Welcome Address

Dear Colleagues,

Welcome to this EULAR Annual European Congress of Rheumatology in Madrid!
Welcome to the 70th anniversary of EULAR!

The annual EULAR Congresses, which began in 2000, are today a major event in the calendar of world rheumatology. This meeting, which marks the 70th anniversary of our very active society, will once again provide a unique occasion for the exchange of scientific and clinical information. It will facilitate interaction between patients, medical doctors, scientists, health professionals and professionals representing the pharmaceutical industry from Europe and from around the world. Participating in the congress is just one element of the annual educational package provided by EULAR: Almost all oral presentations will be available online after signing up and participants will be provided with a complimentary, one-year subscription to the latest developments and publications in the field of rheumatic and musculoskeletal diseases (RMDs). This is in line with a new, exciting event taking place in Madrid this year – the launch of the EULAR School of Rheumatology, which will be unique in providing education in rheumatology throughout the world.

EULAR has grown rapidly in terms of the number of participants and the quality of the submissions. A record number of more than 4'850 abstracts have been submitted to this year's congress in Madrid, and 180 sessions and poster tours are offered. This tremendous success continues to reflect the increasing interest in RMDs; it also reflects the availability of increased information on the size, burden and cost of these diseases for society – and a significantly improved ability to diagnose and treat them. The incorporation of health professional and patient organisations within EULAR has been a considerable stimulus for these advances.

The EULAR Congress 2017 in Madrid will provide a wide range of topics including clinical innovations, clinical translational and basic science. In addition, there will be significant contributions made by People with Arthritis and Rheumatism (PARE), by Health Professionals in Rheumatology (HPR) and by the health care industry. The core science and central activity of the congress will be the poster presentations and poster tours with their highly interactive exchanges between participants. The Madrid meeting will further promote the reputation of the EULAR Congress as a most innovative and informative venue for clinical research for the practising physician and health professionals. Meanwhile, the EULAR EMEUNET organisation of young rheumatologists aims to attract young colleagues to the meeting and will disseminate the message that rheumatology is one of the most attractive and successful disciplines of medicine.

We are back in the vibrant city of Madrid with its remarkable history, architecture, galleries, museums and ambience, all of which will once again provide an excellent background for clinical exchanges, international collaborations and renewal of friendships. "No pierdas tu tren" and in international language "Don't Delay, Connect Today!" marks the first general EULAR Campaign to be launched in Madrid aiming at early recognition and treatment of RMDs.

It is our great pleasure and a real joy in welcoming medical doctors, patients, health professionals and representatives of the pharmaceutical industry and we hope their stay in Madrid will be delightful, informative, and educational. We wish you a great time, good science, good discussions, good meetings and most of all good memories to take home when you are heading back from Madrid and from our 70th anniversary congress.

Gerd R. Burmester
President of EULAR

SP0001–SP0004 Joint EULAR - APLAR session: novel animal models - where no researcher has gone before... ... 2
SP0005–SP0008 Health professional welcome session 2
SP0009 WIN & HOT session 3
SP0010–SP0012 Moving towards new criteria in SLE, Sjögren's and APS 4
SP0013–SP0016 The differential diagnosis of diffuse skin sclerosis and of Raynaud's phenomenon and a practical approach to assessment 5
SP0017–SP0018 Controling the balance between cancer and autoimmunity 5
SP0019–SP0021 Fibromyalgia: a disease of the peripheral or central nervous system 6
SP0022 Chondrocyte channels (role in mechanotransduction)or "channeling the chondrocyte" 6
SP0023–SP0024 Wearable technologies in 21st century healthcare 7
SP0025–SP0027 Assessment and management of osteoporosis 7
SP0028–SP0030 Systematic literature review: the link from science to clinical practice 8
SP0031–SP0033 EULAR Campaign: Don't Delay, Connect Today 8
SP0034–SP0036 Standing Committee session on paediatric rheumatology 9
SP0037–SP0040 Ultrasound basic I & II 10
SP0041–SP0043 Rehabilitation and modern drug treatment - needs and challenges 10
SP0044–SP0046 Comorbidities: having one RMD is enough - we don't need anything else 11

Thursday, 15 June 2017

SP0047–SP0049 Cytokines and chemokines 11
SP0050–SP0052 Bringing rheumatology research to the next level: addressing the main challenges of patient partnerships in research and health care service design 12
SP0053 WIN & HOT session 13
SP0054–SP0056 Treat-to-target in axSpA: reality or utopy? 13
SP0057–SP0058 Calcium crystal deposition in rheumatic diseases 14
SP0059–SP0060 Fifty shades of remission in RA 15
SP0061–SP0063 Innate immunity 15
SP0064–SP0066 To be and to become: transition from paediatric to adult care 16
SP0067–SP0068 Heterogeneity in JIA 16
SP0069–SP0070 EULAR - EMA session 17
SP0071–SP0073 Barrier free employment for young people with RMDs 17
SP0074 Epidemiology of rheumatic and musculoskeletal diseases - a critical appraisal 18
SP0075–SP0077 Ultrasound advanced I & II 19
SP0078–SP0079 PsA: an integrated perspective 19
SP0080 Autoinflammatory diseases in children and adults 20
SP0081–SP0083 Immunogenicity of biologics; myth or reality? 20
SP0084–SP0085 Which target / outcome is more relevant in the management of SLE? 21
SP0086–SP0087 Joint EULAR - EFIS session: Tilting the balance: from disease to tolerance induction 21
SP0088–SP0090 What to do about comorbidity? 22
SP0091 Data visualisation: tables and graphs for publication and presentation I & II 23
SP0092–SP0094 Difficult to reach patient groups 23
SP0095–SP0097 EULAR Projects in musculoskeletal imaging 24

SP0098–SP0100	Capillaroscopy I & II	24
SP0101–SP0103	Ultrasound, clinical, diagnostic and therapeutic skills I & II	25
SP0104–SP0105	Macrophage M2 polarization: implications in fibrotizing diseases	26
Friday, 16 June 2017		
SP0106	Mucosal B cells: gatekeepers of immune function	26
SP0107	WIN & HOT session	27
SP0108	Comorbidities in rheumatoid arthritis	27
SP0109–SP0110	Life-threatening presentation of rheumatic diseases	27
SP0111	AxSpA: From bug to gut and to disease phenotype	28
SP0112–SP0114	Pregnancy meets rheumatic patients	28
SP0115–SP0116	Neuronal and hormonal alterations in arthritis	29
SP0117–SP0120	Fighting osteoporosis fragilities	29
SP0121–SP0122	Biological agents in juvenile idiopathic arthritis: open issues	30
SP0123–SP0124	Health equity and economy - a vital relationship	31

SP0138–SP0140	Patient engagement in research: best practices, benefits, and challenges	34
SP0141–SP0142	RA treatment in patients wanting to become pregnant - interactive session	35
SP0143–SP0144	Latest advances in the treatment and management of psoriatic arthritis and the latest news on the use of Biosimilars in RMDs	35
SP0145–SP0148	From pre-RA to established RA	35
SP0149	Laboratory course - from the clinic to the lab and back II	36
SP0150–SP0151	Switching T on and off: how T cells drive and regulate chronic inflammation	36
Saturday, 17 June 2017		
SP0152–SP0153	Reverse translation - learning from clinical trials in SLE, Sjögren's and APS	37
SP0154–SP0156	Genomic imprinting and post-translational modifications	37
SP0157–SP0158	Optimizing treatment for osteoarthritis: take the phenotype in account "one size does not fit all"	38
SP0159–SP0162	Targeting adipose tissue inflammation	38
SP0163–SP0165	Trials and tribulations of medication adherence	39
SP0166	Outcome in juvenile idiopathic arthritis	40
SP0167	Getting financial support to research in RMDs through horizon 2020: opportunities, good practices, and successful experiences	41
SP0168–SP0171	EULAR Projects - challenging projects in education and training	41
SP0172–SP0174	Workshop: strengthening your organisation - how to manage volunteers	42
SP0175	WIN & HOT session	42
SP0176–SP0177	Systemic sclerosis	42
SP0178	How diet influences musculoskeletal diseases	43
SP0179–SP0180	Can targeting disease activity in hand osteoarthritis improve our treatment in the 21st century	43
SP0181–SP0184	Why we do develop autoimmunity	44
SP0185–SP0188	Closing the gap between objective measures and self-report in fibromyalgia	45
SP0189	Interactive cases from the HOT and WIN sessions	45
SP0190	Suffering in silence. Optimizing the management of psychological well-being for people with RMDs	46
SP0191–SP0194	Showcasing the EULAR Online Course for Health Professionals	46
SP0195	HPR Highlight session	47

OP0073–OP0080	Risk factors for developing diseases or comorbidities	82
OP0081–OP0088	Scleroderma, myositis and related syndromes, etiology, pathogenesis	85
OP0089–OP0096	Novel insights in inflammatory mediators	89

Thursday, 15 June 2017

OP0097	Cytokines and chemokines	92
OP0098–OP0105	Progress in biological treatment of RA	92
OP0106–OP0113	PsA: a fascinating disease	96
OP0114–OP0121	More or less imaging in axial SpA?	100
OP0122–OP0129	Clinical and therapeutical news in systemic sclerosis	103
OP0130–OP0137	Vasculitis clinical and pathogenic highlights	107
OP0138-HPR–OP0145-HPR	HPR mind over matter - patients perspectives	110
OP0146–OP0153	RA: really a systemic disease?	113
OP0154–OP0161	Advances in RA and SpA pathophysiology	116
OP0162-PARE–OP0163-PARE	Bringing rheumatology research to the next level: addressing the main challenges of patient partnerships in research and health care service design	119
OP0164–OP0171	Osteoarthritis: new horizons for treatment	119
OP0172–OP0179	Cellular drivers of inflammation in rheumatic disease	123
OP0180–OP0187	Joint health & joint damage: a tale of three tissues	126
OP0188–OP0189	Treat-to-target in axSpA: reality or utopy?	129
OP0190–OP0191	Calcium crystal deposition in rheumatic diseases	130
OP0192	Fifty shades of remission in RA	131
OP0193–OP0194	Innate immunity	131
OP0195	To be and to become: transition from paediatric to adult care	132
OP0196–OP0197	Heterogeneity in JIA	132
OP0198-PARE–OP0199-PARE	Barrier free employment for young people with RMDs	133
OP0200	Epidemiology of rheumatic and musculoskeletal diseases - a critical appraisal	134
OP0201–OP0202	PsA: an integrated perspective	135
OP0203–OP0204	Immunogenicity of biologics; myth or reality?	136
OP0205–OP0206	Which target / outcome is more relevant in the management of SLE?	137
OP0207–OP0208	Joint EULAR - EFIS session: tilting the balance: from disease to tolerance induction	138
OP0209-HPR	What to do about comorbidity?	139
OP0210-PARE–OP0211-PARE	Difficult to reach patient groups	139
OP0212–OP0213	Macrophage M2 polarization: implications in fibrotizing diseases	140

Friday, 16 June 2017

OP0214–OP0215	Mucosal B cells: gatekeepers of immune function	141
OP0216–OP0223	PsA: the options grow!	141
OP0224–LB0003	From classics to new: synthetic DMARDs in RA	146
OP0231–LB0002	New treatments in SLE, Sjögren's and APS	150
OP0238–OP0245	Axial spondyloarthritis from risk factors to clinical outcomes	153
OP0246–OP0253	RA - causes and courses	157
OP0254-HPR–OP0261-HPR	HPR move to improve	161
OP0262–OP0269	Gout: advances in diagnosis and management	164
OP0270–LB0001	Low back pain and fibromyalgia	168
OP0276-PARE–OP0282-PARE	PARE abstract session	171
OP0283–OP0290	Imaging and treamtent response in rheumatology	173
OP0291–OP0298	From genetics through epigenetics to proteomics: understanding disease mechanisms	177
OP0299–OP0306	Innovative insights into mechanism of SLE, Sjögren's and APS	180
OP0307–OP0308	Comorbidities in rheumatoid arthritis	182
OP0309	AxSpA: from bug to gut and to disease phenotype	183
OP0310–OP0311	Pregnancy meets rheumatic patients	184
OP0312–OP0313	Neuronal and hormonal alterations in arthritis	184
OP0314-HPR	Fighting osteoporosis fragilities	185
OP0315–OP0316	Biological agents in juvenile idiopathic arthritis: open issues	186
OP0317-PARE–OP0318-PARE	Health equity and economy - a vital relationship	186
OP0319	Biomarkers in cardiovascular rheumatology - state-of-the-art 2017	187
OP0320–OP0321	What is behind vasculitis?	187
OP0322	Cytokine taxonomy: reflection in the therapy of arthritides and other IMIDs	188
OP0323–OP0324	Personalised care for back pain	188
OP0325–OP0326	Regulatory molecules in connective tissue	189
OP0327-PARE	Patient engagement in research: best practices, benefits and challenges	190
OP0328-PARE	Latest advances in the treatment and management of psoriatic arthritis and the latest news on the use of biosimilars in RMDs	190
OP0329–OP0330	Switching T on and off: how T cells drive and regulate chronic inflammation	191

Saturday, 17 June 2017

OP0331	Reverse translation - learning from clinical trials in SLE, Sjögren's and APS	192
OP0332–OP0333	Genomic imprinting and post-translational modifications	192
OP0334–OP0335	Optimizing treatment for osteoarthritis: take the phenotype in account "one size does not fit all"	193
OP0336	Targeting adipose tissue inflammation	194
OP0337-HPR	Trials and tribulations of medication adherence	194
OP0338	Outcome in juvenile idiopathic arthritis	195
OP0339	Systemic sclerosis	195
OP0340	How diet influences musculoskeletal diseases	196
OP0341–OP0342	Can targeting disease activity in hand osteoarthritis improve our treatment in the 21st century	196
OP0343	Why we do develop autoimmunity	197
OP0344-HPR	Closing the gap between objective measures and self-report in fibromyalgia	198
OP0345-PARE–OP0346-PARE	Suffering in silence. Optimizing the management of psychological well-being for people with RMDs	198
OP0347-HPR	Showcasing the EULAR Online Course for Health Professionals	199

Late Breaking Abstracts

Friday, 16 June 2017

LB0001	Low back pain and fibromyalgia	170
LB0002	New treatments in SLE, Sjögren's and APS	153
LB0003	From classics to new: synthetic DMARDs in RA	149

Poster Presentations

Thursday, 15 June 2017

Guided Poster Tours

T1:	THU0001–THU0010	Genetic basis, egpigenetics an genomics in disease	200
T2:	THU0025–THU0034	Inflammatory mediators in rheumatic disease	208
T3:	THU0068–THU0077	RA disease course and prognosis	224
T4:	THU0168–THU0176	MTX, GCs and JAK inhibitors in RA	265
T5:	THU0216–THU0225	Pathomechanism in SLE, SS, APS	286
T6:	THU0246–THU0257	Novelty in the clinical approach to SLE, Sjögren's and APS I	297
T7:	THU0294–THU0303	Vasculities clinical aspects I	314
T8:	THU0345–THU0354	Progress in managment of spondyloarthritis	334
T9:	THU0401–THU0410	A stroll among the crystals	359
T10:	THU0486–THU0495	Paediatric rheumatology	390
T11:	THU0538–THU0547	Clinicial features and treatment of orphan diseases	410
T12:	THU0596–THU0605	Rheumatology training and disease burden	431
T13:	THU0648–THU0657	Economical impact of biosimilars and sicussing risks with patients	450
T14:	THU0695–THU0704	Outcomes across all rheumatology	470

Posters

THU0001–THU0024	Genomics, genetic basis of disease and HLA / T cell recognition	200
THU0025–THU0067	Cytokines and inflammatory mediators	208
THU0068–THU0115	Rheumatoid arthritis - prognosis, predictors and outcome	224
THU0116–THU0167	Rheumatoid arthritis - comorbidity and clinical aspects	245
THU0168–THU0215	Rheumatoid arthritis - non biologic treatment	265
THU0216–THU0245	SLE, Sjögren's and APS - etiology, pathogenesis and animal models	286
THU0246–THU0293	SLE, Sjögren's and APS - clinical aspects (other than treatment)	297
THU0294–THU0344	Vasculitis	314
THU0345–THU0400	Spondyloarthritis - treatment	334
THU0401–THU0467	Crystal diseases, metabolic bone diseases and bone diseases other than osteoporosis	359
THU0468–THU0483	Fibromyalgia	384
THU0484–THU0485	Basic science in paediatric rheumatology	389
THU0486–THU0537	Paediatric rheumatology	390
THU0538–THU0579	Other orphan diseases	410
THU0580–THU0598	Education	425
THU0599–THU0657	Public health, health services research and health economics	432
THU0658–THU0704	Validation of outcome measures and biomarkers	455
THU0705–THU0719	Rehabilitation	474

Friday, 16 June 2017

Guided Poster Tours

F1:	FRI0022–FRI0031	RA stromal cells - reloaded	487
F2:	FRI0129–FRI0138	RA all over the body	529
F3:	FRI0179–FRI0190	TNF inhibitors in RA = always and again	548
F4:	FRI0212–FRI0222, FRI0178	Trends in non-TNF alpha bilogicals for RA I	562, 548
F5:	FRI0255–FRI0265	Novelty in the clinical approach to SLE, Sjögren's and APS II	582
F6:	FRI0303–FRI0312	Vasculities clinical aspects II	601
F7:	FRI0353–FRI0362	Scleroderma and myositis: etiology	620
F8:	FRI0363–FRI0372	Indexes and predictors in systemic sclerosis and myositis	624
F9:	FRI0420–FRI0423, FRI0080–FRI0084	New drivers in RA and SpA pathophysiology	645, 507
F10:	FRI0472–FRI0481	Outcome in AxSpA: does it matter?	665
F11:	FRI0524–FRI0533	Osteoporosis risk assessment and treatment: new tools and new strategies	689
F12:	FRI0582–FRI0591	What's new in orphan diseases	709
F13:	FRI0623–FRI0632	Imaging advances in arthritis - what is new?	724
F14:	FRI0683–FRI0692	Risk factors for RMDs or comorbid conditions	748

Posters

FRI0001–FRI0021	Cartilage, synovium and osteoimmunology	480
FRI0022–FRI0084	Rheumatoid arthritis - etiology, pathogenesis and animal models	487
FRI0085–FRI0128	Rheumatoid arthritis - prognosis, predictors and outcome	509
FRI0129–FRI0177	Rheumatoid arthritis - comorbidity and clinical aspects	529
FRI0178–FRI0211	Rheumatoid arthritis - anti-TNF therapy	548
FRI0212–FRI0254	Rheumatoid arthritis - other biologic treatment	562
FRI0255–FRI0302	SLE, Sjögren's and APS - clinical aspects (other than treatment)	582
FRI0303–FRI0352	Vasculitis	601
FRI0353–FRI0362	Scleroderma, myositis and related syndromes - etiology, pathogenesis and animal models	620
FRI0363–FRI0419	Scleroderma, myositis and related syndromes	624
FRI0420–FRI0429, FRI0431	Spondyloarthritis - etiology, pathogenesis and animal models	645, 649
FRI0430–FRI0481	Spondyloarthritis - clinical aspects (other than treatment)	649
FRI0482–FRI0523	Psoriatic arthritis	670
FRI0524–FRI0581	Osteoporosis	689
FRI0582–FRI0622	Other orphan diseases	709
FRI0623–FRI0682	Diagnostics and imaging procedures	724
FRI0683–FRI0731	Epidemiology, risk factors for disease or disease progression	748

Saturday, 17 June 2017

Guided Poster Tours

S1: SAT0010–SAT0019	Innate mediators and autoantibodies in rhematic disease	772
S2: SAT0027–SAT0036	How B and T cells contribute to rheumatic disease	777
S3: SAT0037–SAT0046	RA - risk factors and consequences	781
S4: SAT0088–SAT0097	From the heart of rheumatology	802
S5: SAT0176–SAT0187	Trends in non-TNF alpha bilogicals for RA II	836
S6: SAT0219–SAT0230	New treatment options in SLE, Sjögren's and APS	856
S7: SAT0312–SAT0321	SSc, myositis and rare diseases: etiology and animal models	890
S8: SAT0372–SAT0381	Last news on systemic sclerosis and myositis	911
S9: SAT0433–SAT0441	A walk through PsA progress	935
S10: SAT0483–SAT0494	Steps forward in osteoarthritis research	958
S11: SAT0556–SAT0565	Infection related rheumatic disease: clinical and epidemiologic aspects	987
S12: SAT0609–SAT0618	Imaging advances in vasculitis, crystal and connective tissue disease	1004
S13: SAT0669–SAT0678	Comorbidities and outcomes in RMDs	1027

Posters

SAT0001–SAT0016	Innate immunity in rheumatic diseases	769
SAT0017–SAT0036	Adaptive immunity (T cells and B cells) in rheumatic diseases	774
SAT0037–SAT0087	Rheumatoid arthritis - prognosis, predictors and outcome	781
SAT0088–SAT0139	Rheumatoid arthritis - comorbidity and clinical aspects	802
SAT0140–SAT0175	Rheumatoid arthritis - anti-TNF therapy	821
SAT0176–SAT0218	Rheumatoid arthritis - other biologic treatment	836
SAT0219–SAT0261	SLE, Sjögren's and APS - treatment	856
SAT0262–SAT0311	SLE, Sjögren's and APS - clinical aspects (other than treatment)	873
SAT0312–SAT0324	Scleroderma, myositis and related syndromes - etiology, pathogenesis and animal models	890
SAT0325–SAT0381	Scleroderma, myositis and related syndromes	895
SAT0382–SAT0432	Spondyloarthritis - clinical aspects (other than treatment)	916
SAT0433–SAT0482	Psoriatic arthritis	935
SAT0483–SAT0555	Osteoarthritis	958
SAT0556–SAT0582	Infection-related rheumatic diseases	987
SAT0583–SAT0608	Back pain, mechanical musculoskeletal problems, local soft tissue disorders	996
SAT0609–SAT0668	Diagnostics and imaging procedures	1004
SAT0669–SAT0716	Epidemiology, risk factors for disease or disease progression	1027

Abstracts Accepted for Publication

Joint EULAR - APLAR session: novel animal models - where no researcher has gone before...

SP0001 RELEVANCE OF ANIMAL MODELS IN OSTEOARTHRITIS

T. Pap. *Institute of Experimental Musculoskeletal Medicine (IEMM), University Münster, Münster, Germany*

Osteoarthritis (OA) is the most frequent joint disease and a leading cause of disability in the Western world. Currently, we do not have a cure for this degenerative disorder and despite a high individual and socioeconomic demand, available therapeutic strategies have not changed substantially within the last 40 to 50 years, largely involving basic symptomatic control using analgesics and NSAIDS, physiotherapy and behavioural changes, and eventual prosthetic replacement in end-stage disease. While prosthetic joint replacement constitutes an effective surgical treatment option for patients whose joints are irreversibly damaged by OA, demographic development together with altered physical activities in our aging society increasingly demonstrate the limitations of joint replacement surgery as the only real treatment modality. There is, therefore, an urgent requirement for disease modifying drugs that aim to halt OA disease progression during the early stages and potentially to kick start cartilage regeneration. This need is contrasted, however, by a sustained "translational roadblock" in OA research with very few conceptually novel therapeutic approaches on the horizon. Amongst others, this "translational roadblock" results from a general lack in our understanding of how articular chondrocytes as the only cells in joint cartilage acquire and maintain their specific and highly specialised phenotype and how this phenotype changes during OA onset and progression. Investigation of this developmental aspect of disease pathology in OA patients and using human samples has many limitations, which is why animal models remain to constitute a key element of cartilage and OA research. This lecture summarizes the relevance of different animal models for understanding fundamental principles of cartilage homeostasis and remodelling in health and osteoarthritic cartilage degeneration. By focusing on the analysis of chrondrocyte phenotypic stability, it provides examples for how the use of such models can contribute to understanding OA and to the development of new therapeutic strategies for the disease.

SP0002 NOVEL ANIMAL MODELS IN SYSTEMIC SCLEROSIS

X. Yu. *Research Center Borstel, Borstel, Germany*

Systemic sclerosis (SSc) is a severe autoimmune disease with a considerable reduction of life expectancy. Autoimmunity, vasculopathy and fibrosis are three hallmarks of SSc, while the pathogenesis of the disease is largely unknown. Animal models of SSc provide an excellent tool to for exploring the disease pathogenesis of the disease. Aiming to provide a concise and curate updates in the field of animal models of SSc, this lecture will concentrate on emerging novel animal models and highlight new development and their impact on understanding pathogenesis of SSc.

SP0003 NOVEL ANIMAL MODEL IN ARTHRITIS

Y. Iwakura. *Research Institute for Biomedical Sciences, Tokyo University of Science, Chiba, Japan*

We have generated two rheumatoid arthritis (RA) models, human T-cell leukemia virus type I (HTLV-I) transgenic mice and IL-1 receptor antagonist (Ra)-deficient (KO) mice, to elucidate the pathogenic mechanisms of the disease. Both models spontaneously developed arthritis that closely resembles RA in humans. We found that TNF-, but not IL-6-, deficiency suppressed development of arthritis in IL-1Ra KO mice, while IL-6 but not TNF was involved in the development of arthritis in HTLV-I transgenic mouse model. IL-17 plays an important role in both models, suggesting the central role of IL-17 in these RA models.

We found that the expression of C-type lectin receptor (CLR) genes was augmented in the affected joints of these models using DNA microarrays. Dendritic cell immunoreceptor (DCIR) is one of such CLRs with a carbohydrate recognition domain in their extracellular carboxy terminus and an ITIM in its intracellular amino terminus. Because human syntenic locus for the CLR genes is linked to several autoimmune diseases including RA and SNPs in the *Dcir* gene is associated with RA, we have generated *Dcir* KO mice to examine the roles of this gene in the immune system. We found that aged *Dcir* KO mice spontaneously developed autoimmune enthesitis and ankyloses accompanied by fibrocartilage proliferation and ectopic ossification. DCs were excessively expanded in *Dcir* KO mice, causing these mice autoimmunity and also highly susceptible to induced-autoimmune diseases. *Dcir* KO mouse–derived bone marrow cells differentiated into DCs more efficiently than did wild-type BMCs upon treatment with GM-CSF, due to enhanced STAT-5 phosphorylation. Furthermore, we found that IFN-g producing T cells were increased in *Dcir* KO mice and IFN-g enhanced bone and cartilage formation, resulting in the increase of bone volume and aberrant ossification in joints. DCIR is also expressed in osteoclasts and suppresses osteoclastogenesis upon activation. These findings suggest that DCIR plays important roles in both immune system and bone metabolism.

SP0004 PEPTIDYL ARGININE DEIMINASE 4 AND RHEUMATOID ARTHRITIS: FROM HUMAN GENETICS TO MURINE MODELS

K. Yamamoto[1,2]. [1]*The University of Tokyo, Tokyo;* [2]*RIKEN, Yokohama, Japan*

We have previously reported that functional haplotypes of peptidyl arginine deiminase 4 *(PADI4*) are associated with rheumatoid arthritis (RA). We found that transcripts of the risk haplotype of *PADI4* are more stable than those of the non-risk haplotypes, suggesting that increased expression and function of PAD4 (encoded by *PADI4* gene) increase the risk of RA. The association has been confirmed by several studies with different ethnics. Further, we also reported *PADI4* polymorphisms highly predispose male smokers to RA. Since PAD4 catalyzes an arginine residue in a protein to citrulline and anti-citrullinated protein antibodies (ACPA) are highly specific in RA, it has been reasonable to speculate that increased PAD4 is associated with increased citrullinated proteins, leading to the initiations of tolerance breakdown or inflammatory arthritis.

However, the mechanisms of PAD4 involvement turned out to be more complex than previously thought in animal models. In order to investigate the pathological process in detail, we made *Padi4* knockout mice. Decreased severity of experimental autoimmune arthritis wad observed in these mice. Further, we found PAD4 regulates the pro-apoptotic fate of neutrophils, and promotes the expression of pro-inflammatory cytokines in macrophages. These actions could result in the pro-arthritic roles of *PADI4*. Recently, neutrophil extracellular traps (NETs) were reported as an important immune stimulator in RA and SLE, and PADI4 is required for the generation of NETs. Especially, NET-containing immune complex (IC) stimulated plasmacytoid dendritic cells to accelerate the interferon secretion in SLE. Therefore, *PADI4* could play several different roles in the immune system and also in the pathogenesis of autoimmune diseases.

Health professional welcome session

SP0005 LOOKING BACK AT 70 YEARS OF EULAR AND 30 YEARS OF HP INVOLVEMENT: A REHABILITATION PERSPECTIVE

T. Vliet Vlieland. *Orthopaedics J11-R, Leiden University Medical Center, Leiden, Netherlands*

The medical treatment of people with rheumatic and musculoskeletal diseases (RMDs) has improved enormously over the past decades. As medical treatment is not completely successful or available for all rheumatic conditions or individual patients, and the demands society imposes on people to participate fully are increasing, there is a substantial proportion of people with RMDs who have functional disabilities.

Health professionals (HPs) play an essential role in the management of people with RMDs with disabilities by enabling to reach and maintain their optimal physical, sensory, intellectual, psychological and social functional levels. They provide people with the tools they need to attain independence and self-determination. As such, their contribution is in line with the World Health Organisation definition of rehabilitation [http://www.who.int/topics/rehabilitation/en/]. An important feature of rehabilitation is its multidisciplinarity. Over the past decades, it has been more and more acknowledged that HPs' role in the management of people with RMDs concerns a team effort rather than the summation of single interventions by individual HPs or specific professions. This view is reflected in multiple guidelines and standards of care for the clinical management of RMDs, where the need for people with RMDs to have access to a multidisciplinary team of HPs is underlined.

The acknowledgement of the importance of the team of HPs runs in parallel with developments in the organization and activities of HPs within EULAR over the past years.
In connection with EULAR, there is a growing network of HPs from multiple professions across Europe. By working together, and collaborating with patients and rheumatologists and other physicians, EULAR HPs have achieved multiple milestones with respect to the quality of clinical care, education, and research over the past years and are equipped to encounter future challenges.

SP0006 LOOKING BACK AT 70 YEARS OF EULAR AND 30 YEARS OF HP INVOLVEMENT: A NURSING PERSPECTIVE

J. Hill[1,1]. *Retired, -Harrogate, United Kingdom*

At the 1987 EULAR Congress held in Athens, a British nurse, Vicky Stephenson, arranged a meeting that was attended by about 30 health professionals. The meeting decided that a working group of Health Professionals from different professions and countries should work towards establishing a Standing Committee within EULAR. This was achieved in 1989 and since that time, the role of Health Professionals within EULAR has changed dramatically.
In this lecture, I will describe the evolution of rheumatology nursing over the past thirty years, and the part that EULAR has played in the dissemination, education and facilitation of best nursing practice and experiences within Europe. This will be illustrated by two pieces of work. In late 2009, EULAR part funded a Web-based survey to evaluate the status of extended roles undertaken by health professionals in Europe. The data from this survey relating to nursing has been extracted and analysed separately and will be presented. The following year, EULAR also funded a study to investigate the role of the nurse in the management of chronic inflammatory arthritis. The important recommendations resulting from this piece of work will also be shown.
Following the recommendations project, a number of other important nursing initiatives have been launched under the auspices of EULAR. These will be highlighted to enable delegates to understand how far rheumatology nursing has developed and how far it still has to go.

SP0007 70 YEARS PAST AND A VIEW OF THE FUTURE: LOOKING BACK AND LOOKING FORWARD

H.W. Bijlsma. *Department of Rheumatology & Clinical Immunology, University Medical Center, Utrecht, Netherlands*

In 1913 the Dutch general practitioner Jan van Breemen, moved by the needs of the many disabled people in his practice, started an international cooperation to fight rheumatic and musculoskeletal diseases. His initiative led to the formation of the International League Against Rheumatism (ILAR), and subsequently to the formation of regional Leagues, such as EULAR in 1947.
EULAR has in the following 70 years developed into a unique organisation of rheumatologists, scientists, health professionals and patients, who together are aiming *to reduce the burden of rheumatic diseases on the individual and society and to improve the treatment, prevention and rehabilitation of musculoskeletal diseases. To this end, EULAR fosters excellence in education and research in the field of rheumatology. It promotes translation of research advances into daily care and fights for the recognition of the needs of people with RMDs by the governing bodies in Europe* (EULAR mission statement 2005).
The first European Rheumatology Congress was held in September 1947 in Copenhagen and was attended by 200 delegates from 16 countries. At the EULAR 2017 Madrid Congress over 14.000 attendees are expected, coming from more than 120 countries.
EULAR is unique in the sense that three pillars work closely together in one organization: rheumatologists, health professionals and patients. Today, I want to focus a bit on the health professionals pillar, since this pillar has its formal 30 years jubilee in 2017 as well. At the American celebration of 50 years of non-physician health professionals in Rheumatology (2015), Brady described three science-driven practice paradigm shifts that play an important role in managing patients with RMDs: 1.The widely used “Self-management programs”, that were developed from information giving and ’patient education’. 2.The positive and intensive use of “Exercise and physical activity”, that were developed from previous acclaimed bed rest and assisted range of motion exercises. 3. The OMERACT initiated definitions and applications of Patient-reported outcome measures, instead of only biomedical assessment of disease activity.
In addition, she recognized two “evolutions in practice”: 1.Understanding Psychological Factors, from accepting “the arthritic personality” to actively addressing depression, anxiety, coping skills, sense of control and confidence. 2. The development of the important role that nurses and other health professionals can play in the treatment of patients with RMDs.
The EULAR health professionals can be very proud of the important part that Europeans have played in these worldwide developments.
My priorities as president-elect of EULAR for the coming two years are:
- Further development of the School of Rheumatology
- Large public awareness campaign: Don’t delay, Connect today
- New EULAR Strategy 2018–2023

I hope and expect that the pillar of health professionals will take an active role in the cooperation that is necessary to reach our common goals.

SP0008 THE FUTURE FOR HEALTH PROFESSIONALS IN RHEUMATOLOGY

A. De Thurah[1,2]. *[1]Department of Clinical Medicine, Aarhus University; [2]Department of Rheumatology, Aarhus University Hospital, Aarhus, Denmark*

In recent years the prevalence of rheumatic diseases has raised leading to increased outpatient activity; at the same time, a general lack of rheumatologists has been described (1). This has created new demands from patients and the health care system towards innovative models of care, e.g. nurse-led follow-up (2), direct access strategies (3) and tele-health interventions (1). In the future this will call for extended and specialized roles for health-professionals within rheumatology, and for future development of compatibility of training of health professionals within the European countries.
Further, the current health-service development is confronting the population with increasing demands to understand and utilize health information and to navigate through this increasingly complex healthcare system. It requires that patients are capable of understanding and managing their health, and calls upon a strong focus on health-literate (HL) skills, and the formation of so-called HL organizations (4). In the future, health professionals within rheumatology will have a key role in supporting the development of HL responsive organizations through self-management strategies and patient centered care.
The present presentation will address some of these future demands for health professionals in Rheumatology

WIN & HOT session

SP0009 WHAT IS NEW (WIN) IN PSORIATIC ARTHRITIS

R. Lories. *Skeletal Biology and Engineering Research Center, Dept. of Development & Regeneration, KU Leuven, Leuven, Belgium*

Novel therapies and targets have transformed the management of psoriatic arthritis and related skin disease psoriasis. The successful introduction and widespread use of anti-IL17, anti-IL12/23 and anti-PDE4 strategies have joined the ranks of TNF inhibitors. Novel biological insights into specific disease mechanisms are co-emerging with this new wave of treatment options. The different available treatments allow the community to further focus on optimal patient management aiming at remission or minimal disease activity. Yet, the assessment of the patient and his/her satisfaction with current health status remains challenging. Treat to target initiatives are trying to define optimal care and cure adapted to the specific characteristics of the disease. Molecular knowledge of the disease processes remains scattered and insufficient to build a comprehensive view on the disease for the individual patient that would allow the personalized definition of effective strategies.

Moving towards new criteria in SLE, Sjögren's and APS

SP0010 CLASSIFICATION OF SLE – CHALLENGES AND POTENTIAL SOLUTIONS

M. Aringer on behalf of SLE Classification Criteria Steering Committee. *Medicine III, University Medical Center TU Dresden, Dresden, Germany*

Systemic lupus erythematosus is characterized by a wide variety of autoantibodies, which, if pathogenic, can lead to inflammation, damage, thrombosis or functional defects of essentially all organ systems. The 1982 American College of Rheumatology classification criteria and their 1997 revision have greatly influence the disease concept over the last decades. With the at least 4 out of 11 criteria to be present, they essentially depict the concept of multiple autoantibodies and multiple organs systems. Putting all items on equal weight made the system relatively easy to use and to memorize, but this approach was not entirely intuitive. Dermatologists have criticized that patients could meet the criteria based on fulfilling all 4 mucocutaneous criteria only. Importantly, sensitivity was felt to be suboptimal, reaching 83% in the cohort of the SLE International Collaborating Clinics (SLICC) group, and lower values in very early disease.

The 2012 SLICC SLE classification criteria introduced two new concepts. First, patients have to be positive for autoantibodies, namely for anti-nuclear antibodies (ANA) or antibodies to double-stranded DNA. Second, if patients are autoantibody-positive, classification criteria can be fulfilled by nephritis on histology without any other items. The SLICC groups also introduced large lists of skin and neuropsychiatric symptoms and refined some of the definitions. While many of these ideas are intuitively correct, not all were derived in a pre-defined scientific way. These criteria managed to increase sensitivity to 97% in their own validation data and to a range of 92–99% in other cohorts. At the same time, however, the SLICC set lost specificity, falling to 84% as compared to the 96% of the ACR criteria. This trade-off was presumably influenced by the SLICC group's choice to keep the overall structure the same. Early disease sensitivity was still not optimal.

In a large transatlantic project jointly supported by EULAR and the ACR, we have over the last years tried to develop (even) better SLE classification criteria. The main goals are to have a relatively intuitive set that helps in teaching, increase sensitivity as compared to the ACR criteria, but maintain specificity in the same range, improve the performance in early SLE, involve the larger SLE community as far as possible, and do this in a strictly scientific way. Given that ANA often are the door to SLE in the diagnostic approach, and that ANA have very high sensitivity, but modest specificity for SLE, we explored whether ANA could be used as an entry criterion. Meta-regression, after compiling ANA data of 13,080 SLE patients from a systemic literature search, gave a sensitivity of 97.8% (CI 96.8–98.5%) for a titer of at least 1:80 on HEp2-ANA immunofluorescence. It was therefore decided that HEp2-ANA of $\geq$1:80 would be used as an entry criterion.

Three different approaches were used to maximize the overview on potential items, namely an SLE expert Delphi exercise involving 123 SLE experts, an international early disease cohort with 389 SLE patients and 227 patients with conditions mimicking SLE, and a patient survey, which 339 SLE patients filled out and mailed anonymously. The resulting 41 items were then reduced in a nominal group technique exercise with 7 international SLE experts, resulting in a list of 20 items plus ANA as an entry criterion. These items were then submitted to multi-criteria decision analysis in a two day conference with 6 international experts together with the steering committee. This approach under the same moderator (Dr. Ray Naden) had already been successfully used for the rheumatoid arthritis and systemic sclerosis criteria.

The present results are 20 weighted items, which can be additively used within a continous scale, and a cut-off for classification. Weights for class III or IV lupus nephritis are much higher than for leukopenia or unexplained fever. This candidate system will now be tested against both the ACR and the SLICC criteria in a large cohort of SLE patients and patients with mimicking conditions. If successful, ANA of $\geq$1:80 and weighted criteria will lead to better performance, particularly in early disease, and give us a system that is hopefully intuitive enough to convey an idea of the disease.

SP0011 SJÖGREN'S CRITERIA REVISITED!

S.J. Bowman. *University Hospital Birmingham Rheumatology Dept, Birmingham, United Kingdom*

In clinical practice it is up to the clinician to use their judgement in making a diagnosis of pSS. In research it is essential to have agreed classification criteria so that there is confidence that participants in a study have the specified condition. During the 1980's a number of classification criteria were proposed with a major debate as to the advantages and disadvantages of each of these criteria.

In 1988 a working group of 29 experts from 12 European countries initiated a study to develop consensus criteria. They published their initial findings in 1993 and in 2002 Vitali et al published the American European Consensus Group Criteria (AECG). The AECG criteria have been the most widely used "gold-standard" criteria for the classification of pSS in research studies. Criteria are never fixed in perpetuity, however, and as new technology such as ultrasound becomes more widely used or new data becomes available further revision is likely. In 2013, an International Collaboration, the Sjögren's International Clinical Collaborative Alliance (SICCA) funded by the National Institutes for Health in the USA collected data from 1618 participants to devise the American College of Rheumatology (ACR) preliminary criteria for SS and in 2016 following a further international consensus group exercise the American College of Rheumatology – European League against Rheumatism (EULAR) consensus criteria for Sjögren's syndrome have been published.

In this presentation I will go through the development of these criteria, the underlying rationale and by the end of the talk attendees should have a better understanding of how these criteria can be used in research and to support clinical practice.

SP0012 ADVANCED APS CRITERIA 2016/2017

P.L. Meroni. *Rheumatology, ASST G Pini - Res. Lab Immunorheumatology, Ist. Auxologico Italiano, University of Milan, Milan, Italy*

The classification of the anti-phospholipid syndrome (APS) is based on the occurrence of arterial/venous thrombotic events and/or pregnancy complications with no identifiable causes in the persistent presence of medium/high titres of anti-phospholipid antibodies (aPL) detectable by solid phase (anti-cardiolipin – aCL or anti-beta2 glycoprotein I – ab2GPI) tests and/or PL-dependent functional coagulation assays (lupus anticoagulant – LA). These classification criteria are currently also used as diagnostic tools.

aPL represent a risk factor, consequently the presence of two/three positive diagnostic laboratory tests is a valuable parameter to stratify the patients at highest risk for developing the syndrome/recurrences.

The syndrome displays a protean clinical picture depending on the involved tissue/organ. The majority of the clinical (criteria) manifestations are clearly related to vascular ischemic events. However some manifestations apparently cannot be supported by a thrombotic mechanism and alternative pathogenic pathways have been suggested. This is the case for thrombocytopenia, central nervous system involvement such as movement disorders and cognitive abnormalities, and APS nephropathy. Heart valve disease, skin ulcers and livedo reticularis are also frequent events in APS patients and their relationship with vascular thrombosis is unclear. Still debated is the suggestion to include these manifestations as additional clinical diagnostic criteria. The possibility to use all these criteria for ranking the patients as having a definite (standard clinical criteria) or probable APS (non classification criteria) is also debated.

The revised criteria for obstetric morbidity comprise otherwise unexplained pregnancy loss. Some of the obstetric criteria might display low sensitivity/specificity for APS. In particular the attribution to aPL of a pregnancy wastage early on gestational course requires the exclusion of a myriad of ethiologies. Conversely, the rate of late foetal losses is very low, making this criterion rather specific. Placenta-mediated obstetric complications provide another critical field: pre-eclampsia and intra-uterine growth restriction are relatively common. To enhance the specificity for APS, the classification criterion included only cases requiring delivery before 34 weeks of gestation. Medium/high aPL titres and double/triple laboratory tests positivities confer a higher risk for pregnancy complications but recent data seem to suggest that also persistent low aPL titres can be predictive for a negative pregnancy outcome. This finding has been recently explained by the availability of large amounts of b2GPI in tissues of the reproductive system. Even though classification criteria have allowed uniformity in APS diagnosis, there still remain some controversies.

The field of the laboratory classification criteria is even more in progress. Epitope profiling for anti-b2GPI antibodies is quite promising since the characterization of reactivity against the domain 1 of the molecule appears to display a higher specificity for APS and stronger predictive value than the antibodies against the whole molecule. However, anti-domain 1 assay is less sensitive and cannot replace the standard test at the moment. Antibodies against prothrombin (PT) have been reported to be associated with both the vascular and the obstetric APS, in particular when the antibodies are detectable against a solid phase complex of PT with phosphatidylserine (PS) (the so called anti-PS/PT assay). However a clear evidence for their usefulness in the clinical diagnosis and risk stratification for APS patients as well as their true pathogenic role is still debated.

The differential diagnosis of diffuse skin sclerosis and of Raynaud's phenomenon and a practical approach to assessment

SP0013 WIDESPREAD CUTANEOUS THICKENING – COULD THIS BE EARLY DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS?

A. Suarez. *Royal National Hospital for Rheumatic Diseases, Bath, United Kingdom*

A case of diffuse sclerosing skin disease shall be presented. The features that initially led the treating team to consider a diagnosis of systemic sclerosis shall be discussed, alongside subsequent features that emerged that cast doubt over this diagnosis and led the team to undertake additional investigative studies. The presentation shall provide a chronological description of the clinical features, laboratory studies, microvascular imaging and histological studies that helped the team to reach a definitive diagnosis and plan management accordingly.
Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.7183

SP0014 THE DIFFERENTIAL DIAGNOSIS OF DIFFUSE SCLEROSING SKIN DISEASE AND A PRACTICAL APPROACH TO ASSESSMENT

J. Pauling[1,2]. *[1]Pharmacy and Pharmacology, University of Bath; [2]Rheumatology, Royal National Hospital for Rheumatic Diseases (Royal United Hospitals), Bath, United Kingdom*

The differential diagnosis for sclerosing skin disease is broad but there are clinical and laboratory features that can help guide clinicians to the correct diagnosis. This presentation shall provide a comprehensive review of the spectrum of sclerosing skin disease. A practical approach to interpreting the clinical, serological, microvascular imaging and histological features that can help differentiate disease states shall be presented to provide rheumatologists with a practical approach to the assessment of patients with sclerosing skin disease. Case histories shall be used to illustrate the pertinent clinical features and investigative approaches that can help distinguish systemic sclerosis from other sclerosing skin conditions such as scleroedema, pan-sclerotic morphoea, lipodermatosclerosis and chronic graft versus host disease. A specific focus shall be placed on the role of autoantibodies in the diagnosis of systemic sclerosis, including recent work reporting the presence of novel systemic sclerosis-specific autoantibodies in patients with antinuclear antibody-negative diffuse cutaneous systemic sclerosis.
Disclosure of Interest: J. Pauling Grant/research support from: Actelion pharmaceuticals, Consultant for: Actelion pharmaceuticals, Speakers bureau: Actelion pharmaceuticals

SP0016 THE DIFFERENTIAL DIAGNOSIS OF RAYNAUD'S PHENOMENON AND PRACTICAL APPROACH TO ASSESSMENT WITH A FOCUS ON IMAGING

A.L. Herrick. *University of Manchester, Manchester, United Kingdom*

Raynaud's phenomenon is the term used to describes episodic vasospasm of the digital vasculature in response to cold exposure and/or emotional distress. The majority of people with Raynaud's phenomenon have primary (idiopathic) Raynaud's phenomenon which is 'benign' in that it does not progress to irreversible digital ischaemia, and is not associated with any underlying disease. Conversely, when Raynaud's phenomenon is secondary to an underlying disease/condition (for example to a systemic sclerosis-spectrum disorder), it can be severe, sometimes progressing to digital ulceration and/or gangrene. Raynaud's phenomenon is often the presenting feature of connective tissue disease and therefore provides a window of opportunity for early diagnosis.
The first step in management of Raynaud's phenemenon is establishing the diagnosis. Is this primary or secondary Raynaud's, and if secondary, then to what? While a careful history and examination are always the first steps, different laboratory tests and vascular imaging studies can be used to reach the correct diagnosis. This presentation will provide practicing rheumatologists with a practical approach to the diagnosis and assessment of Raynaud's phenomenon, focussing on the diagnostic and prognostic role of vascular imaging (including nailfold capillaroscopy and thermography).

Controling the balance between cancer and autoimmunity

SP0017 SHARED MECHANISMS IN CANCER AND AUTOIMMUNITY

A. Rosen. *Medicine/Rheumatology, Johns Hopkins University School of Medicine, Baltimore, Md 21205, United States*

Some rheumatic disease autoantibodies are powerful markers of subgroups of patients who have distinct disease phenotypes and trajectories. Of particular interest are markers of several disease subgroups in whom cancer and rheumatic disease onset are clustered together in time. For example, a subgroup of scleroderma patients have coincident onset of cancer and scleroderma. This is observed in scleroderma patients with autoantibodies against the RNA polymerase-3 (POLR3), and more recently with autoantibodies recognizing the minor spliceosome. In autoimmune myopathies, temporal clustering of diagnosis of cancer and myositis is associated with autoantibodies to NXP2 and components of the TIF1 complex. Interestingly, although the incidence of cancer is higher in patients with these autoantibodies, most patients with these autoantibodies manifest cancer, even with extended periods of follow-up. These observations provide an important opportunity to investigate the potential mechanisms which operate at the cancer-immune interface during development of rheumatic diseases.
We have investigated such mechanisms in scleroderma patients with autoantibodies to POLR3 who also had a cancer diagnosed an average of -2.6 years from scleroderma onset. In cancers from these patients, we found genetic alterations of the POLR3A locus in six of eight patients with antibodies to POLR3 but not in eight patients without these antibodies. 3 antibody-positive patients had somatic mutations in POLR3A; 5 patients had loss of heterozygosity at the POLR3A locus. Analyses of peripheral blood lymphocytes and serum suggested that POLR3A mutations sparked cellular immunity and cross-reactive humoral immune responses. These results offer insight into the pathogenesis of scleroderma, and potentially other autoimmune syndromes. They suggest that somatic mutations in autoantigens in different cancers might initiate an immune response to the mutated autoantigen, which spreads to include the wild type version. Tissues (e.g. blood vessels, regenerating muscle) in which specific autoantigens are expressed at high levels, or potentially play critical functional roles, may be particularly susceptible to immune-mediated dysfunction. The results also provide support for the idea that acquired immunity helps to control naturally occurring cancers in patients with autoimmune rheumatic diseases; it is possible that this immune response may sometimes be fully effective, preventing the emergence of cancer.

SP0018 CONTROLING THE BALANCE BETWEEN CANCER AND AUTOIMMUNITY

A. Marabelle[1,2]. *[1]Drug Development Department; [2]INSERM U1015, Gustave roussy, Villejuif, France*

Immunotherapy is revolutionizing cancer therapy with a paradigm shift: antibodies are now designed to target immune cells rather than cancer cells with the aim of stimulating the anti-tumor immune response. Monoclonal antibodies targeted against CTLA-4, PD-1 or PD-L1 and anti-CTLA-4 + anti-PD-1 combinations have shown potent activity with significant improvements in the overall survival of patients. Multiple other immunomodulatory drugs are currently in development. These novel therapies generate immune related adverse events that mimick auto-immune diseases. These side effects represent a major challenge for the implementation of immunotherapy in oncology. The aim of this talk will be to provide an update on the clinical results of combination therapies and discuss the current challenges and perspectives for the future of immuno-oncology.

Fibromyalgia: a disease of the peripheral or central nervous system

SP0019 SIGNS, SYMPTOMS AND CO-MORBIDITIES OF FIBROMYALGIA

R.-D. Treede. *Medical Faculty Mannheim, Heidelberg University, Heidelberg, Germany*

In the beta browser version of ICD11, fibromyalgia is listed as a chronic primary pain syndrome (Treede et al. 2015). It is categorized as chronic widespread pain, and is distinguished from other chronic widespread pain by a) tender point counts (American College of Rheumatology 1990 criteria), or b) psychosocial distress (ACR 2010). Both ACR definitions are problematic for research purposes: mechanisms of tender points are poorly understood, and using distress as inclusion criterion may lead to circular arguments.

Chronic primary pain is characterized by significant emotional distress and functional disability. It is multifactorial: biological, psychological and social factors contribute to the pain syndrome. The diagnosis is appropriate independently of identified biological or psychological contributors unless another diagnosis would better account for the presenting symptoms. Chronic Primary Pain can occur in any body site (face, low back, neck, upper limb, thorax, abdominal, pelvis, urogenital region), or in a combination of body sites (Widespread pain). In general, multiple sites of pain are associated with higher distress and disability than single sites. Chronic Primary Pain is also often associated with sleep disturbance, adverse side effects of treatments (such as medication dependence), and comorbidities (such as depression, anxiety, anger, guilt, fear, and a range of chronic medical conditions).

As part of the research consortium LOGIN we have compared the pathophysiology of fibromyalgia, other chronic widespread pain and chronic localized pain in the lower back. In those datasets, fibromyalgia patients showed higher comorbidity of anxiety and depression and more functional impairment than the other groups (Gerhardt et al. 2016). A deficit in conditioned pain modulation (CPM) was related to the spatial spread of ongoing pain, consistent with the neurobiology of endogenous pain control systems. FMS differed from CWP with respect to psychosocial burden, consistent with the shift in clinical diagnostic criteria. Tender point counts (an evoked pain measure) were still useful to identify the FMS patients (Gerhardt et al. 2017). A study using the childhood trauma questionnaire suggests that early stress exposure is associated nonspecifically with lowered pressure pain thresholds which may be related to tender points (Tesarz et al. 2016).

Experimental sleep deprivation in healthy subjects or rodents leads to symptom profiles reminiscent of fibromyalgia (e.g. widespread hyperalgesia, anxiety), suggesting a potential vicious circle of pain, hyperalgesia and sleep disturbance in fibromyalgia.

In summary, fibromyalgia is a chronic primary pain syndrome characterized by widespread pain and major comorbidities. A combination of predisposition plus an initiating painful event seem to play a role in its genesis; according to the dual hit hypothesis, traumatic events during childhood may contribute to the predisposition.

Supported by the German Federal Ministry of Education and Research (BMBF; LOGIN consortium, FKZ: 01EC1010A and 01EC1010B) and the German Research Foundation (DFG: SFB 1158 Subproject S01).

SP0020 PERIPHERAL PATHOLOGY IN FIBROMYALGIA

C. Sommer. *Department of Neurology, Universitätsklinikum Würzburg, Würzburg, Germany*

The pathophysiology of pain in fibromyalgia is complex. In recent years, an involvement of the thinly myelinated nerve fibers of the A-delta type and the unmyelinated C-fibers has been reported in fibromyalgia patients. Independent research groups have published consistent findings of objective injury to these "small nerve fibers". These included disturbances in function, electrical properties, and morphological integrity of these nerve fibers. While the reasons for this small fiber pathology and its contribution to FMS pain are still unclear, a new research field has emerged that will focus on uncovering the underlying pathophysiology. In this talk, I will summarize current findings and discuss their significance for the understanding of the fibromyalgia syndrome.

SP0021 CENTRAL PATHOLOGIES IN FIBROMYALGIA

E. Kosek. *Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden*

Fibromyalgia is characterized by widespread, mainly muscular pain that is exacerbated during and following physical activity. Although mechanisms such as muscle ischemia and peripheral nerve fibre pathology have been implicated in fibromyalgia, currently no known peripheral pathology can fully account for the pain. Therefore, the pain in fibromyalgia is most likely explained by a complex interaction between peripheral and central mechanisms. Fibromyalgia patients are characterized by a multimodal, widespread, increase in pain sensitivity and a dysfunction of endogenous pain inhibitory mechanisms. Imaging studies have revealed functional as well as structural cerebral abnormalities in fibromyalgia. During painful stimulation, fibromyalgia patients exhibited an inability to activate cerebral structures associated with the descending pain inhibitory system, i.e., rostral anterior cingulate (rACC) and thalamus[1]. There was no association between depression or anxiety and cerebral processing of evoked pain, indicating segregated mechanisms for mood and pain processing[2]. Furthermore, FM patients had less pain related functional connectivity within the brain's pain inhibitory network and structural changes such as decreased cortical thickness and reduced brain volumes[3]. Longer duration of FM pain was associated with more pronounced functional and structural abnormalities suggesting a time-dependent progress of cerebral pathology, even when controlled for age and mood[3]. In addition, FM patients had elevated interleukin-8 in the cerebrospinal fluid indicating neuro-inflammation[4], possibly due to glia cell activation. Interleukin (IL)-8 is co-localized with translocator protein (TSPO) in glia cells. During glia activation, the production of TSPO is increased and TSPO agonists are involved in the regulation of the expression of IL-8 and it's receptor, thus affecting glia to neuron signalling and central sensitisation. We have recently documented that FM patients who are carriers of the genetic functional polymorphism associated with high TSPO binding affinity report higher pain intensity and more severe fibromyalgia symptoms compared to genetically inferred TSPO low affinity binders and that this genetic polymorphism also affects cerebral pain processing[5]. To our knowledge, this is the first finding of genetic mechanisms associated with symptom severity in FM.

Finally, the effect of different treatments on central pathology in FM will be discussed. Short pain duration was predictive of a positive response to a 12 weeks treatment with a serotonin-noradrenalin re-uptake inhibitor (SNRI)[6]. The degree of symptom improvement and reduced pain sensitivity in SNRI treated FM patients corresponded to the degree of increased pain related activation of cerebral areas associated with pain modulation and the default mode network[6]. In contrast, cognitive behaviour therapy did not affect clinical pain or pain sensitivity but increased activations of cerebral regions implicated in executive cognitive control during painful stimulation and thus likely reappraisal of painful stimuli[7]. Finally, 15 weeks of physical exercise partially normalized resting state activity in FM[8]. The results demonstrated that different treatment modalities affected specific brain mechanisms, indicating that at least some of the cerebral abnormalities in FM are reversible.

Chondrocyte channels (role in mechanotransduction)or "channeling the chondrocyte"

SP0022 TRPA1 CHANNELS IN OSTEOARTHRITIS

E. Moilanen. *The Immunopharmacology Research Group, University of Tampere, Tampere, Finland*

Osteoarthritis (OA) has long been viewed as a degenerative "wear-and-tear" disease of cartilage. There is, however, increasing evidence to confirm that inflammation has a critical role in the pathogenesis and symptoms of the disease. Inflammation in osteoarthritis is distinct from that typical for rheumatoid arthritis; it is generally low-grade in its nature but characterized by exacerbations with joint effusions and more severe symptoms. Osteoarthritis shares many features of innate immunity but the inflammatory mechanisms eventually leading to anatomical and functional changes and symptoms typical for osteoarthritis are not known in detail; but their further understanding is essential for the development of disease-modifying treatments for osteoarthritis.

Transient receptor potential ankyrin 1 (TRPA1) is a ligand-gated membrane-bound cation channel. It has been widely studied in sensory neurons where it acts

as a chemosensor for harmful exogenous compounds and mediates pain and neurogenic inflammation. More recently, TRPA1 has been found to be activated also by endogenous compounds formed in inflammation, such as reactive oxygen and nitrogen species. That prompted us to investigate the role of TRPA1 in inflammatory conditions including osteoarthritis.
Monosodium iodoacetate (MIA) -induced arthritis is a widely used animal model of osteoarthritis. We found that MIA evoked acute inflammation, degenerative cartilage changes and joint pain in wild type mice; but interestingly, those responses were significantly attenuated in TRPA1 deficient animals. Furthermore, TRPA1 was found to be expressed and inducible by inflammatory factors including IL-1 and IL-17 in primary human OA chondrocytes; and the TRPA1 channel was shown to be functional based on calcium influx assays. Pharmacological inhibition and genetic depletion of TRPA1 downregulated the production of inflammatory factors and MMP enzymes in mouse cartilage and primary human OA chondrocytes.
The present results introduce TRPA1 as a plausible factor involved in the pathogenesis of OA and provide a novel target for analgesic and anti-inflammatory drugs with disease modifying potential in OA.

Wearable technologies in 21st century healthcare

SP0023 REVIEW OF WEARABLE TECHNOLOGIES

A.M. Clarke-Cornwell. *School of Health Sciences, The University of Salford, Manchester, United Kingdom*

Working environments have in recent times become less physical with the increase in sedentary, computer-based occupations. Sedentary time is known to be associated with a number of health-related outcomes, including obesity, heart disease, diabetes, cardiometabolic risk factors, some cancers and early mortality, independent of physical activity. There is limited research that has examined sedentary time and physical activity and associations with musculoskeletal conditions, despite these being responsible for the majority of work-related ill health and days absent from work.
The validity and practicality of objective and subjective techniques to measure physical behaviour have been widely reported; however, there is no gold standard that is valid, accurate, reliable and also practical. Self-reported methods can be practical and low-cost, but are subject to recall and social desirability bias; whereas objective devices, such as accelerometers, can be expensive, but allow for information on intensity, frequency and duration of activity to be measured.
The Health Survey for England 2008 used both subjective and objective measures of physical activity: they found that 39% of men and 29% of women were meeting the recommended levels of physical activity when asked via a questionnaire. In comparison, when physical activity was objectively measured using an accelerometer, it was found that only 6% of men and 4% of women met these targets.
Wearable technologies, including research grade accelerometers (e.g. activPAL™) and consumer wearables (e.g. FitBit), are increasingly being used in research, not only to measure physical behaviours but may also be useful in facilitating and monitoring behaviour change. This work will present an overview of wearable technologies used in research, what they can (and can't) measure, and in particular their application in musculoskeletal research.

SP0024 WEARABLE TECHNOLOGIES IN RESEARCH AND CLINICAL TRIALS

M. Mc Carthy. *IT Innovation, Icon Plc, Dublin, Ireland*

The use of wearable technology in clinical trials has the potential to be one of the most disruptive innovations in drug development. The cost and duration of the current clinical trial design has been under scrutiny for a number of years with the sustainability of the exiting model under question. A critical success factor is adequate patient recruitment and retention. Recent initiatives to redesign the clinical trial process have focused on the creation of trials that are more patient focused. A wealth of medical grade physiological data is now readily available from wearable technology, with the potential to create a new future where patients no longer have to visit research sites and where real-time data are available remotely.
However, integrating wearables into a clinical trial is more complex than simply giving the patient a smartwatch and spontaneously generating clinically relevant data. Focusing on technology and sandwiching it into a trial is not a best practice. Wearables need to be viewed as a component of an overall patient-centric strategy rather than solutions in themselves. When creating a remote trial, simply shifting the burden from the sites to the patients, requiring them to carry out a number of tasks in an unsupported, uncontrolled environment is neither welcome nor sustainable. The process for successful selection and integration of wearables needs to take a number of criteria into consideration; clinical hypotheses, the value that is gained by the inclusion of wearables, the robustness of the data generated by the devices, and ensuring that the data adds clarity not additional complexity to the trial.
The re-engineering of the clinical trial to create a patient focused trial goes beyond mere convenience. Wearables and sensor have the potential to generate digital maps of individual's physical behaviours. Wearable technology is facilitating the remote capture of real life data but also has the potential to create new end points and outcome measures that are meaningful to the patient and could hold the key to a new clinical trials paradigm.

Assessment and management of osteoporosis

SP0025 THE USE OF BIOMARKERS FOR OSTEOPOROSIS CLINICS

K. Akesson. *Clinical Sciences Malmö, Lund University, Malmö, Sweden*

The balance between bone resorption and bone formation is maintained through a complex regulatory system of systemic and local factors acting on bone cells, such as calcium regulating and sex hormones, growth factors and cytokins. Furthermore, the competence of the bone cells and the number of active cells will determine the production of bone matrix proteins, while other incompletely understood intrinsic mechanisms will determine mineralization and micro-structure. Exposure of the matrix after osteoclastic activation allows for proteolytic enzymes to commence the degradation of the collagenous structure. The signals responsible for termination of bone resorption and initiation of bone formation (coupling) are not yet completely understood. Nevertheless, a tight coupling between resorption and formation is required to maintain bone mass and to preserve the micro-architectural integrity of bone.
Based on this knowledge markers of bone metabolism have been developed. These markers have been evaluated in terms of their ability to predict fracture, change in bone mass, and response to pharmacological treatments in clinical trials and additionally to monitor treatment in clinic.
The lecture will cover the use of markers in clinical trial, interpretation of change in markers from currently available and potential new drugs and to what extent and how to best apply in clinic.

SP0026 NOVEL IMAGING TECHNIQUES FOR ASSESSING OSTEOPOROTIC FRACTURE RISK

R. Chapurlat[1,2]. [1]*Université de Lyon;* [2]*Medicine, INSERM UMR 1033, Lyon, France*

The measurement of areal bone mineral density (aBMD) by dual x-ray absorptiometry (DXA) has been the mainstay for the diagnosis of osteoporosis for at least two decades. The sensitivity and specificity of this test, however, remains suboptimal. For example, more than 50% of postmenopausal women with fragility fracture are not identified with DXA. A great deal of research has been performed recently to develop alternative or complementary imaging techniques to overcome DXA predictive limitations. These techniques are based on the non invasive analysis of bone microarchitecture and estimation of bone strength by finite element analysis (FEA).
Texture analysis uses mathematical models based on fractal analysis to evaluate bone microarchitecture using various types of bone images. The trabecular bone score (TBS) has emerged as an approach that may improve fracture risk prediction. The TBS is based on the texture analysis of the DXA lumbar spine image to quantify bone microarchitecture. Several cohort studies have shown that a subset of individuals could be reclassified with TBS. A meta-analysis results have allowed for incorporation of the TBS in the FRAX score calculation, that is widely available.
The measurement of volumetric BMD with quantitative computerized tomography (QCT) at the hip has been shown to predict fracture risk. These images can also be used to perform FEA that may increase the fracture risk prediction. The additional value of this technique compared with DXA remains to be established in a clinical setting.
Bone microarchitecture can also be assessed at peripheral sites such as the distal radius and tibia using high resolution peripheral quantitative tomography (HRpQCT). Numerous cross-sectional and case-control studies have shown a significant association between prevalent fracture and bone microarchitecture and estimated bone strength assessed with FEA. The bone parameters measured at distal sites are also associated with fractures at distant sites, e.g., the vertebrae and the femoral neck. In a recent prospective study, bone microarchitecture at the distal radius - especially the trabecular vBMD - has been associated with incident osteoporotic fracture. The FEA models were also predictive of fragility fracture. The best models and the most appropriate architectural parameters - whether they are trabecular of cortical - remain to be dissected out and their comparative diagnostic value with aBMD by DXA remains to be established.
The measurement of the TBS may allow for reclassification of a subset of

postmenopausal women at higher risk for fracture whereas they display a moderately reduced aBMD. Hip QCT and HRpQCT may also improve the prediction for fracture, but they are still research techniques.

SP0027 EMERGING THERAPIES FOR OSTEOPOROSIS

P. Geusens. *Rheumatology, MaastrichtUMC and UHasselt, Genk, Netherlands*

Currently, anti-resorptive drug therapy is the cornerstone of fracture prevention. Anti-resorptive drugs decrease bone remodelling, allowing the remaining bone to increase secondary mineralisation, and, with denosumab, also allowing periosteal bone modelling.
Teriparatide is currently the only available bone-forming drug, which increases bone formation more than bone resorption, and has been shown to reduce the risk of vertebral and non-vertebral fractures.
Recently, two randomized clinical trials have been published on the effect of new bone forming agents on the risk of fracture.
Abaloparatide is a 1–34 fragment of PTHrP, with different pharmacokinetics and potential different signalling mechanisms compared to teriparatide. It increases bone formation more than bone resorption, both to a lesser degree than teriparatide. In the double blind, randomised placebo-controlled 18-month ACTIVE study, abaloparatide significantly reduced the risk of vertebral (-86%), clinical (-43%), non-vertebral (-43%) and major fractures (-70%). In a parallel randomised exploratory open-label comparison with teriparatide, bone density increased significantly more with abaloparatide, but the anti-fracture effect was similar, except for a significantly better result on prevention of major fractures.
Romosozumab is a monoclonal antibody that binds sclerostin, which is an inhibitor of bone formation. In contrast to other bone forming agents, it disconnects the increase in bone formation from a decrease in bone resorption. In the double-blind placebo-controlled FRAME study, romosozumab significantly reduced the risk of vertebral (-63%) and clinical fractures (-36%) during the first year, an effect that was maintained by transitioning to one-year denosumab treatment.
The effect on non-vertebral fractures was not significant, but geographic interaction was found. When excluding patients from South America, in whom fracture risk was low, one-year treatment with romosozumab significantly decreased the risk of non-vertebral fractures by 42%.
Abaloparatide and romosozumab are new bone forming agents, with different effects on bone remodelling and remodelling and early effects on clinical fractures. This opens new perspectives in individualised treatment of patients with high fracture risk and for fracture prevention in patients with low bone turnover, multiple vertebral fractures, very low BMD and fractures or bone loss during anti-resorptive treatment.

Systematic literature review: the link from science to clinical practice

SP0028 SYSTEMATIC LITERATURE REVIEW: WHERE TO START

S. Ramiro. *Rheumatology, Leiden University Medical Center, Leiden, Netherlands*

Starting a systematic literature review (SLR), particularly for the first time, may be an overwhelming task. As its designation indicates, it requires a systematic approach, in order to ensure that all the relevant literature addressing the research question at hand is covered and appropriately summarized.
SLRs are particularly helpful for clinicians, who have a question based on their clinical practice and want to obtain the best evidence based answer. The large and increasing amount of existing literature makes the life of a clinician difficult when trying to search by him/herself for the answer based on the original studies. An SLR may thus be an efficient way to get the answer, by condensing hundreds of studies into a good summary. They are also of the basis, together with expert opinion, of diagnostic and/or management/treatment recommendations.
The first step of an SLR is always to properly formulate the research question, in a way that the literature covering the topic can be searched. The classic approach is the PICO framework, in which the formulated question includes the different elements guiding the literature search, namely the Population of interest, the Intervention to which patients are exposed, the Comparator against which the effect of the intervention is to be compared and the Outcomes on which the assessment of the intervention will rely and in which the SLR will focus (e.g. efficacy, safety outcomes, etc).
A crucial aspect when reviewing the literature is the risk of bias assessment. Studies should be judged for their methodological quality so that one can interpret their findings accordingly. If a study is methodologically not sound, then we know that it will not be very helpful in answering the research question and, most important, this cannot be ignored when performing an SLR. This risk of bias assessment also requires some knowledge of important epidemiology and biostatistics concepts, which are needed to correctly understand how a study is conducted.
These and other steps contribute to shaping an SLR. Challenges involved when performing an SLR will be discussed in detail in this presentation, as well as the different steps of an SLR and the most critical aspects that should be considered. Tips from experiences with SLRs will be shared. This should ultimately encourage (young) clinicians and researchers on where to start when embarking on an SLR challenge, but hopefully also on how proceed with and bring to an end a successful and informative SLR.

SP0029 LINKING SCIENCE TO CLINICAL PRACTICE: FROM THE SYSTEMATIC LITERATURE REVIEW TO THE FORMULATION OF RECOMMENDATIONS

R. Landewe. *Rheumatology & clinical immunology, Amsterdam Rheumatology & immunology center, Amsterdam, Netherlands*

Systematic literature review (SLR) is a scientific method to collect the available data in the literature regarding a specific research question, and to compare the quality of different studies, in order to arrive at the best possible answer. SLR is not the same as data-pooling. In contrast to what many clinicians think, SLR is clinical science and not “easy going”, it takes a lot of time and effort, you can make mistakes, and you need to practice and obtain experience. A proper SLR is all but “low hanging fruit”.
Nevertheless, SLRs from the evidence base of guidelines, and as such are integral parts of them.
This lecture will describe how SLRs should be translated into guidelines, and what pitfalls may prevent that the appropriate evidence will be enclosed in recommendations, or that too weak evidence gets a too prominent place.

SP0030 BEYOND THE RECOMMENDATIONS: EXAMPLES OF SYSTEMATIC LITERATURE REVIEW IN DAILY CLINICAL PRACTICE

K. Visser[1,2]. *[1]VU Medical Center; [2]Academic Medical Center, Amsterdam, Netherlands*

Recommendations and guidelines for management and treatment of rheumatic diseases exist to help rheumatologists deliver optimal care for their patients in an evidence-based way. However, not all practical questions and medical difficulties encountered by rheumatologists in daily clinical practice can be addressed using these existing guidelines. Moreover, time in practice is limited and usually does not allow for extensive systematic literature research to find evidence regarding a specific medical question that needs answering in due time. Therefore, an essential skill for doctors and those in training, besides medical knowledge and examination skills, is to be able to search for, withdraw and appraise published evidence applicable to a confined topic. A so called CAT – critically appraised topic – is a compact systematic literature research following a strictly formulated PICO to answer a clinical question encountered in daily practice. Results can be presented in department meetings and stored in a database for education purposes and use in daily practice. This presentation will address the structure, the carrying out, as well as important pros and cons of the CAT. Examples will be given drawn from the experience of young rheumatologists in training in the Netherlands.

EULAR Campaign: Don’t Delay, Connect Today

SP0031 HOW COULD GPS ENHANCE THE EARLY DIAGNOSIS OF RHEUMATIC DISEASES

C.D. Mallen. *Arthritis Research UK Primary Care Centre, Primary Care and Health Science, Keele, United Kingdom*

Primary care and general practice has a key role to play in the early and accurate detection of patients with rheumatoid arthritis.
This talk will explore some of the current barriers to best practice, highlighting the workload associated with musculoskeletal problems in primary care and the challenges in making a prompt diagnosis. Possible solutions will be explored, highlighting the importance of strong patient and professional partnerships
Disclosure of Interest: None declared

SP0032 THE CONTRIBUTION OF PHYSIOTHERAPISTS TO EARLY DETECTION OF INFLAMMATORY ARTHRITIS

P. Kirwan[1,2]. [1]*Physiotherapy Dept, Connolly Hospital;* [2]*School of Physiotherapy, Royal College of Surgeons in Ireland, Dublin, Ireland*

Early recognition of inflammatory arthritis is of utmost importance, as failure to do so can delay appropriate treatment and result in permanent joint damage and disability. This presentation will set out to explore the role a Physiotherapist/Healthcare Professional can play in recognition of inflammatory joint disease. Healthcare Professionals/Physiotherapists are often the first point of contact for patients suffering from joint/musculoskeletal pain. They are therefore very well positioned to be the first to identify possible inflammatory sources of pain versus non-inflammatory sources. Useful clinical tools which aid in this decision making process will be discussed. The question as to whether a physiotherapist can recognise inflammatory joint disease versus non-inflammatory joint conditions will be explored with the aim being to highlight the important role a physiotherapist can play in this important diagnostic challenge. With reference to ongoing clinical and research work in this field, this presentation will set out to ask whether or not a Healthcare Professional/Physiotherapist can accurately recognise/diagnose inflammatory arthritis and whether they miss inflammatory arthritis.

SP0033 THE EULAR CAMPAIGN "DONT DELAY CONNECT TODAY" AND HOW ORGANISATIONS CAN GET INVOLVED

J. Church. *Arthritis Ireland, Dublin, Ireland*

Arthritis is a chronic disease with multiple co-morbidities. With the development of powerful biologic drugs, improvements in care pathways for patients and very effective self-management interventions, early diagnosis and intervention can lead to significant improvements in liefstyle, physical movement, incerased well-being and work force participation. Despite its significant impact on the population and the cost to the economy, Arthritis still remains an underfunded subspecialty within the health systems and one that is shrouded in public myth. The EULAR campaign "Done Delay, Connect Today", aims to promote early intervention by encouraging those with typical symptoms to take action and consult their doctor at the earliest possible opportunity. The campaign which will be adopted and executted across all PARE members also aims to dispel the myths and educate the public about the seriosness of arthritis and the need to taek action.

Standing Committee session on paediatric rheumatology

SP0034 SHARE RECOMMENDATIONS ON SYSTEMIC VASCULITIDES

M.W. Beresford on behalf of SHARE Systemic Vasculitis Working Group.
Paediatric Rheumatology, Alder Hey children's NHS Foundation Trust, Institute of Translational Medicine, University of Liverpool, Liverpool, United Kingdom

Background: Primary systemic vasculitides (PSV) are very rare in children and consequently, little evidence exists. Evidence-based guidelines are lacking; this is an important and unmet need. The European initiative SHARE (Single Hub and Access point for paediatric Rheumatology in Europe) aims to optimize care for children with rheumatic diseases.
Objectives: To provide recommendations for diagnosis and treatment for children with rare forms of PSV.
Methods: Recommendations were developed by a consensus process in accordance with the European League Against rheumatism standard operating procedures. An extensive systematic literature was performed and evidence-based or evidence-informed recommendations were extrapolated from the included papers. These were evaluated by a panel of 16 experts via an online survey and subsequently in two consensus meetings, using nominal group technique. Recommendations were accepted when $\geq$80% of experts agreed.
Results: A total of 78 recommendations were accepted in the two consensus meetings. Recommendations pertained to general cross-cutting recommendations for diagnosis and treatment of PSV, as well as disease-specific statements for childhood-onset Polyarteritis Nodosa, Granulomatosis with Polyangiitis, Microscopic Polyangiitis, Eosinophilic Granulomatosis with Polyangiitis, and Takayasu Arteritis.
Conclusions: European-wide recommendations for the diagnosis and treatment of rare forms of paediatric PSV have been formulated through an evidence-based consensus process. The SHARE project aims to provide international recommendations and significantly improve the standard of care for children with rheumatic diseases.

DOI: 10.1136/annrheumdis-2017-eular.7205

SP0035 CONSENSUS-BASED RECOMMENDATIONS (SHARE) FOR THE MANAGEMENT OF JUVENILE SCLERODERMA

F. Zulian. *Department of Woman and Child Health, University of Padova, Padova, Italy*

Background: In 2012, a European initiative called Single Hub and Access point for pediatric Rheumatology in Europe (SHARE) was launched to optimise and disseminate diagnostic and management regimens in Europe for children and young adults with rheumatic diseases. Juvenile Scleroderma in its two variety, localized scleroderma (JLS) and systemic sclerosis (JSS) is a rare disease within the group of paediatric rheumatic diseases (PRDs) and can lead to significant morbidity. Evidence-based guidelines are sparse and management is mostly based on physicians' experience. Consequently, treatment regimens differ throughout Europe.
Objectives: To provide recommendations for diagnosis and treatment of both JLS and JSS.
Methods: Recommendations were developed by an evidence-informed consensus process using the EULAR standard operating procedures. A committee was constituted, consisting of 16 experienced paediatric rheumatologists, mainly from Europe. Recommendations derived from a validated systematic literature review were evaluated by an online survey and subsequently discussed at two consensus meetings using nominal group technique. Recommendations were accepted if $>$80% agreement was reached.
Results: In total, 1 overarching principle, 17 recommendations on diagnosis and 13 recommendations on therapy were accepted with $>$80% agreement among experts. Topics covered include assessment of skin and major organ involvement and suggested treatment pathways.
Conclusions: The SHARE initiative aims to identify best practices for treatment of patients suffering from PRD. Within this remit, recommendations for the diagnosis and treatment of JLS and JSS have been formulated by an evidence informed consensus process to produce a standard of care throughout Europe.

SP0036 SHARE RECOMMENDATIONS ON JUVENILE DERMATOMYOSITIS

A. Van Royen-Kerkhof. *Wilhelmina Children Hospital, Utrecht, Netherlands*

Background: In 2012, a European initiative called Single Hub and Access point for pediatric Rheumatology in Europe (SHARE) was launched to optimise and disseminate diagnostic and management regimens in Europe for children and young adults with rheumatic diseases.
Juvenile Dermatomyositis is a rare *Pediatric Rheumatic Disease (PRD)*, associated with significant morbidity. Evidence-based guidelines are sparse and management is mostly based on physicians' experience. Consequently, treatment regimens differ throughout Europe.
Objectives: To provide recommendations for diagnosis and treatment of JDM based on evidence-informed consensus.
Methods: Recommendations were developed by an evidence-informed consensus process using the European League Against Rheumatism standard operating procedures. A committee was constituted, consisting of 19 experienced paediatric rheumatologists and 2 experts in paediatric exercise physiology and physical therapy, mainly from Europe. Recommendations derived from a validated systematic literature review were evaluated by an online survey and subsequently discussed at two consensus meetings using nominal group technique. Recommendations were accepted if $>$80% agreement was reached.
Results: In total, 7 overarching principles, 33 recommendations on diagnosis and 19 recommendations on therapy were accepted with $>$80% agreement among experts. Topics covered include assessment of skin, muscle and major organ involvement and suggested treatment pathways.
Conclusions: The SHARE initiative aims to identify best practices for treatment of patients suffering from PRD. Within this remit, recommendations for the diagnosis and treatment of JDM have been formulated by an evidence-informed consensus process to produce a standard of care for patients with JDM throughout Europe.

Ultrasound basic I & II

SP0037 HOW TO ASSESS US ELEMENTARY LESIONS IN CPPD

G. Filippou. *University of Siena, Siena, Italy*

Ultrasonography has been increasingly used the last years for the identification of calcium pyrophosphate dihydrate crystal deposition (CPPD) in joints and on 2011 has been considered by the EULAR task force on CPPD as a promising tool for the diagnosis of the disease. However, it is common experience between sonographers that in daily clinical practice CPP identification by US is rather challenging as crystal deposits are not always numerous and diffuse. Furthermore, other conditions can mimic CPP deposition leading to a wrong diagnosis. The recently created OMERACT US for CPPD subtask force has created for the first time a set of criteria for identification of CPP deposition and assessed their reliability trying to address some of the issues that impede a wider use of US for CPPD diagnosis. During this section will be exposed the main US features of CPP deposition according to the new criteria as well as the principal pitfals that could mislead diagnosis. The scanning techique and some tips and tricks that could help sonographers to identify correctly CPP deposition will also be explained.

SP0038 HOW TO ASSESS CARTILAGE IN RA AND PITFALLS + DEMO

P. Mandl. *Rheumatology, Medical University of Vienna, Vienna, Austria*

Cartilage damage is a key process in rheumatoid arthritis which appears to be more clearly associated with irreversible physical disability than bony damage. While conventional radiography only allows the evaluation of joint space narrowing, a proxy measure of cartilage loss, musculoskeletal ultrasound is a reliable tool for evaluating cartilage damage. The presentation will introduce the pitfalls and challenges associated with visualizing cartilage in rheumatic diseases in general and rheumatoid arthritis in particular. It will also review recent studies in the filed which have validated sonography for both the quantitative measurement of cartilage thickness and for the semiquantitative scoring of cartilage change. A practical demonstration will also be provided.

SP0039 HOW TO EVALUATE THE SUBTALAR JOINT

A. Iagnocco. *Università degli Studi di Torino, Torino, Italy*

The subtalar joint, also known as the talocalcaneal joint, is a synovial joint of the foot, that occurs between the talus and the calcaneus with the talus that is oriented slightly obliquely on the anterior surface of the calcaneus. The two bones articulate at two different sites (i.e. one anteriorly and one posteriorly). The *anterior talocalcaneal joint* is a convex area of the talus that fits on a concave surface of the calcaneus. The *posterior talocalcaneal joint* is formed by a concave surface of the talus and a convex surface of the calcaneus.
The subtalar joint contributes to the dorsiflexion of the ankle. Three articulating facets (anterior, middle and posterior) are present between the talus and the calcaneus. The sustentaculum tali forms the floor of middle facet, and the anterior facet articulates with the head of the talus, and sits lateral and congruent to the middle facet. The posterior facet is the largest of the three, and separated from the others by the tarsal canal. The most relevant actions done by the joint are inversion and eversion of the foot. The subtalar joint can also be considered a combination of the anatomic subtalar joint discussed above, and the talocalcaneal part of the talocalcaneonavicular joint. When both those joints are accounted together, it allows for pronation and supination to occur.
The subtalar joint is frequently involved in arthritis and, particularly in patients with previous sprains, secondary osteoarthritis can also occur. Symptoms of subtalar joint arthritis include pain, loss of motion through the joint's range of motion, and difficulty walking on uneven surfaces.
Among the imaging techniques that are appropriate for the assessment of the subtalar joint, ultrasound (US) has been increasingly used over the last years. Indeed it is able to image different abnormalities, including both inflammatory and structural changes, and it is helpful in guiding local procedures that can be easily and safely performed with optimal patient's tolerance.
The US scanning technique is quite complex, and the whole joint area should be scanned in the longitudinal (sagittal or coronal) plane with pathology that should be confirmed in the orthogonal (perpendicular) plane. By using a standardised scanning technique and agreed definitions of pathology, US allows an optimal assessment of inflammatory and structural abnormalities, thus filling the gap between clinical and radiographic evaluations of the subtalar joint.

SP0040 HOW TO SCAN THE HIP, NEW APPROACH AND DEMO

I. Möller on behalf of EULAR Working Group Anatomy for the IMAGE.
Rheumatology; anatomy; sonoanatomy-sonopathology, Instituto Poal de Reumatología; University of Barcelona, Hospitalet de Llobregat, Spain

The exploration of the hip includes not only intraarticular findings such as synovitis or lesions of the labrum but also the dynamic exploration of the tendons and muscles surrounding it as well as of the neurovascular bundles of interest. All this is an essential complement in the differential diagnosis of the rheumatic patient. The iliopsoas tendon as well as the hip adductors will be demonstrated during the presentation. The anterior and antero internal part of the groin region constitute a relatively frequent consultation and study of the tendinous snapping and its differential diagnosis with the snapping of intraarticular origin can be made by means of the musculoskeletal ultrasound. It requires systematization and knowledge of the regional anatomy.

Rehabilitation and modern drug treatment - needs and challenges

SP0041 CURRENT NEEDS FOR REHABILITATION

M. Björk. *Department of social and welfare studies, Linköping University, Norrköping, Sweden*

New biological medications and earlier multi professional interventions have led to a reduction in the extent of disability for patients with rheumatic diseases. However disability still remains a key problem for many patients and patients may experience participation restrictions even though they are achieving "remission". To be able to engage in the things we want or need to do is crucial to our health and sometimes a challenge to meet for health professionals. Also, there is an on going discussion of whether today's patients have new rehabilitation needs and if they are met by the health care. This session summarizes both qualitative and quantitative evidence of the disability in today's patients with arthritis. It will further discuss the current needs of rehabilitation in today's patient in relation to existing standards and guidelines. Rehabilitation interventions and patient reported strategies in relation to pain, fatigue and affected activity balance will be highlighted since they are common disabilities among today's patients.

SP0042 THE ART OF JUGGLING - A PATIENT'S PERSPECTIVE

F.M. Catrina. *LRR, Bucharest, Romania*

Diagnosed with ankylosing spondylitis since 2006, when just turned 24 years old. I was very demoralized and could not understand why I have rheumatic pains bigger than my grandmother 70 years old. I did not understand why I can not go, just do anything wrong to anyone. Slowly, slowly I began to understand the disease and help doctors started to move again.But my secret to healthy aging, was family. Therefore we understand that positive thinking can help me more than any drug, and how you can have a more positive attitude as if in a nice family environment?

SP0043 **WORK RETENTION REHABILITATION IN PRACTICE**

Y. Prior[1,2] on behalf of Rehabilitation Research Group, University of Salford. [1]*Health Sciences, University of Salford, Manchester;* [2]*Rheumatology, Mid Cheshire NHS Trust Leighton Hospital, Crewe, United Kingdom*

This session aims to meet health professionals' needs in recognising, examining, and identifying problems that patients with inflammatory arthritis (IA) face at work. We know that one in five people with inflammatory arthritis lose their job within five years of diagnosis and, once work disabled, they are unlikely to return to work. Therefore, preventive interventions targeted at work retention, which aim to help people to stay at work, are needed to avoid the transition from work instability to work disability. Rheumatology health professionals play an important role in identifying patients' work problems at an earlier stage and helping them to stay at work. Currently, there are no set pathways to outline health professionals' approach to identifying people with work problems and/or work rehabilitation interventions in the UK. Further, there is a need to train health professionals in the importance of the early recognition of these problems and evidence-based interventions to address work instability.

This session will focus specifically on the rheumatology occupational therapy-led work rehabilitation taken place in a NHS setting in the UK. Using real life case studies, Dr Prior will discuss the standardised assessments used in identifying work problems, collaborative goal setting and work interventions to provide a snapshot of work rehabilitation in the context of clinical practice.

Comorbidities: having one RMD is enough - we don't need anything else

SP0044 **SCREENING FOR COMORBIDITIES IN DAILY PRACTICE: WHO AND HOW?**

L. Gossec. *Paris 06 University, Pitié-Salpétrière Hospital, Paris, France*

Comorbidities are frequent in RMDs, as in many other chronic diseases. In inflammatory rheumatic diseases, the most frequent comorbidities are cardio-vascular diseases, depression, infections and cancers. Some of these diseases are more frequent than in persons without RMDs, some are not more frequent but are more often under-assessed and under-treated. These comorbidities and their risk factors need to be screened for. Screening in daily practice is not so simple since it necessitates time, physician expertise and patient cooperation. In this talk, we will address recent recommendations on how to screen for comorbidities, how often and in which setting this should be performed, and the respective roles in screening of rheumatologists, rheumatology nurses and persons with RMDs.

SP0045 **DO PATIENT ORGANISATIONS HAVE A ROLE TO PLAY IN PREVENTING CO-MORBIDITIES?**

A.M. Bosworth. *n/a, National Rheumatoid Arthritis Society, Maidenhead, United Kingdom*

My talk will look in detail at how patient organisations can play a role in preventing co-morbidities. NRAS is currently engaged in two major projects which are both directly concerned with the prevention of co-morbidities. During RA Awareness Week in the UK, 19–26 June, NRAS will launch "Love your Heart" an on-line, interactive video programme to educate people with RA about their increased risk of heart disease and atherosclerosis. This programme explains in simple terms why people with RA are at increased risk of cardiovascular disease. The programme provides the opportunity to appraise individual risk factors, complete a QRISK2 assessment with their GP and provides a cognitive-behavioural framework to empower people to change their behaviours and achieve a healthier lifestyle, thereby reducing risk of heart disease. Baseline and 6 months evaluations are built into the programme. It has been developed with input from a consultant rheumatologist, GP, and other health experts as well as patients. If time permits I will also a describe a research study we are undertaking with 3 hospitals in the UK whereby we will randomly assign newly diagnosed patients to receive a targeted support fprogramme rom NRAS or be in a control group which does not receive this support for a period of 6 months. Our aim is to show that the group receiving the targetted support has less anxiety and depression, although other outcomes will also be measured.

SP0046 **PREVENTION AND THE PROTECTIVE ROLE OF EXERCISE AND LIFESTYLE INTERVENTIONS ON COMORBIDITIES IN RHEUMATIC DISEASES**

S. Garcia Diaz. *Rheumatology, Consorci Sanitari Integral, Hospital Moises Broggi Sant Joan Despi, Sant Joan Despi, Spain*

Background: It has been recognised that patients with rheumatic diseases are at increased risk of developing comorbid conditions such as cardiovascular disease (CVD), malignancies, infections and osteoporosis (among others). Lifestyle interventions (non smoking, non alcohol, healthy diet and exercise) may play an important role to reduce comorbidities in these patients.
Objective: To find if lifestyle interventions and especially exercise play a vital role in preventing comorbidities in rheumatic diseases through an extensive review of recent literature.

Cytokines and chemokines

SP0047 **TYPE I INTERFERON SYSTEM IN AUTOIMMUNITY**

L. Rönnblom. *Department of Medical Sciences, Uppsala University, Uppsala, Sweden*

The type I interferon (IFN) system is our main defense against viral infections and can be activated by a large number of sensors of nucleic acid, triggering the production of more than 15 different proteins with antiviral and immunostimulatory capacity. There are several observations suggesting an important role for this system in the etiopathogenesis of SLE and other autoimmune diseases. Among these are the reported development of autoimmune diseases during treatment with IFN-alpha, a prominent increase in the expression of type I IFN regulated genes (an IFN signature) in a number of rheumatic diseases, the existence of endogenous or self derived IFN inducers in SLE patients and a genetic association between autoimmune diseases and gene variants within the type I IFN signaling pathway.

The type I IFN system is closely connected to a number of cytokine and chemokine pathways, which all can contribute to both the IFN signature and the type I IFN effects. Important type I IFN effects are maturation and differentiation of dendritic cells, activation of T and B cells with enhanced antibody production and induction of increased expression of autoantigens. Consequently, type I IFNs can act as an immune adjuvant and promote an autoimmune process. Recent data have also shown that the regulation of the type I IFN system is abnormal in SLE, which all together suggests that inhibition of the type I IFN system could be beneficial in SLE and possible also other autoimmune diseases. Many different therapeutic targets exists and several studies are in progress aiming to block, or down-regulate, the activated type I IFN system in SLE. A number of studies with monoclonal anti-IFN-alpha antibodies have been reported, and a small study investigating vaccination with an interferon-alpha-kinoid against IFN-alpha has been published. Recently, a phase IIb study targeting the type I IFN receptor in moderate to severe SLE was published, reporting substantially reduced disease activity. Other therapeutic possibilities include elimination of the endogenous IFN inducers and inhibition of key molecules in the type I IFN signaling pathway. The results so far shows that it's possible to suppress the IFN signature and improve several biomarkers in SLE patients without major safety problems. The challenge for the future is to modulate the interferon system in autoimmune diseases more precisely and realize that different treatments may be appropriate in various patients.

SP0048 **TARGETING OF ANGIOGENESIS**

S. Tas on behalf of European Synovitis Study Group. *AMC Clinical Immunology & Rheumatology, Amsterdam Rheumatology and immunology Center, Amsterdam, Netherlands*

Angiogenesis is de novo capillary outgrowth from pre-existing blood vessels. This process not only is crucial for normal development, but also has an important role in supplying oxygen and nutrients to inflamed tissues, as well as in facilitating the migration of inflammatory cells to the synovium in rheumatoid arthritis, spondyloarthritis, and other tissues in systemic autoimmune diseases. Neovascularization is dependent on the balance of proangiogenic and antiangiogenic mediators, including growth factors, cytokines, chemokines, cell adhesion molecules and matrix metalloproteinases. In this lecture I will provide an overview of the various pathways that govern these angiogenic processes and discusses potential approaches to interfere with pathological angiogenesis, and thereby ameliorate inflammatory disease, by targeting these pathways specifically in endothelial cells.

Key Messages:

- In chronic inflammatory diseases, angiogenesis enables increased delivery of oxygen and nutrients to immune cell populations accumulating in inflamed tissues, and contributes to further immune cell infiltration

- Angiogenesis is driven not only by hypoxia, but also by proinflammatory mediators produced by immune and stromal cells
- Many pathways downstream of these proinflammatory stimuli contribute to various cellular processes involved in angiogenesis
- Targeting proangiogenic pathways to inhibit neovascularization has been successfully exploited in several cancers, and may also prove beneficial in the treatment of chronic inflammatory diseases

SP0049 DNA AGGREGATES AS ALARMINS

D. Pisetsky. *Medicine, Duke University Medical Center, Durham, North Carolina, United States*

DNA is a large polymeric molecule that displays powerful immunological activities and operates in the context of multi-component aggregates to alarm the immune system and stimulate innate immunity. Although DNA has important roles in normal host defense, DNA can serve as an autoantigen and autoimmunogen by itself or in association with other immunologically active nuclear molecules. In the setting of systemic lupus erythematosus (SLE), DNA is a key target antigen; while antibodies to pure DNA double stranded DNA serve as important biomarkers, the relevant antigenic form of DNA during disease is the nucleosome in which DNA is bound to histones. Furthermore, nucleosomes can be components of microparticles which are small membrane-bound structures that are released from dead and dying cells. MPs can stimulate immune responses and serve as a nidus for immune complex formation. In normal immunity, DNA can interact with nucleic acid sensors in the cytoplasm of cells to stimulate responses including production of type 1 interferon. These sensors respond to DNA from intracellular organisms such as bacteria and viruses although damaged DNA and DNA from mitochondria can also interact with these receptors. While these sensors are intracellular, they can interact with extracellular DNA that is introduced or transfected into the cell; this translocation event occurs with DNA bound with other molecules. In another facet of host defense, DNA can be released from neutrophils during a process termed NETosis. A NET or neutrophil extracellular trap is a mesh-like structure comprised of DNA as well as granule proteins that have antibacterial activity. NETs can trap and kill bacteria. Thus, in its diverse immunological roles, DNA interacts with other molecules to form aggregates or sub-cellular structures that alarm the immune system, promote host defense or drive critical events in autoimmunity.

Bringing rheumatology research to the next level: addressing the main challenges of patient partnerships in research and health care service design

SP0050 ENSURING REPRESENTATIVENESS OF THE PATIENTS' PERSPECTIVES IN THE FINAL RESULTS GENERATED FROM CLINICAL RESEARCH – CHALLENGES FROM THE PERSPECTIVE OF RESEARCHERS

A.-M. Orbai on behalf of GRAPPA-OMERACT Psoriatic Arthritis Core Set Working Group. *Rheumatology, Johns Hopkins University School of Medicine, Baltimore, United States*

Now more than ever, patients are increasingly taking part in shared healthcare decisions with their physicians. Information from clinical research, on which evidence-based medicine draws upon, ideally needs to make sense to patients and not only physicians.

Representativeness of the patients' perspectives in the final results of clinical research is therefore critical for shaping the content and quality of medical knowledge and for shared clinical decision-making. As a result there is increased emphasis and even requirement from organizations around the world to include patient research partners (PRPs) as equal members in the medical research team. PRP inclusion means participation in research question generation, study design, data analysis/interpretation, authorship and results dissemination. Several questions remain: 1) How can we maximize the impact of the perspective patients bring to the table? 2) How can we ensure we capture the patients' perspective accurately and carry it forward into the final product of research? We can maximize impact and reach by including the patients' perspective in research that defines the way we assess disease and disease targeted interventions. Randomized controlled trials (RCTs) and longitudinal observational studies (LOS) are currently our main source of clinical information regarding efficacy of disease targeted interventions. Outcomes assessed in RCTs and LOS, as well as the health measurement tools used to assess these outcomes need to include the patient perspective in order for the information generated from these studies to be valid and usable. A conceptual diagram to illustrate how the patients' perspective is critical in generating health information for patient and physician shared decision making is represented in the Figure.

Case study: the updated Psoriatic Arthritis (PsA) Core Domain Set patient domains. A core domain set is the minimum set of outcomes that need to be assessed to evaluate the effect of disease targeted interventions. The first PsA core domain set was developed in 2006 by physicians and methodologists. The core set update study identified clinical trial outcomes important for patients as a group and for physicians as a group and reconciled both perspectives to recommend an updated PsA core domain set that represents the perspective of both patients and physicians. Five PRPs were members of the working group and contributed during all stages of the project. The perspective of patients was included as follows: a) domain generation through qualitative data collection and analysis from international focus groups; b) first domain prioritization exercise in electronic surveys with patients and physicians; c) a face to face nominal group technique meeting with 12 patients and 12 physicians to prioritize domains; d) second domain prioritization exercise through electronic surveys with patients and physicians; e) discussion and voting at the 2016 Outcome Measures in Rheumatology conference. During the process of achieving consensus we observed the following dynamic for patient prioritized domains (percentages represent proportions of patients ranking each domain important in the first survey and then the second survey): 1) Pain was rated important by 76% of patients in the first survey and 82% in the second survey and remained a core domain; 2) Fatigue 78% then 71% and became core domain; 3) Physical function 72% then 80% and remained a core domain; 4) Participation (daily activities and employment/work) was important to 72–76% of patients in the first survey and to 78% in the second survey and became a middle circle domain (important, not required); 5) Emotional well-being 60% then 57% and was placed in the middle circle; 6) Independence 82% then 63% and placed on the research agenda. In each of these situations the trend in the patient's vote as a group followed the physician's vote with one exception: the domain participation.

Summary of challenges and solutions for ensuring representativeness of the patients' perspective in the final results: Patients may change their views and align with physicians during the course of a research project. PRPs can help increase awareness of the patients' perspective throughout all stages of the research process. Special attention should be given to: 1) use of methods that adequately capture the patient perspective in the initial stages of a research project, and 2) allowing a robust patient perspective to take shape from patients as a group, before the consensus process with additional stakeholders begins. In addition, supporting patients with adequate information and materials and involving PRPs in their development will maximize understanding of the task for patients and their full participation.

SP0051 BECOMING A PATIENT RESEARCH PARTNER IN THE FIELD OF RHEUMATOLOGY. MY EXPECTATIONS AND THE CHALLENGES OF BEING EDUCATED AND TAKEN SERIOUSLY

E.F. Mateus[1,2,3]. [1]*LIGA PORTUGUESA CONTRA AS DOENÇAS REUMÁTICAS, Lisbon, Portugal;* [2]*Patient Research Partner, EULAR, Zurich, Switzerland;* [3]*ENP, EUPATI Portugal, Lisbon, Portugal*

Patients often feel that their experience of illness is not valued nor understood by others. However, there has been a growing recognition of the importance of the patient perspective and involvement in research, improving its methodology and outcomes. The European Medicines Agency has been involving patients' and consumers' representatives on their work since 2005. The "European League Against Rheumatism recommendations for the inclusion of patient representatives in scientific projects" have been published in the "Annals of the rheumatic diseases" in 2011.

I was diagnosed with Juvenile Idiopathic Arthritis when I was 5 years old, back in 1977. Therefore, I have 40 years of experience of living with a Rheumatic and Musculoskeletal Disease (RMD), but no recollection of what my life was like "before" and "after" the diagnosis. I have learned to live and cope with my RMD, with a sense of being different from my peers. This sense of "uniqueness" was

only disrupted when I realised that my experience of illness was quite common to other persons with a RMD. I can still remember my fascination, in a Patient Reported Outcomes workshop, by discovering that our experience as patients had a bigger relevance that the one we usually conceive.

Then, I felt the need of understanding the research process and specific jargon, so I could relate them with my knowledge on living with a RMD. Otherwise, any insight on the patient perspective would be "lost in translation", due to an inability to establish a correspondence between the scientific terminology and mindset regarding the disease, and the experience of illness and sickness by the individuals. Training opportunities were also recognised as desirable by the above mentioned EULAR recommendations, to increase expertise and understanding of research methods and to promote the patients' self-confidence on their contribution to research.

The *Patient Research Partners* (PRP) training by EULAR, in 2013, was the first step towards a better understanding of what could be the role of patients and on how to provide a meaningful input from the patients' perspective into research processes. It was followed in 2014 by the training provided by European Patients' Academy on Therapeutic Innovation (EUPATI) for *Patient Expert on the Medicines Research and Development Process*. This expert-level training was organized in a mixture of independent e-learning coursework and face-to-face training events over a 14-month period. The syllabus involved six modules: Discovery of Medicines & Planning of Medicine Development, Non-Clinical Testing and Pharmaceutical Development, Exploratory and Confirmatory Clinical Development, Clinical Trials, Regulatory Affairs, Medicinal Product Safety, Pharmacovigilance and Pharmaco-epidemiology, HTA principles and practices. Additionally, in 2016, I have attended the 1st EULAR course on Health Economics in Rheumatology.

In the meantime, my background as an anthropologist led me to become interested in Medical Anthropology. Between 2007–2015 my academic research (MA Phil. and PhD) was oriented towards a specialization in Anthropology of Health, with a special interest in Anthropology of Pharmaceuticals.

Based on my personal experience, on this lecture I will focus on the challenges of the role of the PRP trying to fill the gap between the mindsets and practices of different stakeholders.

Navigating through different meanings of symptoms and treatments, the educated patient representative must act like a translator, decodifying the biologic impact of the disease and intervention over the experience of illness on the everyday aspects of living with a RMD. The biggest expectation and challenge might be to bring these aspects forward, as relevant for the other stakeholders, since they shape individual values and patient's preferences.

Although recognised as having a pivotal role, patient's involvement in research may be limited by tokenism or by ineffective patients' participation. Patients' involvement is now a requirement and an added value to any project. But, is the project team ready and willing to listen to patients? Are PRP duly involved in the project, or are they just expected to be recipients without any input of their perspectives into the development and implementation of the research?

The knowledge and education acquired to perform our task enables us to understand science enough to communicate the patient experience in a meaningful way, improving the research. Our added value is, undoubtedly, our experience with the disease, our understanding of the individual values and preferences shaped by the everyday aspects of living with a RMD. We should be taken more seriously, for the benefit of science and patients.

SP0052 BUILDING PATIENT PARTNERSHIP IN HEALTH CARE SERVICE DESIGN AND DELIVERY

H. Lempp. *Rheumatology, Kings College London, London, United Kingdom*

This paper will present details of the approach to patient and public involvement in health service delivery, health service research and health care education in England. The presentation will be based upon a Logical Framework with the following key elements: inputs, processes, outputs, and outcomes/impacts. Key barrier acting to minimise the impact of building patient partnerships will be discussed, illustrated by examples from our experience in the preparatory stages for our departmental strategy to formalise close Patient Partnership for our research portfolio: (i) establish honorary contracts for patients for the academic Institution and local Hospital Trust; (ii) include patients on the interview panels to appoint project researchers (iii) build in a separate funding within the overall project budget for the costs associated with patient partnership and (iv) manage patient expectations of rapid implementation of the results of research after the completion of projects. Patient Partnership is essential and feasible to make health care service and design relevant.

WIN & HOT session

SP0053 HOT SESSION: VASCULITIS TREATMENT

R.A. Luqmani. *University of Oxford, Oxford, United Kingdom*

The systemic vasculitides are characterized by inflammation of blood vessels, which if untreated, results in tissue or end organ damage or death. Chapel Hill nomenclature is widely used to define different forms of vasculitis according to the size of the predominantly affected vessels. Other forms of vasculitis are not defined by a predominant vessel size (e.g. Behcet's syndrome). Vasculitis associated with the presence of anti-neutrophil cytoplasm antibody (ANCA), termed AAV, is less common than giant cell arteritis (GCA), but considerable advances have been made in understanding the pathogenesis and evidence based treatment for AAV. AAV is divided into three major forms: granulomatosis with polyangiitis (GPA) (Wegener's granulomatosis), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA) (Churg–Strauss syndrome). ANCA are implicated in their pathogenesis but not all patients with AAV are ANCA positive.

We will review recent EULAR guidelines on therapy for AAV, based on careful structured clinical evaluation of patients, with stratification according to severity. Cyclophosphamide or rituximab (plus glucocorticoid) is used for severe disease, followed by maintenance with azathioprine (AZA) or methotrexate (MTX), and reducing doses of glucocorticoids; or maintenance rituximab. Additional plasmapheresis is indicated for very severe disease; by contrast for less severe disease, MTX or AZA or mycophenolate (plus glucocorticoids) can be used. The evidence for effectiveness is clear for MPA and GPA. A number of studies are underway to improve our use of these existing agents and to test newer, mechanism based treatments such as inhibition CTLA4Ig or of the C5 complement pathway in GPA and MPA. For EGPA with severe manifestations, cyclophosphamide and glucocorticoids are recommended. A trial of mepolizumab (inhibitor of interleukin 5, a potent driver of eosinophil production) in EGPA has recently been completed. IL-6 inhibition with tocilizumab is a significant advance over glucocorticoid monotherapy in treatment of GCA. Apremilast is effective in treating mucocutaneous manifestations of Behcet's syndrome. Relapse is a common feature of many forms of vasculitis and needs to be monitored by structured clinical evaluation. Monitoring of ANCA titres in AAV or the acute phase response in most forms of vasculitis can be misleading and should not serve as sole guide to therapy in the absence of clinical evidence of active disease. Early survival is over 94% of patients with most forms of vasculitis. Five year survival is 70–75% for AAV with current therapy. However, if the condition is more severe disease, especially with significant renal impairment, mortality is worse.

Vasculitis remains a challenge. Whilst mortality has dramatically reduced as a result of effective immunosuppression, relapse and chronic damage are significant problems for all forms of vasculitis. We need a better understanding of how to manage and limit the long term chronic effects of vasculitis and its therapy.

Treat-to-target in axSpA: reality or utopy?

SP0054 THE CONCEPT OF TREAT-TO-TARGET

J. Braun. *Rheumazentrum Ruhrgebiet, 44649 Herne, Germany*

Many illnesses including most rheumatic diseases have substantial effects on well-being and quality of life, including deterioration of physical and mental function and a reduced life expectancy, since they can cause damage to organs and cells. If healing and regeneration cannot be achieved an impairment of organ function can be expected. In acute diseases this may occur rapidly over hours to days and weeks, while it often takes months to years in chronic diseases. However, if treatment is instituted early enough, organ damage may be prevented or diminished.

Critical for an optimal management of diseases with potentially severe outcomes is to determine the responsible thresholds for, for example, disease activity or to define the maximum level of a surrogate marker at which damage is unlikely to occur and, thus, will not be harmful in the long term. Although the optimal aim of therapy is cure, and appropriate therapy may even normalize life expectancy, many chronic diseases such as hypertension, diabetes, rheumatoid arthritis (RA) and ankylosing spondylitis (AS) have remained without curative therapies in the last decades – even though considerable progress has been made. Thus, a strategic therapeutic approach should aim for prevention of future damage, and maximal improvement of compromised organ function. Therefore, a clearly defined threshold of a validated measure that predicts future harm or no or minimal harm, is a target of critical importance for chronic diseases with potentially severe outcomes. Treat-to-target strategies having been developed to achieve this have widespread implications. They should be routinely followed - as long as the potential harm from treatment is carefully balanced against its benefit. Clearly, if inappropriately managed, the consequences of diabetes and hypertension in

the long run include, myocardial infarction, stroke, renal failure, blindness, etc. Therefore, target values for biological markers have been determined below which organ damage does usually not occur and life expectancy is normalised. Examples for domains in which such thresholds have been defined are blood pressure, glycosylated haemoglobin (HbA1c), and others.
Inflammatory rheumatic diseases lead to organ damage not only in the musculoskeletal system but they may also harm internal organs. A target level of a measure related to its long-term outcome, can be a surrogate measure like the cholesterol level for cardiovascular diseases, or a composite measure of disease activity as used in RA (DAS28) or in AS (ASDAS). The treat-to-target strategy can be reduced to a simple algorithm of, on the one hand measuring activity and on the other hand, in consequence, adapting treatment. Treatment adaptation does not necessarily mean changing a medication or increasing the dosage of a drug but may even also mean life style changes, as long as the therapeutic target is attained or nearly attained - importantly within a prespecified time frame. Therapeutic adaptations should always take patient factors, including comorbidities, adverse events and patient preferences, into account.
However, the musculoskeletal system can mostly not be assessed by using a simple surrogate or direct “gold standard” measures, since rheumatic diseasese with multiple signs and symptoms are mostly rather complex. In RA information derived from physical examination using a quantitative joint count is considered very important. This is different in AS. Additionally, information from the history, which can be collected through patient self-report multifaceted questionnaires, has proven effective in determining patient status and its change. This is even more important in AS. However, functional impairment has reversible and irreversible components. Damage is a consequence of high and/or persisting disease activity. The most important variables contributing to joint damage in RA are swollen joint counts and C-reactive protein (CRP). The latter in combination with questions on back pain is also important in AS, while in RA the use of composite measures of disease activity that comprise joint counts is critical. There is good evidence that, if this strategy is consequently followed, physical function will improve and joint damage be reduced in patients with RA. To determine optimal treatment targets in RA it is necessary to define the thresholds of disease activity measures at which progression of joint destruction is halted. Of note, only remission is associated with maximal reversal of functional impairment and a stop of progression of damage as well as work disability. However, it needs to be realized that some remission criteria are more stringent than others.

SP0055 WHAT ARE THE CHALLENGES FOR APPLYING TREAT TO TARGET IN AXIAL SPONDYLOARTHRITIS?

M. Dougados. *rheumatology Hopital Cochin, René Descartes University, paris, France*

The concept of Treat to Target (T2T) applied in rheumatoid arthritis has been evaluated in psoriatic arthritis and is currently under investigation in two different strategy trials in patients suffering from axial spondyloarthritis (axSpA). Whatever le results of these trials will be, the acceptation of this concept and consequently its implementation in daily practice might be challenging for several reasons.
The concept of T2T necessitates 3 different steps and also the close collaboration of the patient and the availability of different treatment modalities.
The three different steps consist in:
a) the choice of the most relevant outcome measure (e.g. a measure evaluating a domain recognized as predisposing to subsequent clinically relevant damage (either structural damage or important comorbidities such as cardiovascular diseases)).
b) the determination of the threshold of the outcome measure to reach (threshold below which the risk of subsequent damage is abolished or significantly decreased).
c) The time to reach the target is usually related to the treatment modality (a few days for NSAIDs and several weeks for DMARDs).
A part these different steps, two points have to be considered a) this T2T approach is impossible without embarking the patient in a true share decision b) this T2T strategy requires the possibility to adapt/increase the treatment in case the target is not reached after one or several “conventional” treatment modalities.
For each of these different points we will consider past-on ongoing initiatives proposing to resolve the different encountered issues in order to facilitate the elaboration and the implementation of a T2T strategy in AxSpA.

SP0056 UPDATE OF THE T2T RECOMMENDATIONS IN SPA

D. Van Der Heijde on behalf of T2T in SpA working group. *Rheumatology, Leiden University Medical Center, Leiden, Netherlands*

In 2013 the first recommendations for treating spondyloarthritis to target (T2T) were published. These followed the reasoning for the T2T recommendations for rheumatoid arthritis. Although the systematic literature review at that time did not provide evidence to support the recommendations, five overarching principles and 11 recommendations were formulated. There were 9 commen recommendations for axial SpA, peripheral SpA and psoriatic arthritis and 2 additional recommendations for each subgroup specifically. In 2017 the T2T working group met again to update the recommendations. This was based on an updated systematic literature review. Data had been published that there is indeed a clear link between inflammation and subsequent longterm outcomes, which is the basis for the T2T principles.
SpA is characterised by musculoskeletal signs and symptoms (arthritis, enthesitis, dactylitis, axial disease) but also extra-articular manifestations (psoriasis, inflammatory bowel disease, anterior uveitis) are important manifestations. Moreover, comborbidities (such as osteoporosis, cardiovascular disease). All these manifestations are taken into account in the formulation of the recommendations. The overarching principles were kept largely identical. Some changes in the wording were made for a better understanding, but no fundamental changes were made. A total of 11 recommendations were formulated. These are now for all subgroups of SpA and no specific recommendations are proposed. In principle, the treatment target is remission or inactive disease of musculoskeletal and extra-articulaur manifestations, and the target should be individualised. It is important that remission/inactive disease should be based on a combination of clinical and laboratory parameters, and disease activity should be measured on the basis of clinical signs and symptoms as well as acute phase reactants. This is important to realise, e.g. in axial SpA as patient reported outcomes only are at best weakly correlated with structural damage. In certain circumstances, low disease activity may be an alternative target. Because of the heterogeneous presentation of SpA, not only the target, but also the assessments should be individualised. Both in the overarching principles and in the recommendation the shared decision between patient and rheumatologist is listed as the basis of the T2T management.
The updated recommendations will be presented.

Calcium crystal deposition in rheumatic diseases —

SP0057 CALCIUM CRYSTALS AND THEIR LINK TO OSTEOARTHRITIS

J. Bertrand. *Department of Orthopeadic Surgery, Otto-von-Guericke University Magdeburg, Magdeburg, Germany*

Calcification of cartilage is a common finding during osteoarthritis (OA). We have shown that it is mainly of the BCP type and not the CPPD type of crystal formation. BCP cartilage calcification is directly linked to the severity of cartilage degradation and, therefore, OA severity. We have also shown that with increasing hypertrophic differentiation of chondrocytes, the amount of calcification increases in vivo and in vitro. This indicates a link between chondrocyte hypertrophy andcartilage calcification. The pyrophosphate pathway is known to be involved in tissue calcification. It functions to keep the sensitive balance of pyrophosphate (PPi) and phosphate (Pi), thereby preventing the generation of calcium-phosphate crystals. One key player in this pathway is the nucleotide pyrophosphatase phosphodiesterase (NPP1), which has been demonstrated to be regulated by inflammatory mediators such as IL-1. In our cohort of OA patients, the expression of collagen X and NPP1, but not ANK and TNAP, correlated with cartilage calcification and also with the Mankin-Score. NPP1 expression inverse correlated with the calcification, whereas collagen X was upregulated. This finding was confirmed in experimental murine OA using the DMM mouse model. Furthermore, NPP1mut/mut mice (ttw/ttw) exhibit more calcification activity than wild type controls in joints as well as in cartilage of non weight bearing areas, including ear cartilage, suggesting that mechanical stress is not required for the induction of calcification. NPP1mut/mut (ttw/ttw) mice developed typical OA-like changes as evaluated by histological analysis as well as in vivo imaging and histological stainings. Intriguingly, calcification was associated with increased expression of the hypertrophic cartilage marker collagen X and the bone marker collagen I. Additionally, BCP crystals are able to activate chondrocyte differentiation via the WNT signaling pathway.
NPP1 is an important player in OA-associated cartilage calcification. Pathologic calcification of cartilage resembles in many aspects cartilage transformation into bone. Taken together, the data suggest that OA is characterized by the re-activation of molecular signalling cascades that at least in part resemble endochondral ossification.

SP0058 REVIEW OF THE DIFFERENT IMAGING MODALITIES TO DETECT CALCIUM DEPOSITION DISEASES

P. Omoumi. *Lausanne University Hospital, Lausanne, Switzerland*

Crystal deposits in and around the joints are common and most often encountered

as incidental imaging findings in asymptomatic patients.
However, they can also cause chronic or acute arthropathy, generating symptoms. In the chronic setting, imaging features are usually characteristic and allow the differentiation of the type of crystal arthropathy. In the acute phase and in the early stages of the crystal deposition, the signs are often non-specific, and the final diagnosis still relies on the analysis of synovial fluid.
Radiography is the main imaging modality for the workup of these conditions. It can confirm the diagnosis and often characterizes the type of crystal arthropathy. In recent years, US has played an increasingly important role in this setting, and is a useful tool in superficially located crystal-induced arthropathies. CT nicely complements radiography for deeper sites, especially the axial skeleton. DECT is a promising tool for the characterization of crystal arthropathies, in particular gout as it permits a quantitative assessment of deposits, and may help in the follow up of patients.
When performed in the acute stage, MRI may show severe inflammatory changes that could be misleading and correlation to radiographs or CT should help to distinguish crystal arthropathies from infectious or tumoral conditions.

Fifty shades of remission in RA

SP0059 REMISSION: MORE THAN CLINICAL ...?

M. Boers. *Epidemiology & Biostatistics; Amsterdam Rheumatology and immunology Center, VU University Medical Center, Amsterdam, Netherlands*

This session is about defining remission. Most examples will be about rheumatoid arthritis (RA) because most experience has been gathered in that disease. But the concept of remission should be viewed from a wider perspective than one disease. The session includes two pro-con debates (on the utility of including imaging and biomarkers in a definition of remission).
As in all things, when embarking on a scientific project, one must ask:
"Why are we doing this?"
To even begin with answering the question, we must first agree on a clear conceptual definition of remission. When we started on the development of the ACR-EULAR definition of remission in RA, we used dictionary sources and discussions to settle on this:
"The state of absence of disease activity in patients with a chronic illness, with the possibility of return of disease activity." [1]
It is clear that choices are made from the beginning, especially with the concept "disease activity", and the possibility that disease activity returns (as opposed to "healing", where this possibility does not exist). Disease activity is a tangible concept adequately defined in RA, but less so in many other rheumatological diseases. Also, disease activity is conceptually separate from (mostly irreversible) consequences of the disease, such as damage. Finally, note that the above concept does not contain the elements "duration" or "treatment".
If we continue with the above concept, why do we want to proceed to operationalize the remission definition? The two main reasons are research and patient care. For both, it is clear that we are defining a very good, perhaps even the best state a patient can be in, given that we are talking about chronic disease, i.e. the root cause of the disease cannot be taken away to heal the patient. Being in such a good state has immediate benefits (minimal disease impact) and probably also future benefits, if lack of disease activity translates to less consequences (damage etc). In both research and patient care, we want a definition that is both valid (favorable test characteristics; links to prognosis) and feasible (time, costs, interpretability). Validity and feasibility oppose each other to a certain extent (eg, definitions with better sensitivity and specificity are usually more expensive). Research and patient care differ in their use of the definition. In research, validity and feasibility can be lower than in patient care, because research is about groups, and cost and interpretability are less of an issue than in patient care.
Most of the people criticizing the current ACR-EULAR remission definition of RA are confused over its purpose: whereas it was intended for use in trials, they criticize it for lack of validity in the clinic. For instance, it is felt that the patient global criterion is too strict, so that patients with no apparent inflammatory activity but a patient global score of 2 or higher (scale 0–10) are "unjustly" not classified as in remission. Also, the lack of a duration or treatment criterion is felt to be a problem, but this is not an issue in research.
In the following pro-con debates, please consider the following:
Proposals to change existing criteria for remission must also be held to the question: "Why are we doing this?"

SP0060 BIOMARKERS ARE REQUIRED FOR REMISSION: PRO

R. Van Vollenhoven. *Amsterdam Rheumatology and Immunology Center Arc, Amsterdam, Netherlands*

1. Conceptually, remission is thought of as a state where the disease is absent. As we approach a better understanding of the underlying pathophysiological process of a disease, it becomes more and more relevant to include in a definition of remission appropriate biochemical markers of that process.
2. From a practical point of view, definitions of remission in RA have been built upon clinical parameters of disease activity, supplemented in some cases with a single biomarker. However, it is clear that in practice these definitions are insufficiently precise: held against a gold standard of expert opinion, they perform at around 80–90%, misidentifying one or two out of every ten patients. And while there is an understandable and in many ways desiriable development of more patient-reported emphasis in outcomes, it has considerable practical value to be able to objectify an important disease state such as remission.
3. There is convincing evidence to show that biomarkers can be employed succesfully to predict some aspects of RA. In the day-to-day care of patients with this disease, the most important prediction may be whether the effective drug can be tapered or not. Current evidence indicates that biomarkers may be invaluable at helping clinicians and their patients make this important decision.

Innate immunity

SP0061 A DAY IN THE NEUTROPHIL'S LIFE

A. Hidalgo. *Cell & Developmental Biology, Fundación CNIC, Madrid, Spain*

Immunity is essential for life, yet the strength of immune responses are not constant throughout the day. This oscillatory immunity reflects an adaptation of organisms to environmental changes that occur through day-night cycles, so as to optimize and concentrate effective responses to the times of maximal environmental threat. In my talk I will discuss our ongoing efforts to uncover the mechanisms by which neutrophils, the most abundant and aggressive of all immune cells, orchestrate temporal immunity. These mechanisms are reflected in diurnal changes in phenotype and function of neutrophils, which we refer to as neutrophil aging. We propose that the existence of a timed response of neutrophils governed by cell-intrinsic and –extrinsic mechanisms suggests that inflammatory disease co-opts ancestral processes to damage tissues.

SP0062 DIFFERENTIAL SCAVENGING OF APOPTOTIC CELLS AND BACTERIA

G. Krönke. *Internal Medicine 3, University of Erlangen-Nuremberg, Erlangen, Germany*

During inflammation and infection, we are simultaneously confronted with both self and non-self in form of dying cells and microbes, respectively. Mechanisms that facilitate the non-immunogenic clearance of self-antigens derived from apoptotic and necrotic cells and that, in parallel, allow the initiation of an immune response against invading pathogens are incompletely understood. Recent data from our laboratory show that the immune system actively sorts apoptotic cells (ACs) and bacteria into distinct subspecies of phagocytes thereby enabling a segregated processing of self and non-self as well as a differential immune response against these two entities. During inflammation, ACs were cleared by tissue resident macrophages (resMφ) that performed a non-immunogenic disposal of self antigens, whereas bacteria were preferentially ingested by monocyte-derived inflammatory macrophages. We identified the enzyme 12/15-lipoxygenase and the nuclear receptor Nr4a1, both specifically expressed by resMφ, as key factors that control the coordinated and non-immunogenic phagocytosis of ACs by these specialized macrophage subset. Incorrect sorting and aberrant uptake of AC-derived self-antigens by pro-inflammatory and immunocompetent phagocytes, however, resulted in the break of self-tolerance and autoimmunity. Our data thus demonstrate the importance of a sorted clearance of ACs for the maintenance of immunologic self-tolerance.

SP0063 THE ROLE OF MUSCLE IN INNATE IMMUNE RESPONSES

P. Rovere-Querini. *Immunology, Transplantation and Infectious Disease, San Raffaele Scientific Institute and Vita-Salute San Raffaele University, Milano, Italy*

The skeletal muscle represents a unique site from the immunological point of view. Leukocytes are virtually absent in healthy conditions. However they are quickly recruited upon muscle injury, persist during the regenerative phases to disappear again after tissue healing. Thus, it represents and ideal scenario to study the

involvement of the innate immune system in the homeostatic response either to the conventional programmed death of multinucleated myofibers and to the parallel occurrence of "non-canonical" cell death and survival programs, including necrosis and autophagy. Recruited phagocytes are responsible of the clearance of damaged myofibers and of dying muscle stem/progenitor cells, stromal cells and leukocytes. Muscle macrophages in particular are endowed with remarkable plasticity throughout regeneration and healing, switching from activated cells that generate inflammatory cytokines to reparative assets, that play a non redundant role during the resolution phases of the damage and regulate the termination of the inflammatory responses. This dynamic transition between is increasingly felt to be the key to muscle homeostasis. Conversely defects in the process favour maladaptive remodeling with deposition of collagen and fat accumulation and in predisposed individuals autoimmunity leading to inflammatory idiopathic myopathies. A specialized population of regulatory T (Treg) cells, which control the inflammatory response by promoting the M1-to-M2 switch, and the activation of the muscle stem cells, satellite cells is receiving increasing attention for their central role in tissue homeostasis. Thus, the immunological perception of muscle cell death and regeneration – in turn influenced by environmental cues, including mitophagy and alteration of the redox balance - determines whether these events foster successful tissue healing or persisting inflammatory myopathies. The insights that are progressively become available on this original scenario hold promises to develop new approaches for disease treatment. Thus, immunologic perception of death and regeneration of muscle cells determine whether these events promote healing of tissues or persistent inflammatory myopathies. The insights that are becoming increasingly available on this original scenario hold promise for the development of new approaches to the treatment of persistent human muscle disease.

To be and to become: transition from paediatric to adult care

SP0064 TO BE AND TO BECOME: REFLECTIONS ON MY TRANSITION

W. Olsder. *YOUTH-R-WELL.COM, Groningen, Netherlands*

The importance of successfully transitioning pediatric patients to adult care is increasingly recognized across a wide range of health care providers. However, there are still many challenges occurring during the transition phase. This presentation will contribute to these challenges by sharing the journey of a young person with arthritis on the transition to adult care.

As a young patient with arthritis, I made the journey from pediatric care to adult care a couple of years ago. I am diagnosed with arthritis since I was 14 years old. In this presentation, I will show the experiences of my own transition. Furthermore, as the chair of Youth-R-Well.com, an organization for young people with RMDs in the Netherlands, I will share some of the main points around transition I learned from other young patients. For every person, the transition to adult care is experienced different. Therefore, I will try to give some main answers from personal journeys on the questions: How is the transition experienced by a young patient? What are the current challenges faced by a young patient during the transition? What should be the role of the parents during the transition? What are best practices for the transition to adult care?

Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.7193

SP0065 ARE WE ASKING THE RIGHT QUESTIONS IN TRANSITION RESEARCH?

K. Minden[1,2]. [1]*Epidemiology unit, German Rheumatism Research Centre;* [2]*Charite Universitätsmedizin, Berlin, Germany*

Already in 1991 Robert Blum pointed to the diverse set of issues of which the clinicians need to be cognisant to successfully care for youth with chronic illness. Since then, the special health care needs of adolescents and young adults with chronic diseases, including rheumatic diseases, have been on the agenda. Despite efforts to develop holistic services and programmes for youth, there are still inconsistencies in service delivery and practice standards. This revealed a survey among paediatric rheumatologists from 115 centres in 22 European countries in 2016. A minority of European paediatric rheumatology centres have a written transition policy, follow a standardised, structured approach in transitioning patients and measure the success of their interventions with evaluated instruments. To overcome these deficits and existing practice variation, key elements of transitional care, frameworks and pathways to implement and assess transition programmes have been recommended by EULAR and PRES.

However, as long as we don't have robust evidence upon best practice for transition, on the best metrics for measuring "success" and "outcome" of transitional care services and on the impact of interventions on the young people with rheumatic diseases will the service planning and delivery for transition aged youth remain suboptimal and result in adverse long-term outcomes.

The literature about transitional care is exponentially increasing each year and comprises among others assessments of experience of care and clinical outcomes, evaluations of different services and processes of care. What we have learned so far from transition research in the field of rheumatology, which research priorities are currently set on the agenda by health care providers and whether they meet those of young people will be in the focus of this lecture.

SP0066 IMPLEMENTATION OF A BRIEF TRANSITION PROGRAMME FOR ADOLESCENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

L.R. Knudsen. *Department of Rheumatology, Aarhus University Hospital, Aarhus, Denmark*

Background: It is well described that adolescents and parents find transition between the children's and adult ward challenging (1–2) because they feel inadequate prepared, and find communication and cultural differences between child and adult care challenging. Thus, transitional care programmes becomes essential for a successful process (3).

Objectives: We aimed to develop a brief transition programme for adolescents with juvenile idiopathic arthritis (JIA), suitable for daily clinical practice in the children's and adult ward of rheumatology at Aarhus University Hospital, Denmark.

Methods: The development was based upon studies of transitional care programmes and qualitative studies of the patient, parent, and health professionals perspective in the transition process. Needs in the transition process from the perspective of both adolescents and parents were further investigated through semi-structured interviews. We used studies by Janet McDonagh and colleagues (3) as a theoretical framework for the programme development.

Results: The programme focuses on the final part of the transition process by including the adolescent from the children's ward at the age of 14. It runs for two years in the children's ward and continues the first year in the adult ward. The programme focuses on preparing the adolescent and parents for transition by enhancing the adolescent's knowledge and skills in coping with JIA. The programme further focuses on the relation between the adolescents and parents by bringing attention to the need for a gradually separation, and to placing more self-dependence on the adolescents. A guideline, describing the programme, containing concrete instructions to health professionals has been developed. The programme was primarily initiated by the adult ward, but nurses and physicians in both wards have been involved throughout the process.

The programme consists of the following elements;

- Assigned contact persons.
- Information leaflets about transitional care, transfer to adult care and differences between the children's and adult ward, i.e. in ways of working and treatment procedures.
- Independent consultations with health professionals.
- Materials for educational sessions.
- Educational sessions dealing with JIA and treatment, dialogue on adherence and challenges in adolescence.
- Arrangements of visits to the adult ward before transfer.

Conclusions: Our experiences with the programme in practise are generally positive. However, we have experienced that successful implementation calls for good collaboration and continuous involvement of the health professionals involved in the programme on a daily basis. Hence, ongoing meetings and communication have been essential to promote collaboration between the children's and adult ward.

Heterogeneity in JIA

SP0067 CYTOKINES IN JUVENILE IDIOPATHIC ARTHRITIS

W. de Jager. *Pediatric Immunology, University Medical Center Utrecht, Utrecht, Netherlands*

The importance of cytokines in the pathogenesis of inflammatory diseases is highlighted by the success of therapeutic approaches directed against cytokines and cytokine receptors. Cytokines are characterized by their redundancy and pleyotropy: multiple cytokines can target the same receptor, while on the other hand a single cytokine can have multiple, even contradictory immunological effects.

Linking a cytokine/protein biomarker signature with clinical outcome may help to identify and classify patient cohorts. Thus "intelligent" cytokine signatures can be used as biomarkers in human inflammatory diseases. There are however various risks associated with this approach; often it is impossible to obtain material from the site of inflammation and there are various often not well-known technical aspects crucial to obtain reliable and usable results. Although standardization has been prominent in day to day clinical practice, standardization of sample collection and laboratory assessments remains suboptimal. Inconsistency in sample collection can affect the results of biological assays and thus several characteristics require thorough evaluation and standardization. This standardization is not limited to assay validity and reproducibility but also pre-analytical treatment and appropriate specimen types.

SP0068 CLINICAL INSIGHTS INTO JIA HETEROGENEITY

A. Consolaro on behalf of EPOCA Study Group. *Istituto Giannina Gaslini, Genova, Italy*

Several epidemiologic surveys have documented a remarkable, yet unexplained, disparity in the prevalence of juvenile idiopathic arthritis (JIA) subtypes among different geographic areas or ethnic groups. Moreover, the therapeutic approach to JIA is not standardized and the availability of the novel and costly biologic medications is not uniform throughout the world. This disparity may have significant impact on disease outcome. The multinational study of the EPidemiology, treatment and Outcome of Childhood Arthritis (EPOCA study) is aimed to obtain information on the variability of JIA phenotypes in different geographic areas, the therapeutic approaches of pediatric rheumatologists practicing in diverse countries, and the disease status and outcome of children with JIA currently followed worldwide. Participation in the study was proposed to all pediatric rheumatology centers that are part of the Pediatric Rheumatology International Trials Organization (PRINTO), and to several centers in the US and Canada. Each center was asked to enroll 100 consecutive JIA patients or all consecutive patients seen within 6 months. Each patient received a retrospective and cross-sectional assessment. Parent- and child-reported outcomes were recorded through the administration of the Juvenile Arthritis Multidimensional Assessment Report (JAMAR). Participating countries were grouped into 6 geographic areas. Patients were then grouped according to their country's gross domestic product per capita (GDP) and the total expenditure on health per capita (HE) (source www.who.org). Currently, 8,325 patients from 44 countries have been entered in the web database. Comparison of main epidemiology, treatment, and outcome features across the different geographic areas was performed. Patients living in countries with GDP or HE below the median had lower frequency of remission, higher median cJADAS, higher frequency of damage, and were less frequently prescribed biologic DMARDs. These results were confirmed when analyses were conducted only in oligoarthritis or polyarthritis patients. These results provide further evidence of the wide difference of JIA characteristics across geographic areas in terms of age at disease onset, subtype prevalence, and frequency of anterior uveitis. Overall, patients living in non-Western countries had higher levels of disease activity and cumulative damage than patients followed in North America and Western Europe. This disparity in disease outcomes may be partially due to differences in the availability or affordability of biologics, as confirmed by the evidence of worst outcomes in countries with lower GDP or HE.

EULAR - EMA session

SP0069 REGISTRIES IN MUSCULOSKELETAL DISEASES AND THEIR REGULATORY USE

R. Vesely. *Rheumatology, Respiratory, Gastroenterology and Immunology Office, European Medicines Agency, London, United Kingdom*

Patient registries collect information about individuals sharing health-related characteristics, for example, a particular disorder, a treatment or a procedure. While randomised controlled trials typically provide the primary evidence supporting marketing authorisations for new medicines, the patients studied may not be fully representative of everyone ultimately receiving the medicine and the trials may provide limited information about the natural history of the disorder. Information collected in patient registries is potentially of value for filling these evidence gaps in certain situations and for providing post-marketing safety and effectiveness information. Multiple stakeholders stand to benefit from using registry information in this way including patients, healthcare providers, policy makers, manufacturers and healthcare regulators.

In 2014, the EMA commenced a Registry Initiative aiming to optimise the use of registries in supporting medicines authorisations. Establishing a strategy of early engagement between marketing authorisation applicants and registry holders and a task force to support activities, a pilot phase was undertaken aiming to understand the barriers and enablers in using registries to support marketing authorisation applications and to inform the development of recommendations to optimise their use.

On 28 October 2016 the Agency organised Patient Registries Workshop to collect and discuss the information about experience from different patient registries in various therapeutic areas. The topics included:

- Benefits of registries for regulators
- Benefits of registries for HTA and payers
- Benefits for industry
- Benefits for clinicians and researchers
- Benefits for patients
- Challenges in collaboration between registries
- Technical challenges
- Governance
- Sustainability

Conclusions of the pilot and the workshop have been utilised in the following activities including workshops to support registries in individual diseases.

There are multiple advanced registries in RA and JIA. Utilisation of outcomes of these and other existing or newly planned registries in other musculoskeletal diseases for regulatory purposes current environment offers new opportunities that require further analyses and collaboration.

SP0070 NEWS FROM OMERACT – IMAGING AND MORE

V. Strand. *Stanford University School of Medicine, Portola Valley, United States*

Objective In rheumatoid arthritis (RA), MRI provides earlier detection of structural damage than radiography (X-ray) and more sensitive detection of intra-articular inflammation than clinical examination. This analysis was designed to evaluate the ability of early MRI findings to predict subsequent structural damage by X-ray.

Methods Pooled data from four randomised controlled trials (RCTs) involving 1022 RA hands and wrists in early and established RA were analysed. X-rays were scored using van der Heijde-modified or Genant-modified Sharp methods. MRIs were scored using Outcome Measures in Rheumatology (OMERACT) RA MRI Score (RAMRIS). Data were analysed at the patient level using multivariable logistic regression and receiver operating characteristic curve analyses.

Results Progression of MRI erosion scores at Weeks 12 and 24 predicted progression of X-ray erosions at Weeks 24 and 52, with areas under the curve (AUCs) of 0.64 and 0.74, respectively. 12-week and 24-week changes in MRI osteitis scores were similarly predictive of 24- week and 52-week X-ray erosion progressions; pooled AUCs were 0.78 and 0.77, respectively. MRI changes in synovitis at Weeks 12 and 24 also predicted progression of X-ray joint damage (erosion and joint-spacenarrowing) at Weeks 24 and 52 (AUCs=0.72 and 0.65, respectively).

Conclusions Early changes in joint damage and inflammation detected with MRI predict changes in joint damage evident on subsequent X-rays. These findings support the use of MRI as a valid method for monitoring structural damage in short-duration RCTs.

Barrier free employment for young people with RMDs

SP0071 YOUNG PATIENTS: READY, BRILLIANT AND ABLE TO WORK!

L. Kullamaa. *European Patients' Forum, Brussels, Belgium*

In May 2016, European Young Patients Group, an initiative representing young patients from the European Patients' Forum (EPF) and the European Multiple Sclerosis Platform (EMSP), organised a workshop in the framework of the European Youth Event (EYE) 2016 in Strasbourg that corresponded with one of the five main programme themes titled, Exclusion or Access: Crackdown on Youth Unemployment.

The physical and emotional symptoms of chronic conditions, together with social stigma and attitude, create significant barriers to young patients in the job market. With appropriate support, they, like all enthusiastic young people, can be assets for employers. Through interactive discussion, creative expression, education and open dialogue, the workshop aimed to challenge expectations and inaccurate perceptions about the abilities of young people with chronic conditions, tackle societal beliefs and stereotypes of individuals with chronic conditions, stimulate discussion to explore concrete solutions and develop practical actions for young people and their allies accessing employment and steer change to ensure young patients benefit from equal opportunities and treatment at work. By addressing these specific objectives, the workshop was to ultimately raise awareness of the extra burdens faced by young people with chronic conditions transitioning from education to employment, as well as bringing public attention to the stigma and discrimination that exists at both the recruitment stage and in relation to employees disclosing their health conditions. It also was to compliment and

strengthen the EPF and EMSP's wider initiatives on tackling the multiple forms of discrimination faced by patients with chronic conditions.
The workshop demonstrated how many issues surrounding young people with chronic conditions transitioning into the labour market are still prevalent. The expectation of discrimination and stigma in the workplace, along with the unwillingness to disclose their condition when applying for a job for fear of rejection are confounded by young patients' experiences of negative employer attitudes. Moreover, the concept of quota systems and giving people with chronic conditions and/or disabilities preference among applicants for certain jobs possibly suggests that they are employed because they have a chronic condition and/or disability, not because of their abilities. This unambiguous form of positive discrimination also affects how young people manage information about their health. They feel forced to share about their condition to get an interview, however by doing so they risk being subjected to negative reactions in the interview or at the workplace.
Young people with chronic conditions have a great deal to contribute to the workplace and more action should be taken to encourage and support employers with hiring them. Training and resources should be provided to managers and employees to raise awareness of the impact that chronic conditions can have on an individual, and how they can be assisted through small adjustments or specific care requirements. Employees should not assume what someone can or cannot do and how their condition affects them, therefore a place for an open discussion should be created. In addition, where quota systems apply, they should be re-evaluated and designed to recruit young patients on merit, in competition with other workers without a chronic condition and/or disability.

SP0072 CHALLENGES AND POTENTIAL SOLUTIONS ABOUT STAYING IN WORK AS A YOUNG PERSON WITH AN RMD

J. Andersen[1,2,3]. *[1]Lupus Europe, Romford, Essex, United Kingdom; [2]EULAR Young PARE, Zürich, Switzerland; [3]Lupus Dk, Gigtforeningen, Copenhagen, Denmark*

Introduction: A lot of young people with RMDs experience difficulties when it comes to staying in work after diagnosis. Some employers see a young person with an RMD-diagnosis as a liability. They are afraid it will cause a lot of difficulties with sick leaves and less work effort and in the end cost them a lot of money. Often the young person hasn't worked in the company for that many years (because of the age) and hasn't had the chance to make themselves indispensable/a valued work force yet, which makes it easy/obvious for the employer to terminate their employment.
The process of getting a diagnosis can often cause long periods of sick leave in the beginning and many employers don't understand that this will get better over time as the person gets used to having the disease and the medication has a chance to work properly.
Some young people choose not to tell their employer, that they have an illness at all, which can also be a big problem. When the employer and the work colleges don't know about the diagnosis, they cannot take special consideration to the person with the illness. Sometimes, you might a little extra break to be able to work an entire day and without it you risk wearing yourself down and having to quit the job yourself. If you choose to take the breaks yourself or perhaps fail at your job, because you try to do as much as the healthy persons, you risk getting fired, because nobody knows there is a good reason why you cannot do as much as you "should". Young and inexperienced persons can have difficulties demanding special treatment. They are often too insecure to stand their own ground and demand special consideration.
Objectives: I aim to examine the problems young people with RMDs face, when they want to stay in work and find potential solutions to these problems. How big is the problem? What can be done by the young people themselves? How can national patient organisations help them? How can EULAR PARE or other united European patient organisations help? Do we need new regulations? How do we make each country follow the EU-legislation?
Methods: I have asked young people with RMDs from all across Europe about their experiences with staying in work through social media and email. I have also asked patient organisations from all of Europe through email and personal meetings about their experiences, when it comes to young people with RMDs and work.
Results: The challenges differ from country to country. In some countries having an RMD is seen as a taboo, a sign of weakness. In other countries, an RMD-diagnosis makes you no different than the rest of society and the expectations to what you can do are often too high. I will attempt to make a presentation of potential solutions to the different issues. How it could help, if patient organisations spread awareness about RMDs among employers all across Europe. How, if the young person told their employer, that they have an RMD, it might help them in the long run. There are several places where young people with RMDs can get help and advise on how to act, when they want to stay in work. There already exists EU-legislation on the area, but not all EU-states respect them and adhere to them – this has to be changed.

SP0073 PRACTICAL EMPLOYABILITY SUPPORT FOR YOUNG PEOPLE WITH RMDS

M. Mcallister. *Working Well with Arthritis Joint Working Service, Arthritis Care, Glasgow, United Kingdom*

Background: Arthritis Care is a UK national charity providing a range of support through three services;
Working Well with Arthritis - Joint Working employability service (Scotland only).
87% of Arthritis and Work Scotland 2016 survey respondents' state arthritis has a high or very high impact on work. Joint Working (JW) service aims to address this by:
Providing holistic employability support to individuals of working age to improve their capacity to manage their condition in work.
Providing employers support to increase understanding of arthritis within the workplace
Offering employers free Arthritis Awareness training.
Young People and Families Service (YPFS) for age 10 - 25 years.
Series of free, one day or weekend workshops, to help reduce social isolation, increase confidence and management of condition.
Living Well with Arthritis offers adults access to self management support such as:
Managing pain/symptoms; activity/exercise; health walks, Tai chi for arthritis; peer support.
Objectives: Joint Working (JW) service aims to help individuals of working age with arthritis make informed decisions about work, support them to remain in, return to, or explore suitable work, training or alternative employability opportunities.
1 in every 1,000 young people in the UK has arthritis, YPFS complements medical treatment by providing additional social and emotional support, to help reduce isolation and increase resilience. With all services being delivered by Arthritis Care there is a natural crossover and support network for young people around transitioning from education to work.
The services aim to provide individuals with the knowledge, confidence, skills and support to empower them to make informed life and work decisions and access key support services - with the aim of improving their chances of remaining in work.
Method: There is a partnership and referral process to JW via NHS Rheumatology Occupational Therapy staff, within specific NHS areas, though referral to JW is open to anyone with arthritis.
Partnership working with; NHS, employability networks and Arthritis Care YPFS is key to the success of JW service.
Individuals with arthritis often find; communicating their needs, understanding their rights and navigating the system can be complex and overwhelming.
Joint Working provides support through a range of mediums; 1 to 1 meetings (where practical), email and/or phone. Exploring areas of concern, improving understanding of rights, awareness of, and access to national employment support schemes, mainstream or disability employability services.
Results: Young people who have used Joint Working service have been supported to access a range of services; obtaining specialist equipment or travel support to remain in work, returning to work after many years unemployed, work placement to support university course, volunteering or specialist employability opportunities,
Conclusions: The employability interventions have positive psychosocial benefits, reducing feelings of isolation, increasing confidence and raising aspirations.
People with arthritis value the opportunity to discuss any issues they have remaining in, returning to or embarking on a career path.
The ongoing access to all Arthritis Cares services, ensure young people have a long-term support network.

Epidemiology of rheumatic and musculoskeletal diseases - a critical appraisal

SP0074 THE FUTURE OF EPIDEMIOLOGICAL RESEARCH IN RHEUMATIC AND MUSCULOSKELETAL DISORDERS

L. Gossec. *Rheumatology Department, Paris 06 University, Pitié-Salpétrière Hospital, Paris, France*

Epidemiological research has gone through a very exciting time over the past years in rheumatic and musculoskeletal disorders (RMDs). The future is just as exciting. Although 'traditional' epidemiology in terms of prevalence and incidence of diseases is quite well-known now, there are many gaps to our knowledge in particular in the field of outcomes research (what to assess, when and how?) but also in the field of predictive factors (e.g. predictive factors of severity and of treatment response). Better knowledge in outcomes assessment is key to feasibility of standardised assessments and is the basis of shared decision making. Better knowledge of predictive factors will open the door to truly personalised medicine. Some future directions will be discussed in this talk.

Ultrasound advanced I & II

SP0075 ULTRASOUND AND MAGNETIC RESONANCE IMAGING FUSION OF IMAGES EVALUATION OF TENOSYNOVITIS – A PILOT STUDY ON A NEW IMAGING TECHNIQUE IN RHEUMATOID ARTHRITIS PATIENTS

M.A. Danielsen[1,2]. *[1]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup; [2]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark*

Background/Purpose: Image fusion is an advanced imaging technology, which enables fusion of ultrasound (US) and magnetic resonance imaging (MRI). This fusion gives for each US probe position an exact projection of the corresponding anatomical area on a previously obtained MR image, during a live US assessment. This study is the first to address image fusion of US and MRI tenosynovitis.
The aim of this study was to assess and compare US and MRI visualisation of tenosynovitis using image fusion technique.
Methods: Fifteen rheumatoid arthritis patients with US verified tenosynovitis in the wrist or hand had an MRI performed of the affected wrist or hand. A subsequent image fusion was performed, i.e. the MR images and a live US assessment of one tendon sheath were fused. In order to compare the two imaging modalities quantitatively, the area of the tendon and tendon sheath in the transverse axis was measured on US and MRI for each image fusion. Due to partial volume artefacts (voxel containing two different tissues and therefore possessing a signal average of tendon and tendon sheath) on MRI two measures were performed; area 1) the circumference of the black tendon, i.e. excluding voxels containing two types of tissue 2) the circumference of the grey line that surrounds the black tendon, i.e. including voxels containing two types of tissue. Tenosynovitis was assessed using the proposed OMERACT semi-quantitative scoring system for US and MRI. US scoring was therefore based on both grey scale and Doppler, whereas MRI scoring was based only on post-contrast tenosynovial enhancement, measured as distance from the tendon to end of the enhanced tendon sheath.
Results: The median circumference area of the tendons and tendon sheaths on US and MRI 1 and 2 were respectively 0.16 (25;75 pctl: 0.10;0.25), 0.9 (0.06–0.18) and 0.13 of (0.10;0.25) for the tendons and 0.18 (0.13–0.26), 0.27 (0.20–0.45) and 0.23 (0.16–0.40) for the tendon sheaths. Statistically significant differences were found for all measured areas between US and MRI, except for the US tendon area and the MRI tendon area 2 (Wilcoxon's test; p=0.47). Overall agreement between US and MRI tenosynovitis scoring systems was good (see table 1).
Conclusion: In conclusion, we found that US and MRI have good agreement for quantitative assessment of tendons and scoring of tenosynovitis, when comparing the two modalities using image fusion, if the partial volume artefacts on MRI are included in the measure.

SP0076 HOW AND WHEN TO ASSESS THE CERVICAL FACET JOINTS + DEMO

D.A. Bong[1,2] on behalf of EULAR Working Group Anatomy for the IMAGE.
[1]Instituto Poal de Reumatologia; [2]University of Barcelona, Barcelona, Spain

At any given time, 10% of the adult population will be affected by neck pain. Although similar in incidence to low back pain, its has less of a socio-economic impact and uncommonly progresses to neurologic deficit. Pain may result from degenerative, traumatic or inflammatory processes involving the diarthrodial facet (zygapophyseal) joints and/or the facet (medial branch of the dorsal dorsal rami) nerves. Although routinely evaluated by radiography, magnetic resonance imaging and computed tomography, high-resolution musculoskeletal ultrasound (MSKUS) imaging and guidance has become increasingly popular, particularly among pain management specialists, in the evaluation and treatment of these structures owing to its safety, portability, superior resolution and direct real-time visualization. This presentation will discuss the unique anatomy and sonoanatomy of the cervical spine and its innervation/vascularization with particular focus on the facet joints and nerves and the use of MSKUS in the evaluation and treatment of the facet joint/nerve with review of available evidence. Examination technique and sonoanatomic findings will be demonstrated.

SP0077 HOW TO EVALUATE JOINTS IN JUVENILE IDIOPATHIC ARTHRITIS (JIA)

J. Vojinovic. *Pediatric Rheumatology, Clinical Centre, Medical Faculty, University of Nis, Nis, Serbia*

Ultrasound (US) has numerous advantages when used to examine joints in children compared to other imaging modalities. This include non-invasiveness, rapidity of performance, easy repeatability, high patient acceptability and lack of exposure to ionizing radiation. In addition, it does not require sedation for scanning in younger children. US is more sensitive than physical examination and may detect early disease that is not evident on physical examination. Lack of standardized precise definitions of grey scale (GS) and Power Doppler (PD) US findings in different age groups was the biggest limitation for its use. Additional difficulty is age dependent variability of normal sonoanatomy, due to maturation and ossification in children. That is why acquisition, interpretation and comparison of US images are completely different than in adults and had to be addressed specifically. All this may affect the validity of the technique, and without defined standardized examination technique, US can be a challenge in the childhood population. On the other hand, US as an imaging technique is considered to be examiner and equipment dependent. Studies resulting in good intra and inter-reader reliability and validity, based on specific definitions, are essential for its application as a diagnostic tool. Recently developed standardized image acquisition methodology, definitions of joint components in healthy children, as well as, definitions for synovitis components and its grading in GS and PD in children will be presented in details.
US allow precise and thorough visualization of inflammatory and destructive joint abnormalities, including synovial hyperplasia, joint effusion, cartilage damage, bone erosion, tenosynovitis and enthesopathy. In JIA ultrasound is considered particularly useful for its ability to detect subclinical synovitis and improve classification of JIA patients into the subtypes. Current evidences about application of ultrasound in JIA can improve definition of remission necessary to optimize treatment strategies. Due to peculiarities of US examination and image acquisition in children additional educational efforts among pediatric rheumatologists are required for expanding this imaging modality in daily practice.

PsA: an integrated perspective

SP0078 CAN IMAGING BE A PREDICTOR OF PSORIATIC DISEASE?

M. Østergaard. *Copenhagen Center for Arthritis Research, Copenhagen University Hospital Rigshospitalet, Glostrup, Denmark*

Early detection of inflammatory joint diseases is very important to allow prompt initiation of effective therapies. Identifying patients with early arthritic disease can be challenging by conventional clinical, laboratory and radiographic methods, and more advanced imaging modalities such as computed tomography (CT), magnetic resonance imaging, ultrasonography (US) and various nuclear medicine techniques can provide additional information.
This talk describes the current knowledge on the value of different imaging modalities for 1) predicting development of psoriatic disease in undifferentiated patients 2) predicting development of psoriatic arthritis (PsA) in patients with psoriasis with and without musculoskeletal pain and 3) predicting the disease course in patients with PsA.

SP0079 PATHOLOGIES ACROSS THE TISSUES IN PSA

R. Lories. *Skeletal Biology and Engineering Research Center - Dept. Development & Regeneration, KU Leuven, Leuven, Belgium*

The psoriatic disease concept includes the skin disease psoriasis and joint disease psoriatic arthritis. Increasingly, prevalent comorbidities such as obesity and cardiovascular disease are considered to be an integral part of the psoriatic disease concept in many patients.
Within this disease concept, accumulating evidence indicates molecular and cellular cross talk between affected organs and tissues. Skin inflammation affects the bone; nail disease is associated with specific types of arthritis; inflammation links to cardiovascular disease; skin or joint disease may contribute to depression. Novel therapeutic strategies are reaching psoriatic disease patients as never before. Their global impact could be envisioned from a holistic perspective, optimizing the strategy chosen as determined by the active molecular and cellular network that triggers and sustains disease.
Thus, linking the joints with the skin and other organs involved is proposed as an entry point towards personalized medicine in a complex disease.

Autoinflammatory diseases in children and adults

SP0080 RECURRENT EPISODES OF FEVER AND ARTHRITIS IN ADULT PATIENT

C. Deaconu. *Department of Rheumatology and Internal Medicine, Sfanta Maria Hospital, Bucharest, Romania*

Background: Familial Mediterranean Fever (FMF) is a relatively rare condition that belongs to the more recent group of autoinflammatory diseases (AIDs)[1]. It primarily affects patients with Mediterranean or Middle Eastern origins and its clinical setting includes short, recurrent episodes of fever, serositis, skin rash and a high risk of amyloidosis[2]. FMF is an autosomal recessive transmitted disease and several mutations of the Mediterranean fever gene (*MEFV*) on chromosome 16 have been identified[3]. Patients respond well to colchicine therapy or if necessary, biological therapy with anti-IL 1, IL6 or anti-TNF could be initiated[4]. Establishing the right diagnosis might raise difficulties for rheumatologists who are not fully accustomed to this condition.
Objectives: To evaluate the clinical course, specific features and treatment difficulties of a male patient diagnosed with FMF in adulthood, based on the description of a case report.
Methods: Case-description using patient's medical records and investigations.
Results: This is the case report of a 37-year old male patient currently admitted for right knee arthritis and high grade fever (39.1℃). His medical history dates back at age 16 when he presented in the Pediatric Department with recurrent episodes of prolonged fever (up to 40℃), diffuse abdominal pain together with myalgia, arthralgia accompanied by increased acute phase reactants; after various sources of infection and hematological malignancies were excluded, physicians noted positive low titer ANA (1/20) but normal complement fractions, absent lupus (LE) cells. Further medical investigations showed a negative rheumatoid factor, ACPA, negative antibodies' panel (dsDNA, Sm, Ro, U1-RNP) and absent cryoglobulins but a positive HLA B27. No signs of sacroiliitis were detected on the x-ray. Patients' repeated complaints of knee or ankle arthritis together with later finding of positive anti-Salmonella and anti-Shigella antibodies leaded to establishing the diagnosis of reactive arthritis. Due to symptoms' persistence and reoccurrence under non-steroidal anti-inflammatory drugs, he was prescribed high dose corticosteroids and sulfasalazine. At age 20 the patient presented with recurrent arthritis of the knees and ankles, fever (38.5℃) and abdominal pain with markedly elevated inflammatory markers. The abdominal ultrasound highlighted a splenomegaly and peritonitis. Colchicine treatment was initiated and his favorable response led to MEFV genetic testing that revealed a mutation of the 10.1 exon, thus confirming the diagnosis of FMF by fulfilling two major criteria of the Tel-Hashomer diagnostic set. Subsequently, he performed a gingival biopsy that excluded the presence of amyloid deposits. Patient's partial response to colchicine with repeated incomplete attacks of FMF and persistent inflammatory syndrome led to the initiation of biological therapy with Etanercept along with Sulfasalazine and glucocorticoids, due to temporary unavailability of an anti-IL1 agent. Patient's delay in diagnosis and longstanding corticosteroid therapy led to major articular consequences (bilateral aseptic osteonecrosis of the femoral head with requiring hip arthroplasty).
Conclusions: This case presentation depicts the hardships of setting the right diagnosis in a case of late onset FMF due to unusual geographical setting, absence of suggestive family history and heterogeneous clinical presentation together with possibilities in therapeutic approach if patients are non or partially responsive to traditional therapies. Furthermore it points out possible drug side effects and comorbidities that require the same quality medical care as the main rheumatic disease.

Immunogenicity of biologics; myth or reality?

SP0081 THE T CELL RESPONSE TO THERAPEUTIC ANTIBODIES

B. Maillere. *Institute Frederic Joliot, CEA, gif sur Yvette, France*

Therapeutic antibodies (TMabs) are part of the best successful therapeutic products of the last decades. They are currently used to treat many inflammatory diseases such as rheumatoid arthritis (RA) and bowel diseases and represent worldwide a market of several billions of dollars. However they have the major drawback to be potentially immunogenic and therefore might elicit anti-drug antibodies (ADA). ADA could dramatically reduce the efficacy of the drugs or might provoke allergic reactions. Because generally self-proteins are less immunogenic than foreign proteins, the sequence of therapeutic antibodies has been humanized. However humanization even at the highest level does not fully guarantee the lack of immune responses demonstrating the important need to know more about ADA response. Because T cells are known to initiate the ADA response, we are currently investigating the T cell response to immunogenic therapeutic antibodies. With the perspective of immunogenicity prediction, we quantified the number of very rare T cells specific for therapeutic antibodies in the blood of normal donors and found a good concordance between the number of T cells specific to them and their respective clinical immunogenicity level. We then identified the CD4 T cell epitopes of four immunogenic TMabs with different levels of humanization, namely the chimeric antibodies Infliximab (Ifx) and Rituximab (Rtx), the humanized antibody Natalizumab (Ntz) and the fully human Adalimumab (Adm). CD4 T lymphocytes were expanded by several weekly rounds of stimulation with autologous dendritic cells loaded with each of the investigated antibodies and the T cell specificity was assessed by IFNg ELISPOT using overlapping peptides encompassing the whole sequence of their variable parts. Nine epitopes were identified in the VL and VH chains of Rituximab and Infliximab. They overlap CDR or FR regions of both chimeric antibodies and some of them are shared by multiple donors. As inferred from binding experiments, T cell epitopes often exhibited a good affinity for HLA-DR molecules found in the responding donors. Nine CD4 T cell epitopes were found in the VH and VL parts of the humanized therapeutic antibody Natalizumab while the fully human antibody Adalimumab hosted 10 T cell epitopes. As a result, the number of T cell epitopes is very similar across the different therapeutic antibodies but their location is highly variable from one antibody to another one. Finally to assess the clinical relevance of the identified T cell epitopes, we evaluated the ability of Ifx and Rtx T cell epitopes to stimulate T cells of patients having developed ADA. Two third of the T cell epitopes identified from the healthy donors stimulated PBMCs from ADA+ patients and promoted the secretion of a diversity of cytokines. These data emphasize the predictive value of evaluating the T cell repertoire of healthy donors to anticipate and prevent immunogenicity of therapeutic antibodies. Together our data provide new insights on the origin of immunogenicity of chimeric, humanized and human therapeutic antibodies.

SP0082 IMMUNOGENICITY OF BIOLOGICS IN INFLAMMATORY BOWEL DISEASES

A. Gils. *Dept of Pharmaceutical Sciences, KU Leuven, Leuven, Belgium*

Anti-tumor necrosis factor-alpha and anti-integrin monoclonal antibodies show great benefits for inducing and maintaining remission, healing the mucosa and restoring the quality of life of patients with inflammatory bowel diseases. The therapeutic potential of these intrinsically powerful biologicals is tempered by a high variability in clinical response. Whereas primary non-response is defined as the lack of clinical response to treatment, assessed 8–12 weeks after initiation, secondary loss of response is defined as loss of clinical benefit after initially responding which can be attributed to disease-related or drug-related factors. Assays have been developed to determine the concentration of the therapeutic antibody in serum of the treated patient. The trough concentration is the concentration just before the next administration and for practical reasons therapeutic drug monitoring is mainly based on measurement of these trough concentrations. Several studies have reported correlations between through concentration of infliximab, adalimumab, golimumab, vedolizumab and clinical outcome. Optimal therapeutic windows have been defined for both infliximab and adalimumab. A panel of prospective studies in which dosage regimens are adapted in order to achieve target trough infliximab concentrations that correlate with beneficial therapeutic outcomes have been initiated.
Immunogenicity is the capability of biologicals to elicit an unwanted immune response that results in the formation of anti-drug antibodies. Anti-drug antibodies can be non-neutralizing or neutralizing. Non-neutralizing antibodies do not impair the drug-target interaction but may increase clearance of the drug resulting in lower serum concentrations. Neutralizing anti-drug antibodies compete with the target for the antigen-binding site and modulate directly the activity of the drug in addition to the enhanced clearance of the drug. A number of anti-drug antibody assays to quantify the immunogenicity of biologicals have been developed. Most of the assays quantify the total amount of anti-drug antibodies but comparing anti-drug antibody concentrations between different assays is hampered by the

use of different calibrators and by the fact that drug tolerance differs among assays ranging from extreme drug sensitive over various forms of drug tolerant to drug resistant anti-drug antibody asssays. The clinical relevance of the different type of anti-drug antibody assays remains to be proven.
Combining therapeutic drug concentrations and anti-drug antibody concentrations with relevant patient, disease and drug information will lead to optimal dosing of patients aiming at optimal clinical, biochemical and endoscopic outcomes.

SP0083 AS A RHEUMATOLOGIST, DOES IT HAVE ANY CONSEQUENCE IN MY DAILY PRACTICE?

J.W. Bijlsma. *Rheumatology & Clinical Immunology, UMCU, Utrecht, UTRECHT, Netherlands*

It is nearly inevitable that when we administer foreign (even humanised) proteins intravenously or subcutaneously to a person, that said person will develop antibodies to that (foreign) protein. This happens to most of our patients when we administer biologicals; depending on the sensitivity of our methods, we can measure these anti-bodies easily or not at all. These antibodies start becoming a problem when they are actually binding the administered biological, thus making the active drug less available for its targeted function. We can evaluate this by measuring the actual drug-level, so called trough level. Numerous reports have been published, showing that there is indeed a negative correlation between e.g. anti-tumor necrosis factor (TNF) drug antibodies and the efficacy of anti TNF in the treatment of RA. It has also been shown that adding methotrexate (MTX) to the anti-TNF treatment improves its efficacy and reduces the level of anti-drug antibodies. Probably only 10 mg MTX weekly would be enough to obtain this effect.
So what do I do as a clinician when I observe that a patient, who originally did very well, loses response to her biological? Do I measure possible anti-drug antibodies? No, the consequences are zero: When the patient is not responding to the given drug anymore, I need to adapt the treatment; the drug she is using is not effective anymore, so we should change. Would the presence of anti-drug antibodies influence my decision? No, there is no cross-reactivity to other biologicals (even from the same class of action), except to its biosimilar (underscoring that it is a real biosimilar!). In case there is doubt whether a patient is actually using the biological we could better measure the drug-trough level; but –in my practice- this question seldom arises in patients with active arthritis, being treated with a biological.
Measuring drug-trough levels is a completely other item, and perhaps more relevant. Biologicals are in general given in a standard fixed dosage, while there are clear differences in patients characteristics, that could influence bioavailability of the biological. In addition when the disease is more active, it could be that more biological is needed to temper the inflammation compared to low disease activity, where perhaps a lower dosage would be more than effective. To guide physician and patient in personalizing and optimizing treatment with biologicals measuring drug-trough levels might be helpful. Different studies have been performed trying to use through level of the drug in adapting the dosage, and even in predicting possibility to stop the drug treatment. This area is still being evaluated and it is too early to make firm statements, but with a look at cost-effectiveness this will certainly become relevant.
Coming back to the original question: do I use anti-drug antibodies in my daily practice to guide treatment: no, it doesn't influence my decisions. Will I use in the future drug trough levels to guide treatment decisions: this could well be, but it is too early to make a final decision yet.

Which target / outcome is more relevant in the management of SLE?

SP0084 BIOLOGICAL TARGETS IN SLE

C. Chizzolini on behalf of Swiss SLE Cohort Study and PRECISESADS consortium. *Immunology & Allergy, Geneva University Hospital, Geneva, Switzerland*

SLE is a prototypical condition characterized by the complete subversion of immunological tolerance and the generation of autoantibodies directed against a wide array of ubiquitous and tissue-specific antigens. This is possible because the joint dysregulation of the innate and adaptive arms of the immune system; which results from multiple gene polymorphisms, each contributing marginally, distinct epigenetic regulation, alteration of the threshold of activation for T and B cells, enhanced responses of antigen-presenting cells resulting from the altered disposal of apoptotic cells, as well as dysregulation of cytokine circuitries including regulatory networks.
Pathogenic mechanisms resulting in clinically overt SLE very likely are heterogeneous among individuals. Thus, the identification of biological targets in SLE goes also with the identification of selected modules of gene activation in distinct individuals. Very strong signals indicate that type I interferon (IFN) may contribute to autoimmunity in a large proportion of SLE individuals and therapeutic trials targeting IFN signaling suggest the clinical relevance of this mediator. B cells/plasmablasts are also relevant and obvious targets. Refinements in our understanding in B cell sub setting and/or the timing in disease development in which they play a relevant role should result in defining the appropriate targets specific to this cell lineage. Gene modules activated during flares suggest that neutrophils in a subset of individuals may also be relevant targets. Cytokine affecting T cell differentiation, in particular T follicular helper cells, represent additional relevant targets.
Within the last several years a number of novel biological targets have been identified in SLE. However, a single biological agent has been approved for SLE treatment in the last five decades. This underlies the difficulties encountered when translating validated targets in efficacious therapeutic agents. This stress the need for careful preclinical evaluation. It further emphasizes the need of small phase II clinical trials based on stringent inclusion criteria aiming at precisely identifying individual groups more likely to respond to validate the target. Current progress made in the identification of molecular signatures in individuals with SLE will offer the tools for the requested accurate selection.

SP0085 PATIENT REPORTED OUTCOMES

M. Schneider. *Policlinic & Hiller Research Unit for Rheumatology, HHUD, Duesseldorf, Germany*

In SLE as in other rheumatic diseases, the most relevant target of intervention should be a status with controlled disease process assuring no further accrual of damage. If actual expert discussions like DORIS define the frame of such a status, clinical activity measured by a validated lupus disease activity instrument, serologic activity and therapy – because of harm - are the dimensions of remission with its duration as additional factor for outcome. Patient reported outcomes (PROs) were not included. Otherwise, if payers and reimbursement system decide about relevance, patient outcomes are clear of highest importance as target.
Looking on the evidence of PROs for outcome in SLE, PROs were never used as primary endpoint in clinical trials. In RCTs, PROs were often collected and mostly explorative analysed. There is no evidence that PROs can validly define the above described status of controlled disease. But from systematic analyses in RA, we know that pure PRO like VAS of general health status and semi PRO like tender joints are at least as relevant as more "objective" criteria like swollen joints or CRP as clearly exhibited by the ACR/Eular remission criteria for RA.
The challenge in SLE is that the discrepancies between patients' and physicians' perception and perspectives are even more distinct than in RA. Sometimes, there is the expression that physicians and patients are describing different diseases. The burden of illness in lupus is better defined by pain than by organ manifestations; the overall survival in SLE is more related to lupus nephritis than to fatigue. It is obvious that physicians should analyse the actual clinical symptoms and integrate the future consequences of their actual management in their decision, and patients are more focused on release of their actual burden.
Until today, these different and divers perspectives are no integrated, neither in RCTs nor in daily care. But such integration is mandatory, because no side imagines the complete picture of lupus, which may also produce to the poor results of clinical trials. In routine care, this behaviour causes frustration and mental distress, optimal results are prohibited.
So, the answer to what is more relevant in the management of SLE patients - clinical targets, biological targets or PROs – is the integration of all important aspects of lupus. This implies more than the statistical evaluation of the best items of all three aspects, it is the active involvement of patients in their care: patient empowerment in SLE, a fruitful process, in which both sides have to learn a lot from and about each other.

Joint EULAR - EFIS session: Tilting the balance: from disease to tolerance induction

SP0086 PATHOGENIC MEMORY CELLS: ROAD BLOCKS TO TOLERANCE INDUCTION?

H.-D. Chang. *German Rheumatism Research Center Berlin, Berlin, Germany*

While conventional state-of-the-art immunosuppression can lead to significant

improvement for patients suffering from rheumatic diseases, only in rare cases a therapy-free remission is achieved. In most cases stopping of treatment results in disease relapse. Apparently, components of the immune system are refractory to conventional immunosuppression and can drive the inflammation. Experimental and clinical evidence suggests that cells of the immunological memory persist despite immunosuppression and if pathogenic play a major role in the chronification of the disease. In particular long-lived memory plasma cells secreting autoantibodies represent a major therapeutic challenge. Once generated, they are not subject to physiological and even conventional therapeutic immune regulation. Their elimination may be prerequisite to curative therapies. A detailed understanding the lifestyle of long-lived memory plasma cells will be important to address this cell type therapeutically.

SP0087 HOW ANTIGEN PRESENTING CELLS CAN BE TURNED INTO TOLEROGENIC CELLS

J.D. Isaacs. *Insitute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom*

Antigen presenting cells (APCs) lay at the heart of all immune responses. Whereas we generally consider APCs as cells that stimulate immune reactivity, they are also critically important for avoiding autoreactivity. Thus in health our tissues are patrolled by cells such as immature dendritic cells, which downregulate responses to self-antigens. Corruption of this process is a central factor in autoimmunity.

A number of groups have developed methods to generate "tolerogenic" antigen presenting cells, that mimic the cells which regulate self-tolerance in health. It is hypothesised that administration of such cells, loaded with autoantigens, to patients with autoimmune disease should be able to overcome autoreactivity and re-establish immune regulation. Our own group has developed a therapeutic approach based upon autologous tolerogenic dendritic cells, which we derive from circulating peripheral blood monocytes. Unlike conventional mature DC, which produce IL-12p70 and other pro-inflammatory cytokines, tolDC produce no IL-12p70 but high levels of IL-10. They deviate naïve T-cells towards an IL-10-producing, anti-inflammatory phenotype and induce hyporesponsiveness in memory T-cells. In mixed cultures they dominate mature, pro-inflammatory DC and down-regulate T-cell activation. Their phenotype is stable in the presence of pro-inflammatory stimuli. Equivalent murine tolDC switch off collagen-induced arthritis, with immune deviation from IL-17 to IL-10 production by CD4+ T cells and a reduction in type II collagen-specific T cell responses.

In a phase 1 trial (AuToDeCRA), we demonstrated that these cells are safe when administered into a recently inflamed target knee joint of patients with inflammatory arthritis. However, in that safety study we were unable to demonstrate a tolerogenic effect in vivo. Furthermore, we have reason to believe that administered cells may remain in the target joint, whereas a disease-modifying effect is likely to require migration to secondary lymphoid tissues. Moving forwards we are designing a study that will address the optimal administration route for tolDC, based on a technique to track the cells in vivo and to measure their effect on autoreactivity.

What to do about comorbidity?

SP0088 NEW DRUGS, BUT STILL COMORBIDITY

A. Häkkinen. *Health Sciences, University of Jyväskylä, 40014 Jyväskylä University, Finland*

As the population ages the simultaneous presence of multiple pathological conditions in the form of comorbidity and multimorbidity is more a rule than an exception. Comorbidity is reported in 35 to 80% of all ill people (Taylor et al. 2010). Comorbidity and multimorbidity are challenging researchers, clinicians and policy makers as these persons require more frequent appointments and hospitalizations and are at a greater risk for drug interactions, disability and mortality (Slater 2011).

Although numerous chronic disease prevention strategies and treatment guidelines have been developed, they mainly address single conditions and ignore the presence of co-existing conditions (van der Noyen 2016). Especially physical activity in its different forms has numerous preventive and curative effects in most of the diseases in addition to drugs. These benefits are such as increased muscle force and aerobic capacity, maintenance of bone and cardiovascular health, decreased inflammation and pain, improved function and well-being.

Studies reveal that more than 80% of rheumatoid arthritis (RA) patients carry two or more comorbid conditions (Krisnan et al. 2005). However, according to the QUEST-RA study (5,235 patients from 21 countries), only 14% of all patients reported to perform physical exercise at least 3 times weekly. Physical inactivity was associated with female sex, older age, obesity, comorbidity, disability, disease activity, pain and fatigue (Sokka et al. 2008). Traditionally, patients with RA were advised to limit physical exercises due to a fear that exercises might increase disease activity and be harmful for joints but more recent studies show that they benefit from exercise (Baillet et al. 2012).

Compared to RA, osteoarthritis (OA) is more common with prevalence of ∼150 million people world-wide. In OA comorbidity rates vary between 68–85% in different studies. The most frequently occurring co-morbidities are diabetes, hypertension, cardiovascular disorders, obesity and back pain. De Rooij et al. (2016) have developed tailored exercise therapy for knee OA and comorbidity. In their study during the 20-week program 76% of the participants needed adaptations to frequency, type, intensity or duration of exercise sessions. In addition, 96% needed education and coaching related to comorbidities.

In our study group-based strength and balance training for two years was offered for community-dwelling participants aged >75 years. The results showed that those who did not start in the group had more comorbidities, lower cognition, higher sedative load, higher risk of malnutrition, and poorer self-reported health than those who started in the gym. Despite of multimorbidity and hospital admissions, many older adults were capable of long-term regular training (Aartolahti et al. 2015).

With multimorbidity multi-drug therapies are common and they increase the risk of side effects. Exercise is also beneficial for health and it should be considered as a non-pharmacological drug. As for any other drugs, individual dosing of exercise is very important as well.

SP0089 HOW TO PREVENT AND TREAT CARDIOVASCULAR COMORBIDITY WITH EXERCISE?

H. Dagfinrud. *Diakonhjemmet Hospital, Oslo, Norway*

Low cardiorespiratory fitness is a strong predictor of cardiovascular disease and all-cause mortality in healthy people as well as in patient groups. Unfit individuals have twice the risk of death from all causes, and tailored exercise is important to improve fitness.

It is well established that patients with inflammatory rheumatic diseases have increased risk for cardiovascular disease compared with healthy population, and it is therefore particularly important that these patients benefit from the risk-reducing effect of exercise. Exercise has traditionally been recommended as part of the treatment for patients with rheumatic diseases, but exercise programs has mainly focused on improving mobility and reducing pain. Further, patients with active disease has been recommended to exercise with low intensity. To increase cardiorespiratory fitness, however, high intensity exercise is needed. It is therefore encouraging that recent studies show that patients with active rheumatic disease tolerate intensive cardiorespiratory- and strength exercises and can benefit from such health-enhancing training. Recent research in this field will be presented and discussed.

SP0090 COMORBIDITY-ADAPTED EXERCISE FOR PATIENTS WITH KNEE OSTEOARTHRITIS

M. De Rooij. *READE, Center for Rehabilitation and Rheumatology, Amsterdam, Netherlands*

Exercise therapy is a key intervention in the management of patients with knee OA[1]. However, comorbidity is present in 68 to 85% of patients with OA (e.g. cardiac disease, diabetes type 2, obesity)[2,3]. Comorbidity interferes with exercise therapy. In clinical practice, comorbidity is a frequent reason to exclude patients from exercise therapy. If accepted into an exercise program, both therapists and patients tend to reduce exercise intensity to a level unlikely to be effective, because of fear of aggravating symptoms of the comorbid disease. Further, the effect of exercise therapy in patients with knee OA and severe comorbidity is not known. Patients with unstable medical conditions, precluding safe participation in an exercise program, are excluded from clinical trials. In view of the effectiveness of exercise therapy in knee OA and the high prevalence of comorbidity, there is a great need for comorbidity-related adaptations to exercise therapy. In this lecture a strategy (i3-S strategy) will be presented on how to develop comorbidity-related adaptations to exercise therapy in an index disease (e.g osteoarthritis)[4]. According this strategy we have developed a tailored exercise program for patients with knee OA and comorbidity. Subsequently, to evaluate the efficacy of the tailored exercise program for patients with knee OA and comorbidity (cardiac disease, diabetes type 2, COPD and obesity (body mass index $\geq$30kg/m^2) a randomized controlled trial (n=126) was performed in a secondary care setting. The results showed that tailored exercise therapy greatly improved physical functioning, reduced pain and

was also safe for patients with knee OA and (severe) comorbidity[5]. At present we are implementing and evaluating the protocol in primary care.

Data visualisation: tables and graphs for publication and presentation I & II

SP0091 DATA VISUALISATION: TABLES AND GRAPHS FOR PUBLICATION AND PRESENTATION

M. Boers. *Epidemiology & Biostatistics; Amsterdam Rheumatology and immunology Center, VU University Medical Center, Amsterdam, Netherlands*

This workshop (held both on Thursday and on Friday) is an introduction to the principles of good graph and table design as pioneered by Cleveland[1] and Tufte[2] and updated by Few[3] so that the participant can better answer the following questions:

Which of the messages in my research results requires a graph or table? Recognizing how graphs improve on simple statistics and convey much more information. Knowing when a table is better, or keeping the data in the body text.

How can I best convey the message? Striving for clear vision by choice of graph, scaling, discrimination of data series, minimizing non-data ink, avoiding chart junk. Striving for clear understanding through a balance between data and explanation. Using order, subheadings, formatting and rules to guide your reader through your table data.

Is my graph/table truthful? Creating a direct proportion between graph and data quantities, avoiding forms prone to misinterpretation, labels to prevent ambiguity; keeping data in context, avoiding more dimensions in the graph than in the data.

This year's course will extend introductory material available via YouTube clips on the ARD website (ard.com)!

Direct link: https://www.youtube.com/playlist?list=PLXU14EQbU_V9JpmolAKsaCC0VjJzbxzAN

Note that you can also sign up for a special lecture followed by a poster tour after the session, devoted to poster design!

Difficult to reach patient groups

SP0092 THE VICIOUS CIRCLE OF EDUCATIONAL LEVEL AND RISK OF POVERTY IN RHEUMATOID ARTHRITIS - RESULTS OF A CROSS-SECTIONAL MULTICENTER STUDY IN GERMANY

M. Zaenker[1,2]. *[1]Rheumatology Dept., Immanuel Klinikum Bernau & Heart Center Brandenburg, Bernau; [2]Brandenburg Medical School, Neuruppin, Germany*

This lecture will provide an overview on the dimensions of poverty in general and describe methods of assessing the risk of poverty in patients with rheumatoid arthritis (RA).

Based on results of a cross-sectional multicenter study of RA-patients from outpatient-clinics in Brandenburg and Saarland, Germany, this talk will give a rationale for how patients with RA are threatened by poverty due to treatment-related expenses, disability and early retirement compared to the general population.

It will be highlighted, that the equalized disposable income of RA patients is significantly lower than in general population and RA patients share a doubled risk of poverty, even in social-welfare well-secured countries such as Germany.

Further, the talk will demonstrate that both lower educational level and socio-economic state are associated with more severe disease course of RA and various underlying mechanisms will be discussed.

SP0093 THE CHALLENGES AND SOLUTIONS FOR ENGAGING PATIENTS FROM ETHNIC BACKGROUNDS IN RHEUMATOLOGY CARE

K. Kumar. *University of Manchester, Manchester, United Kingdom*

Rheumatoid Arthritis (RA) is a condition with no cure and can cause disability[1]. RA affects nearly 1 in 100 adults. Early disease is characterised by pain and other features of inflammation, such as heat, swelling of joints, and loss of function. RA is associated with increased costs of co-morbid conditions (such as cardiovascular (CVD) associated with RA[2]. CVD associated with RA is the most common cause of death in RA patients. The risk of developing CVD is worse in some ethnic groups[3;3;4]. Furthermore, RA causes physical damage and social, economic, psychological and cultural problems that impact on all aspects of patient life.

There are effective treatments available for RA[5]; however, non-adherence to medicines (not taking medicines as prescribed) is a significant issue in RA[6]. Patients' perceptions play an important role in adherence to medicines. Our research in the UK, has showed differences between individuals from ethnic groups on how they view their medicines[7]. These views can potentially impact on medication adherence and patients' satisfaction with information they receive in clinic.

In the UK, we have recently shown that patients from different ethnic backgrounds with RA were disstaified with the information they receive about medicines[7]. Patients beliefs about medicines and illness pereceptions were found to be associated with satisfaction with information received by clinicans. Furthermore, the British Society of Rheumatology (BSR) led a national audit to investigate the delivery of care across UK rheumatology services. In this audit of early inflammatory arthritis service, we found patients from different ethnic backgrounds expressed greater impact of the disease on functional disability, fatigue, emotional well-being, physical well-being and coping and worse in older patients. This can impact on the way patients perceive their disease activity and information received on treatments. If we understand the needs of patients from ethnic backgrounds we can help improve the health outcomes. This session will provide the audience with insight into some solutions from the UK that might be helpful in order to improve satisfaction with information, disease enagement and treatment adherence.

SP0094 **THE SWEDISH EXPERIENCE - HOW A PATIENT ORGANISATION COULD REACH OUT TO IMMIGRANTS AND DEVELOP THROUGH INTEGRATION**

T. Diao. *The Swedish Rheumatism Association (SRA), Stockholm, Sweden*

Bakground: in the early years of the new millennium many European countries faced an increased number of immigrants due to the second Iraqi war that affected the whole sub region. Some of these immigrants reached the Swedish shores and many of them have RMDs.
In an attempt to help integrate them to the Swedish society, the SRA reached out to these immigrants with RMDs to give them the tools and the knowledge of how to live a decent life with RMDs and also to inform them about how the Swedish healthcare system works. By informing them and giving them the tools to live their lives to the fullest in Sweden the SRA participated indirectly to reduce the burden of the welfare system and also increased the number of our members and embraced the diversity in the organisation.
Objectives: By running some tests with our local chapters the SRA noticed that the lack of knowledge about the RMDs was immense among these minorities. So the SRA decided to act together with other actors to facilitate the inclusiveness of these minorities into the society.
Methods: To achieve this giant task the SRA applied and received financial support from the Swedish General inheritance fund and collaborated with several health providers, the employment office, some Folk High Schools, ABF (Adult Liberal Education Association) and our local chapters and joinders in 5 of the biggest cities: Stockholm, Örebro, Gothenburg, Norrköping and Umeå.
Results: This experience was a breakthrough for the SRA. The SRA was the firth patient organisation that walked this new path. The iconoclastic experience enriched the SRA and gave it a great knowledge of how to reach out to minority groups and giving them the tools to be a fully part of the society despite the burden of the RMDs.
Conclusion: The SRA increased it's knowledge, capacity and flexibility during this experience. Today the SRA is cited as a reference in Sweden when it comes to reaching out to different minorities suffering of RMDs. Many organisations are now lining up to work with the SRA in these matters. In 2007 the SRA received the price for best project from the Swedish General Inheritance Fund.

EULAR Projects in musculoskeletal imaging

SP0095 **EULAR RECOMMENDATIONS FOR THE USE OF IMAGING IN THE DIAGNOSIS AND MANAGEMENT OF LARGE VESSEL VASCULITIS IN CLINICAL PRACTICE**

C. Dejaco [1,2] on behalf of Taks force to develop the EULAR recommendations for the use of imaging in LVV. [1] *Rheumatology, Medical University Graz, Graz, Austria;* [2] *Rheumatology Service, Hospital of Bruneck, Bruneck, Italy*

Large vessel vasculitis (LVV) is the most common form of primary vasculitis comprising giant cell arteritis (GCA) and Takayasu arteritis (TA).
Although temporal artery biopsy and conventional angiography are still the golden standard diagnostic tests for GCA and TA, respectively, modern imaging methods including ultrasound, magnetic resonance imaging, computed tomography (CT) and ^{18}F-FDG positron emission tomography - CT are increasingly used. In clinical practice however, these methods are inconsistently applied and rheumatologists and other specialists are still uncertain about the specific value of these modalities. This project has been conducted with the aim to provide user-friendly, evidence-based recommendations for the use of modern imaging methods for diagnosis, monitoring and outcome prediction of primary LVV. Specifically, we give advice on 1) when to use these imaging techniques, 2) what specialists might conclude from imaging results and 3) what technical standards are required to achieve high quality imaging results.
These recommendations aim at an early and specific diagnosis as well as an improved assessment of LVV, thus ultimately leading to better outcomes of patients with LVV.

SP0096 **EULAR/PRES STANDARDISED PROCEDURES FOR MUSCULOSKELETAL ULTRASOUND (MSUS) IMAGING IN PEDIATRIC RHEUMATOLOGY**

P. Collado. *Rheumatology, Hospital Universitario Severo Ochoa, Madrid, Spain*

Musculoskeletal ultrasound (MSUS) is a readily available and suitable imaging technique to asses the immature skeleton of paediatrics in different musculoskeletal rheumatic diseases (MSRD). Besides the potential operator –dependent feature of this technique, the age-related variation of normal sonoanatomy due to the child's growth makes more difficult acquisition, interpretation and comparison of images than in adults. Hence, to use MSUS as a valid technique for diagnosis of MSRD, it is needed to develop specifically evidence-based recommendations for paediatrics. Additionally, the variability in background and experience of ultrasonographers in different countries requires an international multidisciplinary contribution for an optimal standardization of MSUS performance in paediatric MSRD.
Reflecting the perceived need for developing recommendations on the standardization of procedures for performing MSUS examination in MSRD, a collaborative international EULAR/PReS task force was convened. In the talk, it is going to summarize the original proposed specific aims and update on work for each aim previously mentioned. A systematic literature search was performed in Medline and Embase from databases inception to 1st June 2016 as the first step. One hundred and eighty-eight articles were finally included after reviewing 6059 records identified. The scanning for the knee and the ankle joint was the most common reported, whereas the paediatric wrist was uncommon.

SP0097 **REPORT OF ANATOMY FOR THE IMAGE REPORT OF THE EULAR WORKING GROUP OF ANATOMY FOR THE IMAGE**

I. Möller on behalf of EULAR Working Group Anatomy for the IMAGE. *Rheumatology; anatomy; sonoanatomy-sonopathology, Instituto Poal de Reumatología; University of Barcelona, Hospitalet de Llobregat, Spain*

The EULAR Working Group for the Image became an official "working group" 2 years ago with the purpose of furthering anatomic study and education related to the human musculoskeletal system and relevant non-musculoskeletal structures important in the practice of rheumatology and, more specifically, rheumatologic imaging including but not limited the high-resolution musculoskeletal ultrasound and MRI.
Studies performed:
- "Sonographic and anatomical description of the subtalar joint" – submitted for publication.
- "The anterior rotator cuff – a link between anatomy and ultrasound" – submitted for publication.
- "Learning model for successful ultrasound-guided synovial biopsy": pending submission.

New/Ongoing projects:
- Deep layer of the abdominal subcutaneous fat pad and cardiovascular risk: ultrasound measurement and relationship with visceral fat
- The mechanical function of the Hoffa fat pad as seen in a dynamic musculoskeletal ultrasound study.
- Ultrasound study of the neurovascular supply to the joints.
- The relevance of ligaments in inflammatory disorders of the articulations of the hand and wrist.
- The principles of anatomy as seen in musculoskeletal ultrasound.

Activities promoted by the group:
- Barcelona Sonoanatomy IX and X under scientific endorsement of EULAR.

Support:
- OMERACT: "Reliability exercise of synovitis at the subtalar joint".

In collaboration with the University of Barcelona:
- Certificate Course "Expert in Musculoskeletal Ultrasound".

Capillaroscopy I & II

SP0098 **THE IMPORTANCE TO DIFFERENTIATE NORMAL FROM ABNORMAL CAPILLAROSCOPIC IMAGES FOR AN EARLY DIAGNOSIS OF DISEASE**

V. Smith. *Department of Rheumatology, Faculty of Internal Medicine, Ghent University Hospital, Ghent University, Gent, Belgium*

Medical doctors frequently get patients with Raynaud's phenomenon (RP), a frequent symptom in the general population, referred. The importance of distinguishing normal capillaroscopic findings from (pathognomonic) abnormal (pathological) findings, lies in the fact that this distinction allows the differentiation between a primary RP (not connected to any connective tissue disease [CTD]) from a secondary RP due to systemic sclerosis (SSc) and diseases of the scleroderma spectrum.
What is normal in primary RP? A normal capillaroscopic pattern, by qualitative assessment, is characterized by a homogeneous distribution of hairpin shaped capillaries as a "comb-like structure", with a density of between 9–14 capillaries per mm. Yet, there exists a wide intra- and inter-individual variety in a normal population which will be discussed in this session.
What is pathognomonic abnormal in patients with RP due to SSc? Patients with the RP who have an underlying clinically recognizable (= with skin involvement) SSc show a very characteristic combination of capillary abnormalities in the nailfold, which can easily be assessed through qualitative assessment (= pattern

recognition). Maricq et al. described last centrury, with the widefield technique (magnification X12–14) the scleroderma pattern. This pathognomonic combination contains the following: a striking widening of all three segments of the capillary loop (arterial, venous and intermediate), loss of capillaries, disorganization of the nailfold capillary bed. Many branched "bushy" capillaries may also be observed.
In 2000, Cutolo et al. qualitatively assessed the nailfolds of an SSc cohort with patients fulfilling the American College of Rheumatology (ACR) criteria for SSc with the nailfold videocapillaroscopic (NVC) technique (magnification X200). According to the different proportions of the hallmark parameters of the scleroderma pattern (giants, capillary loss, hemorrhages and (neo)angiogenesis Cutolo et al. defined three patterns "early", "active" and "late".
The central role of capillaroscopy in distinction between a primary and secondary RP due to SSc is reflected by the fact that capillaroscopy is one of the new ACR/EULAR criteria for classifying a patient as having SSc.
Besides playing a paramount role in distinguishing a primary from secondary RP, capillaroscopy has an additional role. It can inform the rheumatologist dealing with a patient population with merely the RP and no other signs of a CTD, who will futurely develop SSc. This role is reflected by capillaroscopy playing a central role in the LeRoy and VEDOSS criteria for (very) early diagnosis of SSc.
What about capillaroscopic morphology in connective tissue diseases other than SSc?
No large scale prospective cohorts exist describing capillaroscopic morphology in connective tissue diseases other than SSc. Moreover, several morphologic defintions exist across literature of different schools. The EULAR Study Group on microcirculation in Rheumatic diseases was set up in 2014 to tackle, in between others these working points.

SP0099 WHY CAPILLAROSCOPY CAN PREDICT DISEASE SEVERITY AND PROGNOSIS

M. Cutolo on behalf of EULAR Study Group on Microcirculation. *Internal Medicine, Research Lab Division Rheumatology University of Genova, genova, Italy*

Nailfold capillaroscopy (NVC) is today considered to be safe biomarker in order to make an early diagnosis of slected Connective Tissue Diseases (CTDs) in presence of Raynaud' phenomenon, and to measure progressive microvascular and tissues damage including response to long term treatment,
Systemic sclerosis is the only CTD to date in which prognostic indices have been described to predict clinical complications. Predictions have been made based on baseline capillaroscopic images and based on sequential capillaroscopic follow-up.
Baseline qualitative-assessed scleroderma patterns have been described to be linked with future organ involvement in any of the nine organ systems affected by SSc according to the disease severity scale of Medsger (general, peripheral vascular, skin, joint, muscle, gastrointestinal tract, lung, heart and kidney) (1). Additionally, baseline capillaroscopic evaluations have been linked to future development of digital trophic lesions in SSc. A simple scoring system has been used recently in the largest pan-European study evaluating the role of capillaroscopy in predicting digital ulcers in SSc (2). More specifically, in this study, simply the number of capillaries per linear mm had been evaluated. Besides counting the number of capillaries/capillary alterations, dimensions can also be measured. The latter has also been used in prediction of patients with RP whether, because of SSc, there will be a possibility for them to develop a secondary RP. Similarly, it has recently been attested that if the average capillary diameter (average of the largest apical, efferent and afferent limb in 16 fields, more specifically 2 fields per finger, fingers 2–5 from each hand) is less than 30 μm in a group of patients with RP but without scleroderma characteristic findings on nailfold videocapillaroscopy (NVC), the patient has a low chance of developing SSc, while if $>$30 μm, then the patient has 50% chance to develop SSc (3). Concerning the ability of capillaroscopy to measure response to treatment, there are yet no prospective randomized, double-blind, placebo-controlled trials, evaluating the ability of capillaroscopy to monitor response to therapy concerning RP-related outcome measures. It is noteworthy and promising that in small studies showing response of immunosuppressive/vasomodulating treatment on disease severity, outcome measures are available (4–6).

SP0100 HOW TO SELECT THE MOST APPROPRIATE CAPILLAROSCOPIC DEVICE: PROS AND CONS

W. Hermann. *Department of Rheumatology and Clincial Immunology, Kerckhoff-Klinik, Bad Nauheim, Germany*

One of the most important indications for performing capillaroscopy is to differentiate between primary and secondary Raynaud's syndrome. Different kinds of microscopes are at hand and generally vary in terms of picture quality or price. Before purchasing a microscope and capillaroscopy software, several considerations about the required standards of examination should be made; some of which are summarized as follows:

- The region of interest (ROI). Normal capillaries have a mean diameter of about 8 μm. For an accurate assessment a magnification of 100–200x is recommended, for an overview the magnification of 50x is sufficient.
- Measurement. Beside qualitative measures like changes in vessel architecture, there should be the possibility of quantifying the number of capillaries/mm or vessel diameters.
- Documentation. All parts of the examination have to be stored and assigned to patient and case.
- Practical aspects and handling of the device.
- Different kinds of microscopes are on the market of which three will be discussed in detail. Briefly summarized:
- Stereo microscopes.

Advantages: Very good image quality, zooming in and out without problems, relatively easy to use.
Disadvantages: device is not mobile, in patients with finger contractures examinations are difficult to perform, relatively high costs.

- Videocapillaroscopes:

Advantages: Very good image quality, easy to use, "gold standard" for capillaroscopy.
Disadvantages: No overview, zooming in and out not applicable (change of lenses required), relatively high costs.

- USB microscopes:

Advantages: low costs, zooming in and out without problems, easy to use.
Disadvantages: limited picture quality, documentation laborious.
Selecting a capillaroscopic device depends on the conditions of use ("quick look" vs. "academic evaluation and follow up"), which should be clarified before buying a device. The price range is significant and usually differs between 100€ for USB microscopes and up to 10,000€ for stereo and videocapillaroscopes

Ultrasound, clinical, diagnostic and therapeutic skills I & II

SP0101 DIAGNOSTIC AND THERAPEUTIC ULTRASOUND-GUIDED PROCEDURES

P. Mandl. *Rheumatology, Medical University of Vienna, Vienna, Austria*

The lecture will provide an overview of sonography-guided musculoskeletal interventions which can be grouped broadly as diagnostic and therapeutic procedures. Primarily diagnostic procedures include arthrocentesis, biopsy from various musculoskeletal tissues (synovial, bone, muscle etc.), aspiration of fluid from cystic lesions, tendon sheaths and bursae. The therapeutic group features joint and soft tissue injections, needling of periarticular calcification, including barbotage. Both indirect and direct-guidance techniques will be detailed and published literature on accuracy, outcome and safety of sonographic-guided interventions will be reviewed.

SP0102 HOW TO PERFORM A QUICK AND EFFICIENT PHYSICAL EXAMINATION

M. Doherty. *Academic Rheumatology, University of Nottingham, Nottingham, United Kingdom*

The GALS (Gait, Arms, Legs, Spine) screen is a quick and reasonably sensitive way to detect common musculoskeletal (MSK) abnormalities as part of a general medical assessment (1). However, for a person with MSK complaints a detailed assessment is required to determine the diagnosis and the impact of the condition on that person. The key starting point is the history. This needs to be holistic and individualised as the enquiry proceeds since the impact of any condition is

person specific and influenced by many factors (e.g. psychosocial factors, illness perceptions, sleep, comorbidity etc.). A thorough history alone usually suggests the single most likely cause for the patient's problem(s). The history should then guide the subsequent physical examination – an efficient targeted "rapier" approach is recommended in which the practitioner selects the appropriate skills from a range of competencies according to specific elements in the history. This contrasts with a more lengthy hypothesis-free "general screen" in which the same set of uniform procedures is undertaken in each patient.
This presentation will cover key principles and considerations of assessment and illustrate how the history guides the subsequent "rapier" examination (2). Examples include:
(1) in the *history:* determination of pain localisation and features that associate with radiated pain; important pain and stiffness characteristics that differentiate mechanical usage-related pain, inflammatory pain, acute crystal synovitis pain, destructive bone pain and neurogenic pain; non-specific symptoms of inflammation (2) in the *examination:* usual order of inspection at rest, inspection during movement, then palpation at rest and during movement of symptomatic regions; contrasting clinical findings that quickly differentiate joint and peri-articular problems; initial selection of the movement(s) that is affected first and most severely by arthropathy - the tight pack position(s); detection of "stress pain" (pain worse in tight-pack positions but reduced/absent in loose-pack positions - the most sensitive sign of inflammation); examination for effusion, soft-tissue and firm swelling; use of resisted active movements and stress tests for peri-articular lesions; a targeted screen for asymptomatic disease prompted by main diagnosis.
EULAR learning resources available at http://www.eular.org/edu_training_dvd.cfm include: (1) The "GALS" screen and (2) Principles of the musculoskeletal history and examination.

SP0103 **HOW TO ASSESS US COMPETENCY SKILLS**

H.B. Hammer. *Dept of Rheumatolgy, Diakonhjemmet Hospital, OSLO, Norway*

To optimize and standardize musculoskeletal ultrasonography education for rheumatologists, there is a need for competency assessments addressing the required training and practical and theoretical skills. Because of the increasing use of MSUS in rheumatology, there has been a focus over the past years on training.
A minimum training requirements are described by The European Federation of Societies for Ultrasound in Medicine and Biology (EFSUMB) where a 3 levels competency assessment (COMPASS) has been developed for rheumatologists, including an in-detail description of what theoretical and practical competencies to be acquired at each level with a related log book (1). The rheumatology-COMPASS levels are closely related to the levels of the EULAR MSUS courses, thereby ensuring that the content is supported by already provided courses such as the EULAR and EULAR-endorsed MSUS courses to facilitate the implementation of the rheumatology-COMPASS. In COMPASS level 1 the course contents resemble the EULAR MSUS basic and intermediate courses, level 2 resembles the EULAR MSUS advanced course whereas level 3 requires attendance in a "teach-the-teachers course" or experience as a teacher in at least 2 international MSUS courses. Level 3 also includes an academic level requiring research activity and acceptance of level 1 and 2 sonographers for training.
The EULAR MSUS courses have been organized since 1998 and the interest in these courses has been increasing. In 2007, the first 3 level EULAR MSUS course was conducted with great success and the 3 level courses (basic, intermediate and advanced) have been running ever since in relation to the EULAR congress, focusing mainly on the relevant content on the individual levels and the distribution between practical and theoretical skills.
EULAR has developed the following competence levels; level 1 and 2. The EULAR level 1 competency includes the performance of EULAR Online MSUS course and attendance to basic, intermediate and advanced MSUS courses, where attending the intermediate and advanced courses require a certain number of US examinations (however, if already reached COMPASS level 1, 2 or 3, there is no need of images for the EULAR courses), and the advanced course requires in addition to pass a practical examination. The EULAR level 2 competency is organized to ensure a minimum level of US knowledge for teachers in MSUS courses (2). This level includes the EULAR Teach the Teachers course as well as passing a theoretical and practical examination. Since there is a growing number of EULAR endorsed MSUS courses, it is of highly importance that the teachers in these courses have equal qualifications thereby providing comparable training and competencies beneficial for the clinical use of US. Information about the competence requirements is found at the EULAR website (http://www.EULAR.org).

Macrophage M2 polarization: implications in fibrotizing diseases

SP0104 **REPROGRAMMING OF MYELOID CELLS IN CANCER: MECHANISMS AND SIGNIFICANCE**

A. Sica. *Pharmacological Sciences, University of Eastern Piedmont, NOvara, Italy*

Chronic inflammation mediates tumor development by promoting a constant influx of inflammatory cells capable of modulating genes involved in cancerogenesis and creating micro and macroenvironments that support cancer growth. A major side effects of cancer inflammation is the pathological expansion and recruitment of myeloid cells endowed with immunosuppressive activity, to control the unresolved inflammation. Tumors reprogram myeloid cell differentiation and functions through various mechanisms, including altered metabolism, cancer-related inflammation andalteration of the hematopoietic output. These events govern the expansion of myeloid suppressor populations, mainly myeloid-derived suppressor cells (MDSCs) and tumor associated macrophages (TAMs). MDSCs and TAMs orchestrate tumor immunosuppression in concert with regulatory T cells, inhibitory cytokines and immune check points receptors, and act to subvert anti-tumor immunity, hence causing that eventually support immune evasion establishing a bottleneck for cancer immunotherapy. I will discuss inflammatory circuits and epigenetic events sustaining the expansion and the tumor-promoting reprogramming of myeloid cells in cancer bearers.

SP0105 **MACROPHAGES, METABOLISM AND INFLAMMATION**

N.O.S. Camara. *Immunology, University of Sao Paulo, Sao Paulo, Brazil*

Macrophages are a heterogeneity population implicated in several diseases and correlated with distinct tissue outcomes after injury. M2 macrophages have been associated with tissue repair whereas M1 macrophages participate in early phase of tissue damage. Recent works have also suggested that upon activation, macrophages can use distinguished nutrients as source of energy and these metabolic pathways lead to their activation and differentiation. Nutrient sensors are intimae associated with innate receptors and therefore connected with inflammatory response. Uric acid is a damage-associated molecular pattern (DAMP), released from ischemic tissues and dying cells which, when crystalized, is able to activate the NLRP3 inflammasome through frustrated phagocytosis. Soluble uric acid (sUA) is found in high concentrations in the serum of great apes, and even higher levels in some diseases, before the appearance of crystals. sUA can be released in a hypoxic environment and triggers NLRP3 through the production of mitochondrial ROS, with increased maximum and reserve oxygen consumption ratio (OCR) and higher VDAC protein levels. This process is followed by ASC speck formation, caspase-1 activation and IL-1β release. These findings may have profound implications for inflammatory-related diseases.

Mucosal B cells: gatekeepers of immune function

SP0106 **THE LUNG AS A DRIVER OF RA-ASSOCIATED AUTOIMMUNITY**

A. Catrina. *Department of Medicine, Rheumatology Unit, Karolinska University Hospital and Institutet, Stockholm, Sweden*

Rheumatoid arthritis (RA) is a chronic inflammatory disease resulting from the complex interaction between genes and environment. In a large majority of patients this interaction leads to formation of disease-specific anti-citrullinated proteins antibodies (ACPA). Systemic autoimmunity may be triggered at mucosal sites (such as the lungs) long before the first signs of inflammation are starting in the joints. According to this model, smoking (and others environmental triggers) induces subclinical inflammation in the lungs, leading to increased local citrullination and formation of ACPA in genetically susceptible individuals. Lung changes on high-resolution computer tomography are present in both early-untreated ACPA positive RA and ACPA positive individuals at risk for but not yet having disease. Further, signs of subclinical inflammation and immune activation with germinal centers formation and ACPA enrichment is present in early untreated RA. Shared citrullinated targets have been described in the lungs and joints of patients with RA and more recent data unravels novel mechanisms showing how this extra-articular triggered autoimmunity progresses to joint-specific inflammation. Beside an initiating role, the lung might also be a secondary target for antibodies, especially in longstanding seropositive RA.

WIN & HOT session

SP0107 HOT SESSION: SCLERODERMA TREATMENT

C.P. Denton. *Centre for Rheumatology, Royal Free Hospital and Ucl Medical School, London, United Kingdom*

This presentation will provide an up to date summary of current management of SSc that can be applied across the disease spectrum. Systemic sclerosis (SSc) remains a challenging multifaceted rheumatic disease with high mortality and morbidity. However, treatments are emerging for some aspects of the disease and long term survival has improved significantly over the past decades. This session will review the clinical challenge and current therapeutic landscape of SSc focusing on practical aspects of management such as identifying and treating significant organ based complications in the lung, heart, kidney and gastrointestinal tract. Current approaches to overall disease management will be summarized including the use of haemopoietic stem cell transplant in selected poor prognosis cases. Recently updated EULAR/EUSTAR treatment recommendations will be reviewed and other evidence based management guidelines will be considered within a practical patient-focused framework.

Comorbidities in rheumatoid arthritis

SP0108 HERPES ZOSTER: HOW TO PREVENT, TO DIAGNOSE AND TO TREAT

L. Calabrese. *Rheumatology, Cleveland Clinic, -Cleveland, United States*

Herpes Zoster is a major public health problem and is an infection that results from re-activation of latent varicella infection acquired most commonly naturally or more recently through immunization. The incidence of HZ is approximately twice that of the general population in patients with immune mediated inflammatory diseases (IMIDs). Underlying mechanisms are largely those which compromise cell mediated immunity and epidemiologic risks largely follow immunosenescent patterns (i.e. aging). Rheumatologists use a large variety of immunosuppressive drugs which further increase the risk of HZ and are obliged to recognize the clinical syndrome, its complications, apply effective therapy and be actively engaged in strategies to maximize immunization and prevention. This discussion will focus on recent advances in each of these areas highlighting newly described complications of HZ such as stroke and advances in vaccine development.

Life-threatening presentation of rheumatic diseases

SP0109 ACUTE RESPIRATORY FAILURE, MACULO-PAPULAR RASH, INDURATIVE EDEMA OF THE EXTREMITIES AND CERVICAL LYMPHADENOPATHY IN A 6-WEEK-OLD INFANT

C. Birolo. *Pediatric Rheumatology Unit, Department for Woman and Child Health, University of Padua, Italy, Padua, Italy*

Case report: A previously healthy 40-days-old male infant, from non-consanguineous parents from Morocco, presented in a peripheral hospital with fever for 48 hours, associated with rhinorrhea, mild diarrhea and progressive irritability during the last 24 hours. Initial laboratory studies revealed elevated acute phase reactants (CRP 116 mg/L), mild neutrophilia, elevated liver enzymes (AST 315, ALT 174 U/L), direct hyperbilirubinemia, discoagulopathy. Cerebral spinal fluid analysis and microbiology cultural workup resulted negative. A wide-spectrum antibiotic and antiviral therapy was initiated. On the 6th day of illness he developed diffuse maculo-papular rash, indurative edema of the extremities, right cervical lymphadenopathy and bilateral conjunctival injection. On the basis of a certain clinical diagnosis of Kawasaki disease and the infant was treated with IGIV 2 g/kg. An echocardiography performed prior to the IGIV infusion showed homogeneously dilated coronary arteries (left coronary artery 3.2 mm, right coronary artery 2.2 mm). Twelve hours after the end of IVIG infusion, the child presented a rapidly progressive, severe respiratory failure requiring endotracheal intubation and was transferred to our ICU. On admission (day 7th), physical examination revealed a feverish, critically ill-infant with hepatomegaly (5–6 cm below the right costal margin), diffuse maculo-papular rash, “sock-like” erythema and swelling of the feet, cheilitis, bilateral conjunctival injection and right cervical adenopathy. The urine output was markedly decreased; he rapidly developed hemodynamic instability with hypotension and tachycardia. Complete blood count showed anemia (6.8 g/dl), thrombocytopenia (16.000/mmc), elevated CRP (240 mg/L), hypoalbuminemia (18 g/dl) and hypofibrinogenemia (0.83 g/L); liver enzymes were normal. Intensive ventilatory and hemodynamic support therapy were started, in addition to a massive transfusional regimen.

