our center during that period. The majority of patients were women (89.8%), mean age at diagnosis was 30±12.29 years (range: 7–75) and duration of disease was 127 months (range: 2–411). Thirteen patients (12.03%) had findings compatible with JA. There were no significant differences in age, sex or race, but the duration of disease was higher in JA patients (190 vs. 118.2 months, p=0.0299). There were significant differences in the presence of malar rash (p=0.0009), photosensitivity (p=0.0050), oral ulcers (p=0.0032) and pericarditis (p=0.000001), which were more frequent in patients without JA, but arthritis, nephritis, pleuritis, seizures, psychosis, Raynaud's phenomenon and antiphospholipid syndrome had a similar distribution between both groups. Among the immunological features, no significant difference was found in relation to hemolytic anemia, lymphopenia, thrombocytopenia, ANA, anti-ENA, anti-DNA, anticardiolipin, anti-β2 glycoprotein I and lupus anticoagulant, but leukopenia was also more frequent in patients without JA (p=0.0041).
Conclusions: In the analyzed sample of patients in our center JA was a relatively frequent finding and was associated with a longer duration of the disease. It was not possible to corroborate other JA associations suggested in previous studies such as a lower frequency of lupus nephritis or major secondary antiphospholipid syndrome, probably due to limited sample size, but there are also other studies that do not demonstrate significant differences in relation to clinical and serological findings in patients with SLE with JA with respect to those who do not present it. Studies involving a larger number of patients with JA associated with SLE are required in order to better identify these differences, so a multicenter initiative could be of great help.

FRI0267 **HEMOPHAGOCYTIC SYNDROME IN PATIENTS FROM SLE REGISTRY FROM THE SPANISH SOCIETY O RHEUMATOLOGY (RELESSER)**

A. Lois-Iglesias[1], I. Rua-Figueroa[2], F. deToro-Santos[1], A. Zea-Mendoza[3], J. López-Longo[4], J. Calvo[5], M. Galindo[6], E. Uriarte-Isacelaya[7], J. Pego-Reigosa[8,9] on behalf of EASSER-RELESSER. *[1]University Hospital A Coruña, A Coruña; [2]Hospital Universitario Dr Negrin, Gran Canaria; [3]University Hospital Ramón y Cajal; [4]HGUGregorio Marañón, Madrid; [5]Hospital, Araba; [6]University Hospital 12 de Octubre, Madrid; [7]University Hospital Donostia, Donostia; [8]Hospital Vigo; [9]IISGS, Vigo, Spain*

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune systemic rheumatic disease that, in our area, presents hematologic manifestations in approximately 70% of cases[1]. Some of them are very rare so there are no large series whose analysis could provide relevant information.
Objectives: To study the characteristics of patients with Hemophagocytic Syndrome (HS) in a large sample of SLE patients.
Methods: SLE patients from RELESSER database were studied. We analysed SLE manifestations present at 12 different domains (mucocutaneous, renal, musculoskeletal, constitutional, hematologic, vascular, cardiac, respiratory, neuropsychiatric, gastrointestinal, ophthalmic and serological) before, during and after HS diagnosis and until the last available assessment. We also studied activity (SELENA-SLEDAI) and damage (SLICC/ACR DI) indices at those moments.We evaluated the treatment received, HS recurrences and the number of deaths by this entity.
Results: 3,656 SLE patients (≥4 ACR criteria) from 45 Rheumatology Units across Spain were studied. Seven patients (<0.5%) with HS were identified. 71.4% were women, with a mean age (± S.D.) at SH diagnosis of 35.1 (± 17.1) years. In 5 of the 7 cases the HS occurred 115.5 (± 162.9) months after SLE diagnosis. In the other 2 cases the diagnosis of both entities was simultaneous. The main triggers of HS were infections, followed by SLE activity flares. At the time of HS diagnosis, they had high SLE activity with a mean SLEDAI score of 13.1 (± 11.3) and 1.4 (± 2.3) SDI score.
Clinically, 100% of the patients presented fever and alterations of the liver profile, 85.8% cytopenias and 71.5% dermatological manifestations. Respiratory manifestations and hemolytic anemia were present in 57.2% of the cases, both; lymph nodes and coagulopathy in 42.9%. Hepatomegaly was detected in 28.6%, as well as neuropsychiatric, digestive and renal manifestations. Splenomegaly was detected in 14.3%. The mean hemoglobin level was 8.6 (± 1.1) g/dl, platelets 85,585 (± 83,390)/mm^3, ferritin 7,410 (± 6,470) ng/ml and triglycerides 404.7 (± 235.6) mg/dl. All patients were admitted and undergonebone marrow study, requiring a mean of 2.2 (± 1.5) treatment lines, using 2.8 (± 1.7) drugs. One patient died during the HS episode by the HS itself and another 2 patients had 2 and 3 recurrences, respectively.
The following table shows the characteristics of each patient.

	Patient 1	Patient 2	Patient 3	Patient 4	Patient 5	Patient 6	Patient 7
Number of organ systems affected by SLE before HS diagnosis	9	4	5	5	6	Simultaneous diagnosis of SLE and SH	Simultaneous diagnosis of SLE and SH
Number of organ systems affected by SLE at HS diagnosis	4	1	2	4	2	4	3
Number of organ systems affected by SLE until last assessment	Died	2	2	Follow-up lost	1	5	1
SLEDAI//SLICC-ACR DI at HS diagnosis	4//6	4//0	5//0	29//3	4//1	25//0	21//0
SLEDAI//SLICC-ACR DI 1 year after HS	*	0//0	0//0	*	2//1	0//0	2//13
SLEDAI//SLICC ACR DI at last assessment	*	0//0	0//0	*	0//1	2//0	2//13
Number of treatment lines	1	0	3	2	2	4	3
Number Treatments administered	2 GC and CsA	0	5 GCs, etoposide, iv Ig, CsA, platelets,red cells	3 GC, CYP and iv Ig	2 Amphotericin B, miltefosine	4 GC, iv Ig, CsA, MM	4 GC, Cs A, anakinra and CYP
Relapses	0	2	0	3	0	0	0
Deaths	Yes	No	No	No	No	No	No
Follow-up time (months)	Died	45	80	Follow-up lost	Unknown	26	24

GC:Glucocorticoids, iv Ig: intravenous immunoglobulins,
CYP: Cyclophsphamide, CsA:Ciclosporine A, MM: Mycophenolate mofetil

Conclusions: HS is a rare life-threatening SLE manifestation. It must be suspected in SLE patients with persistent fever who do not respond to antibiotics, cytopenias and evidence of multiorgan involvement. Relapses and death are common in HS associated to SLE.

FRI0268 **ULTRASOUND VS. MAGNETIC RESONANCE IMAGING IN DIAGNOSIS OF PRIMARY SJÖGREN'S SYNDROME**

A. Haidmayer[1], M. Magyar[2], M.H. Stradner[1], T. De Zordo[3], A. Lutfi[4], B. Unger[2], W.B. Graninger[1], J. Hermann[1], C. Dejaco[1]. *[1]Department of Internal Medicine; [2]Department of Neuroradiology, Univ. Klinik Graz, Graz; [3]Department of Radiology, Medical University of Innsbruck, Innsbruck; [4]Department of Radiology, Univ. Klinik Graz, Graz, Austria*

Background: Salivary gland (SG) biopsy is the gold standard for the diagnosis of primary Sjögren's syndrome (pSS). Ultrasound (US) and magnetic resonance imaging (MRI) of the SG are emerging techniques. The comparison of both imaging methods for diagnosis and assessment of functional limitation is yet not well investigated.

Objectives: To assess the accuracy of US and MRI and to define possible cutoff values for the diagnosis of pSS.
Methods: Twenty-three patients with pSS according to AECG criteria and typical histology of the SG biopsy and 12 patients with sicca-syndrome and normal SG histology were included in the study. Two experienced ultrasound experts (C.D. 6y, T.D.Z. 5y) did ultrasound of the SG using a B-mode score (0–48 points [1]) and real-time sonoelastography (RTS; 0–16 pts [2]). Morphology of the parotid glands was also assessed by MRI (0–12 pts). We obtained clinical data (C-reactive protein (CRP), antinucleary-antibodies (ANA), Ro-/La-antibodies, Gamma globulins, patient questionaires ESSDAI and SSDI). The statistically analysis was carried out using Kolmogorov-Smirnov-test, student's t-test, or Man-Whitney-U-test. Correlations were performed using Spearman-rang-correlations.
Results: Patients with pSS had significantly higher B-mode- (average =25 [2–44] vs. 9 [1–20], $p<0.001$) and RTS-scores (6.5 [2–13] vs. 4 [1–9], $p<0.001$) than sicca-patients. The same was also found for MRI-assessment (6,96 vs. 2,33, p=0.001). In a Spearman rank correlation, clinical parameters were linked to the imaging techniques The B-mode showed significant inverse correlations with the Saxon-test (r=-0.505, p=0.002) and a positive correlation with MRI (r=0.792, $p<0.0001$). No correlation was found for the activity scores ESSDAI (p=0.221) or SSDI (p=0.219). The MRI score had an inverse correlation with the Saxon-test (r=-0.523, p=0.001). Both imaging techniques showed no relationship with ESR or CRP. We also generated ROC curves of both imaging methods to define possible cutoff values for the diagnosis. For B-Mode we would recommend a value of 12 points (sensitivity 82,6% and specificity 91,7%) and for MRI 3.5 points (78,3% and 91,7%).
Conclusions: Sonography and MRI detected typical morphological changes in the SG of pSS with high sensitivity and specificity. Both methods could become valuable tools for the diagnosis of pSS.

FRI0269 "IF IT'S NOT MULTIPLE SCLEROSIS, LOOK FOR A CONNECTIVE TISSUE DISEASE": ATYPICAL DEMYELINATING DISORDERS REFERRED TO A TERTIARY RHEUMATOLOGY CENTRE

A. Fanouriakis[1], K. Voumvourakis[2], M. Papathanasiou[3], T. Doskas[4], T. Karageorgas[1], D. Tseronis[1], D. Kassara[1], A. Erden[5], P. Katsimbri[1], D. Boumpas[1]. *[1]Rheumatology and Clinical Immunology, 4th Department of Internal Medicine; [2]2nd Department of Neurology; [3]2nd Department of Radiology, "Attikon" University Hospital; [4]Department of Neurology, Athens Naval Hospital, Athens, Greece; [5]Department of Rheumatology, Hacettepe University, Faculty of Medicine, Ankara, Turkey*

Background: Central nervous system (CNS) demyelination is the hallmark of multiple sclerosis (MS), but may rarely occur in connective tissue diseases (CTD), mainly systemic lupus erythematosus (SLE) and antiphospholipid syndrome (APS).
Objectives: To examine whether patients with demyelinating syndrome and atypical features for MS may exhibit an underlying connective tissue disease.
Methods: Patients referred to the Rheumatology and Clinical Immunology Unit of "Attikon" University Hospital for a demyelinating disorder characterized as "atypical for MS" following neurologic evaluation, were included in the study. All cases were discussed with a neurologist with expertise in MS and CNS magnetic resonance imaging were assessed by an experienced neuroimagist. Cases included either i) a clinical syndrome suggestive of a demyelinating process (demyelinating optic neuropathy, myelopathy, internuclear opthalmoplegia etc.) and/or ii) abnormal imaging of the central nervous system (CNS) with features suggestive of demyelination (ie. presence of supra- and infratentorial lesions, periventricular location, gadolinium enhancement, Dawson's fingers, hypointense T1-lesions ("black holes"), "dirty" white matter). Patients with brain lesions in MRI more compatible with non-specific white matter hyperintensities (WMHI, ie. of possible ischemic/microvascular etiology) were excluded from the study.
Results: 21 patients were included in the study [all women, mean (SD) age at first neurologic manifestation 37.7 (10.6) years]. 17 patients had MRI findings of a demyelinating process in the CNS (brain lesions only in 7, spinal cord lesions only in 4 and both brain and spinal cord lesions in 5 patients); WMHI or normal findings were found in 4 patients with optic neuritis. In this selected group of patients, detailed rheumatologic evaluation revealed clinical and laboratory findings suggestive of a CTD in all patients. The most common findings were: arthritis (80.5%), Raynaud's phenomenon (42.8%), photosensitivity (38.1%), malar rash/erythema (33.3%), livedo reticularis (23.8%) and leukopenia (23.8%). Antinuclear antibodies were positive in two-thirds of patients (66.7%), anti-Ro/La in 19.0% and aPL only in one patient (4.8%). Final diagnoses were undifferentiated CTD, in 10 patients, frank SLE in 9 patients, primary obstetric APS and RA, in one patient each. After a median (range) follow-up of 3 (1–14) years, three patients fulfilled the criteria for MS and received MS-specific therapy, thus were subsequently classified as having an overlap of two diseases.
Conclusions: CNS lesions suggestive of demyelination on MRI must be distinguished from non-specific lesions of microvascular etiology. In cases of demyelinating syndromes not fulfilling criteria for MS, features of an underlying CTD, suggestive of SLE, are frequently found. A small percentage of patients may go on to develop frank MS during follow-up, thus longitudinal monitoring is necessary.

FRI0270 URINARY AND SERUM NEUTROPHIL GELATINASE-ASSOCIATED LIPOCALIN AS A BIOMARKER IN INDIAN CHILDREN WITH SYSTEMIC LUPUS ERYTHEMATOSUS: RELATION TO RENAL INVOLVEMENT AND OVERALL DISEASE ACTIVITY

B. Abujam[1], S. Singh[2]. *[1]Pediatric Allergy Immunology unit, Post Graduate Institute Medical Education Research; [2]PGIMER, Chandigarh, India*

Background: Renal involvement often results in long-term morbidity in childhood Systemic Lupus Erythematosus (cSLE). Neutrophil gelatinase associated lipocalin (NGAL) has been shown to be a reliable structural biomarker for the early diagnosis of kidney injury in many clinical scenarios.
Objectives: This study aimed to detect levels of urinary and serum NGAL and changes in flare and improvement on longitudinal follow up in cSLE in a real world clinical scenario.
Methods: Children <14 years of age attending the Pediatric Rheumatology clinic, fulfilling the 1997 SLE criteria were recruited. Urine and serum samples were collected during routine clinical review and SLE Disease Activity Index (SLEDAI) assessed. Children were divided into 3 categories, active renal, active non-renal and inactive lupus. Active lupus was defined as SLEDAI >4. Urinary and serum levels of NGAL (uNGAL; sNGAL) were assessed by ELISA. Urinary values were normalized for urinary spot creatinine. In addition, some patients were longitudinally followed up and resampled when their disease activity changed.
Results: The study included 122 (F:M =91:31) children, 54 had active renal,14 had active non-renal and 54 had inactive disease. Median (IQR) age was 8.8 (6.5–10.7) years and disease duration was 10 (3–24) months.26 children with nephrotic syndrome and 49 age and gender matched healthy controls were also recruited. Children with active renal lupus had significantly higher uNGAL as compared to other categories.Although sNGAL was significantly higher in active renal as compared to inactive lupus,there was no difference between renal and non-renal active lupus (Table 1). On longitudinal follow up, uNGAL levels increased markedly prior to a flare, significantly higher in renal compared to a non-renal flare ($p<0.05$). On the other hand, active lupus children had a significant fall in their uNGAL on follow up. Their was good correlation between change in SLEDAI and change in absolute uNGAL levels (r =0.84, $p<0.01$). Overall, on ROC analysis, uNGAL classified active renal versus active non-renal and inactive combined with an AUC of 0.986 (95% CI 0.972–1.0). The sensitivity and specificity of a uNGAL cutoff off value of 25750 ng/ml was 96.3 and 91.2% respectively.
Conclusions: Urinary NGAL is a sensitive marker of renal involvement in SLE disease activity and can also be a reliable tool for monitoring renal disease activity changes.

Abstract FRI0270 – Table 1

	Inactive cSLE (n=54)	Active renal cSLE (n=54)	Active non-renal cSLE (n=14)	Healthy controls (n=49)	Nephrotic controls (n=26)
Demographics					
Age (years) (mean±SD)	10.6±3.2	10.9±2.5	10.7±1.9	–	11.0±2.0

FRI0271 PREVALENCE AND ASSOCIATED FACTORS OF DEPRESSIVE DISORDERS IN CHINESE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

C.C. Mok[1], L.Y.T. Lo[2], K.S. Poon[2], C.W. Cheng[2]. [1]*Medicine, Tuen Mun Hospital;* [2]*Psychiatry, Castle Peak Hospital, HK, Hong Kong*

Background: Psychiatric symptoms are common in patients with SLE. Most studies utilized self-rated scales of psychiatric symptoms for evaluation. Formal diagnosis of depression was not established by psychiatric interviews.
Objectives: To determine the prevalence of depressive disorders, severity of depressive symptoms and the associated clinical and socioeconomic factors in Chinese patients with SLE.
Methods: Patients who fulfilled ≥4 ACR criteria for SLE were randomly recruited from rheumatology out-patient clinics and hospital admission in a 9-month period. Psychiatric disorders were diagnosed by a direct interview with the psychiatrist using the Chinese-bilingual Structural Clinical Interview for DSM-IV Axis I disorders, patient research version (CB-SCID-I/P). The severity of depressive symptoms was assessed by the validated Chinese Hamilton Depressive Rating Scale (HAM-D). Patients were also asked to complete the Beck Depression Inventory (BDI), Medical Outcomes Study Social Support Survey (MOS-SSS-C) and the WHO Quality of Life Measure-Abbreviated Version (WHOQOL-BREF, BREF (HK)). SLE disease activity (SLEDAI), organ damage (SLICC/SDI) and socio-demographic were collected and correlated with the presence of psychiatric disorders. Logistic regression models were used to study the independent factors associated with depressive disorders and the severity of depressive symptoms.
Results: 175 SLE patients were studied (95%women, age 39.2±12.4 years, SLE duration 10.3±6.7 years). 27 (15%) and 37 (21%) patients were diagnosed with a current depressive (52%major depressive disorder, 22%dysthymia) or anxiety (35%generalized anxiety, 14%panic, 14%phobia, 8%adjustment) disorders, respectively. Patients with depressive disorders, as compared to those without psychiatric disorders, had more active SLE (p=0.03) and were more likely to have a history of psychiatric diagnosis (p<0.001) and financial assistance from Government (p=0.04). Independent factors associated with a depressive disorder were SLEDAI score (1.13 [1.02–1.24];p=0.02), perceived poor social support (p=0.03) and a past history of psychiatric disorders (p=0.003). Age, disease duration and other socio-economic variables such as educational level and marriage status were not correlated with the presence of a depressive disorder. Being separated/divorced (β=0.19;p=0.02), having a higher SLEDAI score (β=0.16;p=0.02), SLE duration (β=-0.18;p=0.02) and a past history of psychiatric disorders (β=0.18;p=0.01) were independently associated with higher HAM-D scores, which reflect more severe depressive symptoms. Depressive disorders and severity of depressive symptoms were significantly associated with poorer quality of life. ROC analysis showed that a cut-off of 14 points of the self-rated BDI had a sensitivity of 89% and a specificity of 83% for differentiating a current depressive disorder from those without.
Conclusions: A diagnosis of depressive disorders is prevalent in Chinese patients with SLE. Independent risk factors are more active disease, perceived poor social support and a past history of psychiatric disorders. Patients with more active SLE, shorter disease duration, a past history of psychiatric disorders and being separated were associated with more serious depressive symptoms. The self-rated BDI provides a good screening tool for identifying depressive disorders in SLE patients.

FRI0272 EARLY DAMAGE ASSESSMENT AND PREDICTION OF DAMAGE ACCRUAL IN PRIMARY SJÖGREN'S SYNDROME USING SALIVARY GLAND ULTRASONOGRAPHY DURING 2 YEARS OF FOLLOW-UP

C. Baldini[1], N. Luciano[1], C. Seghieri[2], F. Ferro[1], E. Elefante[1], M. Mosca[1]. [1]*Clinical and Experimental Medicine, Rheumatology Unit, University of Pisa;* [2]*Laboratorio Management e Sanità, Scuola Superiore Sant'Anna, Pisa, Italy*

Background: Early detection and prediction of glandular damage in primary Sjögren's syndrome (pSS) is of pivotal importance in patients' stratification and treatment. Recently, ultrasonography (SGUS) has appeared as a promising tool for the assessment of salivary gland involvement in pSS. However, few studies have specifically explored its role in the early identification of salivary gland damage and in monitoring disease progression over the follow-up.
Objectives: a) to explore the contribution of SGUS in the early assessment of pSS-induced glandular damage and in monitoring damage accrual during the follow-up b) to identify predictive factors associated with the development and progression of sonographic changes in salivary glands.
Methods: An inception cohort of 54 pSS (AECG 2002) patients was included in this study at the diagnosis and prospectively followed after 6, 12 and 24 months. Demographic, clinical data and the ESSDAI of the patients were collected at each study visit as well as SGUS score that was calculated every time by the same radiologist. Sonographic assessment of glandular damage was performed by evaluating the size of the parotid and submandibular glands (normal/reduced) and the presence/absence of hyperechoic bands in more than 50% of the glands (i.e fibrosis). Descriptive statistics and logistic regression were used for the data analysis.
Results: We included 54 patients (51F:3 M) with a median duration of symptoms before diagnosis of 11 months (range 36–5 mo) and a median (IQR) ESSDAI at baseline of 5 (1–8). We found that at baseline 13 patients out of 54 (24.1%) already presented one element of damage in their SGUS evaluation, 14/54 (25.9%) more than one element of damage, whereas only 27/54 (50%) of patients did not present any sonographic sign suggestive for damage. In particular, hyperechoic bands were detected in the parotid glands of 12/54 (22%) patients and in the submandibular glands of 21/54 (38.9%); reduced parotid and submandibular gland size were described in 5/54 (9.3%) and in 10/54 (18.5%) of the cases, respectively. Predictive factors associated with sonographic salivary gland damage at the diagnosis were the ESSDAI at baseline (OR =1.13 [95% CI 1.0 to 1.27], p=0.04) and the positivity for Rheumatoid factor (RF) (OR =4.47 [95% CI 1.29 to 15], p=0.02). During the follow-up, 15/54 (27.8%) patients presented a progression of their salivary gland damage. We specifically observed a significant increase in the frequency of reduced parotid (9.3% vs 25.9%, p=0.004) and submandibular gland size (18.5% vs 33.3%, p=0.008) at the end of follow-up. Predictive factors for damage accrual during follow-up were: minor salivary gland focus score (OR =3.5 [95% CI 1.1 to 10.6], p=0.03) and the ESSDAI at baseline (OR =1.64, [95% CI 1.0 to 2.6]p=0.03).
Conclusions: Sonographic assessment of glandular damage apparently revealed a relative high frequency of already established signs of glandular damage in pSS patients at baseline, especially in patients with positive RF and higher ESSDAI. When routinely used, SGUS may accurately allowed to monitor damage accrual over the follow-up, ultimately contributing to a better clinical management of patients.

FRI0273 ROLE OF PROCALCITONIN AND C-REACTIVE PROTEIN IN SCREENING OF INFECTION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

C.H. Ho, A.M.H. Leung. *Department of Medicine, Queen Elizabeth Hospital, Kowloon, Hong Kong*

Background: Previous studies revealed conflicting results regarding the role of procalcitonin in predicting infections in patients with systemic lupus erythematosus (SLE).
Objectives: This retrospective study aimed to analyse the role of procalcitonin (PCT) and C-reactive protein (CRP) in predicting infections in SLE patients, and to determine an optimal cut-off value for PCT and CRP for defining sepsis.
Methods: This study was carried out in one single tertiary centre. Adult patients (>18-year-old) with underlying SLE who were admitted to hospital between 1st Jan 2007 and 31st Dec 2015 were included. Demographic data, PCT and CRP upon admission, and other clinical parameters were obtained. Infection was defined by positive culture, or based on clinical and radiological evidence with subsequent response to antimicrobial treatments. Active SLE disease activity was defined by SLEDAI, and also by SLE-related manifestations not included in SLEDAI. Mann-Whitney test was used to test the difference between numerical parameters between patients with and without infection. Spearman's correlation was used to analyse the correlation between PCT and CRP. Receiver operating characteristic (ROC) curves were plotted to define an optimal cut-off values for PCT and CRP in infection.
Results: 33 (27 female & 6 male) SLE patients were included. Both mean and median age were 42-year-old. Among the 21 septic patients, 9 had active lupus and 12 had inactive disease. All but one of the 12 non-septic patients had active lupus. All 4 patients with underlying renal failure belonged to the infection group. There were 13 and 3 patients on immunosuppressive treatments in infection and non-infection groups respectively.
In patients with infection, mean PCT was 5.74ng/ml and mean CRP was 77.22mg/L. In those without, these were 0.29ng/ml and 20.04mg/L respectively. Both PCT (p=0.014) and CRP (p=0.016) levels were significantly higher in patients with infection than those without. There was no significant difference between the PCT and CRP levels in both septic patients (PCT p=0.862, CRP p=0.247) and non-septic patients (PCT p=1.000, CRP p=0.500) regardless of their SLE disease activity.
PCT level correlated positively with CRP level (r=0.456, p=0.008), but it had no correlation with age (p=0.978), gender (p=0.424), underlying renal failure (p=0.304), steroid (p=0.053) or other immunosuppressants (p=0.132) use.
ROC curves of PCT and CRP showed a similar area under curve (AUC) of 0.756 and 0.752 respectively. The cut-off for PCT was 0.78ng/ml (sensitivity 61.9%, specificity 91.7%), giving a positive predictive value (PPV) of 92.9%. The cut-off for CRP was 9.35mg/l (sensitivity 85.7%, specificity 66.7%), giving a PPV of 81.8%. Combining both PCT and CRP above their cut-offs, the specificity of predicting infection improved to 100% but the sensitivity worsened to 52%.
Conclusions: Both PCT and CRP were useful in predicting infection SLE patients regardless of their disease activity. The cut-off of PCT at 0.78ng/ml and CRP at 9.35mg/l gave satisfactory positive predictive value for infection.

FRI0274 MORFOLOGICAL INDEXES IN LUPUS NEPHRITIS – DO THEY HAVE PROGNOSTIC VALUE?

