FRI0330 FATIGUE AND DEPRESSION IN PATIENTS WITH BEHCET'S DISEASE

J.L. Silva, D. Santos-Faria, J. Sousa-Neves, J. Rodrigues, J. Costa, C. Afonso, D. Peixoto. *Rheumatology, ULSAM, Ponte de Lima, Portugal*

Background: Behcet's disease (BD) is a systemic vasculitis of unknown etiology defined by a classic triad consisting of aphtous ulcers of the mouth and genital and uveitis. In addition to these, BD may involve cardiovascular, pulmonar, neurological, articular and gastrointestinal manifestations. Fatigue, anxiety and depression are important problems in chronic inflammatory diseases. There are few studies on fatigue in BD patients. *Ilhan et al.* [1] reported more fatigue in BD patients than in healthy controls.
Objectives: The objective of this study was to investigate fatigue and depression in patients with BD and to examine the relationship between these symptoms and disease activity and gender.
Methods: Forty four patients with BD and thirty nine healthy controls (HC) were included in this study. Age, gender, disease duration and clinical involvements were recorded. All subjects completed the FACIT Fatigue Scale (FACIT-F), Short Form-36 (SF-36), Hospital Anxiety and Depression Scale (HADS) and Health Assessment Questionnaire (HAQ). Disease activity among BD patients was assessed using the Birmingham Vasculitis Activity Score (BVAS).
Results: The mean age was 40.0 years for BD patients and 38.7 for HC. 77% of BD patients were women. The mean disease duration for BD patients was 6.1 years. All patients had oral ulcers and genital ulceration; 20 had pseudofolliculitis; 9 had uveitis, 9 had erythema nodosum, 12 had articular involvement, 5 patients had vascular involvement, 4 had pathergia, 1 had orchitis and one had gastrointestinal involvement. Thirty two BD patients were taking medication, including colchicine or DMARDs or their combinations. Seventeen patients had inactive disease and twenty seven had BVAS $\geq$1. As shown in Table 1, both the HADS-depression (HADS-D) (4.7 *vs* 2.5) and HADS-anxiety (HADS-A) (8.3 *vs* 5.7) scores were elevated in BD patients compared to healthy controls. FACIT-F was higher in healthy controls in comparison with BD group (44.1 *vs* 36.6), revealing lower levels of fatigue. There were no differences between gender on these scores.

Table 1. Comparison of BD patients and HC

Scales	BD (n=44)	HC (n=39)	P-value
FACIT-F	36.6±7.3	44.1±6.4	**<0.001**
HADS-D	4.7±2.4	2.5±2.4	**0.004**
HADS-A	8.3±4.2	5.7±2.8	**0.03**

There were no significant differences in FACIT-F, HADS-A and HADS-D scores with the disease activity (P=0.952, P=0.391 and P=0.286, respectively).
FACIT-F had a negative correlation with HAQ and HADS and a positive correlation with the different components of SF-36 and age. FACIT-F score was not correlated with disease duration (Table 2).

Table 2. Correlations between FACIT-F and HAQ, HADS-A, HADS-D, SF-36, age, disease duration in BD

	HAQ	HADS-A	HADS-D	SF-36	Age	Disease duration
r-value	-0.670	-0.569	-0.562	0.857	-0.370	0.053
P-value	**<0.001**	**<0.001**	**<0.001**	**<0.001**	**0.013**	0.103

Conclusions: In our study, fatigue and increased levels of anxiety and depression were more common in BD patients. Contrary to the study of *Ilhan et al* [1], we found that fatigue was not higher in patients with active disease. Similarly, there were no correlation between the assessed scores and gender. In spite of these results, the authors believe that controlling the symptoms may improve the quality of life in BD patients.

FRI0331 IDENTIFICATION AND VALIDATION OF POTENTIAL METABOLOMIC BIOMARKERS FOR RELIABLE DIAGNOSIS OF BEHCET'S DISEASE USING GAS CHROMATOGRAPHY WITH TIME-OF-FLIGHT MASS SPECTROMETRY

J.K. Ahn[1], J. Hwang[2], H.-S. Cha[3], E.-M. Koh[3]. *[1]Department of Internal Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine; [2]Department of Internal Medicine, Natonal Police Hospital; [3]Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic Of*

Background: Although many diagnostic criteria have been developed and revised by experts in the field, diagnosing Behcet's disease (BD) is still complicated and challenging. Metabolomic studies can lead to a better understanding of pathophysiological processes and may uncover new diagnostic markers for classification of disease subgroups and assessment of disease activity in rheumatic diseases. No metabolomic studies on serum have been attempted to improve the diagnosis and to identify potential biomarkers of BD.
Objectives: The purposes of this study were to investigate distinctive metabolic changes in serum samples of BD patients and to identify metabolic candidate biomarkers for reliable diagnosis of BD using the metabolomics platform.
Methods: Metabolomic profiling of 90 serum samples from 45 BD patients and 45 healthy controls (HC) was performed via gas chromatography with time-of-flight mass spectrometry (GC/TOF-MS) with multivariate statistical analyses. Thirty-five patients with BD and age- and sex-matched 35 HCs were randomly selected to form the discovery set, and the validation set is composed of 10 patients with BD and 10 HCs.
Results: We identified a total of 104 metabolites in the serum samples of the discovery set. To maximise the discrimination between groups BD and HCs, we applied supervised partial least squared-discrimination analysis (PLS-DA). A PLS-DA score plot of the discovery set indicated that the cluster of BD patients is well separated from HC clusters in component 1. The variation values of the PLS-DA model are R^2X of 0.246, R^2Y of 0.913, and Q^2 of 0.852, respectively, indicating strong explanation and prediction capabilities of the PLS-DA model. The PLS-DA models did not show clear and consistent discrimination between groups according to drug administration, indicating that drugs used in patients with BD had a negligible effect on the distinct metabolic profiles discriminating BD patients from HCs. A panel of five metabolic biomarkers, namely, decanoic acid, fructose, tagatose, linoleic acid, and oleic acid were selected based on their variable importance on projection values and adequately validated as putative biomarkers of BD (sensitivity 100%, specificity 97.1%, area under the curve 0.993) in the discovery set and validation set. Principal component analysis showed clear discrimination of BD and HC groups by the five metabolic biomarkers in the validation set.
Conclusions: This is the first report on detection of a characteristic metabolic profile of BD and identifying and validating potential metabolite biomarkers in

serum from BD patients using GC/TOF-MS. Further studies including a larger number of patients with BD would be warranted to validate the metabolite profiles for clinical use and to ascertain the feasibility of metabolomic analysis in BD.

FRI0332 DIFFERENCES BETWEEN TEMPORAL ARTERY BIOPSY-POSITIVE AND BIOPSY-NEGATIVE GIANT CELL ARTERITIS: A COMPARATIVE COHORT STUDY

K. Yeruva, K.J. Warrington, C.S. Crowson, M.J. Koster. *Rheumatology, Mayo Clinic, Rochester, United States*

Background: Giant cell arteritis (GCA) is the most common systemic vasculitis in patients aged 50 years or older. The presence of cranial features and an abnormal temporal artery biopsy have historically been the primary focus for diagnosis of this condition. A notable percentage of patients with symptoms of GCA have negative temporal artery biopsies, however, few cohort studies exist comparing the presentation and outcome of patients based on temporal artery positivity.
Objectives: To establish a large, single institution cohort of patients with temporal artery biopsy-negative GCA. To identify differences in presentation and outcome among patients with temporal artery biopsy-negative and temporal artery biopsy-positive GCA.
Methods: Patients with temporal artery biopsy-negative GCA diagnosed between 1/1/1998 and 12/31/2013 were identified retrospectively. Final diagnosis was confirmed by consensus among two rheumatologists and a physician abstractor. Baseline characteristics and outcomes were compared to a previously established biopsy-positive GCA cohort (n=286) from the same institution.
Results: 110 patients with temporal artery biopsy-negative GCA were identified. Unilateral biopsies were performed in 73, bilateral-sequential in 10, and bilateral same day in 27 cases. Median duration between steroid initiation and biopsy was 3 days. Median length of first biopsy was 14mm and second biopsy (if performed) was 22mm. Among biopsy-negative patients with advanced imaging within 6-months of diagnosis, 67% (41/61) had evidence of large vessel vasculitis. Patients with biopsy-negative GCA were younger (72.0±9.0 vs 75.0±7.6; p=0.001), met fewer ACR criteria ($\geq$3 criteria 64% vs 95%; p<0.001) and had a shorter time from symptom onset to diagnosis (median 1.1 vs 2.1 months; p<0.001). Vascular risk factors evaluated at diagnosis showed a higher rate of pre-existing hypertension and obesity among patient with biopsy-negative GCA but similar rates of smoking and diabetes mellitus. Frequency of headache and vision loss at time of presentation were similar between groups. However, biopsy-negative GCA patients had more temporal artery tenderness (35% vs 16%; p<0.001) and arm claudication (13% vs 2%; p<0.001) but less frequent jaw claudication (19% vs 52%; p<0.001). Anorexia, fatigue, and arthralgia were also more commonly noted in biopsy-negative patients. Baseline CRP was lower among patients with negative biopsies (44.3±53.6 vs 70.4±63.9 mg/L; p<0.001).
Initial prednisone dose was similar among both cohorts. Although cumulative glucocorticoid (GC) was lower in biopsy-negative patients at 1 year (6.3±2.6 vs 7.2±2.7 g; p=0.004), cumulative GC doses at 2-years and 5-years were equivalent. Biopsy-positive patients (5-years, 56±3%) were able to discontinue GC sooner than biopsy-negative patients (5-years, 30±5%; p<0.001). The number of relapses, time-to-first relapse, annual relapse rate and mortality did not differ based on biopsy positivity.
Conclusions: While similarities are present, notable differences are observed at diagnosis in patients with biopsy-negative GCA. Further research is needed to confirm and understand the variability in GC duration.

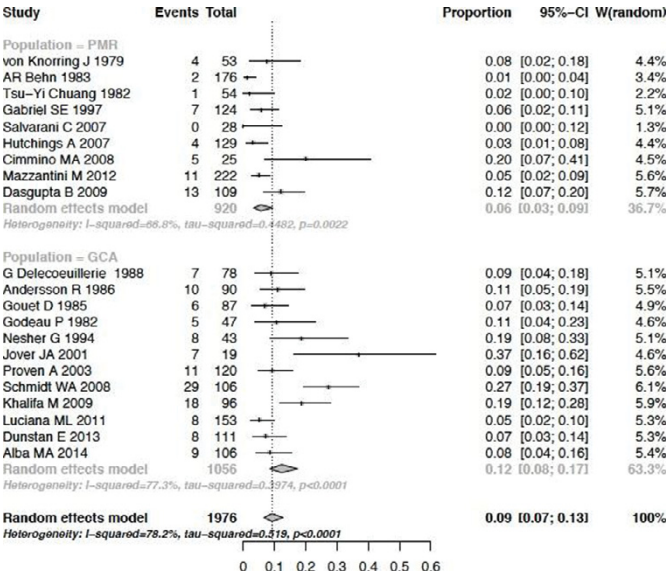
FRI0333 OCULAR INVOLVEMENT IN BEHÇET'S DISEASE ABOUT 221 CASES



K. Echchilali, W. Bouissar, M. Moudatir, F.-Z. Alaoui, H. Elkabli. *Internal Medicine Department, University Hospital Centre Ibn Rochd, Casablanca, Morocco*

Background: Behçet's disease (BD) is a chronic systemic inflammatory disorder of unknown etiology. It's chracterised by recurrent oral aphtosis and genital ulcer. Ocular involvement has been recognized since the time of Hypocrates. Estamates of the prevalence vary in different countries and may represent differences in the disease, in acces to health care and in availabale treatments.
Objectives: The aim of this study is to describe the epidemiological and clinical characteristics in moroccan patients with ocular BD.
Methods: retrospective study in internal medicine department over 13 years and including 221 patients with ocular BD. The diagnosis was performed by the International Study Group for Behçet's Disease and/or the International Criteria for Behçet's Disease.
Results: 221 (prevalence: 43%) had ocular involvement.154 men and 63 women (sex ratio: 2.5). The mean age at the onset of ocular involvement was 30.5 years. This achievement was inaugural in 18.55% of cases. The average time of diagnosis in other cases was 3.41 years.There was a high prevalence of Uveitis (total: 34%, anterior: 32%, posterior: 31.2). Retinal Vasculitis was noted in 37 eyes and retinal detachment in 17 eyes. Neurological events were associated in 13.57% of cases, joint and vascular events in respectively 18 and 17 cases. The topical corticosteroid therapy was prescribed in 27, 14% of cases, oral in 47, 51% and bolus in 29, 41%. 47, 51% of casers received Cyclophosphamide and 19% received Azathioprine. Cyclosporine was administered in 3 cases, interferon and Infkiximab in 2 cases each. The evolution was good in 111 cases (50.22%), treatment failure was noted in 24% of cases and recidivism in 16.74% of cases.63 patients have evolved into blindness which was bilateral in 51.1% of cases.
Conclusions: Only early diagnosis and appropriate management can improve the prognosis of ocular involvement in BD.

FRI0334 WHAT IS THE ABSOLUTE RISK OF DEVELOPING DIABETES MELLITUS IN PATIENTS WITH GLUCOCORTICOID-TREATED POLYMYALGIA RHEUMATICA AND GIANT CELL ARTERITIS? A SYSTEMATIC REVIEW AND META-ANALYSIS

L. Lai[1], E. Harris[1,2], R.M. West[3], S.L. Mackie[1,4]. *[1]Leeds Institute for Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]School of Human and Health Sciences, University of Huddersfield; [3]Leeds Institute of Health Sciences, University of Leeds; [4]NIHR-Leeds Musculoskeletal Biomedical Research Unit, Leeds, United Kingdom*

Background: Polymyalgia rheumatica (PMR) and giant cell arteritis (GCA) are treated with glucocorticoids (GCs) but long-term GC use is associated with diabetes mellitus (DM). The absolute incidence of this serious complication in this patient group remains unclear.
Objectives: To quantify the absolute risk of GC-induced DM in PMR and GCA in published literature.
Methods: We identified literature from inception to February 2016 reporting diabetes following exposure to oral GC in patients with PMR and/or GCA without pre-existing diabetes. A random-effects meta-analysis was performed to summarise the literature. Risk of bias was assessed using the Cochrane Collaboration tool.
Results: 21 eligible publications were identified. In studies of patients with GCA, mean cumulative GC dose was almost two times higher than in studies of PMR (8.9g vs 5.0g), with slightly longer treatment duration but much longer duration of follow-up (8.8years vs 4.4years). The incidence proportion (cumulative incidence) of patients who developed new-onset DM was 6% (95% CI: 3–9%) for PMR and 12% (95% CI: 8–17%) for GCA. Heterogeneity between studies was high (I^2=78.2%), as there were differences in study designs, patient population, geographical locations and treatment strategies. Based on UK data on incidence rate of DM in the general population[1], the expected background incidence rate of DM over 4.4 years in PMR patients and 8.8 years in GCA patients (the duration of follow-up) would be 4.8% and 9.7%, respectively. Very little information on predictors of DM in PMR or GCA patients was found. The overall risk of bias was high for many of the observational studies, especially relating to definition and recording of outcome and prognostic variables.

Conclusions: Physicians should screen patients treated for PMR/GCA for DM but it remains unclear what is the time-period of greatest risk and the influence of risk factors. Our meta-analysis produced plausible estimates of DM incidence in patients with PMR and GCA but there is insufficient published data to allow precise quantification of the DM risk or, crucially, which patients are at greatest risk.

FRI0335 EARLIER ONSET AND BRAINSTEM INVOLVEMENT AS KEY FEATURES IN A BRAZILIAN NEURO-BEHÇET'S DISEASE COHORT

L.L. Prado[1], G. Tinone[2], D. Callegaro[2], C.G.S. Saad[1], M. Levy-Neto[1], C. Goncalves[1]. *[1]Rheumatology Division; [2]Neurology Division, Faculdade de Medicina Da Universidade de Sao Paulo, São Paulo, Brazil*

Background: Behçet's disease (BD) is a multisystem disease in which central nervous system involvement – neuro-Behçet's disease (NBD) – may strike young patients with devastating consequences. In this regard, early diagnosis and treatment is essential to prevent injury.
Objectives: This study aimed to analyze NBD clinical features compared to non-neurological BD in order to distinguish disease patterns.
Methods: A retrospective study was performed in 101 BD outpatients from a single tertiary center followed between 2011 and 2016. BD diagnosis was based on the 2014 International Criteria for Behçet's Disease. Demographic, clinical and imaging features of 28 NBD patients were compared to 73 BD patients without neurological involvement.
Results: Earlier disease onset was found in NBD compared to BD (26.0±10.2 vs. 30.2±8.8 years, p=0.04). There were no differences between genders incidences, with a female predominance in both groups (64.3 vs. 72.6%, p>0.05). Over half of patients (53.6%) presented NBD as the first symptom and the mean time between diagnosis and NBD onset was 3.8±5.9 years. Uveitis was less frequent in NBD patients (25% vs. 47.9%, p=0.04), together with cutaneous disease (50% vs. 76.7%, p=0.01) and articular involvement (17.9% vs. 46.5%, p=0.01). Oral ulcers, genital ulcers, intestinal and vascular involvement frequencies were similar in both groups. Regarding NBD presentation, brainstem involvement was the most prevalent (67.9%), followed by central venous thrombosis (32.1%), aseptic meningitis (17.9%), stroke (3.6%) and peripheral neuropathy (3.6%). Most patients (82.1%) had a single neurological attack whereas relapsing disease was found in 18.5%.
Conclusions: Our study found an earlier disease onset in NBD patients and a lower frequency of ocular, cutaneous and articular involvement. Moreover, several patients may unfold the disease as NBD, with lack of other manifestations. In addition, brainstem lesions occurred in most patients. Recognizing these disease patterns might support to expedite NBD diagnosis.

Sánchez-Andrade[7], P. Vela[8], E. Díez[9], C. Moriano[9], P. Lluch[10], C. Moll[10], Í. Hernández[11], V. Calvo-Río[1], J. Ivorra[12], A. Corrales[1], F. Ortiz-Sanjuán[12], C. González-Vela[1], M.Á. González-Gay[1], R. Blanco[1]. *[1]Rheumatology; [2]Internal Medicine, Hospital Universitario Marqués de Valdecilla. IDIVAL, Santander; [3]Rheumatology, Hospital Universitario de la Princesa, IIS-IP, Madrid; [4]Rheumatology, Complejo Hospitalario Universitario de Santiago, Santiago de Compostela; [5]Rheumatology, Hospital de Sierrallana, Torrelavega; [6]Rheumatology, Hospital de Bellvitge, Barcelona; [7]Rheumatology, Hospital Universitario Lucus Augusti, Lugo; [8]Rheumatology, Hospital General Universitario de Alicante, Alicante; [9]Rheumatology, Complejo Asistencial Universitario de León, León; [10]Rheumatology, Hospital Mateu Orfila, Menorca; [11]Rheumatology, Complexo Hospitalario Universitario de Vigo, Vigo; [12]Rheumatology, Hospital Universitario y Politécnico la Fe, Valencia, Spain*

Background: Giant cell arteritis (GCA) is often a disease refractory to corticosteroids and, besides, the efficacy of immunosuppressive agents is not well established. In recent years, several case reports and small case series have shown efficacy with the use of tocilizumab (TCZ).
Objectives: Our aim was to assess in a clinical practise setting the short and long-term efficacy of TCZ in GCA patients with refractory disease and/or with unacceptable side effects due to corticosteroids.
Methods: Retrospective multicenter open-label study on 31 GCA patients treated with TCZ [intravenously at standard dose of 8 mg/kg/monthly (n=29), and subcutaneously at a dose of 162 mg/week (n=2)]. We assessed the efficacy on clinical and laboratory parameters, the reduction of the dose of corticosteroids, as well as the short and long-term side effects and the possibility of discontinuation or reduction of the dose of TCZ. Wilcoxon test was used to compare laboratory parameters across time.
Results: We included 31 patients (24 women/ 7 men), with a mean age of 73±9 years. The main clinical features at TCZ onset were: polymyalgia rheumatica (n=21), asthenia (n=8), headache (n=8), constitutional syndrome (n=11), jaw claudication (n=3), and visual loss (n=4). Besides corticosteroids and before TCZ onset, 26 patients had also received several conventional immunosuppressive and/or biologic drugs. Twenty-seven of 31 patients achieved a rapid and maintained clinical improvement after TCZ therapy (Table). After a median follow-up of 18 [interquartile range, 6–30] months we observe a reduction of the median of: a) CRP from 1.9 [1.1–3.7] to 0.1 [0.1–0.7] mg/dL; b) ESR from 44 [17–74] to 12 [4–16] mm/1st hour; and c) the dose of prednisone from 20 [10–45] to 2.5 [0–7.5] mg/day. In this follow-up period, the outcome of patients was as follows: a) discontinuation of TCZ (n=8) due to sustained remission; b) dose reduction due to improvement (n=5) or side effects (n=2); c) withdrawal of TCZ because of side effects (n=7); and d) the same dose that at onset (n=8). The reasons why TCZ had to be discontinued were: severe neutropenia; recurrent pneumonia; colon adenocarcinoma; cytomegalovirus infection; hypertensive crisis during infusion; myelodysplastic syndrome; and overall health deterioration. The latter patient died because of stroke. Another patient also died after the second TCZ infusion due to stroke in the context of an infective endocarditis.

	Baseline	Month 6	Month 12	Month 18	Month 24
Clinical improvement, % (n)		100** (27/27)	95** (20/21)	85** (11/13)	100** (11/11)
Laboratory markers, median [IQR]					
ESR (mm/1st/h)	44 [17-74]** (28)	6 [2-11]** (24)	7.5 [3-23]** (18)	9.5 [2-19]* (12)	6 [2-14]** (10)
CRP (mg/dl)	1.9 [1.1-3.7]** (31)	0.1 [0.1-0.7]** (27)	0.2 [0.1-0.7]** (19)	0.1 [0.1-0.5]* (13)	0.2 [0.1-0.4]** (11)
Dose of corticosteroids, median [IQR]	20 [10-45]** (31)	5 [5-9]** (29)	3.75 [0-5]** (21)	2.5 [0-5]** (13)	2.5 [0-5]** (11)

The number of patients with available data is shown in parentheses
* p <0.05 ** p <0.01 (Wilcoxon test).

Conclusions: TCZ therapy leads to a rapid and maintained improvement in patients with refractory GCA and/or with unacceptable side effects related to corticosteroids. However, the risk of neutropenia and infection should be kept in mind when using this biologic agent in patients with GCA.
Disclosure of Interest: None declared

FRI0337 ANCA PATTERN IN GRANULOMATOSIS WITH POLYANGITIS AND MICROPOLYANGITIS. A RETROSPECTIVE ANALYSIS ON A MULTICENTRIC INCEPTION COHORT

M. Felicetti[1], R. Padoan[1], S. Monti[2], A. Berti[3], G. Paolazzi[3], G. Brunori[4], R. Caporali[2], F. Schiavon[1]. *[1]Department of Medicine DIMED, Operative Unit of Rheumatology, University of Padova, Padova; [2]Department of Rheumatology, IRCCS Policlinico S.Matteo Foundation, University of Pavia, Pavia; [3]Rheumatology Unit; [4]Nephrology Unit, Santa Chiara Hospital, Trento, Italy*

Background: Granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) are multi-systemic diseases associated with anti-neutrophil cytoplasmic antibody (ANCA) often characterized by overlapping clinical manifestations. Recently ANCA pattern has been reported to define different clinical manifestations and long-term outcomes1.
Objectives: To analyze how ANCA could influence clinical manifestations and long-term outcomes in ANCA-associated vasculitis (AAV) patients, previously classified as GPA or MPA, from three different referral centers of Northern Italy.
Methods: Clinical manifestations and long-term outcomes of GPA and MPA patients were retrospectively collected. We considered clinical (including BVASv3 and VDI), radiological and histological data at diagnosis, relapse and mortality rates at the last follow-up. The complete cohort was splitted into three groups based on ANCA (anti-myeloperoxidase (MPO), anti-proteinase 3 (PR3), and ANCA negative) for statistical analysis.
Results: We included 171 patients, 90 (52.6%) anti-PR3 positive, 52 (30.4%) anti-MPO positive and 25 (14.6%) ANCA negative. Patients were mainly middle aged (52.5±15.9 years), Caucasian (98.2%) and both sexes were equally represented (Female 53.2%).
Anti-MPO positive patients were older (65 [52.5–69.7] years) at disease onset (p<0.001), affected by more comorbidities (p=0.045). They presented more frequently renal involvement (p<0.001) with higher creatinine levels at diagnosis (0.98 [0.75–1.92] mg/dL, p<0.001) (Fig. 1), systemic symptoms (p=0.039) but lower frequency of upper airways involvement (p=0.005).
Anti-PR3 positive scored higher BVASv3 at onset (p<0.001) and presented more upper airways involvement (p=0.033), lung nodules (p=0.002) and skin purpura (p=0.016).
ANCA negative showed a longer diagnostic latency (8.5 [3.5–49] months, p<0.0001), they presented with a higher VDI at diagnosis (1 [0–2.7], p<0.0001)

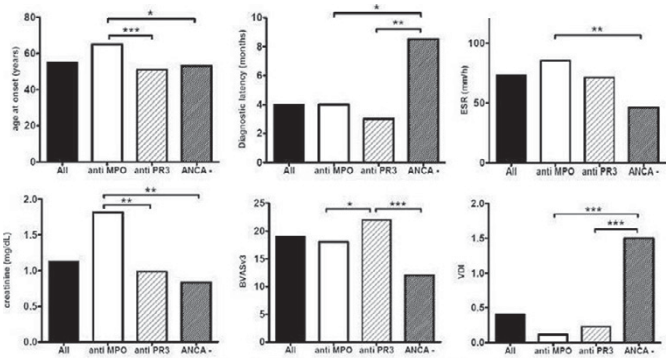

Figure 1: Post hoc analysis results. *Significance level: * p=0,05-0,01; ** p=0,01-0,001; *** p<0,001.*
ESR: erythrocyte sedimentation rate; BVASv3: Birmingham Vasculitis Activity Score version 3; VDI: Vasculitis Damage Index (VDI)

and the highest frequencies of sinuses (p=0.031), laryngeal (p=0.026) and CNS (p=0.020) involvement.
Long-term outcomes were available only in 113 patients. A low long-term mortality rate (8, 7.1% deaths) was noted (mean follow-up of 66.6±30.6 months), significantly higher in anti-MPO positive patients 7 (21.9%) when compared to anti-PR3 positive 1 (1.6%) and ANCA negative 0 (0%) ($p<0.001$). Nevertheless, the highest number of relapses/years were associated with anti-PR3 positivity (0.7±1.3 vs 0.1±0.3 in anti-MPO and 0.4±0.7 in ANCA negative, p=0.012). At multivariate analysis, anti-PR3 pattern resulted an independent predictive factor of relapses (p=0.0036, OR 5.8, IC95%: 1.1–29).
Conclusions: Our study confirms the hypothesis that each ANCA pattern could define a specific disease subset with different clinical manifestations and outcomes in AAV. Furthermore, in our cohort we observed a lower rate of recurrence and a better long term survival (92.9%) than in literature.

FRI0338 THERAPEUTIC CONFORMITY TO GUIDELINES AND DRUG-APPROVAL IN ADAMANTIADES-BEHCET'S DISEASE: A RETROSPECTIVE ANALYSIS OF A MIDDLE-EUROPEAN COHORT

T.M. Moosmann[1], C. Veraar[1], A. Frech[2], G. Ratzinger[3], B. Teuchner[4], G. Fraedrich[2], M. Schirmer[1]. *[1]Internal Medicine VI; [2]Vascular Surgery; [3]Dermatology; [4]Ophthalmology, Lkh - Medizinische Universität Innsbruck, Innsbruck, Austria*

Background: Adamantiades-Behcet's disease (ABD) is a chronic systemic vasculitic disease. Because of multiorgan involvement with diagnostic and therapeutic challenges for physicians, treatment decisions can be very difficult.
Objectives: To retrospectively assess the use of medication for ABD-therapy in view of 1.) current guidelines and 2.) approval by authorities in a Middle-European tertiary care center.
Methods: Data between 1997 and 2016 from a Middle-European ABD-cohort were retrospectively analysed. First, medical treatment was evaluated for conformity with the EULAR-recommendations for ABD-management and the anti-TNF therapy recommendations by Sfikakis et al. (1,2). Second, medical treatment was evaluated for use according to indications approved by authorities. Therefore official prescribing informations of the Bundesamt für Sicherheit im Gesundheitswesen (BASG)/European Medicines Agency (EMA), exemplary for Europe, and the Food and Drug Administration (FDA), exemplary for the USA, were screened (3–5). The study was approved by the local ethics committee.
Results: A total of 174 medical interventions were identified in 76 patients. Until 2008, treatment of ABD was based only on few clinical trials. According to EULAR-recommendations 93,7% were considered as being treated appropriately, including 55.2% of therapeutic approaches exactly matching the recommendations. 88.9% of TNF-inhibitors were indicated according to the anti-TNF-therapy recommendations (n=8/9). Out of 27 used drugs only prednisolone was approved by BASG/EMA- and FDA-authorities for a general indication including ABD, and cyclosporin A had the specific BASG/EMA-indication for ABD-uveitis. Another 12 medications had the indications for different symptoms of ABD, and thirteen medications were not authority-approved for any ABD-treatment.
Conclusions: Approvals by BASG/EMA- and FDA-authorities are often missing the indication of ABD. Therefore physicians not only face the complexity of ABD as a rare multiorgan disease, but also have to treat their ABD-patients with unapproved drugs. We propose that medications recommended by international guidelines for the management of rare diseases should be recognized by BASG/EMA- and FDA-authorities, even in case of low evidence.

FRI0339 B CELL REPOPULATION KINETICS AFTER RITUXIMAB TREATMENT IN ANCA-ASSOCIATED VASCULITIDES COMPARED TO RHEUMATOID ARTHRITIS, AND CONNECTIVE TISSUE DISEASES: A LONGITUDINAL OBSERVATIONAL STUDY ON 120 PATIENTS

J. Thiel, M. Rizzi, A. Troilo, U. Salzer, A. Venhoff, R. Lorenzetti, R. Voll, N. Venhoff. *Department of Rheumatology and Clinical Immunology, University Medical Center Freiburg, Freiburg, Germany*

Background: B cell depletion with rituximab (RTX) is approved for treatment of rheumatoid arthritis (RA) and ANCA-associated vasculitides (AAV). Recently, RTX has been shown to be effective in AAV maintenance therapy, but an optimal RTX treatment schedule is unknown and the time to B cell repopulation after RTX has not been studied.
Objectives: To compare kinetics of B cell repopulation after RTX treatment in AAV, RA and connective tissue diseases (CTD) to improve the design of RTX-retreatment schedules in AAV and other autoimmune diseases.
Methods: Retrospective single-center analysis of patients with AAV, RA or CTD treated with RTX and a follow-up of >9 months were included. B-cell-repopulation was defined as a peripheral B-cell count >0.5% and >5/μl. Prolonged B cell depletion was defined by a B cell repopulation starting later than 12 months after RTX treatment.
Results: 120 patients were included in the study. Sixty-six patients had AAV with 55 classified as granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA) and 11 as eosinophilic granulomatosis with polyangiitis (EGPA). Thirty-five patients had RA and 19 were treated with RTX because of CTD. There were no significant differences between the groups regarding age and sex. Most patients were treated with RTX 1000mg twice, two weeks apart. Cumulative CYC doses were higher in patients with AAV or CTD than in RA patients. In RA and CTD we observed a B-cell repopulation in all patients (100%) while only 33 AAV patients (50%) had started B-cell repopulation ($p<0.0001$). 93% of the RA and 88% of the CTD patients showed a normal repopulation within the first 12 months after RTX compared to only 10% in GPA and 0% in EGPA ($p<0.0001$). Mean time to repopulation was significantly longer in GPA/MPA (21 months) and in EGPA (20 months) compared to RA (8.5 months) and CTD (8.7 months). Median time of persistent depletion was 26 months in GPA/MPA, 21 months in EGPA compared to 9 months in RA and 8 months in CTD ($p<0.0001$). In 25 AAV patients B cell depletion persisted longer than 24 months (mean time 4.4±18.1 years). In ten of 55 GPA/MPA patients B-cells were still depleted 4 years, in six patients even after more than 5 years after only one RTX treatment cycle. One patient had a complete B cell depletion even 8 years after the second RTX treatment. Immunoglobulin production was affected by RTX-treatment with a significant decrease in IgG, IgA and IgM compared to baseline values in GPA/MPA, but not in RA or CTD. In EGPA only IgM declined significantly. Significantly more patients with GPA/MPA and EGPA developed a hypogammaglobulinemia (IgG<7g/L, IgM<0.4g/L). In some AAV patients hypogammaglobulinemia became clinically relevant and required IVIG treatment.
Conclusions: In contrast to RA and CTD, in AAV RTX induces long-lasting depletion of B cells that is associated with decreased antibody production. This observation points towards potential defects in the B cell compartment in AAV and has important implications for the design of maintenance treatment schedules using RTX.

FRI0340 B-CELL ACTIVATING FACTOR AS A BIOMARKER OF ACTIVITY OF SYSTEMIC NECROTIZING VASCULITIS (SNV)

L. Petelytska[1], O. Iaremenko[1], K. Iaremenko[2]. *[1]Bogomolets National Medical University; [2]Oleksandrivska City Clinical Hospital, Kyiv, Ukraine*

Background: Non-specific marker of inflammation such as C-reactive protein (CRP) and the erythrocyte sedimentation rate (ESR) have limited value in assessment of vasculitis activity. Normal ESR values do not exclude the diagnosis of active vasculitis, and its increase may be due to concomitant infection.
Objectives: To evaluate the levels of B-cell activating factor and ESR in pts with different activity of SNV.
Methods: The serum levels of B-cell activating factor (BAFF) and ESR were measured in 48 pts with SNV (granulomatosis with polyangiitis – 22, eosinophilic granulomatosis with polyangiitis – 9, microscopic polyangiitis – 6, polyarteritis nodosa – 11). The 48 pts included 18 male and 30 female with median age 49; 24 were positive for cytoplasmic antineutrophil cytoplasmic antibodies and 11 for perinuclear antineutrophil cytoplasmic antibodies. At screening, 9 pts were without any treatment, 26 pts were receiving glucocorticoids (GCs) and 13 pts were receiving some cytotoxic agents and GCs. Clinical activities of pts were calculated by the Birmingham Vasculitis Activity Score (BVAS). All pts were divided into 3 groups according to the value of BVAS: group 1 (BVAS≤11; n=12), group 2 (BVAS =12–23; n=23) and group 3 (BVAS≥24; n=13). The outcomes of this study were the differences in marker levels between groups estimated by analysis of the absolute changes in marker levels and the areas under receiver operating characteristic (ROC) curves.