Given the clinical and hematological picture, the diagnosis of MAS was considered and subsequently confirmed by high ferritin level (2197 mcg/L), AST above the normal value (61 U/L) and hypertriglyceridemia (181 mg/dl) [2]. The clinical suspicion was supported by persistent cytopenia despite daily transfusions, low erythrocyte sedimentation rate (3 mm/h) with concomitant rising CRP, elevated IL2-R level (28.320 KU/L) and decreased NK function. The patient was treated with high dose methylprednisolone pulse therapy (25 mg/kg) for 3 consecutive days 12–14), followed by a maintenance of 1 mg/kg/daily. By day 15th, a progressive decrease in inflammatory markers and a concomitant improvement of general conditions was observed, with the possibility to discontinue inotropic support on day 12th and invasive ventilation on day 25th. Since day 17th, a diffuse cutaneous desquamation was noted. The fever settled on day 35th.

Echocardiography follow-up revealed an increasing, irregular dilation of left (max 5 mm) and right (max 3.5 mm) coronary arteries, with a progressive left ventricular apex hypocinesis, but a stable ejection fraction (55%). ECG showed persistent repolarization abnormalities.

Of note, Adenovirus-PCR was found positive in the bronchoalveolar washing performed on admission.

The differential diagnosis included: Kawasaki disease complicated by respiratory distress syndrome and MAS, familiar hemophagocytic lymphohistiocytosis, autoimmune lymphoproliferative syndrome, criopyrinopathies and immunodeficiency.

Comment: Kawasaki disease can be catastrophic in the early infancy, due to atypical presentation and resistance to the conventional therapy. Despite typical in its presentation, this case was complicated by two challenging conditions, respiratory distress syndrome and MAS, which hampered the diagnostic and therapeutic management during the course of the disease and required massive intensive support.These two complication are rarely associated to KD. In this particular case, respiratory failure can probably be explained by a combination of causes: fluid overload, systemic vasculitis and the concomitant and probably triggering Adenovirus infection.

SP0110 LIFE-THREATENING COMPLICATIONS IN SYSTEMIC VASCULITIS

M.C. Cid on behalf of G. Espigol-Frigolé, S. Prieto-González, J. Hernández-Rodríguez, A. García-Martínez. *Systemic Autoimmune Diseases, Hospital Clinic. University of Barcelona, Idibaps, Barcelona, Spain*

Systemic vasculitis may present with life-threatening complications that need to be promptly recognized and appropriately managed to ensure patient survival and minimize irreversible organ damage.

The most common life-threatening events differ between large and medium or small-vessel vasculitis. In large-vessel vasculitis, particularly giant-cell artertis (GCA), vascular remodelling in response to inflammation may lead to severe stenosis leading to ischemic stroke in 3–6% of patients and, rarely, myocardial infarction, mesenteric ischemia or critical extremity ischemia. For these complications, particularly when happening in treated patients, intensifying immunosuppressive therapy is not the best or only option and additional interventions may be required. Stroke occurs as a consequence of carotid or vertebral stenosis. Stenosis of the carotid siphon has been repeatedly reported. In necropsy studies, vasculitic involvement and thrombosis of proximal intracranial branches has been observed. Infarcts are usually multiple, usually happen shortly after the initiation of glucocorticoid therapy, convey a 30% mortality or lead to remarkable disability. If critical stenosis is suspected before irreversible infarction, percutaneous intraluminal angioplasty may be function and life saving.

Acute aortic syndrome (aortic dissection or intramural haematoma) is an increasingly recognized hurdle in patients with GCA. It is usually a delayed complication occurring months and frequently years after diagnosis. Its frequency has not been delimitated but in a recent prospective follow-up study it was demonstrated to affect at least 2% of patients. Emergency open surgery repair, when feasible, is the best option for ascending aorta involvement (type A) and endovascular repair for involvement of the descending aorta (type B).

In small-vessel vasculitis, life-threatening presentations include rapidly progressive glomerulonephritis leading to kidney failure, alveolar haemorrhage, alithiasic colecistitis with perforation and intestinal ischemia. Rapidly progressive glomerulonephritis and alveolar haemorrhage are more frequently seen in anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) and anti glomerular basement membrane disease. Alveolar haemorrhage can be occasionally seen in cryoglobulinemic or IgA vasculitis. In addition to supportive measures, these patients are usually treated with high-dose methyl-prednisolone, cyclophosphamide or rituximab and plasma exchange. Plasma exchange has been found superior to IV methyl prednisolone mega-doses in preserving or recovering renal function but this advantage do not seem to persist over long-term follow-up. This approach is usually applied also to alveolar haemorrhage although there is not strong evidence supporting it.

Gastrointestinal complications, particularly intestinal ischemia and intestinal or gallbladder perforation are life-threatening complications which may require emer-

gent surgery. These may be observed in polyarteritis nodosa, cryoglobulinemic vasculitis, eosinophilic granulomatosis with polyangiitis and other AAV. High-dose glucocorticoids and cyclophosphamide are usually applied.Children with IgA vasculitis may develop bowel intussusception
Deep venous thrombosis and pulmonary embolisms are significantly more frequent in AAV and Behçet disease than in the general population, especially during active disease. Anti-coagulation may be needed in AAV, although this approach is controversial in Behçet's disease. By contrast, aneurysm formation is typical in polyarteritis nodosa and Behçet's disease and may be occasionally seen in AAV. Massive bleeding derived form aneurysm rupture usually requires arterial embolization.
It is important to keep in mind that during the early course of diagnosed vasculitis, intense immunosuppressive therapy may favour life-threatening infections including opportunistic infections such as pneumocystis jiroveci pneumonia or disseminated CMV.
In summary, systemic vasculitis may present with a variety of severe complications and other may develop during follow-up. These complications are heterogeneous, vary according to the size of vessels involved, and usually require specific procedures or treatments in addition to immunosuppressive therapy. Due to the life-threatening nature of these complications their immediate recognition and management are crucial to patient survival.

AxSpA: From bug to gut and to disease phenotype –

SP0111 INHIBITING BONE FORMATION IN THE CLINIC. ARE WE THERE YET?

R. Landewe. *Rheumatology& immunology, Amsterdam Rheumatology & immunology Center, Amsterdam, Netherlands*

One of the most characteristic features of axial spondyloarthritis (axSpA) is bone formation in the spine (syndesmophytes). Syndesmophytes may occur at any time during the course of the disease, are more frequent in patients with radiographic axSpA (AS) than in those with non-radiographic axSpA, and are best seen on conventional X-rays of the spine. Currently, it is suggested that (low-radiation) CT-scanning of the spine provides a better (more sensitive) picture of developing syndesmophytes than conventional X-rays.
Syndesmophytes matter in that they interfere with spinal mobility and physical function independent of inflammation. As such, it makes sens to try and prevent their occurrence or to inhibit their progression.
It is a matter of debate whether current available treatments are able to inhibit syndesmophyte growth or occurrence. Part of the debate is the methodological challenges related to measuring syndesmophyte progression properly.
In this lecture I will address current issues related to inhibition of syndesmophyte formation in patients with axial SpA.

Pregnancy meets rheumatic patients

SP0112 WHICH DRUGS IN PREGNANT PATIENTS?

M. Ostensen. *Department of Rheumatology, St.Olavs Hospital, Trondheim, Norway*

Management of rheumatic disease during pregnancy starts with prepregnancy counselling.Assessment of maternal and fetal risks is necessary for adjusting therapy before and during pregnancy. The aim of therapy is to keep the disease in remission or at least at low activity throughout pregnancy.
Immunosuppressive drugs requiring withdrawal before conception are methotrexate, cyclophosphamide,and mycophenolate which are known teratogenic drugs. Other drugs like leflunomide, tofacitinib and several biological should be discontinued because pregnancy experience is at present insufficient and safety for the fetus has not been proven.Flares of rheumatic disease showing be treated immediately and with pregnancy compatible drugs.For patients with inflammatory arthritis like rheumatoid arthritis,spondyloarthritis and juvenile idioipathic arthritis disease activity during pregnancy can be controlled with antimalarials, sulfasalazine and TNF inhibitors. Women with systemic lupus erythematosus should continue basic therapy with hydroxychloroquine, and azathioprine, ciclosporine or tacrolimus added when necessary due to organ manifestations. Severe flares during pregnancy may require biologics like rituximab,abatacept,tocilizumab or Anakonda, in SLE corticoid pulses or, if life threatening, intravenous gamma globulin or cyclophosphamide.
Treatment during pregnancy demands balancing suppression of maternal disease and no harm to the child. Selecting the adequate type, the right dose and the right timing of medications for optimal care of pregnant patients remains a challenge.

SP0113 PREGNANCY IN SLE: STILL CHALLENGING FETAL AND MATERNAL ISSUES

R. Fischer-Betz. *Rheumatology, Heinrich-Heine-University, Duesseldorf, Germany*

Patients with SLE are mostly young women diagnosed during their childbearing years. Several "unmet needs" in the management of reproductive health issues may impact on the decision to have children. Because of earlier recognition of disease and advances in medical treatment, family planning has gained greater importance. Concerns include the effect of pregnancy on maternal disease, the impact of disease activity on fetal health, and the safety of medications during pregnancy and breastfeeding. Preconception counselling and risk stratification (including life style, disease activity, autoantibody profile, previous vascular and pregnancy morbidity, hypertension and the use of drugs with emphasis on benefits from hydroxychloroquine and antiplatelets/anticoagulants) are essential for prevention of unwanted complications during pregnancy. Recommendations for the management of family planning and antirheumatic treatment during pregnancy and lactation have been published recently by EULAR. However, many lupus patients still do not feel that their family planning concerns are adequately addressed in current clinical practice and report that they receive inconsistent advice from the various healthcare professionals. There is a clear need for provision of up-to-date and consistent information/support to our patients.

SP0114 CHILDREN OF PATIENTS WITH RHEUMATIC DISEASES: ISSUES RELATED TO MATERNAL DISEASE AND TREATMENT

L. Andreoli. *Rheumatology and Clinical Immunology, University of Brescia, Brescia, Italy*

A major source of anxiety for women with systemic autoimmune diseases (SADs) who wish to become pregnant is the possible impact of maternal disease and medications on the offspring, in terms of physical and mental development. A recent multicenter survey conducted in 24 Italian Rheumatology Centers showed that more than 50% women affected by SADs restricted their family size mainly because they were afraid that children could get an autoimmune disease or could be harmed by intrauterine exposure to maternal autoantibodies and anti-rheumatic drugs (Dall'Ara, ACR abstract, Arthritis Rheumatol 2016; 68, suppl 10). Therefore, the long-term follow-up children born to mothers with SADs is a topic of major relevance for the counselling on family planning.
First of all, it should be emphasized that preterm birth and other foetal complications, such as low birth weight and babies small for gestational age, are more common in patients with systemic autoimmune diseases as compared to the general population. These conditions carry themselves an increased risk for poorer physical and neuropsychiatric development. Therefore, the prevention of foetal complications should be operated by means of close obstetrical monitoring and tight control of maternal disease activity, which would be detrimental for foetal wellbeing. In this context, the use of "safe" anti-rheumatic drugs is of paramount importance for pregnant women with SADs.
Recently, a dedicated EULAR Task Force has released points to consider for the use of anti-rheumatic drugs during pregnancy and lactation (Gotestam Skorpen, Ann Rheum Dis 2016). The work of this Task Force was focused on updating the information about the use of "conventional synthetic" (cs) DMARDs but also to provide for the first time evidence-base indications on the use of "biologic" (b) DMARDs, mainly anti-TNFalfa agents.
No significant impairment in the maturation and functioning of the child's immune system has been observed for several csDMARDs, supporting their safety of use during pregnancy (Andreoli, J Autoimm 2012).
Turning to bDMARDs, a case-control study on the long-term follow-up of children exposed in utero to anti-TNFalfa drugs showed the safety of use either until the positive pregnancy index or during the second and third trimester of gestation (Dall'Ara, EULAR abstract, Ann Rheum Dis 2016; 75, Suppl 2:493). No differences between exposed and non-exposed children were found in terms of congenital defects, developmental milestones, response to vaccinations and major health problems. No particular problems were also observed in children who were breastfed while maternal anti-TNFalfa intake. The use of anti-TNFalfa agents during breastfeeding had been proposed to women who were strongly motivated based on the following considerations: 1) these drugs are poorly or absolutely not excreted into breast milk as recently demonstrated for certolizumab pegol (Clowse, ACR abstract, Arthritis Rheumatol 2016; 68, suppl 10); 2) even this was the case, the drug will be degraded in the baby's gastrointestinal tract and absorption could not be possible.
Regarding maternal disease, major concerns are linked to fetal exposure to maternal autoantibodies, mainly anti-Ro/SSA (for the development of Neonatal Lupus) and antiphospholipid antibodies (aPL). Therefore, the evaluation of these autoantibodies with potential negative impact on pregnancy and neonatal outcome should be part of the preconception work-up of women with SADs in order to provide adequate counselling and preventative strategies (Andreoli, Ann Rheum Dis 2017).

The transplacental passage of maternal aPL does not generally produce any thrombotic complication in the neonate. The registry of infants born to mothers with APS, started by the European Forum on aPL in 2003, is collecting precious information for the assessment of neonatal outcome and subsequent development. The exposure to maternal aPL was linked to learning disabilities (LD) in children born to both mothers with SLE and with APS, based on the experimental observation that aPL can affect neural cells functioning. A recent study on the long-term neurodevelopment of children exposed in utero to aPL was reassuring for a normal neurological functioning and intelligence level, but found a higher rate of LD as compared to the general population (19% vs 3%) (Nalli, Lupus 2017). These affected children were all born at term to triple aPL positive mothers.

Although systemic autoimmune diseases are not hereditary, newborns may receive from the mother a genetic background that may predispose to the emergence of autoimmunity and, possibly, of related symptoms. However, the incidence of autoimmune diseases in the offspring was rather low (1%) among 269 children with a mean age of 15 years collected in the previously cited survey of Italian Rheumatology Centers.

Neuronal and hormonal alterations in arthritis

SP0115 NEUROTRANSMITTERS AND INNERVATION IN SYNOVIUM

R.H. Straub. *Dept. of Internal Medicine, University Hospital, Regensburg, Germany*

The synovial tissue is innervated by nociceptive sensory nerve fibers and sympathetic postganglionic nerve fibers. While sensory nerve fibers have afferent (by transmitting pain to the CNS) and efferent functions (by local release of neuropeptides), sympathetic nerve fibers exert mainly efferent vasoregulatory, energy-regulating and immunomodulating roles. In synovial tissue of patients with rheumatoid arthritis (RA), the major proinflammatory neuropeptide of sensory nerve fibers is substance P, which is upregulated relative to anti-inflammatory calcitonin gene-regulated peptide (CGRP). In addition, sensory nerve fibers undergo a sprouting response leading to sensory hyperinnervation of RA synovial tissue. Removal of sensory nerve fibers exerts anti-inflammatory effects, and it is thought that this elimination is beneficial during hemiplegia, which can spare the paralytic limb from developing RA. Therapeutic neutralization of substance P was not successful, most probably due to vast receptor redundancy. Furthermore, the sensory nervous system undergoes a sensitization response (aggravation of pain and inflammation) in the synovial tissue, the dorsal root ganglion, the spinal cord, and more central in the brain. Chemical sympathectomy or suppression of adrenergic signaling significantly reduce inflammatory processes in the initial acute state of inflammation whereas the same procedures may increase inflammation at later stages. These findings indicate that the sympathetic nervous system supports the development of inflammation but can reduce inflammation at more chronic stages. During chronic inflammation, the density of sympathetic nerve fibers in synovial tissue is reduced but other tyrosine hydroxylase-positive cells secreting noradrenaline appear in the inflamed joint. In addition to local vascular effects in the joint, the sympathetic nervous system influences numerous immune processes in the joint and in lymphoid organs. Hence the net effect of the sympathetic nervous system on inflamed tissue results from local sympathetic effects in the joint as well as from sympathetic influences on major systemic immune processes and energy regulation. This lecture summarize the central aspects of the two nervous systems.

SP0116 HOW TO TARGET NEURONAL AND HORMONAL ALTERATIONS IN ARTHRITIS

M. Cutolo on behalf of ACR and EULAR Study Groups on Neuro Endocrine Immunology of Rheumatic Diseases (NEIRD). *Internal Medicine, Research Lab Division Rheumatology University of Genova, genova, Italy*

Neuroendocrine pathways link the central nervous system (CNS) with the periphery by means of hormones and nerve fibres. Neuroendocrine connections are important for integrating signals throughout the body. Hormones are soluble factors circulating in the blood and lymph, while nerve fibres are solid cables connecting brain centres with distinct anatomical sites in the periphery.

Several network connecting the NeuroEndocrine Immune (NEI) system are target for the treatment of chronic immune inflammatory diseases, including arthritis in RMD (1).

The hypothalamic–pituitary–adrenal (HPA) axis is the best studied connection between the CNS and peripheral sites of inflammation. The HPA axis hormones comprise CRH, adrenocorticotropic hormone (ACTH) and several steroid hormones of the adrenal gland, including cortisol and adrenal androgens such as dehydroepiandrosterone (DHEA), its biologically inactive degradation product DHEA sulfate (DHEAS), and androstenedione (ASD). The adrenal gland synthesises glucocorticoids (GCs) following a circadian rhythm and the exogenous administration of GCs in chronic arthritis should be regarded as a replacement therapy for adrenal gland hypofuntion (2).

The hypothalamic–pituitary–gonadal (HPG) axis has been linked to rheumatic diseases because we observe a female preponderance in the prevalence and incidence of rheumatic diseases, which is most probably linked to sex hormones. Hormones of the HPG axis comprise gonadotropin-releasing hormone, luteinising hormone/follicle-stimulating hormone and the two major bioactive steroid hormones of the gonadal glands, testosterone and oestrogens. Increased peripheral metabolism of sex hormones is seen in chronic arthritis (ie. synovial tissue).

The hypothalamic–pituitary–prolactin axis is important since Prolactin is thought to have proinflammatory effects in RMD. Blood levels rise sharply at the beginning of sleep so this hormone can be a regulatory element in the circadian rhythms of the immune system (1).

Similar condition for the melatonin pathway, that in addition is increased I rheumatoid arthritis patients. Blood levels rise sharply at the beginning of sleep and melatonin might, thus, be a regulatory element in the circadian rhythms of the immune system. Melatonin at normal concentrations has proinflammatory effects. Finally, the vitamin D endocrine system, which is one of the most complex and diffuse systems controlling bone mass and also the immune response in autoimmune rheumatic diseases. Vitamnin D deficiancy is common in chronic RMD and decreased in winter with related flares of RMD.

Finally, vitamin D, via its active hormonal metabolite 1,25(OH)2D3 (D hormone), regulates both innate and adaptive immunity, potentiating the innate response (monocytes/macrophages with antimicrobial activity and antigen presentation) but suppressing adaptive immunity (T and B lymphocyte functions). D hormone deficiency is a risk factor for autoimmunity and for infections and cancer.

By considering that all steroid hormones before mentioned, are also produced *via* intracrine synthesis by the inflammatory cells (ie. macrophages) at the site of arthritis, it is increasing in presence of localized inflammatory conditions the local treatment (ie injection of GCs in joints). On the other hands, the immune stimulating action of estrogens should noy suggest their use in pathological conditions. Same caution with the use of melatonin in presence of arthritis, whereas 1,25(OH)2D3 is considered an adhiuvant in immune system suppression at dosages over 2,000 IU/day.

Fighting osteoporosis fragilities

SP0117 OSTEOPOROTIC FRACTURES IN EUROPE: ARE WE DOING ENOUGH

J.A. Kanis. *University of Sheffield & Australian Catholic University, Melbourne, Cobham, Surrey, United Kingdom*

The past 30 years has seen significant milestones in assessment and management of osteoporosis. These include the development of DXA and FRAX to identify individuals at high risk of fragility fracture and the development of interventions that have been shown to significantly decrease the risk of fracture in well-designed clinical trials. A major challenge has been how to apply these treatments. Measurements of bone mineral density (BMD) are used for diagnosis and for fracture risk prediction. Facilities for BMD testing are patchy and many European countries have inadequate resources to service the societal needs. In addition, BMD has poor sensitivity for the prediction of fracture so that the majority of fractures occur in individuals with T-scores >-2.5 SD. The development of FRAX has improved the sensitivity of fracture risk prediction and is now adopted in many assessment guidelins.

Despite these advances, there are a number of challenges to be faced. Of paramount importance is that few patients with a prior fracture and even less with osteoporosis alone actually receive treatment. In Europe, there is wide inter-country variation in the treatment of women at high risk for osteoporotic fractures. The treatment gap varies from 25% in Spain to 95% in Bulgaria. Large treatment gaps were identified in countries with populations at both high and low risk of fracture. In total in the EU, it is estimated that, out of the 18.4 million women that exceed the risk level in 2010, 10.6 million were untreated. These figures are conservative since an undetermined proportion of low-risk women will have received treatment. Moreover, the treatment gap is increasing in many countries. Thus the disease is under-recognised by the medical community.

Urgent action is required to address the under-recognition of osteoporosis and fragility fracture. Simple measures include:

- The development of country-specific guidelines,
- Piloting screening strategies in the elderly,
- Identifying the determinants of imminent risk,
- The development of fracture liaison services.

Whereas osteoporosis is recognized, worldwide, as a major Public Health issue, with one in two women and one in five men over the age of 50 years presenting

a fragility fracture, a vast proportion of women at high risk remain untreated. Case-finding strategies prioritizing assessment of men and women with prior fracture are required to alleviate this problem.

SP0118 ESTABLISHING AND IMPLEMENTING A FRACTURE LIAISON SERVICE

S. Stephenson on behalf of National Osteoporosis Society. *Service Development - Operations, National Osteoporosis Society, Bath, United Kingdom*

Objectives: The objective of the National Osteoporosis Society (NOS) is to establish a Fracture Liaison Service (FLS) in every NHS Trust in the United Kingdom (UK). The Service Delivery Manager supports sites to establish, implement and develop a new FLS, as well as to improve the quality of existing services. The FLS model enables secondary fracture prevention through identification of fragility fractures in every person who breaks a bone aged over 50 using dedicated case-finding, with assessment and appropriate management of osteoporosis where necessary. The object of FLS is to prevent secondary fractures, in particular expensive hip and vertebral fractures, thereby providing both clinical and cost effectiveness for patients and payers. The NOS has developed a unique service to support FLS across the UK.
Developments: A team of specialist development managers with clinical and commissioning experience support providers and payers in the process of establishing new FLS's by offering consultation and guidance at every step of the process from pathway development to successful funding of services. This model has been replicated across the UK since April 2015 with the support and expertise of the NOS. Once an FLS is established the NOS provides support with service improvement, whether through additional commissioning of funds, Peer review or Gap analysis.
Results: Results from a range of analyses show that FLS has a positive impact on fracture rate and in particular hip fractures.
At the time of writing, the NOS is currently supporting 166 sites across the UK. 83 sites are improving the quality of their service; 58 sites are developing new services. 13 new services have been commissioned since commencement of the work programme, delivering new FLS provision to an additional 1.6 million people over 50, preventing 1,482 hip fractures over a 5-year period. Figures have been calculated from the NOS FLS Benefits Calculator https://benefits.nos.org.uk
Challenges: The primary challenge in establishing an FLS is identifying a clinical champion - this maybe a nurse, an allied health professional, rheumatologist or ortho-geriatrician in the hospital, or a representative from Public Health or from a Clinical Commissioning Group (CCG). The champion can lead and take the FLS from an idea to implementation.
To support the establishment and implementation of FLS the NOS has developed the FLS Implementation Toolkit as well as the Clinical Standards for FLS. The Clinical Standards will shortly be supported with a supplementation - New Clinical Guidance on the identification of Vertebral Fractures.
Furthermore, the Charity has developed the Fracture Prevention Practitioner (FPP) training for those wishing to implement an FLS. This is backed by the Competency Framework for Nurses, allied health professional and doctors to ensure best practice in fracture prevention.
Conclusion: The NOS service development model of support is successful in driving the establishment, implementation and improvement of FLS across the UK. This is tough in an economic climate where health budgets are constrained. However, there is strong evidence that investment in FLS improves the quality of care as well as illustrating financial savings in health and social care. NHS England recommends that every patient with/or at risk of osteoporosis and fragility fractures should have access to a commissioned service.

SP0119 PREDICTING FRACTURE RISK: ACCURACY AND FEASIBILITY OF TOOLS

A.A. Marques. *Rheumatology, Centro Hospitalar e Universitario de Coimbra, Coimbra, Portugal*

Several therapeutic options and screening strategies are available to effectively decrease fracture risk. However the main clinical challenge still consists in accurately identifying and selecting individuals for bone densitometry and for pharmacological treatment, in order to increase efficiency and minimize individual and societal costs.
The World Health Organization provided an operational definition of osteoporosis as a bone mineral density (BMD) that lies 2.5 or more standard deviations below the average value for young healthy women of the same gender and ethnical background [T-score $\leq$-2.5]. However, BMD has limited sensitivity and specificity in the prediction of fracture. In fact, a large number of conditions have been firmly established as risk factors for the occurrence of fragility fractures, independently from BMD. These have been combined into prediction algorithms to estimate fracture probability and are currently available for calculate the risk of fractures. However, the existing tools differ in many relevant aspects: from their own feasibility, to the number and availability of clinical risk factors included, the accessibility of BMD measurements and, finally, their performance in different settings.
With this session we aim to identify and synthesize the best available evidence on the accuracy and feasibility of the currently available tools designed to predict fracture risk.

SP0120 PREDICTING THE RISK OF FALLS AND PROMOTING BALANCE IN OLDER ADULTS

D. Rose. *Kinesiology, California State University, Fullerton, Fullerton, United States*

Falls are the leading cause of injury and death due to injury among the older adult population in the United States. Of those who fall, 24% will sustain serious injuries and 6% will experience fractures. In addition to injury, older adults who fall may experience decreased functional ability, loss of independence, a poorer quality of life, or premature mortality. At a global level, these statistics are similar among developed countries. It is important to first identify the intrinsic and extrinsic risk factors that contribute to falls and then intervene appropriately once the level of fall risk has been identified. It is important to understand that there is no one size suits all fall risk reduction program and that the type of program will vary as a function of the level of risk. Core components of successful fall risk reduction programs include exercise, environmental modifications, and behavior change techniques aimed at fostering long-term adherence to engaging in fall risk reducing behaviors. The purpose of this presentation will be to describe appropriate methods for identifying fall risk, and intervention strategies that have been shown to significantly reduce fall risk and/or fall incidence rates across the continuum of fall risk.

Biological agents in juvenile idiopathic arthritis: open issues

SP0121 LONG TERM SIDE EFFECTS OF BIOLOGICAL AGENTS IN JIA

J.F. Swart on behalf of Pharmachild and Foreum (Comorbidity in JIA). *Pediatric Rheumatology, UMC Utrecht, Utrecht, Netherlands*

In the last years, the interest in the concept of comorbidity and its societal as well as individual impact has increased. Juvenile idiopathic arthritis (JIA) is a chronic inflammatory disease starting in childhood which often persists into adulthood. Clinicians are facing an aging population with multiple morbid conditions occurring in one individual. Long term outcome studies show the high prevalence and the potential interaction of coexisting diseases. For JIA recent studies reported that uveitis, asthma/atopic diseases and diabetes mellitus are prevalent comorbidities in JIA with 11.6–30%, 10.8% and 3.5% respectively, followed by cardiovascular disease, malignancies and inflammatory bowel diseases. Childhood long term outcome studies and Pharmacovigilance registries already revealed associations of co-existing diseases and the role of used medication (especially biologicals). It is important to plan preventive and screening strategies in order to prevent or early detect and treat comorbidities and integrated follow up once comorbidity exists.

SP0122 **AUTOIMMUNE PHENOMENA ASSOCIATED WITH BIOLOGICAL AGENTS**

P. Quartier[1,2]. [1]*Pediatric Immunology-Hematology and Rheumatology Unit, Necker-Enfants Malades Hospital;* [2]*IMAGINE Institute, Paris-Descartes University, Paris, France*

Biologic agents are being increasingly used in pediatric rheumatology, particularly TNF antagonists but also abatacept, tocilizumab, interleukin (IL)-1 antagonists and some other drugs. In Juvenile Idiopathic Arthritis (JIA) and some autoinflammatory diseases, data from phase 3 and extension trials or from cohorts such as Pharmachild allow to prospectively collect information on adverse events "of special interest", including autoimmune complications. A few patients develop autoimmune/dysimmune features while on biologics, as seen in adults, including central nervous system lesions, inflammatory bowel disease or psoriasis. In addition, in patients with systemic-onset JIA, anti- IL-1 treatment is usually associated with the appearance of a type 1 interferon signature (gene expression analyses) which might in some cases favour lupus-like autoimmune features.
On the other hand, among patients with early-onset arthritis, vasculitis, recurrent fever or other inflammatory manifestations, an increased number of children are diagnosed with complex monogenic diseases resulting in auto-inflammation, immune deficiency and autoimmunity. In such cases, biologics might not be responsible for the occurrence of autoimmune features that may sometimes be diagnosed on treatment. This distinction is important as biologics are useful treatments also in some of these patients, as was shown in patients with a diagnosis of Systemic-onset JIA and ANCA-associated glomerulonephritis in whom anti-IL-1 treatment was beneficial. It was also more recently shown in patients with *lipopolysaccharide-responsive beige-like anchor* (*LRBA)* mutations associated with autoimmunity and inflammation, including polyarthritis: as LRBA is a partner of cytotoxic-T lymphocyte antigen-4 (CTLA4),. abatacept has been used as a targeted treatment and shown efficacy.
We hence aim to discuss the way to explore patients who develop autoimmune features while on biologics in order to take the right decisions regarding treatment maintenance, withdrawal or modification and regarding patients follow-up.

Health equity and economy - a vital relationship

SP0123 **UNCOVERING THE EQUITY GAP IN RHEUMATIC AND MUSCULOSKELETAL DISEASES**

P. Putrik. *Rheumatology, Maastricht University Medical Center (MUMC), Maastricht, Netherlands*

The aim of this lecture is to discuss the current evidence on the socio-economic inequities in disease outcomes in RMDs. Socio-economic determinants at the individual and country level will be considered, as well as the interplay between these factors. In particular, attention will be given to the role of different socio-economic factors in the access to biologic DMARDs in rheumatoid arthritis.
Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.7164

SP0124 **HEALTH ECONOMICS AND HEALTH EQUITY: TWO COMPLEMENTARY DISCIPLINES**

B. Fautrel[1,2,3]. [1]*Rheumatology, APHP - CHU Pitié Salpétrière;* [2]*Rheumatology, UPMC - Pierre and Marie Curie University;* [3]*CRI-IMIDIATE Clinical Research Network, FCRIN Clinical Research Infrastructure Networks, Paris, France*

Health equity in the one hand refers to the absence of systematic disparities in health between different social groups in a given Society, a province, a country or a group of country. Health inequity thus corresponds to a situation in which health services are not similarly available to all people with the same health conditions and health needs, due to individual personal or socioeconomic characteristics.
Health economics in the other hand focuses on how to allocate health budgets in order to maximize the general health of the population as a whole. With regards to this, no specific attention is dedicated to socially disadvantaged subgroups. In addition, the most visible action in the field of health economics was the valorization of therapeutic innovation, i.e., the determination of its price not on production costs but on the value associated with this innovation.
Economic evaluation – i.e., determination of incremental cost-effectiveness ration – has lead during the last 20 years to substantial financial pressure on health care systems with dramatic increase in health expenditures mainly due to the costs of therapeutic innovation. Several studies have shown that such a process may increase health inequities within a country or a group of countries if specific actions are not taken to maintain or improve treatment availability and access to care to all the population members whatever their social, educational and economic characteristics.

Biomarkers in cardiovascular rheumatology - state-of-the-art 2017

SP0125 **INFLAMMATION AND CARDIOVASCULAR DISEASE – RELEVANT METABOLIC BIOMARKERS**

E. Choy. *Section of Rheumatology, Cardiff University, Cardiff, United Kingdom*

Patients with RA have increased mortality compared with the general population mostly due to higher cardiovascular disease (CVD), which is up to 50% more frequent [1]. Even after adjusting for traditional cardiovascular risk factors such as smoking, diabetes and hypertension, the risk for CVD is increased by up to twofold compared with the normal population [2]. Whilst traditional cardiovascular risk factors, contribute to the increased risk of mortality in RA patients, they do not fully explain increase in cardiovascular risk [3,4]. European League Against Rheumatism (EULAR) recommend regular assessment of cardiovascular risk in patients with RA [5]. Since traditional cardiovascular risk factor assessment equations, such as Framingham and the Systematic Coronary Risk Evaluation Score (SCORE) models, underestimate cardiovascular risk in RA, EULAR recommends multiplying such traditional cardiovascular risk scores by 1.5 for patients with RA. Such adjustment operates at the population level. Ideally, cardiovascular biomarkers that can predict future cardiovascular event in the individual patient will improve screening and management.
Biomarkers of cardiovascular disease can be divided into five major categories: lipids, inflammation, endocrine, vascular and prothrombotic [7]. HDL and LDL are used in routine clinical practice. However, they do not predict future cardiovascular events in patients with RA as the levels of HDL and LDL are suppressed during inflammation [8]. The ratio of HDL/LDL or total cholesterol/HDL is less affected by inflammation. Other lipid biomarkers include apolipoprotein A-1, apolipoprotein B, cholesterol ester transfer protein lipoprotein-associated phospholipase A2, small-dense LDL and paraxonase-1. They have been measured in patients with RA but their precise value in predicting cardiovascular risk in RA has not been determined.
High level of inflammation as measured by ESR and CRP is associated with increased cardiovascular risk in patients with RA. EULAR recommended adequate suppression of inflammation as a key strategy to reduce cardiovascular events [5]. Disease flares increased cumulative cardiovascular risk [9]. Many inflammatory mediators are elevated in RA, whether they can add to traditional cardiovascular risk score to improve individual risk prediction should be evaluated.
The vascular biomarker of cardiovascular disease, VCAM-1, has also been shown to elevated in patients with RA. High level of VCAM-1 was associated with high cardiovascular risk score[ix].
Metabolic syndrome is common in patients with inflammatory arthritis. Insulin resistance is a feature of metabolic syndrome. Fibrinogen and other prothrombotic molecules are part of the acute phase response, their levels are elevated in RA. Neither endocrine nor prothrombotic factors have been studied systematically in RA.

SP0126 **THE VESSEL WALL IN IMIDS – NEW EMERGING VASCULAR MARKERS**

Z. Szekanecz. *Department of Rheumatology, University of Debrecen, Faculty of Medicine, Debrecen, Hungary*

Cardiovascular disease dependent on inflammatory accelerated atherosclerosis

leads to increased mortality in rheumatoid arthritis (RA). In addition to traditional, Framingham risk factors, several immuno-inflammatory cells, mediators and molecules may link atherosclerosis to arthritis. Among immune cells, primarily TH1 cells, as well as endothelial cells play a crucial role in synovial and vascular inflammation. Various cell surface molecules, such as adhesion receptors, CD40-CD40 ligand or members of the RANK-RANK ligand-osteoprotegerin system, as well as soluble pro-inflammatory cytokines, chemokines, autoantibodies and proteases have been implicated in RA and vascular damage. The early assessment of atherosclerosis and early intervention would decrease cardiovascular risk in RA.

SP0127 TAPERING BIOLOGICS INDUCES A PROTHROMBOTIC STATE IN RHEUMATOID ARTHRITIS?

M.T. Nurmohamed on behalf of M. Heslinga, J. Meijers & M. Nurmohamed. *Rheumatology, Amsterdam Rheumatology immunology Center | VUmc & Reade, Amsterdam, Netherlands*

In addition to the "traditional" risk factors for venous trombo-embolism (VTE), like age, trauma and immobilisation, inflammation could also be regarded a risk factor for VTE. For example, patients with acute inflammatory conditions (sepsis), but also patients with chronic inflammation, like inflammatory bowel disease (IBD) and rheumatoid arthritis (RA), have an increased risk of thrombosis.

Inflammation can lead to activation of coagulation, and vice-versa, coagulation also has considerable effects on overall inflammatory activity. First, the inflammatory cytokine network induces several pro-thrombotic conditions including insulin resistance, dyslipidaemia, endothelial dysfunction and alteration of coagulation and fibrinolysis. Second, activation of the extrinsic coagulation system and impairment of the fibrinolytic pathway may contribute to amplify and perpetuate the inflammatory response. Previous studies have reported several blood parameters that reflect a prothrombotic state in RA. These include increased levels of thrombin-antithrombin complex, prothrombin fragment F1+2, von Willebrand factor, plasmin-alpha2-antiplasmin complex and D-dimer, as well as an increased platelet count. Impaired fibrinolysis combined with increased antithrombin levels have also been reported in RA. An important mediator in the inflammatory pathway is tumor necrosis factor-α (TNF-α). In the general population, TNF-α induces a disbalance between clotting and fibrinolysis, resulting in a hypercoagulable state. Since TNF-α is the key player in RA, RA is an ideal "human model" to study the interplay between inflammation and coagulation. Hence, RA can be considered as a pro-thrombotic state, which explains partly why patients with RA are at increased risk of thrombo-embolic cardiovascular events.(1)

Only one small study suggested that TNF-inhibitors (TNFi) is accompanied with normalization of thrombotic biomarkers: an improvement of clinical and laboratory parameters as well as a reduction in the activation of coagulation and endothelial dysfunction was found in RA patients treated with a TNFi. In addition, we previously demonstrated that combination therapy with corticosteroids improves the procoagulant state that exists in early RA. (2)

Nowadays, tapering of biological therapies is becoming more and more standard of care. However, the effects on the coagulation status in RA are unknown. In light of the growing evidence of an increased cardiovascular morbidity and mortality in RA, mostly independent of traditional risk factors, treatment strategies in RA should not only aim at relieving symptoms and inhibiting joint destruction but should have a beneficial effect on the vasculature and haemostasis to reduce cardiovascular events. Although modest, there is evidence suggesting a beneficial effect of TNFi on the haemostatic status in RA. Unfavourable changes in haemostatic markers, such as TAT, F1+2, vWF, PAP, D-dimer and thrombin generation, which indicate a pro-thrombotic state, may therefore (re)occur when RA patients stop with TNFi treatment. We first assessed arterial wall inflammation with 18F-FDG PET scans in RA patients in remission under TNFi therapy or DMARD therapy versus controls. The FDG uptake in the aorta in DMARD remission patients was similar to the controls, whereas the uptake in RA patients in remission under antiTNF was significantly higher than in controls either when looking at the overall aortic uptake or the most diseased segment. Theoretically, stopping TNF blockade in these patients might lead to increased inflammation and thus coagulation activation. Therefore, we are presently investigating it and to what extent tapering/stopping TNFi therapy induces a pro-thrombotic state in RA patients.

FRIDAY, 16 JUNE 2017

MRI I & II

SP0128 MRI OF ENTHESITIS – BY CONVENTIONAL AND WHOLE-BODY MRI - INCLUDING QUIZ CASES

I. Eshed[1,2]. *[1]Diagnostic Imaging, Tel Aviv University, Tel Aviv; [2]Diagnostic Imaging, Sheba Medical Center, Ramat Gan, Israel*

Entheses are sites of attachment of tendons, ligaments, fascia, or capsule into bone, providing a mechanism for reducing stress at the bony interface. Entheses dissipate biomechanical stress and, in doing so, are thought to be subjected to repeated micro traumas.

Inflammation of the entheses, enthesitis, is a well-known hallmark of spondyloarthritis (SpA), playing a central role in disease pathogenesis. It can also be associated with degenerative, endocrinologic, metabolic and traumatic conditions. Magnetic resonance imaging (MRI) is a sensitive tool for the detection of early signs of enthesitis in patients with SpA. The MRI features of enthesitis are well described, and include thickened enthesis with altered signal intensity and perientheseal soft tissue edema. Bone marrow edema and erosions at the adjacent bone appear mainly in SpA-associated enthesitis. Contrast material administration improves the reliability, sensitivity and specificity of detecting enthesitis on an MRI.

Whole-body (WB) MRI allows assessment of all peripheral and axial joints and entheses from "head-to-toe" in one examination. The promising role of WBMRI in the evaluation of enthesitis in SpA and other rheumatic diseases was evaluated in several cross sectional and prospective studies. Indeed WB MRI was shown to be sensitive in the detection of inflammatory lesions, including enthesitis, on multiple sites, potentially serving as a one stop shop for the estimate of active disease load.

In the current presentation, the typical imaging properties of enthesitis on conventional and WB-MRI will be presented along with several challenging quiz cases.

SP0129 CLASSIFICATION, DIAGNOSIS AND DIFFERENTIAL DIAGNOSIS OF AXIAL SPONDYLOARTHRITIS BY MRI - INCLUDING QUIZ CASES

M. Østergaard. *Copenhagen Center for Arthritis Research, Copenhagen University Hospital Rigshospitalet, Glostrup, Denmark*

Magnetic resonance imaging (MRI) is essential in the process of diagnosis of axial spondyloarthritis (axSpA) in clinical practice, as described in recent EULAR recommendations (1). However, several important differential diagnoses need to be considered. MRI is also key in the Assessment in SpondyloArthritis International Society (ASAS) classification criteria for axSpA (2), for which a consensus definition of a positive MRI was made in 2009 (3). The ASAS MRI working group has recently provided an updated definition of what is needed to fulfill the MRI-criterion in the ASAS criteria (4), based on a consensus excercise. This talk will describe the evidence behind the use of MRI for diagnosis of axSpA, describe the current ASAS consensus on how to use MRI for classification of axSpA, and examples of the most important differential diagnoses will be shown. The presentation will include patient cases for audience review.

WIN & HOT session

SP0130 WIN SESSION: OSTEOPOROSIS

P. Geusens. *Rheumatology, MaastrichtUMC and UHasselt, Genk, Belgium*

The clinical pathway for fracture prevention consists of a 5-step approach: case finding, risk evaluation, differential diagnosis, treatment and follow up. For each of these steps new insights have emerged during the last year.

Epidemiologic studies have shown that not only fracture risk, but also mortality is increased after fracture, and that adequate therapy can not only decrease fracture risk but also increase survival.
Fracture risk is not constant over time. It is highest the years following a fracture, and immediately increases in some instances, such as after starting glucocorticoids or androgen deprivation therapy. This has raised the concept of "imminent" fracture risk, in contrast to long-term fracture risk as included in FRAX. In this context, we present the the EULAR initiative, in collaboration with EFORT, that published recommendations for multidisciplinary acute fracture care, including orthogeriatric care after hip fracture, and subsequent fracture prevention at the Fracture Liaison Service.
The presence, number and severity of vertebral fractures contribute to fracture risk, independent of BMD. Most vertebral fractures are subclinical and can therefore only be diagnosed by imaging of the spine. The role of vertebral fracture assessment (VFA) using DXA will be discussed.
New treatment insights will be reviewed, including for glucocorticoid users, combined and sequential treatments with anti-resorptive and bone forming drugs, real world data and the role of fall prevention.
Prescription of and adherence to treatment are still major issues. In patients adherent to therapy, new insights and recommendations will be reviewed on the need for early treatment, duration of treatment and the clinical approach when considering stopping drug therapy.

What is behind vasculitis?

SP0131 AUTOIMMUNE ATHEROSCLEROSIS

Z. Szekanecz. *Department of Rheumatology, University of Debrecen, Faculty of Medicine, Debrecen, Hungary*

Arthritides have been associated with accelerated atherosclerosis to increased vascular disease risk. Traditional risk factors, as well as the role of systemic inflammation including cytokines, chamokines, proteases, autoantibodies, adhesion receptors and others have been implicated in the development of these vascular diseases. Accelerated atherosclerosis and increased cardio- and cerebrovascular morbidity and mortality have been observed in rheumatoid arthritis (RA) and spondyloarthropathies (SpA).
Endothelial dysfunction, overt atherosclerosis and vascular stiffness may be indicated by brachial artery flow-mediated vasodilation (FMD), common carotid intima-media thickness (ccIMT) and aortic pulse-wave velocity (PWV), respectively. These abnormalities have been described in most inflammatory rheumatic diseases. While ccIMT and stiffness are relatively stable, FMD may be influenced by many confounding factors.
In addition to traditional vasculoprotection, immunosuppressive agents including corticosteroids, traditional and biologic DMARDs may have significant vascular and metabolic effects. The official EULAR recommendations on the assessment and management of cardiovascular disease in arthritides have been published.

SP0132 VIRUSES DRIVING VASCULITIS

L. Calabrese. *Rheumatology, Cleveland Clinic, Cleveland, United States*

Viruses have long been associated with varying forms of vasculitis in both pre-clinical models and human diseases. Immunopathogenic mechanisms have varied and include direct vascular invasion, immune complex mediated and more recently novel mechanisms which include autoinflammatory like responses. This discussion will review major advances in the field of medical virology as it applies to rheumatic diseases, especially vascular inflammatory disease, including an introduction to the human and more specifically vascular microviromes. Major forms of virally mediated vasculitis will be discussed with an emphasis on new viral vasculitis syndromes largely defined by next generation sequencing and their potential clinical impact.

SP0133 ANCA AND THEIR ENVIRONMENT

R.A. Luqmani. *University of Oxford, Oxford, United Kingdom*

The association between antibodies to neutrophil cytoplasm (ANCA) and systemic vasculitis has transformed our understanding of granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA). ANCA undoubtedly play a major role in their pathogenesis. There are different forms of ANCA, but only two of direct clinical relevance: cytoplasmic c-ANCA (usually directed against proteinase 3, PR3), and perinuclear p-ANCA (usually directed against myeloperoxidase, MPO). P-ANCA can also be directed against other antigens including bactericidal/permeability-increasing protein, lactoferrin, human neutrophil elastase, cathepsin G and azurocidin, but their clinical significance is not clear.
Transfer of MPO ANCA in humans (maternal-foetal route) and animal models (necrotizing pauci-immune glomerulonephritis after passive transfer of purified antibody or splenocytes from MPO-deficient mice immunized with murine MPO) has resulted in features of MPA. By contrast, the pathogenicity of anti-PR3 antibodies is less well-established. There is a significant genetic predisposition to disease in patients with AAV. Patients with PR3-ANCA have a strong association with HLA-DP and genes encoding alpha-1-antitrypsin and proteinase 3; by contrast, patients with MPO-ANCA have an association with HLA-DQ. Other factors that could interact with ANCA include: loss of B cell and T cell tolerance; direct involvement by neutrophils and their mediators in vascular injury and damage, degranulation and cytokine production; environmental exposure to silica or certain strains of Staphylococcus aureus, coupled with a lack of effective T cell regulation to prevent inflammation. Neutrophils spontaneously release of neutrophil extracellular traps (NETS), which directly cause endothelial cell damage and complement activation. NETS retain proteinase 3 and myeloperoxidase, helping to break immune tolerance and inducing antibody formation. The alternative complement pathway plays a crucial role in the pathogenesis of AAV. Activated neutrophils produce C5a, which in addition to recruitment, primes additional neutrophils for further activation by ANCA. C3a, C5a, soluble C5b-9 are elevated in active disease and plasma levels of complement factor H, a regulator of the alternative complement pathway is significantly lower in patients with active AAV.
Central to the pathogenesis of AAV is a dysregulated immune response to ANCA and aberrant expression of their target autoantigens, MPO and PR3. Environmental exposure to silica may inactivates α1-antitrypsin, whilst activating monocytes and macrophages releasing cytokines such as interleukin-1 and TNF-α, oxygen radicals and lysosomal enzymes (such as PR3 and MPO). Other environmental interactions include CpG-ODN, a short synthetic DNA containing unmethylated CpG and several drugs, especially propylthiouracil and levamisole-adulterated cocaine. Some of these associations could provide a better insight into the development of ANCA associated disease.
ANCA play a central role in the pathogenesis of systemic vasculitis, supported by a dysregulated immune system, with significant interactions with micro-organisms, environmental toxins and drugs, all of which can contribute to the development and severity of disease.

Cytokine taxonomy: reflection in the therapy of arthritides and other IMIDs

SP0134 INTERLEUKIN-2 THERAPY IN SLE

J.Y. Humrich. *Department of Rheumatology and Clinical Immunology, University Hospital Schleswig-Holstein, Campus Lübeck, Lübeck, Germany*

There is an unmet need for more effective and selective therapeutics in severe autoimmune diseases such as systemic lupus erythematosus (SLE). A deeper understanding of the pathogenic mechanisms in the past has led to the clinical translation of low-dose interleukin-2 (IL-2) therapy which primarily aims to restore the activity of regulatory T cells. First results from phase I/II studies are promising by proving the selective expansion of regulatory T cells *in vivo* and by providing first evidence for the clinical efficacy of low-dose IL-2 therapy in SLE. Here we will summarize key findings which led to the development of this novel therapeutic concept and will highlight the main rationales for the clinical translation of low-dose IL-2 therapy in SLE.

Regulatory molecules in connective tissue

SP0135 MYOSTATIN, SCLEROSTIN, SYNDECAN AND MORE

T. Pap. *Institute of Experimental Musculoskeletal Medicine (IEMM), University Münster, Münster, Germany*

Rheumatoid arthritis (RA) is the prototype of an inflammatory arthritis that is characterized by chronic inflammation, progressive cartilage destruction and bone erosion. Development of RA is marked by the hyperplasia of the synovial membrane as caused by an infiltration and accumulation of inflammatory cells such as macrophages and lymphocytes as well as an increase in the number of resident mesenchymal cells. These fibroblast-like synoviocytes (FLS) are a key part of the local immune system in the joints and integrate signals

form different sources into a pathological tissue response. Resorption of the juxtaarticular bone is part of this pathological tissue response and is denoted as focal bone erosion which occurs early in this disease and over time is associated with significant morbidity. Focal bone erosions are observed at the interface of pannus and bone tissue both marginally, where pannus invades cortical bone, and in the immediate subchondral bone, where the pannus invades the marrow space. Many of the cytokines and growth factors implicated in the inflammatory processes are secreted by FLS and have also been demonstrated to impact directly or indirectly on osteoblast and/or osteoclast differentiation and function. However, research of the last years has also identified some novel pathways by which i) osteoclast- mediated bone resorption is regulated and fine-tuned under inflammatory conditions such as in RA and that ii) link inflammatory bone resorption to other features of systemic autoimmunity such as the activation of developmental pathways or muscle weakness. This lecture will review some of these novel mediators and pathways, including members of the Wnt- signalling pathway (e.g. sclerostin), members of the GDF- family of growth differentiation factors (e.g. myostatin) and cells surface anchored proteoglycans (e.g., syndecans). Focusing on the role of these molecules in the FLS-mediated regulation of osteoclastic bone resorption, the lecture will point to general principles of inflammatory bone remodelling and discuss potential therapeutic implications for RA.

SP0136 MULTIFACTORIAL TISSUE GROWTH FACTORS

C.P. Denton. *Centre for Rheumatology, Royal Free Hospital and Ucl Medical School, London, United Kingdom*

Connective tissue is a critical component of all organs and has special importance in the musculoskeletal system. In specialist tissues, such as bone, cartilage of muscle an in vascular structures and internal organs there is a mixture of less specialized connective tissue together with the specific tissue and organ specific cellular components. In addition to physiological function there are two other areas in which it plays a central role. Normal embryonic an postnatal growth and development, and tissue repair in response to injury. It has emerged that there are shared pathways, mediators and mechanisms in these different processes and that multifactorial tissue growth factors have an important role. In this way, these proteins can have a profound influence on multiple cell types and provide a mechanistic link in many complex chronic diseases. It is notable that pathways that are perturbed in one chronic disease, such as atherosclerosis or osteoarthritis may be similarly disrupted in different context in conditions such as lung fibrosis or scleroderma. Transforming growth factor beta family members are prototypic examples of this class of protein. This included TGFbeta isoforms but also the related bone morphogenetic (BMP) and activin family of proteins. They share chemical structure and an ability to regulate multiple cell types in a context specific way. In addition, there is remarkable complexity in their regulation with intrinsic inhibitory mechanisms to protect from inappropriate biological activity. Their role in repair means that activation of preformed protein may regulate biological effects. Proteins regulated by the TGFbeta family, such as the CCN family of matricellular proteins and some for the cardinal growth factors and cytokines share properties. There is functional and signaling redundancy and cross talk. Conceptually it is interesting to envisage dysfunctional networks of cytokines in disease that may be attenuated by extracellular blocking or antagonism. Insights for many areas of developmental biology and pathology have informed about this challenging area of molecular medicine.

SP0137 FROM GLYCOSYLATION TO INFLAMMATION

M. Herrmann. *University Hospital Erlangen, Erlangen, Germany*

One of the best studied posttranslational modification of immunoglobulin G (IgG) is the addition of a complex glycan to asparagine 297, which is required for IgG to bind to Fc-receptors and for the activation of complement via the classical activation pathway. In the absence of the glycan the IgG usually behave like a lame duck unable to execute its effector functions. The sugar tree is polymorphic and there are several functional consequences related to the glycan. The terminal sialylation, the presence of galactose, the core fucosylalation and the insertion of a bisecting third sugar chain all reportedly modify the biological and functional activities of IgG.

As examples for the impact of Asp-297 associated glycans to the activity I will present (I) the sialylation of anti-histon autoantibodies in patients with systemic lupus erythematosus (II) the exposure of sugar epitopes by random IgG isolated from patients with rheumatoid arthritis (III) the molecular analysis of the glycan of random IgG isolated from patients with inflammatory diseases and controls and (IV) and finally the glycosylation of IgG-anti-phospholipid autoantibodies in healthy children.

(I) The autoantibodies are mainly found in the non-sialyated fraction of the anti-histon autoantibodies which can be considered inflammatory IgG.

(II) The circulating random IgG from patients with rheumatoid arthritis show an increased exposure of the Asp-297 associated glycans.

(III) The molecular analysis of the glycan of random IgG isolated from patients with systemic lupus erythematosus, rheumatoid arthritis, sepsis showed disease-specific glycans.

(IV) The non-pathogenic IgG-anti-phospholipid autoantibodies isolated from healthy children displayed an increased sialylation when compared to the pathogenic autoantibodies from adults with anti-phospholipid syndrome.

The examples point to a strong impact of IgG glycosylation in the etiopathogenesis of chronic inflammatory rheumatic diseases. One should consider to include IgG glycan analyses into the diagnostic repertoire for autoantibodies.

Patient engagement in research: best practices, benefits, and challenges

SP0138 THE CHALLENGES OF PATIENT INVOLVEMENT IN SCIENTIFIC RESEARCH. HOW TO ACHIEVE TRUE REPRESENTATION OF THE PATIENTS' VOICE?

M. De Wit on behalf of the EULAR Working group for Collaborative Research. *Dept. Medical Humanities, EMGO+ research institute, VU University Medical Centre, Amsterdam, Netherlands*

There is a strong call in the western world for collaborative research. Rheumatology is one of the disciplines that has explored best practices and paved the way to implement lessons learned. Although good methodologies for evaluating the impact of patient participation stay behind, we have been able to develop expert-based recommendations for collaboration. They are helpful for both researchers and patient representatives, but they do not address all concerns that occur in daily practice. In this lecture current challenges of integrating the perspectives of patients in clinical research will be discussed: 1. Defining the role and complementary value of patient research partners; How can patients in the role of collaborative partner contribute to research in addition to the data that patients provide as respondent or study participant? 2. Facilitating and guiding researchers in collaborative research; We have experience in preparing and educating patient representatives for their role in research, but how should researchers be trained and supported? 3. Preserving the patients' voice throughout the research process; Qualitative research may elicit patients' experiences with health care or health interventions, but what is needed to guarantee that these findings are not lost in the rigorous process of producing scientific knowledge? 4. Demonstrating impact of collaborative research to funders and the public; Despite many case studies reporting a great variety of patient participation methods, there are no clinical trials nor consensus on a validated methodology for assessing the outcomes of patient involvement in research.

For each challenge we will try to propose a way forward. These challenges will also be discussed at the newly established EULAR working group for collaborative research.

SP0139 MEANINGFUL PATIENT AND PUBLIC INVOLVEMENT IN PLANNING RESEARCH

A. Redmond. *Leeds Institute for Rheumatic and Musculoskeletal medicine, University of Leeds, Leeds, United Kingdom*

Historically, services providing care for people with long term conditions (LTCs), together with any associated research agendas, have been driven entirely by clinicians. In many cases this is well meaning and is done with some consideration of what patients need, but almost always the end result relies on the clinicians' interpretation of what *they* think patients need.

Recently it has become more usual to involve patents in planning research projects and service changes directly. Initial attempts to give patients genuine input were *ad hoc* in nature and so patient contributions could be lacking, ignored or misinterpreted.

In many cases having poor patient input is worse than no input at all as it lends false credibility to the process. Lately a range of formal requirements, arrangements and methods have become adopted and this presentation will focus on how these can be brought to bear to ensure meaningful patient and public involvement in planning research. From national guidance such as the UK's INVOLVE initiative, to local standard operating procedures we will share experiences and lessons learned.

The session will close with a practical summary of how to make PPI contributions genuine and meaningful, and some insights into possible future developments as this aspect of the research process matures and consolidates.

SP0140 **PATIENT ENGAGEMENT IN RESEARCH: A PCORI EXEMPLAR**

J. Poole. *Occupational Therapy Program, University of New Mexico, Albuquerque, United States*

This session will discuss patient and stakeholder involvement as members of the research team on a grant funded by the Patient Centered Outcomes Research Institute (PCORI). Patients with a rare chronic disease, systemic sclerosis, and members from key stakeholder organizations were involved in evaluating, revising and testing the effectiveness of an internet self-management program. They participated at several levels of engagement including planning the study, conducting the study, and disseminating the results. This session will discuss how engagement occurred at each of these levels through different opportunities such as creating interventions, identifying outcomes, recruiting, presenting findings, and planning dissemination efforts. The benefits and challenges for both researchers and patient research partners will also be described.

RA treatment in patients wanting to become pregnant - interactive session

SP0141 **NEW RA, BUT WHAT ABOUT A NEW BABY?**

A. Willemze. *Rheumatology, LUMC, Leiden, Netherlands*

Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease affecting women often in their childbearing years. In this case presentation a 35 year old female patient is illustrated with a recently diagnosed rheumatoid arthritis with active disease and a wish to conceive in the nearby future. Management of disease activity in patients who wish to conceive or during pregnancy might be a challenge due to limited treatment options. How should we treat this patient taking into account her wish to conceive in the nearby future? Should the patient postpone her wish to conceive because of active disease?

SP0142 **FOREPLAY AND FINALE: FACTORS AFFECTING FERTILITY, BIRTH AND LACTATION IN RHEUMATOID ARTHRITIS PATIENTS. CLINICAL CASE**

P. Nero. *Rheumatology, Hospital CUF Descobertas, Lisboa, Portugal*

We present the clinical case of a 38 year old woman diagnosed with rheumatoid arthritis at the age of 32. She went into remission of her disease during treatment with subcutaneous methotrexate (25 mg/week) for 2 years. She decided to become pregnant and stoped treatment. RA relapses 4 months later and she has no response to classic DMARD's (sulphassalazine and hydroxychloroquine) and starts etanercept (50mg/week). She gets pregnant and achieves remission at week 16 of her pregnancy. At week 36 she is still in remission and stops etanercept. 2 months after giving birth the disease relapses but she wants to breastfeed and would like to restart etanercept. We agreed and 3 months after restarting anti-TNF RA is again in remission. In January 2017 her RA is inremission for 15 months and keeps her medication with etanercept every other week because she plans another pregnancy.

Latest advances in the treatment and management of psoriatic arthritis and the latest news on the use of Biosimilars in RMDs

SP0143 **A NEW DAY FOR PEOPLE WITH PSORIATIC ARTHRITIS: A HETEROGENEOUS DISEASE THAT CAN BE TREATED WELL?**

L.C. Coates. *Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom*

This talk will summarise recent advances in research around the treatment of psoriatic arthritis (PsA). Firstly there will be an update on research that shows the importance of treating patients promptly when they are diagnosed. Then results from studies of new therapies for both psoriasis and psoriatic arthritis will be shown to highlight the drugs that have recently become available in the clinic or are likely to be become available in the next few years. This will include new biologic disease modifying drugs with different targets including those that target interleukin 17 and interleukin 23 as well as new oral medications that are part of a family called small molecules. The role of these new therapies and how they compare to existing therapies in the clinic will be addressed. Finally there will be a summary on the research of how to use the existing and new therapies in the clinic including the use of the "treat to target" strategy.

SP0144 **BIOSIMILARS IN RHEUMATIC DISEASES: SOCIETY CHANCES VERSUS PATIENT CONCERNS**

A.A. Den Broeder. *Rheumatology, St. Maartenskliniek, Ubbergen, Netherlands*

Biosimilars are biologically but also in clinical practice for all intents and purposes identical to the original drug, as has been shown in blinded trials. But the perception amongst patients and sometimes physicians is one of possible inferiority, therefore they are often reluctant to transition to a biosimilar. However, although the listed prices of biosimilars and original products are the same, discounts are often higher for biosimilars, and widespread adoption of biosimilars drives the mean discount opt. So, society, hospitals, insurance companies and governments have preference for introduction of biosimilars to drive costs down.
Starting in new patients with a biosimilar is not controversial. Transitioning existing users from originator to biosimilar however is. This field has some interesting aspects, two of which will be elaborated on:
1/ balance of power, interests and ethics: different approaches are used by hospitals, insurance companies and governments to get biosimilars in use (collective buy e.g.). Big pharma are sometimes using campaigns to discredit biosimilars (create FUD, Fear Uncertainty and Doubt) towards patients and doctors, although some pharmaceutical companies are making original biologicals as well as biosimilars. Scientific societies of doctors have different recommendations, based on different beliefs towards biosimilars. In Most countries, Patients freedom of choice and right for best care are seen as paramount, but the other side of the coin might be that patients can be asked to adhere to a "social contract" to help in making healthcare financially sustainable for all.
2/ nocebo and attribution in open label transitioning: blinded research has shown that tansitioning to a biosimilar is not different with regard to safety and effect than continuing the original biological. However, in clinical practice a patient and physician knows that the patient has changed to a biosimilar. This may lead to nocebo effects (due to the perceived inferiority of the drug, experiences of subjective adverse effects and loss of efficacy are induced). In addition, adverse events of loss of efficacy that occurs independent of drug switch might be attributed to the biosimilar, called incorrect causal attribution. Both effects lead to more patient stopping a biosimilar after unblinded switch than in blinded studies. Prevention of nocebo and attribution in daily care is perhaps possible using a variety of techniques (e.g. restriction of fall back to originator, n=1 blinded provocation test, biobetter communication, patient incentive, patient/physician education), but this requires more research.
In summary, the use of biosimilars is a chance for society to maintain healthcare affordable, but it represents a challenge to maximise this potential.

From pre-RA to established RA

SP0145 **PATHOPHYSIOLOGIC PROCESSES LEADING TO THE DEVELOPMENT OF AUTOIMMUNITY**

R. Toes. *Rheumatology, Leiden University Medical center, -Leiden, Netherlands*

Rheumatoid arthritis (RA) is a common complex disease characterized by chronic inflammation which results in joint destruction and significant disability in those affected. According to the World Health Organisation, within 10 years of onset, at least 50% of patients in western countries are unable to sustain a full-time job bringing about detrimental consequences to patients as well as exorbitant societal costs. The cause of RA remains unknown. Human genetic studies have provided valuable insight with over 100 genetic risk factors identified to date. Genetic variants at the human leucocyte antigen (HLA) locus remain the most prominent genetic risk factor. Smoking is the best known environmental factor to date. Microbial triggers have also long been postulated in RA although specific microbes involved in disease pathogenesis remain to be identified.
The majority of RA patients (60–70%) harbors autoantibodies, including Rheumatoid factors (RF) and autoantibodies against modified self-antigens, commonly termed Anti-Modified Protein Antibodies (AMPA). A prominent example of AMPA are Anti-Citrullinated Protein Antibodies (ACPA). ACPA are highly disease-specific biomarkers of important diagnostic and prognostic value, with ACPA-positive patients being at risk for rapidly progressive, destructive and systemic disease. The strongest genetic risk factors for RA, the so-called HLA-shared epitope (SE) alleles, associate only with ACPA-positive-disease, indicating that ACPA define a specific disease entity within the complex group of symptoms clinically defined as RA. Current concepts of RA pathogenesis hold that a sequence of events leads to the development of ACPA-positive disease. Environmental factors are thought to cause an initial break of tolerance leading to the generation

of ACPA. This initial development of auto-immunity appears to be independent of the disease-predisposing HLA-molecules. In most patients, this early event generates a polyclonal yet limited, mostly low-level autoantibody response that can be present for many years in the absence of clinical symptoms. Upon a putative second trigger, the ACPA epitope recognition repertoire broadens, more isotypes are being used, and ACPA serum levels rise. This is followed by precipitation of disease and is likely associated with the presence of the predisposing HLA-molecules. While the nature of this second trigger is presently unknown, the second event that initiates the broadening of the auto-immune response, in particular the citrulline-specific immune response, could mark a crucial moment upon which the auto-immune response becomes self-perpetuating and, potentially, irreversible.

Despite the many facets of ACPA revealed in the past two decades summarized above, it is not known how a breach of tolerance towards citrullinated proteins is mediated, or how ACPA-producing B-cells emerge.

Provision of T-cell help is crucial to convey the ability to B cells to modify the B cell receptor through somatic hypermutation. At present, it is unknown how ACPA- or other Anti-Modified Protein Antibody (AMPA)-producing B cells are "helped" by CD4+ Thelper cells, but it is often speculated that an auto-reactive T-cell response is crucial for their appearance. Our recent data show that such help could be provided by T-cells recognizing foreign proteins that have undergone a post-translational modification. In mice, AMPA-responses recognizing modified self-proteins are readily induced by immunization with modified proteins of non-selforigin. This is explained by the observation that the murine AMPA-response was, both at the monoclonal- and polyclonal level, highly cross-reactive towards multiple modified proteins, including proteins of self- and foreign origin. A similar observation was made analyzing the AMPA response in sera from RA patients. These data are important as the cross-reactive nature of AMPA could explain how autoreactive B-cell responses against PTM self-proteins can be induced by exposure to PTM foreign proteins thereby providing new insights on the breach of autoreactive B-cell tolerance.

Taken together, the analysis of the fine-specificity and recognition pattern of antibodies against modified proteins in RA during different phases of disease, together with detailed studies on the the identification, isolation and phenotypic characterization of auto-reactive B cells that express AMPA starts to shed light on the earliest phases of autoimmunity in RA.

SP0146 CAN WE PREDICT WHO IS GOING TO DEVELOP RHEUMATOID ARTHRITIS?

D. Van Der Woude. *Rheumatology, Leiden University Medical Center, Leiden, Netherlands*

To accurately predict disease development can be considered the "holy grail" of risk factor research. It holds the potential to employ preventive treatment thereby nipping RA in the bud.

This presentation will review familial risk in RA and the underlying genetic risk factors, as well as environmental risk factors for disease. Autoantibodies are a potent prognostic marker when it comes to the risk of developing RA, and play a key role in current pathophysiological hypotheses. The newest players in the autoantibody field, and latest concepts of how the various risk factors contribute to disease onset will be discussed.

SP0147 CAN WE PREVENT THE ONSET OF RHEUMATOID ARTHRITIS IN HIGH RISK INDIVIDUALS?

K.D. Deane. *Division of Rheumatology, University of Colorado Denver, Aurora, United States*

Multiple studies have demonstrated that rheumatoid arthritis (RA) related biomarkers can identify individuals without inflammatory arthritis who are at high-risk for the future development of clinically apparent synovitis and classified RA. These findings have led to the development of several prevention trials in RA that have either been completed, or are underway. With these exciting developments as background, this lecture will discuss multiple aspects of RA prevention including the role of biomarkers and other factors in developing robust prediction models for future RA, and methods to identify individuals before they develop RA. In addition, this lecture will discuss specific preventive approaches to RA such as clinical trial design and choice of preventive interventions that are based on our growing understanding of the mechanisms of RA development.

SP0148 PATHOPHYSIOLOGY OF ESTABLISHED RA SYNOVITIS

B. Lauwerys. *Department of Rheumatology, Université catolique de Louvain, Brussels, Belgium*

Access to synovial tissue through - minimally invasive - synovial biopsy procedures led to the implementation of new translational approaches to our understanding of established RA. In this lecture, we will illustrate how the identification of different synovial pathotypes and related molecular pathways translated into clinically relevant phenotypes, such as disease severity or response to therapy. Validation of these concepts in ongoing large-scale multi-centric trials will be key to the integration of synovial assessment tools in clinical practice.

Laboratory course - from the clinic to the lab and back II

SP0149 NEW TRENDS IN BIOMARKERS IN INFLAMMATORY JOINT DISEASES

E. Feist. *Rheumatology, Charite University Hospital, Berlin, Germany*

This lecture provides an overview on new developments in biomarker research and standardization in inflammatory joint diseases. The presentation includes an introduction of established and new biomarkers in serum and synovial fluid as well as methods for their detection. Furthermore, an overview on different modifications of auto-antigens (including citrullinated and carbamylated isoforms) and their role in immune response and pathogenesis of disease will be given. The diagnostic performance of new and established biomarkers will be discussed including antibodies against modified antigens also illustrated by difficult to diagnose cases. In this context, special attention will be attributed to the predictive value of biomarkers for diagnosis of disease and treatment response.

Switching T on and off: how T cells drive and regulate chronic inflammation

SP0150 TH17 CELLS DRIVE AND REGULATE TISSUE INFLAMMATION

V. Kuchroo on behalf of Basic and Translation Science. *Evergrande Center for Immunologic Diseases, Harvard Medical School, Boston, United States*

Recently a subset of interleukin (IL)-17-producing T cells (T_H17) distinct from T_H1 or T_H2 cells was described and shown to have a crucial role in the induction of autoimmune tissue injury. Accumulating data suggests that there are three distinct steps in Th17 differentiation: *Induction*, *Amplification* and *Stabilization* mediated by distinct cytokines. Whereas TGF-b + IL-6 or IL-1 + IL-6 induces them, IL-21 amplifies Th17 cells, IL-23 stabilizes the phenotype of Th17 cells. Loss of any of the cytokines (TGF-β, IL-1, IL-6, IL-21 or IL-23) in the pathway results in a defect in generation of Th17. However not all Th17 cells are pathogenic and induce autoimmunity, IL-23 is a key cytokine that induces pathogenicity in Th17 cells (Lee et al., 2012). Using expression profiling at very high temporal resolution, novel computational algorithms and innovative nano-wire based "knock-down" approaches, we have developed a regulatory network that governs the development of Th17 cells. In addition to high-density temporal microarray analysis, we have performed single-cell RNA-seq of Th17 cells in order to characterize cellular heterogeneity, identify subpopulations, functional states and learn how gene expression variation affects Th17 effector functions. We have identified novel regulators of Th17 cells both *in vivo* and *in vitro* that do not affect Th17 differentiation but affect pathogenic vs. non-pathogenic functional states of Th17 cells. Some of the regulators that make Th17 cells non-pathogenic are also utilized by CD8+ T cells to induce T cell "exhaustion" or "dysfunction". These novel inhibitory molecules cooperate with other known "check-point" co-inhibitory receptors to suppress anti-tumor immunity.

SP0151 SWITCHING OFF UNWANTED IMMUNE RESPONSES: THE MECHANISM OF ANTIGEN-SPECIFIC IMMUNOTHERAPY WITH T CELL EPITOPES

D.C. Wraith. *Institute of Immunology & Immunotherapy, University of Birmingham, Birmingham, United Kingdom*

Control of autoimmune and allergic conditions can be reinforced by tolerance induction with peptide epitopes; this presentation will focus on the mechanisms involved. Peptides must mimic naturally processed epitopes. Peptide induced peripheral tolerance is characterised by the generation of anergic, IL-10 secreting $CD4^+$ T-cells with regulatory function. $CD4^+$ T-cells become anergic following their first encounter with peptide. The loss of proliferative capacity correlates with a cytokine switch from a pro-inflammatory to a phenotype characterised by secretion

of the anti-inflammatory cytokine IL-10. IL-10 Treg/Tr1 cells suppress dendritic cell maturation, prevent Th cell differentiation and create a negative feedback loop for Th driven immune pathology. Tolerance induction involves upregulation of transcription factors controlling IL-10 and inhibitory receptors limiting T cell signalling. Results from clinical trials of peptide immunotherapy will be discussed.

Reverse translation - learning from clinical trials in SLE, Sjögren's and APS

SP0152 LEARNING FROM CLINICAL TRIALS IN SYSTEMIC LUPUS ERYTHEMATOSUS

D.A. Isenberg. *University College London/University College Hospital London, London, United Kingdom*

An enormous sense of frustration has surrounded the results of clinical trials in patients with systemic lupus erythematosus (SLE). A steady stream of trials including those studying the effects of Epratuzumab, Abatacept, Rituximab, Tabalumab and Silfalimumab have failed to meet their endpoints. Even though Benlysta (which blocks the B-cell activating factor BAFF) did meet its endpoints, it only demonstrated a difference of around 10% between the Benlysta-treated and placebo-treated arms in trials involving over 800 patients.
However, there are some bright spots on the horizon. Trials comparing the use of Mycophenolate with other classic immunosuppressive drugs clearly showed it to be as good as Cyclophosphamide in getting patients into renal remission and demonstrated its superiority in maintaining that remission compared to Azathioprine[(1)]. The use of Atacicept which blocks two B-cell activating factors has shown some extremely promising results[(2)] as have trials of both Rontalizumab and Anifrolumab[(3)] (which block interferon-alpha).
Some key messages learnt from the running of the lupus trials include the importance of minimising the concomitant steroids and immunosuppression; ensuring the quality of those assessors participating in the clinical trials and the utility of employing an independent peer-review panel to monitor data as it is collected from the participating centres during the course of the trial. It is also evident that selecting patients who are more serologically active is likely to be of benefit both in clinical trials and in the clinic. However, we still need better biomarkers to help guide us; the identification of individuals expressing a high interferon alpha signature (and who thus might better benefit from an interferon alpha blocker) is one such example.
It remains ironic that Rituximab, the most widely used monoclonal antibody in SLE, failed its endpoint in two clinical trials. However, detailed analyses of data from those trials have shown some encouraging trends including falls in dsDNA antibodies and improvement in some clinical parameters.

SP0153 LESSONS FROM APS TRIALS

M. Khamashta[1,2]. *[1]Rheumatology Dept, Dubai Hospital, Dubai, United Arab Emirates; [2]Lupus Research Unit, St Thomas Hospital, London, United Kingdom*

Prevention of thrombosis in patients with APS remains a vexing clinical problem. In patients with a history of thrombosis, there is considerable risk of recurrence, and long-term anticoagulation treatment with warfarin is effective in most cases. Existing evidence suggest that the use of DOACs for secondary thromboprophylaxis for APS patients with previous VTE is promising. Until new data from ongoing clinical trials are available, there is not enough evidence to consider using DOACs in patients with APS and previous arterial events. The efficacy of heparin and low-dose aspirin in APS patients with previous pregnancy losses is supported by 3 meta-analysis available on the topic. In patients with antiphospholipid antibodies but without a previous thrombotic event, most physicians in the field recommend thromboprophylaxis with low-dose aspirin. Given the diversity of clinical presentations and medical specialties involved, it is not surprising that treatment of APS has been subject of intense debate. Due to the difficulty in conducting trials in the setting of a relatively rare condition, well designed multicenter studies (such as registries) using actual classification criteria and standardized tests should be performed in the future to answer all the opened questions regarding management of APS.

Genomic imprinting and post-translational modifications

SP0154 RATIONALE TO TARGET IMMUNE MEMORY RESIDING IN INFLAMED TISSUES

H.-D. Chang. *German Rheumatism Research Center Berlin, Berlin, Germany*

T helper (Th) lymphocytes play a major role in the regulation of immune responses and are thought to initiate and drive chronic rheumatic inflammation. Memory Th lymphocytes persist in the inflamed tissue and are refractory to therapeutic intervention. In chronic inflammation Th lymphocytes have undergone molecular adaptations, such as the upregulation of Twist1 and the microRNA miR-148a, which are not found in circulating Th lymphocytes, and support the survival of the Th cells within the inflamed tissue. Within the inflamed tissue, the Th lymphocytes constantly recruit and activate inflammatory cells, such as monocytes/macrophages and granulocytes through the secretion of particular chemokines and interleukins. The monocytes/macrophages in turn can recruit more Th cells into the inflamed tissue. Disrupting this vicious circle by specifically targeting the memory Th cells resident in the inflamed tissue by interfering with their molecular adaptations could be an interesting therapeutic option.

SP0155 THE ROLE OF POST-TRANSLATIONAL MODIFICATION AND AUTOREACTIVITY

R. Toes. *Rheumatology, Leiden University Medical Center, -Leiden, Netherlands*

Rheumatoid arthritis (RA) is a prototype autoimmune disease, with the hallmark signs of synovial inflammation and the presence of autoantibodies. Of the different autoantibody systems present in RA, rheumatoid factors (RF) are probably the best studied. Their presence was first detected >70 years and it was in the late 1950s when it was realized that RF reacted to gamma globulins. Since the discovery of RF several other autoantibody systems have been discovered in RA, many of them directed against post-translationally modified protein antigens. The most prominent example of such autoantibodies are anti-citrullinated protein antibodies (ACPA), which are directed against a wide-array of citrullinated proteins. Now RF and ACPA determination are the two major diagnostic laboratory tests for RA and part of the EULAR and ACR criteria for RA.
In the past few years, it has become clear that the autoantibody response present in RA extends towards several other modified proteins, such as proteins modified by acetylation or carbamylation. As all these auto-antibodies recognize Post-Translationally Modified (PTM) proteins, these antibodies are collectively called Anti-Modified Protein Antibodies (AMPA). In the context of this presentation, I will focus on the auto-antibody response against citrullinated, carbamylated and acetylated proteins.
Carbamylation leads to the formation of homocitrulline. Structurally, homocitrulline greatly resembles citrulline but is one methylene group longer. Citrulline is generated when PAD enzymes modify the amino acid arginine. In contrast, the amino acid homocitrulline is generated by a chemical reaction in which cyanate reacts with the amino acid lysine. Arginine and lysine are located at different positions in the amino acid sequence of proteins, and therefore these modifications occur at different positions in proteins with different flanking amino acids. Intriguingly, although homocitrulline residues can also be recognised by auto-antibodies, these auto-antibodies often do not crossreact with citrulline. Acetylation is a process where acetyl groups are added to free amines of lysine residues by acetyl transferases. Acetylated lysine does not resemble citrulline but bears similarity to homocitrulline except at the side chain terminal amine, which is replaced by a methyl moiety.
By now it is clear that AMPA consist of different auto-antibody families that are largely distinct, but that can also display a certain degree of cross-reactivity. Therefore, the notion is emerging that, although cross-reactivity exist, different classes of AMPAs are generally seen as distinct auto-antibody families that target different antigens, but intriguingly often co-occur. As the AMPA-responses in RA are often found together, it indicates that –somehow- AMPA-reactivity has a commonality that is currently not understood.
Although, the reason why an immune response starts against PTM proteins is not known, it appears crucial to obtain understanding on the breach of tolerance towards PTM proteins as the immune response against these proteins has been intimately implicated in disease-pathogenesis. Understanding the full AMPA response, the triggers that drive AMPA production, their mutual crosstalk and the pathways by which AMPA and/or AMPA-expressing B cells possibly contribute to RA will be important for the development of curative interventions in RA. In the context of this presentation, some of these aspects will be discussed.

SP0156 **HOW BIG DATA HELP US UNDERSTAND NEW AND OLD THERAPY TARGETS**

P.E. Lipsky. *Ampel Biosolutions, Charlottesville, United States*

Gene expression profiling is a valuable tool to identify the altered cellular status of cells or tissues. Metaanalysis of available gene expression profiles from numerous sources provides a means to assess the molecular alterations characteristic of autoimmune diseases, such as systemic lupus erythematosus (SLE) and to develop insights into possible new therapies. Toward this end, all of the publicly available gene expression datasets from SLE blood and tissue were assembled and a variety of analytic algorithms were employed to identify differentially expressed genes, gene modules associated with clinical features, molecular pathways associated with SLE and potential upstream regulators. This information was employed to cross-reference a variety of databases to predict novel molecular pathways and potential drug candidates. Specifially, gene expression profiles obtained from lupus affected skin, synovium and kidney were obtained, compared to metaanalyzed data obtained from active lupus B cells, T cells and myeloid cells, and cross-referenced to various pathway analytic tools including Molecular Signature (MS©)-Scoring, Ingenuity Pathway Analysis© Upstream Regulator (IPA©-UR) and Library of Integrated Network Based Cellular Signatures (LINCS). More than 300 arrays from lupus patients and appropriate controls were analyzed to determine differentially expressed (DE) genes [8279 discoid skin, 5465 lupus synovium, 6381 lupus nephritis glomerulus, 5587 lupus nephritis tubulointerstitum]. Notably, the majority of lupus affected tissue DE genes were detected in more than one tissue and 439 were differentially expressed in all tissues. Tissue inflammatory/immune cell infiltration was documented by genes encoding specific cell markers as well as by unique gene expression signatures (Biologically Informed Gene Clustering, BIG-C©). Examination of curated predicted functional groups from the STRING (Search Tool for Retreaval of Interacting Genes/Proteins) output of common up-regulated transcripts in lupus tissue predicted therapeutic targets and drugs using STITCH (Search Tool for Interacting Chemicals) and IPA's BioProfiler© that were confirmed by connectivity using LINCS. Analysis of gene expression datasets for the presence of specific gene modules using GSVA (Gene Set Variation Analysis) documented the overall similarity of active lupus gene sets as well as the uniqueness of individual patient samples.These results demonstrate the value of comprehensive application of orthogonal curated bioinformatics tools in identifying the role of inflammatory/immune cells in lupus pathogenesis and tissue damage. This approach demonstrated that there are molecular pathways common to all lupus patients and tissues, and there are pathways involved in inflammatory response of some but not all patients and tissues. Further analysis should generate a molecular model of lupus immunopathogenesis and could identify therapies that may be useful in all lupus patients versus those with involvement of specific tissues and treatments specifically targeted to individual lupus patients.

Optimizing treatment for osteoarthritis: take the phenotype in account "one size does not fit all"

SP0157 **METABOLIC PHENOTYPE: THE TWO FACES OF OBESITY IN OSTEOARTHRITIS**

F. Berenbaum[1,2,3]. *[1]Department of Rheumatology, Sorbonne University; [2]INSERM; [3]AP-HP Hospital Saint-Antoine, Paris, France*

Osteoarthritis (OA) has long been considered as the consequence of tear and wear due to mechanical triggers. In that paradigm, the increased risk of OA in obese patients can be explained by overload on weight-bearing joints. The discovery of an increased risk of hand OA in obese patients has changed the paradigm by opening up an additional hypothesis (not ruling out the mechanical hypothesis) based on systemic factors secreted by the adipose tissue (even the central one or/and the intraarticular one), which could have a deleterious effect on joints. More recently, cohorts data have suggested that obese patients with a metabolic syndrome (MetS) (an association of cardiometabolic factors that increase the risk of cardiovascular events i.e. diabetes, hypertension, dyslipidemia) have an increased risk of OA compared to obese patients without MetS. The most recent researches in that field highlight the role of metabolic-triggered inflammation (called meta-inflammation) on the initiation/progression of OA and the role of each of the components of the MetS independently (hyperglycemia, insulinoresistance, oxLDL, endothelial dysfunction, etc.). A better understanding of this newly defined OA phenotype, namely the MetS-associated OA, should lead to the discovery of new drugs specifically targeting this phenotype or/and to assess the efficacy of drugs in OA already on the market for diabetes, hypertension or dyslipidemia.

SP0158 **PAIN PHENOTYPE: CAN WE TAKE ADVANTAGE OF THE PLACEBO EFFECT**

A. Abhishek. *Academic Rheumatology, University of Nottingham, Nottingham, United Kingdom*

The discordance between pain and structural changes in osteoarthritis has been recognised for over two decades. Recent research has also identified different pain phenotypes in people with osteoarthritis. This suggests that the changes in the peripheral and central nervous system may affect both the severity and character of pain and associated features in osteoarthritis. Placebo response, the improvement in symptoms in those in the placebo arm of a randomized controlled trial, and placebo effect, the difference in improvement in those treated with placebo (in placebo arm of a randomized controlled trial) and those who have had no treatment (e.g. in the observation only arm of a three arm randomized controlled trial) are mediated by complex neural mechanisms and are especially relevant to the management of osteoarthritis. Indeed, the placebo response associated with most osteoarthritis treatments is stronger than their treatment effects. While a large placebo response is a significant obstacle to the development of new drugs and non-drug interventions for the treatment of osteoarthritis, it can be utilised as a "friend" in the day to day and long-term management of a person with osteoarthritis. This lecture will outline the pain phenotypes associated with osteoarthritis and describe the potential for placebo effect in improving osteoarthritis pain. The pain phenotypes associated with osteoarthritis that are most likely to be improved by optimizing placebo response and the underlying mechanisms will be discussed.

Targeting adipose tissue inflammation

SP0159 **ADIPOSE TISSUE – BYSTANDER OR THERAPEUTIC TARGET?**

M.I. Bokarewa. *Rheumatology and Inflammation Research, University of Gothenburg, Gothenburg, Sweden*

Adipose tissue (AT) is a complex endocrine organ with profound effects on body physiology. Research of recent years generated remarkable volume of information on metabolic and immune functions of AT. The lecture will focus on topics of AT biology that shed light on areas of interest linking metabolic, immune and rheumatic conditions.

AT is a recognized master regulator of energy balance and nutritional homeostasis. Cells of AT are active part in establishment of autoimmunity, and also osteoarthritis and osteoporosis. Macrophages enrich AT, change its phenotype and mediate inflammation, enhance antigen presentation. Th17 and regulatory T cells reside and operate in AT, having distinct transcriptional and functional characteristics from counterparts of the lymphoid organs. IL6 and IL33 signaling contribute to this distinction. Adipocytes communicate with other cell types by means of signal molecules adipokines, interleukins, and fatty acids and may affect blood pressure, muscle functions, wound healing, bone formation, hematopoiesis and tumor growth. Localization of AT plays important role for its properties including cellular composition, their gene expression profile and secretome, response to external forces and their therapeutic potential. Subcutaneous AT and bone marrow AT are most available and studied in humans.

Adiposity has been revealed as a risk factor for development of multiple autoimmune conditions including type 1 diabetes, rheumatoid arthritis, inflammatory bowel disease, multiple sclerosis, psoriasis and thyroiditis. It also associates with low response rate to both biologic and non-biologic anti-rheumatic treatment. Notably, cumulative evidence show a surprising protective action of AT for radiographic joint damage in arthritis.

Antirheumatic drugs have remarkable effect on the body fat composition and serum lipid profiles, and could therefore be considered as AT-targeting agents. Impact of these drugs on the composition and function of AT localized subcutaneously and in the bone marrow remains in focus of research and will provide new insights in mechanisms of insulin resistance, cardiovascular risk, bone metabolism and autoantibody production.

Production of adipokines has been proposed a mechanism through which AT fuels inflammation and severity of autoimmune diseases however direct evidence still awaits. Several adipokine targeting and adipokine stimulating therapies have been designed and experimentally tested in the models of collagen-induced arthritis, autoimmune diabetes and insulin resistance, encephalitis, and osteoporosis induced by estrogen-deficiency. In human settings, the experience of leptin substitution in anorexia neurosa and in lipodistrophy revealed positive effects on bone metabolism and improved cognition.

In conclusion, AT attracts increasing attention as an active contributor of inflammation and autoimmunity. Further studies are needed to confirm and specify the effects and pathogenic links within AT. Novel insights in mechanisms regulating the diversity of AT composition and functions may assist conversion of AT into a teammate of anti-rheumatic processes.

SP0160 IS DIABETES AN INFLAMMATORY DISEASE AND SHOULD BE TREATED LIKE THAT?

A. Schaeffler. *Department of Internal Medicine-III, Endocrinology and Diabetes, University of Giessen, Germany, Giessen, Germany*

It is a well-known clinical observation that inflammatory diseases are accompanied by metabolic implications such as hyperglycemia, insulin resistance and increased fatty acids. On the other hand, metabolic diseases have inflammatory implications. There is a chronic and low-grade state of inflammation in obesity and type 2 diabetes. Physiological insulin resistance during infection or inflammation re-distributes glucose and fatty acids to immune cells. On the basis of systemic and adipose tissue inflammation such as MCP-1/TLR-4-driven macrophage infiltration and pro-inflammatory polarization of these cells, this lecture will give a summary of anti-diabetic effects of anti-inflammatory drugs used in rheumatology.

What is the evidence from clinical studies using anti-inflammatory approaches to treat patients with type 2 diabetes mellitus?

Basically, TNF plays an important role in insulin resistance in rodents. Blocking TNF in rodents reverses obesity-related diabetes. There are no state of the art clinical studies showing convincing evidence of an anti-diabetic potential due to underpowered cohorts and short duration of the studies. Only one single study over 6 months showed a 10% improvement of fasting glucose levels in 40 prediabetic obese patients.

Diacerein belongs to the chemical group of anthranoids. Although the mechanism of action is unknown, diacerein decreases the levels of TNF and of IL1b and has therefore been used in rheumatic diseases. Diacerein has potent effects on insulin secretion and glycemic control with a reduction of HBA1c level by 1.6%.

IL-1 receptor antagonists such as anakinra (a recombinant human IL-1 receptor antagonist) have also been studied in diabetes. Anakinra was able to improve glycemia, inflammation and insulin secretion. Two additional studies in patients with impaired glucose tolerance or prediabetes demonstrated positive effects of anakinra on beta cell secretory capacity. Since anakinra requires daily injections and often causes adverse effects at the injection site, humanized antibodies against IL1b have been developed. Each of these antibodies had beneficial effects in patients with type 2 diabetes. However, studies were either underpowered or showed only little improvements of glycosylated HBA1c levels, probably due to low pre-study levels.

Inhibition of the IKK/NFkB pathway might also be of benefit in insulin resistance. Salsalate improves insulin sensitivity, insulin secretion and glycemic control to a moderate extent of 0.4–0.5%. Salsalate also has effects in prediabetic patients and in drug-naive type 2 diabetic patients.

There is upcoming evidence of potential benefical effects of CCR2 antagonism in diabetes.

Obesity causes an increased flux of fatty acids into muscle and liver with an accumulation of DAG in these organs. DAG activates specific isoforms of protein kinases, that is PKC T in muscle and PKC E in the liver. These isoforms cause an inhibitory phosphorylation of IRS-1 and the insulin receptor itself leading to insulin resistance. Weight reduction by diet, physical activity and bariatric surgery remove ectopic fat and are able reverse diabetes. Most interestingly, PKC-isoform specific inhibitors such as FGF-21 might represent new drug targets.

Finally, targeting ectopic fat is more close to the pathophysiology of diabetes than anti-inflammatory therapy.

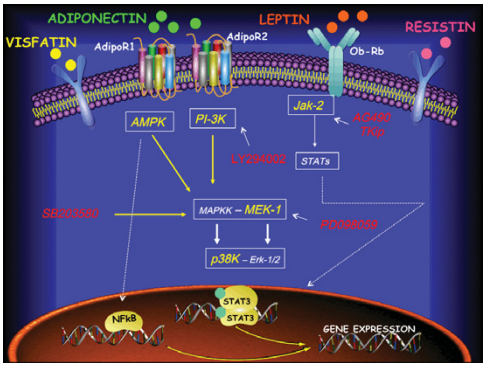
SP0161 THE ROLE OF ADIPOSE TISSUE IN OSTEOARTHRITIS

A. Ioan-Facsinay. *Leiden University Medical Center, Leiden, Netherlands*

The association between obesity and osteoarthritis (OA) is nowadays well-accepted. This association is present both in weight-bearing and non-weight-bearing joints, indicating that next to local effects, systemic effects associated with obesity could play a role in disease. The relative contribution of local and systemic effects could be different in each joint. In this presentation, I will summarize the current knowledge about the contribution of local and systemic adipose tissues to osteoarthritis in different joints, with emphasis on knee OA. Moreover, obesity-associated changes and their role in OA will be highlighted.

The key messages I would like to convey are:



- Mechanical stress is a major contributor to knee OA
- The infrapatellar fat pad (IFP), an intra-articular adipose tissue in the knee, is dostinct from other adipose tissues and could play a role in knee OA
- Only few obesity-related features have been described in IFP in OA

SP0162 ADIPOKINES IN THE PATHOPHYSIOLOGY OF CARTILAGE

O. Gualillo. *NEIRID Lab (Laboratory of NeuroEndocrine Interactions In Rheumatology and Inflammatory Diseases), Sergas Idis, Santiago de Compostela, Spain*

Fat mass dysregulation is a marked characteristic of overweight and obesity. Obesity is, historically, a classic risk factor for osteoarthritis development and progression and shares with osteoarthritis a huge societal impact but also several common biochemical features that are strongly related to the low-grade inflammatory status. Even though OA has been considered during decades a disabling degenerative disease related to mechanical, age and genetic factors with poor inflammatory component, the current consensus is that OA, in particular OA associated with metabolic alterations, is a global muscle-skeletal diseases in which pro-inflammatory and catabolic mediators, most of them produced by a dysregulated visceral or periarticular white adipose tissue (WAT), are at play. The coexistence of obesity and OA is a clinical reality and is changing the traditional view of this degenerative disorder. Thus, chronic low-grade inflammation is a common characteristic shared by both obesity and OA. It has been demonstrated that obesity increases the incidence of OA, particularly in weight-bearing joints such as knees. However, the fact that obese individuals have an increased risk of developing OA in non-weight bearing joints such as hands and wrists suggests that factors produced by WAT play a role in the onset and/or progression of OA. In addition to a growing body of evidence demonstrating that obesity has a direct mechanical effect joint cartilage, recent research shows that pro-inflammatory factors produced by WAT (collectively known as adipokines) promote further inflammation and degradation of cartilage, also influencing the whole joint environment (i.e. synovium, muscle, bone and immune cells). Accumulating evidence shows another potential source of inflammatory adipokines in the joint is the Hoffa infrapatellar fat pad. Adipokines including leptin adiponectin, visfatin and lipocalin 2 have been demonstrated to exhibit a wide spectrum of biological activity including the activation of pro-inflammatory and catabolic pathways mediated by elevated levels of NO, ROS, MMPs and PGE2. The discovery of adipokines has made a major contribution to our understanding of the complex relationship between diabesity and OA, encompassing a variety of factors that include the immune system, metabolism and biomechanics. A critical aspect that must constantly be borne in mind is that diabesity and OA share a low-grade inflammatory state that heavily influences the course of OA progression. Therefore, the prevention and correction of diabesity should be the first line approach for tackling the detrimental effects of weight gain, adiposity and altered metabolic WAT function in OA. The aim of this lecture is to summarize the role of adipokines in bone and cartilage function, as well as in inflammatory and degenerative joint disease. We discuss clinical implications and then survey attempts to exploit this role for therapeutic gain, which holds potential as a novel approach for drug development in bone and joint disease.

Trials and tribulations of medication adherence

SP0163 INTERVENTIONS TO IMPROVE MEDICATION ADHERENCE IN PATIENTS WITH INFLAMMATORY ARTHRITIS

J.E. Vriezekolk. *Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands*

Non-adherence to medication in rheumatic diseases is a major concern for patient's health, because incorrect use can result in *less* therapeutic benefits of treatment, including more disease activity and increased radiological damage. As a consequence, non-adherence may lead to more disability and lower health-related quality of life. Using Lowe's taxonomy[1], the current state of evidence around medication adherence interventions will be presented. Examples of promising intervention strategies will be highlighted.

DOI: 10.1136/annrheumdis-2017-eular.7081

SP0164 **BARRIERS AND FACILITATORS TO ADHERENCE TO MEDICATION IN PATIENTS WITH INFLAMMATORY ARTHRITIS**

K. Koutsogianni. *The Arthritis Foundation of Crete, Heraklion, Crete, Greece*

Background: Inflammatory arthritis can cause pain, stiffness, joint damage and even disability without proper and early guided treatment. The full benefits of several treatments recommended, can be achieved if patients strictly follow drug regimens. However, rates of adherence to prescribed medications in patients with inflammatory arthritis seem to be suboptimal.
Objectives: To identify the barriers and facilitators for adherence to medication on patient's perspective and to suggest ways to facilitate the patients with chronic conditions as the inflammatory arthritis are, to understand the value of compliance to treatment.
Methods: The problem of poor patient compliance was detected about 2,000 years ago when Hippocrates taught his students to pay particular attention to the analysis of the causes that led their patients to lie regarding compliance with medical instructions given to them. The adherence to medication of patients suffering from chronic diseases reaches only 50% (WHO-2003) while the rate of compliance to prescribed medicines for patients with rheumatoid arthritis tend to be quite low and range from 30–80%.
Fear and insecurity about the side effects of the medicines, the doubt of efficacy of medications, the refusal to accept the IA diagnosis and the long term treatments, the desire to stop treatment to be free of the ongoing dependency on medication, the lack of competence by some physicians to involve the patient in the treatment procedure and the large amount of patients co-payment are the most significant barriers to patients adherence. A survey conducted among patients of the Arthritis Foundation of Crete aiming to assess the degree of their adherence to MTX showed that 1 in 4 patients reported missing at least one dose of MTX on their own initiative during the last 6 months without referring to their doctor and the main reason was due to side-effects.
Experiencing beneficial effects of the medications and being able to maintain autonomy and social participation, receiving clear and understandable information about the treatment options, having support from family and friends, having a good relationship with the treating physician and being involved in shared decision making process are the keys for leading the patients to better adherence.
Conclusion: A good patient-health professional relationship, knowledge about treatment options and appropriate amount of information provided by HCPs as well as the patients' acceptance of their health condition and understanding of the necessity of long term therapy appear to improve adherence to medication for patients with inflammatory arthritis.

SP0165 **CAN MUSCULOSKELETAL ULTRASOUND INFORM HEALTH BELIEFS AND PLAY A ROLE FOR MEDICATION ADHERENCE?**

K. Kumar. *University of Manchester, Manchester, United Kingdom*

Rheumatoid Arthritis (RA) is a condition with no cure and can cause disability[1]. RA affects nearly 1 in 100 adults. Early disease is characterised by pain and other features of inflammation, such as heat, swelling of joints, and loss of function. RA is associated with increased costs of co-morbid conditions (such as cardiovascular (CVD) associated with RA[2].
Medication can ease symptoms and limit disease progression in RA[3]. Despite this, nonadherence to medication is common in RA[4]. In the UK, we found that showing patients their joint swelling via musculoskeletal ultrasound scan as an educational tool helped to increase beliefs about the necessity of treatment[5]. Our study provided a deeper understanding of adherence to disease modifying anti-rheumatic drugs (DMARDs) in patients with RA. Improving adherence is likely to be facilitated by incorporating visual representations of the disease process and better explanations of the consequences of poorly controlled RA into the consultation. This session will uncover some suggestions around the use of musculoskeletal ultrasound in improving adherence to DMARDs.

Outcome in juvenile idiopathic arthritis

SP0166 **LONG-TERM OUTCOME OF JIA INTO ADULTHOOD**

B. Flato[1,2]. *[1]Institute of clinical medicine, University of Oslo; [2]Dep of Rheumatology, Oslo University Hospital, Oslo, Norway*

Background: In patients with juvenile idiopathic arthritis (JIA), scarce information on disease outcomes into adulthood are available.
Objectives: To review the long-term outcome and possible time trends in adult JIA and discuss how JIA in adulthood is similar to or different from adult onset rheumatic diseases.
Results: JIA is a heterogeneous group of diseases, but across different categories patients with JIA share some clinical, prognostic and genetic characteristics different from those found in adult onset arthritis (i.e. growth disturbances, more varying prognoses, and HLA-DRB1*08). The most common categories of JIA, oligoarthritis and RF-negative polyarthritis, do not have any adult counterpart. On the other hand, 82–96% of patients with systemic, RF-positive polyarticular, psoriasis related, and enthesitis related JIA were recently found to fulfil the criteria for adult Stills, RA, psoriatic arthritis, and adult spondylarthropathy, respectively. Furhermore, recent analyses of large patient groups show that patients with oligoarticular and RF-negative polyarticular JIA share HLA associations with seronegative RA (HLA-DRB1 amino acid at position 13).
At transition to adult care, about half of the JIA patients (range 42–67%) have active disease or are on anti-rheumatic medication. In adult JIA patients, active disease after more than 20 years of disease duration occured in 40 percent (range 37–43%). Differences in definitions of remission, classification criteria and/or selection of patient may explain these variations.
Within a cohort, no reduction were found in the proportion of patients with active JIA from childhood to adulthood in 3 long-term longitudinal studies; 62% at 5- and 60% at 17-year followup, 42% at 10- and 37% at 26-year followup) and 45% at 15- and 41% at 30-year followup.
Limitation in physical functioning has been found in 45–50% of adult JIA patients. The proportion with severe disability has increased with increased disease duration in several cross sectional and one longitudinal study. However, no definite trends towards detoriation of physical functioning over time were found in two recent longitudinal studies. The proportion of JIA patients with severe disability was low in long-term studies from this century, 3% to 11%, compared to 15–48% in studies from 1960 to 1990.
Up to 90% of the patients with childhood polyarthritis had radiographic damage in studies from 1966–76, compared to about 40% in studies from this century. In the total group of JIA patients, 24%>36% developed erosive disease, most frequently in wrists and hips. However, the use of radiographic scoring systems in JIA has been hindered by growth disturbances and varying joint distributions. Thus radiographic progression has never been investigated in clinical trials.
Several studies have shown that adults with JIA experience more pain, poorer health related quality of life and lower employment rates than age and sex matched controls from the general population, in spite of similar or higher education levels. A new study shows that JIA has a detrimental effect on HRQOL both in patients with and without clinical remission, and physical, but not mental, HRQOL deteriorate slightly from adolescence to adult life.
Ongoing active uveitis into adulthood has been found in half of the patients with JIA associated uveitis. One third of them have visual impairment and 40% need ocular surgery in early adult life. Recent studies indicate that adult JIA patients have increased rates of subclinical atherosclerosis and malignancies.
The use of arthroplasties in JIA patients decreased dramatically from 1990 to 2005, while the rates were stable in RA and increased in spondylarthropathy and osteoarthritis patients. Joint surgery now occurs in less than 15% of adult JIA patients.
Previous long-term followup studies have mainly been performed before biologic agents were available or early methotrexate was used. Long-term outcomes in JIA patients treated with biologic agents have been described in two registry based studies. Inactive disease was achieved in 24–67% of the adult JIA patients and 52–74% were still on a biologic agent at last followup. It has been found that biologics improve physical HRQOL in children with JIA, and that most of the acquired improvement is maintained in adult life. However, biologics were started several years after disease onset in these studies. Only 38–56% of adult JIA patients with long-term active disease were on synthetic or biological DMARDs according to recent followup studies.
Conclusion: About half of JIA patients have active disease into adulthood. JIA affects physical outcome, HRQOL and visual outcome, but adult patients with long-term active JIA seems to receive inadequate therapy. So far, the long-term outcome in patients receiving early biologic and/or synthetic DMARDs is not known.

Getting financial support to research in RMDs through horizon 2020: opportunities, good practices, and successful experiences

SP0167 HORIZON 2020: OPPORTUNITIES FOR MEDICAL RESEARCH AND INNOVATION

S. Hogan. *DG Research, Directorate Health, European Commission, Brussels, Belgium*

Horizon 2020 is the largest EU Research and Innovation programme ever with nearly €80 billion of funding available over 7 years (2014 to 2020). It is an opportunity for supporting excellence and collaboration in research, on a scale and scope that is seldom feasible at global level.
Horizon 2020 contributes to the Innovation Union, a Europe 2020 flagship initiative aimed at securing Europe's global competitiveness. By coupling research and innovation, Horizon 2020 is helping to achieve this with its emphasis on excellent science, industrial leadership and tackling societal challenges. The goal is to ensure Europe produces world-class science, removes barriers to innovation and makes it easier for the public and private sectors to work together in delivering innovation. This it is seen as a means to drive economic growth and create jobs, Horizon 2020 has the political backing of Europe's leaders and the Members of the European Parliament.
Horizon 2020 is open to everyone, with simplified and more rapid application and reporting procedures.
The next work programme for the period 2018 – 2020 will be published in Autumn 2017.

EULAR Projects - challenging projects in education and training

SP0168 THEORY OF POSTER DESIGN AND PRESENTATION

M. Boers. *Epidemiology & Biostatistics; Amsterdam Rheumatology and immunology Center, VU University Medical Center, Amsterdam, Netherlands*

This lecture introduces basic elements of poster design, and is followed after the session by a special poster tour devoted to design. It strongly links to the concepts discussed in my workshop on data visualization.
To design an effective poster, its message and the intended audience must be clear. Effective posters stand out because they convey their main message almost instantly, and then seduce participants to stay longer and learn more. Much more than oral presentations, posters are about selling your work in competition with all those other people presenting in your session.
In a good poster, all elements work together like a symphony orchestra:
Title, headings, text, tables, graphs, format, colors, layout, handouts, gimmicks, and ... you!
For the design process, you need a good plan (including timelines!), good tools (templates, software!) and a ruthless editor. Editing is about throwing out more and more stuff, until finally you reach the point where throwing out more destroys understanding. So the "orchestra" has single instrumentation, and is wonderfully transparent.
Posters are not "comprehensive"! All the details you love can go into a specially designed handout (NOT an exact replica of your poster).
Your role as presenter is special: you must be visible but unobtrusive, and flexible to accommodate different viewer styles, and have different modes of presentation (eg. walkthrough, answer questions, respond to critique). Also make sure your contact details are visible and correct (if no handout, be sure to have business cards). If you are playful you can use gimmicks to increase your visibility: match your clothes to your color scheme, make something in real 3D on your poster, use sound, etc. But don't overdo it: this is just the icing on the cake: this is a science, not a commercial exhibit.
When we go to assess posters in the upcoming poster tour, we will be looking for the following elements:
1. Overall message clear?
2. Text quality: brevity, clarity
3. Table quality: clear vision, clear understanding
4. Graph quality: clear vision, clear understanding
5. Design elements: layout, choice of font, color
6. Handout: not a replica, elements 1–5 repeated
7. Presenter: style, contact details

SP0169 EULAR SCHOOL OF RHEUMATOLOGY. A CHALLENGING EDUCATIONAL EULAR PROJECT. WHERE ARE WE NOW?

J.W. Bijlsma. *Rheumatology & Clinical Immunology, UMCU, Utrecht, UTRECHT, Netherlands*

In the last decade EULAR has further developed its educational portfolio. Apart from very educational tracks in the EULAR Congress, EULAR offers:
- on-line courses (Rheumatology, Connective Tissue Diseases, Scleroderma, Paediatrics, Ultrasound, Health Professionals), that are being followed by thousands of students all over the world
- text-books, based on the on-line courses
- live courses, such as the Postgraduate Course, Ultrasound courses, capillaroscopy, epidemiology, immunology, teach the teachers
- exchange programs, for trainees, scientists, health professionals and patients
- on-line image library, on-line outcome registry
- learning DVDs for medical students
- scientific endorsement of other courses

To bring all these offerings under one umbrella, EULAR decided to found the School of Rheumatology.
But the School is doing substantially more: we identified 7 areas (classrooms) where we bring enthusiastic and involved people together to evaluate the present needs in those areas and to prioritize new educational activities for those unmet needs. The following classrooms are actively developing new products:
Classroom medical students: formulating standard curriculum for musculoskeletal diseases and providing video-materials to support teachers and students.
Classroom trainees in rheumatology: start of a journal club, evaluating possibilities to install a European (EULAR) examination to become a rheumatologist, imaging on-line course.
Classroom teachers: course on assessment questions was already held, a teach the teachers event is planned.
Classroom rheumatologists: development of a pocket primer on rheumatic diseases, to be used as an app.
Classroom scientist: preparing a possible on-line course on epidemiology and clinical (trial) research, evaluating possible webinars for basic science methodology.
Classroom health professionals: preparing an accreditation system for health professionals; expanding on-line courses.
Classroom patients: implementing and distributing lays versions of recommendation; development of a patient partner program in research; webinars on actual items in the form of questions and answers (eg biosimilars).
Some of the items on this agenda can be organised within one year, for some others many years are foreseen; it will be a dynamic process. Ideas and support are very welcome via the EULAR Standing Committee on Education, or directly to the EULAR office, attention of the education program manager.

SP0170 ASSESSING RHEUMATOLOGY SKILLS

C. Haines. *The Medical School, The University of Nottingham, Nottingham, United Kingdom*

Medical Education is making great advances in understanding the power of assessment. Modern learners seek frequent, faster feedback on their learning to study more effectively. It is now common for examinations to be statistically monitored in order to show that acceptable levels of reliability have been reached. But, a test is only as good as its questions. Clinicians are not often trained in how to create valid and reliable test questions. This session will describe some basic principles for creating valid and reliable tests for the knowledge, skills and attitudes which are required by practising rheumatologists. The speaker is currently the Eular Educationalist, who advises Eular on how to continually enhance assessment processes for the online courses and the new trainee examination.
As a result of the session participants will be better able to:
- Describe how face validity and reliability apply to Eular assessments
- Describe the differences between formative assessment for learning and summative assessment for grading
- Identify improvements which they could make to test questions
- Identify improvements which they could make to tests

SP0171 HOW TO SELECT THE MOST APPROPRIATE CAPILLAROSCOPIC DEVICE: PROS AND CONS

F. Ingegnoli. *Dept. of Clinical Sciences and Community Health, Università degli Studi di Milano, ASST Gaetano Pini, MILANO, Italy*

Nailfold capillaroscopy is a simple noninvasive imaging technique mainly used to observe capillaries within the first few micrometers from the skin surface. After application of a drop of immersion oil, capillaries can be observed with a magnification lens because they run parallel to the epidermis at the nail bed area. The study of the morphology of superficial nailfold capillaries provides clinically

relevant information in the management of patients with scleroderma-spectrum diseases.
Recently, an international survey on non-invasive techniques to assess the microcirculation performed under the aegis of members of the European League Against Rheumatism (EULAR) Study Group on Microcirculation in Rheumatic diseases (SG_MC/RD) showed that nailfold capillaroscopy was the one most used technique in both clinical and research settings by adult physicians and paediatric rheumatologists to assess patients with Raynaud's phenomenon.
A number of different instruments are available to perform the exam. They have different characteristics in terms of their cost, quality of images, magnifications, training period, portability, software for image analysis and storage.
Some of these instruments can be used both in clinical and research settings such as the stereomicroscope and the videocapillaroscope. The stereomicroscope allows the widefield visualization of the nailfold with low magnifications, the training is relatively short, but the examination is difficult to perform in patients with digital flexion contractures.
There appears to be consensus regarding the use of videocapillaroscopy that allows a detailed visualisation of capillary morphology using higher magnifications (100–300x). Contact probe with polarized light microscopy permits easier observation of the skin surface, and the training period is briefer. Specific softwares are available for images analysis, storage, and complete medical reports (text + images) can be produced.
By contrast, in a clinical setting, nailfold capillaries can generally be visualised using more simple but also efficient tools such as a dermatoscope, USB microscope, ophtamloscope or smartphone device. The quality of images can be quite good, although the lower magnification means that some details are unlikely to be seen, and they often lack the possibility of image storage and measurement. In particular, the dermatoscope with magnification of the order of x10 is a small, inexpensive and easily portable piece of equipment that has been suggested to be comparable to videocapillaroscopy in routine clinical practice.

Workshop: strengthening your organisation - how to manage volunteers

SP0172 MANAGING VOLUNTEERS- A UK PERSPECTIVE

C.B. Jacklin. *External Affairs, National Rheumatoid Arthritis Society, Maidenhead, United Kingdom*

Volunteers are an integral part of any charity and it would be impossible to run a charitable organisation without the support of volunteers. Like paid staff they need to be trained, nurtured and rewarded but as volunteers they need to be handled in a very different way to employees.
People who volunteer do so for many differernt reasons and not always perhaps for the right reasons so managing volunteers takes great skill and diplomacy.
My talk will cover how to value volunteers, lessons we have learned from managing volunteers over many years as well as how to manage issues with volunteers and the lessons I've learned from my mistakes!
Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.7227

SP0173 THE CHALLENGES OF A SMALL ORGANIZATION

M. Kosanovic. *Association of Rheumatic Diseases Patients of the Republic of Serbia (ORS), Belgrade, Serbia*

When a group of citizens establishes a non-profit and a non-government organisation in our country, those volunteers are carried by great enthusiasm. At the beginning when founding an NGO the main problems are lack of experience and financial resources. Those deficiencies can be overcome by some other qualities such as the personal competencies of volunteers.
As NGOs are seen by the public rather critically in our country, our organization had to face several additional challenges. In my presentation I will illustrate the following aspects: the non-attractiveness of NGOs for volunteers, the lack of awareness how volunteering is important for a society, the lack of knowledge how to attract volunteers and how to manage them, the lack of knowledge how to define the volunteers' positions and how to monitor their work, the lack of their systemic, continuing education and the lack of rewards, recognition and appreciation to acknowledge the most dedicated volunteers.

SP0174 WAYS OF SUPPORTING VOLUNTEERS

S. Ssymank. *Rheuma-Liga Baden-Württemberg E.V., 76646 Bruchsal, Germany*

The promotion of volunteer workers is an indispensable part of the human resources policy of self-help organizations and requires specific concepts. Using the example of the rheumatism league Baden-Württemberg -an organization with 65,000 members, 3,000 volunteers and 10 fulltime employees- there will be shown best- practice examples.
A successful concept covers the areas of recruitment, training, support and integration.
The support of volunteers should include four key areas:
1. Transfer of knowledge and professional competences
2. Individual support for personal development
3. Promotion of teamwork and social skills
4. Framework conditions (insurance cover, reimbursement of expenses)

The implementation of these requirements should be carried out by specifically trained volunteer managers on the basis of a strong and motivating personal relationship.
This strategy can be seen as a precondition for establishing a long-term relationship of the volunteer with the association, a successful local work, satisfied members and volunteers who perceive their work as satisfying and fulfilling.

WIN & HOT session

SP0175 WHAT IS NEW IN JUVENILE IDIOPATHIC ARTHRITIS

N.M. Wulffraat. *Dept. of Paediatrics, University Medical Center Utrecht, Dept. Pediatric Rheumatology, Utrecht, Netherlands*

Juvenile Idiopathic Arthritis comprises 7 subcategories. As the insights in pathogenesis progress so does the need for reclassification that is based more on biology than on clinical phenotypes. After a series of clinical trials for new biologicals, now trials are started that test specific treatment strategies such as treat to target an d step down studies. Especially rapid induction of remission is currently a major aim, followed by biomarked guided tapering of medication.
The expending number of potential biomarkers forms the basis for the creation of personalized medicin, a strategy aimed at providing individualized medication choices. Since most pediatric rheumatic conditions are rare, international collaboration is vital. The recently created European Reference Networks (ERN) will prove instrumental here.

Systemic sclerosis

SP0176 TARGETING VASCULOPATHY FROM THE BEGINNING

M. Cutolo on behalf of EULAR Study Group on Microcirculation in Rheumatic Diseases. *Internal Medicine, Research Lab Division Rheumatology University of Genova, genova, Italy*

In systemic sclerosis (SSc), the natural history of microvascular damage progresses from capillary dilation to capillary loss and reactive angiogenesis, as detectable by nailfold videocapillaroscopy (NVC) [1]. The process is systemic and determines multiple clinical manifestations, from the early appearance of Raynaud's phenomenon, trough formation of digital ulcers (DUs), until severe organ involvement, impairing patient's quality of life or leading to main death causes, including interstitial lung disease and pulmonary arterial hypertension (PAH), hearth involvement, scleroderma renal crisis [2,3]. Although microvascular and macrovascular abnormalities frequently coexist in disease such as diabetes mellitus and other vascular diseases, the possible association between microvascular failure and macrovasculopathy in SSc patients has not been deeply investigated. However, significant correlations seem to exist between increased Intima-Media Thickness (IMT) of periferic small-caliber arteries (macrocirculation) and altered peripheral BP (LASCA) at the level of hand microvessels (microcirculation) in SSc patients.
SiIn addition, sgnificant capillary loss, observed at NVC, is peculiar of the "Late" scleroderma pattern of microangiopathy and is mainly preceded by progressive capillary enlargement, microhemorrhages and their collapse, leeding to presence of large avascular areas [4]. The importance of capillary loss was already demonstrated by a simple and reliable prognostic index, capable to predict digital trophic lesion development in SSc-related microvascular disease, when evaluated as part of the semi-quantitative NVC scoring [5]. Moreover, microvascular function and its alterations in SSc, can be reliably assessed by laser-doppler flowmetry (LDF) and laser speckled contrast analysis (LASCA), evaluating blood perfusion at fingertips or at larger body areas [6–9].
The most frequently used drugs for treatment of complications in SSc patients, approved with evidence grade Ia, are vasoactive drugs. In particular, for severe

RP and for prevention of DUs onset and treatment of PAH, both intravenous prostanoid iloprost (ILO), and the dual endothelin-1 receptor antagonist (ERA) BOSE are used, respectively [10]. Bosentan seems to block pathogenic activities of Endothelin-1, the endothelial derived mediator determining both vasoconstriction and also the fibrosis genes induction [11–14].
Previous long-term follow up studies, showed that treatment with BOSE in combination with ILO interferes with progression of nailfold microvascular damage, evaluated through both capillary number semi-quantitative scoring at NVC and fingertip blood perfusion (FBP) at LDF [15,16].
In particular, an open label, prospective study of 4 follow up years showed that long-term treatment with BOSE added to ILO infusions administered quarterly in SSc patients, exerts a remodelling effect on structural and functional microvascular alterations and on stabilization of lung function, compared to ILO mono-therapy [17].

SP0177 NEW APPROACHES BY TARGETING SOLUBLE MEDIATORS

C.P. Denton. *Centre for Rheumatology, Royal Free Hospital and Ucl Medical School, London, United Kingdom*

Although the aetiopathogenesis of systemic sclerosis (SSc) remains incompletely understood there is now sufficient knowledge about the pathobiology of the disease and mechanisms underlying development of fibrosis, autoimmunity and vasculopathy to permit informed selection of candidate soluble mediators that may be important drivers of the disease. This has permitted testing of potential targeting approaches in preclinical models and in vitro tissue culture systems. The data from these studies has informed understanding of the disease and has started to be translated into clinical trials that test hypotheses in vivo in patients. This approach has in turn fueled the concepts of reverse translation that are being applied to further understand SSc mechanisms in model systems and observational cohort studies. Soluble mediators that have emerged as strong targets for therapeutic intervention include TGFbeta superfamily members, connective tissue growth factor, IL13, IL4 and IL6. Studies of agents that target these proteins have been proposed or undertaken. Targeting TGF-beta appears to have benefit for skin thickening and attenuate some of the characteristic TGF-beta regulated genes and proteins in skin. However, the most encouraging data have emerged from targeting the IL6 axis using anti-IL6R neutralizing antibodies. This approach was promising in a Phase II study and further trials are ongoing. Interestingly this approach appears to attenuate macrophage gene expression signatures in the skin, may prevent worsening of lung fibrosis and showed significant benefit in the skin by biomarker analysis and a strong trend of benefit over 48 weeks for skin sclerosis score. Other small clinical trials testing TNF-alpha blockade have been more disappointing. Finally, it is possible that soluble mediators may be identified that directly attenuate the fibroproliferative mechanism of SSc. Experimental studies have suggested that increasing alpha-MSH may have benefit for skin fibrosis in a small controlled clinical trial. Clinical trial design is critical to the success and interpretation of studies targeting soluble mediators to define target engagement, mechanism of action, and possible clinical benefit. Advances in trial design are facilitating progress and it seems likely that, as in other rheumatic diseases, targeting key soluble mediators will become a therapeutic reality of the next few years. Defining the place of such approaches compared to other emerging treatment strategies will remain challenging.

How diet influences musculoskeletal diseases

SP0178 GUT DYSBIOSIS AND OTHER CHALLENGES PRECIPITATE ARTHRITIS

C. Mackay. *Biodiscovery Research Institute, Monash University, Clayton, Australia*

Environmental factors contribute to development of autoimmune diseases. For instance, human autoimmune arthritis can associate with intestinal inflammation, cigarette smoking, periodontal disease, and various infections. The cellular and molecular pathways whereby such remote challenges might precipitate arthritis or flares remain unclear. We have defined many of the pathways in the gut that contribute to homeostasis, particularly GPCRs such as GPR43 and their ligands the short chain fatty acids. Such receptors and their ligands are anti-inflammatory. To probe peripheral inflammation connections to arthritis, we used a transfer model of self-reactive arthritis-inducing CD4 cells from KRNtg mice that, upon transfer, induce a very mild form of auto-inflammatory arthritis in recipient animals. This model enabled us to identify external factors that greatly aggravated disease, such as microbiota effects or disruption of gut homeostasis. We show that several distinct challenges precipitated full-blown arthritis, including intestinal inflammation through DSS-induced colitis, and bronchial stress through Influenza infection. Both triggers induced strong IL-17 expression primarily in self-reactive CD4 cells in lymph nodes draining the site of inflammation. Moreover, treatment of mice with IL-1b greatly exacerbated arthritis, while transfer of KRNtg CD4 cells lacking IL-1R significantly reduced disease and IL-17 expression. Thus, IL-1b enhances the autoaggressive potential of self-reactive CD4 cells, through increased Th17 differentiation, and this influences inflammatory events in the joints. We propose that diverse challenges that cause remote inflammation (lung infection, colitis, gut dysbiosis) result in IL-1b -driven Th17 differentiation, and this precipitates arthritis in genetically susceptible individuals. Thus the etiology of autoimmune inflammatory arthritis likely relates to diverse triggers that converge to a common pathway involving IL-1b production and Th17 cell distribution.

Can targeting disease activity in hand osteoarthritis improve our treatment in the 21st century

SP0179 WHAT IS DISEASE ACTIVITY IN FINGER OA?

R. Wittoek. *Rheumatology, University Hospital Ghent, Gent, Belgium*

Osteoarthritis of the interphalangeal finger joints constitutes one of the most prevalent musculoskeletal diseases with variable clinical impact ranging from nearly asymptomatic to severe inflammatory pain in and around affected joints, presence of soft tissue and bony swelling, stiffness and gradual loss of function. Current therapeutic options are limited to analgesic treatment but research on targeted therapies is increasing.
In order to improve the current treatments, a critical appraisal of the needs for improvement in finger OA is needed and how disease activity is best defined.
Assessing disease activity or joint activity in finger OA is challenging: disease activity can comprise pain, inflammatory activity and structural damage.
In clinical practice, a combination of patient-reported (e.g. visual analogue scale or Likert scale pain), more objective and performance-based measures (e.g. grip strength) are used to assess and follow disease activity. In clinical research, pharmacological trials and epidemiological studies, a standardized approach to assess the disease activity is necessary to estimate the burden of disease and to evaluate the efficacy of potential new treatments. The instruments being used, depend mostly on the aim of the study or research question. In case structural disease progression is being studied, imaging-based outcome measures are mostly used. Structural changes can be assessed on joint level or on patient level, both by conventional radiographs, ultrasound and magnetic resonance imaging. Several imaging based outcome measures and scoring systems are being suggested but true consensus about the instruments of preference is still lacking. Therefore, further validation of these instruments is warranted.
This lecture will give an overview of the current instruments to measure activity in finger OA in several domains and discuss its strengths and limitations.

SP0180 BIOLOGICS AND OTHER INFLAMMATORY THERAPIES IN FINGER OA. WHAT HAVE WE LEARNED?

X. Chevalier. *Dept. of Rheumatology, University Paris XII, UPEC, Créteil, France*

Hand osteoarthritis (HOA) is the most frequent form of osteoarthritis. A subset of digital hand OA is marked by an “inflammatory” like presentation with painful interphalangeal joints, refractory to NSAIDS and analgesics.

This clinical form of OA may be associated with a so called "erosive" radiographic aspect marked by subchondral erosions of the finger joints and ankylosis. Many mediators of inflammation have been involved in the pathogenesis of osteoarthritis such as prostaglandin E2, free radicals and main cytokines (IL1B, IL6, and TNFa). Using Doppler power ultrasonography and magnetic resonance imaging, it has been shown that synovitis is frequently associated with HOA and correlates with pain and with disease progression.
Taking all those considerations together, it appears logical to target synovitis in HOA, especially with an erosive form.
Because erosive hand OA is a polyarticular disease, the treatment is more systemic than local.
Local or oral NSAIDS are out of scope because this presentation focuses on patients with HOA non responders to analgesics and NSAIDS. So far, none of the disease modifying drugs such as methotrexate has proved its efficacy.
Regarding biologics, several strategies have been approached. The first biotherapy used in HOA was IL2 receptor plus hydroxychloroquine in a very limited number of patients. Then and more recently, anti-TNFa strategy has been tested in well done RCT, in painful hand OA: one with adalimumab over a year, one with adalimumab 40 mg with 2 sub-cutaneous injections, one using Etanercept (50 mg/week 24 weeks and then 25 mg/week the next 24 weeks). None of those anti-TNFa blockers demonstrated a structural or an analgesic effect. However in the long term trial published by Verbruggen G, the incidence of new erosive lesions was decreased in Adalimumab group compared to placebo, only in a subgroup of patient with clinically inflamed IP joints.
Using anti-IL1B strategy, a decrease in pain has been observed in 3 patients using daily subcutaneous injection of Anakinra (100mg) over 3 months ( ).
In this Eular meeting a double inhibition of IL-1 Beta and IL-1 Alpha (using a monoclonal antibody directed against both cytokine) failed to demonstrate any benefit compared to placebo injection over 26 weeks.
Finally anti-IL6 strategy has been presented in this 2017 Eular meeting in a limited number of patients (n=18) with erosive HOA. Using monthly IV perfusion, the authors showed an improvement in pain level and functional status.
Conclusion: though anti-inflammatory strategy in painful HOA is logical, no treatment so far has been able to demonstrate a beneficial effect. Further studies should contemplate either news targets, or new modalities of repeated injections and should be adapted according to the phenotype of pain.

Why we do develop autoimmunity

SP0181 FAILURE OF NATURAL REGULATORY AUTOANTIBODY NETWORK AS CAUSE OF AUTOIMUNITY

O.C. Marques on behalf of Lubeck University. Prof. Riemekasten. *Reumathology, University of Lübeck, 23562 Lübeck, Germany*

The role of autoantibodies in normal physiology is under debate. In investigating autoantibody (aab) concentrations against G protein-coupled receptors (GPCR) in different autoimmune diseases, we found both increased and decreased aab concentrations, which suggests physiological anti-GPCR aab levels may be dysregulated in autoimmune diseases. During our analysis of healthy donor antibodies to 16 GPCR and 15 growth factors and related signaling molecules, we discovered several clusters of correlations in these antibody concentrations. Possible functional interactions of these 31 autoantibody target molecules were studied by STRING, DAVID, and enriched Gene Ontology analyses. Through these analyses, a network of GPCR, growth factors, and signaling molecules with endothelin receptor type A (ETAR) in the center was revealed. Migration and locomotion were suggested to be the most significant functions regulated by the antibody network. Accordingly, IgG from healthy donors induced both IL-8 expression by peripheral blood mononuclear cells (PBMCs) as well as migration of neutrophils and tumor cells, which was specifically diminished by the ETAR inhibition. These data supports a change of paradigm from the notion that autoantibodies are an exclusive autoimmune phenomenon to the concept that they are part of the normal human physiology, which become dysregulated under the influence of different factors and subsequently cause autoimmune diseases.

SP0182 ALTERATIONS IN THE ANTIBODY REPERTOIRE AND SUGAR MODULATION AS CAUSE FOR AUTOIMMUNITY

H.U. Scherer. *Department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands*

Many auto-immune diseases are hallmarked by the presence of auto-reactive B cells that can develop into autoantibody-secreting plasma cells. In most cases, the secreted autoantibodies have extensively been studied in their role as disease-associated biomarkers, and for some, specific pathogenic effector functions have been demonstrated supporting the use of interventions that target the plasma cell compartment. In other cases such as rheumatoid arthritis (RA), however, the pathogenicity of specific autoantibodies is less clear, and the therapeutic efficacy of B cell depleting therapy that spares the plasma cell compartment indicates that auto-reactive B cells themselves can have pathogenic effector functions that contribute to disease. In this context, it is of great interest to understand the mechanisms that allow auto-reactive B cells to emerge from the naïve repertoire, a process that marks the onset of systemic autoimmunity and frequently precedes the clinical onset of disease.
RA is characterized by a remarkable appearance of autoantibodies that target post-translational modifications of proteins, of which anti-citrullinated protein antibodies (ACPA) display the highest specificity for disease. In addition, ACPA associate with active destructive RA and pose individuals with arthralgia at-risk for progression towards arthritis. We recently found that ACPA display significant alterations with regard to the glycosylation of both the Fc-tail as well as the F(ab)-domain. While the ACPA-IgG Fc-tail loses galactose and sialic acid residues prior to the onset of arthritis, a process associated with enhanced inflammatory antibody activity that occurs potentially under the influence of IL-17 producing T cells, ACPA also carry abundant glycans in the antigen-binding region of the F(ab) domain. These latter glycans are reminiscent of F(ab)-glycans found in follicular lymphoma B cells, and were here identified as N-linked, biantennary glycans composed of a remarkably high frequency of sialic acid residues. Notably, N-glycosylation requires the presence of glycosylation consensus sequences in the protein. As such sequences are normally scarce in the germline encoded variable regions of B cell receptors (BCR), the acquisition of F(ab)-glycans requires mutations of the amino-acid sequence to generate N-glycosylation sites. This process is mediated by somatic hypermutation, which is mainly induced by T cells that provide help to B cells. As >90% of all ACPA-IgG molecules carry such F(ab)-linked N-glycans, and as protective antibodies in the same individuals and many autoantibodies in other diseases do not show this feature, it is conceivable that the acquisition of F(ab)-glycans by ACPA-IgG is a T cell –mediated process that provides a selective advantage to ACPA-expressing B cells. This notion is supported by the observation that additional F(ab)-glycans are not found on ACPA-IgM. How F(ab)-glycans facilitate the emergence and/or expansion of auto-reactive B cells in this context, however, remains unclear. Using recently developed technology to identify and isolate citrullinated antigen-specific B cells from patients, we can now address this question by studying the frequency and localisation of N-glycosylation sites in the antibody repertoire and by studying the phenotype and functional characteristics of ACPA-expressing B cells. Together with our investigations on the modulation of ACPA Fc-glycans, these studies provide a deeper understanding of mechanisms that allow the development of autoimmunity as such, and of the mechanisms that underlie the progression from systemic autoimmunity towards overt autoimmune disease.

SP0183 FAILURE OF TREG CONTROL TO UNDERSTAND AUTOIMMUNITY

J.Y. Humrich. *Department of Rheumatology and Clinical Immunology, University Hospital Schleswig-Holstein, Campus Lübeck, Lübeck, Germany*

Regulatory T cells (Treg) expressing the transcription factor FoxP3 are crucial for the maintenance of immunological tolerance to self and thus for the control of autoimmunity. There is strong evidence that numeric or functional defects in Treg cell biology are involved in the pathogenesis of particular autoimmune diseases. Here we will focus on the fundamental role of Treg cells in diverse autoimmune and rheumatic diseases and will explain how a failure of the Treg cell system can evolve and contribute to the development of such diseases. Furthermore, therapeutic approaches aiming to overcome these Treg cell defects and to restore Treg cell activity in the patients will be discussed.

SP0184 ROLE OF MICROENVIRONMENT AND ENDOGENOUS PATHWAYS TO BREAK TOLERANCE

P. Lamprecht. *Universität Zu Lübeck, Lübeck, Germany*

Break of tolerance driving autoimmune disease is initiated by a combination of predisposing genetic and environmental factors resulting in self-perpetuating chronic inflammation and tissue damage. Effector molecules and cells targeting tissues housing the inciting autoantigen(s) maintain tissue damage and the autoimmune response. Granulomatosis with polyangiitis (GPA, formerly Wegener's granulomatosis) is a prototypical autoimmune disease characterized by extravascular necrotizing granulomatous inflammation and a systemic autoimmune vasculitis associated with anti-neutrophil cytoplasmic autoantibodies specific for the neutrophil- and monocyte-derived serine-protease proteinase 3 (PR3-ANCA). GPA is strongly associated with *HLA-DPB1*0401* polymorphisms. Its association with the *R620W* variant of the *PTPN22* gene has been linked to reduced immune-regulatory interleukin (IL)-10 transcription. Epidemiological studies and molecular analysis of immune cells suggests a multifactorial pathogenesis of GPA, in which a potentially metachronous and individually varying sequence of infectious agents contributes to the break of tolerance and chronic inflammation sustaining autoimmunity in GPA.

Closing the gap between objective measures and self-report in fibromyalgia

SP0185 DIVERGENCES BETWEEN OBJECTIVE AND SELF-REPORTED PHYSICAL FUNCTION IN FIBROMYALGIA

M. Henriksen. *Parker Instituttet Frederiksberg Hospital, Copenhagen, Denmark*

In fibromyalgia (FM), intolerance to physical activity, with increased pain and experience of early muscle fatigue, is a predominant feature. Furthermore, shorter endurance times and higher perceived effort during physical activity compared with healthy controls are characteristic. However, there are discrepancies between physical functioning as perceived by the patients and as measured objectively or during performance tests. For example, in 840 FM patients and 122 healthy controls, we found reduced muscle strength in approximately 50% of the FM patients. However, the patients with subnormal muscle strength did not self-report worse symptoms or more physical disablement than those with normal muscle strength. Much like central sensitization of pain, it has been suggested that impaired sensory-motor interaction is present in FM, which may be a cause for observed discrepancies between perceived and objective signs of muscle fatigue. That is, the sensory inputs to the central nervous system during a physical activity are over-interpreted, leading to amplified sensations of fatigue and discomfort normally associated with exhausting muscle work.
To illuminate this we conducted a controlled experiment, in which FM patients and health controls completed a muscle exhaustion test, while objective measures of muscle fatigue were collected by electromyography in parallel with reporting of perceived muscle fatigue. The results suggest that among FM patients, central nervous system processes normally associated with muscular fatigue were present, yet without any evidence of peripheral muscle fatigue. The study supports a hypothesis about abnormal sensory-motor interaction among FM patients that can explain the discrepancies between perceived and observed physical disability in FM.

SP0186 COGNITIVE FOG: SUBJECTIVE AND OBJECTIVE UNDERSTANDINGS OF THE SYMPTOM OF DYSCOGNITION

B. Walitt. *National Institute of Nursing Research, National Institutes of Health, Bethesda, United States*

Dyscognition refers to the complaint that a person's ability to perform thinking tasks is impaired. This complaint is colloquially known as "brain fog". It is a major symptom of a variety of disorders and associated with considerable work and social disability for those experiencing it. However, attempts to demonstrate objective cognitive impairment in persons reporting "brain fog" have not been straightforward. In this lecture, the symptom of cognitive dysfunction will be described from the patient's point of view, using fibromyalgia as a disease model. The cognitive tests used to determine objective alterations in cognitive ability will be reviewed, the amount of objective impairment demonstrated in fibromyalgia will be placed into clinical context, and the "disconnect" between what the experience of dyscognition is and the cognitive content measured by modern testing will be discussed. The poor relationship between the magnitude of subjective dyscognition and objective cognitive performance will be examined, including evidence gleaned from neurological imaging studies. In conclusion, the experience of cognitive fog is not well captured by current testing paradigms. Subjective complaint is a poor predictor of objective cognitive performance. The neuronal mechanisms responsible for the experience of cognitive fog may be separate from those required to perform cognitive tasks.

SP0187 ASSOCIATIONS OF PAIN-RELATED COGNITIONS WITH THE DISCORDANCE BETWEEN SUBJECTIVE AND OBJECTIVE PHYSICAL FUNCTION IN FIBROMYALGIA: THE AL-ÁNDALUS PROJECT

F. Estévez-López[1,2]. *[1]Department of Physical Education and Sport, Faculty of Sport Sciences, University of Granada, Granada, Spain; [2]Department of Psychology, Faculty of Social and Behavioural Sciences, Utrecht University, Utrecht, Netherlands*

Background: In fibromyalgia, there is a disagreement between patients' self-reports and performances; i.e., subjective and objective status, respectively.
Objectives: First, to test the discordance between subjective and objective measures of physical function. Second, to determine whether catastrophizing and self-efficacy are independently associated with this discordance.
Methods: Four hundred and five fibromyalgia females and 193 age-matched female controls. Participants filled out the Pain Catastrophizing Scale, Chronic Pain Self-efficacy Scale, and physical functioning subscales of the Revised Fibromyalgia Impact Questionnaire (FIQR) and Short Form-36 (SF-36) health survey. Objective physical function was measured with a battery of performance-based tests (e.g., 6-min walk test). Subjective and objective physical function were expressed as deviation from the general population in standard deviation (*SD*) units using means and *SD* of the control group.
Results: Fibromyalgia participants reported a worse physical function than performed ($p<.001$). We found a consistent association of higher catastrophizing with greater discordance between subjective and objective physical function. A significant association of higher self-efficacy with lower discordance was only found when subjective physical function was reported on the SF-36 but not on the FIQR.
Conclusions: Although both are markedly impaired, subjective physical function is more impaired than objective physical function in fibromyalgia. Catastrophizing is associated with this discordance. In rehabilitation settings, physical function of fibromyalgia females should be evaluated by both subjective and objective assessments to fully understand their physical function.

SP0188 THE DRUGS DON'T WORK

L. Piggott. *Fibromyalgia, Nantwich, United Kingdom*

This presentation will depict the journey of Louise, a previous school teacher and a single mother of two, living with Fibromyalgia as well as multiple other diagnoses. Louise will discuss her feelings around being diagnosed with Fibromyalgia, how this was communicated to her and what this meant for her career and family life. Following this, Louise will share her journey through the secondary care as a Fibromyalgia patient, and her own search for answers and cure to Fibromyalgia in an attempt to salvage her life and independence, prior to accepting that this is a long-term condition which will require self-management and perseverance. In addition, Louise will share her thoughts on pain and fatigue in Fibromyalgia, and how the "drugs don't work".

Interactive cases from the HOT and WIN sessions

SP0189 HOT SESSION: INTERACTIVE CLINICAL ASPECTS AND CASES ON VASCULITIS TREATMENT

R.A. Luqmani. *University of Oxford, Oxford, United Kingdom*

The systemic vasculitides are characterized by inflammation of blood vessels resulting in end organ, or tissue damage or necrosis. They are defined by the Chapel Hill nomenclature according to the calibre of the predominantly affected vessels. Other forms of vasculitis not defined by a predominant vessel size are also recognized (e.g. Behcet's syndrome). Large vessel vasculitides include giant cell arteritis and Takayasu arteritis; medium vessel vasculitides includes Kawasaki disease and PAN; small vessel vasculitides are divided into: immune complex small vessel vasculitis and anti-neutrophil cytoplasm antibody (ANCA) - associated vasculitis (AAV). The immune complex group, with moderate to marked vessel wall deposits of immunoglobulin and/or complement, is represented by anti-glomerular basement membrane disease, cryobulinaemic vasculitis, hypocomplementaemic urticarial vasculitis (anti-C1q vasculitis) and IgA vasculitis (Henoch–Schönlein). By contrast, AAV has few or no immune deposits and is associated with (in most cases) the presence of ANCA specific for myeloperoxidase (MPO-ANCA) or proteinase 3 (PR3-ANCA). Depending on their clinical presentation and ANCA specificity, AAV is divided into three major variants: granulomatosis with polyangiitis (GPA) (Wegener's granulomatosis), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA) (Churg–Strauss syndrome). In some cases, vasculitis is relatively trivial and may lead to minor, often asymptomatic clinical features such as splinter haemorrhages. However, in severe forms of ANCA associated vasculitis, the consequences of rapid onset of ischaemia and occlusion of blood vessels can lead to organ failure and death.
The multisystem involvement in most forms of vasculitis can be a real challenge. Patients may present to different specialists resulting in diagnostic delay. The investigation of patients with suspected vasculitis should follow on from a careful history and examination to determine the likely diagnosis. The differential diagnosis is very wide. It is important to correctly identify patients with vasculitis as early as possible, but it is also important to rule out more common causes. In acutely unwell patients, the differential diagnosis depends on the combination of clinical features. Vasculitides tend to involve multiple organ systems. In fact, the more organ systems affected, the more likely it is that the patient has vasculitis.

We will review some examples of cases with what might appear to be unusual clinical features which form a more consistent pattern. Initial treatment is generally straightforward, but the evaluation of patients during the course of their illness is often difficult due to variation in disease, as well as drug toxicity, damage and co-morbidity. We will discuss examples of patients where relapse is suspected but not always confirmed.
In this overview we will summarise current practice in vasculitis, illustrated by cases to provide a clinical context in which to interpret and implement evidence based management of vasculitis

Suffering in silence. Optimizing the management of psychological well-being for people with RMDs

SP0190 FACTS AND FIGURES: HOW MENTAL HEALTH CARE ADDRESSES THE PSYCHOLOGICAL BURDEN OF RMD'S IN EUROPE

E. Dures. *University of the West of England, BRISTOL, Bristol, United Kingdom*

It is recognised that patients have to make behaviour changes and psychological adjustments to address the impact of inflammatory arthritis on their lives. Challenges include fluctuating pain, fatigue and flares of disease activity, and emotional consequences. Meeting these challenges effectively requires patients to engage in medical management, role management, and emotional management. For some patients this can be a struggle, and the rheumatology team can be a valued source of support.
This session will examine patient perspectives on the psychological impact of inflammatory arthritis and the role of the rheumatology team in meeting the associated support needs. It will look at the relationship between psychological distress, well-being and self-management, and will highlight patients' views on the characteristics of patient-centred, collaborative care. It will look at factors that influence psychological impact, adaptation and self-management; present data from patients on ways in which well-being and self-management can be enhanced or diminished through clinical interactions with the rheumatology team; and will consider the implications for clinical practice, including the training needs of the rheumatology team.

SATURDAY, 17 JUNE 2017

Showcasing the EULAR Online Course for Health Professionals

SP0191 PRINCIPLES OF NON-PHARMACOLOGICAL MANAGEMENT OF REGIONAL MUSCULOSKELETAL DISORDERS

P. Oesch. *Physiotherapy, Kliniken Valens, Valens, Switzerland*

The two main components of non-pharmacological management of regional musculoskeletal disorders are a thorough assessment followed by rehabilitative care.
Assessment includes a careful history, level of daily activities and participation, including occupation, rehabilitative care to date, possible presence of psychosocial problems, sports and hobbies. Special attention must be given to patient's expectations and personal objectives. A systemic enquiry is also important, as regional pain may be due to an underlying medical condition. Clinical examination consists of observation of posture, mobility, and whether there is evidence of wasting, asymmetry, deformity, or muscle imbalances. Palpation of soft tissue and bony structures follows to identify areas of tenderness, lumps, myofascial trigger points, tendon crepitus. Assessment of active and passive movements in all planes follows looking for specific restrictions. Examination is not restricted to the site of pain; as for example upper limb pain syndromes may be referred from the neck. In some patients further medical investigation is necessary when a thorough history, examination, and ultrasonography do not provide sufficient diagnostic information. This may involve blood tests, plain radiography, CT or MRI.
Rehabilitative care is a customized process, which aims to achieve an optimal functional outcome and participation in all aspects of life. Active rehabilitation and a gradual return to normal activities are key points in successful treatment of regional pain syndromes. Progressive exercise is a fundamental part of the treatment of most regional musculoskeletal complaints. The goal is to work towards full, specific, pain free functional activity. In myofascial pain syndromes and non specific arm pain in particular, there is a need for review of postural issues and ergonomics and building aerobic fitness. In addition, providing information to the patient about the nature of the condition, beneficial and negative habits and activities, self help exercises, expected response to treatment and outcome should all be part of the approach to these patients. Psychological interventions may complement rehabilitative care. Cognitive and behavioral methods focus on changing the patient's interpretation and reaction to pain. The main assumption of a behavioral approach is that pain and pain disability are influenced by somatic pathology and also by psychosocial factors (eg, patient's attitudes and beliefs, psychological distress and illness behavior). Consequently, the behavioral treatment of regional musculoskeletal disorders does not primarily focus on removing an underlying organic pathology, but on the reduction of disability through modification of environmental contingencies and cognitive processes.

SP0192 PRINCIPLES OF NON-PHARMACOLOGICAL MANAGEMENT OF RHEUMATIC DISEASES

T. Vliet Vlieland on behalf of Dr. Keegan Knittle, Professor Jo Adams and Dr. Mwidmi Ndosi. *Orthopaedics J11-R, Leiden University Medical Center, Leiden, Netherlands*

Background and aims: Rheumatic and musculoskeletal diseases (RMDs) have a major impact on patients' lives. Apart from symptoms such as pain, stiffness and fatigue, many patients may experience limitations in daily activities and participation in society. Rheumatology health professionals (HPs) play a pivotal role in the improvement and maintenance of patients' functioning, a crucial aspect of patients' quality of life. To ensure the quality of care, HPs need to be appropriately trained. For this purpose, one module of the EULAR online course for HPs is dedicated to HPs' interventions related to various RMDs.
Methods: Using the same methodology, expertise and technology used in other EULAR online courses, the following components of the module were developed: A Main Text, Interactive Clinical Cases, Indepth Discussions and two Assessment sets.
Results: First, 4 learning aims were formulated: After completing the module, the student a. Has an overview of interventions commonly provided by HPs in the treatment of patients with RMDs; b. Demonstrates appropriate understanding of opportunities and limitations of the various interventions employed by HPs on the individual patient level; c. Can properly advise and support patients regarding self-management strategies including e.g., appropriate medication usage, exercises, the application of joint protection and energy conservation, the usage of orthoses and adaptive equipment or other; and d. Can make a substantiated decision on when to refer a patient to another health professional, a physician or a multidisciplinary team. Second, a wide range of modalities, such as exercise therapy, self-management support, cognitive behavioural therapy, the provision of orthoses, assistive devices or physical modalities were described. These were further applied and/or explained by means of Interactive Clinical Cases and Indepth Discussions (Patient education and Physical Activity Interventions).
Conclusions: A module of the EULAR Online course for HPs specifically describes and explains HPs' interventions employed in the management of people with various RMDs. Its contents will be updated according to new clinical and scientific insights. Moreover, it will be adapted to the educational needs of HPs, by taking into account the comments of the students and perspectives from HPs across Europe.

SP0193 PRINCIPLES OF NON-PHARMACOLOGICAL MANAGEMENT OF FIBROMYALGIA

J.E. Vriezekolk. *Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands*

Having fibromyalgia greatly impacts person's mental and physical wellbeing, his activities of daily living, and the society at large. Despite scientific progress to unravel the aetiology of fibromyalgia syndrome, no cure is yet available. The management of fibromyalgia comprises both pharmacological and non-pharmacological treatment option to alleviate the symptom burden of the disease. The recently published EULAR revised recommendations for the management of fibromyalgia[1], proposes that the management of fibromyalgia should take the form of a graduated approach with the aim of improving health-related quality of life. It should focus first on non-pharmacological treatment, including education, self-management and physical therapy with graded physical exercises. In this talk a brief overview of the current evidence regarding non-pharmacological care in fibromyalgia will be given. The importance of patients' self-management, (tailored) interventions to support self-management, and its dissemination and implementation in clinical practice will be highlighted.

SP0194 **PRINCIPLES OF ASSESSMENT IN CLINICAL PRACTICE**

R. Hilfiker. *Physiotherapy, HES-SO Valais-Wallis, Leukerbad, Switzerland*

In clinical practice, assessment is important for the selection of intervention strategies, goal setting, prognosis and the evaluation of the progression made towards the treatment goals. For example, we need to assess the patients' perceptions on how the disease, functioning and disability interferes with their life situation. Furthermore, we should assess how they can cope with stressful events, what social support they experience and how they adjust to living with a chronic disease. The assessment should provide information on problems, needs and priorities of the patients, as well as on strengths and resources. Based on the initial assessment, mutually agreed treatment goals and treatment strategies can be defined together with the patients.

We need to be aware of the differences, strengths and weaknesses of observations (e.g. Barthel Index), measures (walking speed) and self-reported questionnaires (patient-reported outcomes) or individualised, patient specific measures (e.g. the Patient-Specific Functional Scale).

In most situations, it is recommended to combine generic and specific measures to cover general as well as specific issues of health, functioning and disability or contextual factors. This will also allow the comparison across groups of patients.

Each tool used in the assessment should serve a clear objective and should be able to achieve this objective in the given situation. We need to know the relevant measurement properties on reproducibility and validity for the instrument in a given situation. The agreement or the measurement error will tell us, for example, how small a change can be to be detected (i.e. smallest detectable change). This is important when we want to monitor change (evaluation). Reliability indices will tell us how good we can distinguish groups of patients and whether we can use an instrument in a group setting (i.e. in a study; the ICC should be at least 0.7) or for the use with individuals in clinical practice (ICC should be at least 0.9).

We can distinguish three types of validity, content validity, construct validity and criterion validity. The content validity informs on how good a tool covers all relevant aspects of the construct to be measured and whether all items cover relevant aspects. An instrument has a good criterion validity if its results are similar to a so-called gold standard (instrument that is known to be valid). The construct validity tells us whether the scores of the measurement instrument are associated with instruments that measure a similar construct and are not associated with scores from instruments that measure non-related concepts.

Other important aspects are responsiveness and interpretability. Responsiveness is the ability of an instrument to detect change over time in the construct to be measured. Interpretability means that the scores are understandable and meaningful. Aspects of interpretability are floor and ceiling effects, and whether the smallest detectable change and the minimal important change are known.

Of course, the application of an instrument has to be feasible. Therefore, there is often a trade-off between measurement properties and feasibility, i.e. the perfectly reliable and valid instrument might be too expensive or too time consuming. Therefore, a less "perfect" instrument might be chosen.

All the mentioned aspects need to be considered when defining an individual assessment strategy for a patient. The assessment and evaluation should be an integrated part of the treatment process. It verifies that the treatment is in line with the needs and priorities of the patients; the documentation of changes might motivate both patients and health professionals and it might increase adherence to the recommended treatments.

HPR Highlight session

SP0195 **HIGHLIGHTS FROM THE HEALTH PROFESSIONAL SESSIONS**

R.J.O. Ferreira[1,2]. [1]*Health Sciences Research Unit: Nursing (UICiSA:E), Escola Superior de Enfermagem de Coimbra;* [2]*Rheumatology department, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal*

EULAR congress is one on the biggest events in the world of rheumatology. To accommodate all the diversity of topics, several sessions take place at same time, in different rooms. It is very hard, even impossible, to be in all sessions, poster tours, social meetings and other learning events of your interest. It often happens that one want to be at 3 or 4 places at same time.

This "Highlights" session is designed to summarize the most important conclusions of the talks given in all sessions from Health Professionals programme. By this way you can catch on what you missed to be in other places. Of course you can also read the abstracts in the EULAR app or Annals of Rheumatic Diseases Suplement or even to watch the podcasts after the event. However, this highlights session will provide you an integrated view of the different contents in a more appealing and interactive perspective.

Moving towards new criteria in SLE, Sjögren's and APS

OP0001 THE LUPUS LOW DISEASE ACTIVITY STATE (LLDAS) DEFINITION DISCRIMINATES RESPONDERS IN A SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) TRIAL: POST-HOC ANALYSIS OF THE PHASE IIB MUSE TRIAL OF ANIFROLUMAB

E. Morand[1], A. Berglind[2], T. Sheytanova[2], R. Tummala[3], G. Illei[4]. *[1]Monash University, Melbourne, Australia; [2]AstraZeneca, Mölndal, Sweden; [3]AstraZeneca; [4]MedImmune LLC, Gaithersburg, United States*

Background: A LLDAS definition has received preliminarily validation. Achieving low disease activity by this definition is associated with protection from damage accrual for patients (pts) with SLE.[1] However, it has not been evaluated as an endpoint in randomized controlled trials (RCTs).
Objectives: We evaluated LLDAS as an RCT endpoint in a *post-hoc* analysis of the MUSE trial of anifrolumab in pts with moderate to severe SLE.[2]
Methods: During the 52-week MUSE study, pts with active SLE received intravenous placebo, anifrolumab 300 mg, or 1,000 mg, in addition to standard of care, every 4 weeks for 48 weeks. LLDAS requires all of the following: SLEDAI–2K $\leq$4 without major organ activity, no new disease activity, PGA (0–3) $\leq$1, prednisolone $\leq$7.5 mg/day, and tolerance of standard immunosuppressant dosages.[1] LLDAS utility, its association with other endpoints, and discrimination between anifrolumab- and placebo-treated pts, were explored using descriptive statistics, logistic regression, and Gray's test. All randomized pts in MUSE were included in the analyses, and non-response imputation was performed after dropout.
Results: For pts receiving placebo (n=102), anifrolumab 300 mg (n=99), or anifrolumab 1,000 mg (n=104), LLDAS criteria were met at least once by 35%, 52%, and 46% of pts, respectively (odds ratio [OR] vs. placebo; 300 mg: 1.97, 95% CI 1.08, 3.58; p=0.027; 1,000 mg: 1.63, 95% CI 0.90, 2.95; p=0.103). Positive associations were observed between LLDAS and both the SLE Responder Index (SRI[4]) and BILAG-based Composite Lupus Assessment (BICLA), with 87% and 74% of pts attaining LLDAS at Week 52 also being SRI(4) and BICLA responders, respectively (χ^2=57.61 and 55.18; both $p<0.0001$). However, only 47% and 51% of SRI(4) and BICLA responders reached LLDAS. Increased LLDAS attainment from Week 12 (300 mg) or 28 (1,000 mg) was associated with anifrolumab treatment, compared with placebo (OR range; 300 mg: 1.7–3.6; 1,000 mg: 1.7–2.5). LLDAS was attained earlier (300 mg: χ^2=6.39, p=0.012; 1,000 mg: χ^2=2.44, p=0.119) in anifrolumab-treated pts (Figure 1). At Week 52, more anifrolumab-treated pts attained a LLDAS (OR vs. placebo; 300 mg: 3.41, 95% CI 1.73, 6.76, $p<0.001$; 1,000 mg: 2.03, 95% CI 1.01, 4.07, p=0.046). More anifrolumab-treated pts spent $\geq$50% of observed time in LLDAS (OR vs. placebo; 300 mg: 3.04, 95% CI 1.34, 6.92; p=0.008; 1,000 mg: 2.17, 95% CI 0.93, 5.03; p=0.072), and the OR of sustained LLDAS for at least six consecutive visits from Week 12 to 52 were 4.02 (95% CI 1.38, 11.73; p=0.011) (300 mg) and 2.95 (95% CI 0.99, 8.78; p=0.052) (1,000 mg).
Conclusions: LLDAS is associated with validated treatment response measures, SRI(4) and BICLA, but is more stringent than either. Anifrolumab was associated with $\leq$3.6-fold OR increases in LLDAS attainment, as well as greater aggregate and sustained time in LLDAS. This LLDAS definition should be considered as a study endpoint in SLE RCTs.

OP0002 MULTICRITERIA DECISION ANALYSIS FOR DEVELOPING NEW CLASSIFICATION CRITERIA FOR SYSTEMIC LUPUS ERYTHEMATOSUS

S. Tedeschi[1], S. Johnson[2], D. Boumpas[3], D. Daikh[4], B. Diamond[5], T. Dorner[6], S. Jacobsen[7], D. Kamen[8], W. McCune[9], M. Mosca[10], R. Ramsey-Goldman[11], G. Ruiz-Irastorza[12], M. Schneider[13], J. Smolen[14], M. Urowitz[2], D. Wofsy[4], M. Aringer[15], R. Naden[16], K. Costenbader[1]. *[1]Harvard Medical School, Boston, United States; [2]Univ. Toronto, Ontario, Canada; [3]Univ. Athens, Athens, Greece; [4]Univ. California, San Francisco; [5]Feinstein Institute, Manhasset, United States; [6]Charite Univ. Hospitals, Berlin, Germany; [7]Copenhagen Univ. Hospital, Copenhagen, Denmark; [8]Medical Univ. S. Carolina, Charleston; [9]Univ. Michigan, Ann Arbor, United States; [10]Univ. Pisa, Pisa, Italy; [11]Northwestern Univ., Chicago, United States; [12]Biocruces Institute, Barakaldo, Spain; [13]Univ. Dusseldorf, Dusseldorf, Germany; [14]Medical Univ. Vienna, Vienna, Austria; [15]Univ. Medical Center Carl Gustav Carus, Dresden, Germany; [16]McMaster Univ., Hamilton, Canada*

Background: EULAR and ACR are supporting multi-phase development of SLE classification criteria based on weighted criteria and a continuous probability scale. Prior steps included criteria generation, criteria reduction through Delphi and Nominal Group Technique exercises, literature review for sensitivity/specificity of candidate criteria, and organization of candidate criteria into seven clinical and three immunologic domains.
Objectives: To refine definitions of candidate criteria, determine relative weights using multicriteria decision analysis, and determine a threshold score for SLE classification.
Methods: An SLE Expert Panel (9 North American, 8 European) submitted 167 unique cases with a range of SLE probability. Experts scored 20 representative cases using the candidate criteria and rank-ordered them. In a 2-day meeting, experts reviewed inter-rater reliability of scoring, refined criteria definitions, and participated in a multicriteria decision analysis (MCDA) exercise using 1000Minds™ software. Experts were presented a series of decisions between two cases, each with different criteria from two domains (e.g. oral ulcers [cutaneous] and acute pericarditis [serositis] vs. alopecia [cutaneous] and pleural effusion [serositis]) and anonymously voted for the case more likely to be classified as SLE. Votes were discussed until consensus was reached for each decision. Using the consensus decisions, 1000Minds™ calculated criteria weights, assigned a total score to each of remaining 147 cases and rank-ordered the cases. Experts voted on whether each case should be classified as SLE. MCDA was repeated for criteria whose calculated weights were inconsistent with expert opinion until group consensus was achieved. 1000Minds™ then re-calculated criteria weights and re-ranked cases once. The score of the last case for which expert consensus was achieved was the threshold score.
Results: Inter-rater reliability was good; human data entry error, not following instructions, and differing interpretations of criteria definitions accounted for discrepancies. Arthritis and pericarditis definitions were modified through group discussion. The MCDA involved 74 pairwise decisions. Cranial neuropathy and Class VI lupus nephritis were removed as they added little to SLE classification. MCDA was repeated for the arthritis and cutaneous domains as initial weights did not match expert opinion. After criteria weights and scores were re-calculated once, experts reached consensus for SLE classification for case score $>$83.
Conclusions: Using an iterative process, the expert panel refined definitions, weighted candidate criteria and determined a threshold score of $>$83 for SLE classification, which will undergo validation.

Controlling the balance between cancer and autoimmunity

OP0003 RHEUMATIC IMMUNE RELATED ADVERSE EVENTS OF CHECKPOINT THERAPY FOR CANCER: CASE SERIES OF AN EMERGING NOSOLOGIC ENTITY

C. Calabrese[1], E. Kirchner[1], A. Kontzias[1], V. Velcheti[2], L. Calabrese[1].
[1]Rheumatologic and Immunologic Diseases; [2]Hematology and Oncology, Cleveland Clinic, Cleveland, United States

Background: Immune checkpoint therapy is a major advance in the field of oncology. Agents targeting CTLA-4, programmed cell death protein 1 (PD-1) and PD-ligand 1 have produced significant survival benefits in patients with malignancies. With these therapies have come a unique spectrum of adverse events related to over-activation of the immune system with resultant autoimmune disease. To date reports of rheumatic immune related AEs (irAEs) have not been adequately characterized, as they are infrequently reported in clinical trials. We describe the largest series of rheumatic irAEs secondary to checkpoint inhibitors to date.
Objectives: To report our 22 month experience with 19 patients evaluated in the Cleveland Clinic Rheumatology department.
Methods: A retrospective chart review was performed on 19 patients, 16 without pre-existing autoimmune disease (AID) and 3 with pre-existing AID, seen in our rheumatology department February 2015-December 2016. 2 designated rheumatologists evaluated all patients. Recorded information included gender, age, age at malignancy diagnosis, malignancy details, checkpoint inhibitor, nature of rheumatic irAE, time of onset, diagnostic data, treatment of irAE and response to treatment.
Results: In the group without pre-existing AID 56% developed a rheumatic irAE within 16 weeks of starting immunotherapy, with median time to onset of 14.5 weeks (table 1). Of the 3 patients with pre-existing AID, 1 experienced a disease flare after starting immunotherapy.
Conclusions: Rheumatic irAEs is a new field that will continue to grow. At this stage we have more questions than answers regarding their epidemiology, natural history and pathophysiology. Our findings reinforce that rheumatic irAEs are complex, at times require aggressive immunosuppression and can impact checkpoint inhibitor therapy for the underlying malignancy.

OP0004 RHEUMATOID ARTHRITIS OCCURING AFTER IMMUNE CHECKPOINT INHIBITORS

R. Belkhir[1] pagebreak, S. Le Burel[1], O. Lambotte[1], G. Mouterde[2], E. Pertuiset[3], L. Dunogeant[4], A. Marabelle[5], A. Leary[6], A.-L. Voisin[7], X. Mariette[1]. *[1]Hôpitaux Universitaires Paris-Sud, Université Paris-Sud, AP-HP, le Kremlin Bicêtre; [2]Lapeyronie Hospital, Montpellier; [3]CH René Dubos, Pontoise; [4]Centre Hospitalier du Pays d'Aix, Aix-en-Provence; [5]Drug Development; [6]Université Paris-Saclay; [7]Unité Fonctionnelle de Pharmacovigilance, Université Paris Saclay, Gustave Roussy Cancer Center, Villejuif, France*

Background: Immune checkpoints inhibitors (ICIs) targeting cytotoxic T lymphocyte-associated protein 4 (CTLA-4) and Programmed cell death protein 1 (PD-1) have demonstrated survival improvement in multiple cancers. Immune Related Adverse Events (IrAE) have been described with ipilimumab and anti PD1. Relapse or flare of preexisting auto-immune diseases has been reported but occurrence of new auto-immune diseases seems to be less frequent. A series of 13 patients with non-classified rheumatic IrAE has been published: 9 patients developed non-specific inflammatory arthritis but no seropositive rheumatoid arthritis (RA) and 4 presented with sicca symptoms but did not fulfill criteria for Sjögren syndrome [1].
Objectives: We did a retrospective study for collecting patients who developed seropositive rheumatoid arthritis (RA) after exposition to ICIs.
Methods: We used the "Club Rhumatismes et Inflammation (CRI)" network, a section of the French Society of Rheumatology and the Gustave Roussy Cancer

Abstract OP0003 – Table 1. Demographic features, cancer types, immunotherapy and rheumatic irAEs

6	M 68 y	Lung adenocarcinoma	nivolumab	June 2015	July 2015	RA	Resolution after stopping nivolumab and after 1 month of methotrexate 10 mg/w (maintained 3 months)	anti-CCP >300U/ml RF: 246 UI/ml

Center register of safety of ICI for collecting patients treated with an ICI and who developed symptoms of arthritis with diagnosis of RA.
Results: We report 6 patients without any previous rheumatic disease, who developed seropositive rheumatoid arthritis (RA) after exposition to ICIs, all of them after anti-PD1.
Conclusions: This is the first description of RA occurring after anti-PD1 treatment for cancer. All cases responded to corticosteroids or with immunosuppressive therapy. This suggests that the PD1/PDL1 axis plays a role in RA pathophysiology. The combined expertise of oncologists, immunologists and rheumatologists is crucial in the successful management of these patients.

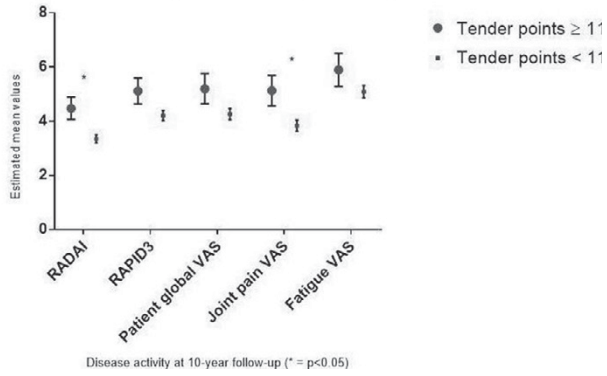
WEDNESDAY, 14 JUNE 2017

Fibromyalgia: a disease of the peripheral or central nervous system

OP0005 FIBROMYALGIA IN PATIENTS WITH RHEUMATOID ARTHRITIS IN A 10-YEAR PERSPECTIVE

S.A. Provan, C. Austad, V. Halsaa, H.B. Hammer, T.K. Kvien, T. Uhlig.
Rheumatology, Diakonhjemmet Hospital, Oslo Norway, Oslo, Norway



Background: Approximately 10% of patients with rheumatoid arthritis (RA) have coexisting fibromyalgia (FM). Little is known of the cross-sectional and longitudinal relationship between FM and RA disease activity.
Objectives: To examine the cross-sectional and longitudinal relationship between FM and RA disease activity.
Methods: Oslo RA register (ORAR) was established in 1994 as a prospective, observational, longitudinal nested cohort study. The inclusion criteria were RA according to the 1987-ACR classification criteria and a residential address in Oslo. 636 patients in ORAR were asked to participate in a clinical examination in 1999. A trained study-nurse systematically assessed the 18-tender point count and performed 28-tender and 28-swollen joint counts (TJC/SJC). Patients self-reported disease activity and pain related to RA, and completed the Stanford Health Assessment Questionnaire (HAQ). RA disease activity was calculated as DAS28. Fibromyalgia was diagnosed if $\geq$11 tender points were reported. FM associated variables; fatigue, muscular tenderness, headache, abdominal pain and difficulties concentrating were also scored (0–10 VAS).
At the 10-year follow-up patients completed a questionnaire that included RA Disease Activity Index (RADAI) and Routine Assessment of Patient Index Data (RAPID-3).
In cross-sectional and longitudinal analyses RA disease activity, FM associated variables and health status were compared between patients with $\geq$11 and $<$11 tender points. Level of significance was calculated using ANCOVA models corrected for age, gender, BMI and level of education. The FM associated variables at baseline were also corrected for baseline SJC 28 and C-reactive protein (CRP). The variables in the longitudinal study were corrected for the same variables as the cross-sectional analyses, but additionally for baseline values of the dependent variable when available.
Results: 488 patients agreed to participate in the baseline data-collection and 192 participated at the 10-year follow-up. The mean (SD) age was 59.5 (12.5) years, and 87% were female. There were no significant differences in age, disease duration or participation at follow-up between patients with and without FM, but only women had FM.
Patients with FM in addition to RA had higher DAS28, SJC, TJC, pain and patient global VAS, but also higher levels of fatigue, abdominal pain and concentration difficulties (table 1).

Table 1. Baseline cross-sectional associations

Variables Tender points $\geq$11 Mean (SD)	Tender joint count $<$11 n=40	Adj. Bivariate n=440	p
RA disease activity			
RA disease duration (years)	16.3 (8.9)	14.9 (9.3)	0.31
CRP (mg/L)	17.4 (24.4)	14.5 (13.4)	0.08
DAS28	5.3 (1.0)	4.4 (1.3)	0.002
PainVAS	4.5 (2.2)	3.5 (2.3)	0.03
SJC	9.8 (5.7)	6.8 (5.1)	0.04
TJC	13.3 (5.6)	7.4 (6.5)	$<$0.001
Patient disease activity VAS	4.7 (2.2)	3.7 (2.3)	0.03
Fibromyalgia related variables			
Muscular tenderness VAS	5.9 (2.7)	3.2 (2.6)	$<$0.001
Fatigue VAS	6.6 (2.7)	4.4 (2.7)	$<$0.001
Headache VAS	2.0 (2.4)	1.4 (2.1)	0.25
Abdominal pain VAS	3.7 (3.5)	1.9 (2.3)	$<$0.001
Difficulty concentrating VAS	2.9 (2.7)	1.7 (1.1)	0.003
Health Status			
HAQ	1.2 (0.1)	1.0 (0.0)	0.09

At the 10-year follow-up patient with FM had significantly higher levels of RA disease activity and pain (figure 1).

Figure 1 Longitudinal analyses
Disease activity at 10-year follow-up grouped according to baseline presence of FM

Conclusions: Presence of FM in patients with RA was associated with significantly higher levels of RA disease activity both in the cross-sectional and longitudinal perspectives. Secondary FM should be considered in patients with RA not reaching remission.

OP0006 INFLUENCE OF AUTONOMIC NERVOUS SYSTEM DYSFUNCTION IN THE GENESIS OF SLEEP DISORDERS IN FIBROMYALGIA PATIENTS

M. Rizzi[1], D. Radovanovic[2], P. Santus[2], A. Airoldi[1], F. Frassanito[1], S. Vanni[1], A. Cristiano[1], R. Casale[3], R. Furlan[4], F. Atzeni[5], P. Sarzi-Puttini[5]. *[1]Respiratory Unit, Center for Sleep and Respiratory Disorders "Luigi Sacco" University Hospital; [2]Department of Biomedical Sciencies L. Sacco, University of Milan, Milan; [3]Habilita, Care & Research Rehabilitation Institutes, EFIC Pain School, Department of High Technology Rehabilitation & Pain Rehabilitation Unit, Zingonia di Ciserano, Bergamo; [4]CNR Institute of Neuroscience, Milano, Italy; IRCCS Humanitas, Rozzano; [5]Rheumatology Unit, University Hospital L. Sacco, Milan, Italy*

Background: Fibromyalgia (FM) is characterised by chronic musculoskeletal pain, autonomic nervous system (ANS) dysfunction, and disturbed sleep.
Objectives: The aim of this study was to evaluate the influence of ANS dysfunction on the genesis of sleep disorders.
Methods: Fifty consecutive Caucasian women (age 51.2±7.3 years) whose FM had been diagnosed on the basis of the 2010 ACR classification criteria were compared with 45 healthy female controls matched for age and body mass index.All of the FM patients underwent a clinical, polysomnographic and autonomic profile evaluation at rest and during a tilt test to determine muscle sympathetic nerve activity (MSNA), plasma catecholamine levels, and the spectral indices of cardiac sympathetic (LF_{RR}) and vagal (HF_{RR}) modulation computed by means of the spectrum analysis of RR during sleep.
Results: The FM patients had more tender points ($p<0.001$), a higher ESS score ($p<0.001$), and more signs and symptoms of orthostatic intolerance ($p<0.001$) than the controls. They also had a higher heart rate (HR), more MSNA and a higher LF/HF ratio, and lower HF_{RR} values at rest. The increase in tilting-induced MSNA was less in the FM patients (2±1 *vs* 16±3.1 bursts/min, $p<0.05$; 2±1 *vs* 12±2.8 bursts/100 $p<0.05$), whereas the trend in the spectral indices of the cardiac autonomic profile (LF_{RR} and the LF/HF ratio) and plasma catecholamine levels were similar in the two groups; furthermore, the decrease in the index of cardiac vagal modulation (HF_{RR}) was also less in the patients (HF_{RR}NU -17.3±3.2 *vs* -32.4±4.8, $p<0.05$; $HF_{RR}ms^2$ -148±50 *vs* -857±374, $p<0.05$). The stepwise tilt induced syncope or pre-syncope in 23 of the 50 patients (46%) and two of the 45 controls (5%) ($p<0.001$),Their sleep was less efficient ($p<0.01$), and they had a higher proportion of stage 1 non-REM sleep ($p<0.001$), experienced many arousals and periodic limb movements (PLMs) per hour of sleep ($p<0.001$) and a high proportion of periodic breathing (PB%) ($p<0.0001$). Their cyclic alternating pattern (CAP) rate was significantly increased ($p<0.001$).During sleep, the patients had a higher HR, and LF/HF ratio, and lower HF_{RR}, differences that were more marked during non-REM sleep, as were the presence of CAP, PB and PLMs. PLMs were mainly observed during CAP subtype A2 and A3. As in the tilt test, there was also a decrease in the index of cardiac vagal modulation during sleep: the decrease in HR_{RR} during sleep and in comparison when awake was less in the FMS patients than the controls (11.6±4.2 *vs* 31.1±5.3 NUs, $p<0.01$; 45±38 *vs* 403±281 ms^2, $p<0.0001$)
The number of tender points, pain VAS, the CAP rate, the PB% of sleeping time and the PLMI all seemed to correlate positively with HR and the LF/HF ratio, and negatively with HF_{RR} during sleep
Conclusions: Our data confirm that the FM patients have an autonomic nervous system dysfunction that is consistent with sympathetic over-activity due to the

intensity of chronic pain when awake and during sleep. These findings explain the excessive rate of syncope observed in the FM population during wakefulness, and the increased presence of CAP, PB and PLMs during sleep.

Chondrocyte channels (role in mechanotransduction) or "channeling the chondrocyte"

OP0007 CCR2 INHIBITION ABROGATES IL-6–INDUCED ACTIVATION OF MATRIX METALLOPROTEINASES IN CARTILAGE

A. Latourte[1,2], J. Maillet[1,2], J. Goossens[1], H.-K. Ea[1,2], M. Cohen-Solal[1,2], E. Haÿ[1], P. Richette[1,2]. [1]*Inserm U1132 BIOSCAR, Hôpital Lariboisière;* [2]*Rheumatology Department, Hôpital Lariboisière, University Paris Diderot, Paris, France*

Background: Interleukin 6 (IL-6) plays a crucial role in many rheumatic diseases, including osteoarthritis (OA) [1]. In cartilage, IL-6 activates chondrocyte catabolism by increasing the production of matrix-degrading enzymes, including matrix metalloproteinase 3 (MMP-3) and MMP-13, but it could have other roles.
Objectives: We aimed to identify new biological processes regulated by IL-6 in cartilage.
Methods: RNA-seq analysis (Illumina HiSeq platform) was used to determine biological pathways associated with IL-6/IL-6R (100 ng/ml) stimulation in mouse primary articular chondrocytes. Results were further validated by qPCR and western blot analysis. The effect of stimulation with CC chemokine ligand 2 (CCL2; 10 ng/ml), CCL7 and CCL8 (100 ng/ml) was investigated *in vitro* and *ex vivo* in mouse femoral head cartilage explants. The impact of targeted inhibition of CCL2 or CCL7 by siRNA or blockade of their common receptor CCR2 by a specific antagonist (RS-504393) was determined in IL-6–treated chondrocytes and/or cartilage explants.
Results: Transcriptomic analysis revealed overrepresentation of multiple functional clusters of genes in IL-6–stimulated chondrocytes, with strongly increased expression of signalling molecules and especially cytokines. Two of the 10 top genes upregulated by IL-6 were *Ccl7* (log2 fold change [FC] 2.33, adjusted p-value [p_{adj}] =3.35x10^{-62}) and *Ccl2* (log2 FC 1.85, p_{adj} =9.10x10^{-26}), which encode for CCR2 ligands. qPCR and western blot validations confirmed these results and revealed that IL-6 stimulation also increased the mRNA level of *Ccl8*, another CCR2 ligand not identified by RNA-seq analysis. CCL2 and CCL7 but not CCL8 activated extracellular signal-regulated kinase 1/2 and c-Jun N-terminal kinase signalling and increased MMP-3 and MMP-13 production and activation. CCR2 blockade but not the specific inhibition of CCL2 or CCL7 by siRNA, greatly abrogated the IL-6–induced catabolism *in vitro* and *ex vivo*.
Conclusions: We identified 2 chemokines, CCL2 and CCL7, as key targets of IL-6 in chondrocytes. Although their main role is to mediate monocyte/macrophage recruitment to the joint, their receptor, CCR2, is also strongly involved in IL-6–induced cartilage catabolism. These results suggest a novel mechanism by which CCL2/CCR2 and CCL7/CCR2 signalling could be involved in rheumatic diseases, especially OA [2].

OP0008 DEFICIENT AUTOPHAGY INDUCES CHONDROCYTE DYSFUNCTION THROUGH LAMIN A/C ACCUMULATION IN AGING AND OSTEOARTHRITIS

P. López de Figueroa[1], U. Nogueira-Recalde[1], V. Calamia[2], F.G. Osorio[3], M. Lotz[4], C. López-Otín[3], F.J. Blanco[5], B. Carames[1]. [1]*Rheumatology Division. Background: Aging-related Osteoarthritis (OA) is characterized by insufficient extracellular matrix synthesis and articular cartilage degradation. Autophagy is essential to maintain chondrocyte homeostasis by regulating the intracellular macromolecule and organelle turnover (1). Previous findings indicated that autophagy is defective in Aging and OA articular cartilage (2,3). However, the specific target/-s that regulates this homeostatic mechanism and affect cartilage integrity are still unknown.
Objectives: The objective of study is to identify targets regulating autophagy in human chondrocytes.
Methods: We performed quantitative proteomic analysis of Atg5 knockdown primary uman chondrocytes using iTRAQ (isobaric tags for relative and absolute quantitation) labeling coupled with on-line 2D LC/MS/MS. Protein identification and quantification were performed using Protein Pilot Software v 4.0. Each MS/MS spectrum was searched in the Uniprot/Swissprot database for *Homo sapiens*. Human chondrocytes and human cartilage from healthy, aged and OA patients were employed to confirm the role of the identified target by Western Blot (WB), Inmunofluorescence (IF) and Inmunohistochemistry (IHC). Importanly, CRISPR/Cas9 genome editing technology was used for mechanism of action studies.
Results: 24 out of 487 proteins were significantly altered ($p<0.05$) in response to defective autophagy. Cytoskeleton organization, collagen catabolism, oxidative stress, and aging pathways were affected. Interestingly, Lamin A/C, a nuclear protein implicated in cell senescence, was found upregulated under defective autophagy. Increased Lamin A/C expression was found in human chondrocytes with reduced autophagy. Furthermore, aged and OA human cartilage showed increased Lamin A/C expression. Induction of chondrocyte senescence by genetic deletion of Zinc Metalloproteinase STE24 (Zmpste24) via CRISPR-Cas9, lead to Lamin A/C accumulation, accompanied by a reduction of LC3 and increased chondrocyte death and mitochondrial dysfunction, suggesting that deficient autophagy is correlated with senescence of human articular cartilage.
Conclusions: Lamin A/C, a nuclear protein contributing to structural integrity to the nucleus and matrix was identified as candidate target for regulating cartilage function under defective autophagy, such as aging and OA. These results support the hypothesis that autophagy is decreased with aging. Therefore, targeting Lamin A/C might be a promising strategy to find novel therapeutics for cartilage aging and OA.

Wearable technologies in 21st century healthcare

OP0009-HPR THE EFFECT OF AN 8-WEEK WATER EXERCISE PROGRAM ON ANAEROBIC EXERCISE CAPACITY IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

D. Bayraktar[1], S. Savci[2], O. Altug-Gucenmez[3], E. Manci[4], B. Makay[3], N. Ilcin[2], S.E. Unsal[3]. [1]*Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Izmir Katip Celebi University;* [2]*School of Physical Therapy and Rehabilitation;* [3]*Faculty of Medicine, Division of Pediatric Rheumatology;* [4]*Instute of Health Sciences, Dokuz Eylul University, Izmir, Turkey*

Background: Anaerobic exercise capacity was reported to be lower in children with juvenile idiopathic arthritis (JIA) than healthy children. However, to our knowledge, there is no study focusing on improving anaerobic exercise capacity in JIA.
Objectives: To investigate the effect of an 8-week water exercise program, which was performed at the weekends, on anaerobic exercise capacity in children with JIA.
Methods: Forty-two children with JIA were divided into two groups as exercise and control. Prior to the study, anaerobic exercise capacity was measured performing a 30-second Wingate test. Deep water running was employed as the progressive water exercise program for the exercise group. Control group did not receive any additional treatment other than their usual care. Weekends were chosen for the exercise sessions considering the educational program of the children. Exercise intensity was set as moderate. Exercise intensity was determined with a wearable heart rate tracking system during the exercises. All children were reassessed regarding to anaerobic exercise capacity two months after the first assessment.
Results: All children completed the study without any adverse effects. Twenty-one children were in the exercise group, others were assessed as controls. No significant differences were determined between groups prior the study regarding to age, disease duration, height, weight, body-mass index, and anaerobic exercise capacity related parameters ($p<0.05$). While all anaerobic exercise capacity parameters improved in the exercise group, no improvement were seen in the control group. The in-group comparisons were shown at Table 1. The comparison of the changes between groups after 8 weeks were demonstrated at Table 2.

Table 1. In-group comparison before and after the study

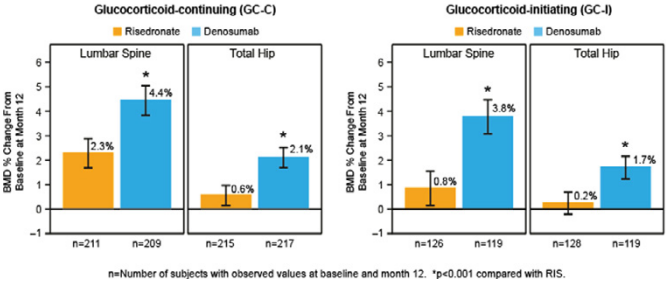
Assessment and management of osteoporosis

OP0010 EFFECT OF DENOSUMAB COMPARED WITH RISEDRONATE IN GLUCOCORTICOID-TREATED INDIVIDUALS: RESULTS FROM THE 12-MONTH PRIMARY ANALYSIS OF A RANDOMIZED, DOUBLE-BLIND, ACTIVE-CONTROLLED STUDY



K. Saag[1], R.B. Wagman[2], P. Geusens[3], J. Adachi[4], O. Messina[5], R. Emkey[6], R. Chapurlat[7], N. Daizadeh[2], N. Pannacciulli[2], W. Lems[8]. *[1]University of Alabama, Birmingham, AL; [2]Amgen Inc., Thousand Oaks, CA, United States; [3]Maastricht University, Maastricht, Netherlands; [4]McMaster University, Hamilton, ON, Canada; [5]Cosme Argerich Hospital, Buenos Aires, Argentina; [6]Emkey Arthritis & Osteoporosis Clinic, Wyomissing, PA, United States; [7]Hôpital Edouard Herriot, Lyon, France; [8]VU University Medical Centre, Amsterdam, Netherlands*

Background: Glucocorticoid (GC)-induced osteoporosis (GIOP) remains the most common secondary cause of osteoporosis. Despite approved therapies, many subjects do not receive GIOP prevention or treatment. There is increased RANKL and decreased osteoprotegerin (OPG) expression in patients with GIOP. Denosumab (DMAb) is a monoclonal antibody to RANKL. This study was designed to assess the safety and efficacy of DMAb compared with risedronate (RIS) in GC-treated individuals, in whom treatment guidelines advocate a GIOP intervention.
Objectives: The primary objective was to demonstrate, in separate GC-continuing (GC-C) and GC-initiating (GC-I) subpopulations, that DMAb was not inferior to RIS with respect to percentage change from baseline (%Δ) in lumbar spine (LS) bone mineral density (BMD) at 12 months. Secondary objectives were to assess superiority of DMAb over RIS with respect to %Δ in LS and total hip (TH) BMD at 12 months.
Methods: This was a phase 3, randomized, double-blind, double-dummy, active-controlled study to evaluate DMAb vs. RIS in GC-treated individuals for 24 months. Eligible subjects were women and men ≥18 yrs receiving GC therapy at a dose ≥7.5 mg prednisone daily or its equivalent for ≥3 months or <3 months prior to screening (GC-C and GC-I, respectively). All subjects <50 yrs were required to have a history of osteoporotic fracture. GC-C subjects ≥50 yrs were required to have a LS, TH, or femoral neck BMD T-score ≤-2.0; or a T-score ≤-1.0 with a history of osteoporotic fracture. Subjects were randomized 1:1 to SC DMAb 60 mg every 6 months or oral RIS 5 mg daily for 24 months. Subjects were to receive daily calcium (≥1000 mg) and vitamin D (≥800 IU) supplementation. Primary outcome was %Δ in LS BMD at 12 months (non-inferiority in GC-C and GC-I). Secondary outcomes included %Δ in LS and TH BMD at 12 months (superiority). The study remains blinded and is ongoing.
Results: A total of 795 subjects (505 GC-C and 290 GC-I) enrolled in the study. Baseline characteristics were balanced between treatment groups (Table). Non-inferiority and superiority with DMAb were demonstrated for both the GC-C and GC-I subpopulations, as indicated by significantly greater BMD gains compared with RIS at the LS and TH in both subpopulations (Figure). The incidences of adverse events (AEs) and serious AEs, including serious AEs of infection, as well as fracture, were similar between treatment groups and consistent with the known safety profile of DMAb.

Table. Baseline Characteristics

Figure. BMD Percentage Change From Baseline at Month 12

n=Number of subjects with observed values at baseline and month 12. *p<0.001 compared with RIS.

Conclusions: DMAb significantly increased BMD more than RIS at the spine and hip at 12 months. The overall safety profile was similar between treatment groups. DMAb has the potential to become another treatment option for patients newly initiating or continuing GC who are at risk for fracture.

Systematic literature review: the link from science to clinical practice

OP0011 DOES A VERY EARLY THERAPEUTIC INTERVENTION IN VERY EARLY ARTHRITIS / PRE-RHEUMATOID ARTHRITIS PATIENTS PREVENT THE ONSET OF RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW AND METANALYSIS

B. Hugues, S. Hilliquin, S. Mitrovic, L. Gossec, B. Fautrel. *Paris 06 University (UPMC); AP-HP, Pitié Salpêtrière Hospital, Paris, France*

Background: Recent progress in the understanding of rheumatoid arthritis (RA) pathogenesis leads to growing interest in the concept of pre-RA, a clinical stage in which very early intervention could be more efficacious.
Objectives: To assess the efficacy of very early therapeutic interventions in pre-RA patients, i.e., with either undifferentiated arthritis, or ACPA-positive arthralgia/arthritis (ie, very early RA, VERA), through a systematic literature review (SLR) and meta-analysis (MA).
Methods: The SLR was performed following Cochrane guidelines. The search used "undifferentiated arthritis" or "very early rheumatoid arthritis" (VERA) associated with "therapy" or "treatment", and was limited to randomized controlled trials (RCTs) published in English over the last five years. It was conducted in Pubmed, Embase and Cochrane RCT databases, as well as EULAR and ACR congress abstracts of the last two years. Two independent readers (SH, BH) extracted the following data through a standardized form: study quality, patient status at baseline (either undifferentiated arthritis or VERA), the type of intervention, and disease characteristics over time as well as occurrence of RA.

The main outcomes that were analysed for the meta-analysis were RA occurrence at 52 weeks and beyond and the absence of radiographic progression at week 52. The meta-analysis was performed using RevMan with Mantel-Haenszel method.

Results: The search identified 595 abstracts, of which 9 RCTs were finally selected (including 2 congress abstracts). Eight were related to undifferentiated arthritis; 1 to VERA. The studies included 1156 patients, weighted mean age 45.8+/-15.2 years, mean symptoms duration 16.2+/-12.6 weeks; 66.0+/-17.7% were female.

The occurrence of RA at week 52 or more was available in 7 studies (assessing 800 patients). Early therapeutic intervention – either methylprednisolone (80 to 120mg IM), methotrexate, TNF-blocker, abatacept or rituximab -reduced the risk of occurrence of RA with a pooled odds ratio (OR) of 0.72 (95% CI [0.54; 0.96]), p 0.02 (Figure).

There was no statistically significant difference between the treatments or placebo, for the absence of radiographic progression (pooled OR 1.36 [0.82;2.27])

The outcome was assessed at Week 52 for all studies, except for Van Dongen 2007 (PROMPT), where it was assessed at Week 120. MethylPDN, methylprednisolone; MTX, methotrexate.

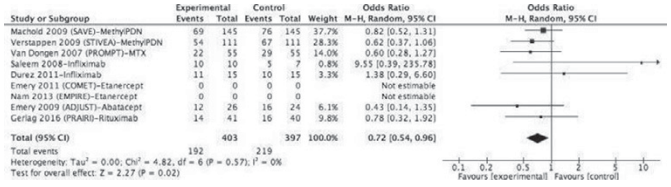

Figure 1. RA appearance at week 52 or more.

Conclusions: This meta-analysis demonstrates that early therapeutic intervention significantly reduces the risk of RA onset in pre-RA patients. The benefit /risk balance and feasibility in clinical practice remain to be further assessed.

EULAR Campaign: Don't Delay, Connect Today

OP0012-PARE RHEUMATOSPHERE: REACH NEW HEIGHTS IN DIAGNOSIS AND TREATMENT OF ARTHRITIS BY ENGAGING, EMPOWERING AND INSPIRING

L.A. Bennett, J.S. Nijjar, G. Fragoulis, S. Siebert, I.B. McInnes. *Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, United Kingdom*

Background: We aim to reach new heights in diagnosis and treatment of arthritis through research and we believe that part of this encompasses public engagement. Engaging the public is an essential part of scientific life, as the majority of work carried about by researchers is publically funded. Therefore the public are entitled to and should be encouraged to see the conclusions of this work in an easily accessible manner.

Objectives: 1) *Engage* the public about rheumatic disease, what it is, what it does to the body and how we, as scientists and clinicians, address unmet needs in this field.

2) *Empower* patients in order to help them understand their disease and treatments thereby improving patient satisfaction and compliance to therapy.

3) *Inspire* the next generation of scientist by encouraging children to study science at school and raise the profile of these subjects with education authorities and the government.

Methods: Rheumatosphere was established to address public engagement needs in the arthritis research field. We have used a variety of techniques to capture the attention of small and large audiences of all ages. Techniques include: Ultrasound scanning, coffee with a scientist at our cell cafe, posters displays, multidisciplinary classroom lessons in a school environment and comic book drawing. These resources and activities have been deployed at 5 major science events across Scotland in the last 3 years, and at the British society for rheumatology's annual conference in 2016. Further to this we have also attended regular events at the Glasgow science centre and schools across Scotland.

Results: During our first three major events we have had approximately 3000 encounters with the median age of participants being 33 years. Over half (51%) of the people that we engage with directly knew someone affected by rheumatoid arthritis. Engaging the public and patients with visualisation of their own joints using ultrasound is effective in demonstrating how joints function. This then serves as a starting point to highlight current research and celebrate the newer treatment strategies which have resulted in better outcomes for our patients. Feedback from our events show that people are keen to engage and learn more about arthritis, with 80% wanting to know more about autoimmunity and 83% wanting to know more about the clinical work going on throughout Glasgow.

Children at these events and in the classroom are encouraged to learn about the immune system and it's role in health and disease through the medium of comic books and art. Allowing the children to relate scientific topics to an already established and popular media has proven to be an effective learning tool. In 2016, 94% of school pupils who interacted with Rheumatosphere said that they had learned something new about arthritis, including careers options through which they could become involved in helping to better understand and treat disease.

Our future plans include partnering with Government and National Science Centre stakeholders to further develop educational curricula in the arena of musculoskeletal science and immunology.

Conclusions: We feel that engaging with the public and patients is an essential part of our vocation as scientists and clinicians and only by empowering them will we be able to reach new heights in diagnosis and treatment of arthritis.

Standing Committee session on paediatric rheumatology

OP0013 PULMONARY MANIFESTATIONS IN JUVENILE ONSET MIXED CONNECTIVE TISSUE DISEASE AFTER LONG-TERM DISEASE DURATION – A NORWEGIAN CASE-CONTROL STUDY

S.O. Hetlevik[1], T.M. Aaløkken[2], M.B. Lund[3], B. Flatø[1], E.B. Nordal[4], M. Rygg[5], V. Lilleby[1]. *[1]Rheumatology; [2]Radiology; [3]Respiratory medicine, Oslo University Hospital, Oslo; [4]Pediatrics, University hospital of North Norway, Tromsø; [5]Pediatrics, St. Olavs University Hospital, Trondheim, Norway*

Background: Pulmonary manifestations in mixed connective tissue disease (MCTD) are common and a major cause of morbidity and mortality [1]. Data on lung involvement in patients with juvenile onset MCTD (JMCTD) are scarce.

Objectives: The aim of this study was 1) to compare pulmonary function abnormalities in a nationwide representative Norwegian JMCTD cohort with that of matched controls, 2) investigate occurrence of interstitial lung disease (ILD) in JMCTD and 3) to evaluate possible associations between pulmonary findings and disease related variables.

Methods: Inclusion criteria were fulfillment of the Kasukawa or Alarcon-Segovia criteria and symptom-onset before 18 years. The control group was randomly drawn from the national population register, after matching for age and gender. Fifty-two patients with JMCTD were examined after mean disease duration 16.2 years, 44 (85%) were female. Patients and controls performed pulmonary function tests (PFT) and a 6 min walk test (6MWT). The patients had a high-resolution CT (HRCT) of the lungs.

Results: Abnormal PFT were found in 24 patients (46%) and in 12 controls (23%) (p=0.01) (table 1).

Variable	JMCTD patients	Controls	P value
Age at examination, years	28.0 (10.3)	29.0 (10.1)	0.61
BMI, kg/m^2	22.7 (3.5)	23.4 (3.0)	0.29
Current smokers daily/occasionally, n (%)	7 (14)	9 (17)	0.59
Never smokers, n (%)	35 (67)	34 (65)	0.83
6MWD, meters	634.3 (76.5)	698.9 (86.6)	<0.01
FVC, litre	3.4 (0.6)	4.3 (1.0)	<0.01
FVC (% of predicted)	89 (14)	109 (11)	<0.01
FEV1, litre	2.9 (0.5)	3.5 (0.8)	<0.01
FEV1 (% of predicted)	89 (13)	102 (11)	<0.01
FEV1/FVC	0.86 (0.06)	0.82 (0.07)	<0.01
DLCO/VA (mmol/kPa min/l)	1.6 (0.2)	1.8 (1.0)	0.26
DLCO/VA (% of predicted)	88 (12)	92 (13)	0.14

More patients than controls had abnormal FVC (11 patients and 0 controls, p<0.01) and FEV1 (12 patients and 2 controls, p<0.01). Diffusing capacity for carbon monoxide adjusted for alveolar volume was abnormal in 12 patients and 8 controls (p=0.34). One patient and 3 controls had a pathological FEV1/FVC (less than 70% of predicted, p 0.62). HRCT showed ILD in 15 patients (29%). The extent of lung parenchyma involved was median 2% (range 1–75) in the patients with ILD. Two patients had more than 20% of lung parenchyma involved (graph 1). The most common abnormalities were reticular patterns, being present in 13 patients (25%). 2 patients (4%) had ground glass attenuation.We could not find correlations between the extent of ILD and PFT or 6MWT. There were no significant differences in PFT values or other disease related variables between the patients with and without ILD.

Conclusions: Patients with JMCTD had significantly reduced pulmonary function after mean 16.2 years disease duration compared to matched controls. However, overall lung function was only moderately reduced. The occurrence of ILD assessed with HRCT was 29%, but the majority of patients with ILD had mild disease. To our knowledge, this is the first systematic case-control study of pulmonary manifestations in JMCTD.

Background: Juvenile idiopathic arthritis (JIA) may lead to structural damage. Yet radiographic assessment is seldom considered in studies.
Objectives: To provide pragmatic guidelines concerning conventional radiography (CR) in each subtype of JIA (exclusion of systemic JIA).
Methods: A multidisciplinary task force of 15 French experts (rheumatologists, pediatricians, radiologists) plus one patient's representative, was convened. Following the GRADE[1] method, they formulated a series of research questions concerning CR assessment, at diagnosis and follow-up of each subtype of JIA. Systemic JIA was ruled out. A systematic literature review was conducted, considering articles in which structural damage was detailed (erosion, joint space narrowing, bone deformities). A series of recommendations was elaborated, following evidence-based data, and expert opinion. It underwent an evaluation from an independant committee (including patient's representative), and a final round of Delphi-voting process from the whole expert group.
Results: Of 646 publications identified, 73 original articles were included. The task force produced 4 principles and 31 recommendations. Level of evidence ranked from B to D, level of agreement was high. The experts insisted on weighing indication of CR considering structural risk. The importance of assessing structural progression, the need for constant attention to radioprotection were asserted. Systematic CR of hands and feet are thus recommended in polyarthritis JIA rheumatoid factor positive, and in polyarticular JIA with pejorative prognostic factors. Systematic CR are not recommended in oligoarticular JIA. CR is not the prime imaging technique of the axial skeleton.
Conclusions: These are the first pragmatic recommendations upon CR in JIA. They mostly rely on experts' opinion, due to lack of evidence-based data. CR is still relevant in many situations in JIA, but should not be overlooked, while non-irradiating imagine techniques are developing.

Still breaking news on TNF inhibitors in rheumatoid arthritis

OP0015 **INDUCTION OF REMISSION AND MAINTENANCE IN EARLY, AGGRESSIVE RHEUMATOID ARTHRITIS USING ADALIMUMAB IN COMBINATION WITH METHOTREXATE WITH OR WITHOUT SHORT-TERM HIGH-DOSE GLUCOCORTICOIDS: RESULTS OF A PHASE IV MULTICENTER, RANDOMIZED, DOUBLE BLIND STUDY (CLINTRIAL.GOV: NCT00480272)**

Ferraccioli [8]. *[1]IRCCS San Matteo, Pavia; [2]University of Perugia; [3]Biometry Unit, IRCCS San Matteo, Pavia; [4]University of L'Aquila, L'Aquila; [5]University of Palermo, Palermo; [6]University of Genoa, Genoa; [7]ASST G Pini, Milano; [8]Policlinico Gemelli, Roma; [9]University la Sapienza, Rome; [10]Seconda Università, Napoli; [11]Università delle Marche, Ancona; [12]Azienda Policlinico, Bari; [13]Azienda Ospedaliera Universitaria, Siena; [14]Azienda Ospedaliera Universitaria, Firenze; [15]Azienda Ospedaliera, Padova, Italy*

Background: Remission is the current aim of early RA treatment. In patients with early, aggressive RA, combination with adalimumab (ADA) plus methotrexate (MTX) was superior to either MTX or ADA alone in obtaining clinical remission. Moreover, it has been demonstrated that a short-term aggressive treatment with high-dose glucocorticoids (GC) plus conventional DMARDs lead to long-term (up to 5 years) benefits.
Objectives: To compare the proportion of patients who achieve remission at 12 months, between two groups of subjects treated with ADA + MTX + high dose GC (intensive) and ADA + MTX + placebo (standard), and to evaluate the proportion of those maintaining remission at 24 months, after discontinuation of GC at 6 and ADA at 12 months.
Methods: The main inclusion criteria were: active RA, disease duration ≤1 year, GC and MTX-naïvity, at least one predictor of aggressive disease. All subjects received ADA for 12 months and MTX (20 mg/w) to the end of month 24. Subjects were randomized to receive prednisone (orally, 50 mg/d, progressively tapered to 6.25 mg and stopped at month 6) or placebo. Response was evaluated using DAS28, CDAI, SDAI and ACR response criteria. The difference in rate and 95% CI will be computed with a binomial regression model and identity link, while clustering on center. An intention-to-treat analysis was performed.
Results: 118 patients were assigned to standard and 115 patients to intensive group. Remission (DAS28<2.6, SDAI≤3.3, CDAI≤2.8) at 1 year in standard vs intensive group were: 56.25% vs 45.28% (RD= -11%, 95% CI -23 to1, p=0.07), 30.36% vs 21.69% (RD= -9%, 95% CI -20 to 3, p=0.14), and 28.57% vs 22.64% (RD= -6%, 95% CI -18 to 6, p=0.34). DAS28 remission at 2 years was 36.84% in standard vs 30.93% in intensive (RD= -6%, 95% CI -17 to 5, p=0.28). No superiority of the intensive group was seen in ACR20–50–70 response rates at 4, 8, 12, 24 months. The overall frequency of adverse events (AE) in patients that completed the trial was comparable between groups. The percentage of patients who discontinued for AE was higher in the intensive group (9.32% in standard vs 16.52% in intensive, RD=7%, 95% CI 1 to 13, p=0.01).

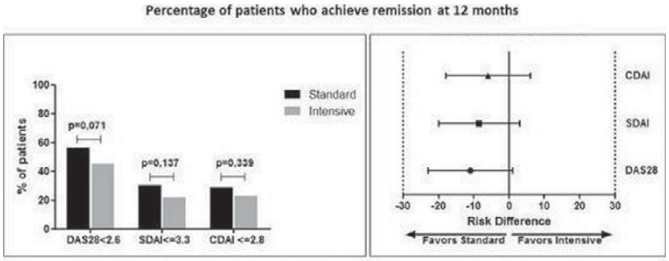

Figure 1. The percentage of patients who achieve DAS28 remission at 12 months was 56,25% in standard vs 45,28% in intensive, with RD of -11% (-23 to 1, p=0,07); SDAI remission of 30,36% in standard vs 21,69% in intensive, with RD of -9% (-20 to 3, p=0,14); CDAI remission of 28,57% in standard vs 22,64% in intensive, with RD of -6% (-18 to 6, p= 0,34).
RD= Risk Difference

Conclusions: Our results confirm that intensive treatment with biologics in early, aggressive RA might be considered to induce and maintain clinical remission. The addition of high-dose GC to a first line treatment with ADA and MTX did not prove to induce a further improvement in efficacy. Although these results should be tested with other biologic therapies, the high rate of drop out for AE in the intensive group should be carefully considered in the risk-benefit ratio.

OP0016 COMPARATIVE EFFECTIVENESS AT 1 YEAR OF DIFFERENT ANTI-TNF DRUGS AS FIRST BIOLOGIC DMARD IN PATIENTS WITH RHEUMATOID ARTHRITIS – RESULTS FROM THE NATIONWIDE SWEDISH REGISTER

C. Turesson[1,2], T. Frisell[3], M. Dehlin[4], D. Di Giuseppe[3], N. Feltelius[5], A. Kastbom[6], J. Askling[3] on behalf of ARTIS study group. *[1]Department of Rheumatology, Skåne University Hospital; [2]Rheumatology, Department of Clinical Sciences, Malmö, Lund University, Malmö; [3]Department of Medicine, Karolinska Institutet, Stockholm; [4]Department of Rheumatology and Inflammation Research, Sahlgrenska Academy, Gothenburg University, Gothenburg; [5]Medical Products Agency, Uppsala; [6]Rheumatology/AIR, Department of Clinical and Experimental Medicine, Linköping University, Linköping, Sweden*

Background: Treatment with TNF inhibitors is part of the management of patients with severe rheumatoid arthritis (RA). There is limited data on the comparative effectiveness of different TNF inhibitors from clinical trials and observational studies of patients treated in clinical practice.
Objectives: To compare effectiveness of different TNF inhibitors in a large, population representative, sample of bionaïve patients with RA.
Methods: The study was based on the Swedish Rheumatology Quality register, in which clinical data are prospectively recorded at treatment initiation and at subsequent visits. Patients with RA initiating a TNF inhibitor as their first ever biologic DMARD in 2010–2014 were included and followed through 2015. The proportion remaining on drug at 1 year (±90 days) after starting therapy was compared. Furthermore, effectiveness at 1 year was assessed as the proportions with EULAR good response, remission (DAS28 <2.6), HAQ improvement (>0.2) and swollen and tender joint counts of 0, all corrected for drug survival (1). The relative response was estimated with log-binomial regression, adjusting for potential confounders and using the largest group (etanercept) as reference.
Results: A total of 5568 patients were included. There was a significant difference in the adjusted chance of drug survival across TNF inhibitors (Table). Patients treated with certolizumab or infliximab were less likely to remain on treatment compared to those started on etanercept. The chance of achieving each of the clinical response measures was significantly lower for those initiating infliximab compared to patients treated with etanercept. There were no significant differences in these outcomes compared to etanercept for any of the other TNF inhibitors.
Conclusions: Patients with RA starting infliximab as their first biologic DMARD were less likely to remain on treatment with significant improvement at 1 year compared to those initiating etanercept. There was a similar trend for certolizumab vs. etanercept, but there were no consistent differences in clinical effectiveness between etanercept and adalimumab or golimumab. Treatment context may affect these patterns.

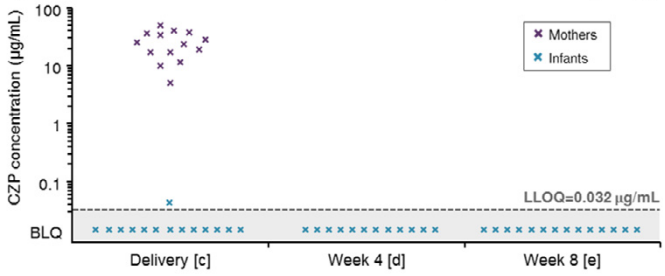
OP0017 LACK OF PLACENTAL TRANSFER OF CERTOLIZUMAB PEGOL DURING PREGNANCY: RESULTS FROM CRIB, A PROSPECTIVE, POSTMARKETING, MULTICENTER, PHARMACOKINETIC STUDY



X. Mariette[1], A. Flynn[2], F. Förger[3], A. Moltó[4], R.-M. Flipo[5], A. van Tubergen[6], L. Shaughnessy[7], J. Simpson[7], M. Teil[8], E. Helmer[9], M. Wang[7], E. Chakravarty[10]. *[1]Université Paris-Sud, le Kremlin-Bicêtre, France; [2]University of Utah, Salt Lake City, United States; [3]Inselspital, University of Bern, Bern, Switzerland; [4]Groupe Hospitalier Cochin, AP-HP, Paris; [5]Centre Hospitalier Régional Universitaire de Lille, Lille, France; [6]Maastricht University Medical Center, Maastricht, Netherlands; [7]UCB Pharma, Raleigh, United States; [8]UCB Pharma, Slough, United Kingdom; [9]UCB Pharma, Brussels, Belgium; [10]Oklahoma Medical Research Foundation, Oklahoma City, United States*

Background: There is a need for effective and safe treatment during pregnancy in women affected by chronic active inflammatory diseases, such as rheumatoid arthritis. Adequate disease control is crucial to ensure the best fetal and maternal health, and reduce adverse pregnancy outcomes.[1,2] Anti-TNFs are an effective therapeutic option, but because most cross the placenta, they are often stopped during pregnancy.[3,4] Certolizumab pegol (CZP), due to its Fc-free molecular structure, has no active placental transfer compared to other anti-TNFs.[5,6]
Objectives: To accurately measure the potential level of placental transfer of CZP from mothers to infants using a highly sensitive, CZP-specific assay.
Methods: CRIB (NCT02019602) was a pharmacokinetic (PK) study of pregnant women (≥30 weeks [wks] gestation) receiving commercial CZP (maintenance dose) for an approved indication; last dose was within 35 days prior to delivery. Blood samples were collected from the mothers, umbilical cords, and infants at delivery, and infants again at Wks 4 and 8 post-delivery. CZP concentration was measured with a sensitive, CZP-specific electrochemiluminescence immunoassay validated in plasma (LLOQ=0.032 μg/mL; 10-fold lower than assay used in prior CZP PK studies[6,7]).
Results: 21 CZP-treated pregnant women were screened; 16 entered the study (Table). Maternal CZP plasma levels at delivery were within the expected therapeutic range (median [range]: 24.4 [5.0–49.4] μg/mL). Of the 16 infants delivered, 2 samples were excluded: 1 due to missing data, 1 due to implausible PK data. 13/14 infants had no quantifiable CZP levels at birth (<0.032 μg/mL); 1 infant had a minimal CZP level of 0.042 μg/mL (infant/mother plasma ratio: 0.09%); no infants had quantifiable levels at Wks 4 and 8 (Figure). 3/15 umbilical cord samples had quantifiable CZP levels (maximum: 0.048 μg/mL); 1 umbilical cord collapsed and was excluded. No anti-CZP antibodies were detected in mothers, umbilical cords, or infants. The infants of CZP-exposed mothers had a safety profile consistent with that of unexposed similar-age infants.