D. Navarro, A.C. Ferreira, H. Viana, F. Carvalho, F. Nolasco. *Nephrology Department, Hospital Curry Cabral, Lisboa, Portugal*

Background: Lupus nephritis (LN) is a serious complication of systemic lupus erythematosus (SLE). With current therapies, a high remission rate is observed, this being the most important prognostic factor. Currently, therapy is guided by findings in the renal biopsy, following the ISN/RPS classification. Although recommended by EULAR, Austin and Hill's morphological indexes are not routinely obtained.
Objectives: To analyze the importance and applicability of the different morphological indexes in predicting response to treatment and prognosis.
Methods: Retrospective single center study of consecutive SLE and biopsy proven LN patients, diagnosed from 2010 to 2016. We evaluated the following outcomes: clinical remission, renal function and proteinuria at end of follow-up (FUP) (g/24h). Complete remission was defined as a reduction of proteinuria to <0,5g/24h, inactive urinary sediment and serum creatinine <115% of baseline; partial remission same parameters, except proteinuria <1g/24h if initial value <3h/24h, or reduction to <3g/24h if initial value >3g/24h. The studied predictors were the INS/RPS LN classification and the morphological indexes described by Austin (Activity and Chronicity) and Hill, obtained after histomorphological review of renal biopsies. Statistical analysis was performed with STATA software.
Results: During 6 years, there were 46 biopsy-proven LN cases, 84,8% (n=39) woman, median 35 years old (27 – 42,5) and 57,6% (n=19) caucasian. 39 patients were already known to have SLE, 7,44 (1,13 – 12,3) years previously.
The median FUP was 31,9 (13,2 – 45,6) months. Based on biopsy findings, 35 patients were started on immunosuppression – induction in 50% of cases with MMF and in 50% with cyclophosphamide; maintenance in 81% with MMF, the remaining with azathioprine. Complete remission was achieved in 58% of patients, 27% achieving partial remission. We observed 4 LN relapses. 96% (n=44) of the patients survived at the end of FUP, with a median serum creatinine of 0,8 mg/dl (0,7 – 0,99), eGFR 99,8 ml/min (71,2 – 116,8) and proteinuria of 0,6 g/24h (0,2 – 1,6).
We observed that Class IV patients had, at presentation, lower eGFR (67,3 vs 94,6 ml/min; p=0,02), higher proteinuria (4,26 vs 2,37; p=0,02) and a tendency towards higher C3 consumption (58,9 vs 77,4; p=0,06). We did not observe correlations between ISN/RNP Classification and the outcomes at the end of FUP. The correlations between clinical findings and morphological indexes (Hill and Austin) are summarized in table 1:

Table 1

	Hill Biopsy Index		Activity Index		Chronicity Index	
	R	*p*	R	*p*	R	*p*
Anti-dsDNA (IU/ml)	0,2	NS	0,3	0,005	-0,07	NS
C3 (mg/dl)	-0,2	NS	-0,3	0,003	0,1	NS
C4 (mg/dl)	-0,2	NS	-0,3	0,004	0,1	NS
Presentation serum creatinine (mg/dl)	0,3	0,03	0,1	NS	0,3	0,03
Presentation eGFR (ml/min)	-0,5	0,01	-0,3	NS	-0,4	0,004
Presentation proteinuria (g/24h)	0,6	0,001	0,4	0,009	-0,3	0,006
End of FUP serum creatinine (mg/dl)	0,3	0,046	0,07	NS	-0,4	0,002
End of FUP eGFR (ml/min)	-0,2	NS	0,09	NS	-0,5	0,002
End of FUP proteinuria (g/24h)	0,4	0,02	0,2	NS	0,3	0,003

Both the Hill biopsy index and the Chronicity index were correlated with renal function and proteinuria at the end of FUP. The Activity index correlated with the immunological findings – C3, C4 and anti-dsDNA.
Conclusions: EULAR guidelines suggest that histomorphological evaluation in LN should go beyond ISN/RNP classification, and our data supports that – we observed a correlation between the renal outcomes and the indexes described by Austin and Hill.

FRI0275 SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITH POSITIVES AUTOANTIBODIES WITH REMISSION OR LOW ACTIVITY EXHIBIT BOTH LOWER INTERFERON ALPHA AND INTERLEUKIN-10 LEVELS

E. Grau Garcia[1], F.M. Ortiz-Sanjuan[1], M. Fernandez Matilla[2], C.M. Feced Olmos[1], E. Labrador Sánchez[1], N. Fernández-Llanio[2], I. Chalmeta Verdejo[1], K. Arévalo Ruales[1], R. Negueroles Albuixech[1], J. Ivorra Cortes[1], J.J. Fragio Gil[1], I. Martínez Cordellat[1], R. González Mazarío[1], L. Gonzalez Puig[1], C. Alcañiz Escandell[1], C. Nájera Herranz[1], I. Cánovas Olmos[1], E. Vicens Bernabeu[1], J.E. Oller Rodriguez[1], J.A. Castellano Cuesta[2], V. Fornés Ferrer[3], D. Hervás Marín[3], J.A. Román Ivorra[1]. *[1]Rheumatology Department, HUP la Fe; [2]Rheumatology Section, Hospital Arnau de Vilanova; [3]Biostatistics Unit, IIS la Fe, Valencia, Spain*

Background: Systemic lupus erythematous (SLE) is an autoimmune disease characterized by immune system disruption, including T and B cell activation and upregulation of autoantibody and immunocomplexes production that could damage different organs. Sometimes, patients with positives autoantibodies and serological manifestations show low disease activity or clinical remission. There is not enough information about persistent positive autoantibodies in absence of clinical activity neither the role of proinflamatory cytokines in this context.
Objectives: To assess the clinical and molecular differences in SLE patients with positives autoantibodies and with low clinical activity or in clinical remission compared to the group with clinical activity.
Methods: A cross-sectional, observational study of patients diagnosed of SLE according to SLICC 2012 criteria was performed. In these patients a complete blood-test was made, and clinical data by personal interview was collected. We analyzed the serum concentration of IL10, BLyS and INF1A by colorimetric methods. Biostatistical analysis was performed with R 3.3.2.
Results: We selected 130 SLE patients with serological manifestations (defined by RELESSER study) out of 142 SLE patients. 91 cases showed low activity or remission (SLEDAI<6) and 39 presented moderate or high activity (SLEDAI>6). SLE patients with positives autoantibodies without clinical activity showed significantly lower anti-dsDNA levels (P=0.006), lower complement consumption (P=0.003) and lower accumulated damage evaluated by SLICC score (P=0.041). No differences on time of evolution in both groups were observed. In addition, SLE patients with positives autoantibodies without clinical activity exhibit significantly lower levels of IL10 (P<0.001) and INF1A (P=0.019). No differences on BLyS levels in both groups were observed. Finally, SLE patients with positives autoantibodies with clinical activity present more mucocutaneous lesions (P=0.014), musculoskeletal manifestations (P=0.004), neuropsychiatric manifestations (P=0.002), renal manifestations (P<0.001) and lymphopenia (P=0.008) than patients with positives autoantibodies and without clinical activity.
Conclusions: In our series of SLE patients with both serological manifestations and low clinical activity have lower levels of IL10 and INF1A, compared to patients with high clinical activity. This result would suggest that differences in the cytokine levels are not related to autoantibodies presence but there are other mechanisms involved in cytokine production that would also be involved in maintenance of clinical remission.

FRI0276 PREVALENCE OF DEPRESSION BY BECK II AND IMPORTANCE OF FATIGUE BY FACIT IV QUESTIONNAIRES IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS VS CONTROLS IN A SINGLE CENTER OF ARGENTINA

E. Avid, A. Braillard-Poccard, M. Garcia Carrasco, N. Perez, G. Nasswetter, D. Dubinsky. *Rheumatology Division, Hospital de Clinicas Jose de San Martin, Capital Federal, Argentina*

Background: Estimated prevalence of neuropsychiatric symptoms in SLE is among 17 to 71%[1]. Depressive symptoms are around 54%[1,2]. Fatigue is frequently referred, predicts high morbidity and may be influenced by lifestyle and individual psychological characteristics[1].
Objectives: To evaluate the prevalence of depressive symptoms and its association with demographics and clinical variables in patients with SLE. To determine the predictive value of FACIT for fatigue in SLE vs controls.
Methods: Observational, retrospective case- control design. Patients ≥18 years old with SLE (ACR 97) were consecutively evaluated in our centre from January to July 2015. We analyzed age, disease duration, clinical manifestations, antibodies profile, SLEDAI (≥4 scored as active) and SLICC. We recorded familiar psychiatric diseases, educational and socioeconomic level (Graffar Scale), employment and marital status. Beck II and FACIT (IV version) questionnaires were used for evaluate depression and fatigue respectively. We tested two cut points for fatigue:<22 and<40 to determine sensitivity/specificity for this tool in SLE patients vs controls[3]. Continues data were compared using t Student and Mann Whitney. Categorical data: chi-square or Fisher's exact test by SPSS version 20.0. To predic fatigue we calculated the area under the curve by Receiver Operating Characteristic (ROC). Statistical significant= p<0.05.
Results: 77 SLE and 100 controls, all female. *SLE vs control group:* Mean of age ys: 34 (19–49)vs 38 (19–60). Prevalence of depression: 52% (44/77) vs 29% (29/100) (p<0.05). Prevalence of fatigue (FACIT<40): 42% (33/77) and 36% (36/100) (p>0.05). Mean disease duration (months) 48 (24–114). Socio-demographic characteristics, SLICC/SLEDAI, clinical and serological manifestations were not correlated with major depression p>0.05. *FACIT:* Median value: 31 (range 22–40) SLE group. *FACIT<22 total SLE:* 12/77 (15%) and *FACIT<40:* 33/77 (42%). *Cut points FACIT SLE vs controls:* <22: 15% (12/77) vs 1% (1/100) (p<0.05), 30% sensitivity/100% specificity, 100% PPV and 57% NPV. AUC FACIT <22: 0.65 (0.65–0.77). FACIT<40 in SLE vs controls: 42% (33/77) vs 26% (26/100) (p<0.05), 69% sensitivity and 84% specificity, 82% PPV and 70% NPV. AUC FACIT<40: 0.75 (0.64–0.87).
Conclusions: Prevalence of depression was high in our cohort and similar to

previously reported[1]. Our patients showed low levels of SLEDAI/SLICC. There was not relation between activity levels and baseline damage with the presence of depression[4]. FACIT IV scale was a good independent predictor of fatigue in SLE patients with or without depression vs controls.

FRI0277 ANTI-SSA ANTIBODY STATUS IN COMBINATION WITH ULTRASOUND OF MAJOR SALIVARY GLANDS: A SHORTCUT IN THE CLASSIFICATION OF PRIMARY SJÖGREN'S SYNDROME?

E. Mossel[1], K. Delli[2], J.F. Van Nimwegen[1], A.J. Stel[1], F.G.M. Kroese[1], F.K.L. Spijkervet[2], A. Vissink[2], S. Arends[1], H. Bootsma[1] on behalf of EULAR US-pSS Study Group. *[1]Rheumatology and Clinical Immunology; [2]Oral and Maxillofacial Surgery, University Medical Center Groningen, Groningen, Netherlands*

Background: Ultrasound of major salivary glands (sUS) is an upcoming diagnostic method to assess the involvement of major salivary glands in primary Sjögren's syndrome (pSS). In the AECG, ACR and recently published ACR-EULAR criteria, a positive salivary gland biopsy and/or presence of anti-SSA antibodies are necessary to classify a patient as pSS, while sUS is not included as a diagnostic item.
Objectives: To assess whether combining anti-SSA antibody status with sUS outcome can predict classification of patients as pSS in our inception cohort study.
Methods: Consecutive outpatients clinically suspected with pSS underwent sUS of the parotid and submandibular glands. Parenchymal echogenicity, homogeneity, hypoechogenic areas, hyperechogenic reflections and clearness of salivary gland border were scored according to the Hocevar scoring system (total score 0–48).[1] Positive sUS was defined as total score ≥15. Patients underwent a diagnostic work up according to the AECG, ACR and ACR-EULAR criteria. We analyzed the predictive value of the combination of anti-SSA antibody status and sUS outcome for classification as pSS or non-pSS. Separate analyses were done considering either i) parotid gland biopsy or ii) labial gland biopsy as an item, when applying these classification criteria.
Results: Anti-SSA antibody status was positive in 53 (51%) patients and sUS was positive in 40 (39%) patients.
When parotid gland biopsy outcome was considered as an item of the criteria, 45 of 97 patients were classified as pSS according to the AECG, 44 of 97 according to the ACR and 52 of 99 according to the ACR-EULAR criteria. The combination of presence of anti-SSA antibodies with positive sUS showed a very high positive predictive value for classification as pSS (94–97%) and the combination of absence of anti-SSA antibodies with negative sUS highly excludes classification (negative predictive value 98–100%).
When labial gland biopsy outcome was considered as an item of the criteria, 49 of 96 patients were classified as pSS according to the AECG, 43 of 93 according to the ACR and 55 of 97 according to the ACR-EULAR criteria. The combination of presence of anti-SSA antibodies with positive sUS showed a high positive predictive value for classification as pSS (94–97%). However, the combination of absence of anti-SSA antibodies with negative sUS did not per se exclude classification (negative predictive value 89–93%).
Conclusions: In our prospective inception cohort study derived from daily clinical practice, the combination of presence of anti-SSA antibodies and positive sUS outcome highly predicts classification as pSS according to the AECG, ACR and ACR-EULAR classification criteria.

FRI0278 PREVALENCE OF PRIMARY SJÖGREN'S SYNDROME IN A POPULATION-BASED COHORT IN THE UNITED STATES

G. Maciel[1,2], C. Crowson[3], E. Matteson[2], D. Cornec[4,5]. *[1]Maciel Hospital, Montevideo, Uruguay; [2]Rheumatology; [3]Division of Biomedical Statistics and Informatics, Department of Health Sciences Research, Mayo Clinic, Rochester Minnesota, United States; [4]Rheumatology, CHRU Brest, Brest, France; [5]Pulmonary and Critical Care Medicine, Mayo Clinic, Rochester Minnesota, United States*

Background: Different studies worldwide reported highly discrepant estimates for the prevalence of primary Sjögren's syndrome (pSS), ranging from 0.01% of the general population to more than 3%. No previous study reported the prevalence of pSS in the United States.
Objectives: To report the 2015 point prevalence of pSS in the first population-based study performed in the U.S.
Methods: Cases of all potential pSS patients living in Olmsted County, Minnesota on January 1, 2015 were retrieved using the Rochester Epidemiology Project resources, and ascertained by manual medical record review. Definite pSS cases were defined according to physician diagnosis. All patients with doubtful cases and all patients with an associated systemic autoimmune disease were excluded. The use of diagnostic tests was assessed and the performance of classification criteria in this community-based cohort was evaluated. The number of prevalent cases in 2015 was also projected based on 1976–2005 incidence data from the same source population.
Results: A total of 106 patients with pSS were included in the study: 86% were female, with a mean (SD) age of 64.6 (15.2) years and disease duration of 10.5 (8.4) years. A majority were anti-SSA positive (75%) and/or anti-SSB positive (58%), but only 22% met American-European Consensus Group or American College of Rheumatology criteria because the other tests required for disease classification were rarely performed in clinical practice (ocular dryness objective assessment, salivary gland functional or morphologic tests, or salivary gland biopsy). According to the physician diagnosis, age and sex adjusted prevalence of pSS was 10.3/10,000 inhabitants, but according to classification criteria this prevalence would be only 2.2/10,000. The analysis based on previous incidence data projected a similar 2015 prevalence rate of 11.0/10,000. Using figures from the 2015 general U.S. population census, a total of 248,000 patients with pSS (35,000 males and 213,000 females) would currently live in the country. If only cases fulfilling classification criteria are considered, there would be only about 53,000 prevalent cases of pSS in the U.S.
Conclusions: This study reports the first prevalence rate of physician-diagnosed pSS in a well-defined population in the U.S. The estimated prevalence of 10.3/10,000 inhabitants in 2015 is higher than previous results obtained in other geographical areas, probably due to different methodological designs of the studies. Because physicians rarely used tests included in the classification criteria to diagnose the disease in this community setting, current classification criteria do not reflect accurately the diagnosis of pSS in routine clinical practice.

FRI0279 PREVALENCE AND FACTORS ASSOCIATED WITH PRECONCEPTIONAL COUNSELING IN WOMEN WITH AUTOIMMUNE RHEUMATIC DISEASES

G. García-Garza[1], M.A. Saavedra[1], D. Miranda-Hernández[1], A. Sánchez[1], G. García-Collinot[2], R. Bustamante-González[1], L.J. Jara[3]. *[1]Rheumatology; [2]Research Division; [3]Education and Research Direction, Hospital de Especialidades, Cmn la Raza, IMSS, México, Mexico*

Background: Adequate prenatal counseling in women with autoimmune rheumatic diseases (ARDs) may help minimize maternal-fetal complications. However, the available information about the frequency and quality of prenatal counseling given to these patients is limited.
Objectives: To estimate the prevalence of preconceptional counseling and associated factors in women with ARDs.
Methods: A survey was conducted on socio-demographic data, gynecological-obstetric history, and domains related to preconception counseling in women with ARDs at the reproductive stage. It was defined as adequate preconception counseling if the patient knew that the pregnancy should be medically planned, that the complications are associated with severity/activity of the disease, that they should use an effective contraceptive method and that their medications may or may not be used during pregnancy. Descriptive statistics, Student's T test for quantitative variables with normal distribution, Mann-Whitney U test for non-normal and chi-square distribution were used for categorical or ordinal variables.
Results: Of a total of 146 surveys, 131 were analyzed. Only 49 (37.4%) patients received adequate preconception counseling. Two thirds of the patients had systemic lupus erythematosus (Table). The time of evolution of the disease was a factor associated with receiving adequate counseling (5.6 vs 3.6 years, p=0.023). Illness, marital status, and level of education were not factors associated with

	Adequate Counseling (n=49)	Inadequate counseling (n=82)	P value
Age (years) [a]	30.8±7.0	30.5±8.5	0.836
Time of evolution (years)[b]	5.6 (0.25–29)	3.6 (0.25–27)	0.023
Previous pregnancies[b]	1 (0–4)	1 (0–5)	0.192
Rheumatoid arthritis[c]	13 (26.5%)	18 (22%)	0.69
Systemic lupus erythematosus[c]	31 (63.3%)	52 (63.4%)	
Use of contraceptive method[c]	31 (63.3%)	44 (53.7%)	0.282
Use of embryotoxic/teratogenic drugs[c]	39 (79.6%)	34 (41.5%)	0.001
Counseling for a rheumatologist[c]	37 (75.5%)	28 (34.1%)	0.001
Counseling by other doctors[c]	35 (24.5%)	31 (65.9%)	0.197
Professional education[c]	23 (46.9%)	31 (37.8%)	0.616
Married[c]	15 (30.6%)	32 (39%)	0.774

[a]Student's t-test; [b]U of Mann Whitney; [c]Chi square.

adequate counseling. The adoption of a contraceptive method and the number of pregnancies were not different between the two groups. The history of use of embryotoxic/teratogenic drugs was associated with a higher frequency of adequate counseling (79.6% vs 41.5%, p=0.001). According to the patients, adequate counseling was given by the rheumatologist in 75.5% of the cases (p=0.001).
Conclusions: Adequate preconceptional counseling in our patients with ARDs at the reproductive stage is deficient. A multidisciplinary strategy is required to improve the frequency and quality of preconception counseling in patients with ARDs.

FRI0280 ASSOCIATION BETWEEN INSULIN RESISTANCE, SUBCLINICAL ATHEROSCLEROSIS AND ACTIVITY/DAMAGE STATUS IN SLE PATIENTS

H. Sánchez-Pérez[1], B. Tejera Segura[1], M.A. Gonzalez-Gay[2], I. Ferraz-Amaro[1]. *[1]Rheumatology, Hospital Universitario de Canarias, la Laguna; [2]Rheumatology, Hospital Marques de Valdecilla, Santander, Spain*

Background: Insulin resistance (IR) may contribute to an increase in cardiovascular risk in general population as well as in Systemic Lupus Erythematosus (SLE) patients.
Objectives: The aim of this study was to examine the association between IR and disease activity, disease characteristics, drug exposure and subclinical atherosclerosis in patients with SLE.
Methods: Cross-sectional study that encompassed 87 SLE patients and 82 sex-matched controls. IR by homeostatic model assessment (HOMA2), insulin, C-peptide serum levels and lipid profile were assessed in both groups. Activity (SLEDAI), severity (Katz) and damage (SLICC) scores, carotid intima-media thickness (cIMT) and carotid plaques (ultrasound) were assessed in SLE patients. A multivariable regression analysis, adjusted for IR related factors, was performed to evaluate the differences between groups in IR indexes and, in SLE patients, the interrelation between IR and disease activity/characteristics as well as subclinical atherosclerosis.
Results: Median disease duration was 16 years (IQR 9–21). Body mass index, abdominal circumference, hypertension or dyslipidemia did not differ between groups. According to the SLEDAI score, 40% of patients were in no activity, while 32, 21, 18 and 1% were in mild, moderate, high and very high activity respectively. HOMA-IR-C-peptide (beta coefficiente 0.53, [95% CI 0.25–0.82], p=0.00) was increased in SLE patients when compared to controls, as well as HOMA %B C peptide levels (beta coef. 35, 95% CI 18–52, p=0.00). Similarly, insulin sensitivity estimated through HOMA-S% was inferior in SLE patients (-beta coef. -37, 95% CI -63–11, p=0.01).This diferences remained significant even after adjustment for IR related factors.
SLICC damage index was clearly asociated with IR indexes; higher index values were related to higher HOMA-IR-C-peptide (beta coef. 37, [95% CI 16–57], p=0.00) and lower HOMA-S% levels (beta coef. 30%, [95% CI -47–14], p=0.00). Katz severity index showed correlation with HOMA-IR-C-peptide (beta coef.-5, [95% CI -11–0], p=0.04). These associations remained significant after adjustment for age, gender, smoking, hypertension and dyslipidemia, and, in relation with the SLICC index, also after adjustment for prednisone intake. SLEDAI activity index was not related to IR indexes.
The use of prednisone was positively associated with HOMA-IR both when considered binary (beta coef 47, [95% CI 31–63], p=0.00) and continous (beta coef 2 [95% CI 0–5] per mg, p=0.03). Hydroxycloroquine (or other drugs) use was not associated with IR indexes, neither were disease duration, antiDNA titers and complement serum levels.
Carotid plaques were found in 20% of the SLE patients. The presence of carotid plaques was correlated with a higher HOMA-IR-C-peptide (OR 3.15 [95% IC 1.17–8.51], p=0.02), and a higher cIMT value was associated with a lower HOMA-IR-S%>C-peptide (beta coef. 0.98 [95% CI 0.96–0.99], p=0.03). Nevertheless, after adjustment for cardiovascular risk factors this relation was lost.
Conclusions: Activity and damage indexes in SLE patients are independently related to the development of IR. IR is associated with subclinical carotid atherosclerosis in SLE patients on the univariate analysis.

FRI0281 UTILITY OF MORNING SAMPLE OF URINE PROTEIN/CREATININE RATIO FOR ASSESSMENT OF PROTEINURIA IN PATIENTS WITH LUPUS NEPHRITIS

H. Zhang, J. Liang, B. Hua, L. Sun. *Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

Background: Proteinuria is the principal urinary biomarker for the screening of Lupus nephritis (LN) and for monitoring disease progression. 24-hour urine collection has been the foundation for monitoring disease activity in patients with LN, but collections are often inaccurate and inconvenient. The European League Against Rheumatism and American College of Rheumatology have recommended the urine protein/creatinine ratio (UPCR) for use in management of LN.
Objectives: We aimed to evaluate the diagnostic accuracy of the morning sample of UPCR compared with 24-hour urine collection for the detection of proteinuria and to determine the UPCR for different proteinuria ranges in patients with LN.
Methods: Three hundred and thirty seven LN patients were enrolled. The correlation between the UPCR in the morning spot urine samples and urinary protein excretion in the 24-hour collections was examined using the Pearson correlation test. The best cutoffs for UPCR predicting a 24-hour protein excretion were determined with the receiver operating characteristic curve (ROC).
Results: It was found a good positive correlation between the UPCR and 24-hour protein excretion, with a correlation coefficient (r) of 0.891 (Fig 1). The best cutoff which gave the maximum area under the curve was 0.44 for 0.5 g, 0.92 for 1.0 g, 2.21 for 2.0 g, 2.70 for 3.0 g, 3.49 for 4.0 g and 4.59 for 5.0g.

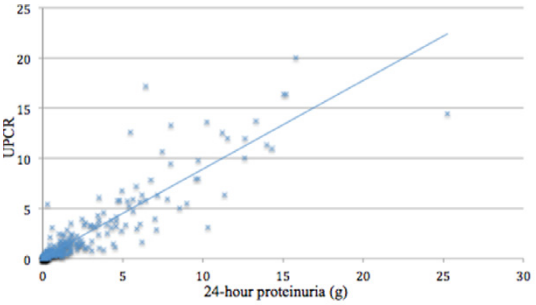

Fig. 1 Scatterplot of correlation between protein content in a 24-hour urine collection sample and morning sample of UPCR

Conclusions: The UPCR can be used as a screening test as a good predictor for proteinuria of LN patients. Also, UPCR is a valuable tool with which to monitor disease progression.

FRI0282 CARDIOVASCULAR DAMAGE IN DECEASED PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

I. Padjen[1,2], M. Erceg[3], M. Cerovec[1,2], M. Mayer[1,2], R. Stevanović[3], B. Anić[1,2]. *[1]Department of Internal Medicine, Division of Clinical Immunology and Rheumatology, University Hospital Centre Zagreb; [2]University of Zagreb, School of Medicine; [3]Croatian Institute of Public Health, Zagreb, Croatia*

Background: Cardiovascular comorbidities are a major contributor of damage in patients with SLE. They are driven by classical, as well as SLE-related risk factors, i.e. disease activity and immunosuppressive treatment.
Objectives: We aimed to analyze cardiovascular damage (CVD) in a group of 90 deceased SLE patients regularly followed-up in a routine academic setting at our Department, and to identify features associated with accrual of CVD.
Methods: We retrospectively observed 90 SLE patients (68 females) deceased within the 2002–2011 period. All patients were ≥18 years of age and Croatian residents at the time of death, fulfilling ≥4 classification criteria of the American College of Rheumatology (ACR). We identified patients with CVD, including the following components of the Systemic Lupus International Collaborating Clinics (SLICC)/ACR damage index: cardiovascular damage as defined by the index (cardiac damage), peripheral vascular damage, cerebrovascular accident, pulmonary infarction, bowel infarction and avascular necrosis. An extensive set of variables was compared between patients with and without CVD: demographics, ACR criteria at diagnosis and death, damage (according to the SLICC/ACR index) and its components one year following diagnosis and at the time of death, disease activity at diagnosis (according to the European Consensus Lupus Activity Measurements index, ECLAM), as well as features of the metabolic syndrome, smoking and immunosuppressive treatment. Frequencies were compared using the χ^2 and Fisher's exact test, and continuous variables using the t-test and Mann-Whitney U test. Variables associated with CVD in the univariate analysis were included in a multivariate logistic regression model.
Results: We identified 63/90 patients with CVD, including 46/63 (73%) with cardiac damage, 19/63 (30%) with peripheral vascular damage, 21/63 (33%)

with cerebrovascular accident, 4/63 (6%) with bowel infarction, 14/63 (22%) with avascular necrosis and a single patient with pulmonary infarction (Figure 1). Patients with CVD had a higher disease duration at time of death compared to patients without CVD (12±8 vs. 7±6 years), as well as higher cumulative proportions of hematologic disorder (60/63 vs. 15/27), lymphopenia (48/63 vs. 10/27), pulmonary damage (19/63 vs. 1/27), fractures (25/63 vs. 2/27), higher overall damage (6.0±3.0 vs. 2.4±2.0) and a higher proportion of secondary antiphospholipid syndrome (14/63 vs. 1/27) ($p<0.05$). Conversely, patients with CVD had a lower proportion of discoid lupus at diagnosis (7/49 vs. 9/24) and a lower proportion of skin damage one year following diagnosis (2/63 vs. 5/27) ($p<0.05$). Parameters associated with cardiovascular damage in the multivariate model were cumulative fulfillment of lymphopenia as a classification criterion (odds ratio, OR 4.7 (95% confidence interval, CI 1.3–17.0)) and accrual of pulmonary damage (OR 13.1 (95% CI 2.2–76.3)).