Results: The levels of BAFF were significantly higher in group 3 (0.88±0.19 ng/ml) compared with group 1 (0.68±0.13 ng/ml, $p<0.05$), but did not distinguish from the group 2 (0.90±0.35). There were not significant differences in ESR between groups. ROC analysis indicated that the AUC for ESR is 0.63±0.10 ($p=0.17$) and for BAFF – 0.72±0.12 ($p<0.05$), which indicates fair capacity for BAFF differentiate groups of pts with low activity or remission of SNV and pts with severe SNV (sensitivity - 61.5%, specificity - 88.9%), while it was poor for ESR (sensitivity - 85.7%, specificity - 46.4%).
Conclusions: There are significant differences in levels of BAFF between pts with BVAS≥24 and pts with BVAS≤11. According to ROC analysis evaluation of serum BAFF level distinguishes pts with active SNV from pts with low activity or remission better than determination of ESR.

FRI0341 CLINICO-PATHOLOGICAL DISCREPANCIES AND CAUSES OF DEATH IN TAKAYASU ARTERITIS: A RETROSPECTIVE ANALYSIS OF 60 FATAL CASES

O. Zimba[1], M. Bagriy[2]. *[1]the Department of Internal Medicine, Danylo Halytsky Lviv National Medical University, Lviv; [2]Department of Pathological Anatomy, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine*

Background: Takayasu arteritis (TA) may present with a wide spectrum of symptoms common to other diseases leading to delayed or missed diagnosis.
Objectives: To investigate the rate of undiagnosed clinically cases of TA, and provide a detailed analysis of the wrong diagnoses and the underlying causes of death.
Methods: A retrospective clinicopathological analysis of sixty autopsy cases (52 males and 8 females aged 18 to 45 years) of TA over period of 11 years have been performed. The median age at disease onset was 25, 7 years.
Results: In 33 cases (55%), TA was not diagnosed during the clinical stages but only in autopsy. The most common incorrect clinical diagnosis was atherosclerosis of the aorta and its branches (celiac trunk, renal, mesenteric and iliac arteries) that has misdiagnosed in 14 cases (42.4%) of TA. TA was misdiagnosed as myocardial infarction/ischaemic heart disease in 5 (15.1%), perforated peptic ulcer in 3 (9.1%), polyarteritis nodosa in 3 (9.1%), and infective endocarditis in 2 cases (6.1%). There were other discrepancies in 6 cases (18.2%); in these cases, cerebral haemorrhage, rheumatic heart disease, pulmonary embolism, pheochromocytoma, chronic glomerulonephritis and lung cancer were the wrong clinical diagnoses. The leading position in the mortality structure due to TA belongs to septic shock that observed in 19 cases (31.7%) due to peritonitis/acute abdomen caused by mesenteric artery occlusion with subsequent intestinal necrosis in 12 (63.1%), lower limb gangrene in 6 (31.6%), and prosthetic aortic graft infection in 1 (5.3%). The second-leading cause of death was acute heart failure due to myocardial infarction, and renovascular arterial hypertension (25%). The third common cause of death was haemorrhagic shock in 14 cases (23.3%). The acute bleeding was caused by ruptured aortic aneurysm in abdominal part in 6 cases (42.8%) and ascending aorta with cardiac tamponade in 4 (28.6%). In 2 cases (14.3%), the source of hemorrhage was ulcers of gastrointestinal tract. The surgery has complicated by lethal bleeding in 2 cases (14.3%). In other patients, causes of death were cerebral haemorrhage in 6 (10%), renal failure in 3 (5%), respiratory failure in 1 (1.7%), and revascularization syndrome in 1 (1.7%). In one case, TA coexisted with scleroma of larynx, and asphyxia was direct cause of death.
Conclusions: Our date show a high number of cases of TA (55%) that were identified at autopsy but were not diagnosed clinically. It can be assumed that aortic atherosclerosis, myocardial infarction/ischaemic heart disease were the most common wrong diagnoses in TA. The leading causes of death in TA are septic shock, acute heart failure, and haemorrhagic shock. In addition, it should be noted that in our series of autopsy cases of TA, males (86, 7%) were most frequently affected compared with results other investigations. Interestingly, that the correct diagnosis of TA was established before death in all females' cases. It seems to be a trend to miss the clinical diagnosis of TA in male patients.

FRI0342 DISTRIBUTION OF VASCULITIDES IN EASTERN MEDITERRANEAN: RESULTS OF A PROSPECTIVE COHORT

O. Karadag, A. Erden, E.D. Batu, E. Bilgin, A.O. Uyaroglu, E. Seyhoglu, E.C. Bolek, E. Firat, H.E. Sonmez, S.Z. Arici, L. Kilic, A. Akdogan, S.A. Bilgen, S. Kiraz, I. Ertenli, S. Ozen. *Hacettepe University Vasculitis Center, Ankara, Turkey*

Background: The ethnic and geographical differences have been commented on, mainly from European data. We lack large data sets from the eastern part of Europe.
Objectives: This study is aimed to present the distribution of vasculitides in the Pediatric and Adult Vasculitis patient groups.
Methods: Hacettepe University is one of the main referral centers in the capital of Turkey, serving approximately 470,000 adult and pediatric patients/a year. Hacettepe University Vasculitis Centre (HUVAC) was established to organize a prospective cohort in 2014. All patients starting from October 2014 have been recorded to the database. Additionally electronic patient recording database between October 2014-December 2016 was searched for the patients having any of the 10th revision of the International Statistical Classification of Diseases (ICD)-10 code for the particular vasculitis. The study group of Hacettepe University Vasculitis Centre (HUVAC) re-evaluated the ascertained patients' hospital records to review their diagnosis according to the 2012 revised Chapel Hill nomenclature criteria.
Results: A total of 1196 patients had been newly followed in this period. 271 (22.7%) of them were pediatric patients and 31.8% of them were newly diagnosed. The leading vasculitis among adult patients was Behcet's Disease whereas in pediatric patients it was HSP/IgA Vasculitis (Table). Granulomatous polyangiitis was the most common small vessel vasculitis in adults. Takayasu arteritis was more frequent than giant cell arteritis among the adult patients. There was a female predominance in patients with large vessel vasculitis.
During prospective follow up, 22 (1.9%) patients deceased; 7 due to the primary disease, 6 due to infections, 7 due to cardio and cerebrovascular diseases.

Table. Distribution and gender of Adult and Paediatric Vasculitides Patients

Adult Patients (n=925)		
Type	Frequency,%	Female, %
Behcet's Disease	50.5	53.7
ANCA Associated Vasculitis	11.9	46.4
• GPA	• 8.9	47.9
• EGPA	• 2.2	52.3
• MPA	• 0.8	57.1
Takayasu's Arteritis	10.7	90
IgA Vasculitis	4.3	47.5
Giant Cell Arteritis	3.8	71.4
Cutaneous Vasculitis	3.2	70
Polyarteritis Nodosa	3.1	44.8
IgG4 Related Disease	2.8	48.2
CTD-Secondary Vasculitis	2.3	71.4
Polimyalgia Rheumatica	2.2	95
Primary CNS Vasculitis	0.8	42.8
Isolated Aortitis	0.8	50
Cryoglobulinemic Vasculitis	0.4	25
Others	3.2	57.3
Paediatric patients (n=271)		
Type	Frequency,%	Female, %
IgA Vasculitis	46.5	45.6
Behcet's Disease	22.5	45.9
Kawasaki Disease	17.3	45.6
Polyarteritis Nodosa	3.7	50.0
Takayasu's Arteritis	2.6	100
ANCA Associated Vasculitis	1.5	75
Vasculopathies (SAVI, DADA2)	1.5	37.5
Others	4.4	52.3

Conclusions: Behcet's Disease is the most frequent vasculitis in Turkey and more than half of the patients had organ/system involvements. GPA is the most common small vessel vasculitis whereas Microscopic polyangiitis is very rare. Among children Kawasaki was less and Behçet's disease markedly more when compared to Western European figures. Even though this study is a single-center one, the number of annual admitted patients of our hospital along with more than 2 years-prospective recruitment, reflects the true burden of vasculitides in Turkey, at the cross-roads between Europe and Middle East.

FRI0343 COGNITIVE DISORDERS IN BEHÇET'S DISEASE: SOME CLINICAL AND PATHOGENESIS RELATIONS

P. Ovcharov[1], T. Lisitsyna[1], D. Veltishchev[2], D. Burenchev[3], D. Ishchenko[2], O. Seravina[2], O. Kovalevskaya[2], Z. Alekberova[1], E. Nasonov[1]. *[1]Nasonova Research Institute of Rheumatology, Moscow, Russia; [2]Moscow Research Institute of Psychiatry; [3]City policlinic No. 12 Moscow Department of Health, Moscow, Russian Federation*

Background: the cognitive disorders (CD) is a special psychopathological problem for Behçet's Disease (BD) patients. The causes of CD aren't enough investigated. Anxiety/depressive disorders and primary neural parenchymal lesions due to BD usually related to CD in these patients.
Objectives: to determine the prevalence of CD in BD patients and its associations with some clinical and magnetic resonance imaging (MRI) scan features.
Methods: the investigation has been realized in accordance with the inter-disciplinary program "Stress factors and mental disorders in immune-mediated inflammatory rheumatic diseases".
106 BD patients were enrolled in the study. The majority of patients were men (72,6%), natives of the North Caucasus (51,9%), with mean age (M±m) 33,3±0,98 years. All the patients met the criteria of the International Study Group for BD (1990) classification. The disease activity was assessed by scoring system BDCAF.
CD were diagnosed with psychology and neuropsychology methods. Mental disorders (MD) were diagnosed by psychiatrist in accordance with the ICD-10 in semi-structured interview. The severity of depression and anxiety was evaluated

by Montgomery–Asberg Depression Rating Scale (MADRS) and Hamilton Anxiety Rating Scale (HAM-A).
Brain MRI including T1- weighted images, T2- weighted images and fluid-attenuated inversion-recovery images (FLAIR) was done in 44 (41,5%) BD patients.
Results: CD of mild to moderate severity were diagnosed in 82 (77,4%) of BD patients. The mechanical memory (50%) and attention deficit (80,5%) were the most frequent manifestations of CD, impairment of associative memory (31,7%) and logical thinking (36,6%) were less frequent. The presence of CD didn't depend on BD activity, severity and duration, as on patient's ethnicity, use of prednisone and immunosupressive agents. The frequency of neurological manifestations (headache, seizures, myelopathy, ataxia) did not differ significantly in patients with and without CD (28% vs 32%, p=0,44). The patients with CD were older (34,3±1,07 vs 29,0±2,14, p=0,006), more often had chronic/recurrent depressive disorders (84,1% vs 50,0%, p=0,001) of moderate severity (MADRS 16,1±0,74 vs 12,2±1,06, p=0,005), chronic stressful life events (91,5% vs 62,5%, p=0,001) and multifocal subcortical parenchymal MRI changes (57,6% vs 9%, p=0,005).
Conclusions: the results have shown high rates of different CD in BD patients. CD were not associated with BD activity and presence of neurological symptoms. CD were related to the diagnoses of stress-related mild to moderate chronic depressive disorders and minor brain multifocal subcortical parenchymal MRI lesions.
Disclosure of Interest: None declared

FRI0344 NOVEL BIOMARKERS OF SUBCLINICAL ENDOTHELIAL DYSFUNCTION IN BEHÇET'S SYNDROME: EVALUATION OF CROSS-SECTIONAL DISTENSIBILITY AND INTIMA-MEDIA-THICKNESS IN A HOSPITAL-BASED POPULATION

R. Talarico[1], C. Stagnaro[1], S. Barsotti[1], R. Neri[1], C. Tani[1], C. Baldini[1], N. Di Lascio[2], E. Bianchini[2], A. Morales[2], M. Mosca[1]. *[1]Department of Clinical and Experimental Medicine, University of Pisa, Rheumatology Unit; [2]CNR, Institute of Clinical Physiology, Pisa, Italy*

Background: Growing interest exists on the role of markers of subclinical cardiovascular disease as independent predictors of cardiovascular events. Poor data are available on the role of these markers as prognostic factors for Behçet's syndrome (BS).
Objectives: The primary aim was to explore Intima-Media-Thickness (IMT), mean arterial diameter and distensibility (DC) in a group of patients with BS, comparing these data with a healthy control group and a disease control group; the secondary aim was to correlate the vascular parameters with demographic/clinical profile.
Methods: Thirty BS patients (females:12;mean age±SD:43±10.5; mean disease duration±SD:13±5.8) fulfilling the ISG criteria were prospective enrolled. Demographic data, level of disease activity, frequency of smokers, hypertension, family history of cardiovascular risk factors, body mass index (BMI) and current therapies were analysed. For each subject, ultrasound B-mode image sequences of right common carotid arteries were acquired and analysed by an automatic system (Carotid Studio,Quipu) for the measurement of IMT and mean arterial diameter. In addition, carotid pulse pressure (PP) was estimated by tonometry and DC coefficient was obtained. The systolic and diastolic carotid diameters were automatically measured on the distal wall of the common carotid artery, 1–2 cm beneath the bifurcation. Carotid diameter was calculated as the distance between media-adventitia interfaces. Cross-sectional DC was estimated through the variations in arterial cross-sectional area and blood pressure during systole. DC was computed as DC=ΔA/(PP*A) where A is the diastolic lumen area, ΔA is the stroke change in lumen area, and PP is the local pulse pressure.
Results: At time of evaluation, 4/17 patients presented active disease (50% ocular involvement, 25% joint involvement, 25% gastro-enteric involvement; mean BS activity score 5). Mean IMT±SD value resulted of 0.57±0.81, mean arterial diameter±SD value was 6.879±0.81 and mean DC± SD 27.3±14.34. All the vascular parameters considered were significant correlated with BMI, while only IMT and DC were also significant correlated with arterial hypertension. Using a correction analysis for age and sex, we found significant correlations between mean arterial diameter and disease activity and between DC and disease duration. These data resulted significantly different compared to healthy control and a disease control groups, in terms of smaller arterial diameter and higher DC.
Conclusions: Our data have shown that there is a consistent influence of disease activity and duration of disease on mean arterial diameter and DC, respectively. Thus, it is desirable that future pharmacological researches on BS target on this issue.

FRI0345 CLINICAL IMPACT OF ALPHA-1-ANTITRYPSIN DEFICIENCY IN GRANULOMATOSIS WITH POLYANGIITIS

S. Deshayes[1], A. Aouba[1], F. Grandhomme[2], K. Kathy[3], D. Mariotte[3], J. Boutemy[1], G. Maigné[1], C. Brière-Bellier[4], C. Delmas[1], B. Bienvenu[1], N. Martin Silva[1]. *[1]Department of Internal Medicine; [2]Department of Biochemistry; [3]Department of Immunology, CHU Côte de Nacre, Caen; [4]Department of Infectious Diseases, CH Mémorial, Saint-Lô, France*

Background: Deficiency in α-1-antitrypsin (AAT), which is the main proteinase 3 (PR3) inhibitor, is now recognized as a pathogenic factor in some cases of anti-PR3 anti-neutrophil cytoplasmic antibodies (ANCA) related granulomatosis with polyangiitis (GPA). However, the clinical impact of AAT deficiency remains poorly established in this setting.
Objectives: The purpose of our study was to describe the clinical phenotypes and outcomes of anti-PR3 GPA patients according to their AAT status.
Methods: A retrospective monocentric study carried out in Caen University Hospital led to identify anti-PR3 GPA patients, from 09/21/2011 to 06/10/2016. AAT dosage and phenotype (isoelectric focusing in agarose gel) were performed for all patients. Categorical variables were reported as percentages and compared using Chi^2 or Fisher's tests according to expected frequencies. Continuous variables were expressed as means and analysed using Student's t-test. Associations between survival, renal survival or relapse-free survival, and AAT phenotype were evaluated by the log-rank test. A p-value <0.05 was considered to be statistically significant.
Results: Among the 72 identified anti-PR3 GPA patients, 40 (56%) were male. Median age at diagnosis was 60.5 years old. Patients mainly had constitutional symptoms (51, 71%), pulmonary (52, 72%), ear, nose or throat (ENT) (49, 68%), rheumatologic (45, 63%), and renal (44, 61%) involvements. Median initial BVAS score was 38 (maximum score: 63). Twelve (17%) deaths and 33 (46%) relapsing patients were noted (median follow-up: 55 months). Forty-eight (67%) patients had MM phenotype, 10 (14%) MZ phenotype, 8 (11%) MS phenotype, 3 (4%) M-variant phenotype, 2 (3%) ZZ phenotype and 1 (1%) ZS phenotype. Allele frequencies of M, Z and S allele were 81, 10 and 6%, respectively. The whole patient cohort had the same immunosuppressant drug regimen.

Tab;e 1

	Z carriers (n=13)	Non-Z carriers (n=59)	p-value	Z or S carriers (n=21)	Non Z or S carriers (n=51)	p-value
Initial BVAS (median)	18	18	0.91	18	18	0.71
Death (%)	15	17	1	14	18	1
Age at diagnosis (years, median)	61	60	0.91	61	59	0.62
Relapse (%)	38	47	0.56	43	47	0.75
Intra-alveolar hemorrhage (%)	47	14	**0.004**	43	12	**0.009**
ENT (%)	92	63	**0.05**	67	69	0.88
AAT level (g/L, median)	1.07	1.65	**<0.001**	1.11	1.65	**<0.001**

Only intra-alveolar hemorrhage (IAH), that was more frequent in Z or S deficient allele patients, and ENT involvement, that was more frequent in those with Z allele, were significantly associated with AAT deficiency. Among the 13 patients carrying Z allele, 9 had normal AAT level, including 6 without any biologic inflammatory parameter at the time of AAT dosage. Global survival, renal survival or relapse-free survival were identical between Z carriers compared to non-Z carriers (respectively 0.77, 0.75 and 1), and between Z or S carriers compared to those without (respectively 0.91, 0.44 and 0.32).
Conclusions: This study confirms the epidemiological association of anti-PR3 GPA with AAT deficiency, and find an interesting higher risk of IAH in this setting. The identical prognosis of both subgroups should be related to other therapeutic added in IAH, including plasma exchanges. Prospective studies are required to specify these data and to assess the need for replacement therapy in AAT deficient patients.

FRI0346 RENAL INVOLVEMENT IN GRANULOMATOSIS WITH POLYANGIITIS

N. Bulanov[1], E. Makarov[2], E. Kuznetsova[1], M. Bulanova[3], P. Novikov[1], S. Moiseev[1]. *[1]Sechenov First Moscow State Medical University; [2]Lomonosov Moscow State University, Moscow; [3]Vladimir Regional Clinical Hospital, Vladimir, Russian Federation*

Objectives: We assessed the frequency, clinical features and prognosis of renal involvement in granulomatosis with polyangiitis (GPA) and current treatment approaches.
Methods: We performed a retrospective analysis of 234 patients with GPA, diagnosed according to Chapel-Hill Consensus Conference 2012 classification, 81 male and 153 female, aged 53 (41; 62) years. 54 patients (23.1%) had localized GPA. 174 (74.4%) were ANCA positive. Median follow up was 61.5 (32; 105) months. 103 patients (44%) had a history of renal involvement. Frequencies of proteinuria, hematuria, hypertension, rapidly progressive glomerulonephritis (RPGN), acute kidney injury (AKI) and chronic kidney disease (CKD) grades were analyzed.
Results: In 25 patients (24.3% of 103) renal involvement developed at disease

onset, the other 78 patients (75.7%) developed glomerulonephritis after a median of 3 (1; 12) months. Hematuria was present in 94 (91.3%), proteinuria in 85 patients (82.5%), nephrotic syndrome in 11 patients (10.7%), hypertension in 31 patients (30.1%). Rapidly progressive glomerulonephritis (RPGN) defined by the doubling of serum creatinine within ≤3 months developed in 29 patients (28.2% of 103). Myeloperoxidase-ANCA-positive patients (n=12) developed RPGN significantly more often than proteinase-3-ANCA-positive patients (n=78): 7 (58.3%) vs 22 (28.2%) (p=0.0499). 11 (10.7%) patients developed AKI, stage 3 being the most common (in 8 patients). 40 (38.8%) patients exhibited indolent renal disease course, i.e. without worsening of renal function. By the end of the follow-up, 33 (32.0%) patients were diagnosed with CKD grade 3b-5, among them 11 patients (10.7%) developed end-stage renal disease (ESRD). 6 patients (5.8%) died. As the first line induction therapy all patients received corticosteroids in combination with cyclophosphamide in 93 patients (90.3%), rituximab (RTX) in 3 patients (2.9%), mycophenolate mofetil in 7 patients (6.8%). RTX was used for remission induction in 27 (26.2%) patients due to refractory or recurrent disease. During follow-up, 74 patients (71.8%) developed one or more severe relapses with a relapse rate of 0.27 per patient-year. 50 (48.5%) patients had renal relapses (0.096 per patient-year).

Conclusions: Prevalence of renal involvement in the studied group was lower than expected, most likely because of a large proportion of patients with localized GPA. Our study showed that RPGN was not the most common feature of renal involvement. Almost 40% of patients developed indolent course of kidney disease. Nevertheless one third of patients developed CKD G3B or worse by the end of the follow up. Despite effective induction therapy with high-dose corticosteroids, cytotoxic agents and/or RTX relapses, both renal and extrarenal, are frequent.

FRI0347 RHEUMATOID FACTOR IS CORRELATED WITH DISEASE ACTIVITY AND INFLAMMATOTY MARKERS IN ANTINEUTROPHIL CYTOPLASMIC ANTIBOTY-ASSOCIATED VASCULITIS

S. Watanabe, T. Gono, K. Nishina, N. Sugitani, E. Watanabe, H. Yabe, C. Terai.
Rheumatology, Jichi Medical University, Saitama Medical Center, Saitama, Japan

Background: Raised levels of serum rheumatoid factors (RFs) of different immunoglobulin classes had been reported in a high proportion of patients with rheumatoid vasculitis. RF used to be studied and was shown elevated in some forms of vasculitides. Patients with antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) are often positive for RF. However, the clinical significance of RF has been seldom examined in AAV.

Objectives: The aim of this study was to investigate association between the presence of RF and clinical features and outcomes in AAV.

Methods: Eighty-one patients were diagnosed with AAV from 2006 to 2015 in our hospital. Among 81 patients, forty-seven patients (17 males, median age 67 years) who were not complicated with rheumatoid arthritis and in whom RF was measured before the treatment, were studied, retrospectively. Patients were classified using the European Medicines Agency vasculitis classification algorithm. AAV included eosinophilic granulomatosis with polyangitis (n=10), granulomatosis with polyangitis (n=14), microscopic polyangitis (n=16) and unclassifiable vasculitis (UV) (n=7). Patients with UV with MPO-ANCA or PR3-ANCA were included in this study. IgM-RF was measured using a latex agglutination assay. Disease activity was assessed with Birmingham vasculitis activity score (BVAS). IgM-RF, C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), serum ferritin, IgG, IgM, IgA, MPO-ANCA and PR3-ANCA were obtained from hospital records. Clinical manifestations between RF-positive subset (n=29) and RF-negative subset (n=18) were analyzed using Fisher's exact and Wilcoxon rank sum tests. Correlation coefficients were established with Spearman's correlation coefficient. Data were shown as medians (interquartile range).

Results: BVAS was higher (14 (12–22) vs 12 (6–16), P=0.026) in the RF-positive subset than the RF-negative subset. CRP and ESR were higher (P=0.020 and 0.007, respectively) in the RF-positive patients. IgM-RF titers significantly correlated with BVAS (r=0.50, P=0.0004). In addition, CRP, ESR, IgM and IgG also had a significant correlation with IgM-RF titers. The frequency of initiation of dialysis therapy (14% vs 6%), usage of mechanical ventilation (14% vs 0%) and mortality (10% vs 0%) were higher in the RF-positive subset than in the RF-negative subset although no significant differences were shown.

Conclusions: In AAV, IgM-RF titers are significantly correlated with disease activity and inflammatory markers. Presence of RF could be a poor prognostic factor in patients with AAV.

FRI0348 ASSOCIATED INFLAMMATORY SYNDROMES IN TAKAYASU'S ARTERITIS: MANY FACES OF A DISEASE

S.N. Esatoglu[1], A.M. Celik[2], D. Ucar[3], A.F. Celik[4], S. Ugurlu[1], G. Hatemi[1], M. Melikoglu[1], I. Fresko[1], V. Hamuryudan[1], H. Ozdogan[1], S. Yurdakul[1], H. Yazici[1], E. Seyahi[1]. *[1]Istanbul University, Cerrahpasa Medical School, Department of Internal Medicine, Division of Rheumatology; [2]Istanbul University, Cerrahpasa Medical School, Department of Internal Medicine; [3]Istanbul University, Cerrahpasa Medical School, Department of Ophthalmology; [4]Istanbul University, Cerrahpasa Medical School, Department of Internal Medicine, Division of Gastroenterology, Istanbul, Turkey*

Background: Case reports and series suggest that Takayasu's arteritis (TA) can co-exist with various inflammatory disorders.

Objectives: We conducted a formal study to look specifically at the frequency of inflammatory disorders and symptoms in a large cohort of TA followed by a single tertiary center.

Methods: There were 238 patients registered with a diagnosis of TA. Of these, 19 died, 18 were lost to follow-up and 3 did not wish to response our questionnaire. The remaining 198 patients were called back at the outpatient clinic. A standardized form sought whether the patient was also diagnosed as inflammatory bowel disease (IBD), ankylosing spondylitis (AS), Behçet's syndrome (BS), amyloidosis, uveitis, rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), systemic sclerosis (pSS), Sjögren syndrome, psoriatic arthritis, inflammatory myositis, small vessel vasculitis, autoimmune/demyelinating or any other inflammatory disorder.

Results: Overall, 198 (175 F/ 23 M) patients were studied. The mean age at the time of TA diagnosis was 34±12 years. Subclavian artery was the most common involved artery (84%), followed by common carotids (78%) and aorta (65%). Currently, while 25 (16%) patients were off treatment, 72 (47%) patients were using glucocorticoids, 47 (31%) azathioprine, 32 (21%) methotrexate and 44 (29%) biological agents.

We identified in total 37 (19%) patients with inflammatory diseases (IBD: n=12; AS: n=15; and BS: n=10). Table shows their demographic characteristics. Among the remaining 161 patients, the most frequent feature was inflammatory back pain (36%), followed by recurrent oral ulcers (15%), erythema nodosum (11%), arthritis (10%), papulopustular lesions (7%), uveitis (4%), and genital ulcer (1%). It was noted that inflammatory back was mostly located on the dorsal area. Regarding autoimmune diseases, we also observed RA (n=3), psoriasis (n=2), autoimmune hepatitis (n=2), SS (n=1) and SSc (n=1).

Table 1. Demographic features of 37 TA patients with inflammatory bowel disease (IBD), ankylosing spondylitis (AS) or Behçet's syndrome (BS)

Concomitant disease	F/M	Mean age at TA diagnosis (SD)	Mean age at concomitant disease (SD)	Time of TA diagnosis in relation to concomitant disease
AS (n=15)	13/2	31±8	27±11	Simultaneous (n=3) TA preceded (n=7) AS preceded (n=5)
IBD (n=12)	11/1	33±9	31±9	Simultaneous (n=9) TA preceded (n=1) IBD preceded (n=2)
BS (n=10)	7/3	35±13	32±13	Simultaneous (n=5) TA preceded (n=1) BS preceded (n=4)

Conclusions: TA does co-occur with IBD, AS or BS in about 1/5 of the patients, at least in a hospital setting and without a clear temporal pattern. This could be due to the close association of TA with MHC class-1 diseases. In addition, the high prevalence of inflammatory back pain in the dorsal spine in TA needs further scrutiny.

FRI0349 THE SNP RS6871626 LOCATED IN IL12B REGION MAY INFLUENCE ON VASCULAR LESIONS OF TAKAYASU ARTERITIS

T. Nakajima[1], H. Yoshifuji[1], C. Terao[2], K. Murakami[1], R. Nakashima[1], Y. Imura[1], K. Ohmura[1], T. Mimori[1]. *[1]Department of Rheumatology and Clinical Immunology, Graduate School of Medicine, Kyoto University; [2]Center for Genomic Medicine, Kyoto University, Kyoto, Japan*

Background: Takayasu arteritis (TAK) is a type of large vessel vasculitis, which affects aorta and its main branches. We previously found a single nucleotide polymorphism (SNP), rs6871626 located in *IL12B* region, as a susceptible gene to TAK and reported that the risk allele at the SNP is associated with the risk of aortic regurgitation (AR)[1)]. However, there have been no studies on the association of the SNP with the organ involvements other than AR in TAK patients.

Objectives: To investigate the association of the SNP with arterial and organ involvements except for AR.

Methods: We examined the medical records of 85 patients with TAK, stratified

Abstract FRI0349 – Table 1. Organ involvements in patients

Organ involvements	AA	AC	CC	p-value	p-values of multiple comparisons†		
					AA vs. AC	AA vs. CC	AC vs. CC
Carotid arterial lesion	78.9% (15/19)	63.9% (23/36)	80.0% (8/10)	0.48*	1.00	1.00	1.00
Descending aortic lesion	75.0% (18/24)	44.2% (19/43)	25.0% (4/16)	0.0048*	0.064	0.0096	0.71
eGFR (ml/min/1.73m^2)	61.3 ± 26.9	72.9 ± 22.8	81.5 ± 28.8	0.011**	0.21	0.042	0.75

Mean ± SD, *Fisher's exact test, **one-way ANOVA, †p-value is corrected by Bonferroni's method.

them into three groups according to the allele at the SNP, AA (n=26), AC (n=43) and CC (n=16) (A is a risk allele), and investigated the association of the SNP and organ involvements.

Results: There were no differences in the complication rates of carotid arterial lesions among the groups (AA 78.9%, AC 63.9% and CC 80.0%). The proportion of patients with lesions in descending aorta (Numano classification[2] IIb∼V) was 75.0% in AA, 44.2% in AC 44.2% and 25.0% in CC and the proportion in AA was significantly higher than in CC (p=0.0096). Moreover, estimated glomerular filtration rate (eGFR) was significantly lower in AA than in CC (61.3±26.9ml/min/1.73m^2 vs. 81.5±28.8 ml/min/1.73m^2, p=0.042).

Conclusions: The SNP rs6871626 located in *IL12B* may influence on the occurrence of descending aortic lesions in TAK patients and this may lead to renal dysfunction.

FRI0350 INVESTIGATING THE LINK BETWEEN ISCHEMIC HEART DISEASE AND BEHCET'S DISEASE: A CROSS-SECTIONAL ANALYSIS

Y. Yavne[1], S. Tiosano[2], A. Watad[2], D. Comaneshter[3], A.D. Cohen[3,4], H. Amital[2]. *[1]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv; [2]Department of Medicine 'B', Zabludowicz Center for Autoimmune Diseases, Sheba Medical Center, Tel Hashomer; [3]Chief Physician's Office, Clalit Health Services, Tel Aviv; [4]Siaal Research Center for Family Medicine and Primary Care, Faculty of Health Sciences, Ben Gurion University of the Negev, Beer Sheva, Israel*

Background: Behcet's disease (BD) is a multi-systemic chronic inflammatory disorder which involves the vasculature tree of all sizes. Subclinical endothelial injury as a result of chronic inflammation in BD has been associated with thrombosis and arterial stiffness, risk factors for ischemic heart disease (IHD)[1–4]. However, data regarding the association between BD and IHD and the impact of various risk factors on this association, is scarce[3–5].

Objectives: To examine the association between BD and the development of IHD and its potential impact as a cardiovascular risk factor.

Methods: This study was conducted as a case-control study utilizing the database of Clalit Health Services. The proportion of IHD was compared between patients diagnosed with BD and age- and gender-matched controls. Univariate analysis was performed using Chi-square and student *t-test* and a multivariate analysis was performed using a logistic regression model.

Results: 871 BD patients and 4,439 age- and gender-matched controls were included in this study. The proportion of IHD amongst BD patients was increased in comparison with controls (10.9% vs. 7.52% respectively, *p*-value =0.001). After controlling for cofounders, BD was associated with IHD on multivariate analysis (odds ratio 1.485, 95% confidence interval 1.106–1.982, Table 1). When the comparison between BD patients with IHD and controls with IHD was stratified according to risk factors, age younger than 70 and male gender were both found to be significantly elevated in the BD group.

Table 1. Multivariate logistic regression for IHD (*n*=5,220)

Variable	OR	95% CI	*p*-value
Behcet	1.485	1.106–1.982	0.008
Age	1.059	1.047–1.071	<0.001
Male gender	2.929	2.248–3.841	<0.001
BMI	1.010	0.987–1.034	0.388
High SES *vs.* low	0.709	0.503–0.994	0.048
Intermediate SES *vs.* low	0.793	0.600–1.048	0.104
Arab ethnicity	0.872	0.618–1.221	0.430
Hypertension	3.050	2.332–4.010	<0.001
Hyperlipidemia	7.895	5.119–12.781	<0.001
Diabetes	1.624	1.268–2.078	<0.001
Smoking	1.849	1.445–2.371	<0.001

IHD = ischemic heart disease, OR = odds ratio, CI = confidence interval, BMI = body mass index, SES = socioeconomic status.

Conclusions: BD patients have an increased proportion of IHD in comparison with matched controls. The population of BD patients with IHD has a higher proportion of younger males in comparison with controls with IHD. Preemptive screening for IHD may be warranted in this subgroup.

FRI0351 PAPULOPUSTULAR LESIONS ACCORDING TO AGE, SEX AND LOCALIZATION IN BEHCET'S SYNDROME PATIENTS COMPARED HEALTHY AND DISEASED CONTROLS

Z. Kutlubay[1], Y. Ozguler[2], G. Hatemi[2], K. Tascilar[3], C. Mat[1], H. Yazici[2]. *[1]Department of Dermatology; [2]Department of Internal Medicine Division of Rheumatology, Istanbul University Cerrahpasa Medical Faculty; [3]Department of Internal Medicine, Okmeydani Research and Training Hospital, Istanbul, Turkey*

Background: Papulopustular lesions (PPL) are the most common skin lesions in Behçet's syndrome (BS).

Objectives: To assess whether PPL are different in BS according to localization, age, sex and medications used when compared to rheumatoid arthritis patients (RA) and apparently healthy subjects (HS).