Table: Baseline characteristics of mothers and infants

Median (min, max), unless stated otherwise	All mothers (n=16) [a]
Age, years	31 (18, 40)
Mother's indication for CZP treatment, n	
Rheumatoid arthritis	11
Crohn's disease	3
Psoriatic arthritis	1
Axial spondyloarthritis/ankylosing spondylitis	1
Median (min, max), unless stated otherwise	**All infants (n=16)**
Female, n (%)	10 (62.5)
Gestational age at birth, weeks	39.9 (37.7, 41.7)
Weight at birth, kg	3.3 (2.6, 4.0)

Figure: Plasma CZP concentrations in mothers and infants (n=14 mother-infant pairs [b])

[a] Mothers who entered the study; [b] 2/16 infant samples were excluded: 1 due to missing data, and 1 due to implausible PK data (ie. data not consistent with a paediatric CZP PK model, based on the expected range of clearance, volume of distribution, and subsequent elimination half-life); [c] ±24 hours; [d] ±7 days (2 samples not collected); [e] ±7 days. Min: minimum; Max: maximum; BLQ: below the LLOQ (<0.032 μg/mL); LLOQ: lower limit of quantitation.

Conclusions: Using a highly sensitive assay, CZP levels were below LLOQ in 13/14 infant blood samples at birth, and all samples at Wks 4 and 8. This indicates no to negligible placental transfer of CZP from mothers to infants, suggesting lack

OP0018 TOOL AND THRESHOLD PREDICTING A SUCCESSFUL BIOLOGICAL DMARDS TAPERING IN PATIENTS WITH RA REMISSION DETERMINATION

C. Barral[1], D. Hajage[2], B. Fautrel[2], P. Lafforgue[3], F. Tubach[2], T. Pham[3]. *[1]Aix Marseille University, APHM, Marseille; [2]Univ. Paris Diderot, Sorbonne, APHP, Paris; [3]Aix Marseille University, APHM, Marseille, France*

Background: Tapering trials confirmed the feasibility of TNF inhibitors (TNFi) tapering for a relevant proportion of patients in remission and/or low disease activity. However, there are no consensual predictors of a good response to therapeutic spacing among patients with rheumatoid arthritis (RA) in remission.

Objectives: To determine the most predictive tool and threshold of a successful TNFi tapering.

Methods: *Population:* The Spacing of TNF-blocker injections in Rheumatoid Arthritis Study (STRASS) trial included 137 RA patients fulfilled the ACR 1987 criteria with sustained (at least 6 months) DAS28 <2.6. Patients were randomly assigned to one of the two following strategies: in the Maintain arm, patients continued to receive TNFi at the standard full regimen and in the Spacing arm, the strategy applied progressive spacing of ADA or ETN subcutaneous injections up to discontinuation at the forth step in the spacing arm. We used the data of the Spacing arm.

Analysis: The performances of several variables (DAS28, SDAI, CDAI, CRP, ACPA status, HAQ, patient/physician global assessment, and booleen remission criteria) were assessed for the prediction of successful TNFi tapering, defined as reaching at least 25% tapering of the full regimen during at least 6 months, using sensitivity and specificity for dichotomous variables, or the area under the ROC curve (AUC) and its 95% confidence interval for continuous variables. A predictive score of successful tapering was constructed using LASSO regression modeling technique to avoid overfitting (R software version 3.2.1).

Results: The main characteristic of the 64 patients of the Spacing arm were the following (mean ± SD): age 54.3±10.7 years, disease duration 8.3±5.4 years, and DAS 28 1.9±0.6.

The baseline variables were similar between patients who failed or succeeded at TNFi spacing, except for the HAQ score (0.30 in the group success and 0.89 in the failure group, p=0.01) and the CRP (2.35 mg/l versus 3.48 mg/l, respectively, p=0.02).

Baseline variables performance in predicting successful TNFi spacing: None of the tested variables was able to predict successful TNFi spacing, except the HAQ score and the CRP. A HAQ threshold $\geq$1.125 had a specificity (Spe) of 93% and an AUC: 0.713 (CI95%: 0.540–0.886). A CRP threshold $\geq$6.8 mg/l had a Spe of 0.97 and an AUC: 0.689 (CI95%: 0.547–0.831).

Composite criteria: A composite criteria able to predict successful TNFi spacing has been elaborated, including ACPA status, Boolean criteria, SDAI, CRP and HAQ. A composite score lower than 0.502 was able to predict a successful TNFi spacing: Spe: 100%; Se: 54%; AUC: 0.829 (CI95%: 0.671 - 0.986).

Conclusions: The remission maintenance in rheumatoid arthritis after TNFi spacing is possible. Our results showed that in a population of RA patients in remission with TNFi, baseline HAQ and CRP are independent predictor factors of successful tapering. We have developed a composite index able to predict successful TNFi spacing, with an AUC of 0.829 and a specificity of 100%. A validation study will be needed to confirm its ability to select patients for treatment decrease.

OP0019 DMARD WITHDRAWAL IN RA PATIENTS ACHIEVING THERAPEUTIC RESPONSE WITH CERTOLIZUMAB PEGOL COMBINED WITH DMARDS: INTERIM RESULTS FROM A CANADIAN OBSERVATIONAL RANDOMIZED STUDY

J. Pope[1], E. Rampakakis[2], E. Grant[3], L. Bessette[4], J. Lazovskis[5], B. Haraoui[6], J.S. Sampalis[2,7]. *[1]Medicine, University of Western Ontario, London; [2]JSS Medical Research, St-Laurent; [3]Private Practice, Saint John; [4]Medicine, Laval University, Quebec; [5]Riverside Professional Centre, Sydney; [6]Institut de Rhumatologie de Montréal; [7]McGill University, Montreal, Canada*

Background: The efficacy and safety of certolizumab pegol in the treatment of adult patients with moderate to severe rheumatoid arthritis (RA), when administered either in combination with methotrexate (MTX) or as monotherapy, has been previously shown in several controlled clinical trials. However, a detailed assessment of certolizumab pegol in combination with a wide range of non-biologic disease-modifying drugs (nbDMARDs) used in real-life routine clinical practice is lacking compared to switching to monotherapy after achieving a response when added to nbDMARD(s).

Objectives: The objective is to compare the effectiveness and tolerability of certolizumab pegol given as add-on to nbDMARDs, including MTX and others, or as monotherapy after achieving a DAS28(ESR) improvement of $\geq$1.2 In this descriptive interim analysis, preliminary data on the effectiveness of certolizumab pegol given in combination nbDMARDs or monotherapy, are presented.

Methods: RA patients who had certolizumab pegol added to their existing DMARD regimen due to inadequate response to their nbDMARD(s) were eligible. At 3 or 6 months, those patients who achieved a change in DAS28 of $\geq$1.2 were randomized to continue combination therapy (Combination group) or withdraw nbDMARD therapy (Monotherapy group) and be followed for 18 months. A sample size of 125 randomized patients per group was calculated to have 100 randomized (50 per group) to find a difference of 15% in response.

Results: A total of 121 patients were enrolled, of whom 79 were randomized to continue combination therapy (n=35) or withdraw nbDMARDs (n=44). No significant differences were observed between-groups in baseline age, gender (83% vs. 71% female), race (89% vs. 91% Caucasian), rheumatoid factor status (56% vs. 60% positive), or prior biologic experience (17% vs. 11%).

At 18 months, upon adjusting for baseline scores, similar improvements were observed between groups in DAS28 ESR (-2.1 vs. -2.0). Furthermore, the odds of achieving DAS28 LDA (OR [95% CI]: 0.96 [0.28–3.31]), ΔDAS28$>$1.2 (0.97 [0.29–3.26]), or both (1.00 [0.29–1.49]), were not different between the Combination and Monotherapy groups. Similarly, no differences were observed between groups at 12 months of treatment with respect to these outcomes.

Conclusions: The results of this interim analysis suggest that, among RA patients achieving a therapeutic response when on combination therapy with certolizumab pegol and nbDMARDs, nbDMARDs could be withdrawn without impact on treatment effectiveness over the next year. Additional analyses with the full number of patients will be conducted to confirm this finding.

OP0020 ASSESSMENT OF 3-MONTH CHANGES IN BONE MICROSTRUCTURE UNDER ANTI-TNFα THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS USING HR-PQCT

T. Shimizu[1], H.J. Choi[1], U. Heilmeier[1], M. Tanaka[1], A.J. Burghardt[1], J. Gong[1], N. Chanchek[1], T.M. Link[1], J. Graf[2], J.B. Imboden[2], X. Li[1]. *[1]Department of Radiology & Biomedical Imaging, Musculoskeletal Quantitative Imaging Research; [2]Department of Medicine, Division of Rheumatology, University of California San Francisco, San Francisco, United States*

Background: Bone erosions are usually thought to be irreversible and occur in the first few months of RA onset. With its resolution of up to 81 μm, HR-pQCT has emerged as valuable tool to assess bone changes in RA[(1,2)]. Although one previous study showed minimal erosive progression in patients with RA one year after TNFα inhibition therapy [(3)], no studies have investigated yet the very early bone changes after the initiation of anti-TNFα treatment.

Objectives: To investigate the early changes in bone erosion progression and bone microarchitecture in the MCP joints and wrist of RA patients using HR-pQCT, radiographs, and 3T MRI after 3 months of anti-TNFα treatment.

Methods: 26 RA patients underwent 3T MRI wrist scans and HR-pQCT scans of the MCP and wrist joints at baseline (BL) and at 3 months (3M). Radiographs were obtained at the baseline time point only. DAS28 was assessed at BL and 3M. Patients were divided into two groups: the anti-TNFα group and the MTX-only group.HR-pQCT-derived erosion volume, joint volume/width and bone microarchitectural parameters were computed using methods previously developed[(4–6)], and the joint destruction was assessed via Sharp and RAMRIS scorings using radiographs and MR images respectively.

Results: Patients in the Anti-TNFα group were slightly younger than patients in the MTX only group and had a higher initial DAS28 score,but otherwise displayed similar anthropometerics and demographics (Table).

DAS scores significantly improved in the anti-TNFα group from BL to 3M (Fig. A). 75 erosions were identified at BL by HR-pQCT. The anti-TNFα group showed a significant decrease of erosion volume from BL to 3M at MCH3 (with decreasing trend at MCH2 and wrist). The MTX-only group in contrast, displayed significant

Table 1. Characteristics of patients

	All patients (n=26)	MTX only (n=9)	Anti-TNFα (n=17)	*p*
Age (years)	51.9±15.4	60.0±15.1	47.7±13.8	0.056
Sex (Female :Male)	21:5	6:3	15:2	0.331
Disease duration (years)	6.5±5.4	7.5±5.0	5.7±5.6	0.518
BMI (kg/m^2)	28.3±7.1	25.2±5.1	30.1±7.6	0.109
DAS28 -ESR	4.27±2.03	2.17±0.53	5.79±1.08	<0.001
DAS28 -CRP	3.82±1.88	1.93±0.61	5.19±1.09	<0.001

increases in erosion volume at MCH2 and wrist despite low disease activity (Fig. B). In the anti-TNFα group, joint space width and volume of the MCP joints decreased significantly from BL to 3M and were positively correlated with erosion volume changes. Although microstructural parameters at the wrist and MCP remained largely unchanged, erosion volume changes were significantly negatively correlated with changes of trabecular BMD in the anti-TNFα group (Fig. C). No significant correlations were observed between HR-pQCT parameters and RAMRIS and DAS scores.

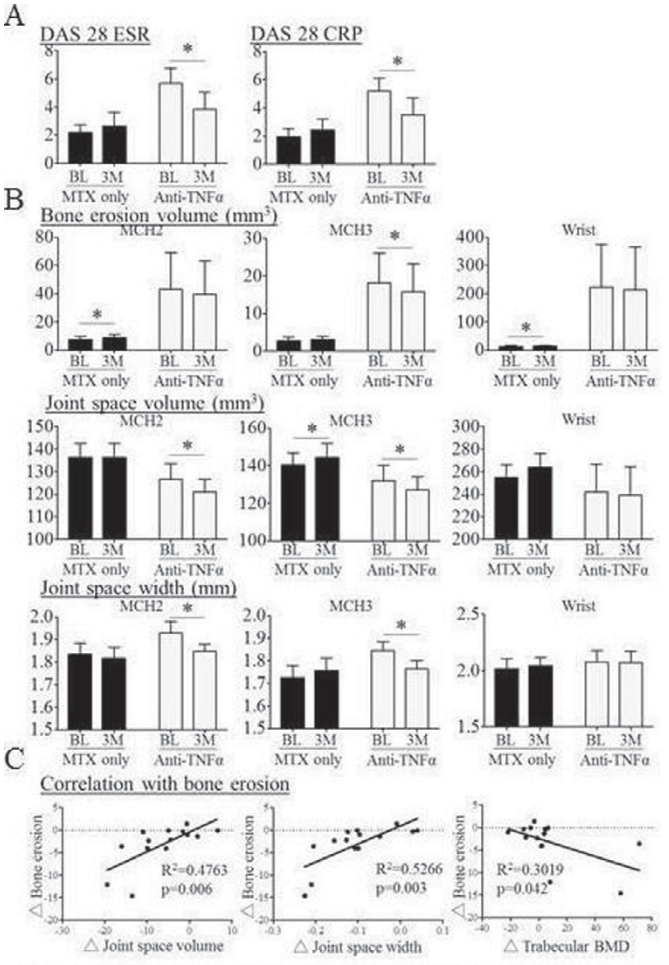

Figure. (A) Comparisons of changes of DAS 28 ESR and CRP from baseline (BL) to 3-months (3M). (B) Comparisons of changes of bone microarchitecture parameters from BL to 3M. *p<0.05; paired T test .(C) Spearman correlations between changes of erosion volume and each bone parameter in MCP in the anti-TNFα group

Conclusions: We found that anti-TNFα treatment can prevent erosion progression and deterioration of bone microarchitecture within the first 3 months of treatment. HR-pQCT can serve as a sensitive and powerful tool to quantify bone changes and monitor RA treatment even over short time periods.

OP0021 EFFICACY AND SAFETY RESULTS OF A PHASE III STUDY COMPARING FKB327, AN ADALIMUMAB BIOSIMILAR, WITH THE ADALIMUMAB REFERENCE PRODUCT IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS

R. Alten[1], J. Glover[2], N. Matsunaga[3], D. Chisholm[4], M. Genovese[5]. *[1]University Medicine Berlin, Berlin, Germany; [2]Coephycient Pharmaceutical Consultancy, Guildford, United Kingdom; [3]Fujifilm Kyowa Kirin Biologics, Chiyoda-ku, Tokyo, Japan; [4]Fujifilm Kyowa Kirin Biologics, Galashiels, United Kingdom; [5]Stanford University, Palo Alto, CA, United States*

Background: FKB327 is a proposed biosimilar of the adalimumab reference product (ADL). This randomised, double-blind, Phase III study (NCT02260791; FKB327-002) evaluated the therapeutic equivalence of FKB327 and ADL in patients (pts) with active rheumatoid arthritis (RA) inadequately controlled on methotrexate (MTX).

Objectives: To assess the efficacy, safety, pharmacokinetics (PK) and immunogenicity of FKB327 compared with ADL in pts with active RA.

Methods: Pts aged ≥18 years with moderate to severe, active RA for ≥3 months and taking MTX for ≥3 months (10–25 mg/week [wk] stable dose for ≥8 wks) were enrolled. Pts were randomised 1:1 to receive FKB327 or ADL (40 mg subcutaneous injection) every 2 wks with continuing MTX, stratified by prior biologic treatment (yes/no) and screening disease activity (Disease Activity Score 28 using C-reactive protein [DAS28-CRP] ≤5.1/>5.1). The primary efficacy endpoint was American College of Rheumatology (ACR) 20 response rate at Wk 24; equivalence margins of ±13% were prespecified for a two-sided 95% confidence interval (CI) based on ADL treatment effect in previous studies. Secondary endpoints included ACR20 response rate over time, DAS28-CRP at Wk 24 and over time. Safety was assessed by the incidence/severity of adverse events (AEs) and laboratory abnormalities.

Results: 730 pts from 105 sites in 12 countries were randomised; 728 pts were treated with either FKB327 (n=366) or ADL (n=362). Demographics and baseline RA characteristics were comparable between the groups, with overall mean age of 55.3 years, mean DAS28-CRP score of 6.1 and mean MTX dose of 15.7 mg/wk. ACR20 response rates at Wk 24 (full analysis set) were comparable between the FKB327 (270/363; 74.4%) and ADL groups (271/358; 75.7%). 95% CIs for treatment difference (FKB327 – ADL: –7.6 to 5.0) fell within the ±13% equivalence margins, meeting the primary study objective. ACR20 response rates over time overlapped during Wks 4–24 (Figure 1). Least squares mean DAS28-CRP at Wk 24 were 3.43 on FKB327 and 3.42 on ADL and were equivalent using prespecified margins; changes in scores over time were also comparable. The proportions of pts reporting treatment-emergent AEs (TEAEs) on FKB327 or ADL were similar (FKB327 55.5% vs ADL 61.6%); AEs were mainly mild or moderate. The most common TEAEs (≥5%) were nasopharyngitis (7.1% vs 8.0%) and upper respiratory tract infection (3.6% vs 5.0%). Incidences of serious AEs were similar (4.1% vs 5.2%). One death due to treatment-related disseminated tuberculosis (TB) was reported in the FKB327 group; reports of active TB were slightly higher with ADL (1 vs 3 pts). Mean serum trough concentration-time profiles of the two groups were comparable. The prevalence and titres of antidrug antibodies (ADA) were similar, including at final sampling (57.9% vs 55.8%).

Figure 1. ACR20 response rate by time (full analysis set)

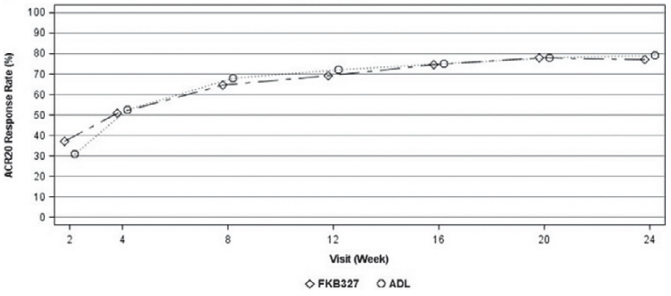

Figure 1

Conclusions: The study met its prespecified equivalency endpoint for ACR20 response rate at Wk 24, with comparable rates over time. Safety profiles, ADA formation and PK were also similar, supporting the comparability of FKB327 and ADL in pts with active RA.

OP0022 TNFI AND TOFACITINIB MONOTHERAPY AND COMPARATIVE EFFECTIVENESS IN CLINICAL PRACTICE: RESULTS FROM CORRONA REGISTRY

G.W. Reed[1,2], R.A. Gerber[3], Y. Shan[1], L. Takiya[4], K.J. Dandreo[1], D. Gruben[3], J.M. Kremer[5], G.V. Wallenstein[3]. *[1]Corrona, LLC, Southborough; [2]UMass Medical School, Worcester; [3]Pfizer, Inc., Groton; [4]Pfizer, Inc., Collegeville; [5]Albany Medical College, Albany, United States*

Background: TNF inhibitors (TNFi) can be used as monotherapy (mono) or in combination (combo) with conventional DMARDS (cDMARDS). Data from randomized clinical trials and European registries suggest there is evidence of better effectiveness of TNFi combo therapy than mono. Effectiveness of TNFi mono vs combo in US clinical practice, in particular among biologic naïve and experienced patients, has not been assessed. There have also been no assessments of tofacitinib (tofa) mono vs tofa combo nor tofa mono vs TNFi combo in US clinical practice. Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA.
Objectives: This study quantifies the prevalence and effectiveness of TNFi monotherapy use compared to TNFi combination therapy by line of therapy in US clinical practice. Secondary objectives were to compare tofa monotherapy use and effectiveness separately to tofa combo and to TNFi combo therapies.
Methods: RA patients initiating a TNFi (adalimumab, etanercept, infliximab, golimumab, certolizumab pegol) or tofa with a six month follow-up in Corrona US were identified. A subcohort of TNFi initiations after 11/6/2012 (market approval of tofa) were used for comparisons with tofa initiators. We defined combo therapy as TNFi or tofa used with MTX only and mono as no use of any cDMARD. The primary outcome was achieving LDA (low disease activity) or remission based on CDAI ($\leq$10) at 6 months. Patients switching to another biologic prior to 6 months were defined as non-responders. Secondary outcomes included modified ACR20/50/70 and mean change in CDAI. Combo and mono initiators were matched within line of therapy using a propensity score. Covariates for the model were selected if the standardized mean difference between the groups $>$0.1.
Results: From 10/2001 to 8/2016 there were 7976 eligible TNFi initiations in Corrona, with 2511 (31%) mono initiations. Mono by line of therapy was 21%, 36% and 42% for 2nd, 3rd and 4th line therapy, respectively. There were 555 tofa initiations with 338 (61%) mono and mono rates of 47%, 58% and 63% for 2nd, 3rd and 4th line therapy, respectively. In the matched populations, across outcome measures (Table 1), TNFi combo was more effective than TNFi mono in 2nd line therapy (55.6% LDA vs 47.1% LDA) and differences diminished with 3rd line (43.2% vs 36.6%) and 4th line (32.0% vs 34.0%). Tofa combo therapy was similar to mono in the matched 3rd and 4th + line populations combined (35.2% LDA vs 31.1% LDA). Tofa mono was similar to TNFi combo therapy in the matched 3rd and 4th + line populations combined (33.6% LDA vs 37.5% LDA).

Table 1 Matched Patients		TNF Combo vs TNF Mono			Tofa Combo vs Tofa Mono	TNFi Combo vs Tofa Mono
		2nd line* (n=1206)	3rd line* (n=1180)	4th line* (n=800)	3rd and 4th line (n=244)	3rd and 4th line (n=304)
LDA	OR [95% CI]	1.3 [1.0-1.6]	1.3 [1.0-1.7]	0.9 [0.7-1.2]	1.2 [0.7-2.1]	1.2 [0.7 – 1.9]
mACR20	OR [95% CI]	1.2 [1.0-1.6]	1.2 [0.9-1.6]	1.2 [0.9-1.7]	0.8 [0.4-1.6]	0.8 [0.5 – 1.4]
ΔCDAI	meanΔ [95% CI]	-0.7 [-2.2–0.8]	-1.1 [-2.6 - 0.3]	-1.5 [-3.5- 0.4]	-0.3 [-3.9 –3.3]	0.6 [-2.6 – 3.7]

*Line of Therapy defined as follows: 2nd line = prior use of at least one cDMARD and no prior use of any biologic; 3rd line = prior use of at least one cDMARD and prior use of 1 biologic; 4th line+ = prior use of at least one cDMARD and prior use of 2+ biologics

Conclusions: TNFi monotherapy is common in U.S. clinical practice. TNFi monotherapy is less effective than combination therapy especially in biologic naïve patients or with one prior biologic. There is no evidence that tofacitinib monotherapy is less effective than tofa combination therapy or TNFi combination therapy in the outcome measures reported.

Progress in managment of SpA

OP0023 FOUR-YEAR IMAGING OUTCOMES IN AXIAL SPONDYLOARTHRITIS PATIENTS TREATED WITH CERTOLIZUMAB PEGOL, INCLUDING PATIENTS WITH ANKYLOSING SPONDYLITIS AND NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS

D. van der Heijde[1], X. Baraliakos[2], K.G. Hermann[3], R. Landewé[4], P.M. Machado[5], W. Maksymowych[6], O. Davies[7], N. de Peyrecave[7], B. Hoepken[8], L. Bauer[8], T. Nurminen[8], J. Braun[9]. *[1]Leiden University Medical Center, Leiden, Netherlands; [2]Ruhr-University Bochum, Herne; [3]Charité Medical School, Berlin, Germany; [4]Academic Medical Center, Amsterdam & Atrium Medical Center Heerlen, Amsterdam, Netherlands; [5]University College London, London, United Kingdom; [6]University of Alberta, Edmonton, Canada; [7]UCB Pharma, Slough, United Kingdom; [8]UCB Pharma, Monheim; [9]Rheumazentrum Ruhrgebiet, Herne, Germany*

Background: RAPID-axSpA (NCT01087762) was a long-term study in patients (pts) with axial spondyloarthritis (axSpA) treated with certolizumab pegol (CZP). This is the first report of 4-year imaging results in CZP-treated axSpA pts, including ankylosing spondylitis (AS) and non-radiographic (nr-)axSpA.
Objectives: To report 4-year X-ray and MRI data in CZP-treated axSpA pts.
Methods: RAPID-axSpA[1] was double-blind and placebo (PBO)-controlled to Wk24, dose-blind to Wk48, and open-label to Wk204. Pts fulfilling ASAS axSpA criteria were stratified using a local read according to presence/absence of radiographic sacroiliitis (AS/nr-axSpA) at randomization and had active disease. Wk0 CZP-randomized pts (200mg Q2W/400mg Q4W) continued assigned dose; PBO pts received CZP after Wk16/24. Centrally-read lateral X-rays of cervical/lumbar spine at baseline (BL), Wk96, and Wk204 were assessed using the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS). Sacroiliac (SI) joint X-rays were scored for sacroiliitis at BL and Wk204. MRI scans performed at BL, Wks12, 48, 96, and 204 were assessed using Spondyloarthritis Research Consortium of Canada (SPARCC) score for SI joints and Berlin score for spine. Data are shown for CZP-treated pts including those starting on PBO. SI joint X-rays (recorded at BL and Wk204) and magnetic resonance imaging (MRI) observed data are presented for pts with valid assessments. mSASSS data were estimated for all pts using observed data and by mixed model for repeated measures (MMRM) analysis.
Results: Of 315 CZP-treated pts, 196 had available spinal X-rays and were included in MMRM analyses (BL mean mSASSS: 9.47). 158 pts had MRI assessments (BL mean SPARCC: 8.17 [n=151]; Berlin score: 6.10 [n=153]) and 137 pts had SI joint X-rays at BL and Wk204 (BL: 67.9% radiographic sacroiliitis). In AS pts, mean mSASSS change between BL and Wk204 was 0.98; 0.67 from BL to Wk96, and 0.31 from Wk96 to Wk204 (0.06, -0.01, and 0.07 respectively for nr-axSpA) (Table A). MMRM estimates were similar to observed values (0.62 and 0.70, respectively [axSpA Wk204 mean change]). Limited changes in SI joint X-ray grading were observed to Wk204: only 4.5% of pts progressed to AS, whilst 4.3% moved from an AS classification to nr-axSpA. MRI assessments showed sustained improvement (Table B).

Table A: Mixed model for repeated measures (MMRM) estimates of mSASSS to Week 204 of the RAPID-axSpA study for all patients treated with CZP

	Baseline	Week 96		Week 204	
	LS mean score (95% CI)	LS mean score (95% CI)	LS mean change from BL (95% CI)	LS mean score (95% CI)	LS mean change from BL (95% CI)
axSpA (n=196)	9.47 (7.20–11.73)	9.86 (7.52–12.21)	0.40 (0.11–0.69)	10.08 (7.71–12.46)	0.62 (0.22–1.01)
AS (n=113)	13.17 (9.79–16.56)	13.84 (10.35–17.34)	0.67 (0.21–1.13)	14.16 (10.61–17.71)	0.98 (0.34–1.63)
nr-axSpA (n=83)	4.42 (2.02–6.82)	4.41 (1.97–6.84)	-0.01 (-0.19–0.17)	4.47 (2.06–6.88)	0.06 (-0.17–0.28)

Table B: MRI outcomes to Week 204 of the RAPID-axSpA study for all patients treated with CZP (observed values)

	Baseline		Week 204		
	n	Mean score (SD)	n	Mean score (SD)	Mean change from BL (SD)
SI Joint Inflammation (SPARCC)					
axSpA	151	8.17 (13.08)	72	1.90 (5.00)	-4.70 (9.40)
AS	91	8.50 (13.83)	41	1.84 (5.60)	-4.35 (8.49)
nr-axSpA	60	7.66 (11.93)	31	1.97 (4.18)	-5.16 (10.60)
Spinal Inflammation (Berlin)					
axSpA	153	6.10 (8.68)	82	2.13 (4.46)	-4.84 (8.33)
AS	92	7.38 (8.80)	50	2.62 (5.23)	-5.51 (7.61)
nr-axSpA	61	4.17 (8.21)	32	1.36 (2.75)	-3.78 (9.38)

Data shown for all CZP-treated patients with valid assessments (including patients re-randomized from PBO at Week 16 or 24). mSASSS: modified Stokes Ankylosing Spondylitis Spine Score; SPARCC: Spondyloarthritis Research Consortium of Canada; LS: least squares. SI: sacroiliac.

Conclusions: This is the first trial to report imaging data in both AS and nr-axSpA pts over 4 years. Limited spinal radiographic progression was observed in CZP-treated pts with lower progression between Wks96 and 204 compared with the first 96 wks. Limited change in radiographic sacroiliitis was observed. Early reductions in MRI inflammation were maintained to Wk204.

Valleala[1], M. Romu[1], T. Rannio[2], K. Paalanen[2], A. Juha[2], P. Ekman[9], K. Tadesse[1], J. Borodina[2], P. Elfving[4], R. Peltomaa[1], M. Leirisalo-repo[1], H. Kautiainen[10], S. Jokiranta[11], K.K. Eklund[12]. *[1]Rheumatology, Helsinki University Hospital, Helsinki; [2]Rheumatology, Central Finland Central Hospital, Jyväskylä; [3]Immunobiology, United Medix Laboratories Ltd, Helsinki; [4]Rheumatology, Kuopio University Hospital, Kuopio; [5]Rheumatology, Tampere University Hospital, Tampere; [6]Rheumatology, Päijät-Hämeen Central Hospital, Helsinki; [7]Rheumatology, Turku University Hospital, Turku; [8]Rheumatology, Central Hospital of Lapland, Rovaniemi; [9]Rheumatology, Satakunta Central Hospital, Pori; [10]Unit of Primary Health Care, Helsinki University Central Hospital; [11]Research Programs Unit, Immunobiology, Helsinki University; [12]Rheumatology, Helsinki University Central Hospital, Helsinki, Finland*

Background: Immunization to biological drugs can reduce the treatment efficacy and increase the risk of adverse events.

Objectives: To determine the drug trough concentrations and anti-drug antibody (ADAb) levels of self-injected TNF-inhibitors, in non-selected patients with ankylosing spondylitis (AS) attending the rheumatological outpatient clinic, and to study the patient related factors affecting the immunization to antiTNF drugs.

Methods: A total of 313 patients with AS were recruited. A blood sample, taken 1–2 days prior to next drug injection, was obtained from 273 patients. Trough concentration of the anti-TNF drugs were measured with capture-ELISA (Promonitor EIA, Progenica), the levels of ADAb with radioimmunoassay (Sanquin Laboratories, The Netherlands), and the serum TNF-blocking capacity by using an in-house reporter gene assay. The clinical activity of AS was assessed using the Bath AS Disease Activity Index (BASDAI), the Bath AS Functional Index (BASFI), and the Maastricht AS Entheses Score (MASES).

Results: ADAbs were observed in 21% of patients on adalimumab (n=99), in 0% of those on etanercept (n=83), in 3% of those on golimumab (n=79) and in 50% of those on certolizumab pegol (n=12). The BASDAI in ADAb positive patients was 1.4 (sd 1.4) and in the ADAb negative patients 2.0 (sd 1.8 p=0.060). Factors affecting the immunization to biological drug could be further analyzed in patients using adalimumab. Trough drug concentrations of adalimumab correlated with the presence of ADAb (r=-0.54, rp<0.0001). In adalimumab users higher BMI was associated with the presence ADAb (p=0.019, adjusted for gender, age, and the time of biological use). Of patients who used methotrexate (MTX) 12% were ADAb positive and of those who did not use MTX 28% were ADAb positive (p=0.048 adjusted for gender, age, weight, and the time of biological use). The use of sulphasalazine was not associated with lower number of ADAb positive patients. Of adalimumab users with ADAb+ the mean BASDAI was 1.2 (sd 1.4) and of those without ADAb 1.9 (sd 1.9) (p=0.091). Of adalimumab users the drug concentration was in the target range (5–10 mg/l) in only 33% of patients.

Conclusions: The disease activity of AS patients using self injected antiTNF drugs was low. The immunization to adalimumab was relatively common in nonselected AS patient population. However, no clear association was observed between the presense of ADAb and the disease activity.

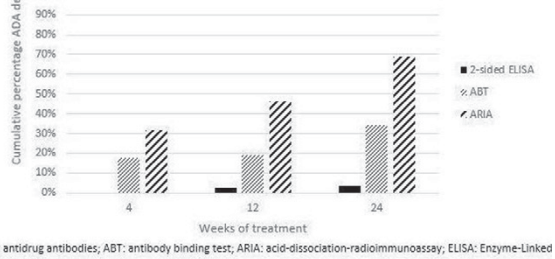
OP0025 ANTIDRUG ANTIBODIES DETECTION IS STRONGLY INFLUENCED BY THE TYPE OF ASSAY USED

J. Ruwaard[1], A.F. Marsman[1], M.T. Nurmohamed[1,2], H. te Velthuis[3], K. Bloem[3], T. Rispens[3], G.J. Wolbink[1,3]. *[1]Amsterdam Rheumatology and immunology Center | Reade; [2]Amsterdam Rheumatology and immunology Center | VU medical center; [3]Department of Immunopathology, Sanquin Research and Landsteiner Laboratory Academic Medical Center, Amsterdam, Netherlands*

Background: Direct comparison of immunogenicity data is hampered due to different assays used with different sensitivity for drug interference. This is the first study to compare detection of antidrug antibodies (ADA) with different assays in ankylosing spondylitis (AS) patients. Studying immunogenicity in AS patients with a drug tolerant assay may contribute to a better understanding of development of ADA.



Objectives: To compare the detection of ADA in different assay techniques with differences in drug interference, acid-dissociation-radioimmunoassay (ARIA) antidrug binding test (ABT) and the more frequently used 2-sided Enzyme-linked Immuno Sorbent Assay (ELISA) in AS patients. Second, to study the relation of adalimumab drug levels with the detection of ADA.

Methods: In this study, the detection of the ADA in ARIA and ABT was compared with the detection of ADA in the 2-sided ELISA in 84 consecutive AS patient over a period of 24 weeks; at 4, 12 and 24 weeks of treatment. Adalimumab drug levels were measured using an ELISA. The assays were designed by Sanquin, Amsterdam. For the difference in drug levels we divided the patients in four different groups; all assays negative (group 0), only ARIA positive (group 1), ARIA and ABT positive, 2-sided ELISA negative (group 2) and all assays positive (group 3). We used last observation carried forward to imputate missing data.

Results: As shown in Figure 1, 26% of the patients tested positive for ADA in the ARIA compared to 14% in the ABT and no detection in the 2-sided ELISA at week 4. At weeks 12 and 24 respectively, cumulative 46% and 69% of patients, tested positive in the ARIA for ADA, compared to 19% and 35% in the ABT and 2% and 4% with the 2-sided ELISA.

Median adalimumab levels at week 24 in group 0, 1, 2 and 3 were 9.5 (5.3–13.3), 8.4 (5.3–11.0), 2.8 (0.9–4.3) and 0.002 (0.0–1.3) respectively. No significant differences were found in median adalimumab levels between patients with no ADA detection and patients tested positive in only the ARIA, respectively, 8.4 (5.3–11.0) and 9.5 (5.3–13.3) p=0.385. However, when both ARIA and ABT tested positive, drug levels significantly differed from patients with no ADA detection, 2.8

Figure 1. Cumulative percentages of ADA detection per assay type at different time points

ADA: antidrug antibodies; ABT: antibody binding test; ARIA: acid-dissociation-radioimmunoassay; ELISA: Enzyme-Linked Immuno Sorbent Assay

(0.9–4.3) and 9.5 (5.3–13.3), p=0.000. When patients tested positive in the ARIA, ABT and the 2-sided ELISA almost all patients had undetectable drug levels.
Conclusions: The fast majority of the AS patients develop ADA. The ARIA detects more ADA compared to the assays susceptible for drug interference, the ABT and the more frequently used 2-sided ELISA. Immunogenicity data should be interpreted with the knowledge of the assay and in context of drug levels.

OP0026 HIGH DRUG-FREE REMISSION IN EARLY PERIPHERAL SPONDYLOARTHRITIS AFTER INDUCTION THERAPY WITH GOLIMUMAB

P. Carron[1,2], G. Varkas[1,2], H. Cypers[1,2], L. Van Praet[1], D. Elewaut[1,2], F. Van den Bosch[1,2]. *[1]Rheumatology, Univeristy of Ghent; [2]VIB Inflammation Research Center, Ghent University, Gent, Belgium*

Background: In rheumatoid arthritis there is accumulating evidence for a so-called "window of opportunity" remission induction treatment at an early stage of the disease. Whether a similar concept also applies to Spondyloarthritis is currently unknown. Given the higher chance of obtaining remission or low disease activity with early aggressive (biologic) treatment in early axial SpA, one could speculate that there is at least also a possibility of a "window of opportunity" for drug-free remission in peripheral SpA (pSpA).
Objectives: To evaluate sustained drug-free clinical remission after induction therapy with golimumab in patients with active peripheral Spondyloarthritis in a very early stage of the disease.
Methods: CRESPA (Clinical REmission in peripheral SPondyloArthritis) is an ongoing monocentric study of golimumab treatment in pSpA patients. Eligible patients were $\geq$18 years and fulfilled the Assessment of SpondyloArthritis international Society (ASAS) classification criteria for pSpA. All patients had a symptom duration $<$12 weeks. Patients were randomized 2:1 to receive golimumab 50 mg every 4 weeks or matching placebo for 24 weeks. The primary endpoint was the percentage of patients achieving clinical remission at week 24, defined as the absence of arthritis, enthesitis and dactylitis on clinical examination. If patients were in clinical remission at two consecutive visits (major evaluations at week 12, 24, 36 and 48) treatment was stopped.
These patients were prospectively followed to assess the percentage of patients in sustained drug-free clinical remission, compared to those experiencing a clinical relapse of arthritis, dactylitis or enthesitis. In case of clinical relapse patients were retreated with open-label golimumab in the extension part of this trial.
Results: In total 60 patients were randomized of whom 20 received placebo and 40 golimumab. Baseline demographics and disease characteristics were generally similar between the 2 groups. At week 24 a significantly higher percentage of patients receiving golimumab achieved clinical remission compared to patients receiving placebo (75% (30/40) versus 20% (4/20); $P<0.001$). At week 12 similar results were observed (70% (28/40) versus 15% (3/20); $P<0.001$). In 49 out of the 60 patients treatment could be stopped because they fulfilled sustained clinical remission at 2 major consecutive visits. All patients had at least a follow up of 12 months after discontinuation of treatment with a maximum of follow-up of 58 months. 53% (26/49) of these patients are still in drug-free sustained clinical remission and 47% (23/49) had a clinical relapse after withdrawal. The majority of relapsed patients experienced their flare within 6 months after discontinuation.
Conclusions: In patients with active, very early peripheral spondyloarthritis, treatment with golimumab led to high percentages of clinical remission at week 12 and 24. A remarkably high percentage of patients are still in sustained drug-free clinical remission after induction therapy with golimumab which indicates a window of opportunity for drug-free remission in this disease.

OP0028 LOW DOSE IL-2 THERAPY CAN RECOVERY TH17/TREG CELL BALANCE IN PATIENTS WITH ANKYLOSING SPONDYLITIS

D. Xu[1], J. Fan[1], Q. Chen[1], K. Qin[1], X. Li[1], C. Gao[2]. *[1]The Department of Rheumatology, The Second Hospital of Shanxi Medical University, Taiyuan, China; [2]Department of Pathology, Joint Program in Transfusion Medicine, Brigham and Women's Hospital/Children's Hospital Boston, Harvard Medical School, Boston, United States*

Background: Recent studies have shown that increased number of Th17 cells and decreased number of Treg cells in the peripheral blood contribute to ankylosing spondylitis (AS). However, current therapy for AS, including biological agents, immunosuppressant and glucocorticoid, can not correct the imbalance of Th17 and Regulatory T (Treg) cells in AS patients effectively. It has been reported that low dose IL-2 can selectively expand Treg cells and had a critical effect on homeostatic balance between the Th17 and Treg cells.
Objectives: The study is to explore the effect of low dose IL-2 therapy on the balance of Treg and Th17 cells in patients with AS and observe the efficiency and side effects of the therapy.
Methods: Seventeen patients, who met the 1984 modified New York criteria and had evidence of active inflammatory spondylitis (defined as Bath AS Disease Activity Index (BASDAI) score >4) despite of receiving standard therapy including glucocorticoid, immune-suppressants, biological agents or combination of them, were enrolled. These patients were not only given traditional treatment, but also injected subcutaneously low-dose IL-2 (50 WIU/day for 5 days). Clinical and laboratory indicators were compared before and after IL-2 treatment. The side effects were observed in the course of therapy.
Results: The number of Treg cells significantly increased after the treatment by 1 week (22.58±12.80 vs. 73.46±33.79, p<0.001). At the same time, there was a significantly decrease in the ratio of Th17/Treg cells (0.67±0.70 vs. 0.32±0.33, p=0.068). Besides, Th17 cells were also increased (12.83±9.24 vs. 19.26±13.24, p=0.054). Clinical manifestations were improved after the combination treatment of IL-2 and traditional drugs, especially BASDAI was decreased (4.57±0.61 vs. 1.98±0.83, P<0.001). No obvious adverse reactions were observed.
Conclusions: Low dose IL-2 therapy can restore and maintain the balance of Th17 and Treg cells in the active patients with AS. Manifestation improved after the combination therapy. The therapy is safe. Further research is needed to investigate long term benefits of low-dose IL-2 therapy.

OP0029 EVALUATION OF THE EFFICIENCY OF SACROILIAC JOINTS CORTICOID INJECTIONS UNDER SCAN CONTROL AND ITS RELATIONSHIP WITH THE PRESENCE OR ABSENCE OF SACROILIITIS LESIONS SEEN ON MRI OF PATIENTS WITH SPONDYLOARTHRITIS

A.M. Devauchelle[1], O. Vittecoq[1], T. Lequerre[1], P. Michelin[2], F. Vincent[2]. *[1]Rheumatology department of Rouen; [2]Radiology department of Rouen, rouen, France*

Background: Sacroiliitis is a common symptom for patients suffering from axial and/or peripheral spondyloarthritis. Several studies have demonstrated that long standing corticosteroid injections of the sacroiliac joints can reduce significantly sacroiliitis pain. However, it is difficult to identify predictive factors of good response to the infiltration.
Objectives: Hence, our purposes were to evaluate the benefit from sacroiliac long standing corticosteroid injections and to determine if MRI sacroiliac images could predict infiltration's response.
Methods: This monocentric study was conducted in real-life circumstances between January 2013 and June 2016 from a standardized procedure. Thirty-one patients having inflammatory pain originating from the sacroiliac joints were infiltrated with a long acting corticosteroid (cortivazol) under CT scan guidance. Hence, 56 sacroiliac joints were injected. To be included, patients had to suffer mainly from low back and/or buttock region in the context of axial or peripheral spondyloarthritis defined by the 2009 ASAS criteria. A contrast enhanced MRI was performed if the last MRI dated more than six months before the infiltration. The main clinical outcome was a global benefit expressed by the patient at day 15 after the infiltration (D15), 1 month (M1), 3 months (M3) and 6 months (M6).
Results: 44.1% of patients had a global benefit of at least 50% at D15, 63.6% at M1, 48.3% at M3 and 35.7% at M6. Besides, there was a decrease of the spontaneous Visual Analog Scale for pain (VAS) of the sacroiliac joint at D15, M1 and M3. Likewise, there was a decrease of the provoked VAS of the sacroiliac at D15, M1, M3 and M6. The decrease of the spontaneous VAS was at least of 50% for 35.2% of patients at D15, 41.5% at M1, 25.6% at M3 and 33.3% at M6. There was no decrease of the BASDAI, BASFI, ESR, CRP, ASDAS ESR and ASDAS CRP. Moreover, no relationship was found between the efficiency of sacroiliac infiltrations in terms of global benefit as well as of decrease of the VAS of at least 50% and the presence of sacroiliitis images on the MRI. Neither when looking at the different subtypes of sacroiliitis lesions (bone marrow oedema, synovitis, osteitis). Among the non active sacroiliitis structural lesions (erosions, subchondral sclerosis, bone brigdes...), only fatty involution was statistically more present in the group with a global improvement or a VAS of less than 50%.
Conclusions: Long acting corticosteroid infiltrations of the sacroiliac joints are useful in patients suffering from inflammatory sacroiliitis pain. However, the majority of sacroiliac joints images found on a concomitant MRI does not predict the treatment response except fatty involution that seems to be associated with a lower response. Likewise, composite indexes/scores as well as parameters of systemic inflammation are not relevant for the patients follow up in that indication.

OP0030 INEQUITY IN BIOLOGIC DMARD PRESCRIPTION FOR SPA ACROSS THE GLOBE. RESULTS FROM THE ASAS COMOSPA STUDY

E. Nikiphorou[1], D. van der Heijde[2], S. Norton[1], R. Landewé[3], A. Moltó[4], M. Dougados[4], F. van den Bosch[5], S. Ramiro[2]. *[1]KCL, London, United Kingdom; [2]LUMC, Leiden; [3]ARC, Amsterdam, Netherlands; [4]Paris Descartes University, Paris, France; [5]Ghent University Hospital, Ghent, Belgium*

Background: The value of biologic DMARDs (bDMARDs) in SpA is well recognized but global access to these treatments can be limited due to high cost and other factors.
Objectives: This study explores variation in the use of bDMARDs in SpA across countries and to what extent socio-economic (SE) factors may explain variation.
Methods: Patients fulfilling the ASAS SpA criteria in the multi-national, cross-sectional ASAS COMOSPA study were studied. Multi-level logistic regression models with random intercept for country were constructed with current use of bDMARDs as the dependent variable. Contribution of socio-economic factors using country health expenditures and gross domestic product (GDP) (all low vs medium/high tertiles) as independent country-level factors, was explored in models adjusted for socio-demographic as well as clinical variables known to determine bDMARD-use in SpA.
Results: In total, 3370 patients from 22 countries were included (mean [SD] age 43 [14] years; 66% male; 88% axial disease). Across countries, 1275 (38%) were bDMARD users. Crude mean bDMARD-use varied between 5% (China) to 74% (Belgium). After adjustment for relevant socio-demographic and clinical variables, important variation in bDMARD-use across countries remained (Figure, p<0.001). Country-level socio-economic factors, specifically higher health

Figure. bDMARD uptake (%) by country. Adjusted percentage use shown along with 95% CI, based on models with socio-economic, socio-demographic and clinical variables. Crude bDMARD uptake indicated by the orange squares.

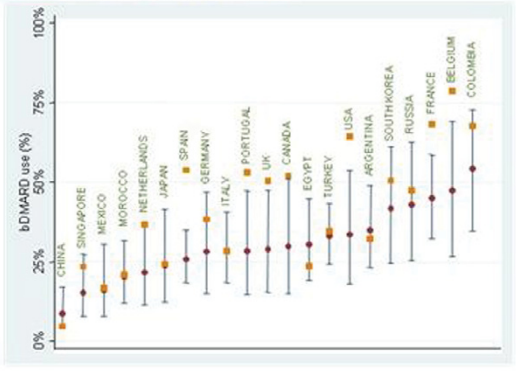

Table. Impact of country socio-economic factors on the use of bDMARDs in a model adjusting for socio-demographic and clinical variables (country included as random effects).

Independent predictors	bDMARD use OR (95% CI) (n=2758)
Country health expenditure (US dollars)	1.91(0.93,3.92)
Age (years)	1.00(0.99,1.01)
Male gender (vs females)	1.25(1.03,1.52)
Axial (vs peripheral)disease	1.55(1.09,2.22)
ASDAS (CRP based)	0.80(0.73,0.87)
Sacroiliitis on X-ray	1.38(1.09,1.74)
History of extra-articular manifestations	1.36(1.13,1.65)
BMI (kg/m²)	1.02(1.00,1.04)
Total NSAID score (0-100) in last 3 months	0.99(0.99,1.00)
Current csDMARD use	0.71(0.58,0.87)
Past csDMARD use	1.98(1.63,2.41)
Past bDMARD use	2.53(1.96,3.25)
Education (secondary/university vs primary)	0.75(0.51,1.10

expenditures were related to higher bDMARD uptake (Table), though not meeting statistical significance (OR 1.91; 95% CI 0.93,3.92). Similar findings were found with country GDP (OR 1.72;95% CI 0.83,3.57).
Conclusions: There remains important residual variation across countries in bDMARD uptake of patients with SpA followed in specialized SpA centers. This is despite adjustment of well-known factors for bDMARD use such as clinical and country-level socio-economic factors.

Early diagnosis of systemic sclerosis and myositis: biomarkers and diagnostic tool

OP0031 DEVELOPMENT OF A NOVEL EPITOPE-BASED DIAGNOSTIC ASSAY FOR SYSTEMIC SCLEROSIS

G. Moroncini[1], M. Mozzicafreddo[2], M. Cuccioloni[2], A. Grieco[1], C. Paolini[1], C. Tonnini[1], S. Salvucci[1], E. Avvedimento[3], A. Funaro[4], A. Gabrielli[1].
[1]Department of Molecular and Clinical Sciences, Università Politecnica Marche, Ancona; [2]School of Biosciences and Veterinary Medicine, University of Camerino, Camerino; [3]Department of Molecular Medicine, Università Federico II, Napoli; [4]Department of Medical Sciences, University of Torino, Torino, Italy

Background: We described the conformational PDGFRα epitope of V_HPAM–Vκ16F4 agonistic autoantibody[1], cloned from memory B cells of a SSc patient, that can induce fibrosis in vivo[2]. We showed that peptides composing this epitope may be specifically recognized by serum IgG of patients with systemic sclerosis (SSc), but not of controls.
Objectives: i. To identify the immunodominant peptide within the discontinuous PDGFRα epitope of V_HPAM–Vκ16F4; ii. to identify other immunodominant epitopes recognized by agonistic autoantibodies; iii. to use these immunodominant peptides to develop an epitope-based assay for diagnosis of SSc and classification of SSc clinical subtypes.
Methods: i.The large PDGFRα peptide library used for epitope mapping of monoclonal anti-PDGFRα antibodies[1] was screened with 25 SSc (12 limited, 13 diffuse) and 25 healthy control (HC) serum samples. ii. A smaller PDGFRα peptide library containing only the top 20 conformational binders plus 20 linear and 20 conformational controls was synthesized. 60 conformational and linear peptides of a cognate protein forming a molecular complex with PDGFRα were included in the array. 20 scrambled peptides were added as negative controls. This library was screened with the same 50 serum samples. iii. A third library was synthesized, retaining the top cognate protein peptide binders, and 15 chimeric PDGFRα/cognate protein peptides, chosen among the best binders, with some nonbinding controls. This library was tested as before. Libraries were synthesized by Pepscan Presto, Netherlands. Statistical analysis was performed by Wilcoxon-Mann-Whitney test. Correlations between serological results and clinical status were made.
Results: i. An immunodominant peptide discriminating SSc from HC serum samples was identified in the first library. ii. This was confirmed by the second library, which highlighted also one immunodominant epitope from the cognate protein. Statistical analysis identified two cohorts of SSc samples (reactive vs nonreactive, the latter undistinguishable from HC) each composed by limited and diffuse SSc subtypes. iii. The third peptide library identified the chimeric peptide recognized exclusively by the reactive SSc serum samples, which were taken from patients with active, progressive disease regardless of limited vs diffuse classification, whereas the nonreactive SSc samples were taken from subjects with less active, non progressive disease.
Conclusions: We developed a conformational epitope-based assay detecting SSc-specific, agonistic, serum autoantibodies. The preliminary results suggest that this novel array may identify SSc patients with active disease, regardless of the canonical classification criteria. We propose this assay for prospective screening of large cohorts of patients affected by, or suspected for, SSc, to validate it as a tool for disease activity assessment and/or early diagnosis.

OP0032 IS IMMUNOHISTOCHEMISTRY USEFUL TO PREDICT RESPONSE TO TREATMENT IN NECROTIZING MYOPATHIES?

S. Fernandes[1], B. Lopez[2], P. Gordon[2], S. Al-Sarraj[3]. *[1]Rheumatology, Instituto Português de Reumatologia, Lisbon, Portugal; [2]Rheumatology; [3]Clinical Neuropathology, King's College Hospital, London, United Kingdom*

Background: Muscle biopsy is the gold standard for the diagnosis of inflammatory myopathies, but the role of immunohistochemistry in Necrotizing Myopathies (NM) has not been fully characterized yet.
Objectives: To determine if MHC-I expression and pattern of C5b-9 deposition in capillaries correlate with clinical phenotype and response to treatment in NM.
Methods: The Neuropathology Departmental database was searched to identify patients with a histological diagnosis of NM and follow up data for at least 6 months (30 patients). Electronic patient records were reviewed retrospectively to record demographics, autoantibodies, treatment, proximal muscle power at 3, 6 and 12 months by Manual Muscle Testing (MMT) (2), levels of CK and flares. Patients were classified as responders when there was improvement of MMT $\geq$20% and non-responders when MMT improvement was $<$20% (3). All biopsies were reviewed blindly by an experienced neuropathologist. MHC-I expression was classified as positive only if over expressed in all fibers. The patterns of C5b-9 deposition in endomysial capillaries were classified as specific (solid), non-specific (granular) or negative.
Results: MHC-I positive group (n=16/30) had a higher proportion of responders (62,5% vs 7,7%, p=0.002), higher number of patients with total recovery of muscle power (66,7 vs. 15,4%) and were more commonly positive for autoantibodies (75% vs. 35.7%, p=0.030) when compared to the MHC-I negative group (n=14). 17 patients were positive for auto-antibodies of which 9 were myositis specific antibodies [SRP (n=6), HMG-CoA reductase (n=1), Jo-1 (n=1), P155/140 (n=1)] and 4 were myositis associated antibodies [Ro-52 (n=2), Ku (n=1), Pm/Scl (n=1)]. 13/30 patients had C5b-9 deposition, with a specific pattern in 5 and non-specific in 8. The specific pattern group had a greater reduction of CK after 6 months compared to non-specific and negative respectively (98% vs. 77% vs. 56.8%, p=0.006), greater reduction in CK after 12 months (96.6% vs. 68.9% vs. 59.6%, p=0.024) and higher rates of responders (80% vs. 60% vs. 18,8%, p=0.001). Six patients were on immunosuppressants (azathioprine/hydroxychloroquine, n=2), steroids (n=3) or both (n=1) for a minimum of 4 weeks when the biopsy was performed. Differences in age, gender, clinical features or treatment were not found to be statistically significant.
Conclusions: Upregulation of MHC I and solid staining pattern of C5b-9 in the capillaries of NM patients appears to be associated with a better outcome.

OP0033 SPECT- AND PET/CT IMAGING IN NEWLY ONSET IDIOPATHIC INFLAMMATORY MYOPATHY

J. Simonsen[1], S. Hvidsten[1], P.F. Høilund-Carlsen[1], K.F. Thøgersen[1,2], O. Gerke[1], S. Jacobsen[3], L.P. Diederichsen[4,5]. *[1]Nuclear Medicine, Odense University Hospital, Odense C; [2]Aalborg University Hospital, Aalborg; [3]Copenhagen Lupus and Vasculitis Clinic, Center for Rheumatology and Spine Diseases, Copenhagen University Hospital, Rigshospitalet, Copenhagen; [4]Reumatology, Odense University Hospital, Odense C; [5]Clinical Research, University of Southern Denmark, Odense, Denmark*

Background: Diagnosis of idiopathic inflammatory myopathies (IIMs) is challenging and so far no pathognomonic signs exist by imaging. Few radionuclide imaging techniques have been tested for this purpose, mainly ^{99m}Tc-pyrophosphate planar imaging and ^{18}F-fluorodeoxyglucose positron emission tomography/computed tomography ($^{18F-}$FDG-PET/CT). However, ^{99m}Tc-PYP uptake has been assessed visually and at best graded semi-quantitatively.
Objectives: We aimed for quantitative ^{99m}Tc-pyrophosphate single photon emission computed tomography/computed tomography (^{99m}Tc-PYP-SPECT/CT) as well as ^{18F}-FDG-PET/CT imaging in a group of newly onset IIM patients.
Methods: Thirteen patients (mean age 62 years) with newly diagnosed, untreated IIM underwent ^{99m}Tc-PYP SPECT/CT of the thorax, pelvis, and thighs. Seven of the patients also had a whole-body ^{18}F-FDG PET/CT scan. Forty-nine healthy controls (mean age 59 years) underwent ^{99m}Tc-PYP SPECT/CT and 26 healthy controls (mean age 57 years) had a ^{18}F-FDG PET/CT scan done. Volumes of interest (VOIs) covering the right biceps, triceps, and quadriceps muscles were drawn manually on each series. Registered ^{99m}Tc-PYP counts, respectively standardized uptake values (SUVs) of ^{18}F-FDG were obtained from all VOIs. Registered counts were decay- and attenuation-corrected and adjusted for body weight and administered dose of ^{99m}Tc-PYP, yielding a parameter similar to the SUV [g mL^{-1}].

Results: IIM patients had visible tracer uptake in the skeletal muscles of the extremities. The muscular ^{99m}Tc-PYP uptake was significantly higher in upper limbs of patients than the uptake in the same muscle groups in healthy controls (uptake[biceps] 0.46 vs. 0.33 g mL^{-1}, p=0.01; uptake[triceps] 0.40 vs. 0.27 g mL^{-1}, p=0.003). The ^{99m}Tc-PYP uptake tended to be higher in the lower limbs of patients than in the lower limbs of controls (uptake[quadriceps] 0.59 vs. 0.48 g mL^{-1}, p=0.06). The muscular FDG uptake was significantly higher in patients than in controls in both upper limbs (SUV_{mean}[biceps] 1.35 vs. 0.72 g mL^{-1}, p=0.006; SUV_{mean}[triceps] 0.91 vs. 0.44 g mL^{-1}, p=0.0008) and lower limbs (SUV_{mean}[quadriceps] 0.84 vs. 0.62 g mL^{-1}, p=0.0001). The muscular FDG uptake values were consequently higher than the ^{99m}Tc-PYP uptake values, although not by a constant factor.
Conclusions: Quantitative ^{99m}Tc-PYP SPECT/CT as well as ^{18}F-FDG PET/CT imaging revealed muscular inflammation in patients with newly onset, untreated IIM. Patients had higher tracer uptake in skeletal muscles groups than healthy controls. Quantification of muscular tracer uptake with the potential to objectively distinguish physiology from pathophysiology could be a valuable tool in the challenging diagnosis of IIMs.

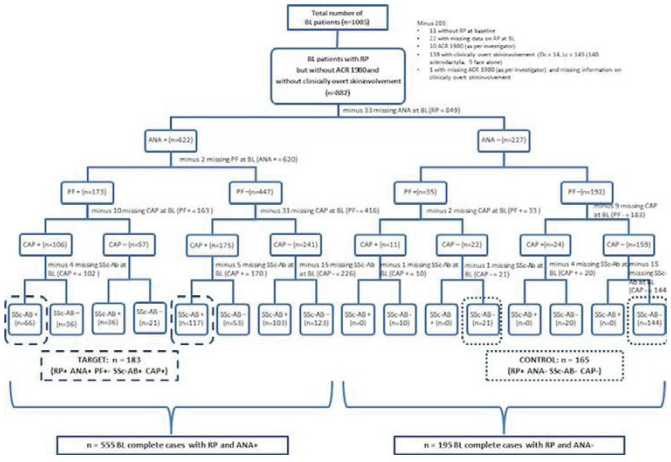
OP0034 FACTORS ASSOCIATED WITH DISEASE PROGRESSION IN EARLY-DIAGNOSED PULMONARY ARTERIAL HYPERTENSION ASSOCIATED WITH SYSTEMIC SCLEROSIS: LONGITUDINAL DATA FROM THE DETECT COHORT



C. Mihai[1], M. Antic[2], R. Dobrota[1,2], D. Bondermann[3], H. Chadha-Boreham[4], G. Coghlan[5], C.P. Denton[6], M. Doelberg[4], E. Grünig[7], D. Khanna[8], V.V. McLaughlin[9], U. Müller-Ladner[10], J.E. Pope[11], D.M. Rosenberg[4], J.R. Seibold[12], M.C. Vonk[13], O. Distler[2]. *[1]Internal Medicine and Rheumatology, Cantacuzino Hospital, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; [3]Department of Internal Medicine II, Division of Cardiology, Medical University of Vienna, Vienna, Austria; [4]Actelion Pharmaceuticals Ltd, Allschwil, Switzerland; [5]Cardiology Department; [6]Centre of Rheumatology, Royal Free Hospital, London, United Kingdom; [7]Centre for Pulmonary Hypertension, Thoraxclinic, University Hospital Heidelberg, Heidelberg, Germany; [8]Division of Rheumatology, Department of Medicine; [9]Division of Cardiology, Department of Medicine, University of Michigan, Ann Arbor, MI, United States; [10]Department of Rheumatology and Clinical Immunology, Justus-Liebig University, Giessen, Germany; [11]Division of Rheumatology, Department of Medicine, Western University of Canada, London, Ontario, Canada; [12]Scleroderma Research Consultants LLC, Litchfield, CT, United States; [13]Department of Rheumatology, Radboud University Medical Centre, Nijmegen, Netherlands*

Background: Pulmonary arterial hypertension (PAH) is a severe complication of systemic sclerosis (SSc).
Objectives: In this longitudinal study we aimed to identify factors associated with an unfavourable outcome in SSc patients with early PAH (SSc-PAH) from the DETECT cohort.
Methods: DETECT enrolled patients with SSc fulfilling the 1980 ACR classification criteria, with a minimal disease duration of 3 years since the first non-Raynaud symptom, and with a lung diffusion capacity for CO (DLCO) <60% of the predicted value. A broad range of clinical and laboratory parameters potentially associated with PAH were assessed, and right heart catheterisation (RHC) was performed in all patients at baseline. Patients diagnosed with PAH were followed up for up to 3 years in centers that agreed for the longitudinal part of the DETECT study, collecting data on survival, World Health Organization (WHO) Functional Class (FC), hospitalization, and PAH-specific treatment. Disease progression was defined as the occurrence of any of the following: WHO-FC worsening, PAH therapy with a drug combination, hospitalization, or death. Associations between baseline variables and disease progression were assessed by univariable logistic regression.
Results: Of the 145 SSc patients with PH enrolled in DETECT, 87 patients were diagnosed with PAH, of whom 57 participated in the longitudinal study (median follow-up time 12.6 months, interquartile range 10.7–21.7 months). Among these 57 patients, 33/57 (57.9%) had mild PAH, in WHO FC I or II. During follow-up, 25/57 (43.9%) patients had disease progression (4 deaths, 11 hospitalizations for PAH, 14 with worsening in WHO FC, and 8 received PAH-specific combination treatment), with a 1-year survival rate of 93%. The following factors [odds ratio, (95% confidence interval)] were associated with disease progression: male gender [4.1 (1.2–14.1)], high Forced Vital Capacity (FVC) % predicted/ DLCO % predicted ratio [3.6 (1.2–10.7)], and high Borg dyspnoea index [1.7 (1.1–2.6)]. Low DLCO (% predicted) was also significantly associated with progression [area under the curve (95% CI) 0.8 (0.6–0.9)], but the relationship was not linear.
Conclusions: More than 40% of early-diagnosed SSc-PAH patients in the DETECT cohort who were followed over time had disease progression during a rather short follow-up time, with male gender, functional capacity, and pulmonary function tests (low DLCO, high FVC%/DLCO % predicted ratio) at PAH diagnosis being associated with progression. This suggests that even mild and early detected PAH should be regarded as a high-risk complication of SSc, and every effort to make an early diagnosis is valuable.
Acknowledgements: The authors thank all investigators and patients involved in DETECT.

OP0035 PRELIMINARY ANALYSIS OF NAILFOLD CAPILLAROSCOPY IN THE VERY EARLY DIAGNOSIS OF SYSTEMIC SCLEROSIS (VEDOSS): THE CAPI-VEDOSS EXPERIENCE

M. Cutolo[1], V. Smith[2,3], O. Distler[4], O. Kowal-Bielecka[5], Y. Allanore[6], M. Matucci-Cerinic[7] on behalf of EUSTAR coworkers. *[1]Research Laboratory and Academic Unit of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genova, Italy; [2]Department of Internal Medicine, University of Ghent; [3]Department of Rheumatology, Ghent University Hospital, Ghent, Belgium; [4]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; [5]Department of Rheumatology and Internal Medicine, Medical University of Bialystok, Bialystok, Poland; [6]Department of Rheumatology, Paris Descartes University, Cochin Hospital, Paris, France; [7]Department of Experimental and Clinical Medicine, Division of Rheumatology, University of Florence, Florence, Italy*

Background: In Systemic Sclerosis (SSc), before the onset of clinical signs of fibrosis, puffy fingers, specific autoantibodies and microcirculatory modifications are present and are identified in the VEDOSS criteria for "(very) early" disease. No large scale studies are available indicating the prevalence of nailfold video-capillaroscopic (NVC) SSc patterns or quantitated capillaroscopic characteristics in a "(very) early" cohort.
Objectives: Evaluation of the prevalence of SSc patterns and quantitated capillaroscopic characteristics in a "(very) early" crossectional SSc cohort.
Methods: Multicentre observational cohort study of patients with two strata (Figure): 1.Raynaud's phenomenon (RP), Anti Nuclear Antibody (ANA) positive (+), 2. RP+, ANA negative (-). "Target" (RP+, ANA+, puffy finger [PF] +/-, SSc- antibody (SSc-AB)+, NVC+) and "control" (RP+, ANA-, SSc-AB-, NVC-) subsets were described. NVC patterns (normal/non-specific alterations; non-specific abnormalities; SSc-patterns ("Early", "Active";"Late"; "Sclerodermalike") and quantitative ("absent (="none" or "rare") and "present" (="moderate" or "extensive") capillaroscopic alterations for giants, haemorrhages, capillary loss and abnormally shaped (=bushy capillaries) were evaluated). Generalized Estimating Equations (GEE) were used to assess differences in prevalences of NVC patterns between strata, taking clusters of patients within centers into account.
Results: 1085 RP patients from 40 centres (median number [n°] of pt 12 (minimum [min] 1-maximum [max] 393) per centre were enrolled in the VEDOSS online database. Due to erroneous included/missing data (e.g. erroneous: absence/missing information on RP, presence of former ACR criteria for SSc, skin involvement at baseline; missing info on: ANA positivity, PF, Cap, SSc-AB) 750 patients (median n° of 7 (min:1-max:271) were retained for the analysis. SSc nailfold videocapillaroscopic (NVC) patterns ("Early", "Active", "Late", "Scleroderma like" were present in 79%,13%,0%, 8%) as well as presence of "moderate" or "extensive" giants (49%), hemorrhages (32%), capillary loss (11%) and abnormal shapes (11%) of "target" patients and per definition in 0% of "controls". Estimated distribution of SSc patterns differed in the ANA+/- stratum: 49%/15% ($p \leq 0.001$) ("Early" 40/13%; "Active" 5/2%; "Late" 0/0%; "Scleroderma like" 3/0%). For the quantitative capillaroscopic characteristics a statistically significant difference in the presence of "moderate" or "extensive" giants (23/5%, p=0.027) between the ANA+/- stratum was found, hemorrhages (18/9%, p=0.200), capillary loss (5/2%, p=0.798) and abnormal (ramified) shapes (7/2%,p=0.445).

Conclusions: The VEDOSS cohort presents predominantly an "Early" NVC SSc pattern. Notably the prevalence of NVC SSc patterns was higher in the ANA+ than ANA- stratum. This evidence further reflects the pivotal role of NVC in the very early diagnosis of SSc.

OP0036 SEROLOGICAL BIOMARKERS OF ECM TURNOVER ARE ASSOCIATED WITH SKIN FIBROSIS AND LUNG INVOLVEMENT IN SYSTEMIC SCLEROSIS

S. Kubo[1], A.S. Siebuhr[2], A.-C. Bay-Jensen[2], P. Juhl[2], M.A. Karsdal[2], K. Nakano[1], S. Nakayamada[1], Y. Tanaka[1]. *[1]The First Department of Internal Medicine, University of Occupational and Environmental Health, Japan, Fukuoka, Japan; [2]Nordic Bioscience, Biomarkers and Research, Herlev, Denmark*

Background: Extracellular matrix (ECM) unbalance of the skin is a hallmark of systemic sclerosis (SSc). However, currently there is no objective tool to monitor the ECM unbalance in SSc patients allowing for better understanding of the disease stage and activity.
Objectives: We investigated the potential of serological biomarkers of ECM turnover (collagen formation and degradation) as biomarkers of skin fibrosis and internal organ involvement in SSc patients.
Methods: Peripheral blood obtained from 79 SSc patients and 19 healthy subjects was included in the study. Type I, III, IV, V and VI collagen formation (P1NP, PRO-C3, P4NP7S, PRO-C5, PRO-C6) and degradation (C3M, C4M2, C5M, C6M) biomarkers were detected by ELISA in serum. Modified Rodnan skin score (mRSS) and extent of internal organ involvement (renal, lung, vasculopathy and gastrointestinal) were recorded for SSc patients with a scoring between 0 and 4, with 0 being no involvement and 4 being severe involvement. Mann-Whitney t-test was used to test difference in the biomarker levels between the patient groups and in groups with and without internal organ involvement. Spearman's correlation coefficient investigated the association between biomarkers and clinical manifestations.
Results: SSc patients had a mean age of 63.0 years, mean disease duration of 98.3 months and a mean mRSS of 11.1. SSc patients compared to healthy individuals had higher levels of C5M, C6M and PRO-C6 ($p=0.0001$, $p<0.0001$, $p<0.0001$, respectively). The levels of type VI collagen formation and degradation (PRO-C6 and C6M) were twice as that of healthy controls (12.6 vs. 5.4 and 26.0 vs 16.7 ng/ml, respectively). C4M2, PRO-C3 and PRO-C6 was associated with skin fibrosis assessed by mRSS (Spearman's rho=0.24, 0.39 and 0.29, respectively). Patients with signs and manifestation of lower gastrointestinal lesion compared to patients without lesion had higher levels of C3M (median 10.7 vs 13.8ng/mL, $p=0.017$; figure). PRO-C6 was higher in patients with pulmonary hypertension compared to patients without any signs of pulmonary hypertension (median 9.6 vs 14.3ng/mL, $p=0.006$) with a Spearman's correlation coefficient of 0.31. C6M was higher in patients with definite pulmonary hypertension (>1) compared to patients with signs of or no pulmonary hypertension (median 22.1 vs 29.9ng/mL, $p=0.026$). P1NP was lower in patients with interstitial pneumonia, whereas C6M was higher. There was no difference in the biomarker levels with and without upper gastrointestinal lesions, renal dysfunction or vasculopathy.

	Healthy	SSc	P-value	Spearman's correlation to mRSS Rho (p-value)
C3M	12.8	13.4	–	0.21 (0.06)
C4M2	31.1	34.0	–	0.24 (0.03)
C5M	2.6	3.9	0.0001	0.03 (0.81)
C6M	16.7	26.0	<0.0001	0.18 (0.11)
P1NP	136.9	130.4	–	0.03 (0.80)
PRO-C3	14.2	20.8	–	0.39 (<0.001)
P4NP7S	286.8	290.3	–	0.19 (0.10)
PRO-C5	525.2	484.4	–	0.07 (0.52)
PRO-C6	5.4	12.6	<0.0001	0.29 (0.01)

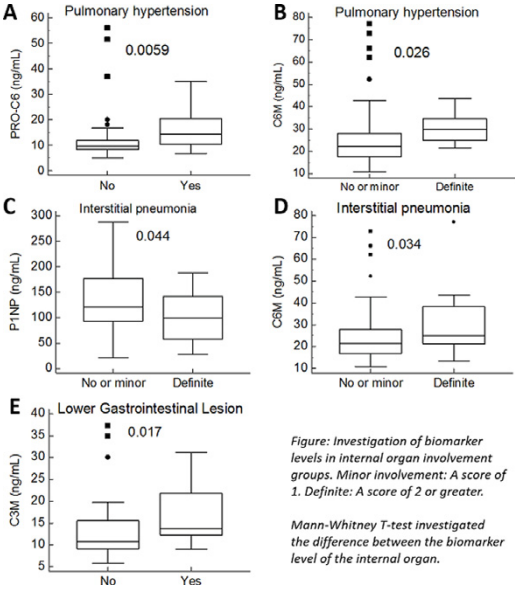

Figure: Investigation of biomarker levels in internal organ involvement groups. Minor involvement: A score of 1. Definite: A score of 2 or greater.

Mann-Whitney T-test investigated the difference between the biomarker level of the internal organ.

Conclusions: Serological biomarkers of type V and VI turnover (C5M, C6M, PRO-C6) were associated with SSc, but not serological biomarkers of type I, III and IV collagen. Especially, turnover of type VI collagen was associated with skin sclerosis, pulmonary hypertension, interstitial pneumonia and renal dysfunction. This study indicates that biomarkers of collagen turnover have a potential as new objective tool of skin fibrosis and internal organ involvement in SSc.

OP0037 EVALUATION OF SKIN INVOLVEMENT IN SYSTEMIC SCLEROSIS PATIENTS BY USING TWO ULTRASOUND TRANSDUCERS WITH DIFFERENT FREQUENCY

B. Ruaro, A. Sulli, S. Paolino, C. Pizzorni, M. Ghio, E. Alessandri, A.C. Trombetta, C. Cosso, M. Cutolo. *Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS AOU San Martino, Genoa, Italy*

Background: The modified Rodnan skin score (mRSS) is the validated method to evaluate the extension of skin involvement in systemic sclerosis (SSc) and to distinguish between patients with limited cutaneous skin involvement (lcSSc, skin involvement is confined to the extremities) or diffuse (dcSSc) (1,2). Recently several studies have demonstrated that skin high frequency ultrasound (US) is a valid and reproducible technique to measure dermal thickness (DT) in patients with SSc (3–6).
Objectives: To compare the values of DT obtained by two ultrasound transducers with different frequency (18 MHz and 22 MHz) in evaluating the DT in lcSSc patients and healthy controls.
Methods: Thirty-seven lcSSc patients (mean age 62±13SD years, mean disease duration 5±5SD years) and 37 healthy controls (CNT) sex and age matched were enrolled after informed consent. Both US transducers of 18 and 22 MHz (Esaote, Genova) were used to evaluate DT in the seventeen areas of the skin (zygoma, fingers, dorsum of hands, forearms, arms, chest, abdomen, thighs, legs, feet) of SSc patients where Rodnan skin score (mRSS) is usually assessed. Skin US was also performed in the same seventeen areas of CNT, looking for DT differences in comparison with lcSSc patients. Statistical analysis was carried out by non parametric tests.
Results: DT evaluated with the 22 MHz probe was found significantly higher in all body areas in comparison with the 18 MHz transducer, both in lcSSc patients ($p<0.01$) and in CNT ($p=0.05$). The median difference of DT values between the two probes was of 0.11 millimetres in lcSSc patients (minimum 0.0023, maximum 0.28 mm) and 0.01 millimetres in CNT (minimum 0.0029, maximum 0.03 mm). Of interest, in lcSSc DT evaluated by 18 MHz transducer was recognized significantly higher ($p<0.001$) also in four out of six skin areas where the mRSS was found normal (score=0) (upper-arms, chest and abdomen), with exclusion of thighs ($p=0.08$), in contrast with the classification of lcSSc. However, by using the 22

MHz transducer a statistically significantly higher median DT was showed in all skin areas, included thighs ($p<0.01$). Finally, a positive statistically significant correlation was observed between the two transducers in the evaluation of DT ($p<0.0001$), as well as between both probes and mRSS ($p<0.0001$ for both).
Conclusions: This study suggests that subclinical dermal involvement may be detectable by skin high frequency US already in patients with limited cutaneous SSc. This study confirms that DT can be better assessed in SSc patients by using a 22 MHz US probe, and suggests that DT might be underestimated by using US probes of lower frequency (18 MHz). However, the DT values obtained using both probes resulted significantly correlated together and with the mRSS.

OP0038 MYOSITIS AUTOANTIBODIES OUTPERFORM CLINICAL SUBGROUP CLASSIFICATION IN PREDICTING MUSCLE WEAKNESS IN MYOSITIS PATIENTS

I. Pinal-Fernandez[1], W. Huang[1], M. Casal-Dominguez[1], E. Tiniakou[2], C. Parks[1], K. Pak[1], J. Albayda[2], J.J. Paik[2], S.K. Danoff[3], L. Christopher-Stine[2], A.L. Mammen[1]. *[1]Muscle Disease Unit, NIAMS/NIH, Bethesda; [2]Rheumatology; [3]Pulmonology, Johns Hopkins University, Baltimore, United States*

Background: Myositis patients may be classified as belonging to one of four clinical groups: dermatomyositis (DM), polymyositis (PM), clinically amyopathic dermatomyositis (CADM) or necrotizing myositis (NM). Alternatively, myositis patients may be classified according to myositis autoantibody status.
Objectives: The aim of this study was to determine whether clinical groups or myositis autoantibodies provide better prognostic categories with regard to muscle involvement in these patients.
Methods: All Johns Hopkins Myositis Center patients from 2002 to 2015 with a myositis specific autoantibody confirmed by two different immunologic techniques were included. Autoantibody groups accounting for less than 2% of the final sample size were excluded. Strength (analyzed as the average of deltoid and hip flexor strength using Kendall's scale) and log transformed CK levels were compared between the different autoantibody groups using multilevel regression models adjusted for age, time from disease onset, sex, race and treatments. Models with different combinations of key variables were compared using the likelihood ratio test to ascertain if autoantibody groups and clinical subgroups provided the same amount of information regarding muscle weakness and CK levels over time.
Results: 483 patients with 4181 visits were included and 10 different autoantibody groups were identified. Muscle weakness and CK levels followed a gradient among both antibody and clinical groups. Anti-SRP patients had the greatest weakness, followed by anti-HMGCR, anti-Mi2 and anti-NXP2, and then anti-Jo1. CK levels were highest in anti-HMGCR patients, followed by anti-SRP, anti-PL7, anti-Jo1 and anti-Mi2. Interestingly, strength and CK levels were dissociated in two groups: anti-NXP2 patients had significant weakness with low CK levels and anti-PL7 patients were relatively strong despite high CK levels. Multilevel regression models showed autoantibody groups explained the strength and the CK variability better than the clinical groups (AIC difference>20). Indeed, adding clinical groups to a model using only autoantibodies did not improve the model's ability to predict strength (p=0.2) and only mildly improved its ability to predict CK (p=0.01). In comparison, adding the autoantibodies to a model using the clinical groups resulted in a marked improvement in predicting both CK and strength (both $p<0.001$).
Conclusions: In patients with myositis, autoantibody status predicts strength and CK levels better than clinical grouping.

SLE, Sjögren's and APS - clinical aspects

OP0039 A POPULATION-BASED STUDY ON MORTALITY AND THE INFLUENCE OF MEDICATION USE IN 4356 PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND 21845 MATCHED CONTROLS FROM THE UNITED KINGDOM

I.E. Bultink[1], A. Lalmohamed[2,3], F. de Vries[3,4]. *[1]Rheumatology, Amsterdam Rheumatology and immunology Center, VU University Medical Center, Amsterdam; [2]Clinical Pharmacy, University Medical Center Utrecht; [3]Pharmacoepidemiology and Clinical Pharmacology, Utrecht University, Utrecht; [4]Clinical Pharmacy and Toxicology, Maastricht University Medical Centre, Maastricht, Netherlands*

Background: Systemic lupus erythematosus (SLE) has been associated with an increased mortality rate. However, population-based data on all-cause, age-specific and sex-specific mortality risk are limited and data on the influence of medication exposure on mortality risk in SLE are scarce.
Objectives: To estimate the magnitude of the risk from all-cause, age-specific, and sex-specific mortality in patients with SLE and relative risks compared with matched controls, and to evaluate the influence of medication exposure on mortality risk in SLE.
Methods: We conducted a population-based cohort study using the Clinical Practice Research Datalink (from 1987 to 2012). Each SLE patient (n=4356) was matched with up to 6 controls (n=21845) by age and sex. Multivariate Cox regression analysis estimated adjusted relative rates (RR) of mortality, and time interaction terms to evaluate mortality timing patterns. Time-dependent Cox models were used to evaluate the association of glucocorticoid use and hydroxychloroquine use on mortality and were adjusted for age, sex, lifestyle parameters, comorbidities and comedication.
Results: A total of 442 out of 4356 SLE patients died during the study period. Patients with SLE had an increased mortality rate for all-cause mortality compared with age- and sex-matched subjects, after adjustment for confounders (adjusted RR 1.80, 95% CI 1.57–2.08). Glucocorticoid use in the previous six months raised the mortality rate while the adjusted RR was 45% decreased with low dose hydroxychloroquine use. The RR was highest in patients aged 18–39 years (adjusted RR 4.87, 95% CI 1.93–12.3) and slightly higher in females (adjusted RR 1.82, 95% CI 1.56–2.13) compared to male patients (adjusted RR 1.68, 95% CI 1.19–2.39). The mortality rate was significantly increased for patients with a history of dementia, seizures, diabetes, cancer, and renal disease (Table 1).

Table 1. Risk of all-cause mortality within SLE patients (n=4356), stratified according to organ damage (reference = no risk factor)

	Person years (x1000)	Deaths	IR (/1000)	Adjusted RR* (95% CI)
Dementia	0.1	14	140.0	2.99 (1.74–5.14)
Seizures	1.4	37	26.4	2.33 (1.66–3.28)
Cerebrovascular event	1.9	73	38.4	1.28 (0.99–1.65
Renal disease	2.0	86	43.0	1.40 (1.09–1.78)
Osteoporotic fracture	5.1	110	21.6	1.06 (0.85–1.32)
Diabetes mellitus	0.9	45	50.0	1.90 (1.39–2.59)
Malignancy	2.0	95	47.5	1.90 (1.50–2.40)

*Adjusted for: recent use of corticosteroids, recent use of antimalarials, recent use of benzodiazepines.

Conclusions: Patients with SLE have a 1.8-fold increased mortality rate compared with the general population. Glucocorticoid use, female sex and young age are associated with an increased mortality risk while low dose hydroxychloroquine use significantly reduces the mortality rate. In addition, special attention should be paid to lupus patients with neuropsychiatric complications, diabetes, malignancy or renal disease since these subgroups of patients are at high risk of death.

Background: The recent classification criteria sets for primary Sjögren's syn-

drome (AECG 2002 and ACR/EULAR 2017) did not include major salivary glands ultrasononography (SGUS).
Objectives: The UTOPIA study was undertaken to determine if and how SGUS may improve the ACR/EULAR criteria.
Methods: Twenty four international experts in pSS evaluated on an internet-secure relational database 512 randomly realistic vignettes derived from 150 patients with suspected pSS included in the french DiapSS cohort. Each vignette contained sections on "history" (duration of the symptoms, gender, age), clinical symptoms (dry mouth, dry eyes and systemic manifestations), results of the SGUS evaluation (score > ou < to 2), and results of the major tests to diagnose pSS (Schirmer's test, ocular staining score (OSS), salivary flow, focus score on salivary biopsy, presence of anti-SSA antibodies). Each expert had to score the diagnosis of pSS as absent, unlikely, likely or present for 64 vignettes. Each vignette was evaluated by 3 experts. Diagnosis of pSS was obtained when at least 2 of 3 considered it as likely or present. Univariate and multivariate analysis (Wald test) were performed to evaluate the association between the SGUS criteria, the ACR/EULAR criteria and its different individual items with the diagnosis of pSS as defined by the experts. Data were then replicated on independent cohorts of suspicion of pSS.
Results: Univariate and multivariate analyses confirmed that ACR/EULAR criteria and SGUS were independently associated with the diagnosis of pSS. Disease duration, OSS and ocular dryness were not associated with the diagnosis of pSS. Only 6 variables were selected by logistic regression analysis: presence of anti-SSA (weight:4), focus score (weight:3), SGUS (weight:2), Schirmer's test (weight:1), dry mouth (weight:1) and salivary flow rate (weight:1). According to ROC curve analysis, a score of ≥5 had 96% Se and 84% Sp, compared with 90% Se and 84% Sp for the ACR/EULAR criteria. The corrected C statistic (AUC) for the new weighted score was 0.98.
Conclusions: Inclusion of the SGUS item in the ACR/EULAR criteria improves their diagnostic performance.

OP0041 ALL-CAUSE, CARDIOVASCULAR AND MALIGNANCY RELATED MORTALITY IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE): A POPULATION-BASED STUDY

B. Moghaddam[1], J.A. Avina-Zubieta[2,3], E.C. Sayre[2]. *[1]Division of Medicine, University of British Columbia, Vancouver; [2]Arthritis Research Canada, Richmond; [3]Division of Rheumatology, University of British Columbia, Vancouver, Canada*

Background: SLE is associated with increased risk of overall mortality; however morality trends due to specific causes including cardiovascular disease (CVD), malignancies or other causes are largely unknown.
Objectives: Our objective was to assess trends in cause-specific mortality among SLE patients between January 1, 1997 and December 31, 2012 in a general population-based context.
Methods: We conducted a population-based matched cohort on SLE patients diagnosed between January 1,1997 and December 31,2012 using an administrative health database from the province of British Columbia, Canada. We identified all incident cases of SLE and up to 10 non-SLE controls matched on sex, age, and calendar year of study entry. The cohort was divided into two cohorts based on year of SLE diagnosis (1997–2004 and 2005–2012). All-cause mortality and cause-specific incidence of death rates (IR) were calculated. Cox proportional hazard regression models were used to estimate the mortality hazard ratios (HR), adjusting for possible confounders (i.e. Charlson Comorbidity Index, number of outpatient visits, hospitalization, cardiovascular medications, glucocorticoids and NSAIDs at baseline).
Results: 4238 SLE and 42380 matched controls were studied. SLE patients had significantly increased all-cause mortality with HR 1.29 (95% CI, 1.15–1.46) and increased cause-specific mortality from CVD and other causes with HRs of 1.43 (95% CI, 1.15 -1.79) and 1.74 (95% CI, 1.46–2.09), respectively. The cohorts did not differ in the rate of death from malignancy. SLE patients had an approximately 2-fold increase in death from other causes in both early (HR 1.86 (95% CI 1.33–2.60)) and recent cohorts (HR 1.90 (95% CI 1.42–2.56)). There was no significant improvement in all-cause and cause-specific mortality trends between the two cohorts.
Conclusions: This study demonstrates that despite advances in therapy with novel biologic agents, there are no significant differences in all-cause and CVD mortality from SLE between early and recent cohorts. Death from other causes, which includes a composite of death related to for example renal disease and infections, remains high suggesting areas for future targeted research and therapy.

OP0042 BACTEREMIA IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS FROM RELESSER REGISTRY: RISK FACTORS, CLINICAL AND MICROBIOLOGICAL CHARACTERISTICS AND OUTCOMES

I. Rua-Figueroa[1], J. López-Longo[2], M. Galindo-Izquierdo[3], V. Del Campo[4], J. De la Torre Cisneros[5], E. Uriarte[6], P. Vela[7], E. Tomero[8], J. Pego-Reigosa[4]. *[1]Rheumatology, Hospital Dr. Negrin, Las Palmas GC; [2]Gregorio Marañón Hospital; [3]Doce de Octubre Hospital, Madrid (Spain), Madrid; [4]Hospital Complex of Vigo and IISGS, Vigo; [5]Reina Sofía Hospital, Córdoba; [6]Donosti Hospital, Guipúzcoa; [7]Alicante G Hospital, Alicante; [8]La Princesa Hospital, Madrid, Spain*

Background: According to RELESSER (Spanish Society of Rheumatology Lupus Registry) data, bacteremia is the main cause of death by infection in systemic lupus erythematosus (SLE). However, the available information about this severe infection in SLE patients remains scarce.
Methods: Retrospective, nested case-control study of SLE patients (ACR-97 criteria) with at least one bacteremic episode and random controls from RELESSER Registry. Descriptive, bivariate and multivariate analysis (logistic regression)
Results: 114 bacteremic episodes in 83 patients were recorded. Incidence rate: 2,7/ 1,000 patient-years (n total: 3658). At the time of the bacteremia: median age: 40.5 (8–90) years, 88.6% female, disease duration: 9.7 (IR16.7), median SELENA-SLEDAI: 4 (IR8), 66% with severe flare (SFI criteria), active nephritis: 16.7%, median SLICC/ACR DI: 3 (IR4), any comorbidity: 64% (McCabe-Jackson criteria: 28.1% rapidly or ultimately fatal), more frequently renal failure (15.8%) or diabetes (11.4%). SLE treatment at the time of bacteraemia: 88.6% corticosteroids (68,6%>10mg/day), 57% immunosuppressors (mycophenolate 17.5% and cyclophosphamide 12.3%), 27% antimalarials. 44.7% suffered invasive procedures, more frequently intravascular catheter (24.6%). The bacteremia was nosocomial in 35.1% and the source was more frequently urinary (27.2%). 64% developed systemic inflammatory response syndrome and 35% needed intensive care unit admission, with multiorganic failure in 22.8%. The most frequent microorganism was *E.coli* (29.8%) followed by *Staphylococcus aureus* (16.7%) (22% methicillin-resistant) and *Salmonella spp.* (10.5%). 16% of the gram-negative enteric bacilli were extended-spectrum b-lactamase positive. 17.5% were multidrug resistant. 68,4% started the antibiotherapy before blood culture results, resulting finally active in susceptibility testing in 56 cases (71.8%), indicating an appropriate empirical antibiotic therapy in 49%. The bacteremia-related mortality was 14%. The risk of death was higher in patients with severe sepsis (Pitt index >8) (OR: 13 (IC95%: 3.71–45.17). The bacteremia was recurrent in 26.3%. Associations with bacteremia in bivariate analysis (114 bacteremias vs 688 controls) are shown in Table 1. Antimalarials were protective. In the multivariate analysis (adjusted for disease duration), only elevated creatinine (OR 1.31 (95% CI 1.01–1.70), p=0.045), diabetes (OR 6.01 (95% CI 2.26–15.95), p=0.000), cancer (OR 5.32 (95% CI 2.23–12.70), p=0.000), immunosuppressors (OR 6.35 (95% CI 3.42–11.77), p=0.000), cyclophosphamide (OR 9.37 (95% CI 5.12–17.14), p=0.000) and SLICC/ACR DI (OR 1.65 (95% CI 1.31–2.09), p=0.000) remained statistically significant.
Conclusions: Bacteremia occurred mostly in active SLE, frequently in the context of a severe flare. Gram negative bacilli predominated, with high rate of multidrug resistance. The empiric treatment was inappropriate in a half of the cases. The

Abstract OP0041 – Table 1. Overall and cause-specific mortality in SLE patients compared to general population; HR, hazard ratio

OP0043 THE NUMBER OF CIRCULATING REGULATORY T CELLS IS REDUCED AND LOW-DOSE IL-2 SELECTIVELY STIMULATES ITS PROLIFERATION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

X. Liu[1], X. Jing[1], X. Wu[1], J. Wang[1], Z. Liang[1], M. Hao[1], J. Chen[1], C. Gao[2], X. Li[1]. *[1]Rheumatology, The Second Hospital of Shanxi Medical University, Taiyuan, China; [2]Pathology, Brigham and Women's Hospital, Harvard Medical School, Boston, United States*

Background: The imbalance of T help 17 cells (Th17)/regulatory T cells (Tregs) is considered to be a pivotal cause of autoimmune diseases[1], including systemic lupus erythematosus (SLE). However, previous reports[1,2] describing the respective changes of Tregs and Th17 cells in SLE patients were controversial because a few samples or diverse markers were used to identify Tregs with little consensus.

Objectives: To clarify the status of Tregs and Th17 in SLE, we investigated the frequencies of Tregs and Th17 cells on a large scale and whether those defects can be corrected by the supplementation of low-dose human recombinant interleukin-2 (IL-2).

Methods: Two hundred and thirty-five SLE patients (219 women and 16 men), with mean age of 37.80±14.00 years, were enrolled. The disease activity using European League Against Rheumatism (EULAR) criteria was judged for SLE patients with erythrocyte sedimentation rate (ESR) and SLEDAI scores. The frequencies of CD3+CD4+FOXP3+Treg cells and Th17 cells in peripheral blood from these patients were measured by flow cytometry. And low-dose IL-2 was used among 127 patients at a dosage of fifty WIU every day for five days. Immunological and clinical assessments were performed again at the end of IL-2 treatment. Ninety healthy volunteers, matched for patients' age and gender, were also included for the estimation of CD4+ T cell subsets.

Results: As compared to healthy controls (median of Treg cells: 33.09 cells/ul), the frequencies of circulating CD4+CD25+FOXP3+Treg cells were significantly decreased in SLE patients (median: 15.49 cells/ul, $P<0.001$). The median ratios of Th17/Tregs cells in patients were greatly higher than those of healthy volunteers [0.42 (0.19, 0.88) vs. 0.21 (0.15, 0.34), $P<0.001$]. There was not significantly different in circulating Th17 cell between two groups. Moreover, CD4+CD25+FOXP3+Treg cells were negatively correlated with ESR and SLEDAI score (r=-0.198, $P=0.01$; r=-0.25, $P=0.002$).While no obvious correlation was seen between Th17 cells and SLEDAI score. After IL-2 therapy in SLE, there was a four-fold increase in circulating CD4+CD25+FOXP3+Treg cells [43.73 (24.08,74.22) vs. 11.95 (7.51,20.34),$P<0.001$], whereas Th17 cells were increased slightly. The ratio of Th17/Tregs was decreased significantly in patients with IL-2 treatment [0.19 (0.09,0.41) vs. 0.52 (0.23,0.95),$P<0.001$], tended to balance and had no difference with healthy individual ($P=0.275$).

Conclusions: With the increase of disease activity,CD4+CD25+FOXP3+Treg cells were gradually reducing, while Th17 cells did not show a significant change, indicating that the reduction of Tregs but not the elevation of Th17 cells may be the major reason for imbalance of Th17/Tregs. It is speculated that SLE is an autoimmune disease triggered by the defect of immunotolerance. More importantly, low-dose IL-2 selectively modulated the abundance of Tregs, which effectively induced autoimmune tolerance and further improved clinical symptoms.

OP0044 ANTIBODIES ANTI-SACCHAROMYCES CEREVISIAE IN PRIMARY SJÖGREN'S SYNDROME: PREVALENCE, CLINICAL ASSOCIATIONS AND POSSIBLE CROSS-REACTIVITY WITH DISEASE SPECIFIC AUTOANTIGENS

A. Alunno[1], O. Bistoni[1], F. Carubbi[2,3], G. Cafaro[1], E. Valentini[4], R. Giacomelli[2], R. Gerli[1]. *[1]Department of Medicine, Rheumatology Unit, University of Perugia, Perugia; [2]Department of Biotechnological and Applied Clinical Sciences, Rheumatology Unit, University of L'Aquila; [3]Department of Medicine, ASL 1 Avezzano-L'Aquila-Sulmona, L'Aquila; [4]Department of Medicine, Rheumatology Unit, University di Perugia, Perugia, Italy*

Background: Saccharomyces cerevisiae is a common yeast used in the food industry. Antibodies against the phosphopeptidomannan part of the cell wall of S. cerevisiae (ASCA) are a well established biomarker of Crohn's disease and have been assessed in several organ-specific and systemic autoimmune diseases (ADs) (1–2) Although the pathogenic significance of ASCA is not yet fully understood, the molecular mimicry of self-antigens in several associated ADs has been suggested as putative mechanism.

Objectives: Since to date ASCA have not been tested in primary Sjogren's syndrome (pSS), the purpose of this study was to assess these antibodies in a large cohort of pSS patients and investigate their significance as potentially helpful biomarker in a clinical setting.

Methods: One hundred and four patients with pSS according to the 2002 American European Consensus criteria and 30 healthy donors (HD) were enrolled. ASCA IgG+IgA were assessed in serum samples with ASCA screen dot (Alphadia sa/nv). T cell phenotyping was performed in paired peripheral blood samples by flow cytometry. To compare the aminoacid sequence of mannan of Saccharomyces cerevisiae and well characterized auto-antigens peculiar of pSS (52kD and 60kD Ro/SSA, La/SSB) we browsed the protein database of the National Center for Biotechnology Information (NCBI) and run the Basic Local Alignment Search Tool (BLAST).

Results: ASCA were detected in 5 out of 104 pSS patients, therefore the prevalence in our cohort is 4.8%. None of the ASCA$^+$ pSS patients displayed IBD or other autoimmune conditions that could account for ASCA positivity. ASCA$^+$ pSS patients displayed more frequently a reduction of C3 and C4 complement fractions as well as pulmonary, articular and cutaneous involvement (all $p<0.05$). Binary logistic regression revealed that ASCA$^+$ pSS patients display an odds ratio of 14 ($p=0.006$) to have cutaneous manifestations of pSS. All ASCA+ patients but only 39% of ASCA- patients displayed anti-Ro52, anti-Ro60 and anti-La autoantibodies together ($p=0.01$). No differences concerning T regulatory and Th17 cell proportion could be observed in ASCA$^+$ compared to ASCA$^-$ pSS patients. S. cerevisiae mannan displays a consistent similarity with 52kD and 60kD Ro/SSA, La/SSB autoantigens. The highest similarity was observed when aligning the mannan with 60kD Ro/SSA (identities 7/11, 64%; positives 8/11, 72%, E value 2.2.).

Conclusions: Our study assessed for the first time ASCA IgG+IgA with a highly specific immunoblot assay in a large cohort of pSS patients, showing that ASCA positivity identifies a peculiar clinical and serological pSS phenotype. In particular, ASCA$^+$ pSS patients display anti-Ro52, anti-Ro60 and anti-La antibodies, low complement and cutaneous involvement. The high similarity between S. cerevisiae mannan and Ro60/SSA autoantigen may suggest that: i. ASCA may bind pSS autoantigens, such as anti-Ro, as already postulated for other autoantigens (2); ii. ASCA may bind more likely Ro60 autoantigen rather than the Ro52 or La autoantigens in pSS. A possible pathogenic/prognostic significance of ASCA in pSS may therefore be speculated.

OP0045 PREDICTORS OF PERSISTENT DISEASE ACTIVITY AND PERSISTENT LONG QUIESCENCE IN SYSTEMIC LUPUS ERYTHEMATOSUS – RESULTS FROM THE HOPKINS LUPUS COHORT

I. Giannakou[1], K. Chatzidionysiou[1], L. Magder[2], R. van Vollenhoven[1], M. Petri[3]. *[1]ClinTRID - Unit for Clinical Therapy Research, Inflammatory Diseases, Department of Medicine, Karolinska Institutet, Stockholm, Sweden; [2]University of Maryland School of Medicine; [3]Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, United States*

Background: Systemic lupus erythematosus (SLE) is characterized by a diversity of disease activity.

Objectives: The aim of this study was to identify prognostic factors of persistent disease activity and persistent long quiescence using baseline demographics and clinical characteristics.

Methods: Patients enrolled in the Hopkins Lupus Cohort from 1987 to 2014, who had at least 3 visits per year during 3 years following cohort inclusion and available information on disease activity were included. Three major patterns of SLE disease activity over time (1 year intervals) based on the modified SLE Disease Activity Index have been previously described: long quiescent (LQ), chronic active (CA) and relapsing-remitting (RR) *(1)*. Based on maintenance of the aforementioned

patterns over 3 consecutive years, patterns have been defined as: Persistent Long Quiescent (pLQ), Persistent Relapsing-Remitting (pRR), Persistent Chronic Active (pCA) and Mixed, at least 2 different pattern types. Predictors of pCA (vs. pLQ, pRR and mixed) and pLQ (vs. pCA, pRR and mixed) were identified by univariate and multivariate logistic regression analyses. Several baseline demographics (age, sex, ethnicity, disease duration, tobacco use, years of education and combined annual family income), disease characteristics at baseline (SLEDAI, PGA) and treatment categories (hydroxychloroquine, prednisolone and cytotoxic treatment followed at ≥75% of visits vs <75% of visits) were used as independent variables.
Results: 916 patients were identified. The results of the univariate analyses for pCA are shown in table 1. In the multivariate model, African American ethnicity (OR: 2.43, 95% CI: 1.19–4.94, p: 0.01) and high baseline SLEDAI (OR: 1.09, 95% CI: 1.03–1.16, p: 0.004) remained significant predictors of pCA. Higher education (>12 years; OR. 2.16, 95% CI: 1.11–4.20, p: 0.02) and low baseline SLEDAI (OR: 0.62, 95% CI: 0.52–0.75, p:<0.001) were significant predictors of pLQ in the multivariate analysis while African American ethnicity (OR: 0.36, 95% CI: 0.16–0.78, p:0.01) and female patients (OR: 0.26, 95% CI: 0.12–0.56, p:0.001) were less likely to achieve persistent long quiescence.

Table 1. pCA (vs. pLQ, RR and mixed)

	OR (95% CI)	p-value
Sex (female vs. male)	1.6 (0.4–6.7)	0.54
Age (>40 vs. ≤40 yrs)	1.4 (0.7–2.8)	0.32
Disease Duration	1.0 (0.9–1.1)	0.17
African American (vs. other)	2.6 (1.3–5.3)	0.007
Years of education (>12 vs. ≤ yrs)	0.7 (0.3–1.4)	0.27
Income		
<30000$	Ref	
30000–65000$	0.4 (0.2–1.0)	0.06
≥65000$	0.5 (0.2–1.2)	0.12
Smoking baseline (yes vs. no)	2.1 (1.0–4.6)	0.06
SLEDAI baseline	1.1 (1.0–1.2)	0.002
PGA baseline	1.5 (1.0–2.2)	0.04
Cytotoxic therapy (≥75% vs. <75% of visits)	1.1 (0.5–2.3)	0.85
Antimalaria therapy (≥75% vs. <75% of visits)	0.5 (0.3–1.0)	0.06
Prednisolone therapy (≥75% vs. <75% of visits)	1.1 (0.6–2.2)	0.82

Conclusions: In this large SLE cohort, African American ethnicity and high disease activity at the time of diagnosis are predictors of chronic activity, regardless of treatment, even after adjustment for education years and income, while higher education and low disease activity at baseline predict long-term quiescence.

OP0046 RISK FACTORS FOR ADVERSE PREGNANCY OUTCOME IN ANTIPHOSPHOLIPID ANTIBODIES CARRIERS: RESULTS FROM A MULTICENTER ITALIAN COHORT OVER 20 YEARS OF EXPERIENCE

M.G. Lazzaroni[1], L. Andreoli[1], C.B. Chighizola[2], T. Del Ross[3], M. Gerosa[2], A. Kuzenko[3], M.-G. Raimondo[2], A. Lojacono[1], F. Ramazzotto[1], S. Zatti[1], L. Trespidi[2], P.L. Meroni[2], V. Pengo[3], A. Ruffatti[3], A. Tincani[1]. *[1]-, Brescia; [2]-, Milano; [3]-, Padova, Italy*

Background: Antiphospholipid antibodies (aPL) are risk factors for Adverse Pregnancy Outcome (APO). In particular, for aPL carriers (patients with aPL positivity with no thrombotic or obstetric history) pregnancy outcome and treatment are still undefined.
Objectives: To review pregnancy outcome in a large multicenter cohort of aPL carriers patients, according to different serological profile and treatment protocols.
Methods: We reviewed 69 pregnancies in 61 patients, prospectively followed in 3 Italian centers (1994–2015). Patients with any complication in previous pregnancies or concomitant autoimmune diseases were excluded. aPL profile was defined as the combination of the 3 criteria tests for aPL (Lupus Anticoagulant, anti-cardiolipin, anti-Beta2 Glycoprotein I). APO was defined as: miscarriage (<10w), fetal death (≥10w), severe preterm delivery (≤34w) with or without preeclampsia (PE), HELLP syndrome or perinatal death.
Results: Regarding aPL profile: 44 (64%) were single positive, 16 (23%) were double and 9 (13%) were triple. aPL non-criteria manifestations were present in 6 (9%) and lupus-like manifestations in 5 (7%). Eight pregnancies had a combination treatment with prophylactic low molecular weight heparin (LMWH) plus low dose aspirin (LDA), 37 had LDA alone and 24 had no treatment. We observed 2 thrombotic events (3%, 1 deep venous thrombosis and 1 ischemic stroke) and 6 APO (9%): 3 fetal deaths and 3 pre-term birth ≤34w with PE. We compared 8 complicated (6 APO,2 thrombosis) with 61 non-complicated pregnancies (Table 1). Acquired risk factors (p:0.006), non-criteria aPL (p:0.018) and lupus-like manifestation (p:0.010), triple positive aPL profile (p:0.001) were associated with APO. The combination treatment was also more frequent in APO pregnancies (p:0.005).

	Complicated pregnancies (n=8)	Non-complicated pregnancies (n=61)	P-value ^	OR (95% CI)
Mean age at pregnancy (mean (SD))	28.3 (5.8)	32.7(4.6)	0.015 §	
Acquired risk factors #	6 (75%)	14 (23%)	0.006	10.7 (1.55-82.4)
Congenital thrombophilia	2 (25%)	4 (7%)	0.140	
Non criteria aPL manifestations *	3 (38%)	3 (5%)	0.018	11.6 (1.37-108)
Lupus-like manifestations	3 (38%)	2 (3%)	0.010	17.7 (1.77-213)
Single positive	3 (38%)	41 (67%)	0.128	
Double positive	0 (0%)	16 (26%)	0.183	
Triple positive	5 (63%)	4 (7%)	0.001	23.7 (3.22-211)
No treatment	1 (13%)	23 (38%)	0.246	
LDA	3 (38%)	34 (56%)	0.457	
LDA+LMWH	4 (50%)	4 (7%)	0.005	14.2 (1.98-116)

Table 1. Complicated pregnancies (APO and thrombosis) compared with non-complicated pregnancies – univariate analysis
^ Fisher's exact test, except otherwise indicated; p significant <0.05
§ Student's T- test
# Acquired risk factors. Obesity (BMI>30w), hypertension (>140/90), hyper-cholesterolemia, hyper-triglyceridemia, hyper-homocysteinemia, diabetes mellitus
* Non-criteria aPL manifestations were defined as the presence of at least one of the followings: (livaedo reticularis, thrombocytopenia, headache, hemolytic anemia, cardiac valvulopathy, epilepsy)

Conclusions: Acquired risk factors,aPL profile (triple positivity), lupus-like and non-criteria aPL manifestations could represent risk factors for pregnancy complications and could determine failure to conventional treatment.These patients may deserve additional treatment, for example LMWH at higher/anti-coagulant dose or immunomodulatory treatment (e.g.hydroxychloroquine, also considering its anti-platelet/anti-thrombotic effects).

Osteoporosis treatment gap, new options and new strategies

OP0047 OSTEOPOROTIC HIP FRACTURE PREVENTION: ARE WE IN A CRISIS?

M. Sehgal[1], A. Mithal[2], A. Mithal[3], G. Singh[4]. *[1]Student, Menlo Atherton High School, Atherton, United States; [2]Student, IIIT Delhi, Delhi, India; [3]Epidemiology, ICORE, Woodside; [4]Gastroenterology and Hepatology, Stanford University, Stanford, United States*

Background: Osteoporotic hip fractures are a significant cause of morbidity and mortality in the elderly. With the aging of the US population, it was expected that there would be a nationwide "epidemic" of osteoporotic fractures; however, Medicare reimbursement for osteoporosis screening and the rapid uptake of bisphosphonate therapy in the late 1990s and early 2000s probably forestalled this epidemic. In fact, osteoporotic hip fractures numbers *declined* during this time, despite the dramatic growth of the elderly population (1). However, bisphosphonate prescriptions have dropped precipitously by over 50% from their peak in 2008 (2), likely because of concerns regarding their adverse events. In this era of "crisis" in osteoporosis prevention, has the pendulum swung back on hip fracture numbers?
Objectives: To study the number and prevalence of osteoporotic hip fractures in patients 50 years and older over the last 22 years (1993–2014) in the US?
Methods: The Nationwide Inpatient Sample (NIS) is a stratified random sample of all US community hospitals. It is the only US national hospital database with information on all patients, regardless of payer, including persons covered by Medicare, Medicaid, private insurance, and the uninsured. We examined all inpatient hospitalizations in NIS from 1993 to 2014 with a primary diagnosis of non-traumatic hip fractures, and calculated age-adjusted prevalence rates. We excluded patients with concomitant diagnosis of major trauma, primary or secondary tumors locally, osteopetrosis and procedures for revision surgery or surgery for complications.
US population estimates and projections for the resident US population were obtained from the US Census Bureau.
Results: There were 407 million all-cause hospitalizations in 1.88 billion person-years of observation among people 50 years of older from 1993 to 2014 (21,626 hospitalizations per 100,000 person-years). During this time-period, there were 6.15 million hospitalizations for osteoporotic hip fractures in this population (327 per 100,000 person-years). After an initial increase in hip fractures from 1993 to 1996, there was a decline of 10.6% in total number of hip fractures from 300,154 in 1996 to 268,356 in 2010 even though population of 50 years and older increased from 69.9 million to 99.6 million in the same time. After bottoming out in 2010, the total number of hip fractures increased by 6.2% to 285,050 in 2014 (Figure, blue broken line). However, the age-standardized prevalence rate of hip fractures declined steadily (from 414/100,000 in 1996 to 269/100,000 in 2014, p<0.0001, Figure solid red line), although the rate of decline has ameliorated somewhat from 2010 onwards (not statistically significant).
Conclusions: The total number of osteoporotic hip fractures in 50 years and

older declined since 1996, bottomed out in 2010 but has started increasing again. It is critical to evaluate risks and benefits of preventive treatments for optimal management of this potentially serious problem.

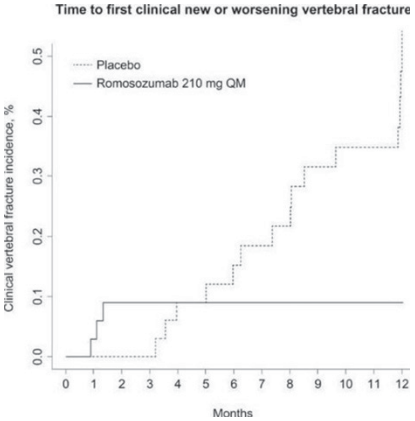
OP0048 ROMOSOZUMAB RAPIDLY REDUCES CLINICAL VERTEBRAL FRACTURE INCIDENCE: RESULTS FROM THE FRAME STUDY



P. Geusens [1,2], M. Oates [3], A. Miyauchi [4], J. Adachi [5], M. Lazaretti-Castro [6], P.R. Ebeling [7], C.A. Perez Nino [8], C.J. Milmont [9], A. Grauer [9], C. Libanati [10]. *[1] Maastricht UMC, Maastricht, Netherlands; [2] UHasselt and ReumaClinic, Genk, Belgium; [3] Pacific Central Coast Health Center, Santa Maria, United States; [4] Miyauchi Medical Center, Osaka, Japan; [5] McMaster University, Hamilton, Canada; [6] IMA Brazil, São Paulo, Brazil; [7] Monash University, Clayton, Australia; [8] UNIENDO, Bogota, Colombia; [9] Amgen, Thousand Oaks, United States; [10] UCB, Brussels, Belgium*

Background: Romosozumab (ROMO) inhibits sclerostin and has a dual effect on bone, increasing formation while decreasing resorption, resulting in significant increases in bone mineral density (BMD) at 6 months (m), which at 12m reach 13.3% vs placebo (PBO) at the spine.[1] Using high resolution quantitative computed tomography, BMD increases were observed at both trabecular and cortical compartments of the spine, explaining the significant reductions in radiographic vertebral fracture (VFx) risk in women with osteoporosis (OP) enrolled in the FRAME trial (NCT01575834).

Objectives: Here, we report the effect of ROMO on clinical (clin) VFx incidence over 12m in women in FRAME with back pain.

Methods: FRAME enrolled 7180 postmenopausal women with OP, mean age 70.9 yrs (total hip T-score –2.5 to –3.5) and no severe VFx. Patients received monthly ROMO (n=3589; 210mg) or PBO (n=3591) for 12m. At monthly visits, women with back pain consistent with a clin VFx had a confirmatory spinal X-ray. Clin VFx risk (ROMO vs PBO) was calculated by Cox-proportional hazards model.

Results: Of 119 women reporting back pain over 12m, 20 women were diagnosed with a new or worsening VFx. With ROMO, 3 clin VFx (<0.1%; all at <2m) were identified vs 17 (0.5% at 12m) with PBO (Figure). Clin VFx risk was 83% lower in the ROMO group vs PBO at 12m (hazard ratio 0.17; 95% CI, 0.05–0.58; p=0.001). In women with clin VFx vs no clin VFx, the lumbar spine T-score was numerically lower and the FRAX score higher at baseline; other baseline characteristics were comparable among all women who reported back pain.

Conclusions: ROMO treatment for 12m was associated with rapid and large reductions in clin VFx risk vs PBO. In the ROMO group, all clin VFx occurred <2m; clin VFx risk was ≥5 times higher with PBO vs ROMO. Monthly study visits in FRAME allowed for timely radiologic confirmation of a suspected clin VFx.

OP0049 SYSTEMATIC REVIEW OF RANDOMIZED CONTROLLED TRIALS EVALUATING BISPHOSPHONATES FOR THE PREVENTION AND TREATMENT OF GLUCOCORTICOID-INDUCED OSTEOPOROSIS

A. Makhzoum [1], L. Petriw [2], M. Sattin [3], T. Towheed [4]. *[1] Department of Rheuamtology; [2] Department of Internal medicine, Queen's University, Kingston; [3] Department of Internal medicine, University of Western Ontario, London; [4] Department of Rheumatology, Queen's University, Kingston, Canada*

Background: Glucocorticoid therapy is a major risk factor for osteoporosis related fractures. A previous meta-analysis conducted by Homik et al reported that bisphosphonates therapy increased BMD in glucocorticoid- induced osteoporosis (GIO) when compared to placebo, whereas results for incident vertebral fracture did not reach statistical significance

Objectives: To evaluate the efficacy of bisphosphonates in GIO based on randomized controlled trials (RCTs). Both placebo controlled and active comparator trials were analyzed.

Methods: Two authors screened citations from the following electronic databases: Medline (1998–2015), EMBASE (1998–2015), Cochrane Library (1998–2015). A manual search was completed for conference proceedings from the ACR (2010–2015), CRA (2009–2015), and ASBMR (2009–2014). We used the study by Homik et al to identify RCTs published prior to 1998. Only RCTs that had a minimum prednisone dosage of 5 mg/day or equivalent and treatment duration of at least 3 months were included. Primary outcomes were changes in BMD and incident fractures. Two authors abstracted data using a standardized data abstraction form. We used the Cochrane Risk of Bias Tool to evaluate the quality of the selected RCTs and devised a quality score ranging from 0 to 6, where 6 represents the highest quality.

Results: A total of 466 citations were identified (239 Medline, 217 EMBASE, and 10 Cochrane Library). Fourteen RCTs met the inclusion criteria. An additional two RCTs were identified from conference proceedings. Eleven RCTs compared bisphosphonates to a placebo, three RCTs compared bisphosphonates to a vitamin D derivative, one RCT compared alendronate to teriparatide, and one RCT compared zoledronic acid to risedronate. The RCTs were of reasonably good quality with a mean quality score of 4.

Overall, of the 11 RCTs that compared bisphosphonates to a placebo, all found that the bisphosphonates were superior. Nine RCTs were pooled for mean percentage change in lumbar spine BMD (bisphosphonates n=667, placebo n=654). The pooled mean percentage change was in favor of bisphosphonates compared to placebo [weighted mean difference (WMD) of 4.03%, 95% CI (1.59–6.47), p=0.001]. Six RCTs were pooled for mean percentage change in femoral neck BMD (bisphosphonates n=486, placebo n=481) and the results favored bisphosphonates compared to placebo [WMD of 2.95%, 95% CI (0.09 -5.82), P=0.04]. Seven RCTs were pooled for outcome of incident fractures (bisphosphonates n=613, placebo n=469) and the results favored bisphosphonates compared to placebo [RR of 0.65, 95% CI (0.48–0.88), P=0.006] (Figure 1). Results were pooled using RevMan (version 5.3).

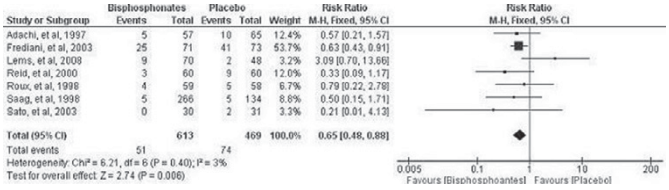

Figure 1

Conclusions: Bisphosphonates mitigate adverse changes in BMD and lower fracture risk in patients treated with glucocorticoids.

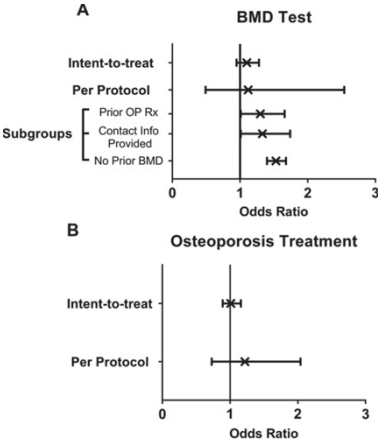
OP0050 THE TREATMENT GAP AFTER FRACTURE IN OSTEOPOROSIS PATIENTS IN SWEDEN



A. Spångéus[1], K. Åkesson[2], Ö. Ljunggren[3], J. Banefelt[4], L. Karlsson[4], G. Ortsäter[4], C. Libanati[5], E. Toth[5], O. Ström[4,6]. *[1]Linköping University Hospital, Linköping; [2]Lund University, Skåne University Hospital, Malmö; [3]Uppsala University Hospital, Uppsala; [4]Quantify Research, Stockholm, Sweden; [5]UCB Pharma, Brussels, Belgium; [6]Karolinska Institutet, Stockholm, Sweden*

Background: In Sweden, ~50% of women and ~25% of men are expected to suffer an osteoporosis (OP)-related fracture (Fx) during their lifetime, and hip Fx incidence in Sweden is one of the highest worldwide. Despite this, nationally only 12% of patients with Fx are prescribed an OP treatment following Fx.[1] Understanding the reasons for the marked under-treatment of patients with Fx may provide insights into how to improve deficiencies in the management of OP.
Objectives: To assess rates of OP treatment initiation within 1 year (<1 yr) following first Fx in treatment-naïve patients with fracture in Sweden and to evaluate the determinants of treatment initiation.
Methods: Patients aged ≥50 yrs with any type of Fx were identified from Swedish national registers between 2006–2012 and followed from time of first Fx. Patients who were treatment-naïve at the time of first Fx were included in the analysis. Here, we report OP treatment initiation <1 yr after Fx in the different baseline subgroups considering gender, age, Fx type, steroid use and comorbidities.
Results: 258,827 treatment-naïve patients with a first Fx (68% female; mean age 72.7 [SD 12.9] yrs) were included. Overall, 6.6% of patients initiated OP treatment <1 yr; the proportion was higher in females (8.5%) than in males (2.3%), and was highest in patients aged 70–80 yrs (10.7%) vs other ten-year age groups (mean 5.5%). Patients with a diagnosed vertebral Fx were more likely to start OP treatment (21.2%) compared with non-vertebral Fx (5.6%). The proportion of patients starting OP treatment was higher in patients receiving glucocorticoid (GC) treatment (17%) compared with those not treated with glucocorticoids (6.1%). In general, comorbidities were not positively associated with treatment initiation, except for those indirectly connected to known contributors of Fx risk, i.e. chronic pulmonary disease (GC use) and rheumatoid arthritis (FRAX-algorithm risk factor), which were associated with increased treatment initiation. Although both dementia and dependency are known to be associated with increased risk of Fx, the tendency to initiate treatment was lower in patients with these conditions compared with those without (1.5% vs 6.9% and 2.3% vs 7.4%, respectively).
Conclusions: This study confirms the large treatment gap in OP treatment initiation following a first Fx in Sweden; rate of OP treatment initiation was below the post-Fx treatment initiation rate goal of 30% and also lower than the 12% published national indicator for treatment exposure (2015).[1] The proportion of patients initiating OP treatment appears to be somewhat influenced by gender, age, Fx type, GC use, rheumatic disease, dependency and dementia; nevertheless, treatment initiation rates were low. These data highlight the need for significant efforts to improve OP management post Fx in Sweden.

OP0051 THE ACTIVATING PATIENTS AT RISK FOR OSTEOPOROSIS STUDY: A RANDOMIZED TRIAL WITHIN THE GLOBAL LONGITUDINAL STUDY OF OSTEOPOROSIS IN WOMEN COHORT

M. Danila[1], F. Anderson[2], S. Greenspan[3], A. LaCroix[4,5], J. Nieves[6], S. Silverman[7], N. Watts[8], J. Curtis[1], K. Saag[1]. *[1]University of Alabama at Birmingham, Birmingham; [2]University of Massachusetts Medical School, Worcester; [3]University of Pittsburgh, Pittsburgh; [4]Group Health Cooperative, Seattle; [5]University of California San Diego, la Jolla; [6]Helen Hayes Hospital, West Haverstraw; [7]Cedars-Sinai Medical Center, Los Angeles; [8]Mercy Health Osteoporosis and Bone Health Services, Cincinnati, United States*

Background: Osteoporosis treatment rates are declining, even among those with past fractures. Novel, low cost approaches engaging and activating patients are needed to improve care.
Objectives: To test a multi-modal, tailored, direct-to-patient, behavioral, video intervention aimed at improving rates of osteoporosis medication use.
Methods: We conducted a controlled, randomized clinical trial of our novel intervention among US women in the Global Longitudinal Study of Osteoporosis in Women cohort with self-reported fracture history who were not currently using osteoporosis therapy. The primary outcome at 6-months was self-report of osteoporosis medication use. Secondary and exploratory outcomes included starting calcium and vitamin D, bone mineral density (BMD) testing, readiness for behavioral change, and barriers to treatment.
Results: We randomized 2684 women to receive the intervention materials or usual care. Study participants were 92.6% Caucasian, with a mean (SD) age 74.9 (8.0) years, and a self-reported lower than average risk for osteoporosis (40.0%). In the 12 months prior to randomization, 1390 women reported talking with their doctor regarding osteoporosis, 7.4% reported a fracture, vitamin D or calcium supplementation were reported as 83.5% and 68.6%, respectively. We observed no differences in sociodemographic characteristics and no significant differences in the primary (11.7% vs 11.4%) and secondary (calcium, 31.8% vs 32.6%; vitamin D, 41.3% vs 41.9%; bone density, 61.8% vs 57.1%) end points between the intervention and usual care groups. Exploratory post-hoc analyses demonstrated that women in the intervention arm had more favorable views towards osteoporosis medications compared with the usual care arm and a lower proportion were in the unaware and uninvolved stages of behavior change regarding osteoporosis medications (OR=1.57, CI[1.11, 2.23]). We found that barriers to treatment were higher in the intervention, as compared to usual care arm at 6 months: concerns regarding osteonecrosis of the jaw (OR=1.58[1.14, 2.18]). We found significant differences in self-report BMD testing among the subgroup of women with no history of osteoporosis medication use (OR=1.30 [1.01, 1.66]), among those who provided a contact phone number or email address (OR=1.33 [1.01, 1.74]), and among those who did not report past BMD testing on the baseline survey (OR=1.53 [1.40, 1.68]) (Figure A). The proportion of self-reported osteoporosis treatment was similar between those with appreciable exposure to the online intervention compared with the control group (adjusted OR=1.22 [0.73, 2.04]) (Figure B).

Conclusions: This randomized study testing a novel, personalized educational intervention, did not increase the use of osteoporosis therapy at 6 months. The intervention appeared to have influenced participants' readiness for behavior change.

OP0052 CORTICAL BONE LOSS IS AN EARLY FEATURE OF AXIAL SPONDYLOARTHRITIS

J. Haschka[1,2], A. Neumann[1], A. Kleyer[1], L. Schuster[1], M. Englbrecht[1], C.P. Figueiredo[1,3], C. Muschitz[2], R. Kocijan[2], H. Resch[2], J. Rech[1], G. Schett[1]. *[1]Department of Internal Medicine 3, University of Erlangen-Nuremberg, Erlangen, Germany; [2]Department of Internal Medicine II, St. Vincent Hospital, VINFORCE Study Group, Vienna, Austria; [3]Division of Rheumatology, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil*

Background: Systemic bone loss is a well-known and severe consequence in axial spondyloarthritis (axSpA). To date deterioration of bone microstructure has only been described in patients with long-standing ankylosing spondylitis while bone microstructure has not been assessed in axSpA.
Objectives: The aim of the present study was to investigate bone microstructure, geometry and volumetric bone mineral density (vBMD) using high resolution peripheral quantitative CT (HR-pQCT) in a cohort of axSpA patients at an early stage of disease and to search for potential factors for deterioration of bone microstructure.
Methods: An inception cohort of 101 axSpA patients and 50 healthy controls of similar age and sex was assessed for geometric, volumetric and microstructural parameters of bone using HR-pQCT scanning of the radius. Additionally, demographic and disease specific characteristics of SpA patients were recorded.
Results: SpA patients and controls were comparable in age (median (IQR) 45.0 (15.0) vs. 44.76 (26.0) years, p=0.917), sex (female 41.6% vs. 40%, p=0.852) and BMI (median (IQR) 26.3 (6.5) vs. 23.8 (5.2), p=0.118). 75% of patients showed HLA-B27 positivity. Median disease duration was 6.5 (9.0) years, 58.4% of patients were on biological treatment and 14.9% of patients in disease remission according to ASDAS-CRP. Geometric and microstructural analysis by HR-pQCT revealed a significantly reduced cortical area (p=0.022) and cortical thickness (p=0.006) in SpA patients compared to controls. No differences in cortical porosity (p=0.685), trabecular geometry or microstructure were detected. Total and cortical vBMD were significantly reduced in SpA patients (p=0.042 and p=0.007), while there was no difference in trabecular vBMD (p=0.376). Patients with a short disease duration <2 years (n=46) showed a significant reduction of cortical thickness and cortical area (p=0.050 and p=0.032) compared to controls. Patients with a disease duration >2 years (n=55) additionally developed a decrease of cortical and total vBMD (p=0.004 and p=0.036). Multivariate regression models identified male sex to be associated with lower cortical vBMD and female sex with lower trabecular vBMD. History of prednisolone treatment (>5mg >3months) was associated with lower trabecular vBMD, and disease duration with higher trabecular vBMD. Remission status, treatment with TNF inhibitors, HLA-B27 status and presence of peripheral arthritis did not influence bone microstructure independently.
Conclusions: Bone microstructure in SpA patients is primarily characterized by deterioration of cortical bone. Cortical bone loss starts early and is evident within the first 2 years of disease.

OP0053 BONE LOSS AND CARDIOVASCULAR RISK IN PATIENTS WITH EROSIVE AND NON-EROSIVE HAND OSTEOARTHRITIS

O. Ruzickova, O. Sleglova, K. Pavelka, L. Senolt. *Revmatology, Institute of revmatology, Prague 2, Czech Republic*

Background: Hand osteoarthritis (OA) and its more severe subset erosive hand OA are common causes of pain and morbidity. Some metabolic factors were suggested to be implicated in erosive disease. Furthermore, few studies investigated differences in systemic bone loss and cardiovascular risk factors between erosive and non-erosive hand OA.
Objectives: To compare bone mineral density (BMD) and major cardiovascular risk factors between patients with erosive and non-erosive hand OA in a cross-sectional study.
Methods: Patients with symptomatic disease fulfilling the American College of Rheumatology (ACR) criteria for hand OA were included in this study. Erosive hand OA was defined by at least one erosive interphalangeal joint. All patients underwent clinical assessments of joint swelling and radiographs of both hands. DEXA examination of lumbar spine, total femur and femur neck was performed. Metabolic risk factors (body mass index, hypertension, diabetes, dyslipidaemia) were collected. Patients were examined at baseline, one-year and two years follow-up.
Results: Altogether, 129 patients (12 male) with symptomatic nodal hand OA were included in this study and followed between April 2012 and January 2017. Out of these patients, 72 had erosive disease. The disease duration (p<0.01) was significantly higher in patients with erosive compared with non-erosive disease at baseline. Patients were taking symptomatic slow acting drugs (SYSADOA) twice a year, non-steroidal anti-inflammatory drugs (NSAIDs) and analgesics on demand. Baseline population characteristics did not differ between both groups. Osteoporosis (T-score <-2.5 SD) was diagnosed in 12.5% (9/72) of patients with erosive hand OA and in 8.06% (5/57) of patients with non-erosive hand OA. Although bone mineral density did not significantly differ between the groups, T-scores of lumbar spine (-0.46 vs. -1.04 SD, p<0.001), total femur (-0.36 vs. -1.20 SD, p<0.001) and femur neck (-0.92 vs. -1.20 SD, p<0.01) were significantly lower in patients with erosive compared with non-erosive disease. After two years, the decrease in T- score of lumbar spine was significantly higher in patients with erosive compared with non-erosive hand OA (-0.08 SD vs. 0.07SD, p<0.01; total difference between groups is 10.92%). The decrease of T-score in femur neck, total femur and the decrease of BMD (g/cm^2) in all regions were also higher, although not significantly, in patients with erosive compared with non-erosive hand OA. In addition, more patients with erosive compared with non-erosive hand OA were treated for dyslipidaemia at baseline and after two years (32% vs. 28% and 32% vs.30%, p<0.01 for both comparisons).
Conclusions: These results suggest that patients with erosive hand OA are at risk for development of general bone loss and cardiovascular diseases.

OP0054 INCIDENCE OF VERTEBRAL FRACTURES IN EARLY SPONDYLOARTHRITIS: 5-YEAR PROSPECTIVE DATA OF THE DESIR COHORT

J. Sahuguet[1], J. Fechtenbaum[1], A. Molto[1], A. Etcheto[1], P. Richette[2], M. Dougados[1], C. Roux[1], K. Briot[1]. *[1]Rheumatology department, Hôpital Cochin; [2]Rheumatology department, Hôpital Lariboisière, Paris, France*

Background: Osteoporosis is a well-recognized feature of axial spondyloartyhritis (ax-SpA) and an increased risk of vertebral fractures (VFs) has been reported in patients with SpA. The prevalence of VFs is highly variable across studies, up to 30%. These data are unexpected in a disease affecting a young population, predominantly males. These results could be related to differences in methods of diagnoses of VFs and in populations with highly variable duration of the disease. We hypothesized that the prevalence and incidence of VFs be lower than the ones previously reported, especially in early spondyloarthritis.
Objectives: Our primary aim was to assess the prevalence of VFs in a cohort of early inflammatory back pain suggestive of early axial SpA and their incidence over 5 years.
Methods: Study population: patients from the DESIR (DEvenir des Spondylarthropathies Indifférenciées Récentes) cohort, which is a french national longitudinal prospective cohort including adults between 18 and 50 years old, and presenting with inflammatory back pain suggestive of axSpA for less than 3 years. Follow-up is still ongoing, but the data presented here includes the first 5 years of follow-up. All patients had thoracic and lumbar spine X-rays at baseline, 2 years and 5 years. For this particular study, all radiographs of the DESIR cohort were centrally read by one reader, an expert in the field of the diagnosis of VFs according to Genant's method. Careful assessment was used to distinguish true VFs not to be mistaken with deformities. Using a temporal sequence of reading (i.e. unblinded for chronological order), an incident VF was defined as a change in the score of a vertebra from grade 0 to a subsequent grade 1 or more. All vertebrae between T4 and L4 were evaluated. In doubtful cases, an adjudication by two other senior experts was performed. Prevalence at inclusion and the incidence of VFs over the first 5 years of follow-up were described.
Results: A total of 708 patients with inflammatory back pain were included in the DESIR cohort. Plain dorsolumbar spine X-rays were available for 694 patients, and thoracic and/or lumbar X-rays were available for 643 patients at baseline. Twenty eight VFs were identified in 21 patients (19 grade 1 VFs and 9 Grade 2 or 3 VFs); therefore, the prevalence of VFs was 4.5%.
Complete X-ray follow up between baseline and M60 was available for 433 patients. Seven incident VFs were identified in 6 patients: at 2 years 3 grade 1 VFs and 1 grade 2 VF were identified; and at 5 years, 2 grade 1 VF and 1 grade 2 or more VF were identified. The 5-year incidence of VFs was 1.6%.
Conclusions: In this study focused on a population of early spondyloarthritis, the reported low prevalence of VFs of 4.5% and incidence of 1.6% confirm our hypothesis that the real prevalence and incidence of VF in SpA is probably much lower than what was reported in previous studies. These discrepancies might be explained by the variability in the methods of vertebral fracture's assessment as vertebral deformations might be inappropriately considered as fracture.

Rehabilitation and modern drug treatment - needs and challenges

OP0055-HPR PREFERENCES FOR SELF-MANAGEMENT AND SUPPORT SERVICES IN PATIENTS WITH INFLAMMATORY ARTHRITIS: A DANISH NATIONWIDE CROSS-SECTIONAL STUDY

N.M. Hammer[1], C. Flurey[2], K.V. Jensen[1], L. Andersen[1], B.A. Esbensen[1,3]. *[1]Rigshospitalet - Glostrup, COPECARE, Centre for Rheumatology and Spine Diseases & Research Unit, Glostrup, Denmark; [2]Rheumatology Unit, Bristol Royal Infirmary, Bristol, West England, United Kingdom; [3]Department of Clinical Medicine, Faculty of Health and Medical, University of Copenhagen, Copenhagen, Denmark*

Background: During recent years the medical treatment of inflammatory arthritis

(IA) has improved and become more efficient. However, many patients still continue to experience serious negative impact on both their physical and psychosocial health and wellbeing. Therefore, it is essential to identify patients' needs for support for managing IA in everyday life.
Objectives: To explore preferences for self-management and support services in patients with inflammatory arthritis.
Methods: Adult patients with IA (rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthritis (axSpA)) were invited through The Danish Rheumatism Organization, arthritis networks, and hospitals' rheumatology departments across the country to participate in a cross-sectional study using online survey methodology. The questionnaire included questions on patient's interest in participation (requiring an answer of yes or no) in a total of 30 different self-management and support services within eight overall categories (i.e. discussion groups, one-to-one sessions, question and answer sessions, organised talks, physical activity, education sessions, raising arthritis awareness events, and online services), and preferences regarding practical issues of taking part. Descriptive statistics were applied.
Results: In total, 664 patients (85% female) responded, of which 53% had RA, 27% had PsA and 20% had axSpA. Respondents' mean age was 50 years (SD=13), and median disease duration was 10 years (IQR=4–16). Of the 30 different self-management and support services, the most popular was *Online service: Website for information (about symptoms, treatment and self-management of arthritis)* with 91% of the respondents indicating interest. This was followed by *One-to-one session with a rheumatologist (about coping with arthritis)* (89%) and *Organised talks by researchers (about current rheumatology research)* (83%). Also, *One-to-one session with a nurse*, *One-to-one session with a physiotherapist*, and *Education session on managing symptoms* were all chosen by more than 80% of the respondents. The vast majority of respondents (81%) indicated to prefer a group with no fixed commitments and an advertised time table. Regarding timing of support, the majority (70%) indicated that self-management and support services should optimally be offered whenever needed. However, respondents also stated it would be helpful within the first six months of being diagnosed (49%) as well as during flares (30%).
Conclusions: Patients with IA show high overall interest in taking part in self-management and support services. Especially, websites for finding disease related information, one-to-one sessions with health professionals, organised talks about rheumatology research and education on symptom management are requested. The preference regarding practical issues seems to be for a flexible delivery according to the patients' fluctuating needs during their illness course.

Basic and clinical science in paediatric rheumatology

OP0056 IL-23P19 IS UP-REGULATED IN MONOCYTE-DERIVED MACROPHAGES FROM HLA B27 POSITIVE PATIENTS WITH ENTHESITIS RELATED ARTHRITIS

C. Fisher, D. Eleftheriou, D. Sen, Y. Ioannou. *Arthritis Research UK Centre for Adolescent Rheumatology, University College London, London, United Kingdom*

Background: Enthesitis related arthritis (ERA) is an HLAB27-associated subtype of JIA most similar to the adult spondyloarthropathies (SpA). The innate immune system, intracellular stress response (the unfolded protein response (UPR)) and IL23/IL17 pathway are strongly implicated in the pathogenesis of adult SpA. However, these systems remain relatively unexplored in ERA.
Objectives: To compare levels of the IL23 subunit, IL23p19, produced by monocyte-derived macrophages (MDMs) in the presence of lipopolysaccharide (LPS) and an inducer of the UPR (tunicamycin (TM)) from patients with ERA and healthy controls. Other pro-inflammatory cytokines and markers of the UPR were also studied.
Methods: Peripheral blood monocytes isolated from 30 patients with ERA (20 HLAB27 positive, 10 HLAB27 negative, median age 16yrs 4mths, median disease duration 3yrs 9mths, M:F 7:1) and 16 age and gender-matched healthy controls were differentiated in vitro with macrophage-colony stimulating factor. Cells were treated with IFNγ and then stimulated with LPS alone or LPS with TM for 24 hours. Pro-inflammatory cytokines and markers of the UPR were measured by expression of mRNA using qPCR and normalised against GAPDH.
Results: IL23p19 expression was higher in MDMs from HLAB27 positive patients with ERA compared to healthy controls treated with LPS [median relative expression 384.7 (IQR 179.2–1340) vs 90.5 (49.9–455.9), p=0.02]. With the addition of the UPR inducer, TM, enhanced IL23p19 mRNA expression was also seen in HLAB27 positive patients compared to those who were HLAB27 negative and healthy controls [median relative expression 608.9 (IQR 282–3286) vs 283.0 (IQR 20.1–928.2) vs 195.1 (IQR 9.8–853.7); p=0.02]. When the groups were divided in to males and females, significantly higher IL23p19 expression was seen in MDMs treated with LPS from male HLAB27 positive patients with ERA compared to male healthy controls [661.7 (IQR 169.7–1531) vs 78.3 (39.01–139.6), p=0.0095] (figure 1). This was also the case for MDMs treated with LPS and TM [537.5 (IQR 295.3–3054) vs 93.05 (IQR 2.7–1109); p=0.02]. To investigate the effect of UPR induction on IL23p19 mRNA expression, percentage increase was calculated for each patient between MDMs treated with LPS alone and MDMs treated with LPS and TM. Interestingly, median percentage increase for HLAB27 positive patients with ERA was 63% but a decrease was seen in IL23p19 mRNA expression for in HLAB27 negative patients (-3.8%) with the addition of TM. When HLAB27 positive patients not oh TNF inhibitors were compared to those on treatment, the median percentage increase between LPS and LPS + TM treated MDMs was significantly modulated [78.7% vs 10.1%, p-0.049]. mRNA expression for other pro-inflammatory cytokines including TNF, IL1 and IL6, in addition to markers of the UPR (XBP1, CHOP and BiP) demonstrated no significant differences between patients and healthy controls.
Conclusions: Expression of IL23p19 mRNA in MDMs is significantly enhanced in HLAB27 positive patients with ERA. In this group, the induction of the UPR appears to further enhance IL23p19 expression but this effect is modulated by treatment with TNF inhibitors. These results suggest a potential role for IL23 and the UPR in the pathogenesis of ERA, particularly in those who are HLAB27 positive and may have implications for treatment stratification, indicating a subgroup of patients who may respond to IL23 blockade.

OP0057 FLUORESCENCE OPTICAL IMAGING IN JUVENILE IDIOPATHIC POLYARTICULAR DISEASE BEFORE AND DURING ANTIRHEUMATIC TREATMENT

A. Klein[1], G.-W. Just[1], S.G. Werner[2], I. Becker[3], P. Oommen[4], K. Minden[5], H.-E. Langer[2], G. Horneff[1]. *[1]Asklepios, Sankt Augustin; [2]RHIO, Duesseldorf; [3]University Cologne, Cologne; [4]University, Duesseldorf; [5]Charite, Berlin, Germany*

Background: Valid detection of inflamed joints is essential for correct classification, therapeutic decisions and assessment of treatment efficacy in juvenile idiopathic arthritis (JIA).
Objectives: Fluorescence optical imaging (FOI) enables visualization of inflammation in arthritis of finger and hand joints and might be used in JIA.
Methods: A 24-week observational study in polyarticular JIA patients newly starting treatment with either methotrexate or a biologic was performed. Patients were evaluated clinically, by ultrasound B–mode, power-Doppler and FOI at baseline, week 12 and 24.
Results: Of 37 patients enrolled, 24 patients started MTX and 13 a biologic for the first time (Etanercept n=11, Adalimumab and Tocilizumab one 1). Composite measures, mean JADAS 10 decreased significantly from 17.7 at baseline to 12.2 and 7.2 at week 12 and 24 respectively and JIA-ACR 30/50/70/100 response rates at week 24 were 85%/73%/50%/27%. In total 1110 joints were examined clinically, 990 by US/PD and 990 by FOI. At baseline/week12/week24 23.6%/16.4%/9.0% joints on hand and fingers were clinically active joints, by US 19.4%/16.1%/11.5% joints showed effusions, 18.8%/12.7% and 9.6% showed synovial thickening and by PD 6.9%/1.8%/5% joints showed hyperperfusion. Any sign of arthritis was detected by US/PD in 24.5%/19.2%and17%. By FOI at 38.7%/29.2%/27.6% showed a signal enhancement in at least one phase. Summarizing all 3 points

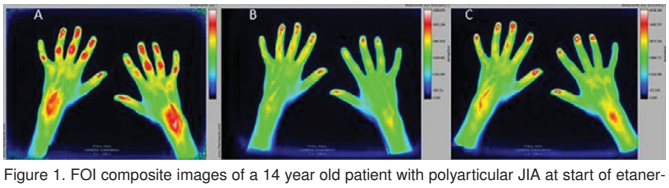

Figure 1. FOI composite images of a 14 year old patient with polyarticular JIA at start of etanercept treatment (left), after 3 (middle) and 6 months (right).

Abstract OP0057 – Table 1. Numbers of joints of a total of 2970 evaluated joints at 3 different points of time and comparison of number of joints with increased FOI signal and detection by US according to detection by clinical examination. Data on US examination were available for 2550 joints in total

	FOI					US/PD			
n (%)	Any signal 947	Composite image 530	Phase 1 396	Phase 2 783	Phase 3 180	Any signal 527	Effusion 430	Synovitis 375	Hyper-perfusion 120
Signal in clinically active joints (n=519)	320 (33.8%/61.7%)* r	205 (38.7%/39.5%)	161 (40.7%/31.0%)	277 (35.4%/ 53.4%)	81 (45.0%/15.6%)	239 (45.4%/46.0%)	211 par (49.1%/40.7%)	164 (43.7%/31.6%)	47 (39.2%/9.0%)
Signal in clinically inactive joints	627 (66.2%/25.6%)	325 (61.3%/13.3%)	235 (59.3%/9.6%9)	506 (64.6%/20.6%)	99 (55.0%/4.0%)	288 (54.6%/ 11.8%) (54.6%/11.8%)	219 (51.0%/8.9%)	211 (56.2%/8.6%)	73 (60.8%/3.0%)

*First percentage refers to columns, second to rows.

of time, the highest numbers of signals were detected by FOI with 32% of joints, especially in phase 2 while by US/PD 20.7% and by clinical examination 17.5% were active. A high number of joints (21.1%) had FOI signals but were clinically inactive. 20.1% of joints with signals in FOI did not show effusion, synovial thickening or hyperperfusion by US/PD. Due to the high number of negative results specificity of FOI compared to clinical examination/US/PD was high (84–95%), sensitivity was moderate only.
Conclusions: Improvement upon treatment with either methotrexate or a biologic can be visualized by FOI. FOI and US/PD could detect clinical but also subclinical inflammation. FOI detected subclinical inflammation in higher extent than US.

OP0058 IMPROVEMENT IN PATIENT-REPORTED OUTCOMES IN PATIENTS WITH POLYARTICULAR-COURSE JUVENILE IDIOPATHIC ARTHRITIS AND INADEQUATE RESPONSE TO BIOLOGIC OR NON-BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS TREATED WITH SC ABATACEPT

N. Ruperto[1], H. Brunner[2], N. Tzaribachev[1], G. Vega-Cornejo[1], I. Louw[1], J. Anton[1], D. Viola[1], I. Foeldvari[1], V. Keltsev[1], D. Kingsbury[2], C. Wouters[1], B. Lauwerys[1], E. Alemao[3], R. Wong[3], M. Nys[4], S. Banerjee[3], A. Martini[1], D. Lovell[2]. *[1]PRINTO, Istituto Gaslini, Genoa, Italy; [2]PRCSG, CHMC, Cincinnati; [3]Bristol-Myers Squibb, Princeton, United States; [4]Bristol-Myers Squibb, Braine L'Alleud, Belgium*

Background: In patients (pts) with polyarticular-course juvenile idiopathic arthritis (pJIA), SC abatacept (ABA) 125 mg weekly has a similar pharmacokinetic profile, therapeutically equivalent efficacy and comparable safety to IV ABA 10 mg/kg every 4 weeks.[1] Although some data on paediatric pt-reported outcomes (PRO) have been published for IV ABA,[2] PRO data following treatment with SC ABA have not.
Objectives: This analysis examined the effect of SC ABA treatment on PROs (activities of daily living [ADL] limitation questionnaire of parent/caregiver, childhood HAQ [CHAQ]-DI, and parent global assessment of overall pt well-being [PaGA]) in 6–17-year pts with active pJIA in a Phase III trial (NCT01844518).
Methods: Pts with pJIA aged 2–17 years with an inadequate response/intolerance to $\geq$1 DMARD were enrolled in this single-arm, open-label study and received SC ABA weekly for 4 months based on body weight tier (10–<25 kg [50 mg ABA], 25–50 kg [87.5 mg ABA] and >50 kg [125 mg ABA]). JIA-ACR 30 criteria (ACR Pediatric 30) responders at Month 4 could receive ABA for another 20 months. For the 6–17-year cohort reported here, ADL limitation questionnaire of parent/caregiver (mean [SD] number of days [D] of parental/caregiver missed activity, paid care and missed school [absolute values per month and percentage of D missed per month relative to an assumed average of 20 school D/month]); CHAQ-DI (0–3 scale across 8 domains of disability component); and PaGA (0–100 mm visual analogue scale) were evaluated.
Results: Baseline characteristics of the 173 pts with pJIA from the 6–17-year cohort were: median (min, max) age, 13.0 (6.0, 17.0) years; median (min, max) number of active joints, 10.0 (2.0, 42.0); 78.6% of pts used MTX (median dose: 11.6 mg/m^2/week); and 26.6% were with prior biologic failure. All ADL limitation components improved from baseline to D113 (Month 4); these improvements were largely maintained at D309 (Figure). Relative percentage D missed from school decreased from 15% (D1) to 5.5% (D309, Figure D). CHAQ-DI and PaGA improved from baseline to D309 (Table). Further 2-year data are pending.

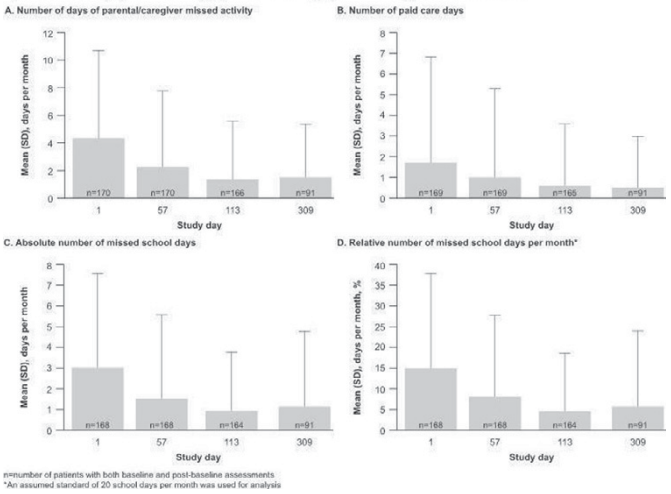

Table 1. CHAQ-DI and PaGA scores over time in the 6–17-year cohort

	Day						
	1 (n=170)	29 (n=170)	57 (n=170)	85 (n=167)	113 (n=166)	197 (n=144)	309 (n=89)
CHAQ-DI	0.99 (0.69)	0.82 (0.71)	0.73 (0.65)	0.63 (0.65)	0.61 (0.64)	0.52 (0.57)	0.46 (0.56)
PaGA (mm)	45.6 (25.97)	32.2 (24.56)	28.7 (24.58)	23.8 (23.59)	23.6 (24.32)	20.0 (23.04)	21.7 (23.58)

Data are mean (SD). For CHAQ-DI (scale 0–3) and PaGA (0–100 mm visual analogue scale), higher scores indicate greater dysfunction and lower well-being, respectively.

Conclusions: In this analysis of patients with pJIA aged 6–17 years, SC abatacept demonstrated a beneficial effect on PROs including reductions in activity limitation and disability (CHAQ-DI) and improvement in well-being (PaGA) up to D309.

Vegas-Revenga[1], C. Fernández-Díaz[1], J. Hernández[1], M. González-Gay[1], N. Palmou-Fontana[1], R. Blanco[1]. *[1]HUMV, Santander; [2]H Fe, Valencia; [3]H Clinic, Barcelona; [4]H, Donostia; [5]HUAC, A Coruña; [6]H Nieves, Granada; [7]H V d'Hebron, Barcelona; [8]H Regional Universitario, Málaga; [9]H, León; [10]H S Carlos, Madrid; [11]H, Pontevedra; [12]H Servet, Zaragoza, Spain*

Background: Uveitis is a severe manifestation of Juvenil Idiopathic Arthritis (JIA). Anti-TNFa are recommended in refractory cases, mainly infliximab (IFX) or adalimumab (ADA) (Levy-Clarke et al. Ophthalmology 2014; 121: 785–796). However, sometimes they are ineffective, contraindicated or not tolerated. The next therapeutic step is not defined.
Objectives: To compare the efficacy of Golimumab (GLM) and Tocilizumab (TCZ) in related AIJ uveitis refractory to conventional immunosuppressive drugs and anti-TNFα.
Methods: Multicenter study of 33 patients with uveitis associated-JIA. They were refractory to conventional treatment with high dose of corticosteroids and at least a) one conventional immunosuppressive drug and b) one anti-TNFa. For this reason it was decided to iniciate TCZ or GLM. TCZ was used in 25 patients: 8 mg/kg/4 w iv (n=21), 8 mg/kg/2 w (n=2); 8 mg/kg/8 w (n=1) and 2.9 mg/kg sc/w (n=1). GLM was used in 8 patients (50 mg/sc/month). We assessed visual acuity (VA), degree of intraocular inflammation, vitreous inflammation and macular thickening (with OCT). Quantitative variables were expressed with mean±SD or median [IQR], according to its distribution. They were compared with the Student t or the Mann-Whitney U test, respectively. Dichotomous variables were expressed as percentages and compared by the chi-square test.
Results: We studied 33 patients/61 affected eyes. There were no significant differences between TCZ and GLM at baseline in sex (♂/♀;4/21 vs 3/5; p=0.19), mean age (18.5±8.3 vs 19.9±8.7; p=0.55), positive ANA (95% vs 100%; p=0.7), uveitis duration before TCZ or GLM onset (116.4±93.6 vs 142.3±74.7

p=0.46), number of previous biological treatments (1.9±1.1 vs 2±1.4; p=0.84), VA (0.57±0.35 vs 0.5±0.37; p=0.42), combined immunosuppressive therapy (88% vs 75%; p=0.37), presence of cells in the anterior chamber (median, 1 [0–1] vs 1 [0.25–1.5]; p=0.6), vitritis (0 [0–0] vs 0 [0–1]; p=0.7), macular thickening (358.7±92.2 vs 313.6±77.1; p=0.32).
There were no significant difference in the efficacy between TCZ and GLM (TABLE).
After a mean follow-up of 20.48±11.7 months with TCZ and 24.25±17 months with GLM the following side effects were observed: TCZ: viral conjunctivitis plus bullous impetigo (n=1), severe thrombocytopenia and pneumonia. This last patient showed hemolytic anemia, thrombocytopenia and splenomegaly, for this reason treatment with TCZ was discontinued. With GLM cutaneous reaction was observed in 2 patients.

Table. Evolution of ocular parameters with TCZ and GLM

	TCZ (n=25)	GLM (n=8)	p
BASELINE			
VA	0.57±0.35	0.5±0.36	0.43
Cells in the anterior chamber	0.92±0.81	2.79±4.82	0.63
Vitritis	0,43±0,91	0.33±0.5	0.78
OCT	358.69±92.17	313.60±77.05	0.31
1ST MONTH			
VA	0.59±0.33	0.56±0.32	0.75
Cells in the anterior chamber	0.26±0.52	2.33±4.57	0.083
Vitritis	0.31±0.71	0±0	0.32
OCT	313.40±91.28	292.50±111.42	0.57
6TH MONTH			
VA	0.63 ±0.32	0.62 ±0.33	0.85
Cells in the anterior chamber	0,1±0,34	0±3,28	0.43
Vitritis	0,07±0,33	0,25±0,62	0.62
OCT	274,91±101,32	261,37±75,15	0.94
1ST YEAR			
VA	0.63 ±0.34	0.54 ±0.31	0.35
Cells in the anterior chamber	0±0.2	0±0	0.71
Vitritis	0.058±0.23	0±0	0.81
OCT	245.45±29.34	255±120.8	0.74

Results are expressed as mean±SD

Conclusions: TCZ and GLM seem to be equally effective and safe for refractory uveitis associated-JIA. The superiority of one or the other should be established with prospective randomized studies "Head to Head"

OP0060 HEALTH BEHAVIOR IN ADOLESCENTS WITH JUVENILE IDIOPATHIC ARTHRITIS- RESULTS OF THE INCEPTION COHORT OF NEWLY DIAGNOSED PATIENTS (ICON)

M. Listing[1], I. Liedmann[1], M. Niewerth[1], J. Klotsche[1], K. Mönkemöller[2], I. Foeldvari[3], J. Kümmerle-Deschner[4], T. Hospach[5], K. Minden[1]. *[1]Deutsches Rheuma-Forschungszentrum Berlin, Berlin; [2]Klinik für Kinder- und Jugendmedizin, des Kinderkrankenhauses der Stadt Köln, Köln; [3]Hamburger Zentrum für Kinder- und Jugendrheumatologie, Hamburg; [4]Universitätsklinik für Kinder- und Jugendmedizin Tübingen, Tübingen; [5]Zentrum für pädiatrische Rheumatologie, Klinikum Stuttgart, Stuttgart, Germany*

Background: Knowledge concerning health behavior in adolescents with juvenile idiopathic arthritis (JIA) is essential for assessing their health risks. Although there is some evidence about a relationship between low socioeconomic status (SES) and health risk behavior in adulthood, it is less clear whether this association is also true for adolescents with JIA.
Objectives: To compare the health behavior between adolescents with JIA and healthy peers and to examine the association with sex and SES.
Methods: Data of adolescents (aged 13 to 17) with JIA and healthy peers enrolled in ICON were considered for this analysis. Health behavior was assessed via questionnaire within the first years of disease. SES- Score (low, moderate, high) was determined by using an established German multidimensional aggregated index and based on the parents' education level as well as household net income.
Results: A total of 334 adolescents with JIA (61% female, mean age 15.1 (SD 1.1), mean disease duration 1.3 (SD 1.7)) and 181 healthy peers (57% female, mean age 15.3 (SD 1.3)) were included. Adolescents with JIA were less physically active and reported less consumption of alcohol compared with healthy peers (see Table). In both groups, boys were more frequently physically active and spent more time in playing video games than girls. Whereas girls with and without JIA used more often mobile phones than boys. No gender specific differences in both groups were found in consumption of illicit and legal drugs.
After stratification in groups according to the SES- Scores, socioeconomic differences were the same in adolescents with JIA and healthy peers. Teenagers with low social background (n=200) spent significantly more time in consumption of TV, mobile phones and video games than those from families with high SES (n=122). No significant relationship was found between parental SES and alcohol, nicotine and drug consumption by adolescents. The parental SES- Score was strongly associated with the education level of adolescents.

	Adolescents with JIA (n=334)	Healthy peers (n=181)	p-value
Watching TV <1h/day, n (%)	110 (33%)	68 (38%)	0.3
Playing games and computer use <1h/day, n (%)	121 (37%)	61 (34%)	0.6
Mobile phone use <1h/day, n (%)	159 (48%)	94 (52%)	0.4
Physical activity ≥ once per week, n (%)	226 (80%)	169 (94%)	<0.001
No smoking, n (%)	313 (94%)	173 (96%)	0.3
No consumption of alcohol, n (%)	168 (52%)	70 (40%)	<0.01
No consumption of illicit drugs in the last 12 months, n (%)	301 (96%)	162 (96%)	0.9
Ever sexual intercourse, n (%)	27 (8%)	13 (7%)	0.7

Conclusions: Adolescents with JIA have a similar health behavior as healthy peers, except for alcohol consumption and physical activity level. Gender and socioeconomic status are associated with health behavior of adolescents with and without JIA. Parental SES may affect adolescents' educational outcomes.

Silva[2,3] on behalf of Brazilian Childhood-onset Systemic Lupus Erythematosus Group. *[1]Pediatric Rheumatology Divisions, Brazilian Childhood-onset Systemic Lupus Erythematosus Group, São Paulo state; [2]Pediatric Rheumatology Unit, Children's Institute, Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de São Paulo; [3]Pediatric Pulmonology Unit, Children's Institute, FMUSP; [4]Division of Rheumatology, FMUSP; [5]Pediatric Rheumatology Unit, Universidade Federal de São Paulo; [6]São Paulo State University (UNESP), Faculdade de Medicina de Botucatu; [7]São Paulo State University of Campinas (UNICAMP); [8]Irmandade da Santa Casa de Misericórdia de São Paulo; [9]Ribeirão Preto Medical School – University of São Paulo; [10]Hospital Darcy Vargas; [11]Hospital Menino Jesus; [12]Pontifical Catholic University of Sorocaba, São Paulo, Brazil*

Background: Data of diffuse alveolar hemorrhage (DAH) in childhood-onset systemic lupus erythematosus (cSLE) patients are limited due to the small representation of this complication in previous case series or the focus on the comparison to adult SLE, precluding an accurate analysis of associated factors and outcomes in patients with and without this severe complication.
Objectives: To evaluate prevalence, clinical manifestations, laboratory abnormalities and treatment in a multicenter cohort study including 847 cSLE patients with and without diffuse DAH, as well as concomitant parameters of severity.
Methods: DAH was defined as the presence of at least three respiratory symptoms or signs associated with diffuse interstitial/alveolar infiltrates on chest x-ray or high-resolution computer tomography and sudden drop in hemoglobin levels with no other source of bleeding. Holm-Bonferroni correction for multiple comparisons was performed adjusting the significance level ($p<0.0022$).
Results: DAH was evidenced in 19/847 (2.2%) cSLE patients. Cough/dyspnea/tachycardia/hypoxemia occurred in all cSLE patients with DAH. Concomitant parameters of severity observed were: mechanical ventilation in 14/19 (74%), hemoptysis 12/19 (63%), macrophage activation syndrome 2/19 (10%) and death 9/19 (47%). Further analysis of cSLE patients at DAH diagnosis compared to 76 cSLE control patients without DAH with same disease duration [3 (1–151) vs. 4 (1–151) months, p=0.335], showed higher frequencies of constitutional involvement (74% vs. 10%, $p<0.0001$), serositis (63% vs. 6%, $p<0.0001$) and sepsis (53% vs. 9%, $p<0.0001$) in the DAH group. The median of disease activity score (SLEDAI-2K) was significantly higher in cSLE patients with DAH [18 (5–40) vs. 6 (0–44), $p<0.0001$]. The frequencies of thrombocytopenia (53% vs. 12%, $p<0.0001$), intravenous methylprednisolone (95% vs. 16%, $p<0.0001$) and intravenous cyclophosphamide (47% vs. 8%, $p<0.0001$) were also significantly higher in DAH patients.
Conclusions: This is the largest study to evaluate DAH. This complication, although not a disease activity score descriptor, occurs in the context of significant moderate/severe cSLE flare. Importantly, we identified that this condition is associated with serious disease flare complicated by sepsis and with high mortality rate.

Sibilia[11], B. Bodaghi[12], I. Touitou[13], C. Miceli-Richard[1]. *[1]Hopital Cochin, paris; [2]Hôpital Purpan, Toulouse, France; [3]Chiba University Hospital, Chiba, Japan; [4]Hopital de la Croix Rousse, Lyon; [5]CHRU Lille, Lille, France; [6]Anna Meyer Children's Hospital, Florence; [7]University of Padova, Padova, Italy; [8]Hopital des Enfants, Toulouse; [9]CHU Bicetre, le Kremlin Bicetre; [10]CHU Rouen, Rouen; [11]CHRU Strasbourg, Strasbourg; [12]CHU pitié Salpetriere, Paris; [13]CHU Montpellier, Montpellier, France*

Background: Blau Syndrome (BS) is a rare autosomal dominant inflammatory disease characterized by early-onset granulomatous arthritis, dermatitis and recurrent uveitis (1). Mutations in the nucleotide-binding domain (NBD) of *CARD15/NOD2* gene (mainly R334W, R334Q and L469F) have been identified in Blau syndrome (2). Despite advances in BS knowledge, patients' functional prognosis remains uncertain, BS potentially leading to visual impairment or joint deformities. Optimal treatments have not been determinated yet.
Objectives: To assess the efficacy of several biologic agents in this affection
Methods: We conduct an observational, international, retrospective cohort of BS collecting clinical, biological and histological data.
Results: Among the twenty-three patients included in the cohort, 14 patients were treated by one or several lines of biologic agents, mostly by TNF blockers (80%), IL1 blockers (16%) or treatment targeting CTLA-4 (4%). Fifty-seven percent of patients achieved remission after almost two lines of treatment (1.75 lines; [0.8–2.7]). Association with csDMARDs did not significantly improved response to biologics. Considering the 3 mains symptoms independently, TNF blockers were associated with a better response in case of articular or skin features but less effective in case of ocular involvement, a clinical situation in which IL-1 targeting should be preferentially chosen.
Conclusions: Biologic treatments appeared to be effective in BS but additional data prospectively collected are still needed in order to define their place in the therapeutic strategy in order to minimize functional consequences.

Background: Canakinumab (CAN) is a fully human monoclonal antibody targeting IL-1β, a key cytokine in the pathogenesis of periodic fever syndromes (PFS) including familial Mediterranean fever (FMF), hyper-IgD syndrome/mevalonate kinase deficiency (HIDS/MKD) and TNF receptor-associated periodic syndrome (TRAPS).
Objectives: The CLUSTER trial (NCT02059291) studied efficacy and safety of CAN in crFMF, HIDS/MKD and TRAPS. The primary objective was to demonstrate that CAN150 mg every 4 weeks (q4w) is superior to placebo (PBO) in resolving the flare by Day 15 with no new flares over 16 weeks (wks). Secondary objectives included the proportion of patients (pts) who maintained optimal control of disease activity (absence of new flares) between Wk 16 and Wk 40 after dose reduction.
Methods: The study comprised 4 epochs (E1-E4).[1] After lead-in E1, in E2 patients at time of an active fever flare were randomised to CAN 150mg q4w or PBO for 16 wks. Responders in E2 were re-randomised to PBO or 150 mg q8w for 24 wks. During E3, pts who escaped to open-label CAN in E2, were similarly down-titrated to open-label CAN q8w to gain additional information on the long-term maintenance dose. In pts with a flare, dose could be escalated up to 300 mg q4w. Safety assessments included adverse events (AEs) and serious AEs.
Results: The proportion of responders at Wk 16 was statistically higher with CAN vs PBO (Table). In E3, among the 41 re-randomised pts (PBO vs CAN 150 mg q8w) the proportion of pts who did not present new flares was numerically higher in the CAN vs PBO group (Table). Overall at Wk 40 (end of E3), including re-randomised pts and pts treated in open-label, 46% of the crFMF pts, 53% of the TRAPS pts and 23% of the HIDS/MKD pts maintained disease control with 150 mg q8w. Conversely, up-titration to 300 mg q4w was required in 28.8% of HIDS/MKD pts, and in 10.2% and 8.3% of pts with crFMF and TRAPS, respectively. In E3, the majority of pts who received CAN had PGA <2, normal CRP and SAA levels in all 3 cohorts. No new safety findings nor death were reported in CAN-treated pts through E3 (Table).

Table. Efficacy results and summary of safety

Efficacy

	Cohort	CAN 150 mg q4w N=90	PBO N=91	OR (95% CI)	p-value
Proportion of responders at Week 16 (E2), n/m (%)	crFMF	19/31 (61.3)	2/32 (6.3)	23.8 (4.4, 227.5)	<0.0001*
	HIDS/MKD	13/37 (35.1)	2/35 (5.7)	8.9 (1.7, 86.4)	<0.002*
	TRAPS	10/22 (45.5)	2/24 (8.3)	9.2 (1.5, 94.6)	0.005*
	Cohort	CAN 150 mg q8w N=19	PBO N=22	OR (95% CI)	p-value
Proportion of pts with no new flare at Week 40 (E3), n/m (%)	crFMF	7/9 (77.8)	3/10 (30.0)	8.2 (0.8, 113.4)	0.0513
	HIDS/MKD	3/6 (50.0)	1/7 (14.3)	6.0 (0.3, 366.2)	0.2168
	TRAPS	3/4 (75.0)	2/5 (40.0)	4.5 (0.15, 313.5)	0.3571

Safety: Summary of AEs and SAEs

	All	crFMF		HIDS/MKD		TRAPS	
	PBO N=24	Any CAN* E2 N=58	Any CAN* E2+E3 N=61	Any CAN* E2 N=68	Any CAN* E2+E3 N=71	Any CAN* E2 N=43	Any CAN* E2+E3 N=61
Exposure to CAN, PY	2.0	16.4	45.6	19.1	51.0	12.1	39.2
Number of AEs	34	134	332	251	613	112	265
AE rate/100 PY	1698.8	816.7	728.2	1313.6	1201.2	925.7	676.2
Number of SAEs	1	7	17	11	20	3	5
SAE rate/ 100 PY	50.0	42.7	37.3	57.6	39.2	24.8	12.8

*Indicates statistical significance (one-sided) at the 0.025 level. *Any patient who received a dose of CAN during E2 or 3. n=number of patients who responded; m=number of patients evaluated for response; AE, adverse event; CAN, canakinumab; CI, confidence interval; E, epoch; OR, odds ratio; PBO, placebo; PY, patient-years; q4w, every 4 weeks; q8w, every 8 weeks; SAE, serious adverse event

Conclusions: Canakinumab (150 mg q4w) was efficacious in resolving flare at Day 15 and preventing new flares over 16 wks. In the longer term (40 wks), absence of flares was maintained in more than half patients at the extended dosing interval (150 mg q8w) in the crFMF and TRAPS cohorts. A higher dose was needed in HIDS/MKD patients. No unexpected safety issues were reported over 40 wks of canakinumab treatment.

Impact of rheumatic diseases

OP0064 CLEFS DE DOS: A UNIQUE PARE-LED VIDEO PROGRAM TO IMPROVE COPING SKILLS OF PEOPLE LIVING WITH AXIAL SPONDYLOARTHRITIS

C. Beauvais[1], C. Sordet[2], A. Leboime[3], D. Vandame[4], C. Saadoun[4], G. Genin[5], F. Gerald[6]. *[1]Hôpital Saint Antoine, Paris; [2]CHU de Strasbourg, Strasbourg; [3]Hôpital Amboise-Paré, Paris; [4]UCB Pharma, Colombes; [5]Agence Catalpa, Paris; [6]Association Action contre les Spondylarthropathies - ACS, Nice, France*

Background: Diagnosis of axial spondyloarthritis (axSpA) is often delayed, with an estimated time to diagnosis of 6 years,[1] leading to patient (pt) anxiety and difficulties in coping with daily life. Many fears and beliefs have been identified,[2] including unpredictability of the disease course and concerns for the future. A survey revealed that 61% of pts want to share such experiences with other pts.[3]
Objectives: The goals were to: 1) create a video program to help pts share experiences and promote coping strategies; 2) establish the program on the internet and social networks; 3) assess the usefulness of the program for pts and healthcare professionals (HCPs).
Methods: Clefs de dos is a national French program initiated in 2015. It is led by a pt organisation, ACS-France (Action Contre les Spondyloarthropathies), Catalpa (conducted interviews, made visuals) and UCB Pharma (co-creation and promotion). Pts with axSpA were recruited by ACS on a voluntary basis to participate in focus groups; pts were selected according to their level of disease acceptance (denial [Gp1] or acceptance [Gp2]). 4 steps were planned: 1) Gp1 focus group interviews to collect feelings, words and voices; 2) Gp2 interviews to describe the pt pathway and stages in the process of disease acceptance; 3) face-to-face Gp1+Gp2 meetings for pts to share their own experiences and confront their own views; 4) rheumatologist interviews to evaluate the impact of pt testimonies on their own practice.
Results: 13 axSpA pts (10 Gp1, 3 Gp2) participated, aged 25–65 years (yrs), with 5–17 yrs disease duration; 10 were female. An animated visual was produced using Gp1 pt interviews; analysis revealed feelings of loss prior to diagnosis. Photographs and audio testimonies were used to create 3 documentary portraits of Gp2 pts, illustrating the process of disease acceptance and acquisition of coping skills (Figure). Videos of Gp1+Gp2 meetings emphasised interpersonal help and counselling between pts. 3 rheumatologists participated in step 4. They identified the importance of pt interaction to develop positive strategies, pt perspective and removal of barriers in the physician-pt relationship, and use of videos in self-management programs. By December 2016, >5,000 people had visited the website (www.clefsdedos.com), with ~500 Facebook followers from March–December 2016 (www.facebook.com/Clefsdedos/) reaching ~30,000 people via link sharing.

Figure: Example of a Clefs de dos visual creation

Conclusions: Clefs de dos was developed by and for axSpA pts. The program answers unmet needs by sharing pt experiences, particularly in situations of delayed diagnosis and lack of disease acceptance. Online access reflects good acceptability of the program, which can also be used as an educational tool in self-management. The next step is to involve other HCPs (eg. nurses, physiotherapists, psychologists).

OP0065 NURSE-LED VACCINATION PROGRAM DRAMATICALLY IMPROVES PNEUMOCOCCAL VACCINATION COVERAGE AMONG PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES: A PROSPECTIVE PILOT STUDY

T. Goulenok, J. Serre, C. Francois, M.-C. Van der Haegen, J.-F. Alexandra, T. Papo, K. Sacre. *Paris-7 University, APHP, Bichat Hospital, Paris, France*

Background: Patients with chronic inflammatory rheumatic diseases (IRD) receiving immunosuppressive therapy are at high risk for invasive pneumococcal disease. Despite national recommendations regarding pneumococcal vaccination, vaccination rate remains low in this population.
Objectives: We aimed to determine whether a nurse-led vaccination program improve pneumococcal vaccination coverage among patients with chronic IRD.
Methods: From April to August 2015, all consecutive adult patients with a chronic IRD admitted in our day hospital unit (Department of Internal Medicine, Bichat Hospital, Paris, France) were screened. Eligibility for pneumococcal vaccination was assessed according to French national recommendations. Patients were identified as candidate for pneumococcal vaccination, informed on the benefice and risk of vaccination and vaccinated by nurses. Pre-intervention (i.e. percentage of patients candidate for vaccination vaccinated before the intervention program) and post-intervention (i.e. percentage of patients candidate for vaccination vaccinated after the intervention program) pneumococcal vaccination rate were compared using Chi2 test.
Results: 126 consecutive patients (43 [24–89] years, 61.9% females) with a chronic IRD were admitted in our day hospital unit during a 4 months period. Among them, 76 (60.3%) patients were candidate for pneumococcal vaccination because receiving prednisone, immunosuppressive drugs and/or biotherapy. The pre-intervention pneumococcal vaccination rate was 17.1 (13/76) %. Among patients candidate for pneumococcal infection but not vaccinated (n=63), 56 (88.9%) were accurately identified by nurses. Ten patients refused to be vaccinated and 46 eventually received pneumococcal vaccination. The post-intervention pneumococcal vaccination was 77.6 (59/76) % ($p<0.001$ as compared to the pre-intervention rate).
Conclusions: Nurse-led vaccination program dramatically improves pneumococcal vaccination coverage among patients with chronic IRD.

OP0066 THE PROBLEM BASED LEARNING APPLIED TO TEACHING RHEUMATOLOGICAL TOPICS AMONG NON RHEUMATOLOGY RESIDENTS

C.A. Guillen-Astete[1], A. Braña-Cardeñosa[2], M. Zamorano-Serrano[2], P. Gallego-Rodriguez[2], C. De la Casa-Resino[2]. *[1]Rheumatology Department; [2]Urgency Department, Ramon y Cajal University Hospital, Madrid, Spain*

Background: Many pedagogical models have been included to the teaching strategies available in almost all fields of knowledge in the last 20th years. In the field of medicine teaching, the traditional teaching (TT) model based on an expert speech aid by a multimedia slide projection is now only one of many strategies. One of them is the Problem-Based learning (BPL) model, which is one of the most applied in undergraduate education; however the documented experience on residents education with rheumatologic contents in Spain is inexistent. BPL model consist in a lecture based in a clinical case or cases that the students must affront using several tools, most of them provided previously by the teacher, and the opinion of their classmates. Groups are encouraged to try to solve the medical problem while the teacher leads debates among the groups.
Objectives: Our goal is to test the impact of PBL model compared to TT among non rheumatology residents who participated in an rheumatology educational program using long term measures in their clinical practice.
Methods: We developed an educational program for second year residents of all medical specialties in our teaching hospital. The topic included the assessment and treatment of lumbar acute pain and was programmed in two separated dates using both the TT and PBL models. Students were unaware of the teaching strategy. Contents of both courses were the same and were prepared by two different experts. We reviewed the registries of medical attention performed by all residents for patients who consulted due to acute lumbar pain, and collected data about three aspects: Adherence to image test recommendations (AITR),

adherence to treatment recommendation (ATR) and recidivism before the 15th day after the day of consultation (need of further consultation due to the same medical problem). Registries included those generated along the first 12 months after the end of the courses.
Results: The TT group generated 175 registries while PBL generated 219. Both groups were formed by 20 non rheumatology second year residents. Proportion of AITR were 73.3 and 60.2% for BLT and TT groups, respectively ($P<0.001$). Considering only the registries generated in the first trimester after the courses, those proportions were respectively 80.2 and 79.5%. Proportion of ATR were 69.9 and 55.7%, respectively ($P<0.001$), however when considering only registries generated in the first trimester those proportions were 77.1 and 76.9%, respectively. Global recidivism rate (number of patients who need a further consultation due to the same medical problem or due to the side effects of their treatment among all patients attended) at the first 15th day since the first assessment was 8.7% in the PBL group and 17.5% in the TT group ($P<0.001$). At the end of both courses a survey to the students were performed. The satisfaction index –measured by a 0–10 progressive ordinal scale- were 9.1 SD 1.3 for the PBL model and 8.2 SD 1.4 for the TT model ($P<0.05$).
Conclusions: The pedagogical PBL teaching method shows a better academic impact in terms of concept retention and appliance into the medical practice along the time. In our opinion and according to our experience, most programs of education on transversal topics of rheumatology should be taught using the PBL method.

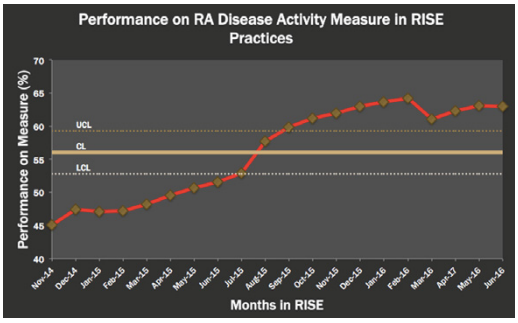
OP0067 DEVELOPMENT AND VALIDATION OF A MODEL TO FACILITATE RECOGNITION OF ARTHRITIS BY GENERAL PRACTITIONERS



B.T. van Dijk, R.M. ten Brinck, H.W. van Steenbergen, A.H. van der Helm-van Mil. *Rheumatology, Leiden University Medical Centre, Leiden, Netherlands*

Background: Early initiation of treatment of rheumatoid arthritis is strongly associated with an improved outcome, but requires the early identification of arthritis. Physical examination of joints is crucial to this end, but is difficult for general practitioners (GPs) who have little experience. Another difficulty is that GPs see many persons with musculoskeletal symptoms per year but only few patients with clinical arthritis. To promote early recognition of arthritis, the Early Arthritis *Recognition* Clinic (EA*R*C) was initiated in Leiden, the Netherlands in 2010. GPs were instructed to refer to this clinic in case of doubt on the presence of arthritis (and not to wait and see, or to perform additional laboratory tests). At this clinic, patients filled out a form with questions on their symptoms and were seen by a rheumatologist in a short visit that comprised a full joint examination. As reported previously, this clinic importantly improved the early identification of arthritis and RA (1), but this approach may not be easily implemented in other centres or regions.
Objectives: To assess if a combination of symptoms and signs that are easy to assess can differentiate patients with and without clinical arthritis at joint examination.
Methods: 1,288 patients in whom GPs doubted on the presence of arthritis visited the EA*R*C between 2010 and 2015. Reported symptoms and signs were studied with the presence of synovitis (joint examination by experienced rheumatologist) as outcome. Multivariable logistic regression was used. A model was derived in 644 patients, and validated in the second set of 644 patients.
Results: 41% of the patients who visited the EARC had arthritis at examination. Age (per year OR 1.02; 95% CI 1.01–1.03), male sex (OR 1.8; 95% CI 1.3–2.7), symptom duration (4–12 weeks OR 3.83; 95% CI 2.22–6.60), morning stiffness >60 min (OR 1.7; 95% CI 0.9–2.9), difficulty with making a fist (OR 1.6; 95% CI 0.97–2.5), number of tender joints (1–3 tender joints OR 9.7; 95% CI 1.1–81.8) and self-reported swollen joints (OR 3.5; 95% CI 1.8–7.0) were associated with the presence of arthritis in multivariable analysis. The AUC was 0.75 (SE 0.02) in the derivation set and 0.71 (SE 0.02) in the validation set. To facilitate application in practice, a simplified model was made. This consisted of 7 variables and the total score ranged between 0–7. The AUC was 0.73 (SE 0.02). Depending on the cut-off, the PPV of the simplified model ranged between 41 and 74% and the NPV between 100 and 62%. With a cut-off of 4, the NPV was 86%, PPV 49%, specificity 35%, and sensitivity 91%.
Conclusions: A set of clinical characteristics that can be easily assessed by GPs had a reasonable discriminative ability for clinical arthritis, and can be applied by GPs in case of doubt on the presence of arthritis. This model requires further validation in general practices, but may lead to a tool that could assist GPs in their decision making regarding referral or ordering additional tests for patients with suspected early arthritis.

OP0068 PRACTICES PARTICIPATING IN THE ACR'S RHEUMATOLOGY INFORMATICS SYSTEM FOR EFFECTIVENESS (RISE) NATIONAL REGISTRY SHOW IMPROVEMENTS IN QUALITY OF CARE

J. Yazdany[1], R. Myslinski[2], T. Johansson[2], S. Kazi[3]. [1]*Medicine/Rheumatology, University of California, San Francisco, San Francisco;* [2]*American College of Rheumatology, Atlanta;* [3]*University of Texas Southwestern, Dallas, United States*

Background: The ACR launched the RISE registry in 2014 to facilitate quality improvement on a national scale. The registry passively extracts electronic health record (EHR) data from rheumatology practices, aggregates and analyzes these data centrally, and feeds performance on quality measures back to clinicians using a web-based dashboard.
Objectives: We used data from RISE to 1) examine variation in performance on quality measures across practices, and 2) evaluate trends in measure performance over time.
Methods: RISE's informatics platform continuously collects data from the EHRs of participating practices, allowing centralized aggregation and analysis of quality measures. We analyzed data collected between July 1, 2014-July 1, 2016 on all patients seen by 294 clinicians across 63 practices. Measures in the areas of rheumatoid arthritis, drug safety, preventive care and gout were examined. Performance on quality measures, defined as the percentage of eligible patients receiving recommended care, was examined at the practice level. To examine trends in performance over time, we took the subset of practices that continuously participated in RISE since its inception (n=44), and developed 1) control charts and 2) logistic regression models, in which the outcome was practice-level performance each month and the predictor was time.
Results: Data from 289,812 patients was examined. Mean (SD) age was 59 (16) years, 75% were female, 21% were racial/ethnic minorities, and 37% had public insurance. Most rheumatologists were in a group practice (73%); 25% were in solo practice and 2% part of a larger health system. Performance on measures varied significantly across practices (Table). The largest gaps were observed for gout and preventive care. For 4 of 5 measures for which the Medicare program has set national benchmarks, average performance of RISE practices exceeded targets. Of 11 measures, performance improved over time on 5 measures ($p<0.05$ in logistic models; see Figure for example control chart), was at goal on 4 measures, and saw no improvement on 2 measures (BMI screening and urate target).

Conclusions: We found significant variation in performance on quality measures across RISE practices, with the largest gaps seen in gout care and preventive care. Some practices have achieved a very high level of performance. Over time, RISE practices demonstrated improvement in over half of the measures

Abstract OP0068 – Table 1

Electronic Quality Measure (eCQM)	Measure denominator (N)	Average performance across patients (%)	Average practice-level performance (percentile)		CMS benchmark
			50th	100th	
RA: Assessment of Disease Activity	63,472	52.1	56.1	100	
RA: Functional Status Assessment	63,472	50.0	56.1	100	
RA: DMARD	63,472	90.1	91.4	98.2	9.0
Drug Safety: TB screening pre-biologic	7,842	61.1	66.6	95.7	9.0
Drug Safety: ≥1 High-Risk Medication in Elderly*	101,820	4.7	2.8	0	89.7
Drug Safety: ≥2 High-Risk Medications in Elderly*	101,820	0.1	0	0	57.8
Preventive Care: Tobacco screening and counseling	219,415	85.3	89.3	99.8	68.5
Preventive Care: BMI documentation, follow-up plan	154,501	26.4	26.7	50.7	
Preventive Care: Blood pressure management	30,607	70.0	63.2	100	

*Lower number indicates higher performance.

examined. As rheumatologists aim to improve quality of care, RISE will, by design, allow participants to measure, benchmark, and continuously monitor performance improvement.

OP0069 THE BURDEN OF ANKYLOSING SPONDYLITIS: A POPULATION BASED STUDY

J.S. Lee [1], H.Y. Lee [2], E.E. Lee [1], Y.W. Song [1], E.Y. Lee [1]. *[1]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul; [2]Center for Preventive Medicine and Public health, Seoul National University Bundang Hospital, Seongnam, Gyeonggi-do, Korea, Republic Of*

Background: Ankylosing spondylitis (AS) is an inflammatory rheumatic disease with musculoskeletal and systemic manifestations. Because AS is typically diagnosed before the age of 40 years and follows a chronic progressive course, its impact on the patient is life-long. In addition to the burden on the individual patient, that on the society is also increasing cumulatively every year [1]. The burden of AS is not confined to healthcare cost spent due to back pain and stiffness of the disease itself [2–4], but also encompass extra-articular manifestation (EAM), comorbidities, disability, and mortality contributed from AS [5].
Objectives: This study aimed to evaluate the disability, mortality, and healthcare cost for quantifying the burden of AS.
Methods: We conducted a nationwide population-based study based on national health insurance data in Korea. The patients with incident AS (n=1111) were identified with controls (n=5555) who were matched by age, sex, income, and geographic region from the year 2003 to 2013. EAMs, comorbidities, mortality and type and severity of disabilities were presented as incidence rate and compared to the controls as incidence rate ratios (IRRs). Annual health expenditure per patient was analyzed by the year and relation to AS.
Results: During the follow-up, 28% of patients in this cohort experienced any kind of EAM. More comorbidities with Charlson comorbidity index ≥3 (OR 2.18, 95% CI 1.91 to 2.48) were significantly associated. Disability rate was higher than controls regardless of causes and severity (OR 2.94, 95% CI 2.48 to 3.48). Crude IRRs for mortality was not significantly increased, but by multivariate analysis, older age at diagnosis (≥45 years old) (OR 10.53, 95% CI 4.31 to 25.68) was most strongly related to increased disability and mortality rates (Fig.1). Biologic agents elevated annual health expenditures of AS but decreased AS unrelated costs (mean 1112 vs 877 USD, p=0.0068) (Fig.2).

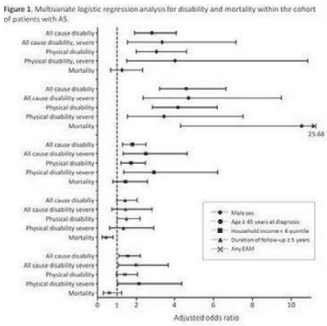

Figure 1. Multivariate logistic regression analysis for disability and mortality within the cohort of patients with AS.

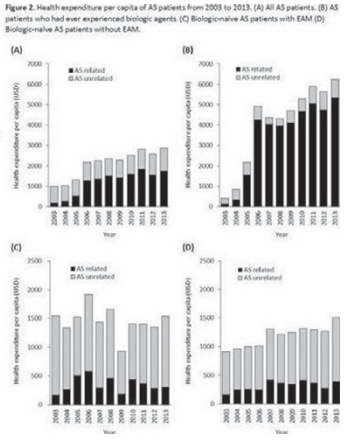

Figure 2. Health expenditure per capita of AS patients from 2003 to 2013. (A) All AS patients. (B) AS patients who had ever experienced biologic agents (C) Biologic-naive AS patients with EAM (D) Biologic-naive AS patients without EAM.

Conclusions: Along with demographic factors, systemic consequences such as EAMs and other comorbidities were associated with increased disabilities and healthcare expenditures in AS. Older age at diagnosis was significantly associated with increased mortality rates.

OP0070 THE ROLE OF INDIVIDUAL AND COUNTRY-LEVEL SOCIO-ECONOMIC FACTORS IN WORK PARTICIPATION IN PATIENTS WITH SPONDYLOARTHRITIS ACROSS 22 COUNTRIES WORLDWIDE: RESULTS FROM THE COMOSPA STUDY

S. Rodrigues Manica [1,2], A. Sepriano [2,3], S. Ramiro [3], F.M. Pimentel-Santos [1,2], P. Putrik [4], E. Nikiphorou [5], A. Moltó [6,7], M. Dougados [6,7], D. van der Heijde [3], R. Landewé [8], F. Van den Bosch [9], A. Boonen [4]. *[1]Rheumatology Department, Centro Hospitalar de Lisboa Ocidental; [2]CEDOC - NOVA Medical School | Faculdade de Ciências Médicas, NOVA University of Lisbon, Lisbon, Portugal; [3]Leiden University Medical Center, Leiden; [4]Department Internal Medicine, Division of Rheumatology, Maastricht University Medical Center, Maastricht, Netherlands; [5]KCL, London, United Kingdom; [6]Rheumatology B Department, Paris Descartes University, Cochin Hospital, AP-HP; [7]INSERM (U1153), Clinical Epidemiology and Biostatistics, PRES Sorbonne Paris-Cité, Paris, France; [8]ARC, Amsterdam & Atrium MC Heerlen, Amsterdam, Netherlands; [9]Department of Rheumatology, Ghent University Hospital, Ghent, Belgium*

Background: Spondyloarthritis (SpA) carries substantial financial costs, including direct costs (use of medical services and treatments) and indirect costs (loss of work productivity). While disease related factors have been repeatedly shown to be associated with work outcomes, information on the role of educational attainment and the economic wealth of the patients' country of residence is scarce.
Objectives: To explore the role of individual and country level socio-economic (SE) factors on employment, absenteeism and presenteeism across 22 countries.
Methods: Patients with a clinical diagnosis of SpA, fulfilling the ASAS SpA criteria and in working age (≤65 years old) from COMOSPA were included. Outcomes explored were employment-status, absenteeism and presenteeism according to the Work Productivity and Activity Impairment Specific Health Problem (WPAI-SHP) questionnaire. Absenteeism and presenteeism were assessed in employed patients. Multilevel logistic (for work status) and linear (for absenteeism and presenteeism) regression models with random intercept for country were constructed. Independent contribution of individual (education) and country level socio-economic factors (country healthcare expenditures and gross domestic product (GDP) (all low vs medium/high tertiles) were assessed in models adjusted for clinical factors.
Results: In total 3,114 patients from 22 countries were included (mean (SD) age 40.9 (11.8) years; 66% males; and 63% employed). Of these, 89% had axial SpA and 11% a peripheral SpA. Unadjusted employment rates ranged from 28% (Colombia) to 83% (Canada). After adjustment for relevant socio-demographic and clinical variables, differences between countries in work status persisted (Figure).

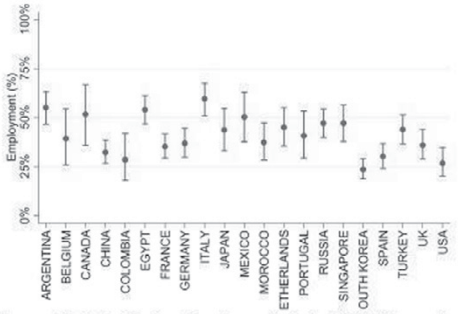

Figure – Adjusted estimates of employment rate (and 95%CI) by country derived from final multivariable, two-level model for work status, adjusted for health expenditure per capita (in USD), socio-demographic and clinical

Table – Impact of individual and country SE factors on work outcomes, in two-level models adjusted for socio-demographic and clinical variables

Independent predictors	Outcome		
	Work status (employed vs not) (N=2,897)	Absenteeism (0-100%) (N=1,619)	Presenteeism (0-100%) (N=1,497)
	OR (95% CI)	β (95% CI)	β (95% CI)
Country health expenditure per capita (US dollars)	2.42 (1.53;3.81)	-3.42 (-13.07;6.23)	-4.53 (-8.90;-0.17)
Age (years)	0.98 (0.97;0.99)	-0.04 (-0.17;0.09)**	-0.20 (-0.31;-0.10)
Gender (ref: Female)	2.26 (1.88;2.72)	-4.38 (-7.28;-1.49)	-4.30 (-6.59;-2.01)
Education (ref: Primary school or less)			
-Secondary	2.35 (1.77;3.11)	-5.42 (-10.45;-0.40)	-3.09 (-7.03;0.85)
-University	3.90 (2.91;5.24)	-7.25 (-12.33;-2.27)	-7.48 (-11.44;-3.51)
Marital status (ref: single)			
-married/living together;	2.28 (1.83;2.85)	¥	£
-divorced	2.37 (1.54;3.67)		
-widower	2.00 (0.84;4.73)		
RDCI (0-9)	0.83 (0.84;0.91)	¥	2.43 (1.21;3.66)
ASDAS-CRP	¥	3.83 (2.17;5.50)	7.43 (6.12;8.74)
BASFI (0-10)	0.98 (0.98;0.98)	0.13 (0.05;0.20)	0.45 (0.39;0.51)

RDCI=Rheumatic Disease Comorbidity Index; ASDAS-CRP= Ankylosing Spondylitis Disease Activity Score; BASFI=Bath Ankylosing Spondylitis Functional Index;
¥ Not selected during multivariable regression analysis (p ≥0.05).
£ Not selected during univariable analysis (p>0.20)

High healthcare expenditures were associated with higher employment (OR=2.42; 95% CI=1.53;3.81) and lower presenteeism (β=-4.53;CI=-8.90;-0.17). Similarly, higher GDP was associated with higher employment (OR=1.70; 95% CI=1.02;2.83), and in the same direction with presenteeism but without reaching statistical significance (β=-3.42;CI=-13.07;6.23). No significant association between any country SE indicators and absenteeism was found. At individual level, higher education was positively associated with employment-status, presenteeism and absenteeism.

Conclusions: Individual- and country-level SE factors affect work participation in SpA, and this varies significantly across countries. Better socio-economic welfare seems to support SpA patients to stay employed and productive.

OP0071 SICK LEAVE AFTER SIX MONTHS IN 664 PATIENTS WITH RECENT-ONSET INFLAMMATORY ARTHRITIS

E.S. Norli[1,2], G. Hetland Brinkmann[2,3], T.K. Kvien[2], S. Lillegraven[2], O. Bjørneboe[1], A. Julsrud Haugen[3], H. Nygaard[4], C. Thunem[5], E. Lie[2], M.D. Mjaavatten[2]. *[1]Rheumatology, Martina Hansens Hospital, Sandvika; [2]Rheumatology, Diakonhjemmet Hospital, Oslo; [3]Rheumatology, Østfold Hospital Trust, Grålum; [4]Rheumatology, Lillehammer Hospital of Rheumatic diseases, Lillehammer; [5]Rheumatology, Betanien Hospital, Skien, Norway*

Background: Musculoskeletal disorders, including inflammatory arthritis (IA), are among the most common reasons for work disability and sick leave. Early IA patients with risk factors for persistent and/or erosive disease, such as high swollen joint count (SJC), acute-phase reactants, RF- or ACPA-positivity, are treated aggressively to prevent joint damage and disability.

Objectives: To study the rate of sick leave according to clinical diagnosis in an unselected very early IA cohort, and to investigate whether the predictors for sick leave are the same as the known predictors for persistent and/or erosive disease.

Methods: Data from the Norwegian Very Early Arthritis Clinic (NOR-VEAC), a longitudinal observational study of adults with IA of ≤16 weeks' duration, were used. Exclusion criteria were arthritis due to crystal deposits, trauma, osteoarthritis and septic arthritis. For the present study we included patients eligible for work participation, i.e. <65 years with no retirement or disability pension, who had information about work in the baseline and six-month case report forms. Independent samples t-test, Mann-Whitney-U test or chi-square test were used as appropriate to compare patients on sick leave after 6 months with patients not reporting sick leave. Clinically relevant baseline variables with univariate p-value <0.2, as well as age and sex, were included in the multivariable logistic regression analyses with manual backwards selection to find predictors for sick leave after six months.

Results: Of 880 patients eligible for analysis (<65 years, no retirement or disability pension), 664 (75.5%) had complete work participation data. Duration of joint swelling before inclusion [median (25–75 perc.)] was 35 (14–69) days, mean (SD) age 42.1 (12.1) years, 56.0% were females, 27.3% current smokers, and 22.4% anti-CCP and/or RF positive. The most common final clinical diagnoses were undifferentiated arthritis (35.2%), rheumatoid arthritis (22.1%) and reactive arthritis (19.7%).

The overall rate of sick leave at presentation was 37.7% and after 6 months 23.2%. More than one-third of the patients reported sick leave at first visit, regardless of diagnosis (Figure 1). At six months >20% sick leave was still reported in all groups except sarcoid arthritis and reactive arthritis. Smoking, low education (≤ high school), longer duration of joint swelling, ACPA and RF positivity, joint pain, fatigue, patient's global assessment, SF-36 (physical and mental component summary scores), HAQ-DI and tender joint count at baseline were univariably associated with sick leave after six months, whereas SJC, ESR and CRP were not. Independent predictors were current smoking (OR 2.1 (95% CI 1.4–3.2)), low education (OR 1.7 (95% CI 1.1–2.5)), longer duration of joint swelling and low SF-36 (physical and mental component summary scores).

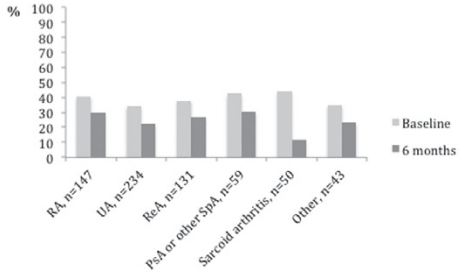

Figure 1. Proportion of patients with sick leave at baseline and after six months according to diagnosis
RA, rheumatoid arthritis; UA, undifferentiated arthritis; ReA, Reactive arthritis; PsA, psoriatic arthritis; SpA, spondyloarthritis.

Conclusions: Sick leave in IA is common, even six months after diagnosis. Predictors for sick leave after six months were associated with lifestyle and level of education rather than factors commonly considered to be predictive for unfavourable arthritis outcomes. In early IA care, health care providers should focus not only on disease activity, but also on work ability and early facilitation efforts at work.

Comorbidities: having one RMD is enough - we don't need anything else

OP0072-PARE PREGNANCY AND PARENTING WITH ARTHRITIS – DEVELOPING AN EDUCATIONAL RESOURCE FOR PATIENT BY PATIENTS

L. Proulx, N. Robertson, D.P. Richards, L. Wilhelm, J. Gunderson, C. Reece, A. Sirois, A. McKinnon. *Canadian Arthritis Patient Alliance, Ottawa, Canada*

Background: For any individual, the decision to start a family is an important one. For individuals with arthritis, the decision to start a family is even more difficult. Many decisions need to be taken, including the risks of taking or not taking medication while trying to conceive and during pregnancy, and the ability to carry out their role as a parent. Few resources exist to help individuals navigate these important, life-changing decisions[1,2]. It is for this reason and through our collective experience as people living with arthritis that the Canadian Arthritis Patient Alliance (CAPA) launched a project on pregnancy and parenting with arthritis. The first phase of the project involved a survey[3] to identify patient information needs as it relates to pregnancy and parenting. The second phase focused on the creation of a medically-reviewed resource for people living with arthritis.

Objectives: An educational resource was developed for patients by patients living with inflammatory arthritis. The resource was medically reviewed by healthcare professionals.

Methods: Priority was placed on developing content for the topics identified as "very important" and "important" from the pregnancy and parenting survey. One Board member acted as project manager to develop the resource content and obtain input from people living with arthritis, researchers and rheumatologists. Methods to obtain input include software tools, e-mails and in person meetings. The educational resource was reviewed by medical experts to improve overall reliability and uptake.

Results: The educational resource is divided in two sections – one focused on pregnancy and the other on parenting. The pregnancy section includes information on fertility and family planning, talking to your partner about parenting, medication use during pregnancy and breastfeeding, managing arthritis during pregnancy and labour and delivery. The parenting section provides a variety of "life hacks" or tips for the physical care of children and dealing with fatigue and flares as well as impact of living with arthritis on a patient's children. Ongoing efforts will be made to promote the resource and use will be monitored through social media, website metrics and surveys.

Conclusions: CAPA developed a resource for people living with arthritis regarding pregnancy and parenting. CAPA aims to raise the profile of this issue and help people living with arthritis engage in dialogue with their healthcare providers during these critical life events. It is expected that use of the resource will enable shared decision-making, improve communication with health care professionals, and reduce overall stress for people living with arthritis and their families.

Risk factors for developing diseases or comorbidities

OP0073 PERFORMANCE OF THE EULAR DEFINITION OF ARTHRALGIA SUSPICIOUS FOR PROGRESSION TO RHEUMATOID ARTHRITIS – A LONGITUDINAL STUDY

L.E. Burgers[1], F. Siljehult[2], R.M. ten Brinck[1], H.W. van Steenbergen[1], R.B. Landewé[3,4], S. Rantapää-Dahlqvist[2], A.H. van der Helm-van Mil[5]. *[1]Rheumatology, Leiden University Medical Centre, Leiden, Netherlands; [2]Public health and clinical medicine/rheumatology, Umea University Sweden, Umea, Sweden; [3]Rheumatology, Atrium Medical Center, Heerlen; [4]Clinical immunology and rheumatology, Academical Medical Center, University of Amsterdam, Amsterdam; [5]Rheumatology, Umea University Sweden, Leiden, Netherlands*

Background: Recently a European League Against Rheumatology (EULAR)-taskforce has defined arthralgia suspicious for progression to rheumatoid arthritis (RA)[1], in order to allow inclusion of homogeneous sets of arthralgia patients in clinical studies. This was done as the field is currently shifting towards performing trials in very early disease phases as there is growing evidence that very early treatment initiation allows better disease modification and treatment of arthralgia may even prevent the development of RA. The definition was developed with the clinical expertise as reference. It is intended for use in arthralgia patient that rheumatologists' consider to be at risk for progression to RA

Objectives: To longitudinally evaluate the EULAR definition of arthralgia suspicious for progression to RA in: (1) patients in whom rheumatologists felt that imminent RA was more likely than other arthralgia's (Clinically Suspect Arthralgia, CSA); this target population fulfils the entry criterion and (2) in arthralgia patients referred to secondary care prior to rheumatologic evaluation; in these patients the entry criterion was ignored.

Methods: The definition was assessed in 241 Dutch CSA-patients and 113 patients referred to the Umeå university hospital with recent-onset arthralgia in small joints. The external reference was arthritis development <2-years follow-up.

Results: CSA-patients with a positive definition (≥3/7 parameters present) had an increased risk on arthritis development compared to definition-negative CSA-patients (HR 2.1, 95% CI 0.9–4.7). The sensitivity of a positive definition was 84% and the positive predictive value (PPV) 30%. In arthralgia patients in whom the definition was applied prior to rheumatologic evaluation, a positive definition was neither sensitive (10%) nor predictive (PPV 3%). Sensitivity analyses with fulfilment of the 2010 criteria for RA or initiation of DMARDs <2-years of follow-up as external reference showed similar results.

Conclusions: The EULAR definition of arthralgia suspicious for progression to RA is sensitive when used to support the expert's opinion on imminent RA. It was not discriminative in patients without prior rheumatologic evaluation. These data suggest that the definition should be used as designed and serves to further homogenize patients that rheumatologists consider at risk for RA.

OP0074 ASSOCIATION BETWEEN A HISTORY OF MYCOBACTERIAL INFECTION AND THE RISK OF SJÖGREN'S SYNDROME: A NATIONWIDE, POPULATION-BASED CASE-CONTROL STUDY

H.-H. Chen[1,2], W.-C. Chao[1], T.-L. Liao[1], Y.-M. Chen[1,2], C.-H. Lin[1], D.-Y. Chen[2,3]. *[1]Department of Medical Research; [2]Division of Allergy, Immunology and Rheumatology; [3]Department of Medical Education, Taichung Veterans General Hospital, Taichung, Taiwan, Province of China*

Background: An increased risk of tuberculosis (TB) has been found in subjects with Sjögren's syndrome (SS); however, whether TB or nontuberculous mycobacteria (NTM) infection is associated with the risk of SS is still unknown.

Objectives: To explore the association between a history of mycobacterial infection and the risk of newly diagnosed SS.

Methods: After excluding those who had rheumatoid arthritis and systemic lupus erythematosus, we identified 5,751 newly diagnosed SS cases and 86,265 non-SS patients matched (1:15) for age, sex, and the year of first diagnosis date as controls using nationwide, population-based, claims data. The association between the risk of incident SS and a history of treated mycobacterial infection, including TB and NTM, was quantified by odds ratios (ORs) with 95% confidence intervals (CIs) using conditional logistic regression analysis after adjusting for Charlson comorbidity index (CCI) and bronchiectasis.

Results: The mean ± SD age was 55±14 years and the proportion of female gender was 87.8% in newly diagnosed SS cases and non-SS controls. An association was observed between NTM infection (OR, 11.24; 95% CI, 2.37–53.24) and incident SS, but not between TB infection and incident SS (OR, 1.29; 95% CI, 0.97–1.71) after adjustment for CCI and bronchiectasis. The magnitude of the association between NTM and SS risk was greatest among those aged between 45 and 65 years (OR, 39.24; 95% CI, 3.97–387.75).

	Univariable analysis OR (95% CI)	Multivariable analysis OR (95% CI)
Nontuberculous mycobacteria	20.00 (4.48–89.36)	11.24 (2.37–53.24)
Tuberculosis	1.86 (1.41–2.45)	1.29 (0.97–1.71)
CCI ≥1	1.89 (1.77–2.01)	1.83 (1.71–1.94)
Bronchiectasis	3.19 (2.76–3.69)	2.74 (2.36–3.18)

Conclusions: The present study demonstrates a statistically significant association of newly-diagnosed SS with a history of NTM, but not TB infection.

OP0075 OSTEOPOROTIC FRACTURE RISK ASSESSMENT USING FRAX FOLLOWING HEMATOPOIETIC STEM CELL TRANSPLANTATION

H. Lu, W.A. Murphy Jr., C. Ebede, E. Karim, S. Manocha, D. Don-Pedro, G. Rondon, L.C. Hong, L. Suyu, R.E. Champlin, X. Pundole. *The University of Texas MD Anderson Cancer Center, Houston, TX, United States*

Background: Bone loss and fractures following hematopoietic stem cell transplantation (HSCT) is common,(1, 2) and identifying patients at high risk for osteoporotic fractures following HSCT remains challenging. In the general population, the World Health Organization fracture risk assessment tool - FRAX is utilized to estimate a patient's 10-year probability of developing a major osteoporotic fracture and hip fracture.(3) However, the utility of the FRAX model in predicting fractures following HSCT has not been evaluated.

Objectives: To assess the predictive value of FRAX in osteoporotic fracture risk assessment following HSCT.

Methods: We conducted a retrospective cohort study of patients >18 years that received a HSCT at The University of Texas MD Anderson Cancer Center, from January 1, 2001 to December 31, 2010. Patients were considered to have entered the cohort at the time of HSCT. All patients were retrospectively followed until December 31, 2013 for assessment of osteoporotic fracture. Osteoporotic fractures following HSCT were identified using ICD-9 codes, and confirmed by radiology and physician documentation. FRAX probabilities were calculated from baseline information obtained by chart review.

Results: A total of 5,170 patients underwent a HSCT during the 10-year study period. During an average of 3.3 years of follow up, 10% of patients developed a fracture. Fracture rates were higher (14%) in patients that underwent an autologous HSCT in comparison to those that received an allogeneic HSCT (6%). Mean major osteoporotic fracture FRAX scores were significantly higher in individuals who sustained an osteoporotic fracture compared to individuals who did not. The area under the receiver operating characteristic curve at 5 and 10 years following the HSCT were 0.61 and 0.66 respectively (Figure). We assessed the ability of the FRAX model for prediction of osteoporotic fracture with and without considering death as a competing risk. The hazard ratios were similar for both models (HR, 2.63, 95% CI, 1.93, 3.59; HR, 2.54, 95% CI, 1.86, 3.47, respectively).

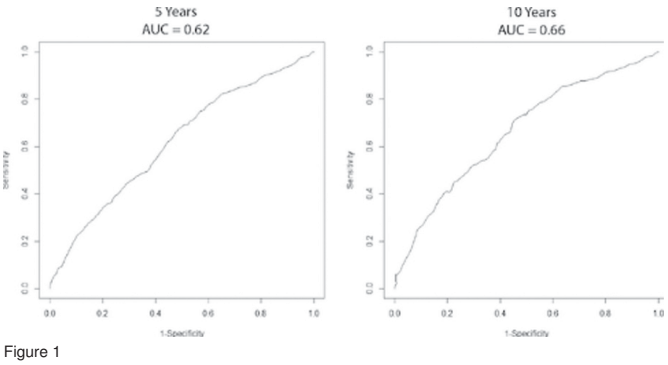

Figure 1

Conclusions: To the best of our knowledge, this is the first study to demonstrate that the FRAX model has modest discriminative ability in predicting osteoporotic fractures following HSCT. Further independent validation of our findings is necessary, before routinely using the FRAX model in clinical practice.