Figure 1. Distribution of cardiovascular damage in the analyzed group (numbers represent frequencies of each subtype of cardiovascular damage)

Conclusions: More than two thirds of deceased patients accrued CVD over the disease course. Lymphopenia and pulmonary damage may be associated with CVD in deceased SLE patients.

FRI0283 AN IMMUNOLOGICAL PROFILE COMBINING INNATE AND ADAPTATIVE IMMUNITY BIOMARKERS IDENTIFY RISK FOR EVOLUTION INTO SLE IN WOMEN WITH RECURRENT PREGNANCY LOSS

J. Carbone, E. Sarmiento, J.P. Navarro, E. Fernandez-Cruz. *Clinical Immunology, Hospital General Universitario Gregorio Marañon, Madrid, Spain*

Background: Autoantibodies, low complement levels and higher NK cell counts are present in a subset of women with recurrent pregnancy loss (RPL). The combination of these abnormalities might be a surrogate profile for the presence of a subclinical inflammatory or autoimmune condition.

Objectives: In a cohort of women with unexplained RPL we evaluated if an immunological profile combining innate and adaptive immunity mediators was associated with the presence of distinct clinical characteristics that are commonly observed in autoimmune diseases and if it was a risk factor for developing these diseases. In a small subset of women with the immunological profile we evaluated the activation status of CD4+ and CD8+ cells.

Methods: We evaluated 366 women with RPL defined as 2 or more pregnancy losses and 93 control women. We defined the immune profile as the presence of 2 or more of the following abnormalities: Peripheral blood NK cell percentages >15%, positive antiphospholipid antibodies, positive antinuclear antibodies, positive anti-thyroid antibodies, low complement C3 levels and low C4 complement levels. Evolution to autoimmune diseases was detected during follow-up. Lymphocyte subsets were evaluated by flow-cytometry. Statistics: Chi-square test. Logistic regression.

Results: The prevalence of women with 2 or more immunological abnormalities was 57 out of 366 women (15.6%) and was significantly higher than in control women. Demographic clinical characteristics were similar in women with 2 or more immunological abnormalities as compared with women with only one immunological alteration or no abnormalities. The presence of the immunological profile was significantly associated with the presence of the following clinical characteristics: Leucopenia (p=0.048), lymphopenia (p=0.007), livedo reticularis (p=0.01), cutaneous rash (p=0.009), and arthritis (p=0.001). During follow-up 17 patients (4.6%) developed an inflammatory or autoimmune disease that was not present at the time of the diagnose of RPL including SLE and lupus like disease. Women with the immunological profile were at higher risk for evolution into these diseases: OR 4.19, 95% confidence interval 1.52–11.51, p=0.0055. In 10 women with the immunological profile we observed significantly higher levels of CD4+DR+ and CD8+DR+ T-cells as compared with women without the immune profile.

Conclusions: A subgroup of women with unexplained RPL are at risk of developing clinical characteristics of an inflammatory or autoimmune disease. In this regard, the immunological evaluation of women with RPL might be necessary not only to identify a potential cause of abortion but also to identify women that could require a more careful clinical follow-up. Higher CD4+DR+ and CD8+DR+ T-cells might be a pathogenic pathway leading to development of autoimmune diseases in RPL women.

FRI0284 PREDICTORS OF ARTERIAL VASCULAR EVENTS IN A COHORT OF SYSTEMIC LUPUS ERYTHEMATOSUS

J.-G. Erdozain[1], I. Villar[2], J. Nieto[2], I. Ruiz-Arruza[1], J.-I. Pijoan[3], G. Ruiz-Irastorza[1]. *[1]Unidad de Investigacion de Enfermedades Autoinmunes-Servicio de Medicina Interna. BioCruces Health Research Institute. Universidad del País Vasco/Euskal Herriko Unibertsitatea; [2]Servicio de Medicina Interna; [3]Unidad de Investigación. Unidad de Epidemiología Clínica y Soporte Metodológico. BioCruces Health Research Institute., Hospital Universitario de Cruces, Barakaldo-Vizcaya, Spain*

Background: Arterial vascular events (AVE) are among the major causes of morbidity and mortality in patients with Systemic Lupus Erythematosus (SLE). Several studies have been carried out to identify the main factors related to AVE in this population. The ankle brachial index (ABI) is one of the tools currently used to identify patients at greater risk of arterial events in the general population; however it has been scarcely studied in patients with SLE.

Objectives: The objectives of this prospective cohort study were to determine the predictive value of the ABI for occurrence of AVE in patients with SLE and to identify other possible factors associated with an increased risk of AVE.

Methods: 216 patients with SLE were evaluated using an ABI and followed up for 5 years. Pathological ABI is considered an ABI <0.9. Different potential vascular risk factors (traditional, non-traditional and related to SLE and/or the treatments used) were jointly evaluated. AVE: coronary events (angina pectoris, acute myocardial infarction, coronary revascularization by angioplasty or surgery), cerebrovascular events (transient ischemic attack, cerebrovascular accident), peripheral arterial disease (symptomatic intermittent claudication, distal ischemia, revascularization by angioplasty or surgery), and death related to vascular disease. Survival analysis was performed using a competitive risk regression approach, considering non-vascular death as a competitive event, to identify the predictive value of ABI and other factors studied. The Ethical Committee for Clinical Research at Cruces University Hospital approved the study protocol in accordance with the Declaration of Helsinki (CEIC E09/07). All patients signed an informed consent at the time of entry into the study.

Results: During follow-up, 4/216 (1.8%) patients were lost to follow-up. 18 AVE were identified in 17 patients, with one patient having 2 episodes of angina requiring angioplasty (4 coronary events, 11 cerebrovascular events, 2 peripheral arterial disease events and 1 sudden death) and 14 deaths (6 per AVE or their sequelae, 4 due to neoplasias and 4 due to cardio-respiratory pathology). In the competitive risk regression analysis, independent predictors of higher risk of AVE were identified: pathological ABI (subhazard ratio (SHR) 3.51, 95% confidence interval 0.96–12.79, p=0.057), family history of AVE (SHR 6.3, 95% CI 1.97–20.21, p=0.002), cumulative total prednisone (grams) (SHR 1.02, 95% CI 1.01–1.04, p=0.004) and a history of arterial thrombosis (SHR 4.60, 95% CI 1.45–14,59, p=0.010).Female gender was a protective factor for the occurrence of AVE (SHR 0.12, 95% CI 0.04–0.40, $p<0.0001$).

Conclusions: Being male, having a higher cumulative dose of prednisone, having a family history of early vascular disease and having suffered previous arterial thrombosis are independent risk predictors of an AVE in patients with SLE. Having abnormal ABI, even without statistical significance, showed a marked tendency to increase this risk despite the low number of events recorded in the studied cohort.

FRI0285 LUPUS NEPHRITIS IS ASSOCIATED WITH INCREASED RATES OF HOSPITALIZATION AND IN-HOSPITAL MORTALITY COMPARED WITH NON-RENAL LUPUS AND MATCHED CONTROLS: AN ANALYSIS OF INSURANCE CLAIMS DATA

K.A. Belendiuk, H. Trinh, M.D. Cascino, L. Dragone, D. Keebler, J. Garg. *Genentech, Inc., South San Francisco, CA, United States*

Background: Systemic lupus erythematosus (SLE) is heterogeneous in its clinical presentation, course, and prognosis and lupus nephritis (LN) continues

to be a major cause of morbidity and mortality among children and adults with SLE. Up to 60% of adult and 80% of pediatric SLE patients (pts) will eventually develop overt renal disease [1]. To date the excess burden of comorbidities, risk of inpatient hospitalization, and in-hospital death associated with SLE and LN remains incompletely understood.

Objectives: To identify differences in comorbidities, hospitalizations, and in-hospital mortality of SLE and LN cohorts compared to: 1) each other; 2) reference populations of pts without an autoimmune condition (non-AI) matched on gender and age. Reference populations were allowed to have claims for non-autoimmune conditions.

Methods: We conducted a retrospective cohort study using the Truven Healthcare MarketScan® Commercial Claims and Encounters and Medicare Supplemental and Coordination of Benefits database, which together comprise 65 million insured US lives between 1999 and 2014. Cohort identification is based on validated algorithms [2, 3] for identification of pts with either LN or SLE without renal involvement using claims data. Pts were matched on age and gender at index date. All eligible participants had 365 days of enrollment prior to and after the index date. End of study for post-index follow-up was captured as whichever of the following occurred first: 1) end of enrollment; 2) end of database; 3) date of death. Results are presented separately for pediatric and adult pts.

Results: 54,813 SLE pts without renal involvement and 8,839 LN pts were identified and matched to reference non AI populations. Compared to the non-renal SLE cohort, pts in the LN cohort were older (49.9±16.6 vs. 48.6±14.3 years) with a higher proportion of males (15.4% vs. 11.2%). Pts with LN had the highest scores on the Charlson Comorbidity Index modified to exclude renal involvement (Table 1). Additionally, adults with LN had higher rates of hospitalizations and longer hospitalizations compared with adults with non-renal SLE, who already had higher rates of hospitalizations and longer hospitalizations than matched controls (Table 2). This pattern of findings was consistent for children. Rates of in-hospital mortality were highest among those with LN but also increased among those with SLE compared with matched controls (Figure 1).

Figure 1: Rates of in−hospital mortality by group and age

Conclusions: An SLE diagnosis was associated with a higher burden of comorbidities and higher rates of hospitalizations and in-hospital mortality than non-AI matched controls. Pts with LN had the highest burden of comorbidities and rates of hospitalizations and in-hospital mortality. SLE and LN impose a high burden of morbidity and mortality and the medical need for safe and effective treatments of LN and SLE remains unmet. Clinicians should consider these factors in their assessment and treatment of pts with SLE and LN. The retrospective, claims-based results do not permit pt-level assessment of the relative contributions of disease, treatment, and potential confounders to these findings.

FRI0286 SEROLOGICAL EVOLUTION IN PATIENTS WITH THROMBOTIC ANTIPHOSPHOLIPID SYNDROME

L. Riancho-Zarrabeitia[1], S. García-Canale[1], M. Cubería[1], G. Daroca[1], M. Agudo[1], M. López-Hoyos[2], P. Muñoz[1], V. Martínez-Taboada[3]. *[1]Hospital Universitario Marqués de Valdecilla, Santander, Spain; [2]Immunology; [3]Rheumatology, Hospital Universitario Marqués de Valdecilla, Santander, Spain*

Background: Antiphospholipid syndrome (APS) is an autoinmune disease characterized by the presence of antiphospholipid antibodies (aPL) and at least one clinical event (thrombosis and /or pregnancy morbidities). The titers of aPL can fluctuate and eventually become negative. This negativization, particularly if persistent, may be associated with a lower frequency of clinical events.

Objectives: To describe the clinical and serological course of patients with thrombotic APS as well as the factors related with the aPL negativization

Methods: We performed a retrospective study including patients attended at the Rheumatology clinic from a tertiary hospital in Northern Spain. We included 94 patients with thrombotic APS according to Sidney criteria of 2006. They were classified according to the serological evolution as persistently negative aPL, transiently positive, and persistently positive aPL according to previously established criteria.

Results: After a mean follow-up of 145±56 months, 48.9% of patients presented a persistently negative serology, whereas in 12.8% it was transiently positive, and persistently positive in 38.3%. When analyzing potential factors related to the negativization (table 1), we found that patients with positive lupus anticoagulant tended to have a persistently negative serology during follow-up, but it did not reach statistical significance (OR 2.7; 95% CI 0.8–9.4; p=0.145). We found no association between traditional cardiovascular risk factors or previous treatments and the serological evolution.

Variable	Total	Persistently negative (n=46)	Persistently positive and transiently positive (n=48)	P
Age	45±16	44±14	47±17	0.33
Male sex, n (%)	19 (21)	8 (18)	11 (24)	0.61
SLE, n (%)	25 (27)	12 (26)	13 (27)	1
Load of antibodies, n (%)		0.94		
1	29 (31)	15 (33)	14 (29)	
2	40 (43)	19 (41)	21 (44)	
3	25 (27)	12 (26)	13 (27)	
Anticardiolipin antibodies, n (%)	76 (81)	36 (78)	40 (83)	0.60
Antiβ2-GlycoproteinI antibodies, n (%)	59 (63)	27 (59)	32 (67)	0.52
Lupus anticoagulant, n (%)	35 (66)	18 (78)	17 (57)	0.14
Family history of thrombosis, n (%)	17 (31)	10 (40)	7 (24)	0.25
Tobacco use, n (%)	41 (44)	21 (46)	20 (42)	0.83
Hypertension, n (%)	45 (48)	21 (46)	24 (50)	0.69
Dyslipidemia, n (%)	43 (46)	21 (46)	22 (46)	1
Diabetes, n (%)	4 (4)	2 (4)	2 (4)	1
Antimalarials, n (%)	34 (36)	16 (35)	18 (37)	0.83
Heparin, n (%)	34 (36)	16 (35)	18 (37)	0.83
Oral anticoagulants, n (%)	68 (72)	33 (72)	35 (73)	1
Antiplatelets, n (%)	71 (76)	33 (73)	38 (79)	0.63
Corticosteroids, n (%)	5 (5)	2 (4)	3 (6)	1
Immunosuppressants, n (%)	4 (4)	1 (2)	3 (6)	0.36

Conclusions: After a mean follow-up of 12 years, 49% of thrombotic APS patients presented a persistently negative serology. We found no significant association between immunological, traditional cardiovascular risk factors or previous treatments and the persistently negative serology.

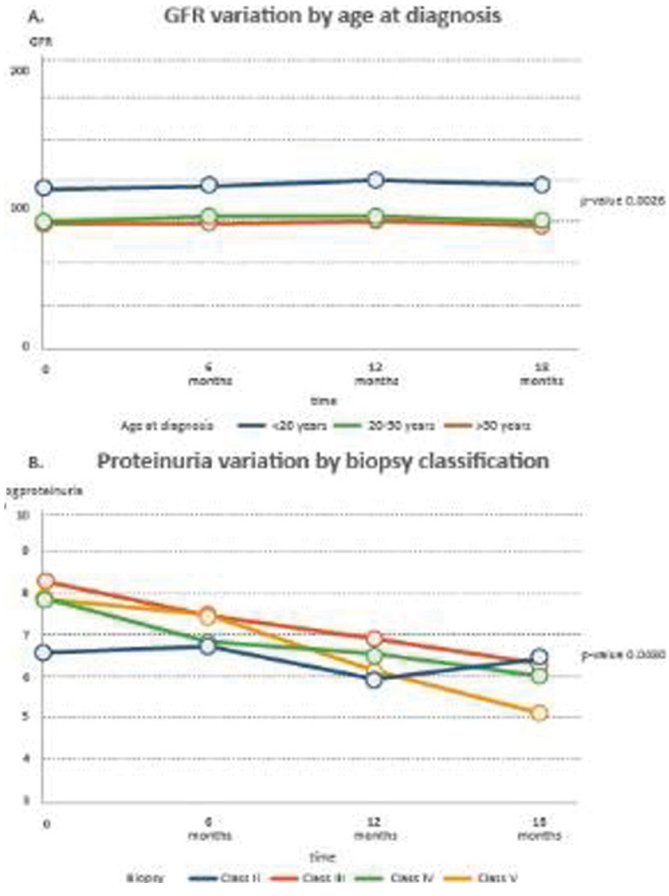
FRI0287 INCIDENCE OF LUPUS NEPHRITIS AND 18-MONTH FOLLOW UP IN COLOMBIAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS



M.A. Alzate[1], D. Hernandez-Parra[1], J.C. Salazar-Uribe[2], P. Ortiz-Salazar[1], R. Pineda[1] on behalf of Artmedica IPS, Medellin, Colombia. *[1]Clinical information group, Artmedica IPS; [2]School of Statistics, Faculty of Sciences, National University of Colombia, Medellin, Colombia*

Background: Lupus nephritis (LN) is one of the major indicators of poor prognosis in patients with systemic lupus erythematosus (SLE). Multiple studies with Latin-

American SLE population have shown a higher prevalence of LN, higher severity, and less favorable outcomes (1).
Objectives: To determine the incidence of lupus nephritis and end-stage renal failure, as well as evaluate progression of renal function and proteinuria during an 18-month follow up in colombian patients with SLE.
Methods: A retrospective cohort study was conducted in 1448 patients with SLE, 41 of which were diagnosed with LN between August/2014 and July/2015. Follow up was made for 18 months, analyzing glomerular filtration rate (GFR) and proteinuria, induction and manteinance therapy, renal relapses, hospitalizations and mortality. Univariate analysis was done to describe sociodemographic and clinical variables. Longitudinal data analysis was performed using linear mixed models with random intercepts. In all cases, a p value <0.05 was considered statistically significant.
Results: Clinical characteristics of patients with LN are shown in table 1. Eighty-five percent of LNs where biopsy-proven. Incidence of LN was 2,83 cases/100 SLE patients/year. The incidence of end-stage renal failure was 7,31 cases/100 LN patients. During the 18-month follow up, 34% of patients had hospitalizations related to SLE activity or complications, 7,3% renal relapse, 2,4% rebiopsy, and no mortality cases. Induction therapy was done with cyclophosphamide in 58,5% and with mycophenolate mofetil in 41,4%, with 30% of the patients requiring re-induction therapy, Ten percent of patients required use of rituximab due to refractory response to multiple treatments. In longitudinal linear analyses, age at diagnosis and anti dsDNA was positively associated to GFR variations (Figure 1,A), while anti Sm, hematologic involvement and biopsy classification were associated to proteinuria variations during time of follow-up (Figure 1,B).
Conclusions: In a real life scenario, anual incidence of lupus nephritis was 2,83 cases/100 SLE patients. A high proportion of patients with refractory response to multiple immunomodulatory treatments for LN were identified.

Table 1. Clinical characteristics of patients with lupus nephritis

Characteristic (N=41)	Mean (SD)
Age	37,2 (11,2)
Age at diagnosis	32,2 (11,1)

FRI0288 NAILFOLD CAPILLAROSCOPIC PICTURES IN A COHORT OF UNDIFFERENTIATED CONNECTIVE TISSUE DISEASE (UCTD) PATIENTS AND IN THOSE THAT MOVE TO SYSTEMIC LUPUS ERYTHEMATOSUS

M. Meroni[1,2], C. Pizzorni[1], A. Sulli[1], M. Limonta[2], M. Cutolo[1]. *[1]Research Laboratory and Academic Division of Clinical Rheumatology, Internal Medicine Dept., University of Genova, Genova; [2]Rheumatology Unit, ASST Papa Giovanni XXIII, Bergamo, Italy*

Background: Nailfold capillaroscopy (NVC) is a useful, non-invasive, reproducible and cost-effective diagnostic tool, able to assess the shape of capillaries in the nailfold bed. According to the presence of peculiar abnormalities, it is essential in the early differential diagnosis of connective tissue diseases (CTDs), mainly "scleroderma-spectrum disorders" (SSD). Despite its large diffusion, no univocal NVC patterns have been ascribed to undifferentiated connective tissue disease (UCTD) as well as to systemic lupus erythematosus (SLE).
Objectives: The aim of the study was to evaluate the most common NVC pictures in a population of UCTD patients and if selected NVC pictures might be linked to SLE onset in these patients.
Methods: We evaluated a cohort of 42 UCTD-affected women, diagnosed according to 2014 criteria proposed by Mosca et al. (age, 38 years±46 months; duration of disease, 71±54 months) presenting Raynaud's phenomenon. During the observational period (3 years), all of the UCTD patients were evaluated every 6 months. We considered the following NVC parameters/pictures: presence of ectasic capillary loops (diameter $\geq$20 μm); giant capillaries (diameter $\geq$50 μm); hemosiderin deposits/microhemorrages; capillary number reduction; meandering capillaries (tortuosity); elongated capillaries; ramified/bushy capillaries; micro-vascular array disorganization. SLE diagnosis was posed according to the 2012 SLICC/ACR criteria. Qualitative variables were expressed in frequencies; their association, by non-parametric tests; quantitative variables, by analysis of co-variance.
Results: Non-specific NVC alterations (for instance, not suggestive of SDD) were detected in 40 (98%) of the UCTD patients during the observational period. On the other hands, the presence of hemosiderin deposits, ectasic loops, elongated and ramified capillaries was found associated to the clinical subgroup of UCTD patients that later developed SLE (4/42 subjects, 10%; OR=10.5). In particular, the independent variables "hemosiderin deposits/microhemorrages" (OR=8.32) and "elongated capillaries" (OR 6.28), were found significantly linked to the SLE onset ($p<0.05$), whereas the independent variables "tortuosity" (OR=12.16) and "ramified/bushy capillaries" (OR 9.47) were, at the opposite, predictive for the prosecution of the status of UCTD patient ($p<0.05$).
Conclusions: The present study reports NVC pictures that can be more frequently observed in UCTD patients that include "tortuosity" and "ramified/bushy capillaries". In addition, the NVC analysis suggests the presence of typical capillaroscopic microvascular abnormalities, "hemosiderin deposits/microhemorrages" and "elongated capillaries", that more frequently seem observed in those UCTD patients that move to SLE onset.

FRI0289 CEREBROVASCULAR DISEASE IN THE ANTIPHOSPHOLIPID SYNDROME

M. Estévez, A. Argibay, L. Rodriguez, M. Freire, B. Gimena, J. Fernández-Martín, A. Rivera. *Systemic Autoimmune diseases and Thrombosis Unit, University Hospital Complex of Vigo, Vigo, Spain*

Background: Antiphospholipid syndrome (APS) is a thrombophilic disorder characterized by recurrent arterial and venous thrombosis, and also pregnancy losses associated to antiphospholipid antibodies (APA). Cerebrovascular disease (CVD) is the most common and severe arterial thrombotic manifestation in patients with APS.
Objectives: 1.To determine the prevalence and the type of CVD in patients with APS. 2.To compare the recurrent strokes, affected brain areas, hospitalization, treatment and mortality between patients with CVD, with and without APS.

Abstract FRI0289 – Tabe 1

	Age	OAC	APT	Vascular risk factors	Valvular disease	Brain stem	Frontal lobe	Strokes (≥2)	Mortality	Follow-up
CVD with APS	57,48±21,52	48%	20%	80%	20%	0%	12%	44%	40%	8,64±6,72
CVD without APS	61,16±20,6	0%	72%	68%	0%	20%	36%	16%	44%	2,04±2,99
	p 0,76	p<001	p<001	p 0,33	p 0,02	p0,02	p 0,04	p 0,03	p 0,77	p<001

Methods: Retrospective and, descriptive study of patients with APS (Sidney criteria) and CVD followed for a long period of time in a specific Systemic Autoimmune Diseases and Thrombosis Unit. Subsequently, retrospective case-control study was performed. Case definition: patients with CVD attributable to APS. Control definition: patients with CVD without APS. The controls were matched with cases by sex and age (within the same decade). Chi-square and t-student were used, using the statistical package SPSS22.0.
Results: 25 patients (25/88 28,4%) had CVD, 19 (76%) of primary APS and 6 (21%) of secondary APS. 17 patients (71,6%) were female. The mean age was 57,48±21,52 [range 13–89], with a mean follow-up of 8,64±6,72 years. 24% of patients had atrial fibrillation, 80% had one cardiovascular risk factor and 48% had two or more factors (hypertension 68%, hypercholesterolemia 36%, diabetes 20%, tabaquism 4%). Echocardiographic study was performed in 72% of patients with APS. Mitral valve was mainly involved. Most CVD were ischemic events (92%). The brain areas most involved were the basal ganglia (36%), together with the parietal and temporal lobe (16% respectively). 40% had two or more affected regions. 44% of the patients had two or more episodes of stroke. Lupus anticoagulant was positive in 40%, anticardiolipin antibodies in 76% and anti-β2 glycoproteinI antibodies in 20%.No differences were found with isotypes of APA and recurrent thrombosis or mortality. The treatment applied was oral anticoagulants (OAC) (48%), antiplatelet therapy (APT) (20%) and low molecular weight heparin (20%). In 10 patients (40%) CVD was diagnosed before APS (mean 8.64±6.7 years). The mortality was 44% and 40% of the patients were hospitalized more than once. When we compared the groups: treatment, performed echocardiogram, valvular disease, affected brain areas, recurrent strokes and follow-up time, revealed significant differences (see table 1).OAC were more used in the patients with APS and APT was the most common in control group. Valvular disease was more frequent in case group. The brainstem and the frontal lobe were the areas more affected in patients without APS.The number of strokes was higher in APS group. The patients with CVD and APS had a long-term follow-up.
Conclusions: The prevalence of CVD in our series of APS was 28.4% and most often were ischemic events. Most of the patients were women with high recurrent strokes and mortality. No differences were found with isotypes of APA and recurrent thrombosis or prognosis. CVD with APS patients had more recurrent strokes and longer follow-up.

FRI0290 INTERLEUKIN 10 GENE POLYMORPHISMS IN PRIMARY SJÖGREN SYNDROME IN A TUNISIAN POPULATION

M. Tougorti[1], A. Kallel[2], I. Ben Ghorbel[1], R. Jemaa[2], M.H. Houman[1], N. Kaabachi[2]. *[1]Internal Medicine; [2]Biochemistry, Rabta university hospital, Tunis, Tunisia*

Background: Primary Sjögren syndrome (PSS) is one of the most common auto-immune systemic rheumatic diseases although its prevalence anging between 0.6 and 1.7%. PSS affects exocrine glands and lead to sicca syndrome. Interleukin-10 (IL-10) is a pleiotropic cytokine that is involved in the inflammation process of PSS.
Objectives: The aim of our study was to determine in a Tunisian population, clinical and biological characteristics of patients with primary PSS, allelic and genotypic frequencies of (-1082G/A, -819 C/T and -592 C/A) polymorphisms in IL-10 gene and to evaluate the association of these polymorphism with PSS.
Methods: The population we studied consisted of 242 subjects with female predominance (average age at diagnosis =49 years), divided into 84 PSS patients (fulfilling the revised AECG criteria 2002 and/or ACR proposed criteria 2012),recruited in the internal medicine department of the Rabta hospital and 158 controls recruited in the Greater Tunis. Il 10 level was assessed by ELISA. Polymorphisms genotyping of the IL-10 gene was done using PCR-RFLP technique.
Results: Il10 plasma level was lower in PSS patients (23.71pg/ml, n=73) compared to healthy volunteers (42.27pg/ml, n=60) and the difference was statistically significant (p=0.01).
The genotype frequencies of our population respected Hardy-Weinberg equilibrium distribution both in patients by primary SS than in controls. In PSS patients, the genotype frequencies of -592C/A are 53% for the CC genotype, 41% for the CA and 6% for the AA genotype. In controls these frequencies are respectively 60.3%, 32.9% and 6.8%. The genotype frequencies of -1082 G/A are 29.6% for the AA genotype, 63% for the AG and 7.4% for the GG genotype. In controls these frequencies are respectively 41.5%, 52.1% and 6.3%.
The genotype frequencies of -819 C/T are 47.6% for the CC genotype, 43.9% for the CT and 8.5% for the TT genotype. In controls these frequencies are respectively 41.5%, 52.1% and 6.3%.
No significant differences in genotypic frequencies were observed between cases and controls in the three polymorphisms.
Statistical analysis preformed revealed that there was neither protective nor aggravating hapoltype. However ATC haplotype seems to have a protective impact in controls (p=0.06 and OR=0.20)
Conclusions: IL10 level was significantly higher in PSS patients in precedent studies (1) (2). In our case Il10 level was associated with PSS in Tunisian patients but it was statistically lower than controls. Our results show that the three polymorphisms of gene of IL-10 are not a marker of SGS in the Tunisian population. This result might be explained by allelic variation or ethnic group.