Methods: 209 consecutive BS patients who were routinely followed in our dedicated BS center were studied. Patients with RA (n=146) who were followed up in the rheumatology outpatient clinic of the same unit and HS (n=149) were used as controls. All subjects were clinically evaluated by the same dermatologist and all skin lesions (papules, pustules, comedones, folliculitis, cysts, nodules) on the face, trunk and legs were separately counted. Information regarding the demographic and clinical features of primary disease and medications used were obtained from patients' charts.

Results: Subjects without PPL were excluded before analyses. Demographic features and mean number of PPL according to site of body were summarized in Table-1. Mean number of total PPL were similar between BS and HS and significantly higher than in RA (p<0.001). Mean number of total PPL according to sex were similar in RA and HS but higher in male BS patients compared to female BS patients (p=0.04). When we analyzed the number of PPL according to different body sites, we observed that BS patients had significantly more lesions on the legs when compared to the RA patients and HS (p<0.0001). Number of PPL lesions tend to decrease as the patient ages in BS similar to RA and HS. When leg lesions were analyzed according to age, this difference remained in the age groups 31–50 and >50 but not in the age group ≤30. Corticosteroid use did not impact the results.

Table 1

	BS	RA	HS
N	155 (74%)	57 (39%)*	101 (68%)
F/M	95/60	46/11	52/49
Mean age (SD)	38.6 (10.0)	47.5 (13)†	34.7 (12.0)
N of pts on corticosteroids	24 (15 M/9 F) (15%)	37 (9 M/28F) (65%)	–
Mean n of PPL (SD)	7.8 (8.0)	3.9 (3.8)‡	9.7 (9.5)
Trunk	107 (58F/49M) (70%)	36 (28F/8M) (63%)	81 (37F/44M) (80%)
Face	120 (80F/40M) (77%)	37 (32F/5M) (65%)	84 (50F/34M) (83%)
Legs	48 (21F/27M)§ (31%)	2 (1F/1M) (3.5%)	13 (5F/8M) (13%)

*p<0.001, †p<0.02, ‡p<0.05, §p<0.0001.

Conclusions: BS patients have significantly more PPL on the legs when compared to HS and RA. Number of PPL tend to decrease as the patient ages in BS similar to RA and HS however BS patients still have more PPL on the legs after the age of 50 suggesting that these lesions somehow differ from acne vulgaris, in pathogenesis.

FRI0352 **EFFICACY OF BIOLOGICS IN PATIENTS WITH REFRACTORY TAKAYASU ARTERITIS AND ANALYSIS OF THEIR GENETIC BACKGROUNDS**

Y. Gon[1], H. Yoshifuji[1], T. Nakajima[1], K. Murakami[1], R. Nakashima[1], K. Ohmura[1], C. Terao[2], T. Mimori[1]. *[1]Department of Rheumatology and Clinical Immunology, Graduate School of Medicine, Kyoto University; [2]Center for Genomic Medicine, Kyoto University, Kyoto, Japan*

Background: Takayasu arteritis (TAK) is a rare disease that mostly affects young females and causes inflammation, stenosis and dilatation of the aorta and its main branches. Although glucocorticoids are effective, relapses occur frequently [1]. Recently, the efficacy of biologics has been reported in refractory TAK. HLA-B*52 is a major genetic risk factor and associated with the severity [2]. Our group reported a SNP in the regions of *IL12B* gene associated with the onset of TAK, and the patients with risk alleles at the SNP showed significantly severer symptoms [3].
Objectives: To evaluate the efficacy and safety of biologics in the treatment of refractory TAK, we analyzed the clinical profiles and genetic information of patients treated with biologics in our institute.
Methods: We searched for TAK patients who used biologics in 163 TAK cases treated in Kyoto University Hospital from 2000 to 2016. From medical records, we extracted information of classifications, symptoms, complications, ESR, CRP, dose of prednisolone (PSL), use of immunosuppressive agents (IS), and adverse events at 0, 1, 6 12 months after the initiation of biologics.
Results: Of 163 cases, 12 (7.4%) were treated with biologics. Two were excluded because biologics were used for coexisting rheumatoid arthritis. Remaining 10 cases were treated with infliximab (IFX, 3–5 mg/kg div. bimonthly, N=4), tocilizumab (TCZ, 8 mg/kg div. monthly, N=3) or ustekinumab (UST, 45 mg s.c. trimonthly, N=3). Sex ratio was 1:9. The age of onset was 29.4±12.2 y.o. (mean±S.D.). According to Hata's classification [4], they were categorized into types I (N=3), IIa (2) and V (5). Three patients had aortic regurgitation. The number of IS used in the past was 1.7±0.8 per patient. B*52 was positive in 7 (70%) patients. All the cases had risk-type alleles (A vs. C) of *IL12B* SNP (AA: AC: CC =4: 6: 0). ESR was significantly decreased (p=0.009) and CRP showed a tendency to decrease after 12 mo. (Table 1). Dose of PSL was significantly decreased from 10.6±1.9 to 7.7±2.4 mg/day after 12 mo. (p=0.018). We could not find significant improvements in imaging modalities such as MR and ultrasonography. Overall duration of treatments with biologics was 39±22 months. Two cases discontinued IFX due to occurrence of breast cancer and infusion reaction, respectively. Chronic heart failure was exacerbated in a case treated with TCZ. Two of 3 patients treated with UST exhibited steroid- sparing effects and none of them discontinued UST in the mean observation period of 31 mo.

Table 1. Changes after the treatment with biologics

	Before	1 mo.	6 mo.	12 mo.	*P* (before vs. 12 mo.)
ESR (mm /h)	31±16	14±9	14±12	12±12	0.009
CRP (mg/L)	15±19	8±13	4±5	2±4	0.075
PSL (mg/day)	10.6±1.9	10.5±2.0	9.0±2.3	7.7±2.4	0.018

Conclusions: Biologics showed steroid-sparing effects in refractory TAK. Besides, there was a tendency that patients who used biologics had B*52 and the risk-type allele of *IL12B* SNP, implicating the refractory courses of them.

FRIDAY, 16 JUNE 2017

Scleroderma, myositis and related syndromes - etiology, pathogenesis and animal models

FRI0353 **SERUM PROTEOMICS PROFILE IN SYSTEMIC SCLEROSIS PATIENTS**

M. De Santis[1], E. Generali[1], A. Ceribelli[1], N. Isailovic[1], M. Caprioli[1], G.M. Guidelli[1], C. Selmi[1,2]. *[1]Rheumatology and Clinical Immunology, Humanitas Research Hospital, Rozzano; [2]BIOMETRA Department, University of Milan, Milan, Italy*

Background: Systemic sclerosis (SSc) is characterized in virtually all patients by anti-nuclear antibodies (ANA) with anti-centromere (ACA), anti-topoisomerase I (ant-Scl70), and anti-RNA polymerase III antibodies identifying patient subgroups. However, there are no reliable biomarkers predicting SSc susceptibility and internal organ involvement.
Objectives: We aimed to identify serum protein biomarkers associated with SSc and interstitial lung disease (ILD), using a highly multiplexed proteomic technology.
Methods: We analyzed serum samples of 3 patients with SSc and ILD (2 limited SSc: one ANA positive and one anti-Scl70 positive, and one diffuse SSc anti-Scl70 positive), 3 patients with SSc and no ILD (ACA positive limited SSc), and 4 healthy controls. All subjects were women and age matched. Serum proteomics profiling was performed using the SOMAscan platform (SomaLogic, Inc., Boulder, CO, USA). Statistical analysis included Student's t-test and were performed using the SomaSuite software (SomaLogic, Boulder, CO, USA).
Results: Proteomic analysis identified 33 proteins which differentiate SSc from HC and 9 proteins which differentiate SSc patients with and without ILD. Compared to healthy controls, SSc cases showed an altered expression of proteins involved in extracellular matrix formation and cell-cell adhesion, angiogenesis, and lymphocyte recruitment, activation, and signaling, while an overall inhibition of neutrophil function was noted. An interferon and IL-1 signatures were also found. Patients with SSc and ILD manifested increased protein levels related to intracellular signaling and cell cycle, along with an increase of monocyte chemoattractants and ligands for the leukocyte adhesion compared to SSc without ILD. We further observed a decrease in B cell stimulating factor and IL-22 signaling in SSc with ILD.
Conclusions: Serum proteomic profiles can differentiate SSc from healthy controls and SSc patients with and without ILD; moreover, our results identify biomarkers with a putative pathogenetic significance.

FRI0354 **CIRCULATING MICROPARTICLE SUBSETS ARE ASSOCIATED WITH PATIENTS WITH EXTENDED FIBROTIC PHENOTYPE IN SYSTEMIC SCLEROSIS**

K. Sakata[1], H. Yasuoka[1], M. Koseki[1], K. Yoshimoto[1], M. Kuwana[2], T. Takeuchi[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine; [2]Department of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine, Tokyo, Japan*

Background: In systemic sclerosis (SSc), systemic remodeling, microvascular injuries and production of autoantibodies are well known as disease hallmarks. However, the master regulator of these characteristics is still unclear. Microparticle (MP) is a small membrane vesicle, released from various kinds of cells, and distributes systemically through circulation[1)]. Recent reports revealed that MP contains various growth factors, proteases and cytokines including TGF-b[2)], suggesting that MP can contribute to immune and mesenchymal responses as a conveyor[3)]. and involve with disease process of SSc. Although, the possible involvement of MPs in the pathogenesis of SSc is indicated, the detailed association of MPs including MP subsets with SSc is not well clarified.
Objectives: To elucidate the association between circulating MP subsets and patients' characteristic of SSc.
Methods: Thirty-six patients with SSc and 13 healthy controls were involved in this study. Platelet-rich plasma containing microparticles was isolated from whole blood using gradient centrifugation and analyzed using flow cytometer. MP was defined as particles smaller than 1.0 μm diameter using Megamix®, and identified each MP subsets based on expression of cell type-specific surface markers; platelet ($CD31^+CD41^+$), endothelial cell ($CD31^+CD41^-$) and monocyte ($CD14^+CD45^+$) using fluorescence-tagged antibodies. Clinical information was retrospectively collected from patients' records, and the correlation with the number of each MP subset was analyzed.
Results: Mean age of 36 patients with SSc was 60.9±1.8 years, 94% was female, and mean disease duration was 11.2±9.5 years. Patients with diffuse cutaneous SSc (dcSSc) was 6 (17%). As for the proportion of MP subsets, platelet-derived MP (PMP) was the largest subset, followed by endothelial cell-derived MP (EMP) and monocyte-derived MP (MoMP) in all samples. In patients with SSc, the number of total MP and all MP subsets were higher than those in healthy controls ($p<0.05$). Also, all MP subsets were significantly higher in patients with dcSSc compared to limited cutaneous SSc ($p<0.001$). We also found that the number of PMP, EMP and MoMP were higher in patients who were positive against anti-topoisomerase I antibody than those negative ($p<0.01$, $p<0.05$ and $p<0.05$, respectively), whereas there were no significant differences in the numbers of each MP subset between the patients positive or negative against other SSc-specific autoantibodies. In addition, the number of PMP and EMP were higher in patients with interstitial lung disease than those without ($p<0.05$). Moreover, all MP subsets were significantly inversely correlated with the percentage of predicted forced vital capacity ($p<0.05$, $p<0.01$, and $p<0.01$, respectively).
Conclusions: These results suggest that MP subsets are associated with extended fibrotic phenotype in patients with SSc, and might be utilized as novel biomarkers.

FRI0355 IL-17A UP-REGULATION IN PERIPHERAL BLOOD MONONUCLEAR CELLS CO-CULTURED WITH AUTOLOGOUS SKIN FIBROBLASTS IS ASSOCIATED WITH DOWN-REGULATION OF PRO-FIBROTIC MEDIATORS AND INCREASED FIBROBLAST APOPTOSIS

S. Vettori[1], G. Barra[2], G. Pasquale[3], L. Pellecchia[1], L. Vicedomini[1], R. De Palma[1], G. Valentini[1]. *[1]Internal and Experimental Medicine "F. Magrassi", University of Campania "Luigi Vanvitelli", Naples; [2]Internal and Experimental Medicine "F. Magrassi", University of Campania "Luigi Vanvitelli", Napoli; [3]Internal and Experimental Medicine "F. Magrassi", University of Campania "Luigi Vanvitelli", Naples, Italy*

Background: IL-17A has been implicated in the pathogenesis of systemic sclerosis (SSc) (1). We previously showed that skewed peripheral blood mononuclear cells (PBMCs) from SSc patients can induce Fas-mediated apoptosis in co-cultured autologous skin fibrobalsts (2).
Objectives: We therefore aimed to investigate IL-17A expression and effects in these co-cultures.
Methods: PBMCs and skin fibroblasts from 5 dcSSc patients with disease duration <3 years were co-cultured up to 10 days in presence of hrIL-2 [20 U/ml] in a 1:10 ratio, as previously described. IL17A, IL17RA, CXCL1, CCL2, CCL3, TGFBR2, SMAD3, CTGF, COL1A1, COL3A1 mRNA expression was assessed by Sybr Green real-time PCR. Chemokine production was further investigated at the protein level by multiple suspension immunoassay. In subset experiments, co-cultures were treated with either IL-17A or IL-17A *plus* anti-IL17 receptor A neutralizing monoclonal antobodies (anti-IL-17RA mAb), then cells were stained with Annexin V, anti-IL17RA, and anti-FAS antibodies and were investigated by flow-citometry.
Results: IL17A mRNA in co-cultured PBMCs was increased by 11.5 fold ($p<0.01$), and IL17RA by 4.3 fold ($p<0.05$) in co-cultured fibroblasts. CXCL-11, CCL2, and CCL3 were also up-regulated at both mRNA (11.9 fold, 773.3 fold, and 29 fold, respectively; $p<0.05$) and protein level (8.9 fold, 11.2 fold, and 252.4 fold, respectively; $p<0.05$). Profibrotic mediators, such as COL1A1, COL3A1, and CTGF mRNA expression in co-cultured fibroblasts was reduced to 0.33 fold, 0.24 fold, and 0.31 fold, respectively ($p<0.05$). This effects were associated with mRNA down-regulation of two key effectors of TGF-β signaling, TGFBR2 and SMAD3 to 0.59 and 0.79 fold, respectively. At flow cytometry analysis, we observed a reduction in co-cultured fibroblasts apoptosis by adding IL-17RA neutralizing mAb to IL-17A treated cells (39% to 16.8%; $p<0.05$), as compared to controls treated with IL-17A and isotype controls. Moreover, IL17RA mAb addition also reduced Fas expression in co-cultured fibroblasts as compared to IL-17A treated cells (47.7% to 10.6%; $p<0.05$).
Conclusions: Our results support the role of IL-17A in the pathogenesis of SSc. Furthermore, here we first show that IL-17A up-regulation in co-cultured PBMCs might play antifibrotic effects in autologous skin fibroblasts and might be implicated in fibroblast apoptosis, interphering with the FAS/FASL pathway.

FRI0356 ANTISENSE LONG NONCODING RNAS ARE DEREGULATED IN SKIN TISSUE OF SSC PATIENTS

T. Messemaker[1], L. Chadli[2], G. Cai[3], V. Goelela[2], M. Boonstra[1], A. Dorjee[4], S. Andersen[2], H. Mikkers[4], T. Huizinga[4], Z. Li[3], O. Distler[5], M. Whitfield[3], R. Toes[4], J. Aarbiou[2], J. De Groot[2], J. De Vries-Bouwstra[4], F. Kurreeman[4]. *[1]Rheumatology, LUMC; [2]Charles River Lab, Leiden, Netherlands; [3]Geisel School of Medicine at Dartmouth, Hanover, United States; [4]LUMC, Leiden, Netherlands; [5]University Hospital Zurich, Zurich, Switzerland*

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized by fibrosis of skin and multiple organs of which pathogenesis is poorly understood. Here we studied differentially expressed coding and non-coding genes in relation to SSc pathogenesis with a specific focus on antisense non-coding RNAs.
Objectives: Here we studied differentially expressed coding and non-coding genes in relation to SSc pathogenesis with a specific focus on antisense non-coding RNAs.
Methods: Skin biopsy-derived RNAs from fourteen early SSc patients and six healthy individuals were sequenced with ion-torrent and analysed using DEseq2. Protein-coding and non-coding genes annotated in GENCODEV7 were analysed. Significant long non-coding RNAs were independently replicated in a Northern American dataset.
Results: 4901 genes with a fold change >1.5 and a false discovery rate of less than 5% were detected in patients versus controls. Upregulated coding genes clustered in immunological, cell adhesion and keratin-related processes as previously found by microarray studies. Interestingly, 676 deregulated non-coding genes were detected, 257 of which were classified as antisense genes. 42% of these antisense genes had a concurrent deregulated sense gene. The majority of the sense-antisense genes had a similar effect sizes in an independent North American dataset with three genes (OTUD6B-AS1, CTBP1-AS2 and HMGN3-AS1) exceeding the study-wide Bonferroni-corrected ρ-value ($P_{Bonf}<0.0024$, $P_{combined}=1.6x10^{-9}$, $1.7x10^{-6}$, $2.6xx10^{-6}$, respectively). Intriguingly, the correlation of sense-antisense gene pairs deregulated in SSc is stronger than sense-antisense gene pairs not deregulated in SSc ($p<0.001$).
Conclusions: For the first time we highlight that together with coding genes, (antisense) long noncoding RNAs are deregulated in skin tissue of SSc patients suggesting a novel class of genes involved in pathogenesis of SSc.

FRI0357 MICROPARTICLES AS A BIOMARKER AND A REDOX-DEPENDENT REGULATOR OF NEUTROPHIL ACTIVATION AND PROTEOLYTIC ACTIVITY IN PATIENTS WITH SYSTEMIC SCLEROSIS

N. Maugeri, P. Rovere Querini, S. Franchini, E. Tombetti, G. Ramirez, V. D'Alberti, M.G. Sabbadini, M. Bianchi, C. Lunardi, A. Gabrielli, A. Manfredi. *AILS Patient Association on Scleroderma, Milan, Italy*

Background: Persistent oxidative stress and unrelenting vascular inflammation are hallmarks of Systemic Sclerosis (SSc). Platelet-derived microparticles (PD-uP) that express a bioactive redox-dependent moiety, HMGB1 accumulate in the peripheral blood of patients with SSc.
Objectives: To verify whether PD-uP might represent a biomarker of SSc clinical involvement and whether their biological actions is regulated by environmental redox.
Methods: Fifty-four patients with SSc were enrolled so far. Twenty healthy controls (HC) matched for sex and age were studied in parallel. PD-uP were characterized and quantified by flow cytometry. Leukocyte features, including expression and distribution of myeloperoxidase (MPO), were assessed by flow cytometry and confocal microscopy. PD-uP ability to regulate neutrophil activation and proteolytic action was assessed *in vitro* in defined redox conditions and *in vivo* upon intravenous (i.v.) injection in immunocompromised NSG mice, and traced at various times based on recognition of the human platelet antigen CD61. Action on fibroblasts derived from SSc patients and HC are being assessed using biochemical and functional assays.
Results: PD-uP are present in the blood of SSc patients. Their concentration is significantly higher than in the blood of HC ($p<0.0001$). A substantially higher fraction of SSc PD-uP express the prototypic DAMP, HMGB1 (70% SSc vs 5% HC). Among SSc patients, those with pulmonary hypertension had a significantly higher concentration of HMGB1+ PDuP ($p=0.002$). In contrast other disease-associated variables, including the extent of fibrosis and the presence of active SSc pattern at the NVC, were not apparently influent. Neutrophils of SSc patients were activated, as demonstrated by the MPO redistribution from the primary granules to the plasma membrane. Moreover, they had a substantially higher ability to degrade fibrin in vitro, suggesting that enzymes at the plasma membrane are bioactive. Circulating neutrophils appeared to be viable and the fraction of cells undergoing apoptosis was similar in SSc patients and HC. The extent of neutrophil activation was associated with the concentration of HMGB1+ PDuP ($p<0.001$). SSc PDuP but not HC PDuP induced MPO redistribution in vitro. The effect was dependent on HMGB1 and increased by oxidizing moieties. Injection in immunocompromised mice resulted in time-dependent association of SSc PDuP to mouse neutrophils, which contextually redistributed MPO at the plasma membrane.
Conclusions: HMGB1 expression on PD-up of SSc patients could help identify functionally relevant population of microparticles, involved in neutrophil activation/function and possibly valuable as a novel biomarker of vascular remodeling.

FRI0358 99MTC-RHANNEXIN V-128 AS A NOVEL EARLY DIAGNOSTIC MARKER FOR INTERSTITIAL LUNG DISEASE ASSOCIATED WITH SYSTEMIC SCLEROSIS

L. Guo[1,2], J. Schniering[1], R. Schibli[3], A. Blanc[3], D. Chicco[4], S. Ye[2], O. Distler[1], M. Béhé[3], B. Maurer[1]. *[1]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; [2]Department of Rheumatology, Renji Hospital, Shanghai Jiao Tong University, Shanghai, China; [3]Center for Radiopharmaceutical Sciences, Paul Scherrer Institute, Villigen-PSI, Switzerland; [4]Advanced Accelerator Applications, Colleretto Giacosa, Italy*

Background: Interstitial lung disease (ILD), the primary cause of death in systemic sclerosis (SSc), often occurs early in the disease course, yet only becomes symptomatic when there is already substantial functional impairment and morphologic changes. Thus, there is an unmet need for early diagnosis. Apoptosis is considered the first pathophysiologic event in SSc-ILD. Monitoring of apoptotic processes with nuclear imaging, a sensitive, specific and noninvasive

methodology, might be a promising new approach for the diagnosis of early SSc-ILD.

Objectives: To evaluate the radiotracer ^{99m}Tc-rhAnnexin V-128, which specifically targets a pathophysiologic key molecule of early apoptosis, for the detection of earliest stages of lung involvement in animal models of SSc-ILD with single photon emission computed tomography (SPECT/CT).

Methods: C57BL/6J mice were treated with a single intratracheal injection of bleomycin or saline. Animals were euthanized at days 3, 7, 14 and 21 post-injection (n=6). Lung injury was evaluated by analysis of HE and Sirius red staining. The Ashcroft score was applied for the semi-quantitative evaluation of fibrotic changes. Immunofluorescence using the TUNEL assay and double staining with specific cell markers were performed to determine apoptotic cells. Positive nuclei were quantified by manual and automatic counting with Image J analysis software. Three days after injection with bleomycin or saline, mice were injected with ^{99m}Tc-rhAnnexin V-128 (Advanced Accelerator Applications, Italy). After 1h, images were acquired using small animal SPECT/CT, followed by *ex vivo* autoradiography.

Results: In the model of bleomycin-induced lung fibrosis, inflammatory infiltrates (CD45+) occurred as early as day 3 with peak at day 7, whereas pulmonary fibrosis developed from day 7 as assessed by Sirius red staining and was most pronounced at day 21 (mean Ashcroft score=4.6, p=0.0286). Notably, the number of apoptotic cells evaluated by TUNEL staining, was highest at day 3 (mean ± SE=6.5±1.5positive cells/HPF, p=0.0436) compared with saline controls (mean ± SE=0.7±0.1, p=0.0095) and then decreased over time. To determine the type of apoptotic cells, we performed immunofluorescent co-stainings with different cell markers. Data displayed that endothelial cells (vWF+) and epithelial cells (cytokeratin+), but not inflammatory cells (CD45+) were the primary cells undergoing apoptosis in earliest inflammatory stages of ILD.

In accordance with the findings on tissue level, at day 3 post-injection, we detected *ex vivo* with autoradiography, yet not with *in vivo* SPECT/CT, an increased pulmonary uptake of ^{99m}Tc-rhAnnexin V-128 in the lungs of bleomycin-induced mice compared with saline treated controls.

Conclusions: Apoptosis of epithelial and endothelial cells preceded the development of pulmonary inflammation and fibrosis in the model of bleomycin-induced lung fibrosis. Thus, the use of ^{99m}Tc-rhAnnexin V-128 might be a promising approach for the diagnosis of earliest stages of ILD. However, sensitivity of *in vivo* imaging has to be further improved.

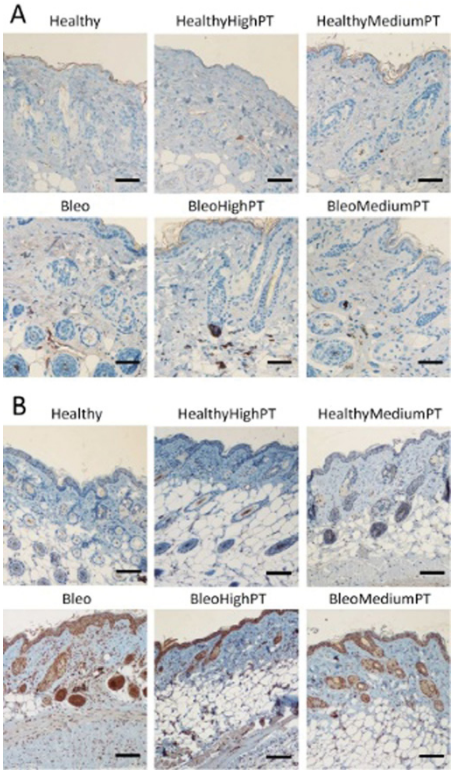
FRI0359 THE IMPACT OF NARROWBAND ULTRAVIOLET A1 ON PROLIFERATION AND APOPTOSIS MARKERS IN ANIMAL MODEL OF SCLERODERMA



D. Karpec[1,2], R. Rudys[2], L. Leonaviciene[2], Z. Mackiewicz[2], R. Bradunaite[2], G. Kirdaite[2], R. Rugiene[1,2], A. Venalis[1,2]. [1]*Center of Rheumatology, Vilnius University;* [2]*State Research Institute Centre for Innovative Medicine, Vilnius, Lithuania*

Background: Narrowband ultraviolet A1 (UVA1) phototherapy implications for systemic sclerosis still remain the area of research.

Objectives: To define the efficacy and safety of 365±5 nm UVA1 for the dermal fibrosis treatment in bleomycin-induced mouse model of scleroderma.

Methods: DBA/2 strain mice were randomly divided to 6 groups: I – healthy animals; II – control group with bleomycin induced scleroderma, III and IV – mice with established scleroderma, treated with high and medium dose of UVA1, V and VI – healthy mice, treated with high and medium dose of UVA1. Scleroderma model was induced according to the protocol [1]. Light source emitting a narrowband UVA1 of 365±5 nm and of 21 mW/cm^2 power density was used in the study. Phototherapy was performed 3 times weekly for 5 weeks. The average cumulative doses were 1200 J/cm^2 for high and 600 J/cm^2 for medium dose treatments. Histological analysis with hematoxylin-eosin staining for dermal thickness measurement was performed. The immunohistochemical staining for p53, Ki-67 and active caspase-3 proteins was performed using specific antibodies. Statistical significance was expressed by a P value <0.05.

Results: The dermal thickness of mice treated with high and medium dose of UVA1 was significantly reduced to 272.9±113.2 and 394.0±125.9 μm, respectively, in comparison to the control group II (599.0±55.7 μm). The percentage of Ki-67 positive cells in mice with scleroderma after high- and medium-dose of UVA1 did not differ from the control group (II). The expression of p53 was significantly higher in the skin of the control group (II) compared to that of healthy mice skin (group I). After treatment of mice with scleroderma with high- and medium-dose of UVA1, the expression of p53 in the dermal layers did not differ from the control group (II) of non-treated mice. There was no change of p53 nor Ki-67 expressions between healthy (group I) and UVA1-treated healthy mice skin (groups V and VI). The statistically significant increase of active caspase-3 expression in the skin of mice with scleroderma was present after high- and medium-dose of UVA1 (groups III and IV) as compared to that of non-treated mice group (II). The expression profile of active caspase-3 did not differ between healthy (group I) and UVA1-treated healthy mice skin (groups V and VI). Results are summarized in Table 1 (Ki-67) and Figure 1 (A - active caspase-3; B - p53 immunohistochemical analysis).

Conclusions: The cumulative doses of 1200 J/cm^2 and 600 J/cm^2 of narrowband UVA1 effectively reduced the dermal thickness, and the impact was dose-dependent. Phototherapy course did not up-regulate p53 nor Ki-67 proteins in the healthy mice and mice with scleroderma skin. UVA1 radiation caused the increase of the active caspase-3 expression in the skin of mice with scleroderma reflecting the apoptotic feature of narrowband UVA1. The results of this study indicate that 365±5 nm UVA1 phototherapy is safe and effective for the treatment of dermal fibrosis.

FRI0360 ANALYSIS OF ENDOCANNABINOID SYSTEM ELEMENTS AND RELATED INFLAMMATORY MOLECULES IN PERIPHERAL BLOOD LEUKOCYTES OF PATIENTS WITH SYSTEMIC SCLEROSIS

C. Perez-Sanchez, R. Ortega-Castro, C. del Río, M.A. Aguirre, P. Ruiz-Limon, N. Barbarroja, Y. Jimenez-Gomez, I. Arias-de la Rosa, M.C. Abalos-Aguilera, E. Collantes-Estevez, E. Muñoz, C. Lopez-Pedrera. *IMIBIC/Reina Sofia University Hospital/University of Cordoba, Cordoba, Spain*

Background: The Endocannabinoid system (ECS) is a potential target for treatment of systemic sclerosis (SSc). Several cytokines/chemokines have been implicated in the induction of fibrosis in SSc, but their profile in peripheral blood

Abstract FRI0359 – Table 1

Percentage of Ki-67 positive cells	Healthy (I)	Bleo (II)	BleoHighPT (III)	BleoMediumPT (IV)	HealthyHighPT (V)	HealthyMediumPT (VI)
Average (%)	50.4	36.1	35.4	37.2	50.1	49.4
SD	2.6	3.0	3.2	2.8	2.0	1.4

mononuclear cells (PBMCs), and a relationship among specific inflammatory mediators, ECS, and organ involvement has not been established

Objectives: To analyze ECS elements and related inflammatory molecules in PBMCs of SSc patients, and evaluate their relationship with the clinical profile of the disease

Methods: 24 SSc patients [including 5 Pre-SSc, 13 limited cutaneous SSc (lc-SSC) and 6 difusse cutaneous SSc (dc-SSc)] and 24 healthy donors (HD) were included. Purified PBMCs were used for analysis of gene expression of molecules belonging to the ECS: CB1, CB2, GPR55, PPARγ, FAAH, MAGL and TRPV. Inflammatory mediators were evaluated in PBMCs by RT-PCR. Clinical evaluation of patients was performed and correlation/association studies were developed

Results: Cannabinoid type-2 receptor, GPR55 and TRPV1 gene expression were reduced in PBMCs of SSc patients, while FAAH levels were elevated. CB2 levels were lower in lc-SSc in relation to sc-SSc, and related to the presence of auto-antibodies anti-Scl70. Concomitantly, levels of FAAH were higher in dc-SSc in relation to lc-SSc, and associated to the presence of anti-centromere antibodies. A relationship between the low levels of GPR55 and the presence of pulmonary arterial hypertension was further demonstrated. Reduced levels of TRPV were associated to pulmonary involvement.

Analysis of the inflammatory profile showed significantly increased PBMC expression levels of IL-1, IL-8, IL-12, MCP-1, TGFβ, TNFα, and VEGF-A in SSc. In addition, in the patient's group of Pre-SSc, specific elevation in various cytokines was demonstrated (i.e.IL-1,IL-17,VEGF-A), suggesting that these cytokines might act as early biomarkers of disease development. Patient's positive for anti-centromere antibodies showed increased expression of IL-4, IL-17 and MCP-1 in relation to those positive for anti-scl70. PBMCs expression levels of TGFβ, IL-12 and MCP-1 were higher in lc-SSc compared to ds-SSc. Interestingly, we observed a direct relationship between levels of these three cytokines and the occurrence of pulmonary hypertension, a pathology more frequent in lc-SSc, thus suggesting a role for these inflammatory molecules in pulmonary involvement in this form of the disease. Correlation studies demonstrated an interrelation among deregulated expression of various molecules belonging to the ECS (i.e. FAAH, GPR55 and TRPV1) and inflammatory mediators over-expressed in serum and immune cells (i.e. CRP, ESR, MCP-1, TNFα and VEGF-A)

Conclusions: SSc patients show altered gene profile of ECS and inflammatory mediators in PBMCs, which might allow the discrimination between limited and diffuse forms of the disease, and are associated with the presence of specific auto-antibodies and the internal organ involvement. Our overall data suggest an appealing potential target of ECS for treatment of SSc, as it seems to be related to the inflammatory profile

FRI0361 INTERLEUKIN-4 INDUCES CLASS-SWITCHING TO IGG4 AND SYNERGISTICALLY CONTRIBUTES TO PLASMABLASTS DIFFERENTIATION WITH INTERLEUKIN-21 THROUGH CD40 DEPENDENT MANNER IN IGG4-RELATED DISEASE

M. Akiyama, H. Yasuoka, K. Yoshimoto, T. Takeuchi. *Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan*

Background: IgG4-related disease (IgG4-RD) is a lymphoproliferative disorder characterized by elevated serum levels of IgG4 and increased numbers of circulating plasmablast. We have previously reported that class-switching to IgG4 and plasmablast differentiation are mediated by follicular helper type 2 T cells which are known to secrete interleukin (IL)-4, IL-13, IL-10 and IL-21 (1, 2). However, the cytokines which play a role in the IgG4 class-switching and plasmablast differentiation through cell to cell contact remain unclear in IgG4-RD.

Objectives: The aim of this study was to elucidate the role of follicular helper type 2 T cell cytokines (IL-4, IL-13, IL-10, and IL-21) and cell to cell interaction in the pathogenesis of IgG4-RD.

Methods: Peripheral blood mononuclear cells (PBMCs) were prepared from seven consecutive patients with active, untreated, newly diagnosed IgG4-RD and five healthy controls. To identify the cytokines which induce IgG4 class-switching, the cells were stimulated with IL-4, IL-13 or the combination with other cytokines, such as IL-10 or IL-21. The amounts of IgG4 and IgG in the culture supernatants were measured by cytometric bead arrays. The expression level of activation-induced cytidine deaminase (AID; an enzyme essential for class-switch recombination) was analyzed by quantitative PCR to confirm the induction of class-switching by stimulation with cytokines. The numbers of plasmablasts and plasma cells induced by cytokines stimulation were examined by flow cytometry. Moreover, an anti-CD40 antibody was added to the culture to elucidate the effects of cell to cell interaction on the differentiation of plasmablasts or plasma cells.