OP0076 RISK OF DEVELOPING ADDITIONAL IMMUNE MEDIATED MANIFESTATIONS FOR PATIENTS WITH SYSTEMIC ARTHRITIDES

D. Aletaha[1], R. Panaccione[2], M. Davis[3], S. Johnson[3], M. Skup[4], V. Garg[4]. *[1]Medical University of Vienna, Vienna, Austria; [2]Univerity of Calgary, Calgary, Canada; [3]Medicus Economics, LLC, Milton; [4]AbbVie Inc., North Chicago, United States*

Background: Patients with the systemic arthritides ankylosing spondylitis [AS], psoriatic arthritis [PsA], rheumatoid arthritis [RA] may develop additional, non-musculoskeletal immune mediated manifestations (nms-IMMs).
Objectives: To compare the risk of developing nms-IMMs between patients with and without an existing AS, PsA, or RA.
Methods: Risk for nms-IMMs was estimated in the MarketScan Commercial Claims and Encounters database (1/2006–9/2015) for case patients with AS, PsA, RA (the "systemic arthritides"). Up to 1,000 controls were matched with replacement by age, sex, state of residence and insurance type to case patients aged 18–64. The systemic arthritides ("cases") were identified by ICD-9 diagnosis codes on ≥2 medical claims ≥30 days apart. A case patient's earliest nms-IMM claim was designated as the index date for the case and all matched controls. Onset of 6 nms-IMDs was identified by the first post-index claim: celiac disease [CE], hidradenitis suppurativa [HS], inflammatory bowel disease [IBD], lupus [SLE], psoriasis [PsO], uveitis [UV]; some of these are well-known manifestations of seronegative spondylarthropathies, like PsA and AS; some are not. All subjects had continuous health plan enrollment for ≥365 days before and after index date. Cumulative incidence of nms-IMMs was assessed at 5 years. Their risk was analyzed with stratified Cox proportional hazards models. Standard errors were adjusted for clustering by case-control match group.
Results: Among 117,794 cases, mean age was 49 years and 71% were female. Mean number of matched controls per case was 664. Across the 3 initial cohorts of patients with AS, PsA, or RA, median follow-up ranged 939–972 days for cases and 931–950 days for controls. Among case patients, 5-year cumulative incidence of any nms-IMM occurrence was 17.5% for AS, 41.8% for PsA, and 14.4% for RA. Patients with nms-IMMs had significantly higher risk than matched controls of developing each, any 1, or any 2 of the 6 manifestations (P≤0.002) (Table).

Initial IMID		Secondary IMID							
		CE	HS	SLE	PsO	UV	IBD	1st of Any 1	2nd of Any 2
AS	N Cases	6,339	6,344	6,282	6,275	6,103	6,263	6,352	6,352
	5-yr Incidence	0.9	0.2	2.9	4.2	7.7	3.4	17.5	1.2
	Hazard Ratio	11.2	3.3	23.7	8.6	54.9	16.0	17.9	24.6
PsA	N Cases	8,382	8,389	8,311	6,111	8,351	8,347	8,406	8,406
	5-yr Incidence	0.5	0.6	2.1	51.0	1.8	1.7	41.8	2.5
	Hazard Ratio	5.3	10.5	14.1	163.2	10.0	7.3	50.9	43.3
RA	N Cases	102,708	102,810	100,414	101,965	102,424	102,318	103,036	103,036
	5-yr Incidence	1.0	0.5	7.5	3.4	1.5	1.8	14.4	1.0
	Hazard Ratio	10.3	8.1	55.3	7.2	8.2	7.6	14.1	14.3

Notes: Hazard ratios from Cox proportional hazards models. Hazard ratios >1 indicate higher risk for case patients relative to controls. All hazard ratios are significant at P<0.002.

Conclusions: The risk of developing non-musculoskeletal manifestations was significantly higher for patients with AS, PsA, and RA than for matched controls. These included not only the well-known manifestations of PsA and AS but also others like manifestations leading to claims for SLE, celiac disease or HS. When managing these systemic arthritides, surveillance for additional immune mediated manifestation is warranted.

Lee[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic Of; [2]Division of Clinical Immunology & Rheumatology, University of Alabama at Birmingham, Birmingham, United States*

Background: Pneumocystis pneumonia (PCP) is a significant cause of morbidity and mortality in patients with rheumatic diseases, especially in the case of patients receiving high-dose steroid treatment.
Objectives: To investigate the efficacy and safety of PCP prophylaxis using trimethoprim/sulfamethoxazole (TMP-SMX) in patients with rheumatic disease receiving prolonged, high-dose steroids
Methods: This study includes 1522 cases of prolonged (≥4 weeks), high-dose (≥30mg/day prednisone or equivalent) steroid treatment from 1092 patients with any rheumatic diseases during a 12-year period in a single tertiary referral center in South Korea. Of them, prophylactic TMP-SMX was administered in 262 cases (prophylaxis group) with a mean (SD) duration of 229.0 (272.7) days whereas other 1260 cases received no prophylaxis (control group). Primary outcome was 1-year incidence of PCP between the two groups. Secondary outcomes included PCP-related mortality, ICU admission rate, all-cause in-hospital mortality and incidence of any adverse drug reactions (ADRs) of TMP-SMX. To minimize the baseline imbalance between the two groups, we introduced propensity-score matching and performed the same analysis in the post-matched population as a sensitivity analysis.
Results: Patients in the prophylaxis group were treated more often with secondary immunosuppressive drugs and had a higher proportion of patients with PCP high-risk diseases (ANCA-associated vasculitis and dermatomyositis) and lymphopenia at baseline. Overall, 30 cases of PCP occurred and resulted in death in 11 cases (36.7%). In the prophylaxis group, only one non-fatal case of PCP occurred. One-year PCP incidence was significantly lower in the prophylaxis group (adjusted HRs=0.096 [0.013–0.719]) (Figure). TMP-SMX also significantly reduced the PCP-related mortality (adjusted HR=0.101 [0.001–0.809]) whereas

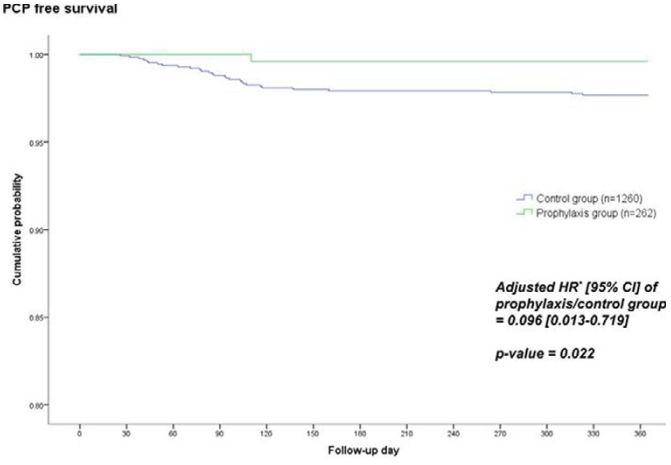

Figure. Kaplan-Meier curve of 1-year incidence of PCP between the two groups

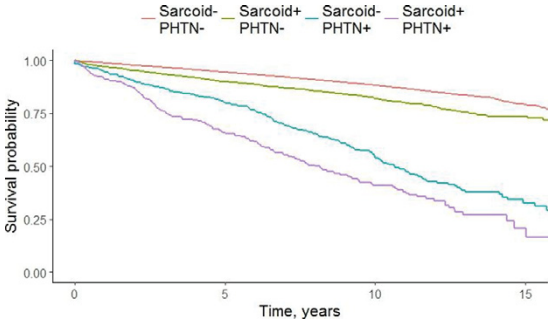

*, HR was adjusted for patient's age, concomitant cyclophosphamide pulse and baseline lymphopenia

ICU admission rate and in-hospital mortality rate were not different between the two groups during the observation. This result was consistent in the sensitivity analysis where same analysis was performed in the post-matched population.
Thirty-four cases of ADRs of TMP-SMX occurred, with an incidence rate (95% CI) of 24.2 (17.3–33.0) per 100 person-year. There were two cases of serious ADR (one pancytopenia and one Steven's Johnson syndrome) but they all recovered shortly after the discontinuation of TMP-SMX. The number needed to harm (NNH) of serious ADR was 109 whereas the number needed to treat (NNT) to prevent one case of PCP in the whole population was 52.
Conclusions: In patients with rheumatic disease receiving prolonged, high-dose steroid treatment, TMP-SMX prophylaxis significantly lower the incidence of PCP with favorable safety.

OP0078 THE LONG TERM PROGNOSTIC SIGNIFICANCE OF PULMONARY HYPERTENSION IN SARCOIDOSIS - A BIG DATA ANALYSIS

S. Tiosano[1,2], O. Gendelman[1,2], A. Watad[1,2], D. Comaneshter[3], A. Cohen[3,4], H. Amital[1,2]. *[1]Internal Medicine 'B', Sheba Medical Center, Ramat-Gan; [2]Sackler School of Medicine, Tel-Aviv University; [3]Chief physician's office, Clalit Health Services, Tel-Aviv; [4]Siaal Research Center for Family Medicine and Primary Care, Faculty of Health Sciences, Ben Gurion University of the Negev, Beer Sheva, Israel*

Background: Sarcoidosis is a multisystem, chronic, progressive, granulomatous disease. Sarcoidosis-associated pulmonary hypertension is well described, but not common complication of sarcoidosis[1]. In small scale studies, it has been previously described as a manifestation of advanced disease and was found to be associated with increased morbidity and mortality[2]. Previous studies have shown that treatment may be safe and improve pulmonary hemodynamics in sarcoidosis-associated pulmonary hypertension[3,4]. However, big data analyses regarding the exact magnitude and prognosis of sarcoidosis-associated pulmonary hypertension are lacking.
Objectives: To assess the long-term prognostic significance of sarcoidosis-associated pulmonary hypertension using a big data registry with a 15-year follow-up period.
Methods: Utilizing the medical records of Clalit Health Services, the largest HMO in Israel, we extracted a cohort consisted of sarcoidosis patients along with their age-and-sex matched controls. Dates of registration in the medical records of sarcoidosis, pulmonary hypertension and death, as well as anthropometric information and medical comorbidities were extracted from the database. To compare the distribution of variables across the cohort strata, univariate analysis was performed using Chi-square and student t-test. Multivariate analysis using a logistic regression model was used to find variables associated with pulmonary hypertension. Survival analysis using cox proportional hazards method and log-rank test was performed to find variables associated with increased risk of all-cause mortality.
Results: The cohort included 3,993 sarcoidosis patients and 19,856 age-and-sex matched controls. The mean age of both groups was 56, and both consisted about 63% females. Pulmonary hypertension was observed among 269 sarcoidosis patients (6.74%) vs. 400 controls (2.01%), $p<0.001$. In multivariate analysis, sarcoidosis was found to be independently associated with diagnosis of pulmonary hypertension (OR 3.09, 95% CI 2.6–3.67). After more than 15 years of follow-up, 710 (17.8%) of the sarcoidosis patients had died, compared to 2121 (10.7%) of the controls ($p<0.001$). In multivariate survival analysis, both sarcoidosis and pulmonary hypertension were found to be significantly associated with increased risk to all-cause mortality (HR 1.83, 95% CI 1.66–2.02 and HR 2.32, 95% CI 2.05–2.63, respectively).

Conclusions: Sarcoidosis-associated pulmonary hypertension is associated with poor prognosis. Proper screening methods are recommended to assess whether early identification and treatment may improve life expectancy.

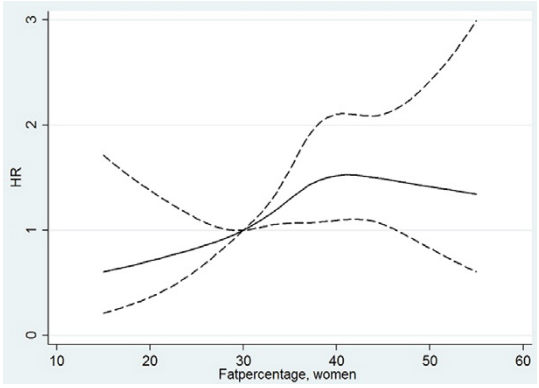
OP0079 BODY FAT PERCENTAGE AND WAIST CIRCUMFERENCE WERE ASSOCIATED WITH THE DEVELOPMENT OF RHEUMATOID ARTHRITIS – A DANISH FOLLOW-UP STUDY



A. Linauskas[1], A.L. de Thurah[1], K. Overvad[2], M.B. Johansen[3], K. Stengaard-Pedersen[1]. *[1]Department of Rheumatology, Aarhus University Hospital; [2]Depatment of Public Health, Section of Epidemiology, Aarhus University, Aarhus; [3]Unit of Clinical Biostatistics, Aalborg Univeristy Hospital, Aalborg, Denmark*

Background: Several studies have investigated the association between overweight and the development of rheumatoid arthritis (RA) and have come out with conflicting results. Body Mass Index (BMI) has been the preferred surrogate measure for overweight in these studies. However, BMI correlates only modestly with total amount of body fat and does not reflect fat distribution.
Objectives: To investigate the association between BMI, waist circumference, bio-impedance-derived total body fat percentage and the incidence of RA.
Methods: A population-based cohort study conducted within the Danish Diet, Cancer and Health cohort, which included individuals aged 50 to 64 years at the recruitment in the period between 1993 and 1997. Body fat composition measurements and data on lifestyle factors were collected at the enrolment into the cohort. The participants who subsequently developed RA were identified via linkage to The Danish National Patient Registry. The participants were followed until development of RA, death, loss to follow-up or October 2016, whichever came first. Data were analyzed by Cox proportional hazards regression model with delayed entry and age as the underlying time variable. Analyses were stratified by gender. Cox regression analyses with restricted cubic spline were carried out to elucidate the dose-response association between anthropometric measures and risk of RA. Smoking, socio-economic status, alcohol consumption, physical activity and intake of n-3 fatty acids were included in multivariate analyses as potential confounders.

Table 1. Cox proportional hazard ratios for association between body composition measurements and incidence of RA

Variable	Hazard ratio (95% confidence interval)) Multivariable adjusted*	
	Men	Women
BMI <18.5 kg/m^2	N/A	0.86 (0.21 -3.48)
BMI 18.5–24.99 kg/m^2	1 (ref)	1 (ref)
BMI 25–29.99 kg/m^2	0.83 (0.55–1.24)	1.48 (1.14 – 1.91)
BMI >30 kg/m^2	0.69 (0.37–1.30)	1.54 (1.09 – 2.17)
Abdominal obesity (waist circumference >102 cm for men, >88 cm for women)		
No	1 (ref)	1 (ref)
Yes	1.16 (0.75–1.80)	1.24 (0.96–1.61)
	Hazard ratio (95% confidence interval) per 1% increment of body fat Multivariable adjusted*	
	Men	Women
Fat percentage	0.99 (0.96–1.03)	1.03 (1.01–1.05)

*Adjusted for age, smoking status, total tobacco consumption (g/day), smoking duration, alcohol consumption (g/day), socio-economic status, physical activity (Metabolic Equivalent of Task, MET), total intake of n-3 fatty acids.

Results: Data were available on 54 284 subjects (52% female). During follow-up (median 21 years), 283 women and 110 men developed RA. The median (IQR) time to onset of RA was 7 (4–11) years. The adjusted hazard ratio's (HR) for developing RA are presented in Table 1. Restricted cubic spline analysis of body fat percentage displayed a positive slope in women (Image). There was no linear association between amount of fat and incidence of RA among men.
Conclusions: Overweight and obesity, defined by BMI, abdominal obesity and higher body fat percentage, especially above 30%, were in women associated with a higher risk for the development of RA. In men the associations were not consistent.

OP0080 RISK OF AUTISM SPECTRUM DISORDER IN CHILDREN BORN TO MOTHERS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND RHEUMATOID ARTHRITIS IN TAIWAN

P.-H. Tsai, C.-F. Kuo, L.-H. Huang, S.-F. Luo. *Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, Province of China*

Background: There is emerging evidence suggesting that offspring born to patients with rheumatic diseases has higher risk of neuropsychiatric diseases. Previous data from Quebec showed children born to women with SLE have an increased risk of autism spectrum disorder (ASD) but data regarding risk of ASD in offspring of mothers with systemic lupus erythematosus (SLE) or rheumatoid arthritis (RA) mothers have not been reported in other population.
Objectives: We aimed to examine whether offspring of mothers with SLE and RA in Taiwan has a higher risk of developing ASD using data from a linkage between National Health Insurance (NHI) database and National Birth Registry in Taiwan.
Methods: We established a birth cohort of all live-births between 2001 and 2012 in Taiwan established using the National Health Insurance database and the National Birth Registry. Children born to mothers with SLE or RA were identified and matched up to 8 controls by maternal age, 1-minute Apgar score, 5-minute Apgar score, mode of delivery, sex of child, gestational age, birth weight, socioeconomic status (place of residence, income level, occupation). A marginal Cox proportional hazard models were used to estimate the relative risk (RR; 95% confidence interval [CI]) for ASD in newborns with affected mothers.
Results: Of 1,893,244 newborns, 0.08% (n=1,594) were born to mothers with SLE (mean age 30.43±4.37 years old) and 0.04% (n=673) were born to mothers with RA (31.97±4.51 years old). Overall, 5 of 673 (0.74%) RA offspring developed ASD, 7 of 1594 (0.44%) SLE offspring developed ASD and 10,631 of 1,893,244 (0.56%) all infants developed ASD. The incidence of ASD was 140.39 (95% CI, 45.58–327.62) per 100,000 person-years for RA group, 76.19 (95% CI, 30.63–156.97) per 100,000 person-years for SLE group, 89.85 (95% CI, 88.15–91.57) per 100,000 person-years for non-RA group and 89.87 (95% CI, 88.17–91.60) per 100,000 person-years for non-SLE group. The children born to RA and SLE mothers did not have higher risk of ASD with a HR (95% CI) of 1.42 (0.60–3.40) and 0.76 (0.36–1.59) for ASD, respectively.
Conclusions: Children born to women with SLE and RA do not have higher risk of developing ASD.

Scleroderma, myositis and related ethology

OP0081 PAN-PPAR AGONIST IVA337 IS EFFECTIVE IN THE PREVENTION OF EXPERIMENTAL LUNG FIBROSIS AND PULMONARY HYPERTENSION

J. Avouac[1], I. Konstantinova[2], C. Guignabert[3], J. Sadoine[4], G. Thomas[5], S. Pezet[5], A. Cauvet[5], L. Tu[3], J.M. Luccarini[2], J.L. Junien[2], P. Broqua[2], Y. Allanore[1]. [1]*Rheumatology A and INSERMU1016, Paris Descartes University, Cochin Hospital, Paris;* [2]*Inventiva, Daix;* [3]*INSERM UMR_s 999, le Plessis Robinson;* [4]*Université Paris Descartes, Montrouge;* [5]*INSERM U1016, Paris, France*

Background: Peroxisome proliferator-activated receptors (PPARs) are nuclear receptors known to modulate fibrosis. The pan-PPAR agonist IVA337 recently demonstrated efficacy in prevention and treatment of experimental skin fibrosis [1].
Objectives: Our objective was to evaluate the antifibrotic effects of IVA337 in preclinical mouse models of pulmonary fibrosis and related pulmonary hypertension (PH).
Methods: IVA337 has been evaluated in the mouse model of bleomycin-induced pulmonary fibrosis and in Fra-2 transgenic mice, this latter being characterized by non-specific interstitial pneumonia and severe vascular remodeling of pulmonary arteries leading to PH. Mice received 2 doses of IVA337 (30 mg/kg or 100 mg/kg) or vehicle administered by daily oral gavage up to 4 weeks.
Results: Both 30 mg/kg and 100 mg/kg doses of IVA337 were well tolerated in all mouse models.
IVA337 demonstrated at a dose of 100 mg/kg a marked protection from the development of lung fibrosis induced by bleomycin compared to mice receiving 30 mg/kg of IVA337 or vehicle. Indeed, IVA337 (100 mg/kg) strongly reduced by 61% and 28% tissue density on histological measurements and total lung hydroxyproline concentrations, respectively, as compared to vehicle. IVA337 at 100 mg/kg also significantly decreased col1, col3 and fibronectin in lesional lungs.
Similarly, Fra-2 transgenic mice treated with 100 mg/kg of IVA337 displayed reduced lung density (20% *vs.* vehicle) and significant increase of functional residual capacity (30% *vs.* vehicle) when assessed by chest micro-CT imaging. These results were emphasized by a 50% reduction of the Ascroft fibrosis score (Figure 1A) and by a 48% reduction of hydroxyproline concentrations upon IVA337 (100 mg/kg) compared to vehicle treated mice.
Successful targeting of the TGF-b signaling axis was observed in both mouse models upon treatment with 100 mg/kg of IVA337. 100 mg/kg IVA337 also significantly reduced T cell and B cell infiltration in lesional lungs of Fra-2 transgenic mice.
Regarding vessel remodeling and related pulmonary hypertension, treatment with 100 mg/kg of IVA337 led to a substantial attenuation of right ventricular systolic pressure and right ventricular hypertrophy compared to mice receiving the vehicle (Figure 1B and 1C). Furthermore, IVA337 given at 100 mg/kg markedly reduced medial wall thickness (Figure 1D) and the number of muscularized distal pulmonary arteries.
In vitro in primary human lung fibroblasts, IVA337 inhibited in a dose-dependent manner TGFβ-mediated fibroblasts to myofibroblasts transition and PDGF-mediated proliferation.

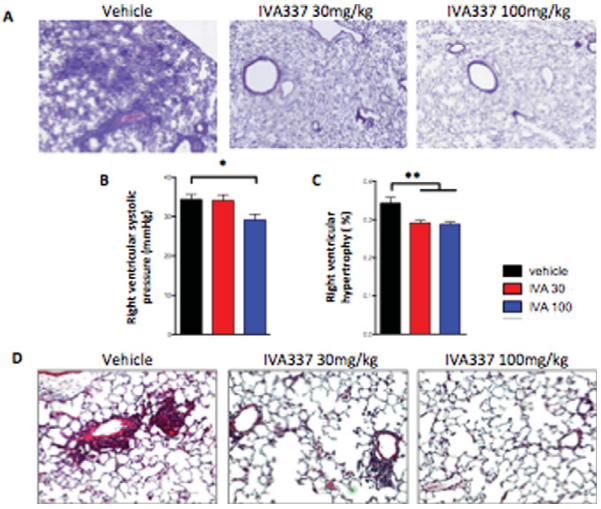

Figure 1

Conclusions: We demonstrate that treatment with 100 mg/kg IVA337 prevents lung fibrosis in two complementary animal models and substantially attenuates PH in the Fra-2 mouse model. These findings confirm that the pan-PPAR agonist IVA337 is an appealing therapeutic candidate for systemic sclerosis both, for skin and key cardiovascular complications.

OP0082 FIBROSIS AND MICROANGIOPATHY ARE THE MAIN HISTOPATHOLOGICAL HALLMARKS OF SCLERODERMA-RELATED MYOPATHY

C. Corallo[1], M. Cutolo[2], S. Soldano[2], N. Volpi[1], D. Franci[1], A. Montella[1], C. Chirico[1], R. Nuti[1], N. Giordano[1]. *[1]Medicine, Surgery and Neurosciences, University of Siena, Siena; [2]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, Genoa, Italy*

Background: Systemic sclerosis (scleroderma, SSc) is an autoimmune connective tissue disease characterized by skin and internal organ fibrosis, coupled with widespread vascular pathology. Skeletal muscle involvement in SSc has often been considered as a minor component of the disease associated with disuse.
Objectives: The goal of this study is to identify specific histopathological hallmarks of skeletal muscle involvement in SSc.
Methods: A total of 50 SSc patients presenting clinical, serological and electromyographic (EMG) features of muscle weakness, were enrolled. Patients underwent vastus lateralis biopsy, assessed for individual pathologic features including fibrosis [type I collagen (Coll-I), transforming growth factor β (TGF-β)], microangiopathy [cluster of differentiation 31 (CD31), pro-angiogenic vascular endothelial growth factor A (VEGF-A), anti-angiogenic VEGF-A165b], immune/inflammatory response [CD4, CD8, CD20, human leucocyte antigens ABC (HLA-ABC)], and membranolytic attack complex (MAC). SSc biopsies were compared to biopsies of (n =50) idiopathic inflammatory myopathies (IIMs) and to (n =50) noninflammatory myopathies (NIMs). Ultrastructural abnormalities of SSc myopathy were also analyzed by transmission electron microscopy (TEM).
Results: Fibrosis in SSc myopathy (90%) is higher compared to IIM (30%, p <0.05) and to NIM (15%, p <0.05). Vascular involvement is dominant in SSc muscle (95%), and in IIM (75%) compared to NIM (20%, p <0.05). In particular, CD31 shows loss of endomysial vessels in SSc myopathy with respect to IIM (p <0.05) and to NIM (p <0.01). VEGF-A is downregulated in SSc myopathy compared to IIM (p <0.05) and to NIM (p <0.05), while VEGF-A165b is upregulated in SSc myopathy. The SSc immune/inflammatory response suggested humoral process with majority (80%) HLA-ABC fibral neoexpression and complement deposits on endomysial capillaries MAC, compared to IIM (p <0.05), characterized by CD4+/CD8+/B-cell infiltrate, and to NIM (p <0.05). TEM analysis showed SSc vascular alterations consisting of thickening and lamination of basement membrane and endothelial cell 'swelling' coupled to endomysial/perimysial fibrosis.
Conclusions: The predominat features of SSc-related myopathy are fibrosis, microangiopathy and humoral immunity. However, it is difficult to identify specific histopathological hallmarks of muscle involvement in SSc, since they could be present also in other (IIM/NIM) myopathies.

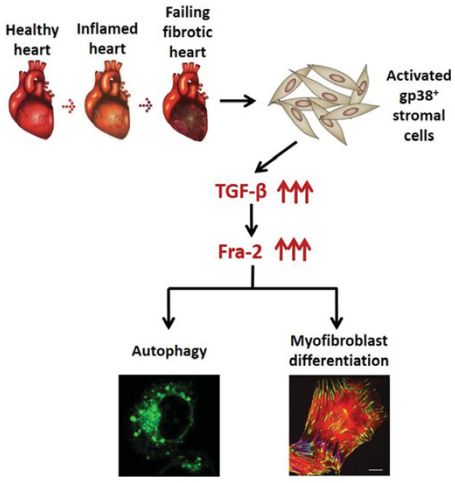
OP0083 MOLECULAR TARGETED IMAGING BIOMARKERS FOR PERSONALIZED MEDICINE STRATEGIES IN SYSTEMIC SCLEROSIS-RELATED INTERSTITIAL LUNG DISEASE

J. Schniering[1], M. Benešová[2], M. Brunner[1], C. Feghali-Bostwick[3], R. Schibli[2], O. Distler[1], C. Müller[2], B. Maurer[1]. *[1]Department of Rheumatology, University Hospital Zurich, Zurich; [2]Center for Radiopharmaceutical Sciences, Paul Scherrer Insitute, Villigen-PSI, Switzerland; [3]Division of Rheumatology & Immunology, Medical University of South Carolina, Charleston, SC, United States*



Background: Interstitial lung disease (ILD) is a life-threatening complication in systemic sclerosis (SSc). Substantial research progress has identified distinct genomic and molecular subtypes in SSc-ILD and brought molecular targeted therapies within reach. However, personalized medicine approaches are still lacking since clinically applicable tools for individualized patient stratification are not yet available.
Objectives: To assess the possibility of imaging molecular targets as a biomarker for stage-dependent assessment of ILD in the mouse model of bleomycin-induced lung fibrosis.
Methods: Expression of integrin $\alpha_v\beta_3$ and folate receptor β (FR-β) was analyzed in lung tissues from patients with idiopathic pulmonary fibrosis (IPF), SSc-ILD, and healthy controls as well as from bleomycin treated mice and saline treated controls using immunohistochemistry and qPCR (n=5–11). SPECT (Single Photon Emission Computed Tomography) or PET (Positron Emission Tomography) was performed at days 3, 7, and 14 after bleomycin instillation using the integrin $\alpha_v\beta_3$-specific ^{177}Lu-c(RGDfK)-ligand and the FR-β-specific ^{18}F-Azafol. Additionally, ^{18}F-FDG-PET and high resolution CT (HRCT) scans were performed. The specific lung uptake of the radiotracers over time was assessed by *ex vivo* SPECT or PET/CT scans and biodistribution studies.
Results: Expression of FR-β was significantly increased at the mRNA and protein level of SSc-ILD patients as compared to healthy subjects (p<0.05), whereas only its gene expression was upregulated in IPF patients (p<0.01). Integrin $\alpha_v\beta_3$ was increased at the protein level of both SSc-ILD and IPF patients (p<0.05), while its mRNA expression was not significantly altered.
Similarly, in lungs of bleomycin treated mice, but not of controls, FR-β expression was increased time-dependently at the mRNA and protein level with higher expression at day 3 and day 7, the inflammatory stages of bleomycin-induced lung fibrosis (p<0.05). In contrast, expression of integrin $\alpha_v\beta_3$ was upregulated at day 7 and day 14 at the protein, but not at the mRNA level in bleomycin treated mice, and thus not only in the inflammatory but also in the fibrotic stages (p<0.05). ^{18}F-FDG-PET and HRCT detected time-dependent changes of metabolic activity and ILD morphology in bleomycin treated mice. However, compared with these routinely employed unselective imaging techniques, molecular targeted imaging of integrin $\alpha_v\beta_3$ and FR-β successfully visualized ILD and discriminated lung inflammation and/or fibrosis in a time-dependent manner and in correspondence with the expression changes at the tissue level. The specific lung uptake of ^{177}Lu-c(RGDfK)-ligand and ^{18}F-Azafol as compared with the unspecific uptake of ^{18}F-FDG in diseased lungs over time was demonstrated by biodistribution studies and *ex vivo* SPECT or PET/CT scans.
Conclusions: Our data suggest that stage-dependent visualization of ILD with radiotracers that target key markers of lung inflammation and/or fibrosis shows promise for clinical application. As opposed to unselective imaging techniques such as ^{18}F-FDG-PET and HRCT, the introduction of specific imaging biomarkers for individualized management of SSc-ILD patients could represent the first step towards precision medicine.

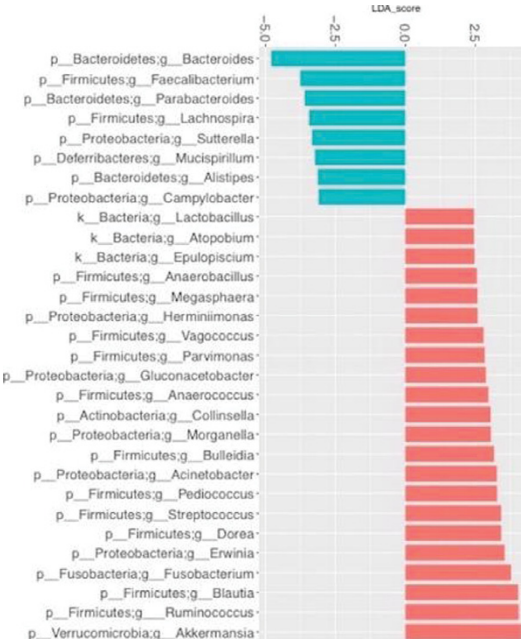
OP0084 RESCUE FROM THE FAILING HEART IN SYSTEMIC SCLEROSIS, A NOVEL INSIGHT: TARGETING TGF-β/FRA2-DEPENDENT AUTOPHAGY

M. Stellato[1], M. Rudnik[1], F. Renoux[1], E. Pachera[1], D. Kayalar[1], K. Sotlar[2], K. Klingel[3], J. Henes[4], P. Blyszczuk[5], O. Distler[1], G. Kania[1]. *[1]Department of Rheumatology, University Hospital, Zurich, Switzerland; [2]Institute of Pathology, Ludwig Maximilians University, Munich; [3]Department of Molecular Pathology; [4]Division of Rheumatology, University Hospital, Tubingen, Germany; [5]Department of Clinical Immunology, Jagiellonian University Medical College, Krakow, Poland*

Background: The majority of Systemic Sclerosis (SSc) patients have subclinical primary cardiac involvement, which resembles the inflammatory dilated cardiomyopathy (iDCM) with inflammation and fibrosis. Firstly, cellular progenitors of pathological myofibroblasts remain undescribed.
Secondly, autophagy may favor fibrosis through enhanced differentiation of fibroblasts in myofibroblasts
Objectives: To unravel the role of Fos-related antigen 2 (Fra2)/autophagy crosstalk in TGF-β-driven myocardial fibrosis in SSc
Methods: Genetically modified mice overexpressing Fra2 were used. Endomyocardial biopsies (EMBs) from SSc/iDCM patients and hearts from Fra2 tg and control mice were analysed by immunohistochemistry (IHC) and immunofluorescence (IF). Murine myocardial gp38$^+$ (podoplanin$^+$) stromal cells were sorted and stimulated *in vitro* with TGF-β. The cellular phenotype was assessed by qPCR, IF, stress fiber staining, SIRCOL and contraction assay on sorted cells. The antisense oligonucleotide GapmeR was used to knock-down Fra2
Results: The myocardium of SSc/iDCM patients (n=10) showed the typical phenotype of iDCM: increased fibrotic area with extended collagen deposition and enlarged number of pathological myofibroblasts, expressing Fra2 and, interestingly, the autophagy markers LC3B and Atg5. Similarly, Fra2 tg mice showed higher expression of profibrotic markers: αSMA, vimentin and collagen I compared to control mice (n=5), as well as the expression of the autophagy markers LC3B and Beclin in fibrotic regions.
Among cardiac stromal cells (Ter119$^-$CD45$^-$CD31$^-$Sca1$^+$CD29$^+$) the frequency of gp38$^+$ cells was significantly higher in Fra2 myocardium compared to control mice. The majority of gp38$^+$ cells co-expressed αSMA, vimentin and collagen I together with autophagy markers (LC3B and Beclin, n=3). Following *in vitro* stimulation with TGF-β, gp38$^+$ cells entered fibroblast-to-myofibroblast transition characterized by increased mRNA and protein levels of αSMA, collagen I, fibronectin (n=3–6), αSMA-fiber and stress-fiber formation (n=3), increased cell proliferation (n=4; p=0.04) and contraction capability (n=2; p<0.05) and enhanced collagen secretion (n=3; p=0.04). Importantly, Fra2 tg gp38$^+$ cells showed the presence of αSMA and stress fibers even without TGF-β stimulation as well as an increased contraction capability compared to control cells.
TGF-β stimulation of control gp38$^+$ cells induced the expression of LC3B, Beclin and Atg5 at mRNA and protein level (n=3–5). In contrast, TGF-β inhibition caused the downregulation of these markers (n=3).
In addition, Fra2 silencing resulted in a decreased differentiation capability of

gp38+ cells: mRNA and protein levels of the profibrotic genes αSMA and collagen I were significantly downregulated (n=5; p=0.007). Moreover, Fra2 downregulation impaired the secretion of collagens (n=4; $p<0.05$) and the formation of αSMA fibers (n=3) in addition to a significant downregulation of mRNA and protein expression of LC3B, Beclin and Atg5 (n=3)



Conclusions: The TGF-β/Fra2 axis fosters an enhanced autophagy flow, leading in turn to the stromal-to-myofibroblast transition. Therefore, targeting this process might be a therapeutic strategy to abrogate fatal cardiac remodeling in SSc

OP0085 LONGITUDINAL ANALYSIS OF THE GASTROINTESTINAL MICROBIOTA IN SYSTEMIC SCLEROSIS

E.R. Volkmann[1], A.-M. Hoffmann-Vold[2], Y.-L. Chang[1], J. Jacobs[1], K. Tillisch[1], E. Mayer[1], P.J. Clements[1], J. Hov[2], M. Kummen[2], Ø. Midtvedt[2], V. Lagishetty[1], Ø. Molberg[2], J. Braun[1]. *[1]University of California, Los Angeles, Los Angeles, United States; [2]Oslo University Hospital, Oslo, Norway*

Background: Gastrointestinal tract (GIT) dysfunction affects the majority of patients with systemic sclerosis (SSc). While the etiology of SSc-related lower GIT dysfunction remains elusive, we have recently demonstrated that the SSc disease state is associated with a distinct colonic microbial consortium and that specific genera are associated with SSc-GIT symptoms in a cross-sectional analysis using colonic lavage specimens.[1]
Objectives: To evaluate changes in GIT microbial composition over time in relation to GIT symptoms in SSc patients.
Methods: Adults SSc patients not on chronic antibiotic therapy were eligible to participate. Stool specimens were collected at 0, 3, 6, 9, and 12 months. Healthy controls were matched to SSc patients in a 1:1 ratio at baseline. SSc patients completed the GIT 2.0 questionnaire to assess GIT symptom severity at each collection time. The microbiota from these samples were determined by Illumina HiSeq 2500 16S sequencing. Linear Discriminant Analysis Effect Size was used to identify the genera that showed differential expression in SSc versus controls. Mixed models evaluated changes in GIT symptoms and microbial composition over time.
Results: Among 17 patients with SSc (88% Female; Median age 52.1 years), the mean (SD) baseline total GIT 2.0 score was 0.7 (0.6). The majority of participants (71%) provided at least 4 stool samples over the course of the 12-month study. Principal coordinate analysis illustrated significant microbial community differences in SSc versus healthy controls (p=0.001). Consistent with the results of our prior study using colonic lavage specimens,[1] SSc patients had decreased commensal genera, such as *Faecalibacterium* and *Bacteroides* and increased pathobiont genera, such as *Fusobacterium* and *Erwinia* compared with healthy controls (Figure 1). GIT 2.0 scores did not change significantly over the course of the 12-month study for each subject. However, patients with longer disease durations had increased GIT symptoms over time for the total score (P=0.0038), and the following domains: fecal soilage (P=0.0217), social functioning (P=0.0116), emotional well-being (P=0.0474), and constipation (P=0.0039). There was no difference in the course of GIT symptoms over time between patients with limited versus diffuse cutaneous disease. Both the absolute and relative abundances of specific genera did not change over time within individual subjects. After controlling for age, gender, ethnicity, disease duration and SSc subtype (i.e. limited vs. diffuse), low abundance of *Bacteroides* was associated with increased GIT symptoms over time.
Figure 1. Genus level taxa associated with UCLA-SSc patients versus healthy subjects. Negative and positive effect sizes denote genera decreased (blue) or increased (red) in SSc patients, respectively.

Conclusions: This study is the first to characterize lower GIT microbiota in SSc patients at multiple time points. The findings provide further evidence that lower GIT dysbiosis is a feature of the SSc disease state and that specific genera may contribute to GIT symptoms and serve as potential targets for therapeutic intervention.

OP0086 LONG NONCODING RNA H19X AS A NEW THERAPEUTIC TARGET FOR FIBROSIS

E. Pachera[1], A. Wunderlin[1], S. Assassi[2], G. Salazar[2], M. Frank-Bertoncelj[1], R. Dobrota[1], M. Brock[3], C. Feghali-Bostwick[4], G. Gerhard Rogler[5], G. Dijkstra[6], T. van Haaften[5], J. Distler[7], G. Kania[1], O. Distler[1]. *[1]Center of Experimental Rheumatology, University Hospital Zurich, Zurich, Switzerland; [2]Department of Internal Medicine, University of Texas, Houston, United States; [3]Department of Pulmonology, University Hospital Zurich, Zurich, Switzerland; [4]Division of Rheumatology, Medical University of South Carolina, Charleston, United States; [5]Department of Gastroenterology and Hepatology, University Hospital Zurich, Zurich, Switzerland; [6]Department of Gastroenterology and Hepatology, University Medical Center Groningen, Groningen, Netherlands; [7]Department of Internal Medicine 3, University of Erlangen, Erlangen, Germany*

Background: Long noncoding RNAs (lncRNAs) are an emerging class of transcripts involved in the regulation of gene expression. We have recently identified a novel lncRNA, H19X, to be upregulated in systemic sclerosis (SSc). We also demonstrated that H19X is a key mediator of TGFβ-driven myofibroblast development and extracellular matrix synthesis.
Objectives: To assess whether (1) H19X upregulation in SSc fibroblast is anti-apoptotic and pro-proliferative thereby favoring fibrosis (2) H19X is a regulator of fibrotic diseases in general.
Methods: To study the function of H19X in apoptosis and proliferation of of dermal fibroblasts we silenced H19X using locked nucleic acid oligonucleotides (LNA GapmeRs followed by microarray analysis, qPCR, BrdU cell proliferation assay, Caspase 3/7 apoptosis assay and scratch assay. Cells were treated with 10 ng/ml TGFβ. Lung tissues were obtained from patients with SSc and idiopathic pulmonary fibrosis (IPF) undergoing transplantation, and from healthy controls (HC). Resected gut tissue from fibrotic and non-fibrotic areas was obtained from Crohn's disease patients. Non-cancer-affected gut tissue from resections because of adenocarcinoma was used as control. Expression of H19X was analyzed by quantitative (q)PCR.
Results: H19X knockdown followed by microarray analysis (n=5) showed that FAS signaling pathway, cyclins and cell cycle regulation, regulation of cell cycle progression by Plk3, and free radical induced apoptosis were among the

pathways with the highest number of significantly enriched genes (n=5; $p<0.005$). Apoptosis markers like BCL2, IGFBP3 and FAF1 (n=5, $p<0.05$) were upregulated in H19X-silenced fibroblasts. This indicated that targeting H19X might have a pro-apoptotic effect on fibroblasts thereby protecting from fibrosis. Functional studies showed enhanced fibroblast apoptosis after H19X silencing and TGFβ stimulation (n=5, $p<0.05$). In addition to decreased apoptosis, increased fibroblast proliferation might also favor fibrosis. Indeed, H19X downregulation led to reduced cell proliferation as measured by BrdU assay (n=5, $p<0.05$). Scratch assay (n=5) showed that H19X knockdown decreases TGFβ reduced wound healing. H19X expression was significantly increased in SSc interstitial lung disease and IPF patients versus HC (n=11 each, $p<0.05$). A significant H19X overexpression was also detected in fibrotic tissue from Crohn's disease patients (n=4–10, $p<0.05$).

Conclusions: H19X supports TGFβ driven fibrosis not only by favoring myofibroblast development and extracellular matrix synthesis, but also by inducing proliferation and reducing apoptosis of dermal fibroblasts. These effects are not limited to SSc, but appear operative in a wider range of fibrotic diseases. Our results highlight the lncRNA H19X as a potent new therapeutic target in fibrotic diseases opening thereby new possibilities for the treatment of TGFβ driven fibrosis.

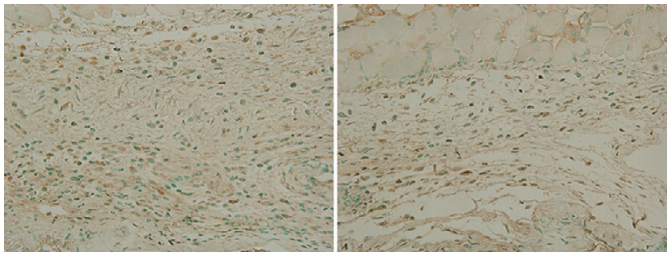
OP0087 PLATELET-SPECIFIC FLI1-KNOCKOUT MICE SHOW ACCELERATED WOUND CLOSURE ASSOCIATED WITH INCREASED MYOFIBROBLAST FORMATION IN THE INFLAMMATORY PHASE



M. Hirabayashi, Y. Asano, T. Yamashita, R. Saigusa, S. Miura, K. Nakamura, T. Miyagawa, Y. Ichimura, T. Taniguchi, A. Yoshizaki, S. Sato. *Dermatology, University of Tokyo, Graduate School of Medicine, Tokyo, Japan*

Background: Systemic sclerosis (SSc) is a systemic connective tissue disease characterised by autoimmunity, vascular disorder and fibrosis of skin and other organs (1). Although substantial reports have been hitherto provided upon its pathogenesis in relation to microvasculature, among which are on endothelial and fibroblastic Fli1 deficiencies (1, 2), adequate investigation into hemocytic involvement is yet to be attained. Platelets are well known for its function in hematostasis whereas they also play a part in inflammation, immunity and cellular proliferation (3), thus prompting us to speculate their cardinal role in the development of the disease.

Objectives: Here we aim to unravel the role of platelets in the pathogenesis of SSc, with generation of platelet-specific conditional *Fli1* knockout (*Fli1* PcKO) mice to scrutinise its dermal wound healing process.

Methods: We generated *Fli1* PcKO mice using the Cre-Lox system along with *PfCre* +/- mice as an appropriate control. We made two excisional wounds on the dorsal skin of each mouse (three months old) using an eight-millimeter-diameter punch and traced the wound surfaces every other day to measure their areas using Image J until all the wounds were epithelised. On a separate experiment, perilesional skin was harvested on the day two, from which we extracted mRNA for the measurement of proinflammatory and profibrotic cytokines. An immunostaining for α-SMA was performed on the skin samples.

Results: The areas of the wounds were calculated and shown in ratio to their initial areas (day 0). *Fli1* PcKO mice showed a significant decrease in the areas compared to the control on day 2. mRNA measurement revealed a significant increase in *Mmp13* and significant decreases in *Tgfb1*, *Ifng* and *Il13* for *Fli1* PcKO. In histopathology, α-SMA positive fusiform-shaped cells were abundant in the granulation tissue of *Fli1* PcKO mice (Figure; left, *PfCre* +/-; right, *Fli1* PcKO; original magnification, ×400).

Conclusions: In dermal injuries on *Fli1* PcKO mice, inflammatory disturbances precipitate myofibroblast formation in the granulation tissue, thus anticipating wound closure by mechanical contraction.

OP0088 THE ROLE AND FUNCTION OF MONOCYTE-DERIVED FIBROBLAST-LIKE CELLS IN MULTI-ORGAN FIBROSIS IN SYSTEMIC SCLEROSIS

M. Rudnik[1], M. Stellato[1], V. Milleret[2], P. Błyszczuk[3], B. Maurer[1], K. Klingel[4], J. Henes[5], K. Sotlar[6], M. Ehrbar[2], O. Distler[1], G. Kania[1]. *[1]Department of Rheumatology; [2]Department of Obstetrics, Univeristy Hospital Zurich, Zurich, Switzerland; [3]Department of Clinical Immunology, Jagiellonian University Medical College, Krakow, Poland; [4]Department of Molecular Pathology; [5]Department of Rheumatology, University Hospital Tuebingen, Tuebingen; [6]Institute of Pathology, Ludwig Maximilian University, Munich, Germany*

Background: Animal studies indicated bone marrow-derived cells as a source of pathological myofibroblasts in multiple organ fibrosis such as lungs, heart, skin and kidney. Monocytes are implicated in the pathogenesis of systemic sclerosis (SSc), however detailed role of specific monocyte subsets in multi-organ fibrogenesis in SSc remains unclear.

Objectives: We aimed to determine the role and the contribution of circulating monocytes in the onset and progression of multi-organ fibrosis in SSc.

Methods: Endomyocardial biopsies (n=10) from SSc patients and healthy controls were screened by immunohistochemistry. $CD14^+$ monocytes isolated from peripheral blood of SSc patients and healthy donors were differentiated towards a myofibroblast phenotype by stimulation with TGF-β1, IL-4, IL-10 and IL-13. In addition, $CD14^+$ monocytes were co-cultured in 2D and 3D models with dermal fibroblasts originating from SSc patients or healthy subjects, or with adult cardiac fibroblasts. TGF-β signalling was blocked by SD208 and A83–01 inhibitors. Profibrotic gene expression and protein secretion were evaluated by qPCR, Western blot, protein array, immunofluorescence and ELISA.

Results: The myocardia of SSc patients revealed the presence of CD45-expressing infiltrates, an extended collagen I deposition and the presence of CD14-expressing elongated cells in the fibrotic tissue. Stimulated monocytes acquired a myofibroblast-like phenotype with increased expression of collagen I ($p<0.0001$), fibronectin ($p<0.05$), and α smooth muscle actin (α-SMA) in comparison to untreated cells. Similarly, $CD14^+$ monocytes exposed to dermal or cardiac fibroblasts acquired spindle shape and expressed higher levels of profibrotic genes. The process of monocyte-to-myofibroblast differentiation employed TGF-β/SMAD signalling. Blocking of the TGF-β receptor I and canonical SMAD-dependent pathway with inhibitors resulted in the abrogation of collagen I secretion by monocytes ($p=0.002$). $CD14^+$ monocytes from SSc patients were characterised by higher secretion of CXCL10 ($p<0.001$), which was significantly decreased after cytokine stimulation ($p<0.001$). Additionally, a tendency towards higher secretion of CCL20, CCL22, Leukemia Inhibitory Factor and neurotrophin-3 was observed for SSc monocytes.

Conclusions: Here we demonstrated the capability of peripheral blood monocytes to differentiate towards the functional myofibroblast phenotype, designating these cells as one of the potential sources of pathological tissue myofibroblasts in SSc. Additionally, these cells sustained pro-fibrotic cytokines secretion, highlighting their important regulatory functions in the fibrogenesis in SSc. Further studies of monocytes involvement in SSc might lead to novel treatment strategies.

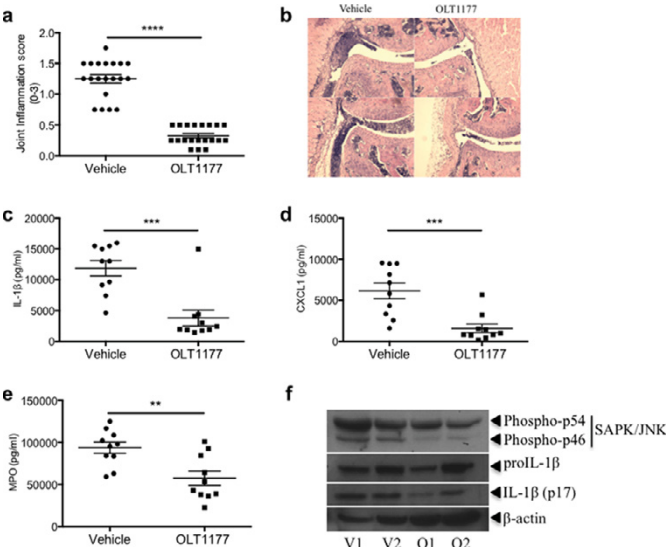
Novel insights in inflammatory mediators

OP0089 COMBINATION THERAPY OF SELECTIVE MMP9 AND TNF INHIBITORS ARE EFFICACIOUS IN THE MOUSE CIA MODEL OF RHEUMATOID ARTHRITIS



S. Kim, B. Carr, L. Tong, D. Jin, R. Wang, D. Marshall, D. Gossage, V. Smith.
Gilead sciences, Inc., Foster city, United States

Background: Matrix metalloproteinase-9 (MMP9) is highly expressed by infiltrating inflammatory cells, pannus tissue, and multinucleated cells in the synovium and subchondral bone tissue, including osteoclasts. MMP9 is implicated in rheumatoid arthritis (RA) by its involvement in joint destruction, activation of cytokines and chemokines, and promotion of tissue destruction by degrading the basement membrane of epithelia and vasculature. MMP9 knockout mice are protected from collagen-induced arthritis (CIA) disease progression. A potent, allosteric antibody inhibitor of MMP9 is currently being investigated in clinical trials. The ability of a functional murine analog of this antibody to reduce disease signs and symptoms in established, chronic mouse CIA model both as a single agent and in combination with anti-TNF, was investigated.
Objectives: We evaluated the efficacy and safety of selective MMP9 inhibition both alone and in combination with anti-TNF (etanercept), in CIA models of RA.
Methods: CIA was induced in male DBA/1J mice (n=15/group) and treatments were administered after disease establishment. Efficacy was assessed via metrics of joint injury including clinical score (erythema/ paw swelling, score 0–4) in addition to histopathological assessment of destructive joint remodeling (soft tissue changes: edema, necrosis, inflammatory cell infiltration, and fibroplasia, sum score 0–16; bone changes: cartilage damage, bone erosion, periosteal bone formation, synovitis, pannus formation, and joint destruction, sum score 0–24).
Results: All animals were included in the evaluation. In all endpoints assessed, treatment with each therapeutic agent, on its own or in combination, resulted in improvement with respect to body weight change, clinical score, and histopathological measures. The combination group provided the best overall trend for therapeutic benefit, although statistical significance as compared to each single agent alone was not met in most parameters. Body weight recovery was superior in combination as compared to single agent therapies (52% vs. 12–34%, relative to sham; $p<0.05$ combination vs. single agents). Clinical score and histopathology measures in soft tissue and bone changes were most improved in the combination therapy group, although it did not achieve statistical significance as compared to each single agent (26% vs. 17–21%; 1.5 vs. 1.5–1.8; and 7 vs. 7–9, respectively). Importantly, combination therapy resulted in a significant number of limbs with zero or mild disease as compared to single agents (no disease sign: 256% vs. 172–223%; mild disease sign: 178% vs. 138–141%). Analysis of complete blood count at the end of study revealed no abnormalities in any treatment group.
Conclusions: Selective inhibition of MMP9 was active in reducing disease severity in CIA models of RA. The combination of anti-MMP9 with anti-TNF was well tolerated and increased the number of limbs with no or mild disease compared to anti-TNF alone. Further studies are required to examine combination therapy of selective anti-MMP9 and anti-TNF therapies in a clinical setting.

OP0090 THE HUMAN SAFE NLRP3 INFLAMMASOME INHIBITOR OLT1177 SUPPRESSES JOINT INFLAMMATION IN MURINE MODELS OF EXPERIMENTAL ARTHRITIS

C. Marchetti[1], B. Swartzwelter[1], M.I. Koenders[2], C.A. Dinarello[1], L.A. Joosten[3].
[1]Department of Medicine, University of Colorado, Aurora, United States; [2]Department of Rheumatology; [3]Department of Medicine, Radboud University Medical Center, Nijmegen, Netherlands

Background: NLRP3 is an essential component of the inflammasome, an intracellular macromolecular complex, which activates caspase-1 for the processing and release of active IL-1β and IL-18. Activation of the NLRP3 inflammasome takes place in inflammatory joint diseases, including gout. Although inhibition of IL-1β with either the IL-1 receptor antagonist anakinra or canakinumab, a neutralizing monoclonal antibody for IL-1β is highly effective for reducing the gout flares, a clinical need remains for a safe, oral treatment of recurrent gout flares refractory to standard of care. The small orally active and safe β-sulfonyl nitrile molecule OLT1177 is a specific inhibitor of the NLRP3 inflammasome, and currently being evaluated in a Phase 2 study for the treatment of acute gout flares.
Objectives: To investigate the anti-inflammatory effect of NLRP3 inflammasome inhibitor OLT1177 in mouse models of acute joint inflammation.
Methods: Two models of experimental arthritis were used in mice: zymosan- and monosodium urate (MSU)-induced arthritis. Knee joints of male C57BL/6 mice were injected intraarticularly with 180 μg heat-killed Zymosan or 300 μg of monosodium urate (MSU) crystals mixed with 200 μM C16.0 fatty acid and bovine serum albumin. Joints were assessed 24 and 4 hours after the zymosan or MSU/C16.0 injection, respectively, for clinical, histological and cytokine analyses.
Results: Intraarticular Zymosan induced a severe joint swelling with neutrophil infiltration, high levels of synovial IL-1β, IL-6 and the neutrophil chemokine CXCL1. Treatment with OLT1177 induced reduction of joint swelling and neutrophil infiltration ($P<0.0001$ and $P=0.006$ respectively) and suppression of IL-1β and IL-6 by 55% and CXCL1 by 30% compared to mice treated with the vehicle. Four hours following intra-articular injection of MSU crystals, an elevated clinical score for knee joint inflammation was observed in vehicle-treated mice (Fig. 1). Oral treatment with OLT1177 showed reduction in joint inflammation as depicted in Fig. 1a when compared to the vehicle group ($P<0.0001$). Histological analysis of the knee revealed suppression of the influx of inflammatory cells in the articular space with OLT1177 treatment ($P<0.05$; Fig. 1b). Treatment with OLT1177 showed significant reduction in synovial tissue extracts for IL-1β (69%; $P<0.001$; Fig. 1c); IL-6 (70%; $P<0.001$); CXCL1 (75%; $P<0.001$; Fig.1d) and MPO (39%; $P=0.006$; Fig. 1e). Mice were also treated with a single dose of OLT1177 1 hour after of intraarticular MSU and reduced joint swelling and IL-1β levels ($P<0.05$) were observed. OLT1177 treatment suppressed activation of the mitogen-activated protein kinases (MAPK) family, c-jun N-terminal kinase (JNK), which is implicated in the pathophysiology of rheumatoid arthritis and gout (Fig. 1f).

Conclusions: The orally active molecule OLT1177 is a potent inhibitor of IL-1β-driven inflammatory arthritis, particularly in a model of acute gout. Considering the outstanding safety profile in humans, OLT1177 is a potential therapeutic strategy to target NLRP3-driven IL-1β-mediated disorders.

OP0091 S100A8 TRIGGERS A NOVEL IMMUNE-REGULATORY MECHANISM IN DEVELOPING DENDRITIC CELLS

D. Popp[1], F. Rühle[2], W. de Jager[3], T. Vogl[1], J. Roth[1]. *[1]Institute of Immunology; [2]Institute of Human Genetics, Münster, Germany; [3]Multiplex Core Facility, Wilhelmina Children's Hospital (UMC Utrecht), Utrecht, Netherlands*

Background: S100A8/A9 heterodimers are well-known alarmins that, upon release from activated or necrotic phagocytes, promote inflammation by binding to Toll-like receptor 4 (TLR4). These proteins are highly expressed in synovial phagocytes during arthritis and proved to be reliable biomarkers for monitoring disease activity in RA. Interestingly, we now identify a novel immune-regulatory mechanism of S100A8 in human monocyte-derived dendritic cells (moDCs).
Objectives: This study aims to analyze immune-regulatory functions of S100 proteins in human DCs.
Methods: MoDCs are differentiated with or without exposure to S100A8 prior to maturation with LPS. After characterization of the activation status using flow cytometry, the ability of these cells to induce autologous $CD4^+$, $CD8^+$, and γδ T-cell proliferation is investigated. Cytokines, secreted during development are analyzed by Luminex cytokine arrays. The metabolic state of DCs is examined by using Seahorse XFp Analyzer assays. Finally, to identify molecular mechanisms leading to an immune-regulatory phenotype, the mRNA expression of moDCs is analyzed by genome-wide gene expression arrays.

Results: Our results demonstrate that early exposure to S100A8 interferes with *in-vitro* differentiation of moDCs. Compared to controls S100A8-exposed moDCs show dramatically reduced surface expression of co-stimulatory molecules upon LPS-induced maturation. In addition, early treatment of moDCs with S100A8 alters the secretion of immune-regulatory cytokines and chemokines depending on the developmental state of moDCs. S100A8-induced effects on moDC maturation are not limited to TLR4 stimulation but rather trigger a common state of unresponsiveness. Furthermore, mitochondrial respiration and glycolytic function is diminished in S100A8-treated moDCs.

As a consequence, S100A8-exposed moDCs have a reduced potential to induce autologous T-cell proliferation. We can show that these differences are mainly caused by reduced surface expression of co-stimulatory molecules on S100A8-treated moDCs.

Mechanistically, genome-wide gene expression analysis reveals dramatic differences in gene expression between S100A8-exposed and conventionally differentiated moDCs. We demonstrate that S100A8 pre-treatment of moDCs significantly blocks LPS-induced gene expression during moDC activation. Interestingly, *in-silico* analysis of transcription factor networks predicts NFκB and C/EBPδ as master regulators of S100A8-induced effects in developing moDCs. C/EBPδ on protein level, indeed, shows reduced expression in S100A8-differentiated moDCs prior and after LPS-induced maturation when compared to conventionally differentiated moDCs.

Conclusions: Taken together, our results demonstrate a novel regulatory mechanism of innate immunity to prevent overwhelming immune responses. Dysregulated repression of detrimental adaptive immune responses might very well contribute to the disease phenotype in auto-immune disorders with high systemic S100A8/A9 levels. Therefore, S100A8-differentiated immune-suppressive DCs potentially represent a promising therapeutic tool to treat auto-immune diseases in the future.

OP0092 INTERLEUKIN 37 REVERSES THE METABOLIC COST OF INFLAMMATION, INCREASES OXIDATIVE RESPIRATION AND IMPROVES EXERCISE TOLERANCE

G. Cavalli[1], D. Ballak[2], J.J. Justice[2], K. Boyle[3], A. D'Alessandro[3], L.A. Joosten[4], L. Dagna[1], C.A. Dinarello[5]. *[1]Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UniRAR), Vita-Salute San Raffaele University, Milan, Italy; [2]University of Colorado Boulder, Boulder, CO; [3]University of Colorado Denver, Aurora, CO, United States; [4]Radboud University Medical Center, Nijmegen, Netherlands; [5]Medicine, University of Colorado Denver, Aurora, CO, United States*

Background: The IL-1 family cytokine interleukin 37 (IL-37) has broad anti-inflammatory effects and functions as a natural suppressor of innate inflammation and acquired immunity (1). We have reported that administration of recombinant human IL-37 to wild type mice or expression in mice transgenic for human IL-37 suppress proinflammatory cytokines and curb excessive inflammation in various conditions including inflammatory arthritis (2). Besides these anti-inflammatory effects, IL-37 also induces complex effects on metabolism. In particular, IL-37 can directly activate AMP-activated protein kinase (AMPK), a central regulator of cellular energy homeostasis and exercise-regulated metabolism (3).

Objectives: In this study, we evaluate the effects of IL-37 treatment on exercise tolerance in mice with systemic inflammation induced by LPS injection. We further investigate the effects of IL-37 on exercise tolerance in healthy mice, with specific focus on the metabolic changes induced by IL-37 administration and possibly responsible for a reduction in the metabolic costs of inflammation.

Results: Exogenous administration of IL-37 to healthy mice, not subjected to an inflammatory challenge, also improved exercise performance by 82% compared to vehicle-treated mice (p=0.01). Treatment with 8 daily doses of IL-37 resulted in a further 326% increase in endurance running time compared to the performance level of mice receiving vehicle (p=0.001). These properties required the engagement of the IL-1 decoy receptor 8 (IL-1R8) and the activation of AMP-activated protein kinase (AMPK), since both inhibition of AMPK and IL-1R8 deficiency abrogated the positive effects of IL-37 on exercise performance. Mechanistically, treatment with IL-37 induced marked metabolic changes with higher levels of muscle AMPK, greater rates of oxygen consumption and increased oxidative phosphorylation. Metabolomic analyses of plasma and muscles of mice treated with IL-37 revealed an increase in AMP/ATP ratio, reduced levels of pro-inflammatory mediator succinate and oxidative stress-related metabolites as well as changes in amino acid and purine metabolism.

Conclusions: These effects of IL-37 to limit the metabolic costs of chronic inflammation and to foster exercise tolerance provide a rationale for therapeutic use of IL-37 in the treatment of inflammation-mediated fatigue.

OP0093 IL-38 OVEREXPRESSION INDUCES ANTI-INFLAMMATORY EFFECTS IN MICE ARTHRITIS MODELS AND IN HUMAN MACROPHAGES IN VITRO

M.-A. Boutet[1], A. Najm[2], G. Bart[2], R. Brion[1], S. Touchais[2], V. Trichet[1], P. Layrolle[1], C. Gabay[3], G. Palmer-Lourenco[3], F. Blanchard[1], B. Le Goff[2]. *[1]Inserm UMR957, Université de Nantes; [2]Rheumatology Unit, Nantes University Hospital, Nantes, France; [3]Department of pathology and immunology, University of Geneva school of medicine, Geneva, Switzerland*

Background: IL-38 is a newly characterized cytokine that belongs to the IL-1 family. This cytokine is expressed in the rheumatoid arthritis (RA) synovial tissue (1) and IL-38 deficient mice have exacerbated arthritis (2).

Objectives: This work aims to analyze the effect of IL-38 overexpression in the joints of arthritic mice, in human macrophages and synovial fibroblasts *in vitro*.

Methods: Articular injections of an adeno-associated virus (AAV2/8) encoding IL-38 were performed in Collagen-Induced Arthritis (CIA), K/BxN Serum Transfer-Induced Arthritis (STIA) and Antigen-Induced Arthritis (AIA) in mice. The effect of IL-38 overexpression was evaluated through clinical scores, immunohistochemistry, microCT, Luminex and RT-qPCR analysis. THP-1 monocytes/macrophages were transduced with a lentiviral vector to overexpress IL-38. Effect of conditioned media from these transduced THP-1 cells was also tested on primary culture: M1 macrophages and fibroblast-like synoviocytes from RA patients (RA-FLS).

Results: Clinical inflammatory scores were significantly decreased after AAV IL-38 injection in joints of mice with CIA and STIA, but not AIA. This decrease was accompanied by reduced macrophage infiltration and a decreased expression of Th17 expressed cytokines (IL-17, IL-23, IL-22, TNFα). However, IL-38 overexpression had no effect on cartilage or bone destruction. *In vitro*, the THP-1 monocytic cell line expressed less IL-6, TNFα and IL-23 after IL-38 overexpression. Conditioned media from these cells, containing released IL-38, was also able to exert an anti-inflammatory effect on human primary M1 macrophages and RA-FLS by reducing their IL-23 (M1) and IL-6 (M1 and RA-FLS) expression.

Conclusions: This study shows for the first time that IL-38 overexpression attenuates the severity of experimental arthritis in two mice arthritis models. IL-38 may exert its anti-inflammatory effects by decreasing the production of pro-inflammatory cytokines by macrophages and synovial fibroblasts. This effect can lead to the development of novel treatment strategies in arthritis.

OP0094 DEVELOPMENT OF A 37-CHANNEL MASS CYTOMETRY (CYTOF) PANEL TO PREDICT TREATMENT RESPONSE IN RHEUMATOID ARTHRITIS

B. Mulhearn[1,2,3], S. Viatte[3], T. Hussell[1], A. Barton[2,3]. *[1]Manchester Collaborative Centre for Inflammation Research (MCCIR), University of Manchester; [2]Kellgren Centre for Rheumatology, Central Manchester University Hospitals NHS Foundation Trust; [3]Centre for Musculoskeletal Research, Division of Musculoskeletal & Dermatological Sciences, University of Manchester, Manchester, United Kingdom*

Background: It is well-established that reducing the inflammation of rheumatoid arthritis (RA) early leads to improved patient outcomes. Patients who fail to respond to conventional DMARDs move on to biologic drugs, however 30% will fail to respond to the first drug tried. Biologics are trialled for at least 3 months before their efficacy can be assessed, during which time irreversible joint damage may occur.

Currently there is no way to predict which drug will be effective in individual patients. It is therefore a research priority to develop a method to predict response to each class of biologic drug. I hypothesise that the immune phenotype of a patient will influence treatment response.

Objectives: This study aims to immunophenotype T cells using mass cytometry and to test novel unbiased methods of analysing high-dimensional data.

Methods: Ten healthy controls (HC) and 10 RA patients with established disease were included. T cells were isolated and stimulated for 4 hours using anti-CD3/anti-CD28 beads in the presence of monensin and brefeldin A. Cells were stained with a 37-channel mass cytometry panel including surface markers, intracellular antigens and transcription factors.

Analysis was performed by conventional biaxial gating alongside tools available on the MRC Cytobank platform, namely Visual t-distributed stochastic neighbour embedding (viSNE), and Cluster identification, characterization, and regression (CITRUS). The CITRUS analysis compared stimulated HC with RA T cells. To

compare abundances of cell clusters, the association model Prediction Analysis for Microarrays (PAMR) was applied with a minimum cluster size of 2.2%, 5 cross-validation folds and a false discovery rate of 1%.

Results: Conventional biaxial gating showed that there were large differences in the proportions of both IFNγ^+ CD4 T cells (1–15%) and IL-17A$^+$ CD4 T cells (0–9%) within and between RA and HC. The proportion of IFNγ^+ CD4 T cells (Th1) did not correlate with that of IL-17A $^+$ T cells (Th17), leading to the generation of 4 immunophenotypes: "Th1", "Th17", "double-hi", and "low", determined by cytokine expression.

Using CITRUS we identified 3 clusters of cells which differed significantly in abundance between HC and RA. Cluster 1 was CD4$^+$CD38$^+$, had characteristics of regulatory T cells and was more abundant in HC. Cluster 2 was CD28^{low}CD8$^+$ expressing perforin and Tbet, and cluster 3 a CD127^{high}CCR6$^+$population, both of which were more abundant in RA.

Conclusions: Cytokine expression of *ex vivo* stimulated T cells from RA and HC is highly variable and can be detected using mass cytometry. Cytokine signatures of this kind may be informative when predicting treatment response.

CITRUS identified 3 cell clusters which may have been missed using conventional methods of analysis. Importantly, CITRUS allowed inspection of the phenotype of each cluster.

Our next step is to compare RA responders to non-responders using the methods described. The function of these clusters will be further investigated by cell isolation with fluorescence-activated cell sorting (FACS) and may go some way in predicting treatment response. Finally we recommend the use of both automated clustering algorithms alongside conventional gating methods when analysing high-dimensional data.

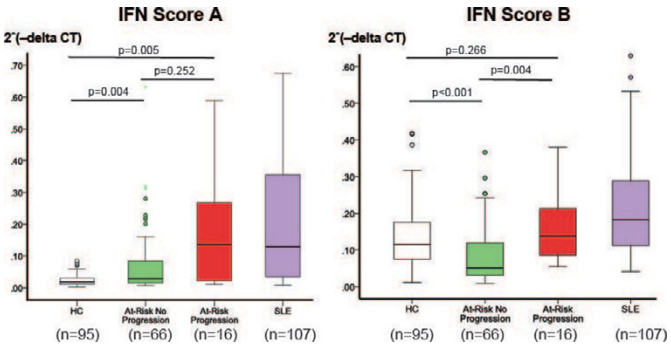
OP0095 PREDICTION OF CONNECTIVE TISSUE DISEASE IN AN AT-RISK COHORT USING A NOVEL INTERFERON STIMULATED GENE EXPRESSION SCORE

M.Y. Md Yusof, Y. El-Sherbiny, A. Psarras, E. Hensor, A. Alase, A. Mohamed, M. Wittmann, P. Emery, E.M. Vital. *Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom*



Background: A period of ANA positivity and other immune dysregulation precedes connective tissue disease, providing a potential opportunity for disease prevention. Type I interferons (IFN-I) play a role in pathogenesis but their role in disease initiation is unclear.

Objectives: To develop biomarkers of progression to systemic autoimmunity, with a view to enabling early intervention for disease prevention.

Methods: A prospective observational study was conducted in 125 patients At Risk of CTD defined by (i) ANA; (ii) $\leq$1 clinical SLE criteria; (iii) symptom duration $<$12 months and (iv) treatment-naïve. Progression was defined by meeting 2012 ACR/SLICC SLE, 2016 ACR/EULAR Primary Sjogren's, or other diagnostic criteria. Expression of 30 selected="selected" ISGs was measured using Taqman. Factor analysis was used to reduce the gene expression data to a limited set of factors, which were compared between patient groups using Mann Whitney U Test. Two factor scores explained 80% of the data variance; "Score A" (composed of IFN-α responsive genes) and "Score B" (genes responsive to IFN-α and γ). 95 healthy controls and 107 SLE patients were used as negative and positive controls.

Results: 82 patients with 1-year follow-up data were studied. 71 were female with mean age 48±15 years. 16 (20%) patients progressed to CTD (SLE=12, Sjogren's=4) in the following 12 months. At baseline, only IFN Score A was increased in both At Risk-CTD and SLE vs healthy controls; p$<$0.001. IFN Score B was only increased in true established SLE.

In At-Risk patients, IFN Score B was low in patients who did not progress and increased in those who did progress; p=0.004. However, there was no difference in IFN Score A between these two groups; p=0.252 (Figure 1). Although complement levels and lymphocyte counts were lower in SLE, these were not different between the At-Risk progression and non-progression groups. Anti-dsDNA titres were higher in SLE but not different between the progression groups; all p$>$0.10.

Conclusions: A novel ISG score predicts progression from ANA+ to clinical autoimmune disease. This may allow early intervention to prevent CTD. Analysis of other clinical, immunological and imaging biomarkers are in progress as well as a validation cohort.

OP0096 INTERFERON SIGNATURE IN SYSTEMIC SCLEROSIS LUNG MICROVASCULAR ENDOTHELIAL CELLS

F.A. Mendoza [1], S. Piera-Velazquez [2], P. Wermuth [2], S. Addya [3], C. Feghali-Bostwick [4], S.A. Jimenez [2]. *[1]Division of Rheumatology and Scleroderma Center; [2]Jefferson Institute of Molecular Medicine and Scleroderma Center; [3]Kimmel Cancer Center, Thomas Jefferson University, Philadelphia; [4]Division of Rheumatology & Immunology, Medical University of South Carolina, Charleston, United States*

Background: Systemic Sclerosis (SSc) is characterized by severe fibroproliferative vasculopathy, exaggerated deposition of extracellular matrix molecules (ECM) in skin and multiple internal organs, and alterations of humoral, cellular and innate immunity. Vascular changes are responsible for the earliest and most severe SSc clinical manifestations, however, the mechanisms responsible have not been elucidated.

Objectives: The goal of this study was to analyze the gene expression differences between normal and SSc lung microvascular endothelial cells (EC) to improve the understanding of SSc vasculopathy pathophysiology.

Methods: Pulmonary microvascular EC were isolated employing immunomagnetic procedures from lungs from patients with SSc undergoing lung transplantation. Control pulmonary microvascular EC were isolated from autopsies of individuals who died from non-pulmonary causes. Following isolation, microarrays were performed in EC from each group. Expression of genes with the highest differential expression was validated with RT-PCR and Western blots.

Results: Interferon-stimulated genes (ISGs) including IFI44L, IFI44, IFI6, IFIH1, IFIT1 displayed the highest differential expression; being overexpressed in EC obtained from the three SSc donors (Figure 1). Other genes such as those encoding ECM production related proteins, genes associated with post-translational methylation, and genes for numerous chemokines and cytokines were also differentially overexpressed in SSc EC. Increased gene expression and increased protein levels of selected ISGs were confirmed by Western blots.

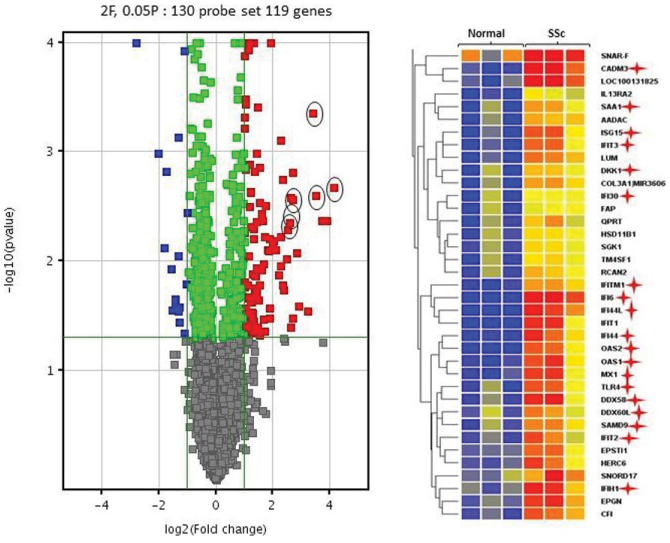

Figure 1. A: Volcano Plot showing differentially expressed transcripts with 2 fold or greater difference (p$<$0.05) in expression between SSc and normal control microvascular ECs (130 transcripts corresponding to119 genes). Selected ISGs are encircled (IFI-6, IFIT1, IFI-44,IFI44L,IFIT-3, OAS-1) B: Detail of the resulting heat map of a dendrogram (hierarchically clustered) reveals groups of genes with high expression levels (red squares), low expression levels (blue squares) or background expression levels (yellow squares). Interferon related genes are marked with a red star.

Conclusions: Numerous ISGs are differentially overexpressed in SSc pulmonary microvascular EC in comparison with normal control EC. These results suggest that events leading to an interferon response in these cells may play a role in the pathogenesis of SSc lung vasculopathy.

Cytokines and chemokines

OP0097 SYSTEMIC IFN TYPE I AND TYPE II SIGNATURES IN PRIMARY SJÖGREN'S SYNDROME REVEAL DIFFERENCES IN DISEASE SEVERITY

I. Bodewes[1], S. Al-Ali[2,3], C.G. van Helden[1], N.I. Maria[1], J. Tarn[2], D. Lendrem[2], M.W. Schreurs[1], E.C. Steenwijk[1], P.L.A. van Daele[1,4], T. Both[4], S. Bowman[5], B. Griffiths[6], W.-F. Ng[2,7], M.A. Versnel[1]. *[1]Immunology, Erasmus MC, Rotterdam, Netherlands; [2]Musculoskeletal Research group, Newcastle University, Newcastle upon Tyne, United Kingdom; [3]University of Basrah, Basrah, Iraq; [4]Internal Medicine, Erasmus MC, Rotterdam, Netherlands; [5]Rheumatology, University Hospital Birmingham, Birmingham; [6]Newcastle upon Tyne Hospitals NHS Foundation Trust; [7]National Institute for Health Research, Newcastle Biomedical Research Centre, Newcastle upon Tyne, United Kingdom*

Background: Local and systemic activation of interferons (IFNs) has been demonstrated in primary Sjögren's syndrome (pSS).[1–4] Type I IFNs are associated with higher disease activity and autoantibody levels.[5] Recent findings also show activation of interferon type II (IFNγ) induced gene expression in salivary glands of pSS patients.[6, 7] Although IFN type I and II bind to different receptors they induce partially overlapping gene expression patterns. Understanding the relative contribution of IFN type I and type II may deepen our knowledge in pSS pathogenesis and promote a stratified approach to therapeutic development.
Objectives: Determine IFN type I and II inducible gene expression in patients with pSS and correlate this to disease manifestations.
Methods: In whole blood of 50 pSS patients modular IFN scores were determined using real-time quantitative PCR followed by principal component analysis. Subsequently, five indicator genes per module were analysed in two independent European cohorts with a total of 141 patients.
Results: Three groups were distinguished: without IFN activation (19–47%), with IFN type I (53–81%) and with IFN type I+II activation (35–55%). Patients with IFN activation (I or I+II) have a higher presence of auto-antibodies, IgG levels and lower lymphocyte counts compared to IFN negative patients. The biological domain of the EULAR Sjögren's Syndrome Disease Activity Index (biological-ESSDAI) was higher in patients with IFN activation, while total-ESSDAI scores were not significantly different.
66–67% of the IFN type I positive patients had an additional IFN type II inducible gene expression. Patients with IFN type I+II activation have significantly higher IgG levels and lower lymphocyte counts compared to patients with only IFN type I activation. There were no differences in fatigue or dryness, but pain scores were lower.
Conclusions: pSS patients can be stratified according to their systemic IFN activation patterns. IFN activation (I or I+II) is present in patients with the highest activity of the biological-ESSDAI. These data raise the possibility that the biological-ESSDAI rather than total-ESSDAI score may be a more sensitive endpoint for trials targeting either type I or type II IFN pathways.

Progress in biological treatment of RA

OP0098 REMISSION AND MAINTENANCE OF EFFICACY IN A PHASE 2B STUDY OF VOBARILIZUMAB, AN ANTI-INTERLEUKIN 6 RECEPTOR NANOBODY, IN PATIENTS WITH MODERATE-TO-SEVERE RHEUMATOID ARTHRITIS DESPITE TREATMENT WITH METHOTREXATE

T. Dörner[1], M. Weinblatt[2], P. Durez[3], R. Alten[4], K. Van Beneden[5], E.J. Dombrecht[5], K. De Beuf[5], P. Schoen[5], R.K. Zeldin[5]. *[1]Rheumatology and Clinical Immunology, Charité University Hospitals, Berlin, Germany; [2]Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Boston, United States; [3]Department Rheumatology, Cliniques Universitaires St-Luc, Sint-Lambrechts-Woluwe, Belgium; [4]Schlosspark-Klinik, Berlin, Germany; [5]Ablynx NV, Zwijnaarde, Belgium*

Background: Vobarilizumab is a Nanobody® consisting of an anti-IL-6R domain and an anti-human serum albumin domain in development for treatment of RA. The efficacy and safety were assessed in a 24-week double-blind global phase 2b study in patients with active RA on a stable background of MTX. Main efficacy and safety results were previously reported [1].
Objectives: To report the impact of treatment with vobarilizumab on secondary efficacy endpoints including SDAI and CDAI remission and the sustained response at 4 consecutive visits based on ACR50, ACR70 and $DAS28_{CRP}$.
Methods: Patients were randomized to receive subcutaneously administered placebo or 1 of 4 dose regimens of vobarilizumab in addition to MTX. SDAI and CDAI remission at Week 24 was evaluated, as was maintenance of efficacy as defined by sustained $DAS28_{CRP} < 2.6$ responses at 4 consecutive visits (i.e., at Weeks 12, 16, 20 and 24). In addition, a post-hoc analysis was performed on sustained ACR50 and ACR70 responses from Week 12 through Week 24. Proportions of patients achieving response for these endpoints were summarized by treatment group. Subjects with missing values were analyzed as non-responders.
Results: A total of 345 patients were randomized. Demographics and baseline characteristics were similar across groups with mean baseline $DAS28_{CRP}$ between 5.8 and 6.2. At Week 24, up to 19% and 20% in the vobarilizumab groups reached CDAI and SDAI remission, respectively vs. 10% and 9% who received placebo (Table 1).

Table 1. Percentage of patients with CDAI and SDAI remission at Week 24

	Placebo (N=69)	Vobarilizumab 75mg q4w (N=69)	Vobarilizumab 150mg q4w (N=70)	Vobarilizumab 150mg q2w (N=68)	Vobarilizumab 225mg q2w (N=69)
CDAI remission (≤2.8)	10	15	19	12	19
SDAI remission (≤3.3)	9	10	19	15	20

At Week 24, up to 61% and 45% of the patients in the vobarilizumab groups achieved an ACR50 or ACR70 response, respectively (39% and 17% on placebo). Approximately one third of the randomized patients in the 3 highest treatment groups had a sustained ACR50 response from Week 12 through Week 24 (Table 2). Sustained remission defined by $DAS28_{CRP} < 2.6$ at 4 consecutive visits, i.e. at weeks 12, 16, 20 and 24, was observed in 20% to 25% of the patients in the 3 highest dosing arms compared with 3% of those receiving placebo.

Table 2. Percentage of patients with sustained efficacy response at 4 consecutive visits (Weeks 12, 16, 20 and 24)

	Placebo (N=69)	Vobarilizumab 75mg q4w (N=69)	Vobarilizumab 150mg q4w (N=70)	Vobarilizumab 150mg q2w (N=68)	Vobarilizumab 225mg q2w (N=69)
$DAS28_{CRP}$ <2.6	3	4	20	25	20
ACR50	16	14	29	31	39
ACR70	4	7	11	13	13

Conclusions: In patients with active RA, treatment with vobarilizumab at the 3 highest dose regimens in addition to MTX had a positive and sustained impact on disease activity through Week 24 as defined by clinically relevant efficacy endpoints.

OP0099 SAFETY, TOLERABILITY AND INITIAL SIGNS OF EFFICACY OF THE FULLY HUMAN IMMUNOCYTOKINE DEKAVIL (F8IL10): A NOVEL THERAPEUTIC APPROACH FOR RHEUMATOID ARTHRITIS

M. Galeazzi[1], G. Sebastiani[2], R. Voll[3], J. Wollenhaupt[4], O. Viapiana[5], J. Dudler[6], E. Selvi[1], C. Baldi[1], M. Bardelli[1], B. Bannert[3], S. Finzel[3], C. Specker[7], P. Sarzi Puttini[8], F. Bootz[9], D. Neri[10] on behalf of the DEKAVIL Study Group. *[1]University Hospital, Siena; [2]San Camillo-Forlanini Hospital, Rome, Italy; [3]University Medical Center, Freiburg; [4]Schoen-Klinik, Hamburg Eilbek, Germany; [5]University Hospital, Verona, Italy; [6]Cantonal Hospital, Fribourg, Switzerland; [7]University Hospital, Essen, Germany; [8]Luigi Sacco Hospital, Milan, Italy; [9]Philochem AG, Otelfingen, Switzerland; [10]Philogen SpA, Siena, Italy*

Background: The antibody-based targeted pharmacodelivery of cytokines by means of immunocytokines has the potential to enhance therapeutic activity at the site of disease while sparing healthy tissues. Dekavil (F8IL10) is a fully human immunocytokine composed of the vascular targeting antibody F8 (specific to

EDA) fused to the cytokine interleukin-10. Dekavil is currently in phase II clinical development for the treatment of rheumatoid arthritis (RA).
Objectives: In the phase Ib dose escalation study, the primary objective was to explore safety, tolerability and the maximum tolerated dose of Dekavil when administered in combination with methotrexate (MTX). The aim of the currently ongoing phase II study is to assess therapeutic activity of Dekavil plus MTX over MTX alone by measuring the mean change from baseline of DAS28-CRP. Immunogenicity of F8IL10 and its PK and PD profile will also be explored.
Methods: Patients with active RA despite MTX therapy and who failed anti-TNF treatment are the target population of both studies. In the phase Ib trial, cohorts of 3–6 patients were treated with escalating doses of Dekavil (6, 15, 30, 60, 110, 160, 210, 300, 450 and 600 μg/kg) in combination with a fixed dose of MTX (10–15 mg). In the multicenter, double-blind, placebo-controlled phase 2 study, patients are randomized into two treatment groups (Dekavil 30 or 160 μg/kg plus MTX) and one placebo group (placebo plus MTX). Dekavil is administered once weekly by *s.c.* injection for a maximum of 8 weeks in both studies.
Results: Dekavil has been shown to be well tolerated up to the highest investigated dose (600 μg/kg) and an MTD was not reached. In 33 out of 34 patients treated in the phase 1 study, no DLTs, no SAEs and no SUSARs have been reported. One patient in cohort 9 (450 μg/kg) experienced a DLT (G2 purpura) and a SAE (G2 dyspnea, not drug related). The patient received corticosteroids and fully recovered within one week. Mild injection site reactions were the most frequently observed adverse events and occurred in 62% of the patients. Furthermore, two cases of drug related anemia (G2 and G3) were reported in this study. All adverse reactions resolved completely. At the first efficacy assessment after 4 cycles of treatment, 48% of evaluable patients (16/33) revealed ACR and/or EULAR responses. The fraction of responding patients increased to 57.7% (15/26) after 8 cycles of treatment. Two patients benefited from ACR70 responses for more than 12 months after the last drug administration. As of January 2017, 22 out of 87 patients have been treated in the phase 2 clinical study and neither SUSAR nor treatment-related deaths were recorded.
Conclusions: The currently available data suggest that Dekavil is a safe and promising novel therapeutic for the treatments of RA.

OP0100 OVERALL CANCER RISK IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH TNF INHIBITORS, TOCILIZUMAB, ABATACEPT, OR RITUXIMAB

H. Wadström, T. Frisell, J. Askling on behalf of The ARTIS study group.
Department of Medicine, Solna, Karolinska Institutet, Stockholm, Sweden

Background: Immune incompetence may lower host surveillance against incipient tumours. Conversely, immune therapies have emerged as a promising therapeutic approach to cancer. Malignancies thus constitute an important aspect of the safety of biologics as used in Rheumatology, including agents targeting TNF, CD20 and IL6, and immunomodulation using CTLA4. Whereas previous reports concerning TNF inhibitors (TNFi) and risk of malignancies in rheumatoid arthritis (RA) have mostly been reassuring, risks with other biological disease modifying anti-rheumatic drugs (bDMARDs) are less studied.
Objectives: To assess the risk of malignancies in patients with RA treated with bDMARDs.
Methods: Through linkages of Swedish national and population-based registers we assembled cohorts of patients with RA initiating (Jan 2006 through Dec 2014) a first ever treatment of tocilizumab, abatacept, rituximab, or a TNFi, one cohort of patients initiating a second TNFi, one cohort of biologics-naïve csDMARD treated RA. Through linkage with the Swedish Cancer Register information on incident cancers was collected. Outcomes were defined as a first ever solid or hematologic malignancy excluding non-melanoma skin cancer (NMSC) during follow-up. Patients with a previous malignancy were excluded. Patients were followed from treatment start until death, emigration, outcome or end of follow up (Dec 2014). Hazard ratios were calculated using Cox-regression adjusted for age, sex, educational level, comorbidities, sero-positivity, number of hospitalizations and days spent in inpatient care, use of prednisolone at baseline, use of non-steroidal anti-inflammatory drugs (NSAIDs) at baseline, number of prescription drugs at baseline, and sick leave and disability (yes/no) the year before cohort entry.
Results: Adjusted for age, sex, disease- and treatment characteristics (see above), and educational level, there were no statistically significant differences in risk of a first solid or hematologic malignancy between initiators of tocilizumab, abatacept, rituximab, or a first- or second TNFi, and RA patients treated with csDMARDs.

Table 1. Number of persons, events, crude incidence, and hazard ratios for a first invasive solid or hematologic malignancy excluding NMSC

Outcome definition Cohort	Number of persons at risk	Number of events	Crude incidence per 10,000 pys	HR*
First invasive solid or hematologic malignancy excluding NMSC				
Tocilizumab	1408	30	80	0.78 (0.54–1.12)
Abatacept	1565	45	104	0.95 (0.70–1.28)
Rituximab	2793	108	103	0.86 (0.70–1.04)
First TNFi	9355	369	93	0.91 (0.82–1.01)
Second TNFi	3610	129	87	0.88 (0.73–1.05)
csDMARD RA	40071	2797	131	1 (reference)

*Adjusted for age, sex, disease- and treatment characteristics, and educational level.

Conclusions: The overall risk of malignancies among RA patients initiating, tocilizumab, abatacept, rituximab, or a first- or second TNFi in clinical practice did not differ substantially from that of RA patients treated with csDMARDs. Increased risk of tumours at specific sites, or with longer latency, cannot be excluded.

OP0101 RISK OF OPPORTUNISTIC INFECTIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS INITIATING ABATACEPT: ANALYSIS OF ALL AVAILABLE CLINICAL TRIAL DATA

T. Simon[1], T. Gelarden[1], E. Nkhoma[1], M. Zhou[1], S. Banerjee[1], K. Winthrop[2].
[1]*Bristol-Myers Squibb, Princeton;* [2]*Oregon Health & Science University, Portland, United States*

Background: Opportunistic infections (OI) during treatment with abatacept (ABA) have been previously reported but are lacking a comprehensive analysis.
Objectives: To present the overall incidence rates of OI and herpes infections observed in patients (pts) receiving ABA using combined clinical trial data.
Methods: OI adverse events were summarized from 16 clinical trials (both placebo-controlled and cumulative abatacept exposure); all pts randomized to placebo were on a non-biologic DMARD. Incidence rates (per 100 person-years [p-y]) were calculated by the number of pts experiencing the first event divided by the total number of p-y of exposure. The p-y of exposure was censored at the time of the first event, death, discontinuation or end of study. Random effects meta-regression was performed across the trials to estimate the frequency of OI after adjusting for between-study heterogeneity. OI were identified using a pre-specified list in the setting of biologic therapy for patients with RA. Criteria for consideration were based on type, location of the infection and causing organism. Excluded from the list were non-specific infections caused by organisms considered to be opportunistic, but common in the general population.
Results: A total of 7044 pts with RA with ~21,330 p-y of ABA exposure were included in the cumulative randomized trial data (Table). The frequency of OI

OP0102 PATIENT REPORTED BENEFITS OF SARILUMAB MONOTHERAPY VERSUS ADALIMUMAB MONOTHERAPY IN ADULT PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS

V. Strand[1], L. Gossec[2], C. Proudfoot[3], C. Chen[4], M. Reaney[3], S. Guillonneau[5], T. Kimura[4], J. van Adelsberg[4], Y. Lin[6], E. Mangan[4], H. van Hoogstraten[6], G.R. Burmester[7]. *[1]Stanford University, Palo Alto, United States; [2]Universite Pierre et Marie Curie and Hopital Pitie-Salpetriere, Paris, France; [3]Sanofi, Guildford, United Kingdom; [4]Regeneron Pharmaceuticals, Inc., Tarrytown, United States; [5]Sanofi, Paris, France; [6]Sanofi, Bridgewater, United States; [7]Charité - University Medicine, Berlin, Germany*

Background: The phase 3 MONARCH superiority study (NCT02332590) compared efficacy and safety of sarilumab (a human anti-IL-6Rα monoclonal antibody [mAb]) 200 mg administered subcutaneously every 2 weeks (q2w), with adalimumab (an anti-TNF-α mAb) 40 mg administered q2w, in patients with active rheumatoid arthritis (RA) who were either intolerant of, or inadequate responders to methotrexate treatment. Sarilumab monotherapy demonstrated superiority to adalimumab monotherapy in reduction of disease activity and improvements in physical function and signs and symptoms of RA, with safety and tolerability consistent with IL-6R or TNF blockade.

Objectives: To compare patient-reported outcomes (PROs) with sarilumab vs adalimumab from MONARCH.

Methods: PROs assessed at baseline, weeks 12 and 24 included ACR components (Patient Global Assessment of Disease Activity [PtGA], Pain visual analog scale [VAS], Health Assessment Questionnaire Disability Index [HAQ-DI]), Medical Outcomes Study Short Form-36 (SF-36), Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), Morning Stiffness VAS, RA Impact of Disease (RAID) and RA-specific Work Productivity Survey (WPS-RA). Least-squares mean (LSM) between-group differences were determined by mixed-model for repeated measures with treatment, visit, treatment-by-visit interaction and region as fixed effects, and the corresponding baseline PRO scores as continuous covariates. A *P*-value <0.05 was considered statistically significant for PROs in a predefined hierarchy (ACR components, SF-36 physical component summary [PCS], FACIT-F and SF-36 mental component summary [MCS] scores). For PROs not in the hierarchy, significance is not claimed. Changes from baseline were compared with published values for minimum clinically important differences (MCIDs).

Results: Baseline demographics, disease characteristics and PROs were generally balanced between treatment groups (n=184 sarilumab; n=185 adalimumab). Improvements from baseline to week 24 were greater with sarilumab vs adalimumab across PtGA, Pain VAS, HAQ-DI, SF-36 PCS, Morning Stiffness VAS, RAID and WPS-RA global scores (all $P<0.05$, statistical significance is claimed only for PROs in the hierarchy; see table). Between-group differences in FACIT-F and SF-36 MCS scores were not significant. Improvements ≥MCID were reported by a greater percentage of patients with sarilumab than adalimumab for HAQ-DI (≥0.22 units), RAID (≥3 units), SF-36 PCS (≥2.5), and Morning Stiffness VAS (≥10) (all nominal $P<0.05$).

Table. Mean change from baseline to week 24 with sarilumab 200 mg q2w or adalimumab 40 mg q2w

PRO	Mean (SD) Baseline score		LSM Changes (SE) from Baseline to Week 24		Least-Squares Mean Between-Group Difference (95% CI)	*P*-value*

OP0103 THE EFFECT OF SIRUKUMAB PLUS METHOTREXATE ON CIRCULATING BIOMARKERS OF JOINT DESTRUCTION IN MODERATE TO SEVERE RHEUMATOID ARTHRITIS PATIENTS FROM THE SIRROUND-D PHASE 3 STUDY

B. Dasgupta[1], K. Campbell[1], A.-C. Bay-Jensen[2], M. Karsdal[2], K. Sweet[1], M. Sims[3], M.J. Loza[1]. *[1]Janssen Research & Development, LLC, Spring House, PA, United States; [2]Nordic Bioscience, Herlev, Denmark; [3]GlaxoSmithKline, Stevenage, United Kingdom*

Background: Rheumatoid arthritis (RA) is an autoimmune disease characterized by chronic inflammation that can lead to progressive bone and joint damage. The cytokine interleukin-6 (IL-6) is implicated in inflammatory pathways associated with bone and cartilage degradation in RA. Inhibition of IL-6 signaling by sirukumab (SIR), an anti-IL6 cytokine monoclonal antibody, was shown to significantly reduce structural damage progression, relative to placebo (pbo), in disease-modifying antirheumatic drug inadequate responder (DMARD-IR) RA patients (pts) in the Phase 3 SIRROUND-D study.

Objectives: To investigate the mechanism of SIR on joint tissue remodeling, a panel of serum biomarkers associated with matrix metalloproteinase (MMP)-driven interstitial matrix and basement membrane degradation (C1M, C3M, C4M), bone turnover (β-isomerized C-terminal telopeptides of type I collagen, CTX-I), osteoblast formation (osteocalcin/NMID), synovial destruction (MMP-3), and tissue inflammation (MMP-mediated destruction of CRP/CRPM) were assessed in pts with moderate to severe RA from SIRROUND-D.

Methods: Serum samples from a sub-cohort of SIRROUND-D (for whom radiographic data were available) were analyzed ad hoc for the following biomarkers: C1M, C3M, C4M, CRPM, MMP-3, CTX, and osteocalcin. Samples from 100 pts treated with pbo and methotrexate (MTX) and 100 pts treated with SIR 50mg q4w + MTX were tested. Biomarkers were measured in all pts at baseline (BL) and Wk 4; samples from SIR and pbo-treated pts (50/group) were tested at Wk 52. Differences between groups were evaluated by comparing within-subject $\log_2$ ratio of Wk 4 or Wk 52 over BL values between treatment groups. Structural damage progressors versus non-progressors were defined based on changes from BL in Sharp/van der Heijde score (SHS) at Wk 52 (≥5 vs <5). Differences between groups were tested using General Linear Models.

Results: SIR significantly reduced serum levels of C1M (-48%), C3M (-30%), C4M2 (-42%), and CRPM (-22%) by Wk 4 vs pbo ($P<0.001$), with similar reductions observed at Wk 52; MMP-3 levels were more substantially decreased by SIR at Wk 52 (-39%) vs Wk 4 (-20%). In contrast, treatment with SIR resulted in increased levels of CTX-I (+20%) and osteocalcin (+12%) by Wk 4 ($P<0.001$; Figure 1). As 95% of the total study population included in this biomarker analysis did not progress (defined as ≥5 Wk 52 change in SHS), we were unable to demonstrate an association between changes in pharmacodynamic markers and radiographic progression. Nor were significant associations with pharmacodynamic changes with SIR treatment observed for comparisons among patients grouped by Wk 52 changes in SHS of ≥5 (n=5), <5 to ≥0.5 (n=41),

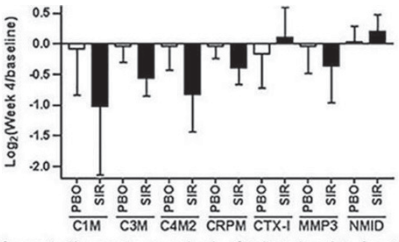

Figure 1. Changes in serum levels of indicated analyte (x-axis), displayed as mean ± SD of log2-transform of within-subject week 4/baseline ratios, stratified by treatment group (PBO, placebo; SIR, sirukumab 50mg q4w). P<0.05 for SIR vs. PBO for each analyte.

and <0.5 (n=51). BL or Wk 4 changes in levels of individual analytes were not associated with Wk 24 ACR50 or DAS28-CRP responses.
Conclusions: SIR 50mg q4w + MTX, vs pbo + MTX, inhibited radiographic progression in RA pts in SIRROUND-D and strongly inhibited biomarkers of joint and tissue destruction while enhancing markers of bone formation. These data suggest SIR may actively suppress inflammatory pathways implicated in joint destruction in RA pts.

OP0104 TOCILIZUMAB: DOSE REDUCTION OR INTERVAL SPACING – WHICH PROVES A BETTER TAPERING STRATEGY FOR RHEUMATOID ARTHRITIS IN CLINICAL REMISSION?

Y. Urata[1], S. Abe[2], B. Devers[3], Y. Nakamura[4], H. Takemoto[5], K.-I. Furukawa[6].
[1]Department of Rheumatology, Tsugaru General Hospital, Gosyogawara; [2]Marketing Department; [3]Marketing Department, Diagnostics Division, Sekisui Medical Co., Ltd., Tokyo; [4]Departments of Orthopaedic Surgery; [5]Departments of Dermatology, Tsugaru General Hospital, Gosyogawara; [6]Department of Pharmacology, Hirosaki University Graduate School of Medicine, Hirosaki, Japan

Background: A number of studies have revealed that reduction of biological disease-modifying anti-rheumatic drugs (bDMARDs) is possible for some rheumatoid arthritis (RA) patients in whom bDMARD treatment has induced clinical remission or low disease activity.
For tocilizumab (TCZ), while there have been studies concerning tapering, there have been no studies regarding which tapering option is better in RA after clinical remission has been achieved: a dose reduction strategy (DRS) or an interval spacing strategy (ISS).
We previously demonstrated that a twin target strategy [targeting both a simplified disease activity index (SDAI) score of less than 3.3 and normalization of matrix metalloproteinase (MMP) 3 levels] can achieve effects non-inferior to standard care with regard to maintaining clinical remission in the rT-4study.
Objectives: To evaluate any significant differences that may be present between the two strategies (DRS and ISS) while tapering TCZ in RA patients who satisfied the SDAI remission and MMP-3 normalization targets under the twin target scheme.
Methods: DRS was used in patients treated with intravenous (IV) TCZ, whereas ISS was used for those treated by subcutaneous injection (SC). 57 RA patients who demonstrated SDAI remission and MMP-3 normalization using TCZ (IV, n=42; SC, n=15) participated. Dose reduction methodology (every 3 months): DRS- dose reduced by 80mg; ISS- period between injections increased by one week; up to a minimum dose of: DRS- 80 mg every 4 weeks; ISS-162 mg every 6 weeks. The dose was reverted to the previous level in the event that the target scores were exceeded, and the lower dose was eventually reattempted after the target was re-achieved. The primary outcome was the difference in the number of the times when a patient's SDAI exceeded 3.3 across the four time points.
Results: Fifty-five patients completed the observation period of 12 months and were analyzed (ITT). There were differences in the number of the times which SDAI scores exceed the target over the 12 months in the DRS group vs the ISS group: 2.4±1.7 and 0.9±1.2, respectively (p=0.0027). DRS had a duration (months) of maintained SDAI remission significantly shorter than that of ISS (3.9±5.0 vs 7.4±5.1, p=0.0213). At month 12, the proportions for DRS and ISS, respectively, for ΔmTTS$\leq$0.5 were 71.4 and 66.7% (p=0.7293); for maintained HAQDI=0 were 83.3 and 66.7 (p=0.4227) and for AE were 81.0 and 46.7 (p=0.0112). The total dose for TCZ in DRS tended to be lower than that for ISS (1367±840vs 1626±583mg, p=0.0824). The rate of total TCZ reduction showed a significant difference between DRS and ISS (29.3±15.2% vs41.8±15.0%, p=0.0037). Comparing three groups consisting of 400mg<, 401<<500mg and 500mg< across the DRS with ISS groups, there were significantly greater number of times when SDAI exceeded 3.3 in the DRS vs the ISS group; 2.3±1.6, 2.7±1.8 and 2.4±1.9, p=0.0395.
Conclusions: ISS using the twin targets as defined by the rT-4 study is an excellent strategy that is both safe and cost-effective for RA patients who are both being treated with TCZ and have reached said targets.

OP0105 LONG-TERM SAFETY OF TOCILIZUMAB FROM LARGE CLINICAL TRIAL AND POSTMARKETING POPULATIONS

S. Mohan, M. Michalska, J. Yourish, J. Pei, S. Gale, C. Birchwood, E. Berber.
Genentech, Inc., South San Francisco, CA, United States

Background: Tocilizumab (TCZ) is a recombinant humanized monoclonal antibody targeted against the interleukin-6 receptor that was approved to treat rheumatoid arthritis (RA) in the EU in 2009 and in the US in 2010. TCZ has now completed long-term extension (LTE) follow-ups in a number of intravenous and subcutaneous RA trials.
Objectives: To provide an updated report on the incidence of safety events during TCZ treatment in patients with RA using data from multiple completed clinical trials and their LTEs, as well as to provide an update from the global TCZ postmarketing safety database.
Methods: Incidence and reporting rates of adverse events (AEs) of special interest, including infections, malignancies, anaphylaxis, bleeding events, myocardial infarctions, gastrointestinal perforations, strokes, hepatic events and demyelination, were estimated from 2 distinct patient data sets. Incidence rates were calculated from 12 completed TCZ RA clinical trials and their LTE periods and are reported as events per 100 patient-years (PY). Reporting rates were also estimated from the global TCZ postmarketing safety database (Oct 2008 to Oct 2015), which includes information from all spontaneously reported cases and non-interventional programs as well as literature cases, and are reported as cases per 100 patients.
Results: The clinical trial all-exposure population consisted of 7647 TCZ-treated patients with RA (81.6% female; mean [SD] age, 52 [12.6] years), constituting 22,394 PY (mean follow-up, 2.93 years) of exposure. The overall rate (95% CI) of serious AEs in the clinical trial population was 14.16 (13.67–14.66) per 100 PY. Overall incidence rates for individual events for the clinical trial population are reported in the Table and were consistent in each 6-month period over the 5-year duration. The global postmarketing population included 606,937 patients. The overall spontaneous reporting rate (range) of AEs of special interest in the postmarketing population was 9.37 (7.35–10.56) cases per 100 patients. Reporting rates of individual safety events of interest in the global postmarketing population are shown in the Table and were consistent in each 6-month period over the 7-year duration.

Table. Adverse Events Across 12 RA Clinical Trials and the Global Postmarketing Safety Database in Patients Who Received TCZ

	RA Clinical Trial All-Exposure Population (N = 7647; 22,394 PY)		Global Postmarketing Safety Database Population* (N = 606,937)	
Adverse Event of Special Interest	Patients With ≥ 1 AE, n (%)	Incidence Rate (95% CI), Events/100 PY	Cases, n	Reporting Rate (range), Cases/100 Pts
Serious infections	730 (9.5)	4.29 (4.02-4.57)	17,350	2.86 (2.11-3.62)
Malignancies†	242 (3.2)	1.18 (1.05-1.33)	1560	0.26 (0.18-0.51)
Injection site reactions	444 (5.8)	6.51 (6.18-6.85)	NA	NA
Strokes/cerebrovascular disorders	130 (1.7)	0.67 (0.56-0.78)	2069	0.34 (0.22-0.94)
Serious bleeding events	89 (1.2)	0.43 (0.35-0.52)	2440‡	0.40‡ (0.28-0.76)
Myocardial infarction	72 (0.9)	0.33 (0.26-0.42)	1946	0.32 (0.21-0.88)
Gastrointestinal perforations†	39 (0.5)	0.20 (0.15-0.27)	632	0.10 (0.06-0.30)
Serious hypersensitivity reactions§	56 (0.7)	0.26 (0.20-0.33)	NA	NA
Anaphylaxis	21 (0.3)	0.09 (0.06-0.14)	1222	0.20 (0.09-0.38)
Serious hepatic events	9 (0.1)	0.04 (0.02-0.08)	3567‡	0. 59‡ (0.34-1.21)
Demyelination	8 (0.1)	0.04 (0.02-0.07)	66	0.01 (0.00-0.02)

AE, adverse event; NA, not available; pt, patient; PY, patient year; RA, rheumatoid arthritis; TCZ, tocilizumab.
* Data are for multiple indications and from several sources (spontaneous reports, non-interventional programs, literature cases) reported following market authorization.
† Events of malignancies and gastrointestinal perforations were medically confirmed.
‡ Includes both serious and non-serious cases.
§ Serious hypersensitivity was defined as a serious adverse event occurring during or within 24 hours of the injection or infusion, excluding injection site reactions, and not judged unrelated to study treatment by the investigator.

Conclusions: The safety profile of TCZ in the current analysis, which includes information about safety events from 12 clinical trials and their LTEs and across 7 years of real-world postmarketing reports encompassing ≈ 600,000 patients, was consistent with previous safety reports. These findings are consistent with the previously reported profile of TCZ and indicate that there is no evidence of increased safety risk with increasing exposure to TCZ.

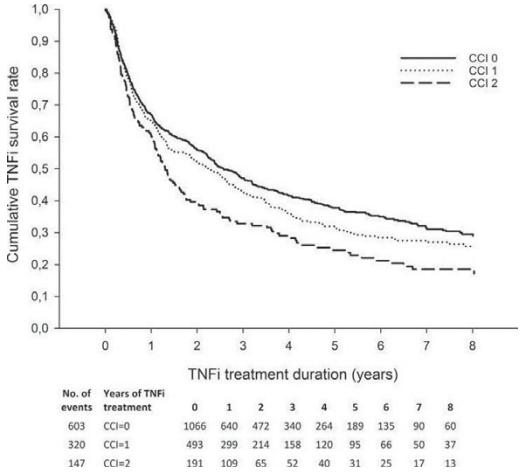
PsA: a fascinating disease

OP0106 THE IMPACT OF COMORBIDITIES ON EFFECT AND DISCONTINUATION OF TUMOUR NECROSIS FACTOR INHIBITOR THERAPY IN PSORIATIC ARTHRITIS: A POPULATION-BASED COHORT STUDY



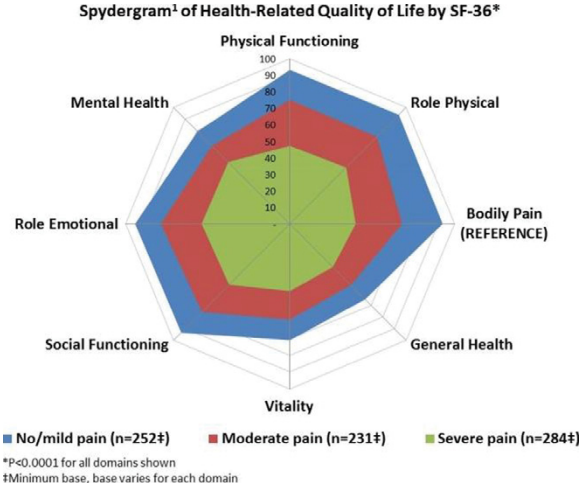
C. Ballegaard[1], P. Højgaard[1], L. Dreyer[2], R. Cordtz[2], T.S. Jørgensen[1], M. Skougaard[1], S. Tarp[1], L.E. Kristensen[1]. *[1]The Parker Institute, Copenhagen University Hospital, Bispebjerg and Frederiksberg; [2]Gentofte Hospital, Department of Rheumatology, Copenhagen University Hospital, Copenhagen, Denmark*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disorder associated with several severe comorbidities such as cardiovascular diseases, diabetes, and depression. Tumour necrosis factor inhibitor (TNFi) therapy fails among half of patients with PsA treated in routine care.
Objectives: The objective of this population-based cohort study was to investigate if the presence of comorbidities were associated with disease activity, treatment response and adherence to therapy in patients with PsA treated with their first TNFi.
Methods: Data on patient characteristics, disease activity and treatment adherence was obtained from the DANBIO register. Information on comorbidities according to the Charlson Comorbidity Index (CCI) and psychiatric comorbidities was obtained through linkage with the Danish National Patient Register. We performed Kaplan-Meier plots and multivariate Cox proportional hazard regression analyses adjusted for sex, age, disease duration, DAS28-CRP, obesity, smoking, concurrent methotrexate treatment, calendar period, and diagnosis with depression and/or anxiety. Percentages of patients achieving relevant clinical responses were calculated.
Results: We identified 1750 patients eligible for analyses. Patients with higher CCI scores had statistically significantly higher disease activity measures at baseline compared with patients without comorbidities (Table 1). Kaplan–Meier curves showed shorter adherence to treatment for patients with CCI ≥2 compared with patients with lower CCI scores (CCI =0: 2.6 years [2.2 to 2.9], CCI =1: 2.2 years [1.7 to 2.8], CCI ≥2: 1.3 years [1.0 to 1.6], p<0.001) (Figure). Also, for patients with depression and/or anxiety the adherence to treatment was shorter compared with patients without depression and/or anxiety (absence of depression and/or anxiety: 2.4 years [2.1 to 2.6], presence of depression and/or anxiety: 1.7 years [0.26 to 3.0], p<0.027). In the multivariate Cox regression analysis a CCI score ≥2 was associated with increased risk of TNFi treatment discontinuation compared with patients without comorbidities (HR 1.72, [95% CI 1.26 to 2.37], p=0.001). A statistically significantly smaller proportion of patients with a CCI score ≥2 achieved EULAR good response (CCI =0: 41%; CCI ≥2: 23%) and EULAR good-or-moderate response (CCI =0: 54%; CCI ≥2: 47%) at 6 months compared with patients without comorbidities.

Table 1. Baseline characteristics according to Charlson Comorbidity Index (CCI)

	CCI =0 (n=1066)	CCI =1 (n=493)	CCI ≥2 (n=191)	p value
Tender joint count (28) (no.)	6 (2–11)	6 (3–12)	8 (3–15)	0.001
Swollen joint count (28) (no.)	2 (0–5)	3 (0–6)	2 (0–6)	0.016
DAS28-CRP (0 – 10)	4.4 (3.5–5.2)	4.6 (3.8–5.4)	4.9 (3.9–5.7)	<0.001
HAQ score (0 – 3)	0.88 (0.5–1.4)	1.1 (0.6–1.5)	1.4 (0.88–2.0)	<0.001
VAS patient global (0 – 100)	68 (48–84)	69 (52–84)	75 (58–88)	0.021
Depression and/or anxiety, n (%)	46 (4.3)	33 (6.7)	15 (7.9)	0.042

Values are the median/interquartile range except where stated otherwise. Comparisons were assessed by χ^2/Kruskal-Wallis test.



Conclusions: Presence of comorbidities was associated with higher baseline disease activity, increased risk of TNFi treatment discontinuation and reduced clinical response rates in a cohort of Danish patients with PsA.

OP0107 PAIN STILL REMAINS A HIGH UNMET NEED AMONG PSORIATIC ARTHRITIS PATIENTS RECEIVING EXISTING BIOLOGIC TREATMENT: RESULTS FROM A MULTI NATIONAL REAL-WORLD SURVEY

P.G. Conaghan[1], V. Strand[2], R. Alten[3], E. Sullivan[4], S. Blackburn[4], L. Huneault[5], H. Tian[6], K. Gandhi[7], S. Jugl[8]. *[1]University of Leeds, Leeds, United Kingdom; [2]Division of Immunology/Rheumatology, Stanford University, Palo Alto, United States; [3]Internal Medicine, University Medicine Berlin, Berlin, Germany; [4]Adelphi Real World, Manchester, United Kingdom; [5]Global Patient Relations, I&D Global Communications & Advocacy, Novartis Pharma AG, Basel, Switzerland; [6]Real World Evidence; [7]Global Market Access, Novartis Pharmaceuticals Corporation, East Hanover, United States; [8]Global Patient Access Immunology & Dermatology, Novartis Pharma AG, Basel, Switzerland*

Background: Many patients diagnosed with Psoriatic Arthritis (PsA) experience pain which can persist during treatment and may impair health related quality of life (HRQOL) and the ability to work.
Objectives: To assess self-reported pain in patients with PsA receiving biologic therapy, and evaluate the association of increasing severity of pain with HRQOL and employment status.
Methods: Cross-sectional survey data from Rheumatologists and Dermatologists (specialists) treating PsA and their patients in 13 countries spanning the Americas, Asia Pacific, EU, Turkey and the Middle East were analyzed. A geographically diverse sample of specialists in each country completed a detailed form for consecutive consulting PsA patients recording information such as demographics, clinical state and treatment details. Patients voluntarily completed questionnaires providing demographics, self-reported intake of non-prescription pain medication, work status, HRQoL (EQ-5D, SF-36), impairment in physical function (HAQ-DI), and impairment in work productivity and activity (WPAI). Patient reported pain was stratified using tertiles of the SF-36 "Bodily Pain" (BP) subdomain.
Results: Results are presented from 782 patients with PsA receiving traditional biologic treatment (mainly anti-TNF) for ≥3 months who completed SF-36 questionnaires. SF-36 BP domain tertiles were: no/mild pain: BP: >75 to 100: 33.1%; moderate: BP: >52 to ≤75: 30.1%; and severe: BP: 0 to ≤52: 36.8%. A strong positive linear relationship between BP tertiles and EQ-5D pain was observed (correlation coefficient: 0.6678). More severe pain was associated with increased use of prescription NSAIDS (p=0.0026) and opioids (p=0.0065), as well as non-prescription pain medication (p<0.0001).
The level of HRQOL impairment among PsA patients increased as pain increased: SF-36 domains (excluding BP) were lower, all differences were clinically[1] and statistically significant (all p<0.0001); EQ-5D domains (excluding pain/discomfort) were also lower (p<0.0001). More severe pain was associated with greater disability (higher HAQ-DI scores), and greater activity impairment, overall work impairment, work time missed and impairment while working due to PsA (all p<0.0001). Among patients of working age (≤65), the likelihood of unemployment or retirement due to PsA was higher among patients reporting severe pain: Mild (n=21): 19.0%, Mod (n=30): 10.0%, Severe (n=36): 58.3%; p<0.0001.
Conclusions: This analysis of real world patient reported data suggests that pain is common among PsA patients receiving biologic therapy. Increasing severity of pain is associated with more impaired HRQOL, physical functioning, engagement

in activities and work productivity. These results suggest there is a need for treatments that provide fast and sustained improvement in pain to reduce the impact pain has on patients' daily life as well as societal costs.

OP0108 INHIBITION OF RADIOGRAPHIC PROGRESSION IN PSORIATIC ARTHRITIS BY ADALIMUMAB INDEPENDENT OF THE CONTROL OF CLINICAL DISEASE ACTIVITY

R. Landewé[1], C.T. Ritchlin[2], L.C. Coates[3], D. Aletaha[4], B. Guérette[5], Y. Zhang[5], F. Ganz[6], M. Hojnik[7]. *[1]University of Amsterdam, Amsterdam, Netherlands; [2]University of Rochester Medical Center, Rochester, United States; [3]University of Leeds and Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; [4]Medical University of Vienna, Vienna, Austria; [5]AbbVie Inc, N Chicago, United States; [6]AbbVie AG, Baar, Switzerland; [7]AbbVie, Ljubljana, Slovenia*

Background: Patients (pts) with psoriatic arthritis (PsA) may experience structural damage and irreversible functional impairment if not treated appropriately. Treatment with TNF inhibitors in rheumatoid arthritis (RA) pts showed inhibition of radiographic progression larger than expected based on the control of clinical disease activity.[1] Preliminary results showed that such a disconnect phenomenon may also be observed in PsA pts following treatment with adalimumab (ADA).[2]
Objectives: The objective of this analysis was to further examine the relationship between inhibition of radiographic progression and control of clinical disease activity using different disease activity measures following treatment with originator ADA versus placebo (PBO) in pts with active PsA.
Methods: ADEPT[3] was a 24-week (wk), randomized, double-blind trial comparing the safety and efficacy of ADA with PBO in pts with active PsA. In this post hoc analysis, radiographic progression, defined as change from baseline (BL) to wk 24 in modified total Sharp score (ΔmTSS) >0.5, was calculated in pts with evaluable radiographs at both time points. Pts were classified based on achieving minimal disease activity (MDA) and different subcategories of disease activity (remission, low, moderate, or high) based on time-averaged (TA) DAS28(CRP), DAPSA, and PASDAS. The associations between ΔmTSS and disease activity were assessed by Pearson (r_p) or Phi (r_φ) correlation coefficients.
Results: Of the 296 pts (ADA, N=144; PBO, N=152) included in this analysis, higher proportions of pts receiving ADA compared with PBO achieved MDA and remission/low disease activity status across all the outcome measures.

Table Change from Baseline to Week 24 in modified Total Sharp Score (ΔmTSS) categorized by Disease Activity Status Across Each Outcome Measure in ADA and PBO Treated Patients.

Outcome measure Mean (SD)	ΔmTSS		P-value*
	ADA	PBO	
TA-DAS28 (CRP)†	n = 144	n = 152	
Remission (≤2.6)	-0.3 (1.3)	0.1 (0.7)	.135
Low disease activity (>2.6–3.2)	-0.2 (1.3)	0.6 (1.7)	.054
Moderate disease activity (>3.2–5.1)	0.2 (1.3)	1.5 (3.6)	.085
High disease activity (>5.2)	1.7 (2.9)	4.9 (8.2)	.893
TA-DAPSA†	n = 144	n = 152	
Remission (≤4)	-0.1 (0.5)	0.0 (0.0)	.824
Low disease activity (>4–14)	-0.2 (1.0)	0.0 (0.0)	.741
Moderate disease activity (>14–28)	-0.2 (1.4)	0.4 (1.0)	**.044**
High disease activity (>28)	-0.1 (1.8)	1.4 (3.5)	**.002**
TA-PASDAS†	n = 136	n = 150	
Low disease activity (≤3.2)	-0.1 (0.9)	0.2 (0.4)	.373
Moderate disease activity (>3.2–<5.4)	-0.4 (1.5)	0.4 (1.3)	**.001**
High disease activity (≥5.4)	0.2 (1.9)	2.0 (4.3)	**.039**
MDA‡	n = 139	n = 146	
Yes	-0.2 (1.6)	0.0 (0.0)	.884
No	-0.2 (1.3)	1.1 (3.1)	**<.001**

*P-value for difference between treatment groups is based on ANCOVA.
†Time averaged (TA) variable is calculated as area under the curve (AUC) of that variable and standardized by length of study (24 weeks).
‡Minimal disease activity (MDA) was calculated in patients with at least 5 out of 7 MDA components available.
ADA = adalimumab, PBO = placebo; TA = time-averaged; DAS28(CRP) = 28-joint disease activity score based on C-reactive protein, DAPSA = disease activity index for psoriatic arthritis, PASDAS = psoriatic arthritis disease activity score; index, MDA = minimal disease activity; ANCOVA = analysis of covariance.

There was a significant interaction between treatment and disease activity status with respect to radiographic progression (P<.001 for all outcome measures). In addition, treatment with ADA for 24 wks compared with PBO resulted in significantly lower mean ΔmTSS even in pts with moderate or high disease activity (TA-DAPSA or TA-PASDAS) or not achieving MDA (Table). Radiographic progression showed a weak, but significant correlation with disease activity status in pts treated with PBO ($r_p \geq 0.3$, P<.001 for TA-DAS[CRP], TA-DAPSA, and TA-PASDAS; $r_\varphi = -0.14$ [95% CI:–0.20 to –0.09 for MDA), but not ADA.
Conclusions: The results showed that the relationship between disease activity as determined by various outcome measures differed between ADA and PBO treated pts. ADA provided inhibition of radiographic progression which was somewhat larger and independent of the control of clinical disease activity. This supports the disconnect phenomenon in PsA following ADA treatment.

OP0109 IS MENTAL HEALTH COMPARABALE IN RHEUMATOID AND PSORIATIC ARTHRITIS PATIENTS? A COMPARATIVE ANALYSIS OF REAL LIFE LONGITUDINAL DATA FROM THE NOR-DMARD STUDY

B. Michelsen[1,2], E. Lie[1], K.M. Fagerli[1], E.K. Kristianslund[1], H.B. Hammer[1], G. Haugeberg[2,3,4], T.K. Kvien[1]. *[1]Dept. of Rheumatology, Diakonhjemmet Hospital, Oslo; [2]Dept. of Rheumatology, Hospital of Southern Norway Trust, Kristiansand; [3]Dept. of Rheumatology, Martina Hansens Hospital, Bærum; [4]Norwegian University of Science and Technology, Trondheim, Norway*

Background: Only few studies have compared health related quality of life (HRQoL) between rheumatoid arthritis (RA) and psoriatic arthritis (PsA) patients.
Objectives: To compare the Medical Outcomes Survey Short Form-36 (SF-36) Physical Component Summary (PCS) and Mental Component Summary (MCS) in RA and PsA patients from a large prospective observational registry.
Methods: We included RA and PsA patients from the prospective observational multicenter Norwegian-Disease-Modifying Antirheumatic Drug (NOR-DMARD) study, who started first-time tumour necrosis factor inhibitors or DMARD naïve patients starting methotrexate between year 2000 and 2012. Continuous variables were compared using independent t-test (normally distributed data). Prespecified ANCOVA analyses adjusted for age, gender and years since diagnosis were performed to compare SF-36 PCS and MCS between the RA and PsA patients at baseline and after 3 and 6 months follow-up.
Results: A total of 2735 RA and 1236 PsA patients were included. Mean (SD) age was 55.0 (13.5)/ 48.3 (12.4) years, median (25th-75th percentile) years since diagnosis 0.7 (0.02–6.4)/ 1.3 (0.09–7.7), 69.7/48.4% were women and 31.7/29.8% current smokers. Mean (SD) 28-joint Disease Activity Score was higher in RA vs. PsA patients at baseline (4.9 (1.4)/ 4.2 (1.3)) and at 3 (3.6 (1.5)/ (3.1 (1.4)) and 6 months follow-up (3.3 (1.4)/ 3.0 (1.3)), respectively ($p \leq 0.001$). Unadjusted means (SD) of SF-36 PCS and MCS were similar between the RA and PsA patients (Table 1).
In adjusted analyses SF-36 PCS was slightly higher and SF-36 MCS similar between RA and PsA patients at 3 and 6 months follow-up (Table 2).
Conclusions: Mental HRQoL reflected through SF-36 MCS was similar between RA and PsA patients at all time points, in spite of slightly worse physical HRQoL reflected through lower SF-36 PCS in the PsA group at 3 and 6 months follow-up.

OP0110 ASSOCIATION OF PHARMACOLOGICAL BIOMARKERS WITH TREATMENT RESPONSE AND LONG-TERM DISABILITY IN PATIENTS WITH PSORIATIC ARTHRITIS: RESULTS FROM OUTPASS

M. Jani [1,2], H. Chinoy [1,2], A. Barton [1,2] on behalf of Outcomes of Psoriatic Arthritis Study Syndicate (OUTPASS). *[1]NIHR Manchester Musculoskeletal Biomedical Research Unit, Manchester Academic Health Science Centre, Central Manchester Foundation Trust and University of Manchester; [2]Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom*

Background: Up to 40% of patients with inflammatory arthritis on TNF-α inhibitor (TNFi) treatment fail to respond either due to primary inefficacy or loss of response. One explanation is immunogenicity leading to the development of anti-drug antibodies (ADAb) and subsequent low drug levels. Few data exist on whether such pharmacological tests correlate with treatment response in psoriatic arthritis (PsA). The clinical utility of whether such tests should be incorporated into practice is in question.
Objectives: To identify (i) whether the presence of ADAbs/drug levels predict treatment response and disability in TNFi-treated PsA patients (ii) the factors associated with drug levels (iii) a drug level threshold for optimal therapeutic response.
Methods: 75 patients were available from the Outcomes of Treatment in PsA Study Syndicate (OUTPASS) [n=49 adalimumab; n=26 etanercept], a national UK prospective observational cohort. Serum samples were collected at 3, 6 and 12 months following initiation of TNFi therapy. ADAbs were measured using radioimmunoassay (RIA) and random (non-trough) drug levels using ELISA assays at 3, 6 and 12 months. Disease activity (DAS28) scores were measured at each visit. Patient self-reported adherence to TNFi was measured at each time-point. Generalised estimating equation (GEE) was used to test the association between ADAbs and drug levels, both biomarkers and treatment response [as assessed by change in DAS28 score between pre-treatment and 12 months post-treatment (ΔDAS28)], Health assessment Questionnaire (HAQ) and the association between longitudinal/baseline factors with drug levels.
Results: 264 serial samples were suitable for pharmacological testing (n=174 adalimumab; n=90 etanercept). Mean age was 51±12 years; 61% were female; median BMI 28.9 (IQR 26.0–34.9). 20% (n=10/49) of adalimumab-treated patients were positive for ADAbs, but none were detected in etanercept-treated patients. There was no significant association between etanercept drug levels and ΔDAS over 12 months [β= -0.039 (95% CI -0.31, 0.23), p=0.77]. Using GEE, adalimumab drug levels were significantly associated with ΔDAS28 over 12 months [β=0.055 (95% CI: 0.011, 0.099) p=0.014] and inversely with HAQ scores over 12 months [β= -0.022 (95% CI: -0.043, -0.00063]. ΔDAS28 was not independently associated with ADAb level [β=-0.0015 (95% CI: -0.0031, 0.000047), p=0.057]. Adalimumab concentrations between 4.5–8.5 mg/L were associated with an optimal treatment response at 6 months using concentration-effect curves. Factors that were significantly associated with adalimumab drug levels were ADAb level [β=-0.0073 (95% CI: -0.0014, 0.18), p<0.0001] and BMI [β=-0.15 (-0.29, -0.00450, p=0.043] in the final GEE model (adjusting for age, gender, adherence, BMI).
Conclusions: TNFi drug-level testing in adalimumab-initiated PsA patients may be useful in determining treatment response and disability over 12 months; interestingly, both the presence of ADAbs and BMI were inversely associated with drug levels. Identification of a drug level threshold for optimal response may help tailor adalimumab therapy for PsA patients in the future.

OP0111 THE ASSOCIATION BETWEEN SONOGRAPHIC ENTHESITIS AND RADIOGRAPHIC JOINT DAMAGE IN PSORIATIC ARTHRITIS

A. Polachek [1], R. Cook [2], V. Chandran [1,3], D. Gladman [1,3], L. Eder [3,4]. *[1]Centre for Prognosis Studies in the Rheumatic Diseases, University Health Network, Toronto; [2]Department of Statistics and Actuarial Science, University of Waterloo, Waterloo; [3]Department of Medicine, University of Toronto; [4]Women's College Research Institute, Women's College Hospital, Toronto, Canada*

Background: Enthesitis is a common clinical finding and a key pathogenic feature in psoriatic arthritis (PsA). Ultrasound is emerging as a preferred method to assess enthesitis. Little is known about the relation between the presence of enthesitis and the severity of joint damage in patients with PsA.
Objectives: Our objective was to examine the association between sonographic enthesitis and the severity of radiographic features of damage in the peripheral and axial joints in PsA.
Methods: A cross-sectional study was conducted in consecutive patients with PsA. The MAdrid Sonography Enthesitis Index (MASEI) scoring system was used to quantify the extent of sonographic entheseal abnormalities in 12 entheseal sites. Total MASEI was further categorized into: bone scores (enthesophytes, erosions) and soft tissue scores (structural changes, vascularization, bursitis). Radiographic joint damage in the peripheral joints and spine was assessed independently of the ultrasound results using the modified Steinbrocker score, Modified New York Criteria for sacroiliitis and the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). Additionally, the presence of ankylosis, arthritis mutilans and periostitis in the hands or feet was determined. Linear and logistic regression models were used to assess the association between MASEI score and the radiographic features of joint damage after controlling for age, sex, BMI, PsA duration and the use of DMARDs and biologic medications.
Results: 222 patients were included (58% men) with mean (s.d.) age of 55.9 (12.9) years and PsA duration of 16.7 (12.4) years. The mean MASEI score was 15.6 (12.6). The mean modified Steinbrocker score was 18.1 (32.3), *mSASSS* was 1.7 (7.3) and 37% had sacroiliitis. Multivariate regression analyses found an association between higher scores of MASEI scores and peripheral joint damage: modified Steinbrocker score (β 9.26, p<0.0001), joint ankylosis (Odds Ration (OR) 2.09, p=0.0001) and arthritis mutilans (OR 1.73, p=0.005). The association between MASEI scores and periostitis was of borderline statistical significance (OR 1.29, p=0.06). Similarly, an association was found in multivariate analyses between higher MASEI scores and axial damage as measured by mSASSS (β 1.55, p$\leq$0.0001) and sacroiliitis (OR 1.36, p=0.02). Sub-analysis showed that the MASEI bone score were more strongly associated with radiographic damage outcomes than the MASEI soft tissue score.
Conclusions: The severity of sonographic enthesitis is a marker of radiographic peripheral and axial joint damage in PsA. The association was found with both erosive and bone formation lesions. These findings highlight the potential role of enthesitis in the pathogenesis of articular damage in PsA.

OP0112 IN PSORIATIC ARTHRITIS FATIGUE IS DRIVEN BY INFLAMMATION, DISEASE DURATION, AND CHRONIC PAIN: AN OBSERVATIONAL DANBIO REGISTRY STUDY

M. Skougaard [1], T.S. Jørgensen [1], S. Rifbjerg-Madsen [1], L. Coates [2], A. Egeberg [3], K. Amris [1], L. Dreyer [1], P. Højgaard [1], J. Guldberg-Møller [1], J.F. Merola [4], P. Frederiksen [1], H. Gudbergsen [1], L.E. Kristensen [1]. *[1]The Parker Institute, Copenhagen University Bispebjerg and Frederiksberg, Copenhagen F, Denmark; [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; [3]Department of Dermatology and Allergy, Copenhagen University Hospital Gentofte and Herlev, Hellerup, Denmark; [4]Department of Dermatology and Department of Medicine, Devisions of Rheumatology, Brigham and Woman's Hospital, Boston, Massachusetts, United States*

Background: Fatigue has been identified as one of the most significant symptoms and an outcome of great importance to patients with psoriatic arthritis (PsA), but the association between underlying components of experienced fatigue and the disease has been sparsely investigated. [1]
Objectives: To describe the degree of fatigue in a PsA population. Secondly, to explore which components of inflammation and non-inflammatory factors contribute to experienced fatigue.
Methods: The study was designed as a cross-sectional survey including patients

registered in DANBIO, the Danish nationwide rheumatologic registry, from December 2013 to June 2014. Principal component analysis was used to identify clustering factors associated with fatigue

Results: A total of 1,062 PsA patients were included in the study. The median Visual Analog Scale (VAS) fatigue score was 57mm. Patients with moderate to severe fatigue (VAS score ≥57) had higher scores of pain, DAS28, HAQ, patient global assessment, and more tender and swollen joints ($p<0.001$) (Table 1). In the principal component analysis the clinical co-variables were reduced to 3 components explaining 63% of experienced fatigue (figure 1); The first component, contributing to 31%, was mainly constituted by inflammatory factors as swollen and tender joints, doctors-global evaluation, higher CRP, and pain score, whereas the second component mainly consisted of contributions from age and disease duration, explaining 17% of experienced fatigue. The third component, contributing to 15%, consisted of patient pain, tender joint count, increasing age, and by concomitant low CRP. The remaining 37% was considered residuals.

Table 1

Characteristics	Fatigue Non to mild VAS score <57 n=520		Fatigue Moderate to severe VAS score >57 n=542		p-value
		n		n	
Female, n (%)	253 (48.7%)	520	358 (66.1%)	542	<0.001
Age, yrs	53.0 (44.0–62.0)	520	52.0 (42.8–60.0)	542	0.070
Disease duration, yrs	6.0 (3.0–11.5)	449	5.0 (2.0–10.0)	456	0.022
C-reactive protein, mg/L	3.0 (1.0–6.0)	421	4.0 (2.0–7.0)	464	0.008
Patient global assessment, 0–100 mmVAS	27.0 (15.0–43.0)	520	75.5 (61.0–86.0)	542	<0.001
Doctors global assessment, 5-grade Likert scale	7.0 (3.0–15.0)	432	14.0 (7.0–14.0)	438	<0.001
PDQ pain score	9.0 (6.0–14.0)	520	17.0 (13.0–23.0)	542	<0.001
DAS28-CRP	2.3 (1.8–2.9)	400	3.5 (2.6–4.4)	418	<0.001
HAQ, 0–3	0.4 (0.1–0.8)	507	1.1 (0.8–1.6)	530	<0.001

All values are median (Q1-Q3) unless otherwise indicated. VAS; visual analogue scale, PDQ; pain assessment questionnaire, DAS28-CRP; disease activity score-C-reactive protein, HAQ; health assessment questionnaire.

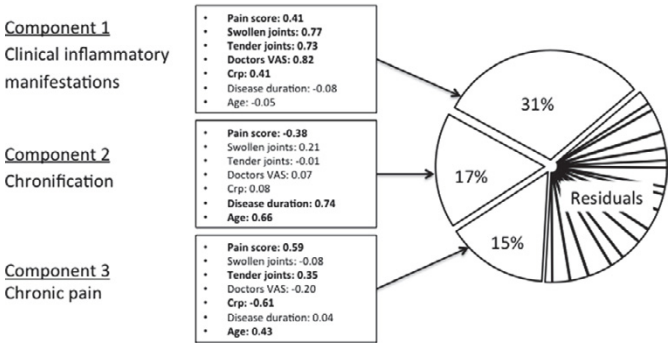

Figure 1

Conclusions: Clinical inflammatory disease activity, chronification, as well as pain in the absence of inflammation were all identified as important factors explaining 63% of moderate to severe fatigue in the current PsA population.

OP0113 METABOLIC SYNDROME AND LIVER STIFFNESS IN PSORIATIC ARTHRITIS AND PSORIASIS PATIENTS: A CASE-CONTROL STUDY

A. Ortolan[1], M. Lorenzin[1], G. Tadiotto[1], F. Oliviero[1], A. Hoxha[1], S. Piaserico[2], L. Punzi[1], R. Ramonda[1]. *[1]Rheumatology Unit, Department of Medicine DIMED; [2]Dermatological Clinic, University of Padova, Padova, Italy*

Background: Psoriatic arthritis (PsA) and psoriasis (PsO) are commonly associated to various comorbidities, among which metabolic syndrome (MetS) has been demonstrated to be more prevalent in these groups with respect to the general population. However, few data are available regarding the comparison between PsA/PsO. Besides, a possible consequence of MetS is the development of a non-alcoholic fatty liver disease (NAFLD), which can progress to fibrosis, the latter rarely assessed in PsA/PsO.

Objectives: The aim of this case-control study was: 1) to compare prevalence of MetS in PsA and PsO 2) to evaluate the presence of liver fibrosis in these two groups using hepatic elastography.

Methods: Forty-three consecutive PsA patients classified according to CIASsification criteria for Psoriatic ARtritis (CASPAR), and 33 consecutive PsO patients without history/manifestations of arthritis, attending the Rheumatology and Dermatology Units of University of Padua, were studied. Exclusion criteria were: conditions which may cause liver fibrosis other than NALFD (eg viral hepatitis, autoimmune or genetic liver disease), alcohol consumption >20 grams/day, active smoking, daily use of non-steroidal anti-inflammatory drugs. Anamnestic, laboratory (cholesterol, triglycerides, uric acid, fasting glucose, insulin, albumin, transaminase) and metrological (blood pressure, waist circumference, height, weight) data were collected. MetS was defined according to the criteria of National Cholesterol Education Program's Adult Treatment Panel III report. Insuline resistance was quantified through HOMA (Homeostatic Model Assessement). All patients underwent hepatic elastography to evaluate liver stiffness; values >7 kPa were taken as indicator of liver fibrosis. PsO severity was assessed through Psoriasis area severity index (PASI). Differences in variables between PsA/PsO were compared through non parametric Mann-Whitney test, and Chi-square test for categorical variables. Correlations between variables were evaluated through Spearman test.

Results: PsA and PsO patients showed similar characteristics (mean age 60,2±8,4 vs 54,5±19,6 years, 74,4% vs 63% males, artritis/PsO duration 12,6±8,5 vs 18,2±14,2 years). The only variables which differ in PsA/PsO groups were Body Mass Index (BMI) (25,7±3,4vs 29,1±6,3), PASI (5±4,6 e 1,5±2,5) and serum uric acid (4,9±1,5 vs 5,7±1,4 mg/dL), all higher in PsO (p-values 0,0092, 0,0355 and 0,0001 respectively). Prevalence of MetS and liver fibrosis in the 2 groups were was similar: 34,9% and 30,8% in PsA vs 33,3% and 27,6% in PsO (p=ns). Among all correlation studied, only serum uric acid, liver stiffness and PASI correlated with other variables (Table). Most interestingly, liver stiffness very well correlated with serum uric acid in PsO ($p<0,0001$ r=0,73).

Table. Correlations found between serum uric acid, liver stiffness and PASI with other variables studied

Uric acid			Liver Stiffness			PASI	
Variables	**PsA**	**PsO**	**Variables**	**PsA**	**PsO**	**Variables**	**PsA**
BMI	n.s	p=0,019 r=0,41	**BMI**	n.s	p=0,020 ρ=0,43	**Waist circumference**	p=0,019 r=0,36
Waist circumference	n.s	p<0,0001 r=0,59	**Waist circumference**	n.s	p<0,0001 ρ=0,69	**HDL cholesterol**	p=0,012 r=-0,38
PASI	p=0,001 r= 0,47	n.s	**Fasting glucose**	p=0,037 ρ=0,33	n.s	**HOMA**	p=0,044 r=0,31
HDL cholesterol	p=0,004 r=-0,42	p=0,015 r=-0,42	**Glycated hemoglobin**	p=0,027 ρ=0,35	p=0,022 ρ=0,42	**Serum uric acid**	p=0,001 r=0,47
Triglycerides	n.s	p=0,005 r=0,48	**Insulin**	p=0,014 ρ=0,38	p<0,0001 ρ=0,64		
Fasting glucose	n.s	p<0,0001 r=0,66	**HOMA**	p=0,018 ρ=0,37	p<0,0001 ρ=0,71		
Serum insulin	n.s	p<0,0001 r=0,74	**Serum uric acid**	n.s	p<0,0001 ρ=0,73		
Glycated hemoglobin	n.s	p<0,0001 r=0,63	**Triglycerides**	n.s	p=0,016 ρ=0,44		
HOMA	p=0,025 r=0,34	p<0,0001 r=0,80					
Liver stiffness	n.s	p<0,0001 r=0,73					

BMI=Body mass Index; HDL=High Density Lipoprotein; PASI= Psoriasis area severity index; HOMA= homeostatic model assessment

Conclusions: We observed a similar prevalence of MetS and hepatic stiffness in PsA and PsO. The correlation found between uric acid level and hepatic stiffness could lie on the fact that uric acid seems to favour insulin resistance, hypertension, dyslipidemia and other MetS risk factors. MetS could be therefore one of the major determinants to liver fibrosis in PsA and PsO, thus highlighting how comorbidities are not only coexhisting conditions, but are strongly linked to each other and need to be treated as well as the skin and joint aspect.

More or less imaging in axial SpA?

OP0114 LOW DOSE COMPUTED TOMOGRAPHY DETECTS MORE PROGRESSION OF BONE FORMATION IN COMPARISON TO CONVENTIONAL RADIOGRAPHY IN PATIENTS WITH ANKYLOSING SPONDYLITIS: RESULTS FROM THE SIAS COHORT

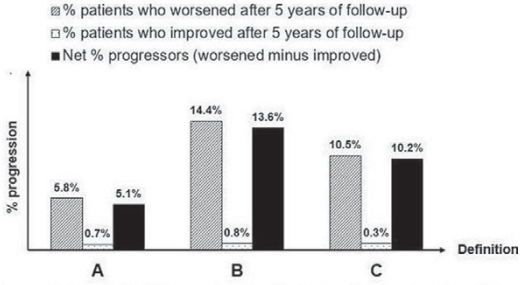
A. de Koning[1], F. de Bruin[1], R. van den Berg[2], S. Ramiro[1], X. Baraliakos[3], J. Braun[3], F.A. van Gaalen[1], M. Reijnierse[1], D. van der Heijde[1]. *[1]LUMC, Leiden; [2]Erasmus MC, Rotterdam, Netherlands; [3]Rheumazentrum, Herne, Germany*

Background: Recently we presented the good interreader reliability and sensitivity to detect changes with a newly developed scoring method of bone formation on low dose computed tomography (LD-CT) of the whole spine in patients (pts) with Ankylosing Spondylitis (AS)[1]. Next step in the validation is the comparison with conventional radiographs (CR).
Objectives: To compare the assessment of syndesmophyte formation and growth on CR and LD-CT in pts with AS.
Methods: Pts from the SIAS (Sensitive Imaging of Axial Spondyloarthritis) cohort from Leiden and Herne were analysed. Inclusion criteria were modified NY criteria, ≥1 syndesmophytes on either the cervical and/or lumbar spine on CR, and ≥1 inflammatory lesion on MRI-spine. Pts had CR of the lateral cervical and lumbar spine and LD-CT (approximately 2–3mSV) of the entire spine at baseline and two years. Two readers independently assessed both CR and CT in separate sessions. Images were paired per patient, blinded to time order, patient information, and result of the other imaging technique. CR was assessed using the mSASSS scoring method. On CT, syndesmophytes were scored in the coronal and sagittal planes for all "corners" per view, thus scoring 8 "corners" per vertebral unit. Syndesmophytes were scored as absent (score 0), <50% of the intervertebral disc height (IVDH) (score 1), ≥50% of the IVDH but no bridging (score 2) or as bridging the IVDH (score 3)[1]. The formation of new syndesmophytes (CR score 0 or 1→2 or 3, CT 0→1 or 2 or 3) and growth of existing syndesmophytes (CR score 2→3, CT 1→2 or 3, or 2→3) and the combination of both was calculated per vertebral corner. Consensus about each of these outcomes was defined by agreement of both readers on the same vertebral level. Data of CR and CT was compared per reader and for the consensus score.
Results: 50 patients (mean age 48.6 years; 84% male; 80% HLA-B27) were included in the analysis. The number (%) of pts with newly formed, growth or combined newly formed and growth of syndesmophytes for separate readers and consensus score are presented in table 1. In all comparisons, CT detected more patients with progression. This is especially apparent in case of growth and for cut-offs of a higher number of (newly formed or growth of) syndesmophytes per patient. E.g. with the strictest comparison of the consensus score for both CR and CT, 30% of the patients show bony proliferation (newly formed and growth) at ≥3 sites on CT compared with only 6% on CR.

Table 1. Comparison of CR and CT per reader and consensus* for the formation and/or growth of syndesmophytes in 50 patients with ankylosing spondylitis.

New syndesmophytes	Reader 1		Reader 2		Consensus	
	CR	CT	CR	CT	CR	CT
≥1	27 (54)	43 (86)	30 (60)	44 (88)	19 (38)	21 (42)
≥2	14 (28)	38 (76)	14 (28)	41 (82)	7 (14)	15 (30)
≥3	6 (12)	32 (64)	8 (16)	30 (60)	2 (4)	10 (20)
Growth of syndesmophytes						
≥1	10 (20)	35 (70)	7 (14)	32 (64)	3 (6)	16 (32)
≥2	8 (16)	36 (52)	6 (12)	27 (54)	3 (6)	11 (22)
≥3	2 (4)	23 (46)	4 (8)	18 (36)	1 (2)	6 (12)
New syndesmophytes or growth of syndesmophytes						
≥1	28 (56)	45 (90)	33 (66)	48 (96)	21 (42)	25 (50)
≥2	18 (36)	42 (82)	19 (38)	44 (88)	9 (18)	20 (40)
≥3	12 (24)	36 (72)	12 (24)	38 (76)	3 (6)	15 (30)

Results are presented as the number (%) of patients with ≥1, ≥2 and ≥3 newly formed syndesmophytes and syndesmophytes that grew, as well as for the combination of new formation and growth.
*Both readers agree about the formation or growth of a syndesmophyte at the same vertebral corner.
CR: conventional radiography, CT: computed tomography



Conclusions: LD-CT covering the whole spine, is a more sensitive method for assessing the formation and growth of syndesmophytes than CR which is limited to cervical and lumbar spine in pts with AS and is a promising method of assessment for clinical research.

OP0115 EVALUATION OF THE CHANGES IN STRUCTURAL DAMAGE IN AXIAL SPONDYLOARTHRITIS ON PLAIN PELVIC RADIOGRAPHS: THE 5 YEARS DATA OF THE DESIR COHORT

M. Dougados[1], A. Sepriano[2], A. Molto[3], S. Ramiro[4], M. De Hooge[4], R. Van Den Berg[4], V. Navarro Compan[4], C. De Mattei[5], R. LandewÉ[4], D. Van Der Heijde[4]. *[1]Department of Rheumatology, Paris, France; [2]Rheumatology, Lisbon, Portugal; [3]Hopital Cochin, Paris, France; [4]Department of Rheumatology, Leiden, Netherlands; [5]Department of Biostatistics, Nimes, France*

Background: The structural damage of axial spondyloarthritis can be evaluated either at the spine or at the Sacroiliac Joint (SIJ) level and by using either plain X-Rays or MRI. So far, the evaluation of the changes in structural damage at the SIJ level has referred mainly to plain X-Rays and to a binary variable (e.g. fulfillment of the modified New York (mNY) criteria yes/no).
Objectives: To evaluate the reliability and the sensitivity to change of different outcome measures of SIJ structural damage observed at pelvic X-Rays.
Methods: *Study design:* Prospective longitudinal (5 years) follow-up of patients with recent onset (≤3 years) axial SpA (according to the treating rheumatologist) enrolled in the DESIR cohort. *Data collected:* Pelvic X-Rays at baseline and after 2 and 5 years of follow-up. *Reading procedure:* The films were evaluated by 3 trained readers unaware of their chronology according to the 0–4 mNY grading scale (from 0 = normal to 4 = fusion) for each SIJ (left and right). *Outcome measures:* One continuous variable: change in the total score (from 0 to 8) and 3 dichotomous variables: A/ Switch from non-radiographic (nr) to radiographic (r) axial SpA according to the mNY definition (e.g. at least unilateral grade III or bilateral grade II), B/ Change of at least one grade in at least one SIJ C/ Change of at least one grade in at least one SIJ and an absolute final value of the worsened joint of at least 2. *Statistical analysis:* a) inter-reader reliability of the changes in the outcome measures (intra-class correlation coefficient for the continuous outcome and Kappa statistics for the dichotomous outcomes) b) sensitivity to change by evaluating the % of net progressors (e.g. worsened minus improved) on both the completer population and the patients with at least one post baseline radiological evaluation using different missing data handling technics (Last Observation Carried Forward, Linear Extrapolation).
Results: The number of patients with available readings from all 3 readers were: 416 (baseline and 5 years), 378 (all time points) and 557 (baseline and at least one post baseline). The results were similar whatever the technic of data missing handling.
In the completer population, (a) The inter-reader reliability was low to modest: 0.21 (0.15–0.28) for the continuous variable and 0.23 (0.10–0.41), 0.24 (0.16–0.34) and 0.23 (0.13–0.35) for the dichotomous variables A, B and C, respectively.
(b) The changes in the total continuous score (from 1.41±1.68 to 1.60±1.83) was modest but highly significant (e.g. 0. 19±0.55 $p<0.0001$). The percentage of net progressors are summarized in the figure. These were 5.1%, 13.6% and 10.2% for the dichotomus variables A, B and C respectively.

Fig: changes in different binary SIJ-Plain X-Rays outcome measures

A = Switch from nr to r-axSpA according to the mNY criteria (worsened) *minus* switch from r to nr-axSpA
B = Change in at least one grade in at least one SIJ
C = Change in at least one grade in at least one SIJ and a final (at year 5) absolute value of at least 2 in the worsened joint (worsened) *minus* change in at least one grade in at least 1 SIJ and a baseline (year 0) absolute value of at least 2 in the improved joint

Conclusions: These data suggest that the structural progression at the SIJ level in recent onset SpA does exist but is modest. Different definitions of changes (e.g. at least one grade in at least one SIJ) seem to be more sensitive than the conventional definition (e.g. switch from nr to r) while reliability was similar. Therefore, these definitions might be useful to evaluate the natural history of the disease.

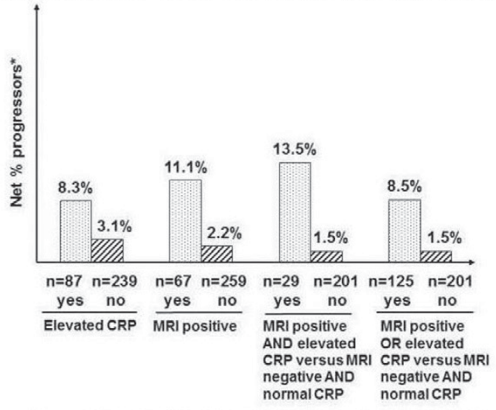
OP0116 SWITCH FROM NON-RADIOGRAPHIC TO RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS IS HIGHLY DEPENDENT OF BASELINE OBJECTIVE SIGNS OF INFLAMMATION: 5 YEAR DATA OF THE DESIR COHORT

M. Dougados[1], A. Sepriano[2], A. Molto[3], S. Ramiro[4], M. De Hooge[5], R. Van Den Berg[5], V. Navarro Compan[5], C. De Mattei[6], R. LandewÉ[5], D. Van Der Heijde[5]. *[1]Department of Rheumatology, Paris, France; [2]Rheumatology, Lisbon, Portugal; [3]Hopital Cochin, Paris, France; [4]Department of Rheuamtology; [5]Department of Rheumatology, Leiden, Netherlands; [6]Department of biostatistics, Nimes, France*

Background: The natural history (e.g. appearance of structural damage) of non-radiographic (nr) axial (ax) Spondyloarthritis (SpA) is not well known.
Objectives: To evaluate the switch from nr- to radiographic (r) status of recent onset axSpA after 5 years of follow-up and its predisposing factors.
Methods: *Patients:* Recent onset axial SpA (DESIR Cohort). *Outcome measure:* Radiographic SIJ status according to the mNY criteria after 5 years follow-up. *Reading of the SIJ-X-Rays:* 3 trained readers unaware of the chronology of the films. *Potential predisposing factors:* Demographics, smoking status, HLA-B27, Bone Marrow Edema (BME) at MRI of the SIJ, CRP, disease activity and



treatment. *Statistical analysis:* The radiographic progression has been evaluated in both the completers and after Linear Extrapolation (LE) and Last Observation Carried Forward (LOCF) technique in case of missing data. The predictive factors of radiographic progression were evaluated on the completer population using multilevel binomial GEE analysis incorporating measurements from all readers at 5-years and taking into account the within-reader correlation.Moreover, the progression rate was assessed in subgroups of patients according to CRP status and MRI-SIJ status at baseline.

Results: At baseline, 62 out of the 416 patients (14.9%) were considered r-ax-SpA. Out of these 416 patients, 24 (5.8%) changed from mNY negative to mNY positive after 5-years. Conversely, 3 patients changed from mNY positive at baseline to negative at year 5 (e.g. 0.7%) resulting in a net progression of 5.1%. These results were similar when applying LOCF and LE (4.1% and 3.8% net progression).

In the multivariate analysis, presence of BME at MRI-SIJ was highly predictive of radiographic progression (OR=4.85 [95% CI: 2.95–7.97]) together with a younger age (OR=0.97 [95% CI: 0.94–0.99]) and longer symptom duration (OR=1.40 [95% CI: 1.04–1.89]).

Of the 383 patients with complete data, the net % patients who switched from nr-axSpA to r-axSpA after 5 years ranged from 2.0% to 13.5% according to the presence of objective signs of inflammation at baseline (see figure).

Fig: Net % patients who switched from nr to r-axSpA after 5 years of follow-up

*% patients who switched from nr to r-axSpA *minus* % patients who switched from r to nr-axSpA according to the mNY criteria

Conclusions: This is the first cohort in early axSpA with 5-year follow-up demonstrating the importance of presence of objective signs of inflammation as predisposing factors of development of radiographic sacroiliitis.

OP0117 BONE MARROW OEDEMA IN SACROILIAC JOINTS OF YOUNG ATHLETES SHOWS MOST FREQUENTLY IN THE POSTERIOR INFERIOR ILIUM

U. Weber[1], A.G. Jurik[2], A. Zejden[2], E. Larsen[3], S.H. Jørgensen[3], K. Rufibach[4], C. Schioldan[3], S. Schmidt-Olsen[3]. *[1]University of Southern Denmark, Odense; [2]Aarhus University, Aarhus; [3]North Denmark Regional Hospital, Hjørring, Denmark; [4]F. Hoffmann-La Roche, Basel, Switzerland*

Background: Low grade bone marrow oedema (BMO) was reported in the sacroiliac joints (SIJ) of up to 25% of healthy individuals and mechanical back pain patients, challenging the imaging discrimination from early spondyloarthritis (SpA) [1]. Potential explanations range from mechanical stress lesions to vascular signals and anatomical SIJ variants.

Objectives: To determine BMO frequency and anatomical distribution in 8 SIJ regions in hobby and professional athletes.

Methods: The sample consisted of 2 cohorts of 20 healthy hobby runners (HR) before and after running and 22 professional ice hockey players (IP) from the Danish premier league: HR/IP 40%/100% men; mean age (SD) 27.2 (5.4)/25.9 (4.6) years; mean BMI (SD) 22.6 (1.5)/25.7 (1.6) kg/m^2. Semicoronal MRI scans of the SIJ with T1SE and STIR sequences were obtained in HR before and 24 hours after a running competition over 6.2 kilometers (mean duration 35.4 minutes, mean speed 10.4 km/h), and in IP during the competitive season. The scans were assessed for BMO independently by 3 blinded readers (AGJ, AZ, UW) according to the quadrant based MORPHO module (www.carearthritis.com). Paired images of HR were read blinded to timepoint. 7 MRI scans (2 paired images) of SpA patients under TNF treatment served to mask readers. A pre-test reader calibration used MRI scans from 11 patients with active sacroiliitis and 9 healthy volunteers. Reader agreement was assessed by ICC (3, 1). Descriptive analysis comprised mean frequency of SIJ quadrants with BMO and distribution of BMO quadrants in 8 anatomical SIJ regions: upper/lower ilium and sacrum, subdivided in anterior and posterior slices, as concordantly recorded by the majority (≥2/3) of readers.

Results: Agreement among 3 readers for SIJ BMO was excellent in calibration (ICC 0.93) and moderate in athletes (ICC 0.59) due to low frequency of BMO. The mean number (SD) of SIJ quadrants showing BMO was 3.1 (4.2)/3.1 (4.5) in HR before/after running, and 3.6 (3.0) in IP. The posterior inferior ilium was the single most affected region, followed by the upper anterior sacrum, consistently across 2 cohorts of athletes.

Table 1. Frequency and anatomical distribution of SIJ quadrants with BMO in 2 cohorts of athletes

Cohort	SIJ quadrants	Upper Ilium		Lower Ilium		Upper Sacrum		Lower Sacrum	
		Anterior	Posterior	Anterior	Posterior	Anterior	Posterior	Anterior	Posterior
HR before									
	Mean (SD)	0.1 (0.4)	0.1 (0.3)	0.2 (0.7)	1.4 (1.9)	0.5 (0.9)	0.1 (0.4)	0.3 (0.6)	0.5 (1.6)
	≥1 Q (n)	3	0	1	8	4	2	3	1
	≥2 Q (n)	0	0	1	6	3	0	0	1
	≥3 Q (n)	0	0	1	2	1	0	0	1
	≥4 Q (n)	0	0	0	1	0	0	0	1
HR after									
	Mean (SD)	0.2 (0.4)	0 (0.1)	0.3 (0.8)	1.2 (1.7)	0.5 (1.0)	0.2 (0.7)	0.3 (0.7)	0.5 (1.6)
	≥1 Q (n)	2	0	2	9	3	2	3	1
	≥2 Q (n)	0	0	1	6	2	1	0	1
	≥3 Q (n)	0	0	1	3	2	0	0	1
	≥4 Q (n)	0	0	1	1	0	0	0	1
IP	Mean (SD)	0.1 (0.4)	0.1 (0.3)	0.5 (0.8)	1.9 (1.9)	0.6 (1.1)	0.1 (0.4)	0.2 (0.6)	0.1 (0.6)
	≥1 Q (n)	0	1	7	13	3	0	3	0
	≥2 Q (n)	0	0	4	11	2	0	1	0
	≥3 Q (n)	0	0	0	6	2	0	0	0
	≥4 Q (n)	0	0	0	3	1	0	0	0

Abbreviations. Q: SIJ quadrants with BMO. ≥1/2/3/4 Q (n): number of subjects (n) with ≥2/3 readers indicating ≥1/2/3/4 SIJ quadrants with BMO.

Conclusions: In hobby and professional athletes, BMO showed on average in 3–4 SIJ quadrants. The posterior lower ilium was the SIJ region most frequently affected by BMO. These findings in healthy controls may help refine thresholds for a positive SIJ MRI in early SpA.

OP0118 IMPACT OF RADIOGRAPHIC DAMAGE IN THE SACROILIAC JOINTS ON FUNCTION AND SPINAL MOBILITY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: RESULTS FROM THE GERMAN SPONDYLOARTHRITIS INCEPTION COHORT

M. Protopopov[1], J. Sieper[1], H. Haibel[1], J. Listing[2], M. Rudwaleit[3], D. Poddubnyy[1]. *[1]Department of Gastroenterology, Infectiology and Rheumatology, Charité Universitätsmedizin Berlin; [2]German Rheumatism Research Centre, Berlin; [3]Klinikum Bielefeld Rosenhöhe, Bielefeld, Germany*

Background: It has been shown in the past that the spinal mobility in patients with axial spondyloarthritis (AxSpA) is associated with spinal structural damage, disease activity parameters and spinal inflammation [1]. The impact of radiographic damage in the sacroiliac joints on functional parameters in patients with axial spondyloarthritis has not been investigated so far.

Objectives: To analyze the association between radiographic sacroiliitis and parameters of the functional status and spinal mobility in patients with axSpA.

Methods: Altogether 210 patients with definite axSpA (115 with radiographic and 95 with non-radiographic axSpA) from the German Spondyloarthritis Inception Cohort (GESPIC) were included in the current study. Radiographs of sacroiliac joints were obtained at baseline and after 2 years of the follow up and were scored by two trained readers according to the conventional grading system of the modified New York criteria (grade 0 to 4 per joint). A mean of two readers score for each joint and a sum score for both SIJ were calculated for each patient, giving a total sacroiliitis score between 0 and 8. Functional status and spinal mobility were assessed by means of the Bath Ankylosing Spondylitis Functional Index (BASFI) and the Bath Ankylosing Spondylitis Metrology Index (BASMI), respectively. Both baseline and year 2 data were included in the longitudinal mixed models analysis that was corrected for the dependencies between the two time-point values of each individual and adjusted for the structural damage in the spine (modified Stoke Ankylosing Spondylitis Spine Score - mSASSS), disease activity (the Bath Ankylosing Spondylitis Disease Activity Index – BASDAI and level of C-reactive protein – CRP), and sex.

Results: In the longitudinal mixed model analysis adjusted for the presence of structural damage in the spine (mSASSS), disease activity (BASDAI and CRP) and sex, radiographic sacroiliitis demonstrated an independent association with the BASFI: β=0.10 (95% CI 0.01–0.19) and the BASMI: β=0.12 (95% CI 0.03–0.21), respectively – table. These data indicate that change by one radiographic sacroiliitis grade in one sacroiliac joint is associated with a BASFI/BASMI worsening by 0.10/0.12 points independently of structural damage in the spine and disease activity. Assuming linear association, progression of radiographic sacroiliitis from grade 0 bilaterally to grade 4 bilaterally would result in a worsening by 0.8 points in BASFI and 0.96 points in BASMI. Sensitivity analysis performed in radiographic and non-radiographic axSpA subgroups provided similar results for both outcomes.

Conclusions: Radiographic damage in the sacroiliac joints might have an impact,

Table. Association between the sum radiographic sacroiliitis score and functional status / spinal mobility in patients with axial spondyloarthritis.

Parameters	Unadjusted mixed model analysis β (95% CI)	Adjusted mixed model analysis β (95% CI)
Outcome: BASFI		
Sacroiliitis sum score (0-8)	**0.09 (-0.05 to 0.22)**	**0.10 (0.01 to 0.19)**
mSASSS, points (0-72)	-	0.05 (0.03 to 0.07)
BASDAI, points NRS (0-10)	-	0.81 (0.74 to 0.88)
CRP, mg/l	-	0.00 (-0.01 to 0.01)

OP0119 EVALUATION OF THE PREDICTIVE VALIDITY OF THE ASAS AXIAL SPONDYLOARTHRITIS CRITERIA IN THE DESIR COHORT

B. Meghnathi[1], A. Etcheto[1], A. Saraux[2], M. Dougados[1], A. Moltó[1]. *[1]Paris Descartes University, Medicine Faculty; APHP, Rheumatology B Department, Cochin Hospital, Paris; [2]La Cavale Blanche Hospital, Rheumatology and Université Bretagne Occidentale, Brest, France*

Background: The face validity[1] and cross-sectional external validity[2] of the Assessment of SpondyloArthritis international Society (ASAS) criteria for axial spondyloarthritis (axSpA), and its arms has been already confirmed in previous studies. However, so far, only one study[3] has reported data regarding the predictive validity of such criteria after 4 years of follow-up.

Objectives: To evaluate the predictive validity of the ASAS criteria and its arms after 5 years of follow-up. The predictive validity of the other axSpA sets of criteria (Amor, ESSG and mNY) was also evaluated.

Methods: Patients: This analysis was performed on the DESIR cohort. A total of 708 adult (>18 and <50 years) patients presented with inflammatory back pain suggestive of axSpA (according to the rheumatologist's conviction of ≥5/10) for >3 months but <3 years duration. They were followed up every 6 months for the first 2 years and then yearly up to 5 years. Starting from month 24, as per protocol, patients could be excluded from the cohort in case another diagnosis (different from SpA) was made.

Methods: The gold standard for this analysis was the diagnosis of axSpA according to the rheumatologist at 5 years of follow-up. For this analysis, patients were considered as axSpA, if the rheumatologist at 5 years with a conviction of ≥7/10 for an axSpA diagnosis. Conversely, patients excluded as per protocol due to another diagnosis or patients with a rheumatologist conviction at 5 years of ≤3/10 for axSpA were considered as Non-axSpA. The set of criteria collected at baseline (ASAS, and its arms, Amor, ESSG and mNY: fulfilled/not fulfilled) were tested against the Rheumatologist's axSpA diagnosis (fulfilled/not fulfilled) after 5 years of follow-up. Predictive validity of all sets of criteria at baseline was evaluated by the positive predictive value (PPV).

Results: In total, among the 708 patients included in the DESIR cohort at baseline, data on Rheumatologists diagnosis at 5 years was available in 454 patients; amongst them, 352 (77.5%) had an axSpA diagnosis according to the rheumatologist. Among these 352 patients, 245, 300, 291 and 88 patients fulfilled the ASAS criteria for axSpA, Amor, ESSG and modified NY criteria's respectively. Figure 1 shows the PPV (95% CI) of the different sets of criteria below.

Conclusions: Predictive validity of the ASAS criteria for axSpA (including both arms) at 5 years was excellent; it is worth noting that the performances of the other criteria were also very good.

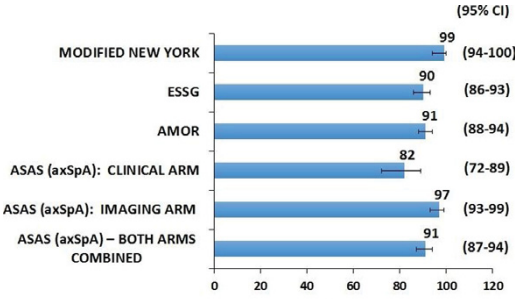

Figure 1. Bar diagram representing Positive Predictive Value (95% Confidence Interval) of various axSpA criterias

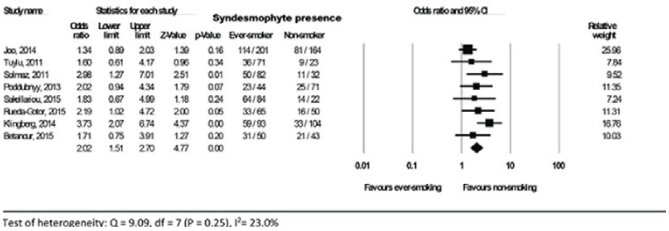
OP0120 THE ROLE OF SMOKING IN THE DEVELOPMENT AND PROGRESSION OF STRUCTURAL DAMAGE IN PATIENTS WITH ANKYLOSING SPONDYLITIS: THE PRELIMINARY RESULTS OF A SYSTEMATIC REVIEW AND META-ANALYSIS

S. Akar[1], Y.C. Kaplan[2], S. Ecemis[1], E.K. Arslan[2], O. Gercik[1], D. Solmaz[1]. *[1]Rheumatology; [2]Pharmacology, Izmir Katip Celebi University Faculty of Medicine, Izmir, Turkey*



Background: Smoking may constitute a major risk factor for not only disease susceptibility but also disease severity in patients with ankylosing spondylitis (AS). Some previous cross-sectional and longitudinal studies suggested that smoking may be associated with cumulative spinal radiographic damage and regarded it as an independent predictor of spinal radiographic progression.

Objectives: The objective of this study is to determine whether smoking is associated with the cumulative radiographic spinal structural damage and radiographic progression in AS patients. In order to reach this objective, we conducted a systematic review and meta-analysis of the available studies to-date.

Methods: An electronic search was conducted from inception to June 21 2016 in EMBASE, MEDLINE/PubMed Cochrane Central Register of Controlled Trials databases. Cross-sectional and longitudinal cohort studies investigating the association between smoking and cumulative spinal structural damage or radiographic progression were included. The outcome of interest were the presence of syndesmophytes in cross-sectional studies and radiographic progression in longitudinal studies. Two independent reviewers carried out the screening process. The Quality assessment was done using The Agency for Healthcare Research and Quality (ARHQ) checklist and Newcastle-Ottawa scale. Authors of potential relevant studies were contacted for the unpublished data. Data from eligible cross-sectional studies were extracted and arranged in a 2x2 table. The odds ratios (ORs) and 95% confidence intervals (CIs) for the dichotomous outcome of interest were computed. Random-effects method was used to combine the outcome data in Comprehensive Meta Analysis Software Version 3.3.070.

Results: The combined data of eight eligible cross-sectional studies for the assessment of association between smoking and cumulative spinal structural damage suggested a significant association (OR, 2.02; 95% CI 1.51–2.70)

Figure 1. Forest plot of the association between ever-smoking and cumulative spinal structural damage in AS patients

Test of heterogeneity: Q = 9.09, df = 7 (P = 0.25), I^2 = 23.0%

(Figure 1). No significant heterogeneity was detected between studies (P=0.25, I^2=23.0%). The data from the longitudinal studies investigating the association between smoking and spinal radiographic progression is still been assessed.
Conclusions: The preliminary results of our meta-analysis showed that smoking is associated with increased cumulative spinal structural damage in patients with AS. Rheumatologists should encourage AS patients to quit smoking.

OP0121 VALIDATION OF MRI STRUCTURAL LESIONS USING COMPUTED TOMOGRAPHY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

W.P. Maksymowych[1,2], D. Loeuille[3], M. Raynal[4], J. Melchior[5], M.-A. D'Agostino[6], J. Paschke[2], R.G. Lambert[7]. *[1]Medicine, University of Alberta; [2]CaRE Arthritis, Edmonton, Canada; [3]Rheumatology, CHRU de Nancy; [4]Rheumatology, CHRU de Nancy, Vandœuvre-lès-Nancy; [5]Rheumatology, CHRU de Nancy, Vandoeuvre les Nancy; [6]Rheumatology, Université Paris Ouest, Paris, France; [7]Radiology, University of Alberta, Edmonton, Canada*

Background: MRI can detect both inflammatory and structural lesions in the sacroiliac joints (SIJ) of patients with axial SpA. However, standard MRI sequences do not directly depict bone and the appearance of erosion may vary according to the presence/absence of inflammation. Consequently, further validation using an accepted gold standard, namely, computed tomography (CT), is essential.
Objectives: We aimed to assess the detection of structural lesions in the SIJ by MRI using CT as the gold standard.
Methods: CT scans from 44 patients (26 females, mean age 49.4 years, mean symptom duration 9.1 years) were reconstructed in the semicoronal plane parallel to the superior border of the sacrum, as for conventional MRI evaluation of the SIJ, and scoring of lesions by CT was confined to this plane. Structural lesions were scored in consecutive slices in SIJ quadrants (erosion, sclerosis) or SIJ halves (ankylosis) on a dichotomous basis (present/absent) using the same anatomical principles for defining SIJ quadrants as developed for the SPARCC MRI SIJ inflammation and structural scores. T1W MRI scans of the SIJ from the same cases conducted at the same time as CT were assessed independently for structural lesions (erosion, fat, backfill, ankylosis, sclerosis) blinded to CT assessments using the SPARCC method. Agreement between CT and MRI was assessed by kappa statistics. Sensitivity/specificity of MRI for CT lesions was calculated. The primary analysis was based on lesions detected concordantly by both readers at the level of the individual iliac/sacral joint surface (erosion, sclerosis) or the individual joint (ankylosis, backfill).
Results: With CT as gold standard and a lesion defined as being present when recorded in the same location on at least 1 coronal slice by both readers, MRI-defined ankylosis had 56.3% sensitivity and 100% specificity for CT ankylosis (Table). For erosion, sensitivity and specificity of MRI was 81.3% and 96.2%, and for sclerosis, sensitivity and specificity of MRI was 50% and 97%, respectively. Agreement between CT and MRI for erosion increased when the cut-off for presence of a lesion was set at 2 slices but only marginally for sclerosis, even when the cut-off for presence of a lesion was set at 3 slices. Lesions observed on CT corresponding to backfill on MRI were ankylosis, erosion, and sclerosis, in 66.7%, 66.7%, and 80% of backfill lesions, respectively.

Concordance for 2 readers		Type of Lesion	K value	Sensitivity of MRI	Specificity of MRI
MRI lesion +	CT lesion +				
≥1 slice	≥1 slice	Ankylosis	0.67	56.3%	100%
		Erosion	0.76	81.3%	96.2%
		Sclerosis	0.47	50.0%	97%
≥2 slices	≥2 slices	Ankylosis	0.71	60.0%	100%
		Erosion	0.83	84.6%	98.1%
		Sclerosis	0.53	42.9%	99.2%
≥2 slices	≥3 slices	Ankylosis	0.83	75.0%	100%
		Erosion	0.84	90%	98.1%
		Sclerosis	0.53	42.9%	99.2%

Conclusions: Ankylosis and erosion on MRI correspond closely with the same type of lesion observed on CT. Both new bone formation and erosion are frequently evident on CT at locations where backfill is observed on MRI supporting the hypothesis that backfill is an intermediary tissue between erosion and ankylosis.

Clinical and therapeutical news in systemic sclerosis

OP0122 VENOUS THROMBOEMBOLISM IN SYSTEMIC SCLEROSIS: PREVALENCE, RISK FACTORS AND IMPACT ON SURVIVAL

S.R. Johnson[1], N. Hakami[2], Z. Ahmad[1], D.N. Wijeysundera[3]. *[1]University of Toronto, Toronto, Canada; [2]King Fahad Central Hospital, Jizan, Saudi Arabia; [3]Anesthesia, University of Toronto, Toronto, Canada*

Background: Systemic sclerosis (SSc) is characterized endothelial dysfunction and vasculopathy, which may result in thrombosis. Venous thromboembolism (VTE) is a vascular phenomenon that includes deep vein thrombosis (DVT) and pulmonary embolism (PE).
Objectives: To evaluate the epidemiology of VTE in SSc, specifically cumulative incidence, risk factors and impact of VTE on survival.
Methods: We conducted a cohort study of patients who fulfilled the ACR–EULAR classification criteria for SSc attending the Toronto Scleroderma Program 1970–2017. DVT was defined as the presence of thrombus on doppler ultrasound of either upper or lower extremity. PE was defined as the presence of thrombus on CT angiogram of the thorax. Time to all-cause mortality was evaluated in Kaplan Meier and Cox models.
Results: 1181 subjects (971 (82%) female, 210 (18%) male) were included. There were 40 (3.4%) VTE events. The cumulative incidence of VTE was 2.7 (95% CI 1.9, 3.7) per 1000 patient years. The presence of ILD, PAH, ScL70 antibody, anticardiolipin antibody, coronary artery disease, diabetes mellitus and PVD occurred more frequently in subjects who developed VTE.

Table 1. Venous Thromboembolism in SSc

Characteristics	VTE (N=40)	No VTE (N=1141)	Relative Risk (95% CI)
Diffuse subtype	12 (30%)	382 (33%)	1.04 (0.84, 1.30)
Male sex	9 (23%)	201 (18%)	1.28 (0.71, 2.30)
Raynaud's phenomenon	39 (98%)	1087 (95%)	1.02 (0.97, 1.08)
Esophageal dysmotility	35 (88%)	981 (86%)	1.02 (0.90, 1.15)
Interstitial lung disease	23 (58%)	393 (34%)	1.67 (1.26, 2.20)*
Pulmonary arterial hypertension	28 (70%)	367 (32%)	2.18 (1.75, 2.71)*
Abnormal nailfold capillaries	14 (35%)	354 (31%)	1.13 (0.73, 1.74)
Digital ulcers	13 (33%)	386 (34%)	0.96 (0.61, 1.51)
Scl 70 antibody	11 (28%)	186 (16%)	1.73 (1.03, 2.91)*
Anticentromere antibody	5 (13%)	215 (19%)	0.68 (0.30, 1.56)
Anticardiolipin	3 (8%)	14 (1%)	6.27 (1.88, 20.9)*
Coronary artery disease	9 (23%)	98 (9%)	2.69 (1.47, 4.92)*
Hypertension	11 (28%)	237 (21%)	1.32 (0.79, 2.22)
Diabetes mellitus	6 (15%)	61 (5%)	2.81 (1.29, 6.10)*
Hyperlipidemia	5 (13%)	78 (7%)	1.83 (0.78, 4.27)
Peripheral vascular disease	8 (20%)	41 (4%)	5.57 (2.79, 11.08)*
Cancer	7 (8%)	127 (11%)	1.57 (0.79, 3.14)
Atrial fibrillation	6 (15%)	45 (4%)	3.80 (1.72, 8.39)*

*Denotes statistical significance.

On multivariate logistic regression PAH (OR 3.77 (96%CI 1.83, 8.17), ScL70 antibodies (OR 2.45 95% CI 1.07, 5.30), anticardiolipin antibodies (OR 5.70 (95% CI 1.16, 21.2) and PVD (OR 5.31 (95% CI 1.99, 12.92) were independent predictors of VTE. Subjects with ILD more frequently experienced DVT (RR 2.85 95% CI (1.08, 7.54) but not PE (RR 1.82 (95% CI 0.89, 3.70). There were 440 deaths. There was no significant difference in survival between those with and without VTE (HR 1.6 (95% CI 0.70, 1.92). Only the presence of ILD (HR 1.54 (95% CI 1.27, 1.88) or PAH (HR 1.35 (95% CI 1.10, 1.65) remained independent predictors of mortality.

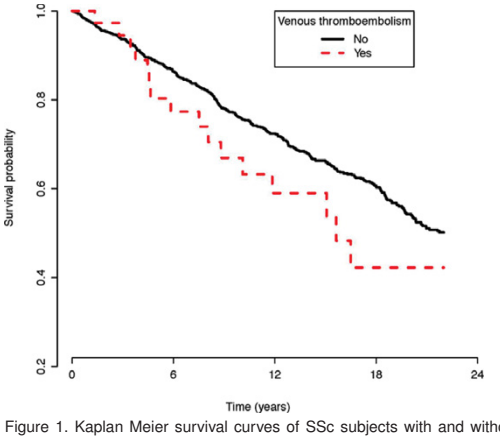

Figure 1. Kaplan Meier survival curves of SSc subjects with and without venous thromboembolism. Log rank test p=0.54

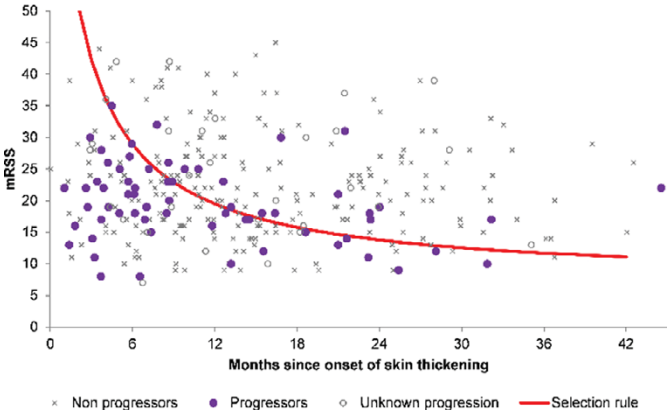

Conclusions: The risk of VTE in SSc is not increased, as the incidence of VTE in SSc is comparable to the general population. The presence of PAH, PVD, ScL70 and anticardiolipin antibodies are risk factors for VTE in SSc. VTE does not independently affect SSc survival.

OP0123 PREDICTION OF PROGRESSIVE SKIN THICKENING IN EARLY DIFFUSE SYSTEMIC SCLEROSIS USING THREE-MONTHLY SKIN SCORES FROM THE EUROPEAN SCLERODERMA OBSERVATIONAL STUDY (ESOS)

A. Herrick[1], S. Peytrignet[1], X. Pan[1], R. Hesselstrand[2], L. Mouthon[3], E. Brown[1], L. Czirják[4], J.H. Distler[5], O. Distler[6], K. Fligelstone[1], W. Gregory[1], R. Ochiel[7], A. Silman[8], M. Vonk[9], M. Lunt[1], C. Denton[7]. *[1]University of Manchester, Manchester, United Kingdom; [2]Lund University, Lund, Sweden; [3]Université Paris Descartes, Paris, France; [4]University of Pécs, Pécs, Hungary; [5]University of Erlangen-Nuremberg, Erlangen, Germany; [6]University Hospital Zurich, Zurich, Switzerland; [7]University College London, London; [8]University of Oxford, Oxford, United Kingdom; [9]Nijmegen University, Nijmegen, Netherlands*

Background: ESOS (European Scleroderma Observational Study) was a prospective observational study of early diffuse cutaneous systemic sclerosis, recruiting from 50 centres in 19 countries and thus providing a unique opportunity to study parameters of disease progression at regular intervals.
Objectives: To describe the characteristics of patients with progressive skin thickening and derive prediction models for progression over 12 months.
Methods: Duration of skin thickening and autoantibody status (anti-topoisomerase-1[anti-Scl-70, TOPO], anti-RNA polymerase III[Pol3], anticentromere[ACA]) were documented. The modified Rodnan skin score (mRSS) was recorded 3-monthly for up to two years after baseline. The main outcome was the progression of mRSS. Progressive patients ("progressors") had to meet a 5-unit and 25% increase in their mRSS within the first 12 monthsof follow-up. Features of progressors vs. non-progressors were compared using the Fisher or Kruskal-Wallis test (for categorical and continuous variables), as were progression parameters between autoantibody groups. Logistic models were fitted to predict progression and, using ROC curves, were compared based on AUC, accuracy and positive predictive value (PPV).
Results: 326 patients were recruited, with median disease duration of 11.9 months. During the first 12 months, 66 patients (20.3%) progressed, 227 (69.6%) did not and 33 (10.1%) could not have their status assessed. At baseline, progressors had shorter disease duration than non-progressors: 8.1 months vs. 12.6 months (p=0.001). Progressors started with a lower mRSS, median 19 units vs. 21 for non-progressors (p=0.030).
124 patients were TOPO+, 50 were Pol3+, 20 were ACA+, 2 were TOPO+/ACA+ and 68 had none. Pol3+ patients had a higher mRSS peak (35 units vs. 27 overall[p=0.001]) and did so earlier (median 17.9 months vs. 23.1 months overall[p=0.214]).
Using an mRSS 22 cutoff point to predict progression in the ESOS cohort (as suggested in the literature) would yield a PPV of 24.3%, a weak improvement from the observed 20.3% share of progressors. A first model (Model A, with mRSS, duration of skin thickening and their interaction) had an accuracy of 60.9%, AUC of 0.67 and PPV of 33.8%. Figure 1summarizes the prediction rule, with patients under the curved line predicted to progress. By adding a variable for being Pol3+ (Model B), the model reached an accuracy of 71%, AUC of 0.71 and PPV of 41%.

Figure 1. Trade-off at baseline between mRSS and disease duration and prediction rule to select progressors (Model A)

Conclusions: 1. Patients with shorter disease duration and a lower mRSS have a higher likelihood of being progressors, with a trade-off between the two.
2. Pol3+ patients experience higher mRSS peaks and tend to reach them earlier.
3. Two prediction models for progressive thickening were derived. The advantage of having two is that Model B, while more accurate and useful in identifying high-risk patients in clinical practice, risks being too restrictive for patient selection into trials and may over-represent Pol3+ patients.

OP0124 TREATMENT WITH CYCLOPHOSPHAMIDE FOR SYSTEMIC SCLEROSIS-RELATED INTERSTITIAL LUNG DISEASE DOES NOT IMPROVE SURVIVAL AFTER 12 YEARS OF FOLLOW UP

E.R. Volkmann[1], M. Sim[1], D.P. Tashkin[1], D. Khanna[2], P.J. Clements[1], M. Roth[1], D. Furst[1], A. Pickney[3], E. Goldmuntz[4], L. Keyes-Elstein[3], R. Elashoff[1], K. Sullivan[5] on behalf of SLS I working group. *[1]University of California, Los Angeles, Los Angeles; [2]University of Michigan, Ann Arbor; [3]Rho Federal Systems, Inc., Chapel Hill; [4]DAIT, Niaid/Nih, Bethesda; [5]Duke University, Durham, United States*

Background: Treatment with cyclophosphamide (CYC) is associated with short-term improvements in lung function, dyspnea, and radiographic fibrosis in patients with systemic sclerosis-related interstitial lung disease (SSc-ILD).[1] However, the effects of CYC therapy on long-term morbidity and mortality outcomes are unknown.
Objectives: To determine whether 1 year of treatment with CYC for SSc-ILD affects long-term morbidity and mortality in patients who participated in the Scleroderma Lung Study (SLS) I.[1]
Methods: SLS I randomized 158 SSc-ILD patients from 13 US SSc centers to 1 year of oral CYC versus placebo. The primary endpoint was the change in FVC%>predicted over 1 year. Twelve years after the study commenced, each study center contacted enrolled patients or designated surrogates to assess the following: mortality, cause of mortality, development of organ failure, need for transplant and functional status. We used counting process cox proportional hazard modeling to determine the variables associated with survival. The model findings were validated using a joint model of longitudinal and survival data. We also tested the model using long-term follow-up data from SLS II (CYC vs. Mycophenolate).
Results: Nearly half of all SLS I patients (43%) died during the follow-up period, and only 24% remained alive in the absence of organ failure. The median follow up period for all patients was 8 years. Where known, the cause of death was attributable most often to SSc. Among patients who developed malignancy (N=13), a similar proportion were treated with CYC compared with placebo. The most common type of organ failure was respiratory failure (N=31 of 33 organ failures) defined as the need for supplemental oxygen therapy (N=29) and/or lung transplantation (N=3). There was no difference in the time to death (Figure 1), or time to organ failure, or time to malignancy in patients randomized to CYC versus placebo. The Cox model identified the following variables as the most important predictors of mortality: baseline skin score (HR 1.033; P=0.0038), age at randomization (HR 1.056; $P<0.0001$), and the course of the FVC from baseline to 24 months (HR 0.975; P=0.0215). The course of the FVC was a better predictor of mortality than the baseline FVC. The joint model identified the same variables associated with mortality.

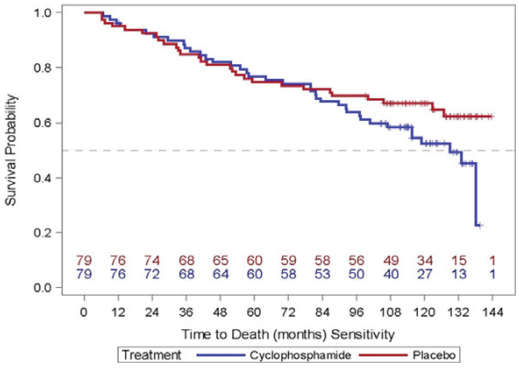

Figure 1. Time to death in patients randomized to CYC (blue line) and placebo (red line).

Conclusions: Treatment with 1-year of oral CYC for SSc-ILD does not decrease long-term mortality, organ failure or malignancy compared with placebo. In addition to identifying traditional mortality risk factors in SSc (i.e. increased skin score and advanced age), this study found that progression of the FVC over 2 years was a more important predictor of mortality than the baseline FVC. These findings suggest that early changes in surrogate measures of SSc-ILD progression may have important effects on long-term outcomes.

OP0125 MORTALITY IN PATIENTS WITH DERMATOMYOSITIS/POLYMYOSITIS IN A CHINESE MEDICAL CENTRE

X. Yang. *Peking University First Hospital, Beijing, China*

Objectives: To investigate the mortality and the causes of death in Chinese patients with dermatomyositis (DM) or polymyositis (PM).
Methods: We collected the clinical data of all DM/PM patients in Rheumatology

department of Peking University First Hospital from January 2007 to May 2016.The primary causes of death were identified, the standardised mortality ratio (SMR) and years of life lost (YLL) were calculated based on the National Bureau of Statistics of China for the general population, the survival in the first decade was performed using Kaplan-Meier analysis, and the predictors of mortality were evaluated by multivariable cox regression.

Results: A total of 226 DM and 54 PM cases were included and the mean age of onset was 49.9±14.8 years for DM and 48.1±17.1 years for PM. The median follow-up duration was 40.6 (11.6–77.6) months. Among 267 patients who were successfully traced, 66 patients died. Infection (50.0%) was the leading cause of death followed by malignancy (19.7%), and interstitial lung disease (ILD) (9.1%). The overall age and sex adjusted SMR was 9.0 (95% CI 6.8–11.2) for DM, and 5.0 (95% CI 2.4–7.5) for PM. The overall age and sex adjusted SMR of DM/PM patients with ILD was 8.4 (95% CI 5.8–11.0), and the SMR of the patients with malignancy was 14.9 (95% CI 8.5–21.2). The YLL of women and men were 37.5 and 28.4 years respectively for DM, and 24.3 and 12.0 years respectively for PM (Table1). The 10-year survival of patients with ILD or malignancy was significantly worse than those without ILD or malignancy respectively (Figure 1 and 2). The independent predictors of mortality for DM were age of disease onset, respiratory muscle involvement and malignancy; and the independent predictor of mortality for PM was age at disease onset (Table2).

Table 1. The standardized mortality ratio (SMR), life expectancy (LE) and years of life lost (YLL)

	Overall (n=280)	Females (n=201)	Males (n=79)
Dermatomyositis	226	163	63
Death number	55	37	18
SMR (95% CI)	9.0 (6.8–11.2)	12.0 (6.8–11.2)	6.0 (3.2–8.7)
LE of general population (years)	–	80.8	75.8
LE of DM patients (years)	–	43.3	47.4
YLL (years)	–	37.5 8	28.4
Polymyositis	54	38	16
Death number	11	8	3
SMR (95% CI)	5.0 (2.4–7.5)	4.2 (1.3–7.2)	9.3 (-1.2–19.8)
LE of general population (years)	–	80.8	75.8
LE of PM patients (years)	–	56.5	63.8
YLL (years)	–	24.3	12.0

Abbreviations: DM: dermatomyositis; SMR: standardised mortality ratio; CI: confidence interval; LE: life expectancy; YLL: years of life lost; PM: polymyositis.

Table 2. Multivariable cox regression analyses of risk factors in the DM/PM patients

Variables	HR	95% CI	*P* value
Dermatomyositis			
Age*	1.04	1.01–1.06	<0.001
ILD	1.35	0.74–2.48	0.319
Respiratory muscle involvement	2.58	1.19–5.58	0.016
Malignancy	3.12	1.49–6.58	0.003
Polymyositis			
Age*	1.08	1.00–1.16	0.044
ILD	2.47	0.18–34.00	0.500
ESR	1.02	0.99–1.04	0.174

*Age: Age at disease onset. Abbreviations: HR: Hazard Ratio; CI: confidence interval; ILD: interstitial lung disease; ESR: erythrocyte sedimentation rate.

Conclusions: Mortality of DM/PM patients in China is substantial, especially in females, and those with ILD or malignancy. Infection was the leading cause of death. Patients with older age at onset, respiratory muscle involvement, ILD, and malignancy need to be paid more attention.

OP0126 A PHASE 2 STUDY OF SAFETY AND EFFICACY OF ANABASUM (JBT-101) IN SYSTEMIC SCLEROSIS

R. Spiera[1], L. Hummers[2], L. Chung[3], T. Frech[4], R. Domsic[5], D. Furst[6], J. Gordon[1], M. Mayes[7], R. Simms[8], S. Constantine[9], B. White[9]. *[1]Hospital for Special Surgery, New York City; [2]Johns Hopkins, Baltimore; [3]Stanford, Palo Alto; [4]University of Utah, Salt Lake City; [5]University of Pittsburgh, Pittsburgh; [6]Arthritis Association of Southern California, Los Angeles; [7]University of Texas, Houston; [8]Boston University, Boston; [9]Corbus Pharmaceuticals, Inc., Norwood, United States*

Background: Anabasum (JBT-101) is a synthetic, oral, non-immunosuppressive, preferential CB2 agonist. It inhibits onset and activates resolution of innate immune responses in animal models of systemic sclerosis (SSc).

Objectives: Evaluate safety and efficacy of anabasum in SSc

Methods: A double-blind, randomized, placebo (PBO)-controlled Phase 2 trial dosed 42 diffuse cutaneous SSc subjects with disease duration ≤6 years on stable medication including immunosuppressive drugs. Subjects received anabasum 5 mg QD, 20 mg QD, or 20 mg BID on Days 1–28, then 20 mg BID on Days 29–84, or PBO on Days 1–84. Subjects were followed off study drug on Days 85–113. The primary safety outcome was treatment-emergent adverse events (TEAEs). The primary efficacy outcome was improvement in ACR Combined Response Index in diffuse cutaneous Systemic Sclerosis (CRISS) score, combined anabasum group vs PBO, Days 29–113 (end of Weeks 4–16). The five domains of the ACR CRISS are the modified Rodnan skin score, HAQ-DI, patient and physician global assessments, and FVC % predicted.

Results: Of 42 dosed subjects, 27 (64%) received anabasum and 15 (36%) received PBO. Three anabasum subjects withdrew: 1 (3.7%) for a TEAE of moderate dizziness; 1 withdrew consent; and 1 by physician decision. One PBO subject withdrew consent. Baseline demographic and CRISS domain scores were similar except slightly more anabasum subjects used background immunosuppressive drugs (93% versus 80%, anabasum vs PBO). Seventeen (63%) anabasum subjects had 66 TEAEs, and 9 (60%) PBO subjects had 35 TEAEs. There were no serious, severe, or unexpected TEAEs related to anabasum. Severity and relationship of TEAEs to study drug were similar in both groups. The most frequent TEAEs by MedDRA system (% anabasum vs % PBO) were: nervous system (37% vs 27%); general disorders (30% vs 7%); gastrointestinal (22% vs 20%); infections (22% vs 20%); musculoskeletal (22% vs 13%); and investigations (0% vs 20%). The most frequent TEAEs in anabasum subjects were dizziness (22%) and fatigue (19%) which were usually mild. Anabasum subjects had greater improvement in ACR CRISS scores than PBO subjects (mixed model repeated measures analysis, p=0.044, 1-sided). The median ACR CRISS scores at the end of Weeks 4, 8, 12, and 16 (anabasum vs PBO) were 3.0% vs 1.0%, 19.0% vs 1.0%, 27.5% vs 1.0%, and 33.0% vs 1.0%, respectively. Among anabasum subjects, ∼50% had ACR CRISS ≥20% after 8 weeks of dosing. The individual domains of the ACR CRISS score showed greater improvement, improvement that reached minimal important differences in several domains, and less worsening in anabasum vs PBO groups. Anabasum subjects had greater improvement in SSc skin symptoms and itch. Plasma metabolipidomic profiles showed anabasum, not PBO, shifted lipid mediator production to increase pro-resolving vs pro-inflammatory lipid mediators.

Conclusions: Anabasum provided significant and medically meaningful efficacy in SSc as assessed by the ACR CRISS score and its individual domains and had acceptable safety and tolerability in this Phase 2 trial. These data support continued clinical development of anabasum for the treatment of SSc.

OP0127 TEN YEARS FOLLOW-UP OF GASTROINTESTINAL INVOLVEMENT BY THE SMALL INTESTINAL CLEARANCE IN PATIENTS WITH SYSTEMIC SCLEROSIS

N. Hashimoto[1], M. Kitano[2], T. Nakazawa[3], T. Iwasaki[4], T. Hashimoto[1]. *[1]Hashimoto Rheumatology Clinic, Osaka; [2]Division of Rheumatology, Department of Internal Medicine, Hyogo College of Medicine, Nishinomiya; [3]Osaka Saiseikai Nakatsu Hospital, Osaka; [4]Department of Pharmacy, Hyogo University of Health Sciences, Kobe, Japan*

Background: Systemic sclerosis (SSc) is an inflammatory autoimmune disease characterized by fibrosis and small vascular involvement in the skin, lungs, heart and gastrointestinal (GI) tract. The esophagus is the most frequently involved GI tract disorder. Although the small intestinal involvement such as malabsorption and pseudo-obstruction is less common, it has been related to morbidity and mortality of SSc patients. We previously reported a close correlation between the

esophageal diameter and the small intestinal clearance (SIC) (EULAR 2011). We also suggested that anti-centromere antibodies (ACA) are an important factor of esophageal dilatation in SSc patients (EULAR 2010). However, changes of small intestinal involvement during long-term follow-up have not yet been defined.

Objectives: The aim of this study was to evaluate a correlation between the small intestinal involvement and clinical features in SSc patients during ten years follow-up.

Methods: Fifty-five patients with a definite diagnosis of SSc [52 female and 3male with mean age of 59.4 years (range 29–77 years)] were included in the study. Thirteen (23.6%) patients were classified as diffuse SSc and 42 (76.4%) as limited SSc. The SIC grade was classified according to barium meal reach at 30 min after intake; grade 1 (>2/3 of the whole small intestine), grade 2 (1/3~2/3), grade 3 (<1/3), grade 4 (the duodenum). The SIC change was classified as follows; grade 1 and 2 or grade non-increase during follow-up was classified as "non-progressive", grade 3 and 4 or grade increase as "progressive". All SSc patients were evaluated the items as used for 2013 ACR/EULAR criteria.

Results: The mean durations of follow-up period were 9.5±0.6 years. The number of SSc patients in each SIC grade at the initial evaluation and the end of follow-up were as follows; grade 1: initial vs end; 23 vs 24, grade 2: 20 vs 9, grade 3: 10 vs 16, grade 4: 2 vs 6. The SIC change "progressive" was 40.0% of SSc patients. Positive correlation between the esophageal diameters and the SIC grade was observed in SSc patients at the initial evaluation ($r=0.61$ $p<0.01$) and the end of follow-up ($r=0.71$ $p<0.01$). The esophageal diameters at the initial evaluation were significantly wider in SIC "progressive" group than in "non-progressive" group (non-progressive vs progressive; 21.8±6.5 vs 30.9±8.6 mm, $p<0.0001$). The frequencies of SSc patients with ACA-positive and sclerodactyly were higher but with puffy fingers were lower in SIC "progressive" group than in "non-progressive" group (non-progressive vs progressive; 24.2 vs 59.1%, p=0.009; 33.3 vs 63.6%, p=0.03; 72.7 vs 45.5%, p=0.03). The prevalence of pitting scar and Interstitial lung disease were tended to be higher in SIC "progressive" compared to SIC "non-progressive" group (non-progressive vs progressive; 15.6 vs 36.4%, p=0.07; 21.1 vs 45.5%, p=0.06).

Conclusions: The present study demonstrated that the progression of small intestinal involvement was associated with esophageal dilatation at the initial evaluation during long-term follow-up of SSc patients. Our findings also suggested that ACA and skin thickening of the fingers were important factors of small intestinal involvement in SSc patients. The SIC may be a useful tool for the assessment of GI tract involvement in SSc patients during long-term follow-up.

OP0128 DETECTION OF SUB-CLINICAL DIFFUSE MYOCARDIAL FIBROSIS BY NATIVE T1 MAPPING MAGNETIC RESONANCE IMAGING IN A PROSPECTIVE SYSTEMIC SCLEROSIS COHORT

V. Poindron, E. Chatelus, M. Canuet, P. Germain, S. El Ghannudi, T. Martin.
National Referral Center for Systemic Autoimmune Diseases, Hôpitaux Universitaires de Strasbourg, Strasbourg, France

Background: Cardiac involvement in systemic sclerosis (SSc) is the second most frequent SSc-related cause of death. It remains mostly asymptomatic in early stages and is underdiagnosed with routine non-invasive screening. Cardiac magnetic resonance imaging (CMR) is becoming a key actor as it has a better sensitivity than echocardiography (echo). CMR can detect diffuse myocardial fibrosis (DMF) by native T1 mapping, myocardial edema (ME) by T2 mapping and focal fibrosis by late gadolinium enhancement (LGE). Ntusi *et al.* reported an increase of 5% of T1 value suggestive of DMF in 10 of 19 SSc patients[1].

Objectives: To determine the prevalence of cardiac involvement by CMR native T1 and T2 mapping and its correlation with echo data and non-cardiac manifestations in SSc patients.

Methods: 72 patients fulfilling ACR/EULAR classification criteria were prospectively included between 2013–2016. They underwent CMR at 1.5T, including native T1 and T2 mapping, and LGE. Normal T1 value determined in our center was 1032±39 msec. In the present study an elevated native T1>1082 msec was likely representing ventricle (especially left) DMF and T2>55 msec representing ME [2].

Results: Patients characteristics: mean age: 56±14.8; diffuse disease: 38 (52.8%); anti-Scl70 positivity: 29 (40.3%); anti-RNApolIII positivity: 6 (8.3%); 21 (29.2%) patients had early disease (<2 years from first non-Raynaud symptom). The mean T1 was 1064±41.6 msec and T2 was 51.8±2.9 msec. 36 patients (50%) had DMF but only 6 (8.3%) had ME. The mean T1 in DMF cases was 1097±14, and the T2 in ME cases was 58.2±1.6 msec. LGE was reported in 25.7% of patients. Although LGE was more frequent in patients with DMF than in those without DMF (13 vs 5, p=0.024), only 13 (36.1%) DMF patients had LGE. Left ventricular ejection fraction (L-VEF), left ventricular telediastolic volume (L-VTDV), Right-VEF and Right-VTDV were similar in DMF and non-DMF (N-DMF) groups. Echo was normal in 18 (50%) patients with DMF and in 25 (69.4%) of N-DMF group (p=0.09). DMF and N-DMF groups were similar for sex ratio, age, cardiovascular risk factors and ischemic heart disease. DMF was more frequent in patients with late disease (27 vs 9, p=0.05). T1 value was positively correlated to pulmonary arterial hypertension and digital ulcerations together ($r=0.31$, p=0.008) but not with Rodnan skin score. Six patients (8.3%) died during the inclusion period: 5 were in DMF group (p=0.09). The alterations of L-VEF and R-VEF were correlated ($r=0.45$, p=0.009). DMF was not associated with skin subsets, interstitial lung disease, auto-antibody profile, all echo parameters, CRP and BNP.

Conclusions: Native T1 mapping detects left ventricular DMF in 50% of patients with SSc including 43% (9/21) of the patients with early disease. Among them, 36% had normal echocardiography and CMR L-VEF and no LGE.

OP0129 MYCOPHENOLATE MOFETIL VERSUS CYCLOPHOSPHAMIDE IN SCLERODERMA-RELATED INTERSTITIAL LUNG DISEASE IN A REAL LIFE SCENARIO

H. Fretheim[1], Ø. Midtvedt[1], E. Volkmann[2], T. Garen[1], M.B. Lund[1], T. Aaløkken[1], Ø. Molberg[1], A.-M. Hoffmann-Vold[1]. *[1]Oslo University Hospital, Oslo, Norway; [2]UCLA, LA, United States*

Background: Systemic sclerosis (SSc) is a serious disease with high risk of interstitial lung disease (ILD); a feared complication with poor prognosis. The SLS 2[1] supported the clinical effectiveness of Mycophenolate Mofetil (MMF) and Cyclophosphamide (Cyc).

Objectives: Evaluate the effect of MMF and Cyc on SSc-ILD in a population based cohort.

Methods: All SSc patients at Oslo University Hospital (OUH) are included in an prospective, observational SSc cohort. All patients are followed annually by rheumatologists and data are recorded in the Norwegian systemic connective tissue disease registry (NOSVAR). Here, we assessed patients diagnosed after the year 2000 (n=433). Longitudinal pulmonary function tests (PFTs), HRCT lung image results, pulmonary hypertension (PH), clinical and demographic data, antibodies and vital status were obtained from NOSVAR. Outcome measures were vital status in December 2016, extent of fibrosis measured on HRCT, FVC and DLCO development.

Results: Among 262 patients with complete data on treatment and ILD, 21 (8%) patients received treatment with Cyc, 14 (5.3%) with MMF and 17 (6.5%) with combination therapy of MMF and Cyc. 55.7% of patients did not receive any treatment for ILD. Baseline characteristics, lung fibrosis and function did not differ significantly between the MMF and Cyc (Table 1). Patients treated with Cyc show a trend of higher mortality. Treatment with Cyc resulted in a significant improvement of lung fibrosis; whereas treatment with MMF resulted in significant progression in lung fibrosis (-1.3% (SD 9.3) and 7.5% (SD 11.1), p=0.024) (Table 1). MMF treatment showed a significant improvement in the DLCO% (1.8% [SD 4.6]); whereas Cyc had a significant decline in the DLCO% (-2.1% [SD 3.5], p=0.14). Less patients treated with MMF developed PH compared with Cyc treatment (1[7.7%] compared to 8[42.1%], p=0.038) (Table 1).

Table 1. Demographics and clinical characteristics of the OUH cohort

n: number; BL:baseline, SD: standard deviation; FVC: Forced vital capacity; DLCO: diffusing lung capacity for carbon monoxide; dcSSc: diffuse cutaneous SSc; PH: pulmonary hypertension.

Conclusions: Preliminary data from our population based cohort indicate that in a real-life scenario treatment effects of Cyc and MMF appear comparable to randomized clinical trials, but there are some potentially important nuances. Cyc seems to halt fibrosis progression, but toxicity is a major concern, while MMF could have effects on DLCO decline and the development of PH.