FRI0291 CD4 AND CD8 COUNT IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS – ASSOCIATIONS WITH INFECTION AND DISEASE ACTIVITY

H. Baharuddin[1], N. Zainudin[2], A. Ahmad[2], A. Rosman[2], M. Mohd Zain[2]. *[1]Rheumatology, Universiti Teknologi MARA; [2]Rheumatology, Hospital Selayang, Selangor, Malaysia*

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease driven by the activation of autoreactive T and B cells. Decreased levels of CD4 counts were found in these patients, although there are conflicting data on whether CD4 is associated with SLE disease activity.[1,2,3]
Objectives: To investigate the associations between CD4 and CD8 counts with (1) active SLE and (2) infection in patients with SLE.
Methods: This was a cross-sectional study conducted in a rheumatology referral centre in Malaysia. Inclusion criteria included patients who fulfilled SLICC SLE classification and was admitted to rheumatology ward for active SLE or infection. We excluded patients who had overlap syndrome, retroviral disease or underlying malignancy. SLE Disease Activity Index (SLEDAI) score was assessed by the same rheumatologist.
Statistical analysis was performed using SPSS 20 and a p-value of <0.05 was considered significant. Pearson correlation was used to analyse associations between 2 continuous variables, while comparison between 2 continuous data was performed using student's t test.
Results: Forty-two patients participated in this study. Majority (90.5%) were females with a mean age of 33.05 (±11.42) years and SLE duration of 8.69 (±5.26) years. There were 40 (95.2%) ANA positive, 23 (54.8%) anti-dsDNA positive, 13 (31.0%) anti-smith positive, 24 (57.1%) low C3 and 16 (38.1%) low C4 in this cohort.
There were significant correlations between SLEDAI score and CD4 (r=-0.59, p<0.01) and CD8 counts (r=-0.57, p<0.01). CD4 and CD8 counts were significantly lower in patients with clinically active SLE vs non-active, however, there were no significant differences in CD4 and CD8 counts in patients with infection vs no infection. We also found significantly high anti-dsDNA level and low complement 3, but not complement 4, in active SLE. White cell count was significantly higher in patients with infection. The details are tabulated in Table 1.

Table 1. CD4, CD8 and other parameters in infection and active SLE

Parameters	Infection			Active SLE		
	Yes (±SD), n=21	No (±SD), n=21	p	Yes (±SD), n=26	No (±SD), n=16	p
CD4	566.05 (482.51)	510.43 (479.08)	0.71	*375.58 (348.07)*	*802.56 (544.34)*	*<0.01*
CD8	659.10 (562.91)	456.48 (221.86)	0.13	*406.0 (346.04)*	*804.44 (460.04)*	*<0.01*
SLEDAI	7.14 (7.79)	6.38 (7.13)	0.74	*10.0 (7.54)*	*1.5 (3.30)*	*<0.01*
Anti-dsDNA	110.17 (145.84)	103.14 (186.87)	0.91	*149.01 (193.48)*	*42.47 (53.62)*	*0.05*
C3	0.85 (0.47)	0.93 (0.35)	0.56	*0.78 (0.39)*	*1.06 (0.38)*	*0.03*
C4	0.21 (0.16)	0.19 (0.08)	0.53	0.19 (0.12)	0.21 (0.13)	0.56
WBC	*8.92 (3.98)*	*6.41 (2.52)*	*0.02*	7.52 (3.72)	7.90 (3.30)	0.74

Conclusions: There were significant negative correlations between SLEDAI score and CD4 and CD8 counts, with low CD4 and CD8 counts found in patients with active SLE. There were no significant differences in CD4 and CD8 counts during infection.

FRI0292 ANTI-PHOSPHATIDYLSERINE/PROTHROMBIN (APS/PT) ANTIBODIES IN PRIMARY ANTIPHOSPHOLIPID SYNDROME

P. Bermudez-Bermejo[1], G. Hernandez-Molina[1], D.F. Hernandez-Ramirez[1], V. Zamora-Legoff[1], E. Olivares-Martínez[1], A.R. Cabral[2], C.A. Núñez-Alvarez[1]. *[1]Immunology and Rheumatology, Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico; [2]Department of Medicine, The Ottawa Hospital. University of Ottawa, Ottawa, Canada*

Background: Several studies have showed conflicting results regarding the presence and meaning of anti-phosphatidylserine/prothrombin (aPS/PT). However aPS/PT antibodies seem to be a risk factor for thrombosis. Nevertheless, most of the studies have focused on patients with SLE and secondary antiphospholipid syndrome (APS).
Objectives: To assess the prevalence of aPS/PT antibodies, as well as their association with other antiphospholipid (aPL) antibodies (specially lupus anticoagulant [LA]) and thrombosis, in a well-established cohort of primary APS from a single center.
Methods: We included 96 consecutive patients with primary APS according the Sydney classification criteria and/or patients with hematological features (thrombocytopenia and hemolytic anemia) attending a referral center in Mexico City. Patients from both groups fulfilled the Sydney laboratory criteria for APS. We registered demographics, disease duration and type of manifestation. aCL (IgG and IgM), antibodies to purified human anti-β2GP-I (IgG and IgM) and aPS/PT antibodies (IgG and IgM) were assessed by ELISA (INOVA Diagnostics). LA was determined by LA/1 screening reactant and a confirmatory test LA/2 according to published guidelines. We used chi-square ($\chi 2$) test, Spearman correlation analysis and logistic regression.
Results: Most patients were females (69.7%), mean age 44.5±14.6 and median disease duration 7.3 years. The main clinical features were thrombosis (n=74, 77%), hematologic involvement (n=49 patients, 51%) and obstetric events (n=24, 25%) (non-exclusive groups). The prevalence of LA was 69.8%, aCL-IgG 56.8%, anti-β2GP-I IgG 43.1%, aCL-IgM 31.5% and anti-β2GP-I IgM 21%. The frequency of aPS/PT antibodies was 61.2% and 61.6% for IgG and IgM isotype, respectively. When we compared patients with LA+ (n=58) vs. LA- (n=25), the first group had a higher prevalence of aPS/PT-IgG (79.3% vs.16%, p=0.0001) and aPS/PT-IgM antibody (81.5% vs. 31.8%, p=0.001), as well as higher titers (aPS/PT-IgG 130.5 U vs. 8.2 U and aPS/PT-IgM 58.5 U vs. 16.6 U, p=0.0001). aPS/PT-IgG antibodies correlated with aPS/PT-IgM (ρ=0.59, p=0.0001), aCL-IgG (ρ=0.62, p=0.0001), anti-β2GP-I IgG (ρ=0.63, p=0.001) and anti-β2GP-I IgM (ρ=0.35, p=0.001). On the other hand, aPS/PT IgM antibodies correlated with aCL-IgG (ρ=0.57, p=0.0001), aCL-IgM (ρ=0.42, p=0.001), anti-β2GP-I IgG (ρ=0.48, p=0.001) and anti-β2GP-I IgM (ρ =0.59, p=0.0001). We found moderate agreement between the presence of LA and both aPS/PT isotypes (k=0.58 p=0.0001 for IgG, and k=0.47 p=0.001 for IgM). Thrombosis was associated with aPS/PT-IgG antibodies (87.7% vs. 61.1%, p=0.003) but not with aPS/PT IgM (73.6% vs. 81.8%, p=0.37). At the logistic regression analysis, the aPS/PT IgG antibodies remained associated with thrombosis after adjusting by all other aPL antibodies, OR 8.6 95% CI 2.1–33.8, p=0.002.
Conclusions: In this cohort of patients with primary APS, aPS/PT antibodies were highly prevalent, correlated with other aPL antibodies and were associated independently with thrombosis.

Sánchez-Berná[2,8], M. Ramos-Casals[2] on behalf of the GEAS-SEMI. *[1]Autoimmune Diseases Unit, Hosp CIMA-Sanitas; [2]Laboratory of Autoimmune Diseases Josep Font, Hosp Clínic; [3]IDIBAPS, Barcelona; [4]Hosp Ramón y Cajal, Madrid; [5]Hosp Universitario Central de Asturias, Oviedo; [6]Complejo Hosp Universitario, Vigo; [7]Hosp Son Espases, Palma de Mallorca; [8]Hosp Virgen de las Nieves, Granada; [9]Hosp Parc Taulí, Sabadell; [10]Hosp Joan XXIII, Tarragona;[11]Hosp Infanta Sofía; [12]Hosp Gregorio Marañón, Madrid; [13]Hosp de Cabueñes, Gijón; [14]Hosp Infanta Leonor, Madrid; [15]Hosp Esperit Sant, Santa Coloma de Gramenet; [16]Hosp de Fuenlabrada, Fuenlabrada; [17]Hosp Virgen del Camino, Pamplona; [18]Complejo Hosp Ruber Juan Bravo, Madrid; [19]Hosp Alvaro Cunqueiro, Vigo; [20]Hosp de Salamanca, Salamanca; [21]Hosp de Sagunto, Valencia, Spain*

Objectives: To characterize the risk of solid and hematological cancer in a large, well-characterized cohort of patients with primary Sjögren syndrome (SjS).
Methods: The GEAS-SS multicenter registry is a network of Spanish reference centers with specific clinical experience in the management of SjS patients. By January 2016, we had analyzed the development of cancer in 1300 consecutive patients fulfilling the 2002 SjS classification criteria. Multivariate Cox proportional-hazards regression analysis allowed adjustment for age at diagnosis, gender and the statistically-significant baseline variables associated with cancer in the univariate analysis. The sex- and age-specific incidence rates (SIR) of cancer were estimated from 2012 Spanish mortality data modeling, using a set of age-, sex- and site-specific incidence:mortality ratios.
Results: After a mean follow-up of 91 months (9922.3 person-years), 127 (9.8%) patients developed 133 cancers. The most frequent type of cancer was B-cell lymphoma (34% of cancers, including 27 MALT and 19 non-MALT B-cell lymphomas). Systemic activity at diagnosis of primary SjS correlated with the risk of hematological neoplasia (HR 1.06, $p<0.001$). Positive cryoglobulins at SjS diagnosis were associated with a high risk of either B-cell or non-B-cell lymphoma subtypes. Patients with cytopenias had a high risk of non-MALT B-cell and non-B-cell cancer, while those with low C3 levels had a high risk of MALT lymphomas and those with monoclonal gammopathy and low C4 levels had a high risk of non-MALT B-cell lymphomas. The estimated SIR for solid cancer was 1.13 (95% CI 0.88–1.46) and 11.02 (95% CI 8.35–14.54) for hematological cancer. SIRs for specific cancers were 36.17 (95% CI 25.44–51.43) for multiple myeloma and immunoproliferative diseases, 19.41 (95% CI 7.29–51.72) for Hodgkin lymphoma, 6.04 (95% CI 3.43–10.64) for other non-Hodgkin lymphomas, 5.17 (95% CI 1.94–13.79) for thyroid cancer, 4.81 (95% CI 1.81–12.83) for cancers of the lip and oral cavity and 2.53 (95% CI 1.05–6.07) for stomach cancer.
Conclusions: One third of cancers developed by patients with primary SjS are B-cell lymphomas. The prognostic factors identified at SjS diagnosis differed according to the subtype of B-cell lymphoma developed. Primary SjS is also associated with an enhanced risk of development of some types of non-hematological cancers (thyroid, oral cavity and stomach).

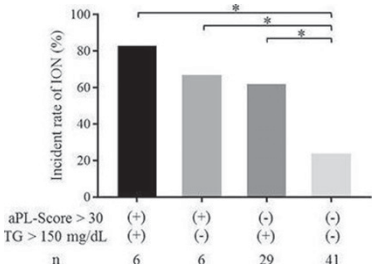
FRI0294 ULTRASOUND OF THE SALIVARY GLANDS HELPS TO DISTINGUISH BETWEEN PRIMARY AND SECONDARY SJÖGREN SYNDROME

R. Bergner[1], H. Sattler[1], D. Wadsack[1], C. Löffler[1,2]. *[1]Medizinische Klinik A, Klinikum Ludwigshafen, Ludwigshafen; [2]5. Medizinische Klinik, Universitätsklinikum Mannheim, Mannheim, Germany*



Background: Previous studies have demonstrated typical findings in the ultrasound of salivary glands (USG) in patients with primary Sjögren syndrome (pSS) compared with healthy controls. However, it is unknown, if these findings are only seen in patients with pSS but also in patients with secondary Sjögren syndrome (sSS) or other connective tissue diseases with positive Ro-SSA/La-SSB antibodies.
Methods: We used an ultrasound score developed by Zhang [1] to investigate salivary glands with a score ranging from 0–48. We compared the score from patients with pSS according the criteria of the American-European Consensus Group (group 1) with patients who fulfilled the clinical criteria (1–4), but were Ro-SSA/La-SSB negative (group 2), with patients who had another rheumatic disease, but had sicca symptoms and were Ro-SSA and/or La-SSB positive (sSS) (group 3), with patients with other rheumatic disease without Ro-SSA or La-SSB antibodies (group 4), with patients with other rheumatic disease with Ro-SSA antibodies but no sicca symptoms (group 5) and with patients with no rheumatic disease (group 6), respectively. We investigated the parotid and the submandibular salivary glands bilaterally. The USG was assessed with a score from 0–48 points with a maximum of 12 points for 4 items each (hyoechoic areas, hyperechoic reflexes, inhomogeneity and distinct organ border). If available the score was correlated with the scintigraphically measured function of the salivary glands.
Results: We included USG of 92 patients in our study. Group 1 (n=33) had a score of 16.6±11.6; group 2 (n=7) 2.4±3.5; group 3 (n=16) 8.6±9.5; group 4 (n=16) 5.3±7.8; group 5 (n=11) 4.5±6.7 and group 6 (n=9) 1.5±2.3, respectively. The score between group 1 and all other groups was significantly different ($p<0.01$), with no significant differences between all other groups. In 25 patients a scintigraphy of the salivary glands was available. The excretory function in the scintigraphy highly significantly correlated with the ultrasound score (r=0.53, $p<0.001$).
Conclusions: USG showed significantly higher scores in patients with pSS, than in patients with sSS or other rheumatic disease. USG as a non invasive investigation might be similarly helpful for the diagnosis of pSS like salivary gland functional tests. USG findings can reliable distinguish between pSS and sSS associated with other rheumatic disease, also if they are positive for Ro-SSA/La-SSB.

FRI0295 HIGH RISK OF IDIOPATHIC OSTEONECROSIS IN SLE PATIENTS WITH HIGH ANTIPHOSPHOLIPID SCORE AND HYPERTRIGLYCERIDEMIA

R. Hisada, M. Kato, N. Ohnishi, M. Kono, S. Tanimura, E. Sugawara, H. Nakamura, K. Ohmura, S. Shimamura, Y. Fujieda, K. Oku, T. Bohgaki, O. Amengual, S. Yasuda, T. Atsumi. *Division of Rheumatology, Endocrinology and Nephrology, Hokkaido University Graduate School of Medicine, Sapporo City, Japan*

Background: Systemic lupus erythematosus (SLE) patients are prone to develop idiopathic osteonecrosis (ION) compared to other connective tissue disease patients or healthy subjects. ION has been shown to occur as a result of ischemia, however, the involvement of antiphospholipid antibodies (aPL) in its pathophysiology remains to be elucidated. In the last years, our group introduced a quantitative marker of aPL "antiphospholipid score (aPL-S)", which well reflected the risk of developing thrombosis [1].
Objectives: We aimed to identify the impact of aPL on the development of ION using aPL-S.
Methods: A single center retrospective study comprising 82 consecutive patients who were diagnosed SLE at the Rheumatology department of Hokkaido University Hospital and underwent magnetic resonance imaging (MRI) of hip joints from January 2000 to December 2016. Among all the enrolled patients, aPL-S, which is calculated from 0 to 86, as well as classical risk factors for ION were evaluated.
Results: All 82 patients (13 males and 69 females) were given glucocorticoids. ION of the femoral head was diagnosed by MRI scan in 37 patients. Male (ION(+): ION(-) 10/37 (27%) vs 3/45 (7%), p=0.016), malar rush (ION(+): ION(-) 22/37 (59%) vs 16/45 (36%), p=0.045), aPL positivity (ION(+): ION(-) 22/37 (59%) vs 15/45 (33%), p=0.026), high aPL-S (>30) (ION(+): ION(-) 9/37 (24%) vs 3/45 (7%), p=0.031), hypertriglyceridemia (fasting triglyceride levels >150 mg/dL) (ION(+): ION(-) 23/37 (62%) vs 12/45 (27%), p=0.002) and high dose of glucocorticoids (equivalent to 0.8mg/kg or more prednisolone) (ION(+): ION(-) 34/37 (92%) vs 21/45 (47%), p<0.001) were identified as risk factors for ION at univariate analysis. Multivariate analysis confirmed high aPL-S (OR 5.27; 95% CI 1.08 to 34.52, p=0.040), hypertriglyceridemia (OR 5.66; 95% CI 1.79 to 20.73, p=0.003) and high dose of glucocorticoids (OR 16.11; 95% CI 4.01 to 92.54, p<0.001) as independent variables. Of note, in 6 patients who had both high aPL-S and hypertriglyceridemia, 83% (5/6) developed ION (Figure 1). Conversely, systemic lupus erythematosus disease activity index and pulsed methylprednisolone therapy were not identified as risk factors for ION.

Conclusions: We newly identified high aPL-S as a risk factor for ION. Furthermore, SLE patients who have both high aPL-S and hypertriglyceridemia are at very high risk of ION. These findings suggest the involvement of microvascular occlusion in the pathophysiology of ION in SLE.

FRI0296 SINGLE CENTER EXPERIENCE WITH 300 SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

S. Tekeoglu, D. Temiz Karadag, O. Ozdemir Isik, A. Yazici, A. Cefle. *Rheumatology, Kocaeli University, Kocaeli, Turkey*

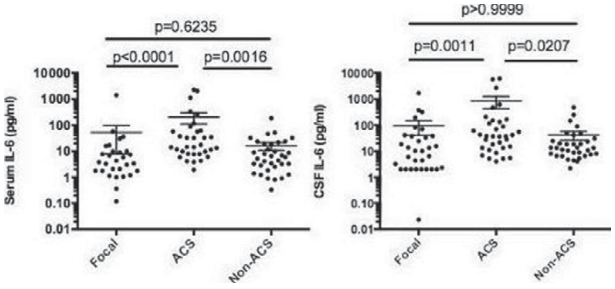
Background: Systemic lupus erythematosus (SLE) is an autoimmune disease with diverse clinical manifestations.
Objectives: Here, we present 300 patients with SLE attending our clinic between 2001 and 2017.
Methods: Demographics, clinics, laboratory findings, Systemic Lupus International Clinics (SLICC)/American College of Rheumatology (ACR) damage index scores and treatments were analyzed. Diagnosis was confirmed with 1997 ACR (1) or 2012 SLICC (2) classifications. Descriptive statistical tests were used for analysis.
Results: Demographics and clinical characteristics are presented in Table 1. Anti-dsDNA was positive in 185 (61.6%), anti-Sm was positive in 35 (11.6%), anti-phospholipid antibodies was positive in 67 (22.3%), direct Coombs test was positive in 69 (23%) patients. Complement levels were low in 171 (57%) patients. In patients with renal disease, class IV lupus nephritis was the most common form (37 patients [12%]) followed by class II nephritis (34 patients [11%]). Forty-six patients had antiphospholipid syndrome. Treatments patients ever received are presented in Table 2. Cyclophosphamide treatment was given mostly for renal disease. Within 22 patients receiving rituximab, 2 had thrombocytopenia and 1 had hemolytic anemia unresponsive to other treatments, 1 had protein-losing enteropathy and 1 had lupus enteritis; the rest had lupus nephritis. One patient received intravenous immune globulin (IVIG) for severe neutropenia and 2 patients for severe thrombocytopenia. One patient received plasmapheresis for vasculitis. One patient received IVIG, plasmapheresis, rituximab for severe renal failure, alveolar hemorrhage requiring intensive care unit admission and 1 patient received same treatment for severe unresponsive hemolytic anemia.

Table 1. Demographics, clinical characteristics of patients

Age (years)	46±13 (min-max: 20–83; median: 45)
Duration of follow up (months)	58±52 (min-max: 1–180; median: 48)
Gender (Female/Male)	267 (89%)/33 (11%)
Muco-cutanous (n, %)	214 (71.3%)
Arthritis (n, %)	198 (66%)
Renal disease (n, %)	121 (40.3%)
Leukopenia/lymphopenia (n, %)	200 (66.6%)
Hemolytic anemia (n, %)	19 (6.3%)
Thrombocytopenia (n, %)	58 (19.3%)
Serositis (n, %)	55 (18.3%)
Nervous system disease (n, %)	24 (8%)
Anti-phospholipid Syndrome (n, %)	46 (15.3%)

Table 2. Treatment

Steroid/pulse treatment (n, %)	294 (98%)/65 (21.6%)
Hydroxycholoroquine (n, %)	300 (100%)
Azathioprine (n, %)	196 (65.3%)
Mycophenolate mofetil (n, %)	83 (27.6%)
Cyclophosphamide (iv) (n, %)	78 (26%); 10±4.5 cycles (min-max: 2–17)
Rituximab (n, %)	22 (7.3%)
Intravenous immunglobulin (IVIG) (n, %)	7 (2.3%)
Plasmapheresis (n, %)	4 (1.3%)



Conclusions: In long term, SLICC/ACR damage index was highest in patients received pulse steroid for renal disease (min:0, max:5). Four (1.3%) patients had pulmonary hypertension, 31 (10.3%) had avascular necrosis, 24 (8%) had viral infections requiring treatment or bacterial infections requiring admission due to immunosuppression, 12 (4%) had malignancy. SLE is an autoimmune disease requiring multi-faceted approach.

FRI0297 ROLE OF SERUM INTERLEUKIN-6 IN BLOOD BRAIN BARRIER DAMAGES IN NEUROPSYCHIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS

S. Hirohata[1], Y. Matsueda[1], T. Yanagida[2], T. Yoshio[3]. *[1]Kitasato University School of Medicine, Kanagawa; [2]Teikyo University School of Medicine, Tokyo; [3]Jichi Medical University, Tochigi, Japan*

Background: Neuropsychiatric manifestation in systemic lupus erythematosus (NPSLE) is one of the most serious complications of the disease. We have recently demonstrated that the breakdown of blood brain barrier (BBB) plays a crucial role in the development of diffuse psychiatric/neuropsychological manifestations (diffuse NPSLE), allowing influx of neuron-reactive autoantibodies from systemic circulation into the brain. However, the mechanism of BBB damages remains unclear. On the other hand, although CSF interleukin-6 (IL-6) has been shown to be elevated in NPSLE, there has been no report on serum IL-6 in NPSLE.
Objectives: The present study was designed in order to elucidate the roles of serum IL-6 in the pathogenesis, especially in development of BBB damages, In NPSLE.
Methods: Paired serum and cerebrospinal fluid (CSF) samples were obtained from 101 SLE patients when they presented active neuropsychiatric manifestations (69 patients with diffuse psychiatric/neuropsychological syndromes [diffuse NPSLE] and 32 patients with neurologic syndromes or peripheral nervous system involvement [focal NPSLE]) and from 22 non-SLE control patients with non-

inflammatory neurological diseases. The levels of albumin and IL-6 in CSF and sera were measured by ELISA.
Results: Serum IL-6 as well as CSF IL-6 was significantly elevated in acute confusional state (ACS) compared with non-ACS diffuse NPSLE (anxiety disorder, cognitive dysfunction, mood disorder and psychosis) or focal NPSLE (figure). Q albumin (CSF/serum albumin quotient) was also significantly higher in ACS than in the other 2 groups of NPSLE. Of note, serum IL-6 (r=0.2801, p=0.0207), but not CSF IL-6 (r=0.1602, p=0.1918), was significantly correlated with Q albumin in patients with diffuse NPSLE, including ACS and non-ACS, although serum IL-6 was significantly correlated with CSF IL-6 in this population (r=0.3205, p=0.082).

Conclusions: These results indicate that serum IL-6 as well as IL-6 is involved in the pathogenesis of NPSLE. The data also confirm that the severity of BBB damages plays a crucial role in the development of ACS, the severest form of diffuse NPSLE. Finally, it is suggested that serum IL-6 might play a most important role in BBB breakdown in NPSLE, whereas CSF IL-6 might be involved in subsequent central nervous system inflammation.

FRI0298 APPLICATION OF PROPENSITY SCORE-MATCHING METHODS TO COMPARE DATA FROM LONG-TERM EXTENSION TRIALS WITH DATA FROM AN EXISTING LUPUS REGISTRY

M.B. Urowitz [1], R. Wielage [2], K.A. Kelton [2], R.L. Ohsfeldt [2], Y. Asukai [3], S. Ramachandran [4]. *[1] Centre for Prognosis Studies in Rheumatic Diseases, Toronto Western Hospital, Toronto, Canada; [2] Medical Decision Modeling Inc., Indianapolis, United States; [3] Value Evidence & Outcomes, GSK, Stockley Park, United Kingdom; [4] Value Evidence & Outcomes, GSK, Philadelphia, United States*

Background: Phase III randomised controlled trials (BLISS 52 and 76) in patients with systemic lupus erythematosus (SLE) have established the efficacy and safety of belimumab plus standard SLE therapy (SoC) vs SoC alone. As with many continuation studies, the long-term extensions (LTE) of the BLISS trials (BEL112233/NCT00724867 and BEL112234/NCT00712933) were single-arm, open-label studies; therefore, comparative long-term efficacy of belimumab and SoC vs SoC was not assessed. Existing observational databases could provide a valuable source of comparison data.
Objectives: This study (BEL206347) explores the use of propensity score (PS) adjustment to enable a post-hoc comparison of LTE patients to patients from an existing SLE cohort, assessing long-term efficacy of belimumab plus SoC vs SoC using the SLICC/ACR Damage Index (SDI) as the outcome.
Methods: Potential PS model criteria were identified by a systematic literature review for factors predicting organ damage. PS model criteria were restricted to baseline (at index [first recorded disease activity of SLE Disease Activity Index {SLEDAI} $\geq$6] for SoC cohort) characteristics available for both cohorts, including age, gender, race, disease duration, clinical and laboratory characteristics, SLEDAI over time, baseline SLEDAI and SDI and SoC (e.g. corticosteroid use/dose). Patients with active severe lupus nephritis/central nervous system lupus, those who had received B-cell-targeted therapy or belimumab or those with an index date before 1990 were excluded from the SoC cohort. The primary PS procedure used 1:1 matching with a 20% calliper (PSM); alternatively, inverse PS weighting (IPSW) was used to preserve the LTE sample. The balance in baseline factors across cohorts pre-/post-PS-adjustment was assessed using standardised distance measures.
Results: The literature review identified the Toronto Lupus Cohort (TLC) as an external registry with a comparable patient cohort. Without PS-adjustment, the standardised distance across cohorts exceeded 25% for 13 of 17 baseline factors in the PSM model. After PSM, standardised distance was <10% for all factors, but less than half of the LTE patients were matched. Using IPSW, data from all patients could be used but with a weighted standardised distance of <10% for 8 and <25% for 15 of the 17 PSM model factors.
Conclusions: The TLC was identified as an existing lupus registry with the endpoints of interest and detailed clinical characteristics. PS matching further maximised the comparability of the LTE and TLC cohorts. The final predictors used in the matching will be validated by two SLE clinicians. The preliminary results indicate a statistically adequate balance in clinical characteristics is attainable. PS matching will allow comparison of long-term organ damage in patients with SLE receiving belimumab plus SoC vs SoC alone. This approach can be applied to other extension studies to assess long-term treatment effectiveness.