Results: IL-4 significantly induced CD40-stimulated PBMCs to undergo IgG4 class-switching in patients with IgG4-RD, while IL-13 did not show any positive effects. Moreover, the IgG4/IgG ratio in culture supernatants was also significantly higher in the stimulation with IL-4 compared to other cytokines in IgG4-RD. In addition, the expression levels of AID mRNA were increased by stimulation with IL-4 compared to that by no stimulation or CD40 stimulation in IgG4-RD. On the other hand, PBMCs from healthy controls showed no significant difference in IgG4 production after stimulation with either IL-4 or IL-13. Furthermore, IgG4 production stimulated with IL-4 was significantly higher in IgG4-RD than that in healthy controls. Assessing additional effects of IL-10 or IL-21 on IL-4, IL-10 and IL-21 did not increase IgG4 production and IgG4/IgG ratio compared to IL-4 alone in IgG4-RD. However, importantly, IL-21 synergistically induced plasmablasts or plasma cells differentiation in combination with IL-4, whereas no obvious change was observed in PBMCs stimulated with IL-4 alone in IgG4-RD. Of note, the differentiation of plasmablasts and plasma cells by IL-4 and IL-21 was markedly abolished in the absence of CD40 stimulation.

Conclusions: Our results strongly suggest that IL-4 plays a pivotal role in IgG4 class-switching, and the effective collaboration between IL-4 and IL-21 contributes to plasmablasts and plasma cells differentiation via CD40 dependent manner in patients with IgG4-RD.

FRI0362 ANGIOGENIC T CELL EXPANSION CORRELATES WITH SEVERITY OF PERIPHERAL VASCULAR DAMAGE IN SYSTEMIC SCLEROSIS

M. Manetti, S. Pratesi, E. Romano, I. Rosa, A. Martiradonna, S. Bellando-Randone, S. Guiducci, L. Ibba-Manneschi, E. Maggi, M. Matucci-Cerinic. *Experimental and Clinical Medicine, University of Florence, Florence, Italy*

Background: The mechanisms underlying endothelial cell injury and defective vascular repair in systemic sclerosis (SSc) remain unclear. Recent studies suggest that a novel T cell subset, the so-called angiogenic T (Tang) cells, may have an important impact on the repair of damaged endothelium. Tang cells are characterised by the co-expression of CD3, CD31 (platelet-endothelial cell adhesion molecule-1) and CXCR4 (or CD184, receptor for the CXC chemokine stromal cell-derived factor-1 (SDF-1)/CXCL12). Tang cells may promote the formation of new blood vessels and endothelial repair by stimulating the function and differentiation of endothelial progenitor cells possibly through the secretion of proangiogenic cytokines, thus fostering postnatal vasculogenesis.

Objectives: This study aimed to analyse the Tang cell population in relation to disease-related peripheral vascular features in SSc patients.

Methods: Tang cells ($CD3^+CD31^+CXCR4^+$) were quantified by flow cytometry in peripheral blood samples from 39 patients with SSc and 18 matched healthy controls (HC). $CD3^+CD31^+CXCR4^+$ Tang cells were expressed as a percentage of total $CD3^+$ T cells. Circulating levels of SDF-1α were assessed in paired serum samples by immunoassay. Skin sections from patients with early diffuse cutaneous SSc (n=7) and HC (n=6) were subjected to CD3/CD31 and CD3/CXCR4 double immunofluorescence staining.

Results: The percentage of circulating Tang cells was not different between the whole SSc patient cohort (median 29.9, interquartile range (IQR) 22.3–36.2) and HC (median 25.2, IQR 23.3–33.5). Subgroup analysis revealed that Tang cells were significantly increased in SSc patients with digital ulcers (DU) (median 35.5, IQR 32.2–42.5) compared either with SSc patients without DU (median 23.3, IQR 18.5–26.6) or with HC ($p<0.0001$ for both). Furthermore, Tang cell percentage was significantly higher in SSc patients with "late" nailfold videocapillaroscopy (NVC) pattern (median 34.9, IQR 25.0–42.0) than in those with "early"/"active" NVC patterns (median 26.5, IQR 20.4–32.9) and in HC ($p=0.01$ and $p=0.04$, respectively). No difference in circulating Tang cell counts was found when comparing either SSc patients without DU or patients with "early"/"active" NVC patterns and HC. In SSc peripheral blood, the percentage of Tang cells was inversely correlated to the levels of SDF-1α (Spearman's rho = -0.59, $p<0.0001$). Immunohistologic assessment of SSc skin sections revealed the presence of Tang cells in perivascular inflammatory infiltrates.

Conclusions: Our findings demonstrate for the first time that Tang cells are expanded in patients with SSc displaying most severe peripheral vascular complications. Such an expansion may be an ineffective attempt to compensate the need for increased angiogenesis and endothelial progenitor cell function. In SSc, Tang cells might represent a potentially useful biomarker reflecting peripheral vascular damage severity. Further studies are required to clarify the function of Tang cells and investigate the mechanisms responsible for their change in SSc.

Scleroderma, myositis and related syndromes

FRI0363 KL6 AND NOT CCL-18 IS A PREDICTOR OF EARLY PROGRESSION IN SYSTEMIC SCLEROSIS RELATED INTERSTITIAL LUNG DISEASE

G. Salazar[1], M. Kuwana[2], M. Wu[1], R.M. Estrada-Y-Martin[3], J. Ying[1], J. Charles[1], C. Bellocchi[4], M. Mayes[4], S. Assassi[4]. *[1]Rheumatology, University of Texas Medical School in Houston/McGovern Medical School, Houston, United States; [2]Department of Allergy and Rheumatology, Nippon Medical Graduate School of Medicine, Tokyo, Japan; [3]Pulmonary and Critical Care, University of Texas Medical School in Houston/McGovern Medical School; [4]Rheumatology, University of Texas Health Science Center at Houston, McGovern Medical School, Houston, United States*

Background: Pneumoproteins are attractive biomarker candidates in systemic sclerosis (SSc) related interstitial lung disease (ILD) because they are easily obtainable and lung-specific. KL-6 and CCL-18 (PARC) have been previously reported as promising predictive biomarkers of lung parenchymal damage in multiple disorders including SSc-ILD.
Objectives: Our goal was to determine the predictive significance of these two pneumoproteins for forced vital capacity % (FVC) decline within the first year of follow-up in patients with early SSc-ILD, in order to inform individualized care in routine clinical practice and facilitate enrichment strategies in clinical trials.
Methods: GENISOS (Genetics versus ENvironment In Scleroderma Outcome Study) cohort patients who had ILD verified by imaging and available pulmonary function tests at enrollment plus 12–18 months thereafter, were included in this study. All patients had disease duration ≤5 years at enrollment. FVC, expressed as percentage of predicted value was used as surrogate for severity of ILD. Annualized percent change in FVC at one year follow up was calculated. Baseline demographic, clinical variables and two pneumo-proteins, KL-6 and CCL-18 were investigated. KL-6 and CCL-18 were measured in the plasma by commercially available, validated ELISA kits. Linear regression with baseline clinical and demographic variables as independent variables was performed in univariable and multivariable models. Only variables that reached p<0.1 were included in the multivariable analyses.
Results: A total of 82 patients with early SSc-ILD were included, 18 were male and 45 had diffuse cutaneous involvement. Mean disease duration was 2.3 years. Rate of FVC% predicted change over time ranged from -0.23 to 0.38, indicating a highly variable course. Baseline KL-6 levels were higher in patients than healthy controls (p<0.0001). Baseline higher KL-6 levels were predictive of faster FVC% decline at the one year follow-up (b=-0.03, *p*=0.04). Upon categorizing KL-6 using a previously determined optimal cut-off of 1273 u/mL (1), its predictive significance remained in the univariate (p=0.01) and multivariable analyses adjusted for Scl-70, disease type and gender (b=-0.03, *p*=0.04). Twenty nine (34.5%) patients had KL6 levels equal or above 1273 u/mL. Although CCL-18 was higher in patients than controls (<0.0001), its levels did not predict rate of FVC decline (provide p-value)

Figure 1. KL-6 levels between patients and controls and %FVC change

a) KL-6 levels (u/mL) in SSc patients versus controls (red line= 1273 cut-off). b) %FVC annualized change in KL-6 positive versus negative patients based on a cut-off of 1273 u/mL. Note: Lower values in %FVC change correspond to a faster FVC decline.

Conclusions: KL-6 but not CCl-18 is predictive of early SSc-ILD progression. In this study, we also validated the previously proposed cut-off of 1273 for KL-6 in an independent cohort. KL-6 is a promising pneumoprotein that can inform individualized clinical care and contribute to enrichment strategies in clinical trials of SSc-ILD.

FRI0364 USEFULNESS OF SERUM HAPTOGLOBIN LEVELS AS A NOVEL MARKER FOR PULMONARY ARTERIAL HYPERTENSION COMPLICATED WITH CONNECTIVE TISSUE DISEASE

H. Nakamura, M. Kato, M. Kono, S. Tanimura, R. Hisada, E. Sugawara, K. Ohmura, S. Shimamura, Y. Fujieda, K. Oku, T. Bohgaki, O. Amengual, S. Yasuda, T. Atsumi. *Division of Rheumatology, Endocrinology and Nephrology, Hokkaido University Graduate School of Medicine, Sapporo, Japan*

Background: Pulmonary arterial hypertension (PAH) is of great clinical significance as a life-threatening complication of connective tissue diseases (CTD). Pulmonary artery thrombotic microangiopathy (PATM) is an important pathophysiology of PAH. The concept of PATM refers to localized thrombotic microangiopathy to be defined histologically and should be discriminated from systemic thrombotic microangiopathy characterized by microangiopathic haemolysis and thrombocytopenia. The degree of PATM has been suggested to be associated with vasodilator response, severity, and prognosis of PAH, and anticoagulation therapy might be effective in PAH patients with features of PATM [1]. Haptoglobin (Hp) is a plasma protein mainly produced by hepatocytes, which binds free haemoglobin released from erythrocytes and protects the kidneys from damage induced by haemoglobin. The Hp is measured in clinical setting as a sensitive marker to detect intravascular haemolysis including thrombotic microangiopathy [2].
Objectives: We hypothesized that serum Hp levels decreased in patients with PAH due to pulmonary microangiopathic haemolysis. The aim of this study was to investigate the association between serum Hp levels and pulmonary artery systolic pressure estimated by echocardiography (ePASP) in patients with CTD.
Methods: This study included CTD patients with suspicion of PAH who were attending Rheumatology Department in Hokkaido University Hospital between August 2015 and August 2016 and underwent echocardiography. PAH was diagnosed based on right heart catheter findings. Serum Hp levels were measured by standardised turbidimetric immunoassay in all patients. Demographic data, laboratory results, and echocardiographic findings were extracted from the medical records. Decreased serum Hp levels were defined as below 19 mg/dL based on the 95th-percentile of healthy controls.
Results: Twenty-four CTD patients with confirmed PAH (CTD-PAH) and 32 CTD patients without PAH (non-PAH) were enrolled. Decreased serum Hp levels were significantly frequent in patients with CTD-PAH compared with non-PAH patients (29% vs 6%, p=0.03). In patients with CTD-PAH, serum Hp levels had a significant negative correlation (r = -0.692, p<0.0001, Figure 1) with ePASP, and serum lactate dehydrogenase (LDH) levels were significantly elevated in patients with decreased Hp levels (233±47 U/L vs 187±42 U/L, p=0.01). Follow up study showed lowering ePASP led to normalizing serum Hp levels.

Conclusions: Serum Hp levels correlated negatively with ePASP in patients with CTD-PAH, and serum LDH levels were higher in CTD-PAH patients with decreased Hp levels. These findings suggest that decreased Hp levels in CTD-PAH patients may reflect PATM and subsequent subclinical haemolysis. Serum Hp levels are a candidate of additional non-invasive marker of CTD-PAH to assess the degree of PATM.

FRI0365 NEW COLLAGEN BIOMARKERS PREDICT PROGRESSION OF FIBROSIS IN SYSTEMIC SCLEROSIS

R. Dobrota[1], S. Jordan[1], P. Juhl[2], B. Maurer[1], L. Wildi[1], A.-C. Bay-Jensen[2], M.A. Karsdal[2], A.S. Siebuhr[2], O. Distler[1]. *[1]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; [2]Nordic Bioscience, Herlev, Denmark*

Background: Systemic sclerosis (SSc) is a complex autoimmune disease with extensive fibrosis of the skin and internal organs in which extracellular matrix (ECM) remodeling is a key pathogenic process. Imbalance in the formation and degradation of collagens results in fibrosis. Quantifying the tissue turnover in a highly fibrotic disease such as SSc is very important for the prediction of disease progression and therapeutic efficacy. Given the clinical heterogeneity of SSc patients, biomarkers facilitating personalized medicine approaches are highly needed.
Objectives: To evaluate the potential of selected ECM neo-epitopes as serological biomarkers for diagnosis, prediction of clinical outcomes and disease progression in SSc.
Methods: Healthy controls (HC; n=29), stable SSc (n=149), and progressive SSc patients (n=23, progression defined either as 10% decrease in FVC% predicted or increase in mRSS ≥25% and 5 points on one year clinical follow up), meeting the 2013 ACR/EULAR classification criteria were analyzed. Longitudinal clinical assessment, data recording and sera collection were done according to EUSTAR standards. ECM-degradation (C3M, VICM, C4M2, BGM) and ECM-formation biomarkers (P1NP, P4NP7S, Pro-C3, Pro-C5, Pro-C6) were measured in serum using newly developed ELISA-based assays (Nordic Bioscience). Differences in biomarker levels were analyzed with respect to several fibrosis-related clinical outcomes. Statistical analysis was performed by Man-Whitney U, Kruskal-Wallis and Spearman tests. Biomarkers' sensitivity and specificity was examined by ROC analysis.
Results: Both ECM-degradation and ECM-formation biomarkers differed between SSc patients and HC: The expression of C4M2, Pro-C3, BGM and C3M was significantly increased in SSc patients compared to HC ($p<0.0001$, AUC=0.93; $p<0.0001$, AUC=0.74; $p=0.003$, AUC=0.67; $p<0.0001$; AUC=0.94, respectively), whereas P1NP was significantly lower ($p<0.0001$, AUC=0.78), Figure 1. Furthermore, Pro-C3, VICM and Pro-C6 levels were significantly higher in SSc progressors vs. HC ($p<0.0001$, AUC=0.86; $p=0.003$, AUC=0.75; $p=0.0005$, AUC=0.81, respectively).
Currently, there is no fully validated biomarker predicting worsening of fibrosis. In this regard, most interestingly, the ECM-degradation markers C4M2, BGM, C3M were significantly lower in SSc patients showing progression of fibrosis on follow up versus SSc patients being stable on follow up ($p<0.0001$; $p<0.008$; $p<0.0001$, respectively). Consistently, the formation marker Pro-C6 was significantly increased ($p=0.001$, AUC=0.71) indicating a profound imbalance of ECM turnover in progressors. The strongest difference between progressive and stable SSc patients was seen for the ratio between the formation and degradation biomarkers Pro-C3/C3M which showed an AUC of 0.86 in progressive vs. stable SSc patients ($p<0.0001$).
Conclusions: These data support ECM neo-epitopes as potential new biomarkers of prognostic interest in SSc. This could help identifying patients at risk of progression of their fibrotic disease at one year follow up. The significant decrease in ECM-degradation markers in SSc progressors compared to stable patients suggests an impairment of collagen degradation in this group. The ratio of Pro-C3/C3M is as a new potential predictive index for differentiation of stable vs. progressive patients.

FRI0366 A PILOT STUDY ON ISCHEMIA AND REPERFUSION INJURY DURING A RAYNAUD'S ATTACK: SEQUENTIAL ASSESSMENT OF REDOX STRESS PARAMETERS IN A UNIQUE COOLING AND REWARMING EXPERIMENT

A.M. Van Roon[1], A. Eman Abdulle[1], A.M. van Roon[1], J.D. Lefrandt[1], A.J. Smit[1], H. Bootsma[2], B.O. Fernandez[3], M. Minnion[3], M. Feelisch[3], H. van Goor[4], D.J. Mulder[1]. *[1]Internal Medicine - Vascular Medicine; [2]Rheumatology and Clinical Immunology, University of Groningen - University Medical Center Groningen, Groningen, Netherlands; [3]Clinical and Experimental Sciences, University of Southampton, Southampton, United Kingdom; [4]Pathology, University of Groningen - University Medical Center Groningen, Groningen, Netherlands*

Background: Oxidative stress plays a role in systemic sclerosis (SSc), but the molecular mechanisms involved are incompletely understood. During an attack of Raynaud's phenomenon (RP) a period of ischemia (I), followed by reperfusion (R) occurs frequently, associated with the severity of vasculopathy. [1] Only in secondary RP digital ulcers develop. We hypothesized that I/R injury may play a role in the pathogenesis and could offer new therapeutic targets.
Objectives: To explore the course of oxidative stress in patients with SSc compared with primary RP and healthy controls.
Methods: A total of 30 patients were included: 10 with limited cutaneous SSc (age: 57 (53–61) yr, male/female 5/5), 10 with primary RP (age: 54 (41–58), 2/8), and 10 healthy controls (age: 25 (22–25), 3/7). A standardized cooling experiment was performed and digital perfusion was assessed in all 5 fingers using photo-electric plethysmography: at baseline (T=0) the dominant hand was submerged in water at 33℃, followed by cooling in steps of 3℃ every 4 minutes, until 6℃ or when pain became intolerable (T=1). Recording was continued 10 (T=2) and 30 (T=3) minutes of rewarming to ambient temperature (23℃). Blood was drawn from ipsilateral cubital vein at T0, 1, 2 and 3, markers for tissue injury (lactate, LDH, creatinine phosphokinase (CPK) [routine methods]), redox status (free thiols corrected for total protein) and nitric oxide (NO) activity (NO_2^-, NO_3^-, RXNO) were measured in plasma. [1–3] Numbers are in median (IQR).
Results: Baseline free thiols were significantly decreased in RP vs. controls (5.18 (4.79–5.63) vs 5.87 (5.41–5.99) umol/g, p=0.013), with no differences in lactate, LDH, CPK, and NO activity. Raynaud's attack was induced in all RP patients but not in controls. Median duration of hypoperfusion was greater in SSc vs. PRP (30 (27–35) vs. 12 (9–14) min, p=0.010), with a considerably longer recovery time (8 (4–10) vs. 0 (0–1) min, p=0.006). No changes were observed in lactate, LDH, and CPK levels. A rise in free thiols occurred at recovery (T4) in all 3 groups (figure 1). The concentrations of NO-related products did not change during cooling or recovery. No association was detected between the extent of I/R and plasma parameters.
Conclusions: In patients with RP free thiols were significantly reduced, indicating increased redox stress. During the cooling and rewarming experiment, a clear rise in free thiols was observed during rewarming, irrespective of the underlying disease or finger perfusion. Meanwhile, NO-related products remained stable.

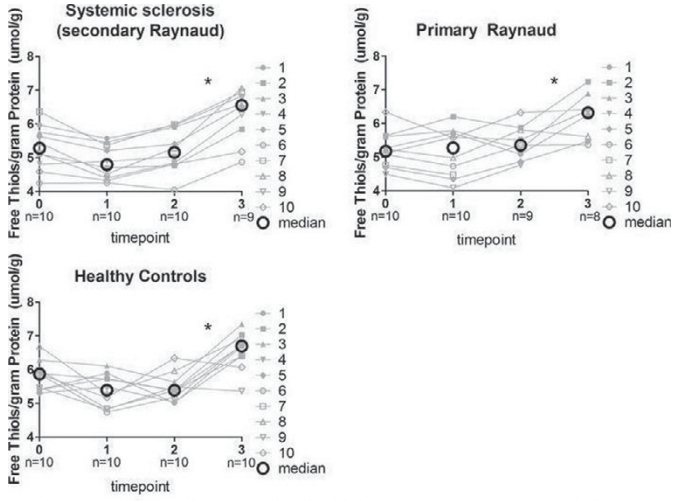

Figure 1. Free thiols per gram protein in all groups * p<0.005 between timepoint 2 and 3

Although these findings need further study, they may suggest activation of ubiquitous antioxidant defense mechanisms during cooling and/or rewarming and should be explored for future use as a potential therapeutic target in RP.

FRI0367 NEW AUTOIMMUNE TARGETS IN IDIOPATHIC INFLAMMATORY MYOPATHIES - AN ANTIGEN BEAD ARRAY APPROACH

A. Notarnicola[1], C. Hellstrom[2], C. Mattsson[2], E. Andersson[2], H. Idborg[1], E. Jemseby[1], M. Neiman[2], P.-J. Jakobsson[1], P. Nilsson[2], I.E. Lundberg[1].
[1]Department of Medicine, Rheumatology Unit, Karolinska University Hospital and Karolinska Institutet; [2]SciLifeLab, KTH - Royal Institute of Technology, Solna, Stockholm, Sweden

Background: The Idiopathic Inflammatory Myopathies (IIM) is a group of rare systemic inflammatory diseases characterized by severe organ involvement and premature mortality. Several myositis specific auto-antibodies (MSAs) have been recognized and associated with specific clinical manifestations and prognosis, still many patients are autoantibody negative. Identification of new autoimmune targets will be helpful in improving diagnosis, better stratifying into subgroups, prediction of prognosis, tailoring treatment and to understand underlying biological pathways.
Objectives: To identify new autoimmune targets in IIM by antigen bead array (1).
Methods: A bead array with 354 antigens was used to explore the autoimmune reactivity in 881 plasma samples from patients with IIM (N=225), Systemic Lupus Erythematosus (SLE) (N=350) and population controls (N=306). The antigens were selected from initial screenings of 160 SLE-samples on a total of 5760 antigens on planar arrays, and a first verification bead array with 355 antigens. The IIM samples represented three groups of patients with distinct diagnoses: Dermatomyositis (DM, N=83), Polymyositis (PM, N=111) and Inclusion Body Myositis (IBM, N=31), who were regularly followed at the Rheumatology Unit of the Karolinska University Hospital from January 2003 until March 2014. Based on 2 possible levels of cutoff, each sample was classified as reactive to each single antigen (Ag) at low or high cut off or non-reactive.
Results: In general, depending on the cutoff stringency, 86–88% of the 354 selected antigens showed reactivity in at least one sample with no difference between IIM, SLE and controls. Comparing PM, DM, IBM according to the number of samples which showed reactivity towards each single Ag, reactivity at high cut off towards NADH dehydrogenase 1 α subcomplex 11 (NDUFA11), poly(A) RNA polymerase D4 (PAPD4), CD163, l(3)mbt-like 1 (L3MBTL1) and calcium release-activated calcium modulator 2 (ORAI2) was discovered with higher frequencies in the IBM samples compared to PM and DM. In the group of IIM patients testing negative for all the known MSAs increased reactivity at high cut off was observed towards E3 ubiquitin protein ligase 2 (SIAH2), leiomodin 2 (LMO2) and RAD23 homolog A (RAD23A). In the group of IIM patients with history of malignancy and no evidence for anti-p155/140 antibodies the antigens early B-cell factor 2 (EBF2), POU class 6 homebox 1 (POUF61) and growth differentiation factor 7 (GDF7) revealed high serum reactivity. In IIM patients with interstitial lung disease increased reactivity at high cut off was found towards zinc finger protein 688 (ZNF688) and prostaglandin D2 receptor (PTGDR). A high frequency of known target reactivities (MSAs) was also confirmed.
Conclusions: Reactivity towards autoantigens corresponding to human proteins was present in plasma samples from IIM, controls, and SLE. Potentially new autoimmune targets have been discovered in IIM subgroups, although further validation in independent cohorts is needed.

FRI0368 NAILFOLD CAPILLAROSCOPY CHANGES REFLECT ENDOTHELIAL ACTIVATION AND INJURY IN PATIENTS WITH SYSTEMIC SCLEROSIS

A.M. Gheorghiu[1], R. Sfrent-Cornateanu[2], D. Marta[3], M. Bojinca[1], S. Magda[4], T. Constantinescu[5], A. Soare[6], R. Dobrota[6], L. Macovei[1], V. Stoica[1], C. Bara[2], C. Mihai[1]. *[1]Internal Medicine and Rheumatology, Cantacuzino Hospital; [2]Immunology and Physiopathology Department, Carol Davila University of Medicine and Pharmacy; [3]Victor Babes National Institute of Research and Development; [4]Cardiology Department, University Emergency Hospital; [5]Marius Nasta National Pneumology Institute, Carol Davila University of Medicine and Pharmacy; [6]Internal Medicine and Rheumatology, Cantacuzino Hospital, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania*

Background: Systemic sclerosis (SSc) is a severe connective tissue disease characterized by vascular and fibrotic changes in the skin and various internal organs. Pathogenesis of SSc includes early-onset vasculopathy with endothelial cell activation, microvascular injury and impaired angiogenesis.
Objectives: We aimed to determine the association of several biological molecules reflecting endothelial cell activation or dysfunction: E- selectin (E-sel), inter-cellular adhesion molecule 1 (ICAM-1), endothelin 1 (ET-1), von Willebrand factor (vWF) and interleukin 6 (IL-6), with distinct capillaroscopic SSc patterns and with more severe disease.
Methods: Forty consecutive SSc patients attending our EUSTAR SSc clinic, aged [median (IQR)] 52 (18) years, male gender 4/40 (10%), diffuse cutaneous subset (dcSSc) 14/40 (35%) were enrolled in this study. Extensive clinical and nailfold capillaroscopy (NFC) pattern assessment, as well as quantification of serum E-sel, ICAM-1, ET-1, vWF, IL-6 and C-reactive protein (CRP) were performed on all patients. Associations between vascular biomarkers and disease characteristics were evaluated by Mann-Whitney U-test and Spearman correlations.
Results: NFC "late" pattern was found in 21 patients, while 6 had "early" and 13 had "active" NFC pattern. All 5 vascular biomarkers correlated with each other good to moderately, with r indices varying between 0.660 and 0.332, the only exception being ET-1 which did not correlate with E-sel. Good correlations (r 0.465 to 0.727) were also found between all 5 biomarkers and CRP. Patients with severe vasculopathy, as reflected by the NFC "late" pattern, had higher levels of IL-6 (median 12.06 vs. 3.08 pg/mL, p=0.001), ET-1 (median 2.06 vs 1.59 pg/mL, p=0.029), vWF (median 3284 vs 2730 IU/mL, p=0.013) and E-sel (median 52.6 vs. 42.3 ng/mL, $p>0.05$), compared to patients with NFC "early" or "active" patterns. There was a significant, negative correlation between lung transfer for carbon monoxide (DLCO) and E-sel, ICAM-1 (both $p<0.001$) and vWF (p=0.013). ET-1 was higher in patients with more severe disease (dcSSc, patients positive for anti-topoisomerase antibodies and patients with a history of digital ulcers – all $p<0.05$).
Conclusions: Serum biomarkers reflecting endothelial cell activation and/or dysfunction are elevated in patients with more severe SSc-associated vasculopathy and correlate with serum CRP. Together with NFC data they might be used for assessing vasculopathy severity in SSc and identifying patients who would benefit from more aggressive vasoactive treatment.

FRI0369 PROSPECTIVE EVALUATION OF THE CAPILLAROSCOPIC SKIN ULCER INDEX (CSURI) IN CLINICAL PRACTICE

U.A. Walker[1], V.K. Jaeger[1], L. Arlettaz[2], M. Banyai[3], J. Beron[4], C. Chizzolini[5], E. Gröchenig[6], R.B. Mueller[7], F. Spertini[8], P. Villiger[9], O. Distler[10]. *[1]University Hospital Basel, Basel; [2]Hôpital du Valais, Sion; [3]Kantonsspital Luzern, Luzern; [4]Actelion Pharma Schweiz AG, Baden; [5]Hôpitaux Universitaires de Genève, Genève; [6]Kantosspital Aarau, Aarau; [7]Kantonsspital St. Gallen, St. Gallen; [8]Centre Hospitalier Universitaire Vaudois, Lausanne; [9]University Hospital Bern, Bern; [10]University Hospital Zurich, Zurich, Switzerland*

Background: Nailfold videocapillaroscopy (NVC) is an imaging technique representing a reliable tool for the classification, diagnosis and monitoring of systemic sclerosis (SSc) patients. The capillaroscopic skin ulcer index (CSURI) was suggested to identify patients at risk of developing digital ulcers (DU) [1].
Objectives: This study aims (1) to describe the practicality of the CSURI in clinical practice, (2) to describe the change of CSURI during follow-up, and (3) to assess associations between the change in CSURI and demographic and disease characteristics.

Methods: This Swiss multicentre, prospective, observational study analysed SSc patients with a history of active DU. Demographic characteristics and routine clinical data were recorded and patients underwent NVC at baseline and at the follow-up visit.

The centres' investigators were trained to perform NVC and, the nailfolds of 8 fingers (digit 2–5 on both hands) were examined if possible. All images were stored centrally and separately analysed by two extensively trained and experienced reviewers (OD & UAW) separately.

In each NVC image the total number of capillaries in the distal row, the number of megacapillaries and the maximum diameter of the megacapillaries were assessed. Based on these 3 characteristics, the CSURI was calculated according to Sebastiani et al. [1] for patients with at least 1 megacapillary present. Data were analysed descriptively.

Results: Between 2011 and 2015, 61 patients fulfilled the eligibility criteria and had at least one follow-up visit (median observation time 1.0 years, interquartile range [IQR] 1.0–1.1). Of these patients, more than a third (reviewer 1: n=24 patients, 39%; reviewer 2: n=26 patients, 43%) had no megacapillaries present on NVC on any assessed finger and hence the CSURI could not be calculated for those either at baseline or follow-up. Therefore, this analysis is based on the remaining 34 patients who had at least one megacapillary present on NVC at baseline and at follow-up by both reviewers (26% male; median age 57 years, IQR 48–65 years).

The median baseline CSURI scores according to reviewer 1 was 5.3 (IQR 2.6–16.3) increasing to a median of 5.9 (1.3–12.0) at follow-up. The CSURI as evaluated by reviewer 2 reduced from baseline (median 6.4, IQR 2.4–12.5) to follow-up (5.0, IQR 1.7–10.0).

None of the assessed demographic or disease characteristics (Box 1) were associated with the changes in the CSURI between baseline and follow-up for the scores obtained by reviewer 1 and reviewer 2 at the same time; although the limited sample size should be kept in mind interpreting this lack of association.

Box 1: Characteristics assessed for associations with the baseline capillaroscopic skin ulcer index (CSURI) as well as the change in CSURI between the baseline and the follow-up visit.

Demographic characteristics
Age
Sex
Smoking habit (Never/previous/current smoker)
Disease characteristics
Time since Raynaud's phenomenon onset
Time since first non-Raynaud's phenomenon manifestation
Time since first digital ulcers
Previous major digital vascular complication (None/soft tissue infection/ auto-amputation/gangrene)
Cutaneous involvement (Diffuse/limited)
Erectile dysfunction
Proteinuria (>300 mg/dl)
Renal crisis
Pulmonary arterial hypertension
Raynaud's phenomenon condition score at baseline
Modified Rodnan skin score at baseline
Number of digital ulcers at baseline
Laboratory parameters
Anti-nuclear antibodies positive
Anti-centromere antibodies positive
Anti-topoisomerase autoantibodies positive

Conclusions: In this study, around 40% of patients could not be evaluated with the CSURI due to the absence of megacapillaries on NVC. Clinical decisions based on the CSURI in routine practice should be made with caution, as it can vary greatly between assessors even if they are extensively trained.

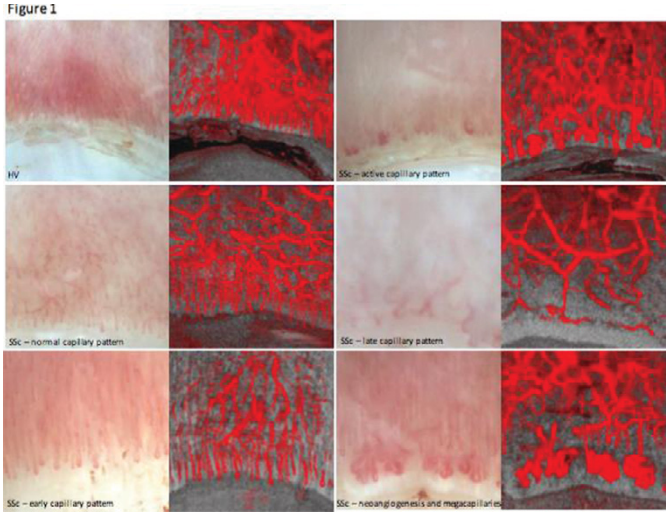
FRI0370 THREE-DIMENSIONAL NAILFOLD CAPILLARY IMAGING BY DYNAMIC OPTICAL COHERENCE TOMOGRAPHY IN SYSTEMIC SCLEROSIS: A VALIDATION STUDY USING NAILFOLD VIDEO-CAPILLAROSCOPY

G. Abignano [1,2], L. Green [1,2], S. Eng [1,2], P. Emery [1,2], F. Del Galdo [1,2]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*



Background: Optical Coherence Tomography (OCT) of the skin has been proposed as imaging biomarker of fibrosis in Systemic Sclerosis (SSc) (1). However, over the past few years, growing efforts have been made to enable OCT to the study of human skin microcirculation including human nailfold (2). Dynamic OCT (D-OCT) is a newly developed OCT technology that allows detection of blood flow in vivo in addition to the images of traditional OCT scans (3).

Objectives: Aims of this study were: 1) to evaluate face/criterion validity and feasibility of nailfold capillary D-OCT imaging as compared with nailfold video-capillaroscopy (NVC) capillary patterns in SSc patients; 2) to investigate whether D-OCT could offer a complementary value to NVC through the 3-dimensional reconstruction and quantification of nailfold capillary abnormalities in SSc patients.

Methods: Fifty subjects including forty SSc patients all fulfilling 2013 EULAR/ACR classification criteria (10 with normal/non-specific, 10 with early, 10 with active, 10 with late capillary pattern respectively) and ten age/gender-matched healthy volunteers (HV) were enrolled in this study. All subjects had NVC done on 8 fingers and classified according to the capillary pattern. Nailfold of the finger with the worst capillary score in SSc patients and the 4th finger (the most affected in the SSc groups) of the dominant hand in subjects with normal capillary pattern was subsequently scanned using Vivosight D-OCT (Michelson Diagnostics Ltd., Kent, UK). D-OCT images were analyzed using the proprietary software tool to extract a quantitative measure of the speckle variance (SV)-signal. Results were expressed as mean±standard error. Statistical analysis was performed using GraphPad Prism software V.7.0.

Results: The finger with the worst capillary score was the 4th (83%) in the SSc patients. The typical nailfold capillary features seen at NVC were visualized at D-OCT images. Representative images are shown in figure 1. Each nailfold D-OCT scan lasted 60 seconds, was well tolerated and did not require use of gel or immersion oil. OCT mean SV-signal measurements were significantly different between HV and SSc patients with any specific capillary pattern (0.16±0.02 vs 0.10±0.01, p=0.0028) and between SSc patients without and with specific capillary pattern (0.14±0.01 vs 0.10±0.01, p=0.02). The mean SV-signal was higher in HV than in SSc patients without specific capillary pattern however the difference was not statistically significant. When analyzing the three specific capillary patterns, SV-signal measurements were not significantly different. Interestingly, within the late capillary pattern, mean SV-signal was significantly lower in patients displaying capillary loss as main feature compared with those with remarkable neoangiogenesis (p=0.03).