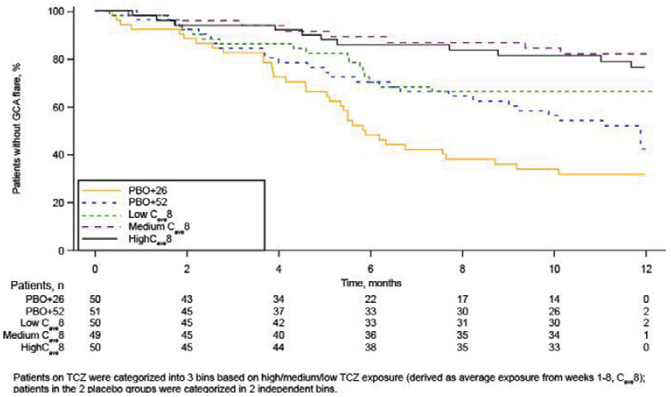
Philipson[12], S.W. Yancey[13], J. Steinfeld[13], P.F. Weller[14], G. Gleich[15]. *[1]National Jewish Health, Denver; [2]UC San Diego Health, la Jolla, United States; [3]University of Cambridge, Cambridge, United Kingdom; [4]NIAID, Bethesda; [5]Cleveland Clinic, Cleveland; [6]University of Pennsylvania, Philadelphia, United States; [7]Schleswig-Holstein Mitte, Neumünster, Germany; [8]Mayo Clinic, Rochester, United States; [9]Hospital Clinic University of Barcelona, Barcelona, Spain; [10]University of Oxford, Oxford; [11]GSK, Uxbridge; [12]Trizell Ltd, Oxford, United Kingdom; [13]GSK, Research Triangle Park; [14]Beth Israel Deaconess Medical Center, Boston; [15]University of Utah Hospital, Salt Lake City, United States*



Background: Mepolizumab reduces blood eosinophils with concomitant clinical improvement in some hypereosinophilic syndromes and eosinophilic asthma.
Objectives: To investigate the efficacy and safety of mepolizumab in patients with eosinophilic granulomatosis with polyangiitis (EGPA, Churg-Strauss).
Methods: We conducted a Phase III, randomised, placebo-controlled, double-blind, parallel group, multi-centre study (NCT02020889) in patients with EGPA and a history of relapsing or refractory disease on stable therapy with prednisolone/prednisone ≥7.5–≤50mg/day with or without additional immunosuppressive therapy for ≥4 weeks. Patients were randomised 1:1 to receive mepolizumab 300mg or placebo subcutaneously, in addition to standard of care, every 4 weeks for 52 weeks. After Week 4, glucocorticoid dose could be tapered, per physician judgment, according to a suggested standard of care protocol. Co-primary endpoints (intent-to-treat [ITT] analysis) were accrued duration of remission (Birmingham Vasculitis Activity Score [BVAS]=0, prednisolone/prednisone dose ≤4mg/day) over 52 weeks; and the proportion of patients in remission at both Weeks 36 and 48. Secondary endpoints included average glucocorticoid dose during Weeks 49–52 and time to first EGPA relapse. Safety was also assessed.
Results: The ITT population included 136 randomised patients (mepolizumab n=68, placebo n=68). Baseline characteristics were similar between groups. Duration of remission accrued over 52 weeks was significantly prolonged with mepolizumab vs placebo (odds ratio: 5.91 [95% confidence interval [CI]: 2.68,13.03]; p<0.001); a significantly higher proportion of patients were in remission at Weeks 36 and 48 (32% vs 3%, odds ratio: 16.74 [95% CI: 3.61,77.56]; p<0.001). Significant reductions in average daily prednisolone/prednisone dose during Weeks 49–52 were seen with mepolizumab vs placebo (odds ratio: 0.20[95% CI: 0.09,0.41]; p<0.001). Median (range) prednisolone/prednisone dose during Weeks 49–52 was 5.0 (0.0–113.4)mg/day in the mepolizumab group and 10.0 (0.0–46.3)mg/day in the placebo group. Time to first EGPA relapse was significantly longer with mepolizumab vs placebo (hazard ratio: 0.32[95% CI: 0.21,0.50] ;p<0.001). Rates of adverse events (AEs) and serious AEs were similar for mepolizumab and placebo.
Conclusions: Treatment with mepolizumab significantly increased the likelihood and duration of remission, while reducing glucocorticoid use, in patients with EGPA, with a safety profile consistent with previous studies in severe asthma and EGPA. This demonstrates consistent and meaningful clinical benefits of mepolizumab in patients with EGPA.

OP0131 OPTIMAL DOSE OF TOCILIZUMAB FOR THE TREATMENT OF GIANT CELL ARTERITIS: EFFICACY, SAFETY, AND EXPOSURE-EFFICACY ANALYSIS FROM GIACTA

J.H. Stone[1], K. Tuckwell[2], S. Dimonaco[2], M. Klearman[3], N.L. Mallalieu[4], M. Aringer[5], D. Blockmans[6], E. Brouwer[7], M.C. Cid[8], B. Dasgupta[9], J. Rech[10], C. Salvarani[11], G. Schett[12], H. Schulze-Koops[13], R. Spiera[14], S.H. Unizony[1], N. Collinson[2] on behalf of GiACTA Investigators. *[1]Harvard Med Sch, Boston, United States; [2]Roche Products Ltd, Welwyn Garden City, United Kingdom; [3]Genentech, S San Francisco; [4]Roche Innovation Ctr, New York, United States; [5]Abteilung für Rheumatologie, Dresden, Germany; [6]U Hosp Gasthuisberg, Leuven, Belgium; [7]U Groningen Med Ctr, Groningen, Netherlands; [8]Hosp Clínic, U Barcelona, IDIBAPS, Barcelona, Spain; [9]Southend U Hosp, Westcliff-on-Sea, United Kingdom; [10]Friedrich-Alexander-U Erlangen-Nürnberg, Erlangen, Germany; [11]Arcispedale Santa Maria Nuova-IRCCS, Reggio Emilia, Italy; [12]Inst Clin Immunol, Erlangen; [13]Div Rheum Clin Immunol, U Munich, Munich, Germany; [14]Hosp Special Surg/Cornell, New York, United States*

Background: GiACTA, a randomized, double-blind, placebo-controlled trial, evaluated the efficacy and safety of tocilizumab (TCZ), an IL-6 receptor-α inhibitor, in patients with giant cell arteritis (GCA).[1,2]
Objectives: Secondary analyses to evaluate the differential efficacy and safety of TCZ between patients with new-onset and relapsing GCA and to evaluate the TCZ exposure-efficacy relationship at week 52 of the trial.
Methods: Patients aged ≥50 years with active GCA were randomly assigned 1:1:2:1 to short-course prednisone (PBO+26), long-course prednisone (PBO+52) (26-week or 52-week prednisone taper + weekly subcutaneous [SC] placebo, respectively), weekly (TCZ-QW) or every-other-week (TCZ-Q2W) SC TCZ 162 mg + 26-week prednisone taper. Subgroup analysis was performed by disease-onset status (new-onset vs relapsing) to evaluate the proportions of patients in sustained remission at week 52 and time to flare. The impact of TCZ exposure, categorized into high, medium and low tertiles, on time to flare was evaluated across all patients in all treatment arms.
Results: Randomization included 251 patients, 119 (47%) with new-onset and 132 (53%) with relapsing GCA, distributed evenly across groups. Higher proportions of patients achieved sustained remission in the TCZ vs placebo groups regardless of disease onset (new-onset, relapsing–TCZ-QW: 59.6%, 52.8%; TCZ-Q2W: 57.7%, 47.8%; PBO+26: 21.7%, 7.4%; PBO+52: 21.7%, 14.3%, respectively). Patients with relapsing disease at baseline were in relapse-free remission longer and thus had lower risk for flare (hazard ratio) when treated with TCZ-QW than TCZ-Q2W. Hazard ratio (99% CI) for flare vs PBO+26 was 0.23 (0.09–0.61) for TCZ-QW and 0.42 (0.14–1.28) for TCZ-Q2W; vs PBO+52 it was 0.36 (0.13–1.00) for TCZ-QW and 0.67 (0.21–2.10) for TCZ-Q2W. TCZ exposure-efficacy analysis showed that most patients in the low exposure tertile had been treated with TCZ-Q2W (80%) whereas those with medium and high exposure primarily received TCZ-QW (84% and 98%, respectively). Kaplan-Meier analysis demonstrated that patients with higher exposure benefited from a longer time to flare (Figure). Adverse events (AEs) were similar across groups. Serious AEs were reported in 15.0% TCZ-QW, 14.3% TCZ-Q2W, 22.0% PBO+26 and 25.5% PBO+52 patients; rates were similar between new-onset and relapsing patients.

Figure. Time to first GCA flare after clinical remission by exposure (tertile of $C_{ave}8$)

Patients, n						
PBO+26	50	43	34	22	17	14	0
PBO+52	51	45	37	33	30	26	2
Low $C_{ave}8$	50	45	42	33	31	30	2
Medium $C_{ave}8$	49	45	40	36	35	34	1
High $C_{ave}8$	50	45	44	38	35	33	0

Patients on TCZ were categorized into 3 bins based on high/medium/low TCZ exposure (derived as average exposure from weeks 1-8, $C_{ave}8$); patients in the 2 placebo groups were categorized in 2 independent bins.

Conclusions: The compelling treatment effect of TCZ in GCA patients as measured by sustained remission to 52 weeks was consistent regardless of disease-onset status. Duration of relapse-free remission until flare was longer in patients with higher TCZ exposure, most notably in relapsing patients treated with TCZ-QW.

OP0132 LOW-DOSE INTERLEUKIN-2 SELECTIVELY RESTORE REGULATORY T CELL NUMBERS IN PATIENTS WITH BEHCET'S DISEASE

X. Fu[1], J. Li[2], X. Li[2], J. Luo[2], C. Gao[2], Q. Chen[2]. *[1]Department of Rheumatism; [2]The Second Hospital of Shanxi Medical University, Taiyuan, China*

Background: The lack of $CD4^+CD25^+Foxp3^+$ T regulatory cell (Treg) has been associated with human systemic autoimmune diseases, such as Behcet's disease (BD). IL-2, an essential growth and survival factor for Treg cells.However, the significance of Treg cells in the pathogenesis and the effect of low dose of IL-2 on BD are remain to investigate.
Objectives: The lack of $CD4^+CD25^+Foxp3^+$ T regulatory cell (Treg) has been associated with human systemic autoimmune diseases, such as Behcet's disease (BD). IL-2, an essential growth and survival factor for Treg cells.However, the significance of Treg cells in the pathogenesis and the effect of low dose of IL-2 on BD are remain to investigate.
Methods: Eighty patients with BD and seventy healthy donors were enrolled. $CD4^+$T cell subsets in peripheral blood mononuclear cells from these people were measured by multicolour flow cytometry. Twenty-six patients were treated daily with subcutaneous injections of 0.5 million IU of human IL-2 for five consecutive days, $CD4^+$T cell subsets were analysed before and after treatment by flow cytometry.
Results: Compared to health control,the absolute counts of circulating Treg cells were significantanty decreased in patients with BD (median:29.93 cell/uL VS median:33.16 cell/uL; p=0.039) and it is negative correlation with disease activity. While the ratios of Th17/Treg in patients with BD (median:0.29;n=80,p=0.034) were significantly higher than those of health control (median:0.2;n=70).No diffrernce in the absolute counts of circulating Th17 cells ($CD4^+IL\text{-}17^+$) between patients with BD and health control. Treatment of patients with BD with a low-dose of IL-2 regimen selectively increased the absolute counts of Treg cells, from a median of 18.97cell/uL to 74.68 cell/uL (at 5 days) (p=0.000). No significant difference was observed in the absolute counts of circulating Th17, Th1 and Th2 cells after IL-2 treatment.
Conclusions: Th17/Treg cells may play a role in the pathogenesis of Patients with BD, low-dose of IL-2 proposes a selective biological treatment strategy by restoring immune tolerance.

OP0133 COLOUR DOPPLER ULTRASONOGRAPHY OF FACIAL AND OCCIPITAL ARTERIES IN PATIENTS WITH GIANT CELL ARTERITIS: THE FREQUENCY OF INVOLVEMENT AND THE ROLE OF THEIR ASSESSMENT IN DAILY PRACTICE: A PROSPECTIVE STUDY

R. Jese, Ž. Rotar, M. Tomšič, A. Hočevar. *Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia*

Background: Giant cell arteritis (GCA) is the most common systemic large and medium size artery vasculitis in Western countries. Colour Doppler Sonography (CDS) allows us to study the involvement of the cranial arteries other than the temporal arteries in GCA which cannot be safely biopsied such as the facial (FaA), and occipital (OcA) arteries.
Objectives: We aimed to estimate the frequency of the FaA, and OcA involvement in GCA; and to explore the clinical characteristics of these subgroups of patients.
Methods: From 1 January 2014 to 31 December 2016, we prospectively performed a CDS of the FaA, and OcA in addition to the temporal (TA), and the extracranial supra-aortic arteries in all newly diagnosed patients suspected of having GCA. We used a Philips IU22 with a 5–17.5 MHz multi-frequency linear probe from January 2014 to August 2016 and a Philips Epiq 7 with a 5–18 MHz multi-frequency linear probe from September 2016 to December 2016. All the arteries were evaluated in two planes for the highly specific *halo*-sign.
Results: During the 36-month observation period we performed a CDS of the cranial and extra-cranial arteries in 93 GCA (66.7% female) patients. The patients' median (IQR) age was 73.7 (66.1–79.1) years, and they had a median (IQR) symptom duration of 30 (21–90) days. We observed the *halo*-sign on the FaA, and OcA in 38 (40.9%), and 29 (31.2%) cases, respectively. The FaA, and OcA were simultaneously affected in 18/93 (19.4%) cases. The FaA, or OcA were affected in 4/22 (18.2%) patients with a negative TA CDS. Patients with an FaA involvement had the highest frequency of severe visual manifestations, with permanent visual loss representing 70% of all visual manifestations. Patients with an OcA involvement least commonly had extracranial large vessel disease.
Conclusions: A fifth of patients with a negative CDS of the TAs had signs of vasculitis only on the CDS of the FaA, or OcA. The CDS of the FaA, and OcA identified approximately 5% more patients with GCA than the CDS of the TA alone.

OP0134 LONG TERM OUTCOME AND PROGNOSIS FACTORS OF COMPLICATIONS IN TAKAYASU'S ARTERITIS: MULTICENTER STUDY OF 318 PATIENTS

C. Comarmond[1], L. Biard[2], M. Lambert[3], A. Mekinian[4], Y. Ferfar[1], J.-E. Kahn[5], Y. Benhamou[6], L. Chiche[7], F. Koskas[7], P. Cluzel[8], E. Hachulla[3], E. Messas[9], M. Resche-Rigon[10], T. Mirault[9], P. Cacoub[1], D. Saadoun[1] on behalf of French Takayasu network. *[1]Internal Medicine and Clinical Immunology, GROUPE HOSPITALIER PITIÉ-SALPÊTRIÈRE; [2]Saint-Louis, Paris; [3]Internal Medicine, CHU Lille, Lille; [4]Internal Medicine, CHU Saint-Antoine, Paris; [5]Internal Medicine, Foch, Suresnes; [6]Internal Medicine, CHU Rouen, Rouen; [7]Vascular surgery; [8]Imagerie CardioVasculaire et de Radiologie Interventionnelle, GROUPE HOSPITALIER PITIÉ-SALPÊTRIÈRE; [9]Vascular Medicine, HEGP; [10]SBIM, Saint-Louis, Paris, France*

Objectives: To assess long term outcome and to elaborate a prognostic score for vascular complications in patients with Takayasu arteritis (TA).
Methods: Retrospective multicenter study of characteristics and outcome of 318 TA patients [86% of females; median age 36 [25–47] years; median follow-up of 6.1 years] fulfilling ACR and/or Ishikawa criteria. Factors associated with the event free survival (EFS), relapse free survival (RFS) and incidence of vascular complications were assessed. A prognostic score for vascular complications was elaborated based on a multivariate model.
Results: The 5- and 10-years event free survival (EFS), relapse free survival (RFS) and complication free survival were 48.2% (42.2;54.9) and 36.4% (30.3;43.9), 58.6% (52.7;65.1) and 47.7% (41.2;55.1), and 69.9% (64.3;76) and 53.7% (46.8;61.7), respectively. Progressive disease course (p=0.018) and carotidodynia (p=0.036) were independently associated with EFS. Male gender (p=0.048), elevated C reactive protein level (p=0.013), and carotidodynia (p=0.003) were associated with RFS. Progressive disease course (p=0.017), thoracic aorta involvement (p=0.009), and retinopathy (p=0.002) were associated with complication free survival. We define high risk patients for vascular complications according to the presence of two of the following factors (i.e a progressive clinical course, thoracic aorta involvement and/or retinopathy). The probability of complication free survival at five years was 78.4% (69.4;88.6) and 51.5% (38.3;69.2) in the low risk and high risk group, respectively.
Conclusions: This nationwide study shows that 50% of TA patients will relapse and experience a vascular complication at 10 years. We could define high risk TA patients for vascular complications.

OP0135 TOCILIZUMAB IN GIANT CELL ARTERITIS: GIACTA TRIAL VERSUS A SERIES OF PATIENTS FROM CLINICAL PRACTISE

L.C. Domínguez-Casas[1], J. Loricera[1], A. Mera[2], E. Pérez-Pampín[2], J.L. Hernández[3], S. Castañeda[4], N. Vegas-Revenga[1], E. Pons[1], M.Á. González-Gay[1], R. Blanco[1]. *[1]Rheumatology, Hospital Universitario Marqués de Valdecilla. IDIVAL, Santander; [2]Rheumatology, Complejo Hospitalario Universitario de Santiago, Santiago de Compostela; [3]Internal Medicine, Hospital Universitario Marqués de Valdecilla. IDIVAL, Santander; [4]Rheumatology, Hospital Universitario de la Princesa, Madrid, Spain*

Background: Baseline characteristics of patients from GiACTA trial have been recently reported at the ACR-2016 conference (1). GiACTA trial is a randomized, phase III controlled clinical trial evaluating the efficacy of tocilizumab (TCZ) in giant cell arteritis (GCA) (2). We had previously published a multicenter study on the use of TCZ in refractory GCA in a clinical practice setting (3).
Objectives: Our aim was to compare both studies, emphasizing on the baseline characteristics of the patients.
Methods: Comparative study between the GiACTA trial and our multicenter clinical practice study. In the latter, the diagnosis of GCA was established by the ACR-1990 criteria and in the GiACTA trial by the ACR modified criteria. In the clinical practice study, TCZ was used at standard IV dose (8 mg/kg/month), while in the GiACTA trial it was given subcutaneously (162 mg every 1 or 2 weeks, depending on the therapeutic arm). Quantitative variables were expressed as mean ± SD and were compared with the Student's t-test. Dichotomous variables were expressed as percentages and compared using the chi-square test.
Results: In the GiACTA trial, 47.4% were newly diagnosed GCAs, while in the clinical practice study were all refractory to conventional treatment. The TABLE summarizes the main baseline characteristics of both studies. Compared with the GiACTA trial, in the clinical practice study were significantly greater: a) the mean time between the diagnosis of GCA and the onset of TCZ, b) the proportion of patients with polymyalgia rheumatica and ischemic optic neuritis, c) the proportion of positive PET/CT scans, d) the mean value of ESR, and e) the proportion of patients who had received conventional immunosuppressant agents (mainly MTX) before starting TCZ. There was also a significant lower proportion of sustained remission in the clinical practice study. When only GiACTA patients with

relapsing-GCA were analyzed, these differences were maintained, except for the mean time from GCA diagnosis and the prevalence of ischemic optic neuropathy. Data on remissions were not available in this subgroup of GiACTA patients.

	GiACTA overall (n= 251)	GiACTA (only relapsing-GCA; n=132)	Clinical Practice (n= 22)	GiACTA (overall) vs Clinical Practice p	GiACTA (relapsing) vs Clinical Practice p

TCZ route	SC	SC	IV	-	-
Sustained remission, n (%) §	82 (54.6)	-	6 (27.3)	**0.029**	-
Severe infection, n (%)§	9/150 (6)	-	3 (13.6)	0.39	-

includes localized headache, TA, or scalp tenderness, jaw claudication, new or worsened extremity claudication.
§ In RCT patients with active TCZ therapy were only considered; *p<0.05

Conclusions: Patients receiving TCZ in the clinical practice study have several baseline clinical and laboratory differences with regard to those included in the GiACTA trial and, therefore, data of this trial should be taken cautiously when applied in a real-world scenario.

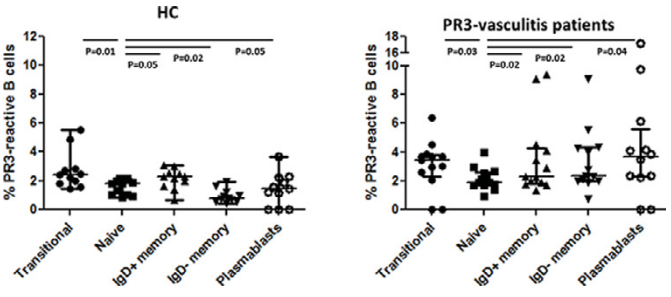
OP0136 MICRORNA-223-3P EXPRESSION IN AFFECTED SKIN OF ADULT IGA VASCULITIS CORRELATES WITH THE SEVERITY OF SKIN INVOLVEMENT

A. Hocevar[1], J. Pizem[2], M. Tomsic[1], D. Glavac[2]. *[1]Department of Rheumatology, University Medical Centre Ljubljana; [2]Institute of Pathology, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia*

Background: IgA vasculitis (IgAV) represents a common systemic vasculitis in paediatric and adult population. Our current knowledge of disease pathogenesis is still very limited and there is no information on miRNAs profile in IgAV.
Objectives: The aim of our study was to determine the expression of three miRNAs (miR-148–3p, miR-155–5p and miR-223–3p) in the affected skin of adult IgAV patients.
Methods: The study included 65 skin samples from consecutive, untreated IgAV patients (61% male, median age 67.6 years, range 29–91), diagnosed between October 2014 and September 2016, and 10 control skin samples. Total RNA was isolated from tissue section of formalin-fixed, paraffin-embedded samples of biopsied IgAV vasculitic skin lesions and normal skin samples. Expression of miR-148–3p, miR-155–5p and miR-223–3p was measured using qRT-PCR. Skin miRNAs expression was then correlated to clinical characteristics of adult IgAV patients. To present relative miRNA expression the ΔΔCT method was used.
Results: We found significantly higher expression levels of miR-223–3p in the affected skin compared to controls (14-fold; $p<0.001$). The expression of the 148b-3p and miR-155–5p was near normal levels (1.05-fold and 1.13-fold increase, respectively). The differences in the expression of miR-223–3p depending on clinical parameters of IgAV are presented in Table 1. Patients with necrotic skin lesions had significantly higher miR-223 tissue expression than those with non-necrotic purpura (p=0.020). Gastrointestinal tract (GIT) involvement inversely correlated with the level of skin miR-223 expression (p=0.024). No significant relationship between renal involvement and skin miR-223 was found.
Conclusions: miR-223 expression was increased in the affected skin of IgAV in comparison to normal skin. Levels of miR-223 expression correlated with severity of skin involvement and inversely with GIT involvement.

Table 1. miR-223–3p expression in IgAV

Characteristics		Number of cases	ΔΔCT miR223–3p median	IQR1	IQR2	P value
General symptoms	YES	10	3.11	1.86	5.55	0.683
	NO	55	3.72	2.53	5.38	
Arthritis	YES	6	3.04	2.67	4.60	0.482
	NO	59	3.72	2.48	4.60	
Generalized purpura	YES	37	3.72	2.46	5.87	0.615
	NO	28	3.63	2.56	5.10	
Skin necroses	YES	32	4.68	2.94	5.84	0.020
	NO	33	3.19	1.97	4.76	
GIT involvement	YES	16	2.78	1.69	3.90	0.024
	NO	49	4.29	2.69	5.62	
Severe GIT involvement	YES	5	2.67	1.88	3.07	0.078
	NO	60	4.22	2.56	5.57	
Renal involvement	YES	28	4.29	2.69	5.72	0.260
	NO	37	3.20	1.82	5.41	
Severe renal involvement	YES	9	4.50	2.44	5.13	0.955
	NO	56	3.60	2.49	5.50	
Elevated serum IgA level	YES	30	4.63	2.71	5.93	0.041
	NO	35	3.19	1.75	4.80	



Legend: generalized purpura - purpura above the waist; GIT - gastrointestinal tract; severe GIT involvement - bloody diarrhoea or ileus or surgical intervention; severe renal involvement - acute kidney injury or nephrotic syndrome.

OP0137 AUTO-REACTIVE B CELLS ESCAPE PERIPHERAL TOLERANCE CHECKPOINTS IN PATIENTS WITH PR3-ANCA ASSOCIATED VASCULITIS

D. Cornec[1,2], A. Hummel[1], T. Peikert[1], J.-O. Pers[2], U. Specks[1]. *[1]Mayo Clinic, Rochester MN, United States; [2]CHRU and University, Brest, France*

Background: While extensive studies have been performed to characterize ANCA, little is known about the auto-reactive B cells that produce these autoantibodies. Indirect evidence previously suggested the presence of circulating PR3-specific B cells in patients with PR3-ANCA-associated vasculitis (AAV).
Objectives: To develop a method to detect circulating PR3-specific B cells in patients with PR3-AAV, to study their proportion among the different B-cell subsets and to assess their relationship with disease activity.
Methods: An enzymatically inactive, conformationally mature, recombinant PR3 (rPR3) was tagged using FITC or biotin. To study the ability of this rPR3 to bind specifically to cells expressing PR3-specific immunoglobulins on their surface, we used two hybridoma cell lines, MCPR3–2 (producing an anti-human PR3 monoclonal antibody) and MCPR3–13 (producing an anti-mouse PR3 monoclonal antibody, with no cross-reactivity with human PR3). We measured the proportion of PR3-FITC positive B cells among PBMCs in 13 patients with PR3-AAV and 14 healthy controls (HCs) by flow cytometry. We then developed a multi-color flow cytometry including CD19, IgD, CD27, CD38, CD24 and biotinylated rPR3 to measure the proportion of PR3-specific B cells among different B-cell subsets in an independent group of 13 patients with PR3-AAV and 11 HCs.
Results: rPR3 efficiently bound MCPR3–2 hybridoma cells but not MCPR3–13. Specificity of the staining was confirmed by competition experiments: pre-incubation of MCPR3–2 cells with untagged human rPR3 totally abrogated rPR3-FITC staining, whereas pre-incubation with mouse rPR3 had no effect. Dose-ranging experiments defined the optimal concentration of rPR3 to stain cells expressing anti-PR3 immunoglobulin. The mean (SEM) proportion of rPR3-FITC-stained B cells was higher in patients with PR3-AAV compared to HCs: 2.10% (2.33) vs 0.45% (0.19) respectively, $p<0.001$. Patients with active disease had numerically higher proportions of PR3-specific B cells than patients in remission: 3.66% (3.28) vs 1.10% (0.52), p=0.09. In HCs, the proportion of PR3-specific B cells was highest among the transitional B-cell subset, and decreased along with the maturation of B cells (figure). Conversely, in patients, the proportion of PR3-specific B cells progressively increased with the maturation of B cells (median 1.9% of naïve B cells, 2.30% of IgD+ memory B cells, 2.37% of IgD- memory B cells, and 3.68% of plasmablasts, $p<0.05$ for all comparisons with the naïve subset).

Conclusions: This study describes an original method to detect and study

circulating auto-reactive B cells in patients with PR3-AAV, and suggests that PR3-specific B cells are associated with disease activity and may represent a promising biomarker to predict relapse risk in patients in clinical remission. The progressive enrichment in PR3-specific B cells during the B-cell maturation steps in patients suggest that auto-reactive B cells are actively selected and escape peripheral tolerance checkpoints.

HPR mind over matter - patients perspectives

OP0138-HPR DO PATIENTS' TREATMENT BELIEFS AFFECT TREATMENT CHOICES IN KNEE AND HIP OSTEOARTHRITIS?

E.M. Selten[1], R. Geenen[2], H.J. Schers[3], F.H. van den Hoogen[1], R.G. van der Meulen-Dilling[4], W.H. van der Laan[5], M.W. Nijhof[6], C.H. van den Ende[1], J.E. Vriezekolk[1]. *[1]Rheumatology, Sint Maartenskliniek, Nijmegen; [2]Psychology, Utrecht University, Utrecht; [3]Primary and Community Care, Radboud University Nijmegen Medical Centre, Nijmegen; [4]Physical Therapy and Manual Therapy, Partnership Velperweg, Arnhem; [5]Rheumatology, Sint Maartenskliniek, Woerden; [6]Orthopaedics, Sint Maartenskliniek, Nijmegen, Netherlands*

Background: Patients' beliefs about treatment modalities for knee/hip osteoarthritis (OA) might influence their treatment choices. The Theory of Planned Behavior predicts that patients' beliefs, the norms and values of one's social environment (subjective norm) and one's perceived self-efficacy influence behaviour[1]. Moreover, symptom severity may influence treatment choices[2]. However, these relationships have not been studied yet in the context of treatment decision-making.

Objectives: To test whether treatment beliefs, subjective norm, perceived self-efficacy and symptom severity were associated with intended treatment choices in OA.

Methods: Patients with knee/hip OA who visited the Sint Maartenskliniek in 2015 and 2016 (N=700) were invited to fill out a booklet. The Treatment beliefs in OsteoArthritis questionnaire was used to assess positive and negative treatment beliefs regarding five treatment modalities: physical activities, pain medication, physiotherapy, injections and arthroplasty. Other measures were demographic and clinical variables, self-efficacy (ASES), and symptom severity (WOMAC). Associations between variables were assessed in three models (Figure 1): 1) whether treatment beliefs are associated with intended treatment choice (model 1); 2) whether treatment beliefs, subjective norm and perceived self-efficacy are associated with intended treatment choice (model 2); 3) whether treatment beliefs, subjective norm, perceived self-efficacy and symptom severity are associated with intended treatment choice (model 3). Path analyses were conducted to examine the hypothesized associations.

Results: 289 patients filled out the booklet. Model 2 had the highest explained variance for each of the treatment modalities (range 32–45%). Positive treatment beliefs and subjective norm were consistently associated with intended treatment choice across all treatment modalities. Negative treatment beliefs were associated with intended treatment choices for pain medication and arthroplasty. Perceived symptom severity was not related to intended treatment choices. No other associations were found.

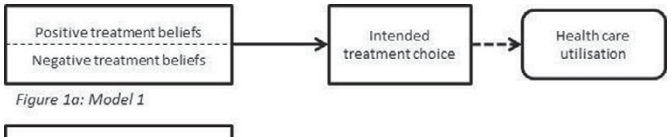

Figure 1a: Model 1

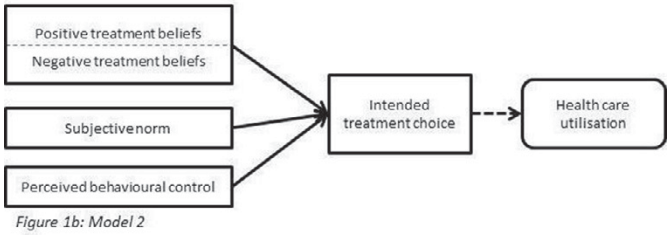

Figure 1b: Model 2

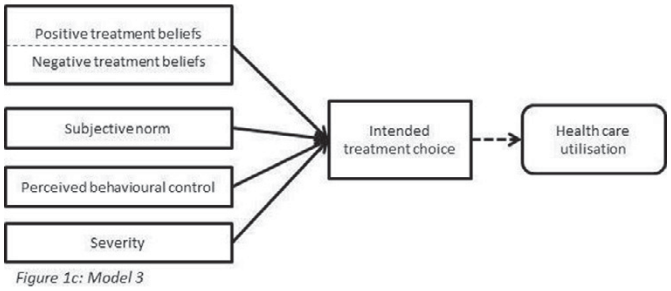

Figure 1c: Model 3

Conclusions: This is the first study that found empirical support for the relationship between treatment beliefs and treatment choices. The findings suggest that positive beliefs about treatment modalities and the norms and values of one's social environment are related to a specific treatment choice for knee/hip OA and should be addressed in the clinician's consulting room.

OP0139-HPR REDUCING ARTHRITIS FATIGUE - CLINICAL TEAMS (RAFT) USING COGNITIVE-BEHAVIOURAL APPROACHES: AN RCT

S. Hewlett[1], N. Ambler[2], C. Almeida[1], P. Blair[3], E. Choy[4], E. Dures[1], W. Hollingworth[3], B. Kadir[3], J. Kirwan[3], Z. Plummer[1], C. Rooke[5], J. Thorn[3], J. Pollock[1] on behalf of RAFT Study Group. *[1]University of the West of England, Bristol; [2]Southmead Hospital; [3]University of Bristol, Bristol; [4]University of Cardiff, Cardiff; [5]Bristol Royal Infirmary, Bristol, United Kingdom*

Background: RA fatigue is common. Group Cognitive Behavioural Therapy by CBT therapists is effective[1] but few rheumatology teams have psychologists, thus we trained rheumatology teams to deliver RAFT, a cognitive behavioural approach (CBA).

Objectives: To test if usual care plus a group CBA course for RA fatigue delivered by rheumatology teams reduces fatigue impact more than usual care alone, in a randomised controlled trial.

Methods: A pair of rheumatology nurses/OTs in each of 7 UK hospitals were trained in RAFT. RAFT is 6, weekly 2hr group sessions and a consolidation session (wk 14). Links between thoughts, feelings and behaviours (pacing, communication, sleep, stress) are addressed, with daily diaries of energy expenditure and weekly goal-setting. Usual care was a 5min discussion of the Arthritis Research UK fatigue booklet. Entry criteria were RA, Bristol RA Fatigue (BRAF-NRS) severity $\geq$6/10 and no recent major medication change. Primary outcome was fatigue impact (BRAF-NRS impact, 0–10) at 26 wks; plus wider aspects of fatigue (BRAF-Multi-Dimensional Questionnaire), pain, disability, sleep, quality of life, mood, self-efficacy, patient global opinion, valued life activities & disease activity. Intention-to-treat regression analysis involved adjustment for baseline scores and centre.

Results: 308/333 randomized patients completed 26 wks. The 25 who withdrew had similar (10yr) disease duration but were older (69 vs 62.4 yrs). Baseline fatigue impact was similar for RAFT (n=156, BRAF-NRS 7.10, SD 1.7) and controls (n=152, 7.23, SD 1.6), as were all clinical variables. At 26 wks the RAFT arm had significantly less fatigue impact than controls (BRAF-NRS 5.74, SD 2.4 vs 6.36, SD 2.4). Mean BRAF-NRS impact was reduced by -1.36 ($p<0.001$) in RAFT vs -0.88 in controls ($p<0.004$). Regression analysis showed the difference between changes in fatigue impact NRS was -0.59 in favour of RAFT (CI -1.11, -0.06). Regression analysis also showed significant differences in secondary outcomes in favour of RAFT: BRAF-MDQ total fatigue -3.42 (CI -6.44, -0.39); Living with Fatigue -1.19 (CI -2.17, -0.21); Emotional Fatigue -0.91 (CI -1.58, -0.23); and RA self-efficacy (RASE, +3.05, CI 0.43, 5.66). There were no differences between arms for changes in fatigue severity or other clinical variables.

99% of RAFT patients would definitely recommend the course to others compared to 50% controls ($p<0.001$). 90% of RAFT patients rated satisfaction $\geq$8/10 (including 62% rating 10/10); in comparison 50% controls rated satisfaction $\geq$8/10 (including 26% rating 10/10, ($p<0.0001$). Over 26 weeks 20 control patients sought extra appointments for fatigue help compared to 8 RAFT patients (14.2% vs 5.3%, $p<0.01$).

Conclusions: Rheumatology teams delivering a manualized CBA group intervention addressing fatigue impact, not only improve RA fatigue impact, but also emotional & overall fatigue, living with fatigue and self-efficacy, with very high patient satisfaction. Providing rheumatology teams with CBA skills is a potential new therapeutic approach to change practice and improve patient outcome.

OP0140-HPR ACCEPTANCE AND COMMITMENT THERAPY: A RETROSPECTIVE STUDY OF OUTCOMES FROM A HOSPITAL-BASED, GROUP, PAIN REHABILITATION PROGRAMME IN RHEUMATOLOGY SERVICES IN THE SOUTH EAST OF IRELAND

N. Nealon Lennox[1,2], S. O'Neill[2], A. Hannigan[1]. *[1]GEMS, University Limerick, Limerick; [2]Psychology, Ulster University, Derry, Ireland*

Background: Acceptance and Commitment Therapy (ACT) is a form of cognitive

behavioural therapy (CBT), which focuses on psychological flexibility and behavior change. ACT has been advocated for the treatment of Persistent Pain. A systematic review concluded that ACT is efficacious for enhancing physical functioning and decreasing distress amongst adults with chronic pain attending Pain Rehabilitation Programmes (Hann & McCracken 2014). A call was made for further studies to examine outcomes from more homogenous groups.

Objectives: To assess the effects of an eight-week group ACT, Rheumatology based programme, for people with persistent pain, on pain acceptance, activity engagement, psychological distress and self-efficacy.

Methods: Patients were referred to the programme by three Consultant Rheumatologists over a five-year period. Over one hundred patients' outcome measures were available for this retrospective study from a convenience sample. Consent had been sought routinely from patients who attended the ACT programme and ethical approval was granted from the Hospital Research Ethics Committee (REC) and Ulster University REC. Baseline measures were taken at assessment, on the final day of the programme and at the follow up six-month review. Data was analysed with One Way Repeated Measures ANOVA using SPSSv20. Effect sizes were calculated using Partial Eta Squared and interpreted using the guidelines proposed by Cohen (1998).

Results: For those with scores at all three time points, mean depression scores, anxiety scores and self-efficacy scores were statistically significantly different over time. In addition, for those with activity engagement and pain willingness scores at all three time points, scores were statistically significantly different over time.

Table 1. Change from assessment to the 6-month review

Measure (n)	Mean (SD) at assessment	Mean (SD) at 6-month review	Mean change[2] (95% CI)	P-value	Cohen's d
Depression (n=91)	8.6 (3.62)	5.9 (3.62)	-2.7 (-3.47, -1.99)	<0.001	0.76
Anxiety (n=91)	11.0 (3.81)	8.1 (3.95)	-2.9 (-3.66, -2.14)	<0.001	0.79
Self-efficacy (n=89)	37.0 (12.72)	49.6 (13.20)	12.6 (9.48, 15.80)	<0.001	0.84
Activity engagement (n=78)	32.5 (12.27)	43.8 (10.26)	11.3 (8.59, 14.03)	<0.001	0.94
Pain willingness (n=78)	16.8 (7.46)	23.6 (8.52)	6.8 (4.84, 8.73)	<0.001	0.79

Conclusions: The ACT Pain Rehabilitation Programme at University Hospital Waterford in Ireland has provided significant outcomes for reducing depression and anxiety amongst its participants as measured by the Hospital Anxiety and Depression Scale (HADS). Increases in self-efficacy were also found to be statistically significant. Increases in activity engagement & pain acceptance, as measured by the Chronic Pain Acceptance Questionnaire (CPAQ) also showed statistically significant increases. A number of limitations should be noted i.e. this was a retrospective study and depended on self report measures only. However, positive outcomes suggest ACT is a helpful intervention for people with persistent pain.

OP0141-HPR AN INNOVATE MEASUREMENT INSTRUMENT TO ASSESS ACTIVITY LIMITATIONS IN HIP AND KNEE OSTEOARTHRITIS: THE COMPUTERIZED ANIMATED ACTIVITY QUESTIONNAIRE (AAQ) AND ITS PSYCHOMETRIC PROPERTIES

W. Peter[1,2], R. de Vet[2], M. Boers[2], J. Harlaar[2], L. Roorda[1], R. Poolman[3], V. Scholtes[3], M. Steultjens[4], E. Roos[5], F. Guillemin[6], M.G. Benedetti[7], A. Escobar Martinez[8], H. Dagfinrud[9], H. Buitelaar[10], J. Boogaard[10], C. Terwee[2]. *[1]READE; [2]VU University Mediacal Center; [3]OLVG, Amsterdam, Netherlands; [4]Glasgow Caledonian University, Glasgow, United Kingdom; [5]University of Southern Denmark, Odense, Denmark; [6]University of Lorraine, Nancy, France; [7]Istituto Ortopedico Rizzoli, Bologna, Italy; [8]Basurto University Hospital, Bizkaia, Spain; [9]Diakonhjemmet Hospital, Oslo, Norway; [10]Patient Research Partner, Amsterdam, Netherlands*

Background: The Animated Activity Questionnaire (AAQ) measures activity limitations in hip and knee osteoarthritis (HKOA), and was developed in close collaboration with patients[1]. Previously we showed an adequate construct- and cross-cultural validity of the AAQ[2]

Objectives: To determine the reliability, responsiveness and interpretability of the AAQ.

Methods: In 6 European countries the AAQ was completed twice on a computer with a 7 days interval by 238 patients (DK (36), FR (37), IT (51), NL (39), SP (36), UK (39)). Reliability was assessed by calculating internal consistency (Cronbach's alpha), the intra-class correlation coefficient (ICC), the Standard Error of Measurement (SEM) and the Smallest Detectable Change (SDC). In the Netherlands, an additional group of 92 patients were followed for 6 months in order to assess responsiveness. Data from the AAQ, a PROM (the Hip disability or Knee injury Osteoarthritis Outcome Score, ADL subscore), and performance-based tests (the Timed Up and Go test, Stair Climbing Test and 30 seconds Chair Stands Test) were collected. To estimate the Minimal Important Change (MIC) of the AAQ an anchor-based MIC distribution method was used with a Global Rating of Change (GRC) as anchor. The Receiver Operating Characteristic (ROC) method was used to find the AAQ change score that best discriminates between patients who improved in activity limitations and who are not. The MIC was compared to the SDC in order to facilitate the interpretation of change scores.

Results: Cronbach's alpha was o.94. ICC for test-retest reliability was 0.93 (95% CI: 0.91–0.95). SEM and SDC were 4.9% and 13.5%, respectively. With regard to responsiveness the change scores of the AAQ after 6 months correlated 0.58 with the PROM, 0.42–0.55 with the performance based tests, and 0.46 with GRC. The ROC curve showed an area under the curve of 0.72 with a sensitivity of 63% and a specificity of 81% for the optimal MIC of 9.1 for discrimination. The MIC was smaller than the SDC meaning that the change is important but cannot be distinguished from measurement error in individual patients.

Conclusions: The AAQ, measuring a new construct in the domain physical functioning in addition to a PROM and performance-based tests, showed good construct validity, cross-cultural validity, internal consistency and test-retest reliability. A change in AAQ score over 13.5% indicates a real improvement in activity limitations in HKOA patients. The AAQ seems to have great potential for international use in research but the application in clinical practice needs caution.

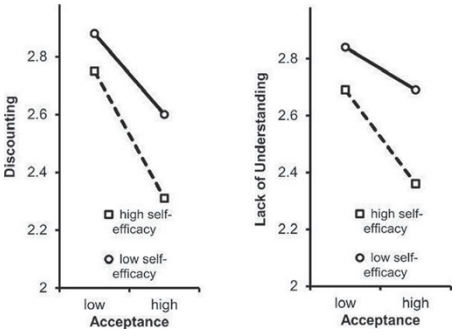
OP0142-HPR THE POTENTIAL BUFFERING ROLE OF SELF-EFFICACY AND PAIN ACCEPTANCE AGAINST INVALIDATION IN RHEUMATIC DISEASES



R. Geenen[1], N. Cameron[1], M.B. Kool[1], F. Estévez-López[2], I. López-Chicheri[3]. *[1]Psychology, Utrecht University, Utrecht, Netherlands; [2]Department of Physical Education and Sport, Faculty of Sport Sciences, University of Granada, Granada; [3]Health Sciences, UCAM Catholic University of Murcia, Murcia, Spain*

Background: A substantial number of people with a rheumatic disease perceive invalidation consisting of "lack of understanding" and "discounting" (negative social responses) [1]. Our study was guided by the notion that high self-efficacy will make people feel competent to deal with situations in which control of invalidation is possible and likely to be successful. In other situations, high acceptance will help people to actively and in full awareness experience even adverse situations such as invalidation without unnecessary attempts to change their frequency or form, which is considered a core aspect of acceptance.

Objectives: To get insight into the potential buffering role of self-efficacy and pain acceptance against invalidation, we examined the association of self-efficacy and pain acceptance with invalidation in people with diverse rheumatic diseases.

Methods: The design was cross-sectional. Spanish speaking people (N=1153, 91% female, mean age 45±11 years) with one or multiple rheumatic diseases completed online versions of the Illness Invalidation Inventory [2], the Chronic Pain Acceptance Questionnaire, and the Chronic Disease Self-Efficacy Scale.

Results: Before and after adjustment for age, gender, education, and fibromyalgia diagnosis, higher self-efficacy and higher pain acceptance were independently associated with discounting and lower lack of understanding ($P<0.001$, see Figure). The combined occurrence of high self-efficacy and high acceptance was associated most clearly with lower lack of understanding (interaction: $P=0.03$) and with discounting (interaction: $P=0.07$, not reaching statistical significance): see Figure.

Conclusions: The present study convincingly shows that self-efficacy and pain acceptance are associated with less invalidation. This suggests the usefulness of examining in prospective studies whether interventions aimed at increasing self-efficacy and pain acceptance can help people with rheumatic diseases for whom invalidation is a considerable burden. A cognitive-behavioral model including self-efficacy and acceptance to deal with invalidation is proposed.

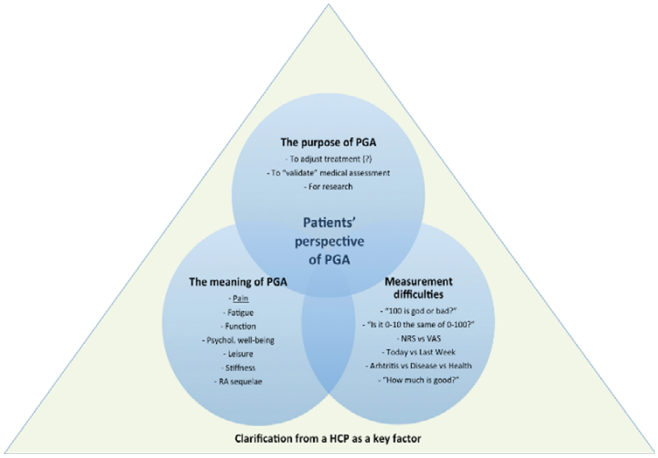
OP0143-HPR DISABILITY IN THE FEET RELATED TO PARTICIPATION IN DAILY LIFE IN PATIENTS WITH EARLY RA – AN INTERVIEW STUDY IN THE SWEDISH TIRA PROJECT

M. Björk[1,2], I. Thyberg[3], E. Valtersson[4], G. Östlund[5], B. Stenström[3], A. Sverker[6]. *[1]Department of Social and Welfare Studies, Linköping University, Norrköping; [2]Rheumatology clinic, Linköping university hospital; [3]Department of Rheumatology; [4]Department of Activity and Health and Department of Medical and Health Sciences, Linköping University, Linköping; [5]School of Health Care and Social Welfare, Mälardalen University, Eskilstuna; [6]Department of Activity and Health, Department of Rehabilitation Medicine, Department of Social and Welfare studies, Linköping university, Linköping, Sweden*



Background: Pain, stiffness and deformity of the feet are related to reduced mobility and participation restrictions in daily activities in patients with established rheumatoid arthritis (RA). The new biological medications are effective and reduce disease activity, but not disability to the same extent. Foot problems are assumed to be related to participation restrictions also in patients with early RA, diagnosed after the introduction of biological medications, hindering for example physical activity. Hence, there is a need for more knowledge about foot problems in order to identify possible needs for rehabilitative interventions.
Objectives: To explore disability related to foot problems in women and men with early rheumatoid arthritis and its relation to participation in daily life.
Methods: 59 patients (58% women, 20–63 years) with early RA were interviewed about participation dilemmas in daily life related to RA, using Critical Incident Technique. The interviews were audio-recorded and transcribed. Data related to foot problems were extracted and analysed thematically. A research partner with RA validated the retrieved categories. The study was approved by the Regional Ethics Committee.
Results: More than 2/3 of the patients mentioned that they had participation restrictions related to foot problems. The analysis revealed 5 categories concerning foot problems and the relation to participation restrictions: 1) foot problems as an early indicator of the disease, 2) hindrance in managing the daily routine and house hold activities, 3) struggling to be mobile, 4) difficulties in doing a god job at work and 5) difficulties in participating in recreation and leisure activities. Both women and men shared many experiences, as difficulties to be physically active. Several women expressed difficulties to use the shoes they wanted. Being able to move on uneven ground in, for example, the forest was something that many men expressed as difficult.
Conclusions: Patients with early RA with access to effective medications and multi professional interventions based on their individual needs still experience a wide range of foot related disability in major life arenas as work, in the household and during leisure time. This indicates a need to pay attention also in today's early RA patients to foot problems in the multi professional rehabilitation to prevent further disabilities and enable physical activity for men and women with RA.

OP0144-HPR "IT CAN'T BE ZERO": A QUALITATIVE STUDY OF PATIENTS' PERSPECTIVE ON PATIENT GLOBAL ASSESSMENT IN RHEUMATOID ARTHRITIS

M. Henriques[1], C. Duarte[1,2], M. Ndosi[3], A. Marques[2], J.A.P. da Silva[1,2], R.J.O. Ferreira[2,4]. *[1]Faculdade de Medicina da Universidade de Coimbra; [2]Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; [3]University of the West of England, Bristol, United Kingdom; [4]UICiSA:E, ESEnfC, Coimbra, Portugal*

Background: Patient Global Assessment (PGA) plays an important role in disease activity assessment and treatment decisions in rheumatoid arthritis (RA). However, the meaning of PGA is open to patient interpretation and this may affect the validity and reliability of clinical assessments.
Objectives: We aimed to explore: (i) patients' perspective on PGA and its different formulations (ii) how patients' perspective may be improved by a brief explanation from a health care professional (HCP).
Methods: This was a qualitative study including consecutive patients with RA attending a day hospital and an outpatient department of a university hospital in Portugal. Data collection included 4 focus-groups (FGD) and 3 individual interviews to determine patients' perspectives. To help the discussions, patients completed 3 different PGA formulations consecutively and then a HCP explained what information was expected to inform their PGA. The 3 PGA formulations and their implications were then discussed between the patient and the HCP. Data from the FGDs and the interviews were transcribed verbatim and inductive content analysis was undertaken by two independent researchers. Data were coded and categorised in themes, which were agreed upon with patients, HCP and patient research partners.
Results: Fourteen patients (12 women) with RA participated. Their age ranged from 49 to 72 years, disease duration 4 to 30 years and 11 were on biologic DMARDs. Four main themes emerged (Figure 1): (1) The purpose of PGA. Some patients did not know whether PGA affects their treatment decisions in the same way as the objective measures do: "*if the answer is not in somehow according to the exams we make (...) obviously they might ignore me*". Some believed that PGA was only used for research purposes. (2) The meaning of PGA. Pain was by far the main meaning of PGA, but also fatigue, function and other dimensions including RA sequelae; (3) Measurement difficulties. Many of these difficulties arose from the presentation of the three different PGA formulations, anchor points and their presentations: *"I always think that 100 is great: you feel 100%", "Usually the scale is 0 to 10, here I can see 0 to 100"; "Usually it has the numbers, I answer 2, it's not like a straight line like this one"; "Today is different (...) when they ask the last week, we have to go back in time and the pain isn't the same anymore*". Also cultural issues and the subjectivity of the concept were expressed: *"We, the patients, can't really assess the intensity of the pain, what could be a 9 for her, for me it might be a 5"; "I can never answer 0, because I always have something that affects me"*. (4) Clarification from a HCP as a key factor for global understanding: ["*Sometimes I just give a random number. (...) now maybe I will think more carefully and try to be as accurate as possible*".

Figure 1. Main themes of Patients' perspective of PGA

Conclusions: Our results suggest that patients' interpretation of PGA is diverse and may reflect different symptoms such as pain or psychological well-being and comorbidities. Standardization of PGA is warranted and dedicated patient debriefing is likely to improve the reliability of this assessment.

OP0145-HPR RHEUMATOID ARTHRITIS PATIENTS' SUPPORT NEEDS REGARDING MEDICATION USE AND THEIR PERSPECTIVES ON THE APPLICABILITY OF EHEALTH INTERVENTIONS TO ADDRESS THOSE NEEDS: A FOCUS GROUP STUDY

E. Mathijssen[1], J. Vriezekolk[1], A. Eijsbouts[1], B. van den Bemt[1,2]. *[1]Rheumatology; [2]Pharmacy, Sint Maartenskliniek, Nijmegen, Netherlands*

Background: Patients with rheumatoid arthritis (RA) encounter various problems with their medication use, including poor knowledge about disease-modifying antirheumatic drugs (DMARDs)[1], concerns about potential adverse consequences of their medication use[2] and struggles with opening the medication's packaging[3]. Additional support might decrease those problems by targeting RA patients with (eHealth) interventions that address their needs. To date, no studies have explored RA patients' support needs regarding medication use from their own perspectives, and it remains largely unknown if, and to what extent, they perceive a need for eHealth interventions.
Objectives: The objective of this study was twofold: 1) to explore RA patients' support needs regarding medication use; and 2) to gain insight into their perspectives on the applicability of eHealth interventions to address those needs.
Methods: Three focus groups with 28 RA patients (mean age: 65 years, mean disease duration: 19 years) were conducted. All focus groups were audio-recorded and subsequently transcribed verbatim. Two researchers independently conducted an inductive, thematic analysis on the transcripts.
Results: Three themes that described RA patients' support needs regarding medication use were identified: 1) Informational support; 2) Practical support; and 3) Emotional and behavioral support. Informational support refers to the provision of knowledge and facts, including advice, suggestions and feedback from healthcare providers. Practical support includes the strengthening of technical skills (e.g. administering subcutaneous injections), as well as the provision of goods and services. Emotional and behavioral support refers to the interventions enabling RA patients to better cope with their medication use. Their perspectives on the applicability of eHealth interventions to address those needs were also identified. RA patients recognized potential advantages of eHealth interventions, such as being less time consuming and easily accessible. However, concerns

on matters such as privacy, the quality and trustworthiness of information and personal interaction with healthcare providers prevailed.
Conclusions: For most RA patients, informational support regarding medication use is the most important (unmet) need. High-quality, unambiguous information about their medication use was emphasised. Moreover, this information should be provided by healthcare providers on an ongoing basis and tailored to their personal situation. Eliminating RA patients' concerns regarding eHealth interventions should be a first priority before such interventions are applicable to address these informational needs. These findings need to be confirmed in a sample of younger RA patients.

RA: really a systemic disease?

OP0146 DECREASE IN CARDIOVASCULAR EVENT EXCESS RISK IN RHEUMATOID ARTHRITIS SINCE 2000': A META- ANALYSIS OF CONTROLLED STUDIES

E. Filhol[1], C. Gaujoux-Viala[2], B. Combe[1], J. Morel[1], C. Hua[1], A. Nutz[2], C. Lukas[1], F. Flaisler[2]. [1]*Lapeyronie Hospital, Montpellier;* [2]*Nimes Hospital, Nimes, France*

Background: Compared with the general population, patients with rheumatoid arthritis (RA) have an increased risk of cardiovascular disease or events (CE): stroke, Myocardial Infarction (MI), Congestive Heart Failure (CHF) and Cardiovascular Mortality (CVM). Systemic inflammation is the cornerstone of both RA and atherosclerosis. Over the past fifteen years, new treatment strategies such as tight control, treat to target, methotrexate optimization, biologic DMARDs use has allowed a better control of this inflammation.
Objectives: The aim of this systematic review was to assess the excess risk of presenting a CE in RA patients as compared to general population, before and after the 2000s.
Methods: We systematically searched literature (via Pubmed, Cochrane and abstracts from recent ACR and EULAR congresses) up to March 2016 for observational studies providing data about the occurrence of a CE (among stroke, MI, CHF, CVM) in patients with RA and in a control group. A meta-analysis of the relative risk (RR) concerning patients with RA in relation to the control group was performed for each cardiovascular event and for each period (before and after the 2000s).
Results: Out of 5714 screened references, 28 studies were included. For studies published before 2000, an increased risk of CEs was observed in RA patients:
– RR=1.12 [95% CI 1.04; 1.21], p=0.002 for stroke
– RR=1.25 [1.14; 1.37], p<0.00001 for CHF
– RR=1.21 [1.15; 1.26], p<0.00001 for CVM
– RR=1.32 [1.24; 1.41], p<0.00001) for MI.
For all studies published after the year 2000, the increased risk was not retrieved for CHF (RR=0.58 [0.11; 3.55], p=0.52) and CVM (RR=1.07 [0.74; 1.56], p=0.71). The excess risk of MI was reduced in comparison with the period before 2000: RR=1.18 [1.14; 1.23], p<0.00001.The excess risk of stroke was stable: RR=1.23 [1.06; 1.43], p=0.006.
Discussion: This meta-analysis confirms an increased risk of CEs among people with RA relative to the general population. It also appears that this excess risk is less prevalent than prior to 2000s. This might have two explanations: a better management of the cardiovascular risk in patients with RA and a better control of chronic systemic inflammation thanks to new therapeutic strategies.
Conclusions: The cardiovascular excess risk of RA patients relative to the general population has decreased since 2000s. This suggests that the recent improvements in RA management may have a positive impact on cardiovascular comorbidities.

OP0147 TRENDS IN MORTALITY, CO-MORBIDITY AND TREATMENT AFTER ACUTE MYOCARDIAL INFARCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS 1998-2013

M. Skielta[1], L. Söderström[2], S. Rantapää Dahlqvist[3], S. Wållberg Jonsson[3], T. Mooe[4]. [1]*Department of Public Health and Clinical medicine, Rheumatology, Umeå University;* [2]*Unit of Research, Östersund Hospital, Östersund;* [3]*Department of Public Health and Clinical Medicine, Rheumatology, Umeå University, Umeå;* [4]*Department of Public Health and Clinical Medicine, Östersund, Umeå University, Östersund, Sweden*

Background: Rheumatoid arthritis (RA) patients have increased mortality due to cardiovascular disease (CVD). Case fatality after an acute myocardial infarction (AMI) has been reported to be increased. Whether the prognosis after AMI has changed over time in RA is unknown.
Objectives: To study the one-year mortality after a first AMI in RA versus non-RA patients during the time period 1998–2013. To identify time trends in mortality, co-morbidities and secondary preventive treatments and to explore any characteristics associated with mortality.
Methods: We identified all patients with a first time AMI in the Swedish Register of Information and Knowledge about Swedish Heart Intensive Care Admissions (RIKS-HIA) between 1998–2013. We used the National Patient Register (NPR) to identify AMI patients with RA (RA defined as ≥2 visits to a Rheumatology or Internal Medicine department with a diagnosis of RA). In total 245376 AMI patients were identified, 4268 of them had RA. To study trends over time, the study period was divided into five consecutive time periods. Multivariate Cox regression analysis was used to identify variables associated with mortality.
Results: The one-year mortality in RA patients was stable and lower compared to non-RA patients during the first time periods but thereafter increased above the non-RA patients. In non-RA patients, mortality decreased over time and stabilised during the last time period (Figure). In RA patients the mean age at admission increased from 69 to 73 years, whilst in non-RA patients it was unchanged, 71 years. Atrial fibrillation (AF) was initially more common in non-RA patients but the prevalence decreased over time (from 19.2% to 17.5%). In RA patients, AF increased over time from 15.6% to 21.4%. The prevalence of congestive heart failure (CHF) during hospitalisation decreased markedly more in non-RA (from 41.5% to 22.7%) than in RA patients (from 36.0% to 29.2%). The most important secondary preventive treatments were similar in RA and non-RA patients. In a multivariate Cox model including data from the last time period, 2011–2013, age, CHF during hospitalisation, ST-elevation AMI (STEMI), AF, prior diabetes mellitus, a diagnosis of RA and oral anticoagulation were significantly associated with higher one-year mortality (Table).

Multivariate Cox analysis for the last time period 2011–2013

		P<0,05	95% CI
Age	1,042	0,000	1,039–1,046
CHF	2,101	0,000	1,998–2,220
STEMI	1,848	0,000	1,738–1,965
Prior diabetes	1,370	0,000	1,294–1,450
AF	1,321	0,000	1,248–1,398
RA diagnose	1,257	0,012	1,051–1,502
Oral anticoagulation	1,120	0,000	1,096–1,145

Conclusions: The marked decrease in one-year mortality after AMI seen over time in non-RA patients was not applicable in RA patients. Our finding might to some extent be explained by an increased age at AMI onset and unfavourable trends for AF and CHF in RA. However, RA *per se* was significantly associated with a worse prognosis during the last years of the study period. Secondary preventive treatment was similar in RA and non-RA patients. Further analyses including RA treatments are necessary to gain further insight into reasons behind the discrepant prognosis in RA vs. non-RA patients.

OP0148 IMPACT OF A CARDIOVASCULAR EVENT ON DMARD TREATMENT AMONG PATIENTS WITH RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS, OR PSORIASIS

J.A. Sparks[1], T. Lesperance[2], N.A. Accortt[2], D.H. Solomon[1]. [1]*Harvard Medical School, Brigham and Women's Hospital, Boston;* [2]*Amgen, Inc, Thousand Oaks, United States*

Background: Chronic inflammatory diseases such as rheumatoid arthritis (RA), psoriatic arthritis (PsA), and psoriasis (PsO) increase the risk of cardiovascular (CV) disease. However, a gap in knowledge exists regarding detailed information on changes in immunosuppressive (DMARD) treatments after a CV event.
Objectives: We describe treatment patterns among patients with RA, PsA, or PsO who were being treated with DMARDs prior to a CV event.
Methods: Patients with RA, PsA, or PsO, who experienced a CV event (acute myocardial infarction, stroke, or cardiac revascularization) between 1/1/2006 and 6/30/2015 were identified in an administrative claims database. Index date was defined as the hospital discharge date for the first CV event during the study period. Patients were required to: be continuously enrolled for 12 months prior to index date; have ≥1 TNFi claim, or a conventional synthetic (cs)DMARD claim, or another biologic DMARD claim within 6 months prior to the index date; and have ≥30 days of follow-up after index date. Treatment patterns were assessed after index date and patients were classified as remaining on ("persistent"), switching, or discontinuing pre-index DMARD medication.
Results: We identified 9,529 patients with RA, PsA, or PsO; prior to the index date, 3,274 (34.4%) patients were on TNFi, 5,177 (54.3%) were on only csDMARDs as monotherapy or combination, and 1,078 (11.3%) were on non-TNFi biologics. Patients on csDMARDs at index date were older (69.4 yrs) than those on TNFi (64.1 yrs) or other biologic DMARDs (66.0 yrs). Approximately 73% of patients were persistent on their pre-CV event treatment, with higher persistence among csDMARD alone (76.0%) and TNFi + csDMARD combo (76.7%) groups and lower in the non-TNFi biologic + csDMARD combo group (60.8%, Table 1). Across all treatment groups, 95% of persistent patients resumed treatment within 90 days after the index CV event. Combination therapy users switched their pre-CV event treatment more than monotherapy users, with non-TNFi biologic users more likely to discontinue all therapy after index CV event. Patients that discontinued all therapy after an index CV event tended to be slightly older females (68.7 yrs vs 67.1 yrs), with a history of PsO (24.4% vs 16.1%), and stroke as index event (49.3% vs 41.3%) compared to those that continued therapy.
Conclusions: In a large US database reflective of typical clinical practice, nearly one-quarter of patients with RA, PsA, or PsO discontinued or switched the pre-event DMARD treatment after a CV event. Further research is needed on whether these DMARD treatment patterns after initial CV event affect risk of repeat CV event.

OP0149 MORTALITY IN NEW-ONSET RHEUMATOID ARTHRITIS - HAS MODERN RHEUMATOLOGY HAD AN IMPACT?

M. Holmqvist[1], L. Ljung[2], J. Askling[1]. [1]*Karolinska Institutet, Stockholm;* [2]*Umeå University, Umeå, Sweden*

Background: A wealth of studies have linked rheumatoid arthritis (RA) with an excess mortality compared to the general population. With increasingly effective anti-rheumatic treatment strategies there is, however, considerable uncertainty whether this mortality gap still exists and, if so, how soon after RA onset it occurs.
Objectives: To assess the mortality in RA compared to the general population with specific focus on when during the course of the disease the risk is increased and if it also applies to patients diagnosed in recent years.
Methods: We performed a population-based cohort study of 17,512 patients with new-onset RA (identified from the Swedish Rheumatology Quality Register) 1997 through 2015, and 78,847 individually matched general population comparator subjects. We followed all individuals using nationwide census registers with full coverage to identify all deaths through 2015. We calculated mortality rates with 95% confidence intervals (CI) and compared the mortality in RA to that in the general population using Cox proportional hazards models adjusted for age, sex, year of diagnosis, and residential area.
Results: During a mean follow-up from RA diagnosis of 7 years, 2,386 RA patients and 9,850 population comparator subjects died (crude incidence: 19 per 1000 in RA and 18 per 1000 in the general population), with only a marginal decline (in the RA and in the general population cohort) during the study period. The overall HR was 0.99 (0.95–1.04), but whereas there was no increase in mortality during the first five years after RA diagnosis; the HR ≥10 years after RA onset was 40% increased. The overall pattern of HRs was similar for patients diagnosed 1997–2001, 2002–2006, and 2007–2011 (table).
Conclusions: The five-year mortality in RA is not increased, neither for patients diagnosed in the past nor for those diagnosed during the most recent five years. By contrast, at least in the most recent inception cohort for which ten-year mortality currently can be calculated (those diagnosed up to 2006), RA is still associated with an increased risk of death.

OP0150 PARADOXICAL EFFECT OF BIOLOGICAL DMARDS IN RHEUMATOID ARTHRITIS PATIENTS WITH OVERWEIGHT AND OBESITY: LESS OFTEN CLINICAL REMISSION, BUT ALSO LESS RADIOLOGICAL DAMAGE

A.V. de Jonge[1], M.M. ter Wee[1,2], I.E. Bultink[1], W.F. Lems[1]. [1]*VU University medical centre, Amsterdam Rheumatology and immunology centre;* [2]*Epidemiology and Biostatistics, VU University medical center, Amsterdam, Netherlands*

Background: The relationship between treatment with biological disease-modifying antirheumatic drugs (DMARDs), including TNF-blocking agents, and disease activity in overweight and obese rheumatoid arthritis (RA) patients has not been clarified yet.
Objectives: The aim of this review is to assess the effect of overweight/obesity on the therapeutic efficacy of these drugs. Secondly, we aimed to assess the influence of overweight/obesity on the occurrence of joint destruction.
Methods: A systematic review of all articles published on these subjects using PubMed and EMBASE was executed. For the first research question, studies were eligible when focused on the clinical efficacy of biological DMARDs only in overweight/obese RA patients versus patients with normal body weight. For the second research question studies were eligible when questioning the relation between overweight and joint destruction in patients with RA. Overweight and obesity were defined according to the following body mass index (BMI) categories; BMI <20 kg/m^2 for underweight, BMI 20–25 kg/m^2 for normal weight, BMI 25–30 kg/m^2 and BMI >30 kg/m^2 for overweight.
Results: A total of 6782 articles were found, of which 12 were eligible for this review. A total of 3647 RA patients were treated with adalimumab, etanercept, infliximab, golimumab, or certolizumab pegol, or TNF blockers, rituximab, or tocilizumab.
Ten studies used disease activity as outcome. In general, these studies showed that higher BMI is associated with poor response, based on either outcome or percentages on remission or improvement defined according to EULAR guidelines. In addition, four studies showed that higher BMI is also associated with higher Health Assessment Questionnaire (HAQ)-scores.
Two articles (of which one article described the results of studies in two different RA cohorts) focused on the association between BMI and joint destruction. These articles showed that higher BMI values were associated with lower odds for having joint destruction. One study also showed that having a BMI <20 kg/m^2 was associated with a higher odds ratio (OR =4.12) for joint destruction.
Conclusions: Higher BMI levels in RA patients treated with biological DMARDs

Abstract OP0148 – Table 1. DMARD treatment patterns for RA, PsA, or PsO patients following an initial CV event (N=9,529)

Treatment prior to CV event	N	DMARD treatment persisted, n (%)	DMARD treatment switched, n (%)	All DMARDs treatment discontinued, n (%)
Entire study sample	9,529	6,985 (73.3%)	1,498 (15.7%)	1,046 (11.0%)
TNFi monotherapy	1,760	1,323 (75.2%)	232 (13.2%)	205 (11.6%)
TNFi + csDMARD combination therapy	1,514	1,160 (76.7%)	299 (19.7%)	55 (3.6%)
csDMARD monotherapy	4,369	3,320 (76.0%)	528 (12.1%)	521 (11.9%)
≥2 csDMARDs combination therapy	808	518 (64.1%)	248 (30.7%)	42 (5.2%)
Non-TNFi biologic monotherapy	718	445 (62.0%)	63 (8.8%)	210 (29.2%)
Non-TNFi biologic + csDMARD combination therapy	360	219 (60.8%)	128 (35.6%)	13 (3.6%)

Abstract OP0149 – Table 1. Hazard ratio (HR) and 95% confidence intervals (CI) adjusted for sex, residential area, year of diagnosis, and age. Overall and stratified by calendar period of RA diagnosis and time since RA diagnosis

		RA duration categories HR (95% CI)			
Calendar period of RA diagnosis	Total follow-up	<1 year	1-<5 years	5–10 years	>10 years
Total study period	1.01 (0.96–1.06)	0.57 (0.48–0.67)	0.90 (0.83–0.97)	1.11 (1.02–1.20)	1.43 (1.28–1.59)
1997–2001	1.09 (1.01–1.18)	0.58 (0.39–0.87)	0.81 (0.68–0.96)	1.06 (0.92–1.21)	1.41 (1.25–1.60)
2002–2006	1.02 (0.94–1.10)	0.37 (0.24–0.57)	0.88 (0.76–1.01)	1.15 (1.03–1.30)	1.48 (1.20–1.82)
2007–2011	0.95 (0.86–1.05)	0.65 (0.49–0.87)	0.98 (0.86–1.11)	1.09 (0.90–1.31)	–
2012–2015	0.77 (0.63–0.95)	0.63 (0.46–0.88)	0.87 (0.67–1.12)	–	–

are associated with reduced therapeutic efficacy as compared to RA patients with normal body composition. The unfavourable effect of body weight on disease activity was paralleled by a favourable, protective effect on joint destruction. This uncoupling is not fully elucidated yet, and should be further investigated.

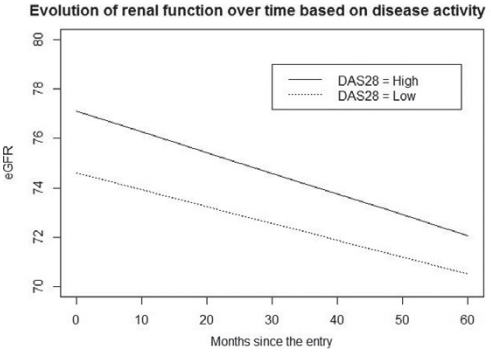
OP0151 DOCOSAHEXAENOIC ACID TREATMENT OF RHEUMATOID ARTHRITIS: A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED, CROSS-OVER STUDY



T. Neumann[1,2], C. Dawczynski[3,4], M. Dittrich[5], K. Goetze[6], A. Welzel[1], P. Oelzner[1], S. Voelker[7], A.M. Schaible[7], F. Troisi[7], L. Thomas[7], S. Pace[7], A. Koeberle[7], O. Werz[7], P. Schlattmann[8], S. Lorkowski[3,4], G. Jahreis[3,4].
[1]Department of Internal Medicine III, Jena University Hospital, Jena, Germany; [2]Department of Rheumatology, Kantonsspital St. Gallen, St. Gallen, Switzerland; [3]Competence Cluster for Nutrition and Cardiovascular Health (nutriCARD); [4]Department of Nutritional Biochemistry and Physiology, Institute of Nutrition; [5]Department of Nutritional Physiology, Institute of Nutrition, Friedrich Schiller University of Jena; [6]Department of Rheumatology, Jena University Hospital; [7]Department of Pharmaceutical/Medicinal Chemistry; [8]Department of Medical Statistics, Informatics and Documentation, Friedrich Schiller University of Jena, Jena, Germany

Background: Epidemiological studies and clinical investigations indicate a beneficial impact of long-chain n-3 polyunsaturated fatty acids (n-3 PUFA) on the inflammatory activity of rheumatoid arthritis (RA). However, the knowledge about the physiological effects of the individual compounds eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) is limited.
Objectives: In our pilot study presented here, we investigated the clinical benefit of daily intake of foods enriched with microalgae oil as source of DHA in RA patients. In particular, the influence on disease activity and changes in the profile of pro-inflammatory/non-resolving and anti-inflammatory/pro-resolving lipid mediators was examined.
Methods: This is a randomized, double-blind, cross-over study on 38 patients (32 females/ 6 males) with active RA (DAS28$\geq$2.4). They were allocated to consume foods enriched with microalgae oil from *Schizochytrium sp.* (2.1 g DHA/day) or sunflower oil (placebo) for 10 weeks while maintaining stable immunosuppressive treatment.
Results: Thirty-two patients finished the study but seven patients were excluded from analysis because their DHA increase in erythrocyte lipids (EL) was less than 25% after 10 weeks of intervention indicating insufficient adherence to the intervention. Supplementation of DHA led to a decline in tender joints (TJ68) 8.4±5.6 to 6.0±5.0 (p=0.03), swollen joints (SJ66) 5.6±3.5 to 3.9±3.5 (p=0.07) and DAS28 4.3±1.0 to 3.9±1.2 (p=0.07). Joint counts in the placebo arm remained stable (TJ68) 6.7±4.9 to 8.8±8.0 (p=0.12), swollen joints (SJ66) 3.5±3.0 to 4.2±3.7 (p=0.40) and DAS28 4.0±0.9 to 4.1±1.2 (p=0.45). Ultrasound score (US-7) remained stable (15.1±9.5 to 12.4±7.0; p=0.160) while it increased in the placebo arm (11.4±7.0 to 14.0±8.8; p=0.03).
The amount of n-3 PUFA in erythrocyte increased in supplemented patients (7.0±1.2% to 10.6±1.4%; p$<$0.001) and the ratios of aracidonic acid (AA) /EPA (18.5±6.3 to 12.6±5.5; p$<$0.001) and AA/DHA (3.8±1.0 to 1.8±0.6; p$<$0.001) dropped significantly. Fatty acid distribution in erythrocyte lipids (n-3 PUFA, AA/EPA and AA/DHA) remained stable in the control arm.
Conclusions: The study shows that microalgae DHA supplements can ameliorate disease activity in patients with active RA along with a shift in the balance of AA- and DHA-derived lipid mediators towards an anti-inflammatory/pro-resolving state.

OP0152 A LONGITUDINAL STUDY OF THE EFFECTS OF DISEASE ACTIVITY ON RENAL FUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS UTILIZING LINEAR MIXED EFFECT MODELS - ANSWER COHORT STUDY -

A. Onishi[1], K. Akashi[1], M. Hashimoto[2], M. Furu[2], W. Yamamoto[2], M. Katayama[3], R. Hara[4], T. Fujimura[4], S. Yoshida[5], K. Nagai[5], T. Hirano[6], K. Ebina[7], Y. Son[8], H. Amuro[8], H. Yamada[1], Y. Ichise[1], D. Waki[1], I. Naka[1], K. Tsuda[1], T. Okano[1], S. Takahashi[1], S. Sendo[1], Y. Ueda[1], Y. Kogata[1], J. Saegusa[1], A. Morinobu[1]. *[1]Department of Rheumatology, Kobe University Hospital, Kobe; [2]Department of the Control for Rheumatic diseases, Graduate School of Medicine, Kyoto University, Kyoto; [3]Department of Rheumatology and Clinical Immunology, Osaka Red Cross Hospital, Osaka; [4]The Center for Rheumatic Diseases, Nara Medical University, Nara; [5]Department of Internal Medicine (I), Osaka Medical College; [6]Department of Respiratory Medicine, Allergy and Rheumatic Disease, Graduate School of Medicine, Osaka University; [7]Department of Orthopaedic Surgery, Osaka University, Graduate School of Medicine; [8]First Department of Internal Medicine, Kansai Medical University, Osaka, Japan*

Background: Patients with RA have higher risk of developing chronic kidney disease compared to the general population. Although some causes of renal impairment in RA include nephrotoxic medications, amyloidosis, and glomerulonephritis, specific causes are not determined among most patients with RA. While experimental researches showed inflammatory process per se might also contribute to renal dysfunction, the results of previous clinical studies that assessed the effects of disease activity or C-reactive protein on renal function were inconsistent. This inconsistency might be attributable to their cross-sectional design, small sample size, and assessment of association between only baseline characteristics and renal outcomes without consideration for the fact that disease activity and medications had changed over time.
Objectives: To identify the effects of disease activity on renal function in RA in a multi-center cohort study.
Methods: RA patients with a sampling interval of less than 150 days were enrolled because wide sampling intervals could not take into consideration changes in disease activity and medications during their follow-up. An estimated glomerular filtration rate (eGFR) was calculated using an equation approved by the Japanese Society of Nephrology and used as an outcome variable. Linear mixed effect models were used to evaluate the renal trajectories of patients. Time from baseline (months), disease activity, and their interaction were included as fixed effects while participant identification number and time from baseline were included as random factors. Age, sex, disease duration, RF, ACPA, NSAIDs, and DMARDs that were known as a cause of renal impairment, such as tacrolimus, iguratimod, and tofacitinib, were included as covariates.
Results: A total of 25661 samples (mean sampling interval: 2.0 months) from 2104 patients was included. Patients with lower DAS28-CRP had worse renal function at inclusion, but a significantly better longitudinal trajectory on eGFR (0.0079 ml/min/1.73m^2 per month, P=0.025). Although all RA patients had naturally progressive renal impairment as they got older, patients who achieved remission or low disease activity had slower renal impairment rate of -0.068 ml/min/1.73m^2 per month compared to patients with moderate or high disease activity (-0.084 ml/min/1.73m^2 per month; P=0.037). These results were also similar using SDAI or CDAI.

Conclusions: Lower disease activity results in slower renal impairment. Because the effects of disease activity on renal function are mild, additional measures to protect renal function, such as avoiding nephrotoxic medications and treating cardiovascular risk factors are important.

OP0153 RECURRENT INFECTIONS IN RHEUMATOID ARTHRITIS PATIENTS, RESULTS FROM THE BSRBR

S. Subesinghe[1], A.I. Rutherford[1], R. Byng-Maddick[2], J.B. Galloway[1].
[1]Rheumatology, King's College London; [2]Homerton Hospital, London, United Kingdom

Background: Rheumatoid arthritis (RA) patients have an increased susceptibility to infection.
Objectives: 1.To establish the rate of recurrent infection in RA patients recruited to the British Society of Rheumatology Biologics Registry Rheumatoid Arthritis (BSRBR-RA).2.To establish whether the organ class of index infection predicted future serious infection.
Methods: The BSRBR-RA is a prospective observational cohort, previously described. Patients with at least one episode of serious infection requiring hospitalisation were included if they occurred whilst on anti-rheumatic drug therapy or within 5 drug half-lives of stopping. Infections were coded by MedDRA classification in to 7 categories. Infections occurring over 14 days after the first index infection were considered as new events. Event rates were calculated and compared using a Cox proportional hazards model with adjustments made for age, gender, disease duration, baseline DAS28 score, smoking status and seropositivity.
Results: See Table 1.
In total, 21,943 subjects with 115,423 patient-years follow up were studied, 5365 subjects reported at least one serious infection. Comparing organ classes of prior infection at baseline, each group had comparable age, disease duration, baseline DAS28 and HAQ scores. The cohort characteristics are tabulated. The baseline annual rate of first serious infection was 4.6% (95% CI 4.5–4.7). Following an

Abstract OP0153 – Table 1

	Overall	Patients with infection	Respiratory	Gastrointestinal	Genitourinary	Musculoskeletal	Sepsis	Skin/Soft Tissue	Other

Current smoker, n (%)	4682 (21.7)	1159 (21.9)	1422 (22.1)	165 (17.3)	452 (16.4)	186 (24.8)	122 (22.4)	692 (19.9)	573 (18.0)
RhFactor positive, n (%)	13,340 (63.2)	3533 (67.5)	4176 (66.1)	626 (66.2)	1737 (64.6)	527 (71.4)	361 (66.1)	2241 (65.6)	2003 (64.0)
Recurrent infection rate, % per annum (95% CI)	–	12.7 (12.1–13.2)	15.0 (13.9–16.2)	10.8 (9.2–12.8)	14.5 (12.7–16.5)	10.1 (8.7–11.8)	19.7 (15.1–25.7)	11.2 (10.1–12.5)	9.1 (7.3 -11.4)
Adjusted Hazard Ratio for annual incidence of recurrent infection (95% CI)	–	–	REF	0.79 (0.65–0.95)	0.97 (0.83–1.14)	0.81 (0.67–0.96)	1.33 (1.01–1.76)	0.87 (0.77–1.0)	0.70 (0.54–0.91)

index infection, the annual rate of serious infection was 12.7% (95% CI 12.1–13.3). Respiratory infections were the most common (41.4% of all events). The system class of index infection was associated with the risk of a recurrent event; subjects who experienced sepsis had the highest risk of subsequent serious infection within 12 months:19.7%. Compared to an index respiratory tract infection, sepsis conferred a 33% increased hazard for recurrent serious infection within a year (HR 1.33, 95% CI 1.01–1.76). Increasing age was a significant predictor of infection recurrence.

Conclusions: There is a high risk of recurrent infection in RA patients with past serious infection. Work is ongoing to determine whether organ class of recurrent infection event mirrors index events and the impact of biologic treatment decisions following the index infection.

Advances in RA and SpA pathophysiology

OP0154 ALTERED LYMPH NODE STROMAL CELLS DURING THE EARLIEST PHASES OF RHEUMATOID ARTHRITIS

C. Ospelt[1], E. Karouzakis[1], J. Hähnlein[2], J.F. Semmelink[2], R.E. Gay[1], P.P. Tak[2,3], D.M. Gerlag[2,4], S. Gay[1], L.G. van Baarsen[2]. *[1]Center of Experimental Rheumatology, University Hospital of Zurich, Zurich, Switzerland; [2]Academic Medical Center, Amsterdam, Netherlands; [3]Cambridge and GlaxoSmithKline, University of Cambridge, Stevenage; [4]R&D Projects Clinical Platforms & Sciences, GSK Clinical Unit Cambridge, Cambridge, United Kingdom*

Background: Lymph node stromal cells (LNSC) play a crucial role in shaping the immune response and maintaining peripheral tolerance. We developed an experimental model for studying the functional capacities of human LNSC during the earliest phases of RA and compared their cellular and molecular characteristics to LNSC from healthy volunteers.

Methods: ACPA+ RA patients (n=24), ACPA+ RA-risk individuals (n=23) and seronegative healthy controls (n=14;HC) underwent ultrasound-guided inguinal lymph node biopsy. Human LNSCs were isolated and expanded *in vitro* for cellular (flow cytometry), molecular (methylome, transcriptome and microRNA) and functional (contraction) analyses.

Results: RNA sequencing was performed on LNSC of HC (n=5), ACPA+ RA-risk individuals (n=6) and ACPA+ RA patients (n=4). Of interest, LNSC from ACPA+ RA-risk individuals and ACPA+ RA patients were more similar to each other compared with HC. Pathway analysis of commonly increased genes in RA (-risk) LNSC showed, among others, significant enrichment of pathways affecting actin cytoskeleton, focal adhesion and cell junction.

DNA methylation (Illumina HumanMethylation450 array) analyses revealed 459 differentially methylated CpG sites (DMS) in LNSC from ACPA+ RA patients (n=5) versus HC (n=4), 504 DMS between ACPA+ RA-risk individuals (n=3) versus HC and 665 DMS when comparing RA patients with RA-risk individuals (delta β-value >0.1, $p<0.05$). 34 DMS were different in both RA and RA-risk LNSC compared to healthy LNSC. 80% of these DMS were significantly hypomethylated and associated with antigen processing and presentation (HLA-DRB1), immune response and regulation of actin cytoskeleton.

Accordingly, in a gel contraction assay LNSC from ACPA+ RA-risk individuals and RA patients showed impaired collagen contraction compared to healthy LNSC. Healthy LNSC (n=5) covered 26.5% +/-2.5 of the well, while RA-risk (n=4) and RA (n=5) LNSC only covered 33.9% +/-5.9 and 30.6% +/-6.5.

Conclusions: This data point towards alterations in the cytoskeleton and antigen-processing and presentation in LNSC from ACPA+ RA-risk individuals and RA patients. Further studies are required to investigate the influence of this LNSC abnormality on immune responses.

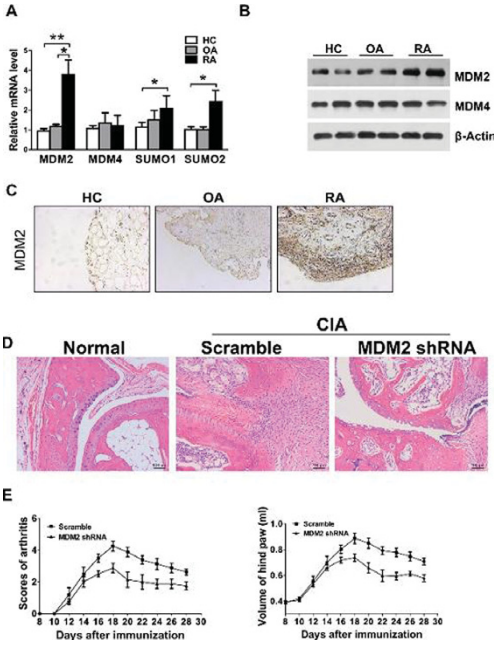
OP0155 MDM2-MEDIATED SUMOYLATION OF P53 CONTRIBUTES TO THE MIGRATION AND INVASION OF FIBROBLAST-LIKE SYNOVIOCYTES FROM PATIENTS WITH RHEUMATOID ARTHRITIS



M. Shi[1,2], H. Xu[1], G. Chen[2]. *[1]Department of Rheumatology, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou; [2]Department of Rheumatology, The First People's Hospital of Foshan, Foshan, China*

Background: Fibroblast-like synoviocytes (FLSs) in the synovial intimal lining are essential in the maintenance of synovial inflammation and progressive joint destruction in the development of Rheumatoid arthritis (RA). However, the precise molecular mechanisms by which this pathogenic process is regulated are not clearly defined.

Objectives: Increasing evidence indicates that p53 plays a critical role in the invasion and metastasis of cancer cells. This study aims to investigate the role of MDM2-mediated sumoylation of p53 in regulating the migration and invasion of fibroblast-like synoviocytes (FLSs) from patients with RA.

Methods: Synovial tissues were obtained from OA and RA patients, and then FLSs were separated from synovial tissues. Protein expression was measured by Western bloting or IHC staining. The sumoylation of p53 in cells was determined by immunoprecipitation. A specific inhibitor of MDM2-p53 interaction was used to inhibit the sumoylation of p53. Migration and invasion of FLSs in vitro were measured by the Boyden chamber assay.

Results: MDM2, SUMO1, and SUMO2 expression was significantly increased in the synovial tissue and FLSs of RA patients. Stimulation with TNF-α increased MDM2 expression and p53 sumoylation in RA FLSs. MDM2 shRNA inhibited p53 sumoylation, pro-inflammatory cytokines and MMPs expression, and capacity of in vitro migration and invasion in RA FLSs. Inhibition of p53 sumoylation by MDM2 shRNA promoted apotosis and reduced prolifeaation of RA FLSs. p38 MAPK signal pathway was involved in the downstream signal transduction in RA FLSs. Administration of MDM2 shRNA expressiong lentivirus attenuate the severity of rats with collagen-induced arthritis (CIA).

Conclusions: Increased MDM2-mediated p53 sumoylation contributes to aberrant aggressive behaviours of RA FLSs. Our findings suggests inhibition of MDM2 or p53 sumoylation might be a a novel therapeutic strategy to prevent synovial invasiveness and joint destruction in RA.

OP0156 METHOTREXATE INCREASES EXPRESSION OF THE CELL CYCLE REGULATORS LBH AND P21 AND REDUCES FIBROBLAST-LIKE SYNOVIOCYTE PROLIFERATION AFTER MITOGEN STIMULATION

B. Bergström, H. Carlsten, A.-K.H. Ekwall. *Rheumatology and Inflammation Research, Gothenburg University, Gothenburg, Sweden*

Background: Activated fibroblast-like synoviocytes (FLS) are key effector cells in the joint in rheumatoid arthritis (RA). Local FLS proliferation is responsible for synovial hyperplasia, a key feature of the RA synovium correlating with disease activity. PDGF and IL-1b are known FLS mitogens. LBH is a transcription regulator and tumor suppressor, recently identified as a RA risk gene. We have demonstrated that LBH regulates FLS proliferation and that LBH expression is regulated by growth factors and by epigenetic mechanisms[1]. Methotrexate (MTX) is still the first-line treatment of RA but the target cells and mechanism of action of the low dose used in rheumatic diseases is largely unknown. Increased expression of cell cycle checkpoint genes[2] and modified DNA methylation[3] in immune cells have recently been described.
Objectives: The aim of this study was to investigate the effects of MTX on PDGF and IL1b-induced FLS proliferation *in vitro* and in particular on the expression of LBH, cell cycle genes (CDKN1A/p21 and CCND1/cyclinD1) and on genes regulating DNA methylation (DNMTs) in order to further understand the pharmacodynamics of this drug in RA and to identify novel markers for drug response.
Methods: Primary FLS from RA patients and from patients with osteoarthritis (OA) were plated on day 0 in DMEM complete, pre-treated 24 hours with MTX or control medium day 1, and stimulated with 20ng/ml PDGF+2 ng/ml IL-1b with or without 1 uM MTX in DMEM with 1% FBS for 24–48 hours starting day 2. Cells were then harvested for qPCR for gene expression and flowcytometry for cell cycle analysis.
Results: Stimulating RA-FLS cultures (n=3) with PDGF+IL-1b for 24 hours, pushed 24,5±3,5% cells into G2/M phase compared to 3,4±0,8% in unstimulated controls. Interestingly, treating PDGF+IL1b stimulated FLS with MTX, significantly inhibited cell cycle progression (4,6±1,9% in G2/M phase, p=0,02). PDGF+IL-1b stimulation of FLS for 24 hours reduced LBH mRNA expression. However, in the presence of 1uM MTX the LBH mRNA expression was significantly higher in RA-FLS (3,2±0,5 fold, p=0.002, n=5) and in OA-FLS (2,2±0,5 fold, p=0,02, n=5) after PDGF+IL-1b stimulation compared to untreated controls. In addition, MTX treatment strikingly increased the CDKN1A expression 14,3±4,4 fold (p=0,006) of treated vs untreated stimulated FLS. Furthermore, we found that 1 uM MTX restored and increased a lowered DNMT1 mRNA expression to 144±12% after PDGF+IL1b stimulation. There were no significant effects of MTX on CCND1 or DNMT3a expression at investigated time points.
Conclusions: Therapeutic doses of MTX reduce mitogen induced FLS proliferation and significantly revert mitogen-induced reduction of LBH and p21 expression in RA FLS. MTX restores expression of DNMT1 suggesting that MTX might regulate gene expression and proliferation by affecting the epigenome.

OP0157 APOPTOSIS RESISTANCE OF SYNOVIAL FIBROBLASTS OF PATIENTS WITH RHEUMATOID ARTHRITIS IS REGULATED BY THE LONG NON-CODING RNA FAS-AS1

A. Pajak[1], Y. Horai[2], E. Pachera[1], M. Brock[2], S. Gay[1], M. Neidhart[1], O. Distler[1], A. Jungel[1] on behalf of yes. *[1]Department of Rheumatology; [2]Division of Pulmonology, University Hospital Zurich, Zurich, Switzerland*

Background: Apoptosis resistance is thought to contribute to the accumulation of synoviocytes in the affected joints of patients with rheumatoid arthritis (RA). Of particular interest, the Fas receptor (FasR) - Fas ligand (FasL) apoptotic pathway appears altered in RA[1]. Long non-coding RNAs (lncRNAs) are emerging as key regulators of gene expression. Their role in disease, however, is still poorly understood. The recently described lncRNA FAS-AS1 has been implicated in alternative splicing of FasR. This results in increased amounts of soluble FasR (sFasR) and thereby prevents FasL-induced cell death[2,3]. Whether lncRNA FAS-AS1 is involved in the apoptosis resistance of synovial fibroblasts in RA is unknown.
Objectives: To assess the regulatory role of lncRNA FAS-AS1 in the apoptosis resistance of synovial fibroblasts from patients with RA (RASF).
Methods: Levels of expression of lncRNA FAS-AS1 were measured in RASF and synovial fibroblasts from patients with osteoarthritis (OASF) by qPCR using SYBRGreen detection. Cells were treated with TNFα (10ng/ml, 24h) and/or with FasL (50ng/ml, 18h) to assess the secreted amount of sFasR by ELISA and the induction of apoptosis by Annexin V staining followed by flow cytometry. LncRNA FAS-AS1 was silenced using locked nucleic acid antisense oligonucleotides (GapmeR).
Results: There was no significant difference in basal levels of lncRNA FAS-AS1 expression between RASF and OASF (n=4 each). TNFα stimulation of synovial fibroblasts, regardless of the disease context (RA or OA), resulted in higher than 6-fold induction of lncRNA FAS-AS1 expression (6.45±1.39; $p<0,05$; n=4 for RASF and 6.26±1.47; p=0.05; n=4 for OASF). In addition, TNFα stimulation induced secretion of sFasR in RASF from 107±74 to 390±274pg/ml ($p<0.05$; n=6) and OASF from 69±54 to 249±134pg/ml ($p<0.05$; n=6). FasL induced apoptosis in both RASF and OASF (55–75±13%). However, pretreatment with TNFα reduced the FasL-induced apoptosis in RASF by 25±19% and in OASF by 15±10%. Silencing with GapmeR successfully decreased the expression of lncRNA FAS-AS1 by 40±22% SEM. Most interestingly, silencing of lncRNA FAS-AS1 reverted the TNFα inhibitory effect on FasL-induced apoptosis by 37±11% (n=4).
Conclusions: Our data revealed a novel mechanism, which may underlie apoptosis resistance in RASF. We showed that in a pro-inflammatory cytokine milieu, lncRNA FAS-AS1 up-regulates the release of sFasR and thereby may lower the responsiveness of cells to death signals. Thus, targeting lncRNA FAS-AS1 might prevent apoptosis resistance and synovial hyperplasia in RA.

OP0158 PREVALENCE OF IMMUNIZATION OF PATIENTS WITH AUTOIMMUNE DISEASE IN MEXICO

A. Arellano-Martinez, V. Gonzalez-Diaz, G.E. Martinez-Bonilla, S. Cerpa-Cruz, S.R. Gutierrez-Ureña, J. Reyes-Rueda, K.M. Garcia-Osuna, E. Gonzalez-Diaz. *Rheumatology Service, Hospital Civil Fray Antonio Alcalde, Guadalajara, Mexico*

Background: Current guidelines recommend immunization in patients with autoimmune diseases and use of immunosuppressants including biological treatment. Despite the above, the frequency of immunization is unknown in our population.
Objectives: To identify the prevalence of immunization in patients with autoimmune disease in a Rheumatology Service of a third level hospital in Mexico.
Methods: Observational, descriptive, cross-sectional study. Consecutive outpatients with autoimmune diseases who attended the Rheumatology Service of the Hospital Civil of Guadalajara during a period of 2 months (Dec. and Jan.) were included. A questionnaire was carried out to obtain demographic and immunization data. Descriptive statistical analysis was performed.
Results: 1208 patients were surveyed, 484 (40%) had a diagnosis of autoimmune disease; of whom 286 (59%) were on immunosuppressant therapy. 321 patients had a complete immunization during childhood. None of the patients knew what vaccines should by received with their diagnosis. When asked if they had been invited for immunization and from whom, 24 reported that their

general practitioner, 126 immunization campaign, 19 nurse, 9 rheumatologist, 4 pulmonologist, 1 infectious disease specialist, 1 family doctor and 1 internist. 260 (54%) reported having their immunization records. Only 37 had been vaccinated with influenza, 27 pneumococcus, 4 human papilloma virus and 2 Hepatitis B in the past. 372 (77%) accepted the invitation to be vaccinated on the day of their interview, but only 72 (19%) went to get the immunization; 41 of whom were given anti-influenza vaccines and 34 Pneumococcus (PPSV 23). The main causes for which the patient considers not to be vaccinated are: 85% "Because *my* treating doctor has not recommended me to go get vaccinated", 36% "They often do not have the vaccine to apply", 36% "I forget to get the vaccine on time", 31% "I think the application of the vaccine can make me sick", 14% "A vaccination center is not accessible", 7% "I think it is not useful to get vaccinated", and 5% "My doctor recommended me not to get vaccinated". These patients presented a total of 172 recurrent infections that included: upper airway infection 55, pneumonia 4 and others; 90 hospitalizations were required due to infection of which the main were due to: pneumonia 29, pulmonary tuberculosis 4, kidney 3, bone 1 and meningitis 1.

Conclusions: Immunization in this group of patients is low and rarely accepted mainly because their rheumatologist does not provide them with this information and due in general to a lack of information. This action is extremely important as it might reduce some serious infectious processes that lead to hospitalizations and increase the mortality in these immunosuppressed patients.

OP0159 THE INITIATION, BUT NOT THE PERSISTENCE, OF EXPERIMENTAL SPONDYLOARTHRITIS IN HLA-B27/HUβ2M TRANSGENIC RATS IS CRUCIALLY DEPENDENT ON THE IL-23 AXIS

M. Van Tok[1], S. Na[2], J. Taurog[3], D. Baeten[1], L. van Duivenvoorde[1]. *[1]Clinical Immunology and Rheumatology/Experimental immunology, Academic Medical Center, Amsterdam, Netherlands; [2]Eli Lilly and Co, San diego, CA; [3]Rheumatic Diseases Division, Department of Internal Medicine, UT Southwestern Medical Center, Dallas, TX, United States*

Background: The pro-inflammatory cytokine IL-17A is a central driver of pathology in human spondyloarthritis (SpA). IL-17A production was originally proposed to be dependent on the upstream cytokine, IL-23. Emerging preclinical and clinical evidence from SpA-related diseases suggest, however, that IL-17A and IL-23 have a partially overlapping but distinct biology.

Objectives: Here, we aimed to assess to what extend pathogenic IL-17A is dependent on IL-23 in SpA by selectively targeting the IL-23R in the HLA-B27/Huβ2m transgenic rat model of SpA, which we showed previously to be IL-17A-dependent.

Methods: HLA-B27/Huβ2m tg rats were immunized with low dose heat-inactivated *M. tuberculosis*/IFA. Rats were treated with a depleting anti-mouse/rat chimeric IL-23R antibody or PBS in a prophylactic (treatment initiation after immunization, before disease onset) or therapeutic (treatment initiation after disease onset) experiment. Clinical measurements included spondylitis and arthritis scores and hind paw swelling (plethysmometry). At the end of the study spleen and lymph nodes were used to assess cytokine expression, serum samples were analyzed for exposure to anti-IL23R.

Results: In the prophylactic treatment strategy, 58% and 67% of the rats in the control group developed spondylitis and arthritis, respectively. The average arthritis score at the end of the study was 3.9±1.1 and the average hind paw swelling was 0.35±0.09 cm^3. Prophylactic treatment with anti-IL-23R completely protected the rats against the development of spondylitis as well as arthritis. In the therapeutic treatment strategy, however, anti-IL23R treatment failed to reduce the incidence or decrease the severity of experimental SpA (fig. 1). With an average increase in arthritis score after the start of treatment of 1.6±2.8 versus 2.1±2.5 and an increase in paw swelling of 0.6±0.7 versus 0.3±0.6 cm^3in anti-IL23R treated versus control animals. The differential effect of IL-23R targeting in the initiation phase versus established disease could not be explained by pharmacokinetic differences as serum analyses revealed similar exposure levels. Mechanistically, the expression of presumably downstream effector cytokines such as IL-17A ($p<0.05$) and IL-22 ($p<0.01$) was reduced in the popliteal lymph nodes of rats treated prophylactically with anti-IL23R versus controls, with a similar trend in spleen. Accordingly, IL-17A production upon ex vivo re-stimulation was reduced in samples from prophylactically treated rats. In contrast, similar popliteal lymph node expression data in samples from the therapeutic experiment indicate a twofold increase in IL-17A expression and no difference in IL-22 expression in the anti-IL23R treated rats compared to controls.

Conclusions: IL-17A expression and production is dependent on the IL-23 axis in the initiation phase of experimental SpA but not in established disease. Accordingly, targeting of this axis with an anti-IL23R antibody completely prevented the onset of arthritis and spondylitis in HLA-B27/Huβ2m transgenic rats, but failed to reduce axial and peripheral joint inflammation in established disease. The cellular origin of IL-23-independent IL-17A production in established disease and the relevance to human SpA remains to be further investigated.

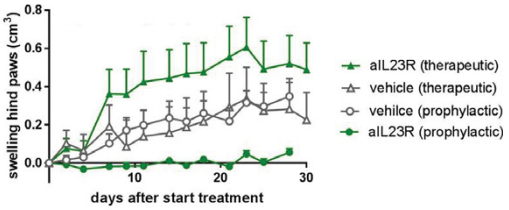

Figure 1: Swelling of the hind paws during follow up in prophylactic versus therapeutic treatment with anti-IL-23R or vehicle control (data are means +/- SEM)

OP0160 GUT-DERIVED TNF AS RISK FACTOR FOR THE DEVELOPMENT OF SACROILIAC INFLAMMATION

K. Debusschere[1], H. Cypers[2], P. Jacques[2], F. Van den Bosch[2], D. Souza[3], M. Brown[3], G. Nabozny[3], D. Dove[3], A. Klimowicz[3], D. Elewaut[1]. *[1]Ghent University - VIB; [2]Ghent University Hospital, Gent, Belgium; [3]Boehringer Ingelheim, Ridgefield, United States*

Background: An intruiging link exists between gut and joint inflammation in spondyloarthritis (SpA). About 50% of patients has subclinical (eg. microscopic) gut inflammation, which represents a risk factor for development of Crohn's disease, sacroiliac inflammation and evolution in to Ankylosing Spondylitis. However, the underlying mechanisms are still relatively poorly understood.

Objectives: Our goal was to examine the relationship between TNF, microscopic gut inflammation and axial inflammation using human samples and a novel mouse model. We speculated that TNF in the gut represents an important risk factor for disease severity and progression in SpA.

Methods: We examined in situ expression of TNF, TNFR1 and TNFR2 using triple in situ hybridisation in gut biopsies of human SpA patients. Furthermore, we generated intestinal specific human TNF transgenic mice, in which hTNF is under control of a rat iFABP (fatty acid binding protein) promoter, generating a mouse-model over-expressing human TNF in the ileum. These mice, together with wild type littermates, were evaluated for the development of arthritis up until the age of 13 weeks after which they were euthanized and ankle and sacroiliac joints as well as ileum were processed for histology.

Results: There was a marked upregulation of TNF in inflamed versus non-inflamed gut biopsies of human SpA patients. We also noted a predominant upregulation of TNFR1 on intestinal epithelium and TNFR2 in lamina propria respectively. Of interest, IL-17 and IL-23 were also markedly increased while IL-22 was most abundant in chronically inflamed samples. In line with this, we found that patients with gut inflammation had a higher need for anti-TNF therapy and their degree of clinical response after anti-TNF was also markedly higher.

Our transgenic mice exhibited a runt phenotype and hallmarks of inflammatory bowel disease, including increased intestinal permeability and inflammation compared to their wild-type littermates. While in peripheral joints no clear signs of arthritis were observed, the sacroiliac joints in transgenic mice, by contrast, showed marked signs of inflammation as well as bone erosion and destruction.

Conclusions: These data propose a new paradigm that gut-derived TNF is sufficient to trigger sacroiliitis and provide an alternate explanation on the relationship between gut inflammation, evolution to inflammatory bowel disease and axial inflammation in SpA.

OP0161 THE JAK1 SELECTIVE INHIBITOR FILGOTINIB REGULATES BOTH ENTHESIS AND COLON INFLAMMATION IN A MOUSE MODEL OF PSORIATIC ARTHRITIS

C. Robin-Jagerschmidt, S. Lavazais, F. Marsais, A. Monjardet, A. Cauvin, C. Saccomani, I. Parent, D. Merciris, E. Chanudet, M. Borgonovi, L. Lepescheux, M. Auberval, S. Dupont, P. Clement-Lacroix, R. Galien. *Galapagos SASU, Romainville, France*

Background: Psoriatic arthritis (PsA) is a heterogeneous chronic inflammatory disease characterized by the association of musculoskeletal involvement and extra-skeletal symptoms such as psoriasis and Inflammatory Bowel Disease

(IBD) with a variable clinical course. Common findings include enthesitis and dactylitis. Current treatments include anti-TNFa and anti-IL-12/IL-23 antibodies with varying success rates but the involvement of several pro-inflammatory cytokines suggests that other targeted therapies may be effective. Notably, the JAKs (a family of 4 non-receptor tyrosine kinases) are crucial for the signaling of many pro-inflammatory cytokines. In this regard, the JAK1-selective inhibitor filgotinib (GLPG0634, GS-6034) demonstrated clinical efficacy in patients with rheumatoid arthritis, a disease that shares some hallmarks with PsA and Crohn's disease, making this molecule a potential therapeutic tool for the treatment of PsA.

Objectives: Filgotinib was evaluated at the dose of 30 mg/kg/d (*per os*) in a mouse model of PsA induced by overexpression of IL-23.

Methods: Overexpression of IL-23 was induced by hydrodynamic delivery of mIL-23 enhanced Episomal Expression Vector (SBI) to male B10.RIII mice[1]. Evolution of inflammation of the paws and fingers was assessed by clinical scoring as well as *in vivo* molecular imaging (Bruker In-Vivo Xtreme imaging system). Enthesis and fingers were collected for expression analysis of inflammatory genes and target-related biomarkers. Neutrophil infiltrate, as well as pSTAT3 positive cells, were analyzed using immunohistochemistry in Achilles' enthesis and subcutaneous area, respectively. Colon was collected for lesion score determination as well as inflammatory and target-related biomarker gene expression.

Results: High levels of IL-23 were maintained during the time-course of the study and were correlated with severity of finger and paw swelling. Localization of the fluorescent signal using ProSense^{TM} imaging was asscociated with inflammation of enthesis and finger reported in PsA. Moderate inflammation of the colon was also observed. Filgotinib significantly improved clinical scoring and tended to prevent neutrophil/granulocyte infiltrate in paw (with significant effect being showed at earlier time point). Filgotinib reversed some up-regulated inflammatory genes in enthesis and/or fingers (CCL20, CXCL1, IL-22, MMP9 and TNFa) and reduced the target-related gene Mx2. Filgotinib significantly counteracted pSTAT3 induction in the subcutaneous area further demonstrating target engagement in the diseased tissue. Finally in line with previous findings[2], Mx2 expression in colon was slightly reversed by filgotinib.

Conclusions: In a mouse model of PsA, filgotinib improved global clinical score and decreased signs of inflammation in hindlimbs. Target engagement both in hindlimbs and colon was also demonstrated. These data support the evaluation of filgotinib in patients with PsA.

Bringing rheumatology research to the next level: addressing the main challenges of patient partnerships in research and health care service design

OP0162-PARE AN EXPLORATION OF LIVED EXPERIENCES AMONGST ADULTS WITH RHEUMATOID ARTHRITIS USING AN ONLINE RESEARCH COMMUNITY PLATFORM: A PILOT STUDY

S.R. Stones[1,2,3], S. Bull[1], S. Becerra[1]. *[1]Double Helix Consulting, Macclesfield; [2]Faculty of Life Sciences, The University of Manchester, Manchester; [3]School of Healthcare, University of Leeds, Leeds, United Kingdom*

Background: Online technology has revolutionised the way in which people connect and share their experiences. It also brings new opportunities to engage patients in health and social care research through the use of an online research community platform (ORCP). For example, it can improve the accuracy and usefulness of information gathered about research priorities, and it can be used to understand behaviours and preferences. Given an increasing prevalence of long-term conditions including rheumatoid arthritis, online technology represents a novel route for participation and engagement in research.

Objectives: To explore the benefits and limitations of an ORCP through understanding lived experiences of adults with rheumatoid arthritis.

Methods: We used a purposive sampling approach to ensure variation of key attributes amongst people with rheumatoid arthritis. A total of eight individuals used the ORCP during the pilot study. Qualitative data were collected through online focus groups, conducted as semi-structured interviews and asynchronous threaded discussions. The study was conducted in line with fieldwork guidelines, and written informed consent was obtained.

Results: The closed ORCP enabled a physically disconnected group to share their experiences of living with rheumatoid arthritis, describing the symptoms, diagnostic experience and support they received. In addition, participants shared their experiences and opinions about treatment delivery and adherence, the impact of rheumatoid arthritis, and the experiences of transitional care from paediatric to adult health services, where appropriate. Reasons and feeling about research participants and drug development processes were also discussed.

Conclusions: Our pilot study provided important accounts from people living with rheumatoid arthritis, highlighting the substantial impact of the disease on their daily lives. The ORCP removed physical contact between the researcher and participants, the absence of which may enable a richer data collection. However, it also has its limitations, primarily because the researcher is less able to gauge participants' attitudes and concerns. ORCPs represent a novel route of data collection, enabling researchers to immerse themselves into a community of individuals, whether they be patients, carers or professionals.

Acknowledgements: The authors would like to thank the individuals who contributed their thoughts and experiences to the pilot study.

OP0163-PARE INVIGORATING THE PRINCIPLE OF PARTICIPATORY RESEARCH IN GERMANY - SETUP OF A TRAINING COURSE FOR PATIENT REPRESENTATIVES

J. Clausen. *Deutsche Rheuma-Liga Bundesverband, Bonn, Germany*

Background: Patient participation in research projects is important because it enhances the legitimacy of research projects and facilitates the implementation of research results after completion of the respective projects. Since 2009, patient representatives have been actively involved in EULAR projects, and the first EULAR training course for patient representatives was conducted in 2010.

Objectives: The aim of the project was to create a training course for German-speaking patient representatives and thereby to invigorate the principle of participatory research in Germany. The training course is supposed to enable patients to make valuable contributions in research projects. In addition the training course aimed at lowering barriers and strengthening the patients' self-confidence, in order to facilitate their integration in the unfamiliar environment among researchers.

Methods: Participants were trained during a two-day interactive training course. For evaluation of the course, each participant anonymously answered 14 questions in a questionnaire.

Results: The training course consists of seven modules. In the first module (I), the history of the EULAR "patient research partners" is described and the tasks of the future German patient research partners are outlined. In the following modules, various types of research and study designs (II), the generation of research questions and hypotheses (III), various scientific tools (IV), the detailed sequence of steps in a typical research project (V), literature research in scientific databases (VI) and the process of reviewing grant applications (VII) are explained. Each module is subdivided in an explanatory section, an exercise section (where the participants have to apply the newly achieved skills) and a final discussion section.

So far, two courses have been conducted. The training course was rated either "very good" or "good" by 77% and 23% of the participants, respectively. Those patients, already actively involved in research projects, acclaim participatory research as interesting and enriching.

Conclusions: The training course was perceived very well by the participants. In future follow-up meetings, the usefulness of the various modules and any missing items will be discussed and the training course adapted accordingly.

Acknowledgements: We thank Dr. C. Sander for her contribution to the training course.

Osteoarthritis: new horizons for treatment

OP0164 OPTIMIZING RECRUITMENT CRITERIA FOR AN OSTEOARTHRITIS STRUCTURE MODIFICATION TRIAL: DATA FROM THE OAI

M.A. Bowes[1], G. Guillard[1], A. Brett[1], G.R. Vincent[1], P.G. Conaghan[2]. *[1]Imorphics, Manchester; [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom*

Background: The design of clinical trials for osteoarthritis is challenging; structural changes in tissues are quantitatively small and proceed very slowly. No clear guidance exists on how to optimise recruitment. KL grade is a poor recruitment criterion as centres interpret KL differently. Quantitative measures should be

better, and metric radiographic joint space width (rJSW) is related to subsequent risk of radiographic progression. Although new MRI measures provide increased responsiveness in DMOAD trials, it is unknown whether selecting for recruitment based on radiographic criteria are well suited for responsiveness of these new measures.

Objectives: (1) To determine which baseline rJSW values are associated with most subsequent progression for rJSW, MRI cartilage and bone outcomes (2) Explore baseline covariates that influence progression rates (3) Estimate the trial numbers needed using the criteria determined by steps (1) and (2).

Methods: We used all knees from the Osteoarthritis Initiative which had all 3 measures recorded (rJSW – Duryea method; MRI cartilage thickness & bone area, Imorphics) at baseline, 1 and 2 years. We categorised knees into bins of 1mm rJSW, and assessed the 2 year changes of each bin, and characterised the distribution of rJSW in KL 0 knees. We used ANCOVA models to consider which covariates (including gender, height, weight, alignment, age, pain severity) affected 2-year slope of change, and responsiveness using SRM. For the final optimised recruitment groups, we calculated SRMs (CIs assessed using the bootstrap method of Efron) and derived the number of patients per arm in a putative trial.

Results: 4796 knees were included (2789 females, mean age 61.45). The lower 95th percentile values for rJSW in women and men were 3.9 and 4.5mm respectively. The mean changes at 2-years for all 3 outcomes were greatest for the categories of 2–3 and 3–4mm baseline rJSW (Figure 1A) with notably little change in knees with rJSW<2mm. Of the covariates, only pain improved responsiveness. Using a total WOMAC pain criterion; ≥3/20 reduced numbers from 726 knees to 331 knees, and improved 1 year SRM (95% CI) from 0.27 (0.17,0.34) to 0.41 (0.29,0.51) in rJSW, from 0.45 (0.37,0.51) to 0.55 (0.45,0.65) in MRI cartilage and from 0.60 (0.52,0.66) to 0.73 (0.62,0.83) in MRI bone. Figure 1B shows the relative SRMs for the 3 outcomes based on 2 inclusion criteria (rJSW 2–4mm and pain ≥3/20; n=331) and demonstrates the required trial numbers (with confidence intervals) based on the SRMs.

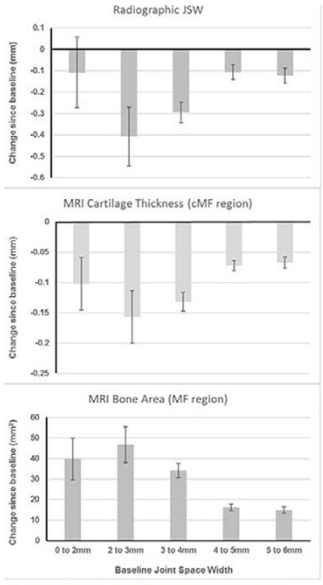

Figure 1A: *Mean 2-year change for 3 imaging outcomes by baseline rJSW*

Units are in mm for rJSW and MRI cartilage thickness, and in mm² for MRI bone area (95% confidence limits for change since baseline in brackets)

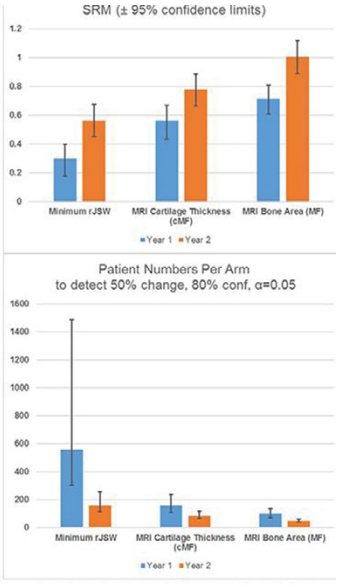

Figure 1B: *Responsiveness of knees selected for JSW 2-4 and pain ≥3 (n=331)*

Top figure shows SRMs plus 95% confidence limits, bottom figure calculates numbers required to identify change from SRMs in top figure

Conclusions: Selecting patients based on 2 simple criteria will improve responsiveness in clinical trials for all 3 imaging outcomes using standard imaging outcomes. Selecting for rJSW of 2–4mm is most important while adding a pain criteria further improves responsiveness; no other covariates improved this. Caution should be applied when using SRM to power a study because of the inherent difficulties in calculating standard deviations; Fig 1B shows for example that the confidence limits for rJSW at 12 months vary from 302 to 1489. This analysis also confirms the advantages of MRI outcomes over rJSW in terms of study size and duration: a 12-month study with cartilage thickness or bone area endpoints needs no more than 238 or 137 patients (including the upper 95th percentile confidence limit).

OP0165 A NEOEPITOPE FRAGMENT OF C-REACTIVE PROTEIN IS PROGNOSTIC OF RADIOGRAPHIC KNEE OA

A.C. Bay-Jensen [1], A. Bihlet [2], I. Byrjalsen [2], J.R. Andersen [2], Y. He [1], A.S. Siebuhr [1], C.S. Thudium [1], B.J. Riis [2], C.H. Christiansen [2], M.A. Karsdal [1].
[1] Rheumatology, Nordic Bioscience Biomarkers and Research; [2] Clinical development, Nordic Bioscience, Herlev, Denmark

Background: There are two major needs in clinical development of DMOADs: 1) Identifying a suitable population with an active and progressive disease in order to demonstrate significant improvements by an efficacious intervention; and 2) Phenotyping patients and linking them to a corresponding treatment mode-of-action (e.g. anti-inflammatory). The biochemical marker CRPM is a neoepitope of C-reactive protein (CRP) and is released from the local inflamed tissue when CRP is degraded by proteases such as matrix metalloproteinases

Objectives: The purpose of this study was to translate the CRPM, from rheumatoid arthritis (RA), where it has been extensively tested, to OA, and to test whether it is predictive of radiographic OA.

Methods: The placebo arms of two phase III OA trial (clinicaltrial.gov: NCT00486434 and NCT00704847), a phase III RA study (the LITHE study, N=490), which included patients with active, moderate-severe RA (NCT00106535), as well as in an early RA cohort (N=92) were used. Subjects with symptomatic and radiographic knee OA: WOMAC pain ≥150mm and/or WOMAC function ≥510mm, and Kellgren-Lawrence grade (KLG) 2 or 3. KLG were scored for both knees at baseline and year 2 (Y2). Serum CRPM and hsCRP were measured at baseline. The association between serum CRPM levels and disease activity score (DAS28) and hsCRP was investigated by Spearman's correlations. Quartile ranges of CRPM in the early RA cohort were used to define the cut-off between inflammatory OA and non-inflammatory OA. OA knees were divided into cases and controls based on a terminology proposed by the FNIH-OAI consortium (1); knees with KLG≥2 at BL were excluded, and incidence OA at Y2 was defined KLG≥2. Logistic regression was used to compare cases and controls.

Results: There was a significant correlation between disease activity measures and CRPM in both RA studies. Seventy-five percent of the LITHE patients had high or very high levels of CRPM at BL, which was changed to a pattern similar to early RA after treatment. The mean CRPM levels were significantly lower in OA (8.5 [95% CI 8.3–8.8] ng/mL) compared to the RA patients (15.6 [9.5–21.6] ng/mL); however, a significant subset of OA patients (41% and 31% in SMC2301 and SMC2302) had CRPM levels ≥9ng/mL, as 75% of patients with early RA. Patients with BL or Y2 CRPM levels ≥9ng/mL were more likely to develop knee OA than patients with low level of CRPM. Overall, moderate to very high levels of CRPM at BL and Y2 were predictive of incidence OA with odds ratio of 4.6 [1.2–17] and 2.5 [1.2–4.8].

Table		Early RA	Moderate-Severe RA	SMC2301	SMC2302
hsCRP	Rho (p-value)	0.54 (<0.0001)	0.66 (<0.0001)		
DAS28	Rho (p-value)	0.43 (<0.0001)	0.24 (<0.0001)		
CRPM level	Quartile range	No. of patients (%)			
		Before treatment	*After treatment*	*n_1*	*n_2*
Low	<9 ng/mL	49 (8.2%)	87 (18%)	267 (59%)	233 (69%)
Moderate	9-12	100 (17%)	123 (25%)	137 (31%)	71 (21%)
High	12 – 15	132 (22%)	105 (21%)	26 (6%)	23 (7%)
Very high	>=15	318 (53%)	175 (36%)	19 (4%)	11 (3%)

Conclusions: A subset of OA patients, up to 41%, appear to have tissue inflammation comparable to that of RA, reflected by the level of CRPM. Furthermore, high CRPM levels was prognostic of incident knee OA. These data suggest that CRPM is blood-based biochemical marker for finding OA patients with an inflammatory phenotype.

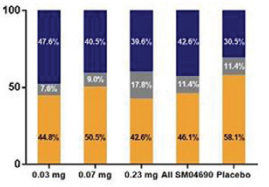
OP0166 RADIOGRAPHIC OUTCOMES FROM A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED, PHASE 2 STUDY OF A NOVEL, INTRA-ARTICULAR, INJECTABLE, WNT PATHWAY INHIBITOR (SM04690) IN THE TREATMENT OF OSTEOARTHRITIS OF THE KNEE: WEEK 26 INTERIM ANALYSIS

Y. Yazici[1], T.E. McAlindon[2], A. Gibofsky[3], N.E. Lane[4], N. Skrepnik[5], E. Armas[6], C.J. Swearingen[1], A. DiFrancesco[1], J.R. Tambiah[1], M.C. Hochberg[7].
[1]Samumed, LLC, San Diego, CA; [2]Tufts Medical Center, Boston, MA; [3]Weill Cornell Medical College and Hospital for Special Surgery, New York, NY; [4]UC Davis Medical Center, Davis, CA; [5]Tucson Orthopedic Institute, Tucson, AZ; [6]Well Pharma, Miami, FL; [7]University of Maryland School of Medicine, Baltimore, MD, United States



Background: Knee osteoarthritis (OA) is characterized by pain, functional impairment, and joint space narrowing due to degradation of articular cartilage and bone remodeling. The Wnt pathway plays a central role in the formation of joint tissues, and altered Wnt signaling has been associated with cartilage loss in preclinical studies. SM04690 is a small molecule Wnt pathway inhibitor in development as a disease modifying OA drug (DMOAD) and administered as an intra-articular (IA) knee injection. A phase 2, multicenter, 52-week, single-dose, randomized controlled trial of SM04690 is ongoing in subjects with moderate to severe knee OA. Radiographic results from an interim analysis at 26 weeks are reported.
Objectives: To evaluate the safety and efficacy of SM04690 IA injection for the treatment of OA.
Methods: Subjects were randomized to receive a single, 2 mL, IA injection of 0.03 mg, 0.07 mg, 0.23 mg SM04690 or placebo into the target knee on Treatment Day 1. Safety, tolerability and efficacy outcomes were assessed at Weeks 4, 13 and 26. Target knee radiographs were taken at baseline and Week 26; change in medial joint space width (mJSW) was analyzed using an intention-to-treat analysis of covariance (ANCOVA) adjusting for baseline mJSW.
Results: 455 subjects (average age 60.3 [±8.7] years, 268 [58.9%] female, mean BMI 29.9 [±4.6] kg/m^2, 293 [64.4%] Kellgren-Lawrence Grade 3, 291 [64.0%] bilateral OA) were enrolled. At Week 26, 8 serious adverse events (SAEs) in 7 subjects were reported; these were deemed unrelated to drug by the investigators. Mean mJSW change from baseline was -0.22 [±0.64] mm in placebo cohort (table 1). Compared to placebo, mean mJSW change from baseline was -0.07 [±0.62] mm in the 0.03 mg (p=0.069), -0.16 [±0.95] mm in 0.07 mg (p=0.489), and -0.03 [±0.59] mm in 0.23 mg (p=0.019) cohorts, respectively. Increase in mean mJSW was observed in 50 (47.6%) subjects in 0.03 mg, 45 (40.5%) subjects in 0.07 mg, 40 (39.6%) subjects in 0.23 mg and 32 (30.5%) subjects in placebo cohorts, respectively (figure 1). Odds of mJSW improvement, defined as change in mJSW >0, were increased 107% in 0.03 mg cohort compared to placebo (OR=2.1, 95% CI [1.2, 3.7], p=0.011), and odds of mJSW improvement were increased 69% for all SM04690 doses combined compared to placebo (OR=1.7, 95% CI [1.1, 2.7], P=0.029). Additionally, in *a priori* subanalyses, each treatment cohort, and all SM04690 doses combined, had higher probability of improving mJSW in the unilateral OA subgroup, with a 420% increase in odds of JSW response compared to placebo (all SM04690 groups combined OR=5.2, 95% CI [2.1, 12.8], p<0.001).

Table 1. Medial joint space width at baseline and week 26

	0.03 mg	0.07 mg	0.23 mg	All SM04690	Placebo
N	111	117	109	337	116
Baseline (mm) [Mean (SD)]	3.41 (1.28)	3.45 (1.11)	3.08 (1.26)	3.34 (1.24)	3.33 (1.36)
Week 26 (mm) [Mean (SD)]					
Actual	3.38 (1.38)	3.30 (1.40)	3.06 (1.38)	3.25 (1.39)	3.10 (1.52)
Change from baseline	-0.07 (0.62)*	-0.16 (0.95)	-0.03 (0.59)**	-0.09 (0.74)	-0.22 (0.64)

*0.03 mg vs PBO, p=0.069; **0.23 mg vs PBO, p=0.019

Figure 1. JSW Change at 26 weeks: All subjects

JSW Change at 26 weeks: Unilateral subjects

Conclusions: Radiographic outcomes from this interim analysis demonstrated that treatment with SM04690 maintained or increased JSW compared to placebo. These data support the continued development of SM04690 as a potential DMOAD for the treatment of knee OA. Further studies are ongoing.

OP0167 EFFICACY AND SAFETY OF CNTX-4975 IN SUBJECTS WITH MODERATE TO SEVERE OSTEOARTHRITIS KNEE PAIN: 24-WEEK, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED, DOSE-RANGING STUDY

R. Stevens[1], D. Petersen[2], J. Ervin[3], J. Nezzer[4], Y. Nieves[4], J. Campbell[1], K. Guedes[1], R. Burges[1], P. Hanson[1]. *[1]Centrexion Therapeutics, Boston; [2]Noble Clinical Research, LLC, Tucson; [3]The Center for Pharmaceutical Research, Kansas City; [4]Premier Research, Durham, United States*

Background: Osteoarthritis causes joint pain, stiffness, and reduced function, leading to disability. CNTX-4975, a highly purified, synthetic *trans*-capsaicin, targets the transient receptor potential vanilloid 1, producing analgesia via reversible deactivation of end terminals of primary afferent pain fibers within the joint and capsule.
Objectives: This 24-week dose-ranging study evaluated CNTX-4975 efficacy and safety in subjects with chronic, moderate to severe osteoarthritis-associated knee pain.
Methods: Subjects aged 45–80 years with chronic knee osteoarthritis, stable moderate to severe knee pain, and intolerability to oral or intra-articular analgesics were randomized to a single injection of placebo, CNTX-4975 0.5 mg, or CNTX-4975 1.0 mg. The primary efficacy endpoint was the area under the curve (AUC) for change from baseline in daily Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) A1 score through week 12. Least squares mean differences (LSMD) for CNTX-4975 vs placebo were calculated for the primary endpoint and the average weekly AUC WOMAC A1 scores using analysis of covariance. Additional efficacy endpoints, mean change from baseline in weekly WOMAC A1 score, WOMAC B stiffness subscale, and WOMAC C physical function subscale through week 24, were analyzed using a mixed model for repeated measures (MMRM). Statistical tests were 2-sided (alpha, P=0.10). Safety assessments included treatment-emergent adverse events (TEAEs).
Results: Efficacy was evaluated in 172 subjects (placebo, n=69; CNTX-4975 0.5 mg, n=33; CNTX-4975 1.0 mg, n=70). Mean WOMAC A1 pain scores at baseline were 7.4 (placebo), 7.2 (CNTX-4975 0.5 mg), and 7.2 (CNTX-4975 1.0 mg). In the primary efficacy analysis, significant improvements vs placebo in WOMAC A1 scores were observed at week 12 with CNTX-4975 0.5 mg (LSMD: –0.8; P=0.07) and CTNX-4975 1.0 mg (LSMD: –1.6; P<0.0001). Significant improvements vs placebo were also observed at week 24 with CNTX-4975 1.0 mg (LSMD: –1.35; P=0.0002). In the MMRM analysis, significant improvements in WOMAC A1 scores vs placebo were demonstrated with CNTX-4975 0.5 mg at week 12 (LSMD: –0.9; P=0.087) but not week 24 (LSMD: –0.5; P=0.41), and with CNTX-4975 1.0 mg at weeks 12 (LSMD: –1.5; P=0.0003) and 24 (LSMD: –0.9; P=0.067). CNTX-4975 1.0 mg significantly improved WOMAC B (LSMD: –2.5; P=0.0013) and WOMAC C scores vs placebo (LSMD: –18.3; P=0.004) at week 12. Numerically greater improvements were observed in WOMAC B and C at week 24, but differences were not significant (WOMAC B LSMD: –1.2; P=0.14; WOMAC C LSMD: –7.2; P=0.28). In the safety population, the incidence of TEAEs was 30% for placebo or CNTX-4975 1.0 mg, and 47% for CNTX-4975 0.5 mg at week 24. Most TEAEs were considered unrelated to study treatment. Arthralgia was the most common TEAE with CNTX-4975 1.0 mg (placebo, 5.7%; CNTX-4975 1.0 mg, 7.0%).
Conclusions: A single injection of CNTX-4975 1.0 mg improved pain with walking, knee stiffness, and physical function, and was well tolerated in subjects with moderate to severe osteoarthritis-associated knee pain.

OP0168 A PHASE 2A, PLACEBO-CONTROLLED, RANDOMIZED STUDY OF ABT-981, AN ANTI-INTERLEUKIN-1ALPHA AND -1BETA DUAL VARIABLE DOMAIN IMMUNOGLOBULIN, TO TREAT EROSIVE HAND OSTEOARTHRITIS (EHOA)

M. Kloppenburg[1], C. Peterfy[2], I.K. Haugen[3], F. Kroon[1], S. Chen[4], L. Wang[4], W. Liu[4], G. Levy[4], R. Fleischmann[5], F. Berenbaum[6], D. van der Heijde[1], J. Medema[4], M.C. Levesque[4]. *[1]Leiden University Medical Center, Leiden, Netherlands; [2]Spire Sciences, Inc., Boca Raton, FL, United States; [3]Diakonhjemmet Hospital, Oslo, Norway; [4]AbbVie Inc., North Chicago, IL; [5]University of Texas Southwestern Medical Center at Dallas, Metroplex Clinical Research Center, Dallas, TX, United States; [6]University Pierre & Marie Curie and Inserm, DHU i2B, APHP, Hospital Saint-Antoine, Paris, France*

Background: No approved OA therapies reduce pain and slow joint damage. Mouse data suggested that inhibiting IL-1α and -1β with ABT-981 would reduce pain and slow structural progression in EHOA.
Objectives: To test the efficacy and safety of ABT-981 in EHOA.
Methods: Subjects with HOA per ACR criteria, ≥3 inflamed IP joints (tender, swollen, or both), hand pain ≥6 (scale 0–10), and ≥1 erosive IP joint on X-ray (Verbruggen-Veys) were randomized to placebo (PBO) or ABT-981 200 mg SC every 2 wk for 26 wk. The primary outcome was AUSCAN hand pain at 16 wk. Subjects had radiographs of both hands and MRI of the index hand at baseline and 26 wk. Both radiographs (Verbruggen-Veys, GUSS™, OARSI, Kellgren-Lawrence [KL]) and MRIs (HOAMRIS) were read by 2 independent central readers. A modified intent-to-treat population (ie, randomized and treated) was analyzed. Continuous efficacy endpoints were assessed using ANCOVA models with treatment and country as main factors and baseline measurements as covariates with LOCF imputation for the primary endpoint.
Results: Of 131 treated subjects (85% women; mean age 66 y), 61/67 randomized to PBO and 49/64 to ABT-981 completed the study; subject characteristics were well matched. AUSCAN pain was not significantly different vs PBO at wk 16 (*P*=0.39; Table 1, Figure); X-ray data and other endpoints also were not statistically different vs PBO (Table 1). ABT-981 significantly decreased hsCRP, neutrophils, IL-1α, and IL-1β. Immunogenicity had no impact on ABT-981 pharmacokinetics. Besides injection site reactions and neutropenia, ABT-981 was well tolerated and safety was similar vs PBO, with no serious infections (Table 2).

Table 1

Figure

OP0169 EARLY OSTEOPHYTES DETECTED BY MRI ARE ASSOCIATED WITH CHANGES IN KNEE PAIN AND STRUCTURES IN OLDER ADULTS: A POPULATION-BASED COHORT STUDY

Z. Zhu[1], L.L. Laslett[1], W. Han[1], B. Antony[1], F. Cicuttini[2], G. Jones[3], C. Ding[3]. *[1]12779, Hobart; [2]Department of Epidemiology and Preventive Medicine, Monash University, Melbourne; [3]Musculoskeletal Unit, 12779, Hobart, Australia*

Background: Early stage of osteophyte (OP) formations are hard to be detected by radiography, but can be detected by magnetic resonance imaging (MRI). Their subsequent developments on structural and clinical abnormalities are still unknown.
Objectives: To describe the prevalence of early osteophytes (OPs) that were detected by magnetic resonance imaging (MRI) but not by X-ray in older adults and to evaluate the longitudinal associations with knee pain and structural changes.
Methods: 837 participants (mean age 62 years, 50% female) were randomly selected from local community at baseline. T1- or T2-weighted fat suppressed MRI was used to assess knee OPs, cartilage volume, cartilage defects and bone marrow lesions (BMLs) at baseline and after 2.6 years. Knee pain was assessed by self-administered Western Ontario and McMaster Osteoarthritis (WOMAC) Index questionnaire at baseline and after 5 years. X-ray-detected OPs were assessed at baseline using the Osteoarthritis Research Society International atlas. OPs detected only by MRI but not by standard X-ray were defined as early OPs. OPs detected by both MRI and X-ray were defined as definite OPs.
Results: The prevalence of early OPs was 75% while the prevalence of definite OPs was 10% in total knee at baseline. Compared with participants without any OPs, participants with early OPs and with definite OPs had greater cartilage volume loss and increased cartilage defects and BMLs over 2.6 years. Presence of early medial tibiofemoral OPs predicted decreases in total knee pain over 5 years, while definite OPs predicted increases in total knee pain, after adjustment for relevant covariates.

Table 1. Longitudinal associations of OP phenotype status and WOMAC knee pain changes

	Adjusted* β (95% CI)	Adjusted** β (95% CI)
Total		
No OPs (n=103)	*Ref.*	*Ref.*
Early OPs (n=481)	-0.23 (-1.33, 0.88)	-0.28 (-1.40, 0.84)
Definite OPs (n=62)	2.20 (0.51, 3.89)	1.96 (0.17, 3.76)
Medial tibiofemoral		
No OPs (n=447)	*Ref.*	*Ref.*
Early OPs (n=155)	-1.25 (-2.2, -0.30)	-1.51 (-2.50, -0.52)
Definite OPs (n=43)	2.91 (1.21, 4.60)	2.54 (0.74, 4.35)
Lateral tibiofemoral		
No OPs (n=287)	*Ref.*	*Ref.*
Early OPs (n=332)	0.12 (-0.70, 0.94)	-0.05 (-0.91, 0.81)
Definite OPs (n=27)	1.08 (-1.11, 3.27)	0.35 (-1.95, 2.66)

Results of this table are generated from a linear regression model. *Adjusted for age, sex and BMI. **Further adjusted for BMLs and cartilage defects.

Conclusions: Although early OPs are associated with knee abnormal structural changes, they predict decreases in knee pain over time suggesting an adaptive response.

OP0170 LEPTIN AND ADIPONECTIN MEDIATE THE ASSOCIATION BETWEEN BODY MASS INDEX AND HAND AND KNEE OSTEOARTHRITIS

A. Veenbrink[1], F. Kroon[2], R. de Mutsert[3], W. Visser[2], S. le Cessie[3], F. Rosendaal[3], M. Kloppenburg[2]. *[1]Medicine, Universiteit Utrecht, Utrecht; [2]Rheumatology; [3]Clinical Epidemiology, Leids Universitair Medisch Centrum, Leiden, Netherlands*

Background: Associations between adiposity and osteoarthritis (OA) in non-weight-bearing joints suggest that besides mechanical factors also systemic influences contribute to OA. Systemically active substances secreted by adipose tissue, including leptin and adiponectin, are hypothesized to play a role in OA.
Objectives: To examine whether leptin and adiponectin mediate the association between body mass index (BMI) and hand and knee OA.
Methods: Cross-sectional data of a population-based study were used. Participants completed questionnaires and underwent standardized physical examination of hands and knees to define OA according to clinical American College of Rheumatology criteria. Fasting serum leptin and adiponectin were measured with immunoassays. Potential mediation was investigated using the Baron and Kenny framework. Four assumptions were investigated: associations between (1) BMI and OA (pathway *C*), (2) BMI and adipokines (pathway *A*), (3) adipokines and OA (pathway *B*), and (4) attenuation of the total association between BMI and OA after including adipokines (pathway *C'*). No exposure-mediator interaction and mediator-outcome confounding was assumed. Assumptions were investigated using logistic and linear regression analyses as appropriate. Odds Ratios (ORs) were calculated per standard deviation (SD) difference in BMI, and per ten and five units difference in leptin and adiponectin, respectively. Percentage mediation with 95% confidence intervals (CIs) was estimated, only when all four assumptions were fulfilled. Models were adjusted for age, ethnicity and education, and stratified by sex.
Results: In 6462 participants (56% women, median age 56 years (range 45–65), mean BMI 26.3 kg/m^2), prevalence of hand OA, knee OA and combined hand and knee OA were 8%, 10% and 4%, respectively. Median leptin and adiponectin concentrations were 7.1 ug/L (range 0.9–60.9) and 6.0 mg/L (0.5–23.7) in men, and 19.1 ug/L (0.5–262.0) and 10.5 mg/L (0.5–98.6) in women. BMI was positively associated with OA presence and serum leptin in both men and women (Table). A negative association was observed between BMI and serum adiponectin (-0.73 mg/L per SD BMI, 95% CI -0.55;-0.91). Leptin was positively associated with most OA types, except knee OA in men. Leptin partially mediated the association of BMI with hand OA in men (9% mediation, 95% CI 5;17) and women (30%, 13;198), and the association of BMI with knee OA in women (15%, 12;21). Similar analyses for adiponectin revealed a negative association of adiponectin with hand OA in men and partial mediation of the association of BMI with hand OA in men (19%, 12;37), whereas mediation was absent in other subgroups.
Conclusions: Leptin partially mediated the association of BMI and hand OA in both men and women, as did adiponectin in men. In addition, mediation by leptin for the association of BMI and knee OA was demonstrated in women. These findings suggest that systemic mediators contribute to hand OA, and to a lesser extent to knee OA.

Table. Associations of BMI with leptin and different types of OA (OR, 95% CI)

OP0171 SIGNAL INTENSITY ALTERATION WITHIN INFRAPATELLAR FAT PAD PREDICTS TOTAL KNEE ARTHROPLASTY WITHIN FOUR YEARS: DATA FROM THE OSTEOARTHRITIS INITIATIVE

K. Wang[1,2], C. Ding[1,2,3,4], M.J. Hannon[5], Z. Chen[2,6], C. Kwoh[7], D.J. Hunter[8]. *[1]Department of Rheumatology, Arthritis Research Institute, 1st Affiliated Hospital of Anhui Medical University, Hefei, China; [2]Menzies Institute for Medical Research, Hobart; [3]Royal North Shore Hospital and Institute of Bone and Joint Research, Kolling Institute, University of Sydney, Sydney, Australia; [4]Translational Research Centre, Academy of Orthopedics, School of Basic Medical Sciences, Southern Medical University, Guangzhou, China; [5]Division of Rheumatology and Clinical Immunology, University of Pittsburgh School of Medicine, Pittsburgh, United States; [6]School of Mathematics and Information Science, Nanjing Normal University of Special Education, Nanjing, China; [7]University of Arizona Arthritis Center& Division of Rheumatology, University of Arizona College of Medicine, Tucson, United States; [8]Department of Rheumatology, Royal North Shore Hospital and Institute of Bone and Joint Research, Kolling Institute, University of Sydney, Sydney, Australia*

Background: Osteoarthritis (OA) is a common joint disease that frequently affects the knee and is the leading cause of total knee arthroplasty (TKA) in Western countries. The most common reason for TKA is to ease pain and disability. Investigation on prognostic factors associated with TKA could be a possible way to find therapeutic targets to slow disease progression and delay the time for knee replacement.
Objectives: To investigate whether infrapatellar fat pad (IPFP) signal intensity (SI) alteration predicts the occurrence of TKA in patients with knee OA over 4 years.
Methods: Participants with symptomatic knee OA were selected from the Osteoarthritis Initiative (OAI) study. Case knees (n=127) were defined as those that received TKA during 4 years follow-up visit. They were matched by gender, age and radiographic status measured at baseline with a control knee. We used T2 weighted MR images to measure IPFP SI alteration using a newly developed algorithm in MATLAB. The measurements were assessed at OAI baseline (BL), T0 (the visit when TKA was reported), 1 year prior to T0 (T1). Conditional logistic regression was used to assess the relationship between cases and control knees and assess the risk of TKA in regard to SI alteration.
Results: Participants (n=237) were mostly female (57%), with average age of 63.7±8.5 years old and mean BMI of 29.5±4.7 kg/m^2. In multivariable analysis, standard deviation of IPFP SI [sDev (IPFP)] and the ratio of high SI region volume to whole IPFP volume [Percentage (H)] measured at BL were significantly associated with TKA after adjustment for BMI, knee bending activities, self-reported knee injury and surgery history (HR: 3.5, 95% CI 1.1 to 11.4; HR: 8.9, 95% CI 1.2 to 67.2). IPFP SI alterations measured at T1 including sDev (IPFP), Percentage (H) and clustering effect of high SI [Clustering factor (H)] were significantly associated with TKA (HR: 4.0, 95% CI 1.2 to 13.2; HR 10.9, 95% CI 1.9, 63.6; HR: 1.8, 95% CI 1.1 to 2.9). All measurements including mean value of IPFP SI [Mean (IPFP)], sDev (IPFP), mean value of IPFP high SI [Mean (H)], standard deviation of IPFP high SI [sDev (H)], median value of IPFP high SI [Median (H)], upper quartile value of IPFP high SI [UQ (H)], Percentage (H), Clustering factor (H) were significantly associated with TKA at T0.
Conclusions: IPFP SI is an important predictor for TKA in knee OA patients. Targeting IPFP SI could be a potential way to reduce the need for future TKA.

Cellular drivers of inflammation in rheumatic disease

OP0172 EXPANDED T-CELL CLONES PRESENT IN SYNOVIUM AT ONSET OF RHEUMATOID ARTHRITIS ARE ALREADY PRESENT IN THE SYNOVIUM IN THE SEROPOSITIVE "AT RISK" STAGE

G. Balzaretti[1,2], P. Klarenbeek[1], M. de Hair[1], M. Doorenspleet[1], B. van Schaik[3], M. van de Sande[1], D. Gerlag[1,4], A. van Kampen[3], F. Baas[5], P.P. Tak[1,6], N. de Vries[1]. *[1]Clinical Immunology and Rheumatology; [2]Experimental Immunology; [3]Clinical Epidemiology, Biostatistics and Bioinformatics, AMC, Amsterdam, Netherlands; [4]Clinical Unit Cambridge, GlaxoSmithKline, Cambridge, United Kingdom; [5]Genome Analysis, AMC, Amsterdam, Netherlands; [6]GlaxoSmithKline, Stevenage, United Kingdom*

Background: T-cells are thought to be key players in the initiation and progression

of rheumatoid arthritis (RA). Earlier we showed that already at the seropositive "at risk" stage uninflamed synovial tissue contains T-cell infiltrates[1]. In another study we showed that inflamed synovium selectively harbours expanded T-cell clones that are hardly present in paired blood samples[2].

Objectives: Following up on these observations, we longitudinally investigated whether the same expanded T-cell clones found in the inflamed synovial tissue at onset of RA are already present in the synovium in the seropositive "at risk" stage.

Methods: Fifty-five individuals without arthritis but seropositive for IgM rheumatoid factor and/or anti-citrullinated protein antibody (ACPA) were prospectively followed. In five aCCP+ individuals synovial biopsies and paired blood samples at inclusion ("at risk" stage) and after development of RA (ACR2010 criteria; mean time to arthritis 27 months (range 11.7–47.3)) were available for analysis. T-cell clones were identified by their unique TCRβ sequence using RNA-based next generation sequencing[3]. For each sample, 3570 TCRβ sequences were analysed. Clones with a frequency of ≥0.5% were arbitrarily considered as highly expanded clones (HECs). ANOVA and t-test were used for statistical analysis.

Results: T-cell repertoires in "at risk" and RA synovium were similar (mean (± SD) number of clones 488±70 vs 567±204 respectively, p=0.46), number of HECs (37±7 vs 31±18, p=0.41) and the impact of HECs collectively on the TCR repertoire (mean 48% ± 13% vs 50% ± 20%, p=0.84). Interestingly, of the HECs present in the synovium at onset of arthritis 23% (±9%) were already present as HECs in the synovium at the seropositive "at risk" stage. This overlap was significantly higher than that with paired blood samples taken at the arthritis (3% ± 3%; p=0.01) or at the seropositive "at risk" stage (5% ± 7%; p=0.01; Figure 1a-c patient example; Figure 1d summary of results). Further characterization of the synovial CDR3 sequences (length, total charge, polar, aromatic and aliphatic side chains) showed no significant differences between RA HECs that were and those that were not expanded in the seropositive "at risk" stage.

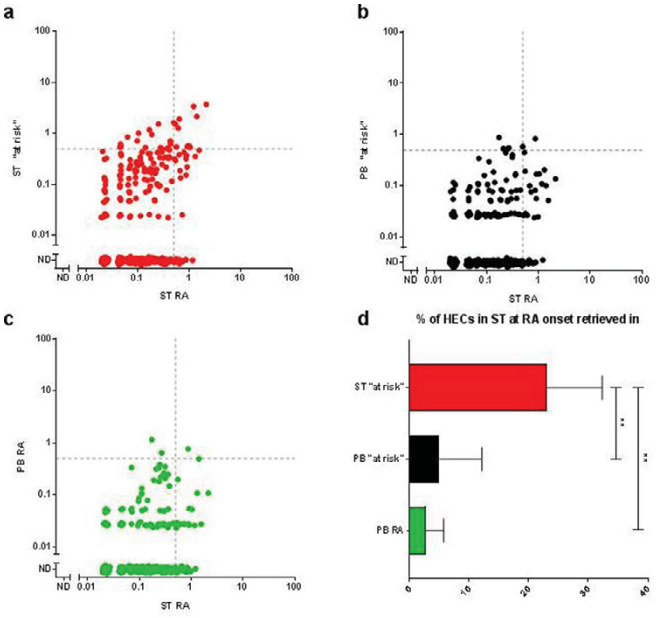

Figure 1: (a-c) Axes show the frequency of the TCR clones in the depicted samples for one patient. ND = non-detected. **(d)** Summary of results from 5 patients, **p=0.01

Conclusions: Many T-cell clones found in early RA synovial tissue are already present in the pre-clinical "at risk" phase. The resemblance in TCR repertoires indicates that the process leading to disease – at least at the T-cell level – constitutes a smooth development. These clones, being already present in the very early stage of this disease and persisting as dominant clones during contraction of active arthritis, form attractive candidates for further characterization.

OP0173 DOMINANT B-CELL RECEPTOR CLONES IN PERIPHERAL BLOOD PREDICT ONSET OF ARTHRITIS IN INDIVIDUALS AT RISK FOR RHEUMATOID ARTHRITIS

P.-P. Tak[1], M.E. Doorenspleet[2,3], M. de Hair[4], P. Klarenbeek[2,3], M. van Beers-Tas[5], A. van Kampen[6], D. van Schaardenburg[5], D. Gerlag[4], F. Baas[3], N. de Vries[2]. *[1]Department of Clinical Immunology and Rheumatology; [2]Amsterdam Rheumatology and Immunology Center; [3]Department of Genome Analysis;[4]Clinical Immunology and Rheumatology, Academic Medical Center; [5]Amsterdam Rheumatology and Immunology Center, Reade; [6]Department of Clinical Epidemiology, Biostatistics and Bioinformatics, Academic Medical Center, Amsterdam, Netherlands*

Background: The onset of seropositive rheumatoid arthritis (RA) is preceded by the presence of specific autoantibodies in the absence of synovial inflammation. Only a subset of these *at-risk* individuals will develop clinical disease. This impedes efforts to implement early interventions that may prevent onset of clinical disease.

Objectives: Here we analyze whether clonal changes in the B-cell receptor (BCR) repertoire can reliably predict onset of clinical disease.

Methods: In a prospective cohort study in 21 individuals *at-risk* for RA, the BCR repertoire of paired peripheral blood and synovial tissue samples was analyzed using next-generation BCR sequencing. BCR clones that were expanded beyond 0.5% of the total repertoire were labeled dominant. The relative risk for onset of arthritis was assessed, using a cut-off of presence of ≥5 dominant BCR clones. Findings in peripheral blood were validated in an independent prospective cohort of 50 *at-risk* individuals. Based on the test cohort, individuals in the validation cohort were considered positive if peripheral blood at study entry showed ≥5 dominant BCR clones.

Results: Both in the test and validation cohort, the presence of ≥5 dominant BCR clones in peripheral blood was significantly associated with arthritis development (validation cohort relative risk (RR) 6.3, 95% confidence interval (CI) 2.7 - 15, $p<1*10^{-4}$). Even when adjusted for the recently described clinical prediction rule the association remained intact (relative risk 5.0, 95% CI 1.2 - 20, p=0.024). When individuals developed arthritis, dominant BCR clones disappeared from peripheral blood and appeared in synovial tissue, suggesting a direct role of these clones in disease pathogenesis.

Conclusions: Dominant BCR clones in peripheral blood predict onset of clinical symptoms of RA in *at-risk* individuals with high accuracy. Our data suggest that during onset of RA these clones shift from peripheral blood to target tissue.

OP0174 NEW PROTEIN ARRAY TECHNOLOGY IDENTIFIES RITUXIMAB TREATED NON RESPONDER RHEUMATOID ARTHRITIS PATIENTS ARE GENERATING A NEW AUTOANTIBODY REPERTOIRE

Z. Konthur[1], M. Wiemkes[2], T. Häupl[2], G. Burmester[1], K. Skriner[2]. *[1]Max Planck Institute, Max Planck Institute; [2]Department of Rheumatology and Clinical Immunology, Charité University Medicine, Berlin, Germany*

Objectives: Rituximab (RTX) has shown clinical efficacy but up to 40% of RTX treated rheumatoid arthritis (RA) patients are poor responders (Ann-Rheum-Dis. 2005 Feb;64(2):246–52) and the commonly used RA biomarkers (*RF/ACPA)* are poor predictors for therapy response. In this study the autoantibody repertoire analysed on protein macorarrays from RA patients under RTX treatment was correlated to clinical DAS28 response.

Methods: Screening of RA sera was conducted on 37.830 unique human proteins on protein marcoarrays (http://www.engine-gmbh.de) with sera taken before and 24 weeks after treatment. The autoantibody response of different immunoglobulin classes IgD, IgA, and IgG was recorded and bioinformatically evaluated. Response was determined according to DAS28 criteria. DAS 28 scores in the responder group before treatment was from 5.4 – 7.8 and in the non-responder group 5,6 – 6,8. We analyzed 26 RA patient sera (9 responder, 7 non-responder and 10 patients with blinded response classification) investigated the data of found autoantigens *in-silico* and by hierarchical clustering

Results: In the cohort of 26 patients 1292 different autoantigens (IgD,IgA,IgG) were detected. Using protein array we investigated clusters of autoantigen responses that disappeared or developed during RTX treatment of RA patients. RA autoantigenic patterns before and 6 month after RTX treatment were patient-specific and no relevant autoantigenic cluster was found that was shared between patients or associated with response. However, RTX reduced the repertoire of autoantibodies after 24 weeks of treatment in the tested RA patient cohort on average by 60%. RA patients which do not respond are generating on average 63% new autoantibodies. In good responders to RTX only 5,5% (+/-3%) new autoantibodies can be detected. The IgA and IgG autoantibody repertoire in the serum after 24 weeks of RTX treatment is reduced (IgA: 41%, IgG: 31%) in good responders whereas it is increased (IgA: 1,3%, IgG: 24%) in non responders to RTX.

Conclusions: After 6 month of RTX treatment the autoantibody repertoire in all good responding RA patients is reduced and non responders to RTX change their autoantibody repertoire directed against new but patient specific antigens. The fast rebuilding of functional B cells is only detected in non-responders to rituximab.

OP0175 CHARACTERIZATION OF NOVEL STROMAL-DERIVED AUTOANTIGENS RECOGNIZED BY RA SYNOVIAL MONOCLONAL ANTIBODIES

E. Corsiero, L. Jagemann, E. Prediletto, C. Pitzalis, M. Bombardieri. *Centre for Experimental Medicine & Rheumatology, William Harvey Research Institute, London, United Kingdom*

Background: We previously showed that up to 40% of RA synovial recombinant monoclonal antibodies (RA-rmAbs) generated from germinal center-like structure (GC-LS+) RA synovium recognize citrullinated antigens contained in neutrophils extracellular traps (NET) (1). The cellular source of other potential autoantigens targeted by the majority of locally differentiated B cells remains undefined. Recently, RA-fibroblast-like synoviocytes (RA-FLS) have been implicated in the release of citrullinated antigens (2, 3). However, whether these cells are targeted by RA-rmAbs is still unknown.
Objectives: Here, we aimed to define the RA-rmAbs immunoreactivity towards i) RA-FLS and ii) identify potential stromal-derived autoantigens.
Methods: 67 RA-rmAbs were generated from single CD19+ B cells FACS-sorted from fresh synovial cell suspensions following IgV_H+V_L genes cloning (1). RA-rmAbs were tested by means of i) cell-based immunofluorescence assays with FLS of RA patients and controls (osteoarthritis (OA)-FLS and RA-dermal fibroblast (RA-DF)), ii) co-localization with stromal specific markers and iii) immunoenzymatic tests with co-localizing antigens. Control rmAbs were also used (Sjögren's syndrome/healthy donor-IgG rmAbs).
Results: Immunofluorescence on RA-FLS demonstrated reactivity of 21% of RA-rmAbs (14/67 rmAbs) towards cytoplasmic components of FLS. Only 4 rmAbs out of 14 were binding both FLS and NET components. For some rmAbs this reactivity was not specific to RA-FLS since it was also observed for OA-FLS and RA-DF. Interestingly, strong co-localization was observed with calreticulin (CRT) which in its citrullinated (cit-CRT) form has been previously shown to recognize the RA "shared epitope" HLA domain sequence (3). When tested in ELISA for native vs cit-CRT, 57% (8/14 rmAbs) of the FLS-reactive RA clones showed binding to CRT with 4 out of 8 rmAbs displaying increased immunoreactivity towards cit-CRT. Controls rmAbs showed no reactivity to either FLS or CRT. Preliminary data suggest that RA patient serum preferentially recognize the lectin-like N-terminal domain of CRT (4).
Conclusions: Here, we provide novel evidence that a subset of locally differentiated B cells within RA synovial GC-LS can react towards RA-FLS derived antigens. Preliminary data suggest that part of this reactivity is directed towards CRT. Identification of immunodominant epitopes within CRT is under investigations.

OP0176 THE PARACASPASE MALT1 PLAYS A CENTRAL ROLE IN THE PATHOGENESIS OF RHEUMATOID ARTHRITIS

E. Gilis[1,2], J. Staal[3,4], R. Beyaert[4,5], D. Elewaut[1,6]. *[1]Department of Internal Medicine, Ghent University; [2]Molecular Immunology and Inflammation Unit, VIB Inflammation Research Center; [3]Department of Biomedical Molecular Biology, Ghent University; [4]Molecular Signal Transduction in Inflammation; [5]Department of Biomedical Molecular Biology; [6]Molecular Immunology and Inflammation Unit, VIB Inflamamtion Research Center, Ghent, Belgium*

Background: One of the hallmarks of many inflammatory arthritides is their strong linkage with MHC-signalling, which is mirrored by the marked role for adaptive immunity. Accordingly, rheumatoid arthritis (RA) is characterized by the activation of auto-reactive T-cells and the development of auto-antibodies. T-cells may additionally respond to non-TCR mediated signals, which are essential in driving their effector functions. Pathways leading to the modulation of both innate and adaptive signals are therefore of marked interest to study in arthritic diseases.
Objectives: The paracaspase MALT1 is a key player in the activation and proliferation of immune and non-immune cells. These cells include the lymphoid, myeloid and mast cells, indicating MALT1's crucial role in both innate and adaptive signaling (1). Therefore, MALT1 is regarded a promising target for the treatment of autoimmune diseases and defining its role in the pathogenesis of inflammatory arthritis is a critical first step.
Methods: To unravel MALT1's role in inflammatory arthritis, we initially assessed MALT1-activation in mice that were challenged with collagen-induced arthritis (CIA), the prototype model for antigen-induced RA. We then addressed the role of MALT1 in the pathogenesis of inflammatory arthritis by challenging MALT1-deficient mice to distinct models of arthritis (CIA and CAIA) or by backcrossing MALT1-deficient mice to TNF^{DARE} mice, representing an SpA-like model. Additionally, CIA was induced in CD4-specific MALT1-deficient mice to determine the importance of MALT1 in T-cells.
Results: We provide evidence that MALT1 plays a crucial role in the pathogenesis of RA as MALT1-deficent mice were completely protected against CIA. This complete protection was additionally observed in CD4-specific MALT1-deficient mice, indicating that the selective ablation of MALT1 in CD4-positive cells is sufficient for the observed resistance against CIA. CAIA on the other hand, which is a T- and B-cell independent model of RA, did not depend on the presence of MALT1, since both $MALT1^{+/+}$ and $MALT1^{-/-}$ mice showed comparable symptoms of RA. Interestingly, TNF^{DARE} mice that were deficient for MALT1 also showed a reduced enthesitis and ileitis phenotype, although TNF-concentration in the serum of these mice was higher compared to $MALT1^{+/+}xTNF^{DARE}$ mice.
Conclusions: Overall, our data highlight that MALT1 plays a crucial role in the pathogenesis of inflammatory arthritis and represents an interesting candidate to target therapeutically.

OP0177 N-GLYCOSYLATION SITES IN THE VARIABLE DOMAIN OF B CELL RECEPTORS SPECIFIC FOR CITRULLINATED ANTIGENS

L.M. Slot[1], R.D. Vergroesen[1], L. Hafkenscheid[1], M.T. Koning[2], T. Rispens[3], H. Veelken[2], R.E. Toes[1], H.U. Scherer[1]. *[1]Department of Rheumatology; [2]Department of Hematology, Leiden University Medical Center, Leiden; [3]Department of Immunopathology, Sanquin Research, Amsterdam, Netherlands*

Background: Recent structural analysis of anti citrullinated protein antibodies (ACPA) in serum and synovial fluid of patients with rheumatoid arthritis (RA) revealed that the vast majority (>90%) of secreted ACPA IgG molecules carry N-glycans in the variable (Fab) domain. This remarkable degree of Fab-glycosylation is absent from ACPA-depleted control IgG and from autoantibodies in other diseases. So far, it is unclear why ACPA carry this feature and which biological effects these glycans mediate in the context of RA. Of note, however, N-glycosylation requires a specific amino acid consensus sequence in the protein backbone, which is very rare in germline-encoded variable region genes.
Objectives: To study the B cell receptor (BCR) repertoire of ACPA-expressing B cells to determine the frequency, origin and localisation of N-glycosylation sites in ACPA Fab domains.
Methods: Citrullinated antigen-specific and non citrulline-reactive control B cells were identified in peripheral blood of ACPA-positive RA patients by antigen-specific tetramer staining and isolated by fluorescence activated cell sorting. Cells were either sorted in pools and directly lysed, or sorted as single cells and cultured for two weeks followed by the detection of ACPA-positive culture wells by ELISA. Full-length immunoglobulin (Ig) rearrangements were identified by anchoring reverse transcription of Ig sequences, amplification by nested PCR and either next generation sequencing (NGS, PacBio platform) or, for single cell transcripts, Sanger sequencing (scSeq). Sequence reads were analysed using IMGT V-QUEST tools.
Results: The mean number of nucleotide mutations in heavy chains (HC) of IgG BCRs derived from ACPA-expressing B cells was high (33 in NGS, 48 in scSeq samples; similarity to germline: 88% in NGS, 84% in scSeq). NGS identified 12 unique IgG clones derived from 4 donors, of which 10 (83%) had at least one N-glycosylation site in the HC or light chain (LC). scSeq identified 86 unique IgG clones derived from 6 donors, of which 68 (79%) had N-glycosylation sites. For 57/86 IgG clones, we could determine the combination of HC and LC sequences. In these, only 7 (12%) clones had no sites, while 19 (33%) had one, 23 (41%) had two, 5 (9%) had three and 3 (4%) clones had four sites. 57 sites were found in the HC and 34 in the LC. All N-glycosylation sites were created by somatic mutations and not encoded in the germline sequence. Several sites were located in antigen-engaging regions. No correlation was found between the number of N-glycosylation sites and the number of somatic mutations.
Conclusions: We demonstrate that B cell surface-expressed ACPA-IgG molecules carry a remarkably high frequency of N-glycosylation sites in the Fab domain, all of which are generated by somatic mutation. This could indicate that ACPA-expressing B cells acquire a selective survival advantage by introducing N-glycosylation consensus sequences in the Fab domain, a process that is likely to occur under the influence of T cell help and that could facilitate the break of tolerance to citrullinated antigens.

OP0178 FIBROBLAST PRIMING IS COMMON TO MANY SITES, AND PSORIATIC SKIN FIBROBLASTS MAY ACQUIRE INFLAMMATORY MEMORY

T. Crowley[1], J.D. O'Neil[1], H.R. Adams[1], T.W. Kragstrup[2], A. Filer[1], C.D. Buckley[1], A.R. Clark[1]. *[1]Institute of Inflammation and Ageing, University of Birmingham, Birmingham, United Kingdom; [2]Biomedicine, Health, Aarhus University, Aarhus, Denmark*

Background: Rheumatoid arthritis (RA) is a common chronic inflammatory

disease of the joints. Whilst the autoimmune element continues to be studied intensely, it is evident that the innate inflammatory response propagates the disease. Fibroblast-like synoviocytes (FLS) are the most abundant stromal cell in the synovium. FLS from RA joints are markedly different from their healthy counterparts in their inflammatory characteristics.

RA FLS exhibit a form of inflammatory memory named priming. Prolonged exposure to TNFα induces an augmented chemokine response to challenges with interferons [1]. Fibroblast priming leads to significantly augmented IL6, CCL5 and CXCL10 responses to a second challenge by TNFα, with a coincident prolonged NFκB nuclear localization (manuscript in press).

Objectives: We wished to assess whether fibroblasts from sites other than the synovial joint would also exhibit this primed response to second challenge.

Methods: Fibroblasts from the joint, skin, lung, tonsil, bone marrow and gum were stimulated with 10ng/ml TNFα for 24h, before the conditioned medium was removed and the cells were washed free of stimulus. Cells were rested for 24h before once again being washed and stimulated with 10ng/ml TNFα for a further 24h. The conditioned medium was removed and secreted mediators compared between first and second response to stimulus. Transcription and intracellular signalling at time points within each challenge were also determined.

Results: Synovial, lung and tonsil fibroblasts augmented IL6 secretion in response to the second TNFα challenge. RA bone marrow-derived fibroblasts varied in their exhibition of priming. Skin fibroblasts from patients undergoing cosmetic surgery and a gingival sample from non-chronic inflammation displayed no evidence of IL6 priming.

Fibroblasts from the skin of psoriasis (Ps) patients mounted a primed response that was significantly augmented compared to their first response to TNFα, and significantly higher than the second response of healthy skin. This augmented response matches that of FLS, as IL6 but not IL8 was increased. This pattern was also matched by gum fibroblasts from periodontitis.

Mechanistically the Ps skin fibroblasts match FLS, in that NFκB nuclear localization is prolonged in the second challenge compared to the first.

Conclusions: We have shown that inflammatory memory in the form of IL6 priming occurs in fibroblasts from a variety of anatomical sites with diverse functions. Its prevalence implies a shared phenomenon, but the variation between sites suggests a specific role required in some tissues and not others.

The finding that Ps skin fibroblasts acquire this memory response may point towards a pro inflammatory mechanism that contributes to psoriatic diseases, including psoriatic arthritis. Our data may help to explain why an estimated 30% of psoriasis patients go on to develop psoriatic arthritis [2].

OP0179 BRAFV600E PROMOTES MYELOID SKEWING IN MULTISYSTEMIC LANGERHANS CELL HISTIOCYTOSIS HUMANIZED MOUSE MODEL

R. Biavasco[1], M. Norelli[2], B. Camisa[2], D. Cesana[1], P. Gallina[1], B. Gentner[1], M. Ponzoni[3], L. Dagna[4], A. Bondanza[2], E. Montini[1]. *[1]Sr-Tiget; [2]Innovative immunotherapy; [3]Pathology Unit; [4]Clinical immunology and rheumatology, San Raffaele Scientific Institute, Milan, Italy*

Background: Multisystemic Langerhans cell histiocytosis (mLCH) is an aggressive disease characterized by the accumulation of mononuclear phagocytes with immunohistochemical features of dendritic cell (histiocytes)[1]. Histiocytes infiltrate mostly the skin, bone marrow (BM), lung and spleen, and produce high levels of proinflammatory cyto/chemokines, leading to organ dysfunction[2,3]. In patients, around 10% of cells in lesions carries an oncogenic mutation in the MAPK pathway, mostly $BRAF^{V600E}$ (70% of cases). $BRAF^{V600E}$ can be detected also in monocytes and BM progenitors (HSPC) from these patients, whereas only a fraction of them carries a mutation in B cells and none in T cells[4].

Objectives: To study the role of $BRAF^{V600E}$ in the pathogenesis of mLCH, we set up a humanized mouse model of mLCH based on the transplantation into immunodeficient mice (NSG) of human HSPC expressing $BRAF^{V600E}$.

Methods: We isolated HSPC from human cord blood and transduced them at two different levels (50% and 20%) with lentiviral vectors that ubiquitously express $BRAF^{V600E}$, $BRAF^{WT}$ or GFP.

Results: All $BRAF^{V600E}$ mice manifested severe weight loss within 7 weeks with a median of 3 and 5 weeks for 50% and 20% transduction groups, respectively. Mice showed dysplastic bone marrow (BM) with infiltration of histiocytes; lesions were present also in lungs, kidneys, CNS, spleen and liver. Immunophenotype of infiltrating histiocytes closely resembles mLCH, staining positive for CD14, CD68, S-100 and langerin. None of the control mice lost weight nor displayed organ alteration. Flow cytometry analyses of BM showed 5- to 7-fold reduction in engraftment of human cells in $BRAF^{V600E}$ vs GFP groups ($p<0,001$). Percentage of myeloid cells increased by 3- to 4-fold in $BRAF^{V600E}$ vs GFP groups ($p<0,001$). On the contrary, percentage of B cells was reduced by 3- to 6,5-fold in $BRAF^{V600E}$ vs GFP groups ($p<0,001$). Moreover, there was no difference in the percentage of GFP-positive cells between myeloid cells, whole BM and *in vitro* sample, suggesting a non-cell autonomous mechanism underlying this myeloid phenotype.

Conclusions: In summary, we generated for the first time a human xenogeneic transplantation mouse model of mLCH, showing that $BRAF^{V600E}$ in human HSPC promotes myeloid skewing rather than proliferation.

Joint health & joint damage: a tale of three tissues –

OP0180 PHARMACOLOGICAL CHARACTERIZATION OF THE ADAMTS-5 INHIBITOR GLPG1972: AN ORAL ANTI-CATABOLIC AGENT FOR THE TREATMENT OF OSTEOARTHRITIS

P. Clement-Lacroix[1], C. Little[2], R. Blanqué[1], S. Meurisse[1], P. Mollat[1], F. Brebion[1], R. Gosmini[1], F. De Ceuninck[3], I. Botez[3], L. Lepescheux[1], E. van der Aar[4], T. Christophe[4], N. Vandervoort[4], C. Cottereaux[1], D. Comas[1], P. Deprez[1], D. Amantini[1]. *[1]Galapagos SASU, Romainville, France; [2]Raymond Purves Bone and Joint Research Laboratories, University of Sydney, Kolling Institute, Northern Sydney Local Health District, Sydney, Australia; [3]Institut de Recherches Servier, Suresnes, France; [4]Galapagos NV, Mechelen, Belgium*

Background: Degradation of articular cartilage and alterations of the underlying subchondral bone are hallmarks of osteoarthritis (OA)[1]. A disintegrin and metalloproteinase with thrombospondin motifs-5 (ADAMTS-5) is a key aggrecan-cleaving enzyme involved in this pathogenic process from the earliest stages of cartilage degradation[2] and as such, is an attractive drug target for the development of a disease-modifying OA drug (DMOAD)[3].

Objectives: In this report we describe the *in vitro* and *in vivo* characterization of the small molecule GLPG1972, an inhibitor of ADAMTS-5. GLPG1972 anti-catabolic activity was evaluated in murine and human cartilage explants and DMOAD activity was investigated in the destabilization of the medial meniscus (DMM) mouse model[4].

Methods: The ADAMTS-5 biochemical assay is based on the cleavage of a fluorescent substrate by recombinant ADAMTS-5. Mouse femoral head cartilage explants were stimulated by interleukin-1a (IL-1a) for 3 days and GAG release quantified[2b]. Human articular cartilage explants were stimulated with IL-1β for 12 or 19 days and the NITEGE epitope quantified using the AGNx1 assay. Unilateral OA was induced in C57BL6 mice by DMM[4]. Mice were treated with vehicle or GLPG1972 at 30, 60 or 120 mg/kg, b.i.d. for 8 weeks. Medial femorotibial joint sections were scored by an evaluator blinded to treatment.

Results: GLPG1972 showed potent inhibition of human ADAMTS-5 (IC_{50}=20 nM). Inhibition of ADAMTS-4 was moderate (IC_{50}=57 nM), and selectivity over 100-fold was observed against a large panel of zinc metalloproteinases. GLPG1972 displayed potent anti-catabolic activity in cartilage explants, with IC_{50} values being 2 μM and <1 μM in mouse and human, respectively. In the DMM mouse model, GLPG1972 demonstrated DMOAD activity, as shown by significant reduction of femorotibial cartilage proteoglycan loss and cartilage damage score, as well as significant impact on subchondral bone sclerosis.

Conclusions: GLPG1972 is an orally bioavailable, potent and selective ADAMTS-5 inhibitor showing significant anti-catabolic activity in cartilage explants. In the DMM model, treatment with GLPG1972 resulted in significant protective effects on both cartilage and subchondral bone pathology. Taken together these results provide support to progress GLPG1972 into the clinic as an oral treatment for OA.

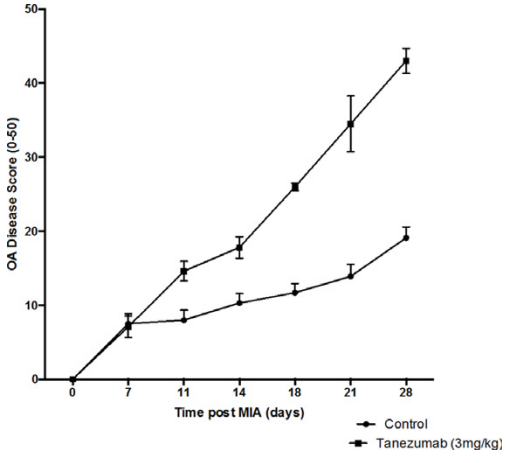
OP0181 DELETION OF THE PROSTAGLANDIN D2 RECEPTOR DP1 EXACERBATES AGING-ASSOCIATED AND INSTABILITY-INDUCED OSTEOARTHRITIS

Y. Ouhaddi, L. Habouri, J.-P. Pelletier, J. Martel-Pelletier, M. Benderdour, H. Fahmi. *Medicine, CRCHUM, Montreal, Canada*



Background: *The D prostanoid receptor 1* (D*P1*), a *receptor* for prostaglandin D_2 (PGD_2) plays important roles in inflammation and cartilage metabolism. However, its role in the pathogenesis of osteoarthritis (OA) remains unknown.

Objectives: We undertook this study to explore the roles of DP1 in the development of OA and to evaluate the efficacy of a DP1 selective agonist in the treatment of OA.
Methods: We compared the development of aging-associated OA and destabilization of the medial meniscus (DMM)-induced OA in DP1-deficient (DP1-/-) and wild-type (WT) mice. The progression of OA was assessed by histology, immunohistochemistry, and microcomputed tomography (micro-CT). Cartilage explants from DP1-/- and WT mice were treated with interleukin-1α (IL-1α) ex vivo, to evaluate proteoglycan degradation. The effect of intra-peritoneal administration of the DP1 selective agonist BW245C on OA progression was evaluated in WT mice.
Results: Compared to WT mice, DP1-/- mice had exacerbated cartilage degradation in both models of OA and this was associated with increased expression of MMP-13, and ADAMTS-5. In addition, DP1-/- mice demonstrated enhanced subchondral bone changes. Cartilage explants from DP1-/- mice showed enhanced proteoglycan degradation following treatment with IL-1α. Intraperitoneal injection of BW245C attenuated the severity of DMM-induced cartilage degradation and bony changes in WT mice.
Conclusions: These findings indicate a critical role for DP1 signaling in OA pathogenesis. Modulation of DP1 functions may constitute a potential therapeutic target for the development of novel OA treatments.

OP0182 CONVERGENCE OF JOINT REPAIR AND PAIN PATHWAYS VIA NERVE GROWTH FACTOR AND P75 EXPRESSING MESENCHYMAL STEM CELLS- A NOVEL EXPLANATION FOR OSTEOARTHRITIS PROGRESSION WITH ANTI-NGF IN OSTEOARTHRITIS

T. Baboolal[1], S. Al Hinai[1], E. Jones[1], J. Reckless[2], M. Foster[3], R. Doyle[4], K. af Forselles[3], S. Westbrook[3], D. McGonagle[1]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds; [2]Rxcelerate Ltd, Cambridge; [3]Levicept Ltd; [4]Tetrad Discovery Ltd, Ramsgate, United Kingdom*

Background: Nerve growth factor (NGF) is a key regulator of pain and anti-NGF therapy reduces osteoarthritis (OA) associated pain. However, anti-NGF therapy is associated with rapidly progressive OA (RPOA) [1]. In hip OA there is a 5-fold increase in mesenchymal stem cells (MSCs) from MRI bone marrow (BM) lesions, areas associated with OA progression [2]. MSCs in such lesions are uniformly positive for the NGF receptor, p75, which is also linked to chemotaxis and proliferation in other stromal cell compartments [3].
Objectives: Evaluate anti-NGF treatment in monoiodoacetate (MIA) induced OA and test whether NGF influences human BM-MSC function.
Methods: Human tibial plateau (TP) bone was isolated from patients undergoing total knee replacement. OA was induced in male Wistar rats (n=6) by intra-articular injection of 0.3 mg MIA. Each animal was treated with subcutaneous injection of control human IgG or anti-NGF (3 mg/kg) at Days 5, 10 and 15. Human and animal tissues sections were prepared for histological analysis using H&E staining and immunohistochemistry (IHC) using anti-p75 and anti-NGF antibodies. BM-MSCs were isolated from iliac crest aspirates and cultured under normal conditions. Expression of p75 was induced following overnight incubation with 400mM ethanol (EtOH) and confirmed by flow cytometry. Proliferation was assessed ± EtOH and 0–1 μg/ml NGF.
Results: Regions adjacent to cartilage loss in human TP showed abundant stromal proliferation, NGF and p75 immunoreactivity. In MIA model, by Day 18 there was substantial loss of cartilage, bone remodelling and stromal proliferation mimicking human disease. By Week 4 animals demonstrated unequal weight-bearing ($p<0.05$). Anti-NGF provided sufficient analgesia to normalise weight-bearing. Compared to IgG control, arthropathy progression was faster (Fig) with complete cartilage loss, bone marrow necrosis and cyst formation by Day 21. p75 immunoreactivity was greatly reduced in MIA-injected rats receiving anti-NGF compared with IgG. NGF positive staining was widespread in naïve and MIA-injected knees, but almost absent from MIA-treated knees of anti-NGF treated rats.

To investigate increased p75 positivity in knee OA, we restored p75 expression loss in expanded cell, to 97% of BM-MSCs (n=3) using EtOH. Increased MSC proliferation was seen at Days 6 and 9 (26%, p=0.03 and 30%, p=0.01 increase respectively, n=7) for 1 μg/ml NGF in the presence of EtOH compared to control (no NGF). In cultures without EtOH induction (absent p75) NGF had no effect.
Conclusions: TP bone from OA patients and rat MIA-treated subchondral bone contains p75 positive staining in regions of cartilage destruction and associated NGF positivity. Anti-NGF treatment exacerbated MIA-induced OA and reduced NGF and p75 expression. In vitro, NGF increased BM-MSC proliferation, suggesting NGF may be involved in the stromal proliferation seen at sites of OA damage. Thus, NGF may regulate MSC function. Complete blockade represents a novel mechanism for accelerated joint destruction in OA.

OP0183 CORDYCEPIN, A NOVEL COMPOUND, REDUCES KNEE JOINT PATHOLOGY AND PAIN IN THE MONOSODIUM IODOACETATE (MIA) RAT MODEL OF OSTEOARTHRITIS

S. Ashraf[1], J. Burston[2], V. Chapman[2], C. de Moor[1]. *[1]Pharmacy; [2]Arthritis Research UK Pain Centre, University of Nottingham, Nottingham, United Kingdom*

Background: Cordycepin (3' deoxyadenosine) is a popular traditional medicine in Asia, taken for conditions associated with ageing. Osteoarthritis (OA) is a common cause of pain and disability in the ageing population. Inflammation is a key component of osteoarthritic pain. Cordycepin is thought to act by inhibiting polyadenylation, the last step of mRNA synthesis, and can potentially have increased therapeutic benefit in OA (anti-inflammatory and analgesic) with fewer side effects than currently available therapies.
Objectives: The aim of this study was to determine whether cordycepin treatment alters osteoarthritic pain and pathology, and to decipher the mechanisms of action by which cordycepin exerts any potential beneficial actions.
Methods: OA was induced in male Sprague Dawley rats by intra-articular injection of mono-sodium iodoacetate (MIA; 1mg/50μl) on day 0. Cordycepin was administered orally (2mg/rat mixed in 1g of wet mash) every other day for 2 weeks (pre-emptive study: day 0 to day 14, therapeutic study: day 14 to day 28). Pain behaviour was measured as hind-limb weight-bearing asymmetry and mechanical paw withdrawal thresholds. Joint tissues were collected at days 14 and 28. Joint changes were quantified using histology and immunohistochemistry techniques. Synovial inflammation was quantified as extent of CD68 positive macrophage and cellular infiltration. Synovial angiogenesis was measured as endothelial cells positive for proliferating cell nuclear antigen (PCNA). Safranin-O staining was used to score cartilage damage and bone changes (osteophytes and channels crossing the osteochondral junction [OCJ]). Tartrate-resistant acid phosphatase (TRAP) positive osteoclasts and ADAMTS-5 and MMP13 positive chondrocytes were quantified as additional markers to detect bone and cartilage changes.
Results: The MIA rodent model of OA pain exhibited significant pain behaviour, synovial inflammation and angiogenesis, cartilage damage, osteophyte formation and subchondral bone changes, compared with non-arthritic controls. A two week pre-emptive and therapeutic treatment with cordycepin reduced MIA-induced pain behaviour and synovial changes (inflammation and angiogenesis). Pre-emptive cordycepin treatment reduced cartilage damage and the level of ADAMTS-5 and MMP13 from the chondrocytes. Pre-emptive and therapeutic cordycepin treatment reduced the number of channels crossing the OCJ and TRAP positive osteoclasts in the subchondral bone, but had no effect on numbers of osteophytes. Therapeutic cordycepin treatment did not alter cartilage damage score or the level of ADAMTS-5 and MMP13 positive chondrocytes.
Conclusions: Our data show that the analgesic effects of orally administered cordycepin in a pre-emptive and therapeutic protocol are associated with synovial changes (inflammation and angiogenesis) and bone remodelling. Administration of cordycepin before the onset of MIA-induced OA reduced cartilage damage and had a chondroprotective effect. Whereas therapeutically administered cordycepin did not alter cartilage damage. Further studies will investigate whether cordycepin mediated reduction in MIA-induced pathology and pain behaviour is as a result of its direct action on polyadenylation inhibition. Polyadenylation inhibitors could therefore be a novel class of drugs for treating OA.

OP0184 IMSYC IMMUNOLOGIC SYNOVITIS SCORE: A NEW HISTOLOGICAL SCORE FOR DISCRIMINATING INFLAMMATORY AND NON-INFLAMMATORY ARTHRITIS

A. Najm[1,2], B. Le Goff[1,2], F. Blanchard[1], J. Amiaud[1], C. Charrier[1], V. Krenn[3]. *[1]Inserm UMR 957; [2]Rheumatology, Nantes University Hospital, Nantes, France; [3]MVZ-Zentrum für Histologie, Zytologie und Molekulare Diagnostik, Trier, Germany*

Background: General Synovitis score (GSS) has been developed by Krenn *et al.* in order to discriminate inflammatory arthritis (IA) and non-inflammatory arthritis (NIA) (1). This score assesses 3 major components of synovitis: lining layer hyperplasia, activation of resident cells (stroma) and inflammatory infiltrate. All components are graded semi-quantitatively from 0 to 3 and the total score is on 9. High-grade synovitis is highly associated with IA and is defined by a score upper than 5 with a sensitivity of 61.7% and a specificity of 96.1%. As immunohistochemistry (IHC) is frequently used to better characterize synovitis, we propose to create a new IMmunologic SYnovitis SCore (IMSYC) adding 5 components to the GSS: CD68, CD3, CD20, CD31 and Ki67 immunostaining.
Objectives: Our work aimed to evaluate the diagnostic performance of this new score including IHC, to define the best cut off for inflammatory arthritis recognition, and to compare its diagnostic performance with the GSS.
Methods: 53 synovial samples from patients were obtained during surgery (arthroplasty or synovectomy). All patients gave written consent prior surgery. Samples were cut and Hematoxylin and eosin stained. CD68, CD3, CD20, CD31 and KI67 Immunohistochemistry were performed. GSS was assessed for each slide and semi-quantitative 4 scale scores (0–3) were given for each immunostaining, in a blind manner. The score is calculated on 24 (GSS 0–9 points, and 0–3 score for each of the 5 immunostaining). A representative amount of slides was read by 2 observers with a good interobserver variability (spearman correlation coefficient of 0.95, $p<0.0005$). They then defined a consensual and reproducible scoring atlas.
Results: 53 patients were included. 25 were females (47,2%), mean age was 62.1 years [Standard deviation (SD) 13.2 years]. 36 had inflammatory arthritis reparsed as follows: 28 Rheumatoid arthritis (RA), 5 had Psoriatic arthritis, 3 had Undifferentiated arthritis. “Non inflammatory” arthritis group included 10 patients with Osteoarthritis and 7 with ligaments or meniscus injuries. Mean GSS was significantly higher in the IA group 5.70 [SD 0.321] vs.3.51 [SD 0.351]; $p<0.001$). Mean IMSYC was significantly superior in the IA group 14.94 [SD 0.747] vs. 8.50 [SD 0.639]; $p<0.001$). In univariate analysis by logistic regression, GSS (Odd Ratio (OR) 2.27; $p<0.001$), CD3 (OR 4.3; p=0.002), CD68 (OR 4.5; p=0.002), Ki67 (OR 11.8; $p<0.001$), and CD31 scores (OR 6.5; p=0.001) were significantly associated with IA, however CD20 score was not (OR 0.9; p=0.34). ROC curve analysis determined the score of 10.5 out of 24 as the best cut off for discrimination between IA and non-IA with a sensitivity of 74.3% and specificity of 100%. The area under ROC curves was statistically superior with IMSYC (0.93) compared to GSS (0.81) (p=0.05).
Conclusions: We hereby propose a new synovitis score including IHC. This score has a better sensitivity and specificity than the Global synovitis score for discrimination between IA and non-IA. Moreover, this score accurately describes synovial membrane immunophenotype and could therefore give a basis for tissue driven therapies in rheumatic diseases, especially in RA.

OP0185 IMMUNOHISTOLOGIC STUDY OF SYNOVITIS FROM PATIENTS WITH UNDIFFERENTIATED ARTHRITIS WHO EVOLVED TO RHEUMATOID ARTRHITIS OR PSORIATIC ARTHRITIS AFTER FOLLOW-UP

A. Cuervo Aguilera, R. Celis, J. Ramírez, M.V. Hernández, V. Ruíz-Esquide, J. Inciarte-Mundo, R. Sanmartí, J.D. Cañete. *Rheumatology, Hospital Clínic Barcelona, Barcelona, Spain*

Background: Undifferentiated Arthritis (UA) is defined as an inflammatory oligo/poly arthritis that does not fulfil criteria for a definitive diagnosis.Delay in diagnosis and treatment leads to poor prognosis. Previous studies have found differences in the cellular infiltrate between the synovitis of Rheumatoid Arthritis (RA) and Spondyloarthritis, including psoriatic arthritis (PsA)
Objectives: To identify synovial biomarkers that may be useful to diagnose patients with early UA
Methods: Retrospective longitudinal study.Patients with UA followed in our Arthritis Unit,who underwent arthroscopy between 2000 and 2014.Synovial biopsy were stained by immunohistochemistry with the following antibodies:CD3 for T cells,CD20 for B cells,CD79 for B cells,CD138 for plasma cells,CD31 for vessels,CD68 for macrophages,CD15 for neutrophils,CD117 for mast cells and hsp47 for fibroblasts, and quantified by Digital Image Analysis (Olympus).The same antibodies were evaluated in RA and PsA control groups
Results: 55 UA and 78 controls were included.Table 1 shows the clinical, serological and demographic characteristics.Among patients with UA, 23 (42%) patients met criteria for RA and 32 (58%) for PsA during follow-up.Synovitis of patients with UA had higher macrophage (CD68+) density in total tissue (p=0.008) and sublining (SL) (p=0.012) than the control group.The UA that evolved to RA had a higher density of CD3 T lymphocytes than the control RA group (p=0.014). No differences were observed in cells of adaptive immunity (CD20 B lymphocytes, CD138 plasma cells), innate immunity (CD117 mast cells, CD15 neutrophils), vessels (CD31) between the 4 groups.The area (%) stained by anti-hsp47 (synovial fibroblasts) in SL was higher in the RA control group than in the PsA (p=0.003)

Table 1. Data are expressed as mean±SD

	UA n=55	UA-RA n=23	UA-PsA n=32	p	RA n=40	PsA n=38	p
Age (years)	47±13	51±13	44±12	0.058	60±12	54±13	0.065
Sex (male)n (%)	22 (40)	6 (26)	16 (50)	0.074	17 (43)	23 (61)	0.111
Disease duration (years)	3±4	3±2	3±4	0.114	3±6	2±2	0.851
Time of follow-up (years)	7±4	8±4	6±4	0.038	7±3	5±3	0.008
CRP (mg/dL)	2.7±3.9	2.4±1.9	3.0±4.9	0.189	3.8±3.2	3.0±3.8	0.102
DAS28 (ESR)	4.17±1.05	4,83±1,06	3,63±0,94	0.000	5,15±1,51	4,02±1,04	0.002
ACPA n (%)	4 (22)	4 (22)	0 (0)	0.000	30 (77)	0 (0)	0.000
RF n (%)	10 (7)	9 (41)	1 (3)	0.000	28 (70)	1 (3)	0.000
csDMARD n (%)	21 (41)	7 (35)	14 (45)	0.472	29 (73)	19 (50)	0.041
bDMARD n (%)	2 (4)	0 (0)	2 (6)	0.243	8 (20)	6 (16)	0.628
PDN n (%)	7 (13)	3 (14)	4 (13)	0.851	11 (28)	5 (13)	0.117

Conclusions: This is the first immunohistological study of synovitis in a significant group of patients with UA who developed AR or PsA during follow-up. Although there are some differences between the UA and control groups in the density of CD68+ macrophages and lymphocytes T CD3+, these do not appear to be useful for an early diagnosis of UA. On the other hand, unlike the results of some previous studies, we not found differences between the cellular infiltrate (adaptive immunity, innate immunity or vessels) in patients with RA and PsA. The fact that some patients with UA were undergoing treatment prior to synovial biopsy and its retrospective character limit the results of this study

OP0186 TENOFOVIR, A NUCLEOSIDE ANALOG REVERSE TRANSCRIPTASE INHIBITOR FOR TREATMENT OF HIV, PROMOTES OSTEOCLAST DIFFERENTIATION AND BONE LOST IN VIVO IN A MECHANISM DEPENDING ON ATP RELEASE AND ADENOSINE, AND DIPYRIDAMOLE MAY BE A USEFUL TREATMENT TO REVERT THE EFFECTS

F.M. Conesa[1], P. Llamas[1], T. Wilder[2], P. Atencio[3], A. Cabello[3], M. Górgolas[3], B. Cronstein[2], R. Largo[1], G. Herrero-Beaumont[1], A. Mediero[1,2]. *[1]Joint and Bone Research Unit, Iis-Fundacion Jimenez Diaz, Madrid, Spain; [2]Division of Translational Medicine, Department of Medicine, NYU School of Medicine, New York, United States; [3]Internal Medicine Department, Iis-Fundacion Jimenez Diaz, Madrid, Spain*

Background: HIV infection devastates the immune system but also affects other tissues and organs Bone alterations have been observed in HIV disease for nearly two decades, in particular a higher risk of low bone mineral density (BMD) and fragility fractures. Treatment with Tenofovir alone or as part of HAART, leads to changes in bone catabolism markers and significant reductions in BMD in children and young adults. Tenofovir is taken up by cells and phosphorylatedand inhibits HIV-reverse transcriptase by mimicking AMP. We have recently found that Tenofovir inhibits Pannexin-1/Connexin-43-mediated ATP release from cells and decreases extracellular adenosine levels and fibrosis in murine models. Inhibition of osteoclast formation *via* adenosine A2A receptor stimulation or increasing local adenosine concentration stimulates new bone formation as well as rhBMP-2.
Objectives: As adenosine and ATP are key regulators of bone homeostasis, we determined whether Tenofovir directly affects bone by an adenosine- or ATP-dependent mechanism and if treatment with Dipyridamole, an agent that increases extracellular adenosine by blocking cellular adenosine uptake, may be a useful treatment to counteract Tenofovir effects.
Methods: M-CSF/RANKL-induced osteoclast (OC) was studied in primary murine bone marrow culture as the number of TRAP-positive cells after challenge with Tenofovir (1nM-100μM) alone or in combination with Dipyridamole (1nM-100μM). OC markers were measured by RT-PCR. Pannexin-1 and Connexin-43 expression were permanently knocked down by lentiviral infection with appropriate shRNA or scrambled shRNA and these cells were induced to differentiate into OC by RANKL. Male C57Bl/6 mice received Tenofovir 75mg/Kg/day alone or in combination with Dipyridamole 1mg/Kg/day for 4 weeks. Double labelling of bone with calcein/Alizarin Red to analized bone formation was performed and long bones prepared for microCT and histology.
Results: Tenofovir produced a dose-dependent increase in OC differentia-

tion (EC50=44.5nM) that was reversed by Dipyridamole (IC50=0.3μM). When Pannexin-1 and Connexin-43 were absent, Tenofovir did not increase OC number. Tenofovir increases Cathepsin K and NFATc1 mRNA levels during OC differentiation, and the effect was reverted by Dipyridamole. Tenofovir reduced bone formation *in vivo* (19±2μm bone aposition vs 35±4μ m untreated $p<0.05$) and this effect was reverted in the presence of Dipyridamole (30±3μm, $p<0.05$ vs Tenofovir alone). microCT revealed decrease BMD and altered trabecular bone in Tenofovir-treated mice, been reverted in the presence of Dipyridamole. TRAP-staining showed increased OC *in vivo* in Tenofovir-treated mice (21±1 vs 16±1 OC/hpf in untreated, $p<0.005$) that was reverted with Dipyridamole. Similar results were obtained for Cathepsin K.

Conclusions: These results indicate that Tenofovir enhances OC differentiation and inhibits osteoblast differentiation by an adenosine-dependent mechanism and suggests that treatment with agents that increase local adenosine concentrations, like Dipyridamole, might prevent bone loss following Tenofovir treatment.

OP0187 TRANSGENIC DISRUPTION OF GLUCOCORTICOID-SIGNALING IN MATURE OSTEOBLASTS AND OSTEOCYTES ATTENUATES STRUCTURAL BONE DAMAGE IN A LONG-TERM MURINE K/BXN SERUM-INDUCED ARTHRITIS MODEL

E. Wiebe[1,2], C. Spies[1,2], J. Tu[2], T. Maleitzke[1,2], Y. Zhang[2], M. Seibel[2,3], H. Zhou[2], F. Buttgereit[4]. *[1]Department of Rheumatology and Clinical Immunology, Charité University Hospital, Berlin, Germany; [2]Bone Research Program, ANZAC Research Institute, University of Sydney; [3]Department of Endocrinology and Metabolism, Concord Repatriation Hospital, University of Sydney, Sydney, New South Wales, Australia; [4]Department of Rheumatology and Clinical Immunology, Charité Universitätsmedizin Berlin, Berlin, Germany*

Background: The role of endogenous glucocorticoids (GC) in bone metabolism in chronic inflammatory arthritis remains unclear. We have previously shown that disruption of GC-signaling in osteoblasts results in a marked attenuation of arthritis in the K/BxN serum-induced and CAIA mouse model with preservation of bone volume and structure[1,2].

Objectives: In order to investigate the impact of endogenous GCs on bone erosion and turnover in chronic inflammatory arthritis, we now studied the effects of disrupted osteoblastic GC-signaling in a *long-term* murine arthritis model.

Methods: Intracellular GC-signaling in osteoblasts was disrupted by transgenic overexpression of 11beta-hydroxysteroid dehydrogenase type 2 (11β-HSD type 2) under the control of a type 1 collagen promoter. Arthritis was induced in 5-week old male transgenic (tg) mice and their wild-type (WT) littermates. In order to maintain a chronically active arthritis, mice were boosted on day 14 and 28 by subcutaneous injection of K/BxN serum, controls (CTR) received PBS, respectively. Severity of arthritis was assessed daily by clinical scoring and ankle size measurements until the endpoint (day 42). Ankle joints were assessed by a histopathologic score and microfocal computed tomography (micro-CT). Systemic effects of inflammation on bone metabolism were quantified by histomorphometry and micro-CT of the tibia.

Results: Acute Arthritis developed in both tg and WT mice and remained active over the period of 42 days, with a reduced, yet non-significant, severity in tg compared to WT mice. Histological indices of inflammation, cartilage damage and especially bone erosion, additionally assessed by micro-CT, tended to be overall reduced in tg mice, yet not reaching a level of significance. Bone volume and bone turnover did not differ between tg and WT arthritic mice.

Conclusions: The modulating effect of disrupted GC-signaling in osteoblasts in serum-induced autoimmune-arthritis prevails in a chronic inflammatory setting, leading to less severe local inflammation and bone destruction. This supports the important role of endogenous GCs for an intact bone metabolism in inflammatory bone disease.

Treat-to-target in axSpA: reality or utopy?

OP0188 DEFINING CLINICALLY IMPORTANT WORSENING BASED ON ASDAS-CRP FOR AXIAL SPONDYLOARTHRITIS: A DATA-BASED CONSENSUS BY THE ASSESSMENT IN SPONDYLOARTHRITIS INTERNATIONAL SOCIETY (ASAS)

A. Moltó[1], L. Gossec[2], R. Landewé[3], D. van der Heijde[4], M. Dougados[1]. *[1]Rheumatology B Department, Cochin Hospital; [2]Pitié Salpêtrière Hospital, Department of rheumatology, Paris, France; [3]Department of Clinical Immunology & Rheumatology, Amsterdam Rheumatology Center, Amsterdam and Zuyderland Medical Center, Heerlen; [4]Department of Rheumatology, Leiden University Medical Centre, Leiden, Netherlands*

Background: Disease flares are increasingly used as outcomes in axial spondyloarthritis (axSpA) trials or observational studies.

Objectives: The objective of this initiative was to define a cutoff for the ASDAS score that best defines the concept of "worsening in axSpA", to be used in the context of clinical trials and longitudinal observational studies.

Methods: Various steps were followed between 2014 and 2017. (a) Initial expert opinion within the steering group to define the scope of the project; (b) systematic literature review to collect cutoffs used for worsening in published studies; (c) vignette-exercise among ASAS members: a theoretical 'paper' patient-vignette, in whom an initial and a final value of an outcome was provided, was judged by the physicians on whether or not the patient had worsened (defining phy-worsening) (ref); (d) real-life multicenter international study: data necessary to calculate different outcomes were collected from real patients at 2 consecutive visits (spaced 7 days to 6 months): external standard was defined as a patient's report that he/she had worsened and he/she felt there was a need for treatment intensification. (e) Testing of different changes in the outcomes against both external standards for worsening (phy-worsening and pt-worsening) followed by a consensus and voting procedure among ASAS members in January 2017.

Results: (a) There was consensus about worsening being an absolute change between 2 time-points (without defining time between the 2 time-points) and about exploring cutoffs for 3 outcomes: ASDAS-CRP, BASDAI and pain. (b) The literature review had yielded 27 different cutoffs in 38 studies indicating important heterogeneity (c) The vignette-exercise yielded 12 preliminary definitions for worsening to be tested (as previously reported). (d) In the prospective study the sensitivity and specificity of each cutoff was tested against pt-worsening and judged by the ASAS-community. (e) No consensus was reached for a BASDAI-based definition due to limited performance of all cut-offs, and it was decided to not define a value for a pain-based definition for worsening. Based on aggregated data (Table), a consensus was reached among the ASAS-members to define worsening as a deterioration in ASDAS of at least 0.9 points. While this cutoff led to only moderate sensitivity when tested against pt-worsening, the overall balance of sensitivity and specificity as well as the overall face validity of this cut-off value for ASDAS was deemed most acceptable.

Table. Sensitivity and specificity of different ASDAS cutoffs to define worsening, against phy-worsening and pt-worsening considered as external standards.

Cutoff values for change in ASDAS	Vignette exercise study (N=1150 physician judgments) against the external standard 'phy-worsening' (worsening in N=591)		Prospective real-life study (N=1169 patients), against the external standard 'pt-worsening' (worsening in N=127)	
	Sensitivity (%)	Specificity (%)	Sensitivity (%)	Specificity (%)
>=0.6	97	65	55	91
>=0.9	85	87	38	96
>=1.1	60	94	33	98

Conclusions: This data-driven ASAS consensus process has allowed to propose an ASDAS-based cutoff value defining worsening in axSpA. As has been observed in other settings, the change defining worsening (at least 0.9) is smaller than the change defining improvement which is 1.2 for ASDAS. This definition should now be applied in trials.

OP0189 TUMOR NECROSIS FACTOR INHIBITOR TREATMENT REDUCES SPINAL RADIOGRAPHIC PROGRESSION IN ANKYLOSING SPONDYLITIS BY DECREASING DISEASE ACTIVITY: A LONGITUDINAL ANALYSIS IN A LARGE PROSPECTIVE COHORT

C. Molnar[1], A. Scherer[1], X. Baraliakos[2], M. de Hooge[3], R. Micheroli[4], P. Exer[5], R. Kissling[6], G. Tamborrini[5], L. Wildi[4], M. Nissen[7], P. Zufferey[8], J. Bernhard[9], U. Weber[10], R. Landewé[11], D. van der Heijde[3], A. Ciurea[4]. *[1]SCQM, Zurich, Switzerland; [2]Rheumazentrum, Herne, Germany; [3]LUMC, Leiden, Netherlands; [4]USZ, Zurich; [5]Private Practice, Basel; [6]Balgrist, Zurich; [7]HCUGE, Geneva; [8]CHUV, Lausanne; [9]Bürgerspital, Solothurn, Switzerland; [10]Univ Southern Denmark, Odense, Denmark; [11]AMC, Amsterdam, Netherlands*

Background: Whether tumor necrosis factor inhibitors (TNFi) have an influence on radiographic progression in ankylosing spondylitis (AS) remains controversial.
Objectives: To investigate the impact of TNFi use on spinal radiographic progression in AS.
Methods: Patients fulfilling the modified NY Criteria for AS (as assessed by central reading) in the Swiss Clinical Quality Management Cohort with at least 2 years of clinical and radiographic follow-up were included. Spinal X-rays were taken every 2 years and scored independently by 2 blinded readers according to the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) in chronological time order. Average score of the readers was used. Radiographic progression was defined as an increase by $\geq$2 mSASSS units over 2 years. The relationship between TNFi use before a 2 year X-ray interval and progression within the interval was investigated using binomial generalized estimating equation models with adjustment for potential confounding and multiple imputation of missing covariate data. Ankylosing Spondylitis Disease Activity Score (ASDAS) was regarded as a potential intermediate variable mediating the effect of TNFi on radiographic progression. It was added to the model as a time-varying variable in a sensitivity analysis.
Results: A total of 420 patients with AS contributed to data for 597 x-ray intervals in adjusted analyses (1–5 intervals per patient); BL characteristics: male sex 66%, HLA-B27 81%, mean (SD) age 40.4 (10.9) years, disease duration 13.9 (9.8) years, mSASSS 6.4 (12.4), ASDAS 2.8 (1.1)). 39% of the patients were already on TNFi at first X-ray. Mean mSASSS progression in 2 years was 0.9 (2.7) units. The multivariable model (Table) shows that prior use of TNFi reduced the odds of progression in the next 2 year interval by 49% (odds ratio (OR) 0.51, 95% confidence interval (CI) 0.28–0.92, p=0.03). BL mSASSS and male sex also significantly affected progression. Adding ASDAS as a covariate to the model decreased the estimated effect of TNFi on progression: OR 0.65, 95% CI 0.36–1.17, p=0.15. In this model, a decrease in ASDAS by 1 unit would lower the odds for progression by 0.62 (p=0.001).

Table 1. Longitudinal multivariable analysis of radiographic progression

Variable	OR	95% CI	P value
TNFi use prior to X-ray interval	0.51	0.28–0.92	0.03
NSAID use at start X-ray interval	0.81	0.40–1.63	0.55
mSASSS at start X-ray interval	1.06	1.04–1.07	<0.001
Male gender	3.01	1.56–5.77	0.001
Disease duration	1.01	0.99–1.04	0.38
Current smoking	0.94	0.55–1.61	0.83
HLA-B27	0.99	0.46–2.12	0.98
Nb of exercise sessions per week	0.93	0.80–1.08	0.35
Peripheral arthritis	1.00	0.56–1.79	1.00

Conclusions: TNFi seem to reduce radiographic progression in patients with AS and this effect is mediated, at least in part, by a decrease in disease activity.

Calcium crystal deposition in rheumatic diseases

OP0190 HISTOLOGICAL CHARACTERIZATION OF ROTATOR CUFF CALCIFIC TENDINOPATHY

C. Darrieutort-Laffite[1,2], A. Najm[1,2], T. Garraud[1,2], P. Layrolle[2], F. Blanchard[2], B. Le Goff[1,2]. *[1]Rheumatology, CHU Hotel Dieu Nantes; [2]Laboratoire Phy-OS, INSERM U1238, Nantes, France*

Background: Calcific tendinopathy is one of the most frequent causes of shoulder pain. Calcific deposits lead to chronic discomfort in daily and professional activity. These deposits are composed of carbonated apatite. Although the disease is frequent, its origin stays still largely unknown. Molecular and cellular mechanisms involved in this pathological mineralization process are not clearly identified.
Objectives: The objective of the study was to analyze calcified tendinous samples to understand the organization of the deposits and to characterize the cells potentially involved in their formation.
Methods: Samples were collected from cadaveric subjects. Ultrasound was first used to detect calcified tendons. Then, tendons were collected and fixed in formalin 4% during 48h. They were first analyzed with micro-CT to know the distribution of the calcific deposits. Samples were then decalcified in EDTA, dehydrated and embedded in paraffin. Some samples were not decalcified to allow a better characterization of the calcific deposits. Several histological staining were performed: hematoxylin and eosin (HE), Safranin O/Fast Green (SO/FG) and Von Kossa (no decalcified samples). Immunohistochemistry using anti-Runx2, anti-Sox9, anti-Collagen II and anti-caspase III antibodies has been performed to characterize the cells and tissue around the calcifications.
Results: Six samples were collected (1 normal and 5 calcified). On HE staining, three different histological patterns were observed. Little calcifications disseminated between tendinous fibers (N=2), voluminous ones encapsulated by a fibrous tissue (N=2) and in one sample an intra-tendinous osseous metaplasia. In the fibrous peripheral area of larger calcifications, we observed cells with round nuclei, different from tenocytes. These cells expressed Runx2 and Sox9 suggesting a chondrocyte phenotype. On SO/FG staining, this peripheral area presented a red coloration (proteoglycan specific) as the fibrocartilage at the tendon attachment. However, collagen II clearly present in the fibrocartilage was not present in these areas. As pathological calcification in cartilage can be associated with chondrocytes apoptosis, we sought for anti-Caspase III expression in the cells of the peripheral area. None of the chondrocyte-like cells located around the larger calcifications expressed Caspase III. Finally, one sample had an osseous metaplasia within the tendon with Runx2 positive cells.
Conclusions: Histological analyses of whole calcified tendon tissues showed three different patterns of calcific deposits. We can hypothesize that these patterns correspond to different stages of the disease. Chondrocyte-like cells were observed around larger deposits and could be involved in the mineralization process. Interestingly, they differ from the cells of the fibrocartilage as they did not express collagen II. Further analyses are necessary to characterize their phenotype and understand the steps leading to these deposits within the tendon.

OP0191 COMPARISON OF ULTRASONOGRAPHY AND RADIOGRAPHY OF THE WRIST FOR DIAGNOSIS OF CALCIUM PYROPHOSPHATE DEPOSITION

A. Combier, M. Forien, A. Gardette, E. Palazzo, P. Dieudé, S. Ottaviani. *Rheumatology Departement, Bichat Hospital, Paris, France*

Background: The gold standard for diagnosis of calcium pyrophosphate (CPP) deposition (CPPD) is the identification of CPP crystals in synovial fluid. However, aspiration of synovial fluid can be challenging in small joints such as the wrist, a usual location of arthritis in CPPD. Despite its low sensitivity, the most widely used imaging modality is conventional radiography but ultrasound (US) seems a useful tool for diagnosis of CPPD.
Objectives: We aimed to compare the performance of US and conventional radiography of the wrist for diagnosis of CPPD.
Methods: Patients with joint effusion (knee, hip, shoulder, ankle or wrist) were consecutively included. CPPD was diagnosed by CPP crystals identified in synovial fluid. Patients without CPP crystals in synovial fluid were controls. As recommended, we used the term chondrocalcinosis (CC) to assess imaging features suggesting CPPD. Two blinded operators assessed CC in all patients by US and conventional radiography of the wrist. The presence of CC in triangular fibrocartilage (TFC) and wrist hyaline cartilage in US and TFC and radiocarpal (RC) joint in radiography was noted. A patient was considered to have CC if at least one wrist had imaging features of CC.
Results: We included 58 patients with joint effusion (32 with CPPD). The remaining 26 patients, controls, had rheumatoid arthritis (n=13), spondyloarthritis (n=6), gout (n=6), and osteoarthritis (n=1). The mean age was 67.1±16.3 years. Location of joint effusion was as follows: 34 knees, 15 wrists, 3 shoulders, 2 ankles, 3 hips and 1 elbow. Among CPPD patients, US revealed CC in 30 (93.7%) and radiography in 17 (53.1%) ($p<0.001$). The sensitivity (Se) and specificity (Sp) of US for the diagnosis of CPPD were 94% and 85%, respectively; the positive likelihood ratio was 6.1. When analyzing US features of CC separately, US Se was higher at the TFC than RC joint, 81% and 50% respectively. The Se and Sp of radiography were 53.1% and 100%, respectively. Intraobserver reliabilities for US and radiographic CC were almost perfect: κ coefficient 0.832 [95% confidence interval 0.651–1.0] and 0.880 [0.314–0.880], respectively. In all 58 patients, 113 joints were analyzed (3 patients had radiography of only one wrist). The κ coefficient between US and radiography for CC was moderate: 0.33 [0.171–0.408].
Conclusions: Our study suggests that wrist US should be considered a relevant tool for the diagnosis of CPPD, with higher sensitivity than radiography.