FRI0299 N-TERMINAL PRO-BRAIN NATRIURETIC PEPTIDE (NT-PROBNP) LEVEL IN PATIENTS WITH UNTREATED SYSTEMIC LUPUS ERYTHEMATOSUS

T. Panafidina, M. Sokhova, T. Popkova, D. Novikova, E. Alexandrova, E. Nasonov. *V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Objectives: The aim of this study was to determine NT-proBNP serum levels in patients with untreated SLE, thus ruling out any potential effect of SLE therapy: to analyze any possible correlation between NT-proBNP values and traditional risk factors (TRF), inflammatory markers and myocardial function parameters.
Methods: The study included 28 pts (82% females, aged 28,5 [25,0–32,0] years (median [interquartile range 25%>75%]) with untreated SLE (ACR criteria, 1997) and 27 healthy controls (89% females, age 30,0 [23,0–49,0] years). None of SLE pts was treated either with prednisone or cytotoxic drugs at the moment of inclusion, 5 (18%) pts received hydroxychloroquine 200 mg/day. SLE-related factors, including disease duration, clinical features, SLE Disease Activity Index (SLEDAI 2K) and Systemic Lupus International Collaborating Clinics damage index (SLICC/DI) were evaluated in parallel with relevant laboratory findings (blood and urine tests, CRP, IL-6, INF-α, immunoglobulins G, A and M, C3 and C4 complement fragments and others), autoantibodies (ANA, antiDNA, ENA-SSA, -SSB, -Sm, -RNP-70, aPL), echocardiography was performed using standard techniques. Serum levels of NT-proBNP (pg/ml) were measured using electrochemiluminescence method Elecsys proBNP II (Roche Diagnostics, Switzerland). Normal NT-proBNP levels should vary within $\leq$125,0 pg/mL.
Results: Mean SLE duration was 21,0 [5,0–60,0] months, SLEDAI 2K score - 11 [8–9], SLICC/DI score - 0 [0–0]. SLE pts had higher levels of NT-proBNP vs control (160,7 [88,6–335,4] vs 55,2 [36,6–70,3] pg/ml, p<0,001). Elevated levels of NT-proBNP (>125,0 pg/ml) was detected in 18 (64%) SLE pts. In SLE pts NT-proBNP serum levels showed positive correlation with creatinine (r=0,480, p<0,01), uric acid (r=0,427, p<0,05), ACL IgG (r=0,710, p<0,001), antiDNA (r=0,395, p<0,05), ANA levels (r=0,256, p<0,05), left ventricle (LV) end-systolic dimension (r=0,442, p<0,05), mean pulmonary artery pressure (r=0,486, p<0,05); and negative correlation with hemoglobin level (r=-0,493, p<0,01), C4 complement component (r=-0,475, p<0,05), glomerular filtration rate (r=-0,558, p<0,01) and LV ejection fraction (r=-0,505, p<0,01); left ventricular diastolic dysfunction (DDLV) was only in pts with NT-proBNP levels >125,0 pg/ml. Mean NT-proBNP concentration in verified DDLV cases (n=5 (18%)) considerably exceeded normal values, reaching up to 799,2 [276,6–1777,0] pg/ml.
Conclusions: Untreated SLE patients without a history of myocardial infarction, coronary procedure or any evidence of heart failure demonstrated higher NT-proBNP concentration as compared to healthy controls (p<0,001). NT-proBNP levels showed correlation with numerous SLE markers (ACL IgG, ANA, antiDNA, C4 fragment of complement), kidney function (creatinine, uric acid, glomerular filtration rate) and myocardial function (end-systolic dimension of the LV, mean pulmonary artery pressure, LV ejection fraction). No correlation was documented between NT-proBNP concentration and TRF or inflammatory markers (CRP, IL-6, INF-α). All abovementioned data suggest presumable SLE-associated autoimmune damage of cardiomyocytes and/or mediated decrease of myocardial function caused by kidney disease.

FRI0300 NEUROLOGICAL INVOLVEMENT IN PRIMARY SJÖGREN SYNDROME

T. Ben Salem [1,1,1], I. Naceur, M. Tougorti, M. Lamloum, I. Ben Ghorbel, M.H. Houman. *Internal Medicine, Rabta university hospital, Tunis, Tunisia*

Background: Prevalence of neurological involvements (NI) in primary Sjögren Syndrome (pSS) varies from 10 to 60% and depends on whether they are screened systematically or only when they are symptomatic.
Objectives: The aim of the study was to describe the prevalence, clinical patterns and treatment of NI in pSS.
Methods: We performed a retrospective study of patients with pSS (American-European Consensus Group criteria) and followed in an internal medical department over a period of 15 years. Patients with NI were enrolled after excluding other potential causes. We did investigate neurologic systems only when patients present with symptoms.
Results: Primary Sjögren Syndrome was diagnosed in 155 patients, 41 had neurological manifestations (26.4%). They were 5 male and 36 female. The mean age at disease onset was 49 +/-13 years. The average delay from NI onset to pSS diagnosis was four months for peripheral nervous system (PNS) and 12

months for central nervous system (CNS). NI revealed the disease in 14 cases (34%). CNS and PNS involvements were respectively found in 27 and 19 cases (six patients had both PNS and CNS). In patients with CNS disorders, headache was the most frequent symptom (n=11). Pyramidal syndrome was found in 9 cases and cerebellar syndrome in one patient. Aseptic meningitis was noted in two cases. Brain MRI was performed in 22 cases and showed abnormalities in 82% of cases. T2 and flair weighted hyperintensities were periventricular (n=11), subcortical (n=5), frontal (n=3) and parietal (n=2). Myelitis was found in one patient.

Patients with PNS showed paresthesia (92%), motor deficit (22%) and decreased tendon reflex (18%). Sensory-motor neuropathy was described in 4 cases, pure sensory neuropathy in 6 cases (including one case of small fiber neuropathy) and motor neuropathy in one patient. Mononeuropathy multiplex was found in 4 cases and polyradiculoneuritis in one patient. Neuromuscular biopsy was performed in five patients and showed vasculitis in two cases. Trigeminal nerve and cochlear nerve were respectively involved in four and one patients. Antinuclear antibodies, anti-SSA and anti-SSB antibodies were respectively positive in 71%, 50% and 28% of cases. NI were treated with corticosteroids and immunosuppressive therapy in respectively 56% and 41% of cases. Outcome was good in 48% of the patients. Comparison of clinical and biological features in patients with and without NI showed no significant differences, only fatigue was significantly associated to NI (45.5% vs 12.9%; p=0.005).

Conclusions: In our series, NI prevalence was similar to other groups.

CNS involvements were more frequent than PNS manifestations whereas in other ethnic groups they are less frequent.

FRI0301 CHARACTERIZATION OF FEVER IN HOSPITALIZED PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: LESSONS FROM THE JIANGSU COHORT

X. Feng[1], W. Pan[2], L. Liu[3], M. Wu[4], L. Sun[1] on behalf of Jiangsu Lupus Collaborative Group. *[1]Department of Rheumatology, The Affiliated Drum Tower hospital of Nanjing University Medical School, Nanjing; [2]Department of Rheumatology, Huaian First People's Hospital, Huaian; [3]Department of Rheumatology, Xuzhou No. 4 People's Hospital, Xuzhou; [4]Department of Rheumatology, The 3rd Affiliated Hospital of Suzhou University, Changzhou, China*

Background: Fever is one of the main symptoms leading to the admission of patients with systemic lupus erythematosus (SLE) and its causes are usually complicated.

Objectives: To explore the prevalence and clinical characteristics of fever in Chinese SLE patients at the time of their first admission and to find out whether fever is related to a poor prognosis.

Methods: A follow-up study aimed to delineate SLE prognosis had been conducted by our Lupus Collaborative Group under the supervisor of Jiangsu Rheumatology Association to collect the data of patients who had ever recorded first admissions during the 1999–2009 decade (1). Among which, those with admission temperature documented were extracted for the assessment of potential factors associated with fever. The independency of various clinical features linked to fever was established by binary logistic regression analysis, and the relation between fever and patient's survival was determined by Cox regression analysis.

Results: Totally 1,348 patients were enrolled, in which 1,049 (77.8%) had normal temperature, 221 (16.4%) had low and moderate fever and 78 (5.8%) had high fever at the time of their first hospitalization. Compared with those having normal temperature, fever patients were more likely to have short disease duration (RR 0.74), concurrent infection (RR 3.29) and gastrointestinal (RR 1.57) as well as hematological involvements (RR 1.56). High C reactive protein level (RR 2.08) and positive anti-Sm antibody (RR1.55) were the two laboratory factors related to fever at admission. However, age, gender, SLEDAI score or erythrocyte sedimentation rate was not independently associated with fever in this cohort. Cox regression analysis showed that there was no correlation between fever and overall deaths (Figure 1) as well as infection induced deaths.

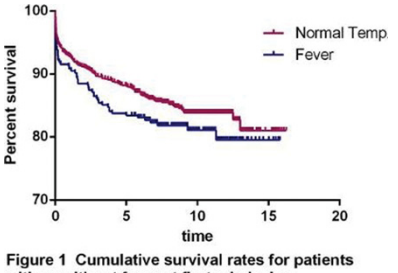

Figure 1 Cumulative survival rates for patients with or without fever at first admission

Conclusions: Both infection and lupus itself (especially gastrointestinal and hematological involvements) contribute to fever in SLE patients. Although the presence of fever increases the complexity of disease treatment, it does not constitute a risk factor for patient's long-term outcome.

FRI0302 ELEVATED CYSTEINE-RICH PROTEIN 61 IN SYSTEMIC LUPUS ERYTHEMATOSUS-ASSOCIATED PULMONARY ARTERIAL HYPERTENSION

Y. Fan[1], J. Qian[2], Y. Hao[1], M. Li[2], L. Gao[3], X. Zeng[2], Z. Zhang[1]. *[1]Department of Rheumatology and Clinical Immunology, Peking University First Hospital; [2]Department of Rheumatology, Peking Union Medical College Hospital, Peking Union Medical College & Chinese Academy of Medical Sciences, Key Laboratory of Rheumatology and Clinical Immunology, Ministry of Education; [3]Department of Rheumatology, Beijing Shijitan Hospital, Capital Medical University, Beijing, China*

Background: Pulmonary arterial hypertension (PAH) is a complex and devastating complication of connective tissue diseases that leads to severe morbidity and mortality.Unlike in Caucasians, it is systemic lupus erythematosus that recognized as the the major underlying cause of CTD associated PAH in Asian countries, especially in China [1]. Early diagnosis and intervention is vital for better long-term outcome in SLE-PAH patients.Previous study has demonstrated Cysteine-rich protein 61 (Cyr61) was highly expressed in SLE patients [2].However,the role of Cyr61 in pulmonary arterial hypertension (PAH) remains unknown.

Objectives: To explore the value of Cyr61 for PAH in SLE patients by comparing the plasma Cyr61 levels in SLE patients with/without PAH.

Methods: Plasma samples from two tertiary medical centers were obtained from 54 patients with definite SLE-PAH, 52 age,gender and SLEDAI matched SLE patients without PAH, and 54 age and gender matched healthy controls. Plasma Cyr61 concentration was measured by enzyme-linked immunosorbent assay.

Results: Plasma Cyr61 concentration in SLE-PAH patients was significantly higher than the matched SLE patients and healthy controls (median (IQR): 172.5 (143.8, 218.2), 124.9 (104.1, 154.7), 58.17 (28.9, 80.4) respectively, $P<0.001$) (Figure1). The sensitivity and specificity of Cyr61 in predicting the presence of PAH in entire SLE patients were 79.6% and 67.3%. Receiver operating characteristic curve analysis showed the area under the curve was 0.757 (95% CI: 0.662–0.852), with 140.6 pg/ml as the cut off concentration (Figure2). Further multivariate logistic regression analyses revealed high Cyr61 level (>140.6) is an independent risk factor for SLE patients to develop PAH (OR:7.822 (95% CI: 2.224–41.138)) (Table 1). Additionally, weak to moderate positive correlations were observed between Cyr61 concentration and serositis, hematological involvement, red blood cell distribution width, right ventricular systolic pressure and right ventricular diameter measured by echocardiography in entire SLE population.

Figure 1

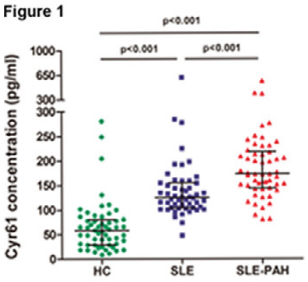

Figure 2

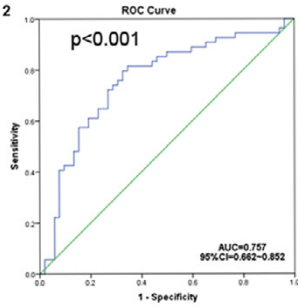

Table 1. Multivariate logistic regression analysis

Variables	OR	95% CI		P value
High Cyr61 level	7.822	2.224	41.138	0.002
Serositis	8.244	1.854	36.663	0.006
Anti-RNP positivity	3.902	1.067	14.267	0.040
Renal disorders	0.174	0.044	0.689	0.013
Anti-dsDNA positivity	0.171	0.046	0.636	0.008

Conclusions: Plasma Cyr61 level was significantly higher in SLE-PAH patients than SLE patients without PAH. Cyr61 may be used as a biomarker for PAH complication in SLE patients.

Vasculitis

FRI0303 THE IGG4:IGG RNA RATIO IS A NEW AND PROMISING DISEASE ACTIVITY MARKER IN GRANULOMATOSIS WITH POLYANGIITIS

A. Al-Soudi [1], M. Doorenspleet [1], R. Esveldt [1], S. Tas [1], R. van Vollenhoven [1], P. Klarenbeek [1], N. de Vries [1,2]. *[1]Amsterdam Rheumatology and Immunology Center; [2]Department of Experimental Immunology, Academic Medical Center, Amsterdam, Netherlands*

Background: Granulomatosis with Polyangiitis (GPA) is a form of vasculitis characterized by inflammation of blood vessels in lungs, kidneys and the ear, nose and throat region. Regular monitoring and treatment adjustments are common, as the disease activity tends to fluctuate over time. Unfortunately, good markers for disease activity are lacking. This leads to both over- and undertreatment. Immunoglobulin G4 positive (IgG4+) B-cells and plasma cells are implicated in the pathogenesis of GPA, but the level of serum IgG4 does not seem to be a good disease activity marker. Recently we developed a test that indirectly measures the presence of IgG4+ B-cells/plasma cells by measuring the IgG4:IgG RNA ratio[1]. We hypothesized that this test could be used as disease activity marker.
Objectives: To test the IgG4:IgG RNA ratio in peripheral blood as a disease activity marker in GPA.
Methods: 27 PR3+ ANCA+ positive GPA patients were included in this cross-sectional study. Mean age was 52 years, 56% were female, and 39% had active disease. For each patient the ESR, CRP, BVAS, and ANCA titre were measured and peripheral blood samples were obtained. Patients were defined as having active disease if the BVAS was ≥3. In addition we included 10 healthy controls, and 63 patients with other immune mediated inflammatory diseases (systemic lupus erythematosus (SLE) (n=24), rheumatoid arthritis (RA) (n=19), primary sclerosing cholangitis (PSC) (n=20)). A validated qPCR test was performed in all groups to measure the IgG4:IgG RNA ratio in peripheral blood samples [1]
Results: The median IgG4:IgG RNA ratio was significantly higher in the GPA cohort (5.7, IQR 2.6 – 19.7) compared to all control groups: 1.2 in SLE (0.7 - 3.3; $p<0.01$), 2.5 in RA (0.7 - 4.1; $p<0.05$), 1.6 in PSC (1.0 - 2.8; $p<0.001$) and 1.3 in HC (0.6 - 1.8, $p<0.01$). In addition, the median IgG4:IgG RNA ratio was significantly higher in patients with active disease (23.8; IQR 12.1 – 29.1) compared to patients in remission (3.5; IQR 2.0 – 5.5) ($p<0.0001$). The height of the IgG4:IgG RNA ratio significantly correlated with height of the BVAS (r^2 =0.76, $p<0.0001$), while the ESR, CRP and ANCA titre did not. Interestingly, IgG4/IgG RNA ratios among patients with active disease were consistently above 9.3, and among patients in remission they were below this threshold.

IgG4:IgG RNA ratio (%) in healthy controls (HC), primary sclerosing cholangitis (PSC), systemic lupus erythematosus (SLE), rheumatoid arthritis (RA) and granulomatosis with polyangiitis (GPA). Red dots represent patients with active disease (resp. SLEDAI, DAS28 and BVAS). * <0.05, **<0.01, *<0.001**

Conclusions: The IgG4:IgG RNA ratio distinguishes active GPA from GPA in remission with excellent specificity and sensitivity. Moreover the ratio shows a significant correlation with disease severity, in contrast to ESR, CRP and ANCA titre. Retesting in another, prospective study is indicated to validate the IgG4:IgG ratio as a novel, highly sensitive and specific marker of disease activity in GPA.

FRI0304 THE UTILITY OF 18F FDG-PET/CT IN DISTINGUISHING BENIGN FROM MALIGNANT RETROPERITONEAL FIBROSIS

Y. Wang [1], Z. Guan [2], D. Gao [1], J. Zhu [1], J. Zhang [1], F. Huang [1]. *[1]Rheumatology; [2]Nuclear Medicine, Chinese PLA General Hospital, Beijing, China*

Background: Retroperitoneal fibrosis (RPF) could be idiopathic or secondary to various factors including malignancy. Pathology remains the most reliable diagnostic approach. However, the pathological features have yet been well defined and the feasibility of biopsy procedure depends on several factors such as the proximity of the lesions to abdominal aorta. ^{18}F FDG-PET/CT may help exclude malignancy by assessing FDG-uptake and mapping the whole body, especially when biopsy procedure is inaccessible.
Objectives: To evaluate the utility of PET/CT in distinguishing benign from malignant RPF.
Methods: Patients with benign or malignant RPF diagnosed between September 2011 and June 2016 were included. Morphologic features, FDG-uptake of retroperitoneal lesions and lymph nodes (LNs) were compared. FDG-uptake of retroperitoneal lesions was assessed visually with the referrence of liver and assessed semiquantitatively with SUVmax. LNs were regarded as specific LNs if frequencies of LNs with high FDG-uptake were observed differently between two forms of RPF. ROC analyses were performed to evaluate the diagnostic accuracy.
Results: Seventy-one cases with benign RPF and 21 cases with malignant RPF secondary to lymphoma (15) or metastatic carcinoma (6) with primary sites of pancreas (2), colon (2), stomach (1) and kidney (1) were included. The craniocaudal length, axial width, and distances between anterior or posterior

Table 1. Morphologic features, FDG-uptake of retroperitoneal lesions and lymph nodes (LNs)

Parameters	Benign RPF (71)	Malignant RPF (21)	*p* value
Morphologic features			
Craniocaudal length, median (IQR), mm	107.0 (80.5,136.4)	164.9 (104.7,229.2)	0.001
Axial width, median (IQR), mm	41.0 (32.3,52.0)	85.0 (62.3,98.5)	<0.001
Aorta lumen to anterior limit, median (IQR), mm	8.9 (6.0,12.0)	20.7 (13.9,45.3)	<0.001
Aorta lumen to posterior limit, median (IQR), mm	2.8 (2.2,4.4)	7.4 (4.5,14.5)	<0.001
FDG-uptake of retroperitoneal lesions			
High FDG-uptake, n (%)	55 (77.5)	21 (100.0)	0.017
SUV max, mean (S.D.)	4.8 (1.7)	12.2 (7.1)	<0.001
LNs with high FDG-uptake, n (%)			
Hilar/Mediastinal	27 (38.0)	13 (61.9)	0.054
Cervical	6 (8.5)	5 (23.8)	0.058
Axillary	4 (5.6)	6 (28.6)	0.003
Retroperitoneal	3 (4.2)	16 (76.2)	<0.001
Supraclavicular	2 (2.8)	8 (38.1)	<0.001
Inguinal	1 (1.4)	5 (23.8)	<0.001
Peritoneal	0 (0.0)	10 (47.6)	<0.001
Number of specific LNs, n (%)	0 (0,0)	2 (1,3)	<0.001

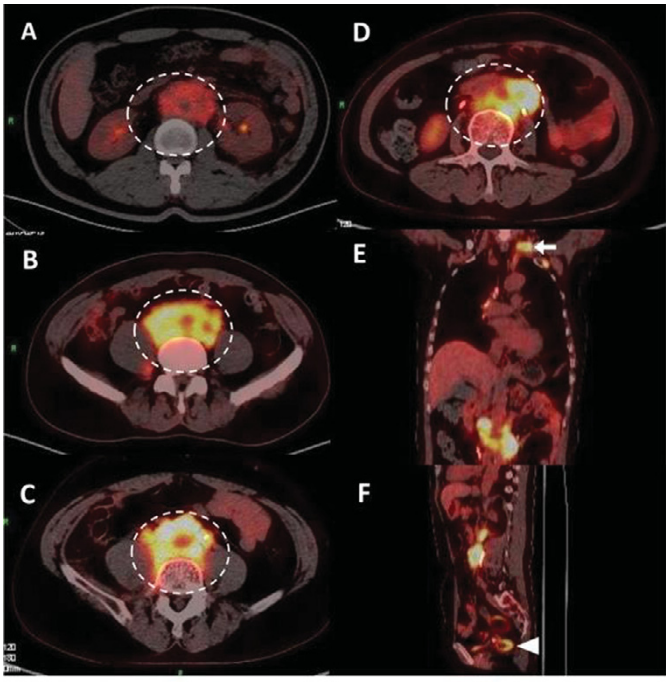

Figure 1. Representative ^{18}F fluorodeoxyglucose positron emission tomograph images for benign retroperitoneal fibrosis (**A**) and malignant retroperitoneal fibrosis secondary to lymphoma (**B, C**) and metastatic carcinoma (**D**). The retroperitoneal process are encircled by circles in the same size with different level of FDG-uptake. **D-F** are images from one patient with histological diagnosis of colon cancer. FDG-uptake is accumulated in left supraclavicular lymph node pointed by the arrow (**E**) and in sigmoid colon pointed by the arrow head (**F**).

limits and aorta were less in benign RPF, however, significant differences were only observed when comparing with lymphoma (p values: all <0.001) but not with metastatic carcinoma (p value: 0.396, 0.181, 0.112 and 0.64). A greater frequency of retroperitoneal lesions with high FDG-uptake (100% vs 77.5%, p value: 0.017) and a higher mean SUVmax (12.2 vs 4.8, p value: <0.001) were observed in malignant RPF. The frequencies of LNs with high FDG-uptake were greater with significance in malignant RPF except for hilar/mediastinal and cervical LNs, hence the rest LNs were regarded as specific LNs. At ROC analyses, the AUCs of SUVmax and specific LNs were 0.893 and 0.947. The sensitivity and specificity were 85.7% and 81.4% when the SUVmax was 6.23. The AUC of logistic regression model combining SUVmax and specific LNs was 0.974 with sensitivity of 90.5% and specificity of 90.1%.

Conclusions: PET/CT could help distinguish benign from malignant RPF, especially when taking into account the FDG-uptake of retroperitoneal process and LNs.

FRI0305 RELATIVE FDG ACCUMULATION OF THE AORTIC WALL LESIONS TO AORTIC BLOOD POOL IN 18F-FDG-PET AND PET/CT COULD BE A USEFUL PARAMETER FOR THE PREDICTION OF DISEASE RELAPSE AFTER SUCCESSFUL TREATMEN IN TAKAYASU ARTERITIS

A. Ihata[1], Y. Kunishita[2], K. Minegishi[2], R. Yoshimi[2], Y. Kirino[2], H. Nakajima[2]. *[1]Department of Rheumatology, Yokohama Medical Center/ National Hospital Organization; [2]Department of Stem Cell and Immune Regulation, Yokohama City University Graduate School of Medicine, Yokohama, Japan*

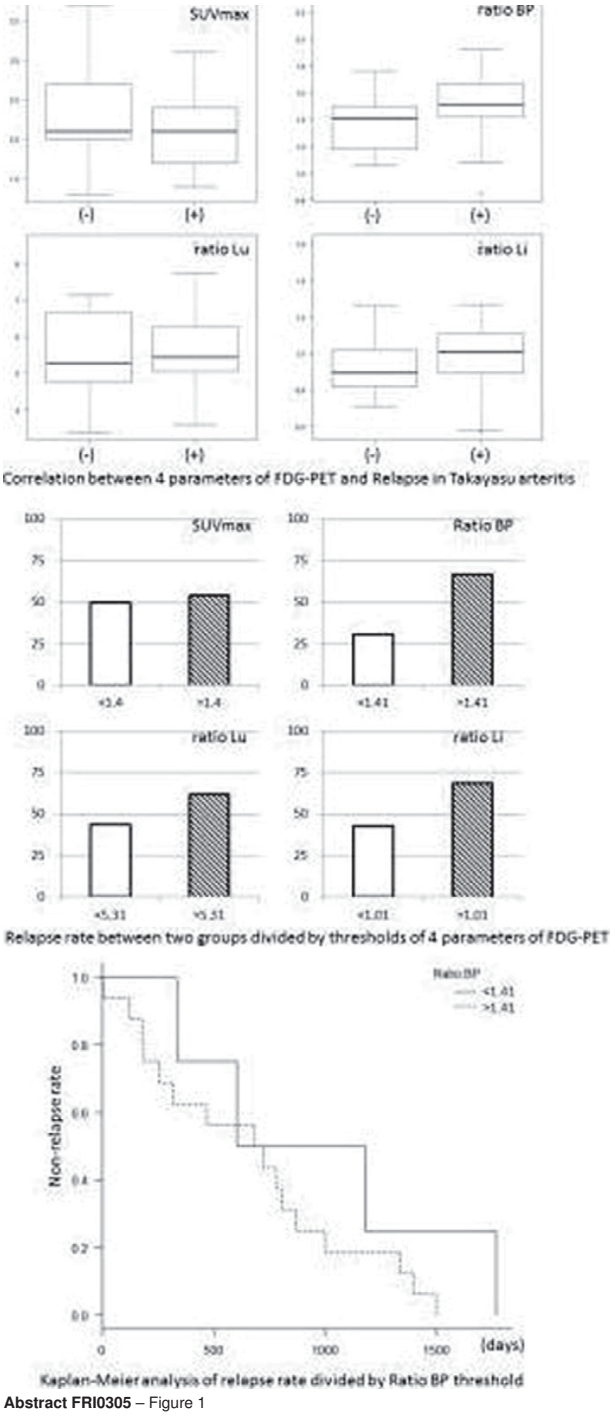
Background: The assessment of disease activity of Takayasu arteritis (TA) is difficult if symptoms and serum inflammatory marker were not detected. Even in those conditions, relapses were frequently observed during the dose reduction of corticosteroid and immunosuppressant. There is accumulating evidence that 18F-fluolodeoxyglucose-positron emission tomography (FDG-PET) and PET/computed tomography (PET/CT) is useful for monitoring patients with TA when TA was clinically active. However, it is not clear the significance of FDG accumulations when TA was inactive.