Figure 1

Conclusions: D-OCT is a feasible technique able to reproduce the capillary changes seen at NVC in SSc patients. More importantly D-OCT could offer a complementary value to quantify peripheral blood flow at capillary level. Future longitudinal studies are needed to evaluate the sensitivity to change over time and the potential of D-OCT as quantitative outcome measure of microvasculopathy in SSc.

FRI0371 CLINICAL ALGORITHMS FOR THE DIAGNOSIS AND PROGNOSIS OF INTERSTITIAL LUNG DISEASE IN SYSTEMIC SCLEROSIS

V. Hax[1], M. Bredemeier[2], A.L.D. Moro[1], T.R. Pavan[1], M.V. Vieira[3], E.H. Pitrez[3], R.M.D.S. Chakr[1], R.M. Xavier[1]. *[1]Rheumatology Service, Hospital de Clínicas de Porto Alegre; [2]Rheumatology Service, Hospital Nossa Senhora da Conceição; [3]Radiology Service, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil*

Background: Interstitial lung disease (ILD) is currently the primary cause of death in systemic sclerosis (SSc). Thoracic high-resolution computed tomography (HRCT) is considered the gold standard for diagnosis. Recent studies have proposed several clinical algorithms to predict the diagnosis and prognosis of SSc-ILD.
Objectives: To test the clinical algorithms to predict the presence and prognosis of SSc-ILD, and to evaluate the association of extent of ILD with mortality in a cohort of SSc patients.
Methods: Prospective cohort study, including 177 SSc patients assessed by clinical evaluation, laboratory tests, pulmonary function tests, and HRCT. Three clinical algorithms, combining lung auscultation, chest radiography and % predicted forced vital capacity (FVC)[1], were applied for the diagnosis of different extents of ILD on HRCT. Univariate and multivariate Cox proportional models were used to analyze the association of algorithms [1,2] and the extent of ILD on HRCT with the risk of death using hazard ratios (HR).
Results: The prevalence of ILD on HRCT was 57.1% and 79 patients died (44.6%) in a median follow-up of 11.1 years. For identification of ILD with extent ≥10 and ≥20% on HRCT, all algorithms presented a high sensitivity (>89%) and a very low negative likelihood ratio (<0.16). For prognosis, survival was decreased for all algorithms, especially the algorithm C (HR 3.47, 95% CI 1.62–7.42), which identified the presence of ILD based on crackles on lung auscultation, findings on chest X-ray or FVC <80%. Extensive disease as proposed by Goh and Wells (extent of ILD >20% on HRCT or, in indeterminate cases, FVC <70%) had a significantly higher risk of death (HR 3.42, 95% CI 2.12 to 5.52). Survival was not different between patients with extent of 10 or 20% of ILD on HRCT, and analysis of 10-year mortality suggested that a threshold of 10% may also have a good predictive value for mortality. However, there is no clear cutoff above which mortality is sharply increased.

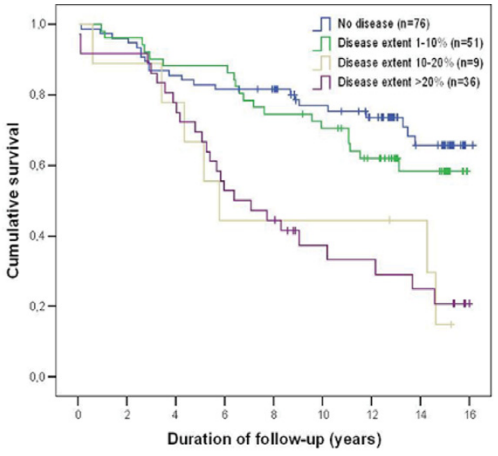

Figure 1. Survival in relation to the extent of lung disease on high-resolution computed tomography ($p<0.0001$ by log rank test).

Conclusions: Clinical algorithms had a good diagnostic performance for extents of SSc-ILD on HRCT with clinical and prognostic relevance (≥10 and ≥20%), and were also strongly related to mortality. Therefore, they probably could be used to obviate the requirement of HRCT in some cases.

FRI0372 THE DUCAS: PROPOSAL FOR A DIGITAL ULCER ASSESSMENT SCORE IN SCLERODERMA

C. Bruni[1], T. Ngcozana[2], F. Braschi[1], S. Guiducci[1], S. Bellando-Randone[1], Y.A. Suliman[3], J. Grotts[4], C.P. Denton[2], D.E. Furst[5], M. Matucci-Cerinic[1]. *[1]Department of Experimental and Clinical Medicine, Division of Rheumatology, University of Florence, Firenze, Italy; [2]Centre for Rheumatology and Connective Tissue Diseases, UCL Division of Medicine, London, United Kingdom; [3]Rheumatology and Rehabilitation Department, Assiut University Hospital, Assiut, Egypt; [4]Department of Biostatistic; [5]Division of Rheumatology, Department of Medicine, University of California at Los Angeles, Los Angeles, United States*

Background: No objective measure is presently available to assess digital ulcer (DU) in SSc patients apart from "healed/non healed" and experience-based clinical judgment.
Objectives: The aim of the current study is to propose a composite DU clinical assessment score (DUCAS) and, to lend it, test its face validity by correlating it with commonly used disease related patient-reported outcomes (PROs) and physician evaluation.
Methods: SSc patients presenting at least one DU and attending the Rheumatology Wound Care Clinic of the Florence University Hospital or the London Royal Free Hospital were enrolled. Patients were assessed with HAQ-DI, Cochin scale, Visual analogic scale (VAS) for DU-related pain (DU_pain, 0–100 mm), patient VAS for global DU status (ptGDU, 0–100mm) and patient global assessment (PtGA, 0–100 mm) as PROs and physician VAS for DU status (phyGDU, 0–100mm). The DUCAS included 7 DU related variables selected by a committee of 8 SSc DU experts - they are outlined in figure 1. Each variable was weighted on a clinical basis and the DUCAS score was the sum of the values for the 7 variables (max=19.5). Spearman's correlation tests were calculated for to examine face validity. A linear regression model with forward and backward stepwise analysis was used to determine the relationship of individual variables with the primary clinical parameter, phyGDU.
Results: 44 SSc patients (9 males, mean age 54,3±15,6 years, mean disease duration 9,9±5,8 years) were enrolled in the study. Mean phyGDU was 44,3±23mm, mean ptGDU was 54±30mm (Wilcoxon p=0.022, phyGDU VAS vs ptGDU) and mean DUCAS score was 4,2±2. Overall DUCAS showed significant positive correlations with all PROs, but when all the individual clinician and patient's variables were modelled, only the overall DUCAS significantly predicted PhyGDU; after backwards stepwise analysis overall DUCAS and ptGDU best predicted PhyGDU, with an adjusted R^2=0,437 and AIC=380,3 (Table 2).

Table 1

A	Linear Regression for DUCAS		B	Linear Model to PhyGDU			Linear Model to PhyGDU after backwards stepwise		
	Spearman Correlation	p		Estimate	SE	p	Estimate	SE	p
PtGA	0,56	<0,001	PtGA	0,011	0,199	0,955			
PtGDU	0,54	<0,001	PtGDU	0,171	0,233	0,467	0,272	0,101	0,01
DU_Pain	0,44	0,003	DU_Pain	0,048	0,182	0,793			
HAQ-DI	0,44	0,003	HAQ-DI	4,58	7,563	0,549			
COCHIN	0,51	<0,001	COCHIN	0,035	0,252	0,891			
PhyGDU	0,63	<0,001	DUCAS	4,636	1,617	0,007	4,841	1,489	0,002

	DUCAS		
1	Number of Digital Ulcers	None	0
		1 DU	1
		2 DUs	2
		More than 3 Dus	3
2	New Digital Ulcers	YES	1
		NO	0
3	Gangrene	YES	3
		NO	0
4	Surgical approch to DU (above standard care)	YES	3
		NO	0
5	Infection of DU	None	0
		Requiring systemic antibiotics	1
		Osteomyelitis	2
		Septicemia	3
6	Unscheduled hospitalisation for DU	YES	3
		NO	0
7	Analgesics to control DU pain	No pain	0
		Non requiried analgesics	0,5
		Non-opioids analgesics	1
		Minor opioids	2
		Major opioids	3
		dose increased since last visit	*+0,5*
		dose decreased since last visit	*-0,5*
	TOTAL SCORE		

Conclusions: DUCAS is a newly proposed clinical score for SSc related DU which has face validity and which may reflect DU status as judged by SSc experts. Further validation of this score will be undertaken.

FRI0373 SUBSTANCE P AND VASCULAR ENDOTHELIAL GROWTH FACTOR PRODUCTION BY PERIPHERAL BLOOD MONONUCLEAR CELLS DERIVING FROM PATIENTS WITH SYSTEMIC SCLEROSIS

A. Corrado, E. Sanpaolo, R. Colia, A. Mele, F.P. Cantatore. *Department of Medical and Surgical Sciences - Rheumatology Clinic, University of Foggia, Foggia, Italy*

Background: Many cytokines may potentially play a relevant role in the pathogenesis of different aspects of SSc, particularly fibrosis and endothelial injury. Some data suggest that substance P (SP) may act in an autocrine/paracrine manner to regulate vasoconstriction and/or immunologic and inflammatory responses. VEGF and MCP1, which are produced by inflammatory cells, may be involved in the pathogenesis of vascular changes and accumulation of extracellular matrix in SSc.
Objectives: The aim of this study was to determine the expression of Substance P (SP), Vascular Endothelial Growth Factor (VEGF), Monocyte Chemoattractant Protein-1 (MCP-1) in SSc patients and their relationship with the main clinical manifestations of disease
Methods: 34 SSc patients fulfilling the 2013 ACR/EULAR criteria for SSc and classified according to Leroy as having limited cutaneous (lSSc) or diffuse cutaneous (dSSc) disease were recruited. 28 sex and age matched healthy subjects was used as control. For each recruited patient we analyzed the disease characteristic, including the extent of skin fibrosis, the pattern of internal organ involvement, the presence of digital ulcers (DU) and autoantibody profile. Peripheral Blood Mononuclear Cells (PBMCs) were isolated and cultured from both SSc patients and healthy controls. The expression of SP, VEGF, MCP1 was analyzed by real-time polymerase chain reaction (PCR) and their concentrations where measured in supernatants of cultured PBMCs using enzyme-linked immunosorbent assay (ELISA). The correlation between cytokine expression and clinical manifestations was evaluated
Results: The results showed that the mRNA and the protein levels of SP and VEGF were significantly higher in SSc patients compared to controls (190,55±59,1pg/mL vs 128,85±69,8pg/mL and 422,31±149,4pg/mL vs 309,25pg/mL respectively, $p<0,05$); further, SP and VEGF levels were higher in dSSc compared to lSSc and correlated to disease duration. No difference was detected in MCP1 synthesis and expression between SSc subjects and healthy controls (507,17±153,9pg/mL vs 481,2±118,2 pg/mL) even if in dSSc patients a slight increase was observed. VEGF production negatively correlated with the prevalence of DU. No correlation between cytokines production and heart, lung and gastrointestinal involvement and autoantibody profile was found.
Conclusions: The preliminary data of this study show that SP and VEGF are over-expressed in PBMCs of SSc subjects and are related to the extent of skin involvement, whereas only VEGF production negatively correlates with the prevalence of DU. The exact role played by SP and VEGF in the pathogenesis of vascular injury and fibrosis in SSc and their relationship with the immune abnormalities observed in this disease is not completely clear and the available data are contrasting. Additional *in vitro* and *in vivo* studies are needed to better understand the role of SP and VEGF in the pathogenesis of SSc.

FRI0374 BONE MINERAL DENSITY AND TRABECULAR BONE SCORE IN TWO SUBSETS OF SYSTEMIC SCLEROSIS PATIENTS

A. Corrado, A. Mele, A. Trotta, R. Colia, S. Di Bello, F.P. Cantatore. *Department of Medical and Surgical Sciences - Rheumatology Clinic, University of Foggia, Foggia, Italy*

Background: Data concerning the relationship between Systemic Sclerosis (SSc) and alterations of Bone Mineral Density (BMD) are very conflicting. The established standard for measuring BMD is Dual X-ray Absorptiometry (DXA), but it does not provide any informations about the bone microarchitecture, which is a parameter very difficult to evaluate in clinical practice but it is essential to define bone strength. The Trabecular Bone Score (TBS) is a new structural parameter that can be obtained by DXA scanning and it is related to bone microarchitecture and provides data on bone quality irrespective of bone density.
Objectives: The aim of this study is to evaluate the differences in BMD and TBS values in two subsets of patients with SSc (limited and diffuse cutaneous disease – lSSc and dSSc) and to analyse their possible relationship with the parameters of body mass composition and phospho-calcium metabolism.
Methods: 64 post-menopausal patients classified according to Leroy as limited cutaneous (lSSc) or diffuse cutaneous (dSSc) SSc, were recruited. The following clinical parameters were evaluated: internal organ involvement, degree of skin involvement (Rodnan Skin Score), bone mass index (BMI). For each recruited patient, spine and hip BMD, TBS and body mass composition (lean and fat mass, total bone mineral content - BMC) were assessed by DXA. Serum calcium, phosphorus, alkaline phosphatase, intact parathyroid hormone (PTH) and 25-hydroxyvitamin D (25 OHD) were also measured.
Results: BMD at femoral neck and spine was significantly higher in lSSc compared to dSSc patients ($p<0,04$). In lSSc subjects also BMC was significantly higher compared to dSSc ones ($p<0,01$) but, interestingly the TBS was significantly lower ($p<0,03$). lSSc patients presented a higher values of fat mass compared to dSSc ($p<0,05$), with a slightly higher BMI (which did not reach statistical significance). 25OH serum levels were higher in lSSc group, whereas no differences between lSSc and dSSc in serum calcium, phosphorus, alkaline phosphatase were observed.
Conclusions: The presented preliminary data show that in SSc patients with limited cutaneous disease, the BMD values are higher compared to patient with diffuse cutaneous disease; nevertheless in this subset (lSSc) bone quality seem to be reduced, as TBS values are significantly lower. Higher BMC values and serum 25OHD levels observed in lSSc patients could be among the factors that contribute to increasing BMD in this clinical subset. Further analysis should be performed to identify the possible causes of the reduced bone quality in spite of higher BMD in lSSc patients, such as the study of serum adipokines, considering that the presented data show a great fat mass in patients with limited cutaneous disease.

FRI0375 REAL-LIFE TREATMENT STRATEGIES FOR SYSTEMIC SCLEROSIS ACCORDING TO EXPERTS

A. Fernández-Codina [1], K.M. Walker [2], J.E. Pope [3] on behalf of the participating members of the Scleroderma Clinical Trials Consortium (SCTC) and Canadian Scleroderma Research Group (CSRG). *[1] Systemic autoimmune diseases unit, Hospital Universitari Vall d'Hebron, Barcelona, Spain; [2] Rheumatology, The Ottawa Hospital, Ottawa; [3] Rheumatology, University of Western Ontario, London, Canada*

Background: Second line treatment options for Systemic Sclerosis (SSc) are limited, and scarce data are available for choosing the order of treatment.
Objectives: The aim of this study is to update the SSc treatment algorithms obtained in 2012[1], based on SSc experts' daily practice.
Methods: An initial survey was designed based on the 2012 algorithms. The survey asked experts whether they agreed with the 2012 algorithms or not, and which changes should be considered. The questionnaire was completed by 62 of 168 surveyed (67% response) between August and October 2016.
Results: For *scleroderma renal crisis* (SRC), there was 65% to 69% agreement with the previous algorithms (1st line angiotensin converting enzyme inhibitors [ACEI], 2nd and 3rd adding: calcium channel blockers [CCB] or angiotensin receptor blockers [ARB], and 4th alpha-blocker). In mild *pulmonary arterial hypertension* (PAH), only 45% of the experts agreed with the old algorithm. The majority suggested first phosphodiesterase 5 inhibitors (PDE5i) or endotelin receptor antagonists (ERA) plus PDE5i, then prostanoids. In severe PAH, 65% agreed with the preexistent scheme (1st prostanoids, 2nd ERA plus PDE5i, 3rd ERA plus prostanoids). For mild *Raynaud's phenomenon* (RP) 66% agreed with the previous algorithm (1st CCB, 2nd adding PDE5i, 3rd ARB or switching to another CCB, 4th prostanoids). Regarding severe RP, 52% agreed with previous (1st CCB, 2nd adding PDE5i, 3rd ERA, 4th prostanoids). Conversely, 60% of the experts did not agree with the prior active *digital ulcer* (DU) treatment, suggesting 1st CCB, 2nd PDE5i, 3rd prostanoids. For *interstitial lung disease* (ILD), for induction only 24% agreed with the older proposal. Experts suggested 1st mofetil mycophenolate (MMF), 2nd intravenous (IV) cyclophosphamide (CYP), 3rd Rituximab. There was a 65% agreement on ILD maintenance (1st MMF, 2nd azathioprine [AZA], 3rd IV CYP, 4th oral CYP). For *skin involvement*, agreement for patients with a modified Rodnan skin score (mRSS) of 10 was 57% (1st methotrexate [MTX]), 2nd MMF); if the mRSS was 24, 32% suggested 1st MMF, 2nd MTX; and mRSS 32, 36% chose 1st MTX, 2nd MMF, 3rd IV CYP, 4th autologous stem cell transplantation (ASCT). In *inflammatory arthritis* 45% agreed with the previous algorithm, whereas others suggested 1st MTX, 2nd low dose steroids, 3rd hydroxychloroquine, 4th rituximab or tocilizumab.
Conclusions: There remains some disagreement for 2nd line treatment of SSc. Combination of PDE5i and ERA are prescribed now in mild *PAH* treatment. Prostanoids have been incorporated as 3rd line agents in active *DU* treatment. MMF is the new 1st line treatment for *ILD* induction and rituximab the 3rd. IV CYA and ASCT were recommended as 3rd and 4th line treatments in patients with severe *skin involvement*. Rituximab and tocilizumab have been incorporated into *inflammatory arthritis* treatment. This can guide therapy in SSc.

FRI0376 DIFFERENCES IN RIGHT VENTRICULAR FUNCTION AND MORPHOLOGY IN SSC-PAH AND IPAH ASSESSED BY RIGHT HEART CATHETERIZATION AND CARDIAC MRI

A.-M. Hoffmann-Vold[1], E. Hopp[2], Ø. Midtvedt[1], T. Garen[1], P. Szodoray[3], Ø. Molberg[1], A.K. Andreassen[4]. *[1]Rheumatology; [2]Radiology; [3]Immunology; [4]Cardiology, Oslo University Hospital, Oslo, Norway*

Background: Systemic sclerosis (SSc) is a serious disorder with high mortality, mainly driven by cardiopulmonary pathologies including *pulmonary arterial hypertension (PAH)*. Patients with SSc-PAH appear to have worse prognosis than idiopathic PAH (iPAH).
Objectives: (A)Compare cardiac magnetic resonance (CMR) of the right ventricle, hemodynamic parameters and immunological markers between patient cohorts with SSc-PAH, iPAH and SSc without PAH, respectively. (B)Evaluate the impact of these variables on PAH-related morbidity and mortality.
Methods: The study cohort included SSc-PAH (n=16), iPAH (n=15) and SSc without PAH (n=20). At baseline, all patients were examined by ventricular volumes by short axis summation of cine CMR, echocardiography and right heart catheterization (RHC). Blood samples were analysed for immune-related factors. At a median follow up of 3 years, clinical data, and new onset of PAH and vital status were registered. A composite outcome for PAH related events was created including: PAH progression, end-stage PAH, hospitalization for PAH worsening and all-cause mortality. Associations between parameters were assessed using ANOVA, Pearson Chi-square, Fishers exact, or independent sample t-test.
Results: Patients with SSc-PAH were significantly older at PAH onset, had lower 6MWD, DLCO% and Hb than the iPAH patients. RHC results are shown in Table 1. CMR showed that SSc-PAH patients had lower right ventricular mass index (RVMI), RV to left ventricular ratio and RV mass to volume ratio (Table 1). Multiplex immune assays demonstrated higher serum levels of IP-10, VEGF and, IL12 in SSc-PAH than in iPAH. At the end of the study, 12/15 SSc-PAH had developed a PAH-related event. Compared to event-free patients, they were marked by significant CMR changes including higher RVM (p=0.006) and RVMI (p=0.005). In the iPAH subgroup, 7/16 patients developed an event. These patients were characterized by younger age at onset (p=0.001), higher NT-proBNP (p=0.017), lower 6MWD (p=0.034), higher RVM (p=0.010), RVMI (p=0.005), RV-to-LV ratio (p=0.001) on CMR.

Table 1. Baseline right ventricle hemodynamic and cardiac magnetic resonance measurements

	SSc-PAH (n=15)	iPAH (n=16)	p-value
RHC			
Cardiac output	6.0 (2.9)	5.4 (1.4)	n.s.
Cardiac index	3.2 (1.5)	2.9 (0.6)	n.s.
RAP, mmHg	4.6 (3.1)	7.2 (3.4)	0.007
sPAP, mmHg	60 (19.8)	88 (23.3)	<0.001
mPAP, mmHg	35.5 (11.7)	55 (17.1)	<0.001
PCV, mmHg	6.2 (2.9)	7.4 (3.1)	n.s.
PA oxygen saturation%	81.3 (33.1)	93.2 (31)	n.s.
PVR (Wood)	5.4 (3.9)	9.7 (4.3)	<0.001
RV MRI			
RVSV index, ml/m^2	40.9 (7.8)	40.4 (7.8)	n.s.
RVESV, ml	144.9 (80.3)	146.8 (46.4)	n.s.
RVEDV, ml	219.5 (84.2)	223.8 (52.8)	n.s.
RVEDV index, ml/m^2	120.8 (50.5)	120.8 (28.3)	n.s.
RVEF, %	37.1 (10.5)	34.5 (10.5)	n.s.
RV mass, g	50.1 (21.3)	72.9 (27.4)	<0.001
RV mass index, g/m^2	26.2 (10.8)	38.2 (14.9)	<0.001
RV-to-LV ratio	0.51 (0.14)	0.82 (0.32)	<0.001
RV mass-to-volume ratio, g/ml	0.22 (0.06)	0.31 (0.08)	<0.001

Conclusions: The CMR measures indicate that the RV adapts differently in iPAH and SSc-PAH; with more pronounced RV hypertrophy in iPAH patients. The mechanisms behind the differences in RV hypertrophy in SSc-PAH and iPAH are not known, but may involve microvascular changes and deregulated inflammatory cascades. This study indicates that CMR may predict PAH progression in SSc.

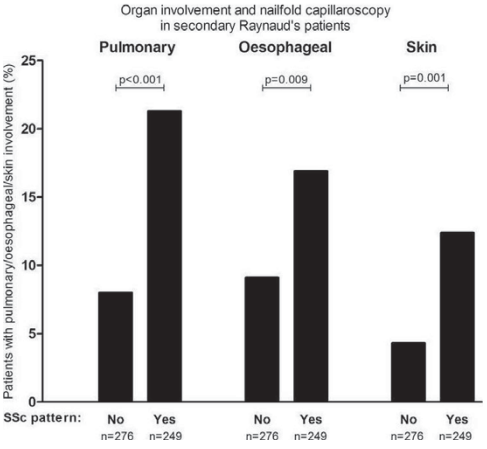
FRI0377 ABNORMAL NAILFOLD CAPILLAROSCOPY PATTERN IS COMMON IN PATIENTS WITH CONNECTIVE TISSUE DISEASE AND ASSOCIATED WITH ORGAN INVOLVEMENT



A.M. Van Roon[1], C.C. Huisman[1], A.M. van Roon[1], D. Zhang[2], A.J. Stel[3], A.J. Smit[1], H. Bootsma[3], D.J. Mulder[1]. *[1]Internal Medicine - Vascular Medicine, University of Groningen - University Medical Center Groningen, Groningen; [2]Rheumatology, Medical Center Leeuwarden, Leeuwarden; [3]Rheumatology and Clinical Immunology, University of Groningen - University Medical Center Groningen, Groningen, Netherlands*

Background: Nailfold capillary microscopy (NCM) has been shown to be associated with disease severity and internal organ involvement in non-consecutive systemic sclerosis (SSc) cohorts. NCM may help in early recognition of connective tissue disease (CTD) but it is unclear to which extent NCM abnormalities occur in several CTD and whether these are associated with organ involvement.
Objectives: To assess NCM in consecutive patients with Raynaud's phenomenon (RP) and whether these are associated with signs of organ involvement.
Methods: NCM was assessed in consecutive patients with RP (n=759) by wide-field videocapillaroscopy, according to standardized procedures at a dedicated vascular laboratory by trained and experienced technicians. The pattern was classified as normal (n=325), non-specific (n=188) or SSc pattern (early (n=106), active (n=140) or late (n=0) based on the Cutolo patterns). Potential pulmonary involvement was defined as forced vital capacity or diffusion capacity <70%. Gastro-intestinal involvement as scintigraphically (Tc-99M colloid) oesophagus dysmotility. Skin involvement as puffy fingers or sclerodactyly.
Patients were classified as primary RP (normal NCM and negative serology, n=226) or secondary RP (abnormal NCM and/or serology) groups: early SSc (n=195), SSc (n=40), incomplete Sjögren's syndrome (iSS, n=5), primary SS (pSS, n=30), incomplete systemic lupus erythematodes (iSLE, n=42), SLE (n=30), mixed CTD (MCTD, n=7), rheumatoid arthritis (RA, n=15) or when not meeting criteria as other (n=169). None were diagnosed with polymyositis or dermatomyositis.
Results: SSc pattern was observed in 33% of patients with pSS, 17% SLE, 71% MCTD and 13% RA. Pulmonary, oesophageal and skin involvement was more frequent in secondary RP patients with an SSc pattern, even when analysing only those fulfilling definite criteria for CTD or after exclusion of early SSc and SSc patients. For secondary RP patients, absence of an SSc NCM pattern had a high negative predictive value for pulmonary (92%), oesophageal (91%) and skin (96%) involvement, while positive predictive values were low.

Table 1. Nailfold capillaroscopic pattern per patient diagnosis group in patients with Raynaud's phenomenon

NCM pattern	Primary Raynaud	Secondary Raynaud								
		Definite diagnosis					No classifiable disease			
		SSc	pSS	SLE	MCTD	RA	early SSc	iSS	iSLE	Other
	n=226	n=40	n=30	n=30	n=7	n=15	n=195	n=5	n=42	n=169
Normal	226 (100)	1 (3)	10 (33)	12 (40)	2 (29)	11 (73)	4 (2)	4 (80)	29 (69)	26 (15)
Non-specific	0 (0)	4 (10)	10 (33)	13 (43)	0 (0)	2 (13)	2 (1)	1 (20)	13 (31)	143 (85)
Early	0 (0)	7 (18)	4 (13)	2 (7)	1 (14)	1 (7)	91 (47)	0 (0)	0 (0)	0 (0)
Active	0 (0)	28 (70)	6 (20)	3 (10)	4 (57)	1 (7)	98 (50)	0 (0)	0 (0)	0 (0)

Data in number (percentage).

Conclusions: SSc pattern on NCM is common in CTD patients and is associated with frequent prevalence of organ involvement, even in the absence of (early) SSc. Although this was a retrospective cohort, these data underline the importance of assessing NCM in RP patients to evaluate the risk for organ involvement in CTD other than SSc, already in early disease stages.

FRI0378 CARDIAC INVOLVEMENT IN UNDIFFERENTIATED CONNECTIVE TISSUE DISEASE AT RISK FOR SYSTEMIC SCLEROSIS. A TISSUE DOPPLER IMAGING STUDY

A. Riccardi[1], M. D'Alto[2], P. Argiento[2], E. Romeo[2], I. Di Stefano[1], S. Fasano[1], A. Mattera Iacono[2], A. D'Andrea[2], A. Sanduzzi[3], M. Bocchino[3], L. Docimo[4], S. Tolone[4], M.G. Russo[2], G. Valentini[1]. *[1]Rheumatology Unit; [2]Department of Cardiology, University of Campania "Luigi Vanvitelli"; [3]Department of Clinical Medicine and Surgery, University "Federico II"; [4]Division of General and Bariatric Surgery, University of Campania "Luigi Vanvitelli", Naples, Italy*

Background: Undifferentiated connective tissue disease at risk for Systemic Sclerosis (UCTD-risk-SSc), previously referred to as very early SSc, is a condition characterized by Raynaud's phenomenon (RP) with SSc marker autoantibodies and/or typical capillaroscopic findings and unsatisfying classification criteria for the disease (1). UCTD-risk- SSc patients have been reported to present, in about 40% of the cases, a preclinical vascular internal organ disease as detected by a diffusing lung capacity for CO <80% of the predicted value (lung involvement) and/or a low esophageal sphincter pressure <15 mmHg (oesophageal involvement) and/or a mitral E/A ratio <1 (heart involvement) (2, 3).

Objectives: Aim of the present study was to assess the prevalence of right (RV) or left ventricle (LV) systolic and/or diastolic dysfunction by standard echocardiography and tissue Doppler imaging (TDI).
Methods: Thirty patients with UCTD-risk-SSc (28 female, aged 47±13 years, range 21–70) and 30 age- and sex-matched controls underwent cardiac assessment by standard echocardiography and TDI.
Results: UCTD-risk-SSc patients and controls did not show any difference at standard echocardiographic evaluation. In particular, an inverted E/A ratio was pointed out in 10/30 patients and 7/30 controls (p=ns). TDI showed a mild impairment of LV and RV diastolic (E_m15±4 vs 19±5, $p<0.0001$;E/E_m 6.1±1.7 vs 4.8±1.2, p=0.001; E_t 14±3 vs 16±2, p=0.02; E_t/A_t0.9±0.4 vs 1.3±0.3, $p<0.002$; increased pulmonary artery wedge pressure 9±2 vs 8±1, p=0.001)and systolic function (S_m 13±3 vs 15±2 cm/sec, $p<0.0003$; S_t 14±2 vs 16±3 cm/sec, $p<0.0001$) in UCTD- risk-SSc patients in comparison to controls.
Conclusions: Our study shows that UCTD-risk-SSc patients present a previously unrecognized, mild biventricular systolic and diastolic dysfunction as compared to controls. The pathophysiologic meaning (i.e.intramyocardial artery disease and/or patchy fibrosis) as well the predictive value of developing overt SScin the short time await to be elucidated.

FRI0379 PREVALENCE OF FAM111 B GENE MUTATIONS IN SYSTEMIC SCLEROSIS

A. Gcelu[1], G. Deshpande[2], A.A. Kalla[1], M. Tikly[3], B. Mayosi[2], B. Hodkinson[1]. *[1]Medicine, Division of Rheumatology; [2]Cardiovascular Genetics Laboratory, University of Cape town, Cape Town; [3]Medicine, Division of Rheumatology, University of Witwatersrand, Johannesburg, South Africa*

Background: Systemic sclerosis (SSc) is a prototypic systemic fibrotic disease with unclearly characterized genetic basis. Implicated genes have been associated with autoimmune dysregulation with relatively few variants associated with fibrosis [1]. We have discovered that mutations in *FAM111B* gene cause hereditary fibrosing poikiloderma with tendon contractures, myopathy, and pulmonary fibrosis (POIKTMP)[2], a multisystem fibrotic condition with clinical aspects of SSc [3]. This observation has established *FAM111B* as a candidate gene for SSc.
Objectives:
The objective is to investigate whether *FAM111B* gene mutations are present in SSc patients and further explore relationships between *FAM111B* mutations and clinical expression of SSc.
Methods: Patients with a definite diagnosis of SSc attending the Rheumatology outpatient departments at Groote Schuur Hospital, Cape Town, and Chris Hani Baragwanath Hospital, Johannesburg, were enrolled into the study. Physical examination assessing the extent of disease was done in all patients and the modified Rodnan skin score (mRSS) was used to determine the extent of the skin involvement. Blood samples were collected for DNA extraction and mutation screening using the high-resolution melt technique. Samples with abnormal electropherograms were selected for Sanger sequencing to identify mutations. Public databases were used to verify the frequency of variants in *FAM111B*.
Results: 131 patients were genotyped, 13 men and 118 women, with a mean age of 26.6 years and mean age of symptom onset at 25.3 years. The majority of patients were black (59.5%). 72% of patients had diffuse systemic sclerosis (DSSc) with a median mRSS of 11. Genetic analysis revealed seven rare genetic variants (C832G>A; C855G>T; C917A>G; C937G>A; C988C>T; C995A>C and C1006G>C) in eight patients (five patients from Johannesburg and three patients from Cape Town) [table 1]. These variants were missense mutations of unknown significance with a minor allele frequency <0.01. No *FAM111B* mutations that cause POIKMT were found in patients with SSc.
Conclusions: Rare genetic variants of unknown significance (GVUS) in *FAM111B* gene were found in patients with SSc. It is possible that the GVUS may modify the function of *FAM111B*, and influence the pathogenesis of SSc or are rare polymorphisms with no functional impact.

FRI0380 PATIENT PREFERENCES AND DIFFICULTIES CONCERNING THE HOME TREATMENT OPTIONS IN SYSTEMIC SCLEROSIS (SSC)

B. Pagnotelli[1], C. Bruni[1], S. Bellando Randone[1], S. Guiducci[1], G. Lepri[1], J. Blagojevic[1], L. Rasero[2], M. Matucci Cerinic[1], D.E. Furst[1,3]. *[1]Division of Rheumatology; [2]Division of Research & Development Clinical Practice, AOUC, Florence, Italy; [3]Division of Rheumatology, UCLA, Los Angeles, United States*

Background: SSc patients suffer from Raynaud's phenomenon, hand skin hardening and scarring, digital ulcers, esophagus/gastric dysmotility, dysphagia and mucosal dryness. These symptoms significantly reduce patient's life autonomy and impair the capacity to handle their therapy usually made by different modalities of administration: oral, topical, inhalation, intramuscular, subcutaneous, intravenous, and rectal.
Objectives: to investigate the methods of administration used by SSc patients, their preferred methods, their compliance to pharmacological therapy, and the difficulties that are encountered by the patients during pharmacotherapy.
Methods: 2 questionnaires were prepared on an ad hoc basis. The first given to patients, the second to be filled out by the patient's physician. The first questionnaire comprised 25 questions to investigate the problems encountered by patients when taking their medications by correlating these with two validated activities indices: SHAQ-DI (activities of daily living) and the COCHIN scale (hand activities). The second questionnaire collected demographic and important SSc-related clinical information (eg.age, sex, disease duration, symptoms). 80 Ssc patients completed the questionnaires, maintaining anonymity. A "difficulty index" was also filled out, where: 0 = no difficulty to 4 = impossible to use or too difficult to use.
Results:

Table 1. Patient use of pharmacological therapies

	% Using	% Users preferring this method	Difficult index†	Comment
Oral	100	91,25	0,83	Most preferred
Eye drops	52,5	2,5	1,07	Least preferred
Topicals	33,75	3,75	0,77	Cannot open the top (safety lock)
Injections	28,25	2,5	2,17	Cannot apply to skin
Inhaler	16,25	0	1,07	Cannot spray
Vaginal/rectal	6,25	0	1,03	

Table 2. Most frequent problems encountered

	% Using	Most frequent problems	Users have these problems	Difficult index†
Oral	100	Blister: pushing out pills	73,75	2,22
Eye drops	52,5	Open thin stoppers	78,75	1,51
Topicals	33,75	Cannot open the top (safety lock)	70,5	1,4
Inhaler	16,25	Cannot spray/push the inhaler	85	1,71

†4 = most difficult.