Fifty shades of remission in RA

OP0192 ADDING ULTRASOUND TO THE TREAT-TO-TARGET STRATEGY SHOWS NO BENEFIT IN ACHIEVEMENT OF REMISSION: RESULTS FROM THE BIODAM COHORT

A. Sepriano[1], S. Ramiro[1], R. Landewé[2], D. van der Heijde[1], S. Ohrndorf[3], O. FitzGerald[4], M. Backhaus[3], M. Larché[5], J. Homik[6], A. Saraux[7], H. Hammer[8], L. Terslev[9], M. Østergaard[10], G. Burmester[3], B. Combe[11], M. Dougados[12], C. Hitchon[13], G. Boire[14], R. Dadashova[15], J. Paschke[15], E. Hutchings[15], W. Maksymowych[6]. *[1]LUMC, Leiden; [2]ARC, Amsterdam, Netherlands; [3]Charité, Berlin, Germany; [4]SVUH, Dublin, Ireland; [5]McMaster University, Hamilton; [6]University of Alberta, Edmonton, Canada; [7]CHU, Brest, France; [8]Diakonhjemmet Hospital, Oslo, Norway; [9]Copenhagen UH, Copenhagen; [10]Copenhagen UH, Copenhagen, Denmark; [11]CHU, Montpellier; [12]Descartes University, Paris, France; [13]University of Manitoba, Winnipeg; [14]University of Sherbrooke, Quebec; [15]CaRE Arthritis Ltd, Edmonton, Canada*

Background: While, a Treat-to-Target strategy (T2T), treating patients with rheumatoid arthritis (RA) towards a certain target (eg. clinical remission; T2T-REM), is highly recommended, several patients in clinical remission often have residual synovitis on ultrasound-imaging (US). This may result in silent radiographic progression and clinical flare. It is arguable whether targeting US-synovitis may result in "deeper" remission in clinical practice.
Objectives: To assess whether using US in a T2T strategy leads to more patients meeting clinical remission than using only clinical information.
Methods: Patients with RA who started or changed csDMARD and/or anti-TNF treatment followed in centers with expertise in US and participating in BIODAM (2-year multicenter prospective observational cohort) were included. Clinical and US data [by the US7-score that includes 7 joints of the clinically dominant hand and foot for synovitis and tenosynovitis on gray-scale US (GSUS) and power-doppler US (PDUS) and erosions on GSUS] were collected every 3 months. Per visit was decided whether the patient was treated according to the clinical definition of T2T with remission as benchmark (T2T-CLIN-REM). Though not mandatory, US-data could also be used for this purpose. T2T-CLIN-REM was considered correctly applied if: either i) a patient already had a disease activity score below the remission target (i.e. ACR/EULAR boolean remission) or ii) if not, treatment was intensified. A T2T strategy taking also US data into account (T2T-CLIN-US-REM) was considered correctly applied if: either i) both clinical and US remission (all joints included in the US7-score with GSUS synovitis <2 and PDUS synovitis=0) were present; or ii) if not, the treatment was intensified. The main outcome was ACR/EULAR boolean remission. The effect of adding US to T2T (T2T-CLIN-US-REM) on clinical remission 3 months later compared to a clinical remission benchmark only (T2T-CLIN-REM) was analyzed using generalized estimating equations with auto-regression.
Results: In total 963 visits of 130 patients were included. T2T-CLIN-US-REM was correctly followed in 33% of the visits, T2T-CLIN-REM in 14%, and any of these in 52%. Remission according to the ACR/EULAR-boolean definition was achieved in 19.6% of the visits. Compared to the conventional T2T-CLIN-REM strategy, using a combined clinical and US benchmark for T2T led to a lower – instead of higher - likelihood of ACR/EULAR-boolean remission 3 months later [OR (95% CI): 0.39 (0.24; 0.63] (table).

Table. Effect of following a T2T strategy taking both clinical and US data into account (T2T-CLIN-US-REM) compared to the clinical definition of T2T (T2T-CLIN-REM; reference) in meeting the targets 3 months later and over a period of 2 years.

T2T approach / Outcome	ACR/EULAR boolean remission aOR* (95% CI)
No T2T *vs* T2T-CLIN-REM alone§	0.49 (0.27; 0.88)
T2T-CLIN-US-REM *vs* T2T-CLIN-REM alone§	0.39 (0.24; 0.63)

*Adjusted for age, gender, HAQ-score, RF, ACPA, previous use of DMARDs, smoking-status, education and number of comorbidities. § Clinical definition of T2T (T2T-CLIN-REM) was used as the comparator for each of the presented treatment strategies.

Conclusions: Our results, from a non-randomized study, did not suggest an advantage of using US of 7 joints in addition to clinical examination as a T2T benchmark as compared to clinical examination alone in getting RA patients into clinical remission.

Innate immunity

OP0193 INFLAMMATION OF ADVENTITIAL NERVES OCCURS IN GIANT CELL ARTERITIS PATIENTS AND IT IS CHARACTERIZED BY INFLAMMASOMES, UPR AND AUTOPHAGY ACTIVATION

F. Ciccia[1], A. Rizzo[1], R. Alessandro[1], S. Raimondo[1], G. Guggino[1], A. Cavazza[2], C. Salvarani[2], G. Triolo[1]. *[1]University of Palermo, Palermo; [2]Arcispedale Santa Maria Nuova, Reggio Emilia, Italy*

Background: Vascular adventitia is a major site of immune surveillance and inflammatory cell trafficking and is the most complex compartment of the vessel wall comprising fibroblasts, dendritic cells and macrophages, progenitor cells, vasa vasorum, pericytes and adrenergic nerves. It has been proposed that activation of adventitial nerves and release of sensory neuropeptides from their peripheral terminals may leads to neurogenic inflammation. Giant cell arteritis (GCA) is an immune-mediated disease of unknown etiology in which the inflammatory process seems to start from the adventitia of affected arteries.
Objectives: aim of the study was to evaluate the occurrence of adventitial nerves inflammation and to immunologically characterize the adventitial neuritis occurring in GCA patients.
Methods: Immunohistochemistry and RT-PCR were used to study the presence of neuritis in temporal artery samples obtained from 30 patients with temporal artery (TAB) positive GCA, 20 TAB negative GCA and 20 controls. Laser capture microdissection (LCM) was used to isolate adventitial nerves and nerve expression of pro-inflammatory cytokines involved in the pathogenesis of GCA such as IL-6, IL-17, IL-32, IL-9, IL-33 was assessed by RT-PCR. Expression of pro-inflammatory cytokines by adventitial nerves was further studied by immunohistochemistry and confocal microscopy. Autophagy, unfoled protein response (UPR) and inflammasomes pathways were also studied by RT-PCR and immunohistochemistry.
Results: Adventitial nerves showed infiltration of $CD3^+$ T cells in all the TAB positive and in 12 out of 20 TAB negative arteries but were never observed in control arteries. RT-PCR expression analysis of different pro-inflammatory cytokines clearly demonstrated specific over-expression of IL-33 in LCM isolated inflamed nerves. Immunohistochemical and confocal microscopy analysis confirmed nerve IL-33 expression. RT-PCR and immunoistochemistry demonstrated that AIM2 and NLRP3, but not NLCR4, inflammasomes were activated in inflamed nerves of GCA patients. According to inflammasomes activation, increased IL-18 expression was observed. Autophagy-related genes such as ATG16L1 and LC3 and UPR-related genes such as XBP-1 and CHOP were also over-expressed in GCA adventitial nerves as demonstrated by RT-PCR and immunohistochemistry. Finally, increased expression of AIM2 and NLRP3 inflammasomes, autophagy and UPR was also observed outside the nerves, in the context of inflamed artery wall.
Conclusions: here we demonstrated that adventitial neuritis is present in both inflamed and non-inflamed arteries of GCA patients. GCA inflamed nerves specifically produce IL-33 a cytokine of the innate immunity that has been demonstrated to be involved in the pathogenesis of GCA. AIM2 and NLRP3 inflammasomes activation was also observed in GCA arteries and in particular in the inflamed adventitial nerves being accompanied by the increased expression of IL-18. Specific activation of autophagy and UPR pathways was also observed in the inflamed GCA nerves. Altogheter these findings seem to suggest a complex immune activation of adventitial nerves in GCA, suggesting a possible role of arterial neuritis in the initiation and perpetuation of GCA artery inflammation.

OP0194 INVOLVEMENT OF TOLL-LIKE RECEPTOR 9 IN THE PATHOGENESIS OF EROSIVE AUTOIMMUNE ARTHRITIS AND DURING OSTEOCLASTOGENESIS

A. Fischer, B. Meyer, B. Niederreiter, G. Steiner. *Internal Medicine III-Rheumatology, Medical University Vienna, Vienna, Austria*

Background: Release and insufficient removal of endogenous nucleic acids may be involved in triggering harmful autoimmune reactions important in the initiation of systemic autoimmune diseases including rheumatoid arthritis (RA). Nucleic acid sensing molecules, such as the endosomal Toll-like receptors (TLRs) 7 and 9, have been linked to pathogenic autoimmune processes, particularly in systemic lupus erythematosus, but their role in RA is less clear. Results previously obtained in rats with pristane-induced arthrits (PIA) suggested involvement of TLR9 in the pathogenesis of this arthritis model (1). Interestingly, rats with PIA develop autoantibodies associated with RA including rheumatoid factor, anti-RA33 and antibodies to carbamylated proteins (2).
Objectives: To gain more insight into the role of TLR9 in the pathogenesis of autoimmune arthritis by investigating the effects of TLR9 inhibition in rats with PIA.
Methods: Arthritis was induced in DA rats with the mineral oil pristane. Rats were treated with a TLR9 antagonist every other day, starting one before disease induction. Arthritis was scored using established scoring systems, inflammation and bone erosion were quantified by histological analysis. Expression of TLR9

and other nucleic acid sensing TLRs was quantified by RT-PCR and Western blotting; activation (phosphorylation) of various signal transduction molecules was determined by Western blotting. Furthermore, the role of TLR9 in osteoclast differentiation and activation was investigated *in vitro*.

Results: The TLR9 antagonist significantly reduced clinical signs of arthritis by approximately 50%. Histological analyses revealed diminshed inflammation, cartilage degradation, bone erosion and significantly reduced numbers of osteoclasts in animals treated with the TLR9 antagonist. However, when treatment was started after onset of arthritis TLR9 inhibition had no effect on arthritis development and severity. IL-6 serum levels were greatly diminished in animals treated with the TLR9 antagonist and expression and activation of NF-kB in lymph nodes was reduced. Remarkably, mRNA levels of TLR7 and TLR9 strongly differed in the course of *in vitro* osteoclastogenesis. Whereas TLR7 expression did not change throughout osteoclastogenesis, expression of TLR9 was higher in precursor cells than in mature osteoclasts and stimulation with a TLR9 agonist (CpG) completely inhibited osteoclastogenesis.

Conclusions: Taken together, the results suggest an important role for TLR9 in the T cell-dependent initiation phase of PIA and thus important involvement of endogenous DNA released during apoptosis, necrosis or netosis in the initiation of autoimmune arthritis and during osteoclastogenesis. The possible relevance of these findings for human RA needs to be further elucidated in future experiments.

To be and to become: transition from paediatric to adult care

OP0195 WHAT IS THE IMPACT OF JUVENILE IDIOPATHIC ARTHRITIS IN ADULTHOOD? THE MONOCENTRIC EXPERIENCE OF 240 PATIENTS FOLLOWED IN A TRANSITION TERTIARY CLINIC OF RHEUMATOLOGY

I. Pontikaki[1], L.M. Argolini[2], C. Artusi[2], P.L. Meroni[3]. *[1]Unit of Pediatric Rheumatology-Department of Rheumatology; [2]Department of Rheumatology; [3]Department of Rheumatology, Chair of Rheumatology, Gaetano Pini Institute, University of Milan, Milan, Italy*

Background: There are many differences in clinical manifestations, assessment and management of Juvenile Idiopathic Arthritis (JIA) between childhood and adults' arthritis onset. The transition from pediatric to the adult care emphasizes a lot of aspects that need to be addressed.

Objectives: To describe the long-term outcome of JIA.

Methods: Two-hundred and forty patients affected by JIA and referred to a transition care rheumatology tertiary centre were considered between 1999 and 2016. The outcome assessment included disease activity, medications, number of prosthesis implantation, pregnancy, mortality, social integration (mobility, employment status and educational level).

Results: Seventy-four (30.8%) males and 166 (69.2%) females were included; 53 (22.1%) patients were lost in follow up. Subtypes of JIA at disease onset included 101 oligoarthirtis (42.1%), 67 polyarthritis (27.9%), 43 systemic arthritis (17.9%), 7 psoriatic arthritis (2.9%), 22 enthesitis related arthritis (9.2%). Forty-eight (20%) patients had persistent uveitis. Ninety-three implant prosthesis and 14 arthodesis were recordered. The average disease duration was 20 years, the median age of the patients was 27 (18–57) years. Five deaths (2.1%) occurred in this cohort. At follow up 117 (48.7%) had low active disease activity, 70 (29.2%) had moderate disease activity, 14 (5.8%) had a high disease activity, 24 (10%) were on remission ON medication and 15 (6.3%) OFF medication. Among patients still on medication, 59 (24.6%) were treated with oral steroids, 18 (7.5%) with csDMARDs and 169 (70.4%) with bDMARDs. Seventy-five (31.3%) patients had a higher educational level (university), 195 (81.3%) had an employment, 128 (53.3%) had a driving license. Twenty-one (8.8%) pregnancies were registered. The transition age was considered after age of sixteen years old. In this contest, it was important the multidisciplinary approach of each patient that was realized with the collaboration of other specialists (ophthalmologist, orthopedic, dermatologist, obstetric, psychologist).

Conclusions: In the era of biologic therapy there was an important improvement in a lot variables of the long-term outcome of JIA. One-hundred-eighty-seven (77.9%) patients were still in tight control, not only because of the continuation of the biological therapy but also because of the multidisciplinary care carried out even during remission. JIA often persists over the adulthood. The long term follow up and care of these patients has to be conducted by a rheumatologist expertized in JIA in collaboration with other specialists.

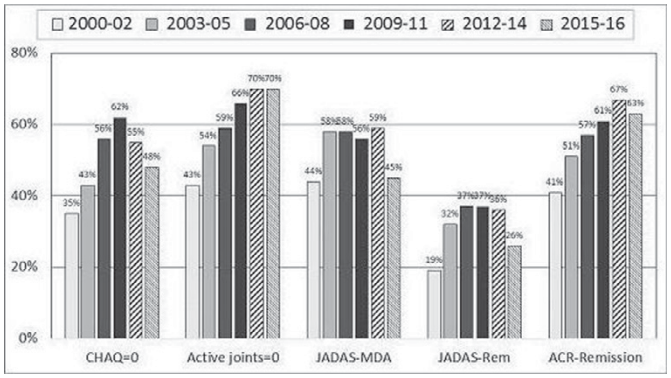
Heterogeneity in JIA

OP0196 CHANGING PATTERNS OF JUVENILE IDIOPATHIC ARTHRITIS PATIENTS TREATED WITH ETANERCEPT FROM 2000 TO 2016 IN THE GERMAN BIKER REGISTRY POPULATION

G. Horneff[1], K. Minden[2], I. Foeldvari[3], G. Ganser[4], J.P. Haas[5], J. Brunner[6], I. Becker[7] on behalf of BIKER collaborative group. *[1]Paediatrics, Asklepios, Sankt Augustin; [2]Charité, Berlin; [3]Private office, Hamburg; [4]Ped Rheumatol, Sendenhorst; [5]German Ped Rheum Centre, Garmisch-Partenkirchen, Germany; [6]University, Innsbruck, Austria; [7]University, Cologne, Germany*

Background: There is increasing experience with Etanercept (ETA) in juvenile idiopathic arthritis in the BIKER Registry.

Objectives: To report on practice changes ETA utilization and outcome over a period of 16 years.



Methods: 6 cohorts of pts were created according to inclusion period. Patients' and disease characteristics,the utilization of DMARDs, steroids, NSAIDs were analysed. Efficacy was judged by PedACR30/50/70/90, JADAS and ACR-remission.

Results: Records from 2105 JIA pts treated with etanercept with at least a baseline and one follow up form were analysed. Most pts were females (67%). The median age of disease onset increased from 5.9 years in the early to 9.3 years in the later cohorts while age at start of treatment remained stable (about 13 years). Median disease duration markedly decreased from 5.3 to about 2 years. Most pts had RF neg. polyJIA followed by extended oligoarthritis. In the more recent cohorts the rate of enthesitis related arthritis increased and the rate f systemic JIA decreased (table). At registry start, 20% of newly enrolled pts belonged to the systemic JIA category compared to <1% in 2016. During the study period, the overall utilization of glucocorticoids at baseline decreased from 54% to 19% ($P<0.0001$), NSAID from 90% to 72% ($P<0.0001$), MTX from 78% to 64% ($P=0.004$). ACR30/50%70/90 response rates at month 12 were 80%/74%/59%/40% and did not vary over time while the rate of patients reaching no active joint/CHAQ DI=0/JADAS-MDA/JADAS-Remission/ACR-Remission increased from 43%/35%/44%/19%/41% to 69%/48%/45%/26%/63%.

Changes in all parameters were significant ($p<0.001$) in Kruskal-Wallis-Test/Chi-quare.

Conclusions: In recent years, children have been treated earlier, received less concomitant treatment with NSAIDS, corticosteroids as well as DMARDs. More recent cohort of patients had less severe disease at baseline, but also showed a markedly better outcome already at one year of treatment reflected by higher rates of patients with no active joint, a CHAQ DI of 0, a JADAS-MDA, and ACR-Remission. These data suggest that early disease control and better pre-selection of patients who need biologics are important to improve outcome and safety in children with JIA.

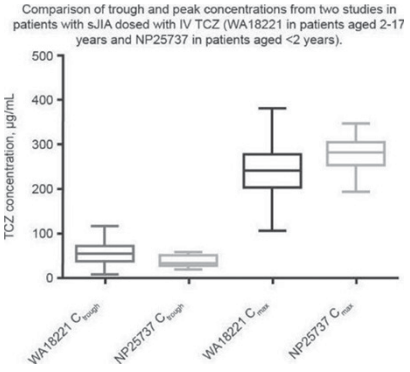
OP0197 **EVALUATION OF A DOSING REGIMEN FOR TOCILIZUMAB IN PATIENTS YOUNGER THAN TWO YEARS OF AGE WITH SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS**

N.L. Mallalieu[1], J. Hsu[1], K. Wang[1], S. Wimalasundera[2], C. Wells[2], I. Calvo Penades[3], R. Cuttica[4], H.I. Huppertz[5], R. Joos[6], Y. Kimura[7], D. Milojevic[8], M. Rosenkranz[9], K. Schikler[10], T. Constantin[11], C. Wouters[12]. *[1]Roche Innovation Ctr, New York, United States; [2]Roche Products Ltd, Welwyn Garden City, United Kingdom; [3]Hosp Universitario y Politécnico la Fe, Valencia, Spain; [4]Hosp General de Niños Pedro de Elizalde, Buenos Aires, Argentina; [5]Professor Hess Children's Hosp, Bremen, Germany; [6]ZNA Jan Palfijn Antwerpen, Antwerp, Belgium; [7]Hackensack U Med Ctr, Hackensack; [8]Tufts Med Ctr, Boston; [9]Children's Hosp Pittsburgh UPMC, Pittsburgh; [10]U Louisville Hosp, Louisville, United States; [11]Semmelweis U, Budapest, Hungary; [12]U Hosp Gasthuisberg, Leuven, Belgium*



Background: Tocilizumab (TCZ) is approved for the treatment of systemic juvenile idiopathic arthritis (sJIA) based on clinical trials in patients (pts) ≥2 years of age. This study (NP25737) is the first for a biologic in sJIA pts <2 years of age.

Objectives: To evaluate the pharmacokinetics (PK), pharmacodynamics (PD), efficacy, and safety of TCZ in sJIA pts <2 years of age in a phase 1 trial.

Methods: Pts with uncontrolled sJIA and symptoms for ≥1 month prescreening who failed treatment with corticosteroids and NSAIDs and had no history of allergy to TCZ or other biologics received open-label TCZ 12 mg/kg intravenously (IV) every 2 weeks (dose calculated at each visit based on body weight). Pts were treated up to week 12 and could continue until the age of 2 years or were treated for 1 year from baseline. End points included PK (primary) at week 12, PD and efficacy (exploratory), and safety. Comparison was made to exposures from a previous trial in sJIA pts ≥2 years of age (WA18221) that was the basis for approval of TCZ in sJIA.

Results: Eleven pts were enrolled; median (range) age was 16 (10–22) months and weight was 10.40 (6.8–11.5) kg. Serum TCZ concentrations, estimated using population PK analysis, peaked immediately after infusion; median (range) maximum concentration was 282 (195–347) μg/mL (steady state reached by week 12), and median (range) trough concentration was 34.3 (19.2–59.7) μg/mL. Peak and trough exposures were within the exposure range in older children (244 [109–382] to 54.3 [10.9–117] μg/mL; Figure). Observed mean±SD soluble IL-6 receptor levels were 47.65±16.40 ng/mL at baseline and 927.83±148.07 ng/mL at day 71. CRP levels were 250.81±425.11 mg/L and 2.80±3.56 mg/L, respectively. ESR levels were 59.40±27.47 mm/h and 2.00±1.00 mm/h, respectively. Mean±SD Juvenile Arthritis Disease Activity Score-71 improved from 22.27±10.09 at baseline to 3.66±4.66 at day 71. By week 12, 10 pts had 32 adverse events (AEs) and 4 withdrew due to AEs. Infections or infestations were the most frequently reported AEs (10 events, 9 pts). Five serious AEs (SAEs) occurred; 3 pts had SAEs of hypersensitivity that led to withdrawal; 1 of these pts then experienced SAEs of foot and mouth disease and sJIA flare after study withdrawal. No actual cases of MAS were reported, but 2 pts had laboratory abnormalities indicative of MAS according to 2016 criteria.[1] No deaths occurred during the study.

Conclusions: TCZ exposures achieved in this study fell within the range of the previous trial in sJIA pts ≥2 years of age. This study provides evidence that TCZ is effective in sJIA pts <2 years of age, achieves PK and efficacy similar to those

demonstrated previously in older pts, and has a similar AE safety profile, but there was a higher incidence of serious hypersensitivity events and suspected MAS.

Barrier free employment for young people with RMDs

OP0198-PARE **FIT FOR WORK ONLINE: SUPPORTING EMPLOYEES WITH RMDS, EMPLOYERS AND HEALTHCARE PROFESSIONALS**

G. OLeary. *Arthritis Ireland, Dublin 2, Ireland*

Background: Seven million working days are lost each year in Ireland due to RMDs, such as back & neck pain or stiffness, arthritis, and limb pain. This is therefore a significant problem which obviously impacts on both employers, employees and healthcare professionals. That is why Arthritis Ireland has developed *Fit for Work Online* - an eLearning programme which focuses on the issues that face these three groups.

Objectives: The objective of the project was to develop an online educational programme to provide information, guidance and support to employees, employers and healthcare professionals on working with RMDs.

Methods: In 2015 Arthritis Ireland began its developments of an online education programme "*Fit for Work Online*" which focuses on the tripartite relationship between the employee, employer and healthcare professional.

3 video lessons were developed as part of this eLearning programme.

- The first lesson is aimed at employees who are living with an RMD
- The second lesson is aimed at employers who have a staff member who is living with an RMD (and finally)
- The third has been developed for health professionals to update them on current guidance around RMDs and ongoing employment

A key message in all 3 videos is that *working is good for your health.*

Since employment has been shown to boost health and happiness, it is crucial, whenever possible, that people who are living with an RMD, remain in employment, or return to work, as soon as they can. That is the central message of this eLearning programme.

A number of issues were addressed in the development of this programme in order to convey these important issues:

- Firstly, employees who are living with an RMD are encouraged to take control of their condition. People living with an RMD are encouraged to consider practical steps and issues which would support them in staying in, or returning to, work.
- Secondly, from an employer's perspective, in addition to concerns about the welfare of their employees, there are other issues to consider, and it is natural for instance to be concerned about the possible impact of any health condition on their employees' performance & reliability, and consequently on their business. Adaptations, supports, flexibility and so on need to be considered.
- Finally, health professionals need to encourage, advise and facilitate people who are living with RMDs to remain in, or return to work.

Results: The *Fit for Work Online* programme will go live in February 2015. It is planned that a report on the first four months of the programme's delivery and implementation will be available at EULAR 2017 in Madrid.

Conclusions: The direct cost of RMDs at work in Ireland is estimated to be

Arthritis Ireland
Little Things make a Big Difference

at least €750 million a year. Ensuring that people who have been recently diagnosed with an RMD (or who have been living with one for a long time), have the opportunity to remain in or return to work, is central to the ideas behind *Fit-for-Work*. Everyone has a role to play to make this happen, and everyone needs to be flexible & realistic, because in the end of the day, everyone stands to benefit.

OP0199-PARE **SUPPORT TO STAY EMPLOYED AND SOCIAL SECURITY ARRANGEMENTS FOR WORK DISABILITY DUE TO RA – PERCEPTIONS OF PATIENTS WITH RA AND RHEUMATOLOGISTS IN 31 EUROPEAN COUNTRIES**

P. Putrik[1], S. Ramiro[2], F. Guillemin[3], B. Rojkovich[4], F. Sivera[5], M. de Wit[6], A. Woolf[7], A. Zink[8], T. Sokka[9], A. Boonen[1] on behalf of Working Group Access to Social Security for patients with RA across Europe. *[1]Rheumatology, MUMC, Maastricht; [2]Rheumatology, Leiden University Medical Center, Leiden, Netherlands; [3]University of Lorraine, Nancy, France; [4]Polyclicic of the Hospitaller Brothers of St. John of God, Budapest, Hungary; [5]Hospital General Universitario de Elda, Alicante, Spain; [6]VU University Medical Centre, Nijmegen, Netherlands; [7]Royal Cornwall Hospital, Truro, United Kingdom; [8]DRFZ, Berlin, Germany; [9]Jyväskylä Central Hospital, Jyväskylä, Finland*

Background: Despite demonstrated influence of country of residence on labour force participation among patients with RA, little attempt has been made to understand the users' perceptions of support and social security (SS) systems.
Objectives: To explore the patterns in perceptions among patients with RA and rheumatologists from different European countries across five domains (1) importance and support to remain employed, (2) process of applying for WD, (3) obtaining and living with WD pension, (4) role of the rheumatologists in support to remain employed or apply for WD pension and (5) performance of the system.
Methods: A survey among RA patients and rheumatologists was conducted in 44 countries of European WHO Region. For each domain, several questions (4 to 6 questions per domain, each on a 1–5 Likert answer scale, dichotomized as 1 ("totally (agree)") and 0 ("not agree, not disagree", "totally (disagree)") were asked (Table). Next, sum scores were calculated for each domain and averaged per country. The domain "remaining employed" was assessed in patients who currently have or ever had work. Analyses in domains "process of applying for WD" and "obtaining and living with WD" were limited to patients who currently have or ever considered applying for WD. Comparisons of scores in all domains were explored by: EU-15, new EU member states and non-EU countries, the five types of social welfare system (Anglo-Saxon, Bismarckian, Mediterranean, Post-Communist, and Scandinavian) and by countries' wealth (GDP per capita adjusted for purchasing power parity [PPP]) using ANOVA or Pearson correlation, as appropriate.

Table. Differences in perceptions of the social security system among patients and rheumatologists by GDP, system type and EU membership status.

		Perceptions among patients¥			Perceptions among rheumatologists¥	
		Importance and support to remain employed (0-4)	Process of applying for WD (0-6)	Obtaining and living with WD (0-4)	Performance of SS system (0-4)	Role of rheumatologist (0-4)
		Mean (SD)				
GDP	GDP < 27,000 USD PPP per capita (n=16)	1.68 (0.48)ξ	2.10 (0.98)£	1.22 (0.61)£	1.39 (0.51)£	2.38 (0.53)α
	GDP ≥ 27,000 USD PPP per capita (n=15)	1.85 (0.60)ξ	2.67 (1.03)£	1.27 (0.57)£	1.74 (0.71)£	1.91 (0.51)α

	Mediterranean (n =7)	1.88 (0.54)	2.12 (0.79)	1.17 (0.51)	1.35 (0.87)	2.12 (0.74)
	Post-Communist (n =15)	1.71 (0.52)	2.24 (0.94)	1.22 (0.63)	1.44 (0.52)	2.32 (0.53)
	Scandinavian (n =3)	**2.86 (0.48)***	**4.18 (1.14)***	**1.66 (0.35)***	**2.36 (0.07)***	2.11 (0.55)
EU status	EU-15 (N=12)	1.97 (0.66)	1.18 (0.59)	2.24 (0.88)	1.59 (0.73)	**1.84 (0.50)***
	EU new member states (n =11)	1.83 (0.53)	1.24 (0.62)	2.25 (1.05)	1.59 (0.60)	2.22 (0.43)
	Non-EU (n =8)	1.66 (0.65)	1.34 (0.58)	2.76 (1.23)	1.54 (0.64)	**2.42 (0.64)***

¥ score on each domain implies the higher, the better *statistically significant differences (p<0.05);
Relationship between GDP (as continuous variable) and each domain was tested with Pearson correlation coefficient ξ 0.41(p<0.05); £ not significant; α -0.44(p<0.05);

Results: Of 44 countries, 31 (70%) and 30 (68%) have provided data for patients and rheumatologists, respectively. In total, 646 patients (mean age (SD) 53 (12), 76% female, 519 (78%) ever worked) and 500 rheumatologists filled in the questionnaires. Overall, positive weak to no relationships were present between the *GDP per capita* and perceptions from rheumatologists or patients about SS arrangements. However, significant differences were observed across the *systems type* with the Scandinavian type (Finland, Norway, Sweden) consistently scoring higher than the others on most domains (table). Remarkably, rheumatologists in less wealthy and non-EU countries felt more confident in their role related to WD pension.
Conclusions: Patients'a nd rheumatologists' perceptions of systems to support persons with RA encountering work restrictions varied mostly according to the type of the social welfare system, while remarkably little differences were related to country's wealth and membership in EU. Scandinavian employment support and social security system appeared to most adequately meet the expectations of patients and rheumatologists in questions of remaining at work and application to WD pension.

THURSDAY, 15 JUNE 2017

Epidemiology of rheumatic and musculoskeletal diseases - a critical appraisal

OP0200 **CONFOUNDING BY INDICATION WILL MAKE NON-TNFI BDMARDS APPEAR MORE HARMFUL THAN TNFI BDMARDS - A NATIONWIDE STUDY OF CHANNELING IN SWEDEN 2010-2014**

T. Frisell[1], E. Baecklund[2], K. Bengtsson[3], D. Di Giuseppe[1], H. Forsblad-d'Elia[4], J. Askling[1] on behalf of the ARTIS Study Group. *[1]Karolinska Institutet, Stockholm; [2]Uppsala University, Uppsala; [3]Sahlgrenska Academy, Göteborg; [4]Umeå University, Umeå, Sweden*

Background: Confounding by indication occurs when factors associated with the choice of therapy are also predictors of the studied outcome, and is generally considered the major limitation of non-randomized comparisons of different therapies. In RA, age, sociodemographic factors, disease activity, and medical history may influence the choice of e.g. a non-TNFi over a TNFi bDMARD. The degree of bias is difficult to assess since most studies have limited data on potential confounders, and residual confounding cannot be separated from true treatment effects.
Objectives: To quantify the expected confounding by indication caused by baseline differences in patient characteristics at initiation of different bDMARDs in RA.
Methods: All RA patients in the Swedish Rheumatology Register (SRQ) were linked to nationwide registers to assess whether a comprehensive list of covariates predicted the choice of bDMARD to such a degree that different rates of adverse events (AEs) would be expected. Among considered confounders were demographic variables, RA related factors (including RF, disease duration, HAQ, DAS28 w. components) and medical history (health care utilization and 20 specific conditions).
We used historical data on the 5 year risk of several AEs among RA patients starting any bDMARD 2005–2009 to predict the risk among RA patients (bionaïve and switching from a first TNFi) starting specific bDMARDs 2010–2014. Risk was modelled in logistic regressions, as a function of baseline characteristics but assuming no effect from the therapy itself.
Results: Patients starting non-TNFi were older than those starting a TNFi, had lower socioeconomic status, higher disease activity and more often a history of diseases including malignancy, serious infections, and diabetes. These factors were in general also significant predictors of AEs, and the predicted proportions of all AEs were substantially higher for non-TNFi compared to TNFi bDMARDs, highest for rituximab. Within the TNFi-group, only minor differences were seen. Age was a strong confounder, and standardizing to the age/sex-distribution of the TNFi group reduced the group difference dramatically.

Predicted percentage with AE within 5 years, based on observed baseline characteristics. Crude and standardized to age-sex distribution of TNFi as first bDMARD

	All-cause mortality		All-cause hospitalization		Malignancy		MACE		Serious infection	
	Crude	Std	Crude	Std	Crude	Std	Crude	Std	Crude	Std
First bDMARD										
TNFi	4.9		60.3		5.4		6.2		15.3	
Rit.	12.8	6.7	74.0	67.6	7.7	5.7	11.9	7.3	25.6	18.9
Toc.	8.5	7.7	63.6	64.2	5.8	5.2	8.4	8.8	19.4	18.8
Aba.	11.6	6.9	67.5	61.5	6.2	5.0	12.4	7.1	22.1	17.3
Switch from TNFi										
TNFi	5.3	5.5	68.8	68.6	5.0	5.1	7.0	7.2	17.8	18.0
Rit.	7.8	6.4	74.6	71.7	5.7	4.9	9.3	7.3	22.4	20.1
Toc.	6.5	6.8	72.3	68.3	5.3	5.0	8.4	8.0	19.8	18.8
Aba.	7.5	5.6	71.1	71.4	5.5	5.0	8.8	7.6	20.7	18.9

Conclusions: Even if there are no true differences in risk by bDMARD,

confounding by indication will make the non-TNFi drugs appear less safe than the TNFi. A simple adjustment for age and sex will reduce this confounding dramatically, but residual confounding is still expected to give higher rates of AEs, and comparisons should be adjusted for medical history and comorbidities when possible.

PsA: an integrated perspective

OP0201 A PHASE 3 STUDY OF THE EFFICACY AND SAFETY OF IXEKIZUMAB IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS AND INADEQUATE RESPONSE TO TUMOUR NECROSIS FACTOR INHIBITOR(S)

P. Nash[1], B. Kirkham[2], M. Okada[3], P. Rahman[4], B. Combe[5], D.H. Adams[6], L.N. Kerr[6], C.H. Lee[6], C.L. Shuler[6], M.C. Genovese[7]. *[1]Univ of Queensland, Brisbane, Australia; [2]Guy's Hospital, London, United Kingdom; [3]St Luke's International Univ, Tokyo, Japan; [4]Memorial Univ of Newfoundland, St. John's, Canada; [5]Lapeyrnie Hospital, Montpellier Univ, Montpellier, France; [6]Eli Lilly and Company, Indianapolis; [7]Stanford Univ, Palo Alto, United States*

Background: Tumour necrosis factor inhibitors (TNF-i) have revolutionised the management of psoriatic arthritis (PsA) yet some patients (pts) have an inadequate response (IR) or intolerance. Ixekizumab (IXE), a monoclonal high affinity antibody that selectively targets IL-17, has shown efficacy in TNF-naïve PsA pts.[1]

Objectives: To compare efficacy and safety of IXE with placebo in pts with active PsA who are TNFi-IR.

Methods: In the 24 week (wk), double-blind, placebo-controlled period of a Phase 3 PsA study (SPIRIT-P2; NCT02349295), pts with prior IR or intolerance to 1 or 2 TNF-i were randomised to SC placebo or IXE 80 mg every 2 (Q2W) or 4 wks (Q4W), following a 160 mg initial dose at Wk 0. Pts with IR to treatment (protocol defined) received rescue therapy at Wk 16. Primary endpoint was ACR20 at Wk 24. Continuous data were analyzed using mixed-effects model for repeated measures; categorical data, using a logistic regression model with missing values imputed by non-responder imputation, which treats IR as non-responders.

Results: 363 pts were randomized: ~52 yrs old on average, female (53%), white (~92%), and IR to 1 or 2 TNF-i (204 [56.2%], 128 [35.3%], respectively) or TNF-intolerant (31 [8.5%]). Most pts had current psoriasis (93.4%) and BSA≥3 (62.5%). The majority (87%) completed the 24-wk, double-blind period. A significantly higher proportion of IXE- vs placebo-treated pts at Wk 24 achieved ACR20 (65 [53.3%], 59 [48%] vs. 23 [19.5%]; Q4W, Q2W, placebo, respectively), ACR50 (43 [35.2%], 41 [33.3%] vs 6 [5.1%]; Q4W, Q2W, placebo, respectively), ACR70 (27 [22.1%], 15 [12.2%] vs 0; Q4W, Q2W, placebo, respectively), MDA (34 [27.9%], 29 [23.6%] vs 4 [3.4%]; Q4W, Q2W, placebo, respectively), DAS28-CRP, and reductions in functional disability (HAQ-DI) (Table). A significantly higher proportion of IXE-Q4W- vs placebo-treated pts reached complete resolution of dactylitis (LDI-B=0). Although enthesitis improved from baseline with both IXE doses, rates of complete resolution (LEI=0) were not significantly different compared to placebo. At Wk 24, significantly greater proportions of IXE-treated pts with ≥3% BSA achieved PASI 75 than placebo-treated patients. The incidence of treatment-emergent adverse events (TEAE) was similar across groups (83 [68%], 90 [73.2%] vs 76 [64.4%]; Q4W, Q2W, placebo, respectively). A numerically higher proportion of IXE-treated pts reported infection and a significantly higher proportion reported injection site reactions (the majority were mild) (Table). Serious infection (0, 3 [2.4%], 0; Q4W, Q2W, placebo respectively), serious AE, and oral candidiasis were numerically higher with Q2W vs placebo. No deaths or cases of inflammatory bowel disease, uveitis, TB reactivation, or grade ≥3 neutropenia were reported.

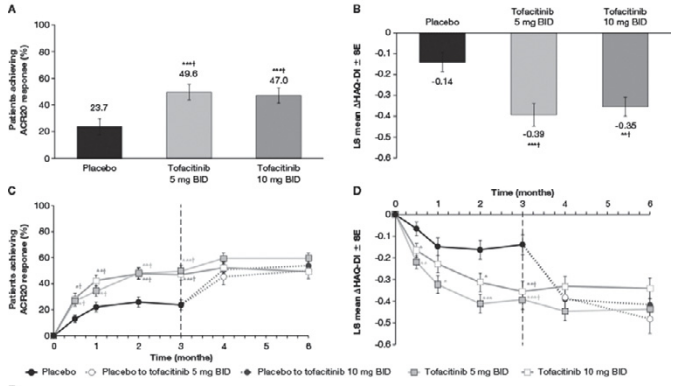
OP0202 EFFICACY AND SAFETY OF TOFACITINIB, AN ORAL JANUS KINASE INHIBITOR, IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS AND AN INADEQUATE RESPONSE TO TUMOUR NECROSIS FACTOR INHIBITORS: OPAL BEYOND, A RANDOMISED, DOUBLE-BLIND, PLACEBO-CONTROLLED, PHASE 3 TRIAL

D.D. Gladman[1], W.F.C. Rigby[2], V.F. Azevedo[3], F. Behrens[4], R. Blanco[5], A. Kaszuba[6], E. Kudlacz[7], C. Wang[7], S. Menon[7], T. Hendrikx[8], K.S. Kanik[7]. *[1]Department of Medicine, University of Toronto, Toronto Western Hospital, Toronto, Canada; [2]Geisel School of Medicine at Dartmouth, School of Medicine, Lebanon, United States; [3]Universidade Federal do Paraná, Curitiba, Brazil; [4]Johann Wolfgang Goethe University & Fraunhofer IME-TMP, Frankfurt, Germany; [5]Hospital Universitario Marques de Valdecilla, Santander, Spain; [6]Specjalistyczne Gabinety Lekarskie "DERMED", Lodz, Poland; [7]Pfizer Inc, Groton, CT; [8]Pfizer Inc, Collegeville, PA, United States*

Background: Tofacitinib is an oral Janus kinase inhibitor under investigation for treatment of PsA.



Objectives: Evaluation of efficacy and safety of tofacitinib vs placebo (PBO) in adult patients (pts) with active PsA and an inadequate response (IR) to TNF inhibitors (TNFi).

Methods: Eligible pts in this 6-month, randomised, PBO-controlled, double-blind, multicentre, Phase 3 study had ≥6 months' PsA diagnosis, met CASPAR criteria, had active arthritis (≥3 tender/painful and ≥3 swollen joints) at screening and baseline, active plaque psoriasis at screening and IR to ≥1 TNFi (discontinued due to inadequate efficacy or adverse event [AE]). Pts were randomised 2:2:1:1 to tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID or PBO (advancing to tofacitinib 5 or 10 mg BID in a blinded manner at Month [M]3). Ongoing treatment with 1 conventional synthetic DMARD was required. Pts were followed through M6. Primary endpoints were ACR20 response rate and change (Δ) from baseline in Health Assessment Questionnaire-Disability Index (HAQ-DI) at M3.

Results: Pts were 92.1% white, 55.3% female and mean age was 50.0 years. At baseline, mean swollen and tender/painful joint counts were 22.0 and 11.8 respectively; mean HAQ-DI score was 1.3; 69.8% of pts had LEI >0; 49.2% had Dactylitis Severity Score (DSS) >0. Most patients (62.7%) had ≥3% BSA affected by psoriasis, for whom median PASI score was 7.9. Discontinuation rate at M3 was 7.6%, and 87.6% completed M6. ACR20 response and ΔHAQ-DI significantly improved with both tofacitinib doses vs PBO at M3 (Fig 1A,B) and were maintained to M6 (Fig 1C,D). Tofacitinib 5 mg and 10 mg BID demonstrated superior ACR20 response vs PBO as early as Week 2 (26.7% [p≤0.05] and

28.8% [p≤0.05] vs 13.0%). Secondary endpoints at M3 for tofacitinib 5 mg and 10 mg respectively were: ACR50 response, 29.8% (p≤0.05), 28.0% (p≤0.05); ACR70 response, 16.8% (not significant [NS]), 14.4% (NS); ≥75% improvement of PASI in pts with baseline BSA ≥3% and PASI >0, 21.3% (NS), 43.2% (p<0.0001); ΔLEI and ΔDSS in pts with baseline score >0: ΔLEI, -1.3 (p≤0.05) and -1.3 (p≤0.05) (least squares mean [LSM]); ΔDSS, -5.2 (p≤0.05) and -5.4 (p≤0.05) (LSM). Effects were maintained to M6. Frequency of serious AEs and discontinuations due to AEs was low and similar across treatment groups (Fig 1E). The most common AEs were upper respiratory tract infection (5.3–10.8%), nasopharyngitis (1.5–10.7%) and headache (4.5–9.1%).

Figure 1. A. ACR20 response rates with tofacitinib vs placebo at M3, B. ΔHAQ-DI with tofacitinib vs placebo at M3, C. ACR20 response rates up to M6, D. ΔHAQ-DI up to M6, E. Safety summary (safety analysis set;[a] all causality)

Immunogenicity of biologics; myth or reality?

OP0203 IMPACT OF ADALIMUMAB SERUM CONCENTRATION ON EFFICACY AND ASSOCIATION BETWEEN ANTI-DRUG ANTIBODIES AND SERUM CONCENTRATION: 24 WEEK RESULTS FROM A PHASE III STUDY COMPARING SB5 (AN ADALIMUMAB BIOSIMILAR) WITH REFERENCE ADALIMUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS

J. Kay[1], M. Weinblatt[2], E. Keystone[3], M. Genovese[4], J. Ghil[5], S.Y. Cheong[5], E.E. Hong[5,5]. *[1]UMass Memorial Medical Center, Worcester;[2]Brigham and Women's Hospital, Boston, United States;[3]Mount Sinai Hospital, Toronto, Canada;[4]Stanford University, Palo Alto, United States;[5]Samsung Bioepis Co., Ltd., Incheon, Korea, Republic Of*

Background: SB5 has been developed as a biosimilar of reference adalimumab (ADL). The 24-week efficacy and safety results comparing SB5 and ADL were reported previously.[1] Here we report results of subgroup analyses of efficacy by adalimumab serum trough concentration (C_{trough}) and association between anti-drug antibodies (ADA) and C_{trough}.

Objectives: To investigate the impact of C_{trough} on efficacy and the association between ADA and C_{trough} in patients with rheumatoid arthritis (RA) treated with SB5 or ADL.

Methods: Patients with moderate to severe RA despite methotrexate treatment were randomly assigned to receive 40 mg of either SB5 or ADL administered subcutaneously every other week up to week 24. Blood samples were taken prior to study drug administration at weeks 0, 4, 8, 12, 16, and 24 to measure C_{trough}. The optimal C_{trough} cut-off point of adalimumab for good EULAR response at week 24 is reported to be 1.274 μg/mL.[2] Efficacy and immunogenicity were analysed in patients with C_{trough} <1.274 μg/mL and ≥1.274 μg/mL.

Results: C_{trough} was measured in 178 patients each from SB5 and ADL group. The post-dose mean C_{trough} was comparable up to week 24 for SB5 (range: 3.850 to 6.761 μg/mL) and ADL (range: 3.892 to 6.773 μg/mL). Generally, efficacy was higher in patients with C_{trough} ≥1.274 μg/mL for both SB5 and ADL but it was comparable between SB5 and ADL regardless of C_{trough} level. At week 24, the proportion of patients achieving good EULAR response, remission or low disease activity based on DAS28 was higher in patients with C_{trough} ≥1.274 μg/mL than in those with C_{trough} <1.274 μg/mL for both treatment groups (Figure). Other efficacy parameters, including ACR responses, DAS28, simplified disease activity index, and clinical disease activity index, showed similar results.

C_{trough} was higher for patients without detectable ADA, compared to those with ADA. Among patients with ADA, the proportion of patients with C_{trough} ≥1.274 μg/mL was 58.0% (29/50) for SB5 and 52.1% (25/48) for ADL. Among patients without detectable ADA, the proportion of patients with C_{trough} ≥1.274 μg/mL was 100.0% (121/121) for SB5 and 97.4% (114/117) for ADL.

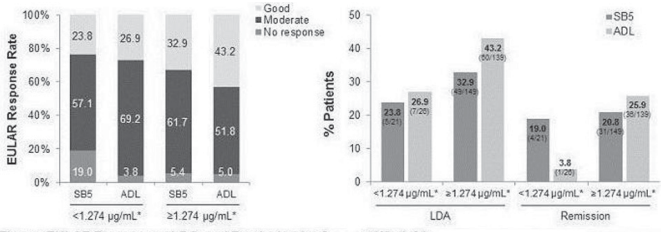

Figure. EULAR Responses, LDA, and Remission by C_{trough} at Week 24
*C_{trough} level; LDA, low disease activity
LDA defined as DAS28 ≤ 3.2 and remission defined as DAS28 < 2.6.

Conclusions: The presence of ADA reduces C_{trough} for both SB5 and ADL. In both treatment groups, almost all patients without detectable ADA, but only slightly more than half of patients with ADA, had C_{trough} ≥1.274 μg/mL at week 24. Efficacy and ADA incidence were generally comparable between SB5 and ADL regardless of C_{trough} level. However, patients with C_{trough} ≥1.274 μg/mL generally experienced greater efficacy of both SB5 and ADL than that in patients with C_{trough} <1.274 μg/mL.

OP0204 **IMPACT OF ANTI-DRUG ANTIBODY AND INJECTION SITE REACTION ON EFFICACY: 24-WEEK RESULTS FROM A PHASE III STUDY COMPARING SB4 (ETANERCEPT BIOSIMILAR) WITH REFERENCE ETANERCEPT IN PATIENTS WITH RHEUMATOID ARTHRITIS**

J. Vencovsky[1], P. Emery[2], E. Keystone[3], J. Ghil[4], S.Y. Cheong[4], E.E. Hong[4]. *[1]Institute of Rheumatology, Prague, Czech Republic; [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom; [3]Mount Sinai Hospital, Toronto, Canada; [4]Samsung Bioepis Co., Ltd., Incheon, Korea, Republic Of*

Background: SB4 is approved by the European Commission as a biosimilar of the reference etanercept (ETN). The phase III clinical study results have been reported previously.[1,2] Data to date shows no correlation between the development of anti-drug antibody (ADA) and clinical response or adverse events with etanercept treatment.
Objectives: To investigate the impact of the presence of ADA or injection site reaction (ISR) on efficacy in patients with rheumatoid arthritis (RA) treated with SB4 or ETN up to week 24.
Methods: In this phase III randomised, double blind study, patients with moderate to severe RA received 50 mg/week of either SB4 or ETN with background methotrexate (MTX) for 52 weeks. Efficacy, safety and immunogenicity were assessed.
Results: Up to week 24, the incidence of ADA (2 patients [0.4%] in SB4 vs 39 patients [13.1%] in ETN, $p < 0.001$) and the incidence of ISR (9 patients [3.0%] in SB4 vs 48 patients [16.2%] in ETN, $p < 0.001$) were significantly lower in SB4 compared to ETN. Due to the low incidence of ADA in the SB4 treatment group, the impact of ADA on efficacy could not be evaluated. Within the ETN treatment group at week 24, there was a trend towards increased efficacy (ACR20, ACR-N, change in DAS28, remission and low disease activity based on DAS28, SDAI, or CDAI) in patients without detectable ADA compared to patients with ADA (Table). In regards to ISR, efficacy tended to be higher in patients who did not experience ISR compared to those who did within each treatment group.
There was no correlation between the presence of ADA and incidence of ISR. In patients without detectable ADA and patients with ADA, respectively, 3.0% (9/297) vs. 0.0% (0/2) of patients from SB4 group and 16.3% (42/248) vs. 15.4% (6/39) of patients from the ETN group experienced ISR.

Table. Efficacy at week 24 by presence of ADA and ISR

	SB4 50 mg		ETN 50 mg	
	(+) ADA (n=2)	(−) ADA (n=297)	(+) ADA (n=39)	(−) ADA (n=257)
ACR20	2/2 (100.0%)	218/285 (76.5%)	24/36 (66.7%)	189/236 (80.1%)
ACR50	1/2 (50.0%)	127/285 (44.6%)	15/36 (41.7%)	101/236 (42.8%)
ACR70	0/2 (0.0%)	69/285 (24.2%)	9/36 (25.0%)	50/236 (21.2%)
ACR-N	48.8±19.38	45.0±29.14	40.3±30.33	44.3±27.70

Change in SDAI	−33.50±3.394	−25.69±14.641	−23.78±15.230	−25.37±12.831
Change in CDAI	−32.65±4.596	−24.73±14.120	−22.45±14.396	−24.57±12.750
	(+) ISR (n=9)	(−) ISR (n=290)	(+) ISR (n=48)	(−) ISR (n=249)
ACR20	5/7 (71.4%)	215/280 (76.8%)	30/39 (76.9%)	183/233 (78.5%)
ACR50	1/7 (14.3%)	127/280 (45.4%)	14/39 (35.9%)	102/233 (43.8%)
ACR70	1/7 (14.3%)	68/280 (24.3%)	7/39 (17.9%)	52/233 (22.3%)
ACR-N	32.6±28.18	45.3±29.06	41.8±28.80	44.1±27.95
Change in DAS28	−1.81±1.282	−2.59±1.371	−2.31±1.280	−2.54±1.324
Change in SDAI	−20.55±11.986	−25.86±14.654	−21.56±12.233	−25.77±13.216
Change in CDAI	−20.17±11.462	−24.88±14.140	−20.74±12.062	−24.89±13.036

Data are presented in either n' (%) or mean ± standard deviation.
ACR20/50/70: American College of Rheumatology 20%/50%/70% response rate; ACR-N: numeric index of the ACR response; ADA: anti-drug antibody; CDAI: clinical disease activity index; DAS28: disease activity score measured by 28 joints; ISR: injection site reaction; LDA: low disease activity; SDAI: simplified disease activity index.
ADA and ISR status defined positive for patients with at least one ADA or ISR up to week 24 regardless of the result at week 0.
ISR counted by treatment-emergent adverse event with high-level group term of administration site reactions.

Conclusions: Significantly fewer patients from SB4 developed ADA or experienced ISR compared to ETN, however the efficacy was still comparable between SB4 and ETN in patients without detectable ADA and in patients who did not experience ISR. Within the ETN group, there was a trend towards increased efficacy in patients without detectable ADA compared to patients with ADA. In both SB4 and ETN group, patients with ISR tended to have higher efficacy than patients without ISR. There was no correlation between the presence of ADA and ISR.

Which target / outcome is more relevant in the management of SLE?

OP0205 **ASSOCIATION BETWEEN T FOLLICULAR HELPER CELL AND PLASMABLAST CORRELATES WITH DISEASE ACTIVITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

S. Nakayamada, S. Kubo, M. Yoshikawa, Y. Miyazaki, S. Iwata, I. Miyagawa, K. Nakano, K. Saito, Y. Tanaka. *The First Department of Internal Medicine, Universitiy of Occupational and Environmental Health, Japan, Kitakyushu, Japan*

Background: Various immunological abnormalities contribute to the development and perpetuation of systemic lupus erythematosus (SLE). Since SLE is a molecularly heterogeneous disease, targeted therapy has not yet been fully established. It seems to be important to explore the characteristic and interaction among the immune cell phenotypes in this disease.
Objectives: The aim of this study was to assess the relationship between the peripheral immune cell phenotypes with clinical manifestations and responsiveness to immunosuppressive therapy in patients with SLE.
Methods: Peripheral blood mononuclear cells were obtained from 143 SLE patients and 26 healthy donors (HD). The blood samples were taken at baseline and week 24 after treatment. The subset of circulating B, T and dendritic cells was defined based on comprehensive 8-color flow cytometric analysis for human immune system termed "the Human Immunology Project" proposed by the National Institutes of Health (NIH) and the Federation of Clinical Immunology Societies (FOCIS). The correlation of immune cell phenotypes with clinical characteristics and responsiveness to immunosuppressive therapies, such as cyclophosphamide, mycophenolate mofetil, or calcineurin, in addition to high-dose glucocorticoids, were evaluated. Patients who were required more than two different immunosuppressant therapies in addition to glucocorticoids were considered treatment resistant.
Results: The frequency of $CD3^+CD4^+CXCR5^+ICOS^+$ T follicular helper (Tfh) cell, but not $CD3^+CD4^+CXCR3^+CCR6^-$ Th1 cell and $CD3^+CD4^+CXCR3^-CCR6^+$ Th17 cell, were higher in SLE than that in HD (mean 1.1 vs 0.8, p=0.01). The frequency of $CD19^+CD20^+IgD^+CD27^+$ central memory B cell and $CD19^+CD20^+IgD^-CD27^-$ effector B cell were higher in SLE than that in HD (mean 23.6 vs 15.1 and 10.7 vs 5.2, $p \leq 0.001$ and $p < 0.001$, respectively). The largest difference relative to the HD was observed in the proportion of $CD19^+CD20^-CD27^+CD38^+$ plasmablast, which was higher in SLE (mean 16.2 vs 3.7, $p < 0001$) and correlated with BILAG index ($r=0.24$, $p < 0.001$). The proportion of Tfh cell significantly correlated with serum IgG level ($r=0.35$, $p < 0.001$), and the proportion of $CD3^+CD4^+CXCR5^+ICOS^+CD69^+$ activated Tfh cell correlated with serum anti-Sm antibody level ($r=0.26$, p=0.01). Among helper T cell subsets (Th1, Th17, Treg and Tfh), the proportion of Tfh cell only showed positive correlation with that of plasmablast ($r=0.24$, p=0.02). Treatment resulted in marked improvement in disease activity scores, such as SLEDAI and BILAG and resulted in significant decreased proportions of plasmablast and Tfh cell (plasmablast; mean 17.6 to 10.1, $p < 0.01$, Tfh; mean 1.1 to 0.7, $p < 0.01$). The percentage of patients who showed treatment resistance was highest among patients with high percentage of Tfh cell (p=0.03).
Conclusions: Peripheral immuno-phenotyping confirmed the importance of Tfh cell and plasmablast in patients with SLE, *i.e.* activation of Tfh cell correlated with autoantibody production while plasmablast did with disease activity of SLE. Our findings supported the relevance of Tfh cell-plasmablast axis as a potential therapeutic target for SLE. The peripheral immunophenotyping might be useful in evaluating the pathogenesis and in determining the therapeutic target of each patient.

OP0206 **PERFORMANCE OF SLEDAI-2K TO DETECT A CLINICALLY MEANINGFUL CHANGE IN SLE DISEASE ACTIVITY: A 36-MONTH PROSPECTIVE COHORT STUDY OF 334 PATIENTS**

D. Jesus[1], M. Rodrigues[1], A. Matos[2,3], C. Henriques[2,3,4], J. da Silva[5,6], L. Inês[1,6,7]. *[1]CHUC Lupus Clinic, Rheumatology Department, Centro Hospitalar e Universitário de Coimbra, Coimbra; [2]School of Technology and Management, Polytechnic Institute of Viseu; [3]Centre for the Study of Education, Technologies and Health, Viseu; [4]Centre for Mathematics; [5]CHUC Lupus Clinic, Rheumatology Department; [6]Faculty of Medicine, University of Coimbra, Coimbra; [7]Faculty of Health Sciences, University of Beira Interior, Covilhã, Portugal*

Background: The Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) is the core determinant of response in the SLE Responder Index (SRI), a primary efficacy outcome in SLE clinical trials. However, SLEDAI is unable to discriminate partial improvement/worsening, as it scores each item

categorically. Furthermore, potentially severe lupus manifestations, such as hemolytic anemia are not scored in SLEDAI.
Objectives: To evaluate the performance of SLEDAI-2K to detect a clinically meaningful change in SLE disease activity.
Methods: Prospective cohort study of SLE patients followed at a tertiary care lupus clinic from January 2014 to December 2016. Consecutive patients fulfilling the ACR'97 and/or the SLICC'12 classification criteria were included. At each outpatient visit, disease activity from the last 30 days was scored in the Physician Global Assessment (PGA) (0–3 cm scale) and in SLEDAI-2k. The association between PGA and SLEDAI-2K at each visit was tested with Spearman's Correlation. A clinically meaningful change in SLE disease activity was defined as difference in PGA $\geq$0.3 cm at follow-up compared to the baseline visit. Performance of change in SLEDAI-2K was tested in two models: against worsening and improvement in PGA $\geq$0.3 cm from baseline using Receiver Operating Characteristic (ROC) curve analysis. Sensitivity, specificity, positive and negative predictive values (PPV, NPV) of SLEDAI-2k to change in PGA was calculated. Statistical significance was set at 0.05.
Results: We included 334 patients (87.1% female, mean age at baseline - 44.8±14.5 years). At baseline, median PGA and SLEDAI-2k score was 0.2 points (range 0–2.5) and 2 points (range 0–19), respectively. Eighty-three patients (24.8%) had a PGA $\geq$0.4 points at baseline. During follow-up of 36 months, 2129 visits were performed. PGA and SLEDAI-2K scores presented a high correlation (rho=0.82, $p<0.0001$) (fig. 1). Reductions in SLEDAI-2K presented in ROC analysis an area under curve (AUC) of 0.697 [95% CI (0.628–0.766), $p<0.0001$] for an improvement in PGA$\geq$0.3. For a worsening of PGA$\geq$0.3 points, increase in SLEDAI-2K presented an AUC of 0.877 [95% CI (0.822–0.932), $p<0.0001$]. Estimated sensitivities, specificities, PPV and NPV are presented in table 1.

Table 1. Performance of Sledai-2K to detect a clinically meaningful change in PGA, using cut-offs of decrease and increase (for a clinical improvement and worsening, respectively) in SLEDAI-2K $\geq$1 and $\geq$4 points

	Δ SLEDAI-2K≥1				Δ SLEDAI-2K≥4			
	Sens.	Spec.	PPV	NPV	Sens.	Spec.	PPV	NPV
Improvement PGA≥0.3	0.7	0.571	0.397	0.825	0.288	0.929	0.622	0.763
Worsening PGA≥0.3	0.725	0.903	0.627	0.936	0.353	0.996	0.947	0.873

Sens: Sensitivity; Spec: Specificity; PPV: Positive predictive value; NPV: Non predictive value.

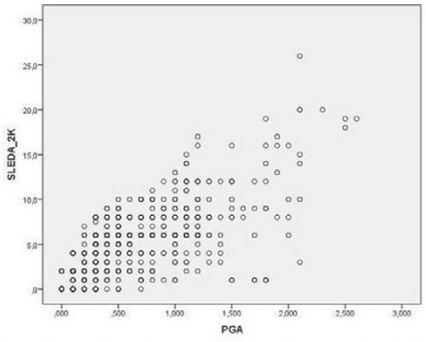

Fig. 1 Scatter diagram showing linear positive correlation between PGA and SLEDAI-2K scores (Spearman's correlation coefficient (rho) = 0.82, p <0.0001).

Conclusions: SLEDAI-2K presents a limited performance in detecting a clinically meaningful change in SLE disease activity, failing to identify more than a quarter of cases with clinically meaningful improvement or worsening. There is a need to optimize SLE disease activity measures.

Joint EULAR - EFIS session: tilting the balance: from disease to tolerance induction

OP0207 B CELL DEPLETION INCREASES REGULATORY T CELLS AND AMELIORATES SKIN AND LUNG FIBROSIS IN A BLEOMYCIN-INDUCED SYSTEMIC SCLEROSIS MODEL MOUSE

H. Numajiri, A. Yoshizaki, T. Fukasawa, S. Ebata, Y. Asano, S. Sato. *Department of Dermatology, The University of Tokyo Graduate School of Medicine, Hongo, Bunkyo-ku, Tokyo, Japan*

Background: B cells play a critical role in systemic autoimmunity and disease expression through various functions such as cytokine production and induction of other immune cell activation. Recently, some clinical studies have shown that the efficacy of B cell depletion therapy with rituximab, a chimeric monoclonal antibody against human CD20, in systemic sclerosis (SSc) patients. However, it still remains unclear why B cell depletion can be an effective treatment for SSc.
Objectives: The purpose of this study is to assess the role of B cell depletion in SSc. We evaluated the skin and lung fibrosis of bleomycin (BLM)-induced SSc model mice treated with B cell depletion. Furthermore, we investigated the effect of B cell depletion on T cell cytokine profile.
Methods: To generate BLM-induced SSc model mice, 300 μg of BLM was injected subcutaneously into the shaved backs of the C57BL/6 mice every other day for 4 weeks. Anti-mouse CD20 monoclonal antibodies, which can deplete mouse B cells, were also injected every 2 weeks from 2 weeks later starting BLM treatment. After 4 weeks of BLM treatment, skin and lung fibrosis were assessed histopathologically. T cells and B cells were isolated from spleen using magnetic cell sorting system. Purified T cells ($5x10^5$ cells) were cultured with B cells ($5x10^5$ cells) in the presence of phorbol 12-myristate 13-acetate, ionomycin, and anti-CD3/CD28 antibodies. Cytokine expressions in the fibrotic skin and lung were quantified by real-time polymerase chain reaction. Cytokine production of T cells and B cells were analyzed by flow cytometric analysis.
Results: Dermal thickness and lung fibrosis score increased in BLM-treated mice compared with phosphate buffer saline (PBS)-treated control mice. Frequencies of interleukin (IL)-10 producing splenic B cells significantly decreased in BLM-treated mice compared with PBS-treated mice, while IL-6 producing B cell frequencies increased. Moreover, interferon (IFN)-γ, IL-4, or IL-17 producing T cell frequencies increased in BLM-treated mice. There were no significant differences in regulatory T cell frequencies between BLM-treated and PBS-treated mice. B cell depletion increased IL-10 producing regulatory T cell frequencies in BLM-treated mice. By contrast, frequencies of IFN-γ, IL-4, or IL-17 producing T cells were significantly decreased by B cell depletion in BLM-treated mice. In addition, fibrogenic cytokine mRNA expression levels of skin and lung decreased in BLM-treated mice with B cell depletion. To assess the role of B cells on T cell cytokine production, purified splenic B cells from BLM- or PBS-treated mice were cultured with naive T cells. T cells which were cultured with B cells from BLM-treated mice produced greater amounts of INF-γ, IL-4, and IL-17 than those cultured with PBS-treated mouse B cells. By contrast, B cells from PBS-treated mice induced a higher amount of IL-10 production from T cells than those from BLM-treated mice.
Conclusions: B cell depletion inhibited skin and lung fibrosis in BLM-treated mice. Furthermore, B cell depletion increased regulatory T cell frequencies in BLM-treated mice, though INF-γ, IL-4, and IL-17 producing T cell frequencies were decreased by B cell depletion. These results suggest that B cell depletion alters T cell cytokine profile, which results in inhibition of fibrosis in this model.

OP0208 SYNOVIAL TISSUE OF RA PATIENTS IN REMISSION CONTAINS A UNIQUE POPULATION OF REGULATORY MACROPHAGES

A. Elmesmari[1], S. Alivernini[2], B. Tolusso[2], D. Vaughan[1], G. Di Sante[2], L. Petricca[2], E. Gremese[2], G. Ferraccioli[2], I.B. McInnes[1], M. Kurowska-Stolarska[1]. *[1]Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow, United Kingdom; [2]Division of Rheumatology, Fondazione Policlinico Universitario A. Gemelli, Catholic University of the Sacred Heart, Rome, Italy*

Background: The majority of RA treatments target inflammation or the adaptive immune response. Partial- or non-response is common and only a minority have sustained remission. There is a knowledge gap in understanding the mechanisms that could reinstate synovial homeostasis in RA. Tissue macrophages may have a role in this process; they are present in healthy synovium and aid resolution of the inflammation in experimental models of RA. However, little is known about the regulatory properties of human synovial tissue macrophages.
Objectives: Our hypothesis is that healthy and RA synovium in remission contain macrophages with anti-inflammatory/repair properties and identifying the effector pathways that drive their function could facilitate therapeutic restoration of synovial homeostasis in RA.
Methods: We developed a flow cytometry sorting strategy for harvesting tissue-resident macrophages obtained from digested synovial biopsies of RA patients (n=21, including in remission n=5; and active RA n=16). Cells were labelled with cell lineage-specific antibodies; then macrophages were gated based on their expression of $CD64^{pos}CD11b^{pos}MHCII^{pos}Lineage^{neg}$. The potential homeostatic/repair macrophage was preliminary identified by the presence of CD206 marker. $CD206^{pos}$ and $CD206^{neg}$ macrophages were sorted using a FACS Aria III and RNAseq performed to characterise their functional signature. In some experiment, macrophages were seeded on collagen-coated plates and production of TNFa evaluated.
Results: All synovial tissue macrophages from RA in remission were $CD206^{pos}$ whereas a substantial number of synovial macrophages from active RA tissue were $CD206^{neg}$. Gene expression analyses and functional assays suggest that these populations represent distinct phenotypes in the activation spectrum. $CD206^{neg}$ macrophages have high expression of microRNA-155, which drives production of inflammatory mediators *e.g.* TNFa. In contrast, $CD206^{pos}$ macrophages showed regulatory properties characterised by increased expression of soluble (*e.g. IL10, TGFB*), surface (*e.g. IL4/14R, TGFBR1/2*) and cellular (*e.g. SHIP1, TAM, SMAD2, STAT6*) inhibitors of inflammatory activation, and increased expression of repair markers (*e.g. ARG2 and CCL18*).
Conclusions: We propose therefore that anti-inflammatory/repair macrophages may be present in human synovial tissues in remission representing a hitherto unnoticed regulatory tissue mechanism.

What to do about comorbidity?

OP0209-HPR INCIDENCE OF FIRST CARDIOVASCULAR EVENT IN SPANISH PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATIC DISEASES: PROSPECTIVE DATA FROM THE CARMA PROJECT

M.A. Martin Martinez[1], S. Castañeda[2], C. Gonzalez-Juanatey[3], F. Sanchez-Alonso[1], S. Marsal Barril[4], M. Romera-Baures[5], J. Santos-Rey[6], J.A. Pinto-Tasende[7], J. Tornero-Molina[8], R. Lopez-Gonzalez[9], M.D. Sanchez-Gonzalez[10], J. Llorca[11], M.A. Gonzalez-Gay[12]. *[1]Research of Unit of Spanish Society of Rheumatology; [2]Division of Rheumatology. Hospital Universitario la Princesa, Iis-Princesa, Madrid; [3]Division of Cardiology. Hospital Lucus Augusti, LUGO; [4]Division of Rheumatology. Hospital Universitario Vall D Hebron; [5]Division of Rheumatology. Hospital Universitario Bellvitge, Barcelona; [6]Division of Rheumatology. Hospital Virgen de la Salud, TOLEDO; [7]Division of Rheumatology. Complejo Hospitalario a Coruña, la Coruña; [8]Division of Rheumatology. Hospital Universitario de Guadalajara, Guadalajara; [9]Division of Rheumatology. Hospital Virgen de la Concha, ZAMORA; [10]Division of Rheumatolgy. Hospital Universitario de Salamanca, Salamanca; [11]Division of Epidemiology and Computational Biology, School of Medicine, University of Cantabria, Ciber Epidemiologia y Salud Publica (Ciberesp); [12]Division of Rheumatology, Hospital Universitario Marques de Valdecilla, and Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Rheumatology Division, IDIVAL, Santander, Spain*

Objectives: To determine the incidence and risk factors implicated in the development of first cardiovascular event (CVE) in patients with chronic inflammatory rheumatic diseases (CIRD) attending rheumatology clinics after 2.5 years of follow-up.
Methods: Analysis of data after 2.5 years of follow-up in an observational prospective study [CARdiovascular in rheuMAtology (CARMA) project] that includes a cohort of patients with CIRD [rheumatoid arthritis (RA), ankylosing spondylitis (AS), and psoriatic arthritis (PsA)] and another cohort of matched individuals without CIRD attending outpatient rheumatology clinics from 67 hospitals in Spain. The cumulative incidence per 1000 patients and the incidence density per 1000 patient-months of non-fatal CVE were estimated in both cohorts at 2.5 years from the start of the project. Weibull proportional hazard model was used to calculate the Hazard Ratio (HR) and 95% confidence interval (95% CI) of the risk factors involved in the development of CVD events. Losses to follow-up and their causes were also analyzed.
Results: The total number patient who completed the follow-up visit at 2.5 years was 2,598 (89.2% of those who started the study). Seven patients had died due to CVE and 23 because of non-CVE. The higher number of losses to follow-up was found in the control group (15.81%), because many of them were not periodically follow-up at the outpatient clinics. Cardiovascular cumulative incidence in patients with CIRD 15.30 cases per 1000 patients (95% CI: 12.93–17.67), being higher in AS patients 22.03 (95% CI: 11.01–33.04). The higher risk of developing a first CVE during the 2.5 years of follow-up was in patients with AS (HR: 4.11, 95% CI: 1.07–15.79; p: 0.04), those with older age (HR:1.09; 95% CI: 1.05–1.13, $p<0.001$), higher systolic blood pressure (HR: 1.02; 95% CI: 1.00–1.04, p=0, 01) and longer duration of the rheumatic disease (HR: 1.07; 95% CI: 1.03–1.12), $p<0.01$). In contrast, woman gender was a protective factor (HR: 0.43; 95% CI: 0.18–1.00, p=0.05).
Conclusions: Patients with AS prospectively followed-up at rheumatology outpatients clinics show higher risk of developing a first CVE than those with RA or PsA. Besides traditional CVD risk factors a longer time course of the disease is a risk factor for the development of CVD in patients with CIRD.

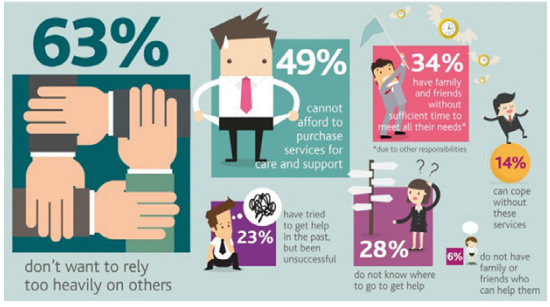
Difficult to reach patient groups

OP0210-PARE THE DEVELOPMENT AND EVALUATION OF AN INTERACTIVE HEALTH COMMUNICATION APPLICATION TO EDUCATE AND EMPOWER YOUNG PEOPLE LIVING WITH JUVENILE IDIOPATHIC ARTHRITIS: A PILOT STUDY

S.R. Stones[1,2], S.M. Cruickshank[3], S.M.M. Verstappen[4] on behalf of MyJIA Expert Advisory Group. *[1]School of Healthcare, University of Leeds, Leeds; [2]Faculty of Life Sciences; [3]School of Biological Sciences; [4]Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester, United Kingdom*

Background: In parallel with clinical care, it is equally important to empower young people with juvenile idiopathic arthritis (JIA) to develop self-efficacy skills, so that they can competently self-manage their health, particularly as they transition into adult health services.[1] Capitalising on the popularity of technology, web-enabled tools represent a novel and effective way of engaging young people with JIA. A Cochrane review of Internet Health Communication Applications (IHCAs) found that IHCAs have a positive effect on self-efficacy, empowering individuals to become more knowledgeable.[2]
Objectives: The aim of this study was to: i) develop and evaluate an IHCA in young people with JIA, aged 16 to 25 years; and ii) investigate whether an IHCA enhanced young people's condition-specific knowledge, and their self-efficacy to manage their health.
Methods: Young people aged 16 to 25 with a self-reported diagnosis of JIA were recruited to take part via social media. The IHCA was built using Microsoft PowerPoint and iSpring Suite (Figure 1). A virtual advisory group of patients, parents and healthcare professionals were involved throughout the design and development of the IHCA. The contents of the IHCA was obtained for existing published sources. Matching anonymous pre- and post-participation questionnaires were used to assess differences in knowledge of JIA and self-efficacy skills.
Results: In total, 23 (79%) young people with JIA completed both pre- and post-participation questionnaires. Most young people reported that their preferred source of condition-related information was obtained via an internet search engine (83%). Prior to completing the IHCA, only 22% of young people reported that they had an excellent understanding of JIA. After completing the IHCA, there was a significant improvement in young people's condition-specific understanding. Similarly, after completing the IHCA, there was a significant improvement in young people's confidence to better self-manage their health. Interestingly, only 30% of young people reported that the information which health professionals provided to them about JIA was adequate, in terms of comprehension and usefulness. Qualitative findings identified three core themes: resource content, practical support and accessibility/functionality. Young people liked the way that information was presented, as well as practical steps they could take to improve their health.



Conclusions: Quantitative results correspond with qualitative findings, indicating that the IHCA was well-received by young people with JIA. Condition-specific understanding was enhanced after completing the IHCA, as was participants' confidence in their self-efficacy and disease self-management capabilities. These results indicate that with ongoing development and larger scale evaluation, implementation of this IHCA is feasible.

OP0211-PARE **WHO CARES? AN INVESTIGATION OF THE HEALTH AND PERCEIVED SOCIAL CARE NEEDS OF PEOPLE WITH RHEUMATOID ARTHRITIS LIVING IN SCOTLAND**

C. O'Neill[1], A. Bosworth[2], K.R. Martin[3]. *[1]Policy & Public Affairs; [2]CEO, National Rheumatoid Arthritis Society, Maidenhead; [3]Epidemiology, University of Aberdeen, Aberdeen, United Kingdom*

Background: Effective and sufficient levels of care and support for individuals newly diagnosed and those with established Rheumatoid Arthritis (RA) are needed to ensure optimal physical and mental health, as well as health-related quality of life. The aim of this study was to explore the extent of care needs among individuals with RA living in Scotland, UK and the factors that contribute to them, such as co-morbidities, perceived caregiver burden and complex care needs.
Objectives: To establish whether the health and social care needs of people with RA in Scotland were being met, if there was regional variation and what other factors impacted such as wealth and age.
Methods: A cross-sectional study of individuals with RA who responded to an online survey (available 11 Nov 2015 to 22 Jan 2016) who were aged ≥16 years, lived in Scotland and reported they had received a clinical diagnosis of RA. Respondents were allowed to skip questions they wished not to answer; standardised instruments were used (e.g., the Self-administered Comorbidity Questionnaire and the Self-Perceived Burden Scale). Descriptive analyses of quantitative data and thematic analyses of free text responses were conducted.
Results: Overall, 387 individuals participated. The majority were female, of White Scottish or White British background, 45–64 years, and lived in a household with ≥2 people. The majority, 83%, reported well established RA (diagnosis ≥2 years ago) and at least one other comorbidity (78%) – most commonly depression (30%). The average number of medications taken for RA was 3.2 (range 0–7) and 30% reported taking 3 medications in total. Of those receiving care, the majority (97/101) named family or friends/neighbours as caregivers and 76% (80/97) had an elevated level of self-perceived burden on their caregiver. Respondents who reported anxiety or depression had significantly higher average self-perceived burden scores when compared to those without, 33.0 versus 27.3.
89% responded that they did not know what types of circumstances might make them eligible for care and support from their local Council, and only 10% reported receiving information about care and support from their local council. Very few (n=40) had an assessment, with half being deemed eligible for support from their local council.

Conclusions: Survey responses suggest individuals with RA lack fundamental information about qualifying for and accessing formal resources and services provided by their local council. This is especially crucial for two reasons: 1) respondents indicated they do not want to rely heavily on others, like family or friends who are often the primary caregivers; 2) depression and anxiety are highly prevalent in this population. It is important to ensure those with RA do not have unmet needs at any stage, from being newly diagnosed to having established RA, so that they can flourish at home, at work and in their leisure time. Local councils should make access to information about help with formal social care easily accessible and ensure that health professionals know how best to sign-post people.

Macrophage M2 polarization: implications in fibrotizing diseases

OP0212 **ENDOTHELIN-1 INDUCES A PROFIBROTIC PHENOTYPE IN CULTURED HUMAN MICROVASCULAR ENDOTHELIAL AND CIRCULATING MONOCYTE/MACROPHAGE CELLS**

S. Soldano[1], P. Montagna[1], R. Brizzolara[1], A.C. Trombetta[1], A. Sulli[1], C. Pizzorni[1], M. Ghio[1], S. Paolino[1], V. Smith[2], M. Cutolo[1]. *[1]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genoa, Genoa, Italy; [2]Department of Rheumatology, Ghent University Hospital, Ghent, Belgium*

Background: The alteration of microvascular endothelial cell (EC) functions and the presence of macrophages in the immune inflammatory infiltrate, followed by the transition of these cell types into a profibrotic phenotype, represent early and crucial pathological features of the fibrotic process in systemic sclerosis (SSc) (1). The alternatively activated macrophage subset M2a was found in several diseases characterized by extensive fibrosis (1). M2a macrophages express specific phenotype markers, CD206 (mannose receptor), CD204 and CD163 (scavenger receptors) as well as profibrotic molecules, primarily transforming growth factor-β1 (TGFβ1) (1). Endothelin-1 (ET1) and/or TGFβ1 are known to induce the transition of fibroblasts into profibrotic myofibroblasts, which are key mediators of fibrosis in SSc.
Objectives: To investigate the effects of ET1 in inducing a profibrotic phenotype in cultured human microvascular ECs (HMVECs) and macrophages.
Methods: HMVECs, at 3rd culture passage, were grown in endothelial cell medium (EGM2MV) and treated for 6 days with ET1 (100nM) or treated for 1 hr with ET1 receptor antagonist ($ET_{A/B}$RA, bosentan 10μM) before stimulation with ET1.
Human monocytes were isolated from peripheral blood mononuclear cells of healthy subjects using a monocyte isolation kit. The cells were maintained in RPMI growth medium for 24 hrs and then treated for 6 days with ET1 or treated for 1 hr with bosentan before stimulation with ET1.
Cultured HMVECs and monocytes maintained in EGM2MV and RPMI growth medium, respectively, were used as untreated cells. Gene and protein expression of profibrotic myofibroblast markers –α-smooth muscle actin (α-SMA), fibroblast specific protein-1 (S100A4), type 1 collagen (COL1) and fibronectin (FN) – were evaluated by quantitative real time polymerase chain reaction (qRT-PCR), Western blotting (WB) and immunocytochemistry (ICC) in cultured HMVECs. Gene and protein expression of M2a phenotype markers (CD206, CD204, CD163) and TGFβ1 were investigated by qRT-PCR and WB in cultured human macrophages. Statistical analysis was carried out by Mann-Whitney non-parametric test.
Results: In cultured HMVECs, ET1 induced the significant upregulation of the gene expression of α-SMA, S100A4 (myofibroblast markers), COL1 and FN, compared to untreated cells ($p<0.001$;$p<0.001$;$p<0.05$;$p<0.01$). $ET_{A/B}$RA significantly contrasted the ET1 mediated transition of HMVECs into a profibrotic phenotype ($p<0.05$ for α-SMA, COL1 and FN; $p<0.01$ for S100A4 vs. ET1-treated cells).
In cultured human macrophages, ET1 induced the significant overexpression of M2a markers ($p<0.05$ for CD204 and CD163;$p<0.01$ for CD206) and TGFβ1 ($p<0.01$) compared to untreated cells. $ET_{A/B}$RA significantly contrasted the ET1-mediated transition of cultured macrophages into profibrotic M2a ($p<0.05$ vs. ET1-treated cells, for all investigated proteins). Data were confirmed by WB and ICC on both cultured cell types.
Conclusions: ET1 seems to be involved in the early phases of the fibrotic process by inducing the transition of both cultured HMVECs and macrophages into a profibrotic phenotype, myofibroblast and M2a respectively (observed in SSc), a process which is apparently contrasted by $ET_{A/B}$RA treatment.

OP0213 **MACROPHAGES FROM A SCLERODERMA SUBGROUP WITH HIGHER SKIN SCORES EXPRESS ACTIVATION MARKERS AND INDUCE FIBROBLASTS IN CO-CULTURE**

J. King, D. Sleep, Y. Sohrabi, A. Tam, B.A. Abdi, D. Abraham, C. Denton, R. Stratton. *Centre for Rheumatology and Connective Tissue Diseases, Royal Free Hospital, London, United Kingdom*

Background: Scleroderma (SSc) is characterized by pathological fibrosis. The mechanisms by which fibrosis occurs in SSc are not fully understood.
Alternatively activated M2-like macrophages are associated with fibrosis and have been found to have an important role in pathological fibrosis in humans. Therefore, there is interest in elucidating their role in SSc. M2 macrophages express mannose receptor CD206 and are known to secrete a number of soluble factors to establish a pro-fibrotic milieu when present in damaged tissues.
Furthermore, we have shown adenosine tri-phosphate (ATP) concentration is increased in the skin of patients with SSc. Within the extra-cellular environment, ATP is a Damage-Associated Molecular Pattern (DAMP), binding the P2X class of purinergic receptors. Such mechanisms may contribute to SSc pathology.
Objectives: In this study, we explore the relationship of macrophage CD206 and $P2X_7$ expression to Rodnan Skin Score. The role of these cells in establishing fibrosis was also examined *in vitro*.
Methods: 17 SSc patients and 9 controls were consented and their skin score recorded. Macrophages were derived from peripheral blood mononuclear cells (PBMCs) and identified through CD14 expression by FACS. CD206 and $P2X_7$

co-expression was quantified. CD206 immunofluorescence of skin biopsies was also performed.
Macrophages were co-cultured with $8x10^4$ and $2x10^4$ fibroblasts in a collagen matrix and within a monolayer respectively.
Collagen gel contraction was quantified as a measure of fibrotic activity. CTGF and Collagen mRNA expression from gel matrices and cellular monolayers was quantified by qPCR.
Results: CD206 and $P2X_7$ expression is higher on SSc PBMC-derived macrophages (mean fluorescence 776.1 SD=409.1, 724.4 SD=455.3) compared to healthy controls (mean fluorescence 632.2 SD=73.7, 472.9 SD=25.4). There is significant correlation of CD206 expression to $P2X_7$ expression ($p<0.001$, r2=0.76) and CD206 expression is significantly correlated to Rodnan skin score ($p<0.05$, r2=0.26). $P2X_7$ expression is positively correlated to skin score. Double positive P2X7 and CD206 cells were seen in a subgroup with higher skin scores. Healthy fibroblasts co-cultured with scleroderma macrophages showed increased collagen mRNA by qPCR compared to co-culture with healthy macrophages ($p<0.01$). CTGF mRNA was positively correlated with macrophage P2X7 (r2=0.23) and CD206 (r2=0.81) expression. Preliminary work suggests contraction of collagen discs in fibroblast and macrophage co-culture is increased with SSc macrophages compared to healthy controls.
Conclusions: Data indicates a correlation between disease severity and CD206 expression by macrophages. Upregulation of CTGF and collagen expression in fibroblasts co-cultured with macrophages expressing high CD206 suggests a role for these cells in pathogenic fibrosis. The co-expression of high levels of $P2X_7$ with CD206 also indicates a possible role for the purinergic pathway in SSc fibrosis.
Future work will examine the mechanism of macrophage-fibroblast cross-talk and investigate the effect of inhibitors of CD206.

Mucosal B cells: gatekeepers of immune function

OP0214 ACTIVATION STATUS OF MUCOSAL-ASSOCIATED INVARIANT T CELLS REFLECTS PATHOLOGY OF SYSTEMIC LUPUS ERYTHEMATOSUS

A. Chiba[1], G. Murayama[1,2], N. Tamura[2], K. Yamaji[2], Y. Takasaki[2], S. Miyake[1]. *[1]Immunology; [2]Internal Medicine and Rheumatology, Juntendo University School of Medicine, Tokyo, Japan*

Background: Mucosal-associated invariant T (MAIT) cells are innate-like lymphocytes that express a semi-invariant TCRα chain (Vα7.2-Jα33 in humans). MAIT cells are restricted by the MHC-related molecule-1 (MR1) and uniquely recognize vitamin B metabolites presented by MR1. Like other innate-like lymphocytes, MAIT cells are also activated by cytokines in the absence of exogenous antigens. Human MAIT cells are abundant and constitute approximately 5% of peripheral blood T cells, suggesting possible roles of MAIT cells in various types of immune responses.
Objectives: We aimed to investigate whether MAIT cells are involved in systemic lupus erythematous (SLE).
Methods: Peripheral blood was collected from SLE patients and healthy volunteers. Informed consent was obtained from all individuals according to institutional ethical guidelines. Disease activity was measured based on the SLE disease activity index (SLEDAI) and a SLEDAI score $\geq$5 was defined as active disease. Peripheral blood mononuclear cells (PBMC) were stained with anti-human monoclonal antibodies against CD3, γδTCR, Vα7.2TCR, CD161, CD95 (Fas) and CD69, and then analyzed by FACS. $CD19^+$B cells or $CD14^+$monocytes were isolated from PBMC of healthy controls (HC) or SLE patients by using magnetic cell sorting. MAIT cells from healthy controls were co-cultured with B cells or monocytes in the presence of MR1 ligand (MR1L), and the expression of CD69 on MAIT cells was evaluated by FACS. Cytokine levels in plasma samples and culture supernatants were measured by ELISA and Bioplex assay. PBMC were cultured in the presence of various cytokines, and CD69 expression on MAIT cells was analyzed by FACS.
Results: The frequency of MAIT cells was markedly reduced in SLE. Reduced numbers of MAIT cells were not attributable to the downregulation of surface markers, but were partially due to the enhanced cell death of MAIT cells, possibly by activation-induced cell death. The CD69 expression levels on MAIT cells in SLE correlated with disease activity. Monocytes from patients with SLE exhibited increased ability to induce MAIT cell activation, and the profound MAIT cell activating capacity of lupus monocytes was associated with enhanced IL-12 production in the culture supernatants. The plasma concentration of IL-6, IL-18 and IFNα positively correlated with the expression levels of CD69 on MAIT cells in SLE. MAIT cells were activated by cytokines including IFNα, IL-15, and IL-12 plus IL-18 in the absence of exogenous antigens.
Conclusions: These results suggest that MAIT cells reflect the pathological condition of SLE and their activated status correlates with disease activity.

OP0215 ROLE OF INHIBITORY IGG FC RECEPTOR IIB ON B CELLS AND MONOCYTES IN YAA-RELATED MURINE LUPUS

S. Hirose[1], L. Qingshun[1], M. Ohtsuji[1], H. Nishimura[1], H. Amano[2], S.J. Verbeek[3]. *[1]Biomedical Engineering, Toin University of Yokohama, Yokohama; [2]Rheumatology and Internal Medicine, Juntendo University School of Medicine, Tokyo, Japan; [3]Human Genetics, Leiden University Medical Center, Leiden, Netherlands*

Background: FcγRIIB-deficient C57BL/6 (B6) mice spontaneously develop severe lupus nephritis in combination with *Yaa* locus (TLR7-duplication).
Objectives: The aim of this study is to clarify the cell type-specific roles of FcγRIIB for the pathogenesis of *Yaa*-related lupus.
Methods: We established B cell-specific ($CD19^{Cre}$.*Yaa*), myeloid-derived cell-specific ($C/EBP\alpha^{Cre}$.*Yaa*), and dendritic cell (DC)-specific ($CD11c^{Cre}$.*Yaa*) FcγRIIB-deficient mice on B6.*Yaa* background, and compared the disease features of these mice with full FcγRIIB-deficient B6.$Fc\gamma RIIB^{-/-}$.*Yaa* mice.
Results: $CD19^{Cre}$.*Yaa* mice developed milder lupus nephritis compared to B6.$Fc\gamma RIIb^{-/-}$.*Yaa* mice, indicating that FcγRIIB deficiency on only B cells is not sufficient for the development of severe disease. Surprisingly, $C/EBP\alpha^{Cre}$.*Yaa* mice developed similar mild disease as $CD19^{Cre}$.*Yaa* mice whereas $CD11c^{Cre}$.*Yaa* stayed disease free. These observations indicate that, in B6. $Fc\gamma RIIB^{-/-}$.*Yaa* mice, FcγRIIB deficiency on both B cells and myeloid cells, but not on DCs, contribute to the development of severe lupus with high autoantibody titers. Flow cytometric analysis showed that the frequency of peripheral $Gr\text{-}1^-$, but not $Gr\text{-}1^+$, monocytes was increased and correlated positively with the frequency of splenic PNA^+ activated B cells in B6.$Fc\gamma RIIB^{-/-}$.*Yaa* and C/EBPa^{Cre}.*Yaa*, but not $CD19^{Cre}$.*Yaa*, mice. This suggests a link between FcγRIIB deficiency on monocytes, the high frequency of $Gr\text{-}1^-$ monocytes and B cell activation. Transcriptome analysis of $Gr\text{-}1^+$ and $Gr\text{-}1^-$ monocytes revealed that B cell-stimulating factor-3 (BSF-3), IL-10, and IL-1β were all up-regulated in $Gr\text{-}1^-$ monocytes.
Conclusions: FcγRIIB on B cells and monocytes controls B cell activation and autoimmune responses via different but synergistic pathways in *Yaa*-related lupus nephritis.

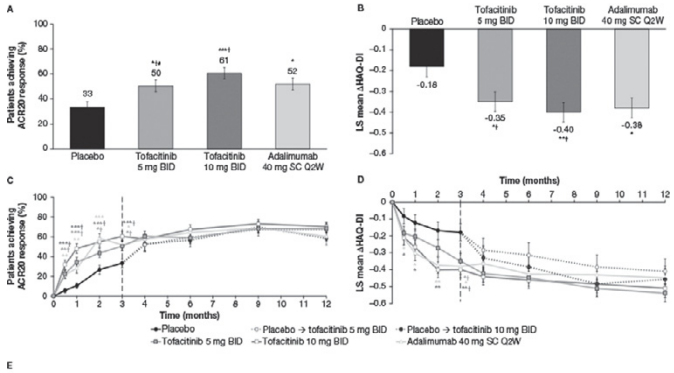
PsA: the options grow!

OP0216 EFFICACY AND SAFETY OF TOFACITINIB, AN ORAL JANUS KINASE INHIBITOR, OR ADALIMUMAB IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS AND AN INADEQUATE RESPONSE TO CONVENTIONAL SYNTHETIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS (CSDMARDS): A RANDOMISED, PLACEBO-CONTROLLED, PHASE 3 TRIAL



P.J. Mease[1], S. Hall[2], O. FitzGerald[3], D. van der Heijde[4], J.F. Merola[5], F. Avila-Zapata[6], D. Cieślak[7], D. Graham[8], C. Wang[8], S. Menon[8], T. Hendrikx[9], K.S. Kanik[8]. *[1]Swedish Medical Center and University of Washington, Seattle, WA, United States; [2]Cabrini Health and Monash University, Melbourne, Australia; [3]Department of Rheumatology, St Vincent's University Hospital, Dublin, Ireland; [4]Leiden University Medical Center, Leiden, Netherlands; [5]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, United States; [6]Centro Multidisciplinario para el Desarrollo Especializado de la Investigacion Clinica en Yucatán S.C.P, Yucatán, Mexico; [7]Poznan University, Poznan, Poland; [8]Pfizer Inc, Groton, CT; [9]Pfizer Inc, Collegeville, PA, United States*

Background: Tofacitinib is an oral Janus kinase inhibitor under investigation for treatment of psoriatic arthritis (PsA).
Objectives: To assess the efficacy and safety of tofacitinib vs placebo (PBO) in patients (pts) with active PsA.
Methods: Eligible pts in this randomised, PBO- and active-controlled, 12-month Phase 3 trial had $\geq$6-months' PsA diagnosis, fulfilled CASPAR criteria, had active arthritis ($\geq$3 tender/painful and $\geq$3 swollen joints) and active plaque psoriasis at screening, inadequate response to $\geq$1 csDMARD, and were tumour necrosis factor-inhibitor (TNFi)-naïve. 422 pts were randomised 2:2:2:1:1 to tofacitinib 5 or 10 mg twice daily (BID), adalimumab 40 mg subcutaneous injection every 2 weeks, or PBO (advancing to tofacitinib 5 or 10 mg BID at Month [M]3).

Stable treatment with 1 csDMARD was required. Primary endpoints comparing tofacitinib vs PBO were ACR20 response rate and change from baseline in Health Assessment Questionnaire Disability Index (ΔHAQ-DI) at M3. Secondary endpoints included: ACR20 response rates and ΔHAQ-DI through M12; pts achieving ACR50, ACR70, ≥75% improvement of PASI and PsARC at all time points; and changes from baseline in LEI, Dactylitis Severity Score and SPARCC Enthesitis Index. Radiographic progression was assessed by van der Heijde-modified Total Sharp Score (mTSS).

Results: 96.9% of pts were white and 53.3% were female; mean age was 47.9 years. 96.2% and 88.4% of pts completed M3 and M12, respectively. At M3, tofacitinib 5 and 10 mg BID significantly improved ACR20 response rates (50.5% [p≤0.05] and 60.6% [p<0.0001] vs 33.3%; Fig 1A) and ΔHAQ-DI (-0.35 [p≤0.05] and -0.40 [p<0.001] vs -0.18; Fig 1B) vs PBO, with responses maintained to M12 (Fig 1C&D). Greater efficacy was also seen for adalimumab vs PBO. Tofacitinib 5 and 10 mg BID were superior to PBO for ACR20 response rates at Week 2 (22.4% [p<0.001] and 31.7% [p<0.0001] vs 5.7%; Fig 1C). Secondary endpoints supported primary findings (data not shown). >91% of pts were radiographic non-progressors at M12 (defined as an increase from baseline in mTSS ≤0.5). M12 safety findings were similar between groups (Fig 1E). The most common adverse events were upper respiratory tract infection (7.5–10.6%), nasopharyngitis (7.5–11.5%) and headache (3.8–10.6%).

Figure 1. A. ACR20 response rates with tofacitinib vs placebo at M3, B. ΔHAQ-DI with tofacitinib vs placebo at M3, C. ACR20 response rates up to M12, D. ΔHAQ-DI up to M12, E. Safety summary (safety analysis set; all causality)

OP0217 USTEKINUMAB IS SUPERIOR TO TNF INHIBITOR TREATMENT IN RESOLVING ENTHESITIS IN PSA PATIENTS WITH ACTIVE ENTHESITIS- RESULTS FROM THE ENTHESIAL CLEARANCE IN PSORIATIC ARTHRITIS (ECLIPSA) STUDY

E.G. Araujo, M. Englbrecht, S. Hoepken, S. Finzel, A. Hueber, J. Rech, G. Schett. *Internal Medicine 3 Rheumatology and Immunology, Universitätsklinikum Erlangen, Erlangen, Germany*

Background: IL-23 is considered to play an important role in the development of enthesitis. Ustekinumab (UST), a combined inhibitor of IL-12/IL-23 shows efficacy in psoriatic arthritis (PsA), which is driven by enthesial and synovial disease, while it has no therapeutic role in diseases driven by synovitis alone, such as rheumatoid arthritis. We therefore speculated that inhibition of IL-23 is particularly effective in enthesitis-driven PsA patients.

Objectives: To compare the efficacy of UST with tumor necrosis factor inhibitor (TNFi) treatment in clearing enthesitis in PsA patients.

Methods: ECLIPSA is a prospective randomized-controlled open study. Patients with PsA with active enthesitis were randomized 1:1, receiving either standard doses of UST (arm 1) or TNFi (arm 2). At baseline the following parameters were assessed: age, gender, BMI, disease duration, previous DMARDs, use of corticosteroids, use of NSAIDs, swollen and tender joint count, VAS-pain, VAS-global, NAPSI, PASI, MASES, SPARCC, LDI, BASDAI, BASFI, HAQ-DI, SF-36, FACIT-F, ESR and CRP. Primary endpoint was a SPARCC of 0 after 6 months. Patients were seen every 3 months and followed for a total of 6 months. In order to investigate the effects of study treatment over time we used 2x3 mixed design ANOVA models for both physician's and patient's reported outcomes. Furthermore, exploratory logistic regression was used to predict a SPARCC of 0 at month 6 from baseline SPARCC, PASI, NAPSI, FACIT-F and BASDAI while additionally accounting for age, gender, PsA duration and study treatment.

Results: 51 patients (UST=25; TNFi=26) were screened and 47 patients (UST=23; TNFi=24) were enrolled with 4 patients not presenting signs of active enthesitis at baseline. Mean ± SD age was 59.11±12.16 years and mean ± SD disease duration was 6.4±7.79 years. Mean± SD SPARCC at baseline was 4.87±2.69 in the UST group and 3.88±2.52 in the TNFi group. Other baseline characteristics were similar between both groups with exception of HAQ-DI, BASFI and SF-36 mental scale. In regards to the effect of study treatment (TNFi vs. UST) and time, the corresponding ANOVAs suggested an important interaction of both factors for measures of enthesitis (MASES and SPARCC), patient-reported disease activity (BASDAI and BASFI), physical well-being (SF-36 physical component summary scale), and PASI all p≤0.044 with superiority of UST. However, TNFi was superior to UST with respect to improvement of fatigue (FACIT-F), p<0.001. After 6 months, 17 out of 24 UST patients (70.8%) and 10 out of 26 TNFi patients (38.4%) reached the primary endpoint (SPARCC=0). Logistic regression predicting enthesitis-free state of disease was significantly related to study treatment only, with patients receiving UST being more likely to show no signs of enthesitis at month 6 (OR=0.037; p=0.005).

Conclusions: These results show that UST is superior to TNFi in resolving the enthesitis component of disease in PsA patients with active enthesial disease. Based on these data more stratified treatment approaches can be designed in PsA patients, where enthesitis-driven patients are targeted by IL-23/IL-17 pathway inhibitors, while more systemic disease manifestations of PsA, such as patients with polyarticular disease or those with high-level fatigue are targeted by TNFi.

OP0218 EFFICACY AND SAFETY RESULTS OF GUSELKUMAB, AN ANTI-IL23 MONOCLONAL ANTIBODY, IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS OVER 24 WEEKS: A PHASE 2A, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY

A. Deodhar[1], A. Gottlieb[2], W.-H. Boehncke[3,4], B. Dong[5], Y. Wang[5], W. Barchuk[6], X.L. Xu[6], E. Hsia[5,7]. *[1]Oregon Health & Science University, Portland; [2]Department of Dermatology, New York Medical College, Valhalla, United States; [3]Division of Dermatology and Venereology, Geneva University Hospital; [4]Dept of Pathology and Immunology, University of Geneva, Geneva, Switzerland; [5]Janssen Research & Development, LLC, Spring House; [6]Janssen Research & Development, LLC, San Diego; [7]University of Pennsylvania School of Medicine, Philadelphia, United States*

Objectives: To evaluate the efficacy, safety, and tolerability of guselkumab (GUS), a fully human monoclonal antibody against the p19 subunit of IL-23, in patients (pts) with active psoriatic arthritis (PsA).

Methods: In this double-blind, placebo-controlled, multicenter study, pts with active PsA and ≥3% body surface area (BSA) of plaque psoriasis despite current or previous treatment with standard-of-care therapies, including those previously exposed to anti-TNFα agents, were randomized 2:1 to receive GUS 100 mg subcutaneously (SC) or placebo (PBO) at wks 0, 4, and every 8 wks (q8w) thereafter through wk44. At wk16, pts from either group with <5% improvement from baseline in both swollen and tender joint counts were eligible for early escape to open-label ustekinumab. At wk24, all remaining PBO pts crossed-over to receive GUS 100 mg, and then received GUS at wk28, and q8w thereafter through wk44. The primary endpoint was ACR 20 response at wk24. Major

secondary endpoints were PASI 75 and ACR 50 responses, change from baseline in HAQ-DI, and improvement in enthesitis (Leeds enthesitis index) and dactylitis score (by a 0–3 scoring system) at wk24; and ACR 20 response at wk16. Other secondary endpoints included change from baseline in SF-36 and proportion of pts achieving Minimal Disease Activity (MDA). Through wk24, efficacy analyses were performed in a modified Intent-to-Treat (mITT) population. Pts who met treatment failure criteria, early escaped or had missing data at wk24, were considered non-responders for ACR and MDA endpoints at wk24.

Results: 149 pts were randomized to receive study agent (PBO: 49, GUS: 100). Baseline demographics and ACR component measures were generally similar between the two groups. Four [8.2%] pts in PBO and 9 [9.0%] pts in GUS were previously exposed to TNFα agents. The study met its primary and all secondary endpoints. Significantly more GUS pts achieved ACR 20/50/70 responses and PASI 75/90/100 responses at wk24 (Table 1). Significant treatment effect on ACR20 response was observed as early as wk4 (21% vs 0, $p<0.001$), and the effect increased over time reaching the maximum by wk16 (60.0% vs. 16.3%, $p<0.001$) vs. PBO. Results for other secondary efficacy endpoints are summarized in Table 1.

Through wk24, proportions of pts with ≥1 AE were comparable between the two groups (PBO: 32.7%; GUS: 36.0%, respectively). Infections were the most common AEs (PBO: 20.4%; GUS: 17.0%, respectively). Two pts had SAEs (knee injury, n=1; myocardial infarction, n=1). There were no serious infections, malignancies, or deaths through wk24.

Table 1 Summary of Efficacy Results at Week 24 in mITT Population[a]

Efficacy Endpoints	PBO	GUS	p-value
ACR 20	18.4%	58.0%	p<0.001
ACR 50	10.2%	34.0%	P=0.002
ACR 70	2.0%	14.0%	P=0.023 (post hoc)
PASI 75	12.5%	78.6%	p<0.001
PASI 90	6.3%	66.3%	P<0.001
PASI 100	6.3%	39.8%	P<0.001
Mean (SD) change from BL in HAQ-DI score	-0.06 (0.53)	-0.42 (0.51)	p<0.001
Median % change from BL in LEI[b]	-33.33%	-100.00%	p=0.009
% of pts with unresolved enthesitis[b]	71.0%	43.4%	P=0.012
Median % change from BL in dactylitis[c]	-33.33%	-100.00%	p<0.001
% of pts with unresolved dactylitis[c]	82.6%	44.8%	P=0.001
Mean (SD) change from BL in SF-36 PCS score	0.46 (6.51)	6.59 (7.47)	P<0.001
Mean (SD) change from BL in SF-36 MCS score	0.42 (6.74)	4.95 (9.06)	p=0.002
% of pts achieving Minimal Disease Activity	2.0%	23.0%	p=0.001
Mean (SD) change from BL in PASDAS	-0.49 (1.33)	-2.50 (1.59)	p<0.001
Mean (SD) change from BL in GRACE Index	-0.35 (1.39)	-2.73 (1.76)	P<0.001
Mean (SD) change from BL in mCPDAI	-0.8 (2.26)	-3.9 (2.79)	P<0.001
Mean (SD) change from BL in DAPSA	-4.97 (20.11)	-23.08 (20.21)	P<0.001

[a]All pts randomized into the study, received at least 1 administration of study treatment (GUS or PBO), and were analyzed according to their assigned treatment group regardless of their actual treatment received; [b]Among the pts with enthesitis at baseline (PBO: N=31; GUS: N=76); [c]Among the pts with dactylitis at baseline (PBO: N=23; GUS: N=58); LEI: Leeds Enthesitis Index, PCS: Physical Component Score, MCS: Mental Component Score, PASDAS: Psoriatic ArthritiS Disease Activity Score, GRACE: GRAppa Composite score, mCPDAI: modified Composite Psoriatic Disease Activity Index, DAPSA: Disease Activity Index for Psoriatic Arthritis, BL: Baseline

Conclusions: In pts with active PsA and ≥3% BSA of psoriasis, GUS demonstrated significant improvement on joint symptoms, physical function, psoriasis, enthesitis, dactylitis and quality of life. GUS was well tolerated with no unexpected safety findings in this population.

OP0219 EARLY ONSET OF EFFICACY WITH APREMILAST MONOTHERAPY IN BIOLOGIC-NAÏVE PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: A PHASE 3B, RANDOMIZED, CONTROLLED TRIAL

P. Nash[1], K. Ohson[2], J. Walsh[3], N. Delev[4], D. Nguyen[4], L. Teng[4], J.J. Gomez-Reino[5], J.A. Aelion[6]. *[1]University of Queensland, Brisbane, Australia; [2]Memorial University of Newfoundland, St. John's, Canada; [3]University of Utah School of Medicine, Salt Lake City; [4]Celgene Corporation, Summit, United States; [5]Hospital Clínico Universitario, Santiago, Spain; [6]West Tennessee Research Institute, Jackson, United States*

Background: ACTIVE is the first apremilast (APR) trial to evaluate time to onset of efficacy beginning at Wk 2 in biologic-naïve psoriatic arthritis (PsA) patients (pts) who may have had exposure to 1 prior conventional DMARD.

Objectives: Report the study results through Wk 52.

Methods: Pts were randomized (1:1) to APR 30 mg BID or placebo (PBO). Pts were eligible for early escape (investigator discretion) at Wk 16. At Wk 24, all pts entered active treatment with APR. The primary endpoint was ACR20 response at Wk 16. Other assessments included changes in DAS-28 (CRP), SJC, TJC, HAQ-DI, morning stiffness duration/severity, and enthesitis, as measured by the Gladman Enthesitis Index (GEI; 0=no enthesitis, 6=all 6 sites active). Along with collection of safety data, tolerability adverse events (AEs) of diarrhea were further characterized.

Results: 219 pts were randomized (APR: n=110; PBO: n=109); overall, 160/180 (88.9%) pts receiving APR completed Wk 52. Separation in the proportion of ACR20 responders to APR vs PBO was noted at Wk 2 (16.4% vs 6.4%; P=0.0252), the first post-baseline (BL) visit. Early onset of response to APR was observed across clinical assessments, with improvements in DAS-28 (CRP), SJC, HAQ-DI, enthesitis, and morning stiffness severity (Table). At Wk 16, significant ACR20 response rates were observed with APR vs PBO (38.2% vs 20.2%; $P<0.005$), with similar rates for the subset of pts with use of 1 prior non-biologic DMARD (39.2% vs 20.5%; $P<0.05$), which comprises 69% of study pts. Significant reductions in PsA disease activity/manifestations vs PBO were also demonstrated by changes in DAS-28 (CRP) ($P<0.0001$), SJC, and HAQ-DI (P=0.0229), and improvements in morning stiffness severity and GEI score (P=0.0014). With continued APR exposure, the Wk 52 ACR20/ACR50/ACR70 response rates were 63.3%/32.4%/14.0%, and percent change in SJC was –74.5%. Among APR pts with BL enthesitis, 62.8% reached a GEI score of 0. Overall incidence of AEs in the PBO-controlled period was generally similar between APR and PBO. The most commonly reported AEs (≥5% of pts) with APR vs PBO were nasopharyngitis (8.3% vs 6.4%), nausea (8.3% vs 1.8%), headache (7.3% vs 3.7%), hypertension (6.4% vs 6.4%), and diarrhea (pt or investigator reported) (14.7% vs 11.0%); using a protocol-defined characterization of diarrhea (≥2 watery/liquid stools/day), overall incidence was lower for APR and PBO (11.0% and 8.3%). Serious AEs were lower with APR vs PBO (2.8% vs 4.6%). No opportunistic infections, reactivations of TB, or cases of marked depression were seen. In general, no increase was seen in AE incidence/severity with longer-term exposure to APR.

	Wk 2		Wk 16		Wk 52
	APR n=110	PBO n=109	APR n=110	PBO n=109	APR n=171
ACR20, n/m (%)	18/110 (16.4)*	7/109 (6.4)	42/110 (38.2)§	22/109 (20.2)	107/169 (63.3)
DAS-28 (CRP), mean change	−0.59*	−0.31	−1.07‡	−0.39	−1.58
SJC, mean % change	−27.7	−17.5	−46.4‡	4.2	−74.5
HAQ-DI score (0-3), mean change	−0.13*	−0.05	−0.21*	−0.06	−0.36
HAQ-DI MCID ≥0.30, n/m (%)	24/110 (21.8)	13/109 (11.9)	39/110 (35.5)	30/109 (27.5)	78/171 (45.6)
SF-36v2 PF score, mean change	NA	NA	2.43§	−1.04	5.5
Improvement in morning stiffness severity, n/m (%)	47/110 (42.7)§	23/109 (21.1)	51/110 (46.4)§	28/109 (25.7)	98/171 (57.3)
GEI score (0-6), mean change#	−1.1*	−0.4	−1.5§	−0.4	−1.5

Full analysis set was used for Wk 2 and Wk 16; for response parameters, pts without sufficient data (observed and imputed) for the determination of response status were categorized as non-responders. Wk 52 analyses were data as observed among all pts who received apremilast, regardless of when apremilast treatment started (BL, Wk 16 or Wk 24); actual number of pts may vary for each end point depending on availability of data.
#Evaluated in pts with enthesitis at BL (GEI >0).
*$P<0.05$; §$P<0.005$; ‡$P<0.0001$ vs PBO; based on a mixed-effects model for repeated measures for continuous parameters and a Cochran-Mantel-Haenszel test for binary parameters.
APR=apremilast 30 mg BID; PBO=placebo; ACR20=20% improvement in American College of Rheumatology response criteria; n/m=number of responders/number of pts with sufficient data for evaluation; DAS-28 (CRP)=28-joint count Disease Activity Score (C-reactive protein); SJC=swollen joint count; HAQ-DI=Health Assessment Questionnaire-Disability Index; MCID=minimal clinically important differences; SF-36v2 PF=36-item Short-Form Health Survey version 2 Physical Functioning domain; NA=not assessed at time point; GEI=Gladman Enthesitis Index; pts=patients; BL=baseline.

Conclusions: In biologic-naïve pts treated with APR, onset of effect was observed starting at Wk 2 across PsA manifestations, including morning stiffness severity and enthesitis, with sustained improvements through Wk 52. AEs were consistent with those reported for other APR phase 3 PsA and psoriasis studies.

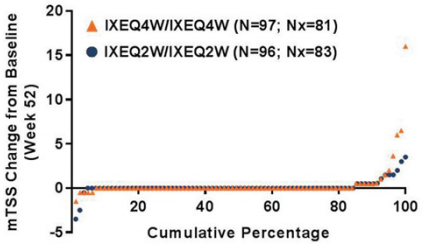
OP0220 RANDOMIZED, DOUBLE-BLIND, GLOBAL CLINICAL TRIAL TO EVALUATE EQUIVALENCE OF CHS-1420 TO ADALIMUMAB IN PATIENTS WITH PSORIASIS AND PSORIATIC ARTHRITIS

J. O'Dell[1], A. Kivitz[2], K. Papp[3], C. Leonardi[4], K. Jensen[5], H. Tang[5], B. Finck[5] on behalf of The PsOsim Study Group. *[1]University of Nebraska Medical Center, Omaha, NE; [2]Altoona Center for Clinical Research, Duncansville, PA, United States; [3]K. Papp Clinical Research, Waterloo, Ontario, Canada; [4]Central Dermatology, St. Louis, MO; [5]Coherus BioSciences, Redwood City, CA, United States*



Background: CHS-1420 is being developed as a proposed biosimilar to adalimumab for the treatment of rheumatoid arthritis, plaque psoriasis (PsO), and other auto-immune diseases.
Objectives: This phase 3, randomized, double-blind, active-controlled, multicenter study evaluated the equivalence of CHS-1420 to adalimumab in patients with active, moderate-severe, chronic plaque PsO, including patients with psoriatic arthritis (PsA).
Methods: Male and female patients (aged ≥18 years) were randomized to CHS-1420 or adalimumab. Patients received 40 mg x 2 on Day 0 and then 40 mg every other week (QOW) by subcutaneous injection. To establish the equivalence of CHS-1420 to adalimumab, the 95% CI of the treatment difference for the primary endpoint, PASI75 at Week 12, had to be within pre-specified equivalence margins of ±15%. The 55-week study is ongoing, and blinded efficacy data at Week 12 and safety data through Week 16 are available. The study was not powered for statistical analysis of the PsA subgroup. Patients with PsA were evaluated based on change in the Health Assessment Questionnaire – Disability Index (HAQ-DI) and highly sensitive C-reactive protein (hs-CRP).
Results: The full analysis population for the primary efficacy endpoint consisted of 545 patients (mean age 43.9 years), with 274 and 271 in Group A and Group B, respectively. The mean BMI was 29.6 kg/m^2, and 72.3% were male. At Week 12, the proportion of patients achieving a PASI75 from Baseline was 77.7% in Group A and 74.5% in Group B. The 95% CI of the treatment difference [-3.63, 10.28] was within the pre-specified equivalence margin [-15.0, 15.0]. Sensitivity analyses supported equivalence of the two treatments.
PsA was present in 65 (23.7%) and 61 (22.5%) patients in Group A and Group B, respectively. A PASI75 was achieved by 81.5% and 77.0% of patients with PsA in Group A and Group B, respectively, at Week 12. Mean HAQ-DI scores decreased from Baseline by 0.6 and 0.7 (95% CI: -0.3, 0.3) at Week 12 in Group A and Group B, respectively. Mean hs-CRP (mg/L) decreased from Baseline by 8.9 and 6.3 at Week 12 in Group A and Group B, respectively.
In the safety population (n=545), adverse events were reported in 48.5% and 45.0% of patients, in Group A and Group B, respectively, through Week 16. Serious adverse events were reported in 1.1% and 2.2% of patients in Group A and Group B, respectively, through Week 16, and none were judged by the investigator to be related to treatment. The most common (≥5% of patients) adverse events were nasopharyngitis and upper respiratory tract infection.
Conclusions: This randomized, double-blind, global clinical trial demonstrated the equivalence of CHS-1420 to adalimumab in the treatment of chronic PsO. Both study drugs were well tolerated. Patients with PsA showed improvement with both study drugs.

OP0221 RADIOGRAPHIC PROGRESSION OF STRUCTURAL JOINT DAMAGE IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS TREATED WITH IXEKIZUMAB OVER 52 WEEKS

D. van der Heijde[1], M. Okada[2], C. Lee[3], C.L. Shuler[3], S. Rathmann[3], C.-Y. Lin[3], P. Mease[4]. *[1]Leiden University Medical Centre, Leiden, Netherlands; [2]St. Luke's international Hospital, Tokyo, Japan; [3]Eli Lilly and Company, Indianapolis; [4]Swedish Medical Center and University of Washington, Seattle, United States*

Background: Ixekizumab (IXE), an anti-interleukin-17A monoclonal antibody, was shown to be superior to placebo (PBO) in clinical responses and inhibiting the progression of structural joint damage in patients (pts) with psoriatic arthritis (PsA) treated for 24 weeks (wks).[1]
Objectives: To assess progression of structural joint damage in PsA pts with IXE for up to 52 wks.
Methods: Biologic DMARD-naïve pts with active PsA (N=417) entered into SPIRIT-P1 (NCT01695239), a double-blind phase 3 trial. Pts must have had ≥1 joint erosion on the hand and foot x-rays confirmed by central reading *or* had a C-reactive protein level >6 mg/L at screening. 417 pts were randomized to IXE 80 mg every 2 wks (Q2W; N=103) or 4 wks (Q4W; N=107) following a 160 mg initial dose, PBO (N=106), or adalimumab 40 mg every 2 wks (ADA; active reference arm; N=101) for 24 wks. In the Extension Period (EXT: Wks 24–52), PBO and ADA pts were re-randomized (1:1) to IXEQ2W or IXEQ4W at Wk 16 (inadequate responders) or Wk 24; ADA pts underwent a washout prior to IXE treatment. All pts were assessed for structural joint damage using the van der Heijde modified PsA Total Sharp Score (mTSS, 0–528 scale). X-rays at Wks 0, 24 and 52 were scored independently by 2 readers blinded to timepoint and clinical data (average of readers). mTSS was excluded from the pre-specified analysis if the radiograph was taken after the scheduled visit date. In a post-hoc analysis, mTSS from a radiograph taken after the scheduled visit date was interpolated and considered as observed data. Any missing data at Wk 52, in either presentation, were imputed using a linear extrapolation if they had at least 1 post-baseline value.
Results: Pts had active PsA at Week 0 (Table). 381 pts (91.3%) entered the EXT, with 374 (98.2%) having radiographs collected during the EXT. Wk 52 mean (SD) mTSS change from baseline were 0.54 (2.11) and 0.09 (1.0) for pts randomized to IXEQ4W and IXEQ2W at baseline, respectively. Similar changes at Wk 52 were obtained with the post-hoc analysis (Table). The majority of IXEQ2W or IXEQ4W pts exhibited no structural progression through 1 year of IXE treatment (Figure). In pts who switched from PBO or ADA to IXE, Wk 52 mean change from baseline mTSS values scores ranged from -0.03 to 0.41 (Table).

Observed mTSS Change from Baseline Values at Week 52, Cumulative Distribution Plot

N=EXT patients; Nx= Pts with baseline and Wk 52 radiograph assessments. mTSS values from radiographs taken after the Wk 52 scheduled visit date were interpolated and considered as observed data.

Conclusions: Over a 52 wk period, minimal changes in mTSS were observed in PsA pts entering the EXT and treated with IXEQ2W or IXEQ4W.

OP0222 SECUKINUMAB PROVIDES SUSTAINED IMPROVEMENTS IN THE SIGNS AND SYMPTOMS OF ACTIVE PSORIATIC ARTHRITIS: 104 WEEKS RESULTS FROM A PHASE 3 TRIAL, FUTURE 2

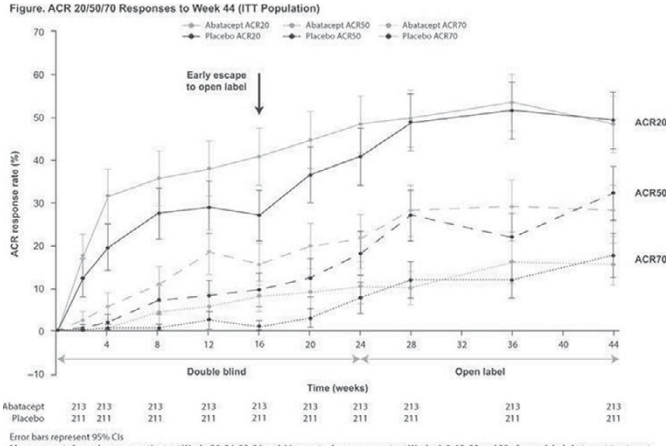
I.B. McInnes[1], P.J. Mease[2], C. Ritchlin[3], P. Rahman[4], A. Gottlieb[5], B. Kirkham[6], R. Kajekar[7], E.M. Delicha[8], L. Pricop[7], S. Mpofu[8] on behalf of the FUTURE 2 study group. *[1]University of Glasgow, Glasgow, United Kingdom; [2]Swedish Medical Centre and University of Washington, Seattle; [3]University of Rochester, Rochester, United States; [4]Memorial University, St. John's, Canada; [5]New York Medical College, New York, United States; [6]Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom; [7]Novartis Pharmaceuticals Corporation, East Hanover, United States; [8]Novartis Pharma AG, Basel, Switzerland*

Background: Secukinumab significantly improved the signs and symptoms of psoriatic arthritis (PsA) over 52 weeks (wks) in FUTURE 2 study (NCT01752634).[1,2]
Objectives: To present longer-term (104 wks) efficacy and safety data of secukinumab from FUTURE 2 study.
Methods: Overall, 397 patients (pts) with active PsA were randomised to secukinumab (300, 150, or 75 mg) or placebo at baseline, Wks 1, 2, 3, and 4, and every 4 wks thereafter. Assessments at Wk 104 are from pts originally randomised to secukinumab and included ACR20/50/70, PASI 75/90, DAS28-CRP, SF-36 PCS, HAQ-DI, dactylitis, and enthesitis. Multiple imputation was used for analysis of binary variables and mixed-model repeated measures for continuous variables. Analyses stratified by anti-TNFα status (naïve/inadequate response or intolerance to these agents) were prespecified and are reported as observed. Safety analysis included all pts who received ≥1 dose of secukinumab.
Results: In total, 86/100 (86.0%), 76/100 (76.0%) and 65/99 (65.7%) pts in the secukinumab 300, 150, and 75 mg groups respectively completed 104 wks. Sustained clinical improvements were observed through Wk 104 with secukinumab across all clinically important domains of PsA (Table). Responses were sustained through Wk 104 regardless of anti-TNFα status. Over the entire treatment period (mean [±SD] exposure to secukinumab of 709±210.99 days), the exposure adjusted incidence rates for serious infections/infestations, candida infections, inflammatory bowel disease and malignant/unspecified tumors with secukinumab were 1.6, 2.3, 0.5 and 1.3, respectively.

Table 1. Summary of Efficacy Results at Wk 104

Variable*	Secukinumab		
	300 mg s.c. (N=100)	150 mg s.c. (N=100)	75 mg s.c. (N=99)
ACR20	69.4	64.4	50.3
ACR50	50.6	36.0	28.2
ACR70	33.1	23.1	14.9
[a]PASI 75	79.5	73.3	58.4
[a]PASI 90	69.6	52.5	33.7
SF-36 PCS, LS mean change from BL (SE)	6.8 (0.85)	5.0 (0.87)	4.1 (0.91)
DAS28-CRP, LS mean change from BL (SE)	?1.9 (0.12)	?1.7 (0.12)	?1.5 (0.13)
HAQ-DI, LS mean change from BL (SE)	?0.58 (0.05)	?0.48 (0.06)	?0.27 (0.06)
[b]Resolution of enthesitis	71.5	61.8	68.4
[c]Resolution of dactylitis	79.9	78.0	88.6

*% responders unless otherwise specified. [a]Assessed in pts with psoriasis affecting ≥3% body surface area at BL (300 mg: n=41; 150 mg: n=58; 75 mg: n=50). [b]Assessed in pts (n=56 [300 mg], 64 [150 mg] and 68 [75 mg]) with this symptom at BL. [c]Assessed in pts (n=46 [300 mg], 32 [150 mg] and 33 [75 mg]) with this symptom at BL. BL, baseline; DAS28-CRP, 28-joint disease activity score using C-reactive protein; HAQ-DI, health assessment questionnaire-disability index; LS, least squares; N, number of pts randomised; PASI, psoriasis area and severity index; SE, standard error; SF-36 PCS, short form-36 physical component summary.



Conclusions: Secukinumab 300 and 150 mg provided sustained improvements in signs and symptoms and multiple clinical domains of active PsA through 2 years of therapy. Secukinumab was well tolerated, with a safety profile consistent with that reported previously.

OP0223 ABATACEPT IN THE TREATMENT OF ACTIVE PSORIATIC ARTHRITIS: 1-YEAR RESULTS FROM A PHASE III STUDY

P. Mease[1], A. Gottlieb[2], D. van der Heijde[3], O. FitzGerald[4], A. Johnsen[5], M. Nys[6], S. Banerjee[5], D. Gladman[7]. *[1]Swedish Medical Center and University of Washington, Seattle; [2]New York Medical College, Valhalla, United States; [3]Leiden University Medical Center, Leiden, Netherlands; [4]St Vincent's University Hospital and University College Dublin, Dublin, Ireland; [5]Bristol-Myers Squibb, Princeton, United States; [6]Bristol-Myers Squibb, Braine-l'Alleud, Belgium; [7]University of Toronto and Toronto Western Hospital, Toronto, Canada*

Background: In the Phase III ASTRAEA trial (NCT01860976), abatacept (ABA), a selective T-cell co-stimulation modulator, significantly increased ACR20 response (primary endpoint; PE) and had an overall beneficial effect vs placebo (PBO) on musculoskeletal symptoms in patients (pts) with active psoriatic arthritis (PsA) at 24 weeks (W).[1]
Objectives: To analyse 1-year results from ASTRAEA.
Methods: Pts with active disease (≥3 swollen and ≥3 tender joints), ≥2 cm target lesion of plaque psoriasis and inadequate response/intolerance to ≥1 non-biologic DMARD were randomized (1:1) to SC ABA 125 mg weekly or PBO for 24W, followed by open-label (OL) SC ABA up to 52W. Randomization was stratified by MTX use, prior TNF inhibitor (TNFi) use and skin involvement ≥3% of body surface area. Pts without ≥20% improvement in joint counts at W16 were switched to OL ABA (early escape; EE) for 28W (total study time: 44W). Pre-specified exploratory endpoints included: ACR20/50/70 responses at W44; adjusted mean changes from baseline (BL) in DAS28 (CRP; *post hoc* analysis) and HAQ-DI at W44 and PsA-modified total Sharp/van der Heijde score (SHS) at W44 (EE pts)/W52 (non-EE pts); complete resolution of BL enthesitis and dactylitis at W44 (EE pts)/W52 (non-EE pts); and Psoriasis Area and Severity Index (PASI) 50/75 responses at W44. Analyses used the ITT population with non-responder imputation for missing values and actual data at each time point for all pts (denominator at each time point equal to number of pts in ITT population). All missing responses were imputed as non-responders, except if the missing value was between 2 visits for which the pt was a responder. In that case the missing value was imputed as a responder.
Results: Of 424 pts enrolled, 213 received ABA and 211 PBO. Most (>60%) pts had received prior TNFis. Of pts in the ABA and PBO groups, 76 (36%) and 89 (42%) were EE, 12 (6%) and 24 (11%) discontinued by PE of W24;

Figure. ACR 20/50/70 Responses to Week 44 (ITT Population)

Error bars represent 95% CIs
Measurements for early escape patients at Weeks 20, 24, 28, 36 and 44 are actual measurements at Weeks 4, 8, 12, 20 and 28 of open-label abatacept treatment
At all time points, if there were missing data, patients were imputed as non-responders, unless data were missing between two time points at which the patient had a response, in which case response was imputed

197 (92%) and 185 (88%) entered the OL period, of whom 165 (84%) and 162 (88%) completed. At W44, ACR responses at W24 were maintained for pts who continued ABA, and improved for those who switched from PBO to ABA (Figure). Continued improvements in DAS28 (CRP) and HAQ-DI after W24 were seen for ABA and PBO/ABA groups, with mean (SE) changes from BL to W44 of –1.81 (0.09) and –1.84 (0.10) in DAS28 (CRP) (changes to W24 were –1.35 [0.10] and –0.94 [0.11]) and –0.37 (0.04) and –0.38 (0.04) in HAQ-DI (changes to W24 were –0.33 [0.04] and –0.20 [0.05]), respectively. There was minimal progression based on mean (SE) change from BL in PsA-modified total SHS at W44/52 in the ABA and PBO/ABA groups: 0.18 (0.12) vs 0.30 (0.12). Complete resolution of BL enthesitis occurred in 48.6% and 43.9% and BL dactylitis in 68.9% and 60.0% of pts with ABA and ABA/PBO, respectively, at W44/52. At W44, for ABA and PBO/ABA, PASI 50 responses were 30.1% and 34.5%; PASI 75 responses were 19.9% and 16.9%. There were no new safety signals.

Conclusions: Responses were maintained across musculoskeletal endpoints up to 1 year in a relatively refractory population of pts continuing on SC abatacept. Abatacept was well tolerated.

From classics to new: synthetic DMARDs in RA

OP0224 SIMILAR SHORT TERM CLINICAL RESPONSE TO INITIAL TREATMENT WITH HIGH VERSUS LOW DOSE METHOTREXATE IN MONO- AND COMBINATION THERAPY IN EARLY RHEUMATOID ARTHRITIS PATIENTS

S.A. Bergstra[1], C.F. Allaart[1], R. van den Berg[1,2], A. Chopra[3], N. Govind[4], T.W. Huizinga[1], R.B. Landewé[5,6] on behalf of METEOR working group.
[1]Rheumatology, LUMC, Leiden; [2]Rheumatology, Erasmus University Medical Center, Rotterdam, Netherlands; [3]Center for Rheumatic Diseases, Pune, India; [4]University of the Witwatersrand, Johannesburg, South Africa; [5]Amsterdam Rheumatology & Immunology Center, Amsterdam; [6]Zuyderland Medical Center, Heerlen, Netherlands

Background: Aiming at rapid decrease of disease activity, there has been a trend to start with higher doses of methotrexate (MTX) in newly diagnosed rheumatoid arthritis (RA) patients, both as monotherapy and in combination with other antirheumatic drugs (DMARDs). We hypothesized that in combination with other very effective medication, there might be no additional benefit of high over low doses of MTX.

Objectives: To compare early clinical response to high versus low doses of MTX in mono- and combination therapy in DMARD naive early RA patients.

Methods: RA patients included in the observational international METEOR cohort with symptom duration ≤5 years, time between diagnosis and first visit ≤2 months, MTX prescribed as (part of) first treatment, no medication change within 3 to 6 months after treatment start and available outcome data on disease activity, were selected. Patients were divided into 4 medication groups: MTX monotherapy, MTX + synthetic (cs)DMARDs, MTX + oral glucocorticoid (+ possibly csDMARDs) or MTX + biologic (b)DMARDs (+ possibly csDMARDs). Missing data were imputed using multivariate normal imputation. MTX dose was dichotomized: low dose ≤10 mg/week; high dose ≥15 mg/week. A propensity score (PS) was calculated to adjust the relationship between MTX dose and outcome for potential confounding by indication. Linear mixed model analyses for DAS, DAS28, and HAQ were performed for each medication group, with MTX-dose and time (days between assessment visit and baseline assessment) as co-variates. Associations were adjusted for the PS. Random intercept and slope were used to account for irregular time intervals between visits.

Results: Patients who started on MTX monotherapy had lower baseline disease activity and fewer were erosive and autoantibody positive; other baseline characteristics were comparable between medication groups. The number of patients on combination therapy with bDMARDs was too small to perform analyses (26 visits in 11 patients). For patients starting on MTX monotherapy, MTX+csDMARDs or MTX+glucocorticoids, the PS-adjusted effects of MTX-dose (high vs low) on DAS, DAS28 and HAQ were small and not clinically meaningful. The unadjusted main associations between MTX-dose and outcomes were often in opposite direction and/or much larger than the PS adjusted associations, suggesting that confounding by indication indeed plays a role and that (at least some) correction was achieved by adjusting for the PS (table 1).

Table 1: Unadjusted and propensity score adjusted results of the linear mixed model analyses to investigate the effectiveness of high versus low methotrexate dose on disease activity (DAS and DAS28) and physical functioning (HAQ), stratified per medication group.

	DAS		DAS28		HAQ	
Methotrexate monotherapy (n patients=449, n visits=975)						
	β	95% CI	β	95% CI	β	95% CI
MTX-dose group PS adjusted	0.052	-0.17; 0.28	0.085	-0.24; 0.41	0.043	-0.11; 0.20
MTX-dose group unadjusted	-0.55	-0.71; -0.39	-0.19	-0.45; 0.071	0.17	0.059; 0.28
Methotrexate + csDMARDs (n patients=265, n visits=574)						
	DAS		DAS28		HAQ	
	β	95% CI	β	95% CI	β	95% CI
MTX-dose group PS adjusted	0.036	-0.26; 0.33	0.0066	-0.39; 0.41	-0.014	-0.21; 0.18
MTX-dose group unadjusted	-0.19	-0.45; 0.071	-0.29	-0.65; 0.065	0.080	-0.094; 0.25
Methotrexate + oral glucocorticoid (+/-csDMARDs) (n patients=485, n visits=1075)						
	DAS		DAS28		HAQ	
	β	95% CI	β	95% CI	β	95% CI
MTX-dose group PS adjusted	-0.017	-0.26; 0.22	-0.14	-0.45; 0.17	-0.023	-0.17; 0.12
MTX-dose group unadjusted	-0.33	-0.50; -0.15	-0.64	-0.86; -0.41	0.14	0.040; 0.25

DAS=disease activity score, HAQ=health assessment questionnaire, PS=propensity score, 95% CI=95% confidence interval, MTX=methotrexate. MTX-dose group is a binary variable with low dose =10 mg/week and high dose =15 mg/week. Low dose is the reference category.

Conclusions: In a daily practice derived database in DMARD-naive early RA patients, we found no early clinical benefit of high over low initial MTX doses, neither for MTX monotherapy nor for combination therapy with MTX and csDMARDs or glucocorticoids. This seems to contradict a general trend over time to start higher MTX-doses.

OP0225 THE EFFECT OF A LOW VERSUS HIGH FIRST PRESCRIBED DOSE OF METHOTREXATE ON EULAR RESPONSE AT SIX MONTHS USING DATA FROM THE RAMS STUDY

R. Davies, M. Lunt, A. Barton, K.L. Hyrich, S.M.M. Verstappen on behalf of RAMS co-investigators. *Division of Musculoskeletal & Dermatological Sciences, Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom*

Background: Methotrexate (MTX) is one of the most commonly used drugs for the treatment of rheumatoid arthritis (RA). Recommendations by an international panel state that oral MTX should be started at 10–15mg/week, with escalation of 5mg every 2–4 weeks up to 20–30mg/week (1). In the UK, practice varies in terms of the starting dose prescribed for MTX, likely because of a lack of published evidence on the importance of MTX dose on its efficacy and safety.

Objectives: To compare 6 month response to MTX in RA patients starting 7.5mg/wk versus those starting a 15mg/wk.

Methods: Patients were recruited to the national, UK, multi-centre (n=35) longitudinal observational Rheumatoid Arthritis Medication Study (RAMS), including patients starting MTX for the first time with complete DAS28 at baseline and six months were included in this analysis. Patients were categorized into EULAR non-responders, moderate responders or good responders. Patients were categorised into those starting a low dose of MTX (≤7.5mg/wk) (LM-group) or a high

Table 1

	LM-group (n=171)	HM-group (n=639)	P
Age, years	58 (47–69)	61 (51–69)	0.13

Non-responders	50 (45)	184 (42)	
Moderate responders	36 (32)	108 (25)	
Good responders	26 (23)	145 (33)	
Fully adjusted RRR (95% CI)*			
Non-responders	–	ref	
Moderate responders	–	1.01 (0.56, 1.82)	0.97
Good responders	–	2.65 (1.37, 5.14)	0.004

Scores are median [IQR].

dose of MTX (≥15mg/wk) (HM-group). A multinomial logistic regression model was used to test the association between MTX start dose and EULAR response at 6 months,with adjustments (see table) (relative risk ratio (RRR), 95% CI). The model was clustered by centre to account for the prescribing preferences of individual centres.
Results: 810 patients were included in this study: 171/810 (21%) starting low dose MTX and 639/810 (79%) starting high dose MTX. Patients in the HM-group had significantly lower physician and patient VAS scores and less functional disability compared to those in the LM-group (table). These patients were also less likely to be prescribed concomitant (nbDMARDs) (17% vs. 10%). DAS28 score at 6 months was significantly lower for patients in the HM-group.
A fully adjusted multinomial logistic regression model, clustered by centre, showed that being in the high dose MTX group does not affect the odds of having a moderate response rather than no response, but does increase the odds of having a good response (RRR: 2.65 (95% CI 1.37, 5.14)).
Conclusions: Patients with RA starting MTX on a higher dose have increased odds of having a good EULAR response compared to non-response at 6 months.

OP0226 SUSTAINED EFFECTIVENESS OF METHOTREXATE WITH STEP-DOWN GLUCOCORTICOID REMISSION INDUCTION (COBRA SLIM) FOR EARLY RHEUMATOID ARTHRITIS IN A TREAT-TO- TARGET SETTING: 2-YEAR RESULTS OF THE CARERA TRIAL

V. Stouten [1], J. Joly [2], D. De Cock [1], S. Pazmino [1], K. Van der Elst [2,3], R. Westhovens [1,2], P. Verschueren [1,2] on behalf of CareRA study group. *[1]Skeletal Biology and Engineering Research Center, KU Leuven Department of Development and Regeneration; [2]Rheumatology, University Hospitals Leuven; [3]Skeletal Biology and Engineering Research Center, KU Leuven Department of Public Health and Primary Care, Leuven, Belgium*

Background: The CareRA trial showed that remission induction with MTX and a moderate-dose of Glucocorticoids (GC) (COBRA Slim) in a treat-to-target setting is effective and safe in early Rheumatoid Arthritis (eRA) patients. This strategy showed equally high remission rates at 52 weeks (W), a favourable safety profile compared to DMARD combinations and GC and very few patients had to start biologicals.
Objectives: To compare the outcome of different intensive combination treatment strategies in high-risk patients of the CareRA trial at W104, focussing on persistent disease control.
Methods: CareRA is a two-year prospective investigator-initiated pragmatic multicentre RCT; csDMARD naïve eRA patients were stratified into a high- or low-risk group based on classical prognostic markers (presence of erosions, RF, anti-CCP and DAS28-CRP). High-risk patients (n=289) were randomized to 1/3 arms: 1) COBRA Classic (n=98): Methotrexate (MTX)+Sulphasalazine+60mg prednisone tapered weekly to 7.5mg daily from W7; 2) COBRA Slim (n=98): MTX+30mg prednisone tapered to 5 mg daily from W6; 3) COBRA Avant-Garde (n=93): MTX+Leflunomide+30mg prednisone tapered to 5 mg daily from W6. From W28, GCs were tapered in all patients and stopped at W34. A predefined treat-to-target approach was applied until W52 and afterwards treatment was at the discretion of the rheumatologist. From W40, DMARD monotherapy was aimed for. From W28 onwards patients were evaluated every 3 months till W104. Efficacy measures were proportions of DAS28-CRP remission, good EULAR response, clinically meaningful HAQ response, HAQ=0 (ITT analysis). Adverse events related to therapy (AEs) were registered. Missing data were imputed by last observation carried forward.
Results: Remission rates at W104 in high-risk patients were 65.3%, 73.5% and 73.1% in the Classic, Slim and Avant-Garde group respectively (p=0.369). Also, other efficacy outcomes did not differ between groups (see table). From the high-risk patients that were in remission at year 1, 54.7%, 67.8% and 70.2% in the Classic, Slim and Avant-Garde group respectively, stayed in remission at every three-monthly evaluation until w104. Also DAS28-CRP scores remained relatively stable during the second year in these groups. In high-risk patients, the total numbers of AEs reported as related to study therapy, were 209 in 72 Classic patients, 164 in 69 Slim patients and 208 in 74 Avant-Garde patients (p=0.029). Serious AEs were reported in 3 Classic, 4 Slim and 3 Avant-Garde patients. Biologicals were started in 44 high-risk patients (15.2%), of which 7 receiving 2 different biologicals and 2 receiving 3 different ones. Biologicals were administered in 18 Classic, 11 Slim and 15 Avant-Garde patients.

	COBRA classic N=98	COBRA slim (high-risk) N=98	COBRA Avant-Garde N=93	p-value
DAS28-CRP change BL-w104	2.6±1.4	2.6±1.3	2.6±1.6	0.966
DAS28-CRP change w52-w104	0.0±1.0	0.2±1.0	0.3±1.1	0.112
DAS28 Remission w52	65.3%	60.2%	61.3%	0.741
DAS28 Remission w104	65.3%	73.5%	73.1%	0.369
Good EULAR response	78.6%	81.6%	78.5%	0.826
Clinically meaningful HAQ change	70.4%	62.2%	70.7%	0.363
HAQ = 0	39.8%	37.8%	38.7%	0.958

DAS28-CRP= 28 Joint disease activity score calculated with C-reactive protein; remission = DAS28-CRP <2.6; low disease activity = DAS-CRP ≤3.2; good EULAR response = low disease activity with a DAS28-CRP change >1.2; HAQ= health assessment questionnaire; clinically meaningful HAQ change = HAQ change >0.22.

Conclusions: All groups showed persistently high remission rates 2 years after remission induction with csDMARDs and GCs in a treat to target setting. COBRA Slim showed comparable efficacy with less adverse events compared to DMARD combinations with moderate or high GC induction dosages. In almost 70% of COBRA Slim patients achieving remission at year 1, this was maintained throughout the second year.

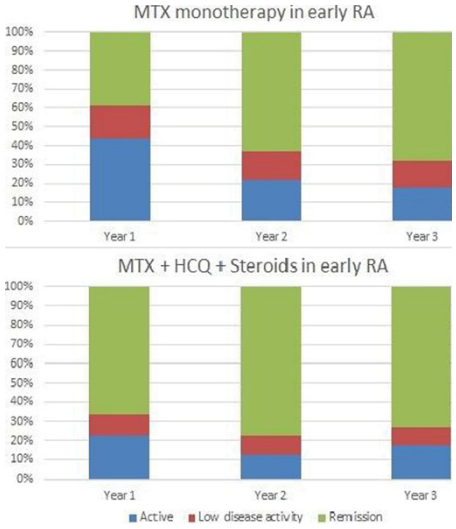
OP0227 REMISSION INDUCTION WITH METHOTREXATE STEP-UP THERAPY VERSUS COMBINATION OF HYDROXYCHLOROQUINE, METHOTREXATE AND TRIAMCINOLONE: 3 YEAR RESULTS



T. Brunekreef, H. Bernelot Moens. *Rheumatology & Clinical Immunology, Ziekenhuisgroep Twente, Almelo, Netherlands*

Background: The effectiveness of treat to target (T2T) in RA is widely acccepted, but there is no consensus regarding the best initial treatment in early rheumatoid arthritis[1]. Therefore, it is important to evaluate the results of such strategies in real life cohorts[2,3].
Objectives: Compare the effectiveness of step-up methotrexate (MTX) monotherapy and combination of hydroxychloroquine (HCQ), methotrexate and intramuscular injection of triamcinolone 80–120mg as initial treatment in early RA.
Methods: Historical cohorts of patients treated with MTX monotherapy (disease onset 2006–2011, N=297) and combination therapy (2012–2016, N=156) were compared. In both cohorts a b-DMARD was advised when no remission was reached within 6 months or in case of sustained activity thereafter. Baseline characteristics and disease activity (DAS28) measurements (N=4956, average 4.1/year) in the first 3 years of follow-up were available. The primary outcome measure was the proportion of patients having reached at least one DAS28 <2.6 (remission) during follow-up. Secondary outcomes were sustained remission over 36 months and time to first b-DMARD.
Results: Three patients did not start MTX, and 11 and 2 patients in the step-up and combination cohorts respectively did not have complete follow-up (Table). Within 12 months, more patients on combination treatment reached remission (88,2% vs 72.2%). In the second year these changed to 86.5% and 82.0% respectively. Combination treatment resulted in a higher percentage of DAS measurements below 2.6 over 3 years, reflecting sustained remission (Figure). A b-DMARD was started within 24 months in 20.6% of patients on monotherapy versus 14.1% on combination treatment, with an equal mean time to first b-DMARD of 12 vs 11 months after start of initial treatment.

Table 1

Table	MTX monotherapy (N=297)	MTX with HCQ and steroids (N=156)
Female, N (%)	180 (60.6)	101 (64.7)
Age (y), mean (SD, range)	59.5 (14.3, 18–89)	58.8 (12.9, 19–86)
Rheumatoid factor (N, %)	183 (61.6)	112 (71.8)
ACPA (N, %)	157 (65.3)	111 (71.2)
Follow-up (months) (range)	81 (8–132)	42 (11–62)
End of follow-up <3 yrs		
Death	4 (1.3%)	1 (0.6%)
Remission	4 (1.3%)	1 (0.6%)
Did not start MTX/Other	5 (1.7%)	1 (0.6%)
Any remission (DAS28 <2.6)		
First year	72.2%	88.2%
Second year	82.0%	86.5%
Third year	85.9%	87.0%
Start b-DMARD therapy		
First year	32 (10.8%)	17 (10.9%)
Second year	29 (9.8%)	5 (3.2%)
Third year	8 (2.7%)	5/104 (4.8%)

Conclusions: Combination treatment results in more remissions in the first year of treatment. In the second and third year the remission percentage on monotherapy comes close to combination treatment, at the cost of a 6% higher proportion of patients stepping up to biologicals. Overall, the combination of MTX with HCQ and triamcinolone results in more sustained remissions.

OP0229

EFFECT OF BASELINE SERUM CRP LEVELS ON CLINICAL EFFICACY IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH FILGOTINIB: POST-HOC ANALYSIS FROM TWO PHASE 2B STUDIES

R. Westhovens[1], A. Kavanaugh[2], C. Jamoul[3], C. Tasset[3], P. Harrison[3], A. Van der Aa[3]. *[1]Rheumatology, KU Leuven, University Hospitals, Leuven, Belgium; [2]University of California, la Jolla, United States; [3]Galapagos NV, Mechelen, Belgium*

Background: Filgotinib (GLPG0634, GS-6034) is an oral, selective JAK1 inhibitor that has shown a favorable safety and efficacy profile both as add-on to methotrexate (MTX) and as monotherapy in two 24-week placebo-controlled phase 2B studies in active rheumatoid arthritis (RA) patients with inadequate response to MTX (MTX-IR)[1,2].

Objectives: To assess effect of baseline serum CRP levels on clinical efficacy in MTX-IR RA patients treated with filgotinib.

Methods: Patients were randomized in a double blind manner to placebo (PBO) or one of 3 daily doses of filgotinib (50mg, 100mg or 200mg) for 24 weeks. In the DARWIN 1 study, filgotinib on the background of MTX was evaluated as once (QD) or twice daily treatment. In the DARWIN 2 study once-daily filgotinib was assessed as monotherapy. The inclusion criterion for CRP was amended during the studies and decreased over time from 13.5 mg/L to 6.3 mg/L. This post hoc analysis included patients treated with the selected Phase 3 filgotinib doses, 100mg and 200mg QD, and PBO. Efficacy outcomes were analyzed by baseline CRP level (low: ≤9 mg/L and high: >9 mg/L, with 9mg/L as ULN).

Results: Baseline disease activity was high, with mean DAS28(CRP) scores of 5.6 and 5.7 in the low CRP subgroups for DARWIN 1 and DARWIN 2, respectively, and 6.3 in the high CRP subgroups for both studies. Mean CRP levels at baseline were elevated (16.3 - 35.3 mg/L). In both low and high CRP subgroups, patients on filgotinib 100mg or 200mg QD for 12 weeks showed efficacy over PBO, as measured by change from baseline in DAS28(CRP), CDAI and HAQ-DI, and ACR20 (Table 1). Despite slight numerical differences, baseline CRP level had no consistent effect on filgotinib efficacy, neither for endpoints including CRP (DAS28(CRP) or ACR20) nor for endpoints not including CRP (CDAI). Results were similar across both studies.

Table 1. Change from baseline in key efficacy parameters at Week 12 by CRP subgroup (mean (SE))

ACR20 by subgroup, n (%)						
Low CRP	15 (45%)	19 (76%)	10 (67%)	2 (18%)	13 (65%)	16 (80%)
High CRP	23 (43%)	35 (58%)	49 (69%)	19 (31%)	33 (66%)	34 (69%)

Conclusions: Post hoc analysis of two Phase 2B studies in MTX-IR RA patients suggests that filgotinib treatment once daily at 100mg and 200mg both on the background of MTX and as monotherapy is consistently associated with improved clinical outcomes compared to placebo, regardless of baseline CRP levels.

OP0230

THE EFFECTIVENESS OF ZOSTER VACCINE IN RA PATIENTS SUBSEQUENTLY TREATED WITH TOFACITINIB

K.L. Winthrop[1], A. Wouters[2], E.H. Choy[3], C. Nduaka[4], P. Biswas[2], L. Wang[5], J. Hodge[2], I. Lazariciu[6], K. Soma[5], C.F. Mojcik[2], W.F.C. Rigby[7]. *[1]Oregon Health and Science University, Portland, OR; [2]Pfizer Inc, New York, NY, United States; [3]CREATE Center, Division of Infection and Immunity, Cardiff University School of Medicine, Cardiff, United Kingdom; [4]Pfizer Inc, Collegeville, PA; [5]Pfizer Inc, Groton, CT, United States; [6]Quintiles, Saint-Laurent, QC, Canada; [7]Giesel School of Medicine at Dartmouth, Lebanon, NH, United States*

Background: Rheumatoid arthritis (RA) patients (pts) are at increased risk of herpes zoster (HZ). The most recent ACR guidelines of 2015 recommend vaccination in pts aged ≥50 years prior to starting biologic DMARDs or tofacitinib,[1]

an oral Janus kinase inhibitor for the treatment of RA. Live zoster vaccine (LZV) has shown 70% efficacy in immunocompetent adults aged 50–59 years and 51% efficacy in those aged ≥60 years.[2] We previously reported that pts with RA on background methotrexate who started 3 months of treatment with tofacitinib after LZV had similar varicella zoster virus (VZV)-specific immunity to placebo (PBO) pts, and their VZV immunity at Week 6 post-vaccination was comparable with healthy individuals aged ≥50 years.[3]

Objectives: To evaluate the long-term effectiveness of LZV in pts with RA via the incidence of HZ after treatment with tofacitinib for up to 27 months.

Methods: Data were analysed from a prior cohort of pts (n=100) given LZV and then randomised 2–3 weeks later to tofacitinib 5 mg twice daily (BID) or PBO for 12 weeks (A3921237 [NCT02147587]). At 14 weeks post-vaccination, pts joining the long-term extension (LTE) study ORAL Sequel (NCT00413699; study ongoing; database not locked) initiated open-label treatment with tofacitinib 5 or 10 mg BID. The incidence of HZ post-vaccination after tofacitinib exposure up to 27 months (based on an extended follow-up beyond January 2016 data snapshot) was evaluated. Among HZ cases, we analysed measures of VZV-specific immunity with average immunity after LZV.

Results: 112 pts were randomised to PBO (n=57) or tofacitinib 5 mg BID (n=55). 100 pts continued to receive tofacitinib in ORAL Sequel. Five cases (not adjudicated) of HZ occurred (#1: 202 days [219 days post-LZV], #2: 267 days [281 days post-LZV], #3: 702 days [748 days post-LZV], #4: 699 days [741 days post-LZV], #5: 446 days [544 days post-LZV] after initiation of tofacitinib. Cases #1, #2, #3 and #4 were monodermatomal; #5 involved 5 dermatomes. All cases resolved with treatment. Cases #1, #4 and #5 had undetectable ELISPOT measures at baseline and Week 6 post-vaccination, indicating a lack of VZV-specific immunity. Cases #2 and #3 responded adequately to vaccination by both immunoglobulin G (IgG) and ELISPOT measures, but had lower than average VZV IgG levels, both at baseline and at Week 6. (Table).

Table. VZV ELISPOT and IgG levels

	Case #1 (HZ 219 days after zoster vaccine)	Case #2 (HZ 281 days after zoster vaccine)	Case #3 (HZ 748 days after zoster vaccine)	Case #4 (HZ 741 days after zoster vaccine)	Case #5 (HZ 544 days after zoster vaccine)	Study A3921237 Tofacitinib 5 mg BID (N=54)
VZV IFNγ ELISPOT at baseline (SFCs/10^6 PBMCs)	25 (LOD)	41	25 (LOD)	25 (LOD)	25 (LOD)	48
VZV IFNγ ELISPOT at Week 6 (SFCs/10^6 PBMCs)	25 (LOD)	76	51	25 (LOD)	25 (LOD)	70
Change from baseline in VZV ELISPOT at Week 6 (SFC fold-rise; SFCs/10^6 PBMCs)	1.00	1.85	2.04	1.00	1.00	1.50
VZV IgG titer at baseline (gpELISA units/mL)	224	37	97	237	208	201
VZV IgG titer at Week 6 (gpELISA units/mL)	444	71	187	232	223	403
Change from baseline in VZV IgG titer at Week 6 (fold-rise; gpELISA units/mL)	1.98	1.92	1.93	0.98	1.07	2.11

Individual values shown for Cases #1–#5, mean values shown for Study A3921237.

One patient who lacked pre-existing varicella immunity developed disseminated primary varicella from the vaccine strain 16 days post-vaccination (reported previously[2]). This case was excluded from calculations for HZ.

BID, twice daily; HZ, herpes zoster; IFNγ, interferon gamma; IgG, immunoglobulin G; LOD, limit of detection; PBMC, peripheral blood mononuclear cell; SFCs, spot-forming cells; VZV, varicella zoster virus

Conclusions: LZV prior to treatment with tofacitinib is effective at boosting IgG levels and cell-mediated immunity towards VZV. No pts who developed both strong cell-mediated and humoral immunity against VZV developed HZ. Of the 5 pts who developed HZ, 3 did not have any cell-mediated response and 2 had a low humoral response.

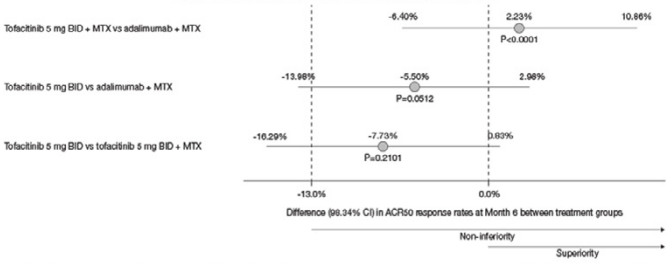
LB0003 TOFACITINIB WITH AND WITHOUT METHOTREXATE VERSUS ADALIMUMAB WITH METHOTREXATE FOR THE TREATMENT OF RHEUMATOID ARTHRITIS: RESULTS FROM ORAL STRATEGY, A PHASE 3B/4 RANDOMISED TRIAL

R. Fleischmann[1], E. Mysler[2], S. Hall[3], A. Kivitz[4], R. Moots[5], Z. Luo[6], S. Tatulych[7], R. DeMasi[8], K. Soma[7], R. Zhang[9], L. Takiya[8], C. Mojcik[9], S. Krishnaswami[7], S. Menon[7], J. Smolen[10]. *[1]Metroplex Clinical Research Center and University of Texas Southwestern Medical Center, Dallas, TX, United States; [2]Organización Médica de Investigación, Buenos Aires, Argentina; [3]Department of Medicine, Monash University, Cabrini Health, Melbourne, Australia; [4]Altoona Center for Clinical Research, Duncansville, PA, United States; [5]Institute of Ageing and Chronic Disease, University of Liverpool, Liverpool, United Kingdom; [6]Pfizer Inc, Shanghai, China; [7]Pfizer Inc, Groton, CT; [8]Pfizer Inc, Collegeville, PA; [9]Pfizer Inc, New York, NY, United States; [10]Medical University of Vienna, Vienna, Austria*



Background: Tofacitinib is an oral JAK inhibitor for the treatment of RA. There is no direct comparison of tofacitinib monotherapy vs tofacitinib +MTX in MTX inadequate responders (IR) and limited data comparing tofacitinib (±MTX) vs adalimumab (ADA) +MTX in patients (pts) with RA.

Objectives: To compare efficacy and safety of tofacitinib monotherapy, tofacitinib+MTX, and ADA+MTX in a head-to-head, non-inferiority trial in MTX-IR pts.

Methods: In this randomised, triple-dummy, active-controlled, 1-year, Phase 3b/4 trial (ORAL Strategy; NCT02187055), pts had active RA (≥4 tender/painful joints on motion and ≥4 swollen joints [28-joint count] at baseline [BL]) inadequately controlled with MTX. Pts were randomised 1:1:1 to receive tofacitinib 5 mg twice daily (5 mg mono BID), tofacitinib 5 mg BID +MTX (5 mg BID+MTX) or subcutaneous ADA 40 mg every other week +MTX (ADA+MTX); MTX dose: 15–25 mg/wk. The primary endpoint was ACR50 at Month (Mo) 6. Non-inferiority between treatments was declared if the lower bound of 98.34% two-sided confidence intervals of the difference of ACR50 response at Mo 6 was larger than -13% (based on meta analysis of ADA trials[1]), and superiority if it was larger than 0%. Other endpoints included: ACR20/50/70 and least-squares mean changes from BL in SDAI, DAS28-4(ESR) and HAQ-DI at Mos 6 and 12. Safety was assessed throughout the trial.

Results: 1146 pts were randomised and treated (5 mg mono BID: n=384; 5 mg BID+MTX: n=376; ADA+MTX: n=386). Demographics and BL disease characteristics were similar across groups. Most pts were female (82.7–83.1%), white (75.9–77.1%), with a mean age of 49.7–50.7 years, median disease duration of 5.4–6.1 years and mean HAQ-DI score of 1.6. Across groups, 80.2–81.6% of pts completed the study. ACR50 response rate at Mo 6 was 38.3% for 5 mg mono BID, 46.0% for 5 mg BID+MTX and 43.8% for ADA+MTX. Non-inferiority was demonstrated for 5 mg BID+MTX vs ADA+MTX (P<0.0001) but not for 5 mg mono BID vs ADA+MTX (P=0.0512) or 5 mg mono BID vs 5 mg BID+MTX (P=0.2101) which, although numerically different, were not statistically different (Figure). Tofacitinib monotherapy achieved the efficacy expected of an effective immunomodulator in this pt population. Secondary efficacy analyses were generally consistent with the primary analysis (Table). Adverse event (AE), serious AE and discontinuation due to AE rates were generally clinically similar across groups, though numerically fewer pts had increased alanine aminotransferase with 5 mg mono BID vs 5 mg BID+MTX or ADA+MTX.

Figure. Difference in ACR50 response rates between treatment groups at Month 6

Non-inferiority was demonstrated if the lower bound of the confidence interval was larger than -13.0%; superiority was demonstrated if the lower bound of the confidence interval was larger than 0.0%. P-values presented are from non-inferiority hypothesis testing. P-values are multiplicity-adjusted and should be compared with 0.025.

Table. Efficacy analyses and summary of safety by treatment group

	Tofacitinib 5 mg BID monotherapy (N=384)		Tofacitinib 5 mg BID + MTX (N=376)		ADA 40 mg EOW + MTX (N=386)

New treatments in SLE, Sjögren's and APS

OP0231 THE EFFECT OF "TRIPLE THERAPY" WITH ANTICOAGULATION PLUS CORTICOSTEROIDS PLUS PLASMA EXCHANGE AND/OR INTRAVENOUS IMMUNOGLOBULINS ON THE MORTALITY OF CATASTROPHIC ANTIPHOSPHOLIPID SYNDROME (CAPS) PATIENTS

I. Rodríguez-Pintó[1], G. Espinosa[1], D. Erkan[2], Y. Shoenfeld[3], R. Cervera[1] on behalf of CAPS Registry Project Group (European Forum on Antiphospholipid Antibodies). *[1]Department of Autoinmune Disease, Hospital Clínic, Barcelona, Spain; [2]Barbara Volcker Center for Women and Rheumatic Disease, Hospital for Special Surgery, New York, United States; [3]Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Tel Aviv, Israel*

Background: Triple therapy (anticoagulation plus corticosteroids plus plasma exchange and/or intravenous immunoglobulins) is empirically prescribed for the management of catastrophic antiphospholipid syndrome (CAPS). However, previous analyses have been inconsistent regarding the beneficial effect of triple therapy on patients' survival.

Objectives: The objective of this study was to assess the effect that triple therapy has on the mortality risk of CAPS patients.

Methods: In a cohort including 525 episodes of CAPS (CAPS Registry), we evaluated the relationship between triple therapy and mortality. Patients were grouped in three based on their treatments: a) triple therapy (anticoagulation plus corticosteroids plus plasma exchange and/or intravenous immunoglobulins); b) drugs included in the triple therapy but in different combinations; c) none of the treatments included in the triple therapy. The primary endpoint was all-cause mortality. Multivariate logistic regression models were used to compare mortality risk between groups taking into account a set of possible confounding variables.

Results: The "CAPS registry" cohort included 525 episodes of CAPS accounting for 502 patients. After excluding 38 episodes (7.2%), a total of 487 episodes of CAPS accounting for 471 patients (mean age 38 years; 67.9% female; primary APS patients 68.8%) were analyzed. Overall, 177 (36.3%) patients died. Triple therapy was prescribed in 197 episodes (40.5%), other combinations in 278 (57.1%), and none of those treatments in 12 episodes (2.5%). According to these three groups, mortality rate increased up to 27.9%, 40.6%, and 75%, respectively. Triple therapy was positively associated with a higher chance of survival when compared to non-treatment (adjusted odds ratio [OR]: 7.7 95%; confidence interval [95CI] 2.0–29.7) or to treatment with other combinations of drugs included in the triple therapy (adjusted OR 6.8; 95CI 1.7–26.9). Triple therapy accounted for a 64% decrease of the risk of death in patients with CAPS that received this combination of drugs.

Conclusions: Triple therapy is independently associated to a higher survival rate among CAPS.

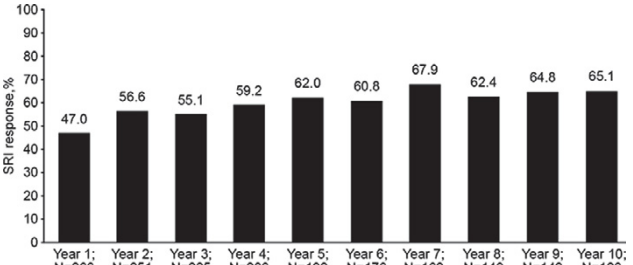
OP0232 SUSTAINED SAFETY AND EFFICACY OVER 10 YEARS WITH BELIMUMAB (BEL) PLUS STANDARD SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) THERAPY (SOC) IN PATIENTS WITH SLE



D.J. Wallace[1], E.M. Ginzler[2], J.T. Merrill[3], R.A. Furie[4], W. Stohl[5], W. Chatham[6], A. Weinstein[7], J. McKay[8], W.J. McCune[9], M. Petri[10], J. Fettiplace[11], D. Roth[12], B. Ji[13], A. Heath[14]. *[1]Cedars-Sinai Medical Center, Los Angeles; [2]SUNY Downstate Medical Center, Brooklyn; [3]Oklahoma Medical Research Foundation, Oklahoma City; [4]Northwell Health, Great Neck; [5]University of Southern California Keck School of Medicine, Los Angeles; [6]University of Alabama at Birmingham, Birmingham; [7]Washington Hospital Center, Washington DC; [8]Oklahoma State University Center for Health Sciences, Tulsa; [9]University of Michigan, Ann Arbor; [10]Johns Hopkins University School of Medicine, Baltimore, United States; [11]GSK (at the time of study), Uxbridge, United Kingdom; [12]GSK, Philadelphia, United States; [13]GSK, Uxbridge, United Kingdom; [14]GSK, Raleigh-Durham, United States*

Background: Preliminary safety and efficacy data from the Phase II BEL open-label extension study (LBSL02; NCT00071487) have been reported.

Objectives: Here we present the final 10-year data.

Methods: This was a multicentre, open-label, continuation trial (BEL112626; NCT00583362) of BEL + SoC in patients with a satisfactory response in the parent study. Patients received intravenous BEL 10 mg/kg every 4 weeks. Baseline was prior to the first ever dose of BEL.

Results: Of 298 patients in the continuation trial, 131 (44%) remained at Year 10. Total BEL exposure was 2154 patient-years. Adverse events (AEs) remained stable or decreased (Table). Two deaths (pseudomonal lung infection; cytomegaloviral pneumonia) were possibly related to BEL. SLE Responder Index (SRI) response increased (Figure). A British Isles Lupus Assessment Group (BILAG) flare (1 new A/2 new B scores) occurred in 72.6% of patients and 41.9% had a severe flare (SLE Flare Index). Prednisone dose decreased from baseline to Year 10 (Table). Of patients receiving >7.5 mg/day baseline prednisone, 32.6%

(14/43) decreased their dose to ≤7.5 mg/day by Year 10; 9.5% (9/95) of patients receiving baseline prednisone ≤7.5 mg/day had a dose increase to >7.5 mg/day.
Conclusions: Over 10 years BEL + SoC was well tolerated and the rates and nature of AEs were consistent with the known profile of BEL. Efficacy was maintained and prednisone use decreased in those receiving >7.5 mg/day at baseline.

OP0233 PRIMARY PROPHYLAXIS OF CARDIOVASCULAR EVENTS IN SYSTEMIC LUPUS ERYTHEMATOSUS: A RETROSPECTIVE ANALYSIS OF 291 PATIENTS FROM TWO ITALIAN CENTERS

S. Fasano[1], D. Margiotta[2], L. Navarini[2], L. Pierro[1], A. Riccardi[1], I. Pantano[1], A. Afeltra[2], G. Valentini[1]. [1]*Rheumatology Unit, University of Campania "Luigi Vanvitelli", Naples;* [2]*Unit of Allergology, Immunology, Rheumatology, Campus Bio-Medico University, Rome, Italy*

Background: Systemic lupus erythematosus (SLE) is associated with an increased cardiovascular (CV) risk (1). By retrospectively investigating a one centre cohort, we have recently reported that low-dose aspirin (ASA) use is associated with a reduced CV risk in SLE (2) and long-term hydroxychloroquine (HCQ) exposure may have an additive effect (3).
Objectives: This study was conducted on 2 Italian SLE cohorts to confirm these results and assess the role, if any, of statins.
Methods: Clinical charts of SLE patients consecutively admitted to 2 University Rheumatology Units from November 2000 to December 2014 who, at admission, had not experienced any CV event, were investigated. ASA, HCQ and statins use and the occurrence of any CV event, were recorded at each visit. Kaplan-Meier analysis was performed to determine the HCQ exposure status associated with a higher CV-free survival. Cox regression analysis was carried out to identify factors independently associated with a first CV event.
Results: A total of 291 SLE patients were included in the study and followed for a median of 8 years. During follow-up, 16 CV events occurred. Kaplan Meier analysis revealed a greater CV event-free rate in the 120 ASA-treated patients taking HCQ at standard dose for more than 5 years than in the 98 patients treated with ASA alone or with HCQ for less than 5 years (Figure 1). At univariate analysis, patients with a first CV event compared with those without any thrombotic events were antiphospholipid antibody (aPL) positive (P=0.017 HR 2.91) and had significantly higher blood pressure (P=0.017 HR 3.58), hypercholesterolemia (P=0,015 HR 3.40) and higher disease damage at last visit (P=0,032 HR 1.56). Moreover, ASA treatment (P=0,012 HR 0.27) and HCQ use (P=0,012 HR 0.26) for more than 5 years were negative predictors, while statins use did not show any association (P=0.619). All other variables examined, including smoking, obesity, hypertriglyceridaemia, diabetes mellitus, disease activity, severe SLE, other medications (immunosuppressive agents, steroids) were not associated, either positively or negatively, with the occurrence of CV events. At multivariate analysis, taking ASA and HCQ for more than 5 years were protective against thrombosis (HR 0.24 and HR 0.27, respectively), while aPL positivity (HR 4.32) increased the risk of a first CV event.

Conclusions: Use of antimalarials for more than 5 years is associated with a reduced risk of a first thrombosis in SLE patients and the HCQ-ASA combination seems to synergistically reduce further the CV risk. Larger, prospective studies are needed to provide a better definition of the role of these drugs in CV primary prevention in SLE.

OP0234 CLINICAL AND BIOLOGIC EFFECTS OF ICOSL BLOCKADE BY AMG 557 IN SUBJECTS WITH LUPUS ARTHRITIS

L.E. Cheng[1], Z. Amoura[2], B. Cheah[3], F. Hiepe[4], B.A. Sullivan[1], L. Zhou[1], G.E. Arnold[1], W.H. Tsuji[1], J.T. Merrill[5], J.B. Chung[1]. [1]*Amgen Inc., Thousand Oaks, United States;* [2]*Hôpital Pitié-Salpêtrière, Paris, France;* [3]*International Medical University, Kuala Lumpur, Malaysia;* [4]*Charité Universitätsmedizin Berlin, Berlin, Germany;* [5]*Oklahoma Medical Research Foundation, Oklahoma City, United States*

Background: Blockade of inducible costimulatory ligand (ICOSL) might be a promising approach for autoimmune diseases such as systemic lupus erythematosus (SLE). We evaluated AMG 557, an anti-ICOSL monoclonal antibody, in an exploratory phase 1b study of SLE subjects with inflammatory arthritis, by withdrawing background therapies to improve interpretability of a small study.
Objectives: To investigate potential efficacy, safety, and tolerability of AMG 557 in subjects with lupus arthritis.
Methods: This double-blind, randomized, placebo-controlled trial enrolled subjects with SLE and active lupus arthritis (≥4 tender and 4 swollen joints) and Systemic Lupus Erythematosus Disease Activity Index [SLEDAI] score ≥6 despite stable background immunosuppressants. Upon enrollment, investigators were permitted to use up to 20 mg/day of prednisone, which was tapered by day 85 to 7.5 mg/day or 50% of baseline, whichever was lower. Subjects received AMG 557 210 mg or placebo once weekly for 3 weeks followed by 10 additional doses every other week until day 155. At day 29, background immunosuppressants were withdrawn. The primary clinical endpoint was a composite Lupus Arthritis Responder Index at day 169; response was defined as achieving: (1) 50% decrease in combined tender and swollen joint counts, and (2) ≥1 letter improvement in the musculoskeletal subsystem of the British Isles Lupus Assessment Group (BILAG) index and (3) prespecified immunosuppressant medication withdrawal and/or prednisone taper. Safety was a co-primary endpoint. Exploratory endpoints included safety, 4-point reduction of SLEDAI, clinical indices (SLEDAI, BILAG), complement components, autoantibodies, and lymphocyte populations.
Results: Twenty subjects (19 females) were randomized (10 AMG 557, 10 placebo) at 8 sites in North America, Asia, and Europe. The primary endpoint was met by 3/10 subjects receiving AMG 557 and 1/10 subjects receiving placebo (*P*=ns). A 4-point decrease in SLEDAI score was achieved by 7/10 subjects on AMG 557 and 2/10 subjects on placebo. At day 169, subjects receiving AMG 557 had decreases from baseline in mean global BILAG and SLEDAI scores of 36% and 48% respectively, compared to 25% and 11% in subjects receiving placebo. Lupus-associated biomarkers, including serum complement indices (C3, C4, and CH50), and autoantibodies, including anti-dsDNA, demonstrated trends towards improvement relative to placebo. Treatment-emergent adverse events (AEs) were similar between placebo and AMG 557 arms; most commonly headache and upper respiratory tract infection.
Conclusions: Results from this exploratory placebo-controlled trial in lupus arthritis suggest potential clinical benefit of ICOSL blockade by AMG 557. These data support further clinical trials intervening in this costimulatory pathway in SLE and other autoimmune diseases.

OP0235 A NOVEL B CELL SPECIFIC IFN-I BIOMARKER IS ASSOCIATED WITH PLASMABLAST NUMBERS FOLLOWING B CELL DEPLETION THERAPY IN SLE

Y.M. El-Sherbiny[1,2], M.Y. Md Yusof[1,2], E. Hensor[1,2], A. Rawstron[3], M. Wittmann[1,2], P. Emery[1,2], E.M. Vital[1,2]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]National Institute of Health Research Leeds Musculoskeletal Biomedical Research Unit; [3]Haematological Malignancy Diagnostic Service, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

Background: SLE is a Type I interferon (IFN-I) mediated disease with autoreactive B cells. Plasmablasts, the immediate progeny of B cells, are expanded in SLE and correlate with disease activity. We showed that their rate of regeneration after therapeutic B cell depletion with rituximab is variable and predicts relapse[1]. IFN-I has been shown *in vitro* to induce the differentiation of B cells into plasmablasts. We previously showed that therapeutic B cell depletion with anti-CD20 mAb leads to a transient reduction in CD20-negative plasmablasts, following which plasmablasts repopulate and their numbers predict clinical relapse. We developed tetherin as a flow cytometric, cell-specific marker for IFN-I response.
Objectives: To test the hypothesis that memory B cell tetherin determines the rate of plasmablast repopulation after rituximab.
Methods: 117 rituximab-treated SLE patients were studied prosectively using BILAG-2004 and flow cytometry. In 97 responders we tested plasmablasts at 6 months as a predictor of clinical relapse before 12 months to validate our previous finding. In 50 patients pre-rituximab and 28 patients post-rituximab we performed additional flow cytometry to measure tetherin on each cell subset. Expression of 18 ISGs was measured using Taqman on PBMCs and an ISG score calculated.
Results: We divided clinical responders to rituximab into earlier relapse (12 months) or later relapse (>12 months). As in our published discovery cohort, plasmablasts were strongly predictive of clinical relapse. ROC analysis indicated that a plasmablast count of >0.0008 x 10^9/L at 6 months yielded 73% (95% CI 45–92%) sensitivity and 90% (95% CI 56–99%) specificity in predicting earlier relapse; area under the curve of 0.86.
Plasmablast numbers after rituximab were associated with Memory B cell tetherin (R=0.38, p=0.047) but not ISG score (R=0.24, p=0.219) (Table 1).
In Pre-rituximab there was no relationship between any IFN assay and plasmablast count. After rituximab treatment there was no correlation between plasmablast count and ISG expression, nor with monocyte or NK cell surface tetherin. However, memory B cell tetherin MFI was positively correlated with plasmablast count (Table 1).

Table 1

Interferon assay	Plasmablast Count (cells x10^9/L)	
	Pre-rituximab (*n* =50)	Post-rituximab (*n* =28)
ISG expression Score:	-0.11, *P*=0.448	0.24, *P*=0.219
Tetherin protein level: Monocytes	-0.08, *P*=0.592	0.20, *P*=0.296
T-cells	-0.16, *P*=0.269	0.32, *P*=0.096
NK cells	-0.14, *P*=0.324	0.05, *P*=0.795
Naïve B-cells	-0.04, *P*=0.801	0.30, *P*=0.121
Memory B-cells	0.07, *P*=0.618	0.38, *P*=0.047

Values are Spearman's Rank Correlation Coefficient and *P* values.

Conclusions: Although interferon stimulated gene expression is commonly used to measure IFN-I activity, tetherin provides a cell-specific assay. We demonstrate that by measuring IFN-I response in B cells specifically, we could explain plasmablast differentiation, and thereby clinical outcome. Memory B cell tetherin is valuable to immunophetype SLE.

OP0236 BENEFIT AND SAFETY OF ANTITHROMBOTIC TREATMENT IN 264 PREGNANCIES IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME

C.M. Yelnik[1], M. Lambert[1], E. Drumez[2], V. Le Guern[3], J.-L. Bacri[4], M. Guerra[5], C.A. Laskin[6], W. Branch[7], L.R. Sammaritano[5], N. Morel[3], G. Guettrot-Imbert[3], D. Launay[1], E. Background: The management of pregnancy in patients with antiphospholipid syndrome (APS) with aspirin and heparin is based on empiric recommendations.
Objectives: Our study aimed to evaluate the outcomes of treated patients with thrombotic and obstetric APS and the safety of antithrombotic treatments prescribed during pregnancy.
Methods: Inclusion criteria were (1) APS (Sydney criteria), (2) live pregnancy at 12 weeks of gestation (WG) with (3) follow up data until 6 weeks post-partum. Data were collected prospectively (PROMISSE study) and retrospectively (four French centers). Adverse pregnancy outcomes (APOs) were defined by fetal death or neonatal death; pre-term delivery before 36 WG due to preeclampsia or placental insufficiency; or small for gestational-age (SGA; <5th percentile). Major bleeding was defined as blood loss greater than 500mL and/or requiring surgery or transfusion.
Results: 264 pregnancies (87 collected prospectively) in 204 patients were included (46% with a history of thrombosis, and 23% with associated systemic lupus erythematosus). During pregnancy, treatment included heparin (n=253; 96%) and low-dose aspirin (n=223; 84%).
The live birth rate was 86%. APOs occurred in 32%, mostly during the 2nd trimester: fetal deaths 11%, SGA 11%, pre-term delivery before 36 WG due to preeclampsia or placental insufficiency 17%. Thirteen maternal thrombotic events occurred in 12 (4.5%) pregnancies. Forty-six maternal hemorrhagic events occurred in 40 (15%) pregnancies (30 events in the post-partum period). Major bleeding was reported in only 6 pregnancies (2.3%) and occurred only after delivery. Except for two events, post-partum hemorrhage occurred in the early post-partum before hospital discharge. No maternal death was observed.
Aspirin therapy during pregnancy was the only independent factor associated with a lower risk of APOs (odds ratio: 0.34; 95% CI: 0.15 – 0.78; p=0.01) in multivariate analysis.
Neither heparin or aspirin alone, nor combined therapy increased the risk of hemorrhage. In the retrospective cohort, emergency caesarian section was the only factor associated with hemorrhagic events during the study period (53% hemorrhages in patients who underwent emergency caesarian compared to 18%, p=0.005). Independent risk factors for APOs were elevated body mass index and the presence of lupus anticoagulant.
Conclusions: We report a high level of obstetrical complications in conventionally-treated APS pregnancies, and a beneficial effect of addition of aspirin to prevent obstetrical morbidity. Moreover, heparin and aspirin were well tolerated and did not increase risk of hemorrhage.

OP0237 LIFITEGRAST OPHTHALMIC SOLUTION 5.0% FOR TREATMENT OF DRY EYE DISEASE: COMBINED EVIDENCE FROM 5 RANDOMIZED CONTROLLED TRIALS

C. Baudouin[1], M. Darvish-Zargar[2], E.J. Holland[3], C.C. Chan[4], K.K. Nichols[5], J. Tauber[6], A. Raychaudhuri[7], M. Roy[7], A. Shojaei[7]. *[1]Centre Hospitalier National d'Ophtalmologie des Quinze-Vingts, Paris, France; [2]McGill University, Montreal, Canada; [3]Cincinnati Eye Institute, Edgewood, United States; [4]University of Toronto, Toronto, Canada; [5]University of Alabama School of Optometry, Birmingham; [6]Tauber Eye Center, Kansas City; [7]Shire, Lexington, United States*

Background: Dry eye disease (DED) is a multifactorial disease of the tear film and ocular surface, characterized by ocular discomfort and visual disturbance.[1] DED is associated with a number of systemic autoimmune diseases, particularly rheumatoid arthritis and Sjögren's syndrome.[2,3] Lifitegrast is a lymphocyte function-associated antigen-1 (LFA-1) antagonist that inhibits T-cell–mediated inflammation (an underlying factor in DED) and is approved in the US for the treatment of signs and symptoms of DED (lifitegrast ophthalmic solution 5.0%, Xiidra®).
Objectives: To evaluate the combined evidence from 5 clinical trials of lifitegrast ophthalmic solution 5.0% (LIF) in subjects with dry eye disease (DED).
Methods: Adults with DED were randomized to LIF or placebo (PBO) in 5 randomized, double-masked, placebo-controlled trials: 4 12-week efficacy/safety studies (phase 2, LIF n=58, PBO n=58; phase 3 trials: OPUS-1, LIF n=293, PBO n=295; OPUS-2, LIF n=358, PBO n=360; OPUS-3, LIF n=355, PBO n=356), and a 1-year safety study (SONATA, LIF n=220, PBO n=111). Individuals with secondary Sjögren's syndrome associated with autoimmune disease (eg, rheumatoid arthritis, systemic lupus erythematosus) were eligible to participate if they were not immunodeficient/immunosuppressed, not taking steroids, and met all other inclusion and exclusion criteria. Change from baseline to day 84 in DED signs and symptoms was evaluated across the 12-week studies. Key measures were inferior corneal staining score (ICSS; 0–4 scale), eye dryness score (EDS; visual analogue scale [VAS], 0–100 scale), and visual-related function subscale of a symptom scale (0–4 scale). Pooled safety data (LIF n=1287, PBO n=1177) from all 5 trials were also analyzed.
Results: LIF improved ICSS versus PBO in the phase 2 study (secondary endpoint; treatment effect 0.35, nominal *P*=0.0209), OPUS-1 (co-primary; 0.24,

Key efficacy results of lifitegrast ophthalmic solution 5.0% across 12-week multicenter randomized controlled trials (ITT population with LOCF)

Study	Symptom endpoint	Sign endpoint
Phase 2	• Visual-related function subscale (secondary, change from baseline to day 84): TE 0.37, nominal *P*=0.0394.	• Primary endpoint of ICSS at day 84 not met. • ICSS (secondary, change from baseline to day 84): TE 0.35, nominal *P*=0.0209.
OPUS-1	• Coprimary endpoint of change from baseline to day 84 on visual-related function subscale not met.	• ICSS (co-primary, change from baseline to day 84): TE 0.24, *P*=0.0007.
OPUS-2	• EDS (VAS; co-primary, change from baseline to day 84): TE 12.61, *P*<0.0001.	• Coprimary endpoint of change from baseline to day 84 in ICSS not met.
OPUS-3	• EDS (VAS; primary, change from baseline to day 84): TE 7.16, *P*=0.0007.	• ICSS (ad hoc, change from baseline to day 84): TE 0.17, nominal *P*=0.0144.

Eye dryness score (EDS; visual analogue scale [VAS]); ICSS, inferior corneal staining score; ITT, intention-to-treat; LOCF, last observation carried forward; TE, treatment effect.

P=0.0007), and OPUS-3 (ad hoc; 0.17, nominal *P*=0.0144). LIF reduced EDS (VAS) versus PBO in OPUS-2 (co-primary; 12.61, *P*<0.0001) and OPUS-3 (primary; 7.16, *P*=0.0007). The OPUS-1 co-primary symptom endpoint of visual-related function subscale, and the OPUS-2 co-primary sign endpoint of ICSS, did not achieve statistical significance. In the pooled safety analysis, total exposure was 415.65 person-years for LIF, and 332.15 person-years for PBO. Adverse events were mostly mild or moderate in severity. There were no serious ocular treatment-emergent adverse events (TEAEs) and withdrawals due to TEAEs were infrequent (LIF, 7.0%; PBO, 2.6%).

Conclusions: LIF improved signs and symptoms of DED in adults with DED and appeared to be well tolerated with no serious ocular TEAEs reported.

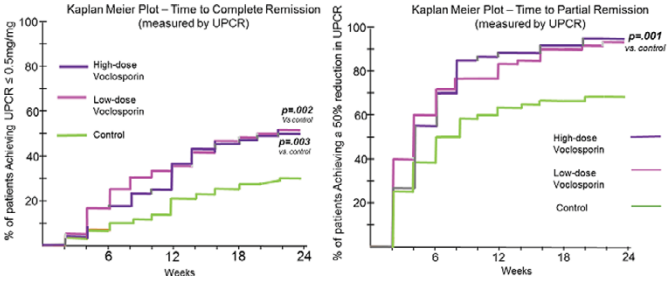
LB0002 48 WEEK COMPLETE REMISSION OF ACTIVE LUPUS NEPHRITIS WITH VOCLOSPORIN

V. Dobronravov [1], M.A. Dooley [2], S.A. Haq [3], I. Adzerikho [4], O. Bugrova [5], D. Isenberg [6], F. Houssiau [7], N. Solomons [8], R. Huizinga [8] on behalf of AURA-LV Study Group. *[1]Pavlov First St. Petersburg State Medical University, St. Petersberg, Russian Federation; [2]UNC, Chapel Hill, United States; [3]Bangabandhu Sheikh Mujib Medical University (BSMMU), Dhaka, Bangladesh; [4]Minsk Regional Clinical Hospital, Minsk, Belarus; [5]Orenburg Regional Clinical Hospital, Orenburg, Russian Federation; [6]University College Hospital, London, United Kingdom; [7]Université catholique de Louvain, Brussels, Belgium; [8]Aurinia Pharmaceuticals, Victoria, Canada*



Background: Voclosporin (VCS) is a novel CNI intended for use in the treatment of autoimmune diseases such as lupus nephritis (LN). VCS's unique structure allows for less pharmacokinetic-pharmacodynamic variability and a potentially improved safety profile compared to other CNIs.

Objectives: Achievement of complete remission (CR) as assessed at week 24 (primary objective) and assessment of the efficacy over 48 weeks (secondary objective), with 2 doses of VCS (low dose VCS: 23.7mg BID and high dose VCS: 39.5mg BID) vs. placebo in subjects with active LN.

Methods: The double blind placebo controlled AURA study enrolled 265 subjects with active LN in 20 countries. Patients were randomized into 3 arms (placebo, low dose VCS or high dose VCS) in addition to MMF 2g/day and steroids (with rapid tapering). CR was defined as a confirmed urine protein/creatinine ratio (UPCR) of ≤0.5 mg/mg using first morning void and confirmed estimated glomerular filtration rate (eGFR, CKD-EPI equation) ≥60 mL/min/1.73 m^2 or no decrease from baseline in eGFR of ≥20% in the presence of low dose steroids. Partial remission (PR) was defined as a 50% reduction in UPCR. UPCR assessments were made at each visit, together with biomarker data at regular intervals.

Results: We now present the 48 week data showing improved CR rates over the 24 week data. The rate of CR was significantly higher in the low dose VCS compared to the control group (32.6% vs. 19.3%; OR: 2.03, p=0.045) at 24 weeks. It was 27.3% in the high dose VCS group (p=NS). Both doses of voclosporin demonstrated superiority to control using time to CR, PR (50% reduction in proteinuria) and time to PR.

At 48 weeks, 23.9% of patients on the control arm achieved CR comparted to 49.4% low dose (OR: 3.21, p<0.001) and 39.8% high dose (OR: 2.10, p<0.026). Over 92% of subjects experienced at least one adverse event (AE) with the most common two being infections (58% low, 66% high and 55% placebo) and GI disorders (43% low, 52% high and 38% placebo). The overall rate of serious adverse events (SAEs) was numerically higher in both voclosporin groups (28% low, 25% high, 19% placebo) with the nature of SAEs consistent with those observed in patients with highly active LN. Most deaths occurred in the first 2 months and were: low dose (infection3, ARDS2, thrombotic3, cardiac tamponade, pulmonary hemorrhage), high dose (infection, PE) and control (CVA). All were considered unrelated to drug exposure by the investigators. 3 additional deaths occurred in placebo patients after the conclusion of the 48 weeks of treatment.

Conclusions: The AURA-LV study is the first global study demonstrating the beneficial effect of VCS, in combination with MMF and steroids, in the treatment of LN. Remission rate was rapid. VCS treatment resulted in increasing CR and PR seen by week 6 despite rigorous steroid taper (mean steroid dose 4 mg at week 16). Adverse events were higher in the treated patient group with the nature in keeping with immunosuppression. These promising data will be used to plan subsequent studies of voclosporin in LN.

Acknowledgements: This data was submitted on behalf of the AURA-LV study investigators.

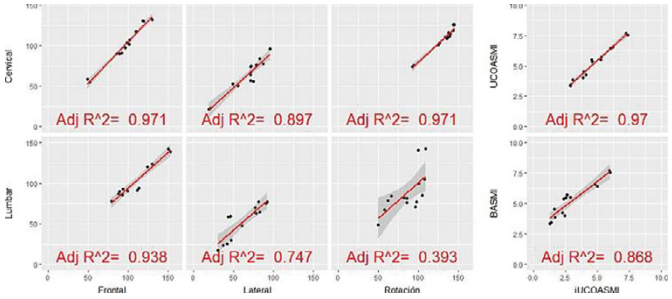
Axial spondyloarthritis from risk factor to clinical outcomes

OP0238 MEASUREMENT OF SPINAL MOBILITY IN AXIAL SPONDYLOARTHRITIS USING INERTIAL SENSORS: RELIABILITY AND VALIDATION PRELIMINARY RESULTS



F.J. Mata-Perdigon [1], I.R. Martínez Sanchez [2], J.L. Garrido-Castro [1], C. González-Navas [1], L.M. Fernandez-Ahumada [2], D.A. Gomez [1], V.C. Perez-Guijo [1], P. Font-Ugalde [1], E. Collantes-Estevez [1]. *[1]Maimonides Institute for Biomedical Research of Cordoba; [2]University of Cordoba, Cordoba, Spain*

Background: Axial spondyloarthritis (axSpA) is a chronic rheumatic disease that causes reduction of mobility in the patients' spine. There are several indices to analyze this mobility: BASMI, which lacks precision and sensitivity to change according to different authors, and UCOASMI (1) based on motion capture, which needs extensive resources that limit its practical applicability. Inertial measurement unit sensors (IMU) give, in real time, the 3D orientation of any anatomical place

Abstract OP0238 – Table 1

	Cervical			Lumbar			Indexes		
	Frontal	Lateral	Rotation	Frontal	Lateral	Rotation	iUCOASMI	UCOASMI	BASMI
Test	104.7 (19.7)	60.9 (17.0)	111.3 (19.0)	112.5 (25.6)	62.5 (18.3)	89.2 (26.3)	4.9 (1.2)	4.7 (1.6)	2.6 (1.4)
Retest	108.1 (20.9) β	63.5 (18.7) α	110.2 (19.0) β	113.5 (25.3) β	64.3 (18.5) β	88.3 (23.0) β	5.0 (1.3) α	–	–
2 Days	104.6 (18.9) γ	62.0 (18.3) α	111.9 (16.1) γ	112.5 (25.6) β	61.7 (18.8) β	88.9 (23.8) γ	5.0 (1.2) β	4.9 (1.5) α	2.7 (1.4) β

of the patient. It could be a sensitive, flexible and cheap technology, useful for assessing mobility in AxSpa, but validation studies are needed.
Objectives: To assess reliability and validity of inertial sensors for measuring spinal mobility in patients with axSpA.
Methods: 14 subjects: 7 patients with axSpA (5 male and 2 female, age 51.4±6.7 years, evolution time 25.4±11.3 years, 85.7% B27 positive) and a control group of 7 healthy individuals matched in gender and age were recruited. Cervical and lumbar movements were evaluated using 3 IMU sensors (located at forehead, D3 and L4) and a 3D motion capture system synchronously. A test/retest was performed at 5 minutes in the same day with the IMUs and in two days with both systems. Measurements of metrology, BASMI and UCOASMI indices were obtained. An index, iUCOASMI, was calculated using the same measurements used for UCOASMI, but obtained by inertial sensors.
Results: Table shows mean values (SD) for each range of movement expressed in degrees. BASMI, UCOASMI and iUCOASMI indexes are also included. Intraclass correlation coefficient (ICC) is indicated as α: >0.98 – Excellent, β: 0.95–0.98 – Very good and γ: 0.7–0.95 – Good, δ: <0.7 – Bad. RMSE error was less than 10° for all measures. There was good correlation ($p<0.01$) between iUCOASMI with BASFI, BASG, UCOASMI and BASMI. Graph shows results of linear regression between measures obtained with both system (for example: cervical frontal flexion obtained by motion capture and IMUs have a R^2 of 0.97) and between iUCOASMI with UCOASMI and BASMI.

Conclusions: The IMU system measured range of movement, showing good ICC both in the same day and in the two days test/retest. The iUCOASMI, has also shown an excellent correlation with UCOASMI, and with BASMI. Therefore, these kind of systems, based on IMU, may be useful for analyzing spinal mobility in patients with axSpA in a more accurate and reliable way compared with conventional metrology, and more flexible and cheap than other advanced systems, improving their practical applicability.

OP0239 HISTOLOGICAL FEATURES OF JOINT AND COLONIC INFLAMMATION IN INFLAMMATORY BOWEL DISEASE PATIENTS TREATED WITH ANTI-TNF

S. Alivernini[1], D. Pugliese[2], B. Tolusso[1], L. Petricca[1], L. Bui[3], L. Guidi[2], G.L. Rapaccini[2], F. Federico[3], G. Ferraccioli[1], A. Armuzzi[2], E. Gremese[1].
[1]Institute of Rheumatology; [2]Ibd Unit; [3]Institute of Pathology, Catholic University of the Sacred Heart, Rome, Italy

Background: New onset of joint inflammation in patients under anti-TNF-alpha for inflammatory bowel disease (IBD) has been previously described. However, histological characterization of synovial and bowel compartments has not been reported so far.
Objectives: Aim of the study was to evaluate the histological characteristics of paired synovial (ST) and colonic tissues in IBD patients under TNF-alpha blockers.
Methods: Consecutive IBD patients without history of co-existing joint involvement who developed peripheral arthritis under TNF-alpha blockers, were prospectively enrolled. Each patient underwent rheumatological evaluation and ultrasound (US) assessment (using Gray scale for synovial hyperthrophy and Power Doppler Signal) of the affected joints. Each patient underwent US guided ST biopsy of the knee, following a standardized procedure[1] and colonoscopy with mucosal biopsies. Each ST and colonic paired sample was stained through immunohistochemistry (IHC) for CD68, CD21, CD20, CD3 and CD117[2]. H&E staining was performed for Paneth cells identification. Clinical and immunological parameters [Anti-citrullinated peptides antibodies (ACPA), IgM-Rheumatoid Factor (RF) and IgA-RF respectively] were collected for each patient.
Results: 10 patients with IBD [46.0±9.7 years old, 13.2±9.9 years of disease duration, 2.5±1.6 years of TNF-alpha blockers exposure, 6 with Crohn's Disease and 4 with Ulcerative Colitis respectively] were studied. All patients were negative for ACPA, IgM-RF or IgA-RF and 4 patients were under Methorexate therapy. 5 (50.0%) patients showed endoscopic and histologically proven inflammation of colonic mucosa. Moreover, IHC revealed that 6 (60.0%) patients had diffuse and 4 (40.0%) had follicular synovitis, respectively. In particular, there was a direct correlation between $CD68^+$, $CD21^+$, $CD3^+$, $CD20^+$ and $CD117^+$ cells distribution in paired ST and gut tissues in the whole cohort ($p<0.05$). No significant differences in terms of disease duration (p=0.48), TNF-alpha blockers exposure time (p=0.29), ESR (p=0.26) and CRP (p=0.91) values were found comparing patients with follicular and diffuse synovitis respectively.
Conclusions: Our findings suggest that patients with IBD may develop histologically proven synovitis during TNF-alpha treatment, showing similar histological features in terms of $CD68^+$, $CD21^+$, $CD20^+$, $CD3^+$ and $CD117^+$ cells between synovial and colonic compartments. Molecular mechanisms triggered by TNF-alpha blockers leading to joint inflammation have to be clarified.

OP0240 HOW STRONG ARE THE ASSOCIATIONS OF SPONDYLOARTHRITIS-RELATED COMORBIDITIES WITH ANKYLOSING SPONDYLITIS, PSORIATIC ARTHRITIS AND UNDIFFERENTIATED SPONDYLOARTHRITIS? A REGISTER-BASED STUDY FROM SWEDEN

K. Bengtsson[1], H. Forsblad-d'Elia[1,2], E. Lie[1], E. Klingberg[1], M. Dehlin[1], S. Exarchou[3], U. Lindström[1], J. Askling[4], L.T. Jacobsson[1]. *[1]Department of Rheumatology and Inflammation Research, Institute of Medicine, Sahlgrenska Academy at University of Gothenburg, Göteborg; [2]Departments of Public Health and Clinical Medicine, Rheumatology, Umeå; [3]Section of Rheumatology, Department of Clinical Sciences, Malmö, Lund University, Malmö; [4]Clinical Epidemiology Unit and Rheumatology Unit, Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden*

Background: Spondyloarthritis (SpA), including ankylosing spondylitis (AS), psoriatic arthritis (PsA) and undifferentiated SpA (uSpA), is a cluster of rheumatic diseases with some common genetic risk factors. These genetic risk factors are likely to result in associations of varying degree with SpA-related comorbidities such as inflammatory bowel disease (IBD), psoriasis and anterior uveitis. There

Abstract OP0240 – Table 1. Prevalence (%) and corresponding Prevalence Ratio (PR) of SpA-related comorbidities in AS, PsA and uSpA

	AS cases n (%)	PR (95% CI) (AS: GP)	PsA cases n (%)	PR (95% CI) (PsA: GP)	uSpA cases n (%)	PR (95% CI) (uSpA: GP)

Psoriasis	85 (2.2)	2.7 (2.0–3.5)	NA	NA	78 (2.9)	3.2 (2.4–4.3)
AV block	39 (1.0)	5.8 (3.6–9.4)	30 (0.3)	1.6 (1.0–2.4)	13 (0.5)	4.6 (2.1–10.0)
Aortic regurgitation*	55 (1.4)	4.7 (3.2–6.9)	41 (0.5)	1.7 (1.2–2.4)	11 (0.4)	3.0 (1.4–6.4)

AV, atrioventricular; NA, not applicable. *Aortic regurgitation includes both ICD codes for aortic regurgitation and procedure codes for aortic valve surgery.

is also a known association between AS and conduction disturbances and aortic regurgitation. Comparative analyses in the same setting of the strengths of these associations with AS, PsA and uSpA are scarce.
Objectives: To assess the strengths of the associations of different SpA-related comorbidities with a diagnosis of AS, PsA and uSpA.
Methods: All patients, aged ≥18 years, with AS (n=3884), PsA (n=8706) and uSpA (n=2665) were identified 2001 through 2005, according to specified ICD codes from the Swedish Patient Register. The register contains diagnoses from all visits in inpatient and non-primary outpatient care. Each patient was matched by year of birth, sex and county to five general population (GP) controls identified in the Population Register. Occurrence of SpA-related comorbidities prior to 1 January 2006 were also retrieved from the Swedish Patient Register. Number and proportion of cases (n (%)) with a recorded SpA-related comorbidity prior to 1 January 2006 and corresponding prevalence ratio (PR) with 95% confidence interval (CI) were calculated, overall and stratified for sex.
Results: PRs for SpA-related comorbidities were significantly elevated in all SpA subtypes compared to their matched GP controls (Table). PRs were substantially elevated in AS, intermediately elevated in uSpA, whereas only moderately increased in PsA. The results were similar in the sex-stratified analyses (not shown).
Conclusions: The strongest associations of SpA-related comorbidities were seen with AS, closely followed by uSpA, compatible with a substantial shared etiology and phenotypical expression for patients given these two diagnoses, whereas the associations between PsA and the SpA-related comorbidities were considerably weaker.

OP0241 ERAP1 IS A SUSCEPTIBILITY FACTOR FOR EARLY AXIAL SPONDYLOARTHRITIS MEETING THE ASAS CLASSIFICATION CRITERIA: RESULTS FROM THE DESIR AND SPACE COHORTS

A. de Koning[1], M. Hameetman[1], C. Micelli[2], M. Dougados[3], D. van der Heijde[1], F. Kurreeman[1], F.A. van Gaalen[1]. *[1]LUMC, Leiden, Netherlands; [2]Hôpital Bicêtre; [3]Hôpital Cochin, Paris, France*

Background: Genetic research in axSpA is performed in patients with longstanding ankylosing spondylitis (AS). Early axial spondyloarthritis (axSpA) is a diverse patient group in which a minority of the patients have AS. Therefore, it is not known if recently identified genetic risk factors for AS are also risk factors for early axSpA.
Objectives: To evaluate if ERAP1 and HLA-B*4001 are susceptibility factors for early axSpA.
Methods: Patients with early axSpA meeting the ASAS classification criteria from the SPACE cohort (inclusion criteria: back pain for ≥3 months, ≤2 years, onset <45 years) and the DESIR cohort (inclusion criteria: inflammatory back pain for ≥3 months, ≤3 years, age <50) were typed for two well established AS genetic risk factors: ERAP1 SNPs rs30187 (susceptibility), rs17482078 (protective) and rs10050860 (neutral) and HLA-B*4001. Analysis of weaker AS risk factors was limited by sample size. For ERAP1, genotyped Dutch healthy controls (n=1085) and published French controls[1] were used as controls. For HLA-B*4001 healthy blood bank donors from the Netherlands (n=5584) and France (n=10177) were used as controls.
Results: In 486 DESIR patients (mean age 32.5 (SD 8.6); 50% male; 84% HLA-B27+; 18% X-SI+) and 144 SPACE patients (mean age 29.5 (SD 8); 51% male; 88% HLA-B27+; 24% X-SI+) ERAP1 SNP rs30187 was more common than in controls (OR 1.2, p=0.01 in meta-analysis; table 1). rs17482078 and rs10050860 were negatively associated with early axSpA (both 0.7 (0.6–0.9) p<0.01 in meta-analysis). Although both cohorts were sufficiently powered, HLA-B*4001 was not positively associated with early axSpA (OR 0.6 (0.4–0.9) in meta-analysis).

Table 1. Minor allele frequency and odds ratio of ERAP1 SNPs in SPACE and DESIR compared with Dutch and French controls respectively.

		SPACE n=144	Dutch controls n=1085		DESIR n=486	French controls* n=384		Meta-analysis
SNP	Risk allele	MAF	MAF	OR (95% CI)	MAF	MAF	OR (95% CI)	OR (95% CI)
rs30187	T	0.38	0.32	1.2 (1.0-1.6)	0.41	0.37	1.2 (0.9-1.5)	1.2 (1.0-1.4) p=0.01
rs17482078	T	0.14	0.21	0.6 (0.5-0.9)	0.18	0.22	0.8 (0.6-1.0)	0.7 (0.6-0.9) p<0.001
rs10050860	T	0.15	0.22	0.6 (0.5-0.9)	0.18	0.23	0.8 (0.6-1.0)	0.7 (0.6-0.9) p<0.001

* Calculated from published data (1)
ERAP1: endoplasmic reticulum aminopeptidase 1

Conclusions: ERAP1 rs30187 is a genetic risk factor for early axSpA. To our knowledge this is the first report of genetic risk factor research in early axSpA patients meeting the ASAS criteria. Larger cohorts are needed to study additional AS risk factors.

OP0242 HEALTH-RELATED QUALITY OF LIFE IMPROVED ONLY SLIGHTLY ALTHOUGH DISEASE ACTIVITY DECREASED OVER 3 YEARS IN EARLY AXIAL SPONDYLOARTHRITIS: 442 PATIENTS FROM THE DESIR COHORT

D. Puyraimond-Zemmour[1,2], C. Desthieux[1,2], A. Ruyssen-Witrand[3], B. Fautrel[1,2], L. Gossec[1,2]. *[1]Paris 06 university, Pierre and Marie Curie; [2]Pitie Salpetriere Hospital, Paris; [3]CHU de Toulouse, Hôpital Pierre-Paul Riquet, Toulouse, France*

Background: Current guidelines emphasize Health-related Quality of life (HRQoL) as a priority in health care but the link with disease activity is incomplete.
Objectives: The objective was to describe in patients with early axial spondyloarthritis (axSpA) the evolution of SF36 and of ASDAS-CRP over a 3 years follow up.
Methods: DESIR is an ongoing prospective, multicenter, longitudinal, observational French cohort (1). Patients had inflammatory back pain of more than 3 months and less than 3 years suggestive of axSpA. For our analysis, only patients with no missing data for MCS and PCS SF36 values during the first 3 years were included. HRQoL was assessed by the SF36 questionnaire and its 2 subscales (scored 0–100 with higher scores indicating better status): the physical composite score (PCS) including physical function, physical role, bodily pain and general health (GH) and the mental composite score (MCS) including mental health (MH), emotional role, social function and vitality. Disease activity was assessed by the ASDAS-CRP. Each outcome was assessed at baseline, 6 months, 12 months, 24 months and 36 months. The mean and median outcomes were calculated at each time-point and comparisons used ANOVA on repeated data. Baseline predictive factors associated with worse SF36 scores (lower half of mean values over 3 years) were identified by univariate then multivariate logistic regression, among the baseline variables age, gender, educational level, work status, smoking, HLAB27, radiological sacroiliitis, extra-articular manifestations (uveitis, psoriasis, inflammatory bowel disease) and ASDAS-CRP.
Results: In all, 442 patients were analyzed: at baseline, mean age was 34.2±8.6 years; mean disease duration was 18.6±10.7 months; 239 (54%) were females, 274 (62%) had HLAB27 and 124 (28%) had radiological sacroiliitis. At baseline, mean PCS, MCS and ASDAS-CRP were respectively 40.5±9.2, 40.4±11.0 and 2.6±1.0. Over 3 years, although mean ASDAS-CRP improved, HRQoL improved only slightly (Figure). All the SF36 subdomains improved (all p<0.001), though GH and MH improved less (data not shown). In univariate analysis, lower educational level, not being in a white collar job, younger age and higher ASDAS-CRP were significantly associated to lower HRQoL over 3 years. In multivariate analysis, only higher baseline ASDAS-CRP (odds ratio=0.49 [95% confidence interval 0.29; 0.79]) was associated to lower HRQoL.

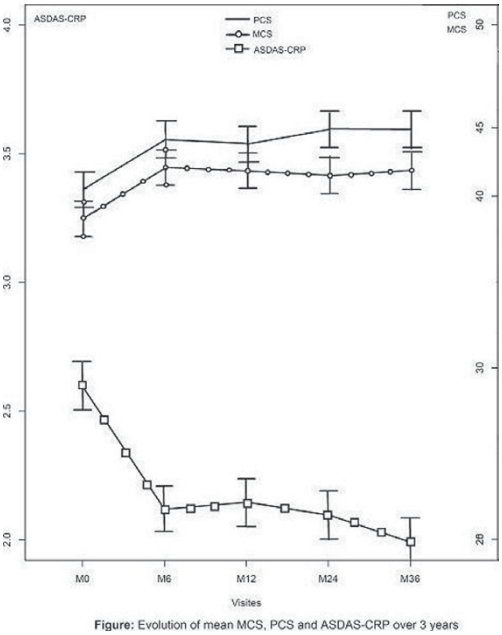

Figure: Evolution of mean MCS, PCS and ASDAS-CRP over 3 years

Conclusions: In early axSpA, HRQoL was affected similarly for the physical and mental components and only slightly improved over 3 years. In contrast, ASDAS-CRP improved substantially. However, ASDAS-CRP was a stronger driver of HRQoL than demographic characteristics. The drivers of HRQoL in inflammatory rheumatic disorders should be further explored.