Objectives: To investigate a quantitative predictor in FDG-PET or PET/CT scans for the relapse of TA.

Methods: We retrospectively investigated 76 FDG-PET or PET/CT scans and extracted 37 scans which were performed in inactive status. These scans were divided in two groups according to relapse of TA for 5years. The relapse was defined the increase of CRP and steroid dose or addition of immunosuppressant. FDG accumulations in aortic wall lesions of TA was evaluated by semi-quantitative index; the standardized uptake value (SUV). In addition to SUVmax in the aortic wall, we also calculated SUV ratio of maximum aortic wall uptake to mean lung uptake (ratio Lu), SUV ratio of maximum aortic wall uptake to mean liver uptake (ratio Li), and SUV ratio of maximum aortic wall uptake to mean aortic blood pool uptake (ratio BP). We compared groups using these parameters. We also determined the cutoff levels, sensitivity, and specificity of 4 sets of SUVs (SUVmax, ratio Lu, ratio Li, and ratio BP) for the prediction of relapse using Receiver Operating Characteristic (ROC) analysis. Moreover, Kaplan-Mayer analysis for the long-term relapse-free survival was performed to assess the reliability of these cutoff levels.

Results:

Table 1. Characteristics of two groups



Relapse	(–)	(+)
#	17	20
Age (yr)	47 [30–72]	28.5 [14–68]
CRP (mg/dl)	0.13±0.03	0.13±0.03
Steroid dose (mg/d equivalent to prednisolone)	15.6±2.4	17.7±3.6
Immunosuppressant	2/17	7/35
Duration until relapse (Days)		702.5 [4–1769]

In 37 total PET and PET/CT scan examinations, non-relapse and relapse groups included 17 and 20 scans, respectively. Relapse group had more immunosuppressant users than non-relapse group. Although CRP level and SUVmax were equivalent, ratio of SUV, especially ratio BP of relapse group was higher than that of non-relapse group (p=0.09) (Figure top panel). The cut-off level of these parameters was calculated as follows; SUVmax 1.4, ratio Lu 5.31, ratio Li 1.01, and ratio BP 1.41, respectively. Using these cut-off level, relapse rates of below and over cut-off level were as follows; SUVmax 50% vs 54%, ratio Lu 43% vs 62%, ratio Li 43% vs 69%, and ratio BP 31% vs 67%, respectively (Figure middle panel). Using Kaplan-Mayer analysis, relapse rate of these two groups divided by ratio BP was not significantly different (p=0.268) though these two curves looked different (Figure bottom panel).

Conclusions: Our data suggest that ratio BP at stable condition, which represents relative FDG accumulation of the aortic wall lesions to aortic blood pool, could be a promising predictor to assess the relapse after successful treatment.

Abstract FRI0305 – Figure 1

FRI0306 LONG TERM DRUG-FREE REMISSION IS FEASIBLE IN SEVERE BEHCET'S DISEASE AFTER CESSATION OF SUCCESSFUL ANTI-TNF TREATMENT: A SINGLE CENTER, RETROSPECTIVE LONGITUDINAL OUTCOME STUDY

P.P. Sfikakis, A. Arida, S. Panopoulos, K. Fragiadaki, G. Pentazos, A. Laskari, M. Tektonidou, N. Markomichelakis. *First Department of Propaedeutic and Internal Medicine and Joined Rheumatology Program, National and Kapodistrian University of Athens Medical School, Athens, Greece*

Background: The efficacy of anti-TNF treatment for patients with severe forms of Behcet's disease (BD) is well established (ref), but long term data on the outcome after cessation of such treatment are lacking.

Objectives: To examine whether sustained long term remission of severe BD is feasible after cessation of successful anti-TNF treatment.

Methods: This retrospective longitudinal outcome study was conducted in December 2016 and included all patients with severe BD refractory to conventional immunosuppressive therapy who were considered complete responders to continuous anti-TNF treatment in our center, the first being treated in 2000.

Study's endpoint was the proportion of patients achieving sustained complete remission of BD for at least 3 years after cessation of the anti-TNF agent.
Results: A total of 28 patients in whom infliximab and/or adalimumab treatment was given, always combined with azathioprine unless not tolerated (n=2), and discontinued anytime before December 2013 were eligible for analysis. Following cessation of successful anti-TNF treatment (median duration of 2 years) 13/28 patients achieved the study's end-point. The main reason for anti-TNF administration was sight-threatening ocular disease (n=12) or intestinal disease (n=1). The remaining 15 patients relapsed within 1.5 year (main reason for anti-TNF: ocular disease, n=9; neuro-BD, n=2; severe mucocutaneous disease, n=3; intestinal disease, n=1; median treatment duration of 24 months); 12/15 were successfully re-treated with anti-TNF. So far, 3 of them (ocular disease, n=2; neuro-BD, n=1) have achieved the study's end-point (median re-treatment duration of 2 years). Overall, our 16 patients who achieved the study's end-point (57%) are in complete disease remission ranging from 3 to 12 years (5.7 years, median). Nine patients with severe ocular disease are currently any drug-free (32%), whereas the 7 remaining patients are on low doses of conventional immunosuppressive therapy (25%). Notably, those patients on drug-free remission had shorter median disease duration at initiation of anti-TNF treatment, compared to the remaining patients (1 versus 3 years, respectively).
Conclusions: Sustained drug-free remission for many years after cessation of successful anti-TNF treatment is feasible in some patients with severe BD. Since anti-TNF-induced "cure" can never be differentiated from a spontaneous remission by natural history, further studies should examine whether early anti-TNF treatment must be intended for every patient with severe BD.

[1]*Department of Internal Medicine Division of Rheumatology;* [2]*Department of Radiology;* [3]*Department of Ophthalmology;* [4]*Department of Neurology, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey*

Background: Behcet's syndrome (BS) is a well-recognized cause of cerebral venous sinus thrombosis (CVST).
Objectives: We aimed to assess the outcome of a large cohort of patients with CVST due to BS attending a single dedicated center.
Methods: We identified 100 (81 M/19 F) patients with BS who were diagnosed as having CVST. All contacted were called back to the outpatient clinic for clinical and imaging re-evaluation.
Results: The mean age of the patients at the onset of the symptoms was 28±10 years. A total of 48 patients developed CVST before or at the onset of ISG fulfillment, while 52 developed CVST after a median 3 [2–8] years of ISG fulfillment. Superior sagittal (n=47) and transverse sinuses (n=46) were most commonly involved followed by sigmoid sinus (n=26) and jugular vein thrombosis (n=15).
A total of 59 (53 M/ 6 F) patients had vascular involvement in addition to CVST: these were deep vein thrombosis of the lower extremities (n=47), pulmonary artery involvement (n=17), Budd-Chiari syndrome (n=9), vena cava superior thrombosis (n=6) and major arterial disease (n=3). In about half (32/59), CVST preceded any type of additional vascular involvement. Eye involvement was seen in 37, parenchymal CNS involvement in 8 (all later than CVST) and gastrointestinal involvement in 5 patients.
Seven patients had died. By the end of the study, 87 patients were alive and contacted with a median follow-up time of 11 [6–15] years. Only 6 patients had a relapsing CVST course.
Information about medical treatment was present in detail in 87 patients of whom 75 received short courses of glucocorticoids with (n=12) or without anti-coagulants. A total of 81 patients received immunosuppressive agents, most commonly azathioprine. Four patients underwent lumbo-peritoneal shunting surgery (1 was successful) and 1 with arterio-venous fistula underwent vascular embolization.
Fifty patients were re-evaluated at the clinic. None had of symptoms of intracranial hypertension. Ophthalmological examination showed that 17 patients had complications such as bilateral optic atrophy (n=3), bilateral papilledema (n=5), bilateral optic disc pallor (n=4) and fibrotic scars around optic disc (n=5). Sensorineural type hearing loss was detected in 4 patients. Neurological examination was found to be normal in 43 patients with isolated CSVT, whereas abnormal in the remaining 7 patients with concomitant parenchymal CNS involvement.
Cranial MR/MR venographies at the end of follow-up, were abnormal in 36 patients showing occlusion/ irregularity/ hypoplasia or collaterals in the sagittal (n=19) or transverse sinus (n=17). In the remaining 14, MR venographies were normal.
Conclusions: CVST due to BS is closely associated with vascular involvement in the body and may be considered as a risk factor for future vascular involvement. CVST relapses are rare; however, the course is not uneventful: visual acuity or field may be impaired totally or partially because of optic disc atrophy; in addition hearing deficits may occur.

FRI0308 PREDICTORS OF HYPOGAMMAGLOBULINAEMIA IN RITUXIMAB TREATED PATIENTS. A RETROSPECTIVE ANALYSIS ON A MONOCENTRIC COHORT

R. Padoan, M. Felicetti, M. Gatto, P. Polito, F. Ometto, D. Astorri, L. Friso, F. Cozzi, A. Doria, L. Punzi, F. Schiavon. *Operative Unit of Rheumatology, Department of Medicine DIMED, University of Padova, Padova, Italy*

Background: Rituximab (RTX), a chimeric monoclonal antibody against CD20, is increasingly used in the treatment of B-cell lymphomas and autoimmune conditions. It has been shown that some patients develop hypogammaglobulinaemia after treatment.
Objectives: To assess frequency and predictors of hypogammaglobulinaemia after RTX treatment in a monocentric cohort of patients affected with granulomatosis with polyangiitis (GPA), microscopic polyangiits (MPA) and connective tissue diseases (CTD).
Methods: We retrospectively reviewed all patients receiving RTX and concomitant/sequential immunosuppressants between 2007 and 2016 in a single rheumatologic center. Serum levels of total Ig and lymphocyte subsets were recorded at the time of RTX administration and 3–6 months later. We investigated the frequency of hypogammaglobulinaemia (IgG<6 g/L) and its related events.
Results: 72 patients, 30 (41.6%) GPA/MPA, 25 (34.7%) systemic lupus erythematosus, 13 (18.1%) systemic sclerosis and 4 (5.6%) poly-dermatomyositis were treated with RTX. We analyzed 113 RTX infusions, with 41 (36.2%) retreatments (median 2 [2–6]). We excluded 12 patients/18 infusions due to incomplete data.
RTX was administered at the dosage of 1000 mg twice in 68.1% of patients and 375 mg/m^2 weekly in 31.9%. IgG levels after RTX infusion were available in 68 (71.6%) patients. We observed a significant decrease of IgG levels between baseline and 3–6 months after RTX infusion in all patients (0.001). The frequency of patients with IgG<6 g/L was 22.1%, and 8.8% had IgG<4 g/L, significantly higher in GPA/MPA patients (0.008), with short disease duration (0.001), lower IgG levels at baseline (0.008), higher prednisone equivalent (PDE) cumulative dosage per year (0.006) and higher daily PDE dosage after RTX (0.001) (Table 1). After RTX, all patients had complete B-cells depletion.
At univariate analysis, IgG<6 g/L was associated with GPA/MPA diagnosis (0.006, OR 6 [1.5–24.2]), disease duration (<0.001, OR 0.2 [0.1–0.9]), RTX 375 mg/m^2 weekly protocol (p=0.017, OR 4.1 [1.2–13.9]), PDE cumulative dosage per year (<0.001, OR 6.6 [1.3–33.6]), daily PDE intake >15 mg/day after RTX (<0.001, OR 12.7 [3.1–52.5]) and IgG levels before RTX (<0.001, OR 18 [1.8–178]).
At multivariate analysis, daily PDE intake after RTX (>15 mg/day) and GPA/MPA diagnosis resulted independent predictive factors for hypogammaglobulinaemia (p=0.03, OR 9.5, [2.2–41.7] and p=0.43, OR 4.7, [1.1–21.5]).
Patients affected with GPA/MPA were compared to CTD, as reported in Table 2. GPA/MPA patients at infusion were older (0.002), presented shorter disease duration (0.001), lower IgG levels at baseline (<0.001) despite lower rate of nephrotic syndrome (0.003). Moreover they were treated more frequently with Azathioprine (0.007), RTX 375 mg/m^2 weekly protocol (<0.001) and higher PDE cumulative and daily dosage (<0.001, 0.01 respectively).
Only 5 patients (5.2%) experienced severe infections within 12 months, more frequently in IgG<6 g/L patients (0.007).

Conclusions: In autoimmune rheumatic diseases, diagnosis of GPA/MPA and glucocorticoid therapy resulted independent predictors of hypogammagobulinaemia after RTX treatment. Despite low IgG levels were associated with higher infections risk, rare severe infectious events were observed.

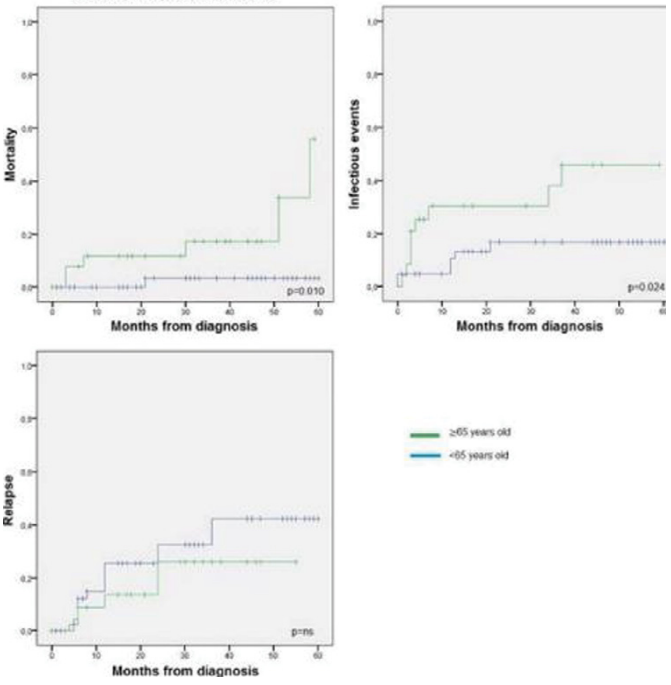
FRI0309 CARDIOVASCULAR EVENTS IN ANCA-ASSOCIATED VASCULITIS: A META-ANALYSIS OF OBSERVATIONAL STUDIES

E. Houben[1], E.L. Penne[1], A.E. Voskuyl[2], J.W. van der Heijden[3], M. Boers[2,4], T. Hoekstra[3]. *[1]Internal Medicine, Northwest Clinics, Alkmaar; [2]Amsterdam Rheumatology and Immunology Centre; [3]Nephrology; [4]Epidemiology and Biostatistics, VU University Medical Centre, Amsterdam, Netherlands*



Background: Several chronic inflammatory diseases are associated with cardiovascular disease, but the cardiovascular risk in ANCA-associated vasculitis is poorly quantified.
Objectives: The aim of the present study is to review the evidence for the increased cardiovascular risk in patients with ANCA-associated vasculitis.
Methods: A comprehensive systematic review was conducted in accordance with guidelines of preferred reporting items for systematic reviews and meta-analyses (PRISMA). The databases PubMed, Embase.com and the Cochrane Library (Wiley) were searched for original observational studies reporting an estimate of the association between ANCA-associated vasculitis and cardiovascular events, including ischemic heart disease, cerebrovascular accidents and/or peripheral arterial disease. The quality of the included studies was assessed with the Newcastle–Ottawa Scale. Summary estimates were derived with a random-effects model and reported as relative risks.
Results: 1375 studies were identified and 7 studies were included comprising 14098 ANCA-associated vasculitis patients versus general population controls in 6 studies and chronic kidney disease patients in 1 study. ANCA-associated vasculitis carried a relative risk of 1.65 (95% confidence interval, 1.23–2.22) for all cardiovascular events, 1.60 (1.39–1.84) for ischemic heart disease and 1.20 (0.98–1.48) for cerebrovascular accidents. We did not find studies that addressed the risk for peripheral arterial disease separately. No heterogeneity was seen in the estimates.
Conclusions: This meta-analysis of observational studies supports an increase in cardiovascular risk of about 65% in patients with ANCA-associated vasculitis, similar to that found in other chronic inflammatory diseases. Hence, there is a clear need for active cardiovascular risk management in patients with ANCA-associated vasculitis.

FRI0310 LONG-TERM MORTALITY AND COMPLICATIONS IN YOUNG AND ELDERLY PATIENTS WITH ANCA-ASSOCIATED VASCULITIS

A. Berti[1], M. Felicetti[2], R. Padoan[2], G. Brunori[3], F. Schiavon[2], G. Paolazzi[1]. *[1]Rheumatology Unit, S.Chiara Hospital, Trento; [2]Rheumatology Unit, Department of Medicine DIMED, Padua; [3]Nephrology Unit, S.Chiara Hospital, Trento, Italy*

Background: Advancing age is a risk factor for complications and mortality in anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV).[1,2]
Objectives: To analyze differences in infectious, metabolic and cardiovascular complications, renal function, and mortality in patients diagnosed with AAV before or after 65 years of age, and followed for up to 5 years.
Methods: We retrospectively collected long-term clinical and laboratory data of AAV patients of two referral centers in Northern Italy from 2000, and grouped patients in young (YP, <65 years old) and elderly (EP, ≥65 years old).
Results: Of the 114 patients included, 83 had a follow-up of at least 2 years (58 YP vs 25 EP). Median follow-up was 55 [32–100] months in YP and 44 [18–59] months in EP ($p<0.013$). 86.1% (68 patients) and 62.9% (22 patients) were diagnosed with GPA in YP and EP subsets, respectively. At baseline, YP and EP patients were similar in terms of BVAS/WG score, glomerulonephritis and alveolar hemorrhage, whereas creatinine levels (1.1 mg/dL [0.8–2.3] vs 1.82 mg/dL [0.98–3.5], p=0.044), renal insufficiency rate (44.7% vs 67.6%, p=0.026) and ANCA pattern (PR3 67.5% vs 26.5%, MPO 19.5% vs 59.8%; $p<0.001$ for both comparisons) were different in YR and ER, respectively. No significant difference in induction and maintenance regimens was found in the two groups, nor in clinical remission rate after induction treatment (all $p>0.05$).
At 2 year, creatinine levels (YP 1.0 mg/dL [0.85–1.31], EP 1.2 mg/dL [1.1–2.2]) and renal insufficiency rate decreased within each group ($p<0.05$). End-stage renal disease, hypertension rate, cardiac or cerebral ischemic attack rate, diabetes, solid or hematological cancer rate and mean vasculitis damage index were not statistically different in the two groups, whereas heart failure was more represented in EP (0.0% vs 8.3%, p=0.027).
Within the first 5 years of follow-up, severe infection (requiring hospitalization) and mortality rates were significantly higher in EP group when compared with YP group (p=0.024 and p=0.010 by Kaplan-Meier analysis, respectively, Figure 1), mirrored by a higher annual severe infection rate (p=0.041; 0.22±0.69 versus 0.05±0.17) and annual mortality rate (p=0.001; 0.33±1.02 versus 0.01±0.08) in EP group. Relapse rate was similar in YP and EP within 5 years (Figure 1). Lymphopenia rate (at least 1 event, $<1000x10^9$/L) was significantly higher in EP only at 6 month ($p<0.05$), whereas severe lymphopenia ($<500x10^9$/L), leukopenia

Figure 1. Kaplan-Meier curves of mortality, infectious events and relapse within 5 years of follow-up in our cohort of patients with AAV.

($<4000x10^9$/L) or hypogammaglobinemia (Ig<5g/L) rates were similar in both groups during the follow-up. Persistent lymphopenia (≥12months, $<1000x10^9$/L) was detected in 3 patients after cyclophosphamide treatment (2 YP and 1 EP). Only relapse before 2 years of follow-up was associated with infections in YP ($p<0.001$, OR 4.0 [CI 95%, 1.2–13.3]), but not in EP.
Conclusions: Heart failure is more frequent in older patients, which have higher infection and mortality rates. Transient lymphopenia is significantly higher in EP after induction treatment, but is not associated with their increase in infectious events. Despite a similar incidence of relapse in YP and EP, relapsing disease associates with infectious events in YP, but not in EP.

FRI0311 ENDOVASCULAR INTERVENTION VERSUS SURGERY IN PATIENTS WITH TAKAYASU ARTERITIS: A META-ANALYSIS

J.H. Jung, G.G. Song, S.J. Choi, Y.H. Lee, J.-H. Kim. *Internal Medicine, Korea University Medical Center, Seoul, Korea, Republic Of*

Background: Although medical treatment has advanced, surgical treatment is needed to control the progression and symptoms of Takayau arteritis (TA). Endovascular intervention or surgical revascularization is performed; however, there are few comparative studies of these methods.
Objectives: There are many studies about surgery and endovascular intervention; however, it is still unclear which treatment has better a benefit/risk ratio. Because neither meta-analysis nor large-scale studies are available for surgical treatment of TA, we conducted a meta-analysis to examine the outcome of surgical treatment.
Methods: A meta-analysis comparing endovascular intervention and surgery outcomes was performed using the MEDLINE and Embase databases.
Results: A total of 14 studies of 598 patients and 1,049 lesions were included. Endovascular intervention was performed in 418 lesions and surgery in 631 lesions. Restenosis was more common in endovascular intervention than in surgery (odds ratio [OR] =2.74, 95% confidence interval [CI] =1.75–4.27, $p<0.00001$). Other complications, including stroke, did not differ between endovascular intervention and surgery (OR =0.75, 95% CI =0.49–1.15, $p=0.19$). There was no difference in mortality between the two groups (OR =1.11, 95% CI =0.50–2.46, $p=0.81$).

Table 1. Outcomes of endovascular intervetion compared to sugery in patients with Takayasu artheritis

	Test of association			Test of heterogeneity		
	OR	95% CI	P-value	Model	P-value	I^2(%)
Restenosis	2.74	1.75–4.27	<0.00001	R	0.05	41
Other complications	0.75	0.49–1.15	0.19	F	0.27	18
Stroke	0.5	0.17–1.50	0.22	F	0.98	0
Death	1.11	0.50–2.46	0.81	F	0.67	0

Conclusions: This meta-analysis showed the superiority of surgical revascularization over endovascular intervention.

Figure 1. ORs and 95% CIs of individual studies and pooled data; comparison of endovascular intervention and surgical revascularization for restenosis.

FRI0312 THE FREQUENCY AND SEVERITY OF PATIENT-REPORTED SYMPTOMS IN GIANT CELL ARTERITIS

S. Monti[1,2], A. Leong[3], J. Robson[4], A. Craven[2], P.A. Merkel[5], R. Watts[6], R. Luqmani[2]. *[1]Rheumatology, University of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia, Italy, Pavia, Italy; [2]NDORMS, Rheumatology Department, Nuffield Orthopaedic Centre, University of Oxford, Oxford, United Kingdom; [3]School of medicine, The University of Queensland, Brisbane, Australia; [4]Rheumatology, Faculty of Health and Applied Sciences, University of the West of England; School of Clinical Sciences at South Bristol, University of Bristol, Bristol, United Kingdom; [5]Division of Rheumatology and Department of Biosatistics and Clincial Epidemiology, University of Pennsylvania, Philadelphia, United States; [6]Rheumatology, Norwich Medical School, Bob Champion Research and Education Building, University of East Anglia, Norwich, Norwich, United Kingdom*

Background: A better understanding of the patients' perspectives is pivotal in the development of patient-reported outcomes (PROs) in vasculitis.
Objectives: To assessed patients' perspective of disease amongst cases with Giant Cell Arteritis (GCA) compared to comparator illnesses mimicking large vessel vasculitis (LVV) included in the Diagnostic and Classification Criteria in Vasculitis Study (DCVAS) database.
Methods: Patient Description of Illness (PDI) forms were circulated amongst Centres participating in the DCVAS study. The PDI form records up to 10 free-text severity ranked symptoms in descending order of severity, a body-map to localise the sites of pain and a free-text short summary of illness description. Free text was reorganized through content and thematic analysis.
Results: PDI forms from 89 patients with GCA and 28 comparators (COM) were analysed. There was no difference in age and sex distribution between groups (mean age 70±8 for GCA and 69±12 for COM). The symptoms description and frequency of the first most severe aspect of disease, including the patient's own words, is presented in Table 1. The symptom regarded as the most severe by both groups was headache. While there were no differences in the frequency of sudden visual loss, visual symptoms were reported more commonly as the most severe feature by COM vs GCA (21% vs 8%, p=0.05). Arthralgia was more frequently reported by COM vs GCA (11% vs 1%, p=0.01). Headache was the most frequently reported symptom in both groups. Patients with GCA reported jaw claudication (37%) as the second most frequently reported symptom, while COM reported arthralgia/arthritis (32%). Shoulder/neck pain was the third most important symptom in GCA (33%), while fatigue was the third most common complaint among COM (21%). Fatigue was reported as the fourth most common feature by 30% of GCA patients.
Conclusions: Headache was the most frequent and most severe symptom reported by patients with GCA and comparators. However, the reported frequencies and severities of other symptoms were significantly different between the two groups.

Abstract FRI0312 – Table 1. Top 10 most recurrent patient-reported symptoms and correspondent severity rank in giant cell arteritis (GCA) and Comparators (COM)

Item	Frequency in GCA	Severity in GCA	Frequency in COM	Severity in COM	Examples of patient's own words
Headache	1	1, 2, 8	1	1, 2, 5	Headaches; Sore head; Thumping headache
Jaw claudication	2	3, 6	6	0	Jaw ache; Pain in jaw and teeth
Shoulder/neck pain	3	3, 4, 5,	0	0	Shoulder upper arm pain
Fatigue	4	5, 6, 10	3	3, 6, 7	Severe tiredness; Fatigue; No energy and exhausted
Myalgia or muscle weakness	5	5, 7, 10	4	3	Aching muscles; Achey limbs; Loss of strength in arms and legs
Blurred vision	6	10	5	4, 8	Blurred vision
Scalp tenderness	7	8	0	4	Irritation to the scalp; Tender scalp
Loss of appetite	8		0	0	Lack of appetite
Flu-like symptoms	9	9	0	0	General ill feeling; Flu-like symptoms; Unwell
Arthralgia or arthritis	10	9	2	3	Hip, knee more on right side; Pain in back of neck, ankles, wrists, and chest
Other ENT	0	0	7	4	Severe sinusitis; sore inside gums
Sudden visual loss	0	0	8		Loss of eyesight to both eyes; Vision loss
Night sweats	0	0	9	4, 8	Night sweats; Night fever sweats
Painful eyes	0	9	10	0	Shooting pain left eye; Pain right eye

FRI0313 THE EFFICACY AND SAFETY OF TOCILIZUMAB THERAPY IN PATIENTS WITH POLYMYALGIA RHEUMATICA WHO WERE RESISTANT OR INTOLERANT TO GLUCOCORTICOIDS AND ADDITIONAL METHOTREXATE

A. Ueno, Y. Yamamura, K. Fujita, N. Shibutou, M. Yamamura. *Center for Rheumatology, Okayama Saiseikai General Hospital, Okayama, Japan*

Background: A recent trial of tocilizumab (TCZ) in patients with newly diagnosed polymyalgia rheumatica (PMR), conducted in Europe and the United States, has shown its efficacy and safety.
Objectives: We examined the efficacy and safety of TCZ for patients with PMR who had been primarily resistant or intolerant to glucocorticoids (GC) and additional methotrexate (MTX).
Methods: Sixty patients had been diagnosed with having PMR since 2011. The patients are all compatible with the 2012 EULAR/ACR provisional classification criteria for PMR, and had been treated first with GC and then, if they were resistant or intolerant to GC, were added MTX, similarly to the 2015 EULAR/ACR recommendations for the management of PMR. The disease activity were measured by PMR-AS.
Results: There were 17 patients with GC/MTX resistant or intolerant PMR (28%). Of them, 9 patients with PMR agreed to the proposal of TCZ addition, and their therapeutic responses to TCZ and its safety were determined. They were at the age of 68.2±10.6, including three males and six females. Before TCZ addition, the patients were treated with prednisolone (PSL) at 7.6±3.0 mg/day plus MTX at 7.1±5.1 mg/week, and serum CRP were at 1.0±1.0 mg/dL. After 8.4±5.7 months of TCZ treatment, PSL and MTX had been reduced to 1.1±1.3 mg/day and 3.3±4.5 mg/week, respectively, with CRP at 0.02±0 mg/dL. GC were able to be withdrawn in 5 patients, and MTX were further withdrawn in 4 patients. Two patients reached drug-free remission (PMR-AS=0.02). During TCZ therapy, each one patient showed the worsening of depression and occlusion of the central retinal vein.
Conclusions: These results indicate that TCZ may provide a therapeutic option for patients with severe PMR who were resistant or intolerant to GC and additional MTX.