In particular, the dimension of the pills is problematic, and has identified a paradoxical situation because large pills are difficult to swallow (41,25% patients who use pills) but at the same time small pills are difficult to pinch with the fingers (62,25% patients who use pills).
Conclusions: SSc patients experience significant problems in maintaining adherence to treatments due to difficulties in the use of blisters and bottles with children proof stoppers. Pills still remain the most preferred method of treatment. In conclusion, patients unanimously wished to avoid the use of blisters, defintively preferring bottles without the children proof stopper to make the treatment easier and provide a more independent life.

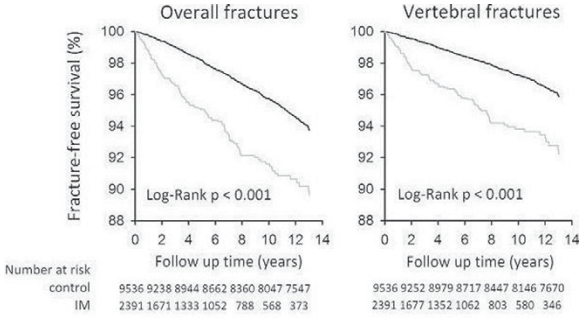
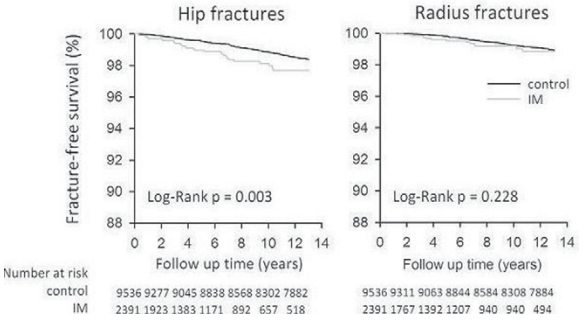
FRI0381 INCREASED RISK OF OSTEOPOROTIC FRACTURES IN ADULT PATIENTS WITH POLYMYOSITIS AND DERMATOMYOSITIS: A NATIONWIDE POPULATION-BASED COHORT STUDY

C.-C. Lai[1], W.-S. Chen[1], Y.-P. Tsao[1], Y.-S. Chang[2]. *[1]Division of Allergy, Immunology, and Rheumatology, Taipei Veterans General Hospital, Taipei City; [2]Division of Allergy, Immunology and Rheumatology, Department of Internal Medicine, Shuang Ho Hospital, Taipei Medical University, New Taipei City, Taiwan, Province of China*



Background: Patients with polymyositis and dermatomyositis (PM/DM) are characterized by chronic muscle weakness due to autoimmune-mediated myositis and are usually treated with corticosteroids initially. PM/DM patients prone to develop osteoporosis and subsequent fractures but are rarely investigated.
Objectives: To explore the incidence rate (IR) and risk factors of osteoporotic fractures (OFs) among adult PM/DM patients.
Methods: We conducted a cohort study by utilizing the Taiwan National Health Insurance database. PM/DM patients and respective age- and gender-matched cohort without PM/DM were enrolled. The primary endpoint was the initial event of OFs. We used the Cox proportional hazard model to study the risk factors of OFs in the PM/DM cohort.
Results: Among 2391 PM/DM patients (67.8% female, mean age: 49.5 years) followed for a mean (SD) of 6.1 (5.0) years, 116 developed vertebral fractures, 32 had hip fractures, and 14 experienced radius fractures (IR: 8.18, 2.20, and 0.96 per 1000 person-years, respectively, Table 1). Compared with the matched cohort, the PM/DM patients had higher IR ratios (IRRs) (95% CIs) of OFs at all age groups at enrollment: 3.27 (2.19 to 4.81, $p<0.0001$) for people <50 years and 2.29 (1.85 to 2.82, $p<0.0001$) for those ≥50 years. The IRRs were 2.39 (1.92



to 2.94, p<0.0001) for vertebral fractures and 1.62 (1.07 to 2.38, p=0.0093) for hip fractures. PM/DM patients experienced vertebral fractures and hip fractures at younger ages (62.2 vs 68.4 and 66.0 vs 75.4 years, respectively; both p<0.001). Multivariable Cox regression analyses showed that being female gender, age ≥50 years, having hypertension, coronary artery disease, asthma, and using daily prednisolone equivalent to >5 mg are associated with OFs.

Table 1. IRs and IRRs of osteoporotic fractures: overall and subgroup analysis

Subgroup	IM IR	Control IR	IRR (95% CI)	p Value
Overall fracture	10.90	5.23	2.08 (1.73 to 2.49)	<0.0001
Age <50 year	4.51	1.38	3.27 (2.19 to 4.81)	<0.0001
Age ≥50 year	22.59	9.85	2.29 (1.85 to 2.82)	<0.0001
Vertebral fracture	8.18	3.43	2.39 (1.92 to 2.94)	<0.0001
Age <50 year	3.39	0.98	3.47 (2.17 to 5.44)	<0.0001
Age ≥50 year	16.82	6.33	2.66 (2.07 to 3.39)	<0.0001
Hip fracture	2.20	1.36	1.62 (1.07 to 2.38)	0.0093
Age <50 year	0.65	0.10	6.56 (1.75 to 24.6)	0.0027
Age ≥50 year	4.87	2.83	1.72 (1.09 to 2.62)	0.0081
Radius fracture	0.96	0.83	1.15 (0.60 to 2.02)	0.3081
Age <50 year	0.43	0.35	1.25 (0.31 to 3.69)	0.3289
Age ≥50 year	1.86	1.40	1.35 (0.62 to 2.63)	0.1857

IR, incidence rate per 1000 person-year; IRR, incidence rate ratio; CI, confidence interval.

Conclusions: Adult PM/DM patients had a high IR of vertebral and hip fractures. Patients who were female, advanced age, having certain comorbidities, and exposed to corticosteroid exhibited a higher risk.
Disclosure of Interest: None declared

FRI0382 USE OF THE DETECT ALGORITHM FOR EARLY PULMONARY ARTERY HYPERTENSION DIAGNOSIS IN PATIENTS WITH SYSTEMIC SCLEROSIS IN EVERYDAY CLINICAL PRACTICE

C. Koutsianas, S. Subasinghe, K. Douglas. *Department of Rheumatology, The Dudley Group NHS Foundation Trust, Dudley, United Kingdom*

Background: The DETECT algorithm (DA)[1] provides a sensitive tool for early identification of patients with Systemic Sclerosis (SSc) at risk of Pulmonary Arterial Hypertension (PAH) and advocates evaluation with Right Heart Catheterisation (RHC). Few published data look into its implementation in everyday clinical practice and compare it to annual echocardiographic (TTE) screening.
Objectives: To compare DA and TTE screening of SSc patients for RHC referral rates and related patient characteristics.
Methods: Data on 57 consecutive patients with a diagnosis of SSc that had at least one visit to Russells Hall Hospital Scleroderma clinic from February to November 2016 was prospectively collected on Excel (clinical history, physical examination, immunological status, treatment, PFTs, NT-proBNP, urate, ECG, TTE, CXR and HRCT results). DETECT scores were calculated (*www.detect-pah.com*) and compared with the TTE probability for PAH as per the 2015 ESC/ERS Guidelines[2].
Results: 31 patients with a full set of data were included in the final analysis. 93.5% were female with a mean age of 64.4±12.9 years, 87% had limited cutaneous (lc) SSc, 58.1% positive anticentromere antibody and mean time since diagnosis was 6.2±3.2 years. The majority of patients (80%) were asymptomatic for PAH. Mean DLCO was 60.9±18.3% predicted (the DETECT study included on patients with DLCO<60%). We did not exclude patients with renal insufficiency; mean eGFR was 74±17.7ml/min.
The implementation of DA recommended RHC in 18/31 patients (DETECT step 2 score ≥35, 58%, see table 1) compared to just 4/31 (13%) based on TTE by 2015 ESC/ERS guidelines. The additional 14 patients identified by DA were found to have no statistically significant differences in SSc type, dyspnea symptomatology, immunosuppressive treatment, presence of interstitial lung disease (ILD), age, time from diagnosis or symptom onset, eGFR and CRP compared to patients where RHC was not recommended. From the 18 patients identified by DA, only 4 reported shortness of breath. 2/18 had existing cardiac conditions (aortic stenosis, left ventricular hypertrophy), while 9/18 had ILD (5 mild, 2 moderate, 2 severe as per HRCT).

Table 1

	DETECT step 2 score			p
	<35	35–39	>40	
Age, years (median (IQR))	65.8 (26.9)	63.2 (22.3)	72.4 (25.1)	*0.875*
Disease duration, years (median (IQR))	8 (4)	4 (7)	5 (9)	*0.996*
eGFR, ml/min (median (IQR))	80 (28)	83 (17)	54.5 (47)	*0.958*
CRP, mg/L (median (IQR))	3 (5)	3 (3)	3 (2)	*0.636*
DLCO, % (median (IQR))	65 (17)	64 (12)	53 (30)	*0.757*
ILD (no. of patients) No	10	5	3	0.087
Mild	1	3	4	
Moderate	2	1	0	
Severe	0	0	2	

Conclusions: Implementation of DA in a largely asymptomatic non-selected SSc patient population is more sensitive for RHC referral than annual TTE screening. Recommendations for RHC per DETECT score are difficult to predict on symptom and other traditional clinical parameters. The use of DA will lead to increased RHC referrals. Cardiologists may need education on this new method for screening and although the ESC/ERS 2015 guidelines discuss DA, they conclude that its cost-effectiveness has not been clarified as compared with symptom-based detection.

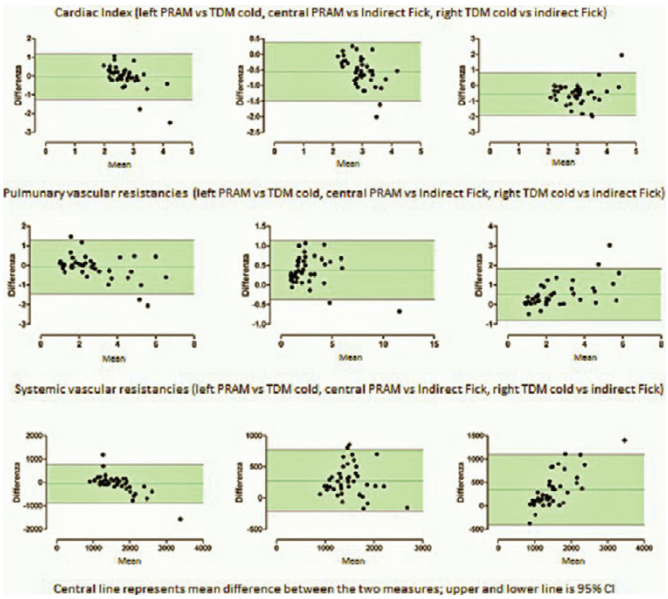
FRI0383 DETECT SCREENING FOR PULMONARY ARTERIAL HYPERTENSION IN SYSTEMIC SCLEROSIS: DATA FROM AN EUSTAR COHORT

C. Ancuta[1,2], C. Pomirleanu[1,2], R. Maxim[2], F. Mitu[1,3]. *[1]University of Medicine and Pharmacy Grigore T Popa Iasi; [2]Rheumatology 2; [3]Cardiology, Clinical Rehabilitation Hospital, IASI, Romania*

Background: Early documentation of pulmonary arterial hypertension (PAH) related to systemic sclerosis (SSc) remains a challenge in daily clinical practice, with major prognostic and therapeutic implications. Although several screening algorithms specifically designed to optimize the detection of secondary PAH have already been proposed (e.g., DETECT, REVEAL), no precise approach received complete validation, especially the use of invasive diagnostic right heart catheterization (RHC).
Objectives: Main objective was to assess the risk of PAH in patients with SSc and to compare with PAH screening promoted by European Society of Cardiology/ European Respiratory Society (ESC/ERS) 2009 guidelines, while secondary one to identify predicting factors for developing PAH among clinical and immunological SSc variables.
Methods: Cross-sectional prospective single-center study, applying the DETECT calculator in patients with SSc recruited in EUSTAR 162 center cohort between January 2013- December 2016; all SSc completing at least two monitoring visits at 6 months were considered.
Standard assessments included MEDS (minimal data set EUSTAR), annual echocardiography with systolic pulmonary artery pressure (sPAP), pulmonary function tests with forced vital capacity (FVC), percentage predicted/diffusing capacity for carbon monoxide (DLCO) % predicted, ECG, serum biomarkers (serum urate, NT-proBNP).
PAH risk calculator (http://detect-pah.com/pah-risk-calculator), a tool developed and validated in the DETECT study, is able to identify patients requiring echocardiography (STEP 1) respectively RHC (STEP 2), and was systematically applied in our cohort. All sPAP ≥45 mmHg or between 35–45 mmHg in the presence of dyspnea were proposed for invasive testing.
Statistical analysis was performed in IBM SPSS-19 version, p<0.05.
Results: 41 out 56 SSc in our database were recruited: mainly women (85.36%) with diffuse cutaneous SSc (63.41%), anti-topoisomerase (up to half) and anti-centromere (about one third) positive disease; one out of four 4 SSc presented with digital ulcers and one of three with active capillaroscopic pattern.



Using the DETECT PAH calculator, 14/ 41 (34.14%) were recommended for RH as follows: an initial value above 300 points in STEP 1 (with further indication of echocardiographic assessment) and subsequent STEP 2 over 35 were recorded. On the other hand, only 9/41 (21.95%) cases met the ultrasound criteria to be addressed to an invasive assessment when applying the ESC/ERS 2009 guidelines, the difference being statistically significant as compared to DETECT ($p<0.05$).
PAH was finally confirmed in 8/41 (19.51%) cases, supporting our preliminary results in a pilot study on a limited number of patients.
Conclusions: DETECT is a reliable algorithm for early detection of PAH in patients with SSc, optimizing PAH screening and prompting the rheumatologist-cardiologist collaboration.

DOI: 10.1136/annrheumdis-2017-eular.4053

FRI0384 A MINI-INVASIVE TECHNIQUE FOR HAEMODYNAMIC EVALUATION: NEW PERSPECTIVES FOR PULMONARY ARTERIAL HYPERTENSION (PAH) DIAGNOSIS IN SYSTEMIC SCLEROSIS (SSC)

E. Bellucci[1], M.S. Romano[2], M. Chiostri[2], C. Bruni[1], C. Giglioli[2], P. Bernardo[3], M.L. Conforti[1], S. Bellando-Randone[1], S. Guiducci[1], M. Matucci-Cerinic[1].
[1]Department of Experimental and Clinical Medicine, Division of Rheumatology, University of Florence; [2]Department of Heart and Vessels, Division of Cardiology I; [3]Department of Heart and Vessels, Division of Structural Interventional Cardiology, Azienda Ospedaliera Universitaria Careggi, Firenze, Italy

Background: PAH is one of the most severe complication and cause of mortality in SSc, with frequent late diagnosis as asymptomatic in its early stages. Right Heart catheterization (RHC) is the gold standard for PAH detection, though its invasive nature with high risk of procedure related complications stress the need for developing new screening methods to investigate it in early and possibly reversible stages. Pressure Recording Analytical Method (PRAM) was recently developed to obtain a minimally invasive haemodynamic monitoring, using an arterial line and proximal pulsossimetry. This analyses arterial blood pressure curve and measure both cardiac [Cardiac Index, Cardiac Contractility and Vascular Stiffness ratio (dP/dT)] and vascular [vascular stiffness, elastance], which can be usually obtained only through RHC.
Objectives: to evaluate the clinical usefulness of PRAM method in SSc patients and to identify haemodynamic parameters related to increased risk of developing PAH.
Methods: 40 ssc patients (35 women, mean age 60±9,3 years; mean disease duration 7.5 years) were evaluated with both RHC and PRAM on the same day. Mean pulmonary arterial pressure (mPAP), cardiac index (CI), systemic vascular resistances (SVR), right cardiac power index (RCPI, calculated with $mPAPXCI_{PRAM}/451$) were measured and concordance of the two methods was assessed through Bland-Altmann analysis. Systolic pulmonary arterial pressure and TAPSE from echocardiography, forced vital capacity, total lung capacity, both absolute and alveolar volume adjusted Carbone oxide lung diffusion (DLCO and DLCO/VA) from pulmonary function tests, blood tests parameters, nailfold videocapillaroscopy scleroderma patterns were recorded. Univariate and multivariate logistic regression analysis identified variables correlating with RHC-diagnosed PAH: a scoring system was then created, giving 1 point for value satisfying cut-off level.

Univariate Logistic Regression	Unadjusted OR	95% CI	p value
Dicrote Pressure	1.04	1.00–1.09	0.064
Arterial Elastance	3.16	0.70–14.24	0.134
Right Cardiac Power index	1.11	1.04–1.18	0.002
DLCO	0.94	0.90–0.99	0.021
Multivariate Logistic regression with backward stepwise analysis	Unadjusted OR	95% CI	p value
Right stroke work index	1.12	1.03–1.21	0.007
DLCO	0.94	0.87–1.01	0.072

Results: PRAM showed concordance with RHC estimate of CI and SVR within 95% interval confidence; 14 patients were diagnosed with PAH (mean age 64,4±9,3, mean disease duration 10.5 years, lSSc 61,5%). Multivariate logistic regression analysis showed DLCO (cut off value 47% obtained through ROC curve analysis, p=0.004) and RCPI (cut off value 0.12 Watt obtained through ROC curve analysis, $p<0.001$) as the most highly PAH-associated variables. When combining these two variables in the scoring system, patient with score=0 (DLCO<47% and RCPI<0,12 Watt), score=1 (DLCO<47% or RCPI≥0,12 Watt) and score=2 (DLCO<47% and RCPI≥0,12) were 0%, 21.4% and 78.6% of the PAH population respectively.
Conclusions: PRAM is comparable to RHC in detecting haemodynamic parameters such as SVR and CI. The scoring system combining DLCO and RCPI, obtained with non-invasive tools, could offer the possibility of detecting PAH patients with a high specificity.

FRI0385 JOINT MANIFESTATIONS IN PATIENTS DIAGNOSED WITH IDIOPATHIC INFLAMMATORY MYOPATHY: MULTICENTER REGISTRY

D.C. Hernández Flórez[1], L. Valor[1], J. Martinez[1], B. Joven[2], L. Nuno[3], C. Larena[4], I. Llorente[5], C. Barbadillo[6], P. Garcia de la Pena[7], L. Ruiz[8], H. Moruno[9], T. Cobo[10], R. Almodovar[11], L. Lojo[12], M. Garcia[13], F. Lopez-Longo[1]. *[1]H. Gregorio Maranon; [2]H.12 de Octubre; [3]H.La Paz; [4]H.Ramon y cajal; [5]H.La Princesa; [6]H.Puerta de Hierro; [7]H.Norte Sanchinarro; [8]H.Nino Jesus; [9]H.Principe de Asturias, Madrid; [10]H.Infanta Sofia, Asturias; [11]H.F.Alcorcon; [12]H.Infanta Leonor; [13]InMusc, Madrid, Spain*

Background: Idiopathic inflammatory myopathies (IIM) comprise a heterogeneous group of autoimmune conditions. Joint involvement can be considered to be part of the IIM systemic manifestations, together with a possible gastrointestinal, cardiovascular and/ or pulmonary involvement. Although articular involvement in the IIM has been described as variable and non-specific with a chronic course it might be an early symptom of dermatomiositis in up to 30% of cases and in those patients with overlap syndromes.
Objectives: To evaluate and to identify joint manifestations in IIM patients.
Methods: We evaluated a cohort of 479 patients that included 12 hospitals in the Community of Madrid belonging to the IIM registry of the Society of Rheumatology of Madrid (SORCOM-REMICAM) with diagnosis from January 1980 to December 2014. All patients were diagnosed of IIM according to Bohan and Peter criteria (1). The presence of arthralgia and arthritis was considered. IIM were classified as dermatomyositis (primary and secondary dermatomiositis) (DM) and polymyositis (PM) including the rest of the patients (classification I). Also, IIM were classified (II) as primary polimiositis (PPM), primary dermatomyositis (PDM), overlap syndrome (OSd), juvenile myopathies (JM), cancer-associated myopathies (CAM), autoimmune necrotizing myopathy and inclusion body myositis (these were grouped as other myositis; OM).
Results: We found 70 (18%) patients with acute arthritis (<6 weeks), 74 (19%) patients with chronic arthritis (>6 weeks) and 245 (65%) patients without any joint manifestations. Using the Tanimoto et al. criteria (1), the presence of erosive arthritis was observed in 149/479 (38.3%) of the patients. When comparing the joint manifestations in the PM and DM groups (n=250, 52.2% vs. n=229, 47.8%) no statistically significant differences were observed. However, assessing joint manifestations according to classification II, we observed that the highest prevalence was found in the OSd group, followed by the PDM group (p=0.0001). The group with less joint manifestations was JM compared to OSd and PDM (Table 1.

Table 1: Joint manifestations in IIM according to classification II

	Comparison between groups		Frequency	P
Joint manifestations	OSd vs.	PPM	90% vs. 54%	0,0001
		PDM	90% vs. 71%	
		JM	90% vs. 45%	
		CAM	90% vs. 49%	
		OM	90% vs. 58%	
Arthralgias	OSd vs.	PPM	90% vs. 54%	0,0001
		PDM	90% vs. 71%	
		JM	90% vs. 44%	
		CAM	90% vs. 49%	
Arthritis	OSd vs.	PPM	90% vs. 34%	0,0001
		JM	90% vs. 28%	
		CAM	90% vs. 33%	

Conclusions: The presence of joint manifestations associated with IIM in our cohort is higher compared to other studies described in the literature so far and

emphasize the importance of an accurate joint examination in these patients. The OSd group showed more joint manifestations which might be explained by the coexistence of SLE and MCTD patients in this group. Currently, no association between the clinical subtypes of IIM, overall, these results are encouraging and suggest that joint assessment in follow up may be helpful in differentiating subtypes of IIM.

FRI0386 THE VALIDATION OF THE SCLERODERMA HEALTH ASSESSMENT QUESTIONNAIRE IN TURKISH SPEAKING PATIENTS WITH SYSTEMIC SCLEROSIS

D. Temiz Karadag [1], F. Karakas [2], S. Tekeoglu [1], O. Ozdemir Işik [1], A. Yazici [1], A. Cefle [1]. *[1] Rheumatology; [2] Internal Medicine, Kocaeli University Medicine School, Kocaeli, Turkey*

Background: The Health Assessment Questionnaire (HAQ) is one of the main instruments for assessing disability in rheumatic diseases.The Scleroderma HAQ (S-HAQ) combines the HAQ with five systemic sclerosis (SSc) related visual analogue scales for Raynaud's phenomenon (RP), digital ulcers, digestive symptoms, pulmonary symptoms, and overall disease severity.
Objectives: To perform cross-cultural adaptation and validation of the S-HAQ in patients with SSc.
Methods: Sixty patients who fulfilled the 2013 ACR/EULAR Classification Criteria for Systemic Sclerosis ACR criteria for SSc were were recruited.Fifty three percent of the patients fulfilled the criteria for limited systemic sclerosis (lcSSc).We evaluated test–retest reliability using the intraclass correlation coefficient (ICC); known-groups construct validity by stratifying patients according to severe organ involvement; and convergent validity using Spearman's correlation with mental and physical components of Short Form 36 version 2 (SF36v2).
Results: Eighty percent of the patients were female and the median age was 56 years old.Finger tip ulcers were observed in 16 patients (26.7%) and severe organ involvements were detected as intersititial lung disease in 32 (53%) and pulmonary hypertension in 5 (8%) of the patients.HAQ Disability Index (HAQ-DI), digestive VAS, pulmonary VAS, digital ulcer VAS, Raynaud's phenomenon VAS and overall disease severity VAS demonstrated high reliability (ICCs=0.819–0.908).The HAQ-DI showed higher correlation coefficients with physical function and role physical components of physical-related scores (r=-0.537 and – 0.453, respectively); social function and role emotional components of mental-related dimensions (r= -0.470 and -0.328, respectively) in the SF-36.Two among five SSc related VAS (VAS digital ulcer and VAS overall disease severity) were highly correlated with HAQ-DI (r=0.527 and 0.481 respectively).The instruments could not discriminate between severe organ involvements and both subsets of SSc.

Table 1. Correlation of HAQ-DI with physical and mental components of SF-36 and, SSc related VAS scores

N=60	Mean±SD and/or %	Correlation Coefficient	*p-value*
Physical function	55.4±23.83	-0.537	0.000
Role physical	33.82±42.67	-0.453	0.001
Body pain	53.82±28.84	-0.290	0.041
General health	39.9±18.43	-0.295	0.037
Vitality	41.08±18.39	-0.286	0.044
Social function	62.25±24.49	-0.470	0.001
Role emotional	49.02±32.9	-0.328	0.02
Mental health	61.12±18.39	-0.295	0.04
VAS digestive	0.39±0.65	0.304	0.028
VAS pulmonary	0.64±0.79	0.380	0.005
VAS RP	0.67±0.74	0.354	0.01
VAS digital ulcer	0.62±0.94	0.527	0.000
VAS overall severity	1.14±0.97	0.481	0.000

Conclusions: The Turkish version of the S-HAQ meet the requirements of reproducibility and validity.More studies are needed to examine the capacity of these instruments to discriminate between severe involvements and disease subsets.This study forms the basis for future studies to evaluate the properties of S-HAQ in Turkish speaking SSc patients more extensively.

FRI0387 ANTI-RNA POLYMERASE III SUBSET OF SCLERODERMA PATIENTS: A MONOCENTRIC STUDY

E. Pigatto, M. Ferranti, M. Favaro, P. Polito, E. Zanatta, P. Galozzi, M. Tonello, L. Punzi, F. Cozzi. *University of Padova, Padova, Italy*

Background: Systemic sclerosis (SSc) is an autoimmune disease characterized by heterogeneous clinical features and variable disease course. Specific antinuclear antibodies (ANA) identify different clinical subsets and are very useful in defining the prognosis of the patients. Recently, the anti-RNA polymerase III antibodies (anti-RNAP) were defined as the third specific ANA of SSc, together with anti-centromere (ACA) and anti-topoisomerase I (anti-Scl70).
Objectives: The aim of this study was to analyze the clinical picture of a group of SSc patients with anti-RNAP in a monocentric cohort of patients and to compare it with other subsets of patients with different specific ANA. In particular, the visceral involvement and the concomitant malignancies were investigated.
Methods: Among the SSc patients referring to the Rheumatology Unit of Padova University, 49 cases with anti-RNAP specific ANA were considered. Patient's demographics data and major clinical manifestations were compared with those of 50 ACA-positive and 52 anti-Scl70-positive patients. The skin score and the presence of digital ulcers, arthritis, interstitial lung disease (ILD), cardiac involvement including pulmonary hypertension, gastrointestinal disease (GI) and scleroderma renal crisis (SRC) were assessed. The presence and type of concomitant malignancies were also evaluated.
Results: 53% of anti-RNAP-positive patients had a diffuse cutaneous form of SSc. The skin score was significantly higher than in ACA-positive patients ($p<0.001$). Digital ulcers were active in 73.5% of cases, without significant difference with the other two subsets. Arthritis was found in 20.4% of cases in comparison to 4% in ACA-positive patients ($p<0.02$). Regarding visceral involvements, GI disease was the most common manifestation in all subsets; SRC was observed in 24.4% of anti-RNAP-positive patients and was significantly more frequent in comparison to ACA-positive ($p<0.005$); ILD showed a prevalence of 42.8% in anti-RNAP subset, lower than in anti-Scl70-positive ($p<0.05$) and higher than in ACA-positive patients ($p<0.01$); cardiac involvement was observed in 32.6% of anti-RNAP-positive patients, without significant difference with the other subsets. Malignancies were found in 33 (67.3%) anti-RNAP-, 18 (36%) anti-Scl70- and 7 (14%) ACA- positive patients. The most common cancer-sites were breast (36%), lung (14%) and colon (10%). The risk of developing cancer was higher in anti-RNAP-positive patients than in other subsets (*OR*:6.35).
Conclusions: Our data demonstrated that anti-RNAP specific antibodies can identify a subset of SSc patients characterized by a severe clinical picture, with a high prevalence of diffuse cutaneous form, SRC, cardiac involvement and ILD. These patients showed also an elevated risk of developing cancer. Our results were consistent with recent published papers on this topic (1,2).

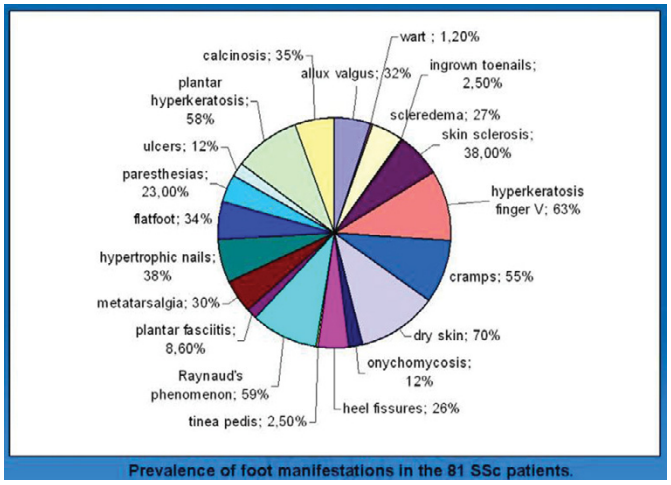
FRI0388 LONG-TERM TREATMENT WITH RITUXIMAB IN SYSTEMIC SCLEROSIS PATIENTS: UPDATE OF OUR CLINICAL EXPERIENCE

F. Lumetti, M. Colaci, C. Esposito, E. Cocchiara, C. Vacchi, A. Spinella, G. Tiengo, D. Giuggioli, C. Ferri. *Scleroderma Unit, Chair of Rheumatology, University of Modena and Reggio Emilia, Policlinico of Modena, Modena, Italy*



Background: Systemic sclerosis (SSc) is an immune-mediated disorder characterized by abnormal fibrosis and diffuse microangiopathy with skin and internal organ involvement. The treatment of SSc represents a great clinical challenge because of the complex disease pathogenesis including vascular, fibrotic, and immune T- and B-lymphocyte-mediated alterations. Therefore, SSc should be treated by combined or sequential therapies according to prevalent clinico-pathogenetic phenotypes. Some preliminary data suggest that rituximab (RTX) may be usefully employed in SSc patients.
Objectives: The present study aimed to evaluate the efficacy of RTX in our SSc patients' series as well as the long-term effects of this treatment.
Methods: A series of 15 SSc patients (M/F 6/9, mean age 52.7±17.9SD years, mean disease duration 10.3±7.1SD years, L/D cutaneous subsets 5/10) were treated with one or more cycles of RTX (4 weekly infusions of 375 mg/m^2). In all patients RTX was repeated every 6 months for a total of 2–6 cycles. Patients' clinical-serological evaluation, including the self-evaluation of quality of life by means of HAQ and visual analogical scale (VAS) assessment, was performed every 6 months for a mean follow-up period of 42±24SD months.
Results: After the first 6 months following RTX treatment the extent of skin sclerosis measured with modified Rodnan skin score (mRSS) significantly improved (from 17.3±10.4 to 13.4±7.6; $p<.01$), and remained stable at the end of the follow-up (13.3±8.1; p=.009). The usefulness of RTX on skin sclerosis was more evident in patients with diffuse cutaneous SSc (n=10) showing a significant decrease of mRSS after the first 6 months (from 24.2±5.1 to 18.1±4.7; p=.006) and at the end of the follow-up period (18.0±6.0; p=.005). Similarly, a valuable improvement of other cutaneous manifestations, namely hypermelanosis (12/12 pts), pruritus (11/13 pts), and calcinosis (3/6 pts) was observed. Moreover, arthritis revealed particularly responsive to RTX treatment leading to a clear-cut reduction of swollen and tender joints in 12/13 patients; while lung fibrosis detected in

12/15 remained stable during the entire follow-up.These positive clinical changes were mirrored by the subjective improvement of patients' well being in all cases (HAQ from 1.45±0.49 to 0.98±0.38, VAS from 64.5±18.5 to 37.5±8.6). Finally, no significant side effects were observed.
Conclusions: The present study reinforces the previous trials showing the usefulness of RTX in the management of SSc patients, along with its good safety profile. The specific therapeutical activity of RTX, able to down-regulate the B-cell over expression, might explain its beneficial effects on some SSc clinical manifestations; in particular the improvement of both skin sclerosis and articular involvement, along with the possible stabilization of lung fibrosis.

FRI0389 FOOT INVOLVEMENT IN PATIENTS WITH SYSTEMIC SCLEROSIS: A SINGLE-CENTRE REPORT

G. Cuomo, D. Ruta, E. Frongillo, L. Pirro, A. Del Mastro, C. Romano.
Dipartimento Assistenziale Integrato di Medicina Interna, UOC Medicina Interna - Università degli Studi della Campania - Luigi Vanvitelli, Napoli, Italy

Background: Foot involvement can be a source of morbidity and disability in patients with systemic sclerosis (SSc). Some studies have previously reported severity, echographic and radiographic manifestations of foot involvement in SSc (1,2).
Objectives: The aim of our study was to assess the nature and prevalence of foot problems in patients with SSc reporting a single centre experience.
Methods: A podiatrist and a rheumatologist assessed 81 (76 female) consecutive patients attending our SSc outpatient clinic. The mean age was 50 years (range 21–70). Thirteen (16%) had diffuse cutaneous SSc with a median disease duration from Raynaud's Phenomenon of 5 years (range 3 –19); 68 (84%) had limited cutaneous SSc with a median disease duration of 11.5 years (range 1–41). The overall median disease duration was 11 years (range 1–41). Thirty (37%) were anticentromere antibodies positive, thirty five (43%) anti-scl70 antibodies positive. The two investigators evaluated the presence of the following features: colour changes, pain, previous ulceration, current ulceration, pre-ulceration (discoloration and thinning of the skin), toenail changes, hyperkeratosis, calcinosis, onychomycosis, dry skin, skin sclerosis, warts, scleredema, flatfoot. The presence of paresthesias, cramps, metatarsalgia were also investigated.
Results: The diagram reports the prevalence of foot manifestations in the 81 SSc patients.
Most SSc patients suffer from symptoms related to their feet, particularly dry skin (70%), hyperkeratosis (plantar 58%, finger V 63%), Raynaud's phenomenon (59%), cramps (55%). No statistically significant differences were found between diffuse and limited SSc groups.