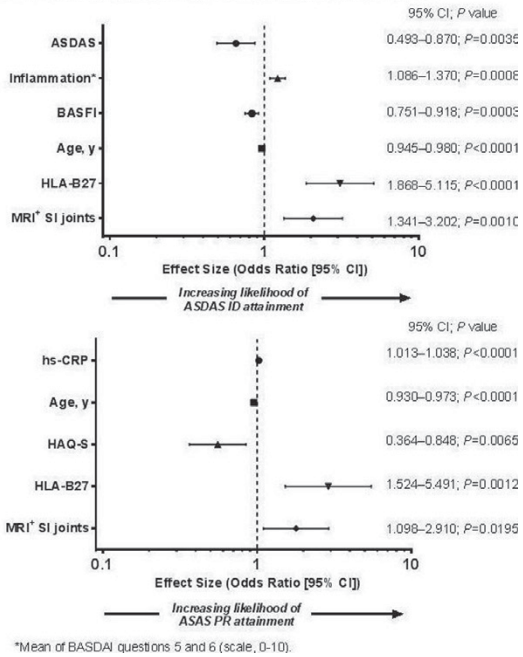
OP0243 PREDICTORS OF REMISSION AT WEEK 12 IN PATIENTS WITH NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS RECEIVING OPEN-LABEL ADALIMUMAB TREATMENT IN THE ABILITY-3 STUDY

J. Sieper[1], R. Landewé[2], M. Magrey[3], J.K. Anderson[4], S. Zhong[4], X. Wang[4], A. Lertratanakul[4]. *[1]Charité Universitätsmedizin Berlin, Berlin, Germany; [2]University of Amsterdam, Amsterdam, Netherlands; [3]Case Western Reserve University School of Medicine at MetroHealth Medical Center, Cleveland; [4]AbbVie, North Chicago, United States*



Background: Patients (pts) with non-radiographic axial spondyloarthritis (nr-axSpA) who fail nonsteroidal anti-inflammatory drug (NSAID) therapy are candidates for tumor necrosis factor inhibitor (TNFi) therapy if they have objective signs of inflammation. Baseline predictors of response to TNFi therapy, including remission, may aid clinical management.
Objectives: Describe baseline predictors of remission in nr-axSpA at wk 12 of open-label adalimumab (ADA) therapy in the ABILITY-3 study.
Methods: ABILITY-3 enrolled adult pts with nr-axSpA (fulfilling Assessment of SpondyloArthritis international Society [ASAS] criteria but not modified New York criteria) with moderately to severely active disease at screening and baseline, objective evidence of inflammation in the sacroiliac (SI) joints or spine on magnetic resonance imaging (MRI) or elevated high-sensitivity C-reactive protein (hs-CRP; defined as > upper limit of normal for the lab) at screening, and an inadequate response to ≥2 NSAIDs. Eligible pts received ADA 40 mg every other week during a 28-wk open-label lead-in period. Clinical remission was defined as Ankylosing Spondylitis Disease Activity Score inactive disease (ASDAS ID; score <1.3) or ASAS partial remission (score <2/10 in each of the 4 ASAS domains). Stepwise logistic regression was used to identify potential baseline predictors of remission at wk 12.
Results: 673 pts were enrolled (Table). Lower disease activity, increased inflammation (morning stiffness), less functional limitation (BASFI), younger age, presence of human leukocyte antigen-B27 (HLA-B27), and positive MRI of the SI joints were the strongest predictors of ASDAS ID; higher hs-CRP levels, younger age, lower functional status (HAQ-S), presence of HLA-B27, and positive MRI of the SI joints were the strongest predictors of ASAS PR (Figure).
Conclusions: In ABILITY-3, younger age, better functional status, presence of HLA-B27, and positive MRI of the SI joints consistently predicted clinical remission at wk 12 of open-label ADA treatment in pts with nr-axSpA.

OP0244 FAMILY MATTERS: VALUE OF FAMILY HISTORY OF SPONDYLOARTHRITIS IN THE DIAGNOSTIC WORK-UP OF PATIENTS WITH CHRONIC BACK PAIN: RESULTS FROM THE SPACE AND DESIR COHORTS

Z. Ez-Zaitouni[1], A. Hilkens[1], L. Gossec[2], I.J. Berg[3], R. Landewé[4], R. Ramonda[5], M. Dougados[6], D. van der Heijde[1], F. van Gaalen[1]. *[1]Rheumatology, Leiden University Medical Center, Leiden, Netherlands; [2]UPMC University Paris 06, Paris, France; [3]Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; [4]Rheumatology, Academic Medical Center, Amsterdam, Netherlands; [5]Rheumatology Unit, DIMED, University of Padova, Padova, Italy; [6]Rheumatology, Université Paris Descartes, Hôpital Cochin, Assistance Publique-Hôpitaux de Paris, INSERM (U1153): Epidémiologie Clinique et Biostatistiques, PRES Sorbonne Paris-Cité, Paris, France*

Background: A positive family history (PFH) of spondyloarthritis (SpA) is considered a risk indicator for the presence of axial spondyloarthritis (axSpA) in patients with chronic back pain (CBP). In the ASAS classification criteria, a PFH of SpA is defined as the presence of any of the following diseases in first- or second-degree relatives: ankylosing spondylitis (AS), acute anterior uveitis (AAU), reactive arthritis (ReA), inflammatory bowel disease (IBD), and psoriasis. It is however not known if a PFH for each of these diseases contributes equally well to making a diagnosis of axSpA in patients presenting with CBP.
Objectives: To assess which SpA diseases in family members are associated with HLA-B27 and axSpA in patients with CBP.
Methods: The SPACE cohort includes patients with CBP (≥3 months, ≤2 years, onset <45 years) from various European rheumatology centers. DESIR is a French prospective multicenter cohort of patients with inflammatory back pain (IBP; ≥3 months, <3 years, onset <50 years), suggestive of axSpA. Patients underwent a full diagnostic work-up at baseline including MRI and radiographs of sacroiliac joints (local reading), laboratory assessments (e.g. HLA-B27), and assessment of all other SpA features. Patients were asked about the presence of SpA diseases in first- or second-degree relatives (AS, AAU, ReA, IBD, and psoriasis). The associations between a PFH and HLA-B27, sacroiliitis, axSpA diagnosis by the rheumatologist, and fulfilment of the ASAS classification criteria in CBP patients were assessed.
Results: In 438 patients from the SPACE cohort and 647 patients from the DESIR cohort, a PFH of AS (odds ratio (OR) 5.9 (3.5–9.9) and OR 3.3 (2.1–5.2), respectively for SPACE and DESIR) and a PFH of AAU (OR 9.8 (3.3–28.9) and OR 21.6 (2.9–160.1)) were significantly associated with presence of HLA-B27 (Table 1).Furthermore, in both cohorts a PFH of AS and a PFH of AAU were positively associated with fulfilment of the ASAS-criteria, but not with sacroiliitis on imaging (data not shown). In SPACE, but not in DESIR, a PFH of AS or AAU was associated with axSpA diagnosis (data not shown). In both cohorts, a PFH of ReA, IBD, or psoriasis was not positively associated with HLA-B27 positivity, sacroiliitis on imaging, axSpA diagnosis or meeting the ASAS criteria for axSpA.
Conclusions: In two recent CBP cohorts, a PFH of ReA, IBD, or psoriasis did not

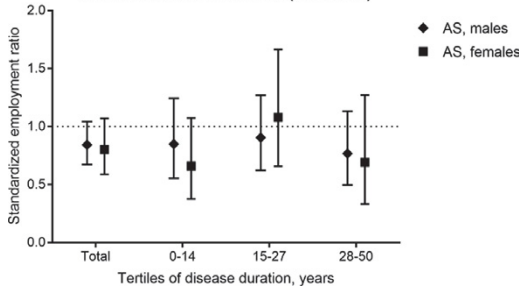
OP0245 EMPLOYMENT PERSPECTIVES OF PATIENTS WITH ANKYLOSING SPONDYLITIS IN THE BIOLOGICS ERA

C. Webers[1,2], L. Vanhoof[1], S. van Genderen[1,2], G. Plasqui[3], L. Heuft[4], M. van de Laar[5], J. Luime[6], D. van der Heijde[7], A. Spoorenberg[8], A. Boonen[1,2].
[1]MUMC; [2]CAPHRI; [3]Human Biology, UM, Maastricht; [4]Laurentius, Roermond; [5]MST, Enschede; [6]Erasmus MC, Rotterdam; [7]LUMC, Leiden; [8]UMCG, Groningen, Netherlands

Background: In the pre-biologics era, employment of patients with ankylosing spondylitis (AS) was decreased when compared to the general population. However, information on standardized employment since the introduction of biologicals is lacking. Also, while mastery (control over disease) has been identified as strong predictor of work outcome within patients with AS, it is not known whether such personality trait plays a similar role in patients compared to population subjects.

Objectives: To update the knowledge on employment and contributing factors, in particular personal factors, among Dutch patients with AS compared to general population subjects.

Methods: Data from patients and population controls participating in the Dutch cross-sectional multicenter survey-based Social Participation in AS Study (SPASS) and ≤65 years were used. Standardized employment ratios (SERs) were calculated using indirect standardization after adjusting for age, gender and education and were stratified by disease duration tertiles. Adjusted absolute employment rate (%) was calculated as "SER[AS]*employment rate [controls]". Modified Poisson regressions were performed to understand the role of mastery as a personal factor (Pearlin's Mastery scale) in patients opposed to controls, independent of socio-demographics (age, gender, education) and health-related factors (comorbidities, Physical Component Summary (PCS) of the SF-36).



Results: 214 patients and 470 controls (127 [59.3%] and 323 [68.7%] males; mean age of 48.3 [SD 10.4] and 39.3 [SD 12.7] years, respectively) completed the online questionnaire in 2011. SERs (95% CI) of patients with AS with controls set as reference (1.00) were 0.83 (0.69–0.98) for the total group, 0.84 [0.67–1.04] for males and 0.83 [0.59–1.07] for females. There was no significant difference in SER between those with short or long disease duration (Figure 1). Adjusted absolute employment rate (%) of patients with AS was 14% lower compared to controls (69% vs. 84%). In both patients and controls, higher PCS (SF-36) was associated with being employed. While AS patients with higher (better) mastery were more likely to be employed, such association was not seen in controls ($p<0.01$ for interaction group*mastery) (Table).

Table 1. Multivariate Poisson regression exploring determinants of work participation, stratified by group (AS vs. controls)

Variable	AS (n=213)			Controls (n=465)		
	IRR	95% CI	p	IRR	95% CI	p
Age, years	0.99	0.98–1.00	<0.01	1.00	0.99–1.00	0.07
Gender, male	1.13	0.91–1.39	0.26	1.08	0.99–1.19	0.09
Education, high	–		ns†	1.09	1.01–1.18	0.02
Comorbidity (SCQ, 0–39)	0.97	0.94–1.01	0.12	0.97	0.94–1.01	0.14
SF-36 PCS (0–100)	1.02	1.00–1.03	<0.01	1.01	1.00–1.02	0.02
Mastery (7–28)	1.03	1.00–1.05	0.03	–		ns†

†Value not significant and no confounder.

Figure 1. Standardized employment ratios of patients with AS with controls set as reference (dotted line)

Conclusions: In the biologics era, employment among Dutch patients with AS remains reduced when compared to the general population, also in those with less than 15 years disease duration. As mastery in patients is independently associated with work outcome, it is worthwhile exploring whether improving personal self-management skills supports future worker participation.

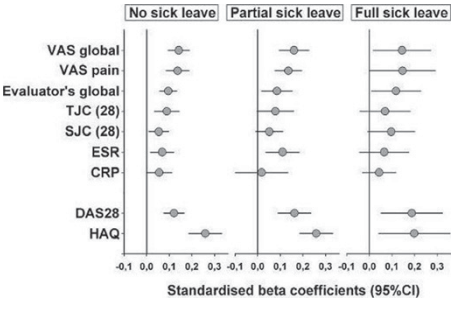
OP0246 IMPACT OF DISEASE ACTIVITY MEASURES ON SICK LEAVE IN BIOLOGICS-TREATED PATIENTS WITH RHEUMATOID ARTHRITIS: OBSERVATIONAL DATA FROM SOUTHERN SWEDEN



J.K. Wallman[1], J.K. Söderling[2], A. Gülfe[1], L.-E. Kristensen[3], M. Neovius[2], T. Olofsson[1]. *[1]Lund University, Department of Clinical Sciences Lund, Rheumatology, Lund; [2]Karolinska Institutet, Department of Medicine, Clinical Epidemiology Unit, Stockholm, Sweden; [3]The Parker Institute, Department of Rheumatology, Copenhagen University Hospital, Frederiksberg and Bispebjerg, Denmark*

Background: Sick leave generally represents the earliest phase of work-loss in rheumatoid arthritis (RA) patients, often on the trajectory towards more permanent disability pension. Sick leave may still change with disease activity fluctuations and is thus potentially reversible and accessible for interventions. However, data remain scarce on the importance of modifiable, non-composite disease activity measures for subsequent sick leave in RA patients treated with biologics.

Objectives: To study the impact of common, non-composite disease activity measures on sick leave in biologics-treated RA patients.

Methods: Study visits of biologics-treated RA patients of working-age (<65y) without disability pension, monitored in the population-based, observational South Swedish Arthritis Treatment Group register 2005–2011, were included (5151 visits; 957 patients). We performed association analyses between various non-composite disease activity measures at each visit and number of objectively assessed sick leave days during the month thereafter, retrieved from the Social Insurance Agency. Separate generalised estimating equation regression models were used, adjusting for age, sex, educational level, disease duration, number of previous biologics, time from start of the present biologic, and calendar year of study visit. Analyses were furthermore stratified on sick leave status the month preceding each visit (no sick leave=0 days out of 30; partial sick leave=1–29 days and full sick leave=30 days) and results are presented as standardised beta coefficients for comparability, with bootstrap-generated 95% confidence intervals. The composite 28-joint disease activity score (DAS28) and the health assessment questionnaire (HAQ) disability score were included as contrast.

Results: Out of common, non-composite disease activity measures, visual analogue scale (VAS) global and VAS pain were most strongly associated with sick leave days the month after the study visit, irrespective of baseline sick leave status (Figure). Generally, the more objective measures (erythrocyte sedimentation rate, C-reactive protein and swollen joint count (SJC)) had less impact on subsequent sick leave than the more subjective variables (VAS global, VAS pain, evaluator's global and tender joint count (TJC)). As expected, HAQ showed the strongest association.

Conclusions: More subjective disease activity measures have greater impact on sick leave in biologics-treated RA patients than do more objective variables, suggesting a stronger focus on the former ones when targeting work-loss or intervening to reduce it.

OP0247 AN IMPROVED MATRIX TO PREDICT RAPID RADIOGRAPHIC PROGRESSION OF EARLY RHEUMATOID ARTHRITIS PATIENTS: POOLED ANALYSES FROM SEVERAL DATABASES

A. Vanier[1], J. Smolen[2], C. Allaart[3], R. Van Vollenhoven[4], P. Verschueren[5], N. Vastesaeger[6], S. Saevarsdottir[4], K. Visser[3], D. Aletaha[2], B. Combe[7], B. Fautrel[1]. *[1]UPMC Univ Paris 6 and AP-HP Pitié-Salpêtrière Hospital, Paris, France; [2]University of Vienna, Vienna, Austria; [3]Leiden University Medical Centre, Leiden, Netherlands; [4]Karolinska Institute, Stockholm, Sweden; [5]Leuven University, Leuven, Belgium; [6]Merck Sharp and Dohme, Lucerne, Switzerland; [7]Université de Montpellier 1, Montpellier, France*

Background: In early rheumatoid arthritis (RA), some patients exhibit rapid radiographic progression (RRP) after one year, associated with poor functional prognosis. Identifying at the time of diagnosis the characteristics predictive of RRP is of importance. Several matrices predicting this risk have been proposed over the last years. They were limited somewhat in terms of precision or were built using specific populations.
Objectives: To develop a matrix to predict RRP with better precision and generalizability by pooling databases from various studies.
Methods: The study is based on the pooling of individual data from cohorts (ESPOIR and Leuven) and clinical trials (BeSt, SWEFOT and ASPIRE). Included patients were adult DMARD-naïve patients with recent suspected or confirmed diagnosis of active RA for which the first therapeutic strategy after inclusion was to prescribe MTX or leflunomide in monotherapy for at least 3 months. The main outcome was the presence after one year of RRP defined as an increase in modified Sharp score (vSHS) of at least 5 points between baseline and year one. Baseline characteristics were compared by the presence of RRP to search for predictors. A logistic regression model to predict RRP was built. The best model was selected by 10-fold stratified cross-validation by maximizing the Area Under the Curve (AUC). Calibration and discriminatory power of the model were assessed. Model parameters were extracted to estimate the probability of a RRP for each combination of level of baseline characteristics.
Results: The data of 1306 patients were pooled. After one year, 236 exhibited RRP (20.6%, $CI_{95\%}$ [18.2–22.9], mean probability of RRP of 0.21). Model of prediction of RRP included as baseline characteristics Rheumatoid Factor (RF) positivity (OR=2.1 $CI_{95\%}$ [1.5–3.0]; p<0.001), erosive disease on X-rays (OR=2.3 $CI_{95\%}$ [1.7–3.2]; p<0.001), CRP>30mg/l (OR=2.1 $CI_{95\%}$ [1.5–3.0]; p<0.001), number of swollen joints>10 (OR=1.5 $CI_{95\%}$ [1.01–2.2]; p=0.048). Model calibration was good (Hosmer and Lemeshow test: p=0.79). AUC was 0.68. The matrix proposes estimated RRP probability for 36 combinations of level of baseline characteristics. Its range goes from patients with a 4.1 fold lower risk of RRP compared to average risk (probability of 0.05 $CI_{95\%}$ [0.03–0.08], patient with CRP <10mg/l, without RF, without erosive disease on X-ray, with <6 swollen joints), to patients with a 2.3 fold higher risk than average (probability of 0.47 $CI_{95\%}$ [0.39–0.55], patient with CRP >30, with RF, with erosive disease on X-ray, with >10 swollen joints).

		Absence of typical RA erosion on radiographs			Presence of typical RA erosions on radiographs		
		SJC < 6	6 ≤ SJC < 10	SJC ≥ 10	SJC < 6	6 ≤ SJC < 10	SJC ≥ 10
RF positivity	CRP ≥ 30	0.21 [0.14 ; 0.29]	0.21 [0.15 ; 0.29]	0.28 [0.21 ; 0.36]	0.37 [0.28 ; 0.47]	0.38 [0.29 ; 0.48]	0.47 [0.39 ; 0.55]
	10 ≤ CRP < 30	0.13 [0.08 ; 0.18]	0.13 [0.08 ; 0.19]	0.18 [0.12 ; 0.24]	0.25 [0.17 ; 0.33]	0.25 [0.18 ; 0.33]	0.33 [0.25 ; 0.41]
	CRP < 10	0.11 [0.07 ; 0.15]	0.11 [0.08 ; 0.15]	0.15 [0.11 ; 0.20]	0.22 [0.16 ; 0.28]	0.22 [0.17 ; 0.28]	0.29 [0.22 ; 0.36]
RF negativity	CRP ≥ 30	0.11 [0.07 ; 0.17]	0.11 [0.07 ; 0.17]	0.15 [0.10 ; 0.21]	0.22 [0.14 ; 0.31]	0.22 [0.15 ; 0.31]	0.29 [0.22 ; 0.37]
	10 ≤ CRP < 30	0.06 [0.04 ; 0.10]	0.07 [0.04 ; 0.10]	0.09 [0.06 ; 0.13]	0.13 [0.08 ; 0.19]	0.14 [0.09 ; 0.20]	0.18 [0.13 ; 0.25]
	CRP < 10	0.05 [0.03 ; 0.08]	0.06 [0.03 ; 0.08]	0.08 [0.05 ; 0.11]	0.11 [0.07 ; 0.16]	0.12 [0.08 ; 0.17]	0.16 [0.11 ; 0.22]

Conclusions: A matrix proposing RRP probability at one year with better precision (i.e. narrower $CI_{95\%}$than those previously published) in early RA for various combinations of levels of a few common baseline characteristics has been built using several databases. However, discriminating power is not ideal. Further investigations will be needed to fully explore the potential complexity of predicting RRP in early RA.

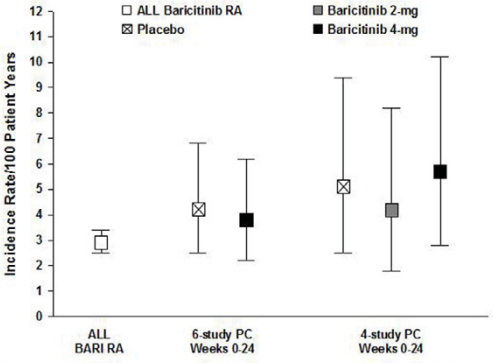
OP0248 SERIOUS INFECTION AND ASSOCIATED RISK FACTORS IN PATIENTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS TREATED WITH BARICITINIB

K.L. Winthrop[1], M.C. Genovese[2], M. Harigai[3], L. Chen[4], C.L. Dickson[4], D.L. Hyslop[4], A. Nishikawa[5], J.D. Bradley[4], M. Dougados[6]. *[1]Oregon Health and Science Univ., Portland; [2]Stanford Univ., Palo Alto, United States; [3]Tokyo Women's Medical Univ., Tokyo, Japan; [4]Eli Lilly and Company, Indianapolis, United States; [5]Lilly Japan, K.K., Kobe, Japan; [6]Paris-Descartes Univ., Paris, France*



Background: Baricitinib (BARI) is an oral Janus Kinase (JAK)1/JAK2 inhibitor in development for patients (pts) with active rheumatoid arthritis (RA). Compared to the general population, RA pts have an increased rate of serious infection events (SIE) due to disease state and concomitant therapies.[1]
Objectives: To evaluate the incidence rate (IR) of SIE and associated risk factors in BARI-treated pts with active RA across 8 completed studies (4 Ph3, 3 Ph2, 1 Ph1) and 1 ongoing long-term extension (LTE) study.
Methods: The ALL BARI RA analysis set included pts exposed to any BARI dose, with exposure up to 5 years (yrs) (Phase [Ph] 1–3 and LTE studies); the comparison with placebo (PBO) was based on 6 studies (Ph 2–3) with BARI 4 mg once daily (QD) and PBO arms up to Week (Wk) 24; dose response assessment was based on 4 studies (Ph 2–3) with both BARI 2 and 4 mg QD arms up to Wk 24. An extensive list of potential risk factors for SIE was investigated in the ALL BARI RA set using Cox models; SIE risk factors among BARI-treated pts are reported (Table).
Results:
The most frequent SIE observed in the ALL BARI RA set (N=3492; 5133 pt-yrs (PY) of exposure [PYE] were pneumonia, herpes zoster, urinary tract infection, and cellulitis (all <1%), and 2 patients with SIE died (IR=0.04/100 PY). In the ALL BARI RA set, SIE were reported in 150 pts (IR=2.9/100 PY). During 0–24 Wks, similar SIE rates were observed in BARI 4 mg (N=997; 417 PYE) and PBO (N=1070; 403 PYE) groups in the 6-study set, and between BARI 2 mg (N=479; 192 PYE) and 4 mg (N=479; 194 PYE) dose groups in the 4-study set (Figure). Prior biologic use, advancing age, region of Asia (excluding Japan), non-normal body mass index (BMI), and corticosteroid use were identified as independent factors for SIE in the ALL BARI RA set (Table). Among these SIE risk factors, none significantly differed between BARI 4 mg and PBO in the 6-study dataset (data not shown).

Table 1. Hazard Ratio and 95% CI for Serious Infection in the ALL BARI RA Analysis Set

Background: Achieving remission is the ultimate treatment goal in patients with rheumatoid arthritis (RA). With the development and wider use of highly effective disease modifying anti-rheumatic drugs (DMARD) about half of RA patients reach the disease remission state (1), raising the question about tapering or stopping anti-rheumatic treatment and appropriate predictors (2).
Objectives: To analyse the effect of a risk-stratified DMARD tapering algorithm based on multiple-biomarker disease activity (MBDA) score and anti-citrullinated protein (ACPA) status for successful DMARD tapering and treatment cost reduction in RA patients in sustained remission enrolled in the prospective randomized controlled RETRO study (3,4).
Methods: MBDA scores and ACPA status were determined in the baseline samples of 146 patients in sustained remission. Patients either continued DMARDs (arm1), tapered dose by 50% (arm 2) or stopped DMARDs after tapering (arm 3) for one year according to the RETRO study protocol. Direct treatment costs (including testing costs at baseline) were evaluated every three months. MBDA and ACPA status were used as predictors creating a risk-stratified tapering algorithm based on relapse rates.
Results: RA patients with a low MBDA score (<30) and negative ACPA showed lowest relapse risk (19%). With either single positivity for ACPA or moderate/high MBDA scores (≥30) relapse risk increased and was high in double-positive patients (61%). In MBDA negative (<30) and MBDA single-positive (≥30) groups, DMARD tapering appears feasible. Considering only patients that did not flare, costs for synthetic and biologic DMARDs in the MBDA-negative and single-positive groups (n=41) would have been 123.751,29€ for full-dose treatment over one year. Tapering and stopping DMARDs in this low-risk relapse groups allowed a reduction of 92.821,50€ (-75%) of DMARD costs. Average reduction of DMARD costs per patient were 2.350,08€ in the double negative (MBDA-/ACPA-) and single negative (MBDA- /ACPA+) group and 1.761,43€ in the MBDA single positive (MBDA+ /ACPA-) group.

Conclusions: Combining MBDA score and ACPA status allows risk stratification for successful DMARD tapering and cost-effective use of biologic DMARD. Given that previous data of the RETRO have shown that patients relapsing after tapering their DMARDs respond well to their reintroduction, a stratified tapering and stopping of DMARDs is not only a cost economic but also clinically feasible strategy.

OP0250 CAN RANKL SERUM LEVELS PREDICT FUTURE PROGRESSION TO RHEUMATOID ARTHRITIS IN ACPA NEGATIVE PATIENTS?

A. Burska[1], J. El-Jawhari[1], A.L. Tan[1], R. Wakefield[1], H. Marzo-Ortega[2], P. Conaghan[1], P. Emery[1], F. Ponchel[1], J. Freeston[1,2,3]. *[1]LIRMM, University of Leeds; [2]NIHR Leeds Musculoskeletal Biomedical Research Centre; [3]Rheumatology, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

Background: Making the earliest diagnosis of rheumatoid arthritis (RA) is crucial to initiate treatment and prevent further disease progression and joint damage. Despite recent advances with the discovery and integration of anti–cyclic citrullinated protein antibody (ACPA) in classification criteria, there is still an unmet need for new diagnostic biomarkers, notably for ACPA-negative disease. Power Doppler ultrasound has been shown to identify poor prognosis disease in ACPA negative patients.
Objectives: The receptor-activator-nuclear-factor-κB axis (RANK/RANKL) is known to regulate bone homeostasis. The aim of this pilot study is to establish whether serum RANKL levels in people with early inflammatory arthritis are associated with RA diagnosis at follow-up and to evaluate the added value of RANKL with ultrasound for early RA diagnosis.
Methods: Serum from 298 subjects (95/204 Male/Female) was collected at the baseline participant visit to the Leeds Early Arthritis clinic. Demographic (age, gender symptom duration) and clinical data (swollen and tender joint counts (SJC, TJC), CRP, DAS28, rheumatoid factor (RF) and ACPA, shared epitope (SE)) were collected.
A commercial ELISA (BioVENDOR) was used to measure RANKL. Ultrasound of 26 joints (bilateral elbows, wrists, MCP 2–3, PIP 2–3, knees, ankles and MTP 1–5) was performed at baseline recording summative scores for power Doppler (PD), grey scale hypertrophy (GS) and erosions (ERO).
Results: At 1 year follow-up, 151 patients had a confirmed diagnosis of RA (EULAR 2010 criteria) and 147 were classified as non-RA (undifferentiated arthritis, other inflammatory diagnoses or non-persistent inflammation). All routinely used biomarkers were associated with RA diagnosis (ACPA, RF, SE, TJC, SJC, CRP, DAS28, $p<0.0001$), as were imaging biomarkers (PD, GS, ERO, $p<0.001$). RANKL levels were significantly higher in RA (RA 1002.4±1053.2pmol/L, non-RA 339.2±451.5pmol/L, $p<0.0001$). A regression analysis suggested that four parameters were sufficient to account for all associations with RA: RANKL, age, SJC, and PD with 75.3% accurate prediction. An AUROC analysis suggested a cut-off for each parameter and a score was calculated, adding 1 point for each of the factors (RANKL>700, age>62, TPD>3, SJC>4). This score predicted RA with an AUROC of 0.782 ((0.23–0.840), $p<0.0001$). The same analysis repeated for ACPA negative patients only (n=193) showed similar results, providing accurate diagnosis of RA (77.6% correct by regression) and with an AUROC of 0.774 ((0.690–0.858), $p<0.0001$).
Conclusions: A score incorporating RANKL, age, SJC and PD showed good predictive value for non-RA when low and for RA when high. Furthermore, the analysis redone in ACPA-negative patients performed particularly well for predicting RA with a good AUROC value.

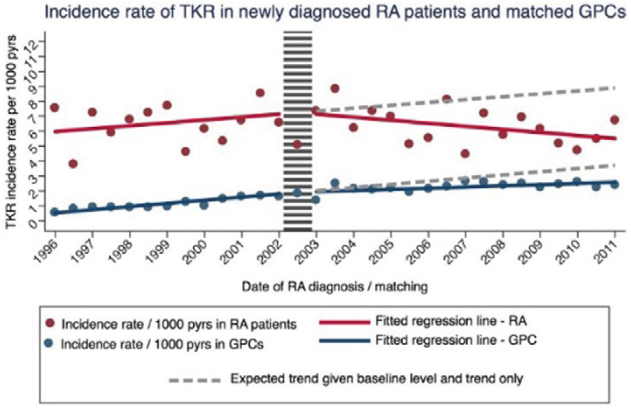
OP0251 INCIDENCE OF KNEE AND HIP REPLACEMENTS IN RHEUMATOID ARTHRITIS PATIENTS FOLLOWING INTRODUCTION OF BIOLOGICAL DMARDS: AN INTERRUPTED TIME SERIES ANALYSIS USING NATIONWIDE HEALTH CARE REGISTERS

R. Cordtz[1,2], S. Hawley[3], D. Prieto-Alhambra[3], L.E. Kristensen[2], S. Overgaard[4], A. Odgaard[5], L. Dreyer[1,2]. *[1]Center for Rheumatology and Spine Diseases, Gentofte, Rigshospitalet; [2]The Parker Institute, Bispebjerg and Frederiksberg Hospital, Copenhagen, Denmark; [3]Musculoskeletal Pharmaco- and Device Epidemiology, NDORMS, University of Oxford, Oxford, United Kingdom; [4]Department of Orthopaedic Surgery and Traumatology, Odense University Hospital, Odense; [5]Depepartment of Orthopaedics, Herlev and Gentofte Hospital, Copenhagen, Denmark*



Background: Previous data have been conflicting regarding a possible impact of treatment with biological DMARDs (bDMARDs) on the need for total knee replacement (TKR) and total hip replacement (THR) in patients with rheumatoid arthritis (RA)[1].
Objectives: To investigate impact of national guidelines recommending bDMARD treatment for RA on the secular trends of TKR and THR among incident RA patients compared with matched general population controls (GPC) in Denmark.
Methods: Nationwide register-based interrupted time-series analysis using the National Patient Register and Civil Registration System.
RA: incident patients diagnosed at a rheumatology department from 1996–2011.
GPC: 10 individuals matched to each RA patient on age, sex and municipality.
Outcome: First TKR and THR, respectively.

Intervention: introduction of bDMARDs and associated publication of bDMARD recommendations in Denmark in 2002.
Statistical analyses: 5-year age- and sex-standardised incidence rates of THR and TKR calculated for incident RA patients diagnosed biannually in 1996–2011, and GPCs. Secular trends in the pre-bDMARD guideline era (1996–2002) were compared with those in the bDMARD period (2003–2016) using segmented linear regression and a 1-year lag period (2002–03). Absolute changes in TKR and THR at the midpoint (February 2007) between guideline implementation and end of study period were estimated.
Results: In total, during 1996 to 2011, 30 868 incident RA patients were identified (mean age at diagnosis 58.3 years, 70% women) and compared with 301 527 GPCs. See Table for results.

Table 1. Changes in 5-year incidence rate of total hip (THR) or total knee replacement (TKR) in incident rheumatoid arthritis (RA) patients following introduction of biological DMARDs compared with secular trends in age, sex and municipality-matched general population controls (GPC)

Cohort		n THR/TKR	Baseline incidence rate/1000 person years	Δ per year* pre-2002	Δ in level 2003	Δ per year post-2003
TKR	RA	865	5.87	+0.19	–	-0.20
	GPC	2438	0.42	+0.21	–	+0.08
THR	RA	935	8.72	-0.38	+2.23	-0.38
	GPC	4744	2.89	+0.11	–	+0.02

Stepwise backward elimination to produce most parsimonious model: p-entry <0.05 and p-exit >0.2. *Δ per year based on biannual data.

Conclusions: Prior to 2002, the incidence of TKR increased among RA patients, but started to decrease after introduction of bDMARDs and their associated guidelines in 2003 (absolute change -1.8 TKRs/1000 person years in Feb. 2007). In contrast, the incidence of TKR increased among GPCs throughout the entire study period. The incidence of THR increased in GPCs for the entire duration of the study period, whereas there was a downward going trend among RA patients, but with a surprising level increase in 2003. The overall patterns of our findings are in line with those recently reported from England and Wales[1].

OP0252 RHEUMATOID ARTHRITIS PATIENTS WITH CONTINUED LOW DISEASE ACTIVITY HAVE SIMILAR OUTCOMES OVER 10 YEARS, REGARDLESS OF INITIAL THERAPY

S.A. Bergstra[1], R.B. Landewé[2,3], T.W. Huizinga[1], C.F. Allaart[1]. *[1]Rheumatology, LUMC, Leiden; [2]Amsterdam Rheumatology & Immunology Center, Amsterdam; [3]Zuyderland Medical Center, Heerlen, Netherlands*

Background: Low disease activity and remission in rheumatoid arthritis (RA) patients is achieved earlier and in higher frequency when the initial treatment includes a combination of methotrexate (MTX) with corticosteroids or a biologic disease modifying anti-rheumatic drug than MTX alone. However, it is unknown whether in patients with early and persistently good response the initial treatment still has an impact on long term outcomes.
Objectives: To compare 10 years disease outcomes of RA patients with persistent low disease activity on MTX monotherapy or on initial combination therapy with infliximab or prednisone and sulfasalazine.
Methods: RA patients with 10 years follow-up from the BeSt study were analyzed. RA patients fulfilling the American College of Rheumatology 1987 criteria with <2 years symptom duration were "treated to target" aiming at disease activity score (DAS) ≤2.4, assessed with 3-monthly intervals. Patients in arms 1 and 2 started MTX monotherapy, patients in arm 3 started MTX, sulfasalazine and prednisone and patients in arm 4 started MTX and infliximab. All had DAS≤2.4 from t=6 months until t=10 years and therefore stayed on initial treatment, with patients in arms 3 and 4 tapering to monotherapy within 10 months. Patients in arms 1 and 2 were compared with patients in arms 3 and 4. Between-group differences over time were compared using (generalized) linear mixed model analyses, for the outcomes DAS, Health Assessment Questionnaire (HAQ), erythrocyte sedimentation rate (ESR), visual analogue scale (VAS) patient global health (range 0–100), percentage patients in remission and drug free remission and percentage patients with Sharp/van der Heijde score progression ≥5.
Results: At t=10 years 28/247 (11%) patients in arms 1 and 2 had sustained DAS≤2.4 compared to 68/261 (26%) patients in arms 3 and 4. Patients in arms 1 and 2 were less often ACPA positive (46% versus 54%, p=0.477), had shorter symptom duration at baseline [median (range) 14 (1–191) versus 18 (4–263) weeks, p=0.004] and less radiologic damage progression after 10 years [0 (0–16) versus 2.5 (0–26), p=0.014] than patients in arms 3 and 4. No between-group differences were found over time, except for the percentage of patients in drug free remission. Significant group-time interactions were found for DAS, ESR and VAS patient's global health, but not HAQ, percentage remission and percentage drug free remission, with slightly worse results over time for arms 3 and 4 compared to arms 1 and 2 (table 1).

Table 2: (Generalized) linear mixed model analyses to assess differences over time between MTX monotherapy responders (n=28) and combination therapy responders (n=68).

	Linear Mixed Model Analyses	β	95% CI
HAQ	Treatment group*	0.076	-0.066; 0.22
	Time	-0.0034	-0.0044; -0.0025
DAS	Treatment group*	0.031	-0.24; 0.18
	Time	-0.029	-0.037; -0.021
	Treatment group*Time	0.0056	0.0012; 0.010
ESR	Treatment group*	-3.30	-7.54; 0.93
	Time	-0.19	-0.31; -0.072
	Treatment group*Time	0.11	0.041; 0.17
VAS patient global health	Treatment group*	-4.07	-9.50; 1.37
	Time	-0.42	-0.57; -0.27
	Treatment group*Time	0.090	0.0048; 0.17
	Generalized linear mixed model analyses	**OR**	**95% CI**
SvdH score progression =5	Treatment group*	0.83	0.17; 4.01
	Time	0.94	0.83; 1.07
Remission	Treatment group*	0.58	0.32; 1.08
	Time	1.04	1.03; 1.04
Drug free remission	Treatment group*	0.14	0.033; 0.61
	Time	1.06	1.03; 1.08

*Difference between treatment groups, MTX monotherapy responders as reference group , SE = standard error, 95% CI = 95% confidence interval

Conclusions: More patients achieved continuous low disease activity on prednisone or infliximab combination therapy tapered to MTX monotherapy than on MTX monotherapy, but there appear no additional benefits of combination treatment strategies for patients who have sustained DAS≤2.4. Regardless of initial induction therapy, those who remain in low disease activity have similar long term outcomes, with only the proportion of patients in drug free remission being higher in the MTX monotherapy group. These results strongly suggest that rapid achievement of remission/LDA itself, rather than how you achieve it, is crucial for determining long-term outcome in RA.

OP0253 PASSIVE SMOKING IN CHILDHOOD AND HISTORY OF CHRONIC DIARRHEA INCREASES THE RISK OF DEVELOPING RHEUMATOID ARTHRITIS (RA)

R. Seror[1,2], G. Gusto[3], M.C. Boutron-Ruault[3], X. Mariette[1,2]. *[1]Rheumatology, Hopitaux Universitaires Paris Sud; [2]INSERM U1184, Université Paris-sud, le Kremlin-Bicetre; [3]Centre de recherche en epidemiologie et santé des populations, Inserm U1018, Villejuif, France*

Objectives: To analyse the impact of active and passive smoking and intestinal transit disorders on the risk of incident RA
Methods: This study is based on the French E3N cohort ("Etude Epidémiologique auprès de femmes de l'Education Nationale"), which included 98,995 women volunteers born between 1925 and 1950 and prospectively followed since 1990. Eleven self-administered questionnaires were sent to the participants between 1990 and 2014 to collect medical, demographic, environmental and hormonal data and dietary habits. The diagnosis of RA was collected on 2 successive questionnaires. Cases were considered certain if having declared RA and had taken a RA specific medication (methotrexate, leflunomide or biologic) since 2004 (period from which drug reimbursement data was available). Only incident and certain cases were included. Women were excluded if they had an inflammatory bowel disease and/or no information on their smoking status. Passive smoking was assessed by the following question: "When you were children, did you stay in a smoky room?". Patients were considered exposed if the answer was "yes, a few hours, or yes, several hours a day". The usual intestinal transit, reported by women prior to RA diagnosis (on average 10 years), were classified as normal

transit, chronic diarrhoea, chronic constipation, and alternation between diarrhoea and constipation.
The risk of incident RA was estimated using an age-adjusted Cox model that considers smoking status as a time-dependent variable.
Results: 70598 women from the E3N study were included in the study. A total of 1239 patients reported an incidental RA, of which 350 cases were included in the study (and 280 in the analysis of intestinal transit disorders). Non-ascertained cases were excluded form the analyses. The age at inclusion in the study was 49.0 years (± 6.4). The mean duration of follow-up was 21.2 (± 1.3) years.
Passive smoking exposure during childhood increased the association between the RA risk active and adult active smoking. In ever smokers who had childhood passive exposure to smoke, the HR was 1.73 [1.20; 2.50] as compared with non-smokers who were not exposed during childhood, while it was 1.37 [1.08; 1.73] in active smokers who were not exposed during childhood.
A history of chronic diarrhea was associated with increased RA risk (HR =2.32 [1.41, 3.81]), while chronic constipation or alternation between diarrhoea and constipation did not.

Smoking status	Controls (%) N=70248	RA (%) N=350	HR [95% CI]
Non smoker No passive smoking in childhood	32440 (46,18)	137 (39,14)	Reference
Non smoker + Passive smoking in childhood	5010 (7,13)	30 (8,57)	1,43 [0,97; 2,13]
Ever smoker No passive smoking in childhood	27394 (39,00)	147 (42,00)	1,37 [1,08; 1,73]
Ever smoker + Passive smoking in childhood	5404 (7,69)	36 (10,29)	1,73 [1,20; 2,50]
Normal transit	44254 (71.48)	187 (66.79)	Reference
Chronic diarrhea	1707 (2.76)	17 (6.07)	2.32 [1.41; 3.81]
Constipation	8661 (13.99)	43 (15.36)	1.16 [0.84; 1.62]
Alternating diarrhea - constipation	7291 (11.78)	33 (11.79)	1.07 [0.74; 1.55]

Conclusions: This study confirms the link between active smoking and the risk of RA. It suggests for the first time that in smokers, exposure to tobacco early in life, through passive smoking in childhood significantly increases this risk. Our study highlights the importance of avoiding any tobacco environment in children, especially in those with a family history of RA. Also, it shows for the first time an association between a history of chronic diarrhoea and the risk of developing RA. The association supports the hypothesis of dysbiosis (microbiota abnormality) as a risk factor for the emergence of autoimmunity. These data perfectly fit with the preclinical scheme of RA where an external event occurs at an early stage to promote emergence of auto-immunity, followed years after by clinical RA.

HPR move to improve

OP0254-HPR HAND EXERCISE FOR WOMEN WITH RHEUMATOID ARTHRITIS AND DECREASED ADL ABILITY: AN EXPLORATORY RANDOMISED CONTROLLED TRIAL

K. Ellegaard, C. von Bülow, A. Røpke, C. Bartholdy, I.S. Hansen, S. Rifbjerg, R. Christensen, M. Henriksen, E. Waehrens. *The Parker Institute, Frederiksberg, Denmark*

Background: Decreased strength and range of motion in the hand are often seen in rheumatoid arthritis (RA). Positive effects on hand function in RA patients after hand exercise and individual education in joint projection including coping strategies (ADL education) is shown (1;2). However, it is unknown if a combination of both will further improve hand performance.
Objectives: To investigate the effect on ADL ability of a hand exercise program as add on to an ADL education program in women with RA.
Methods: Women with RA involving the hand on stable medication for at least three months were recruited.
At baseline participants were examined by a rheumatologist who assessed joints of the hand and ruled out contraindications for participation e.g. massive malalignment of the joints. Inflammatory markers of the blood, hand pain and grip strength were also measured. The ADL motor ability was assessed using the observation-based Assessment of Motor and Process Skills (AMPS). After baseline examination randomized to ADL education + hand exercises (intervention; IG) or only ADL education (control; CG) was made.
All participants received three to four sessions with an occupational therapist learning how to perform ADL tasks overcome their specific hand problems. The intervention group also received a hand exercise program, to be conducted four times a week, for eight weeks, containing exercises for improving range of motion and strength; once a week the exercise program was supervised by a physiotherapist, to correct and prevent overload and to increase load if possible.
Primary outcome measure was change in observed ability to perform ADL tasks (AMPS) at week 8. Secondary outcomes include grip strength, pain, joint count, inflammatory markers and self-reported function.
After eight weeks, all baseline measures were repeated and changes from baseline were calculated based on the Intention To Treat (ITT) population.
Clinicaltrials.gov Identifier: (NCT02140866)
Results: Fifty five patients were randomised to IG (n=28) or CG (n=27); 22 and 25 patients, respectively, completed the trial. The ITT-populations mean age was 63.8 (12.8) years, mean disease duration was 12.4 (11.0) years. Baseline tender and swollen joint count was 5.07 (4.85) and 1.37 (1.72) respectively, the hand pain was 41.95mm (right) and 35.78mm (left) (VAS) and hand grip strength was 18.25 kg (right) and 17.46 kg (left). Baseline AMPS ADL motor measure was 1.36 (0.46). As judged by the 95% confidence intervals, no difference in change from baseline was seen between the groups (see table).

Change from baseline in and between groups (ITT analysis)

	Intervention group (n=28)	Control group (n=27)	Difference between groups	p-value
AMPS motor	0.24 (0.09-0.39)	0.20 (0.05-0.35)	0.04 (-0.17-0.25)	0.70
Tender joint count (28 joints)	-0.57 (-1.86-0.73)	0.35 (-0.95-1.64)	-0.92 (-2.77-0.93)	0.32
Swollen joint count (28 joints)	0.25 (-0.23-0.73)	0.16 (-0.32-0.64)	0.10 (-0.59-0.77)	0.78
CRP	-0.70 (-2.41-1.02)	1.77 (-0.09-3.63)	-2.45 (-5.0-0.06)	0.06
HAQ	-0.07 (-0.17-0.03)	0.01 (-0.09-0.12)	-0.08 (-0.23-0.06)	0.24
Hand pain activity (VASmm) Right/left	-1.17 (-7.82-5.48) -3.43 (-11.07-4.20)	0.55 (-6.23-7.31) -0.81 (-8.59-6.97)	-1.71 (-11.20-7.79) -2.62 (-13.62-8.38)	0.72 0.64
Hand strength (kg) Right/left	1.43 (0.40-2.45) 1.00 (-0.47-2.47)	0.18 (-0.86-1.23) -0.36 (-1.83-1.11)	1.24 (-0.23-2.71) 1.36 (-0.71-3.44)	0.10 0.19

Conclusions: A hand exercise program as add on to an ADL education did not improve ADL ability more than ADL education alone in women with RA experiencing decreased ADL ability involving the hands.

OP0255-HPR AN ADD-ON PROGRAMME IMPROVED THE SHORT-TERM, BUT NOT THE LONG-TERM EFFECT OF REHABILITATION IN PATIENTS WITH RHEUMATIC DISEASES: RESULTS FROM A PRAGMATIC MULTI-CENTRE STEPPED-WEDGE CLUSTER RANDOMIZED CONTROLLED TRIAL

G. Berdal[1], K. Hagen[1], H. Dagfinrud[1], P. Mowinckel[1], I. Bø[2], T.N. Dager[1], A. Dingsør[3], S. Eppeland[4], J. Hagfors[5], B. Hamnes[2], M. Nielsen[5], A.-L. Sand-Svartrud[1], B. Slungaard[6], S. Wigers[7], I. Kjeken[1]. *[1]National advisory unit on rehabilitation in rheumatology, Diakonhjemmet Hospital, Oslo; [2]Hospital for Rheumatic Diseases, Lillehammer; [3]Betanien Hospital, Skien; [4]Sørlandet Hospital, Arendal; [5]The Norwegian Rheumatism Association, Oslo; [6]Martina Hansen's Hospital, Bærum; [7]Jeløy Kurbad Rehabilitation Center, Moss, Norway*

Background: Multidisciplinary rehabilitation is widely used alongside medical treatment of patients with rheumatic diseases. Although beneficial effects of such rehabilitation have been demonstrated, patients are mostly back to their initial health status 6 to 12 months after discharge.
Objectives: To evaluate an add-on rehabilitation programme designed to enhance and prolong the effect of rehabilitation in adult patients with rheumatic diseases.
Methods: We conducted a pragmatic multi-centre stepped-wedge cluster randomized controlled trial in six rehabilitation centres in Norway. All centres started simultaneously to include patients in the control phase (traditional rehabilitation),

whereupon they switched to the intervention phase (add-on programme) sequentially and in randomised order. The add-on programme comprised structured individualized goal planning, motivational interviewing, a self-help booklet and four supportive follow-up phone calls the first five months after discharge. Data were collected on admission, discharge, 6 and 12 months after discharge. Primary outcome was health related quality of life (HR-QoL) measured by the individualized Patient Generated Index (PGI). The main statistical analysis was a linear repeated measures mixed model performed on the intention to treat population (all available data).

Results: 389 patients with various rheumatic diseases (SpA, RA, OA, and SLE) were included (table 1). A significant treatment effect of the add-on intervention on HR-QoL was found on discharge (mean difference =3.32 [95% CI: 0.27, 6.37], p=0.03). There were no significant differences between the groups at 6 and 12 months. Treatment compliance was 94%, and response rate >80% at all time points. Both groups showed a positive effect of rehabilitation in terms of increased HR-QoL at discharge, which subsequently declined, although the values remained at higher levels after 6 and 12 months compared with baseline values (figure 1).

Table 1. Baseline characteristics of included patients (n=389)

	Control group (n=195)	Intervention group (n=194)
Age, yrs, mean (min, max)	56.9 (24, 89)	57.5 (23, 89)
Gender, ♀ , n (%)	127 (65.1)	147 (75.8)
Disease duration, yrs, mean (SD)	21.0 (13.3)	19.1 (13.1)
Paid work, n (%)	69 (35.8)	76 (39.4)
Using TNF-inhibitors, n (%)	44 (22.6)	39 (20.1)

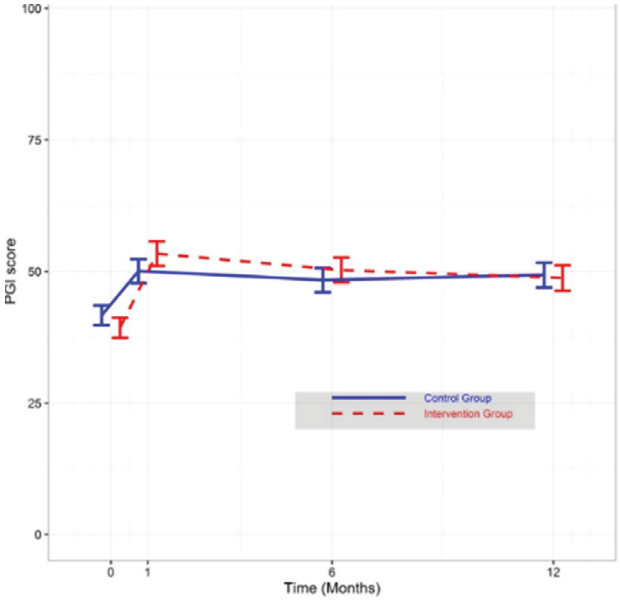

Figure 1. Health related quality of life in patients with rheumatic diseases measured by the Patient Generated Index (PGI, 0-100, 0 low HR-QoL). Vertical lines indicate the mean values (centre) with 95% confidence intervals at the four measurement time points: on admission to rehabilitation stay (baseline), at discharge, and six and twelve months after discharge. Horizontal lines show the fluctuating mean PGI values from baseline to 12 months after discharge.

Conclusions: The add-on intervention enhanced the short-term effect of rehabilitation with respect to HR-QoL, but did not prolong the effect as intended. The findings suggest that individualized structured goal planning should be considered important and relevant in rehabilitation of patients with rheumatic diseases. Although this study evaluated the effect of a complex intervention, and not the effect of single components, the results indicate that supportive telephone follow-up after discharge do not prolong the effect of rehabilitation. However, this study showed a longer lasting effect of rehabilitation in both the control- and intervention group, compared to previous reports.

OP0256-HPR PHYSICAL ACTIVITY AND INACTIVITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

C. Boström[1,2], F. Russ[1], F. Eriksson[1], S. Pettersson[2], I. Gunnarsson[1,2], E. Svenungsson[1,2]. *[1]Karolinska Institutet; [2]Karolinska Universitetssjukhuset, Stockholm, Sweden*

Background: Previous studies indicate that patients with systemic lupus erythematosus (SLE) have a reduced physical activity compared to controls and public health recommendations. However, most studies have used questionnaires without expressing the energy requirements for the activities.

Objectives: We investigated if self-reported physical activity, expressed in Metabolic Equivalent of Task (METs)-minutes/week, in patients with SLE is reduced. The aim was also to investigate if they fulfil the public health recommendations for physical activity.

Methods: 103 patients (93 women/10 men, mean age 51.5 (SD 15.9) years) with SLE according to the 1982 revised ACR criteria for SLE were involved. Physical activity was assessed with the short version of the International Physical Activity Questionnaire (IPAQ), which measure physical activity the last seven days. The IPAQ scientific group classify physical activity into the following categories: “inactive”, “minimally active”(equal to public health recommendations) and “health enhancing physical activity”. Those individuals who do not meet the criteria for the two latter categories are considered inactive.

Results: The patients reported that they were physically active in median 1666 (interquartile range 693; 3759) METs-minutes/week (n=84). The patients answered that they were sitting in median 6 (interquartile range 4; 8) hours/day the last week (n=98). 59.6% of the patients achieved a minimum of at least 600 METs-minutes/week, i.e. they were active 5 or more days with any combination of walking, moderate-intensity or vigorous intensity activities (“minimally active”). 17.9% achieved a minimum of at least 1500 METs-minutes/week, i.e. they were active on vigorous-intensity on at least 3 days or; achieved a minimum of at least 3000 METs-minutes/week, i.e. they were active 7 or more days on any combination of walking, moderate-intensity or vigorous intensity activities (” health enhancing physical activity”). 22.6% of the patients were “inactive”.

Conclusions: In the investigated patients with SLE, the majority were “minimally active” according to IPAQ-categories, which is sufficiently physically active according to the minimum level of public health recommendations. However, only 1/5 reached “health enhancing physical activity” category and 1/5 were considered physically “inactive”. Health professionals could use the short version of IPAQ to find out which patients with SLE need support in physical activity programmes.

OP0257-HPR RELATIONSHIP BETWEEN SLEEP DISORDERS AND DISEASE ACTIVITY IN PATIENS WITH RHEUMATOID ARTHRITIS

L. Villarreal[1], S. Henao[2], D. Buitrago-Garcia[3], P. Santos-Moreno[4]. *[1]Psychology and processes; [2]Patient service; [3]Epidemiology; [4]Rheumatology, Biomab, Center for Rheumatoid Arthritis, Bogota, Bogota, Colombia*

Background: Rheumatoid arthritis (RA) is the prevalent autoimmune inflammatory arthritis found in adults, with the worldwide prevalence ranging from 0.4% to 1.3% (1). Patients with this condition have permanent changes with different severity of arthritis deformities as well as functional disturbances; Studies had shown that every painful condition disturbs sleep, which can lead to mood and abilities disturbances (2).

Objectives: The aim of this study was to describe the socio-demographic profile and sleep disorders in RA patients from a specialized RA clinic in Colombia and relationship with disease activity.

Methods: A descriptive cross-sectional study was performed in a specialized clinic dedicated to care patients with rheumatoid arthritis (RA). Data was collected during our psychology consultation, through semi-structured interviews and non-probability sampling. Descriptive epidemiology was applied for continuous variables, using measures of central tendency and dispersion for categorical and qualitative variables by averages and percentages. We analyzed bivariate association with Pearson’s X^2.

Results: We included 1398 patients attending to our psychology consultation. Mean age was 55±8. 80% were female and 20% male. Mean DAS28 was 2.6±1.3, mean HAQ was 1.6±1. 6; Patients had the disease for an average of 12 years ± 8; 41% of patients had comorbidities associated with non-autoimmune disease, 14% comorbidities related to autoimmune disease; 35% of our patients did not report other comorbidities. Most of patients were married 60%, followed by divorced 19%, single 14% and widowed 7%. Regarding occupation 33% were employees, 25% were housekeepers or retired due to age, 12% were retired due to disabilities, and 3% unemployed. Of the total population 45% had elementary school, 32% high school, 8% college education, 7% graduate education and 7% were illiterate. 17% of patients lived alone. When the psychologist asked about sleep disorders 69% reported no to have any, 25% primary insomnia, 1% hypersomnia, 3% OSAS and 2% alterations on the circadian rhythm. Disease activity was statically associated with sleep disorders ($p<0.00$).

Conclusions: Sleep problems are an important aspect to consider in a patient with RA and are correlated to disease activity; it is important to have a multidisciplinary care team for the patient with RA, including a psychologist that can manage this kind of illness in order to improve the life quality of patients.

OP0258-HPR INTENSIVE PHYSICAL EXERCISE FOR ELDERLY PERSONS WITH RHEUMATOID ARTHRITIS IMPROVES PHYSICAL CAPACITY

E. Lange[1,2], D. Kucharski[3], K. Svensson[4], S. Svedlund[3], I. Gjertsson[2,3], K. Mannerkorpi[1,2]. *[1]Department of Health and Rehabilitation, Institute of neuroscience and physiology, Sahlgrenska academy, University of Gothenburg; [2]University of Gothenburg Centre for Person-centred Care; [3]Rheumatology and inflammation research, Institute of medicine, Sahlgrenska academy, Göteborg; [4]Skaraborg hospital, Skövde, Sweden*

Background: Today, more than 50% of persons with Rheumatoid Arthritis (RA) are over 65 years of age (1). Little is known about the effects of physical exercise in this age group (>65 years).
Objectives: The aim of this randomized controlled study is to investigate the effects of a person-centred progressive aerobic and resistance exercise program, led by a physiotherapist.
Methods: Seventy-four with persons with RA (24% men), mean age 70 years (SD 2.5), were recruited and randomized to an exercise interventions group or an active control group. The intervention consisted of a 20-week individual person-centered exercise program, performed three times a week with guidance from a physiotherapist. Both aerobic and resistance exercise was performed on a high intensity level. The control group followed a home exercise program twice a week. Muscle strength and endurance were assessed by the Chair Stands test, the Timed up and Go and a Bicycle endurance test. Maximal aerobic capacity (VO_2 max) was assessed with ergo spirometry. Activity limitations were assessed by SF36 Physical subscale and the Health Assessment Questionnaire (HAQ).
Results: All participants in the intervention group completed the intervention. The participants had a low disease activity with a mean Clinical Disease Activity Index of 5.4 (SD 3.9). Significant improvements were found for VO_2 max, the Chair Stands test, the Timed up and Go, the Bicycle endurance test on bicycle ($p<0{,}001$) and the SF36 physical (p=0.018) in the intervention group, when compared to the controls. No significant differences between groups were seen on HAQ.
Conclusions: Intensive progressive aerobic and resistance exercise is a feasible intervention for elderly persons with RA. Despite old age and RA the participants gained significant improvements in physical capacity.

OP0259-HPR SUPERVISED WALKING IMPROVES AEROBIC CAPACITY, EXERCISE TOLERANCE, FATIGUE AND PERCEIVED IMPROVEMENT IN WOMEN WITH PRIMARY SJÖGREN'S SYNDROME: A RANDOMIZED CONTROLLED TRIAL

S.T. Miyamoto[1,2], V. Valim[3,4], L. Carletti[5], W.-F. Ng[6], R. Altoé[3], A.J. Perez[5], L.H. Dias[3], É.V. Serrano[3], A.M. Subtil[5], V.B. Cândido[5], M. Trenell[7], D. Lendrem[6], J. Natour[2]. *[1]Departamento de Educação Integrada em Saúde, Universidade Federal do Espírito Santo, Vitória; [2]Disciplina de Reumatologia, Universidade Federal de São Paulo, São Paulo; [3]Serviço de Reumatologia do HUCAM; [4]Departamento de Clínica Médica; [5]Laboratório de Fisiologia do Exercício (LAFEX), Universidade Federal do Espírito Santo, Vitória, Brazil; [6]Musculoskeletal Research Group, Institute of Cellular Medicine; [7]MoveLab, Physical Activity & Exercise Research, Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom*

Background: Fatigue is a very common symptom of primary Sjögren's syndrome (pSS), being reported by up to 70% of patients [1]. It is more pronounced when compared to healthy individuals [2] and patients often report that it is their greatest problem and the most difficult to cope with [3]. There is only one non-randomized controlled study on aerobic exercise in pSS with a small sample size suggesting improvement in fatigue, aerobic capacity, depression and physical function [4].
Objectives: To evaluate the safety and effectiveness of a supervised walking program in women with pSS.
Methods: Forty five sedentary women fulfilling the American European Consensus Criteria for pSS were randomized to a Training Group (TG, n=23) or Control Group (CG, n=22). Patients in the TG were submitted to supervised walking, 3 times a week, for 16 weeks. The patients of the CG were instructed to not perform any kind of regular physical exercise. Outcomes measured were aerobic capacity, fatigue, disease activity, depression, perception of pSS's symptoms and quality of life. An intent-to-treat analysis was performed.
Results: The mean change after 16 weeks of VO_{2max} ($ml.kg^{-1}.min^{-1}$), distance and FACIT-fatigue were higher in the TG than in the CG (p=0.016, p=0.043 and p=0.030, respectively) (Figure 1). Improved aerobic capacity was associated with improvements in fatigue scores and physical components of quality of life measured using SF-36. Furthermore, improved fatigue scores were associated with reduced depression and improvements in the physical and mental components of the quality of life measures. Overall, 95.4% of patients in the TG rated themselves as clinically improved versus 62% of the patients in the CG (p=0.049). There was no flare in disease activity and no serious adverse events with exercise.

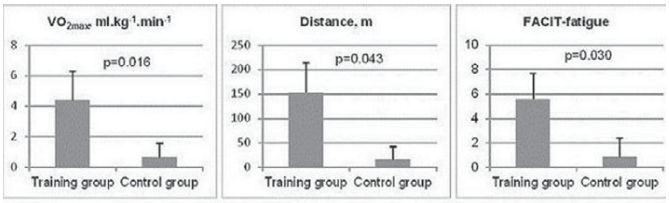

Figure 1. The exercise training group showed improved aerobic capacity, improved exercise tolerance and improved fatigue compared to controls.

Conclusions: This supervised walking program was demonstrated to be feasible and safe with improvements in the aerobic capacity, exercise tolerance, fatigue and patient perception of improvement in pSS patients.

OP0260-HPR HIGHER SATISFACTION WITH ACTIVITY-RELATED SYMPTOMS AFTER 15-WEEK RESISTANCE EXERCISE IN WOMEN WITH FIBROMYALGIA

K. Mannerkorpi[1,2], A. Larsson[2], A. Palstam[1], M. Ernberg[3], B. Gerdle[4], E. Kosek[5]. *[1]Inst of Neuroscience and physiology; [2]Gothenburg Center of Person-centred Care (GPCC), University of Gothenburg, Göteborg; [3]Department of Dental Medicine, Karolinska Institute, Stockholm; [4]Department of Medical and Health Sciences, Linköping University, Linköping; [5]Department of Clinical Neuroscience, Karolinska Institute, Stockholm, Sweden*

Background: Physical exercise is troublesome for most patients with fibromyalgia (FM) due to activity-induced pain. A reason for activity-induced pain is a low pain threshold. In the present study we investigated if experience of physical activity changed after 15-week progressive person-centred resistance exercise. The control group participated in 15-week relaxation program.
Objectives: To investigate how experience of physical activity changed after 15-week resistance exercise in women with FM, and if experiences correlated with pain threshold.
Methods: 130 women (age 22–64 years, symptom duration 0–35 years) with FM were randomized to 15-week resistance exercise or to a parallel relaxation program. The participants completed Experience of physical activity scale (EPA) comprising five subscales (0–7), assessing how exercise was perceived in terms of Physical relaxation (PR), Well-being (WB), Activity beliefs (AB), Activity-related symptoms (ARS), and Activity Habits (AH) (1). A lower score indicates a higher satisfaction. Pain threshold was investigated with algometer. Within-group and between-group analyses were conducted by non-parametric statistics. Correlations between algometry and ratings on EPA were investigated by Spearman correlation coefficient.
Results:
The resistance exercise group scored significantly higher satisfaction at posttest than before the intervention in their ratings on how they experienced exercise in terms of PR, WB, ARS and AH ($p<0.05$), Table 1.
Between-group analyses showed that the resistance exercise group scored significantly higher satisfaction in ARS subscale ($p<0.006$) after the intervention when compared to the relaxation group.
Significant correlations were found between algometry and PR (rs -0.32, p=0.017) as well as ARS (-0.33, p=0.015) at post-test in the resistance exercise group.

Table 1. Baseline and post-test ratings of EPA in the two groups

EPA subscales	Resistance exercise		Relaxation	
	Baseline (n=67)	15 weeks (n=56)	Baseline (n=63)	15 weeks (n=49)
PR	3.9±1.1	3.6±1.0*	4.1±1.3	3.9±1.2
WB	2.9±1.5	2.5±1.2*	2.7±1.3	2.7±1.4
AB	2.0±1.0	1.9±1.2	2.1±1.3	2.0±1.2
ARS	4.7±1.2	4.1±1.1*	4.9±1.1	4.8±1.1
AH	4.1±1.3	3.1±1.5*	3.7±1.3	3.6±1.4

Within-group changes ($p<0.05$) are marked with *.

Conclusions: Women with FM experienced a higher satisfaction with activity-related symptoms after having participated in a person-centered resistance exercise program, which is an important knowledge for health care professionals when motivating patients for exercise. Correlations between algometry and ratings on PR and ARS indicate that activity-related symptoms are partly associated with the pain threshold.

OP0261-HPR PHYSICAL ACTIVITY LEVEL MEASURED BY ACCELEROMETER IS COMPARABLE BETWEEN JUVENILE IDIOPATHIC ARTHRITIS PATIENTS AND CONTROLS, BUT PATIENTS SPEND LESS TIME IN VIGOROUS PHYSICAL ACTIVITY

K. Risum[1], A.M. Selvaag[1], Ø. Molberg[1], H. Dagfinrud[2], H. Sanner[1]. *[1]Oslo University Hospital; [2]Diakonhjemmet Hospital, Oslo, Norway*

Background: Previous studies indicate that juvenile idiopathic arthritis (JIA) patients have lower levels of physical activity (PA), spend more time in sedentary PA and less time in moderate and vigorous PA than controls. Associations between PA and disease variables in JIA patients are inconclusive. To our knowledge, this study is the first to compare objectively measured PA in JIA patients treated in the era of biologics with healthy controls whose data collection were conducted at the same time as the patients.

Objectives: To compare objectively measured levels and intensity of PA in JIA patients who have had access to biological treatment from disease onset with age- and sex-matched controls from the general population. Furthermore, to compare PA between JIA patients with persistent oligo- and poly-articular disease, and to examine associations between PA and disease variables in patients.

Methods: Patients, 10–16 years, with persistent oligo- or poly-articular disease (extended oligoarthritis and polyarticular RF +/-), were recruited consecutively at Oslo University Hospital in 2015. Age- and sex-matched controls were selected randomly from the Norwegian Population Registry. PA was measured with accelerometers during 7 consecutive days. The general level of PA was determined by counts per minute (cpm) and steps daily. Cut-off points for different PA categories of intensity were used as described by Evenson[1]. Present pain, and pain and fatigue during the previous week were assessed in all participants. Disease activity, functional ability, diasease duration, use of medication and lower extremity joints with active arthritis were registered in patients. Differences between study groups were analyzed with paired or unpaired analyses as appropriate.

Results: Acceptable data from the accelerometers were retrieved in 53 matched pairs, of which 45 (85%) were female. Mean age was 13.3±2.2 years in patients and 13.2±2.6 years in controls, p=0.55. 26 (49%) patients had polyarticular disease. No significant differences were found in cpm or steps daily, or in time spent in sedentary PA, light PA or moderate PA in patients vs controls (Table 1). However, patients spent significantly less time in vigorous PA than controls. No significant differences in PA variables were found between JIA subgroups. The use of biologic medication correlated weakly with cpm, r=0.30, p=0.03, while no other disease variables correlated significantly with cpm or with vigorous PA (all $r<0.30$, p=NS).

Conclusions: General level of physical activity and time spent in sedentary PA, light PA and moderate PA in JIA patients treated in the biological era are comparable with controls. However, patients spend less time in vigorous PA.

Table 1. Physical activity

	JIA (n=53)	Controls (n=53)	p-value
Counts per minute	457±194	483±135	0.45
Steps daily	9219±2679	9772±2575	0.27
Sedentary daily (min)	575±69	571±58	0.66
Light PA daily (min)	189±48	183±42	0.39
Moderate PA daily (min)	33±11	37±12	0.08
Vigorous PA daily (min)	21±12	26±14	0.04
Achieves 60 min MVPA daily n (%)	17 (32)	26 (49)	0.09

Numbers are mean ± SD or N (%).

Even though these results are promising regarding PA in JIA patients, the results indicate that patients still need to be encouraged to be physically active, with emphasis on increasing vigorous PA.

Gout: advances in diagnosis and management

OP0262 TRENDS AND COSTS FOR GOUT HOSPITALIZATION IN SWEDEN

M.I. Dehlin[1], V. Sigurdardottir[1], P. Drivelegka[1], A. Svärd[2], L.T. Jacobsson[1]. *[1]Dept of rheumatology and inflammation research, Institution of medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg; [2]Rheumatology Clinic, Falun Hospital, Falun, Sweden*

Background: Gout is the most common arthritic disease in the world with increasing incidence and prevalence. There are differences in gout prevalence and course of disease due to cultural, ethnical and genetic factors stressing the need for data from different parts of the world. An increase in hospitalization for gout has been shown for the last two decades in North America.

Objectives: We evaluated the trend for hospitalization of gout in western Sweden 2000 – 2012 and the health care costs for this 2009 – 2012.

Methods: Hospitalization trends for gout were studied using data from the health care consumption register in the Western Swedish Health Care Region (WSHCR) from 2000–01–01 through 2012–12–31. This area is considered to be representative for the country as a whole. Patients aged 18 years and older who were hospitalized during the study period with a principal ICD-10 diagnosis of gout (M10) at discharge were included. We calculated annual population rates for hospitalization for gout. Inflation-adjusted health care costs for the gout hospitalizations were calculated using the Cost-Per-Patient register (CPP). Dispensation of urate lowering therapy (ULT), allopurinol (M04AA01) and probenecid (M04AB01), within 6 months prior to hospitalization was identified using The Swedish Prescribed Drug Register.

Results: There were 1873 hospitalizations for gout (mean age 75.0–77.6 years, 61–74% men) between 2000 and 2012. Demographic characteristics were similar

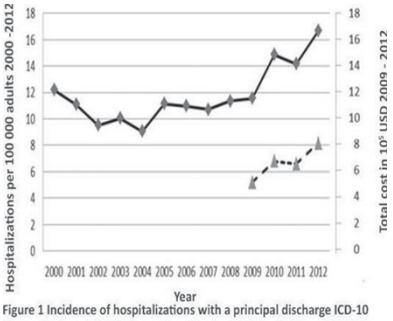

Figure 1 Incidence of hospitalizations with a principal discharge ICD-10 diagnosis of gout (M10) in western Sweden 2000 to 2012 per 100 000 adults (≥18 year) (full line,left side) and total cost for the hospitalizations in 105 USD 2009 to 2012 (dashed line, right side)

Abstract OP0262 – Table 1

	2000	2002	2004	2006	2008	2009	2010	2011	2012

65–84	83	63	67	80	85	89	100	92	108
≥85	33	27	23	34	38	40	60	52	60
ULT, (%), 6 months before hospitalization				28 (21)	38 (27)	27 (19)	38 (20)	47 (26)	45 (21)
Total cost*, 10^5 USD						5.21	6.8	6.6	8.15

over the study period. From 2000 to 2012, the annual hospitalization rate for gout increased from 12.2 to 16.7 per 100 000 adults (p=0.0038). The increase was most pronounced in males aged 65 and above and over the last three years of the study. From 2009 to 2012 the inflation-adjusted health care costs for gout hospitalizations increased from 5.21 to 8.15 10^5 USD. The duration of hospitalizations also increased from 3 to 5 days median 2000 and 2012 respectively (p=0.021). Only a minority of patients, 19 to 27%, received ULT the 6 months preceding their hospitalization, without any obvious secular trend.

Conclusions: Incidence of hospitalization for primary gout is increasing substantially in Sweden over the last decade and this is reflected in the health care costs. The main part of this increase consists of males aged 65 and above. Only a fourth of the patients were on ULT preceding the hospitalization. These findings are further emphasized by the fact that the total amount of days for somatic inpatient care in WSHCR decreased by 9% from 2002 (1 267 900 days, mean duration 5,7 days) to 2012 (1 151 630 days, mean duration 4,9 days). The findings in this study reflects increasing incidence of the gout disease and an ageing population but also a considerable lack of treatment.

OP0263 TRANS-ANCESTRAL META-ANALYSIS IDENTIFIES 13 NEW LOCI ASSOCIATED WITH SERUM URATE LEVELS

T.R. Merriman[1], M. Cadzow[1], R. Topless[1], D. Mount[2], H. Choi[3], Y. Okada[4], J. Boocock[5], E. Stahl[6]. *[1]University of Otago, Dunedin, New Zealand; [2]Brigham and Women's Hospital; [3]Harvard Medical School, Boston, United States; [4]Osaka University, Osaka, Japan; [5]University of California Los Angeles, Los Angeles; [6]Mt Sinai School of Medicine, New York, United States*

Background: Serum urate is an important biomarker for gout disease and kidney function. Genome-wide association study (GWAS) meta-analyses have identified 28 loci in European and East Asian population samples. Combined analysis of these summary data across populations offers the opportunity to discover new serum urate associations through greater sample size and power, and trans-ancestral analyses provide the opportunity for fine-mapping associations with greater resolution given differing linkage disequilibrium patterns between populations.

Objectives: To conduct a meta-analysis of European and East Asian serum urate GWAS.

Methods: Summary statistics from European (N=110,238) (Kottgen et al. 2013) and east Asian (N=21,268) (Okada et al. 2012) meta-analyses were obtained. We used ImpG v1.0 to impute the results into 1000 Genomes phase 3 variants, and performed sample-size weighted z-score meta-analysis. Linkage-disequilibrium (LD)-independent variants with $P_{META} < 5x10–8$, not in LD ($r2<0.1$) with previously identified regions, were considered novel serum urate loci. We used functional partitioned LD score regression on all associated loci in the European GWAS to identify SNP-heritability enriched tissue-specific regulatory regions, for use as functional priors in PAINTOR fine mapping analyses to identify putative causal variants.

Results: The trans-ancestral meta-analysis of European and East Asian GWAS revealed nine new serum urate-associated loci ($P_{META}<5x10^{-8}$). Three of the new loci are located in the 11q12.3–13.2 region near the established SLC22A11/12 locus. Additional novel loci are located near the FGF5, LNC00603, HLA-DQB1, B4GALT1, BICC1 and USP2 genes. Tissue-focused functional partitioning of SNP-heritability indicated the strongest enrichments of kidney, GI and liver tissues ($P<10^{-7}$), among other significant tissues. Trans-ancestral meta-analysis and functional fine-mapping decreases the numbers of SNPs in causal variant credible sets, and for example pinpoints the rs17632159 SNP as likely causal (posterior $P>0.9$) at the TMEM171/174 locus.

Conclusions: Meta-analysis of existing GWAS increases power and leads to the identification of nine new loci associated with serum uric acid levels. Increased resolution in trans-ancestral GWAS, with functional annotation enrichments, improves fine-mapping of serum urate GWAS loci.

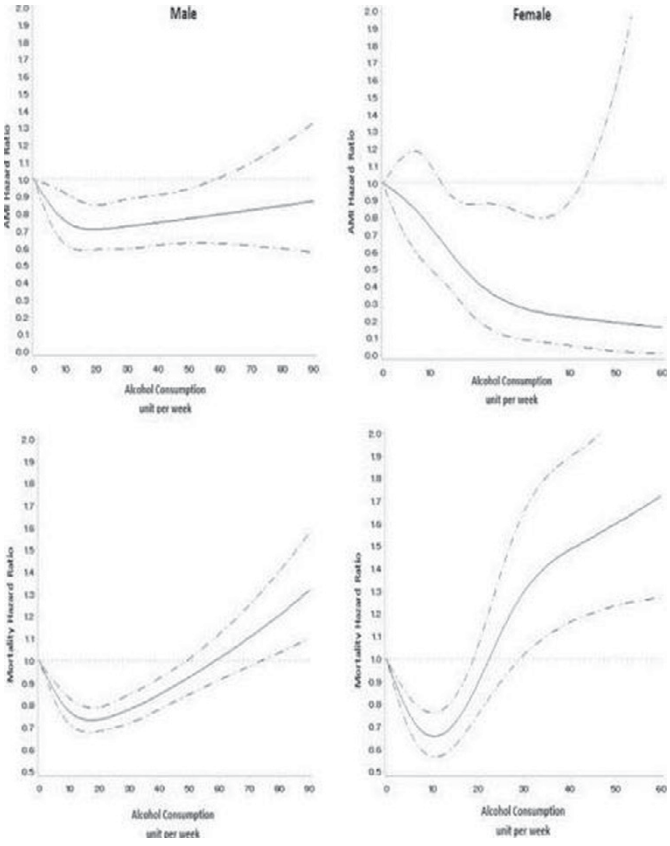
OP0264 CAN MODERATE ALCOHOL INTAKE LOWER THE RISK OF MYOCARDIAL INFARCTION AND MORTALITY EVEN AMONG GOUT PATIENTS?



H.K. Choi[1], N. Lu[1,2], S.K. Rai[1], S.F. Keller[1], A.M. Jorge[1], Y. Zhang[1,2]. *[1]Division of Rheumatology, Allergy, and Immunology, Massachusetts General Hospital; [2]Clinical Epidemiology Research and Training Unit, Boston University School of Medicine, Boston, United States*

Background: While alcohol is a well-established risk factor for gout, many prospective studies have consistently found that moderate alcoholic consumption is associated with a 25–40% reduced risk for coronary heart disease (CHD) and death. As such, the American Heart Association (AHA) suggests that "if you drink alcohol, do so in moderation". As gout is associated with an increased risk of CHD and premature mortality, the potential benefits of drinking in moderation may also be applicable to gout patients provided that their gout is under control with other measures.

Objectives: To examine the relation between alcohol intake and the risk of acute myocardial infarction (AMI) and all-cause mortality among incident gout patients in a general population context.

Methods: We conducted a cohort study using data from an electronic medical record database representative of the UK general population, collected between 1995 and 2015. The exposure of interest was the first alcohol intake measured after gout diagnosis, and our endpoints were incident cases of AMI as well as all-cause mortality. Stratifying by sex, we calculated the hazard ratios (HR) of these endpoints according to alcohol intake categories (i.e., 0, 1–9, 10–24, 25–42, and >42 UK alcohol units/week [1 unit=8gm]), adjusting for age, smoking status, body mass index, duration of gout, comorbidities, and medication use. We performed a spline model analysis using 4 knots of the alcohol intake categories, hypothesizing a J-shaped relation as observed in general population studies.

Results: Among 55,584 gout patients (78% male, mean age of 63 years), 1,332 developed AMI and 8,362 died over a mean follow-up of 5.6 years. Compared with men who did not drink alcohol after gout onset, men who drank alcohol had a lower risk of AMI as well as mortality in a J-shaped manner (Figure 1, left panel). The multivariable HRs for developing AMI were 1.0, 0.76 (95% confidence interval [CI], 0.63–0.93), 0.68 (0.55–0.83), 0.69 (0.53–0.89), and 0.71 (0.52–0.95) for alcohol use categories of 0, 1–9, 10–24, 25–42, and >42 units/week, respectively, and the corresponding HRs for mortality were 1.0, 0.77 (95% CI, 0.71–0.82), 0.71 (0.66–0.77), 0.74 (0.66–0.82), and 0.89 (0.78–1.01) (Figure 1, left panel). While alcohol consumption levels and sample sizes were smaller among women, the J-shaped relation was more obvious and showed a significantly increased risk of mortality in the top consumption category (HR=1.68; 95% CI, 1.09–2.61) (Figure 1, right panel).

Conclusions: This general population-based study indicates that moderate alcohol intake is associated with a lower risk of AMI as well as all-cause mortality among gout patients, similar to many general population studies. These findings suggest that the AHA recommendation about moderate alcohol use may also be applicable to gout patients for their cardiac health and improved survival, provided that their gout is under control with other measures.

OP0265 VALIDATION OF A DEFINITION FOR ATTACK (FLARE) IN PATIENTS WITH ESTABLISHED GOUT

A. Gaffo[1,2], N. Dalbeth[3], J. Singh[1,2], K. Saag[1], W. Taylor[4]. *[1]University of Alabama at Birmingham; [2]Birmingham VA Medical Center, Birmingham, United States; [3]University of Auckland, Auckland; [4]University of Otago, Otago, New Zealand*

Background: A standardized validated definition for gout attacks (flares) is not available. Two provisional definitions published in 2012 were based on patient-reported elements (patient-defined attack, pain at rest greater than 3 in a 0–10 numeric rating scale, presence of at least one swollen joint, presence of at least one warm joint) (1). These definitions had acceptable sensitivity and specificity but lacked external validation which is necessary before they can be adopted in gout clinical studies.
Objectives: To perform external validation of previously published preliminary gout attack (flare) definitions in patients with gout.
Methods: We enrolled 509 participants with gout from 17 international sites in a cross-sectional study performed during routine clinical care. All patients met the 2015 ACR/EULAR classification criteria for gout (2). Criteria for the previously published gout attack definitions were collected by a site investigator and the final adjudication of a gout attack status was done by a local expert rheumatologist, through an evaluation independent from that of the site investigator. Logistic regression, Bayesian statistics, and receiver-operator curves were used to calculate the final diagnostic performance of the gout attack definitions.
Results: The mean age of participants was 57.5 years (standard deviation [SD] 13.9) and 89% were men. Mean disease duration was 12.3 (SD 10.3) years, 35% had tophi, and 75% were taking urate-lowering therapies. The previously published and favored definition requiring the presence of 3 or more out of 4 criteria ("number of criteria") was found, using the current study data, to be 85% sensitive and 95% specific in confirming the presence of an attack in patients with gout (Table). The concurrent logistic regression model had an area under the curve of 0.97. The previously published definition based on a classification and regression tree algorithm (entry point pain at rest >3 followed by patient-defined attack "yes") was 73% sensitive and 96% specific using the current study data (Table). The "number of criteria" approach with a cut-point at 3 or more out of 4 criteria had higher diagnostic accuracy using the current study data than in its initial 2012 description (92% versus 84%, table). (1) Finally, using current study data the "number of criteria" approach at 3 or more out of 4 criteria had higher accuracy to the classification and regression tree algorithm based approach (92% versus 89%) but with a much better sensitivity (85% versus 73%).

Table. Diagnostic performance of gout attack (flare) definitions: "number of criteria"* and classification and regression tree (CART)

	Sensitivity% (95% CI)	Specificity% (95% CI)	PPV% (95% CI)	NPV% (95% CI)	Accuracy% (95% CI)
Number of criteria (current study)					
1 or more	100 (100)	66 (61-715)	57 (51-63)	100 (100)	77
2 or more	97 (94-100)	88 (84-91)	78 (72-84)	98 (97-100)	91
3 or more	85 (80-91)	95 (93-97)	88 (83-93)	94 (91-96)	92
All 4	61 (54-69)	98 (97-100)	94 (90-99)	85 (82-88)	87
3 or more (2012 provisional definition)†	91 (80-97)	82 (75-88)	64 (52-74)	96 (91-99)	84
CART‡ (current study)	73 (66-80)	96 (94-98)	90 (84-95)	89 (86-92)	89
CART (2012 provisional definition)	83	90	85	91	

CI = confidence interval, PPV = positive predictive value, NPV = negative predictive value
CART = classification and regression tree
*Criteria include: patient-defined gout attack, pain at rest greater than 3 in an 0-10 numeric rating scale, Presence of at least one swollen joint, presence of at least one warm joint
†3 or more criteria was found to have the best performance in a receiver-operator curve analysis
‡CART rule: Pain at rest > 3 followed by patient-defined gout attack positive

Conclusions: The definition requiring the presence of 3 or more out of 4 patient-reported criteria is validated to be sensitive, specific, and accurate in identifying attacks (flares) in patients with gout using an independent large international sample. Having a validated gout attack definition will improve ascertainment of outcomes in gout clinical studies.

OP0266 PRESENCE OF MONOSODIUM URATE CRYSTALS BY DUAL-ENERGY COMPUTED TOMOGRAPHY IN GOUT PATIENTS TREATED WITH ALLOPURINOL

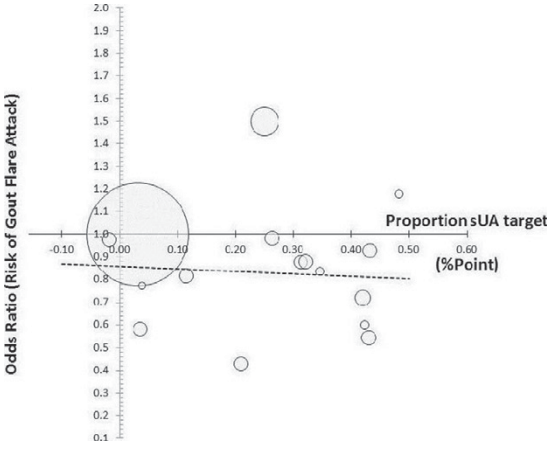
N. Dalbeth[1], S. Nicolaou[2], S. Baumgartner[3], J. Hu[3], M. Fung[3], H.K. Choi[4]. *[1]University of Auckland, Auckland, New Zealand; [2]Vancouver General Hospital and University of British Columbia, Vancouver, Canada; [3]Formerly Ardea Biosciences, Inc, San Diego; [4]Harvard Medical School and Massachusetts General Hospital, Boston, United States*

Background: Chronic hyperuricemia predisposes to deposition of monosodium urate (MSU) crystals in musculoskeletal and other tissues, causing chronic inflammation, acute gout flares, joint damage, and disfiguring tophi. Dual-energy computed tomography (DECT) is a useful imaging tool to detect and quantify MSU crystal deposits.
Objectives: This study assessed the evidence of MSU crystal deposition using DECT scanning among gout patients treated with allopurinol and the potential determinants associated with the observed deposits.
Methods: The multicenter DECT study recruited patients with gout from the USA and New Zealand who were taking allopurinol at ≥300 mg daily for at least 3 months. MSU crystal deposition was measured using DECT in hands/wrists, knees, and feet/ankles bilaterally. The presence of MSU crystals as well as the total volume of crystals were assessed according to gout characteristics and serum uric acid (sUA) levels.
Results: Patients (N=153) were predominately male (92.2%), with mean (SD) age 58.5 (11.4) years, and gout duration 14.9 (10.3) years. sUA was ≥6.0 mg/dL in 49.0% of patients. 81.7% of patients took allopurinol at a stable dose of 300 mg/day and the remainder at >300 mg/day. 69.1% of patients had MSU crystal deposits with a total median crystal volume of 0.16 cm^3 (range, 0.01 to 19.53 cm^3). Those with sUA ≥6.0 mg/dL and palpable tophi showed the highest prevalence of urate deposits (90%), and those with sUA <6.0 mg/dL and no palpable tophi showed the lowest prevalence (47%). Those who reported a gout flare within the prior 3 months (versus none), were prescribed allopurinol doses >300 mg (versus 300 mg), and had palpable tophi (versus none) had greater deposit volume.

Table. Summary of Urate Deposits on DECT Scan According to Palpable Tophus Status and sUA Level.

	Tophi		No tophi		Total
	sUA ≥6.0 mg/dL (n=20)	sUA <6.0 mg/dL (n=28)	sUA ≥6.0 mg/dL (n=55)	sUA <6.0 mg/dL (n=50)[a]	(N=153)[a]
Median volume (range) for nonmissing urate deposits	0.26 (0.00, 19.53)	0.16 (0.00, 4.63)	0. 09 (0.00, 1.23)	0.00 (0.00, 0.89)	0. 07 (0.00, 19.53)
Presence of urate deposits, n (%)	18/20 (90.0)	20/28 (71.4)	44/55 (80.0)	23/49 (46.9)	105/152 (69.1)
	P=0.16[b]		P<0.001[b]		
	P<0.001[c]				
Median volume (range) for positive scans	0.37 (0.01, 19.53)	0.29 (0.05, 4.63)	0.12 (0.01, 1.23)	0.14 (0.01, 0.89)	0.16 (0.01, 19.53)

[a] MSU crystal deposition data missing in 1 patient.
[b] Fisher's Exact test and Pearson's Chi-square test for pairwise comparisons.
[c] Pearson's Chi-square test across the 4 groups.



Conclusions: Despite a stable dose of allopurinol for more than 3 months, and even with sUA at the target level, a substantial proportion of patients with gout continue to have evidence of MSU crystal deposition by DECT scan. Patients with palpable tophi, sUA levels ≥6.0 mg/dL, and gout flares within the prior 3 months have a greater volume of MSU crystal deposition. These patients may need continuation and/or intensification of their urate-lowering therapy regimen.

OP0267 SERUM URATE AS A SURROGATE ENDPOINT FOR GOUT FLARES: RESULTS OF A SYSTEMATIC REVIEW AND META-REGRESSION ANALYSIS OF RANDOMIZED TRIALS

L. Stamp[1], M. Morillon[2], W. Taylor[3], N. Dalbeth[4], J. Singh[5], R. Christensen[6]. *[1]Medicine, University of Otago, CHRistchurch, Christchurch, New Zealand; [2]Odense University Hospital, Odense, Denmark; [3]University of Otago, Wellington; [4]University of Auckland, Auckland, New Zealand; [5]University of Alabama, Birmingham, United States; [6]Musculoskeletal Statistics Unit, The Parker Institute, Odense, Denmark*

Background: The primary outcome measure for efficacy in clinical trials of urate lowering therapy (ULT) is frequently serum urate (SU), effectively acting as a surrogate for patient-centred outcomes (e.g. gout flares). It has not been clearly demonstrated that the strength of the relationship between SU and patient-centred outcomes is strong enough for SU to be considered a surrogate.

Objectives: To determine the strength of the relationship between SU and the incidence of gout flares and thereby to determine whether SU is a valid surrogate endpoint according to the BSES3 framework.
Methods: A systematic search of Medline via PubMed, the Cochrane Central Register of Controlled Trials, EMBase via OVID, the Institute for Scientific Information Web of Science, and other sources identified relevant studies. Standardised data elements were extracted by 2 independent reviewers (LS, MBM) and disagreements resolved by discussion (RC). Eligible trials were parallel-group, randomised trials of ULT of at least 3 months duration in people with gout. For the meta-regression analysis, a mixed linear model was used to combine the ratio of flare rates between groups (SAS software, v9.4 for Windows). Trials with multiple arms were treated as individual trials, referred to as "randomised comparisons" (i.e., 3-arm trials with 2 active interventions was handled as 2 randomised comparisons). Data was analysed by meta-regression using the between-arm difference in proportion of individuals who achieved target SU (<0.36mmol/L) as independent variable from at 3 months (or 6 and 12 months if 3 month values not available) against flare rate (dependent variable).
Results: After screening 234 abstracts, 82 trials were scrutinized, of which 9 trials (with 16 comparisons) met inclusion criteria. A total of 5,696 people with gout entered into the meta-regression model. The longest RCT included was only 12 months duration. The pooled Odds Ratio (OR) suggested a small but statistically significant favourable association between the active and comparator urate lowering therapies and flare frequency (OR, 0.83; 95% CI 0.70 to 0.99]). Substantial heterogeneity was present (between trial variance: 0.07; 0.03 to 0.30). Meta-regression analysis did not reveal any statistically significant association between the proportion of individuals who achieved target SU and the observed flare rate (P=0.82); the model fit did not improve after inclusion of the covariate into the model (between trial variance: 0.08; 0.03 to 0.33) (Figure).

Conclusions: Substituting surrogate endpoints (proportion achieving target SU) for the important clinical outcome (gout flares) allows conduct of shorter smaller trials. However, based on aggregate trial-level data (meta-regression) an anticipated association between SU and gout flare could not be confirmed. Trial duration may have been too short to observe a reduction in flares and further work using data from long-term extension studies is underway.

OP0268 NURSE-LED CARE VERSUS GENERAL PRACTITIONER CARE OF PEOPLE WITH GOUT: A UK COMMUNITY-BASED RANDOMISED CONTROLLED TRIAL

M. Doherty[1], W. Jenkins[1], H. Richardson[1], A. Abhishek[1], D. Ashton[1], C. Barclay[1], L. Duley[2], H. Jones[1], M. Santarelli[1], A. Sarmanova[1], M. Stevenson[3], W. Zhang[1]. *[1]Division of Rheumatology, Orthopedics and Dermatology; [2]Clinical Trials Unit, University of Nottingham, Nottingham; [3]Health Economics and Decision Science, University of Sheffield, Sheffield, United Kingdom*

Background: Despite increasing prevalence of gout in the UK (1), a variety of barriers result in suboptimal care (1,2) with only 40% of gout patients receiving urate-lowering therapy (ULT), usually at fixed dose without titration to a serum uric acid (SUA) target (1,2). Nurses successfully manage many chronic diseases in the community, and we have shown that when people with gout are fully informed and involved in management decisions uptake of ULT is high and subsequent adherence under nurse-led care is excellent (3).
Objectives: To directly compare nurse-led care to general practitioner (GP) care of people with gout in a 2 year randomised controlled trial (NIHR CRN Portfolio No.12943)
Methods: 517 participants with acute gout in the previous year were identified from 56 local GP practices and randomised to nurse-led or continuing GP care. The nurses were trained about gout and its management according to recommended best practice (EULAR and BSR guidelines) involving full information, addressing illness perceptions, and involving patients in management decisions. Assessments were undertaken at 1 and 2 years. Analysis was intention to treat (last observation carried forward).
Results: Nurse (n=255) and GP (n=262) groups were well matched at baseline for mean age (62 v 64yrs), sex (90% v 89% men), mean disease duration (11.6 v 12.7yrs), mean gout attack frequency in prior year (4.2 v. 3.8), tophi (13.7% v. 8.8%), mean SUA (443 v. 439 μmol/L), mean eGFR (71.5 v. 70.2) and ULT use (40% v. 39%) (all p>0.05). By 2yrs, 22 (8.6%) and 54 (20.6%) participants had discontinued the nurse and GP groups (p<0.001), including 2 v. 8 deaths respectively. Comparing nurse and GP groups at 2yrs: 95% v. 29% had SUA <360 μmol/L (primary outcome); 88% v. 16% had SUA <300 μmol/L; mean (SD) SUA was 252±73 v. 418±106; 97% v. 54% were on ULT; and mean (SD) dose of allopurinol was 470 (140) v. 240 (107) mg/day (all p<0.001). Mean (SD) attack frequency during the 2nd year was 0.33 (0.93) in the nurse v. 0.94 (2.03) in the GP group (p<0.001), and at 2yrs tophi were present in 2.6% (reduced) v. 9.6% respectively (p<002). Although equivalent at baseline, mean (SD) SF-36 norm-based physical component scores were better at 2yrs in the nurse group (41.31 (16.76) v. 37.87 (14.31); p<0.05).
Conclusions: Nurse-led care of people with gout in the UK community can result in high uptake and excellent adherence to ULT over a 2yr period, achievement of target SUA in >9/10 cases and consequent improvements in patient-centred outcomes and quality of life. This study reinforces the benefits of "treat-to-target". Compared to standard GP care this model is likely to be cost effective long-term and merits further consideration.

OP0269 EFFECT OF XANTHINE OXIDASE INHIBITORS ON THE INCIDENCE OF CARDIOVASCULAR EVENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMISED CONTROLLED TRIALS

M. Bredemeier, L.M. Lopes, M.A. Eisenreich, G.K. Bongiorno, S. Hickmann. *Rheumatology Division, Hospital Nossa Senhora da Conceição - Grupo Hospitalar Conceição, Porto Alegre - RS, Brazil*

Background: There is evidence that xanthine oxidase inhibitors (XOI) may reduce the risk of major adverse cardiovascular events (MACE) (1,2) and lower blood pressure (3). To date, this evidence is based mainly on observational studies (2).
Objectives: To compare the incidence of MACE, mortality, and total and specific cardiovascular (CV) events in patients enrolled in randomized controlled trials (RCTs) comparing XOI with placebo or no treatment.
Methods: A systematic review (CRD42015016073) searching for RCTs using PubMed, EMBASE, Cochrane Library, Web of Science, and Lilacs databases, and hand searching, was ended in Dec 2016. All RCTs comparing XOIs with placebo or no treatment lasting ≥4 weeks and including only adult individuals were eligible. The primary outcomes were the incidence of MACE (CV death, non-fatal myocardial infarction, unstable angina requiring urgent revascularization, or non-fatal stroke) and mortality; total CV events (TCE), specific CV outcomes, and serious adverse events (SAE) served as secondary outcomes. Associations were tested using the Peto odds ratio (OR) without zero-cell continuity correction.
Results: In total, 81 studies including approx. 11,000 individuals reported extractable data on CV events. The use of XOI tended to be associated with lower incidence of MACE (OR=0.64, 95% CI 0.41–1.01, P=0.056), but not with mortality (0.95, 0.63–1.44). However, there was a significantly reduced incidence of TCE (0.66, 0.54–0.80, P<0.001), especially new/worsening hypertension (0.57, 0.37–0.87, P=0.009), and a trend for reduction in the incidence of new/worsening heart failure (0.74, 0.53–1.04, P=0.086). The incidence of SAE (0.86, 0.71–1.05) did not differ significantly. Subgroup analysis suggested a protective effect for MACE in studies with high prevalence (>50%) of cardiac diseases (0.52, 0.30–0.91, P=0.021). Sensitivity analysis excluding studies at high or unknown risk of bias produced no significant change in results, but reinforced the association with reduced incidence of hypertension (0.26, 0.11–0.60, P=0.001) and heart failure (0.55, 0.32–0.94, P=0.030). Separate analysis of data on purine-like XOI (allopurinol and oxypurinol) confirmed the results of the primary analysis. Exploratory metaregression analysis showed association of dose of allopurinol with higher incidence of TCE (P=0.023, random effects) and SAE (P<0.001, see Figure 1). Accordingly, in the subgroup with doses ≤300 mg/day of allopurinol, a reduction of incidence of MACE (0.36, 0.18–0.68, P=0.002), TCE (0.38, 0.26–0.54, P<0.001), and SAE (0.49, 0.34–0.71, P<0.001) was observed, while the SAE risk increased in doses >300 mg/day (1.39, 1.04–1.91, P=0.047). There was

no association of dose of non-purine-like XOI with incidence of TCE and SAE. Significant statistical heterogeneity was not observed in any test reported here.

Figure 1. Meta-regression analysis of dose of allopurinol versus logarithm of odds ratio (OR) of serious adverse events.

Conclusions: Our data from a meta-analysis of RCTs suggest that XOI reduce the incidence of CV events, an effect possibly related (at least partly) to control of hypertension. However, higher doses of allopurinol (>300 mg/day) may possibly be associated with higher risk of serious adverse events and loss of cardiovascular protection.

Low back pain and fibromyalgia

OP0270 LONG-TERM PROGNOSIS IN CHRONIC PLANTAR FASCIITIS BASED ON DISEASE DURATION AND ULTRASONIC CHANGES

L. Hansen[1], U. Fredberg[1], T.P. Krogh[1], T. Ellingsen[1,2], L.B. Hansen[3].
[1]Diagnostic Centre, Regional Hospital Silkeborg, Silkeborg; [2]Department of Rheumathology, Odense University Hospital, Odense; [3]Radiologic Department, University Hospital Aarhus, Aarhus, Denmark

Background: Plantar fasciitis (PF) affects 7–10% of the population over a lifetime but the long-term prognosis is unknown. This study is the greatest within the long-term prognosis of PF and have the longest follow-up time.
Objectives: The aim was to assess the long-term prognosis of chronic PF based on duration of symptoms and ultrasonic changes (tendon thickness, heel spur, echogenecity and heel fat pad) and assess if any baseline cohort characteristics had an impact on the prognosis (sex, BMI, age, smoker status, physical work/sport and bilateral pain).
Methods: At baseline (2001–11) 269 patients were diagnosed with PF based on symptoms and ultrasound findings.
At follow-up (2016) all the participants were invited to participate in the project. Everyone was interviewed and offered a new ultrasound examination of their plantar fascia at both feet.
Results: 174 (65%) participated in the study, 52% women and 48% men and 137 had an additional US examination. 54% of the participants were asymptomatic at follow-up (asymptomatic group) and the mean duration of symptoms were 725 days (range 41–4018). 46% still had symptoms (symptomatic group). The follow-up period was 9.7 years (range 4.7–27.3). The risk of having chronic PF were 45.6% (95% CI 37.9–53.0) 10 years after debut of symptoms (figure 1). A multiple cox regression analysis found that women ($p<0.01$) and participants with bilateral heel pain ($p<0.01$) had a worse prognosis. The hazard rate ratio was 0.49 (95% CI 0.30–0.80) for women (every time 100 men were getting cured pr. year only 49 women were cured pr. year) and 0.33 (95% CI 0.15–0.72) for participants with bilateral heel pain (every time 100 with unilateral pain were cured pr. year only 33 with bilateral pain were cured pr. year). The remaining baseline cohort characteristics (all p's>0.05), tendon thickness (p=0.49) and heel spur (p=0.88) did not have an impact on the prognosis (table 2).
The mean tendon thickness was at baseline 6.9 mm in the asymptomatic group and 6.7 mm in the symptomatic group. The tendon thickness was reduced significantly to 4.3 mm at follow-up in both groups (both p's<0.01). Only 24% in the asymptomatic group had a normal tendon thickness and echogenicity at follow-up (6% in the symptomatic group).
The participants had in average tried 3.8 (range 1–9) different treatment modalities and 93% received an ultrasound guided steroid injection at baseline. 11% of them were permanently cured 1 month after the injection despite symptoms for an average of 334 days' prior the injection. No atrophy of the heel fat pad was found in the sick foot who got the steroid injections compared to the contralateral foot that did not get the injection (p=0.66).
Conclusions: 45.6% had PF 10 years after debut of symptoms.
The asymptomatic participants had in average plantar fasciitis for 725 days.
The prognosis was significantly worse for women and participants with bilateral pain.

Figure 1:
Kaplan Meier survival function for all the participants. The y-axis shows the part who is symptomatic (1.00=100% is symptomatic). And the x-axis is the time in year since debut of symptoms (year 0 = debut of symptoms).

The tendon thickness decreased over time no matter of symptoms and had no impact on the prognosis, neither did heel spur.
Only 24% of the asymptomatic participants had a normal tendon on ultrasound at long-term follow-up.
Ultrasound guided steroid injection did not give atrophy of the heel fat pad in long-term follow-up.

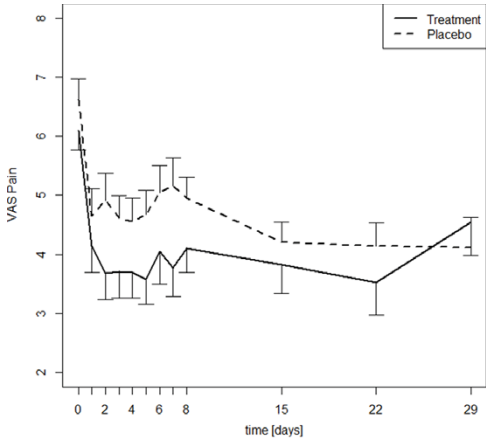
OP0271 CORTICOSTEROID INJECTIONS FOR GREATER TROCHANTERIC PAIN SYNDROME: A RANDOMIZED DOUBLE-BLIND PLACEBO-CONTROLLED TRIAL

M.J. Nissen[1], L. Brulhart[2], A. Faundez[3], A. Finckh[1], D. Courvoisier[1], S. Genevey[1]. *[1]Rheumatology, Geneva University Hospital, Geneva; [2]Rheumatology, Neuchatel Hospital, Neuchatel; [3]Orthopaedics and Traumatology, Geneva University Hospital, Geneva, Switzerland*



Background: Although small observational studies have suggested that local corticosteroid (CS) injection may be effective in the management of the greater trochanteric pain syndrome (GTPS), no prospective placebo controlled study has been carried out to establish the efficacy of this common intervention.
Objectives: To perform a randomized double-blind placebo controlled trial to investigate the efficacy of local CS injection in the management of GTPS.
Methods: The trial was conducted in the Rheumatology unit of a University teaching hospital in Geneva, Switzerland. Inclusion criteria were lateral hip pain (LHP) for greater than 1 month, a LHP score of ≥4 in the preceding week, failure of another standard treatment (physiotherapy, analgesics, etc.) and typical LHP reproduced by palpation of the greater trochanter (GT). Participants were randomised in a 1:1 ratio to: 1) injection with a combination of local anaesthetic and CS (Treatment group), or 2) injection with normal saline solution (Placebo group). The Treatment group received 4ml of 1% Lidocaine (Rapidocain®) and 1ml of Bethametasone (Diprophos®). The Placebo group received 5ml of sterile saline solution. Injections were performed under ultrasound guidance. The study's predefined primary outcome of interest was the difference in pain intensity at 4 weeks post-injection between the 2 groups. Secondary outcomes included the number of "responders" (pain score improvement of ≥1.5) and the number of patients with low disease activity (LDA) (pain score ≤2.0). Patients were followed up for 6 months.
Results: A total of 46 patients were included and there were no significant differences between the 2 groups at baseline (Table 1). There were no significant differences between the 2 groups in terms of the reduction in pain at one month post-injection, with scores of -1.5 and -2.5 (p=0.23) in the Treatment and Placebo groups respectively. When including all measures in the first 3 weeks and using multilevel regression, there was a marginally significant improvement

Table 1. Baseline patient characteristics

	Active treatment (n=21)	Placebo (n=25)	p-value
Age (years) [SD]	56.6 [14.6]	59.6 [13.1]	0.46
Sex (%, female)	81.0	88.0	0.51
Weight (kg) [SD]	74.4 [15.1]	74.7 [15.8]	0.95
Height (cm) [SD]	163.6 [7.7]	153.6 [32.5]	0.18
BMI [SD]	27.9 [6.1]	28.8 [4.9]	0.59
Pain over past 24 hours	6.1 [1.5]	6.6 [1.8]	0.29
Pain on palpation of GT	6.6 [2.0]	7.1 [1.9]	0.40
Past injection of GT (% yes)	38.1	40.0	0.92
Ostwestry total score [SD]	39.9 [13.1]	39.9 [14.9]	0.99
Womac pain score [SD]	251.4 [80.5]	247.2 [87.2]	0.87
Womac function score [SD]	414.6 [154.9]	366.1 [175.7]	0.33

Except where indicated otherwise, values are the mean (± standard deviation). GT = greater trochanter region.

in pain scores in favour of the Treatment group (p=0.08) (Figure 1). There were no significant differences in terms of the percentage of responders (p=0.32), or patients with LDA (p=0.50) between the 2 groups at follow up. There were no significant differences in pain scores between groups at 3 and 6 months post-injection.

Conclusions: Local corticosteroid injection in the management of GTPS is only marginally effective for a few weeks. Given the lack of long-term improvement and the potential for cortisone-related side-effects, this intervention is of limited benefit.

OP0272 CHRONIC LOW BACK PAIN AND ANXIETY: SIGNIFICANT DECREASE WITH GLUCOSAMINE-CHONDROITIN SULFATE TREATMENT IN A LARGE, COMMUNITY-BASED, PILOT, OPEN PROSPECTIVE INTERVENTIONAL STUDY

G. Singh[1], L. Alekseeva[2], D. Goriachev[3], A. Barinov[3], E. Nasonov[2], A. Mithal[4]. *[1]Gastroenterology and Hepatology, Stanford University, Woodside, United States; [2]State NII of Rheumatology of Russian Academy of Sciences; [3]First Moscow State University, Moscow, Russian Federation; [4]ICORE, Woodside, United States*

Background: Low back pain (LBP) is associated with 2.3, 2.2, and 1.6 times greater odds for mood disorders, anxiety disorders and alcohol abuse respectively (1). Continued anxiety may lead to a state of "learned helplessness", and both can propagate in a vicious cycle. Glucosamine-chondroitin sulfate (GCS) combination is widely used in the treatment of OA; however there are few prospective studies of its therapeutic merits in LBP.
Objectives: To study the efficacy of GCS in the decreasing anxiety in patients with chronic LBP in a large open pilot prospective study.
Methods: We enrolled patients 40 - 65 years of age who had LBP for >12 weeks with pain intensity >3 on a 0–10 point VAS in a single-arm, open-label prospective interventional study. Major exclusion criteria were the presence of fibromyalgia, spondylolisthesis, and alcohol and/or drug abuse. All patients were treated with ARTRA (combination glucosamine hydrochloride 500 mg - chondroitin sulfate 500 mg in tablet form; Unipharm Inc.) at a dose of 1 tab bid for the first month and then 1 tab daily for the next two months. The primary endpoint was pain intensity as measured on a 0–10 point VAS. Secondary endpoints included anxiety levels measured by Spielberger's State Trait Anxiety Inventory (STAI) adapted for Russia by Khanin (2). STAI evaluates the current "state" of anxiety, asking how respondents feel "right now," using items that measure subjective feelings of apprehension, tension, nervousness, worry, and activation/arousal of the autonomic nervous system as well as aspects of "anxiety proneness," including general states of calmness, confidence, and security ("trait"). Scores for each scale range from 20 to 80, with higher scores indicating greater anxiety.
Results: A total of 8,598 subjects (mean age 52.1 years, 67.3% women, mean BMI 27.4) were enrolled in the study, and formed the intent-to-treat (ITT) population. All but 95 subjects (1.1%) completed the study. Previously-reported ITT analysis with worst observation carried forward showed an improvement in pain at rest from mean (± SD) of 5.2±1.9 at study entry to 1.4±1.6 at 3 months (p<0.0001). Pain at movement decreased from 6.8±1.6 to 2.2±1.8 (p<0.0001). There was a strong correlation between increasing baseline STAI scores and baseline pain at rest and movement (both p<0.0001). After 12 weeks of GCS treatment, STAI "state" anxiety scores dropped from 49.3 (95% CI 49.1 to 49.6) to 35.8 (95% CI 35.6 -36.0) (p<0.0001). A similar reduction was seen in "trait" anxiety scores from 48.3 (95% CI 48.0–48.5) to 39.6 (95% CI 39.3–39.8) (p<0.001).
Conclusions: Although open and uncontrolled, this large pilot community-based study shows dramatic reductions in pain and anxiety (both "state" and "trait") in patients with LBP treated with GCS. With its benign safety profile, GCS therapy deserves serious evaluation in the management of LBP in a prospective randomized double-blinded clinical trial.

OP0273 A RETROSPECTIVE DATABASE STUDY OF ONE-YEAR ADEHERNCE AND PERSISTENCE WITH PHARMACOLOGICAL THERAPY AMONG FIBROMYALGIA PATIENTS IN ISRAEL

D. Weitzman[1,2], D. Ben-Ami Shor[2,3], S. Dahan[2,4], Y. Bar-On[5], V. Shalev[1,2], G. Chodick[1,2], H. Amital[2,4]. *[1]Epidemiology and Database Resaerch, Maccabitech, Maccabi Healthcare Services; [2]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv; [3]Department of Gastroenterology; [4]Department of Medicine B, Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Tel Hashomer; [5]Department of Medicine E, Tel-Aviv Sourasky Medical Center, Tel Aviv, Israel*

Background: Fibromyalgia (FM) is a chronic debilitating disorder characterized by widespread musculoskeletal pain often accompanied by fatigue, allodynia and hyperalgesia. Literature is scarce regarding adherence to pharmacologic treatments available for FM patients.
Objectives: To assess one-year persistence and adherence with therapy among patients with FM and to identify factors associated with therapy discontinuation.
Methods: Using the comprehensive computerized database of Maccabi Healthcare Services, a large healthcare services provider in Israel, all adults (≥21 yrs) diagnosed with FM between 2008 and 2011 were identified. FM medications included the anti-convulsant pregabalin, SSRI/SNRI and tricyclic antidepressants. Time to treatment discontinuation, defined as a gap of ≥120 days in medication supply days, and proportion of days covered (PDC) with FM-specific therapies during one year from the first dispense were analyzed. Multivariable logistic regression models were constructed to analyze factors associated with low (PDC <20%) and high (PDC ≥80%) adherence.
Results: Overall 3932 eligible FM patients were identified, 88.7% females, mean) SD (age =49.2 (12.7). Pre-diagnosis use of medications of interest was documented in 41% of the patients. Of the remaining 2312, 56.1% were issued a prescription in the year following diagnosis and 45.0% dispensed at least on medication. One-year discontinuation reached 79.3% overall, and was highest for tricyclic antidepressants and lowest for SSRI/SNRI antidepressants (Table 1). Over one half of the patients (60.5%) were poorly adherent (PDC<20%) during the year and only 9.3% were highly adherent (PDC≥80%). Low adherence was less prevalent among patients diagnosed with migraines (OR=0.62, 95% CI: 0.48–0.80) or with both depression and anxiety (OR=0.55; 0.40–0.76). High adherence was positively associated with socio-economic status (p-for-trend=0.022).

Table 1. Medications prescribed and dispensed in the first year from diagnosis, proportion discontinuing and time to discontinuation in the year following first dispense (N=1296)

Drug group	Prescribed N (%)	≥1 dispense N (%)*	Discontinued	
			N (%)**	Days to discontinuation Median (IQR)
Anti-Convulsants	313 (24.1%)	228 (72.8%)	186 (81.6%)	30 (30–106)
SSRI/SNRI antidepressants	606 (46.7%)	471 (77.7%)	347 (73.7%)	41 (30–171)
Tricyclic antidepressants	767 (59.1%)	601 (78.4%)	547 (91.0%)	30 (30–90)
Any drug	1296 (100%)	1041 (80.3%)	825 (79.3%)	40.5 (30–146)

*Percent of patients with at least one dispense out of those prescribed, e.g. 228/313x100=72.8% for anti-epileptic drugs. **% of those with ≥1 dispense.

Conclusions: Persistence and adherence with FM therapy in the year following diagnosis is remarkably low. Further research is needed to assess ways to improve continuation with therapy among FM patients.

OP0274 FIBROMYALGIA IN REAL LIFE: A NATIONAL FRENCH WEB-BASED SURVEY IN 4516 PATIENTS

F. Laroche[1], J. Guérin[1], D. Azoulay[1], J. Coste[2], S. Perrot[3]. *[1]Pain Department, Hospital university Saint Antoine; [2]Biostatistics, Hospital University Hotel Dieu; [3]Pain Department, Hospital University Cochin, Paris, France*

Background: Fibromyalgia (FM) is the most frequent widespread chronic pain disorder (1,6% of the French population) (1). The medical and socioeconomic burden is high and severity depends on medical status and symptoms as defined by the OMERACT criteria (2). Most of the studies are performed in specialized centers, recruiting the most severe patients, but very few data exist on its real impact on daily life.
Objectives: The aims were to collect demographic data, symptoms, function, diagnosis, management strategies and health care utilization in real life, in a large population, and to determine clusters of patients.

Methods: A large internet-based national survey of people suffering from FM was developed by a national patient association (Fibromyalgie-SOS Association) on their website, in France in 2014. The survey included 103 qualitative and quantitative questions that were developed by 3 medical experts (including rheumatologists) and patients.
Results: The questionnaire was completed by 4516 people. Respondents were predominantly middleaged (48 yrs) females (93%), most of whom had FM symptoms duration for 12 years and a diagnosis for 5 years. Diagnosis was made by a rheumatologist in 54% of the cases. The symptoms were concordant with the OMERACT domains (chronic pain, fatigue stiffness and other FM-associated symptoms) as previously published by Bennett in 2007 (3). The mean FIQ (Fibromyalgia Impact Questionnaire) score was 51 (0–100). 55% were currently working but 65% of them have been on sick leave in the 12 previous months. FIQ was mostly impacted by injustice feeling (+4.5), part time job (+2.4) and low income - less than 1000 euros monthly (+2.3) (linear regression).
Somatic comorbidities were mostly osteoarthritis (49%). Psychological comorbidities were injustice feeling (77%), cognitive symptoms (62%), anxiety (52%) and depression (48%). Initiating factors were reported by 73% of them: physical (50%) and/or psychological (76%). Aggravating factors included excess of activities, conflicts, traumatism and displacement. Treatments were provided by general practitioner (85%), physiotherapist (63%), rheumatologist (54%) and osteopathic manual practitioner (41%). Treatment was prescribed in 76.6% of the patients, including paracetamol alone (51.4%), paracetamol and weak opioids (64%), strong opioids (20.1%), antidepressants (81.5%), antiepileptic agents (54.5%), nonsteroidals NSAIDs (53.8%), anxiolytics (52.4%) and steroids (12.8%).
Conclusions: This unique descriptive survey in a large population provides data on symptoms, emotional distress, prescribing habits and impact of FM on daily life and work. Results show that FM is altered by emotional (including injustice feeling) and socio-economic factors.

OP0275 FIBROMYALGIA PREVALENCE AND IMPACT ON DISEASE ACTIVITY SCORES IN RHEUMATOID ARTHRITIS PATIENTS WHO ARE UNRESPONSIVE TO BIOLOGICAL TREATMENT

L.J. Ghib[1], M.M. Tamas[1], I. Felea[2], L. Damian[2], I. Filipescu[1], A. Mociran[2], S.-P. Simon[1], L. Muntean[1], S. Rednic[1]. *[1]Rheumatology, "Iuliu Hatieganu" University of Medicine and Pharmacy; [2]Rheumatology, Emergency County Clinical Hospital, Cluj Napoca, Romania*

Background: Rheumatoid arthritis (RA) treatment uses a treat-to-target strategy and disease assessment is based on disease activity scores (DAS) such as the DAS28 [1]. Biological drugs have proven highly effective for RA treatment in clinical studies[2], however, in real life settings, comorbidities such as fibromyalgia (FM) might influence treatment response assessed by DAS28.
Objectives: In this study we determined FM prevalence and the impact on disease activity scores in patients with RA undergoing biological treatment and if higher tender joint (TJC) correlates with lower pain threshold in patients with active RA who did not satisfy FM criteria.
Methods: We performed a cross sectional study on RA patients undergoing biological treatment who presented in our department for a 6 month period. DAS28 was calculated for all patients. FM diagnosis was considered positive if patients satisfied both the ACR 1990 and ACR 2010 FM Criteria. Pain pressure thresholds (PPT) were measured at the level of the medial knee joint line, mid sternum and middle of the tibia with a manual dolorimeter. Depression, Anxiety, Stress 21 scale (DASS21) and Health Assessment Questionnaire (HAQ) were applied to all patients.
Results: 112 patients were included, 84.8% women, mean age 55.6 (SD 11.6) with a mean disease duration of 14.5 (SD 8.5) years. Acording to DAS28ESR scores 54 (48.2%) had moderate disease activity and 26 (23.2%) had high disease activity. 17 (21.5%) of patients with DAS28ESR scores over 3.2 satisfied FM criteria. FRA and RA groups did not differ significantly concerning age, disease and biological treatment duration, seropositivity, BMI or DASS21 scores. FRA patients had significantly higher values for DAS28 ESR, DAS28 CRP, PGH and HAQ, but similar values for SJC, ESR and CRP compared to RA patients (Table 1). In RA patients without FM, TJC correlated significantly with number of trigger points (r=-0.3), PPT at knee (r=-0.4), sternum (r=-0.3) and tibial level (r=-0.2).
Conclusions: Fibromyalgia is present in a significant percent of patients who are unresponsive to biological treatment as assessed by DAS28 score. Subjective components of DAS28 are significantly higher in FRA compared to RA patients, suggesting that disease assessment should be performed using objective measures in these patients. In patients with active disease despite biological treatment whitout FM, lower pain thresholds are correlated with TJC, suggesting a possible involvement of central pain mechanisms.

Table 1. DAS28 components for RA and FRA patients

	RA (n=63), mean (SD)	FRA (n=17), mean (SD)	P value
PGH	49.9 (19.8)	68.8 (17.2)	<0.001
TJC	5 (3,9)	10 (8.5,17.5)	<0.001
SJC	2 (1,4)	2 (1,5)	0.8
ESR	27.5 (19)	32.8 (23)	0.4
CRP	8.8 (14.4)	12.8 (15.6)	0.2
DAS28 ESR	4.6 (1.08)	5.5 (1.05)	0.003
DAS28CRP	3.99 (1)	4.94 (1.09)	0.002
HAQ	1.2 (0.5)	1.7 (0.6)	0.002

PGH - patient global health, TJC -tender joint count, SJC - swollen joint count, ESR - erythrocyte sedimentation rate, CRP - C reactive protein.

LB0001 INTRADISCAL GLUCOCORTICOID INJECTION FOR PATIENTS WITH CHRONIC LOW BACK PAIN ASSOCIATED WITH ACTIVE DISCOPATHY: A RANDOMIZED TRIAL

C. Nguyen[1], I. Boutron[1], G. Baron[1], K. Sanchez[2], C. Palazzo[1], R. Benchimol[2], G. Paris[1], E. James-Belin[2], M.-M. Lefèvre-Colau[1], J. Beaudreuil[3], J.-D. Laredo[3], A. Béra-Louville[4], A. Cotten[4], J.-L. Drapé[1], A. Feydy[1], P. Ravaud[1], F. Rannou[1], S. Poiraudeau[1]. *[1]Université Paris Descartes; [2]Assistance Publique - Hôpitaux de Paris; [3]Université Paris Diderot, Paris; [4]Université Lille 2, Lille, France*

Background: Active discopathy is associated with a specific phenotype of chronic low back pain (cLBP). Local inflammation has a role in active discopathy-associated symptoms (1).
Objectives: To assess the efficacy of a single glucocorticoid intradiscal injection (GC IDI) in cLBP patients with active discopathy.
Methods: We conducted a prospective, parallel-group, double-blind, randomized controlled study in 3 tertiary care centers in France. 135 cLBP patients with active discopathy on MRI were enrolled. They received a single GC IDI (25 mg prednisolone acetate) during discography (n=67) or discography alone (n=68). The primary outcome was the percentage of patients with LBP intensity in the previous 48 hr <40 on an 11-point numeric rating scale (NRS, 0 no pain - 100 maximal pain) at 1 month. The main secondary outcomes were LBP intensity and persisting active discopathy on MRI at 12 months post-intervention, and spine-specific limitations in activities, health-related quality of life, anxiety and depression, employment status and analgesics and non-steroidal anti-inflammatory drugs consumption at 1 and 12 months.
Results: All randomized patients were included in the primary efficacy analysis. At 1 month, the percentage of responders (LBP intensity <40) was higher in the GC IDI than control group (36/65 [55.4%] *vs* 21/63 [33.3%]; absolute risk difference [95% confidence interval] 22.1 [5.5;38.7]); p=0.009. In the sensitivity analysis, mean reduction [95% CI] in LBP intensity from baseline to 1 month was greater in the GC IDI group compared to the control group (-32.5 [-38.2;-26.8] *vs* -17.5 [-23.3;-11.7], respectively; absolute difference [95% CI] -15.0 [-22.9;-7.1], p<0.001).
At 1 month, the percentage of patients reporting an improvement in spine-specific limitations in activities was higher in the GC IDI than control group (55/65 [84.6%] *vs* 34/63 [54.0%]; absolute risk difference [95% CI] 30.5 [15.7; 45.2], p<0.001). The 2 groups did not differ in LBP intensity at 12 months and in most of the secondary outcomes at 1 and 12 months. 102/119 (85.7%) patients would agree to a second intervention. We found no cases of rapidly destructive disc disease or intervertebral disc calcifications.
Conclusions: In active discopathy-associated cLBP, a single GC IDI reduces LBP at 1 month post-intervention but not at 12 months.
Registration: ClinicalTrials.gov number NCT00804531 (First received: December 8, 2008. Last updated: June 23, 2016).

FRIDAY, 16 JUNE 2017

PARE abstract session

OP0276-PARE MORE PARTICIPATION, BETTER HEALTH – PROMOTING PUBLIC INVOLVEMENT IN HEALTH

S. Crisostomo[1], M. Santos[1], M. Serapioni[2], A.R. Matos[2], E.F. Mateus[3] on behalf of MAIS PARTICIPAÇÃO, melhor saúde. *[1]GAT - Grupo de Ativistas em Tratamentos, Lisboa; [2]Centro de Estudos Sociais da Universidade de Coimbra, Coimbra; [3]Liga Portuguesa Contra as Doenças Reumáticas, Lisboa, Portugal*

Background: In Portugal, the National Health Plan for 2012–2016 (1) and its extension to 2020 (2) consider citizenship-based strategies, including the involvement of patients/citizens and their representatives, as a key strategic axis to maximize health gains. However, actual policy initiatives and concrete actions have been limited to a couple initiatives without significant patient or public involvement. On the other side, several patient and citizen organizations (3–6) have been advocating for increased and meaningful involvement in health decision-making.
Objectives: To develop a Charter for Public Involvement in Health that is widely accepted and recognized by health stakeholders.
Methods: A working group was established with representatives from 13 patient organizations, 1 consumer organization and a research centre. A participatory action research methodology was used. The draft Charter was circulated for review and signature amongst more than 200 non-for-profit health-related organizations and over 50 key individuals publicly renowned for their work in health or public participation. The final version of the Charter was discussed with political and health stakeholders in a Forum held at the Portuguese parliament.
Results: A Charter for Public Involvement in Health, including the principles, scope, guidelines and means of participation was developed. In January 2017, 30 individuals (former and current political decision-makers, health care professionals, researchers and patients) and more than 82 non-for-profit health-related organizations (the majority being Portuguese disease-specific patient organizations) had signed the Charter. The conclusions of the Forum show that the Charter was recognized as a very important initiative to promote public involvement in health in Portugal. Challenges and barriers to further advancing patient and public engagement were also identified (e.g. political will, recognitions of patients as partners, patient empowerment, capacity-building, etc.). The Charter and the Forum were covered in the media and follow-up initiatives with health care professionals and hospital administrators are ongoing.
Conclusions: A patient-led Charter, developed by patient and consumer representatives, in collaboration with academia, and the public discussion with other health care stakeholders have proven successful to put public participation in the political and health care agenda.

OP0277-PARE INITIAL INFORMATION PACKAGE FOR CHILDREN DIAGNOSED WITH JIA

T. Pakkala, M. Ekroth. *Finnish Rheumatism Association, Helsinki, Finland*

Background: Both parents of children with JIA and rheumatology nurses have informed FRA from time to time that there is a need for an initial information package. There was a demand for information that catered to children's needs and provided support for them and their closest relatives at the stage when the diagnosis is shared with the family.
Objectives: The aim of the project was to make an information package for children aged 0 to 12. A child with JIA needed to be provided with information that took into consideration the child's age and developmental stage so that any fears that the child might have as a result of him or her learning of the disease were allayed. Not only information is provided through the information package; the content can also be used to encourage discussions between a parent and a child. We also wanted to include items that give pleasure, such as a stuffed toy in the form of a bunny. A further aim was to increase awareness of FRA among families with children so that as many as possible would find the services offered by FRA and its local member associations.
Methods: *The first stage* of the project involved conducting a survey in order to find out what the package should contain. The survey was directed to parents to children with JIA, rheumatology nurses and rheumatologists. The content of the information package:
1) An initial information binder with the following information: about JIA, food, physical activities & play, sitting & writing, eyes & dental care. There is also a separate section directed to parents. 2) A so-called gym tail and easy-to-do gymnastic instructions. 3) Bunny 4) Coloured pencils and a pen thickener. 5) A picture book about visiting a rheumatology clinic for the child. 6) Brochures: e.g. information about JIA for the closest relatives of a child diagnosed with JIA and health care professionals, information about FRA for families with children. 7) Gymnastics bag *The second stage* involved planning the content and the look of the material. The information package and its content needed be positive and functional – the package as a whole had to be suitable for children. The pictures and text for the picture bookwere also produced in cooperation with the healthcare professionals. Multiple channels were used to spread the information that the package had been completed, e.g. social media, the FRA website and emails to the target group.In addition, the rheumatology careunits were given instructions and informed of what to expect.
Results: The packages were very well received. We have received positive feedback from both rheumatology clinics and families with children suffering from JIA.

Conclusions: There was a real need for the information packages,and the information that they provide help both the families and the healthcare staff. When a child suffers from an illness, it affects the whole family, and hence it is crucial that comprehensive – and comprehensible – information and support are available so that everyday life runs smoothly and is meaningful, and so that a child with an illness does not feel like he or she is a burden to the family but considers him- or herself an equal member of the family.

French Order Council of the Pedicure Podiatrist; [13]Empatient; [14]Vice Presidente; [15]Treasurer, AFLAR, Paris, France*

Background: OA suffers from a lack of interest and not considered serious

enough by Health authorities taking into account the burden of the disease. AFLAR has fostered dynamics by creating a structure called the National Alliance against OA, includes national experts, patients and health professionals (HP). A initiative of this group has been to organize the first General Convention for OA.
Objectives: Its main challenge was to provide a list of actions that could potentially change the face of the disease and improve the visibility of OA along with the needs and demands from French patients.
Methods: 10 regional roundtables (with HP, patients and health institutions, around five topics) has been launched with discussions and debates and enabled the production of patient-related proposals in order to improve their care and information.
Results: 79 proposals have been selected and submitted to an online vote in order to be prioritized. Among the 5 topics addressed by the regional roundtables, cross-cutting issues were identified and 9 fields of action emerged. The final proposals were synthesized in a White Paper document and presented to the national Senate assembly. After it was broadcast to the health and public authorities in a prospect of lobbying. see in the image.

Table of the first 21 proposals from the OA French white Paper for the improvement of his management

	Proposal (keywords + listing number)	% of voting	Average /10	
1	Positioning osteoarthritis as a chronic and functional disabling disease (1.1)	50,1%	9,02	
2	Promote retention in employment for OA patient (3.1)	48%	8,97	
3	Involve supplemental health insurances in the healthcare of OA (3.6)	46,4%	8,88	
4	Develop research programs to improve the management and treatment of OA pain (4.1)	46,3%	8,91	
5	Promote recognition of disability (1.2)	45,7%	8,83	
6	Inform health professionals about the total social coverage of the disease through the national health insurance / ALD 31 or ALD 32 in France (3.7)	45,5%	8,88	
7	Promote an early diagnosis of OA (2.1)	45%	8,68	
8	Promote the training of health professionals in the field of prevention and management of osteoarthritis (2.7)	44,8%	8,86	
9	Promote the training of general practitioners on OA non-pharmacological management (2.16)	44,6%	8,77	
10	Monitor the medico-economic impact of the stoppage of one part of the OA healthcare repayment in France (3.8)	44,5%	8,80	
11	Promote the OA healthcare after surgery by physiotherapists (2.17)	43,4%	8,68	
12	Raise awareness of occupational medicine on OA management (1.3)	43,3%	8,71	
13	Promote access to physiotherapist for OA healthcare (2.18)	42,2%	8,57	
14	Improve the refund of chiropody care for OA patient (3.9)	42%	8,69	
15	Create a national registry of protheses (2.8)	42%	8,69	
16	Find additional means of refunding for OA healthcare (3.10)	41,3%	8,64	
17	Develop research programs to improve the management and treatment of OA with non pharmacological pathway (4.2)	41,2%	8,78	
18	Favour the creation of conditions of contract for the accomodation of the OA patients(3.2)	40,9%	8,62	
19	Promote Patient Therapeutic Education for OA (FTE) (3.16)	40,6%	8,65	
20	Favour the practice of adapted physical activity (2.19)	40,6%	8,48	
21	Create and generalise an "no pain kit " (2.20)	40%	8,51	

Conclusions: Although the impact of this initiative is not yet measurable, we think that it should improve the awareness of the decision-makers on the burden of the disease and provide concrete ideas to governmental and non-governmental policy makers in order to improve the quality of life of OA patients.

OP0279-PARE NRAS KNOW YOUR DAS APP SELF ASSESSMENT TOOL EMPOWERING PATIENTS

C.B. Jacklin[1], S. Arora[2]. *[1]External Affairs; [2]Media & Communications, National Rheumatoid Arthritis Society, Maidenhead, United Kingdom*

Background: NRAS has worked with Roche/Chugai for many years on the Know Your DAS resources. As the DAS28 is the most utilised disease measuring tool available and is used in many countries as part of the access criteria
Objectives: In 2015 the charity was approached about developing an app for mobile phone and tablet use to encourage DAS patient self-assessment. As well as developing the app we worked with the pharmaceutical company to develop printed updated booklets for both patients and health professionals with the addition of information on DAS self-assessment contained within. With increasing pressures on rheumatology clinic time and the emphasis on improving patient education and empowerment this additional NRAS resource is timely and much in demand.
Methods: The Know Your Das app was designed with clear step by step guides and how to video clips to demonstrate how to use the app and show how patients should examine their own joints.
NRAS hosted two user testing focus group meetings and after the launch of version one real time use was analysed. In Jan 2017 version two was released with improvements to the usability and additions including sections on adherence and stock management to aid with prescription refills.
The information entered is held securely by the individual but the DAS results can be printed off or emailed to their clinicians as appropriate. It is not envisaged that the patients' self-assessment should entirely replace the clinicians' DAS measurements but that it will facilitate a better dialogue at clinic appointments as it will give a clearer picture of how the disease has been active or not in the intervening time between appointments.
Results: As of January 2017, 2217 people have downloaded the Know your DAS app and much interest has been shown by users from outside the UK who would like to be able to use the app. Clinicians are keen to utilise the app with their patients
Conclusions: Further research needs to be carried out to compare patients adherence, engagement with their clinicians and ownership of their disease managment as a direct result of using the Know Your DAS app.
Acknowledgements: Roche/Chugai Pharmaceuticals for their funding and development of this resource

OP0280-PARE PATIENT PANELS ON ACCESS AND ADHERENCE TO TREATMENT FOR SLE PATIENTS

S. Badreh, J. Andersen, A. Charlet, K. Lerstrøm, K.H. Wheeler. *Lupus Europe, Essex, United Kingdom*

Background: At the LUPUS EUROPE [forward abbreviated with LE] 2013 Convention in Paris, Professor N. Costedoat-Chalumet illustrated to the participants the critical issue of adherence to treatment (or more precisely, the lack of it). For many reasons, adhering to the prescribed treatment is a challenge for people living with Lupus, yet, "medicine only works if you take it". Understanding this area is critically important to helping people with lupus improve their quality of life.
Objectives: In LE, we wanted to know the reason(s) for this lack of adherence and how to improve it. Is lack of access also a reason for not adhering to treatment?
Methods: Two patient panels were formed to conduct in depth discussion about treatment. For each panel we invited people from our European community through our member groups. The panels were organised to represent different aspects like gender, age, time of diagnosis, main disease area and representing different countries. It was important to LE, that both patient panels were conducted by and for people living with lupus, which gives the participants a feeling of security and being understood: this is very important if you want them to share their experiences openly.
LE organised the first patient panel on November 2nd-4th 2015, bringing together 10 people living with lupus, from 7 countries, to share their experience about "treatment", with a view to help improving the quality of life of people living with lupus. The second patient panel took place on March 11–13, 2016 bringing together 9 lupus affected people from all over Europe to further explore the burden of living with lupus, and to dive into the burden of daily treatment.
The panels were conducted through a series of interactive presentations, team discussions and working groups.
Results: The key findings of both patient panels were:
1. Because "Treatment" is broad; it is both medicine based and non-drug based, and can be categorised in three ways – core, medical, and well-being; there needs to be a more holistic approach to the patient.
2. Access includes ease of contact with Health Care Practitioners, support services such as orthotics and quality information as well as availability of medicines.
3. Patients will take new medicine, provided they understand the reasons why and the side effects.
4. Each patient is responsible for their own treatment and must realise that a positive mind-set can be decisive for the treatment of the disease.
5. Patient Organisations have a critical role to play, creating a community, sharing reliable information, providing hope, raising awareness and advocating for lupus.
Conclusions: Organising a patient panel with a small closed group of patients on neutral ground in a "safe" environment has proven to be a good way of getting the patients to speak openly about a difficult subject and to reveal things, that they might not tell the health professionals. Through this initiative LE has gathered important information about access and adherence to treatment that we can now use to make suggestions about treatment and implement into our strategic plan for the years to come.

OP0281-PARE EDUCATING PATIENT EXPERTS/PATIENT PARTNERS – A NEW WAY

A. Phoka Charalambous[1], I. Cederlund[2], M. Neylander[2]. *[1]Cyprus League Against Rheumatism, Nicosia, Cyprus; [2]The Swedish Rheumatism Organisation, Stockholm, Sweden*

Background: Patients general well-being is largely dependent on health care professionals. The education of these is therefore very important. It is more and more common using patients in the education of health care professionals. The Universities in Cyprus together with other health professional groups have shown interest in involving patients with RheumatoMusculoSceletalDiseases (RMDs) in the education of medical school students regarding RMDs. Besides discussing the disease, they will also learn about the obstacles faced by the patients as well as the impact on their daily life. Through this initiative, the hope is that early recognition and diagnosis is promoted as well as enhancing the knowledge and skills of future doctors.
Objectives: The aim of this project was to implement a Patient Expert project in Cyprus League Against Rheumatism (CYPLAR), and through it train RMD patients to educate medical students and other healthcare professionals regarding

RMDs. A learning partnership should be created between undergraduate medical students/healthcare professionals and the patient experts.
Methods: CYPLAR approached the Swedish Rheumatism Association for collaboration in order to implement the Patient Expert Project in CYPLAR.Funding was received from the EULAR Knowledge Transfer Programme. The collaboration was planned to consist of two meetings, one in Sweden and one in Cyprus.
1. Sweden: Two patients, members of CYPLAR, with RMDs, together with a Rheumatologist from CYPRUS visited the Swedish Rheumatism Association in Stockholm to learn about the Patient Partner Project, and receive Patient Expert training.
2. Cyprus: Two Patient Partner Instructors from the Swedish Rheumatism Association went to Cyprus 6 months after to oversee the progress of the Patient Expert programme and to make an examination of the two Patient Partners educated in Stockholm.
Results: The training session in Stockholm took place on May 2016, for two patients. They received training following the Swedish Patient Expert programme. This training was conducted by two Patient Expert Instructors, one rheumatologist and one Patient Expert. A visit to the Karolinska University Hospital with a tour of the Rheumatology Clinic and a Patient Expert demonstration was also included. The visit ended with a detailed plan formed for the implementation of the Patient Expert programme in CYPLAR.
The visit of the Swedish delegation took place in October 2016. Eight patients participated in the training. The training was made through workshops by the delegates from both organizations together with a Professor of rheumatology and a communication lecturer at the St George's University of London in Nicosia's establishments. Medical students were also involved in discussing their experience in being educated by patients. The programme also involved practice of joint examinations. The workshop was evaluated by the participants on the final day. After the workshop was concluded delegates spent a day discussing the event together. The programme was evaluated, and a future plan of action decided upon.
Conclusions: The implementation of the patient expert programme was successful.10 new Patient Experts are now available in CYPLAR.The next generation of health professionals will benefit and get a larger understanding of RMD's and in the end, the patients will benefit because the health care staff has a greater knowledge.

OP0282-PARE #DOESNTSHOWDOESNTEXIST / #SYNSINTEFINNSINTE – A PHOTO CAMPAIGN BY UNGA REUMATIKER

K. Nordlund, M. Beermann. *Unga Reumatiker, Stockholm, Sweden*

Background: "Rheumatism amongst young people, is that really a thing?" "Isn't rheumatism something that only old people have?" "You seem so happy and so active, surely you can't be in pain?" These are all questions that young people with rheumatism have to listen to, and answer every day.
Yes, it's possible to have rheumatism even as a young person, and to be in pain, even though we're not letting it show. We know adjustment is possible, and that we can live our life to the fullest and follow our dreams, despite rheumatism. But sometimes it demands some extra understanding from the people around us. That's what we wanted to recognize, and created a campaign together with AbbVie.
Objectives: It can be hard to understand and fully grasp something you can't see, something that is invisible. But as young people with rheumatism, we have to live and deal with our swollen joints, with the pain and the fatigue, and with the side effects of our medication. None of which should be questioned.
We recognized that this was an issue for most people with rheumatism, and especially young people. Therefore, we wanted to start a conversation about how it is to go through life with an invisible disability.
The main purpose with our campaign was to acknowledge the fact that you can't always tell whether or not a person has a diagnosis, or is in pain. We also wanted to show young people with rheumatism that they are not alone in their situation.
Methods: We searched for young people with rheumatism in different ages and with different diagnoses. Each person in the campaign is presented in two different photos. One standard full-portrait photo in front of a white background, just showing who they are. One person held a basketball to show off her love for the sport, another one was wearing her dancing shoes and so on. The other photo is instead set in a complete dark room, with the person posing in the same way but this time with their rheumatism-affected areas lit up. We used glow in the dark-body paint and a UV-light to create this effect.
Each pair of photos is put together with the person's story about their passion in life and what it's like to live and deal with an invisible disability.
The campaign was released on October 12th 2016, on World Arthritis Day, with an event at Astrid Lindgren's children's hospital in Stockholm. The photos were printed and presented on large boards together with the personal stories.
The first photo of the campaign, a group photo of everyone participating, was also posted on our social media on October 12th and then one pair of photos was posted every day during the following week. People were also told to share their own stories under the hashtag #synsintefinnsinte
Results: The campaign ended up being our organization's most successful campaign to this date. The spread was especially great on Facebook, with the first post reaching nearly 50'000 people and the other posts reaching between 3'500 and 25'000 people every day. The campaign had more likes and shares on both Facebook and Instagram than any of our other campaigns has had so far.
The opportunity to show the photos at Astrid Lindgren's children's hospital also brought health care into the campaign and attracted great attention on site.
The photos combined with the personal stories make a powerful statement. We managed to show young people with rheumatism that they are not alone in their situation, and we look forward to the conversation continuing on at #synsintefinnsinte

Imaging and treamtent response in rheumatology

OP0283 ULTRASONOGRAPHIC EVALUATION IN RHEUMATOID ARTHRITIS USING THE GLOBAL OMERACT/EULAR ULTRASOUND SYNOVITIS SCORE (GLOESS)

M.S. Stoenoiu[1], A. Pesonen[1], N. Bello[2], R. Christensen[3], M. Østergaard[4], E. Naredo[2], L. Terslev[4]. *[1]Rheumatology, Cliniques Universitaires Saint-Luc, Brussels, Belgium; [2]Rheumatology, University Hospital Gregorio Marañon, Madrid, Spain; [3]Musculoskeletal Statistics Unit, Bispebjerg and Frederiksberg Hospital; [4]Center for Rheumatology and Spine Diseases, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark*

Background: Recently, a global OMERACT/EULAR ultrasound (US) synovitis score (GLOESS) combining grey-scale (GS) and power-Doppler (PD) scores has been proposed as a novel measurement tool to assess disease activity and response to therapy in patients with rheumatoid arthritis (RA)[1,2]. However, the ability of GLOESS to differentiate patients with different states of disease activity *vs.* remission in standard clinical care is not known.
Objectives: To assess the ability of GLOESS to discriminate between different clinical states of activity *vs.* remission in RA patients, and to compare clinical, GLOESS and PD US remission criteria and scores in a cross-sectional study.
Methods: Eighty RA patients from 3 centres were recruited at consecutive clinical visits: 50% were in remission and 50% had active RA according to Simple Disease Activity Index (SDAI). SDAI, Clinical Disease Activity Index (CDAI), 28-joint Disease Activity Score (DAS 28CRP), Health Assessment Questionnaire (HAQ), ACR/EULAR remission criteria were assessed. An independent investigator unaware of clinical results performed all US joint examinations of 26 joints. GLOESS, PD, and GS US sum scores per patient were assessed using OMERACT definitions. PD US remission was defined as the PD sum score =0. GLOESS remission was defined as GLOESS score $\leq$1 thereby also including possible GS grade 1.
Results: PD US remission was observed in 38 (48%) patients and GLOESS remission in 16 (20%) patients. SDAI (r=0.24; p=0.03) and CDAI (r=0.23; p=0.04) but not DAS28CRP (r=0.21; p>0.05) were weakly correlated with GLOESS scores in the whole joint set. SDAI (r=0.41; p<0.001), CDAI (r=0.40; p<0.001), and DAS28CRP (r=0.40; p<0.001) were moderately correlated with PD activity in the whole joint set. A minority of patients were classified both in GLOESS remission and in clinical remission according to SDAI (n=10), to CDAI (n=10), to DAS28CRP (n=10) and to ACR/EULAR 2011 (n=7). Less than one third of patients were classified both in PD US remission and in clinical remission according to SDAI (n=22), to CDAI (n=26), to DAS28CRP (n=27) and to ACR/EULAR 2011 (n=21). The proportion of patients in clinical remission was significantly different according to the definition considered: while 50% of the patients (n=40) were classified in remission according to SDAI, 58% (n=46) were classified in remission according to DAS28CRP, and 43% (n=34) according to CDAI and 43% (n=34) according to ACR/EULAR 2011 remission criteria.
Conclusions: We document major discrepancies between US and clinical findings and between clinical scores classifying patients in active disease *vs.* remission. Patients reaching GLOESS or PD US definitions of remission are partly different from those reaching clinical definitions of remission.

OP0284 EVALUATION OF THE IMPACT OF BASELINE LEVELS OF MRI-DETECTED INFLAMMATION ON TREATMENT RESPONSE IN EARLY, SEROPOSITIVE, MTX-NAÏVE RA: DATA FROM THE AVERT TRIAL

H. Ahmad[1], J. Baker[2], M. Østergaard[3], P. Emery[4], P. Durez[5], J. Ye[1], S. Banerjee[1], P. Conaghan[6]. *[1]Bristol-Myers Squibb, Princeton; [2]University of Pennsylvania, Philadelphia, United States; [3]Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; [4]University of Leeds and Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom; [5]Université Catholique de Louvain, Brussels, Belgium; [6]University of Leeds, Leeds, United Kingdom*

Background: AVERT (Assessing Very Early Rheumatoid arthritis Treatment) was a Phase IIIb, randomized, 24-month (M) trial with a 12M, double-blind treatment period, and included contrast-enhanced MRI of the dominant hand and wrist. MRI can provide direct evidence of joint inflammation, enabling stratification of patient (pt) data according to MRI inflammation level, e.g. low vs high.[1] This stratification is hypothesized to predict clinical treatment response.
Objectives: To evaluate the proportion of pts achieving remission at M12 by baseline (BL) MRI-detected inflammation status and treatment group.
Methods: In AVERT, pts with early RA received abatacept (ABA) + MTX, ABA monotherapy or MTX. MRI inflammation was scored by two central readers at BL and M12. In this *post hoc* analysis, pts were stratified into "low" and "high" BL MRI inflammation groups. Low: ≤3 for synovitis, ≤3 for osteitis and ≤9 when combined (osteitis double weighted);[2] high: >3, >3 or >9, respectively. The proportion of pts achieving CDAI (≤2.8), DAS28 (CRP; <2.6), SDAI (≤3.3) and Boolean (TJC ≤1, SJC ≤1, CRP ≤1 mg/dL and pt global assessment of disease activity ≤1 [0–10 cm scale]) remission at M12 was compared by BL MRI inflammation and treatment group.
Results: Of 351 pts randomized and treated, 337 (96.0%) had MRI data at BL (ABA + MTX, n=114; ABA monotherapy, n=112; MTX, n=111). Mean (SD) BL synovitis, osteitis and total scores, respectively, for pts with low MRI inflammation receiving ABA + MTX vs MTX alone were: 2.6 (2.0) vs 3.1 (2.4), 0.3 (0.6) vs 0.2 (0.5) and 3.1 (2.4) vs 3.5 (2.7); high MRI inflammation: 9.2 (3.6) vs 9.3 (3.6), 10.0 (9.7) vs 10.7 (9.8) and 29.3 (21.3) vs 30.7 (21.3). BL DAS28 (CRP), CDAI and SDAI scores, respectively, for pts with low MRI inflammation receiving ABA + MTX vs MTX alone were: 5.1 (1.1) vs 5.0 (1.3), 34.0 (14.7) vs 32.1 (15.0) and 39.9 (17.4) vs 43.5 (24.6); high MRI inflammation: 6.2 (1.2) vs 5.6 (1.4), 43.4 (16.2) vs 37.7 (18.1) and 76.9 (44.9) vs 61.1 (35.2). The proportion of pts with low BL MRI inflammation attaining remission at M12 was similar regardless of treatment. In pts with high MRI inflammation, remission rates were significantly greater in pts treated with ABA + MTX vs MTX alone (Table).

Table 1. Proportion of Patients in Remission at Month 12 by Treatment and Baseline MRI Inflammation Status*

Remission criteria	Low MRI inflammation		High MRI inflammation	
	ABA+MTX (n=63)	MTX (n=62)	ABA+MTX (n=51)	MTX (n=49)
DAS28 (CRP)	39 (61.9)	31 (50.0)	31 (60.8)†	20 (40.8)
CDAI	24 (38.1)	20 (32.3)	24 (47.1)†	10 (20.4)
SDAI	25 (39.7)	20 (32.3)	23 (45.1)†	8 (16.3)
Boolean	22 (34.9)	18 (29.0)	20 (39.2)†	8 (16.3)

Data are n (%); *low: ≤3 synovitis, ≤3 osteitis and ≤9 combined (osteitis double weighted); high: >3, >3 or >9; †p<0.05 vs MTX alone.

Conclusions: Pts with higher MRI inflammation may derive greater benefit from abatacept + MTX vs MTX alone. BL MRI inflammation is a predictor of subsequent clinical treatment response to abatacept in RA. MRI may have clinical utility in treatment decisions beyond information obtained from clinical assessments alone.

OP0285 ATTENUATION OF FLUORINE-18-FLUORODEOXYGLUCOSE UPTAKE IN LARGE VESSEL GIANT CELL ARTERITIS AFTER SHORT-TERM HIGH-DOSE STEROID TREATMENT – A DIAGNOSTIC WINDOW OF OPPORTUNITY

B.D. Nielsen[1], L.C. Gormsen[2], I.T. Hansen[1], K.K. Keller[1], P. Therkildsen[1], E.-M. Hauge[1]. *[1]Department of Rheumatology; [2]Department of Nuclear Medicine and PET centre, Aarhus University Hospital, Århus, Denmark*

Background: Fluorine-18-fluorodeoxyglucose (FDG) PET/CT is increasingly used to diagnose large vessel GCA (LV-GCA) due to its excellent diagnostic accuracy[1]. However, PET/CT is not always readily available, which may compel the clinician to 1) either delay steroid treatment at the risk of GCA related complications, or 2) initiate treatment at the expense of diagnostic sensitivity of the FDG PET/CT study.
Objectives: To evaluate if FDG PET/CT can accurately diagnose LV-GCA after 3 or 10 days of high-dose steroid treatment.
Methods: Twenty-four treatment-naïve patients (16 women) with a mean age of 69 (range 57–84) years with FDG PET/CT (PET0) proven LV-GCA repeated FDG PET/CT after either 3 (PET3, n=10) or 10 days (PET10, n=14) of treatment with oral prednisolone 60 mg daily. Prior to treatment, clinical examination and laboratory tests were performed to confirm GCA and exclude differential diagnoses. A temporal artery biopsy (TAB) was performed in all patients.
Two experienced nuclear medicine physicians blinded to clinical data reviewed the FDG PET/CT images. LV-GCA was suspected if increased FDG uptake in the wall of the aorta and/or supra-aortic branches was observed. A semi-quantitative approach was applied (a.m. Meller) in which FDG uptake was graded on a 5-point scale (0; no uptake, 1; ≤ blood pool, 2; > blood pool, ≤ liver, 3; ≥ liver, 4; ≥2xliver). A score ≥3 was considered consistent with vasculitis[2]. Vascular composite scores (CS) was calculated summarizing grades from assessed vascular regions; *Aortic:* Aorta ascendens, aorta descendens and aortic arch; *aortic branches:* Vertebral, carotic and subclavian/axillary artery.
Results: Mean CRP and ESR were 72 (95% CI: 55; 94) mg/l and 81 (95% CI: 72; 90) mm/h, respectively. ACR criteria for GCA was fulfilled by 18/24 patients and 17/21 had a positive TAB. Mean number of prednisolone doses before the post-treatment FDG PET/CT were 3.1 (SD 0.3) (PET3) and 10.3 (SD 0.7) (PET10).
Vascular CS in aorta did not decrease at PET3 (9 (IQR 9–9) vs. 9 (IQR 6–9)) whereas a significant decrease was observed in aortic branches at PET3 (6.5 (IQR 6–8) vs 5.5 (IQR 5–7), p<0.01) and both vascular domains at PET10 (Aortic; 9 (IQR 9–9) vs. 5.5 (IQR 3–6), aortic branches; 7 (IQR 7–8) vs 5 (IQR 4–6)). Although, FDG uptake decreased in aortic branches after 3 days, LV-GCA could still be accurately diagnosed in 10/10 patients. By contrast, LV-GCA could only be diagnosed in 5/14 patients after 10 days (PET0 vs. PET10, p<0.01).
At day 10, VAS global was significantly higher in patients with positive PET10 compared to patients with negative PET10 (5.2 (95% CI 3.6; 7.0) vs. 2.7 (95% CI 1.2; 4.2), p<0.05). No clinically significant differences in baseline phenotypical presentation, CRP or PET CS were found between patients with positive and negative PET10, respectively.
Interrater reliability of visual FDG-uptake-grading was substantial (agreement 90%, Cohens weighted kappa 0.67).
Conclusions: In LV-GCA, high-dose steroid treatment for three or ten days differentially attenuates the regional uptake of FDG but diagnostic accuracy remains within the first three days.

OP0286 THE UTILITY OF THE OMERACT ULTRASOUND TENOSYNOVITIS SCORING SYSTEM IN MULTICENTER CLINICAL TRIALS

M. Ammitzbøll-Danielsen[1,2], M. Østergaard[1,2], N. Esperanza[3,4], A. Iagnocco[5], I. Möller[6], M.-A. D'Agostino[7], F. Gandjbakhch[8], L. Terslev[1]. *[1]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup; [2]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [3]Department of Rheumatology, Joint and Bone Research Unit. Hospital Universitario Fundación Jiménez Díaz; [4]Department of Rheumatology, Hospital General Universitario Gregorio Marañón and Universidad Complutense, Madrid, Spain; [5]Dipartimento Scienze Cliniche e Biologiche, Università degli Studi di Torino, Turin, Italy; [6]Department of Rheumatology, Instituto Poal de Reumatología, Barcelona, Spain; [7]Department of Rheumatology, Assistance publique-Hôpitaux de Paris Ambroise Paré Hospital, Boulogne-Billancourt, Université Versailles Saint Quentin en Yvelines; [8]Department of Rheumatology, Praticien Hospitalier, Paris, France*

Background: Tenosynovitis is very common in patients with rheumatoid arthritis (RA) and is associated with lower physical function. Several studies have confirmed the limitations of clinical examination for detection of tenosynovitis in comparison with ultrasound (US) and a highly validated and reliable US scoring

system is therefore needed if implementing US-tenosynovitis as an outcome measure in clinical trials. The Outcome Measures in Rheumatology (OMERACT) US group's tenosynovitis scoring system has a good single and multicenter intra- and inter-observer agreement, whereas the sensitivity to change in a multicenter design has never been tested.
Furthermore, it is unknown whether low grade synovial hypertrophy without Doppler Signal represents true inflammation, i.e. can be eliminated by anti-inflammatory therapy and is sensitive to change.
Objectives: The aim of this study was to test the sensitivity to change of the OMERACT US scoring system for tenosynovitis, including minimal signs of tenosynovitis, in a multicenter design in order to validate it as an outcome measure in RA multicenter clinical trials. Furthermore, to assess the association between US and health assessment questionnaire (HAQ) and Disease Activity Score 28 for joints (DAS28).
Methods: Forty-nine patients with established RA (duration ≥1 year) and 18 early RA patients (<1 year) with US-verified tenosynovitis were recruited from six rheumatology outpatient clinics in four different countries, if they were scheduled for treatment intensification with synthetic and/or biological Disease Modifying Anti-Rheumatic Drug. Tenosynovitis was assessed at baseline, and at three and six months' follow-up, by GS and Doppler, using the semi-quantitative OMERACT scoring system. Furthermore, HAQ and DAS28 were assessed.
Results: At baseline tenosynovitis was most frequently found at the extensor carpi ulnaris and tibialis posterior tendons (70.7% and 44.4%, respectively). The overall GS score showed a statistically significant decrease from baseline median 5 (25th;75th percentile: 2;7) to 6 months 0 (0;3) and the overall Doppler score decreased statistically significant from baseline 3 (2;6) to 6 months 0 (0;1), both with a p<0.01. Both GS and Doppler showed high responsiveness (SRM>0.9), as did HAQ and DAS28 (table 1). Among tendons with grey scale (GS)=1/Doppler=0, 36 of 39 (92.3%) showed therapy-induced improvements. A change of 2.1 (95% confidence interval: 1.2;14.9) and 2.1 (CI: 1.1;13.2) in DAS28 corresponded to a change in GS and Doppler of 1 (both p=0.02) respectively, using a mixed-model for repeated measurement. However, no association between US and HAQ was found.

Table 1. Change in tenosynovitis ultrasound scores, DAS28, HAQ, and their standardized response mean, during 6 month of follow-up, for all patients

All Sites - Imaging modality (n=67)		Baseline	Δ 0-3 month	p	SRM	Δ 3-6 month	p	SRM	Δ 0-6 month	p	SRM
Grey scale	Median [25p;75p]	4 [2;7]	-2 [-3;-0]	<0.01	0.8	-1.0 [-2.0]	<0.01	0.4	-2 [-5;-1]	<0.01	0.9

Doppler	Median [25p;75p]	3 [2;6]	-2 [-4;-1]	<0.01	0.8	0 [-2;0]	<0.01	0.3	-3 [-5;-2]	<0.01	0.9
	Mean ±SD	3.2 ±0.66	-0.8 ±0.6			0 ±0.2			-0.7 ±0.6		
DAS28	Median [25p;75p]	4.6 [3.7;5.4]	-1.4 [-1.8;-0.2]	<0.01	0.9	-0.4 [-1.3;0.1]	<0.01	0.3	-1.6 [-3.2;-0.7]	<0.01	1.1
	Mean ±SD	4.4 ±1.3	-1.4 ±1.5			-0.5 ±1.3			-1.8 ±1.7		
HAQ	Median [25p;75p]	1.0 [0.5;1.5]	-0.25 [-0.75;0]	<0.01	0.8	0 [-0.25;0]	0.02	0.5	-0.375 [-0.875;0]	<0.01	0.9
	Mean ±SD	1.0 ±0.6	-0.4 ±0.4			-0.1 ±0.3			-0.5 ±0.5		

P, p-value for Wilcoxon's test for change of paired data between 2 time points; N, number of patients; SRM, standardized response mean; DAS28, Disease Activity Score for 28 joints, using C-reactive protein; HAQ, health assessment questionnaire;. Values in brackets are values at 25th and 75th percentiles

Conclusions: In conclusion, this RA multicenter study documented a high sensitivity to change of both GS and Doppler US tenosynovitis scores, indicating utility of the OMERACT US scoring system for diagnosing and monitoring tenosynovitis in multicenter trials. Secondly, synovial hypertrophy without Doppler signal, do respond to therapy, suggesting it reflects true inflammation. Finally, changes in US tenosynovitis scores are associated with changes in DAS28.

OP0287 ULTRASONOGRAPHY-DETECTED PERIPHERAL ENTHESITIS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS – ANATOMICAL DISTRIBUTION, MORPHOLOGY AND RESPONSE TO ANTI-TNF THERAPY

S. Seven, S.J. Pedersen, M. Østergaard, I.J. Sørensen, U.M. Døhn, S. Krabbe, L. Terslev. *Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine diseases, Rigshospitalet, Glostrup, Denmark*

Background: Peripheral enthesitis (PE) is a characteristic feature of spondyloarthritis (SpA) that may be asymptomatic and only detectable by imaging. Ultrasonography (US) has greater sensitivity than clinical examination for the detection of PE.[1]
Objectives: The aim of the study was to investigate the anatomical distribution, morphological abnormalities and response to anti-tumor necrosis factor (anti-TNF) therapy of US-detected PE in patients with axial SpA (axSpA) initiating adalimumab (ADA).
Methods: In a randomized, placebo-controlled, double-blinded investigator-initiated trial (NCT01029847), patients with axSpA according to the Assessment of SpA International Society (ASAS) criteria were randomized to subcutaneous ADA 40 mg every other week (eow) or placebo from baseline to week 6. From week 6 to 24, all patients received ADA 40 mg eow. Of 49 patients enrolled, 21 participated in the US sub-study. US assessment applying the OMERACT US definitions for enthesitis[2] of 10 peripheral entheseal regions (Tables 1 & 2) and clinical examination were performed at baseline, weeks 6 and 24. US was performed by an experienced investigator. Hypo-echogenicity, increased thickness and Doppler activity of the enthesis were considered signs of active inflammation, whereas insertional bone erosions, intratendinous calcifications and enthesophytes were regarded as signs of chronic lesions.[2]
Results: See tables.
Conclusions: In this axSpA cohort, US assessment primarily identified PE in the lower extremities, and predominantly chronic lesions. No change in chronic PE lesions were found during treatment indicating a low sensitivity to change of these lesions. The number of entheses with inflammatory activity was too low to detect any changes on US during ADA therapy.

Table 1. Distribution of US findings at baseline (n=21)

Balint[24]. *[1]Medical University of Vienna, Vienna, Austria; [2]Università Politecnica delle Marche, Jesi, Italy; [3]Military Institute of Medicine, Warsaw, Poland; [4]Instituto Poal de Reumatologia, Barcelona, Spain; [5]MC Groep, Lelystad, Netherlands; [6]Medical University of Graz, Graz, Austria; [7]University of Pisa, Pisa, Italy; [8]Medical University of Innsbruck, Innsbruck, Austria; [9]Diakonhjemmet Hospital, Oslo, Norway; [10]Instituto Nacional de Rehabilitación, Mexico City, Mexico; [11]Universitá degli Studi di Torino, Turin, Italy; [12]Chiba University Hospital, Chiba, Japan; [13]Trinity College Dublin, Dublin, Ireland; [14]University of Western Australia, Perth, Australia; [15]Semmelweis University, Budapest, Hungary; [16]Copenhagen University Hospital Glostrup, Copenhagen, Denmark; [17]Hospital Universitario Fundación Jiménez Díaz and Autónoma University; [18]Hospital General Universitario Gregorio Marañón and Complutense University; [19]Hospital Ramón y Cajal, Madrid, Spain; [20]Immanuel Krankenhaus, Berlin, Germany; [21]University of Rochester, Rochester, United States; [22]Asklepios Hospital, Weissenfels, Germany; [23]Université VSQY, Inserm U1173, APHP Ambroise Paré, Boulogne-Billancourt, France; [24]National Institute of Rheumatology and Physiotherapy, Budapest, Hungary*

Background: Joint destruction in rheumatoid arthritis (RA) is comprised of hyaline cartilage and bone damage, with the former more clearly associated with irreversible physical disability than bony damage.
Objectives: To test the reliability of a semiquantitative scoring system for the assessment of cartilage by musculoskeletal ultrasound (US) in a web-based exercise as well as a patient-based reliability study of patients with RA.
Methods: Static images of metacarpophalangeal (MCP) joints 2–5 in RA patients and healthy controls were acquired and a dataset of 123 anonymized images including 25 duplicate images was circulated among an international EULAR-OMERACT taskforce of 25 rheumatologist experts in US who independently scored the images using a semiquantitative scoring system. Subsequently 12 taskforce members participated in a patient-based reliability study. During this

meeting MCP joints 2–5 of 6 patients with RA were assessed twice on the same day by all experts using US machines (GE) equipped with high-frequency transducers (18–22MHz) with presets calibrated for the appropriate assessment of cartilage. Participants assessed metacarpal cartilage both in the standardized longitudinal midline scan as well as by freehand technique utilizing multiple planes and scored by the semiquantitative scoring system. Intraobserver reliability was assessed by Cohen's kappa and interobserver reliability by Fleiss' kappa.

Results: The three-grade semiquantitative (Grade 0, normal cartilage; Grade 1, minimal change; Grade 2, severe change) scoring system demonstrated excellent (kappa: 0.87) to good (kappa: 0.73) intraobserver reliability in the web-based exercise and the patient-based reliability study respectively. Interobserver reliability was good in the web-based exercise (kappa: 0.64) and moderate (kappa: 0.49) in the patient-based reliability study. The dynamic technique performed slightly better than the longitudinal midline scan alone.

Conclusions: A semiquantitative scoring system demonstrated good intra- and moderate to good inter-observer reliability in a web-based exercise and patient-based reliability study. Our study demonstrates that US is a reliable tool for evaluating cartilage and supports the use of a new semiquantitative US scoring system for evaluating cartilage change in RA.

Acknowledgements: The patient-based reliability study was supported by a research grant from UCB.

OP0289 TREAT-TO-TARGET IN EARLY RHEUMATOID ARTHRITIS: ASSOCIATION BETWEEN SUSTAINED REMISSION AND JOINT DAMAGE

N.P. Sundlisater[1], A.-B. Aga[1], I.C. Olsen[1], H.B. Hammer[1], T. Uhlig[1], D. van der Heijde[2], T.K. Kvien[1], S. Lillegraven[1], E.A. Haavardsholm[1] on behalf of The Arctic study group. [1]*Diakonhjemmet Hospital, Oslo, Oslo, Norway;* [2]*Leiden University Medical Center, Leiden, Netherlands*

Background: Modern treatment of early RA is targeted towards remission. Sustained remission is viewed as more beneficial to the patient than remission at one time point, also with regards to inhibition of joint damage,(1, 2) but data are limited. Treat-to-target studies yielding high rates of sustained remission have improved the ability to assess the relationship between sustained remission and joint damage.

Objectives: To assess the frequency of no radiographic progression among early RA patients in sustained remission defined by established criteria and in patients with sustained absence of inflammation assessed by ultrasound.

Methods: RA patients with <2 years from first swollen joint who were DMARD naive with indication for DMARD treatment were included in the ARCTIC trial.(3) Patients in the ultrasound arm aiming for DAS <1.6, no swollen joints and no ultrasound power Doppler (PD) signal were included in the current analyses. Several definitions of sustained remission (12–24 months) were compared; DAS-ESR, DAS28-ESR, SDAI, CDAI, ACR/EULAR Boolean remission (based on 44 joints), no swollen joints (44SJC), no ultrasound PD signal in any joint (0–96) and minimal total ultrasound greyscale (GS) score (defined as GS ≤2, 0–96). No radiographic progression (12–24 months) was defined as <1 unit change in the van der Heijde modified Sharp score (vdHSS). Positive and negative likelihood ratios of no radiographic progression were estimated for patients in sustained remission per definition.

Results: Of 103 patients, 76 (74%) were female, mean [SD] age was 51.4 [12.9] years, disease duration 6.7 [5.3] months and DAS 3.5 [1.1]. The median [25th, 75th percentile] change in vdHSS 12–24 months was 0.49 [0.0, 1.03], and 73 (71%) patients had no radiographic progression. Sustained remission was reached by 23–61% according to the different criteria. Among patients in sustained remission, comparable proportions of patients did not progress radiographically across the different criteria (74–89%), with the most favorable result for minimal GS score (Table). Patients with sustained no PD or minimal GS score had an increased likelihood of no radiographic progression during the concurrent year (Table), but still rather weak to be useful in an individual patient. Based on the low LR+ none of the criteria identifies patients without radiographic progression very well; likewise, as the LR- is relatively high for all definitions, not being in remission does not change the probability of ongoing radiographic progression substantially.

Table The performance of sustained remission 12-24 months for identifying patients without radiographic progression in the same time period. Significant likelihood ratios in bold.

	Patients in sustained remission 12-24 months, n(%)	Patients in sustained remission and no radiographic progression 12-24 months, n(%)	Likelihood ratios of no radiographic progression 12-24 months	
			LR+ (95% CI)	LR- (95% CI)
Clinical outcomes				
DAS<1.6	46 (45)	37 (80)	1.69 (0.94, 3.05)	**0.70 (0.51, 0.98)**
DAS28<2.6	54 (52)	40 (74)	1.17 (0.76, 1.82)	0.85 (0.56, 1.29)
SDAI≤3.3	33 (32)	26 (79)	1.53 (0.74, 3.13)	0.84 (0.65, 1.09)
CDAI≤2.8	31 (30)	26 (84)	2.14 (0.91, 5.04)	**0.77 (0.61, 0.98)**
ACR/EULAR Boolean (based on 44 joints)	24 (23)	18 (75)	1.23 (0.54, 2.80)	0.94 (0.75, 1.18)
SJC44=0, (range 0-44)	50 (49)	39 (78)	1.46 (0.87, 2.44)	0.74 (0.51, 1.06)
Ultrasound				
PD=0, (range 0-96)	63 (61)	51 (81)	**1.75 (1.10, 2.78)**	**0.50 (0.32, 0.79)**
GS≤2 (range 0-96)	27 (26)	24 (89)	**3.29 (1.07, 10.10)**	**0.75 (0.61, 0.91)**

Conclusions: In this treat-to-target early RA study, sustained remission rates were generally high and radiographic progression limited. None of the sustained remission criteria were able to exclude concurrent radiographic progression. Absence of ultrasound inflammation performed best of the definitions assessed.

OP0290 CORRELATION OF CXCL13 AND ULTRASSONOGRAPHIC FINDINGS OF JACCOUD ARTHROPATHY IN SYSTEMIC LUPUS ERYTHEMATOSUS

D.S. Ribeiro[1], C. Lins[1], E. Pimenta[1], V. Galvão[1], W. Santos[1], V. Machicado[1], C. Baleeiro[1], A. Pedreira[1], A.P. Duque[1], G. Rosa[1], A. Atta[2], I. Oliveira[2], M. Santiago[1]. [1]*Escola Bahiana de Medicina e Saúde Pública;* [2]*Faculdade de Farmácia, Universidade Federal da Bahia, Salvador, Brazil*

Background: Joint involvement in systemic lupus erythematosus (SLE) is one of the earliest manifestation of the disease (1).Only 2–5% of the cases develop a deforming and non-erosive type of arthritis, known as Jaccoud Arthropathy (JA). Until now, there is no serum autoantibodies marker for it (2).The chemokine CXC ligand 13 protein (CXCL13) is one of the most potent B-cell chemo attractants and is constitutively expressed in the B-cell follicles of secondary lymphoid organs (3). Its seric level has been associated to the degree of synovitis in patients with rheumatoid arthritis as studied by ultrasonography (US).

Objectives: To perform the first detailed US analysis of hands and wrists of SLE patients, with and without JA, and to correlate those findings with the levels of CXCL13,other clinical and laboratory features and disease activity

Methods: 64 patients with SLE were included, being 32 with JA and 32 without JA paired by age and disease duration. The definition of JA was based on clinical criteria recently described by Santiago (4).Patients and controls underwent a high-resolution US exam of wrists and hands. Synovial hypertrophy,tenosynovitis and erosions were evaluated according a semi-quantitative grading system according definitions provided by OMERACT (5). Serum concentrations of CXCL13 were quantified in both groups utilizing a commercially available kit. Autoantibodies such as antinuclear antibody (ANA), anti-dsDNA,anti-Sm,anti-SSA, anti-SSB were also tested. US findings were correlated with seric levels of CXCL13, other serological parameters and SLEDAI score.

Results: In the JA group, the mean age was 46.2 years and the mean duration of the disease was 17.3 years. Synovitis on US was found in 25 patients and tenosynovitis in 14. All of these findings were more frequent in SLE with JA, particularly tenosynovitis with difference statistically significant (p=0.002). In JA patients the median levels of CXCL13 was 23.21 pg/ml as compared to 11.48 pg/ml in SLE without JA group (p=0.08). There was an association between tenosynovitis and higher levels of CXCL13 in the JA group (p=0.026). Patients with active disease were more common in the JA group (p=0.004) and had increased serum levels of CXCL13 compared to patients with disease inactive (p=0.008).

Conclusions: In conclusion, the present study is one of a few to describe US findings in SLE patients with JA and it confirms that synovitis and tenosynovitis are common features in the majority of these patients. In addition, CXCL13 may be regarded as a biomarker for tendon inflammation in JA.

From genetics through epigenetics to proteomics: understanding disease mechanisms

OP0291 IDENTIFICATION OF NOVEL SUSCEPTIBILITY LOCI IN A LARGE UK COHORT OF JUVENILE IDIOPATHIC ARTHRITIS (JIA) CASES

S.L. Smith[1,2], J. Bowes[1], J. Cobb[1,2], A. Hinks[1], S. Sampath[1], A. Yarwood[1], L. Wedderburn[3], K. Hyrich[2,4], W. Thomson[1,2] on behalf of Childhood Arthritis Prospective Study (CAPS), UK Juvenile Idiopathic Arthritis Genetics Consortium (UKJIAGC), Childhood Arthritis Response to Medication Study (CHARMS), Biologics for Children with Rheumatic Diseases (BCRD) and BSPAR-Etanercept. *[1]Arthritis Research UK CoGG, Centre for Musculoskeletal Research, The University of Manchester; [2]NIHR Manchester Musculoskeletal BRU, Manchester; [3]Arthritis Research UK Centre for Adolescent Rheumatology, UCL GOS Institute of Child Health, UCL, London; [4]Arthritis Research UK CoE, Centre for Musculoskeletal Research, The University of Manchester, Manchester, United Kingdom*

Background: Juvenile idiopathic arthritis (JIA) is a group of chronic arthropathies of unknown cause affecting children under 16yrs, and is the most common childhood inflammatory rheumatic diagnosis. In recent years great advances in dissecting the genetic basis of JIA have been made. In a landmark study, conducted on the two most common subtypes (oligoarthritis and RF-negative polyarthritis), 17 susceptibility loci were identified at genome-wide significance (p-value $<5x10^{-08}$) and a further 11 reaching suggestive significance (p-value $<1x10^{-06}$). These findings were the results of a large international collaboration using the ImmunoChip array, targetting 186 known loci in 12 autoimmune diseases. However, a limitation to the afore-mentioned study was that the analysis is limited to the selected loci; large genome-wide studies are now needed.
Objectives: The aim of this work is to identify novel genetic loci associated with disease susceptibility using a large cohort of UK JIA cases
Methods: Whole-genome genotyping data was generated using four platforms (Illumina). Following stringent quality control common variants to all four platforms were extracted from the individual datasets before merging together. Imputation was performed using the Haplotype Reference Consortium panel on the Michigan Imputation Server using Minimac3 software. SNPs with imputation accuracy ($r^2>0.5$), minor allele frequency >1% and Hardy-Weinberg p-value$>1x10^{-03}$ were retained for analysis. Association was conducted using logistic regression; using the top three principal components as covariates. Bioinformatics analysis was performed using in-house Capture Hi-C data, to study long-range interactions, to elucidate the potential function of the associated SNPs
Results: Post-QC, 2,585 cases and 5,181 controls were available for analysis with ~7.4 million SNPs. Analysis conducted within oligoarthritis and RF-negative polyarthritis cases, (n=1,617) confirmed 13 previously identified JIA risk loci and identified more than 20 potentially novel regions above suggestive significance ($2.25x10^{-05}$). Of these, rs7874896, an intergenic SNP located between *TNFSF15* and *TNFSF8* on chromosome 9 was one of the most strongly associated (p-value $3.67x10^{-07}$). *TNFSF15* is particularly interesting as by homology and function, is very similar to TNFα. Furthermore, in Crohns disease, it has been found that *TNFSF15* drives expression of pro-inflammatory cytokines (IFNγ) and TNFα from CD4+CD161+ T-cells, yet these cells were found to be resistant to anti-TNF treatment; suggesting that blockade of *TNFSF15* may possess therapeutic benefit. Further investigation of SNPs within the *TNFSF15/TNFSF8* gene region using Capture Hi-C data yielded potentially interesting interactions both within this region and with nearby genes within T- and B-cell lines
Conclusions: This study represents the largest GWAS conducted in JIA to date and our preliminary results have identified novel associations with the most common subtypes of the disease and may have highlighted a potentially novel therapeutic target

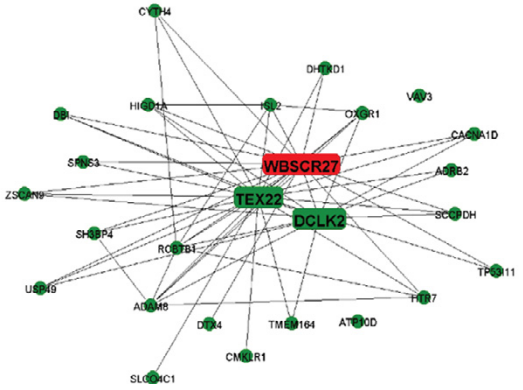
Marqués de Valdecilla, Santander, Spain*



Background: Autoimmune diseases are highly disabling chronic disorders characterized by the activation of multiple immune and inflammatory pathways against self-components. Clinical studies have demonstrated that autoimmune diseases have a higher prevalence of cardiovascular events compared to the general population. Understanding the genetic and biological mechanisms underlying cardiovascular disease (CVD) risk in autoimmunity could therefore be fundamental to develop more efficient preventive and therapeutic strategies.
Objectives: The objective of this study was to characterize the genetic basis of CVD risk in autoimmune diseases.
Methods: A total of 6,485 patients from the six autoimmune diseases RA, PA, SLE, PS, CD and UC were recruited by the Spanish biomedical consortium IMID Consortium. All patients were Caucasian European from the Spain. CVD patients were defined as having ≥1 out of the 3 most frequent cardiovascular phenotypes: (i) ischemic heart disease (ii) cerebrovascular accident and (iii) peripheral arterial disease. In order to characterize the genetic basis of CVD risk in autoimmune diseases, we used genome-wide genotyping data from all autoimmune disease patients included in the study. First, we tested the association of established CVD risk variants within each autoimmune disease. Second, we analyzed the association of autoimmune disease risk variants with an increase in CVD risk. Finally, we used the cross-phenotype meta-analysis approach (CPMA) to perform a genome-wide meta-analysis and identify global genetic patterns associated with CVD risk in autoimmune diseases.
Results: A total of 17 loci previously associated with CVD risk in the general population were significantly associated with CVD risk in the autoimmune patient cohorts ($P<0.05$). From these, 4 loci were found to have significantly different genetic effects across autoimmune diseases ($P<0.05$). We also found that 6 risk loci for autoimmune diseases were associated with an increase in CVD risk, like the RA risk gene *CFLAR-CASP8*. The CPMA identified a total of 10 genetic patterns significantly associated with CVD risk across all autoimmune diseases. Two of these patterns showed a highly significant association with CVD risk in RA, PsA and SLE. The functional analysis of these two genetic patterns revealed a significant enrichment in key pathways related to the etiology of rheumatic diseases like TNFα ($FDR<0.05$) and IFNγ ($FDR<0.05$) cytokine pathways.
Conclusions: The results of the present study represent an important step towards the characterization of the genetic basis of CVD in autoimmune diseases. These findings contribute to explain the higher prevalence of cardiovascular events observed in patients with autoimmune diseases compared to the general population.

OP0293 WEIGHTED GENE CO-EXPRESSION NETWORK ANALYSIS OF DMARD-NAÏVE EARLY RA PATIENTS ACHIEVING SUSTAINED DRUG-FREE REMISSION AFTER INITIATING TOCILIZUMAB THERAPY

X.M. Teitsma[1], J.W. Jacobs[1], M. Mokry[2,3], A. Pethö-Schramm[4], M.E. Borm[5], J.M. van Laar[1], J.W. Bijlsma[1], F.P. Lafeber[1]. *[1]Rheumatology and Clinical Immunology, UMC Utrecht; [2]Division of Pediatrics, Wilhelmina Children's Hospital; [3]Epigenomics Facility, UMC Utrecht, Utrecht, Netherlands; [4]F. Hoffmann-La Roche, Basel, Switzerland; [5]Roche Nederland B.V., Woerden, Netherlands*

Background: Rapidly reducing disease activity is of major importance in the management of newly diagnosed rheumatoid arthritis (RA) patients as early response strongly correlates with long-term clinical outcomes. To select patients for whom it would be favourable to initiate a biological drug from start of therapy, it is crucial to study biological pathways and biomarkers involved in treatment response.
Objectives: To identify biological networks and signature genes among disease modifying anti-rheumatic drug (DMARD)-naïve early RA patients achieving sustained drug-free remission (sDFR) after initiating treatment with tocilizumab (TCZ).
Methods: Data was used from DMARD-naïve early RA patients in the U-Act-Early trial who had been randomized to initiate TCZ therapy. The study design and details have previously been described.[1] Briefly, TCZ (8 mg/kg) was given every 4 weeks and if remission was not achieved, methotrexate (oral) was added. When the target was achieved, therapy was tapered and subsequently discontinued provided remission persisted. sDFR was reached when patients remained ≥3 months in remission while being drug-free until the end of the two-year study period. Before the first dose of medication, whole blood samples were collected and RNA was isolated from CD4 cells and analyzed using RNA sequencing. The DESeq2 package was used to identify differentially expressed genes (DEGs) between responders (achieving sDFR, n=13) and non-responders (not able to taper medication, n=11). Subsequently, weighted gene co-expression network analysis (WGCNA) was used to study clusters (modules) within the 1000 most relevant DEGs.
Results: In total, eight modules with varying sizes (10–470 genes) were identified. The module best correlated (Pearson correlation coefficient 0.52, p=0.009) with achieving sDFR included 26 genes and was used for further functional analysis. Within this module, we found three significantly enriched pathways in the Kyoto Encyclopaedia of Genes and Genomes (KEGG) database. These were calcium signalling pathway ($p=5.81E^{-04}$), carbohydrate digestion & absorption ($p=4.46E^{-02}$), and neuroactive ligand-receptor interaction ($p=2.61E^{-02}$).

Fig. 1: Network visualization of the interaction of gene co-expression in the module best correlated with achieving sustained drug-free remission. Upregulated genes are expressed as green nodes and the down-regulate gene as red node. The three rounded rectangular nodes display the highest co-expressed genes within the module (>10 connections) when applying a weight cut-off of 0.01. The average number of nodes connected at this cut-off was 4.6 (correlation coefficient 0.82).

In addition, we identified 83 overrepresented Gene Ontology (GO) terms of which granulocyte migration (p=2.70E^{-04}), myeloid leukocyte migration (p=8.95E^{-04}) and G-protein coupled amine receptor activity (p=1.25E^{-03}) were most significant. The genes in the module of interest showing the highest connectivity were the upregulated testis expressed 22 (TEX22), doublecortin lie kinase 2 (DCLK2), and the downregulated Williams Beuren syndrome chromosome region 27 (WBSCR27) gene (Fig. 1).

Conclusions: When performing network analyses of the DEGs between responders and non-responders, TEX22 and DCLK2 were identified as signature genes for treatment response to TCZ therapy. WBSCR27 was found to be associated with less chance of achieving sDFR.

OP0294 FRACTURE PREDICTION USING A GENETIC MARKERS ALGORITHM COMPARED TO FRAX IN THREE EUROPEAN COHORTS

S. Ferrari[1], R. Rizzoli[1], R. Chapurlat[2], M.L. Brandi[3], H. Martínez[4], M. Herrero[4], J. Vergés[5], M. Artieda[6], D. Tejedor[6], A. Martínez[6], J. Blanch[7], S. Palacios[8]. *[1]Geneva University Hospital and Faculty of Medicine, Geneve, Switzerland; [2]Division of Rheumatology, INSERM U1033, Université de Lyon, Hôpital e Herriot, Lyon, France; [3]University of Florence, Florence, Italy; [4]Clinical R&D, Bioiberica; [5]Osteoarthritis Foundation International (OAFI), Barcelona; [6]R&D Department, Progenika Biopharma, A Grifols Company, Derio; [7]Hospital del Mar of Barcelona, Barcelona; [8]Palacios Institute of Health and Woman Medicine, Madrid, Spain*

Background: Numerous genome-wide association studies (GWAS) and large meta-analyses have started to unravel the multiple gene polymorphisms associated with BMD and/or fragility fractures. However the clinical utility of these genetic markers for fracture prediction remains to be established.

Objectives: To develop a DNA genotyping tool for predicting osteoporotic fractures in postmenopausal women.

Methods: 768 SNPs previously associated with osteoporosis phenotypes were identified in silico through the NHGRI GWAS catalog and BoneKey Genetics website. They were genotyped on an Illumina GoldenGate assay in 1649 postmenopausal women aged 45+ yrs belonging to three osteoporotic fractures cohorts from Switzerland, Italy and France. SNPs potentially associated (p<0.10) with prevalent and incident clinical fragility fractures in one or more of the cohorts, or in the cohorts together, were then combined in a genetic risk score (GRS). GRS association with fragility fractures was tested by forward logistic regressions adjusting for age and FN BMD. The ability of GRS for fracture prediction was evaluated by the area under the ROC curve (AUC) in the three cohorts combined, as well separately (for internal replication). For comparison, fracture probabilities were computed using FRAX clinical risk factors (without BMD) without and with the addition of GRS.

Results: The average prevalence of fragility fractures in the three cohorts was 25% (range 22 to 28%), of which half were major fractures (FRAX definition). After QC filtering, 632 SNPs in 1625 individuals were correctly genotyped, of which 73 were potentially associated with fractures in one or more cohorts. In single and multiple regression models, GRS was significantly associated with fractures (OR 1.09, CI 1.07–1.12, p<0.0001). The GRS AUC for fracture prediction was significant (0.65) and highly consistent among the three cohorts. GRS predicted major fractures as well as FRAX clinical risk factors without BMD (AUC 0.63 vs 0.58, p=0.08), and when combined with clinical FRAX, the AUC was significantly improved (0.67, p=0.0106).

Conclusions: SNPs previously associated with osteoporosis phenotypes through large GWAS and meta-analyses can be replicated for association with fragility fractures in post-menopausal women from three European countries. Our results provide a proof-of-principle that a genetic risk score (GRS) based on these SNPs represents an independent risk factor for fractures and could be developed into a genetic algorithm to improve the prediction of fragility fractures, either alone or together with FRAX.

OP0295 UNIQUE WHOLE BLOOD MICRORNA BIOSIGNATURE FOR RHEUMATOID ARTHRITIS

V. Anaparti[1,2,3], I. Smolik[1,3], X. Meng[1,2,3], N. Mookherjee[2,3], H. El-Gabalawy[1,2,3]. *[1]Rheumatic Diseases Unit; [2]Manitoba Center for Proteomics and Systems Biology; [3]Internal Medicine, University of Manitoba, Winnipeg, Canada*

Background: RA susceptibility risk is disproportionately high (~2–3fold) in Indigenous North American (INA) tribes compared to other populations[1,2]. Environmental, lifestyle & genetic factors account for <20% of observed disease variance suggesting contribution of additional risk determinants[3]. Emerging evidence suggests small non-coding microRNAs (miRs) e.g. miR-155, miR-146a, miR-26b are key contributors to RA pathogenesis[4]. In this project, we examined the role of miRs on RA incidence, and association with anti-citrullinated protein antibodies (ACPA), whose appearance precedes disease symptoms. We hypothesized that differential expression of specific miRs associated with disease symptoms will facilitate RA transition in genetically susceptible first-degree relatives (FDRs).

Methods: Whole blood and peripheral blood mononuclear cells (PBMCs) were obtained from age-matched ACPA+ RA patients (n=18), non-symptomatic ACPA+ FDRs (n=12) and ACPA- healthy controls (n=12), who belonged exclusively to INA Cree-Ojibway communities of Northern Manitoba, Canada. Total RNA was isolated using miRVANA kit (Ambion). Expression of selected 32 miRs based on the published literature, and associated downstream mRNA targets, were monitored by quantitative real-time PCR, RNU48 and 18sRNA were used for input normalization for miRNA and mRNA expression respectively.

Results: Whole blood expression profiling identified 10 differentially expressed miRs in RA patients compared to control subjects. Expression of miR-103a-3p was significantly up-regulated (~2.3-fold; p=0.0062), whereas that of imiR-16, miR-24, miR-29a, miR-125a-3p, miR-203, miR-222, miR-223, miR-150 and miR-346 were down-regulated in RA patients compared to controls. Increased miR-103a-3p expression was also confirmed in PBMCs from ACPA+ RA patients (~2 fold; p=0.0040) compared to controls. Further, miR-103a-3p expression was increased in ACPA+ FDRs (>4 fold) compared to controls (p=0.0005), and ACPA+ RA patients (p=0.0149). miR-103a-3p expression was consistently elevated in ACPA+ FDRs, when we analyzed samples obtained at two independent time points (1year apart). Consistent with this, expression of AGO1 and DAPK1 mRNA, downstream targets of miR-103a-3p, was decreased significantly (p<0.05) in ACPA+ FDRs compared to controls.

Conclusions: This study defines a unique signature of dysregulated miRs amongst RA patients and their related FDRs within the INA cohort. Our results suggest a potential role of miR-103a-3p as a prognostic biomarker for pre-clinical RA.

OP0296 AUTOIMMUNE ASSOCIATED GENE PTPN22 NEGATIVELY REGULATES DECTIN-1 SIGNALLING IN DENDRITIC CELLS

H. Purvis[1], F. Clarke[1], C. Jordan[1], C. Sanchez-Blanco[1], G.H. Cornish[1], D. Rawlings[2], R. Zamoyska[3], A.P. Cope[1]. *[1]Academic Department of Rheumatology, King's College London, London, United Kingdom; [2]Seattle Children's Research Institute and Departments of Pediatrics and Immunology, University of Washington School of Medicine, Seattle, United States; [3]Institute of Immunology and Infection Research, Edinburgh University, Edinburgh, United Kingdom*

Background: A single nucleotide polymorphism within the phosphatase *PTPN22*

increases the risk of developing multiple autoimmune and connective tissue diseases.[1] Ptpn22 is a negative regulator of Syk and Src family kinases downstream of immuno-receptor signalling cascades.[2] Fungal β-glucan receptor dectin-1, signals via Syk kinase, and induces dendritic cells to secrete pro-inflammatory cytokines IL-1β, IL-6, IL-12/23p40 and TNFα, in turn allowing the induction of IL-17 secreting T-cell responses, which are critical to the clearance of fungal infections.[3] IL-17 has been implicated as a key cytokine in inflammatory responses associated with RA, JIA, and psoriasis.[4]

Objectives: To investigate if Ptpn22 regulates dectin-1 signalling and controls the capability of dectin-1 matured BMDC to promote adaptive immune responses.

Methods: GM-CSF bone marrow derived dendritic cells (BMDC) were generated from C57BL/6 WT, *Ptpn22*$^{-/-}$ or *Ptpn22*^{R619W} (human *PTPN22*^{R620W} orthologue) mice, and pulsed with $OVA_{323-339}$ in the presence or absence of the dectin-1 agonist curdlan. Activated BMDC were co-cultured *in vitro* with OT-II T-cells or adoptively transferred into OT-II mice and the resulting T-cell response assessed. Cytokine secretion from curdlan activated Ptpn22 variant mouse BMDC was determined by immunoassay and the kinetics of Syk and Erk phosphorylation were determined by immunoblot.

Results: We observed that Dectin-1 activated *Ptpn22*$^{-/-}$ BMDC had an enhanced capability to induce T-cell IL-17 secretion both *in vitro* and *in vivo* compared to WT BMDC. Following dectin-1 priming Ptpn22$^{-/-}$ BMDC secreted increased IL-1β compared to WT BMDC, and the increase in IL-1β was found to be sufficient to cause the enhanced IL-17 response induced by Ptpn22$^{-/-}$ BMDC. Dectin-1 induced IL-1β secretion was found to be Syk and Erk dependent and assessment of Syk and Erk kinetics of phosphorylation revealed that dectin-1 activated *Ptpn22*$^{-/-}$ BMDC displayed enhanced Syk and Erk phosphorylation compared to WT BMDC. Furthermore, *Ptpn22*^{R619W} BMDC (orthologue of human *Ptpn22*^{R620W}) exhibited a similar enhancement in IL-1β secretion and induced enhanced T-cell dependent IL-17 responses in vivo, indicating that the PTPN22 polymorphism behaves as a loss-of-function allele in the context of dectin-1 signals.

Conclusions: Data highlight Ptpn22 as a novel regulator of dectin-1 signals and provide a link between genetically conferred perturbation to innate receptor signalling pathways and autoimmunity.

OP0297 FUNCTIONAL POLYMORPHISMS OF THE ABCG2 GENE IN PRIMARY GOUT

B. Stiburkova[1,2], K. Pavelcova[3,4], L. Petru[3,4], P. Cepek[3], J. Zavada[3], K. Pavelka[3]. *[1]Institute of Rheumatology, Prague 2; [2]Institute of Inherited Metabolic Disorders, First Faculty of Medicine, Charles University; [3]Institute of Rheumatology; [4]Department of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic*

Background: The urate transporters are one of the genetic determinants of serum uric acid concentrations. Common dysfunctional variants of *ABCG2* are revealed to be a major cause of gout and hyperuricemia by decreasing urate excretion. In this study we describe the analysis of allelic variants in the *ABCG2* in a cohort with primary gout.

Objectives: The cohort was recruited in the Institute of Rheumatology, Prague. Gouty arthritis was diagnosed in 146 subjects (132 men, 14 women) according to the American college of rheumatology criteria 1977. Patients suffering from secondary gout and other purine metabolic disorders associated with pathological concentrations of serum uric acid were excluded.

Methods: In each patient, the family history of gout, number of gouty attacks, the presence of tophi, the occurrence of associated diseases and therapy have been assessed. All 16 exons of *ABCG2* were amplified using PCR, and sequenced directly.

Results: In the *ABCG2* gene, 19 intronic sequence variants were detected. In the case of c.689+1G>A, related to an individual with severe gouty phenotype, two abnormal splicing variants were identified: a) r.[532_689del]; b) r.[532_689del], r.[944_949del]. Identified deletions lead to frameshift and premature stop codon introduction[1]. From the 12 exon variants detected, there were nine non-synonymous: p.V12M, p.Q141K, p.R147W, p.T153M, p.F373C, p.T421A, p.T434M, p.S476P and p.D620N. Heterozygous p.V12M was detected in seven individuals. Heterozygous variants p.R147W, p.T153M, p.F373C, p.T421A, p.T434M and p.S476P were detected once, variant p.D620N twice. All these allelic variants were *in silico* predicted as a probably damaging. The p.Q141K, previously functionally characterized allelic variant with a strong effect on uric acid secretion impairment, was in cohort of gout patients presented with significantly higher minor allele frequency 0.24 (MAF), 57 heterozygotes/6 homozygotes, than in population of European origin (MAF=0.09) and world-wide population (MAF=0.12). In our cohort, the age of onset of gout had a normal distribution. Remarkably, in 75% of all individuals with early onset of gout between age 10–20 years, we detected allelic variant p.Q141K (in 6 out of 8 patients). In the age group 21–30 years, this allelic variant was detected in 42% of patients (8/19), and in the age group 61–70 years, just in 29% (13/29).

Conclusions: Our results show that genetic factor *ABCG2* should be considered as one of the strong common risks for gout. In summary, we revealed that allelic variants of *ABCG2*, especially dysfunctional variant p.Q141K, have a significant effect on earlier onset of gout.

OP0298 CHROMATIN INTERACTIONS REVEAL NOVEL GENE TARGETS FOR DRUG REPOSITIONING IN RHEUMATIC DISEASES

P. Martin[1], K. Duffus[1], A. McGovern[1], A. Yarwood[1], A. Barton[1,2], J. Worthington[1,2], S. Eyre[1], G. Orozco[1]. *[1]Arthritis Research UK Centre for Genetics and Genomics, University of Manchester; [2]NIHR Manchester Musculoskeletal Biomedical Research Unit, Central Manchester Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom*

Background: The treatment of rheumatic diseases can be both expensive and ineffective with up to 1/3 of patient's failing to respond to current treatments. There is therefore a need to identify new treatments and to target these to individual patients. Although genetic studies have been successful in identifying common variation associated with disease susceptibility, a large proportion of these lie outside protein-coding regions. Many show enhancer activity but it is often unclear which gene(s) they regulate and how they contribute to disease. Chromatin folding brings linearly distant areas of the genome, such as promoters and enhancers, into close proximity, driving gene expression. Capture Hi-C (CHi-C) interrogates these interactions in a high-throughput, high-resolution manner, linking implicated enhancers to causal genes.

Objectives: Utilising our existing CHi-C data on 3 rheumatic diseases, RA, JIA and PsA, targeting all known genetic associations, we explored the potential to identify candidate causal genes that are targets for existing drugs, which could be repositioned for use in these diseases.

Methods: Chromatin interaction data for T- and B-cells in the 3 diseases was analysed using CHiCAGO v2 using a score cut-off of ≥5. Interactions between disease regions and promoters were identified using BEDTOOLS v2.21.0 and intersected with drug targets from DrugBank v4.5.0. Existing treatments for each disease were identified by the presence of the relevant name in the "indication" field.

Results: Overall 850 genes were identified as interacting with a disease associated region. Of these, 61 are existing drug targets (303 drugs) (Table 1) and 9 are existing therapies used in the treatment of disease, primarily RA.

Table 1. Summary of drug targets identified by CHi-C

Disease	Number of identified by CHi-C	Number of genes which are existing drug targets	Number of drugs identified	Number of drugs withdrawn	Number of drugs currently used	Number of drugs for potential repositioning
RA	510	41	106	4	9	93
JIA	324	16	74	0	1	73
PSA	196	13	147	0	0	147
All	850	61	303	4	9	290

Conclusions: Our study identifies genes which are implicated in disease, are the target of existing drugs and offer the potential for drug repositioning. Of the potential drugs identified for RA, 14 are used in the treatment of various cancers and 11 are used in the treatment of diabetes and multiple sclerosis. Interestingly, 17 potential drugs identified for PsA are used in the treatment of schizophrenia and 11 in the treatment of hypertension. This data shows a novel insight into how functional annotation of genetic associations in rheumatic diseases can provide gene targets for re-positioned therapies.

Innovative insights into mechanism of SLE, Sjögren's and APS

OP0299 SERUM AND GLOMERULAR EXPRESSION OF IL32 IN LUPUS NEPHRITIS

S. Truglia[1], C. Alessandri[1], F. Ciccia[2], A. Rizzo[2], T. Colasanti[3], F. Miranda[3], F.R. Spinelli[3], F. Ceccarelli[3], G. Triolo[2], A. Capozzi[4], M. Sorice[4], G. Valesini[3], F. Conti[3]. [1]*Medicina Interna e Specilità Mediche, Reumatologia, Sapienza Università di Roma, Roma;* [2]*Dipartimento Biomedico di Medicina Interna e Specialistica, Sezione di Reumatologia, Università di Palermo, Palermo;* [3]*Dipartimento di Medicina Interna e Specialità Mediche, Reumatologia;* [4]*Dipartimento di Medicina Sperimentale, Sapienza Università di Roma, Roma, Italy*

Background: Lupus nephritis (LN) is one of the most severe features of systemic lupus erythematosus (SLE). Several cytokines and chemokines are secreted locally in case of glomerular inflammation. Interleukin 32 (IL32) is a newly described cytokine that exhibits several properties typical of proinflammatory cytokines. *Ex vivo* and *in vitro* studies supported the role of Toll like receptors (TLRs) in LN pathogenesis and recent investigations demonstrated that Poly I:C, a ligand for (TLR) 3, strongly induced IL32 production from several cell populations.
Objectives: To investigate serum and urinary levels of IL32 in a cohort of LN patients compared to SLE patients without renal involvement and healthy controls (HC). In addition, we investigated kidney expression of IL32 and *in vitro* ability of LN patients' serum IgG to stimulate IL32 production by TLR3 activation in human embryonic kidney 293 cells line stably transfected with a TLR3 plasmid (Hek293/T3).
Methods: Serum and urinary IL32 concentrations were measured using ELISA; a polyclonal rabbit anti-human IL32 was used to evaluate the expression of IL32 in renal biopsies. To assess the production of IL32 induced by patients' IgG and the transduction pathway of TLR3 we performed Western Blot analysis for IL32, TBK1 and NFkB.
Results: We recruited 60 LN patients, 50 SLE patients without renal involvement and 30 HC; 40 LN patients had an active disease (a-LN) and the remaining 20 were in remission (r-LN). IL32 serum levels were significantly higher in patients with r-LN (median 1368, IQR 3910) and HC (median 721, IQR 2271) compared to SLE patients without renal involvement (median 203, IQR 662.8 pg/ml) (p=0.03 and p=0.018, respectively). There were no significant differences in urinary IL32 levels among LN patients, SLE patients without renal involvement and HC. In LN patients a direct association between IL32 serum levels and disease duration (p=0.02; r 0.2978) was observed. Immuno-histochemical analysis performed on renal biopsies of 20 a-LN and 8 HC showed that IL32 was strongly expressed in renal samples of LN patients, especially in patients with class IV, compared to controls. Western Blot analysis showed that antibodies isolated from LN patients induced *in vitro* production of IL32 in Hek293/T3 cells as well as the phosphorylation of NFkB and TBK1.
Conclusions: The results of the present study show increased IL32 serum levels in r-LN patients as well as increased expression of such cytokine in renal tissues of a-LN patients. IL32 renal expression and its production by Hek293/T3 cells after patients' IgG stimulation, probably mediated by TLR3, may suggest the production of IL32 directly at renal level in course of LN.

OP0300 ENRICHMENT OF T FOLLICULAR-HELPER CELLS (TFH) AND EXCLUSION OF T FOLLICULAR-REGULATORY CELLS (TFR) FROM ECTOPIC GERMINAL CENTERS IN SALIVARY GLANDS OF SJOGREN'S SYNDROME PATIENTS

E. Pontarini[1], W. Murray-Brown[1], C. Croia[1], E. Astorri[1], D. Lucchesi[1], N. Lepse[1], N. Sutcliffe[2], A. Tappuni[3], C. Pitzalis[1], M. Bombardieri[1]. [1]*Centre for Experimental Medicine & Rheumatology, William Harvey Research Institute;* [2]*Barts Health;* [3]*Institute of Dentistry, Queen Mary University of London, London, United Kingdom*

Background: B/T cell aggregates in the salivary glands (SG) of Sjögren's syndrome (SS) can give rise to ectopic lymphoid structures (ELS) forming ectopic germinal centers (GCs), which has been linked to the development of MALT lymphoma (MALT-L). T follicular-helper cells (Tfh) and T follicular-regulatory cells (Tfr) are specialized CD4+ T-cells that positively and negatively regulate, respectively, the magnitude of the GCs response and the onset of autoimmunity.
Objectives: To characterize the infiltration of Tfh and Tfr in the SG infiltrates of patients with SS in the context of the presence/absence of ectopic GCs and in subjects with MALT-L.
Methods: SG biopsies with matching histology and RNA from 37 SS and 38 non-specific chronic sialadenitis (NSCS) patients were stratified as ELS-/ELS+ based on CD3/CD20/CD21/CD138 immunostaining (IHC). Histological samples and mRNA from 12 parotid MALT-L were also studied. Gene expression was measured by Taqman rt-PCR. Multicolor immunofluorescence/confocal microscopy for CD3, CD4, CD45RO, ICOS, PD1, BCL6 and FoxP3 was used to identify Tfh and Tfr.
Results: Tfh ($CD4^+CD45RO^+PD1^+ICOS^+FoxP3^-$) cells and Tfr ($CD4^+CD45RO^+PD1^+ICOS^+FoxP3^+$) cells were strongly enriched in ELS+ vs ELS- SS samples. The Tfh:Tfr ratio in ELS+ SG was approximately 2:1. Interestingly, while in tonsils Tfr were routinely detected within GCs, in ELS+ SG Tfr were predominantly excluded from the B cell follicles and accumulated in the T cell rich areas at the periphery of the lymphoid aggregates. Conversely, Tfh densely infiltrated the B cell rich areas and, within ectopic GCs, acquired BCL6. Furthermore, Tfh infiltration closely correlated with SG IL-21 mRNA expression, which in turn was strongly correlated with CD3, CD20 and CD138 IHC scores and with CXCL13, LTb, BAFF, AID and Pax5 gene expression. Finally, MALT-L samples displayed 10-fold higher IL-21 mRNA and twice as much $PD1^+ICOS^+BCL6^+$ Tfh-cells/field compared to ELS+ SS samples.
Conclusions: Within the SG of SS patients Tfh cells closely segregate with lesional IL-21 expression, localize within ELS and are strongly enriched during MALT-L development. Conversely, although Tfr cells are also recruited to ELS+ SG in SS patients, we consistently demonstrated follicular exclusion of this subset from ectopic GCs. This suggests that Tfr in SS SG fail to exert their physiological immunoregulatory properties in controlling the magnitude of the GCs response and B cell autoreactivity, as observed in tonsils.

OP0301 TYPE I IFN GENE SIGNATURE TEST–HIGH AND –LOW PATIENTS WITH MODERATE TO SEVERE SLE DISEASE ACTIVITY HAVE DISTINCT GENE EXPRESSION SIGNATURES OF IMMUNOLOGIC PATHWAYS AND CELL TYPES

H. Liu[1], B. Higgs[1], W. Rees[1], C. Morehouse[1], K. Streicher[1], P. Brohawn[2], G. Illei[1], K. Ranade[1]. [1]*MedImmune LLC;* [2]*MedImmune, Gaithersburg, United States*

Background: Type I interferon (IFN) has been implicated in systemic lupus erythematosus (SLE) pathogenesis, and the majority of patients with SLE have elevated expression of type I IFN-inducible genes in their blood. Anifrolumab, a fully human, $IgG_1\kappa$ monoclonal antibody against the type I IFN receptor, is in Phase III development for the treatment of moderate to severe SLE (NCT02446912 and NCT02446899).
Objectives: We sought to understand other molecular pathways (either dependent on or independent of type I IFN signaling), to elucidate heterogeneous mechanisms in SLE, and to identify patient subsets for personalized disease management.
Methods: Baseline blood samples from adult patients with moderate to severe SLE from two Phase IIb clinical studies (NCT01438489, N=265; NCT01283139, N=416) were profiled with whole genome array analyses. Type I IFN gene signature (IFNGS) test status was determined by a central laboratory utilizing an analytically validated four gene (*IFI27, IFI44, IFI44L, RSAD2)* quantitative polymerase chain reaction-based test from patients' whole blood. A predetermined, delta Ct-based cut-off point, in the trough of the bimodal distribution, was utilized to segregate type I IFNGS test–high from –low patients at baseline. Blood from healthy controls was stimulated *ex vivo* with IFN-β, IFN-γ, IFN-λ, IFN-ω, or a pool of all IFN-α subtypes, with or without blocking antibodies for each IFN type, to develop IFN-type-specific signatures. Cell type- and cytokine pathway-specific gene signatures derived from the literature were also evaluated with the Phase IIb sample data. A Fisher's exact test was used for enrichment calculations (signatures cut at median), and comparisons were adjusted for multiplicity through false discovery rate.
Results: A total of 79% of SLE patients in the combined study population had a type I IFNGS test–high status. From the type I IFNGS test–high patients, 29/95 signatures evaluated had significant enrichment, including those for B cells (q=1.17E-17, odds ratio [OR]=6.4), plasma cells (q=6.96E-11, OR=3.9), and CD40L signaling (q=1.07E-08, OR=3.3), relative to type I IFNGS test–low patients. In contrast, type I IFNGS test–low patients had enrichment for eosinophils (q=5.4E-6, OR=0.39) and type II IFN (IFN-γ) specifically inducible gene signatures (q=4.6E-3, OR=0.47). These findings were significant for the combined study population, as well as for the NCT01438489 study population, and were either significant or trending for the NCT01283139 population ($q<0.05$).
Conclusions: SLE patients who are type I IFNGS test–high had elevated concentrations of B cells, plasma cells, and other inflammatory cytokine pathways. Type I IFNGS test–low patients, by contrast, were enriched for eosinophil and type II IFN pathways. These observations provide new insights into the molecular heterogeneity underlying SLE and suggest new therapeutic approaches, particularly for type I IFNGS test–low patients.