FRI0314 DIFFERENT SERUM CYTOKINE PROFILES REFLECT ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODIES (ANCA) SPECIFICITY IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS

A. Berti[1,2], R. Warner[3], K. Johnson[3], D. Cornec[1], D. Schroder[1], B. Kabat[1], P.A. Merkel[4], C.A. Langford[5], G.S. Hoffman[5], C.G. Kallenberg[6], P. Seo[7], R. Spiera[8], E.W. St Clair[9], J.H. Stone[10], U. Specks[1], P.A. Monach[11] on behalf of the RAVE-ITN Research Group. *[1]Mayo Clinic, Rochester, United States; [2]San Raffaele Scientific Institute, Milan, Italy; [3]University of Michigan Medical School, Ann Arbor; [4]University of Pennsylvania, Philadelphia; [5]Cleveland Clinic,*

Cleveland, United States; [6]University Medical Center, Groningen, Netherlands; [7]Johns Hopkins University, Baltimore; [8]Hospital for Special Surgery, New York; [9]Duke University Medical Center, Durham; [10]Massachusetts General Hospital; [11]Boston University, Boston, United States

Background: Evidence supporting the classification of anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) based on ANCA type is accumulating.[1]
Objectives: To evaluate serum cytokine profiles in patients with AAV classified by ANCA specificity (proteinase 3 (PR3)-ANCA *versus* myeloperoxidase (MPO)-ANCA) or by clinical diagnosis (granulomatosis with polyangiitis (GPA) *versus* microscopic polyangiitis (MPA)) and clinical phenotypes.
Methods: An antibody array testing 30 soluble mediators, already shown to be implied in the pathogenesis of AAV, was performed in each patient with active AAV at inclusion in the Rituximab in ANCA-Associated Vasculitis (RAVE) trial, as previously described.[2,3] By means of Wilcoxon signed rank test for univariate analyses, we analyzed the association of levels of these cytokines with ANCA specificity, clinical diagnosis, and distinct clinicopathologic phenotype categories derived from the BVAS/WG items recorded at the time of enrollment (capillaritis, granulomatous manifestations, renal involvement, and alveolar hemorrhage; new diagnosis and relapsing disease), as described.[4]
Results: All cytokines tested (see Figure 1 and legend for the complete list), except for RANTES, ACE, bFGF and VCAM-1, were significantly increased in the RAVE cohort when compared to healthy controls ($p<0.05$). Median Birmingham vasculitis activity score and steroid use at screening did not significantly differ between PR3-AAV and MPO-AAV, and between GPA and MPA. Within both ANCA specificities, levels of 9 mediators were significantly higher in PR3-AAV (IL-6, NGFb, GM-CSF, IL-15, IL-18, IL-18Bb, sIL-2Ra, IL-8, TARC; $p<0.05$), compared to 5 different cytokines that were higher in MPO-AAV (sIL6R, NGAL, sICAM-1, VCAM-1, sTNFR II; $p<0.05$). In contrast, only 4 cytokines (GM-CSF, IL-15, IL-18, sIL-2Ra) were higher in GPA than MPA, and 1 (NGAL) was higher in MPA than GPA ($p<0.05$). The association of the majority of cytokines was stronger with ANCA specificity than with the clinical diagnosis (Figure 1). Similarly, the defined clinical phenotypes were also not separated by cytokine signatures as clearly as the ANCA specificity was (*data not shown*). Restricting the analysis to newly-diagnosed patients (n=90) showed the most significant cytokine profile differences associated with PR3-AAV (Figure 1).

Heat map of the cytokines' association with ANCA type and AAV clinical diagnosis. All cytokines associated with a pair group with a $p<0.1$ were included in the figure. Colors indicate the strength of association (grey, $0.05<p\leq0.1$; yellow, $0.01<p\leq0.05$; orange, $0.001<p\leq0.01$; red, $p\leq0.001$). The tested panel of 30 biomarkers also included BAFF, BCA-1, bFGF, G-CSF, PAI-1, KIM-1, MMP-3, RANTES, IL-12(p70), ACE, Clusterin, which showed no association ($p\geq0.1$) and therefore were not included in the figure.

*One patient had an indeterminate type of AAV.

Conclusions: Cytokine profiles separate patients more clearly by ANCA specificity than by clinical diagnosis, suggesting important differences in underlying pathophysiology and validating stratification of patients by ANCA specificity for treatment trials.

FRI0315 CLINICAL CHARACTERISTICS OF VASCULAR INVOLVEMENT IN BEHCET'S DISEASE

A. Ateş, M. Torgutalp, E. Okatan, E. Uslu, B. Dinçer, E. Yayla, M. Turgay, G. Kınıklı. *Rheumatology, Ankara University School of Medicine, Ankara, Turkey*

Background: Behçet's disease (BD) is a multisystemic inflammatory disorder classified as vasculitis, which can affect all types of vessels. The prevalence of vascular involvement has been reported at rates ranging from 15 to 50%.
Objectives: In this study, we aimed to determine the characteristics of vascular involvement in patients with BD.
Methods: Six hundred and ninety-two patients with BD, who applied to the multidisciplinary BD policlinic between 2006–2016, were retrospectively analyzed. The diagnosis of vascular involvement was made on clinical signs, by Doppler ultrasonography and/or angiography using computed tomographic or magnetic resonance techniques where appropriate.
Results: One hundred and seventy-six patients (%25.4) had vascular involvement. The mean age of patients with vascular involvement (n=176) and non-vascular involvement (n=516) was similar to 42.5±12.3 and 42.2±12.2 years, respectively, while male sex frequency was significantly higher in patients with vascular involvement (72% to %42, $p<0.001$). Uveitis (45%) and erythema nodosum (EN) (47.7%) were significantly higher in patients with vascular involvement than those without vascular involvement (for Uveitis OR: 1.7, p=0.003/for EN: OR: 2.5, $p<0.001$) (Table 1). Deep vein thrombosis was detected in 142 (80.7%) of the patients with vascular involvement and this was the most common type of vascular involvement (Table 2). Arterial involvement was detected in 52 (29.5%) of 176 patients with vascular involvement. Deep venous thrombosis alone was present in 125 (71%) patients, arterial involvement alone in 12 (6.8%) patients, arterial and venous involvement together detected in 40 (22.7%) patients. Arterial involvement was most commonly seen as pulmonary artery involvement in 45 (25.6%) patients [pulmonary artery thrombosis 35 (20%), aneurysm 10 (5.7%) and thrombosis + aneurysm 6 (3.4%) patients]. Twenty (11.3%) patients had other arterial involvement except pulmonary, 8 of them had thrombosis and 12 had aneurysm.

Table 1. Clinical features in patients with and without vascular involvement

	With vascular involvement	Without vascular involvement	OR	95% CI	P value
n (%)	176 (25.4)	516 (74.6)			
Age (year)	42.5±12.3	42,2±12.2			0.762
Male n (%)	127 (72.2)	217 (42.1)	3.57	2.46–5.19	**<0.001**
Genital ulceration n (%)	123 (69.9)	392 (76.1)	0.728	0.498–1.065	0.101
Uveitis n (%)	79 (44.9)	166 (32.4)	1.698	1.196–2.409	**0.003**
Papulopustular erythema or acneiform rash n (%)	101 (51.4)	186 (57.4)	1.274	0.886–1.832	0.190
EN n (%)	84 (47.7)	98 (27.1)	2.460	1.689–3.582	**<0.001**

Table 2. Venous involvement (%)

Deep vein thrombosis	142 (80.7)
Budd-Chiari syndrome	7 (4.0)
Inferior and superior vena cava syndrome	26 (14.7)
Iliac vein thrombosis	18 (10.2)
Safenous vein thrombosis	23 (13.1)
Femoral vein thrombosis	36 (20.5)
Popliteal vein thrombosis	43 (24.4)
Crural vein thrombosis	12 (6.8)
Cerebral sinus thrombosis	20 (12,2)

Conclusions: Vascular involvement in Behçet's disease is commonly seen in males. Deep vein thrombosis is the most common form of vascular involvement. Arterial involvement is important because of its higher risk of mortality (especially pulmonary artery aneurysm). The incidence of EN and uveitis is higher in patients with vascular involvement.

FRI0316 FACTORS ASSOCIATED WITH SURGICAL OUTCOMES OF SEVERE AORTIC REGURGITATION IN PATIENTS WITH BEHCET'S DISEASE

B. Ghang[1], D.-H. Lim[2], W.J. Seo[3], Y.-G. Kim[1], B. Yoo[1]. *[1]Rheumatology, Asan medical center, Seoul; [2]Rheumatology, Ulsan University Hospital, Ulsan; [3]Rheumatology, Seoul Veterans Hospital, Seoul, Korea, Republic Of*

Background: In rare cases, Behcet's disease (BD) can cause severe aortic regurgitation (AR) or aortic root destruction that might have lethal outcomes. Conventionally, simple aortic valve replacement (AVR) is performed for the management of severe AR in BD patients; however, the reoperation rate is as high as 78 to 100%, while mortality rate range from 20 to 47%. Recently, several series of case reports showed that compared to AVR, aortic root replacement (ARR) improved the surgical outcomes of AR in BD patients.
Objectives: To identify the factors associated with the long-term surgical outcomes of AR in BD patients.
Methods: We identified 23 patients who had been surgically treated for AR caused by aortic root involvement of BD from January 1996 through December 2013. We evaluated the occurrence of post-surgical adverse events, which were defined as follows: death, aortic valve/graft problem, infective endocarditis, cerebral infarction, and/or re-operation of aortic valve or root. Types of surgery were classified as simple aortic valve replacement (AVR), bioprosthesis aortic root replacement (bARR), and mechanical valved composite graft aortic root replacement (cARR). Clinical parameters including baseline characteristics, C-reactive protein (CRP), erythrocyte sedimentation rate, and medications were extracted from electronic medical records.
Results: Appropriate aortic valve or root surgery cases were 35 in total, with a mean follow up duration of 11±5 years in 23 patients. Out of the 11 cases

that underwent AVR, post-surgical events were observed in 8 (73%) cases. Out of the 12 bARR cases (xenograft in 5 cases and homograft in 7 cases), 9 (75%) cases had post-surgical adverse events. Out of the 12 cARR cases, post-surgical adverse events occurred in 4 (33%) cases. Multivariable cox proportional hazards model indicated that levels of CRP at 1 month after discharge and age at operation were independent prognostic factors associated with event-free probability. Notably, performing cARR was the most significant factor that affected the surgical outcome (HR (95% CI) 0.147 (0.028 – 0.766), p=0.023).

Conclusions: In BD patients with severe AR, the occurrence rate of post-surgical adverse events was associated with the levels of CRP at 1 month after discharge, age at operation, and type of surgery. cARR may be a better surgical option in BD patients with aortic root involvement

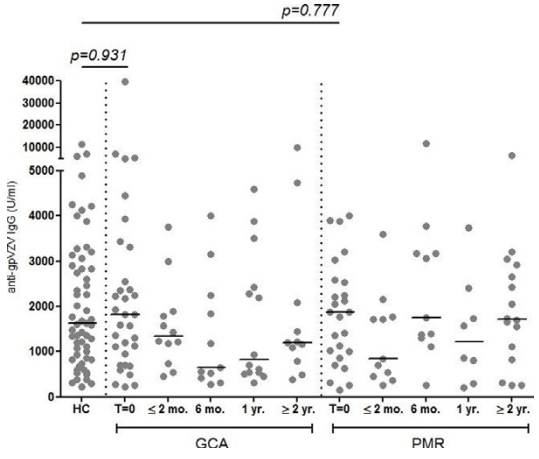
FRI0317 HUMORAL AND CELLULAR IMMUNITY TO VARICELLA-ZOSTER VIRUS IN GIANT CELL ARTERITIS PATIENTS: NO EVIDENCE OF VIRAL REACTIVATION AT ONSET OF DISEASE



C. Rondaan, K. van der Geest, E. Eelsing, N. Bos, J. Westra, E. Brouwer. *Rheumatology and Clinical Immunology, University Medical Center Groningen, Groningen, Netherlands*

Background: Giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) are strongly overlapping diseases that are thought to have a shared etiology [1]. The observation of varicella-zoster virus (VZV) antigen in temporal artery biopsies of GCA patients led to the hypothesis that VZV might be a trigger for the onset of the disease [2]. Herpes zoster occurs when the latently present VZV reactivates. It has been reported that patients with GCA do not appear to be at increased risk of herpes zoster compared with age and sex matched controls, even during treatment with high dose glucocorticoids [3]. Levels of VZV specific immunoglobulin G (VZV-IgG) are known to only slowly decline again after a reactivation [4]. We therefore hypothesized, in line with the proposed etiologic role, to find higher VZV-IgG levels in GCA and PMR patients at disease onset, compared to healthy controls. Furthermore, we expected to find no differences in cell-mediated immunity to the virus between patients and controls assuming that the incidence of herpes zoster is not increased in GCA.

Objectives: To investigate humoral and cellular immunity to VZV in GCA and PMR patients and compare these to results in age-and sex matched healthy controls.

Methods: Antibody responses to VZV glycoprotein were measured in serum samples of 35 GCA patients and 26 PMR patients at baseline (before glucocorticoid treatment) and during follow up, and in 58 healthy controls by an enzyme-linked immunosorbent assay (ELISA). Cell-mediated immunity to VZV was determined by performing interferon-γ (IFNγ) enzyme-linked immunosorbent spot (ELISpot) and intracellular cytokine flow cytometry measurements in 11 GCA patients and 15 PMR patients, and in 26 age and sex matched healthy controls.

Results: Similar levels of VZV-IgG were found in GCA and PMR patients at baseline, and healthy controls. The number of VZV specific IFNγ spot-forming cells was significantly lower in GCA patients than in healthy controls (p=0.029), but not different in PMR patients compared to healthy controls.

Conclusions: Since antibody levels at baseline were not different in GCA and PMR patients compared to healthy controls it seems unlikely that VZV has an important role in the aetiology of GCA or PMR. The finding of a decreased cell-mediated immunity in GCA patients, especially after treatment with high dose corticosteroids may indicate an increased risk of developing herpes zoster.

FRI0318 QUALITY OF LIFE IN PATIENTS WITH BEHCET'S DISEASE

D. Santos-Faria, J.L. Silva, M. Cerqueira, J.R. Rodrigues, J. Sousa-Neves, F. Teixeira, D. Peixoto, J. Tavares-Costa, C. Afonso, S. Alcino. *Rheumatoloy, Unidade Local de Saúde do Alto Minho, Ponte de Lima, Portugal*

Background: Behcet's disease (BD) is a chronic and multisystemic inflammatory disorder affecting the skin, mucosa, joints, eyes, arteries, veins and the nervous and gastrointestinal systems. The symptoms may be separated by long or short intervals, occur simultaneously or in sequence, and exhibit a pattern of exacerbation and remission. The disease itself or the impact of the symptoms affect patients physically, mentally and socially with a negative effect in the quality of life (QoL).

Objectives: To determine the health status and quality of life in patients with BD followed in a rheumatology unit and to identify associated demographic and disease-related parameters influencing them.

Methods: Cross-sectional study of 44 BD patients and 39 healthy controls matched for age and sex. All subjects completed the Health Assessment Questionnaire (HAQ) to assess impairment in daily activities due to illness, Short Form-36 (SF-36) and EuroQol Visual Analogic Scale (EQ-VAS) to assess health related quality of life (HRQL). The disease characteristics, including disease duration and clinical involvements were collected. The Birmingham Vasculitis Activity Score (BVAS) was applied for the evaluation of current disease activity among BD patients. P value <0.05 was defined as statistically significant.

Results: Among 44 patients, 35 (79.5%) were female, with a mean age of 40.07 years and mean disease duration of 5.93 years. BD patients had significantly higher HAQ score (p=0.009) and lower levels of SF-36 ($p<0.001$) than the healthy controls. The predominant contributors to this low SF-36 were general health, vitality and role-emotional domains. In comparison with healthy controls, patients with inactive disease (BVAS=0) also had a higher HAQ, but without significant differences (p=0.53). The total SF-36 score also showed lower levels in patients with inactive disease (p=0.04), but when compared the different components, only half of them maintained significant differences, namely role-physical (p=0.03), general health ($p<0.001$), vitality ($p<0,001$) and social functioning (p=0.05). The controls showed a higher EQ-VAS, with a mean of 88.44 comparing to 68.36 in all BD patients ($p<0.001$) and 74.12 in the subgroup with inactive disease (p=0.003). SF-36 score was negatively correlated with HAQ (r=-,553, $p<0.001$) and positively correlated with EQ-VAS (r=.388, $p<0.001$). Longer disease duration correlated with lower levels of only some SF-36 domains, namely physical functioning (r=-.436, p=0.003), role-physical (r=-.533, $p<0.001$) and role-emotional (r=-.465, p=0.001). There was no correlation between disease activity and disease duration (p=0.678) or different scores evaluating QoL (p=0.876). The gender was not associated with statistical differences when compared clinical involvements, disease duration, current disease activity, HAQ, EQ-VAS or SF-36 scores. The heterogeneous nature of the disease expression did not allow the study of the association with the levels of health status and QoL.

Conclusions: Our findings showed lower levels of QoL and global health status in BD compared to healthy controls, mainly in active disease, accordingly with previous studies. The disease itself could be a determinant of disability.

FRI0319 PREDICTORS OF COMPLETE REMISSION IN POLYMYALGIA RHEUMATICA

D. Birra, A. Zoli, G. Peluso, S.L. Bosello, E. Gremese, G. Ferraccioli.
Dipartimento di Reumatologia e Scienze Affini, Università Cattolica del Sacro Cuore - Fondazione Policlinico Universitario Agostino Gemelli, Rome, Italy

Background: Polymyalgia rheumatica (PMR) is an inflammatory rheumatic condition characterized by aching and morning stiffness in the shoulders, hip girdle, and neck that typically occurs in adults over the age of 50. A rapid resolution of symptoms with low-dose glucocorticoids is a feature of PMR although some patients may experience a disease flare-up during steroid tapering.
Objectives: The aim of the study was to investigate possible clinical or laboratory prognostic factors of remission during a 12 month follow up in PMR patients treated with a starting low prednisone dose following the 2015 ACR-EULAR guidelines(1).
Methods: From 86 consecutive outpatients, diagnosed with PMR following ACR/EULAR 2012 provisional clinical criteria for PMR(2), 79 patients (56 women and 23 men), that achieved a complete follow up of at least 12 months, were selected. Clinical evaluation and laboratory tests were performed every 3 months Clinical remission was defined as lack of shoulder and hip girdle pain and as levels of ESR≤40 mm/h and CRP≤0.5 mg/dl.
Results: 37 PMR patients reached a complete remission after twelve months follow-up. We didn't find any significant difference in the mean age and in ESR and CRP values at the beginning of the disease in patients in remission after 12 month of follow up when compared with patients not in remission. Presence of obesity, dyslipidemia, hypertension, diabetes and smoking habits were not significantly different in the two groups of patients. No significant difference in steroid therapy at the beginning and after 6 month of follow up was noted between the two groups of patients. A statistically significant female low clinical remission was seen at the end of 12 month follow up when compared with male complete clinical remission (33.9% versus 78.2%, p=.000) Moreover it was shown that the patients achieving clinical and laboratory remission after six months of therapy were also those who maintained remission at the 12 month. CRP values, instead of ESR ones, were more predictive of remission after one year of therapy. Therefore patients with clinical remission in the absence of normalization of CRP value had greater risk of exacerbation.

Table 1. Demographic and laboratory characteristic of patients

	Remission T12	Non responders T12	p.
Age	75.1±6.7	69.7±5.7	ns
N°	37	42	
Female	19	37	.000
ESR T0 (mm/h)	56±31.6	50.2±29.4	ns
CRP T0 (mg/dL)	3.3±3.3	3.8±4.2	ns
ESR T6 (mm/h)	24.3±16.2	29.9±20.4	ns
CRP T6 (mg/dL)	0.6±0.7	1.5±2.1	.01
ESR T12 (mm/h)	22±15.4	28.7±17.4	ns
CRP T12 (mg/dL)	0.2±0.2	1±0.8	.000
Remission T6	27	7	.000
Prednisone dosage (mg) T0	16.3±8.4	15.5±6.6	ns
Prednisone dosage (mg) T6	5.9±4.8	7.5±5.1	ns
Prednisone dosage (mg) T12	2.3±2.5	4.4±4.7	.04
Dyslipidemia	9	12	ns
Hypertension	21	21	ns
Obesity	9	8	ns
Diabetes	6	8	ns
Smokers	3	3	ns

T0: Baseline; T6: Six months of follow up; T12: One year of follow up; ESR: erythrocyte sedimentation rate; CRP: C-Reactive Protein.

Conclusions: The sixth month of therapy is a crucial target for the management of PMR, because it can help to identify patients at greater risk of exacerbations, which may benefit from a tighter follow-up and a more aggressive therapeutic strategy. Among prognostic factors female sex and high CRP values at sixth months appear to be associated with higher relapse risk and a longer duration of treatment.

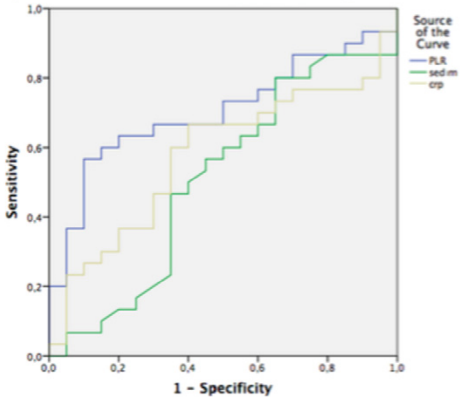
FRI0320 PREDICTIVE VALUE OF PLATELET TO LYMPHOCYTE RATIO IN RENAL INVOLVEMENT IN PATIENTS WITH GRANULOMATOSIS WITH POLYANGIITIS



H. Kucuk[1], D. Tecer[2], O. Varan[1], H. Babaoglu[1], S.C. Guven[2], A. Tufan[1], S. Haznedaroglu[1], M.A. Özturk[1], B. Goker[1]. *[1]Department of Internal Medicine, Division of Rheumatology; [2]Department of Physical and Rehabilitation Medicine, Division of Rheumatology, Gazi University Faculty of Medicine, Ankara, Turkey*

Background: Granulomatosis with polyangiitis (GPA) is a granulomatous necrotizing vasculitis with high morbidity and mortality. Anti-neutrophil cytoplasmic antibody (ANCA) is a rvaluable diagnostic marker, however its titer lacks predictive value for the severity of organ involvement. Platelet to lymphocyte ratio (PLR) and mean platelet volume has been regarded as a potential marker in assessing systemic inflammation.
Objectives: We aimed to investigate PLR and MPV as inflammatory marker in patients with GPA.
Methods: GPA patients and age-sex matched healthy controls were included. Demographic, clinical and laboratory information were extracted from medical records. Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), white blood cell (WBC), platelets (PLT), lymphocyte and neutrophils counts and glomerular filtration rate (GFR) were recorded. PLR was calculated. Disease activity was assessed with Birmingham Vasculitis Activity Score for WG vasculitis (BVAS/WG).
Results: 56 patients with GPA and 53 healty controls were included. Clinical characteristics and laboratory findings of the study population are shown in Table 1. ESR, CRP, MPV and PLR were significantly higher in patients with GPA than controls. PLR positively correlated with ESR and CRP (r:0.389, p:0.005 and r:0.512 p<0.001, respectively). In contrast, MPV negatively correlated with ESR and CRP (r:-0.308, p:0.028 and r:-0.337 p:0.014, respectively). There were no significant correlation between PLR, MPV and BVAS/WG. Patients with renal involvement had statistically significantly higher PLR than patients without renal involvement (303.01±287.33 vs177.98 + 75.43, p: 0.020 respectively). Moreover PLR negatively correlated with glomerlar filtration rate (r:-0.266 and p:0.009). Receiver operating characteristic curve of PLR, ESR and CRP for differentiating renal involvement is presented in Figure 1. Area Under Curves (AUCs) for PLR, CRP and ESR were 0.703 (95% confidence interval [CI], 0.558–0.849, p=0.016), 0.577 (95% CI: 0.416–0.738, p=0.362), 0.508 (95% CI: 0.337–0.678, p=0.929), respectively. The cutoff level of PLR was 204 (sensitive 65.6%, specifity 62.5%, positive predictive value 70%, negative predictive value 57.7%). Patients with alveolar hemorrhage tended to have higher PLR but this difference did not reach statistically significance (266.60 + 182.90 vs 240.61 + 252.43 p=0.382, respectively).
Conclusions: Results suggest that PLR exhibit favorable diagnostic performance in predicting renal involvement in patients with GPA.