Prevalence of foot manifestations in the 81 SSc patients.

Conclusions: Our study suggests that, in patients with SSc, foot problems are common and potentially disabling. A careful assessment of the feet should always be performed in these patients, in order to identify problems at an early stage.

FRI0390 EUROPEAN MULTICENTRE STUDY VALIDATES ELF TEST AS BIOMARKER OF FIBROSIS IN SYSTEMIC SCLEROSIS

G. Abignano[1,2], J. Blagojevic[1,2,3], L.-A. Bissell[1,2], R.B. Dumitru[1,2], S. Eng[1,2], Y. Allanore[4], J. Avouac[4], S. Bosello[5], C. Denton[6], O. Distler[7], G. Ferraccioli[5], S. Jordan[7], M. Matucci-Cerinic[3], V. Ong[6], M. Messenger[8], M. Hutchinson[1], M.H. Buch[1,2], P. Emery[1,2], F. Del Galdo[1,2]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; [3]Department of Experimental and Clinical Medicine, Division of Rheumatology, University of Florence, Florence, Italy; [4]Department of Rheumatology, University of Paris Descartes, Paris, France; [5]Division of Rheumatology, Fondazione Policlinico Universitario Agostino Gemelli, Rome, Italy; [6]Department of Rheumatology, University College London, Royal Free Hospital, London, United Kingdom; [7]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland; [8]NIHR Diagnostic Evidence Co-operative, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

Background: The Enhanced Liver Fibrosis (ELF) test is a serum test including the serum concentrations of amino-terminal pro-peptide of procollagen type III (PIIINP), tissue inhibitor of matrix metalloproteinase-1 (TIMP-1) and hyaluronic acid (HA). A recent single centre study showed that ELF score and its components are markers of overall fibrosis in systemic sclerosis (SSc) mainly reflecting skin and lung involvement (1).
Objectives: To determine the value of ELF score and its single analytes in an independent multicentre cohort of SSc patients.
Methods: 254 SSc patients from 6 European Rheumatology Centres were included in this study. Clinical data were collected at time of sampling. Serum samples were collected and stored according to EUSTAR biobanking recommendations (2). Sera were analysed employing a high-throughput in vitro diagnostic (Siemens Alpha-Centaur). Statistical analysis was performed with SPSS software V.24.
Results: The 254 SSc patients had a mean age 55.8±13.8 years, and included 209 females and 80 patients with diffuse cutaneous SSc (dcSSc). ELF score was overall higher in males than in females (p=0.0236) as well as in dcSSc compared to limited cutaneous SSc patients (p=0.0015). ELF score and the single markers significantly correlated with the degree of skin involvement (mRSS) and inversely correlated with FVC%, TLC% and DLCO%. Concordantly all markers significantly correlated with skin and lung severity as assessed by the Medsger's scale (Table 1). TIMP-1 and PIIINP levels were higher in patients with lung fibrosis assessed by chest HRCT scan (p=0.0126 and p=0.0308 respectively). Significant correlation (p<0.0001) was found between ELF score, TIMP-1, PIIINP, HA and total disease severity and activity. Multivariate analysis indicated that age (p<0.0001), mRSS (p<0.0001) and DLCO% (p=0.005) were independently associated with ELF score.

Table 1. Coefficient correlation (r) between ELF score, PIIINP, TIMP-1, HA serum levels and clinical variables

	ELF score	PIIINP (ng/mL)	TIMP-1 (ng/mL)	HA (ng/mL)
Serum values (median, range)	8.86, 6.22–12.2	6.44, 0.91–34.63	221, 19.09–595.4	36.98, 4.52–355.5
	r	r	r	r
Age	0.41****	0.06	0.26****	0.52****
mRSS	0.36****	0.29****	0.18**	0.16*
FVC%	-0.12	-0.25***	-0.2**	0.02
TLC%	-0.21**	-0.29****	-0.31****	-0.09
DLCO%	-0.25****	-0.39****	-0.30****	-0.18**
Sev_skin	0.28****	0.27****	0.22***	0.17**
Sev_lung	0.25****	0.29****	0.3****	0.18**
Sev_total	0.32****	0.27****	0.33****	0.23***
EScSG-AI	0.30****	0.26****	0.27****	0.22***

*p<0.05; **p<0.01; ***p<0.001; ****p<0.0001.

Conclusions: The value of ELF score as independent marker of skin and lung involvement is confirmed in a second independent multicentre cohort of SSc patients. A longitudinal study paired with analysis of large cohort of healthy controls is currently on going to identify a SSc specific test with the highest predictive value for skin and lung progression independently of age and gender.

FRI0391 A PERFUSION-METABOLIC MISMATCH IN 99MTL AND 123I-BMIPP SCINTIGRAPHY PREDICTS WORSE PROGNOSIS IN SYSTEMIC SCLEROSIS PATIENTS WITH ASYMPTOMATIC CARDIAC INVOLVEMENT

H. Iida, H. Hanaoka, T. Kiyokawa, Y. Takakuwa, T. Okazaki, H. Yamada, S. Ozaki.
Division of Rheumatology and Allergology, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan

Background: Cardiac involvement is a manifestation of systemic sclerosis (SSc) that contributes to significant mortality and morbidity. Since many SSc patients with cardiac involvement are asymptomatic and it may progress silently, early diagnosis is still challenging. The perfusion-metabolic mismatch in cardiac scintigraphy indicates functional abnormality due to myocardial injury and has been expected to detect early cardiac involvement in various diseases. However, its clinical utility has been poorly evaluated in patients with SSc.

Objectives: To evaluate clinical utility of perfusion and myocardial fatty acid metabolism mismatch in SSc patients without cardiac failure.
Methods: All patients who visited St. Marianna University Hospital from 2009 to 2015 and performed cardiac scintigraphy using ^{99m}Tl and ^{123}I-BMIPP were retrospectively evaluated. Patients who fulfilled American Collage of Rheumatology classification criteria of SSc and systemic lupus erythematosus (SLE) were selected. We subtracted %uptake of metabolism (^{123}I-BMIPP) from that of perfusion (^{99m}Tl) on each 17 myocardial segments standardized by American Heart Association. We compared sum of all the scores and each score in 3 coronary artery regions between patients with SSc and SLE. Furthermore, we evaluated incidence of cardiac death or cardiac failure depending on the scores of each coronary artery regions.
Results: Among 177 patients, we analyzed the data in 22 cases with SSc and 23 with SLE. The sum of all mismatch scores was not significantly different between the 2 groups (p=0.37). The mismatch score of left anterior descending coronary artery (LAD) region was significantly higher in SSc than SLE (p=0.05) (Figure 1A). We next divided SSc patients into 2 groups depending on degree of the LAD mismatch score and found the group with low score had higher incidence of cardiac death or cardiac failure (p=0.04) than that with high score (Figure 1B).

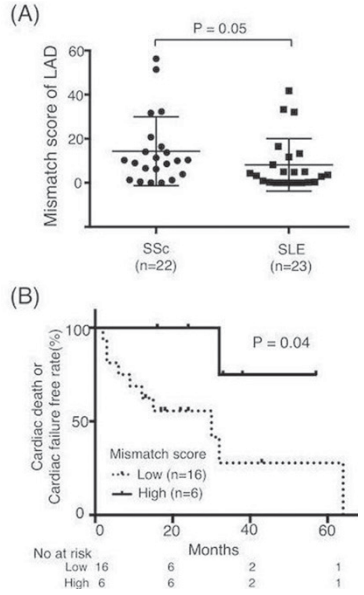

Figure 1

Conclusions: The low mismatch score in LAD region of cardiac scintigraphy could be associated with cardiac death or cardiac failure in SSc patients. Since myocardial fibrosis might replace viable cardiomyocytes leading to loss of ventricular volume, metabolic defect by scintigraphy might be less detectable.

FRI0392 OPPORTUNISTIC INFECTIONS IN PATIENTS WITH MYOSITIS. A RETROSPECTIVE COHORT STUDY

A. Redondo-Benito[1], A. Curran-Fàbregas[2], A. Villar-Gomez[3], E. Trallero-Araguás[4], A. Fernandez-Codina[1], I. Pinal-Fernandez[1], A. Selva-O'Callaghan[5]. *[1]Internal Medicine; [2]Infectious Diseases, Vall d'Hebron General Hospital; [3]Pneumology, Vall d'Hebron General Hospital; [4]Rheumatology Unit. Internal Medicine Dept., Vall d'Hebron General Hospital; [5]Internal Medicine, Vall d'Hebron General Hospital. Universitat Autònoma de Barcelona, Barcelona, Spain*

Background: Idiopathic inflammatory myopathies, also known as myositis, are a heterogeneous group of acquired diseases of probable autoimmune origin, characterized by the presence of inflammatory muscle infiltrates.Infectious complications are not uncommon in myositis, and some predisposing factors, such as upper esophageal involvement, calcinosis cutis, ventilatory insufficiency due to diaphragm involvement, and immunosuppressive drug therapies, seem to be implicated.
Objectives: To describe the prevalence, clinical characteristics, and risk factors for opportunistic infection (OI) in a cohort of patients with inflammatory myopathies, and compare mortality rates between those with and without OIs.
Methods: In total, 204 patients from our myositis cohort were reviewed to identify patients who had experienced an OI during the period 1986–2014. The patients' clinical characteristics, treatment received, and outcome were systematically recorded. Disease activity at the OI diagnosis and cumulative doses of immunosuppressive drugs were analyzed, as well as the specific pathogens involved and affected organs.
Results: The prevalence of OI in the total cohort, was 6.4%: viruses, 44.4% (varicella-zoster virus, cytomegalovirus); bacteria, 22.2% (*Salmonella sp.*, *Mycobacterium tuberculosis*, *M. chelonae);* fungi, 16.7% (*Candida albicans*, *Pneumocystis jirovecii);* and parasites, 16.7% (*Toxoplamosis gondii, Leishmania spp.*) were the pathogens detected. Lung and skin/soft tissues were the organs most commonly affected (27.8%). Overall, 55.6% of OIs developed during the first year after the myositis diagnosis and were significantly associated with administration of high-dose glucocorticoids (p=0.0148). Fever at onset of myositis (p=0.0317), biological therapy (p<0.001) and sequential administration of 4 or more immunosuppressive agents during myositis evolution (p=0.0032) were significantly associated with OI. All-cause mortality in the OI group was 3.69 deaths per 100 patients/year versus 3.40 in the remainder of the cohort (p=0.996).
Conclusions: The prevalence of OI was 6.4% in our myositis cohort. High-dose glucocorticoids at disease onset and severe immunosuppression are implicated in the development of these complications. Mortality did not differ from the remainder of the cohort.

FRI0393 PREVALENCE OF MYOSITIS-SPECIFIC ANTIBODIES IN IDIOPATHIC INFLAMMATORY MYOPATHY COMPARED TO DISEASE AND HEALTHY CONTROLS

J.-B. Vulsteke[1], X. Bossuyt[2,3], D. Dillaerts[3], K. Poesen[4], K. Claeys[5], J. Lenaerts[6], R. Westhovens[6,7], D. Blockmans[1], P. De Haes[8], E. De Langhe[6,7]. *[1]Department of General Internal Medicine; [2]Department of Laboratory Medicine, University Hospitals Leuven; [3]Experimental Laboratory Immunology; [4]Laboratory for Molecular Neurobiomarker Research, KU Leuven; [5]Department of Neurology; [6]Department of Rheumatology, University Hospitals Leuven; [7]Skeletal Biology and Engineering Research Center, Department of Development and Regeneration, KU Leuven; [8]Department of Dermatology, University Hospitals Leuven, Leuven, Belgium*

Background: Myositis-specific autoantibodies (MSA) are increasingly recognized as important diagnostic and prognostic markers in idiopathic inflammatory myopathies (IIM) (polymyositis, dermatomyositis, sporadic inclusion body myositis and necrotizing autoimmune myositis). The prevalence of these MSAs in other systemic autoimmune rheumatic diseases and neuromuscular diseases is unclear.
Objectives: To compare positivity of MSA in a cohort of IIM patients to positivity in healthy controls and different systemic autoimmune rheumatic diseases (SARD) or chronic inflammatory demyelinating polyneuropathy (CIDP).
Methods: A line immunoassay (Myositis 12 IgG DOT for BlueDiver) for IgG autoantibodies against Jo-1, PL-7, PL-12, EJ, SRP, Mi-2, MDA-5, TIF1-γ, HMGCR, SSA/Ro52kD, SAE1/2 and NXP-2 antigens was performed in patients with IIM (n=146), healthy controls (blood donors, n=40) and disease controls (n=200). The disease control group consisted of patients with other SARD (rheumatoid arthritis, RA; systemic sclerosis, Ssc; Sjögren's syndrome, SjS; and systemic lupus erythematosus, SLE) (n=40 for each disease group) and CIDP (n=40). A result >10 arbitrary units was considered significantly positive.
Results: 50% of 146 patients with IIM tested positive for an MSA (table 1), compared to 3,5% of 200 disease controls (table 1). 1 SSc patient was positive for Jo-1, 1 CIDP patient was positive for PL12, 2 SSc patients were positive for TIF1-gamma, 2 patients (1 SSc and 1 SjS patient) were positive for SAE1/2, and 1 SjS patient was positive for NXP2. The prevalence of SAE1/2 and TIF1-gamma positivity was similar in the IIM and disease control group. No healthy control had a significantly positive MSA.

Antibody detected	IIM (n=146)	Disease controls (n=200)	Healthy controls (n=40)
1 positive (>10 AU) MSA detected	68 (47%)	7 (3,5%)	0 (0%)
Jo-1	28 (19%)	1 (0,4%)	0 (0%)
PL12	3 (2%)	1 (0,4%)	0 (0%)
PL7	1 (1%)	0 (0%)	0 (0%)
EJ	2 (1%)	0 (0%)	0 (0%)
Mi-2	7 (5%)	0 (0%)	0 (0%)
MDA-5	7 (5%)	0 (0%)	0 (0%)
SAE1/2	3 (2%)	2 (0,8%)	0 (0%)
TIF1-gamma	2 (1%)	2 (0,8%)	0 (0%)
NXP2	5 (3%)	1 (0,4%)	0 (0%)
SRP	3 (2%)	0 (0%)	0 (0%)
HMGCR	7 (5%)	0 (0%)	0 (0%)
>1 positive (>10 AU) MSA detected	4 (3%)	0 (0%)	0 (0%)
Jo-1 + EJ	1		
Jo-1 + NXP2	1		
SAE1/2 + NXP2	1		
Jo-1 + SAE1/2 + NXP2	1		

Conclusions: MSA positivity in patients with a clinical non-IIM diagnosis (other SARD or CIDP) is infrequent compared to positivity in the IIM group. For TIF1-gamma and SAE1/2 assay performance may need to be optimized. The distribution of subtypes of MSA in this IIM cohort is consistent with data of previous studies.[1]

FRI0394 NEUROPATHIC PAIN IS ASSOCIATED WITH SKIN THICKNESS IN SYSTEMIC SCLEROSIS PATIENTS

J. Sousa-Neves, M. Cerqueira, D. Santos-Faria, J. Leite Silva, C. Afonso, F. Teixeira. *Rheumatology, Hospital Conde de Bertiandos, ULSAM, Ponte de Lima, Portugal*

Background: Systemic Sclerosis (SSc) is a connective tissue disorder characterized by fibrosis of skin and internal organs, vasculopathy and systemic inflammation. To date, few studies assessed pain in SSc patients,(1) namely the neuropathic component. Data is also scarce on defining possible neuropathic pain (NP) predictors in these patients.
Objectives: To determine if patients with SSc have a higher prevalence of NP compared with a group of age and sex matched controls and study possible associations between NP and SSc clinical variables.
Methods: The study evaluated patients diagnosed with SSc fulfilling the SSc classification criteria of the American College of Rheumatology (ACR), older than 18 years old and followed up at our Rheumatology Unit. Forty-eight patients with mean age of 56.98±12.73 years and mean disease duration of 9.77±6.12 years were included. Comparison group comprised 45 age and sex matched controls. Patients and controls were consecutively evaluated at our Unit and NP in 4 questions questionnaire (DN4) was used for assessing the presence of NP. In SSc patients, skin involvement was also evaluated clinically by the modified Rodnan skin thickness score (mRSS) ranging from 0 to 51. Hand mobility (HAMIS) and SSc Severity Scale (SScSS) were also calculated and relevant clinical variables of the disease were collected. Parametric and nonparametric tests were used for comparative analysis. Multivariate logistic regression was used to identify factors associated to NP. Statistical significance was defined as $P<0.05$.
Results: In our study, prevalence of NP assessed by DN4 was significantly higher in SSc patients comparative to controls (56.2% *versus* 13.3%, $p<0.001$). In addition to age and sex, presence of diabetes (p=0.541) was also similar in both groups. In SSc group, patients with and without NP showed some statistically significant differences (table 1).

Table 1. Comparative analysis between SSc patients with and without NP

	NP positive patients (n=27)	No-NP patients (n=21)	P value
Median age, years (IQR)	61 (57–69)	52.38 (42.5–63.5)	0.032
Mean disease duration (years)	11.36±6.55	7.73±4.93	0.04
Diffuse/limited cutaneous subtype (n)	6/21	0/21	0.024
Mean mRSS	22.81±8.74	7.57±3.64	<0.001
Mean HAMIS	10.44±6.16	1.52±2.29	<0.001
Mean SScSS	10.00±4.32	3.90±2.07	<0.001
Digital ulcers n (%)	17 (63.0)	6 (28.6)	0.018
Calcinosis n (%)	15 (55.5)	6 (28.6)	0.062

Multivariate logistic regression revealed that only mean mRSS (odds ratio [OR] =1.90, 95% confidence interval [CI] 1.01 to 3.55, p=0.045) was independently associated with the presence of NP.
Conclusions: To the best of our knowledge, this is the first study evaluating the prevalence of NP in SSc patients in comparison with age and sex matched controls. NP was significantly more prevalent in patients with SSc. Skin thickness assessed by mRSS was independently associated with the presence of NP.

FRI0395 INCIDENCE OF MYOSITIS-SPECIFIC AUTOANTIBODY (MSA) SPECIFICITIES IN SERA REFERRED TO NEW ZEALAND (NZ) MEDICAL LABORATORIES

J. O'donnell[1], P. Keating[1], M. van Voorthuizen[1], J. Liu[1], I. Chua[1], A. Soepnel[2], E. Gumbley[2], M. Spellerberg[1]. *[1]Immunology Section, Canterbury Health Labs, New Zealand, Christchurch; [2]Waikato Hospital Laboratory, Waikato Hospital, Hamilton, New Zealand*

Background: Idiopathic inflammatory myopathies can be classified by clinicopathological phenotype into four major groups: overlap myositis (OM), dermatomyositis (DM), immune mediated necrotising myositis (IMMNM) and inclusion body myositis (IBM). The different phenotypes associate with distinct MSA specificities although a variable percentage within each group are seronegative and the majority of IBM patients are seronegative[1]. No commercial assay for the IBM associated specificity, cN1A, is available. In NZ testing for MSA is restricted to two laboratories: Waikato Hospital (WHL) and Canterbury Health Laboratories (CHL). Both laboratories use the commercial Euroimmun Euroline assay. In addition CHL has developed an ELISA for anti HMGCR autoantibodies and receives referrals from throughout NZ.
Objectives: To define the incidence and specificities of MSA in serum samples referred for testing in New Zealand.
Methods: For the period 3 November 2015 to 2 November 2016 each laboratory information system (LIS) was interrogated for requests for MSA. For the purposes of this report positive results were grouped into the specificities associated with each of the defined clinicopathological phenotypes.
DM: Mi2, Tif-γ, MDA 5 NXP2 SAE1
OM: Ku, PM-Scl-100, PL75, Jo1, PL-7, PL-12, EJ, OJ
IMMNM: HMGCR, SRP
Results: Of screened sera (n=793, CHL=622, WHL=171) 11% were positive for MSA (88/793). Positive sera where distributed amongst three clinicopathological associated autoantibody specificities: DM 23% OM 50%,IMMNM 27%. The most common serum specificities were HMGCR (n=24) and Jo-1 (n=13). No serum with specificities to SRP or OJ was detected. 22/24 sera positive for anti HMGCR had an elevated CPK concentration (CPK>2500u/l in 21/24 and CPK=544 in 1/24, reference range =66–220).
Conclusions: In New Zealand 11% of sera referred for MSA testing were positive. As a group the most common specificities were those associated with OM while the most common antigen specificity was to HMGCR. Anti-HMGCR antibodies were almost invariably associated with major elevations in serum CPK.

FRI0396 LEVELS PENTRAXIN 3 AND C1Q IN SYSTEMIC SCLEROSIS: ASSOCIATION WITH PULMONARY ARTERIAL HYPERTENSION AND CLINICAL FINDINGS

R. Cevik[1], K. Nas[2], T. Bozan[1], A. Ekinci[3], A. Kamanlı[2], I. Tekeoglu[2], M.O. Ayyildiz[4]. *[1]Physical Medicine and Rehabilitation, Dicle University Hospital, Diyarbakir; [2]Physical Medicine and Rehabilitation, Sakarya University, Faculty of Medicine, Sakarya; [3]Department of Biochemistry; [4]Internal Medicine, Dicle University Hospital, Diyarbakir, Turkey*

Background: Systemic sclerosis (SSc) is an autoimmune rheumatic disease with unknown etiology that characterized fibrosis and vascular endotelial damage with obliteration of the microvasculature caused from exaggerated syntesis of collagen and extracellular matrix deposition in skin and internal organs. Pentraxin 3 (PTX3) accepted as a vascular inflammatory marker which secreted in early stage of endothelial dysfunction.
Objectives: In this study, we aimed to investigate plasma PTX3 and serum complement C1q levels and their relations with cytokines and pulmonary arterial pressure in SSc.
Methods: Fifty nine patients diagnosed SSc and 28 subjects without inflammatory rheumatic disease recruited to the study. Plasma PTX3, and serum TNF-α, IL-1β, IL-4, IL-10, INF-γ, TGF-β and complement C1q measured in both groups. Clinical findings and pulmonary arterial pressure of the SSc patients assessed.
Results: Ages of fifty nine with SSc (54 female and 5 male) and 28 control subjects (23 female and 5 male) were 49,47±12.74 and 43,07±13,71 respectively. PTX3, IL-1β and IL-4 levels found decreased in SSc patients. There were no differentiations between limited and diffuse cutaneous SSc subgroups in terms of PTX3, cytikines and C1q levels. Plasma PTX3 and serum IL-1β concentrations found decreased only limited cutaneous SSc subgroup comparing controls. According to the immunosupressive drugs use; PTX3 levels found decreased in using group and TNF-α ve IL-1β levels found decreased in not using group comparing controls. Significant positive association found between PTX3 and C1q and all cytokines except TGF- β.
Conclusions: PTX3 suggested to be used in the pathogenesis and assessment of disease treatment efficacy of SSc, because of found decreased in SSc patients especially in limited cutaneous and immunosupressive drugs using subgroups. Associations between C1q, and PTX3 and pulmonary artey pressure highlighted possible roles of both parameters in development of pulmonary hypertension. It is possible to develop preventive treatment strategies with better understanding of these associations. Advanced studies should be carried out for clarifying this condition.

FRI0397 EVALUATION OF VITAMIN B12 DEFICIENCY AND ASSOCIATED FACTORS IN PATIENTS WITH SYSTEMIC SCLEROSIS

D. Tas Kilic[1], A. Sari[2], B. Armagan[2], A. Erden[2], L. Kilic[2], M. Kilinckaya[3], T. Turhan[3], A. Akdogan[2], S. Karaahmetoglu[1]. *[1]Department of Internal Medicine, Numune Education and Research Hospital; [2]Department of Internal Medicine Division of Rheumatology, Hacettepe University Faculty of Medicine; [3]Department of Biochemistry, Numune Education and Research Hospital, Ankara, Turkey*

Background: Vitamin B12 (Vit B12) deficiency is a common condition, which can be manifested with non-specific clinical features or with neurological and/or haematological abnormalities in severe cases. In systemic sclerosis (SSc)

gastrointestinal involvement (GI), nutritional status and medications may lead to Vit B12 deficiency.
Objectives: We aimed to investigate the frequency of Vit B12 deficiency and its determinants in SSc patients.
Methods: Sixty-two (90.3% female) SSc patients were enrolled in to the study. The nutritional status of patients was assessed with Malnutrition Universal Screening Tool (MUST). Serum Vitamin B12, homocysteine and Helicobacter Pylori Immunoglobulin G (H. Pylori IgG) levels were measured in all patients. Serum Vit B12 levels of patients were classified as; Low (<200 pg/ml), Borderline (200 - 300 pg/ml) and Normal (>300 pg/ml). Serum homocysteine levels of patients were classified as; Elevated (>9 μmol/L) and hyperhomocysteinemia (>15 μmol/L). H. Pylori IgG antibody level >5 U/ml considered as positive. Serum Vit B12 level <200 pg/ml or being on Vit B12 replacement therapy was considered as B12 deficiency.
Results: The mean age of the patients was 50.2 (12.5) years and mean disease duration was 12.0 (7.5) years. Forty-four (71.0%) patients were limited and 18 (29.0%) patients had diffuse SSc. The mean serum Vit B12 level of the patients was 323.6±291.5 pg/ml. Seventeen (27.4%) patients had normal, 23 (37.1%) patients had borderline and 22 (35.5%) patients had low serum Vit B12 level. Forty-four (71.0%) patients were considered as Vit B12 deficient; 22 had serum Vit B12 level <200 pg/ml (4 of these patients were on vitamin B12 replacement therapy), 22 were already on Vit B12 replacement therapy and Vit B12 level ≥200 pg/ml. The mean homocysteine levels were higher in the group with Vit B12 <200 pg/ml as compared to other groups (p=0.005). In the group with Vit B12 level <200 pg/ml, 33.3% (7/21) of the patients had hyperhomocysteinemia and 76.2% (16/21) had 'elevated homocysteine levels (Table). Fifty-one (82.3%) patients had GIS involvement and 16 (25.8%) patients had medium-high risk MUST score. H. Pylori IgG antibody was positive in 40 (64.5%) patients. There were no statistically significant differences between the patients with and without Vit B12 deficiency regarding to age, mean disease duration, hemoglobin level, GI involvement, medium-high risk MUST score, H. Pylori IgG antibody positivity and other clinical features (p>0.05 for all).

	Vit B12 level			
	>300 pg/ml n=16	200–300 pg/ml n=22	<200 pg/ml n=21	p
Homocysteine μmol/L, mean (SD)	9.1 (3.4)	10.4 (3.0)	14.1 (6.5)	0.005
Homocysteine >9 μmol/L, n (%)	7 (43.8)	16 (72.7)	16 (76.2)	0.084
Homocysteine >15 μmol/L, n (%)	1 (6.3)	0	7 (33.3)	0,004

Homocysteine level was not measured in 3 patients.

Conclusions: SSc patients are at risk for Vit B12 deficiency. Using homocysteine level seems to be unpractical for confirmation of Vit B12 deficiency in a complex disease such as SSc because its level is influenced by many factors. Patients with SSc should be closely monitored for Vit B12 deficiency and replacement therapy should be planned if necessary.

FRI0398 INFLAMMATORY MYOPATHIES WITH CAMPTOCORMIA OR DROPPED HEAD SYNDROME ARE ASSOCIATED SCLEROMYOSITIS WITH LATE ONSET AND DELAYED DIAGNOSIS

L. Pijnenburg[1], F. Maurier[2], N. Poursac[3], M. Couderc[4], N. Vernier[5], I. Guichard[6], J. Sellam[7], J. Sibilia[1], A. Meyer[1] on behalf of French Myositis Network, Club Rhumatisme et Inflammation. *[1]Hôpitaux Universitaires de Strasbourg, Strasbourg; [2]Hôpitaux Privés de Metz, Metz; [3]Hôpitaux Universitaires de Bordeaux, Bordeaux; [4]Hôpitaux Universitaires de Clermont Ferrand, Clermont Ferrand; [5]Hôpitaux Universitaires de Dijon, Dijon; [6]Hôpitaux Universitaires de St Etienne, Saint Etienne; [7]Hôpitaux de Paris, Paris, France*

Background: Severe weakness of axial muscle leads to dropped head syndrome or camptocormia. The signification of these symptoms has not been studied in inflammatory myopathies (IM).
Objectives: To assess the signification of dropped head syndrome and/or camptocormia in patients with IM.
Methods: All practitioners of the French Myositis Network and the Club Rhumatisme et Inflammation (>1000 physicians) were invited to report their patients suffering from IM (myopathy with myositis specific autoantibody and/or typical muscle biopsy according to the ENMC criteria) with camptocormia and/or dropped head syndrome. These axial IM cases were included only if no other explanation of axial weakness was found. IM patients without axial involvement (non-axial IM group), were randomly selected from the participative centers, and included as control patients (ratio 1:2). Clinical, serological, muscle pathological features, management and outcomes were studied using a standardized form.
Results: Twenty patients (sex ratio 2.6) with axial involvement (camptocormia: 60%, dropped head syndrome: 40%) were included. Compared with the control group, these axial IM-patients were older (64.05±11.64 y. vs. 48.22±18.28. p<0.005) and diagnosis of IM was delayed (16.4±4.5 months vs. 8.5±2.7, p<0.05).
All patient except one had also proximal weakness of the limbs. CK blood level was 2794±870 UI/L, which was similar to the controls (2864±559 UI/L). According to the ENMC classification, non-specific myositis was the most frequent finding on muscle biopsy (n=5/15, 30% vs. n=1/24, 4% in the non-axial group, p<0.05) and dermatomyositis (DM) pattern tended to be less frequent in axial-IM patients (3/12 20% vs. 11/24, 46%, p=0.10).
Most of the patients (75%) had also extra muscular involvement including acrosyndrome (45%), interstitial lung disease (35%), sclerodactyly (30%), telangiectasia (25%), digital tip ulcer (10%), sclerodermy (5%). By contrast, no patient had polyarthrithis (vs. 20% in the controls, p<0.05). DM rash was hardly threefold less frequent in axial IM patients (15% vs. 42%, p<0.05).
Auto-antibodies associated with scleromyositis were the most frequent in axial-IM patients (30% vs. 10.3%, p=007, manly anti-PM/Scl). One patient (5%) had cancer within the 3 years before or after IM diagnosis (NS vs. controls).
Thus, most frequent diagnosis in axial IM-patients were scleromyositis (35% vs. 5% in the controls, p<0.05) and inclusion body myositis (20% vs. 2.6% in the controls, p<0.05). DM was twofold less frequent than in control (10% vs 41%, p<0.05). Other IM subtypes were not statistically different from the control groups.
Except patients with diagnosis of sIBM, all axial IM-patients received corticosteroids with another immunomodulatory drugs (median number 2, range 1–5). Half of the axial-IM patients received intravenous immunoglobulin. After a mean follow up of 68.4±3.76 months all patients had improvement, including in axial weakness, except in patients with sIBM. One patient died from ischemic cardiomyopathy.
Conclusions: In IM, camptocormia and dropped head syndrome are associated with late onset scleromyositis and sIBM with delayed diagnosis.

FRI0399 EFFICACY OF AN INTENSIVE 24-WEEK PHYSIOTHERAPY PROGRAMME IN PATIENTS WITH SYSTEMIC SCLEROSIS - PRELIMINARY DATA FROM A SINGLE-CENTER CONTROLLED STUDY

M. Spiritovic[1,2], H. Smucrova[1], S. Oreska[1], H. Storkanova[1], P. Cesak[2], A. Rathouska[1], O. Ruzickova[1], H. Mann[1], K. Pavelka[1], L. Senolt[1], J. Vencovsky[1], R. Becvar[1], M. Tomcik[1]. *[1]Department of Rheumatology, 1st Medical Faculty, Charles University, Institute of Rheumatology; [2]Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic*

Background: Involvement of skin and musculoskeletal system in systemic sclerosis (SSc) leads to loss of function, disability and reduced quality of life. Data on efficacy of non-pharmacologic care in SSc is very limited due to variety in studied interventions/outcomes.
Objectives: To address the limitations of existing studies, and evaluate the effect of a controlled, long-term (24-week intervention, 24-week follow-up), intensive (1h physiotherapy + 0.5h occupational therapy twice weekly, and home-exercise for 0.5h 5x weekly), tailored physiotherapy programme on function/impairment of hands/face, and quality of life/disability in cohorts with a substantial number of SSc patients.
Methods: All patients fulfilled ACR/EULAR 2013 criteria, had skin involvement of hands/mouth, and were consecutively recruited from 2014 to 2016 at the Institute of Rheumatology in Prague. Both groups received educational materials and instructions for home exercise at baseline, however, only intervention group underwent the intensive physiotherapy programme. At months 0,3,6,12 all patients were assessed by a physician (physical examination, mRSS-Modified Rodnan's skin score, EUSTAR SSc activity score, Medsger SSc severity score), and a physiotherapist blinded to intervention [validated measurements (dFTP-delta finger to palm, inter-incisor/inter-lip distance, grip strength using Baseline dynamometer); tests (HAMIS-Hand Mobility In Scleroderma)], patients filled out patient reported outcomes/questionnaires (CHFS-Cochin Hand Function Scale, MHISS-Mouth Handicap In SSc Scale, HAQ, SHAQ, SF-36) and provided blood for routine laboratory analysis and biobanking. Normality of data was tested, inter-group analysis was performed with 2-way ANOVA, and intra-group analysis by Friedmann's test with Dunn's post hoc test.
Results: 25 SSc patients (22 female/3 male, 14 limited cutaneous (lc)SSc/11 diffuse cutaneous (dc)SSc, median of age 54.0 and disease duration 7.0 years, mRSS 12) were recruited into the intervention group (IG) and 29 patients into the control group (CG) (25 female/4 male, 16 lcSSc/13 dcSSc, median of age 49.0 and disease duration 5.0 years, mRSS 11). Compared to observed statistically significant deterioration in CG over the period of m0-m6, we found statistically significant improvement in dFTP, grip strength, HAMIS, inter-incisor and inter-lip

Parameter (unit)	Intervention group Mean ± SEM	Control group Mean ± SEM	Intra-group analysis (Friedmann+Dunn)		Inter-group analysis (2WA)

Acronyms: SEM, standard error of the mean; Friedmann, Friedmann's test; Dunn, Dunn's post hoc test; 2WA, two way ANOVA; dFTP, delta finger to palm; HAMIS, Hand Mobility in Scleroderma; m0, month 0 (= at the baseline); m3, month (= in the middle of intervention period); m6, month 6 (= at the end of intervention); p, p-value; NS, not significant

distance (Table 1). Only numerical improvement in IG compared to numerical deterioration in CG, which have not reached statistical significance, were observed in patient reported outcomes (CHFS, MHISS, HAQ, SHAQ, SF-36).