OP0302 SIGNIFICANT REDUCTIONS OF PATHOGENIC AUTOANTIBODIES BY SYNERGETIC RITUXIMAB AND BELIMUMAB TREATMENT EFFECTIVELY INHIBITS NEUTROPHIL EXTRACELLULAR TRAPS IN SEVERE, REFRACTORY SLE - THE SYNBIOSE STUDY

T. Kraaij[1], S.W. Kamerling[1], J.A. Bakker[2], T.W. Huizinga[3], T.J. Rabelink[1], C. van Kooten[1], Y.K. Teng[1]. *[1]Nephrology; [2]Clinical Chemistry; [3]Rheumatology, LUMC, Leiden, Netherlands*

Background: Neutrophil extracellular traps (NETs) are extracellular, decondensed DNA strands covered with antimicrobial proteins that are part of the first-line defence against pathogens. However, in SLE, overall release of NETs is increased and degradation of NETs is impaired leading to a high amount of extracellular nuclear material, potentially leading to formation of SLE-specific antibodies. These pathogenic autoantibodies deposit in glomeruli in lupus nephritis (LN) and perpetuate autoimmunity by inducing more NETs. The present study hypothesized that combining anti-CD20 mediated B-cell depletion with BAFF (B-cell activating factor) inhibition can target autoreactive plasma cells and thereby effectively reduce pathogenic autoantibodies and NET induction in severe SLE.
Objectives: The present study aimed to investigate whether Rituximab (RTX) + Belimumab (BLM) affected pathogenic antibodies in relation to NET induction in severe refractory SLE.
Methods: As part of a phase 2 proof-of-concept study, the SynBioSe study, serum levels of anti-DNA autoantibodies were measured in severe, refractory SLE patients before and after treatment with RTX following BLM. Additionally, ex vivo NET induction was assessed before and after treatment with a novel highly sensitive method based on 3D confocal laser scanning microscopy. In this assay, healthy neutrophils are incubated with 10% serum of patients and healthy controls. Furthermore, we investigated whether NET induction was mediated by immune complexes.
Results: The study included 10 severe, refractory SLE patients with lupus nephritis and 1 patient with neuropsychiatric lupus. NET induction was found to be high at baseline with a median fold induction of 4.5 [range 2.6–11.7]. After 24 weeks, NET induction was significantly decreased (median fold NET induction of 1.6 [0.4–6.1], p=0.01). In addition, treatment with RTX+BLM led to significant reduction of anti-dsDNA antibodies at week 24 with a median of 35 IU/ml [range 10–374] compared to 120 [18–505] at baseline (p=0.012). Total immunoglobulin levels temporarily declined but returned to screening levels at week 24. NET induction correlated significantly with anti-dsDNA antibody levels (r=0.42, p=0.03) and with SLEDAI scores (r=0.53, p=0.003). Therefore, we examined whether the observed NET induction could be explained by circulating immune complexes (ICx). ICx were degraded by pre-incubating anti-dsDNA positive SLE sera with nuclease, resulting in a significant decrease in NET induction (median % decrease of 91.7 [range 67.6–98.1]). In addition, depletion of IgG from anti-dsDNA positive SLE sera resulted in significantly lower NET induction. Finally, immobilized IgG isolated from anti-dsDNA positive SLE sera, but not of control serum, resulted in significant NET induction.
Conclusions: Within refractory SLE patients, RTX + BLM resulted in concordant reductions in pathogenic anti-dsDNA antibodies and NET-inducing capacity. This study strongly suggests that NET induction in SLE is mediated by immune complexes, providing a possible explanation underpinning the clinical benefits of RTX+BLM in SLE. Trial registration:ClinicalTrials.gov NCT02284984

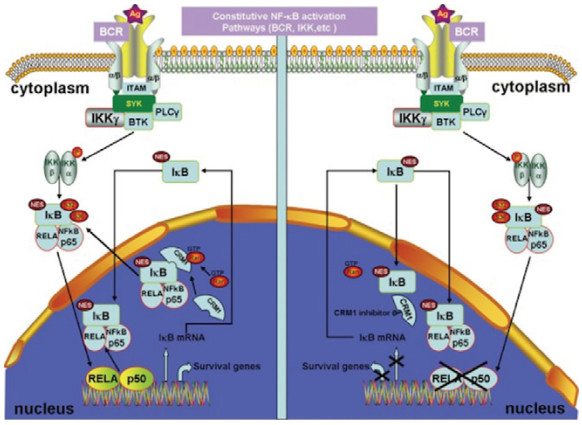
OP0303 THE SALIVARY GLAND SECRETOME AS A POTENTIAL NEW TOOL TO IDENTIFY BIOMARKERS OF DRYNESS AND IMMUNOPATHOLOGY IN PRIMARY SJÖGREN'S SYNDROME AND NON-AUTOIMMUNE SICCA PATIENTS



S.L. Blokland[1,2], M.R. Hillen[1,2], A.A. Kruize[2], W. de Jager[1], A. Pandit[1], J.A. van Roon[1,2], T.R. Radstake[1,2]. *[1]Laboratory of Translational Immunology; [2]Rheumatology & Clinical Immunology, UMC Utrecht, Utrecht, Netherlands*

Background: Salivary gland biopsy is essential in primary Sjögren's syndrome (pSS) diagnostics. However, tissue analysis using traditional methodology has several limitations including inaccurate quantification of lymphocytic infiltration and poor correlation with dryness. To perform biomarker identification in the target organ, tissue would have to be sacrificed. By performing saliva proteomics the biopsy tissue can be saved, but hitherto, this technique has not yielded consistent biomarkers and is limited by the absence of saliva production by many sicca patients.
Objectives: We aimed to explore whether Luminex analysis of a broad panel of cytokines in salivary gland biopsy supernatants (secretome) could provide biomarkers to stratify sicca patients and could give insights into pathogenesis.
Methods: Labial salivary gland (LSG) tissues were rinsed after biopsy and incubated in 200μL of saline for 1h at room temperature. Tissue supernatants were rendered cell-free, frozen in liquid nitrogen and stored at -80°C. In supernatants from pSS and non-Sjögren's sicca (nSS) patients 104 targets were measured by Luminex. Eight pSS and 8 nSS patients were selected for analysis based on matched biopsy weights. Results from this discovery cohort were validated in an additional cohort (n=18 nSS, n=16 incomplete SS: iSS, n=26 pSS) and correlations with clinical parameters were assessed. Non-SS were defined as sicca patients without lymphocytic infiltration in the salivary gland biopsy or anti-SSA/SSB autoantibodies. Incomplete SS patients were defined as sicca patients having lymphocytic infiltration (lymphocytic focus score (LFS)>0) and/or anti-SSA/SSB autoantibodies but do not fulfill the AECG classification criteria and are not diagnosed as pSS.
Results: Levels of 20 cytokines were significantly different between the nSS and pSS patients in the discovery cohort ($p \leq 0.05$). These 20 and 13 additionally selected cytokines based on a trend towards statistical significance and/or literature, were measured in a validation cohort. Weights of the biopsies did not significantly differ: 59.8±48.1mg in nSS vs 72.7±45.2mg in iSS vs 67.4±28.6mg in pSS. Fifteen out of these 20 cytokines were validated. From the 13 cytokines 7 were significantly elevated in pSS vs nSS. In iSS CXCL10 (IP-10) and CCL19 (MIP-3β) were significantly elevated. Cytokines correlating with LFS, ESSDAI, ESSPRI, % IgG and IgM+ plasma cells in LSG, Schirmer and/or serum IgG with Spearman $r \geq 0.4$ and $p \leq 0.05$ in pSS were selected for classification tree analysis, these were IL-2, IL-3, IFN-β, IL-21, CXCL13 (BLC), CXCL10 and CCL19. Using CXCL13 and IL-21 levels, 87.5% of pSS patients could be classified correctly. Based on the used cut off levels, 5 nSS and 9 iSS patients would be classified as pSS. Follow up of these patients may reveal development of pSS.
Conclusions: Elevated levels of numerous cytokines were found in LSG biopsy secretomes from pSS patients versus non-autoimmune sicca patients correlating with clinical parameters. This method represents a novel tool to provide insights in pSS immunopathology and to identify therapeutic targets and biomarkers for diagnosis, prognosis and treatment response.

OP0304 SELECTIVE INHIBITORS OF NUCLEAR EXPORT PREVENT LUPUS PROGRESSION BY TARGETING GERMINAL CENTER FORMATION AND AUTOREACTIVE ANTIBODY SECRETING CELLS

J. Rangel-Moreno[1], S. Cochran[2], S. Tamir[2], M. Lee[2], S. Shacham[2], J. Anolik[1]. *[1]Department of Medicine, Division of Allergy, Immunology and Rheumatology, University of Rochester Medical Center, Rochester; [2]Karyopharm Therapeutics, Newton, United States*

Background: Systemic lupus erythematosus (SLE) is a complex autoimmune disease characterized by simultaneous activation of the innate and adaptive arms of the immune system. The progression of the disease is unpredictable, making its treatment a challenge. Recently the nuclear export protein Exportin 1 (XPO1, also known as CRM1) has surfaced as an attractive target for the treatment of SLE and other inflammatory disorders. Selective Inhibitor of Nuclear Export (SINE) compounds are potent, orally available and well-tolerated XPO1 inhibitors. SINE compounds exert apoptotic and anti-inflammatory effects by mediating nuclear retention of important XPO1 cargos like the NFκB pathway regulatory protein, IκB.
Objectives: Based on the central role of NFκB signaling in the activation of immune cells in SLE, we decided to evaluate the therapeutic ability of SINE compounds to modulate experimental lupus progression.
Methods: To evaluate the efficacy of SINE compounds in a preclinical model of SLE, cohorts of lupus-prone mice with established disease (elevated anti-dsDNA antibody titer and proteinuria) were dosed with SINE compound or vehicle. We used flow cytometry to enumerate immune cells and immunofluorescence to visualize germinal centers (GC) in spleen. Quantitative PCR was used to measure changes in mRNA expression for molecules key in plasma cell attraction and survival, and histology was used to evaluate inflammation, antibody deposition and pathology in kidneys of lupus-prone mice.
Results: We found that treatment with SINE compounds significantly prevented increases in proteinuria (proteinuria scores: Control: 2.12±1.12; SINE (5 mg/kg): 1.06±0.49; SINE (7.5 mg/kg): 0.85±0.55) and drastically decreased IgG deposition and kidney pathology (glomerulonephritis, tubule damage and perivascular cuffing). Prevention of kidney damage was associated with a remarkable disruption of splenic GC, a significant reduction in the number of auto-reactive antibody secreting cells (ASC), and a decrease in the accumulation of auto-reactive ASC in the inflamed kidney. Reduced numbers of plasma cells in the inflamed kidney are likely due to the drastic decrease in the expression of molecules critical for PC attraction (CCL2, CXCL9, CXCL10, CXCL11) and survival (BAFF, APRIL). The potent effect of SINE compounds on GC and auto-reactive ASC is noticeable as early as 1 week after starting therapy. However, kinetics studies showed that a more pronounced elimination of GC and auto-reactive ASC is achieved after 8 weeks. Although SINE therapy has a drastic impact on spleen architecture, recovery experiments showed that complete recovery of immune cells in spleen occurred by 4 weeks. The reversible impact of SINE compounds on SLE provides a potential window of time for immunization of lupus patients.
Conclusions: SINE compounds have demonstrated efficacy in a murine model of SLE by reducing generation, survival and function of auto-reactive immune

cells. It is likely that inhibition of the canonical NFκB pathway underlies KPT-350's inhibitory effect. Together, our findings suggest the potential of SINE compounds to have a significant impact on disease progression in SLE.

OP0305 TYPE I IFN SYSTEM ACTIVATION IN NEWBORNS EXPOSED TO ANTI-RO/SSA AUTOANTIBODIES IN UTERO

M. Wahren[1], M. Hedlund[1], G.E. Thorlacius[1], M. Ivanchenko[1], N. Kyriakidis[1], L. Rönnblom[2], M.-L. Eloranta[2], A. Espinosa[1], S.-E. Sonesson[1]. *[1]Karolinska Institutet, Stockholm; [2]Uppsala university, Uppsala, Sweden*

Background: Overexpression of type I IFN-stimulated genes has been demonstrated in both SLE and SS, and induction of IFNα production in plasmacytoid dendritic cells by immune complexes containing RNA and autoantibodies, including Ro/SSA and La/SSB autoantibodies, has also been shown. During pregnancy, these autoantibodies pass over the placenta to the fetus, but it is not know if an IFN-activation takes place also in the fetus.

Objectives: In the present study, we investigated if the type I IFN system is activated in newborns exposed to anti-Ro/SSA autoantibodies *in utero*.

Methods: Anti-Ro/SSA positive mothers and their babies as well as healthy controls were included in the study. Maternal and cord blood drawn at birth was immediately separated into plasma and PBMC. mRNA expression was analyzed by microarrays, cell surface markers were assessed by flow cytometry and circulating IFNα levels by DELFIA.

Results: We observed increased expression of IFN-regulated genes and elevated plasma IFNα levels not only in anti-Ro/SSA positive women but also in their newborns, with maternal and fetal IFN scores showing a significant positive correlation (r=0.74, p=0.005). Increased expression of MHC class II was observed on $CD14^+$ monocytes of anti-Ro/SSA antibody-exposed babies, suggesting cellular activation. Notably, the IFN score of babies born to mothers receiving immunomodulatory treatment was similar to that of controls.

Conclusions: We demonstrate for the first time that anti-Ro/SSA antibody-exposed babies at risk for neonatal lupus have a pre-activated immune system with an IFN signature, elevated plasma IFNα, and increased MHC class II expression on circulating monocytes. Our data also suggest that maternal immunomodulatory treatment may modulate the IFN activity in the baby.

OP0306 DOWNREGULATION OF MICRORNAS IN PLASMACYTOID DENDRITIC CELLS IS ASSOCIATED WITH A TYPE I INTERFERON SIGNATURE IN SYSTEMIC LUPUS ERYTHEMATOSUS AND ANTIPHOSPHOLIPID SYNDROME

L.L. Van Den Hoogen[1,2], J.A. van Roon[1,2], R.D. Fritsch-Stork[2], C.P. Bekker[1,2], A. Pandit[1,2], M. Rossato[1,2], T.R. Radstake[1,2]. *[1]Laboratory of Translational Immunology; [2]Rheumatology and Clinical Immunology, UMC Utrecht, Utrecht, Netherlands*

Background: The most prominent alteration in the immune system of patients with SLE is a type I interferon (IFN) signature, which we recently also reported in patients with primary APS (PAPS). In SLE and APS, this signature is related to disease activity and vascular disease. Plasmacytoid dendritic cells (pDC) are considered key players in the pathogenesis of SLE and APS as they are major producers of type I IFNs. MicroRNAs (miRNAs) are short non-coding RNAs that modulate gene expression through RNA interference mechanisms and have been implicated in the dysregulation of immune cells in patients with autoimmune diseases. Here we investigated miRNA expression in pDC of patients with SLE and APS in relation to the type I IFN signature.

Objectives: To identify if pDC dysregulation in patients with SLE and APS is associated with alterations of their miRNA expression profile.

Methods: The frequency of circulating pDC was determined by flow cytometry in patients with SLE (n=49), SLE+APS (n=34) and PAPS (n=27) and healthy controls (HC, n=22). RNA was extracted from pDCs isolated from the peripheral blood of patients with SLE (n=20), SLE+APS (n=10), PAPS (n=10) and HC (n=12). pDC miRNA and transcriptome profiles were assessed by RT-qPCR by OpenArray and RNA-sequencing (RNAseq) respectively. Patients were stratified by the presence (IFN-high) or absence (IFN-low) of an IFN signature on the basis of RNAseq. pDC stimulated with TLR7 agonists were analyzed for changes in miRNA expression.

Results: The numbers of circulating pDC were reduced in peripheral blood of patients with SLE, SLE+APS and PAPS (all $p<0.001$) and did not differ among the patient groups. Among 131 expressed miRNAs, 36, 17 and 21 miRNAs were differentially expressed ($p<0.05$) in patients with SLE, SLE+APS and PAPS, respectively, as compared with HC. All but one of these miRNAs were downregulated in the patients versus HC. Only 1 miRNA was differentially expressed when comparing between SLE and SLE+APS patients and between SLE+APS and PAPS patients. No changes in expression of genes related to the biogenesis of miRNAs were observed in the pDC of the patient groups. RNAseq data revealed an IFN signature in pDC, which was strongest in SLE and SLE+APS patients. IFN-high (n=23) patients showed a stronger downregulation of miRNAs as compared with IFN-low (n=17) patients. A total of 9 miRNAs were differentially expressed between IFN-high and IFN-low patients. Pathway enrichment on targets of the top three miRNA ($p<0.001$) distinguishing between IFN-high and –low patients indicated that these miRNAs are potentially regulating pathways relevant for pDC function such as TLR signaling and endocytosis. Activation of pDCs by TLR7 agonists induced a downregulation of miRNAs in pDC, resembling the miRNA expression pattern seen in patients, in particular those with a high type I IFN signature.

Conclusions: Reduced numbers of circulating pDC and downregulation of miRNAs in pDC is shared between SLE, SLE+APS and PAPS patients. Altered miRNA expression in pDC is associated with the presence of a type I IFN signature in SLE and APS. Our data suggest that the reduced expression of a subset of miRNA underlies pDC dysregulation in SLE, SLE+APS and PAPS patients.

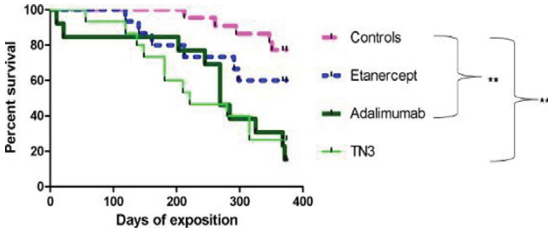
Comorbidities in rheumatoid arthritis

OP0307 TREATMENT OF BAFF TRANSGENIC MICE WITH ANTI-TNF: MONOCLONAL ANTI-TNF ARE ASSOCIATED WITH A HIGHER RISK OF LYMPHOMA THAN ETANERCEPT

G. Nocturne[1], L. Bineta[2], S. Boudaoud[2], J. Pascaud[2], R. Seror[1], C. Nicco[3], C. Chereau[3], F. Mackay[4], F. Vincent[4], T. Lazure[5], S. Ferlicot[5], L. Stimmer[6], S. Roulland[7], R. Krzysiek[8], S. Hacein-Bey[8], F. Batteux[3], X. Mariette[1]. *[1]Rheumatology; [2]INSERM U1184, le Kremlin Bicêtre; [3]U1016, Paris, France; [4]Melbourne University, Melbourne, Australia; [5]Pathology, le Kremlin Bicêtre; [6]CEA, Fontenay aux roses; [7]Marseille Luminy, Marseille; [8]Immunology, le Kremlin Bicêtre, France*



Background: Risk of lymhoma in patients with rheumatoid arthritis (RA) and disease activity is the main risk factor. The impact of treatment, notably of anti-TNF, is unclear: decreasing the risk of lymphoma by controlling activity or alterring anti-tumor immunosurveillance. Anti-TNF are not associated with an increased risk of lymphoma in large epidemiologic studies. However, the risk might vary according to the type or to the dose of anti-TNF.

Objectives: To assess if the risk of lymphoma might differ according to the type of anti-TNF, comparing monoclonal anti-TNF to the soluble receptor. For that, we used BAFF transgenic (Tg) mice as a model of autoimmunity-associated lymphomas. They develop lupus and Sjögren and 3% of them spontaneously developed lymphoma at 12–18 months

Methods: Six months aged BAFF-Tg mice were treated with anti-TNF for 12 months: etanercept (ETA) (n=15, 8 mg/kgx3/week), monoclonal anti-mouse TNF: TN3 19.12 (n=15, 20 mg/kg/week), adalimumab (ADA) (n=12, 20 mg/kg/week) or controls (n=22). Sera were assessed monthly. Crude mortality was compared among the different groups. Histological examination of the spleen was performed. The Fisher's exact test was used to compare the incidence of lymphoma among the groups.

Results: Adjunction of low dose of methotrexate during the 3 first days of treatment prevented immunization in the 3 groups for life. Using L929 cells, a cell line sensitive to TNF induced death, we confirmed that ADA was 8 to 12 times less efficient than ETA to inhibit soluble murine TNF. As expected, the mean level of ETA, TN3 and ADA were 7 μg/ml, 69 μ g/ml and 105 μg/ml, respectively. The

level of auto-antibodies and serum Ig did not significantly differ among the groups. However, crude mortality was significantly higher in mice treated with monoclonal anti-TNF compared to controls (p=0.0001 for ADA and p=0.0003 for TN3) but not for mice treated with ETA (Figure). Incidence of lymphoma was higher in mice treated with monoclonal anti-TNF: *5/15 (33%)* with TN3 (p=0.03/controls), *4/12 (33%)* with ADA (p=0.054/controls), *0/15* with ETA and *1/22 (5%)* in controls.

Conclusions: Higher mortality and increased risk of lymphoma were observed in BAFF Tg mice treated with monoclonal anti-TNF compared to etanercept. This result may be linked either to the different mechanism of action between the soluble receptor and the monoclonals or to a difference of trough level observed in the different groups even if higher levels of ADA was mandatory given the difference of effect on mouse TNF. This study demonstrates the negative impact of a prolonged anti-TNF treatment on the risk of lymphoma in the context of BAFF increase.

OP0308 TNF INHIBITOR TREATMENT AND RISK OF CANCER RECURRENCE IN PATIENTS WITH RHEUMATOID ARTHRITIS: A NATIONWIDE COHORT STUDY FROM SWEDEN

P. Raaschou, J. Söderling, J. Askling on behalf of the ARTIS study group. *Dept of Medicine, Karolinska Institute, Stockholm, Sweden*

Background: Clinical guidelines caution against the use of TNFi in individuals with a recent (5–10 years) history of cancer, but evidence of an increased risk of cancer recurrence is limited (1–2).

Objectives: We investigated the risk of recurrent solid non-skin cancer in patients with rheumatoid arthritis and TNFi-treatment, and if time between index-cancer and TNFi-start influence this risk.

Methods: 61.950 individuals with RA were identified in the Swedish national outpatient-care register Jan 2001-Dec 2014. Among these, 446 Individuals with at least one diagnosis of cancer (index cancer) prior to the start of TNFi-treatment were identified through linkage to the national cancer register and the ARTIS register of biologic treatment. Individuals (n=1.278) with a history of equally recent cancer of the same type and stage (invasive/in situ) were matched 3:1 to each patient starting TNFi against a background of solid cancer. Study participants were required to be in cancer remission during a period of 6 months prior to start of follow-up. The primary outcome was first recurrence or second primary of the same cancer type, identified through register-linkages until Dec 2014. Hazard ratios (HR) for recurrence or second primary were calculated using a Cox regression model with TNFi-treatment start (and a corresponding date among the matched biologics-naïve individuals) as start of follow-up. The final models were stratified for the matching variables sex, birth year, year of diagnosis of the index cancer and index cancer type and stage (invasive vs in situ), and adjusted for education level and comorbidities.

Results: The mean time from index cancer diagnosis until TNFi-treatment/start of follow-up was 9.9 and 9.5 years among the TNFi treated and their matched biologics-naïve controls, respectively. The mean follow-up (SD) from TNFi start was 4.9 (3.5) and 4.1 (3.1) years, respectively. The cancer stage distribution was similar between the two groups, apart from stage IV (0.6% among the TNFi-treated and 1.6% among the biologics-naïve). Thirty individuals (7%) among the 446 TNFi-treated developed a cancer recurrence (crude incidence rate 14/1000 person-years), compared with 89 (7%) among the 1.278 matched biologics-naive (crude incidence rate 17/1000 person-years). This corresponded to an adjusted HR for recurrent cancer of 0.69 (95% CI 0.42–1.12) in the matched analysis (table 1) comparing the TNFi treated to the biologics-naïve individuals. Stratified analyses indicated no increased risk associated with any specific cancer type with the possible exception of uterine cancer where HR for recurrence was 14.8 (95% CI 1.17–187.5), based on only 1 event among the TNFi-treated. HR for recurrence among individuals starting TNFi treatment within 5 year from index cancer was 0.67 (0.31–1.44).

Table 1 Number of patients, recurrent or second primary cancer, incidence rate per 1000 person-years (PY) and hazard ratios (HR) among TNFi treated patients with RA and their matched biologics-naïve comparators

Cancer	TNFi			Matched comparators			Adjusted* HR (95 % CI)
	N	Events (%)	IR per 1000 PY	N	Events (%)	IR per 1000 PY	
Overall	446	30 (6.7%)	13.8	1 278	89 (7.%)	17.0	0.69 (0.42-1.12)
Anorectal	29	0	0	69	4 (5.8%)	15.5	-
Breast	212	22 (10.4%)	19.9	633	46 (7.3%)	16.1	1.04 (0.57-1.89)
CNS	30	1 (3.3%)	7.0	81	3 (3.7%)	7.5	-
Colon	34	0	0	91	3 (3.3%)	11.3	-
Kidney	6	0	0	14	1 (7.1%)	16.4	-
Lung	3	1 (33.3%)	86.1	9	(.%)	0	-
Ovarial	29	1 (3.4%)	6.2	75	4 (5.3%)	12.8	-
Prostate	59	2 (3.4%)	8.7	175	17 (9.7%)	31.0	0.16 (0.03-1.00)
Urinary	16	2 (12.5%)	33.7	47	10 (21.3%)	65.5	0.80 (0.16-4.07)
Uterine	28	1 (3.6%)	6.2	84	1 (1.2%)	2.8	-

Cox regression stratified for the matching variables sex, birth year (±10 years), year of diagnosis (±5 years) of the index cancer, cancer type and stage at diagnosis (invasive vs in situ) of the index cancer, and adjusted for education and comorbidities. Within each matched strata, HRs could therefore be calculated only when events occurred among both TNFi-treated and biologics-naive.

Conclusions: Among patients with RA and a history of cancer, those selected to receive TNFi-treatment in clinical practice did not experience more cancer recurrences than patients with RA treated otherwise. We detected no differential risk depending on the timing of TNFi-start in relation to the index cancer. The generalizability of our findings to individuals with a very recent cancer, or a poor prognosis, remains unknown.

AxSpA: from bug to gut and to disease phenotype

OP0309 INTESTINAL SCLEROSTIN/SEROTONIN AXIS IS MODULATED BY DYSBIOSIS AND REGULATES ILC3 EXPANSION IN AS PATIENTS

F. Ciccia[1], G. Guggino[1], A. Rizzo[1], S. Milling[2], M. Luchetti[3], D. Baeten[4], R. Alessandro[1], G. Triolo[1]. *[1]University of Palermo, Palermo, Italy; [2]University of Glasgow, Glasgow, United Kingdom; [3]University Politecnica delle Marche, Ancona, Italy; [4]University of Amsterdam, Amsterdam, Netherlands*

Background: Sclerostin is an osteocyte-specific factor that binds to low-density lipoprotein receptor-related protein 5 (LRP5) inhibiting the Wnt signaling pathway and possibly contributing to the pathogenesis of Ankylosing spondylitis (AS). Subclinical gut inflammation observed in AS patients is characterized by the presence of dysbiosis and innate immune alterations. In the gut, LRP5 activation by unknown ligands inhibits serotonin production. Serotonin, by inducing glial derived neurotrophic factor (GDNF), controls ILC3 expansion, in the context of glial–ILC3–epithelial cell unit (GIECU). Sclerostin/serotonin axis has been never studied in AS.

Objectives: Aim of this study was to evaluate whether sclerostin is produced in the gut; to study the sclerostin/serotonin axis in AS and the effect of sclerostin on enterochromaffin cells (EC); to evaluate the presence of intestinal GIECU in AS and the role of serotonin in modulating the production of GDNF on isolated intestinal glial derived cells. We finally studied the effect of GDNF on ILC3.

Methods: Ileal, synovial and bone marrow (BM) expression of sclerostin, serotonin and GDNF were investigated by rt-PCR, immunohistochemistry and WB in 30 AS patients and 20 controls. Platelet and plasma unconjugated concentrations of serotonin were assessed by high-performance liquid chromatography (HPLC). Isolated bacteria from AS ileal biopsies were cultured with EC and serotonin expression evaluated by RT-PCR. Sclerostin and serotonin gut expression were evaluated in HLA-B27 TG rats before and after antibiotics treatment. EC were stimulated with sclerostin and the expression of THP1 assessed by RT-PCR. The presence of GIECU was studied by confocal microscopy analysis of GFAP/Tbet/Thy1. Isolated intestinal glial cells were stimulated with serotonin and the modulation of GDNF assessed by RT-PCR. The effect of GDNF on ILC3 was evaluated by flow cytometry.

Results: Sclerostin was produced in the gut and down-regulated in AS. Up-regulation of serotonin was observed in the gut, in the synovia and plasma, but not in BM of AS. Isolated intestinal bacteria from AS reduced EC serotonin production. Sclerostin down-regulation and serotonin over-expression were observed in the gut of HLA-B27 TG rats where Antibiotics increased intestinal sclerostin production and reduced serotonin expression. Treatment of isolated gut EC with sclerostin down-regulated the expression of THP1. GDNF was over-expressed in AS gut and confocal microscopy analysis demonstrated the existence of glial-ILC3-epithelial cells unit in AS patients. Finally, serotonin induces the release of GDNF by isolated intestinal glial cells and recombinant GDNF expanded RET^{+}ILC3.

Conclusions: here we demonstrate for the first time that intestinal sclerostin is the ligand of LRP5 and modulates the release of serotonin. Sclerostin/serotin axis is dysregulated in AS patients and HLA-B27 TG rats. In HLA-B27 TG rats, antibiotics restored sclerostin production and serotonin expression indicating a role of dysbiosis in modulating sclerostin/serotonin axis. Serotonin seems to be an important regulator of ILC3 expansion by inducing the production of GDNF by enteric glial cells, in the context of glial-ILC3-epithelial cells unit.

Pregnancy meets rheumatic patients

OP0310 PREGNANCY OUTCOME IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS, A MULTICENTER COHORT-STUDY

B. Blomjous[1,2], C. Abheiden[2], S. Kroese[3], J. van Laar[3], R. Derksen[3], I. Bultink[1], A. Voskuyl[1], A. Lely[4], M. de Boer[2], J. de Vries[2], R. Fritsch-Stork[5]. *[1]Rheumatology, Amsterdam Rheumatology and Immunology Center, location VU University Medical Center, Amsterdam, Netherlands; [2]Obstetrics and Gynaecology, VU University Medical Center, Amsterdam; [3]Rheumatology and Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands; [4]Obstetrics and Gynaecology, University Medical Center Utrecht, Utrecht, Netherlands; [5]1st Medical Department and Ludwig Boltzmann Institute, Hanusch Krankenhaus and Sigmund Freud University, Vienna, Austria*

Background: Systemic lupus erythematosus (SLE) predominantly affects women during their fertile period. During pregnancy SLE patients are prone to pregnancy complications and may experience increased disease activity.
Objectives: To investigate disease activity around/during pregnancy and pregnancy complications in a European cohort according to antiphospholipid antibody (aPL) status. Additionally data on lifetime pregnancy outcomes and comparison of first and consecutive pregnancies were analyzed.
Methods: All ongoing pregnancies of >16 weeks gestation of SLE patients (according to the ACR revised criteria) receiving joint care from rheumatologists and gynecologists in two tertiary centers in the Netherlands between 2000–2015 were included. Disease activity (using SELENA-SLE(P)DAI around and during pregnancy), flare rate according to the SELENA- SLEDAI definitions and pregnancy complications were assessed by medical chart review.
Results: From 96 women (84% Caucasian) 144 pregnancies were included. Before (<6 months), during and after pregnancy (<6 months) the median SELENA-SLE(P)DAI score was 2 and mild/moderate flare rates were 6.3%, 18.8% and 13.9% respectively. Three patients developed a severe flare during pregnancy, 2 patients postpartum; all were aPL negative. Severe maternal complications (preeclampsia, eclampsia or HELLP-syndrome) occurred in 16.2% of aPL negative, 21.4% of aPL positive SLE patients, and in 30.8% of SLE patients with antiphospholipid syndrome (APS) (GEE; no significant differences between groups). HELLP-syndrome occurred in 23.1% of SLE patients with APS and in 3.1% of SLE patients without APS (Chi-Square; p<0.01). The perinatal complications intrauterine fetal death, preterm birth, small-for-gestational age and neonatal lupus occurred in 4.1%, 32.7%, 14.8%, 1.4%, respectively (GEE; no significant differences between groups). Maternal and perinatal complication rates were similar in first (18.5% and 41.4%) and consecutive (17.6% and 35.1%) pregnancies (Chi-Square; p=0.88 and p=0.44). Of all patients, 42.7% developed a complication during all of their pregnancies (obstetrical history included).
Conclusions: This is the first study in patients with SLE demonstrating that incidence rates of pregnancy complications do not decrease in consecutive pregnancies compared to first pregnancies, in contrast to findings in the general population. Except for HELLP-syndrome, pregnancy complications were not significant different between aPL groups. Despite overall low disease activity and the absence of aPL in the majority of patients, almost half of the patients developed a complication during their pregnancies.

OP0311 HIGH MATERNAL EXPRESSION OF SIGLEC1 ON CD14+ MONOCYTES AS A SURROGATE MARKER OF A TYPE I INTERFERON SIGNATURE IS A RISK FACTOR FOR THE DEVELOPMENT OF AUTOIMMUNE CONGENITAL HEART BLOCK

A.R. Lisney[1,2], F. Szelinski[1], K. Reiter[1], G. Burmester[1], C. Scholz[3], T. Rose[1,2], T. Dörner[1,2]. *[1]Department of Rheumatology and Clinical Immunology, Charité, Universitätsmedizin Berlin; [2]German Rheumatism Research Center (DRFZ); [3]Department of Obstetrics and Gynaecology, Charité, Universitätsmedizin Berlin, Berlin, Germany*

Background: Autoimmune congenital heart block (CHB) is a severe manifestation of neonatal lupus syndrome that is associated with placental transcytosis of maternal autoantibodies directed against the ribonucleoproteins Ro/SS-A and, to a lesser extent, La/SS-B.(1) Around 2/3 of affected mothers are diagnosed with either systemic lupus erythematosus (SLE) or primary Sjögren's syndrome (pSS),(2) which are both pathogenically driven by an upregulation of type I interferons (IFN).(3)
Objectives: Although the pleiotropic effects of type I IFN on the immune system are well documented, a potential role of type I IFN in the development of CHB has not yet been investigated. This study therefore aimed to compare maternal levels of type I IFN activation in affected and unaffected mothers, in order to provide first insights into a potential role of type I IFN in CHB development.
Methods: Blood samples, clinical data and serological parameters from 9 women with CHB pregnancies, 15 pregnant women with antibodies against Ro/SS-A but without a CHB complication ("Disease Controls", DC), and another 30 healthy pregnant women without the respective autoantibodies as controls were studied. Plasma levels of IFN-α (ELISA), interferon-gamma induced protein 10 (IP-10) (Bioplex®) and the expression of SIGLEC1 on CD14+ monocytes (flow cytometry) were analysed.
Results: Pregnant females with a CHB complication had a significantly higher expression of SIGLEC1 (p=0.0034) and IFN-α (p=0.014), but not of IP-10 (p=0.14, all MWU), compared to the DC group. Receiver operating curve (ROC) analysis between the CHB group and the DC group showed that a SIGLEC1 median fluorescence intensity (MFI) of >904 could distinguish between the groups with a sensitivity of 100% and a specificity of 64%, and a concentration of IFN-α >0.70 pg/ml with a sensitivity of 67% and a specificity of 86%. Healthy pregnant females without the respective autoantibodies had the lowest levels for all three parameters. In a cohort of 5 females, both the expression of SIGLEC1 and plasma levels of IFN-α were reduced by hydroxychloroquine and oral glucocorticoids.

Table 1. Antibody profiles

	CHB pregnancies (n=9)	Disease controls (n=14)	Healthy controls (n=30)
Anti-Ro (SS-A), n (%)	9 (100%)	14 (100%)	0
– anti-Ro52, n (%)	7 (78%)	12 (86%)	0
– anti-Ro60, n (%)	9 (100%)	8 (57%)	0
Anti-La (SS-B), n (%)	2 (22%)	4 (29%)	0

Conclusions: This is the first study to report increased type I IFN activation in pregnant females with a CHB complication. Also, we show here that IFN-α directed therapy, e.g. with hydroxychloroquine, may be especially beneficial in these females.

Neuronal and hormonal alterations in arthritis

OP0312 A PROTEOMIC SIGNATURE OF FATIGUE IN PRIMARY SJÖGREN'S SYNDROME

R. Omdal[1,2], E. Larssen[3,4], C. Brede[5], A. Hjelle[4], A.B. Tjensvoll[6], K.B. Norheim[1], K. Bårdsen[4], K. Jonsdottir[7], P. Ruoff[8], M.M. Nilsen[3,4]. *[1]Clinical Immunology Unit, Stavanger University Hospital, Stavanger; [2]Department of Medical Science, Faculty of Medicine and Science, University of Bergen, Bergen; [3]International Research Institute of Stavanger – IRIS; [4]Research Department; [5]Department of Medical Biochemistry; [6]Department of Neurology; [7]Department of Pathology, Stavanger University Hospital; [8]Centre for Organelle Research (CORE), University of Stavanger, Stavanger, Norway*

Background: Fatigue is a frequent and often disabling phenomenon in patients with chronic inflammatory and immunological diseases, neurodegenerative diseases, and cancer. The underlying biological mechanisms of fatigue are largely unknown and hypotheses are conflicting. It is important to uncover the pathophysiology and identify signalling pathways that generate and regulate this substantial phenomenon.
Objectives: Based on the hypothesis that fatigue originates from cerebral processes, we investigated whether relevant proteins and/or signaling pathways for fatigue could be revealed in the cerebrospinal fluid (CSF) of patients with primary Sjögren's syndrome.
Methods: Label-free shotgun mass spectrometry was performed to analyze the CSF proteome of 20 patients with primary Sjögren's syndrome. Fatigue was measured with the fatigue Visual Analogue Scale (fVAS).
Results: After depletion of high-abundance proteins, more than 800 proteins were identified and quantitated. Multivariate analyses showed that patients with low and high fatigue could be separated based on their CSF protein profiles, and 15 proteins were selected as top discriminatory proteins. Among these were apolipoprotein A4, hemopexin, pigment epithelium derived factor, secretogranin-1, secretogranin-3, selenium-binding protein 1, and complement factor B.
The figure shows the top network from Ingenuity Pathway Analysis (IPA) with 14 of

the differentially expressed proteins (red = upregulated, green = downregulated) and proteins that are directly associated to them (white molecules).

© 2000-2017 QIAGEN. All rights reserved.

Conclusions: Most of the discriminatory proteins have important roles in regulation of innate immunity, cellular stress defense, and/or functions in the central nervous system. Some have been associated with severe depression and loss of appetite, which are important features of chronic fatigue. These proteins and their interacting protein networks may therefore have central roles in the generation and regulation of fatigue, and the findings add new, relevant, and important evidence to the concept of fatigue as a biological phenomenon signaled through specific molecular pathways.

OP0313 P75 LOW AFFINITY RECEPTOR OF NERVE GROWTH FACTOR ON PERIPHERAL LEUKOCYTES AND CD11C-POSITIVE DENDRITIC CELLS ARE UPREGULATED IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

S. Welle, A.M. Wolf, M.F. Seidel. *Medizinische Klinik III, Hematology, Oncology and Rheumatology, University Hospital of Bonn, Bonn, Germany*

Background: The nervous system regulates rheumatic diseases in neurogenic inflammation (NI). Nerve growth factor (NGF) plays a pivotal role in NI and chronic nociceptive pain of degenerative musculoskeletal diseases [1]. Clinical trials using NGF antagonists have shown impressive analgesic efficacy in these disorders [2]. However, the role of NGF in autoimmune inflammatory diseases is not completely understood although NI perhaps induces and/or mediates disease activity. NGF-receptor expression on peripheral lymphocytes may reflect NI activity.

Objectives: The aim of this study was to identify the expression levels of the NGF receptor with high affinity (TrkA) and low affinity (p75) on leukocyte subsets of SLE patients, as compared to healthy controls (HC).

Methods: The number of TrkA- and p75-positive cells was quantified in 13 SLE patients (diagnosed according to the 1997 ACR revised criteria). CD4, CD8, CD11b, CD11c, CD14, CD16, CD19, CD56 and CD66b antibodies, and isotype controls were used. Cells were quantified by multicolour flow cytometry and compared to gender and age-matched HC (n=13) using the Mann-Whitney-U-Test. Values <0.05 were considered statistically significant. Patients were further subgrouped for high or low disease activity as determined by SLEDAI, ANA, anti-dsDNA, CRP, complement C3/C4 and ESR, and compared to HC using the Kruskal-Wallis test and Mann-Whitney-U-test. NGF serum concentrations were determined by ELISA.

Results: In SLE, *TrkA* expression on peripheral leukocytes (%±SD) was not different from HC and was highest on CD14+ cells (15.5±20.6). In contrast, *p75* was significantly increased on CD16+ (2.4±3.0 vs. 0.9±0.6, p=0.044) and CD56+ leukocytes (1.5±1.7 vs. 0.4±0.3, p=0.022) in SLE vs. HC. Further subgroup analyses showed that *TrkA* (0.6±0.3 vs. 1.8±1.3, p=0.035) and *p75* (0.4±0.3 vs. 2.3±1.8, p=0.014) were decreased on CD56+ cells in patients with high SLEDAI vs. patients with low SLEDAI scores. Similarly, a reduction of *p75* on CD19+ B cells was associated with high SLEDAI (0.8±0.7 vs. 10.8±16.5, p=0.018) whereas *p75* expression was significantly higher on CD56+ cells in SLE with low SLEDAI as compared to HC (2.3±1.8 vs. 0.2±0.2, p=0.007). CD11c+ dendritic cells (DC) did not show differential expression for TrkA or p75, however, they were increased in SLE as compared to HC (5.4±2.5 vs. 2.5±0.6, p=0.0001). Interestingly, DC were also significantly elevated in SLE with high SLEDAI, anti-dsDNA, ANA and ESR. NGF serum concentrations did not differ between SLE and HC.

Conclusions: Our data for the first time demonstrate differential NGF receptor expression on an extensive panel of peripheral blood leukocytes in SLE and HC. p75 appears to be the major differentially regulated receptor for NGF. The decrease of TrkA and p75 on CD56+ and p75 on CD19+ cells in patients with high SLEDAI activity is unclear and may reflect a negative feedback mechanism. The increased CD11c+ DC might indicate additional inflammatory activation in SLE. Further studies are needed to analyse these findings.

Fighting osteoporosis fragilities

OP0314-HPR A HOME-BASED FALL PREVENTION PROGRAMME REDUCES FEAR OF FALLING IN SENIORS

B. Zindel [1], A. Meichtry [2], V. Krafft [1], K. Niedermann [2]. *[1]Swiss League against Rheumatisme, Zurich; [2]Zurich University of Applied Sciences, Winterthur, Switzerland*

Background: Every year, over 80,000 elderly persons in Switzerland have accidents caused by tripping and falling, and half of these falls happen at home or in the direct vicinity (1). Falls, due to its often severe medical consequences and persistent mobility impairments, together with the demographic development, are one of the most important musculo-sceletal problems and public health issue. Falls are often due to a combination of internal risk factors (such as vertigo, osteoporosis, cognitive impairments, decreased ability for dual tasking) and external risk factors (such as medication and environmental risk factors) (2). The Swiss League Against Rheumatism (SLAR) has developed a multidimensional home-based fall prevention programme, which is supported by health insurances. Trained physiotherapists (PTs) and occupational therapists (OTs) visit the seniors at home in order to perform a detailed assessment of the senior's individual risk of falling. Subsequently the PT or OT eliminates identified environmental risk factors and provide tailored exercises. After 4 weeks, a telephone call was made by the PT/OT to discuss unclear instructions and after 16 weeks, follow up data were collected by telephone.

Objectives: The objective was to evaluate the effects of the fall prevention programme.

Methods: A retrospective analysis was carried out on the data of 671 participants in 2015. Available data were participant's characteristics, fall risk factors, determined by the Timed "Up&Go" with additional motor and cognitive task) (4). Fall Efficacy Scale (5), the recommendations made by the PTs/OTs and satisfaction of the seniors.

Results: The participants were mainly female (62.6%) and had a mean age of 81.7 years (SD=5.5, range 66.1–100 years). Several risk factors were present: 64.1% fell at least once in the last year and 45% were not able to perform a dual task (TUG + additional cognitive task).

Main recommendations made by PTs/OTs were "fixing down of carpets" (56.6%) and instruction of an exercise programme (strength, balance and multi-task capability) (82.6%). After four months, fear of falling had decreased (change in FES-I: -1.24 points 95% CI: (-1.44, -1.04), p-value<0.001). 92% of the participants self-reported to follow the recommendations and 98.4% were satisfied with the programme and would recommend it to others.

Conclusions: The low-threshold, multidimensional home-based fall prevention developed by the SLAR was feasible and effective. Participants implemented the recommendations and the fear of falling' decreased. Reduced fear of falling is considered a strong predictor of falling, however a prospective study is needed to determine if the reduced fear of falling leads to a decreased number of falls.

Duarte[10], I. Brito[11], C. Furtado[12], A. Rodrigues[13], G. Sequeira[14], R. Campanilho-Marques[4], J. Branco[15], M.J. Santos[16], J. Eurico-Fonseca[17], H. Canhão[18]. *[1]Rheumatology, CHLO, EPE; [2]SPR; [3]Rheumatology, Portuguese Institute of Rheumatology; [4]Rheumatology, Pediatric Reumatology Unit, CHLN, EPE, Lisbon; [5]Pediatrics, CHUC, Coimbra; [6]Pediatrics, Centro Hospitalar do Porto - Hospital de Santo Antonio, Porto; [7]Pediatrics, Hospital Dona Estefânia, Lisbon; [8]Pediatrics, Centro Hospitalar do Médio-Ave, Famalicão; [9]Rheumatology, ULSAM - Hospital Conde de Bertiandos, Ponte de Lima, Viana do Castelo; [10]Rheumatology, Centro Hospitalar Universitário de Coimbra, Coimbra; [11]Rheumatology, Centro Hospitalar São João, Porto; [12]Rheumatology, Hospital do Divino Espírito Santo, São Miguel, Ponta Delgada; [13]Rheumatology, Hospital de Santo Espírito, Angra do Heroísmo, Angra do Heroísmo; [14]Rheumatology, Centro Hospitalar de Faro, Faro; [15]CEDOC, Nova Medical School, Lisbon; [16]Rheumatology, Hospital Garcia de Orta, Almada, Almada; [17]Rheumatology research Unit, Faculdade de Medicina de Lisboa; [18]CEDOC, EpiDoC Unit, Nova Medical School, Lisbon, Portugal*

Background: Persistence on medication mainly reflects both effectiveness and safety of a drug. Understanding the reasons to stop bDMARD in routine clinical practice can help to better define the efficacy and safety of biologic medications in children with juvenile idiopathic arthritis (JIA).
Objectives: To investigate persistence on treatment and the reasons for discontinuation of the first biological in patients with JIA.
Methods: Portuguese patients with JIA registered in Reuma.pt who started a bDMARD were analyzed. Persistence was defined as the time between treatment initiation and discontinuation of the first bDMARD. The mean time until discontinuation was calculated using Cox regression survival estimates and the reasons for discontinuation of the first bDMARD were registered.
Results: Of the 1724 JIA patients registered in Reuma.pt, 319 received biological therapy, 62% (198) female. The mean age at disease onset was 7.7±4.8 years and the mean time between the beginning of JIA and the first bDMARD was 8.2±9.4 years. The mean disease duration was 13.7±10.7 years and the mean age at the beginning of biological therapy was 15.8±9.4 years. The distribution of JIA subtypes was: 19.1% polyarticular RF-negative, 17.2% enthesitis-related arthritis, 16.6% polyarticular RF-positive, 16% extended oligoarticular, 13.5% persistent oligoarticular, 12% systemic JIA and 0.9% had undifferentiated arthritis. Considering the whole group, 53.2% have had extra-articular manifestations and 18.4% have or had had uveitis since the beginning of the disease. Persistence on treatment, before discontinuation (due to any cause) was 34.7 months (range: 0.03–182 months) adjusted for gender, biological therapy, JIA subtype, age at the beginning of biological therapy, and disease duration until initiating first bDMARD. The major reasons for drug discontinuation was inefficacy (49.6%), remission (14.2%), adverse events (10.6%), patient decision (1.6%) and pregnancy planning (1.4%). In 22.7% the reason was not specified.
Conclusions: Almost half of the JIA patients stop the first biological agent, due to lack of response, reinforcing the need for the existence of several treatment options fully studied in JIA.

OP0316 DURATION OF CLINICAL REMISSION AND FLARE RATES IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS AFTER WITHDRAWAL OF BIOLOGICAL TREATMENT (PRELIMINARY DATA)

E. Kashchenko[1], E. Alexeeva[1,2], T. Bzarova[1,2], S. Valieva[1], K. Isaeva[1], R. Denisova[1], O. Lomakina[1], T. Sleptsova[1], M. Soloshenko[1], A. Karaseva[1]. *[1]Federal State Autonomous Institution "National Scientific and Practical Center of Children's Health" of the Ministry of Healthcare of the Russian Federation; [2]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation*

Background: Prolonged therapy with biological agents (BAs) may cause adverse events, which leads to the necessity of discontinuation of BAs in patients with juvenile idiopathic arthritis (JIA), once complete disease quiescence has been achieved.
Objectives: To estimate the length of time in clinical remission and time to disease flare after discontinuation of treatment with BAs.
Methods: 83 patients with JIA (33 – with systemic onset, 50 – with oligo- or polyarticular arthritis) were included in the survey. The cohort was 34,9% (29 patients) male and 65,1% (54 patients) female with a mean age of 11±3,69 years (range 5–17 years). All patients with systemic JIA (sJIA) were treated with tocilizumab, 35 (70%) patients with other types of JIA received etanercept, 15 (30%) – adalimumab. 14 (42,4%) patients with sJIA additionally got methotrexate, 5 (15,1%) – cyclosporine, 5 (15,1%) – glucocorticoids, 1 (3,0%) – leflunomide; 9 (25,7%) and 7 (46,6%) patients took combination therapy of etanercept or adalimumab and methotrexate. Patients were randomized into 2 main groups using envelope method: in a first group a BA was discontinued abruptly, while in the second it was tapered gradually by increasing injection/infusion interval.
Results: Duration of inactive disease/clinical remission during tocilizumab treatment was 43±12,16/37±12,16 months, etanercept – 40±13,13/34±13,17 months, adalimumab – 48±11,9/40±12,06 months. Tocilizumab, etanercept, adalimumab were discontinued in 22 (66,6%), 28 (80,0%), 11 (73,3%) patients and were tapered by increasing injection/infusion interval in 11 (33,4%), 7 (20,0%), 4 (26,7%) cases, respectively. After withdrawal of tocilizumab, etanercept and adalimumab 29 (87,9%), 24 (68,6%), 6 (40,0%) patients remained in remission of JIA for 6±10,23 (1–48) months, 6±5,07 (1–20) months and 6±13,33 (4–38) months, respectively. 4 (12,1%), 11 (31,4%), 9 (60,0%) patients flared within 8±5,65 (6–18) months, 5,5±3,49 (1,5–12) months and 4±4,64 (1–13) months after discontinuation of tocilizumab, etanercept and adalimumab, respectively.
Conclusions: Withdrawal of BAs after clinical remission for more than 1,5 years was not associated with a disease exacerbation in more than 70% of patients with JIA. A mean duration of clinical remission after withdrawal of BAs was 6 months.

Health equity and economy - a vital relationship

OP0317-PARE AN INDEPENDENT REVIEW OF PEOPLE WITH RHEUMATOID ARTHRITIS (RA) AND THEIR CAREGIVER'S LOST WORK TIME

A. Bosworth[1], C. Jacklin[1], T. Burke[2], A. Rose[2], I. Jacob[2], S. Verstappen[3]. *[1]National Rheumatoid Arthritis Society (NRAS), Maidenhead; [2]HCD Economics, Warrington; [3]Arthritis Research UK Centre for Epidemiology Division of Musculoskeletal and Dermatological Sciences, University of Manchester, Manchester, United Kingdom*

Background: The National Rheumatoid Arthritis Society (NRAS) is the only patient-led charity in the UK focussing specifically on rheumatoid arthritis (RA) with the key responsibility of raising awareness of the impact and burden of RA. There is a lack of information about the costs and impact of RA on work in the European community; in particular the wider societal costs such as people with RA not being able to perform their job to their best ability, losing days of work due to their RA condition, and the domino effect on caregiver employment.
Objectives: To quantify the burden of RA not only on the healthcare system, but also the wider societal costs associated with RA.
Methods: In 2016 NRAS undertook a partnership with the University of Chester's commercial economics partner HCD Economics who conducted the multinational Burden of Rheumatoid Arthritis: Socioeconomic Survey (BRASS). The study used a bottom-up approach to quantify the burden of disease for people living with RA across 10 European countries including France, Germany, Italy, Spain, Denmark, Sweden, Hungary, Poland, Romania and the UK. The study collected information from patients and physicians on factors associated with managing RA, plus RA sufferers' views on life and workplace impact. It collected information on the resource use and cost of patient care including treatment costs, hospitalisation, tests, and examinations. The wider societal costs included; cost of travel to appointments, requirements for aids/equipment, informal care (non-professional), ability in employment, early retirement due to RA. Work time missed, work and activity impairment were measured using the Work Productivity and Activity Impairment (WPAI) questionnaire.
Results: Voluntary data were collected from 1782 patient forms, of which the average age was 55 years, 1274 (71%) were female and 833 (48%) were currently in work. This study found, on average, persons with RA lose one day of every 4 working days due to not being able to perform their job to their best ability, and completely miss 7% of work time over a 7 day period due to their RA (sample n of 646). In addition to not being able to perform their job to their best ability, almost a third of working persons with RA also had impairment in daily living activities such as shopping and work around the house (sample n of 735). This study also found family/friends have to care for 16% of RA sufferers. This care resulted in reduced employment or inability to work for 25% of family/friend caregivers (sample n of 121).

Conclusions: This study highlights the impact RA has on working life amongst both those with the condition and those providing support. It is hoped these metrics will allow the conversation to open and develop with employers and government on how adapting the workplace can increase productivity. Further research should also be undertaken on the economic impact both to the individuals, their carers and society.
Acknowledgements: The BRASS study was supported by unrestricted research grants from Eli Lilly and Pfizer. The study was approved by the University of Chester Ethics Committee.

OP0318-PARE **CONSULTING SERVICES TO EMPLOYERS OF PEOPLE WITH RMDS**

F.J. Carreira Roca[1,2], A.I. Vázquez Lojo[3], V. Romero Pazos[4,5] on behalf of LIRE-LRG. *[1]Accesibility Dept. and Volunteer, Liga Reumatolóxica Galega (LRG), A Coruña; [2]Accesibility Consultant and Volunteer, Liga Reumatológica Española (LIRE), Madrid; [3]Board of Directors and Occupational Therapy Dept., Liga Reumatolóxica Galega; [4]International Dept., Liga Reumatolóxica Galega (LRG), A Coruña; [5]Board of Directors, Liga Reumatológica Española (LIRE), Madrid, Spain*

Background: The Eurobarometer[1] states that RMDs affect 22% of the general population which means that 10 million people are affected in Spain and more than 600.000 people in the autonomous region of Galicia where our organization, LRG, works.
Knowing that 50% of people with RMDs are currently unemployed because of their condition[2], only part of them have the legal work incapacity recognized and receive a pension. This means that RMDs not only affect the health but also the socio-economic status. Most of this people could stay at work and are willing to do so if some arrangements are made like cutting down hours, work place adaptations, flexible schedule, etc.[3]
Most employers are lacking information on how these conditions affect the employee's hability, desire and need to work and how to make the necessary adaptations for not loosing this person from the work force.
Objectives: Making the employer more aware of the positive aspects of keeping all the employees including people with RMDs not just at the work place but at full capacity, avoiding both absenteeism and presenteeism.
Helping the employer knowing about the needs of people with RMDs and the necessary adaptations for each of them.
Keep people with RMDs at work at the best possible conditions both for the employee and the employer, as efficiently and healthy as possible.
Methods: The employee with RMD has 1 session with the psychologist and 1 session with the occupational therapist (OT) to identify the difficulties in continuing to be active into their work place.
LRG HP give personalized advise to the employer about the RMDs, the needs of the employees and how to facilitate them to stay at work and minimize the work incapacity due to their chronic condition. This kind of advise is given by the OT who has treaten the employees and knows all about their needs, goes to their work place to see what are the actual conditions, identifies manageable obstacles and talks to the employers during a pre-scheduled meeting. After, an architect specialized in accesibility offers specific architectural and ergonomic solutions for adapting the work place.
Also peer support is provided by LRG in group meetings and activities of the organization.
Results: The results of this project are shown in the increase of the employees' self-confidence in their capacity to stay at work and also they are more aware of their solvable and non solvable limitations.
During 2016 we advised 14 associates of LRG, 5 of those 14 employees (1/3) stayed at work or returned to work after the consultancy.
Conclusions: This kind of actions are neccesary to make the work places more adaptable and increasing the number of people with RMDs to start a work live, to stay or go back to work.
Peer support within a patient's association is key to create a secure environment for the employees who find relief in seeing other people with RMDs having a sustainable work life.

Biomarkers in cardiovascular rheumatology - state-of-the-art 2017

OP0319 **HIGH SENSITIVITY CARDIAC TROPONIN T IS A BIOMARKER FOR ATHEROSCLEROSIS IN SYSTEMIC LUPUS ERYTHEMATOUS PATIENTS: A CROSS-SECTIONAL CONTROLLED STUDY**

G. Divard[1], R. Abbas[1], C. Chenevier-Gobeaux[2], B. Escoubet[1], M.-P. Chauveheid[1], A. Dossier[1], M. Dehoux[1], T. Papo[1], K. Sacre[1]. *[1]Paris-7 University, APHP, Bichat Hospital; [2]Paris-5 University, APHP, Cochin Hospital, Paris, France*

Background: Cardiovascular disease (CVD) is the main cause of death in systemic lupus erythematous (SLE) patients. Framingham score underestimates the risk for CVD in this population.
Objectives: Our study aimed to determine whether serum High Sensitivity Cardiac Troponin T (HS-cTnT) helps to identify SLE patients at risk for CVD.
Methods: Presence of carotid plaques was prospectively assessed by ultrasound in 63 consecutive SLE patients asymptomatic for CVD and 18 controls. Serum HS-cTnT concentration was measured using the electrochemiluminescence method. Factors associated with carotid plaques were identified and multivariate analysis was performed
Results: Framingham score was low in both SLE patients (2.1±3.8%) and controls (2.1±2.9%). Nevertheless, 23 (36.5%) SLE patients, but only 2 (11.1%) controls (p=0.039), had carotid plaque detected by vascular ultrasound. In the multivariate analysis, only age (p=0.006) and SLE status (p=0.017) were independently associated with carotid plaques. Serum HS-cTnT concentration was detectable (i.e. >3 ng/L) in 37 (58.7%) SLE patients and 6 (33.3%) controls (p=0.057). Interestingly, 87% of SLE patients with carotid plaques, but only 42.5% in SLE patients without plaques ($p<0.001$), had a detectable HS-cTnT. Conversely, 54.5% SLE patients with a detectable HS-cTnT, but only 11.5% with an undetectable HS-cTnT ($p<0.001$), had a carotid plaque. In the multivariate analysis, only BMI (p=0.006) and HS-cTnT (p=0.033) were statistically associated with carotid plaques in SLE patients. Overall, the risk of having a carotid plaque was increased by 8 (OR [95% CI]: 8.03 [1.41–74.73]) in SLE patients in whom HS-cTnT was detectable in serum.
Conclusions: Detectable HS-cTnT concentration is independently associated with subclinical atherosclerosis in asymptomatic SLE patients at apparent low risk for CVD according to traditional risk factors. These results raise the possibility that this easily obtained biomarker is useful for more rigorous risk stratification and primary prevention of CVD in SLE patients.

What is behind vasculitis?

OP0320 **DETERMINANTS OF RITUXIMAB PHARMACOKINETICS AND CLINICAL OUTCOMES IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS**

D. Cornec[1,2], B. Kabat[1], J. Mills[1], M. Cheu[3], A. Hummel[1], D. Schroeder[1], M. Cascino[3], P. Brunetta[3], D. Murray[1], M. Snyder[1], F. Fervenza[1], G. Hoffman[4], C. Kallenberg[5], C. Langford[4], P. Merkel[6], P. Monach[7], P. Seo[8], R. Spiera[9], W.St. Clair[10], S. Ytterberg[1], J. Stone[11], D. Barnidge[1], U. Specks[1]. *[1]Mayo Clinic, Rochester MN, United States; [2]Rhumatologie, CHRU Brest, Brest, France; [3]Genentech Inc., San Francisco, CA; [4]Cleveland Clinic, Cleveland OH, United States; [5]Univeristy, Groningen, Netherlands; [6]University of Pennsylvania, Philadelphia PA; [7]Boston University, Boston MA; [8]Johns Hopkins, Baltimore MD; [9]Hospital for Special Surgery, New York; [10]Duke University, Durham NC; [11]Massachusetts General Hospital, Boston MA, United States*

Background: Response to rituximab (RTX) is variable in patients with ANCA-associated vasculitis (AAV), and predictors of treatment efficacy/relapse risk would be useful. Previous studies have shown that RTX pharmacokinetics (PK) is associated with treatment efficacy in patients with lymphoma.
Objectives: To study the determinants of RTX PK in patients treated for AAV and its association with clinical outcomes.
Methods: This study included 88 patients from the RTX in ANCA-Associated Vasculitis (RAVE) trial who received the full dose of RTX (4 weekly 375 mg/m^2 infusions) and had available serum samples. RTX was quantified using two different assays: a traditional ELISA and a recently developed mass spectrometry-based assay (referred to as miRAMM). We analyzed week (W)2, W4, W8, W16 and W24 serum levels and the trapezoidal area under the curve (AUC) integrating baseline, W2, W4, and W8 levels. We explored potential determinants of RTX PK using univariate and multivariate analysis, and analyzed the association of RTX PK with clinical outcomes: achievement of complete remission at 6 months (defined by a BVAS/WG score of 0 with no prednisone), time to relapse in patients who achieved complete remission, and B-cell depletion duration.

Results: RTX quantifications using ELISA and miRAMM were highly correlated, but miRAMM measured consistently higher serum levels, suggesting its ability to detect total serum RTX (including free and complexed rituximab). RTX PK was highly variable between patients, with W2 levels ranging between 43 and 259 μg/mL and AUC ranging between 2,668 and 17,513 μg/mL by miRAMM. W2 RTX levels and AUC were significantly lower in males and in newly-diagnosed patients, and were negatively correlated with body surface area, baseline B-cell count, and BVAS/WG. In multivariate analyses, the main determinants of RTX PK were sex and new diagnosis. Patients with a new diagnosis had higher baseline B-cell counts and BVAS/WG. Patients reaching complete remission at month 6 had similar mean RTX levels compared to patients who did not reach complete remission (W2 level by miRAMM: 136±44 vs 139±46, p=0.76; AUC: 8420±2875 vs 8558±3452, p=0.85). Patients with higher RTX levels generally experienced longer B-cell depletion durations, but RTX levels at the different time-points and AUC were not associated with time to any relapse or time to severe relapse. Similar results were observed when using rituximab quantification by miRAMM and by ELISA.
Conclusions: Despite a dosing protocol adjusted for body surface area, rituximab PK is highly variable between patients, its main determinants being sex and newly diagnosed disease. We did not observe an association between rituximab PK and clinical outcomes. Serum rituximab level monitoring does not seem clinically useful in this context.

OP0321 RISK OF CORONARY ARTERY DISEASE AND ISCHEMIC STROKE IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS. A FRENCH POPULATION-BASED STUDY

M. Mourguet[1], D. Chauveau[2], A. Huart[3], D. Ribes[4], S. Faguer[5], L. Sailler[1], G. Pugnet[1]. *[1]Service de Médecine Interne, CHU Toulouse Purpan; [2]Département de Néphrologie et transplantation d'organes; [3]Departement de Néphrologie et Transplantation d'organes; [4]Département de Néphrologie et transplantation d'organe; [5]Département de Néphrologie et transplantation d'organertement de Néphrologie et transplantation d'organe, CHU Toulouse Rangueil, Toulouse, France*

Background: ANCA-associated vasculitis (AAVs), including granulomatosis with polyangiitis and microscopic polyangiitis, are small vessel vasculitides. Modern treatments have greatly improved survival in AAV patients, but significant long-term morbidity and mortality such as cardiovascular disease (CVD) are still associated with this disease.
Objectives: The aim of our study was to assess the incidence, mortality and predictors of CVD in patients with AAVs
Methods: We conducted a retrospective study of AAV diagnosed in Toulouse France teaching hospital between 1981 and 2015. Patients with granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) were included and classified, after thorough medical chart review, according to the criteria proposed by the Chapel Hill Consensus Conference. Eosinophilic granulomatosis with polyangiitis were excuded. A survival analysis was performed. Hazard ratios and the comparative morbidity and mortality figure (CMF) was calculated as the ratio of expected number of deaths in the standard population to those observed as well as predictors of CVD in patients with AAV were also assessed.
Results: We identified 361 subjects, only 125 met the inclusion criteria, 99 GPA and 26 MPA, 65 (42%) were men and mean age was 61.3±15.7 years at CVD occurrence with a mean follow-up of 88.4±78.3 months since diagnosis.Coronary artery disease (CAD) developed in 10 patients, and ischemic stroke developed in 9 patients (incidence rates of 8.5 per 1,000 person-years and 10.2 per 1,000 person-years, respectively). CAD incidence for AAV patients is two times more than in the general population, independent of age differences between the two populations using the Midi-Pyrénées county CAD registry as a reference (CMF of 1.96; 95CI 0.88 to 4.36). Ischemic stroke incidence for AAV patients is three times more than in the general population, independent of age differences between the two populations (CMF of 3.36; 95CI 1.75 to 6.46).
Smoking habits and history of CAD at AAV diagnosis was strongly associated with CAD occurrence (adjusted HR 8.8; 95CI 2.12 to 36.56, p=0.003 and adjusted HR 10.3; 95CI 1.02 to 104.5, p=0.003, respectively). An ENT flare (adjusted HR 0.12) was a independent protective factor for CAD occurrence. We did not find any statistically significant associated factor with ischemic stroke occurrence in our cohort.
Using direct standardisation, the age adjusted mortality rate for the AAV cohort was 22.5 per 1,000 person-years and for the general population 10.2 per 1,000 person-years. This indicates that mortality for AAV patients is one and a half times more than in the general population, independent of age differences between the two populations (CMF of 1.56; 95CI 1.02 to 2.39).
Conclusions: Patients with AAV have a significantly increased risk of mortality and ischemic stroke and a non–statistically significant trend toward an increased risk of CAD. Monitoring for this complication and vigilance in modifying risk factors are particularly warranted in this patient population.

Cytokine taxonomy: reflection in the therapy of arthritides and other IMIDs

OP0322 A NOVEL HIERARCHICAL RELATIONSHIP BETWEEN INTERLEUKIN-17A AND INTERFERON-ALPHA IS INDICATED BY ANALYSIS OF MULTIPLE CYTOKINES IN THE SERUM OF ADULT-ONSET STILL'S DISEASE AND BEHÇET'S DISEASE

K. Sato, Y. Aizaki, Y. Araki, T. Mimura. *Department of Rheumatology and Applied Immunology, Saitama Medical University, Saitama, Japan*

Background: Adult-onset Still's disease (AOSD) and Behçet's disease (BD) are both systemic inflammatory diseases, the causes of which are largely unknown. They have been recently classified as autoinflammatory diseases, a group of diseases in which innate rather than acquired immunity plays important roles in their pathogenesis. As AOSD and BD are clinically distinct diseases, their cytokine networks should also be different.
Objectives: In this study, we attempted to quantify the levels of multiple cytokines in the serum of patients by utilizing a beads-array technique and ELISA, and then compared the serum cytokine profiles of the two diseases by factor analysis. We then sought to clarify the hierarchical relationship between interleukin (IL-) 17A and interferon (IFN-) α using peripheral blood mononuclear cells (PBMCs).
Methods: We quantified the serum levels of 10 cytokines (IFN-α, IFN-γ, IL-1β, IL-2, IL-4, IL-6, IL-10, IL-12p70, IL-17A and tumor necrosis factor α) in 16 AOSD patients and 28 BD patients using multiplex bead array assays and IL-18 along with ELISA. The data were then subjected to factor analysis. We next stimulated PBMCs from three healthy volunteers *in vitro* with class A CpG oligodeoxynucleotides (ODNs) in the presence or absence of IL-17A for 15 hours. We performed flowcytometric analysis to examine the expression of intracellular IFN-α in plasmacytoid dendritic cells (pDCs).
Results: Two factors were extracted from the factor analysis using the data on 8 cytokines that were detectable in the serum of the patients. IL-17A and IFN-α, the levels of which showed a strong positive correlation in the serum of BD patients (Fig. A), were the main components of Factor 1, while Factor 2 consisted of IL-6, IL-10 and IL-18 (Fig. B). Patients were also plotted on a plane determined by Factors 1 and 2 according to each patient's factor scores. Those who were high in Factor 1 but low in Factor 2 were likely to be BD patients and vice versa, many of those who were high in Factor 2 but low in Factor 1 were AOSD patients. In terms of flowcytometric analysis, IL-17A alone did not induce IFN-α expression in pDCs, but it did substantially increase IFN-α-positive pDCs induced by CpG ODNs.

Conclusions: The cytokines examined were clearly separated into distinct groups by the factor analysis. Similarly, the AOSD and BD patients could be separated, although roughly. High levels of serum IL-6, -10 and -18 suggest AOSD while high levels of IFN-α and IL-17A indicate BD. To establish patterns of correlation among cytokines, it is important to focus on the cytokine concentrations in each patient, rather than the average cytokine concentrations in each of the diseases. In terms of the hierarchical relationship between IFN-α and IL-17A, a previous report suggested that IFN-α blocks IL-17A production in PBMCs from BD patients. Thus, we examined the effect of IL-17A on IFN-α production. It should be noted that the real stimulus for IFN-α release in BD is unknown. In addition, cells other than pDCs may be involved in the production of IFN-α. Nevertheless, understanding the hierarchical relationship among cytokines should prove to be helpful in clarifying the pathogenesis of various inflammatory diseases.

Personalised care for back pain

OP0323 DISCOPATHY ASSOCIATED WITH MODIC CHANGES IS NOT RELATED TO ANY INFECTIOUS PROCESS: A PROSPECTIVE MONOCENTRIC STUDY

S. Ahmed Yahia[1], J.-W. Decousser[2], C.H. Flouzat-Lachaniette[3], F. Robineau[3], E. Audureau[4], A. Hourdille[1], F. Eymard[1], X.-J. Chevalier[1]. *[1]Rheumatology; [2]Microbiology; [3]Orthopaedic; [4]Public health, Henri Mondor hospital, Creteil, France*

Background: Low back pain (LBP) is strongly associated with Modic changes. The

hypothesis of local infectious origin was raised, especially with Proprionibacterium acnes (PA).The possibility of contamination with saprophyte germs coming from the skin during surgery by posterior approach or by epidural infiltration preceding the surgery was also discussed, but not proved.

Objectives: The main objective of this study was to evaluate the prevalence of slow growing bacterias (SGB) in the intervertebral disc (IVD) obtained during a lumbar spine surgery by anterior approach in Modic 1 and 2 changes. A secondary objective was to compare the prevalence of SGB in IVD in lumbar spine surgery obtained by anterior approach to that obtained by posterior approach in herniated disc.

Methods: 45 patients with chronic LBP or sciatica were included in the study, representing 48 IVD. When patients underwent lumbar spine surgery by an anterior approach, 2 samples of the disc were collected for bacteriological analysis: one sample from the anterior part of the disc distant from epidural space and one sample from the posterior part of the disc. 77 discs samples were obtained, 32 discs samples in Modic 1 or 2 changes by anterior approach, 26 discs samples in no Modic IVD by anterior approach, 19 disc samples obtained by posterior approach. The method to collect disc material was strictly aseptic. Samples were analysed by conventional microbial *cultures* with specialised enrichmen, molecular detection by universal rRNA gene PCR *plus* sequencing assay. Additionally, all clinical specimens were specifically tested for PA detection using a highly sensitive specific PCR

Results: Regarding bacterial cultures, 12 out 77 disc samples were positive (16%), including 10 (13%) for PA. The PA specific PCR was positive for one (1%) specimen obtained by posterior approach. The 16s RNA detection was positive for 6 specimen (8%), including one for PA (1%).Modic 1–2: Cultures were positive in 5 cases (16%) with 3 for PA (10%). No specific PA PCR was positive. Only one sample was positive for PA in both culture and 16s PCR. Comparison between anterior and posterior approach: Among the PA positive cultures, 5 were identified from anterior specimens (8.62%) and 5 from posterior specimens (26.32%). Regarding PA cultures,the posterior fragments were more frequently positive than the anterior fragments (p=0.046). The number of epidural infiltrations of the lumbar spine does not seem to influence the bacterial contamination prevalence p=0.746. The time between the epidural infiltration of the lumbar spine and the surgery does not seem to influence the bacterial contamination prevalence (more or less 6 month) p=0.23.

Conclusions: SGB has been identified in culture in 16% of the samples obtained in Modic 1 and 2 changes. The prevalence of PA in culture was significantly higher in samples of IVD collected by a posterior approach compared to anterior approach in spine surgery suggesting a contamination. The results of the specific PCR PAs with a single weakly positive sample reinforce the hypothesis of contamination.

OP0324 MANAGEMENT OF MUSCULOSKELETAL PAIN USING AN ALGORITHM FOR SELECTION OF ANALGESICS

A. Karateev, A. Tsurgan, N. Gontarenko. *V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Musculoskeletal pain is the most common manifestation of osteoarthritis (OA) and non-specific back pain (BP). Treatment of pain includes medications with a different mechanism of action such as paracetamol, non-steroidal anti-inflammatory drugs (NSAIDs), opioid analgesics, muscle relaxants, antidepressants or local glucocorticoid (GC) injections. However, a uniform approach to sequential and complex therapy with these medications is not so far available.

Objectives: The study aims at evaluating the efficacy of combined therapy of musculoskeletal pain in real clinical practice.

Methods: In the open-label study were included 3304 patients (54.3% women and 45.7% men with average age of 48.9±14.6 years) with acute/subacute pain due to OA or BP. The exclusion criteria were the presence of severe co-morbidities and BP in association with neurological disorders. Treatment was carried out in accordance with the following algorithm: for a moderate/severe pain (>4 scores according to an 11-point numeric rating scale, NRS) use of NSAID (aceclofenac), when NSAIDs are contraindicated – tramadol with/without paracetamol, in case of mild pain – topical NSAID with/without paracetamol, and muscle relaxants as indicated. Control of treatment efficacy was carried out on day 7 (a total of 4 visits). Change of therapy could be done at each visit and include switching to the other NSAID if the prescribed drug proved to be ineffective or intolerant, local glucocorticoid (GC) injection, addition of tramadol with/without paracetamol or administration of antidepressants or anticonvulsants. The results of treatment were assessed based on the dynamics of pain using NRS, a number of patients in whom pain was relieved completely and treatment satisfaction (a 0 to 5 rating scale where 0 is the absence of the effect or pain aggravation and 5 is an excellent effect).

Results: The first prescribed medication in 97.5% of patients was oral NSAID (aceclofenac 200 mg per day) and in 67.6% of patients it was aceclofenac in combination with muscle relaxant. By visit 4, pain decreased from 6.9±1.5 to 2.2±1.3 points. Pain was completely relieved in 77.0% of patients. 227 patients (6.9%) dropped out of observation, and 16.1% of patients continued the use of analgesics after four weeks of treatment. The vast majority of patients (88.4%) evaluated treatment results as “good” or “excellent”. Switching to the other NSAID was required in 8.1% of patients, local injection of GC in 1.9%, administration of antidepressant or anticonvulsant in 1.5%, and hospitalization in 0.25% of patients. Adverse reactions (mostly dyspepsia) were noted in 2.2% of patients.

Conclusions: The use of treatment algorithm based on a complex pathogenetic approach ensures that patients receive an effective and relatively safe pain relief. Oral NSAIDs are the most expedient as first-line treatment in patients with moderate and severe musculoskeletal pain.

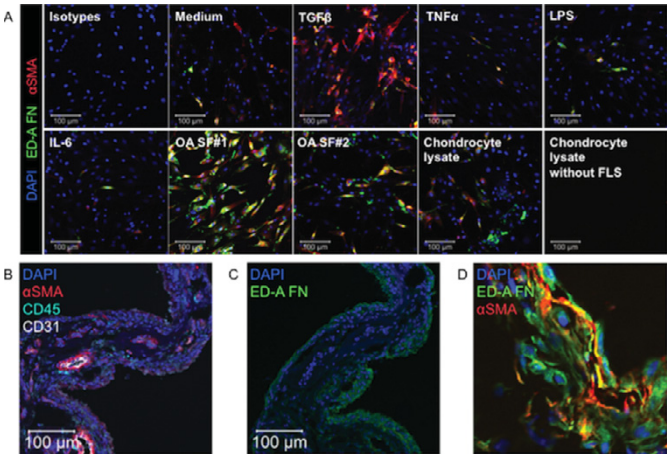
Regulatory molecules in connective tissue

OP0325 TGF-BETA-INDUCED ED-A FIBRONECTIN PRODUCTION BY FIBROBLAST-LIKE SYNOVIAL CELLS CONTRIBUTES TO INFLAMMATION IN OSTEOARTHRITIS



T.W. Kragstrup[1,2,3], D.H. Sohn[1,4], C.M. Lepus[1], K. Onuma[1], Q. Wang[1], W.H. Robinson[1], J. Sokolove[1]. *[1]Department of Immunology and Rheumatology, Stanford University, Stanford, United States; [2]Department of Rheumatology, Aarhus University Hospital; [3]Department of Biomedicine, Aarhus University, Aarhus C, Denmark; [4]Department of Microbiology and Immunology, Pusan National University, Pusan, Korea, Republic Of*

Background: The pathophysiology of osteoarthritis (OA) involves wear and tear, and a state of low-grade inflammation. Wear and tear leads to tissue degradation followed by tissue repair responses including TGFβ-induced myofibroblast production of extracellular matrix (ECM). Fibronectins are an essential part of the ECM, and injection of fibronectin fragments into rabbit joints is an established animal model of OA. Recently, alternatively spliced fibronectin containing the ED-A domain (ED-A FN) has been shown to activate Toll-like receptor 4.

Objectives: In this study, we hypothesize that FN fragments containing the ED-A domain could be one mechanism transducing mechanical events into inflammatory signals in OA.

Methods: Samples of synovial membrane and cartilage were obtained from patients with knee OA undergoing joint replacement surgery. Immunostaining was performed on synovial membranes. Fibroblast-like synovial cells (FLS) isolated by enzymatic digestion of remnant synovial membrane were stimulated with TGFβ, TNFα, lipopolysaccharide, IL-6, OA synovial fluid from two different donors, or chondrocyte lysate, and culture supernatants were analyzed for ED-A FN by immunofluorescence staining. ED-A FN fragments were obtained by plasmin digestion of cellular FN. Synovial cells isolated by enzymatic digestion and human monocyte-derived macrophages (MDM) were incubated with recombinant ED-A FN, plasmin, cellular FN, or cellular FN digested with plasmin; and culture supernatants were analyzed for MCP-1 and TNFα.

Results: We hypothesized that ED-A FN is produced by OA FLS in response to products reflecting tear and wear in OA. Indeed, the production of ED-A FN by OA FLS was increased by TGFβ, OA synovial fluid, and lysed chondrocytes in all experiments (n=3, see figure). ED-A FN co-localized with the myofibroblast marker αSMA in both the OA FLS (n=3) and in the OA synovial membranes (n=8). We further hypothesized that ED-A FN expression is associated with inflammation in OA. ED-A FN staining was associated with both number of lining layer cells (rho=0.85 and p=0.011) and infiltrating sublining cells (rho=0.88 and p=0.007) in the OA synovium (n=8), and co-localized with both MCP-1 and TNFα (n=5). Recombinant ED-A FN increased the production of both MCP-1 and TNFα by MDM (n=3) and OA FLS (n=3). Finally, we demonstrated that the FN fragments containing the ED-A domain generated the same production of both MCP-1 and TNFα as recombinant ED-A FN.

Conclusions: The disease process in OA shares features with the chronic

wound healing response including myofibroblast differentiation and that humeral mediators found in the joint can promote myofibroblast production of ED-A FN. We additionally show that recombinant and plasmin-derived ED-A fragments can induce generation of pro-inflammatory mediators from FLS and MDM. This study supports targeting the formation of ED-A FN or the enzymatic fragmentation of FN to reduce pro-inflammatory responses in OA.

OP0326 EPIGENETICALLY-DRIVEN DISTAL EXPRESSION OF THE LNCRNA HOTTIP SHAPES INFLAMMATORY, ADHESIVE AND PROLIFERATIVE CHARACTERISTICS OF HAND SYNOVIAL FIBROBLASTS IN ARTHRITIS

M. Frank Bertoncelj[1], E. Karouzakis[1], K. Klein[1], A. Bratus[2], C. Kolling[3], O. Distler[1], A. Filer[4], R.E. Gay[1], C.D. Buckley[4], S. Gay[1], C. Ospelt[1].
[1]University Hospital Zurich, Schlieren; [2]Functional Genomics Center Zurich; [3]Schulthess Klinik, Zurich, Switzerland; [4]University of Birmingham, Birmingham, United Kingdom

Background: Rheumatoid arthritis (RA) and other types of inflammatory arthritis show a characteristic pattern of joint involvement. E.g. in RA there is a predilection for the small joints of hands and feet, whereas in spondyloarthropathy, single large joints are characteristically involved. We have recently shown that synovial fibroblasts (SF), which drive joint destruction in RA, display site-specific transcriptomes and functions, shaping unique microenvironments in different joints.

Objectives: To analyze the role of transcripts expressed in SF at specific joint locations in defining location-specific functions of SF, relevant to the pathogenesis of RA.

Methods: SF were isolated from hand, elbow, shoulder, feet, knee and hip joints of RA and OA patients undergoing joint replacement surgery and from knees of nonarthritic subjects with arthralgia. Transcriptomes and epigenomes of SF were determined by RNA-seq (Illumina HiSeq 2000, n=21), qPCR, ChIP-seq (H3K4me3, H3K27me3, H3K27ac, Illumina HiSeq 2500, n=7) and Infinium HumanMethylation450 BeadChip (n=12). Proliferative, adhesive and chemotactic properties of SF were studied by xCELLigence real time cell analysis and leukocyte chemotaxis towards supernatants of SF. The lncRNA HOTTIP was silenced in hand SF using LNA GapmeR oligos, followed by RNA-seq (n=2), pathway enrichment analysis (MetaCore, Thomson Reuters, FDR$<$0.05) and qPCR (n=5).

Results: HOTTIP was the most differentially expressed transcript in distal (hand) vs. proximal (shoulder) SF. HOTTIP was specifically transcribed in SF from hand and feet SF, but absent from other joints, inferring distal-specific function to this lncRNA. Hand-specific HOTTIP expression coincided with the enrichment of activating histone marks H3K4me3 and H3K27ac, absence of repressive H3K27me3 and decreased DNA methylation at the HOTTIP promoter in hand SF. In contrast, the HOTTIP promoter displayed abundant DNA methylation and H3K27me3 in knee and shoulder SF. Silencing of HOTTIP led to downregulation of 3275 genes and upregulation of 4326 genes (log ratio $>|0.5|$, $p<0.01$, FDR$<$0.05). Distal-specific homeobox A13, a known HOTTIP target, was repressed in HOTTIP-silenced SF. Pathway enrichment analysis of genes repressed by HOTTIP silencing showed enrichment for pathways regulating cell adhesion, cell cycle, angiogenesis and inflammation, including NF-kB activation and IL-6 signalling. Meanwhile, upregulated genes were enriched in fewer pathways, e.g. IL17 and Notch signalling. 110 genes that were differentially expressed in hand vs. shoulder SF were also altered by HOTTIP silencing, e.g. TNFRSF1B and MAP3K14. Hand SF showed enhanced proliferative and chemotactic, but decreased adhesive properties compared to shoulder SF.

Conclusions: The lncRNA HOTTIP, which is exclusively expressed in small, distal joints, via epigenetic mechanisms, is a regulator of inflammatory, proliferative and adhesive properties of SF. Such a functional specialization of arthritis relevant pathways in SF might represent an imprinted site-specific "risk" signature in SF, predisposing thereby to location-specific joint pathology, e.g. enhanced severity of hand arthritis in RA.

Patient engagement in research: best practices, benefits and challenges

OP0327-PARE YOUR RHEUM – GIVING YOUNG PEOPLE A VOICE IN RHEUMATOLOGY RESEARCH

K. Cresswell[1,2], S. Parsons[1,2], S. Stones[3], J.E. McDonagh[4,5,6], W. Thomson[4,5,6], L. Lunt[7]. *[1]Public Programmes Team, Central Manchester NHS Foundation Trust, University of Manchester; [2]Manchester Academic Health Science Centre; [3]Public Contributor; [4]Arthritis Research UK Centre for Genetics and Genomics, Centre for Musculoskeletal Research, University of Manchester; [5]NIHR Manchester Musculoskeletal Biomedical Research Unit, Central Manchester NHS Foundation Trust, University of Manchester; [6]Barbara Ansell National Network for Adolescent Rheumatology; [7]Arthritis Research UK Centre for Epidemiology, Centre for Musculoskeletal Research, University of Manchester, Manchester, United Kingdom*

Background: Between 2014 and 2016, the Barbara Ansell National Network for Adolescent Rheumatology (BANNAR) commissioned research to explore young people's rheumatology research priorities and beliefs about research involvement. The next phase of this work has been to establish a UK-wide research advisory group, Your Rheum, to involve 11–24 year olds with rheumatic and musculoskeletal diseases (RMDs) more effectively in shaping research.

Objectives: To describe our experiences of developing a UK-wide research advisory group, for young people with RMDs, using both face-to-face meetings and online involvement approaches.

Methods: From September 2016, we recruited young people to the group using several approaches: including the previous research study database, through BANNAR members, through UK charities, such as Arthritis Care and via social media. To tailor options for involvement, young people were recruited to contribute to both face-to-face meetings and via online channels.

Results: Eight young people attended Your Rheum's first meeting in October 2016, where they discussed how they would like the group to work. Thirteen young people have been engaged online via a closed Facebook group, monitored by the Your Rheum facilitator. Key challenges in establishing the group have included developing age-appropriate communication approaches to appeal to the range of ages involved, devising ways of ensuring online members remain engaged with the group, and finding appropriate tasks for the group to be involved with, that are both suitable and aligned with research project timings. This involves working closely with young people, health professionals and researchers.

Conclusions: There is both a need for young people's involvement in research and a desire from young people themselves to do so. Expansion of the online network and involvement activities will allow young people across the UK to have a valuable input into research, regardless of location.

FRIDAY, 16 JUNE 2017

Latest advances in the treatment and management of psoriatic arthritis and the latest news on the use of biosimilars in RMDs

OP0328-PARE PATIENT SAFETY IN RELATION TO BIOSIMILARS – HOW CAN WE ACT AS A PATIENT ORGANIZATION?

L.M. Thomsen. *Danish Rheumatism Association, Gentofte, Denmark*

Background: During the last years two biosimilars has been approved by the national authorities in Denmark, and implemented in the treatment of patients with arthritis. When the first biosimilars were approved in 2015, the hospitals in Denmark decided to shift native patients from the original drug to the new biosimilar. This decision caused considerable insecurity among the patients, who were afraid of biosimilars and their effectiveness and safety profile. Therefore the Danish Rheumatism Association decided to implement an effort to create better patient information and safety for patients, who had to start with a biological drug or shift from one biological drug to another or to a biosimilar.

Objectives: The purpose of the effort was to increase patient safety and to ensure that patients received independent patient information within biological drugs.
Methods: First the Association conducted a small study of how the shift of drug had taken place in the different regions. Most patients experienced that they were told by the doctors to shift to biosimilars, and furthermore they experienced a lack of information about the new biosimilars. On a national level, nearly all patients on a biological drug are registered in a national database. It is registered in the database and hospital records which drug the patient are prescribed, but it is not registered on a batch-level.
In order to change these conditions the Association started a dialog with the politicians and the authorities on a national level and the hospital-administrations on a regional level. The purpose was to improve the registration of the drugs on batch-level, to improve more independent patient information and to improve the involvement of the patient in the decision making process. The dialog was on a general level, but with several patient-stories from each region.
Results: A new national plan for better monitoring and information about biologic and biosimilars was launched in august 2015 and carried out in 2016. The plan consists of four parts: 1) Monitoring biological drugs and biosimilars on batch level, 2) Information campaign to health professionals and patients, 3) Digital solutions and easy reporting of side effects from health professionals and patients, 4) Focus on monitoring patient safety by the authorities. The Danish Rheumatism Association has participated in the work to implement the plan. In addition to the national plan the hospitals on a regional level, has invited the Rheumatism Association to participate with a representative in the working group, where national recommendations for the use of biological drugs are being made in an attempt to involve the patient perspective more. The content of the national plan and the involvement in the work with national recommendations, will be elaborated and discussed from the patients perspective throughout the presentation.
Conclusions: The implementation of biosimilars created great insecurity among patients. Therefore, the Danish Rheumatism Ass. decided to make an effort to create better patient information and safety for the patients. Through dialog with politicians, national authorities and hospital-administrations, we managed to get a national plan for better monitoring and information about biologic and biosimilars, and to be involved in the work with national recommendations for these drugs. The national plan and work with national recommendations will be elaborated in the presentation.

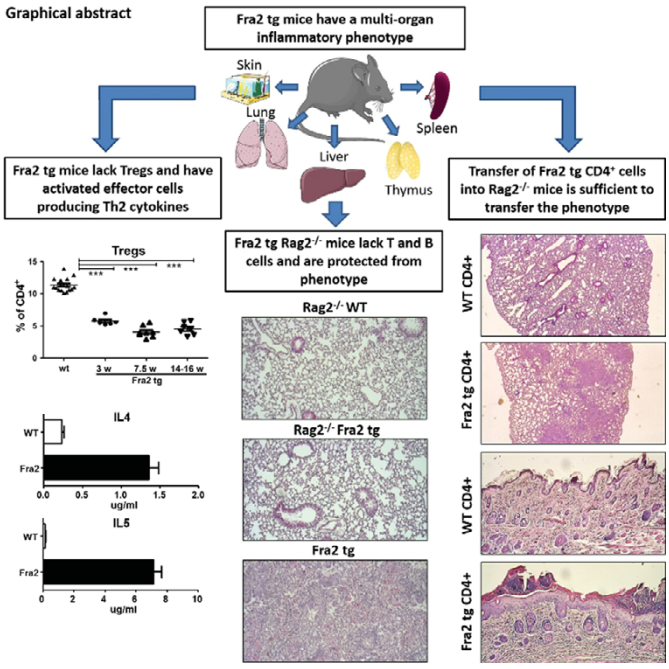
Switching T on and off: how T cells drive and regulate chronic inflammation

OP0329 INVOLVEMENT OF T HELPER 17 CELLS IN INFLAMMATORY ARTHRITIS DEPENDS ON THE HOST INTESTINAL MICROBIOTA



H. Evans-Marin[1], R. Rogier[2], J. Scher[1], D. Roeleveld[2], M. Koenders[2], S. Abdollahi-Roodsaz[1,2]. *[1]Medicine, New York University School of Medicine, New York, United States; [2]Rheumatology, Radboud university medical center, Nijmegen, Netherlands*

Background: Intestinal microbiota have been associated with psoriatic and rheumatoid arthritis. One of the major effects of microbiota is the induction of mucosal T helper 17 (Th17) cells. We therefore reasoned that the efficiacy of Th17-targeted therapies in arthritis may depend on the host microbiota. Previous studies focused on the role of the cytokine interleukin-17A (IL-17), rather than Th17 cells, by using IL-17 inhibitors or IL-17-deficient mice. Therefore, the role of Th17 cells, which produce multiple pro-inflammatory mediators in addition to IL-17, is not yet fully understood.
Objectives: The aim of this study was to determine the role of Th17 cells, beyond the cytokine IL-17, in arthritis, and to investigate whether Th17 cells are differentially involved in arthritis depending on the microbiota present.
Methods: We established conditional Th17-deficient mice, which exhibit a CD4-Cre-induced floxing of a part of the Rorc allele that encodes the Th17 master regulator RORγt. We compared the development of collagen-induced arthritis in Th17-deficient (CD4-Cre$^+$ Rorc$^{flox/flox}$) and -sufficient (CD4-Cre$^-$ Rorc$^{flox/flox}$) littermate mice, either colonized with known Th17 cell inducers segmented filamentous bacteria (SFB) or harboring the SFB-free Jackson microbiota. The abundance of Th1 and Th17 cells and the production of IL-17, IFNγ and GM-CSF were quantified by flow cytometry and multiplex cytokine assay.
Results: CD4-Cre$^+$ Rorc$^{flox/flox}$ mice had significantly lower Th17, but similar Th1 cell abundance, in intestinal lamina propria compared with Cre$^-$ littermate controls. Surprisingly, the total amount of IL-17A production by all lamina propria cells during arthritis was rather increased in Th17-deficient mice, with CD8$^+$ T cells and Gr1$^+$ neutrophils being the main alternative sources of IL-17. Despite this increased total IL-17 levels, conditional Th17-deficient mice developed a less severe arthritis compared with Th17-sufficient mice when intestinal microbiota comprised SFB. This suggests a role for Th17 cells in inflammatory arthritis distinct from IL-17. Accordingly, synovial inflammation, cartilage destruction and proteoglycan depletion were reduced in SFB-colonized Th17-deficient mice. While the production of IL-17 by joint-draining lymph node cells stimulated with PMA and ionomycin was similar between Th17-sufficient and –deficient mice, cells from the latter group produced significantly less IL-17 upon antigen-specific stimulation with type II collagen. Furthermore, the production of GM-CSF, another Th17 cell-derived cytokine, was significantly lower in the lymph nodes of Th17-deficient mice, an effect associated with the protection against arthritis. Importantly, substitution of the intestinal microbiota with SFB-free Jackson microbiota resulted in the loss of Th17 cell dependency of arthritis as Th17-sufficient and –deficient mice showed similar disease progression under this condition.
Conclusions: These data suggest that Th17 cells may mediate inflammatory arthritis partly through IL-17-independent mechanisms. Our observations also suggest that the involvement of Th17 cells in arthritis depends on the microbiota subset present in the host. Therefore, a microbiome-guided stratification of rheumatoid or psoriatic arthritis patients might improve the efficacy of Th17 (or IL-17)-targeted therapies.

OP0330 FRA2 OVEREXPRESSION LEADS TO SYSTEMIC AUTOIMMUNITY BY DECREASING IL-2 RESPONSIVENESS AND THYMIC TREG DEVELOPMENT

F. Renoux[1], M. Stellato[1], D. Impellizzieri[2], A. Vogetseder[3], R. Huang[4], A. Subramaniam[4], C. Dees[5], J.H.W. Distler[5], G. Kania[1], O. Boyman[2], O. Distler[1]. *[1]Department of Rheumatology; [2]Department of Immunology, University Hospital Zurich, Zurich; [3]Pathology, Luzerner Kantonspital, Lucerne, Switzerland; [4]Immune Mediated Diseases, Sanofi-Genzyme, Framingham, United States; [5]Department of Internal Medicine 3, University of Erlangen-Nuremberg, Erlangen, Germany*

Background: Fos-related antigen 2 (Fra2) is a transcription factor belonging to the Fos family proteins which is part of the AP-1 transcription complex. We recently described a Fra2 transgenic (tg) mouse model which develops a multi-organ inflammatory phenotype affecting skin, lungs, thymus, liver and salivary glands. We have observed abnormalities in the T cell compartment, particularly in regulatory T (Treg) cells, which led us to hypothesize that Fra2 tg mice develop a T cell driven autoimmune phenotype.
Objectives: To demonstrate the autoimmune phenotype of Fra2 tg mice and to characterize the mechanisms leading to Treg cell abnormality.
Methods: We used previously generated Fra2 tg overexpressing mice. T lymphocyte populations were analyzed by flow cytometry for expression of activation markers and secretion of cytokines. We transferred purified CD4+ T cells into Rag2-/- mice lacking T and B cells, and we generated Rag2-/-Fra2 tg mice. Bone marrow cells were transferred into lethally irradiated recipients to create Fra2-WT bone marrow chimeric mice.
Results: Fra2 tg mice backcrossed onto a Rag2$^{-/-}$ background did not develop inflammatory manifestations (n=6), demonstrating the dependence on T and/or B cells of the autoimmune phenotype. In line with this, the transfer of purified CD4$^+$ cells from 16 week-old Fra2 tg mice into Rag2$^{-/-}$ recipients was sufficient to transfer the disease phenotype (n=3). Analysis of T cell populations from Fra2 tg mice showed the presence of activated CD4$^+$ and CD8$^+$ cells in the spleen

and lungs. After *in vitro* stimulation, we found that $CD4^+$ T cells from Fra2 tg mice produced the Th2 cytokines IL-4, IL-5 and IL-13. Thus, these data strongly suggest a T cell-driven autoimmune disease in these mice.
We previously reported a striking decrease of Treg cells in Fra2 tg mice, which might explain the autoimmune phenotype observed. Supporting this idea, we found that 3 week-old mice were devoid of organ manifestations and of T cell activation, but presented the same defect in the Treg cell population (n=6, $p<0.001$). Analysis of thymuses from these young tg mice showed an abnormal development of thymic Treg (tTreg) cells. In particular, we could observe a normal population of tTreg precursors ($CD4^+CD8^-CD25^+FoxP3^-$), but a strong decrease in mature tTreg cells ($CD4^+CD8^-CD25^+FoxP3^+$, n=4), suggesting a perturbation in the transition from tTreg precursors to mature tTreg cells in Fra2 tg mice. We also found that *in vivo* stimulation with IL-2 failed to induce the proliferation of Treg cells in Fra2 tg mice compared to WT mice, suggesting that Fra2 overexpression affects IL-2 sensitivity of T cells. Finally, Fra2-WT bone marrow chimera mice also displayed a decreased percentage of Tregs confirming a cell-intrinsic and hematopoietic role of Fra2 in Treg cell development.
Conclusions: Our data suggest that Fra2 controls tTreg cell development, possibly by modulating IL-2 signaling in T cells, which leads to autoimmunity in this mouse model. This new pathway could be targeted in a translational approach to modulate the capacity of T cells to differentiate in Tregs during autoimmune disease.

Reverse translation - learning from clinical trials in SLE, Sjögren's and APS

OP0331 A NOVEL HUMANIZED EFFECTOR-DEFICIENT FCYRIIA ANTIBODY INHIBITS IMMUNE COMPLEX MEDIATED PROINFLAMMATORY RESPONSES

B. Chen[1], K. Vousden[2], S. Turman[1], H. Sun[1], S. Wang[1], L. Vinall[2], B. Kemp[2], S. Kasturiangan[1], E. Grant[1], M.J. Hinrichs[1], S. Eck[1], A. DiGiandomenico[1], X. Xiong[1], J. Griffiths[1], R. Herbst[1], D. Close[2], R. Kolbeck[1], G. Sims[1].
[1]MedImmune Inc, Gaithersburg, United States; [2]MedImmune Inc, Granta Park, United Kingdom

Background: Collectively, the cell surface Fc region of IgG receptors (FcγRs) engage soluble IgG and IgG containing immune complexes and trigger activation or inhibtory signals that play a critical role in the regulation of immune responses. The low affinity FcγRIIA (CD32A) is the most widely expressed activating FcγR in humans and appears to drive autoantibody and immune complex mediated autoimmune disorders. So far a therapeutic targeting this receptor has not been developed.
Objectives: To generate and characterize a novel humanized effector-deficient FcγRIIA antibody (MEDI9600) for clinical development.
Methods: The mode of action of MEDI9600 was assessed by confocal microscopy, whole blood internalization, and binding competition assays. Multiple cell based assays were used to measure autoantibody and immune complex mediated responses.
The safety of MEDI9600 was assessed in *in vitro* by neutrophil migration, activation and opsonophagocytic killing assays. Safety and pharmacokinetics were examined *in vivo* in a single-dose PK/PD study in cynomolgus monkey.
Results: We generated a humanized effector-deficient FcγRIIA antibody (MEDI9600) that potently blocks both autoantibody and immuno complex-mediated proinflammatory responses from a variety of cell types. This includes the inhibition of Toll-like receptor stimulatory immune complexes that induce type I Interferons from pDC, and the inhibition of anti-neutrophil cytoplasmic antibody (ANCA) induced production of reactive oxygen species from neutrophils, which are associated with the pathogenesis of systemic lupus and ANCA vasculitis respectively. MEDI9600 specifically binds FcγRIIA and its suppressive activity is attributed to its capacity to block ligand engagement and to internalize the receptor from the cell surface. Moreover, *in vivo* studies indicate that MEDI9600 has a favorable pharmacokinetic and safety profile.
Conclusions: We have generated MEDI9600, a specific humanized antibody antagonist of FcγRIIA with null effector function that may provide a novel therapeutic approach in the treatment of immune complex mediated diseases.

Background: SLE displays significant immunological and clinical heterogeneity. Understanding the molecular basis of this variability may facilitate early diagnosis, risk stratification and personalized therapy.
Objectives: To perform full transcriptome analysis in SLE patients in order to identify molecular sub-phenotypes and explore the genomic basis for the disease susceptibility and severity.
Methods: Whole blood mRNA and genomic DNA were extracted from 142 SLE patients with varying levels of disease activity/severity and 48 matched healthy volunteers. Paired-end RNA sequencing was performed using the Illumina HiSeq 2000 platform and genotyping with the Infinium CoreExome followed by imputation from the 1000 Genomes. To integrate blood transcriptome with genotype data we used the enrichment analysis of expression-quantitative trail loci (eQTLs). The CIBERSORT tool was used to provide an estimation of the abundancies of different circulating immune cell types.
Results: We found a large number (6730, 5% False Detection Rate [FDR]) of differentially expressed genes (DEGs) between SLE patients and controls. Interferon signaling was significantly upregulated in SLE with most of the DEGs (146 out of 281) being regulated by both type I and type II interferon. Analysis of the blood composition in different immune cell types revealed global upregulation of type I interferon and antiviral response genes as well as immune cell-specific alterations in gene expression in SLE patients. Comparison of the transcriptome in active/inactive SLE and healthy individuals identified distinct "disease susceptibility" and "disease activity" gene signatures encompassing 2738 and 377 DEGs, respectively. Analysis according to individual organ involvement revealed more widespread aberrancies in gene expression in SLE patients with active nephritis as compared to activity from other organs, corresponding to oxidative phosphorylation, granulocyte activation and antimicrobial humoral response pathways. By integration of genotyping data, we mapped a total 3142 (5% FDR) *cis*-eQTLs in SLE patients suggesting extensive genetic effects on whole blood gene expression. Importantly, linear discriminant analysis enabled the definition of a set of DEGs which discriminated SLE versus healthy state with median sensitivity 83% and specificity 100%. Design of gene expression panels and expression profile/clinical trait correlation matrices for improved diagnostics, stratification and personalized therapy is in progress.
Conclusions: Specific gene networks confer susceptibility to SLE as well as to severe forms of the disease. These results may facilitate the early diagnosis, monitoring and prognosis, and the molecular taxonomy of SLE patients into pathophysiologically and prognostically distinct subsets for personalized therapy.

OP0333 DISCOVERY AND VALIDATION OF NOVEL AUTOANTIGENS IN SJÖGREN'S SYNDROME WITH POTENTIAL FOR SUBGROUPING OF DISEASE

P.K. Schulz-Knappe[1], P. Budde[1], H.-D. Zucht[1], D. Wirtz[1], K. Marquardt[1], R. Thomas[1], T. Witte[2], M. Schneider[3], K. Sivils[4], A. Rasmussen[5]. *[1]Protagen, Dortmund; [2]Dept. of Clinical Immunology and Rheumatology, Hannover Medical School, Hannover; [3]Dept. of Rheumatology, Heinrich Heine University, Düsseldorf, Germany; [4]Oklahoma Sjogren's Syndrome Center of Research Translation; [5]Oklahoma Medical Research Foundation, Oklahoma, United States*

Background: Primary Sjögren's syndrome (pSS) is a common autoimmune disease with exocrine gland dysfunction and multi-organ involvement. With the growing interest in conducting clinical trials in pSS, there is a need for new biomarkers that can be used to diagnose pSS, identify clinical subsets of pSS, predict treatment outcome and assessment of disease activity. Activation of B-cells and dysregulation of the cytokine network plays a critical role in the pathophysiology of pSS. In the exocrine glands, elevated levels of cytokines, such as type I interferon (IFN), tumor necrosis factor alpha (TNF), interleukin 12 (IL-12) and B cell activating factor (BAFF) can be found. Dysregulated pathways of the innate and adaptive immune system lead to loss of tolerance and the production of organ-specific and non-specific autoantibodies. Current diagnostic criteria for pSS utilize autoantibodies directed to nuclear antigens (ANA), especially to SS-A/Ro (TRIM21, TROVE2) and La (SSB), but those are not specific, and can be identified as well in SLE and even in healthy volunteers. Several studies have shown that not all patients with pSS are tested positive for Ro and La autoantibodies, but suggested the existence of additional autoantibodies in pSS. This autoantibody burden is not well understood for the importance of disease progression, for its role in patient segmentation, or for response to treatments.
Objectives: The discovery of novel autoantigens may provide a deeper understanding of mechanisms of actions for pSS drugs, and may be useful to stratify patients.
Methods: The autoantibody reactivity pattern of pSS serum patients was analyzed using a Luminex bead-based antigen array (SeroTag) and 1,600 selected human protein antigens from our hPEX protein library of 8,000 recombinant proteins (1). We screened over 2,000 serum samples from patients with autoimmune diseases as active controls targeting Sjögren's Syndrome (n=70), SLE (n=>500), SSc (n=>250), RA (n=>500), and over 1,000 healthy individuals to confirm known and to discover novel autoantibodies. In a validation study, novel biomarker candidate antigens were evaluated using a cohort of 350 Patients with Sjögren's Syndrome.
Results: Apart from clear confirmation the known benchmark autoantigens known for many years we have discovered a small set of additional, novel autoantibodies, which were detected in frequencies of 8 to >20% in pSS. Accumulation of autoantibody reactivities allows for a first subgroup definition of Sjögren's, and for clear segregation of SjS/SLE overlap syndrome patients.
Conclusions: A set of novel autoantigens for diagnosis and subgroup definition in Sjögren's syndrome was discovered by high content screening using a Luminex bead-based array platform. Validation in additional, large patient cohorts is ongoing.

Optimizing treatment for osteoarthritis: take the phenotype in account "one size does not fit all"

OP0334 PREDICTORS AND MRI-DETECTED STRUCTURAL PATHOLOGY WITH TRAJECTORIES OF KNEE PAIN SEVERITY: A 10.7-YEAR PROSPECTIVE STUDY

F. Pan[1], J. Tian[2], D. Aitken[1], F. Cicuttini[3], C. Ding[1], G. Jones[1]. *[1]Musculoskeletal Unit; [2]Public Health, Menzies Institute for Medical Research, University of Tasmania; [3]Department of Epidemiology and Preventive Medicine, Monash University Medical School, Hobart, Australia*

Background: Knee pain is the most common manifestation of knee osteoarthritis (OA) and is generally thought to get worse with time. Risk factors for knee pain have been extensively investigated; however, whether the risk factors are associated with a specific pain trajectory has not yet been comprehensively explored. Furthermore, knee structural pathology on MRI, such as bone marrow lesions (BMLs), effusion-synovitis and cartilage defects, are thought to be the origin of knee pain. However, its underlying mechanisms remain to be elucidated and hampered by a large individual variation of pain course.
Objectives: To identify distinct trajectories of knee pain over 10.7 years in an older population, to describe risk factors with identified trajectories, and to explore MRI-detected structural pathology with the trajectories.
Methods: 1,099 participants (mean age 63 years) from a population-based cohort study were recruited at baseline. 875, 768 and 563 participants attended years 2.6, 5.1 and 10.7 follow-up, respectively. Demographic, psychological, lifestyle and comorbidities data were obtained at baseline. Knee pain was assessed using Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) at each time-point. T1-weighted or T2-weighted MRI of the right knee was performed to measure knee structural pathology. Knee radiographic OA was assessed by X-ray at baseline. Group-based trajectory modelling was applied to identify pain trajectories. Multi-nominal logistic regression was used for the analyses with adjustment for potential confounders.
Results: 1,099 participants were included for the identification of pain trajectories and three distinct pain trajectories were defined. Participants in Group 1 ("Mild pain" n=568, 51.7%) had relatively stable mild pain over time. Participants in Group 2 ("Moderate pain", n=366, 33.2%) had moderate pain over time. Participants in Group 3 ("Severe pain", n=165, 15.1%) developed or displayed fluctuating severe pain over time. Compared with the "Mild pain", higher BMI, emotional problems, and musculoskeletal diseases were significantly associated with both "Moderate pain" and "Severe pain" trajectories. Also, younger age, lower education level and unemployment status were associated with "Severe pain" trajectory. The presence of cartilage defects and BMLs were associated with increased risk of "Moderate pain" and "Severe pain" trajectories before or after adjustment for potential confounders. Effusion-synovitis was not statistically associated with "Moderate pain" (P=0.082), but associated with "Severe pain" trajectory. Furthermore, a dose-response relationship was observed between number of knee structural abnormalities, and "Moderate pain" and "Severe pain" trajectories (both P for trend<0.001).
Conclusions: This is the first long-term study to identify pain trajectories and their risk factors, and explore the associations between structural pathology and pain trajectories. Three distinct pain trajectory groups were identified, suggesting that homogeneous subgroups exist and follow a specific trajectory over time despite large individual variation of pain course. Significant associations between structural pathology and pain trajectories suggest that peripheral stimuli may play a role in the development and maintenance of pain severity.

OP0335 EXPLORING ASSOCIATIONS BETWEEN HISTOLOGICALLY ASSESSED INFLAMMATION AND PAIN AND FATIGUE IN KNEE OSTEOARTHRITIS

M.J. Minten[1], A. Blom[2], G.F. Snijders[2], F.H. van den Hoogen[2,3], A.A. den Broeder[2,3], P. van der Kraan[2], C.H. van den Ende[1,2]. *[1]Dept. of Research, Sint Maartenskliniek; [2]Dept. of Rheumatology, Radboud University medical center; [3]Dept. of Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands*

Background: Pain and fatigue are frequent symptoms of osteoarthritis (OA). However, the exact mechanism causing these symptoms remains unclear. Inflammation is important in OA pathophysiology. Associations between inflammatory aspects and clinical outcomes have been found. However, mainly (contrast-enhanced) MRI was used to assess synovial inflammation in these studies. Using this method, inflammation is assessed in an indirect way (e.g. infrapatellar fat pad signal enhancement, synovial fluid effusion and thickening of synovial tissue). Conversely, histological assessment of synovial inflammation is regarded as the gold standard. Using this method, specific aspects of inflammation can be distinguished and rated for severity.
Objectives: To evaluate the associations of inflammation-related histological parameters of the synovium with pain and fatigue in knee OA patients.
Methods: Fifty-nine patients fulfilling ACR criteria for knee OA were recruited from two prospective studies[1,2] and gave consent for synovial biopsy using a mini knee arthroscopy. Biopsies were taken from visually inflamed areas of the synovium. Tissue sections were histologically assessed for 1) number of synovial lining cells (absolute); 2) sub-synovial infiltration; 3) fibrin deposition; 4) vascularization; 5) fibrosis; and 6) perivascular edema (scores 0–3).[3] Average scores across sections were calculated for each parameter and for all parameters together. These data were combined with longitudinal clinical data from the prospective studies (WOMAC pain, SF36 vitality; 0=worst – 100=best). Associations between individual inflammatory features and clinical outcomes over time were assessed with mixed model analyses.
Results: Patient characteristics are shown in Table 1. Relatively mild levels of inflammation were found, in line with previous research (median 1.1 [95% CI 0.9–1.6]).[3,4] Longitudinal data was available for 56 patients. Age, gender, BMI and time since symptom onset were no confounders. No significant associations were found between any histological parameter and pain or fatigue over time (Table 2).

Table 1. Patient characteristics

	Mean (Sd)
Male/Female	28/31
Age (years)	56.4 (9.8)
Symptom duration (years)	10.1 (10.3)
BMI (kg/m^2)	29.7 (5.9)
Follow-up (years)	1.2 (0.8)

Conclusions: This is the first study to examine different parameters of histologi-

Table 2. Longitudinal associations

	Median [25–75%]	Pain ß [95% CI]	Fatigue ß [95% CI]
Synovial lining cells	2.4 [1.5–3.2]]	0.5 [-2.9–3.9]	-2.3 [-5.6–1.0]
Infiltrate	1.2 [0.5–1.8]	2.9 [-4.3–10.1]	-4.7 [-11.6–2.3]
Fibrin	0.0 [0.0–0.4]	-7.1 [-17.7–3.4]	-0.1 [-10.1–10.0]
Vascularization	1.6 [1.0–2.0]	-1.2 [-8.3–5.9]	-0.5 [-7.2–6.3]
Fibrosis	0.8 [0.2–1.3]	-3.3 [-10.4–3.8]	0.8 [-6.3–7.9]

SATURDAY, 17 JUNE 2017

Targeting adipose tissue inflammation

OP0336 ROLE OF SYSTEMIC INFLAMMATION ASSOCIATED WITH RHEUMATOID ARTHRITIS IN THE GLUCOSE AND LIPID METABOLISM: HUMANS, CIA MOUSE MODEL AND IN VITRO STUDIES

I. Arias de la Rosa[1], S. Rodriguez-Cuenca[2], Y. Jimenez-Gomez[1], P. Ruiz-Limon[1], C. Perez-Sanchez[1], M.C. Abalos[1], I. Cecchi[1], J. Calvo[1], R. Guzman[3], M. Malagon[3], E. Collantes[1], A. Vidal-Puig[2], C. Lopez-Pedrera[1], A. Escudero-Contreras[1], N. Barbarroja[1]. *[1]Rheumatology Service, IMIBIC/Reina Sofia Hospital/University of Cordoba, Cordoba, Spain; [2]Metabolic Research Laboratories, Wellcome Trust-MRC Institute of Metabolic Science, Addenbroke's Hospital, University of Cambridge, Cambridge, United Kingdom; [3]Department of Cell Biology, Physiology, and Immunology, IMIBIC/Reina Sofia Hospital/University of Cordoba, Cordoba, Spain*

Background: Rheumatoid arthritis (RA) patients are at higher risk for insulin resistance (IR). The association between RA and IR, and its role on the different characteristics of the disease, such as duration and activity have not been well defined. In addition, there is a gap of knowledge regarding the link between systemic/local inflammation and insulin sensitivity and lipid metabolism in RA patients.
Objectives: To explore the effects of the inflammation on the glucose and lipid metabolism in the RA context, following three strategies: RA patients, collagen induced arthritis (CIA) mouse model and in vitro treatment of 3T3L1 adipocytes.
Methods: *Human study:* 150 RA patients and 40 healthy donors were included. IR was quantified using the homeostatic model assessment of IR (HOMA-IR). *Mouse model:* 20 CB57J/BL mice were used; 5 mice were used as non-diseased group, and 15 were used in CIA modelling: sorted in low and high activity of the disease based on the number of inflamed digits depending on the duration of the disease. Plasma, leukocytes, skeletal muscle, liver and adipose tissue were collected. *Treatment of adipocytes with serum from RA patients:* 3T3L1 adipocytes were treated with serum 10% of RA patients and healthy donors for 24h. The expression of genes and proteins involved in inflammation, lipid metabolism and insulin signalling was analysed in all the tissues and cells.
Results: Percentages of obesity, hypertension, atherogenic risk, metabolic syndrome and insulin resistance were significantly increased in the RA group. Although mean time of evolution was 7 years, no association between IR and the duration of the disease was found. Levels of HOMA-IR significantly correlated with DAS28 and C-reactive protein levels, suggesting that systemic inflammation might lead to the development of insulin resistance. In mice, the induction of arthritis promoted an alteration of the expression of genes involved in inflammation as well as lipid metabolism and insulin signalling in all the metabolic tissues and leukocytes, pointing out to an increase in lipolysis, decrease in adipogenesis and lipid accumulation and induction of IR. These results were recapitulated after treatment of adipocytes with serum from RA patients with high disease activity.
Conclusions: 1) IR was closely associated with an increase in disease activity and systemic inflammation in RA patients. 2) Induction of arthritis in mice promoted an increase in inflammation markers in skeletal muscle, adipose tissue and leukocytes, and a reduction of genes involved in lipid uptake and storage, generating an insulin resistance state in those tissues. 3) The inflammatory components in RA serum induced lypolisis, reduced adipogenesis, and increase inflammation and insulin resistance in adipocytes 3T3L1.
In sum, our results suggest that chronic inflammation associated with RA might directly impact relevant metabolic tissues, altering glucose and lipid homeostasis and favouring the development of insulin resistance.

Trials and tribulations of medication adherence

OP0337-HPR PREDICTORS OF PATIENT REPORTED DECISION TO DISCONTINUE ANTI-RHEUMATIC MEDICATION IN RHEUMATOID ARTHRITIS PATIENTS: DATA FROM A RHEUMATOID ARTHRITIS COHORT

V. Ahluwalia[1], M. Movahedi[2,3], E. Rampakakis[3], A. Cesta[2], X. Li[2], S. Couto[2], J. Sampalis[3], C. Bombardier[2,4,5] on behalf of OBRI investigators. *[1]Department of Rheumatology, Brampton Civic Hospital, William Osler Health System, Brampton; [2]Ontario Best Practices Research Initiative, Toronto General Hospital, University Health Network, Toronto; [3]JSS Medical Research, Montreal; [4]Department of Medicine (DOM) and Institute of Health Policy, Management, and Evaluation (IHPME), University of Toronto; [5]Division of Rheumatology, Mount Sinai Hospital, Toronto, Canada*

Background: Despite the availability of safe and effective treatments and the establishment of treatment guidelines, real-world effectiveness remains suboptimal largely due to low patient adherence with prescribed treatment.
Objectives: The purpose of this study was to systematically evaluate sociodemographic, health insurance, and disease-related factors associated with patient reported decision for discontinuation of anti-rheumatic medications (ARM) in a large observational cohort of RA patients followed in Canadian routine clinical care.
Methods: RA patients enrolled in the Ontario Best Practices Research Initiative (OBRI) clinical registry and had at least two years of follow-up were included in the analysis. Treatment discontinuation due to patient reported decision was defined as ARM discontinuation. Independent predictors of ARM discontinuation were evaluated with multivariate cox-regression using both time-fixed and time-dependent variables. Factors considered included patient sociodemographics (age, gender, race, education status, annual income, smoking history), health insurance information (private vs. non-private, % coverage), disease parameters (RA duration, presence of erosion, RF positivity, DAS28, physician global, HAQ-DI, number of comorbidities), types of medications used, and physician characteristics (gender, academic position, urban vs. rural, distance from patient's residence).
Results: A total of 1,762 patients were included in the analysis with a mean (SD) age of 57.4 (13.0) years and disease duration of 8.5 (9.3) at the time of enrolment to the registry (baseline). The majorities of patients were female (77.7%), had post-secondary education (55.3%), and had private insurance (67.2%). In terms of disease severity, 54.5% had prior erosion, 69.5% were RF positive, and mean (SD) DAS28 was 4.5 (1.5).
In a multivariate analysis, married status (HR, 0.73; 95% CI 0.56–0.96), RF positivity (HR, 0.73; 95% CI 0.56–0.96), and higher number of comorbidities (HR, 0.92; 95% CI 0.85–0.99) were identified as significant predictors of ARM continuation while higher physician global score (HR, 1.10; 95% CI 1.04–1.15), NSAID use (HR, 1.75; 95% CI 1.29–2.38), and polypharmacy (HR, 1.23; 95% CI 1.07–1.40) were associated with ARM discontinuation due to patient reported decision.
Conclusions: In this systematic approach a variety of factors encompassing sociodemographics, disease, and medication characteristics, were identified as significant independent predictors of ARM discontinuation due to patient reported decision. These results should be taken into consideration when developing patient adherence support programs and in the choice of treatment regimens.

Outcome in juvenile idiopathic arthritis

OP0338 FREQUENCY OF COMORBIDITIES IN JIA PATIENTS – RESULTS OF AN OBSERVATIONAL COHORT STUDY

K. Minden[1], N. Betenstehl[2], J. Klotsche[1], E. Seipelt[3], S. Tatsis[4], I. Foeldvari[5], G. Ganser[6], G. Horneff[7]. *[1]Epidemiology Unit, German Rheumatism Research Centre, Berlin; [2]Oberhavelkliniken, Hennigsdorf; [3]Immanuel Krankenhaus Berlin-Buch, Berlin; [4]Kath. Marienkrankenhaus; [5]Zentrum für Kinder- und Jugendrheumatologie, Hamburg; [6]St. Josef-Stift, Sendenhorst; [7]Asklepios Kinderklinik, Sankt Augustin, Germany*

Background: Juvenile idiopathic arthritis (JIA) is a chronic inflammatory disease that often persists into adulthood. In addition to disability and poorer quality of life, JIA is associated with increased long-term morbidity and mortality. The long-term risk of comorbidities in JIA patients is uncertain and guidance on risk assessment is not currently available.
Objectives: To determine the frequency of comorbid conditions in adult JIA patients.
Methods: Patients with JIA transferred from the biologic registry BIKER to the follow-up (FU) registry JuMBO were included in this analysis. All comorbidities, except for serious infections, prospectively recorded by physicians to BiKeR or JuMBO were considered. Comorbidity rates among the various JIA categories were assessed. The Medical Dictionary for Regulatory Activities (MedDRA) was used for disorder coding. Differences in the occurence of comorbidities between JIA categories were analyzed by multinomial logistic regression.
Results: A total of 1,022 young adults (67% female) with JIA and a mean FU of 7.8 (SD=3.5) years (ys) were included in this analysis. The patients' mean age was 22.5 ys (SD=3.7), and disease duration was 12.9 ys (SD=5.9) at the last FU. The majority were classified as polyarticular JIA (36.4%) at BiKeR enrollment. Patients had received a mean of 2.9 (SD=1.3) DMARDs, 77% were ever treated with biologics.
Comorbidities were reported for more than half of the patients (54%), 24.5% of the conditions were stated for the first time in adult age. Eye disorders were the most common comorbid condition group (15.1%), followed by skin and subcutaneous tissue disorders (9.3%), and psychiatric disorders (5.5%). The most frequently reported single diseases were uveitis in 14.4%, chronic secondary pain syndrome in 4.4%, hypertension in 3.6%, and psoriasis in 3.3%. In addition, inflammatory bowel diseases were reported in 2.5% of cases, other immune-mediated disorders, namely autoimmune thyroiditis in 2.5%, type1 diabetes in 0.7% and celiac disease in 0.3%, depression in 2.3%, anxiety in 0.3%, osteoporosis in 1.6%, and amyloidosis in 0.4%. Among the reported comorbidities, there was one case with a cerebrovascular accident, but none with ischemic heart disease, heart failure or diverticulitis. The rate of comorbid condition accrued in the various JIA categories (table 1) differed significantly, with the highest rate in patients with extended oligoarthritis.

Table 1: Frequency of major comorbidities (in %) in the various JIA categories in young adult age

Comorbid condition	Sys JIA	OA, persist.	OA, ext.	PA, RF-	PA, RF+	ERA	PsA	P value
	N= 48	N=97	N=169	N=278	N=94	N=205	N=97	
Any comorbid condition	58.3	47.2	64.1	45.7	47.9	51.7	62.9	0.007
Uveitis	4.2	14.4	34.9	7.9	0	16.6	10.3	<0.001
Psoriasis	2.1	1.0	0.6	1.1	0	3.4	19.6	<0.001
IBD	4.2	0	3.6	1.4	1.1	3.4	5.2	0.233
Hypertension	10.4	2.1	4.1	2.5	2.1	3.4	3.1	0.032
Osteoporosis	10.4	0	1.8	1.8	1.1	0	1.0	<0.001
Amyloidosis	4.2	0	0	0.4	0	0	0	0.001
Chronic secondary pain syndrome	2.1	5.2	4.7	6.1	3.2	4.9	1.0	0.394
Depression	4.2	1.0	2.4	2.2	1.1	2.4	3.1	0.927
Autoimmune thyroiditis	2.1	1.0	1.8	2.2	5.3	1.5	6.2	0.156
Type 1 diabetes	0	0	0	1.1	2.1	1.0	0	0.445
Celiac disease	0	0	0.6	0	1.1	0	0	0.202

Sys JIA - Systemic JIA; OA persist. – Oligoarthritis persistent; OA, ext. – Oligoarthritis extended; PA - Polyarthritis; RF- - Rheumatoid factor negative; RF+ - Rheumatoid factor positive; ERA - Enthesitis-related arthritis; PsA - Psoriatic arthritis; IBD – inflammatory bowel disease

Conclusions: Young adults with JIA have a high rate of comorbidity overall, with extraarticular JIA manifestations being the most frequently reported comorbid conditions. Comorbidity rates vary among the various JIA categories. Patients with systemic JIA have the highest rate of cardiovascular risk factors and osteoporosis, while patients with extended OA have the highest rate of uveitis. An underreporting or unawareness of comorbidities by rheumatologists is possible, guidance on risk assessment in adults with JIA is needed.
Acknowledgements: The authors thank all rheumatologists for contributing patients to the JuMBO registry. BiKeR is funded by unconditional grants from Abbvie, Germany, Novartis, Germany, and Roche, Germany, JuMBO by unconditional grants from Abbvie, Pfizer, and Roche.

Systemic sclerosis

OP0339 IDENTIFICATION OF A TRANSCRIPTOMIC SIGNATURE CORRELATED WITH MODIFIED RODNAN SKIN SCORE (MRSS) IN PATIENTS WITH DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS

I. Agueusop[1], S. Illiano[2], C. Rocher[2], E. Boitier[3], J. Murphy[4], Y. Allanore[5], C.P. Denton[6], O. Distler[7], D. Khanna[8], F. Benderitter[2]. *[1]Sanofi-Aventis Deutschland GmbH, Frankfurt am Main, Germany; [2]Sanofi R&D, Chilly-Mazarin; [3]Sanofi R&D, Alfortville, France; [4]sanofi, Bridgewater, United States; [5]Paris Descartes University, Paris, France; [6]Centre for Rheumatology, Royal Free Hospital, London, United Kingdom; [7]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; [8]Scleroderma program, University of Michigan, Ann Arbor, United States*

Background: To support internal compound development in systemic sclerosis, a study was performed to identify an mRSS signature in a longitudinal approach by analyzing skin biopsies.
Objectives: Identification of a gene signature that could be used as a quantitative surrogate marker for the mRSS independent of any treatment.
Methods: 77 forearm skin biopsies from 32 patients at baseline, and from the same patients after 8 weeks of treatment with SAR100842 (a LPA1 antagonist) or placebo (N=30) and after an additional 16 weeks of treatment with SAR100842 (N=15) in a phase 2 trial, were collected. Total RNA was extracted with the RNeasy® Fibrous Tissue Mini kit according to the manufacturer's instructions. Total RNA was quantified by spectrofluormetry and qualified by capillary electrophoresis using Agilent Bioanalyzer 2100. Whole transcriptome analysis was performed using Affymetrix chips. Genes highly correlated (Pearson's correlation) with the mRSS were identified at each treatment visit. A signature was identified as a set of genes whose expression levels correlated consistently either positively or negatively with the mRSS at all study visits regardless of treatment group. The correlation value between the genes and the mRSS at baseline had to be >0.5 or $<$ -0.5.The association between mRSS and the single composite marker obtained was investigated. A multivariate analysis of the correlation between the identified genes was performed using the median polish algorithm and PCA. The gene signature underwent pathway analysis using QIAGEN's Ingenuity Pathway Analysis (IPA).
Results: This methodology led to the identification of 64 genes considered for the signature and viewed as a single composite marker that was highly correlated to the mRSS. A principal component analysis was computed and the first component explaining the maximum variance in the signature was highly correlated to the mRSS at baseline and week 8. This correlation was confirmed with the median polish algorithm (Pearson's correlation coefficient of -0.75 and -0.73 respectively). The most significant disease and disorder biological functions associated with the mRSS signature genes were related to immunological diseases. A significant enrichment was also detected for genes associated with inflammatory response and connective tissue disorders with p-values from 2.98E-05 to 2.47E-02.

Conclusions: An mRSS signature was identified using skin biopsies in SSc patients. Some of these genes (i.e. IRF7, THBS1, COMP or BANK1) have been published using similar approaches in other sets of SSc patients (1), which supports our results. The functional categories of this signature are characteristic

for scleroderma pathology reflecting autoimmunity, vasculopathy, inflammation and fibrosis. This mRSS signature needs to be validated in a larger set of SSc patients including assessment of change over time.

How diet influences musculoskeletal diseases

OP0340 WEIGHT LOSS FOR OVERWEIGHT AND OBESE INDIVIDUALS WITH GOUT: A SYSTEMATIC REVIEW OF LONGITUDINAL OBSERVATIONAL STUDIES

S.M. Nielsen[1], E.M. Bartels[1], M. Henriksen[1,2], H. Gudbergsen[1], H. Bliddal[1], A. Astrup[3], F.K. Knop[4,5,6], L. Carmona[7], W. Taylor[8], J.A. Singh[9], F. Perez-Ruiz[10], L.E. Kristensen[1], R. Christensen[1]. *[1]The Parker Institute, Bispebjerg and Frederiksberg Hospital; [2]Department of physical and occupational therapy, Bispebjerg and Frederiksberg Hospital; [3]Department of Nutrition, Exercise and Sports, Faculty of Science, University of Copenhagen; [4]NNF Center for Basic Metabolic Research; [5]Department of Clinical Medicine, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen; [6]Center for Diabetes Research, Gentofte Hospital, University of Copenhagen, Hellerup, Denmark; [7]Instituto de Salud Musculoesquelética, Madrid, Spain; [8]Department of Medicine, University of Otago, Wellington, New Zealand; [9]Department of Medicine, University of Alabama at Birmingham, Birmingham, Alabama, United States; [10]Rheumatology Division, Hospital de Cruces, Baracaldo, Vizcaya, Spain*

Background: Weight loss is a commonly recommended treatment for gout, but the magnitude of effect to expect has to our knowledge not previously been evaluated in a systematic review.
Objectives: The aim of this systematic review was to determine the benefits and harms associated with weight loss in overweight patients with gout.
Methods: Based on a pre-defined protocol (CRD42016037937), we searched six databases for longitudinal studies, quantitatively reporting the effect of weight loss in overweight gout patients. Risk of bias was assessed using the ROBINS-I tool. The quality of the evidence was assessed using GRADE.
Results: From 3,991 potentially eligible studies, 10 were included (incl. one RCT). Interventions included diet with/without physical activity, bariatric surgery, diuretics, metformin, or no intervention. Due to clinical heterogeneity of the included studies, data are presented for each study and synthesised separately. The effect on serum uric acid (sUA) ranged from -168 to 30 μmol/L, and 0% to 60% patients achieved sUA normalisation (i.e. sUA <360 μmol/L). Six out of eight studies (75%) showed beneficial effects on gout attacks. A dose-response relationship was indicated in two studies for sUA, sUA normalisation and gout attacks. At short term (<3 months) after bariatric surgery, one study showed temporary increase in sUA, and another showed temporary increased number of gout attacks. Other possible harmful effects, measured by proxies such as withdrawals due to adverse events and serious adverse events, were poorly reported.
Conclusions: The available evidence is in favour of weight loss for overweight gout patients, with low, moderate and low quality of evidence for an effect on sUA, sUA normalisation, and gout attacks, respectively. At short term, temporary increased sUA and gout attacks may occur after bariatric surgery. There is an urgent need to initiate rigorous prospective studies (preferably RCTs) to provide more trustworthy estimates of benefits and harms of weight loss in overweight gout patients.

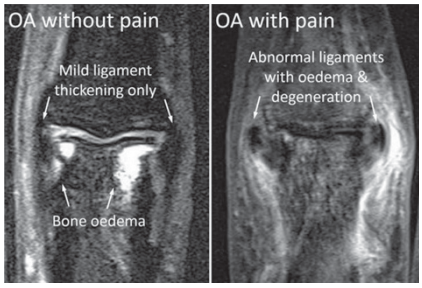
Can targeting disease activity in hand osteoarthritis improve our treatment in the 21st century

OP0341 CAN PAIN IN HAND OSTEOARTHRITIS BE ASSOCIATED WITH MRI COLLATERAL LIGAMENT ABNORMALITIES?

A.L. Tan[1,2], M.-A. D'Agostino[1,3], E. Hensor[1,2], A. Grainger[2], P. Emery[1,2], D. McGonagle[1,2]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]NIHR Leeds Musculoskeletal Biomedical Research Centre, Chapel Allerton Hospital, Leeds, United Kingdom; [3]Rheumatology Department, Hôpital Ambroise Paré, Paris, France*



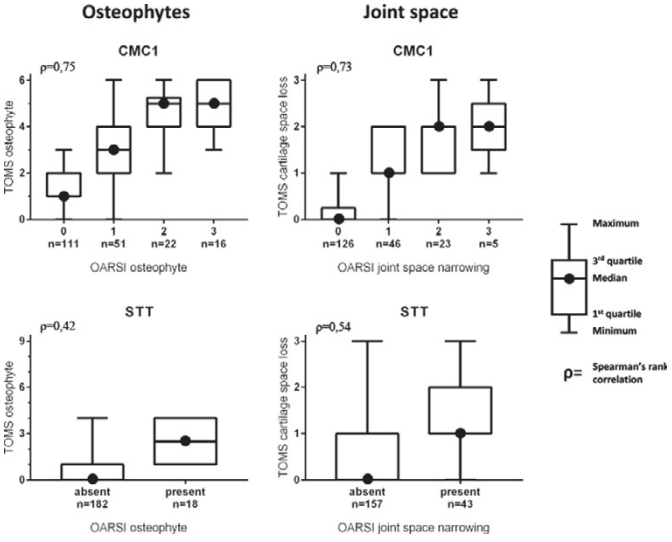
Background: Many patients with hand osteoarthritis (OA) have little symptoms. Bone oedema and synovitis have been associated to pain in OA, but inflammation involving ligaments has not been studied, likely limited by inadequate MRI resolution. We have previously found significant ligament pathology in early and established hand OA (HOA) [1].
Objectives: We hypothesise that the well innervated ligaments are key to a better understanding of the relationship between joint structure and pain in HOA. This

Abstract OP0341 – Table 1

Abnormality	Joints % (n)			Median score (IQR)		Difference* (90% CI)
	HC (n=10)	OA no pain (n=11)	OA pain (n=15)	OA no pain (n=11)	OA pain (n=15)	
Fluid	30 (3)	73 (8)	67 (10)	2 (0, 4)	1 (0, 2)	0 (-2, 1)
Capsulitis/synovitis	– (0)	36 (4)	60 (9)	0 (0, 1)	1 (0, 2)	0 (0, 2)
Extracapsular oedema	– (0)	45 (5)	73 (11)	0 (0, 2)	2 (0, 3)	1 (0, 2)
CL thickening	50 (5)	100 (11)	100 (15)	2 (2, 4)	2 (2, 4)	1 (-1, 2)
CL oedema	40 (4)	91 (10)	87 (13)	2 (1, 3)	3 (2, 4)	1 (0, 3)
CL degeneration	40 (4)	91 (10)	100 (15)	3 (1, 5)	4 (2, 6)	1 (-1, 3)
Proximal joint bone oedema	– (0)	9 (1)	20 (3)	0 (0, 0)	0 (0, 0)	0 (0, 0)
Distal joint bone oedema	– (0)	27 (3)	20 (3)	0 (0, 1)	0 (0, 0)	0 (0, 0)
Proximal joint bone cyst	– (0)	27 (3)	47 (7)	0 (0, 2)	0 (0, 2)	0 (0, 1)
Distal joint bone cyst	10 (1)	27 (3)	7 (1)	0 (0, 1)	0 (0, 0)	0 (0, 0)

*Accounting for clustering of joints within patients. CI = confidence interval; HC = healthy controls; IQR = inter-quartile range; CL = collateral ligaments.

research aims to see if small joint collateral ligament abnormalities are worth exploring further in relationship to pain in HOA.
Methods: High-resolution contrast enhanced MRI of 26 joints in 15 patients (mean (SD) age 58.3 (8.2), 13F:2M) and 10 in 5 healthy controls (age 38 (5.6); 4F:1M) were scanned using a microscopy MRI coil. 15 joints in 8 patients were painful [median (IQR) pain VAS 4 (3, 7)). Joints were scored blinded to clinical data for joint fluid, capsule/synovitis, extracapsular oedema, collateral ligament thickening/oedema/degeneration, extensor and flexor tendons, bone oedema and cysts. All structures were graded 0–3 for normal, mild, moderate, severe, as defined in OMERACT HOAMRIS where available [2]. Proportions of joints with any level of abnormality (score>0) were calculated according to pain status (present/absent).
Results: All OA patients with and without pain had ligament abnormalities. Substantive differences in proportion of joints between healthy controls and OA patients were seen for all pathologies except tendons (no tendon abnormalities were found in all groups). Proportions of joints with capsular/synovium, extra capsular changes and proximal cysts differed between OA joints with and without pain but no substantive differences in pathology score were found. Of painful joints, 93% (14) had both ligament and capsular/synovium or extracapsular abnormality present, compared to 45% (5) of non-painful joints.



Conclusions: Modifiable abnormalities involving capsular/synovium and extra-capsular areas may be more frequently seen in painful OA joints. The presence of collateral ligament abnormalities in HOA joints, whether painful or not, suggest that the severity of ligament abnormalities in small joint OA and the degree of pain may be an important area to investigate further.

OP0342 ASSESSMENT OF STRUCTURAL DAMAGE OF THE THUMB BASE IN PATIENTS WITH HAND OSTEOARTHRITIS: COMPARING THE NEWLY DEVELOPED OMERACT MAGNETIC RESONANCE IMAGING SCORING SYSTEM WITH STANDARD RADIOGRAPHY

S. van Beest[1], F.P. Kroon[1], W. Damman[1], R. Liu[1], M. Kloppenburg[1,2].
[1]Rheumatology; [2]Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands

Background: The thumb base is frequently involved in patients with hand osteoarthritis (OA), resulting in osteophytes and cartilage loss. Radiography is the most commonly used imaging modality to evaluate structural OA signs, however it is insensitive especially due to overprojection. Magnetic resonance imaging (MRI) could be a valuable alternative, however a standardized scoring method for thumb base MR images did not exist until recently OMERACT developed the thumb base OA MRI scoring system (TOMS)[1].
Objectives: Our aim was to investigate the validity of the new TOMS by comparing TOMS scores with radiographic scores.
Methods: Two hundred consecutively included patients (83.5% women, median age 60.5 years) diagnosed with primary hand OA in secondary care, who had both a dorsopalmar radiograph of the right hand and a MRI scan of the right thumb base taken at baseline, were studied. T1- and fat suppressed T2-turbo spin weighted sequences were performed in axial and coronal planes on a 1.5 Tesla extremity MRI unit. Radiographs of the first carpometacarpal (CMC1) and scaphotrapeziotrapezoid (STT) joints were scored using the OARSI atlas (osteophytes and joint space narrowing [JSN] in CMC1: 0–3 and STT: absent/present) by one reader with good intra-reader reliability, blinded for clinical and MRI data. MR images were scored using TOMS (osteophytes in CMC1: 0–6 and STT: 0–9; cartilage space loss [CSL] for both joints: 0–3) by two readers, blinded for clinical and radiographic data, with good intra- and inter-reader reliability. For further analysis we used the average of both readers, rounded down to the nearest integer. To study validity, the distribution of the TOMS scores for osteophytes and CSL were compared for the different radiographic stages for osteophytes and JSN, respectively.
Results: On MR images osteophytes were detected in the vast majority of thumb bases (CMC1 n=172; STT n=102). The score of TOMS increased with more severe radiographic stages (see figures). However, the number of patients without any osteophytes in both CMC1 and STT was considerably lower for TOMS (n=19) than for the OARSI (n=106) scoring. A similar difference was apparent for absence of CSL (n=82) versus JSN (n=108) in both CMC1 and STT. Patients with isolated STT osteophytes were quite rare for both TOMS (n=9) and the OARSI (n=5) scoring. The most prominent discrepancy between TOMS and OARSI sensitivity was found for osteophytes: an additional 168 joints (CMC1 n=84; STT n=84) were found positive with TOMS, while only 1 OARSI-positive CMC1 scored negative with TOMS.

Conclusions: Scores of osteophytes and cartilage loss assessed on MR images by TOMS were correlated with radiographic scores, indicating good validity of the TOMS. Furthermore, the frequencies of joints with osteophytes and cartilage loss assessed on MR images were higher compared to those on radiographs, suggesting high sensitivity for the TOMS.

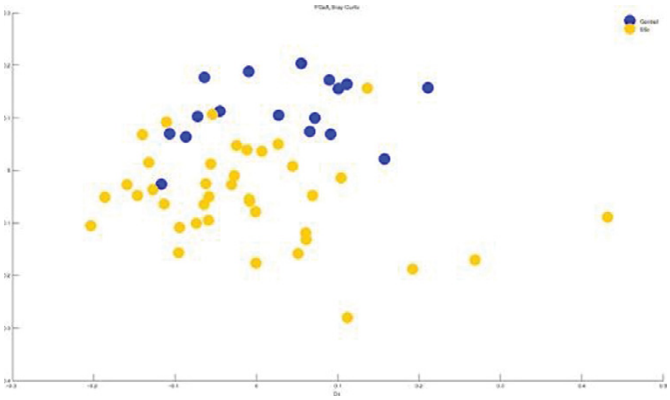
Why we do develop autoimmunity

OP0343 THE INTESTINAL INVOLVEMENT IN SYSTEMIC SCLEROSIS IS CHARACTERIZED BY A PECULIAR GUT MICROBIOTA



G. Natalello[1], S.L. Bosello[1], F. Paroni Sterbini[2], A. Palladini[3,4], G.B. Canestrari[1], F. Parisi[1], E. De Lorenzis[1], G. Berardi[1], B. Posteraro[5], M. Sanguinetti[2], G. Ferraccioli[1]. *[1]Institute of Rheumatology and Affine Sciences; [2]Institute of Microbiology, Università Cattolica del Sacro Cuore, Rome, Italy; [3]Paul Langerhans Institut Dresden of the Helmholtz Centre Munich at the University Clinic Carl Gustav Carus, TU Dresden, Dresden; [4]German Center for Diabetes Research (DZD e.V.), Neuherberg, Germany; [5]Institute of Public Health, Università Cattolica del Sacro Cuore, Rome, Italy*

Background: Gastrointestinal involvement is recognized as a major cause of morbidity and mortality in Systemic Sclerosis (SSc) and its pathophysiology is still unclear. Few data on composition and function of gut microenvironment in SSc are reported in the literature but there is a growing body of evidences supporting the hypothesis of a relation between gut microbiota and the host immune system.
Objectives: The goal of this study was to characterize fecal microbiota in SSc patients compared to healthy subjects to investigate whether specific microbial species may be responsible of dysbiosis in SSc. Furthermore, we investigated the composition of microbiota in the different clinical subsets of SSc.
Methods: Faecal samples were obtained from 17 healthy controls and 39 SSc patients including subjects with different skin involvement (Diffuse and Limited) and disease duration. The BMI was normal and the mean age was similar both in SSc and controls groups. The composition of microbiota was determined through 16S rRNA pyrosequencing performed using the GS Titanium technology. Rarefaction was used to uniform abudance data. α-diversity was defined by the main indexes while β-diversity was determined according to Bray-Curtis and UniFrac, represented trough Principal Coordinate Analysis (PCoA) and compared using PERMANOVA test on distance matrices. Linear Discriminant Analysis Effect Size was used to identify taxa that showed differential expression between the groups.
Results: At genus level SSc patients showed a differential expression in 12 taxa compared to controls with higher levels of *Ruminococcus*, *Streptococcus*,

Lactobacillus, *Blautia*, *Coprococcus* and *Phascolarctobacterium* and a depletion of *Bacteroides*, *Butyciromonas*, *Odoribacter*, *Succinivibrio*, *Sutterella* and *Prevotella*. The differences in microbiota composition between SSc patients and controls were supported also by PCoA of the values representing phylogenetic distance of microbial communities between specimens ($p<0.001$) (see figure). Among scleroderma patients, those with diffuse skin involvement showed a greater abundance of bacteria of Bacteroidetes phylum with significantly lower values of alpha diversity by Chao1 and species richness (p=0.01). Differences were confirmed by PERMANOVA on Bray-Curtis distance matrix (p=0.016).

PERMANOVA analysis of distance matrices (p-values adjusted according to FDR)

	Weighted UniFrac	Bray-Curtis
Control vs SSc	<0.001*	<0.001*
Control vs Diffuse	0,012*	0,0015*
Control vs Limited	0,003*	0,0015*
Control vs Early	0,003*	0,0015*
Control vs Long	0,017*	0,0015*
Diffuse vs Limited	0,259	0,016*
Early vs Long	0,49	0,156

Conclusions: Our analysis demonstrated an altered and distinct composition of gut microbiota in SSc patients compared to healthy controls. Furthermore, scleroderma patients show some differences in microbiota characteristics according to the extent of skin involvement, suggesting that microbiota may influence the severity of the disease. If validated and related to GI symptomathology and nutritional status our findings open up the opportunity of a rational intervention on microbiota to restore the gut equilibrium in SSc patients.

Closing the gap between objective measures and self-report in fibromyalgia

OP0344-HPR **DEVELOPMENT OF RESPONDER CRITERIA FOR MULTICOMPONENT NON-PHARMACOLOGICAL TREATMENT IN FIBROMYALGIA**

V. Vervoort, J. Vriezekolk, C. van den Ende. *Department of Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands*

Background: Despite positive non-pharmacological treatment effects in fibromyalgia (FM) (1,2) these effects are often modest and show large individual variability. In clinical practice it is very important to assess the effectiveness of treatment for the individual patient in order to tailor further treatment. Responder criteria can assess the effectiveness of treatment and define clinically meaningful change in health outcomes on patient level. However, no specific responder criteria for non-pharmacological treatment in FM currently exist. This warrants further exploration in this field.
Objectives: 1) To define responder criteria for multicomponent non-pharmacological treatment in FM; and 2) To estimate and compare their sensitivity and specificity.
Methods: Candidate responder sets were 1) identified in literature (3–5); and 2) formulated by expert group consensus. All candidate responder sets were tested for sensitivity and specificity in a cohort of 144 patients with FM receiving multicomponent non-pharmacological treatment. Therapist's judgement about patient's goal attainment and patients' perspective on health status change, assessed at 6 months after the start of treatment, were used as gold standard.
Results: Seven responder sets were defined (three identified in literature and four formulated by expert group consensus), and comprised combinations of domains of 1) pain; 2) fatigue; 3) patient global assessment (PGA); 4) illness perceptions; 5) limitations in activities of daily living (ADL); 6) sleep. The sensitivity and specificity of literature-based responder sets (n=3) ranged between 17%>99% and 15%>95% respectively, whereas the expert-based responder sets (n=4) performed slightly better with regard to sensitivity (range 41%>81%) and specificity (range 50%>96%). Of the literature-based responder sets the OMERACT-OARSI responder set with patient's gold standard performed best (sensitivity 63%, specificity 75% and ROC area = 0.69). Overall, the expert-based responder set comprising the domains illness perceptions and limitations in ADL with patient's gold standard performed best (sensitivity 47%, specificity 96% and ROC area = 0.71).
Conclusions: We defined sets of responder criteria for multicomponent non-pharmacological treatment in fibromyalgia. Further research should focus on the validation of those sets with acceptable performance.

Suffering in silence. Optimizing the management of psychological well-being for people with RMDs

OP0345-PARE **GROWING UP WITH ARTHRITIS – YES WE CAN! A PROJECT OF DEUTSCHE RHEUMA-LIGA IN CO-OPERATION WITH THE GERMAN ARTHRITIS RESEARCH CENTER. WITH FINANCIAL SUPPORT BY THE GERMAN FEDERAL MINISTRY OF HEALTH**

K. Cattelaens. *Deutsche Rheuma-Liga Bundesverband E.V., Bonn, Germany*

Background: Every third young person with arthritis in Germany stops therapy when he or she enters adult care! Young people with arthritis have to travel long distances to care facilities, which are specialized in transition (about 30 throughout Germany). Because there are too few rheumatologists adults with arthritis often have to wait long for a consultation. Too few doctors have experience with treating young persons with arthritis. The situation of young persons with arthritis results in little knowledge about the condition – only every second young person knows their correct diagnosis. Parents manage everything – only every 5th young person up to 17 years has been alone with their doctor without their parents. Timely and comprehensive support is lacking.
Objectives: Supported by the health ministry and in cooperation with the German Arthritis Research Center the project started in 2014. As a first step the need for support for young person with arthritis was explored. It took two years to develop a pilot project with transition peers, a homepage, camps and information material for parents and doctors. The main goal of the project is to reduce the number of young persons who discontinue care because of the necessary change from children's care to adult care.
Methods: Ten transition peers have been trained for providing support (telephone, online, personal). An online information platform www.mein-rheuma-wird-erwachsen.de (my arthritis is growing up!) was created, filled with the experiences of the peers, information and quizzes and contact offerings. Camps especially for young persons growing up with arthritis took place. For the parents information material were developed and a seminar: learn to let go! is offered to them. The transition peers are going to doctors congresses to spread information material and to present the homepage.
Results: An evaluation of the project is carried out by the German Arthritis Research Center. The online information platform is accepted, it had more than 10.000 visitors during the first year. The young users like the content of the homepage, the transition peers are accepted by the young people as well as by the doctors.
Conclusions: The model project is running for three years – from 2014 until the end of 2017. A subsequent project will focus on the communication between doctors and young patients and should continue the new activities for the young persons with arthritis, their parents and the doctors.

OP0346-PARE **"LISTENING TO PAIN - UN DOLORE DA ASCOLTARE" MULTIDISCIPLINARY SUPPORT FOR WOMEN WITH FIBROMYALGIA**

S. Mingolla, S. Mingolla on behalf of Serena Mingolla Direttore Morfologie author - Francesco Riondino Vice President APMAR Onlus, Ilaria Cinieri Psychologist - Cinzia Assalve fibromyalgia Group APMAR Onlus. *APMAR, Lecce, Italy*

Background: The project "*Listening* to *Pain*- un dolore da ascoltare" is a multidisciplinary and multifactorial project addressed to women with Fibromyalgia. Fibromyalgia pain has no boundaries. People describe the pain as deep muscular aching, throbbing, shooting, stabbing, or intense burning. Quite often, the pain and stiffness are worse in the morning, and muscle groups that are used repetitively may hurt more. Pain in every muscle and the profound exhaustion are not symptoms that people can see, but they are real and may be devastating for the person with Fibromyalgia. Although the invisible nature of the condition causes credibility dilemmas for patients.
Objectives: The project aims at improve the quality of life of women with Fibromyalgia. It has the main following objectives: provide information about Fibromyalgia, raise public awareness, collect useful data for research development, give support to the person, reinforcing social networks, provide mediation of the recognition process and bio-energy structured exercise activities and classes tailored to symptoms (stiffness and fatigue) useful in boosting endurance times.
Methods: The project was launched in 2015 with a communication campaign and supervised by a group of psychologists promoting the use of humanistic bioenergetics therapy for individual consultations and collective supporting group of discussions. Participants were 50 women with a confirmed diagnosis of FMS.
In June 2015, APMAR founded its first "Group for Pathology" and launched new tools as the info point and the toll-free number.
The project includes: psychological support to women suffering from Fibromyalgia, self-help groups where women talk, meet, discuss the pain and jointly organize events and other projects; information, through the creation of brochures and different kind of materials; an info-point managed by APMAR and a toll-free number that provides information and immediate help for women feeling lonely.
Results: The psychological and physical well being of women with Fibromyalgia syndrome were enhanced by social support. Chronic Pain, depression, self-efficacy, helplessness, mood disturbance, health status, impact of FMS, were improved. Psychologists involved in the project observe a decrease of depression, greater security and openness in relations. Women started processing and overcoming the sense of loneliness and isolation, increasing knowledge and therefore awareness, acceptance of the disease.
Analyses indicated that the created social support networks were associated with greater levels of self-efficacy for pain and symptom management, higher levels of self-efficacy for function and symptom management, as well as overall psychological well being.

Conclusions: This multilateral approach was very empowering and consented women to work in the same direction to improve healthcare outcomes for people in their same conditions.
Furthermore, it helped women with Fibromyalgia get more control over their life, and promote understanding of patient empowerment. The project was also a call for action not only among patients and health professionals, but among several kinds of social groups of students, press, local policy makers and other civil society organizations.

SATURDAY, 17 JUNE 2017

Showcasing the EULAR Online Course for Health Professionals

OP0347-HPR **TRAINING RHEUMATOLOGY NURSE SPECIALISTS: WHAT DOES THE FUTURE HOLD?**

M.K. Nisar[1], J. Begum[2]. [1]*Rheumatology, Luton & Dunstable University Hospital;* [2]*Rheumatology, Luton, Luton, United Kingdom*

Background: Since the introduction of the Rheumatology nursing in the UK in 1980s, there has been gradual development of the "specialty". Despite the proven benefits, both clinical and economical, of a well-trained rheumatology nurse specialist and the evolution of the role, there is a lack of a clear career path for the profession.
Objectives: We undertook a pilot survey to understand the present climate of rheumatology practitioner training in the region.
Methods: Following a focus group discussion of an "ideal" development route for rheumatology practitioners, ten items were unanimously identified as areas for job progression. These included appropriate induction, prescribing skills, involvement in research and education, opportunities for combined working and scope for clinical development. A questionnaire was created based on these items and mailed to all the rheumatology units in the East of England. Replies were compiled to ascertain the current picture of regional training.
Results: There are 19 centres providing rheumatology services in the region with 51 rheumatology practitioners. All of them (100%) replied to the questionnaire. Only four units (21%) provide formal induction programme for training. 11/19 (57%) have nurse prescribers. All providers replied positive to the question pertaining nurses' participation in research and audit; 12 (63%) have presented locally or nationally and eight (42%) have submitted posters to conferences. 12 centres have partly nurse delivered early arthritis pathway and 13 have access to departmental ultrasound. Ten units provide patient educational events.
Conclusions: This is a pioneering survey outlining access of rheumatology practitioners and nurse specialists to developmental opportunities. This initiative highlights a wide variation in the provision of clear career pathway regionally. Though most centres are delivering contemporary services, these are not being used effectively for developing key team members. There is lack of formal induction programme. Though most nurses are involved in audit, less than a quarter are presenting at any level and even fewer are publishing research endeavours. Prescribing is limited to 15/51 (29%) members. Less than 20% are training to do intra-articular injections or learning musculoskeletal ultrasound. Despite patient education being a core skill for this group, only 10 units deliver these as a formal event.
In conculsion, there is wide variation in the provision of career advancing opportunities to rheumatology nurse specialists. This can potentially have a negative impact on staff recruitment and retention. There is a need for improving standards and delivery of rheumatology professionals' career development.

Genomics, genetic basis of disease and HLA / T cell recognition

THU0001 DIFFERENTIAL METHYLATION AS A POTENTIAL BIOMARKER OF METHOTREXATE RESPONSE IN PATIENTS WITH RHEUMATOID ARTHRITIS

N. Nair[1], D. Plant[1,2], S.M. Verstappen[1], J.D. Isaacs[3,4], A.W. Morgan[5], K.L. Hyrich[1], A. Barton[1], A.G. Wilson[6] on behalf of MATURA. *[1]Arthritis Research UK Centre for Genetics and Genomics and Centre of Epidemiology, University of Manchester; [2]NIHR Manchester Musculoskeletal BRU, CMFT, Manchester; [3]NIHR Newcastle BRU, Newcastle upon Tyne Hospitals NHS Foundation Trust; [4]Newcastle University, Newcastle; [5]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; [6]University College Dublin School of Medicine and Medical Science, University College Dublin, Dublin, Ireland*

Background: Methotrexate (MTX) is the first-line disease modifying anti-rheumatic drug for the treatment of rheumatoid arthritis (RA). However, many patients do not respond adequately or experience adverse effects[1,2]; therefore, identifying blood-based biomarkers that predict treatment response is a research priority. DNA methylation is an epigenetic marker that modifies but does not alter DNA sequence, and it is thought that MTX may act, at least in part, by inhibiting intracellular methyl donor transfer leading to DNA hypomethylation[2].
Objectives: We aimed to identify differential DNA methylation signatures in whole blood, which may act as biomarkers predictive of response to MTX in patients with RA.
Methods: DNA methylation was measured using the HumanMethylation450 BeadChip in DNA samples from individuals recruited to the Rheumatoid Arthritis Medication Study (RAMS), a one year observational study in the UK including patients with RA starting MTX for the first time. In RAMS, demographic and clinical data are collected prior MTX start (baseline) and at 6 months after commencing MTX. DNA was extracted from whole blood samples collected baseline and at 4 weeks from patients who, at 6 months, had a EULAR good response (n=36) or EULAR poor response (n=36) to MTX. Differentially methylated positions (DMPs) between the baseline and 4 weeks, and between good and poor response were identified using linear regression, adjusting for gender, age, cell composition, baseline disease activity score (DAS28), and smoking status. Analyses also compared methylation with changes in DAS28 and the individual DAS28 components over 6 months. DMPs that showed significant differences in the test cohort were selected for replication by pyrosequencing in an independent group of 100 patients with both baseline and 4 week samples.
Results: Based on percentage change in methylation between pre-treatment and following 4 weeks of therapy, two DMPs were significantly associated with response status in samples taken at 4 weeks (p-value $<10^{-5}$). Three additional DMPs were associated with change in tender joint count, whilst three other DMPs were associated with change in swollen joint count, and a further four DMPs associated with change in C-reactive protein. Of the four DMPs tested to date, hypermethylation at cg23700278 at baseline suggests replicated association with improvement in swollen joint count by 6 months. The nearest gene to the cg23700278 locus is adrenoceptor alpha 2C (*ADRA2C*), involved in neurotransmission.
Conclusions: These preliminary results suggest DNA methylation may provide a biomarker of MTX response but requires replication in other data sets.

THU0002 ETANERCEPT AND ADALIMUMAB EXHIBIT HETEROGENEOUS EARLY SIGNATURES OF RESPONSE IN RHEUMATOID ARTHRITIS THERAPY

J. Oliver[1], D. Plant[2], G. Orozco[1], K. Hyrich[3], A. Morgan[4], J. Isaacs[5], A.G. Wilson[6], A. Barton[1,2]. *[1]Arthritis Research UK, Centre for Genetics and Genomics, Centre for Musculoskeletal Research, Manchester Academic Health Sciences Centre, The University of Manchester; [2]NIHR Manchester Musculoskeletal BRU, Central Manchester Foundation Trust; [3]Arthritis Research UK, Centre for Epidemiology, Centre for Musculoskeletal Research, Manchester Academic Health Sciences Centre, The University of Manchester, Manchester; [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds and NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds; [5]Institute of Cellular Medicine, Newcastle University and National Institute for Health Research Newcastle Biomedical Research Centre at Newcastle upon Tyne Hospitals NHS Foundation Trust and Newcastle University, Newcastle; [6]UCD School of Medicine and Medical Science, Conway Institute, University College Dublin, Dublin, United Kingdom*

Background: Up to 40% of rheumatoid arthritis (RA) patients exhibit insufficient response to TNF inhibitor (TNFi) therapy, which has an adverse effect on long term outcomes. Without reliable biomarkers to direct treatment decisions, many non-responder (NR) patients experience a delay in switching to an alternative therapy. Ideally, blood-based biomarkers would be measured before treatment (baseline) and throughout treatment in order to select and monitor therapeutic response to maximise the chances of responding to the first biologic therapy.
Objectives: To compare transcriptomic changes between patients administered etanercept and adalimumab therapy, and to identify biomarkers to predict or monitor response.
Methods: From the Biologics in RA Genetics and Genomics Study Syndicate (BRAGGSS) cohort, 37 EULAR good-responders in clinical remission (GR) and 18 NR to etanercept, and 50 GR and 20 NR to adalimumab were selected. Total RNA was isolated from Tempus™-stabilised whole blood samples collected at baseline and following 3-months (3M) of therapy using the MagMAX™ RNA extraction kit. RNA was amplified and converted into biotinylated sense-strand DNA using the Affymetrix WT PLUS kit for hybridisation onto Affymetrix GeneChip® Human Transcriptome arrays. Quality control and differential expression/splice analysis were assessed using the Affymetrix Expression and Transcriptome Analysis Console™ and appropriate Bioconductor packages. Differential transcript expression was adjusted for baseline DAS, age, gender and concurrent DMARD therapy. Pathway analysis was performed using the Database for Annotation, Visualization and Integrated Discovery (DAVID) and Ingenuity Pathway Analysis (IPA) tools.
Results: In adalimumab GR, 636 genes were downregulated and 253 upregulated at 3M (FDR $p<0.05$, fold-change >1.2). There was significant upregulation of immune cell components, most notably HLA genes including *HLA-DRB1*, other RA susceptibility genes (*SLC2A4*, *PADI4* and *CD28*) and many B and T cell signalling genes. Etanercept GR exhibited a milder transcriptomic change overall, showing little overlap with adalimumab GR; 395 genes were downregulated and 27 upregulated at 3M (FDR $p<0.05$, fold-change >1.2). Downregulated genes included downstream TNF components such as mitogen activated protein (MAP) kinases, as well as genes involved in NOD-like receptor, Toll-like receptor and NF-κB signalling. Such significant changes were absent in NR to adalimumab and etanercept. Furthermore, alternative splice changes in RA-relevant genes such as *MMP9* were apparent in adalimumab GR at 3M but not etanercept GR.
Conclusions: The heterogeneity in the blood-based transcriptomic profiles of etanercept and adalimumab response observed herein suggests that different TNFi therapies function by alternative mechanisms that impact patient outcomes. It also calls into question the reliability of response studies that consider TNFi therapies as a homogenous group. The candidate biomarkers identified require replication in independent datasets but may provide early and objective response biomarkers to inform timely therapeutic switching in patients who are not responding to their current TNFi drug.

THU0003 CD4+ AND B LYMPHOCYTE EXPRESSION QUANTITATIVE TRAITS AT RHEUMATOID ARTHRITIS RISK LOCI IN UNTREATED EARLY ARTHRITIS: IMPLICATIONS FOR CAUSAL GENE IDENTIFICATION?

N. Thalayasingam[1], J. Massey[2,3], A.E. Anderson[4], N. Nair[2,3], A. Skelton[4], D.W. Lendrem[4], L. Reynard[4], H.J. Cordell[5], S. Eyre[2,3], A. Barton[2,3], J.D. Isaacs[4], A.G. Pratt[4]. *[1]National Institute for Health Research Newcastle Biomedical Research Centre, Newcastle upon Tyne Hospitals NHS Foundation Trust and Newcastle University, Newcastle Upn Tyne; [2]Arthritis Research UK Centre for Genetics and Genomics, Centre for Musculoskeletal Research, Institute of Inflammation and Repair, University of Manchester; [3]NIHR Manchester Musculoskeletal Biomedical Research Centre, Central Manchester NHS Foundation Trust, Manchester; [4]National Institute for Health Research Newcastle Biomedical Research Centre, Newcastle upon Tyne Hospitals NHS Foundation Trust and Newcastle University; [5]Institute for Genetic Medicine, Newcastle University, Newcastle upon Tyne, United Kingdom*

Background: Rheumatoid arthritis (RA) is a genetically complex disease of immune dysregulation. Genome-wide association scans (GWAS) have confirmed its association with variants at >100 genetic loci. Outside of the HLA region,

accumulating data now highlight an overlap between these risk loci and cell-specific enhancer elements that is maximal in CD4+ lymphocytes, followed by B lymphocytes

Objectives: Seeking insight into genetic risk mechanisms, we conducted and compared expression quantitative trait locus (eQTL) analyses of risk loci in CD4+ T cells and B cells from carefully phenotyped early arthritis patients naïve to therapeutic immunomodulation.

Methods: 254 patients donated RNA and DNA from purified B and/or CD4+ T-cells within 4 hours of blood draw. Genotyping and global gene expression measurement were carried out using the Illumina Human CoreExome array and either HT12v4 or WG6v3 BeadChip arrays respectively. Variants in linkage disequilibrium (LD) with 101 confirmed non-HLA RA- SNPs ($r^2>0.8$) were analysed, seeking evidence of *cis*- or *trans*- eQTLs according to whether associated probes were or were not within 4MB of these LD blocks.

Results: Genes subject to *cis* eQTL effects common to both CD4+ and B-lymphocytes at RA risk loci were *FADS1*, *FADS2*, *BLK*, *FCRL3*, *ORMDL3* and *GSDMB*. At the 8p23 *BLK-FAM167A* locus, we found adjacent genes subject to eQTLs whose activity differed markedly between cell types, the *FAM167A* effect displaying striking B-lymphocyte specificity. By contrast, *cis* eQTLs acting on *METTL21B*, *IKZF3,* and *PADI4* were unique to CD4+ lymphocytes, the latter two of these being identified for the first time in this cell subset. No *trans* eQTLs approached experiment-wide significance, and linear modelling did not identify a significant influence of biological co-variates (diagnosis, systemic inflammation, age) upon eQTL effect sizes.

Conclusions: Our findings refine understanding of candidate causal genes in RA pathogenesis, providing an important platform from which downstream functional studies may be prioritised and directed towards particular cell types.

THU0004 CROSS PHENOTYPE ASSOCIATION MAPPING OF THE MHC IDENTIFIES GENETIC VARIANTS THAT DIFFERENTIATE PSORIATIC ARTHRITIS FROM PSORIASIS

J. Bowes[1], J. Ashcroft[1], N. Dand[2], P. Ho[1,3], C.H. Smith[4], J.N. Barker[4], N. McHugh[5], R.B. Warren[6], A. Barton[1,3] on behalf of BSTOP and BADBIR.

Background: The identification of genetic variants that differentiate PsA from psoriasis has the potential to help us understand the underlying biological pathways that lead to the development of PsA. Associations to genetic variants within the major histocompatibility complex (MHC), in particular to *HLA-C*0602*, increase risk of both PsA and psoriasis when compared to control populations. However direct comparisons of PsA to psoriasis have led to paradoxical associations where *HLA-C*0602* has been reported to be protective of PsA. In addition *HLA-C*0602* has been reported to be associated with age of onset of psoriasis. A more recent study has reported the amino acid at position 45 of the HLA-B protein as the most important factor for differentiating PsA from psoriasis.

Objectives: Here we perform a cross phenotype association analysis in an attempt to identify genetic variants in the MHC that differentiate PsA from psoriasis in a large collection of PsA patients and psoriasis patients screened for the absence of PsA.

Methods: A total of 1069 patients with psoriasis and 981 patients with PsA from the UK were genotyped using either the Illumina Immunochip or the Illumina OmniExpress genotyping arrays. SNPs, amino acids and classical HLA alleles were imputed using SNP2HLA. Logistic regression was used to compare the imputed dosage of MHC markers between PsA and psoriasis. All analyses were repeated using age of psoriasis onset as an additional covariate.

Results: The most significant association when comparing PsA to psoriasis was to *HLA-C*0602* ($p=4.17x10^{-15}$) with a protective effect for PsA (OR 0.52, CI 0.44:0.61). *HLA-C*0602* was found to be significantly associated with a younger age of psoriasis onset ($p=1.51x10^{-60}$) where the median age of onset in years for carriage is 22 compared to 33 for non-carriage. We observed a difference in the median age of psoriasis onset in years between the PsA and psoriasis study subgroups (34 vs. 21), highlighting the potential for bias at markers associated with age of psoriasis onset. When controlling for the age of psoriasis onset in the analyses we observed no association of PsA to *HLA-C*0602* (p=0.07) and the most significant association was to the amino acid at position 97 of HLA-B ($p=1.54x10^{-9}$) where the presence of asparagine or serine residue increased risk of PsA. Asparagine at position 97 of HLA-B defines the HLA-B*2705 allele.

Conclusions: Comparing PsA to psoriasis we show *HLA-C*0602* confers no effect, either risk or protective, for PsA after correction for age of psoriasis onset. The results suggest that the previously observed protective effect of *HLA-C*0602* could be due to confounding due to a younger age of psoriasis onset in the psoriasis subgroup. When accounting for age of psoriasis onset, the primary association conferring risk for PsA in patients with psoriasis is to HLA-B amino-acid 97 where an asparagine residue defines the *HLA-B*2705* allele. In addition, this amino acid has been reported as the largest genetic effect for ankylosing spondylitis thereby refining the genetic overlap between these two spondyloarthropathies.

THU0005 ERAP POLYMORPHISMS AND ITS ASSOCIATION WITH HLA-B15 AND HLA-B27 POSITIVE SPONDYLARTHRITIS PATIENTS

J. Londono[1], A.M. Santos[2], J.C. Rueda[2], P. Peña[2], I. Briceño[3], E.-L. Saldarriaga[2], J.-I. Angarita[2], E. Calvo[4], M. Avila[2], N. Martinez-Rodriguez[5], H. Cubides[2], V. Parra[2], J.F. Medina[6]. *[1]Reumatología, Universidad de la Sabana-Hospital Militar Central, Bogotá; [2]Reumatología; [3]Facultad de Medicina, Grupo Genética Humana, Universidad de la Sabana, Chia; [4]Departamento de Imágenes diagnósticas, Universidad Nacional, Bogotá, Colombia; [5]Departamento de Investigación de Salúd Comunitaria, Hospital Infantil de México Federico Gomez, Ciudad de México, Mexico; [6]Departamento de Medicina Interna, Escuela de Medicina, Universidad de Navarra, Pamplona, Spain*

Background: Since 1973, the association of HLA-B27 and spondyloarthritis (SpA) is well known, however in Colombian population it is present in only 40% of patients and HLA-B15 is present almost in 25%. A mechanism of polygenic mechanism has been proposed as an explanation for the development of SpA. Endoplasmic reticulum aminopeptidase (ERAP) genes 1 and 2 have been implicated. ERAP1 is strongly associated with HLA-B27 positive patients and ankylosing spondylitis, but not with ERAP2

Objectives: To determine the association between ERAP polymorphisms and HLA-B27 or HLA-B15 positive SpA patients

Methods: 178 patients with SpA according to ASAS criteria were included in the study. HLA typing was performed by the PCR technique using the Biorad® HLA-SSP plates. The polymorphisms were determined by the RT-PCR technique using Roche® probes for ERAP1 rs27044, rs17482078, rs10050860, and rs30187. For ERAP2 the probes used were rs2910686, rs2248374 and rs2549782. The

Table 1. ERAP2 Haplotypes in HLA-B15 and B27 Patients

Haplotypes	HLA B15 n (AF)	HLA B27 n (AF)	OR (CI 95%)	*p*
TGT	**0.201**	0.078	2.943 (1.264–6.585)	0.009*
TGC	0.055	**0.227**	4.483 (1.524–13.187)	0.003*
CAT	0.021	**0.119**	9.014 (1.181–68.807)	0.009*
CAC	0.643	0.499	1.750 (0.968–3.162)	0.077
CGC	0.016	0.035	0.465 (0.053–4.056)	0.672
CGT	0.031	0.013	2.406 (0.332–17.45)	0.584
TAT	0.019	0.013	1.185 (0.106–13.29)	1.00
TAC	0.013	0.015	1.185 (0.106–13.29)	1.00

ERAP: endoplasmic reticulum aminopeptidase; AF: allelic frequency; OR: odds ratio.

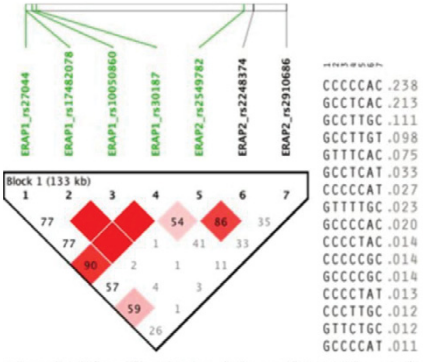

Figure 1. Linkage disequilibrium (LD) map of the ERAP gene. The value of the LD coefficient in each cell D'[(values close to 1.0) x 100] is shown. The colour map of the haplogroups represents the LD relationships, the bright red squares represent evidence of LD (log odds [LOD] score <2 and D'= 1], the light red squares indicate a slight evidence of LD (log odds [LOD] score≥2 and D'<1], and white squares mean that there is no LD and independent segregation [log odds [LOD] score<2 and D'<1]

allele and genotype frequencies polymorphisms were obtained by direct counting. In each group the Hardy-Weinberg equilibrium was evaluated using the ^{2} test. Associations were assessed using odds ratio (OR). Stata v.12.0 program was used to analyse data. The construction and analysis of haplotypes was performed using Haploview v.4.2

Results: In total 70 patients were HLA-B27 positive and 34 were HLA-B15 positive. 78 were women and 100 were men. Linkage disequilibrium map of the ERAP gene is depicted in figure 1. When analysed by ERAP2 haplotype it is observed that there is a statistically significant association with the combinations described in table 1. No associations were observed between ERAP1 haplotypes and HLA-B15 or B27

Conclusions: In the group of patients analysed, a statistically significant association was found between patients with SpA HLA-B15 positive and the haplotype TGT of ERAP2. Also HLA-B27 positive SpA patients were associated with haplotype TGC and CAT of ERAP2 with statistical significance

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized by fibrosis and composed of two subtypes, limited and diffuse cutaneous forms. Previous genetic studies including genome-wide association studies (GWAS) have identified 12 susceptibility loci satisfying genome-wide significance.

Objectives: To expand the list of susceptibility genes and deepen biological insights for SSc.

Methods: We performed trans-ethnic meta-analysis of GWAS in the Japanese and European populations, followed by a two-staged replication study comprising a total of 4,436 cases and 14,751 controls. Associations between significant single nuclear polymorphisms (SNPs) and neighboring genes were evaluated. Enrichment analysis of H3K4Me3, a representative histone mark for active promoter was conducted with an expanded list of SSc susceptibility genes.

Results: We identified two significant SNP in two loci, *GSDMA* and *PRDM1*, both of which are related with immune functions and associated with other autoimmune diseases ($p=1.4x10^{-10}$ and $6.6x10^{-10}$, respectively). *GSDMA* also showed a significant association with limited cutaneous SSc. We also replicated the associations of previously reported loci including a non-GWAS locus, *TNFAIP3*. *PRDM1* encodes BLIMP1, a transcription factor regulating T cell proliferation and plasma cell differentiation. The top SNP in *GSDMA* was a missense variant and correlated with gene expression of neighboring genes, and this could explain the association in this locus. We found different HLA association patterns between the two populations or two subtypes. Enrichment analysis suggested the importance of CD4 naïve primary T cell.

Conclusions: *GSDMA* and *PRDM1* are associated with SSc. These findings provide enhanced insight into the genetic and biological basis of SSc.

THU0007 DEEP SEQUENCING TRANSCRIPTOME ANALYSIS OF THE EFFECT OF TRAUMEEL VERSUS DICLOFENAC THERAPEUTIC ACTION IN WOUND HEALING

G.St. Laurent III[1], B. Seilheimer[2], M. Tackett[1], J. Zhou[1], D. Shtokalo[1], Y. Vyatkin[1], P. Kapranov[1], I. Toma[3], T. Mccaffrey[3]. *[1]The St. Laurent Institute, Vancouver, WA, United States; [2]Biologische Heilmittel Heel, GmbH, Baden-Baden, Germany; [3]Department of Medicine/Division of Genomic Medicine, The George Washington University, Washington, DC, United States*

Background: Anti-inflammatory agents are used widely in treating numerous inflammatory conditions. The effect of Tr14, a multitargeted natural product, was compared to diclofenac, a non-selective cyclooxygenase inhibitor, on cutaneous wound repair in mice.

Objectives: To compare the effect of diclofenac with Tr14 on the transcriptome after cutaneous wounding in the mouse.

Methods: After abrasive wounding, the wounds were treated with topical Tr14 or diclofenac at clinically relevant doses. An additional group received subcutaneous Tr14 injections. The healing wounds were analyzed for RNA transcript profiling by RNAseq at specific times (12h, 24h, 36h, 72h, 96h, 120h, 196h) after injury. Differentially expressed genes (DEGs) were computed at each time point between diclofenac vs control or Tr14 vs control using EdgeR.

Results: Across time points, Tr14 treatment modulated a number of transcripts related to key wound repair pathways such as cellular differentiation, wound contraction, and cell mobility. Diclofenac, in contrast, changed gene expression mainly in two areas: Prominent effects were observed with regard to DNA chromatin regulation and ribosomal function, further effects were observed on the prostaglandin pathway and wound repair factors. In many of the key pathways modulated by Tr14, such as the defense response and cell motility, diclofenac tended to have an opposite effect on gene expression. At 12 hours post-injury, there were 521 transcripts significantly elevated and 1027 transcripts that were decreased by diclofenac treatment. By comparison, using a similar number of transcripts altered by Tr14 treatment, only 4 transcripts were increased in common, and 5 transcripts were decreased in common, suggesting that the therapies have different effects on the transcriptome.

Conclusions: The overall patterns of the Tr14 and diclofenac responses in the transcriptome during wound repair are very different. The Tr14 effect is most pronounced on the defense response, cell motility, and anti-apoptotic pathways. In contrast, diclofenac mainly affected histones and chromatin remodeling systems, as well as ribosomal systems that would be expected to alter the translational pattern of diclofenac-treated cells.

THU0008 MAST CELLS SHOW A REPROGRAMMED TRANSCRIPTIONAL SIGNATURE FOLLOWING REPEATED IGG STIMULATIONS

T. Messemaker, J. Suurmond, K. Habets, M. Heijink, J. Schonkeren, A. Dorjee, M. Giera, T. Huizinga, R. Toes, F. Kurreeman. *LUMC, Leiden, Netherlands*

Background: Mast cell numbers are increased in the rheumatoid arthritis joint. We have previously shown that mast cells can be activated by IgG-ACPA leading to the production of proinflammatory cytokines. However, not much is known about the resulting function when mast cells would repeatedly engage IgG, a likely scenario given the long life span of mast cells (up to a year) and the perpetual presence of IgG-ACPA in the joints. We have recently shown that mast cells triggered repeatedly through their Ig Fc epsilon receptor undergo a reprogramming of their responses (*Suurmond et al. JACI, 2016* by expressing de-novo transcribed genes in the antigen presentation and pathogen defence response pathways.

Objectives: The aim of the current work was to determine whether mast cells show similar changes in their response mode following repeated interactions with IgG.

Methods: Human cord blood-derived mast cells were treated for 2 weeks with plate-bound IgG. The expression profile of naive or treated mast cells was measured through RNA sequencing, quantitative RT-PCR, flow cytometry. Protein secretion was measured with ELISA and Luminex assays. Metabolic changes were measured using HPLC mass-spectrometry.

Results: Similar to our previous work on Fc Epsilon receptor, we observe a dampening of the normal IgG responses with a set of novel genes upregulated. Interestingly, de-novo expressed genes consisted of *DHCR7* and *DHCR24*, key enzymes in the cholesterol pathway. Pathway analysis confirms an enrichment of genes in this pathway following repeated IgG triggering. Preliminary data on metabolic profiling reveals a decrease in phospholipid levels in repeatedly activated mast cells.

Conclusions: Our study provides evidence that mast cells are reprogrammed upon repeated IgG triggering. In contrast to repeated Fc Epsilon Receptor triggering, different pathways are affected, implying stimulus-specific effects. Our work has important implications for the understanding the role of mast cells in rheumatoid arthritis.

THU0009 IN VITRO STUDIES USING CYBRIDS, SHOW THAT MTDNA FROM HEALTHY AND OA PATIENTS HAVE DIFFERENT MITOCHONDRIAL ACTIVITY

M. Fernández-Moreno[1,2], A. Dalmao-Fernandez[2], T. Hermida-Gomez[2], M.J. Sanchez-Dopico[2], M.E. Vazquez-Mosquera[2], E. Cortes-Pereira[2], S. Relaño-Fernandez[2], I. Rego-Perez[2], F.J. Blanco[2]. *[1]Centro de Investigación Biomédica en Red, Ciber-Bbm, Madrid; [2]Servicio de Reumatología. Complexo Hospitalario Universitario (CHUAC), Instituto de Investigación Biomédica de A Coruña (INIBIC), A Coruña, Spain*

Background: Mitochondrial dysfunction is well documented in OA and has the capacity to promote abnormalities in chondrocyte function and viability contributing to cartilage degeneration. Previous studies have showed the mtDNA haplogroup J are associated with incidence and progression of OA. Cybrids are optimal cellular models to study the real mitochondrial biology and function implications in the cellular behaviour, since they carry different mitochondrial variants with the same nuclear background, therefore, excluding the variations because of nuclear genome.
Objectives: The aim of this work is to test the real role of mtDNA in cellular activity, using cybrids with mtDNA from healthy donors (without OA) and from patients with knee OA.
Methods: Cybrids were developed using 143B.TK$^-$ Rho-0 cell line (nuclear donor) and platelets (mitochondrial donors) from healthy (without AO-N-) and knee OA donors. The OXPHOS function was evaluated by SeaHorse XFp after addition of oligomycin, FCCP and Rotenone/Antimycin A. The metabolic status was evaluated by glucose consumption and lactic acid production. The glycolytic activity was measure after addition of glucose, oligomycin and 2-dioxyglucose using Seahorse XFp. Appropriate statistical analyses were performed with GraphPad Prism v6.
Results: OA cybrids had lower basal respiration (92.07±39.9 and 155.5±54.08, $p<0.0005$), and maximal respiratory capacity (114.7±50.1 and 160.6±44.7, $p<0.05$) than N. The analysis of ATP production was lower in OA than in N cybrids (66.69±28.69 versus 101.5±42.04 $p\leq0.05$). The % spare respiratory capacity value for the N was significantly lower than in OA cybrids (107±16.21 versus 124.7±5.97, $p\leq0.0005$). Cybrids carrying the mtDNA from OA patients showed higher glucose consumption than N cybrids (43.77±8.87 mg/ml and 31.91±13.69 mg/ml; $p<0.05$) however in the lactic acid production did not exit differences. The glycolytic activity was evaluated and showed that OA cybrids had lower glycolysis (71.05±4.83 versus 85.43±11.18, $p<0.05$) but higher glycolytic reserve than N cybrids (56.60±7.5 versus 39.73±19.13, $p\leq0.05$).
Conclusions: Cybrids have different metabolic behaviour, being N more efficient using glucose via glycolysis. We found differences statistical significate in the parameters that describe the mitochondrial respiration capacity, in this line OA cybrids had lower mitochondrial respiration and produce less ATP than the cybrids obtained from healthy patients. These results showed that the mitochondria obtained from healthy and OA donors had a different behaviour. These data also offer a real rationale for why mitochondria alterations play an important role in the incidence of OA.

THU0010 ALTERED MIRNAS PROFILES IN PLASMA-DERIVED EXOSOME OF PATIENTS WITH ANKYLOSING SPONDYLITIS BY SMALL RNA-SEQ ANALYSIS

Y. Huang, T. Li, Z. Huang, W. Deng, S. Zheng, X. Guo, Z. Huang. *Guangdong No. 2 Provincial People's Hospital, Guangzhou, China*

Background: Ankylosing spondylitis (AS) is a chronic inflammatory disease, which is difficult to diagnose in the early stages. Increasing evidences have shown that MicroRNAs (miRNAs) may serve as novel biomarkers for AS. Exosome can function as vehicles to deliver miRNAs in body fluids including saliva and plasma. However, the relationship between exosome-delivered miRNAs and AS has yet to be determined.
Objectives: The aim of this study is to detect the altered miRNAs profiles of plasma-derived exosome in AS patients by small RNA-Seq Analysis.
Methods: Ribo^{TM} kit was used to isolate exosome. Small RNA Sample Pre Kit was used to build libraries in 3 AS patients and 3 healthy volunteers (HV), following by IlluminaHiSeq platform sequencing and bioinformatics analysis. Quantitative reverse-transcription PCR (qRT-PCR) was used to confirm the expression of the highly-expressed miRNA in another 10 AS patients and 10 HV, and receiver-operator characteristic (ROC) curve was used to evaluate the diagnostic value of miRNAs.
Results: Small RNA-Seq analysis showed that the Q30 value of HV and AS patients were higher than 95% (Fig.1-A). The amount of miRNA in HV and AS patients were (509.667±77.501) and (632.000±43.555). 80 up-regulated and 19 down-regulated exosomal miRNAs were identified in AS patients, compared with HV ($|\log2Ratio|>1$, $P<0.05$) (Fig.1-B-C). The target genes of the 34 highly-expressed miRNAs from the 99 differently-expressed miRNAs were 7869, and the main function of these target genes are involved in the regulation of endocytosis and protein modification process analyzed by GO and KEGG. The qRT-PCR results indicated that the expression level of miRNA21–5P and miRNA423–5P in AS patients were (2.940±1.572) and (2.520±1.401) times higher than that of HV (Fig.1-D-E). ROC curve analysis showed that miRNA21–5P and miRNA423–5P had significant diagnostic value for AS with the AUC of 0.890 (CI95%: 0.723–1.057) and 0.835 (CI95%: 0.621–1.039) respectively (Fig.1-F).

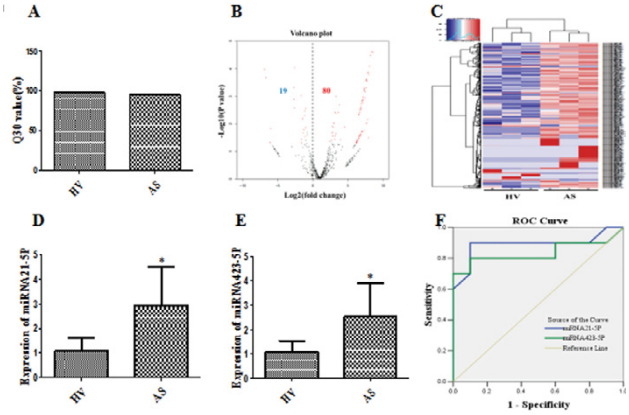

Fig.1 Altered miRNAs profiles in plasma-derived exosome of AS by small RNA-Seq Analysis
A: The Q30 value of each group. B-C: The differentially-expressed miRNAs. D-E: qRT-PCR was used to confirm the level of miRNA21-5P and miRNA423-5P. F: ROC cure was used to evaluate the diagnostic value of miRNA21-5P and miRNA423-5P. *$P<0.05$ vs HV.

Conclusions: The miRNAs profiles in plasma-derived exosome of AS patients are significant different from HV. miRNA21–5P and miRNA423–5P are higher expressed in AS patients. Thus, plasma-derived exosomal miRNAs might be reliable biomarkers to identify AS.

THU0011 IMMUNE SIGNAL 2 CHECKPOINT MOLECULE EXPRESSION IN RHEUMATOID ARTHRITIS DISEASE PROGRESSION

A.M. Walsh[1], M. Canavan[2], Y. Guo[1], T. McGarry[2], X. Yin[1], M.D. Wechalekar[3], M.D. Smith[3], S.M. Proudman[4], C. Orr[5], S. Kelly[6], C. Pitzalis[6], D.J. Veale[5], U. Fearon[2], S. Nagpal[1]. *[1]Janssen R&d, Spring House, United States; [2]Molecular Rheumatology, Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin, Ireland; [3]Flinders University; [4]Royal Adelaide Hospital and Discipline of Medicine, University of Adelaide, Adelaide, Australia; [5]St. Vincent's University Hospital, Dublin, Ireland; [6]Queen Mary University of London, London, United Kingdom*

Background: Deep profiling of synovial tissue samples from rheumatoid arthritis (RA) patients may reveal the molecular underpinnings of phases of RA progression and provide new therapeutic targets to intervene earlier in disease pathogenesis.
Objectives: We sought to identify the molecular pathways expressed in different stages of disease (from seropositive subjects without clinically apparent synovitis to those with established disease) in synovial tissue compared to non-RA controls.
Methods: Transcriptomics profiling was performed on RNA isolated from synovial tissue biopsies. Normal synovium was collected from subjects with knee pain and without diagnosis of OA or RA (n=28). Arthralgia tissue was collected from ACPA-positive subjects without synovitis (n=10). Early RA tissue was collected from patients recently diagnosed (<1 year) with RA (n=57). Established RA tissue was collected from ACPA-positive subjects with >1 year of disease duration (n=95). Protein expression was confirmed on infiltrating immune cells from synovial biopsy cell suspensions by flow cytometry in separate RA subjects.
Results: Several pathways previously identified as important for RA pathogenesis (e.g., lymphocyte activation, osteoclast differentiation, NF-kappa B signaling) were enriched in differentially expressed genes in disease synovial biopsies compared to normal tissue samples. Interestingly, several genes known to function in T cell activation as signal 2 co-stimulatory or co-inhibitory molecules were differentially expressed, even in arthralgia and early RA subjects. 66 of 81 known co-stimulatory or co-inhibitory genes profiled were differentially expressed (FDR <5% and absolute fold-change >2) in disease samples from at least one cohort. The genes encoding co-stimulatory proteins that were increased compared to normal included *CD28*, *CD40LG*, *CD40* and *ICOS*. Interestingly, some of the genes encoding co-inhibitory proteins were increased (*PDCD1*/PD-1, *CD274*/PD-L1, *HAVCR2*/TIM3, *TIGIT, BTLA*), whereas others showed decreased expression (*C10orf54*/VISTA and *LAG3*) compared to normal controls. We focused on *CD28* expression, which is elevated in "pre-RA" arthralgia samples, proposing that anti-CD28 therapeutics could be candidates for RA disease prevention. By flow cytometry we demonstrated that a majority of CD4+ (>90%) and CD8+ (>60%) T

cells from RA synovial biopsy cell suspensions (n=4) showed surface expression of CD28.
Conclusions: We have generated a unique dataset from different phases of RA progression. Our results provide guidance for the selection of co-signaling molecules as therapeutic targets as well as for preventing the progression to RA. In particular, *CD28* expression was elevated in synovial tissue biopsies before the development of RA and it was also expressed on the majority of synovial tissue infiltrating CD4+ and CD8+ T cells from RA patients. These observations provide rationale to target CD28 for both RA treatment and disease interception.

THU0012 HLA-DBR1 ALLELES PROFILE IN PATIENTS WITH RHEUMATOID ARTHRITIS: RELATION TO DISEASE SUSCEPTIBILITY AND SEVERITY

A. Paradowska-Gorycka[1], B. Stypinska[1], E. Haladyj[2], K. Romanowska-Prochnicka[2], A. Pawlik[3], M. Olesinska[2]. *[1]Department of Molecular Biology; [2]Department of Connective Tissue Diseases, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw; [3]Department of Physiology, Pomeranian Medical University, Szczecin, Poland*

Background: Rheumatoid arthritis (RA) is a complex, chronic autoimmune disease (AID) that affects approximately 0.5%–1% of the population worldwide. RA is considered to be complex diseases of unknown etiology, where the environmental, immunological and genetic factors contributed to susceptibility and severity of the disease. Since the first evidence suggesting the involvement of human leukocyte antigens (HLAs) in RA was reported in 1969, the HLA region have been at the center of genetic studies of RA.
Objectives: We undertook this study to elucidate the association between HLA-DRB1 alleles profile and susceptibility to and severity of RA in a Polish population.
Methods: We analyzed the data on a total of 472 RA patients in whom HLA-DRB1 allele genotyping had been performed. DNA sequences for exon 2 of the DRB1 locus were typed using polymerase chain reaction-sequence-based typing (PCR-SBT).
Results: Identification of the variants potentially associated with risk and protection was carried out by comparison to the DKMS Polish Bone Marrow Donor Registry (41306 alleles). A significant increase in the frequency of the HLA-DRB1*15:01 ($p=0.001$), DRB1*04 ($p<0.0001$), DRB1*01:01 ($p<0.0001$),DRB1*10:01 ($p=0.003$) and *09:01 ($p<0.0001$) were identified in patients with RA and showed strong association with the disease susceptibility. Furthermore, the HLA-DRB1*07:01 allele was found to be protective ($p<0.0001$) in our RA patients. In the RA patients with HLA-DRB1*52:01 allele the mean value of PLT ($p=0.03$) and organ symptoms ($p=0.02$) were more frequent than in RA patients without this allele. In RA patients with DRB1*01:01, DRB*04 as well as DRB1*15:01 alleles the number of tender joints ($p=0.03$), diabetes ($p=0.03$) and renal failure) $p=0.03$) were observed less frequently compared with RA patients without these alleles. We also observed that in RA patients with DRB1*10:01 the VAS score was higher than in RA patients without this allele.
No association was detect between the HLA-DRB1*07:01 and DRB1*09:01 and disease activity and laboratory parameters among RA patients.
Conclusions: Current finding indicated that HLA-DRB1*15:01 DRB1*04, DRB1*01:01 and DRB1*10:01 alleles may be associated with susceptibility to as well as severity of RA.

THU0013 TOWARDS THE DEFINITION OF A RISK MODEL PROFILE OF PERICARDITIS IN SYSTEMIC LUPUS ERYTHEMATOSUS: A GENETIC STUDY

C. Perricone[1], F. Ceccarelli[1], C. Ciccacci[2], S. Rufini[2], C. Alessandri[1], F.R. Spinelli[1], E. Cipriano[1], C. Politi[2], A. Latini[2], G. Novelli[2], G. Valesini[2], P. Borgiani[2], F. Conti[1]. *[1]Lupus Clinic, Rheumatology, Department of Internal Medicine, Sapienza University of Rome; [2]Department of Biomedicine and Prevention, University of Rome Tor Vergata, Rome, Italy*

Background: We have recently demonstrated that polymorphisms (SNPs) in TRAF3IP2 gene are associated with susceptibility for systemic lupus erythematosus (SLE) and can predispose to the development of pericarditis (1). Moreover, we found that other genes previously associated with susceptibility to SLE (MIR1279, STAT4, PTPN2) seem to be involved in the development of pericarditis (2). At this purpose, we built a genetic risk model for the development of pericarditis in SLE (3).
Objectives: We aimed to expand the knowledge on the genetic risk of pericarditis in SLE by studying the role of rs2205960 (TNFSF4) and rs2233945 (ATG16L1) SNPs, previously associated with SLE susceptibility, improving our genetic risk model.
Methods: We recruited SLE patients (diagnosed according to 1997 revised ACR criteria) and healthy subjects served as controls. Study protocol included complete physical examination and blood drawing. The clinical and laboratory data were collected in a standardized, computerized, electronically-filled form (3). Clinical and laboratory features were assessed with a dichotomous score (present=1; absent=0). SNPs genotyping was performed by allelic discrimination assay. A case/control association study and a genotype/phenotype correlation analysis were performed and a risk profile model for pericarditis in SLE was built.
Results: Three-hundred fifteen SLE patients [285 F (90.5%), 30 M (9.5%), mean age 43.11±11.28 years, mean age at onset 32.19±11.84 years] and 278 healthy controls were enrolled. Pericarditis was present in 56 (17.8%) SLE patients. Deviations from Hardy–Weinberg equilibrium for the studied SNPs were not observed. The variant alleles of the rs2205960 (TNFSF4, P=0.013, OR=2.14) and of the rs2233945 (ATG16L1 P=0.009, OR=2.32) were significantly associated with susceptibility to pericarditis. A risk profile model for pericarditis considering the risk alleles of TRAF3IP2, MIR1279, STAT4, PTPN2, TNFSF4 and ATG16L1 showed that patients with more than 5 risk alleles have a significantly higher risk to develop pericarditis ($P<0.001$, OR=8.01). Anti-Sm antibodies were the only laboratory parameter associated with the development of pericarditis. Thus, a multivariate analysis by binary regression analysis, considering as dependent variable the presence or absence of pericarditis and as independent variables all the studied SNPs associated with pericarditis, was performed. In a stepwise approach including anti-Sm, TRAF3IP2, MIR1279, STAT4, PTPN2, TNFSF4 and ATG16L1 SNPs, the model explains about 25% (R^2 Cox &Snell) of the variability involved in the susceptibility to pericarditis.
Conclusions: We describe for the first time the contribution of TNFSF4 and ATG16L1 SNPs in pericarditis development in SLE patients. We improved our genetic risk profile model to better and earlier identify SLE patients more susceptible to develop this complication.

THU0014 NO ASSOCIATION OF SNP RS3761847 WITH THE EXPRESSION OF THE TRAF1-C5 LOCUS AND INVASION OF RHEUMATOID ARTHRITIS SYNOVIAL FIBROBLASTS

D. Ferry[1,2], M. Trenkmann[2], K. Creevey[2], A.G. Wilson[2]. *[1]School of Medicine; [2]The Conway Institute of Biomolecular and Biomedical Research, University College Dublin, Dublin, Ireland*

Background: Polymorphisms in the *TRAF1-C5* locus have been associated with susceptibility to rheumatoid arthritis (RA). A single nucleotide polymorphism (SNP) rs3761847, located in the first intron of the *TRAF1* gene, has been identified as an RA risk locus in a genome-wide association study (GWAS); the relationship of rs3761847 with joint damage are unclear. One of the key mechanisms of joint destruction is the degradation of and invasion of cartilage by RA synovial fibroblasts (RASF).
Objectives: To determine whether the expression of *TRAF1-C5* genes and the invasion of RASF are associated with the genotype at rs3761847.
Methods: The genotype at rs3761847 was determined using TaqMan Allelic Discrimination Assay. Invasion assays were performed using Matrigel-coated invasion chambers. Peripheral blood mononuclear cells (PBMC) were obtained by density gradient centrifugation. Neutrophils were isolated from the red blood cell layer by erythrocyte lysis; $CD14^+$ cells were separated using magnetic cell sorting. Macrophages were differentiated from plastic-adhered monocytes in M-CSF (50ng/ml) for 8 days. Cells were stimulated with lipopolysaccharide (LPS, 100ng/ml) plus interferon γ (IFNγ, 20ng/ml), interleukin 4 (IL-4, 20ng/ml) or tumour necrosis factor α (TNF-α, 10ng/ml). Gene expression was measured by SYBR Green real-time PCR using HPRT1 as a housekeeping gene.
Results: rs3761847 was in Harvey-Weinberg equilibrium in RASF (n=54, p=0.98) with genotype frequencies of 0.42 AA, 0.45 AG and 0.13 GG. When grouped by genotype, the expression of TRAF1 (total), TRAF1 transcript variant 2 and complement C5 mRNA showed no significant difference (p=0.929, p=0.583, p=0.980 respectively). This was also the case for invasion of RASF (n=43, p=0.548; mean cell count 10.4 AA, 8.3 AG and 11.1 GG). There was no correlation of genotype with common RA disease markers (CRP p=0.718, ESR p=0.179, RF titre p=0.466, ACPA titre p=0.712). In contrast, analyzing TRAF1 expression in different types of blood cells, significantly higher levels of TRAF1 mRNA were detected in monocytes carrying the AA genotype compared with the GG genotype at rs3761847, both in unstimulated (2.26-fold) as well as LPS+IFNγ-activated cells (2.04-fold; $p<0.05$, n=3 each). No significant association of TRAF1 expression or transcript variant utilization with rs3761847 was observed in the other blood-derived cell types studied, i.e. PBMC, macrophages and neutrophils,

or using other stimuli, i.e. IL-4 and TNF-α, indicating a specific function for the rs3761847 polymorphism in unstimulated and LPS+IFNγ-activated monocytes.
Conclusions: Our findings suggest that there is no relationship between invasive capacity of RASF or expression of TRAF1-C5 genes and genotype at rs3761847. In contrast, we report an association of the rs3761847 genotype and TRAF1 expression in monocytes. These data underline the importance of studying genotype-phenotype associations in the different cell types relevant for RA pathogenesis.

THU0015 INVESTIGATION OF JUVENILE IDIOPATHIC ARTHRITIS (JIA) IN GREECE: NEW SUSCEPTIBILITY LOCI

M.I. Zervou[1], D.G. Dimopoulou[2], E. Eliopoulos[3], M. Trachana[4], P. Pratsidou-Gkertsi[4], A. Andreou[3], A. Garyfallos[2], G.N. Goulielmos[1]. *[1]Medical School, University of Crete, Heraklion, Crete; [2]4th Department of Internal Medicine, Hippocratio Hospital, Aristotle University of Thessaloniki, Thessaloniki; [3]Biotechnology, Agricultural University of Crete, Athens; [4]1st Department of Pediatrics, Aristotle University of Thessaloniki, Thessaloniki, Greece*

Background: Juvenile idiopathic arthritis (JIA) is an autoimmune disease characterized by persistent chronic arthritis, in which both genetic and environmental components are involved [1]. Different genetic variations have been reported as risk factors for JIA, but a difficulty of the replication of results in different ethnic backgrounds indicates the existence of an ethnic heterogeneity of genetic factors for JIA.
Objectives: We sought to validate three single nucleotide polymorphisms (SNPs), namely *PTPRC* (rs10919563), *TYK2* (rs34536443) and *PRKCQ* (rs4750316), previously found to be associated with JIA [2–4], and to investigate whether the 27-bp VNTR polymorphism on intron 4 of *eNOS,* which is associated with various autoimmune diseases so far [5], is associated with risk for JIA in Greece.
Methods: The sample set consisted of 125 JIA patients and 221 healthy controls from Northern Greece. Genotyping of the three SNPs was performed with Taqman primer-probe sets, using a Real-Time PCR platform (Applied Biosystems, ViiA™ 7 Real-Time PCR System), while *eNOS* VNTR polymorphism was genotyped by PCR. Odds ratios (OR) and 95% confidence intervals (CI) were calculated and the statistical difference in allele distribution was assessed by means of x^2 test or Fisher's exact test. Bioinformatic analysis was performed using BlastP, Pymol and Maestro and Desmond (Schrodinger Inc.).
Results: A case–control association study was conducted enrolling 4 successfully genotyped markers. *eNOS* only was found to be associated with JIA. Genotype a/a and allele "a" were more common in individuals with JIA than in controls ($p<0.0001$, OR=0.15, 95% CI 0.065–0.37 and $p<0.0001$, OR=0.34, 95% CI 0.23–0.49, respectively). No associations with JIA were detected for *TYK2, PTPRC* or *PRKCQ*. Aiming to investigate the structural consequences and the structure/function relationships accompanying the Pro1104 to Ala (rs34536443) mutation on TYK2 protein, bioinformatics analysis was performed. Combining 3D-modeling and Molecular Dynamics simulations we have noted changes in structural flexibility, affecting the functionality of the kinase domain of TYK2.
Conclusions: This study demonstrated for the first time that *eNOS* VNTR polymorphism is associated with susceptibility to JIA, thus suggesting that the risk allele "a" may confer susceptibility to clinically distinct disorders. Apart from the previously reported evidence for the role of *PTPRC* rs10919563, *PRKCQ* rs4750316 and *TYK2* rs34536443 in an increased risk for JIA, our results demonstrate no association of these genes with JIA in the Greek population. However, the lack of association of *PTPRC* SNP with JIA is in line with previous data reported from cohorts in US and Australia. Taken together, the results highlight the importance of comparative studies in different populations, considering that replication of previously identified markers is paramount to determine which SNPs represent true risk loci, thus pointing towards key disease pathways which warrant further study.

THU0016 A COMPREHENSIVE CONTRIBUTION OF GENES OF THE HYPOXIA INDUCIBLE FACTOR-1 ALPHA SIGNALING PATHWAY TO KNEE OSTEOARTHRITIS SUSCEPTIBILITY

J. Fernandez-Torres[1,2], G.A. Martínez-Nava[1], A. López-Reyes[1], Y. Zamudio-Cuevas[1], D. Clavijo-Cornejo[1], K. Martínez-Flores[1], M.C. Gutiérrez-Ruíz[2], L.E. Gómez-Quiroz[2], C. Pineda[1]. *[1]Laboratorio de Líquido Sinovial, Instituto Nacional de Rehabilitacion; [2]Cellular Physiology Laboratory, Universidad Autónoma Metropolitana-Iztapalapa, Mexico City, Mexico*

Background: The hallmark of osteoarthritis (OA) is the breakdown of articular cartilage. Articular cartilage is an avascular tissue, and this generates a hypoxic microenvironment. Hypoxia inducible factor-1α (HIF-1α) is the main transcriptional regulator of cellular and developmental response to hypoxia.
Objectives: The present study was designed to investigate whether genetic polymorphisms of the HIF-1α signaling pathway are involved in the development of knee OA.
Methods: A total of 243 unrelated Mexican-mestizo individuals comprising 93 knee OA patients and 150 healthy controls were recruited into the study. 42 genetic polymorphisms from 22 genes involved in the HIF-1α signaling pathway (*PIK3R1*, *AKT2*, *GSK3B*, *IL6*, *AGER*, *HIF1A*, *EGLN1, VHL*, *HIF1AN*, *VEGFA*, *EPO*, *NOS2*, *NOS3*, *IGF1*, *EGF*, *EDN1*, *MMP1*, *MMP3*, *MMP13*, *CA*, *COL2A1*, *COL3A1*) were genotyped in cases and controls using TaqMan-based allelic discrimination assays.
Results: After adjusting for age, sex and admixture, significant associations with knee OA were found for 7 SNPs in the case-control study. The following genotypes and alleles were associated with protection against OA: the CT genotype of the *HIF1AN* rs11190613 polymorphism (OR=0.44, 95% CI=0.19–1.0, *P*=0.05); the AA genotype of the *VEGFA* rs1570360 polymorphism (OR=0.14, 95% CI=0.02–0.69, *P*=0.016); the GT genotype and T allele of the *VEGFA* rs729761 polymorphism (OR=0.47, 95% CI=0.22–1.0, *P*=0.05; and OR=0.51, 95% CI=0.27–0.97, *P*=0.041, respectively); the GA genotype of the *COL2A1* rs1793953 polymorphism (OR=0.40, 95% CI=0.20–0.79, *P*=0.008); and the GG genotype and G allele of the *CKM* rs4884 polymorphism (OR=0.34, 95% CI=0.14–0.84, *P*=0.019; and OR=0.51, 95% CI=0.32–0.82, respectively). Otherwise, the CT genotype of the *COL3A1* rs2138533 polymorphism (OR=2.89, 95% CI=1.28–6.5, *P*=0.01); and the GA genotype of the *IGF1* rs35767 polymorphism (OR=2.22, 95% CI=1.11–4.43, *P*=0.024) were associated with an increased risk of OA. However, by using of epistatic interactions between HIF-1α pathway polymorphisms, we found that the gene-gene interaction had a synergistic effect over the estimated OR-values (see table).