Table 1. Clinical characteristics and laboratory findings of the patients and healthy controls

	GPA patients	Controls	p value
Age (years)	48.14 ± 14.09	46.77 ± 14.14	0.614
Males (n)	33 (58.9%)	26 (49.1%)	0.034
WBC (x 10^3/uL)	12359.96 ± 6604.92	7230.80 ± 1630.33	<0.001
Neutrophils	9267.74 ± 5701.73	4285.73 ± 1597.18	<0.001
Lymphocytes	1805.64 ± 986.24	2311.22 ± 581.93	<0.001

FRI0321 CIRCULATING IL-6 AND OTHER METABOLIC BIOMARKERS COMPARING EFFECTS OF MODIFIED-RELEASE PREDNISONE (MR) AND IMMEDIATE-RELEASE PREDNISOLONE (IR) IN NEW GCA

E. Miler[1], S. Mapplebeck[1], C. Mackerness[1], L. Wilson[1], T. Aung[1], D. Gayford[1], J.P. Schofield[2], B. Dasgupta[1]. [1]*Southend University Hospital NHS Foundation Trust, Westcliff-on-Sea;* [2]*Napp Pharmaceuticals Limited, Cambridge Science Park, Milton Road, United Kingdom*

Background: GCA may be an interleukin-6 (IL-6) driven disease and IL-6 blockade is emerging as an exciting therapy of IL-6.[1] We measured serial IL-6 levels in new patients with GCA treated in an RCT of modified-release prednisone (MR) versus immediate-release prednisolone (IR) used in a tapering regimen conforming to BSR guidelines.[2,3]
Methods: Patients (n=12) were randomised into two treatment arms (7 MR, 5 IR) and followed up over 26 weeks. IL-6 samples were collected at 9am at weeks 4, 10, 18 and 26 and were measured using Beckman Coulter IL-6 immunoassay, validated in a controlled study according to ACB criteria. We also measured bone markers (CTX, P1NP, vitamin D), HbA1c, cortisol, ACTH and PTH.
Results: Significantly higher overall mean IL-6 levels were seen in the IR arm (n=5) compared to MR (n=7) [unpaired two-tailed Student's t test]. IL-6 levels in both arms were lowest between weeks 4–10 and continued to decrease in the IR arm to week 26, whereas lower but constant levels were seen in the MR arm (Figure)
Mean CTX concentration was significantly higher at week 4 (M =0.29, SE =0.04) compared to Week 26 (M =0.13, SE =0.02) p=0.002. No significant difference was seen between treatment arms.
Patients on MR had complete suppression of ACTH compared to IR ($p<0.05$) without a significant difference between groups in 9 am cortisol levels (p=0.3412). No significant differences were seen in levels of vitamin D, calcium, PTH, ESR, CRP, or HbA1c.

Conclusions: Our study suggests that elevated levels of Il-6 are better suppressed by MR prednisone therapy compared to IR prednisolone in new GCA. Bone resorption marker CTX was significantly reduced in both treatment arms. ACTH suppression with MR prednisone may reflect a greater impact on the HPA axis although cortisol levels were not affected.
Our findings suggest that MR prednisone may warrant further clinical trial investigation in GCA.

FRI0322 ASSESSMENT OF DAMAGE AND PROGNOSIS IN PATIENTS WITH ADULT IGA VASCULITIS: RETROSPECTIVE MULTICENTERED COHORT STUDY

F. Alibaz-Oner[1], A. Omma[2], A. Sarı[3], O. Karadag[3], D. Uskudar Cansu[4], C. Bes[5], F. Yildiz[6], M.F. Oksuz[7], S. Yilmaz[8], A. Balkarli[9], S. Ureyen[10], H. Direskeneli[1]. [1]*Rheumatology, Marmara University, School of Medicine, Istanbul;* [2]*Rheumatology, Ankara Numune Education and Research Hospital;* [3]*Rheumatology, Hacettepe University, School of Medicine, Ankara;* [4]*Rheumatology, Osmangazi University, School of Medicine, Eskisehir;* [5]*Rheumatology, Bakırkoy Sadi Konuk Education and Research Hospital, Istanbul;* [6]*Rheumatology, Van Education and Research Hospital, Van;* [7]*Rheumatology, Uludag University, School of Medicine, Bursa;* [8]*Rheumatology, Selcuk University, School of Medicine, Konya;* [9]*Rheumatology, Antalya Education and Research Hospital, Antalya;* [10]*Rheumatology, Sakarya Education and Research Hospital, Sakarya, Turkey*

Background: IgA Vasculitis is a leukocytoclastic vasculitis involving small vessels with depositions of immune complexes containing IgA. There is limited data for the prognosis of adult IgA Vasculitis, with also no damage assessment.
Objectives: We aimed to evaluate the clinical characteristics, treatment, outcome and damage of patients with adult IgA Vasculitis.
Methods: We assembled a retrospective cohort of patients with adult IgA Vasculitis, from tertiary Rheumatology Centers in Turkey. All data were abstracted from medical records. Birmingham Vasculitis Activity Score (BVAS),prognostic Five Factor Score (FFS) and vasculitis damage index (VDI) were calculated.
Results: The study included 52 (male/female:40/12) patients with adult IgA Vasculitis. The mean age was 42.2±17 years. Infection history within 6 weeks before presentation was present in 22 (42.3%) patients (18 upper respiratory tract,3 gastrointestinal and 1 urinary tract). Cutaneous manifestations were the most common clinical manifestations (Table 1). All patients were treated with oral glucocorticoids (GC).As additional immunosuppressive agents, azathiopirine was given to 21 (40.4%) and pulse cyclophosphamide to 11 (21.2%) patients. Twenty-eight patients (53.9%) had follow-up of 28.6 months. Five (17.8%) patients relapsed during follow-up. While 3 relapses were major, 2 of them were minor relapses. At the last visit, disease status was evaluated as active or treatment failure by the treating physician in 6 (21.4%) patients. Mortality was 3.6% (n=1) during follow-up, due to pneumonia. The mean VDI score was 0.6 in the last visit. Nine (32.1%) patients had at least one damage item at the end of follow-up period.

Table 1. Clinical characteristics of patients with adult IgA Vasculitis

	Adult IgA Vasculitis (n=52)
Laboratory parameters	
Erythrocyte Sedimentation Rate (mm/hour)*	32.7±22
C-reactive protein (mg/l)†	25.2 (1–94.9)
Proteinuria (>300mg/24 hours)	28 (53.9%)
Creatinine (mg/dl)*	0.9±0.4
Clinical Manifestations, n/52 (%)	
Fever	7 (13.5%)
Weight loss	14 (26.9%)
Myalgia/Weakness/Leg tenderness	24 (46.2%)
Arthritis and/or arthralgia	46 (88.5%)
Neurologic manifestations	1 (1.9%)
Testicular pain or tenderness	3 (5.8%)
Recent onset or severe hypertension	2 (3.8%)
Cutaneous Manifestations	48 (92.3%)
Gastrointestinal manifestations	39 (75%)
FFS=0	29 (55.8%)
FFS=1	15 (28.8%)
FFS≥2	8 (15.4%)
BVAS score at diagnosis*	4.1±1.7

FFS: Five Factor Score, BVAS: Birmingham Vasculitis Activity score. *Mean ± SD; †Median (Minimum–maximum.)

Conclusions: Our results showed that approximately one fifth of patients with adult IgA Vasculitis had relapses during follow-up. At the end of follow-up, one third of patients had at least one damage item. Although, 45% of patients had FFS≥1, the mortality rate was observed to be low in the present study.

FRI0323 COMPARISON OF BIOPSY PROVEN GIANT CELL ARTERITIS IN NORTH AMERICA AND SOUTHERN EUROPE: A POPULATION-BASED STUDY

F. Muratore[1], C.S. Crowson[2], L. Boiardi[1], M.J. Koster[2], G. Restuccia[1], T.A. Kermani[3], E.L. Matteson[2], C. Salvarani[1], K.J. Warrington[2]. [1]*Rheumatology Unit, Arcispedale Santa Maria Nuova IRCCS, Reggio Emilia, Italy;* [2]*Division of Rheumatology, Mayo Clinic, Rochester, MN;* [3]*Department of Medicine, David Geffen School of Medicine, University of California, Los Angeles, United States*

Objectives: To compare clinical characteristics, treatment, long-term follow-up and prognosis of two population-based cohorts of patients with biopsy-proven giant cell arteritis (GCA) from Olmsted County, Minnesota, USA (Olmsted cohort) and the Reggio Emilia area, Northern Italy (Reggio cohort).
Methods: All patients residing in Olmsted County and the Reggio Emilia area

with a new diagnosis of biopsy-proven GCA in 1986–2007 were retrospectively identified. Patients were followed from GCA diagnosis to death, migration or September 2011. Comparisons were performed using Chi-square and rank sum tests, Kaplan-Meier methods and Cox models.
Results: The study included 110 patients in the Olmsted and 144 in the Reggio cohort. Compared with the Olmsted cohort, patients from the Reggio cohort were younger (mean±SD age 74.6±7.4 years vs 77.8±7.6, p=0.002), more likely to have cranial symptoms (93% vs 86%, p=0.048), temporal artery abnormalities at physical examination (68% vs 42%, p<0.001), partial or complete unilateral or bilateral permanent vision loss (21% vs 6%, p=0.001), systemic symptoms (67% vs 46%, p=0.001) and polymyalgia rheumatica at or before GCA diagnosis (47% vs 26%, p<0.001). Scalp tenderness was less common in the Reggio cohort (36% vs 49%, p=0.033). ESR and CRP were higher (mean 88±29 mm/h vs 73±77, p<0.001 and mean 89.0±60.2 mg/L vs 35.2±43.4, p<0.001 respectively) and hemoglobin lower (mean 11.2±1.4 g/dl vs 11.8±1.4, p=0.004) in Reggio than in the Olmsted cohort. Patients from the Olmsted cohort received a higher initial prednisone dose (mean 53.6±15.3 mg/day vs 49.5±12.8, p=0.001). There were no differences in relapse rates, cumulative glucocorticoid (GC) dosages at 1, 2 and 5 years, and time to first GC discontinuation. However, the Reggio cohort reached a prednisone dose <10 mg/day sooner (median 4.9 months vs 7.9, p=0.012) and had a first relapse later (median 13.6 months vs 7.9, p=0.003) than the Olmsted cohort. Patients from the Reggio cohort had a significantly higher mortality compared to those from the Olmsted cohort (HR 1.72, 95% CI 1.12–2.65 adjusted for age and sex).
Conclusions: Genetic and/or environmental factors may contribute to the differences in clinical characteristics and disease outcomes observed in this study comparing patients with GCA from North America and Southern Europe.

FRI0324 SMALL VESSEL VASCULITIS SURROUNDING A PRESERVED TEMPORAL ARTERY: A DIAGNOSTIC ALGORITHM TO ASSESS CLINICAL SIGNIFICANCE

G. Espigol Frigole[1], M. Terenas[2], S. Prieto-Gonzalez[1], R. Alba[3], J. Hernandez-Rodriguez[1], E. Planas-Rigol[3], M. Corbera-Bellalta[3], N. Terrades[3], M.C. Cid[1]. *[1]Systemic and Autoimmune Diseases Department, Hospital Clinic of Barcelona, Barcelona, Spain; [2]Medicine Department, Hospital de Santa Maria, Lisboa, Portugal; [3]Institut d'Investigacions Biomèdiques Pi i Sunyer (IDIBAPS). CELLEX, Barcelona, Spain*

Background: Systemic vasculitides are complex and heterogeneous diseases with overlapping features that frequently pose a diagnostic challenge to clinicians. The temporal artery biopsy (TAB) is the gold standard for the diagnosis of giant cell arteritis (GCA) but, occasionally, TAB show inflammation of small vessels surrounding a spared temporal artery (SVV) as the only pathologic finding. Ultimate diagnosis and, consequently, optimal treatment remain uncertain in these patient.
Objectives: To analyze the final diagnosis of patients with SVV surrounding a spared temporal artery after a pre-established diagnostic algorithm and to identify clinical and laboratory findings with potential usefulness in predicting the ultimate diagnosis.
Methods: Patients with TAB showing SVV were subjected to the diagnostic algorithm displayed in figure 1, completed by at least 1 year follow-up. Clinical and laboratory features at the time of diagnosis were recorded. The algorithm led to the following final diagnosis: GCA, other systemic vasculitis and undetermined condition. Chi-squared and ANOVA tests were used for statistical comparison using IBM SPSS Statistics 20.
Results: From 1998 to 2007, 380 TAB were performed in our institution. Biopsy disclosing small vessel inflammation surrounding a normal temporal artery (SVV) was described in 47 (12%) patients. In all patients TAB was selected as the first invasive procedure because GCA was initially considered the most likely diagnosis. Accordingly, 24 (51%) fulfilled at least 3 ACR classification criteria for GCA. 7 patients declined to undergo subsequent work-up to complete the diagnostic algorithm, 10 died or were lost to follow –up before completing 1 year. All of them were excluded. The study cohort consisted of 30 patients (19 women and 11 men) aged 77±10.4 years followed for 55.16±55.20 months. In 13 patients the final diagnosis was consistent with GCA based on the absence of SVV in other territories, large-vessel inflammation by imaging or subsequent development of aortic aneurysm; in 12 SVV was subsequently demonstrated in other territories and were diagnosed with other systemic vasculitis (7 AAV, 0 cryo, 3 PAN, 0 vasculitis associated to autoimmune diseases, 2 unclassified small vessel vasculitis), and in 5, diagnosis remained undetermined. No significant differences in clinical or routine laboratory abnormalities were found among patient subgroups stratified according to the final diagnosis.
Conclusions: Inflammation of small vessels surrounding a spared temporal artery in a TAB conveys a substantial diagnostic uncertainly. After a detailed diagnostic work-up most of patients can be diagnosed with GCA. However other systemic vasculitis requiring more aggressive treatment may disclose similar histopathologic findings and are also frequent and diagnosis remains uncertain in a substantial proportion of cases. Search for more accurate molecular biomarkers is necessary for a better interpretation of these findings

FRI0325 PREVALENCE OF TAKAYASU ARTERITIS IN YOUNG WOMEN WITH ACUTE ISCHEMIC HEART DISEASE

G. Cavalli, A. Tomelleri, E. Baldissera, L. Dagna. *Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UniRAR), Vita-Salute San Raffaele University, Milan, Italy*

Background: Takayasu arteritis (TA), a systemic vasculitis typically occurring in female patients aged ≤40, can affect the coronary arteries and cause ischemic heart disease. The prevalence of TA among young females with acute ischemic heart disease is undetermined.
Objectives: In this study, we investigated the prevalence of TA in young women presenting with ischemic heart disease in the Emergency Department.
Methods: We conducted a retrospective evaluation of the hospital records of 172,790 consecutive female patients aged <45, who accessed the Emergency Department of our institution over 8 consecutive years (2007–2015). The prevalence of TA and of other etiologies of ischemic heart disease was determined. Diagnosis of TA was established based on the 1990 American College of Rheumatology criteria.
Results: Overall, 2,090 women aged <45 presented to the Emergency Department with chest pain, dyspnea, palpitations, angina, heart failure, or cardiac arrest; 40 had confirmed acute ischemic heart disease. The etiology was "classic" atherosclerosis in 24 cases (60%), TA in 4 cases (10%), vasospasm and sympathomimetic drug abuse in 3 cases each (7.5%), coronary artery dissection and microvascular angina in 2 cases each (5%), Takotsubo and radiation-induced cardiomyopathy in 1 case each (2.5%).
Conclusions: Although a diagnosis of TA is likely to be overlooked, TA is not infrequent in younger females presenting with acute ischemic heart disease. Specifically, TA accounted for 10% of cases of acute ischemic heart disease in female patients aged <45, a finding relevant to the diagnosis and management of these young patients.

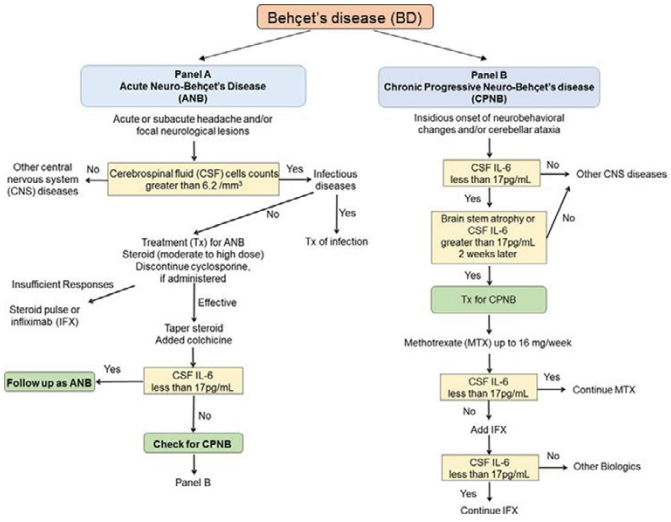
FRI0326 RECOMMENDATIONS FOR THE MANAGEMENT OF NEURO-BEHÇET DISEASE BY JAPANESE RESEARCH COMMITTEE FOR BEHÇET DISEASE

H. Kikuchi[1], T. Sawada[2], M. Okada[3], M. Takeno[4], M. Kuwana[4], Y. Ishigatsubo[5], I. Kawachi[6], H. Mochizuki[7], S. Kusunoki[8], S. Hirohata[9]. *[1]Department of Internal Medicine, Teikyo University School of Medicine; [2]Department of Internal Medicine 3, Tokyo Medical University School of Medicine; [3]Immuno-Rheumatology Center, St. Luke's International Hospital; [4]Department of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine, Tokyo; [5]Department of Internal Medicine and Clinical Immunology, Yokohama City University Graduate School of Medicine, Yokohama, Japan, Kanagawa; [6]Department of Neurology, Niigata University Medical and Dental Hospital, Niigata; [7]Department of Neurology, Osaka University Graduate School of Medicine; [8]Department of Neurology, Kinki University School of Medicine, Osaka; [9]Department of Rheumatology and Infectious Diseases, Kitasato University School of Medicine, Kanagawa, Japan*



Background: Central nervous system involvement is one of the most serious complications in Behçet's disease (BD). This condition is referred to as neuro-

Behçet's disease (NB) and can be classified into acute type (ANB) and chronic progressive type (CPNB) based upon differences in the clinical course and responses to corticosteroid treatment. Diagnostic criteria were generated in 2013 based on a multicenter clinical survey performed by the Behçet's Disease Research Committee of the Ministry of Health, Labor and Welfare of the Japanese Government. Although "Guidelines for Treatment of NB" was also proposed based on the survey, it is still preliminary.

Objectives: The aim of the current study is to develop evidence-based recommendations for the management of NB supplemented by expert opinions where necessary.

Methods: First, clinical questions (CQs) on NB were extracted from a literature search for problem areas and related keywords, and draft CQs and a flow chart were prepared. The expert committee, a task force of the research subcommittee for NB, consisted of 7 board-certified rheumatologists (one was also a board-certified neurologist) and 3 board-certified neurologists. A systematic literature search was performed using Medline and the Japan Medical Abstract Society databases from 1997 to 2016. A total of 15 initial CQs were generated. These yielded the final recommendations developed from 3 blind Delphi rounds, in which the rate of agreement scores on CQs (range 1 [disagree]–5 [strongly agree]) was determined though voting by the whole committee.

Results: Thirteen recommendations were developed for the management of NB (general 1, ANB 7, CPNB 5). The strength of each recommendation was established based on the evidence level as well as rate of agreement. There was excellent concordance between the level of agreement of rheumatologists and that of neurologists. Based on these recommendations, a flow chart was established for the management for ANB and CPNB (Figure).

Conclusions: The recommendations generated in this study are mainly based not only on expert opinions but on the results of uncontrolled evidence from open trials and retrospective cohort studies. Guidelines that can be used for international studies are needed, for which verification by further properly designed controlled clinical trials is required.

FRI0327 GASTROSCOPIC FEATURES AND CLINICAL CHARACTERISTICS IN 172 CASES OF CHILDREN WITH HENOCH-SCHONLEINPURPURA

H. Zeng. *Department of Pediatric Allergy, Immunology and Rheumatolog, Guangzhou Women and Children's Medical Center, Guangzhou, China*

Objectives: To investigate gastroscopic features and explore the relationship between clinical characteristics in children with Henoch-Schonleinpuepura (HSP).

Methods: To take gastroscope in 172 cases of children with HSP in our hospital and summarize the gastroscopic performance.All the case were divided into two groups by gastroduodenal mucosal bleeding or not.It was compared among the total time of abdominal pain, pain relief, hospitalization, fasting and kidney injury case in the groups.

Results: Gastroscope with varying degrees of injury of 172 cases has accounted for 169 cases (98.3%).Gastroscopic mainly revealedgastroduodenal mucosal congestion, edema, rough, erosion, bleeding and ulcer, which involved 148 cases of gastric (86.0%), 158 cases of duodenal involvement (91.9%). Mucosal erosion and bleeding occurs mainly in duodenum,mostly in the descending duodenum. Duodenal bleeding accounted for 36 cases (21.8%) in the bulb and 92 cases (55.8%) in the descendant. Only five cases (2.9%) of ulcer occurred in the duodenum, where four cases of bulbar ulcer, one case of descending ulcer. Esophageal and gastric cardia mucosal just occurred in one case. There were not significant difference ($P>0.05$) among the time of abdominal pain, pain relief, hospitalization and fasting in the group. There was no significant difference ($P>0.05$) in the incidence of kidney injury between two groups of children during hospitalization.

Conclusions: Gastroscopic features of HSP in children is characterized by bleeding, erosion of duodenal mucosa and occasional duodenal ulcer formation, which mostly involve the antral mucosa, rarely involving the esophagus, cardia. There was no significant difference ($P>0.05$) among the severity of gastroscopic performance and the time of abdominal pain, fasting,hospitalization and kidney injury of the cases during hospitalization.

FRI0328 THE DIAGNOSTIC VALUE OF ALPHA-1-ANTITRYPSIN PHENOTYPE IN SYSTEMIC VASCULITIS

I. Belyaeva[1], A. Chudinov[2], M. Pervakova[3], V. Mazurov[1], S. Lapin[3], O. Inamova[2]. *[1]North-West State Medical University named after I.I. Mechnikov, Saint-Petersburg, Russia; [2]Clinical Rheumatological Hospital #25, Saint-Petersburg, RUSSIA; [3]First Pavlov State Medical University of St. Petersburg, Saint-Petersburg, Russian Federation*

Background: Deficiency of alpha-1 protease inhibitor, or alpha-1-antitrypsin (A1AT) is a frequent genetic disorder, which is characterized by low serum level of A1AT and usually manifests as pulmonary emphysema and liver disease. Also the deficiency of A1AT is known to be associated with granulomatosis with polyangiitis (GPA). The influence of A1AT deficiency on GPA clinical course is not clarified.

Objectives: The aim of this study was to estimate the prevalence of pathological A1AT phenotypes in GPA and other systemic vasculitis and to define the influence of A1AT phenotype on clinical course of GPA.

Methods: We enrolled 86 patients with systemic vasculitis, including GPA (N=47), microscopic polyangiitis (MPA, N=16), eosinophilic granulomatosis with polyangiitis (EGPA, N=12), polyarteriitisnodosa (PN, N=11). 46 healthy donors were included in the control group. All blood samples underwent A1AT phenotyping by isoelectrofocusing (IEF) and turbidimetric A1AT measurement. The results of phenotyping were compared to clinical data, such as BVAS activity rate (Birmingham Vasculitis Activity Score), VDI index (vasculitis damage index), organs involvement, inflammatory markers, including antineutrophil cytoplasmic antibodies (ANCA), total IgG concentration and serum levels of C3, C4 complement factors.

Results: Pathological A1AT phenotypes were found in 17% (8/47) of GPA patients, 6,25% (1/16) of MPA patients, 2% (1/46) of healthy donors and were never found in EGPA, PN. The abnormal phenotypes in GPA were 1PiZZ, 4PiMZ, 2PiMF, 1PiMS, and 1PiMS phenotype was identified in MPA patient. Lesion of lung and upper respiratory tract was observed in all patients with pathological phenotypes A1AT (N=8), while in normal phenotype A1AT it was present in 72% and 82% respectively. The mean concentration of A1AT was significantly lower in GPA patients with abnormal A1AT phenotypes, than in patients with normal phenotype A1AT (respectively 1003±148.8 and 1964±127.9 mg/L, $p<0,01$). The average activity by BVAS index in GPA was significantly higher in patients with pathological phenotype A1AT than in patients with normal phenotype A1AT (24,63±2,897 and 18,05±1,444 points, $p<0,05$). Also we revealed excess levels of VDI in cohort of patients with abnormal phenotype A1AT rather, than in cohort of patients with normal phenotype A1AT (6,3±3,1 versus 5,4±2,6, $p<0,05$). The average values concentration of antibodies to proteinase-3 in GPA patients with abnormal phenotype A1AT were significantly higher compared to GPA patients with normal phenotype A1AT (respectively 142,4±25,24 and 86,784±14,98 RU/ml, $p<0,05$). In GPA patients with mutated A1AT phenotypes levels of serum creatinine concentrations ($p<0,01$), levels of total IgG concentration and serum levels of C3 and C4 complement factors ($p<0.05$) also were significantly higher than in group of GPA patients with normal A1AT phenotype.

Conclusions: Pathological A1AT phenotypes are more often observed in GPA patients who have more severe GPA clinical course and higher immunological disease activity.

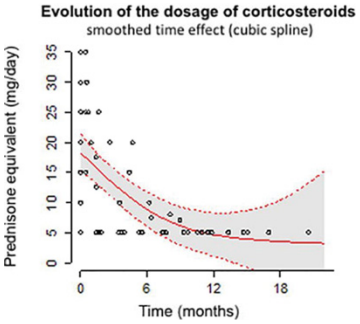
FRI0329 EFFICACY AND SAFETY OF INFLIXIMAB ORIGINATOR IN PATIENTS WITH TAKAYASU ARTERITIS WITHIN THE RTU (TEMPORARY RECOMMENDATION OF USE) IN FRANCE



J.-F. Kleinmann[1], L. Arnaud[1], E. Sauleau[2], N. Gouyette[3], R. Tajima[1], J. Sibilia[1] on behalf of CRI (Club Rhumatismes et Inflammation). *[1]Rheumatology; [2]Public Health, Strasbourg's University Hospital, Strasbourg; [3]MSD France, Courbevoie, France*

Background: The benefit/risk ratio of infliximab in refractory patient with Takayasu arteritis (TA) is assumed to be favorable, based on retrospective studies with limited sample size [1, 2] in which infliximab has been prescribed off-label.

Since 2013, the French Temporary Recommendation of Use (RTU) provides a temporary framework allowing the use of infliximab originator in "TA patients refractory to conventional treatment" during a 3-year period.

Objectives: The aim of the study was to evaluate the real-life efficacy and safety of infliximab originator in TA patients initiating or with ongoing infliximab treatment.

Methods: Prospective, multicenter, observational, open-label, study of TA patients treated with infliximab originator.
Results: As of 2016 (2 years of follow-up), the study included 14 patients (13/14 were female; median age 32 [range 12–56] years) with TA (diagnosis according to Ishikawa criteria). At study entry, the median TA duration was 4.7 (0.4–16) years, 12 patients were already treated with infliximab originator (for a median duration of 34 [1–78] months) and 11 patients were receiving corticosteroids (CS).
Infliximab originator was administered at a median dose of 5 (3–6) mg/kg with a median interval of 8 (2–67) weeks between each infusion. Seven patients had an improvement in at least 1 of the NIH disease activity criteria for TA [3] after a median follow-up time of 2 (0.4–11) months), 4 had smoldering disease and 1 patient worsened.
The median daily dose of CS decreased from 13 (5–35) mg/day of prednisone or equivalent at baseline to 7 (5–10) mg/day at 6 months, to 5 (5–6) mg/day at 12 months, and remained stable up to 22 months of follow-up.
Infliximab was discontinued in 6 patients due to inefficacy (n=3), prior to pregnancy (n=2), or remission of TA (n=1). Two adverse events (1 disease flare and 1 spontaneous miscarriage) were reported, without infliximab interruption.

Conclusions: Infliximab originator appears to provide an effective and favourable benefit:risk treatment option to refractory TA patients.