Conclusions: Our physiotherapy program not only prevented the natural course of progressive deterioration of function of hands/mouth (observed in the control group), but led to a significant improvement in monitored parameters, which was clinically meaningful in a substantial proportion of patients.

FRI0400 EFFICACY OF INTRAVENOUS IMMUNOGLOBULIN THERAPY IN REFRACTORY DYSPHAGIA IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

M. Giannini[1], M.L. Fiorella[2], D. D'Abbicco[3], A. Amati[4], A. Lia[4], F. Girolamo[4], F. Cacciapaglia[1], F. Iannone[1]. *[1]Dipartimento di Emergenza e Trapianti di Organi - Sezione di Reumatologia; [2]Dipartimento di Scienze mediche di base, neuroscienze ed organi di senso - Clinica Otorinolaringoiatrica; [3]Dipartimento di Emergenza e Trapianti di Organi - Chirurgia Marinaccio; [4]Dipartimento di Scienze mediche di base, neuroscienze ed organi di senso - Sezione di Neurologia, Università degli Studi di Bari, Bari, Italy*

Background: Polymyositis (PM) and Dermatomyositis (DM) are systemic inflammatory diseases affecting skeletal muscles and other organs, particularly hypopharynx and the upper tract of the esophagus, causing motility dysfunction. The current treatment for PM and DM relies on steroids and immunosuppressants, but esophageal involvement is often refractory to standard therapies.

Objectives: To assess the efficacy and safety of intravenous immunoglobulins (Ig-iv) as therapy of refractory dysphagia (1) in patients affected with PM/DM who have received conventional treatments for at least three months. These are the extended data of a previous abstract entitled "Improvement of refractory dysphagia in patients with idiopathic inflammatory myopathies receiving immunoglobulin intravenous therapy" accepted to EULAR 2015 Congress.

Methods: We enrolled 17 patients (15 F), 8 with DM, 9 with PM according to Bohan and Peter criteria, treated with prednisone (mean dose 20 mg/day) ± Methotrexate (15 mg/wk) or Azathioprine (100 mg/day) for at least 3 months, without improvement of dysphagia. All patients received one infusion of Ig at a standard dose (2 g/kg in a day) every two months for 3 cycles. In all patients, at entry and before each infusion, creatine kinase (CK) levels and Manual Muscle strength Test on 12 muscle groups (MMT12) were evaluated. Dysphagia assessment included: Eating Assessment Tool (EAT) impaired for score $\geq$3; Three-oz Swallow Test (3oST) and fibrolaryngoscopy (FEES) for pharyngeal muscle propulsion and stasis of liquid/solid bolus detection. Student T-test and Chi-square test were used to compare baseline and follow-up data.

Results: At entry, all patients had an EAT score $\geq$3 with a mean score of 16.2±9, 3 patients presented a 3oST for solid (STPNS) impaired, and only 1 patient also for liquid (STPNL). CK levels were slightly increased (474±720 UI/L), and MMT12 score was 4.45±0.35. Following Ig-iv therapy we observed a significant improvement of EAT score after the first dose (9±8, p=0.006) with a further reduction after the second dose (7.4±8, p=0.007) and stability after the third one (7.6±8, p=0.008). An improvement of pharyngeal muscle propulsion, with a significant resolution of solid stasis and a partial resolution of liquid stasis were observed. In addition, MMT12 score progressively improved after each dose, increasing at 4.86±0.16 after the third dose (p=0.001). Noteworthy, after the third Ig-iv dose, three patients stopped the steroid and the remaining 12 were treated with a significant lower dose of 5 mg/day of prednisone (p=0.04).

Conclusions: According to literature, our findings provided evidence that Ig-iv induced a meaningful improvement of dysphagia, also having a steroid-sparing effect. An improvement of muscle strength was also detected. Although further studies of larger cohort of patients and a longer follow-up time are needed, our findings corroborate the utility of Ig-iv in the treatment of more resistant idiopathic inflammatory myositis related dysphagia.

FRI0401 INITIAL MANIFESTATION DETERMINES CLINICAL ENTITY AND COURSE IN PATIENTS WITH ANTI-CENTROMERE ANTIBODY: A SINGLE CENTER LONGITUDINAL RETROSPECTIVE COHORT STUDY

M. Tsukamoto[1,2], K. Suzuki[1], N. Seta[2], T. Takeuchi[1]. *[1]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo; [2]Department of Internal Medicine, Tokyo Dental College Ichikawa General Hospital, Ichikawa, Japan*

Background: Anti-centromere antibody (ACA) is often detected in sera from autoimmune diseases, such as limited cutaneous systemic sclerosis (SSc) and primary biliary cirrhosis (PBC). ACA-positive Sjögren's syndrome (SjS) is recently considered as a distinct clinical subgroup in SjS [1–2]. The other autoimmune diseases associated with ACA-positive have not fully elucidated and the role of ACA in their pathogenesis still remains unclear. In addition, comprehensive and enough clinical information from the point of view of ACA positive cases has not been accumulated.

Objectives: To clarify clinical features of patients with ACA and their association with autoantibodies.

Methods: Patients with discrete-speckled pattern in anti-nuclear antibody (ANA) test and/or positive ACA, who visited to our department during over 20 years between May 1995 and December 2016, were enrolled. Clinical information and immunological tests including immunoglobulin (Ig) and serum autoantibodies were collected and statistically analyzed.

Results: Discrete-speckled pattern in ANA test and/or positive ACA were identified in 309 patients. There were 292 female and 17 male and the average age was 60 years old. Proportion of concomitant ANA patterns were speckled (16%), homogenous (7%), cytoplasmic (3%) and/or nucleolar (3%) pattern. 186 patients (60%) had Raynaud's phenomenon and 149 patients (48%) had sclerodactyly. 162 patients (52%) had oral and/or ocular dryness symptoms. 21 patients (6%) had interstitial pneumonia and 13 patients (4%) had pulmonary hypertension. 42 patients (13%) had arthritis. 19 patients (6%) had thyroid disease. 214 patients (69%) were classified into 17 autoimmune diseases (including overlap cases) from symptoms at initial visit, while other 95 patients (31%) who did not meet the criteria were not diagnosed. IgG, IgM and IgA in the patients who were classified into autoimmune diseases were higher than that in other patients who were not classified (p=0.0007, p=0.0057 and p=0.0158, respectively). In the 214 patients (69%), there were most of patients who were diagnosed as SSc (n=113, 36%) and/or SjS (n=78, 25%). 25 patients (8%) and 22 patients (7%) were diagnosed with rheumatoid arthritis (RA) and PBC, respectively. On the other hand, the patients who diagnosed as systemic lupus erythematosus were 3 (1%), and nobody was diagnosed as myositis. The mean observation period was 80 months. 2 patients in 95 patients who were unclassified at initial visit were diagnosed as RA or autoimmune hepatitis by developing new symptoms during observation. A patient was newly diagnosed as SSc in addition to SjS because sclerodactyly was newly developed. In other patients, the diagnosis was not changed and added during observation.

Conclusions: Our single center longitudinal retrospective cohort study confirmed that ACA-positive cases were classified into various types of autoimmune disease. Few patients had new symptoms during observation but the initial diagnosis was unchanged. Our data demonstrated that initial manifestation determined clinical entity and course in patients with ACA.

FRI0402 ONSET CLINICAL INVOLVEMENT AS PROGNOSTIC FACTOR IN SYSTEMIC SCLEROSIS (SSC)

M. Pestaña Fernández[1], M. Rubio Rivas[1], C. Tolosa Vilella[2], A. Guillén del Castillo[3], D. Colunga Argüelles[4], L. Trapiella Martinez[5], V. Fonollosa Pla[3], C.P. Simeón Aznar[3] on behalf of RESCLE. *[1]Internal Medicine Department, Hospital Universitario de Bellvitge, Barcelona; [2]Internal Medicine Department, Corporación Sanitaria Universitaria Parc Taulí, Sabadell; [3]Autoinmune Diseases Unit. Internal Medicine Department, Hospital Vall d'Hebron, Barcelona; [4]Internal Medicine Department, Hospital Universitario Central de Asturias; [5]Internal Medicine Department, Hospital de Cabueñes, Oviedo, Spain*

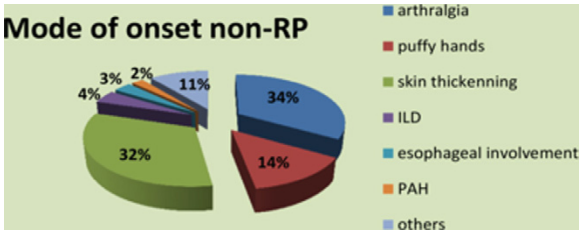
Background: In most patients with SSc, the onset is in the form of Raynaud's phenomenon (RP), but in a few is in the form of visceral or musculoskeletal involvement or skin sclerosis. Several risk factors are related to poor outcome in patients with SSc, but never before has the mode of onset been described as one of them.

Objectives: To asses the mode of onset as prognostic factor in patients with SSc.

Methods: A retrospective and multicentre cohort study including 1625 patients with SSc, based on the National Spanish Scleroderma Registry (RESCLE) which includes 28 referral centres.

RP, puffy hands, arthralgia/arthritis, skin sclerosis, intersititial lung disease (ILD), pulmonary arterial hypertension (PAH) and esophageal hipomotility where included as clinical modes of onset.

Results: The cohort was split up in two groups: 1342 patients (83%) presented as RP and 283 (17%) presented as non-RP (see graphic below)



Non-RP patients where younger at onset of disease (44.7±16.5 vs 49±15.6 years, p<0.001), showed higher percentage of diffuse subtipe (36% vs 19%, p<0.001), developed more visceral involvement during the course of the illness and where more frequently anti-RNAp III positive (29 vs 10%, p<0.001).

Overall mortality was 16% in patients presented as RP vs 23% in non-RP patients (p=0.003). Few differences where noted among causes of death related to SSc, but the higher mortality was observed in RP group due to PAH (19% vs 8.1%, p=0.05) and due to ILD in non-RP group (24% vs 8.3%, p=0.002).

Survival of patients with RP at onset was better at anytime than those with a non-RP onset: 0.97 vs. 0.89 at 5 years, 0.93 vs. 0.82 at 10 years, 0.83 vs. 0.63 at 20 years and 0.71 vs. 0.51 at 30 years from onset (p<0.001).

Risk factors for death. Univariate and multivariate analysis

	Univariate analysis HR (95% CI)	p-value	Multivariate analysis HR (95% CI)	p-value
Age at first symptom	1.08 (1.07–1.09)	**<0.001**	1.07 (1.06–1.09)	**<0.001**

FRI0403 INCREASED CRP LEVEL IS INTERRELATED WITH CLINICAL AND SEROLOGICAL PHENOTYPES OF SYSTEMIC SCLERODERMA AND ASSOCIATED WITH CRP RS1205 GENE POLYMORPHISM

M. Krylov[1], L. Ananieva[1], O. Koneva[1], M. Starovoytova[1], O. Desinova[1], O. Ovsaynnikova[1], E. Aleksandrova[1], A. Novikov[1], I. Guseva[1], N. Konovalova[2], D. Varlamov[2]. *[1]V. A. Nasonova Research Institute of Rheumatology; [2]All-Russian Research Institute of Agricultural Biotechnology, Moscow, Russian Federation*

Background: Recent studies report on increased serum levels of C-reactive protein (CRP) in systemic scleroderma (SSc) pts.
Objectives: The current study was aimed at identifying potential correlations between CRP levels, immunologic SSc phenotypes and *CRP* rs1205 gene polymorphism in the Russian cohort.
Methods: 92 SSc pts were enrolled in the study. Mean age (± SD) was 49,4±12,6 years, mean (± SD) SSc duration was 11,1±9,0 years, increased CRP levels >5 mg/l were documented in 43% pts. CRP levels were analyzed in the following subgroups: with limited (lcSSc) and diffuse (dcSSC) types, with SSc duration <3 years >3, with or without interstitial lung disease (ILD+) and (ILD-), as well as in subgroups with positive antibody titers to DNA topoisomerase I (ATA+) and antibody to centromeres (ACA+). CRP concentrations were measured with highly sensitive immunoturbidimertry method. Allele-specific real time PCR was used to study *CRP* rs1205 gene polymorphism.
Results: Mean CRP (± SD) level was significantly higher in dcSSc vs lcSSc (11,9±15,5 mg/l; vs 4,7±7,4 mg/l, respectively, *p*=0,006). Pts with disease duration <3 years had higher mean CRP levels as compared to pts with SSc duration >3 years, although the difference was not significant. In pts with disease duration >3 years mean CRP levels were significantly higher among subjects with dcSSc than lcSSc (11,0±15,5 mg/l vs 4,8±7,7 mg/l, respectively, *p*=0,027). Mean CRP level was higher in (ATA+) pts than in (ATA-) pts (11,0±15,4 mg/l vs 5,5±13,7 mg/l, respectively, *p*=0,032). No statistical difference in CRP levels was found between (ILD+) and (ILD-) pts, as well as between (ACA+) and (ACA-) pts.
Carriers of rs1205 CC genotype had higher CRP levels than carriers of rs1205 T allele,*p*=0,087). In pts with SSc duration >3 years and carriers of rs1205 CC genotype mean CRP level was significantly higher than in T-allele carriers (12,0±17,4 mg/l vs 5,4±7,4 mg/l, respectively, *p*=0,021). Similar trends for CRP levels depending on genotypes were established among (ATA+) pts (16,9±20,1 mg/l and 7,3±10,5 mg/l, respectively, *p*=0,031).
Conclusions: Increased CRP levels were found almost in 50% of Russian SSc pts. Higher CRP levels were associated with specific clinical and immunological SSc parameters and *CRP* rs1205 CC genotype, signifying unfavorable prognosis.

FRI0404 THE EFFECT OF A HOME-BASED OROFACIAL EXERCISE PROGRAM ON ORAL APERTURE OF SYSTEMIC SCLEROSIS PATIENTS

N. Cuzdan Coskun[1], I. Turk[2], V. Ciftci[3], D. Aslan Tas[2], M.C. Dogan[3], I. Unal[4]. *[1]Department of Physical Therapy and Rehabilitation, Division of Rheumatology; [2]Department of Internal Medicine, Division of Rheumatology, Cukurova University Faculty of Medicine; [3]Department of Pediatric Dentistry, Cukurova University Faculty of Dentistry; [4]Department of Biostatistics, Cukurova University Faculty of Medicine, Adana, Turkey*

Background: Microstomia is one of the major problems that causes multiple dysfunctions and affects quality of life in systemic sclerosis (SSc).[1]
Objectives: The purpose of this study is to evaluate the effect of a home-based orofacial exercise program on the oral aperture (OA) of SSc patients.
Methods: SSc patients who fulfilled the *American College of Rheumatology* (ACR) 2013 criteria with an OA of <40mm were included in the study. Patients were randomly divided into two groups. Group 1 was given oral augmentation and mouth stretching exercises with combination of strengthening exercise to masseter muscle twice a day for one month in addition to oral hygiene care advices; followed by no activity but oral hygiene care for the next four weeks. Group 2 received oral hygiene care advices for the first one month followed by the same orofacial exercise program twice a day for the next four weeks. Patients' OA was measured by a dentist at baseline, 1-month, and 2-months.
Results: A total of 52 patients were included in the study. Twenty-seven patients were assigned to group 1 (mean age 53.70±9.79 years; 96.3% female) and twenty-five patients to group 2 (mean age 50.68±11.93 years; 96.0% female). A total of 28 patients (group 1, n=18; group 2, n=10) completed the study. After four weeks period, OA increased in group 1 ($P<0.001$), whereas no change was observed in group 2 ($P=0.906$). At the end of 2 months the intragroup analysis showed no additional increase in group 1 ($P=0.283$), but a statistically significant increase in group 2, regarding the measurement of OA ($P=0.010$). We didn't find any statistically significant difference between OA measurements of the groups 1 and 2 at the end of the trial ($P=0.830$).
Conclusions: The results of this pilot study suggested that an intervention of combined home-based orofacial exercise program might improve oral aperture of SSc patients. Future studies with longer follow-up period and higher number of patients are needed to observe the long-term benefits of the presented home-based exercise program.

FRI0405 PREVALENCE, CLINICAL CORRELATES AND POSSIBLE CAUSES OF NEUROPATHIC PAIN IN PATIENTS WITH SYSTEMIC SCLEROSIS

P. Ostojic[1], S. Knezevic-Apostolski[2], N. Djurovic[3], B. Stojic[3], D. Bartolovic[4], K. Jankovic[5]. *[1]Institute of Rheumatology, School of Medicine, University of Belgrade; [2]Neurological Outpatient Clinic "Apostolski"; [3]Institute of Rheumatology; [4]Clinic for Medical Biochemistry, Clinical Center of Serbia; [5]School of Medicine, University of Belgrade, Belgrade, Serbia*

Objectives: To assess prevalence, possible causes and clinical correlates of neuropathic pain (NP) in patients with systemic sclerosis (SSc).
Methods: In 42 patients with SSc, presence of NP was assessed using the PainDetect questionnaire and subsequently confirmed by neurological evaluation. Patients with previously diagnosed neurological disorders and diabetes were excluded. Relationship between NP and disease status, symptoms of depression and quality of life was estimated. Index of disease status (IDS) was assessed using the Scleroderma Assessment Questionnaire (SAQ), occurrence of depressive symptoms by the Beck's Depression Inventory (BDI), whilst quality of life was evaluated using the EQ-5D index. In order to evaluate possible causes of NP in SSc, all patients with NP, except one (who did not agree with further assessments) underwent detailed neurological and electroneurography (ENG) examination, as well as $HgbA_1C$ and vitamin B12 level testing.
Results: 12/42 (28.6%) of patients were found to have NP. Patients with and without NP were similar in age and disease duration. NP was found more frequently in patients with lcSSc (32.3%), than in dcSSc (18.2%), as well as in patients with ACA (46.7%) compared to patients with ATA (17.6%) and both ACA and ATA negative patients (20%), but the differences were not statistically significant. Patients with NP had significantly higher mean values of IDS (1.28 vs 0.66) and BDI (18.3 vs 9.9) than patients without NP ($p<0.01$). Mean value of the EQ-5D index was significantly lower in patients with NP (0.39 vs 0.79, $p<0.01$). Patients with NP had significantly higher mean value of Index of vascular status, then patients without NP (2.26 vs 1.36, p=0.02). $HgbA_1C$ and vitamin B12 levels were normal in all SSc patients with NP. Clinical signs of polyneuropathy were noticed in 10 patients by neurological evaluation. Typical symmetric glove-and-stocking hyperesthesia was found in 10/11 (90.9%) of SSc patients with NP, along with symmetric hyporeflexia in 6/11 (54.5%) patients on lower, and 7/11 (63.6%)

on upper extremities. None of patients had allodynia, but impaired vibratory sensibility was found in all patients with NP. Clinical signs of radiculopathy were present in 6 patients. Hypoesthesia was registered in typical dermatomes in 6/11 (54.5%) of patients, with asymmetric hyporeflexia in 2/11 (18.1%) patients on lower, and none of patients on upper extremities. Despite the fact that almost every patient had symptoms and signs suggesting polyneuropathy, in only four of them demyelinating polyneuropathy was detected by ENG.
Conclusions: NP is common in patients with SSc. Presence of NP is associated with more severe SSc, symptoms of depression and worse quality of life. Almost all SSc patients (90.9%) with NP have typical symptoms and signs for polyneuropathy. However, in only few of them polyneuropathy could be detected by ENG. This finding suggests that pure small-fiber polyneuropathy, which is not detectable by ENG, may be the cause of NP in most of patients.

FRI0406 MORTALITY PROFILE IN SYSTEMIC SCLEROSIS: A LARGE RETROSPECTIVE POPULATION-BASED STUDY FROM BRAZIL

R.P. Rezende[1], R. Gismondi[1], H. Maleh[1], M.L. Rosa[2], R. Ramos[1], L.O. Mocarzel[1]. *[1]Clinical Medicine; [2]Epidemiology and biostatistics, Universidade Federal Fluminense, Niterói-RJ, Brazil*

Background: Systemic sclerosis (SSc) is an uncommon autoimmune multisystem disease associated with reduced life expectancy compared with the general population.[1] In order to prolong survival of this patient population, clear information on the most important death-related conditions is undoubtedly necessary. No mortality data in SSc, however, are available from Latin America, as well as few large series studies have looked at the mortality profile in SSc.
Objectives: We aimed to describe the causes of death in SSc occurred in the state of Rio de Janeiro, Brazil, from 2006–2015, and also to compare the data gathered with the general population mortality.
Methods: All death certificates issued in the state of Rio de Janeiro, Brazil, from 2006–2015 were screened for the code attributed to SSc according to the tenth revision of the International Classification of Diseases (ICD-10), either as an underlying (UD) cause of death (also referred to as basic cause of death) or a non-underlying (non-UD) cause. In addition to compiling the causes of death in both settings, we calculated the non-adjusted as well as the age bracket-adjusted (age at death $<$50 years and $\geq$50 years) mortality ratio against the general population for each cause of death when SSc was listed as a non-UD cause.
Results: Of 1.294.491 fatalities recorded over the study period, ICD-10 code for SSc was listed on 374 (0.02%) death certificates, being a basic cause of death on 223 occasions and a non-UD cause on 151 occasions. The overall mean (SD) age at death in SSc was 58.7 (15.6) years, with men (n=56) having an earlier mean age at death than women (n=318) [53.5 vs 59.6 years, respectively; p=0.004]. For SSc as a basic cause of death, the main non-UD causes were respiratory system diseases (61.4%), in particular pneumonia, followed by septicemia (37.6%), diseases of the circulatory system (34.9%), and renal failure (9.4%). There were no significant differences between the genders for each cause of death. The mean age at death was significantly lower among men vs women for diseases of the respiratory system, respiratory failure, certain infectious and parasitic diseases, and septicemia. For SSc as a non-UD cause of death, the major conditions leading to death were circulatory system diseases (39%), in particular pulmonary arterial hypertension (PAH; 13.2%), followed by certain infections and parasitic diseases (11.9%), malignant neoplasms (10.5%) and diseases of the digestive system (9.9%). Compared with the overall population, patients with SSc had an excess of death (odds ratio [OR] $>$1) due to PAH (OR 138.94), septicemia (OR 1.92), gastrointestinal hemorrhage (OR 2.40), other systemic connective tissue diseases (OR 24.78) and pulmonary fibrosis (OR 11.05), as well as due to heart failure (OR 6.40) for deaths occurred before age 50.
Conclusions: We have shown large data on the mortality profile of patients with SSc, the first from Latin America. Of note, infections and cardiorespiratory diseases had a strong impact on mortality, as evidenced by previous publications.[1] Taking all into account, these data support an increased vigilance for infections, as well as the need to implement effective measures to control modifiable cardiovascular risk factors, including screening for PAH.

FRI0407 MACROVASCULAR INVOLVEMENT IN SYSTEMIC SCLEROSIS PATIENTS: IS THERE A RELATIONSHIP WITH MICROVASCULAR PERIPHERAL BLOOD FLOW?

S. Paolino[1], B.M. Colombo[2], B. Ruaro[1], E. Gotelli[1], A. Sulli[1], M. Ghio[1], C. Pizzorni[1], E. Alessandri[1], M. Patanè[1], M. Cutolo[1]. *[1]Department of Internal Medicine, University of Genova, IRCCS AOU San Martino, Genoa, Italy, Research Laboratory and Academic Division of Clinical Rheumatology; [2]IRCCS AOU San Martino, Genoa, Italy, Genoa, Italy*

Background: Raynaud's phenomenon and digital ulcers are common clinical skin manifestations of the microvascular dysfunction in systemic sclerosis (SSc). Although microvascular and macrovascular abnormalities frequently coexist in disease such as diabetes mellitus and other vascular diseases, the possible association between microvascular failure and macrovasculopathy in SSc patients has not been deeply investigated (1).
Objectives: The aim of the study was to estimate in SSc patients the macrovascular function by measuring of the Intima-Media Thickness (IMT) of high-caliber and periferic small-caliber arteries, and to evaluate the possible correlation with microvascular blood perfusion (BP) assessed by Laser Speckle Contrast Analysis (LASCA).
Methods: Twenty-nine female SSc patients (mean age 65.7±12.07 SD years, mean disease duration 97.3±68.01 SD months) were enrolled after informed consent. Carotid IMT was evaluated through B-mode US imaging (Esaote, Genoa) using transducer 18 MHz on both right and left common carotid arteries (CCA) as well as ulnar (UA) and radial arteries (RadA). Therefore, an average IMT score was obtained for any evaluated site. Peripheral BP was assessed by LASCA (Perimed-Sweden) at the level of fingertips, periungueal areas, dorsum and palm of both hands, and face. The BP values were reported as perfusion units (PU) (2). In addition nailfold videocapillaroscopy (NVC) in order to assess the microvascular morphological status was done by nailfold video capillaroscopy (NVC) considering the different progressive SSc patterns and the microangiopathy evolution score (MES) (3–4).
Results: A positive correlation was observed between CCA IMT and age (p=0.004) and disease duration (p=0.02). On the other hand, no significant correlations were observed between IMT of periferic small-caliber arteries (UA and RadA) and age or disease duration. Positive correlations were found between microvascular damage, as assessed by MES and IMT at the level of periferic small-caliber arteries.No significant correlation was observed between macrovascular involvement of high-caliber arteries and peripheral BP as assessed by LASCA. However, at the peripheral site a correlation was observed between RadA IMT and palm (p=0.05), periungueal (p=0.04) and dorsum of hand BP (p=0.0006), as assessed by LASCA. UA IMT showed a correlation limited to the dorsum of the hand (p=0.003).
Conclusions: Significant correlations seem to exist between increased IMT of periferic small-caliber arteries (macrocirculation) and altered peripheral BP (LASCA) at the level of hand microvessels (microcirculation) in SSc patients. These results were found strength by a further correlation with the microvascular damage (MES).

FRI0408 NEOPTERIN AS A SEROLOGICAL MARKER OF DISEASE ACTIVITY IN PATIENTS WITH ANTI-MELANOMA DIFFERENTIATION-ASSOCIATED GENE 5 ANTIBODY POSITIVE CLINICALLY AMYOPATHIC DERMATOMYOSITIS

S. Tsunoda, A. Nishioka, T. Abe, M. Kitano, K. Matsui, H. Sano. *Division of Rheumatology, Department of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Japan*

Background: Anti-melanoma differentiation-associated gene 5 (MDA5) antibody in clinically amyopathic dermatomyositis (CADM) is associated with rapidly progressive interstitial lung disease (RPILD). RPILD is a rare disorder with a bad outcome, and therefore the intensive treatment with combinational immunosuppressive drugs in addition to steroid need to be initiated. However until now, good serological markers to evaluate disease activity in CADM have not been established. Activated alveolar macrophage is one of the possible candidates worsening the condition of RPILD.
Objectives: To investigate new serological markers of disease activity in anti-MDA5 antibody positive CADM for therapeutic indication.
Methods: Thirteen anti-MDA5 antibody positive CADM patients were enrolled. We serially measured serum anti-MDA5 antibody, and neopterin and IL-18 as markers of activated macrophage by serum enzyme-linked immunosorbent assay. We tracked them at three points in each patients: before treatment, soon after a series of intravenous cyclophosphamide pulse therapy (about 3months later after onset) and the remission status (about one year later after onset).
Results: Four patients died soon after the initial treatment because of the deterioration of RPILD. At onset of the disease, the levels of serum anti-MDA5 antibody and neopterin were extremely high (169.75±24.3 index and 27.6±24.1 nmol/l) in all patients. However serum IL-18 level was almost normal (479.3±301.4 pg/ml). Among the 9 surviving patients, it took about one year for anti-MDA5 antibody level to decrease to the normal range. On the other hand, neopterin level decreased quickly after the initial treatment. The level of anti-MDA5 antibody transitioned from 169.75±24.3 index to 93.1±50.1 index, and then to 44.8±45.4 index (P=0.003). Neopterin level transitioned from 27.6±24.1 nmol/l to 9.1±6.5 nmol/l, and then to 6.4±5.0 nmol/l (P=0.006). IL-18 level transitioned from 479.3±301.4 pg/ml to 246.0±175.8 pg/ml, and then to 233.3±180.1 pg/ml (P=0.02). The level of anti-MDA5 didn't correlate with the level of ferritin (r=0.28), neopterin (r=0.16), IL-18 (r=0.06) and soluble IL-2 receptor (r=0.27), but the level

of neopterin was well correlated with the level of ferritin (r=0.95), IL-18 (r=0.77) and soluble IL-2 receptor (r=0.75).
Conclusions: Anti-MDA5 antibody titer is useful if the patients could reach and maintain the remission or not. Serum neopterin level is useful to predict the clinical status at present for therapeutic indication.

FRI0409 OSTEONECROSIS OF THE LUNATE BONE ASSOCIATED TO SYSTEMIC SCLEROSIS

M. Llop Vilaltella, S. Zegarra Mondragón, W.A.A. Sifuentes Giraldo, C. de la Puente Bujidos, M. Vázquez Díaz. *Rheumatology, Ramon y Cajal University Hospital, Madrid, Spain*

Background: Osteonecrosis of the lunate bone (OLB), also known as Kienböck's disease, is a rare disorder that has been recently reported in several patients with systemic sclerosis (SSc)[1], but still it is not clear if this is only a coincidence of 2 rare didsorders or whether OLB is a potentially under-recognized manifestation of SSc.
Objectives: To describe the clinical features of patients with SSc seen in a Spanish tertiary care center, who develop OLB.
Methods: We performed a retrospective observational study that included patients followed in our center between January 2010 and December 2015. Demographic data, clinical and laboratory features, risk factors for osteonecrosis, imaging, treatment and outcome were collected.
Results: A total of 115 SSc patients were identified and 4 of them (3.47%) developed OLB. Mean age of these patients was 59.5 (range: 52–73), being all women. 2 cases were limited cutaneos SSc (lcSSc) and 2 cutaneous diffuse SSc. 3 cases showed anticentromere antibodies and 1 anti-topoisomerase I antibodies, but none presented anticardiolipin antibodies nor had previous thrombotic events. Mean disease duration was 13.5 years (range: 7–17). One patient was ex-smoker, but none had alcohol consumption, and one case was hypertensive. All patients had vascular manifestations (severe Raynaud phenomenon, digital ulcers in treatment with endothelin antagonists and perfusion of iv prostaglandins, and one case had critical digital ischemia); all the patients showed calcinosis in the upper limbs, and they also had joint involvement (50%), gastrointestinal (100%), and pulmonary (50%) manifestations. History of rolonged corticosteroid therapy at low doses (prednisone 5–10 mg/day) was present in all cases and was discontinued one year before the onset of osteonecrosis in one case. OLB was unilateral right in 3 cases and bilateral in one case. The patients presented with clinical pain and/or swelling in the affected wrist in the months prior to diagnosis of OLB, which was evidenced by simple radiography, MRI and bone scintigraphy. One of the cases also showed extensive synovitis in the affected wrist and another one developed collapse of the lunate bone with displaced fragment and edema. Treatment was surgical in 25% of the cases (proximal carpectomy), and conservativein in the rest. Among the total SSc population studied there was another case of lcSSc presenting osteonecrosis of the left tarsal scaphoid bone.
Conclusions: A total of 15 cases of OLB associated to SSc have been reported to date, so it could be an underestimated disease-associated feature of SSc. It has been suggested that its etiology is linked to SSc-related vasculopathy and all our cases had evidence of severe vasculopathy. The location and vascularization of the lunate bone should be taken into account, since no case developed osteonecrosis in other common locations despite corticotherapy, and complete occlusion of the distal ulnar artery has been reported in 3 cases of the literature. The presence of pain, with or without wrist inflammation in SSc patients should make us consider OLB, which is probably more frequent than expected, especially when there is evidence of severe SSc-related vasculopathy.

FRI0410 PREDICTORS OF MORBIDITY AND MORTALITY IN PATIENTS WITH EARLY SYSTEMIC SCLEROSIS: LONG-TERM FOLLOW-UP FROM A SINGLE CENTRE INCEPTION COHORT STUDY

S. Panopoulos, V.-K. Bournia, G. Konstantonis, K. Fragiadiaki, P.P. Sfikakis, M.G. Tektonidou. *First Department of Propedeutic and Internal Medicine and Joint Academic Rheumatology Program, National and Kapodistrian University, Medical School, Athens, Greece*

Background: Several studies have investigated the predictors of morbidity and mortality in Systemic sclerosis (SSc). However long-term follow-up data from inception cohorts of early SSc patients are limited.
Objectives: To identify predictors of morbidity and mortality in a single centre inception cohort of early SSc patients at long-term follow-up.
Methods: Our inception cohort comprised SSc patients who fulfilled the American College of Rheumatology criteria, were recruited within 12 months of disease onset and followed prospectively for at least 3 years. Clinical manifestations, laboratory and lung function tests were recorded for each patient at baseline and at 3rd and 6th years of follow up. Multivariate regression analysis and Cox proportional hazard models were used to identify predictors (clinical manifestations, laboratory and lung function tests at baseline) of morbidity and mortality in SSc, respectively.
Results: A total of 114 patients (96 female, mean age at diagnosis 48.1±13.5 years, 53 diffuse SSc subtype) were included in the study, from January 1997 to December 2012. All patients were followed for at least 3 years and 84 patients for at least 6 years. Twenty (17.5%) of 114 patients died during a mean follow up of 101.8±48.5 months. In multivariate regression analysis predictors for major SSc outcomes at 6 years were: diffuse subtype (OR: 6.2, p=0.015), anti-scl-70 positivity (OR: 3.9, p=0.05), esophageal involvement (OR: 6.5, p=0.017) and digital ulcers (OR: 8.6, p=0.003) at baseline for the development of pulmonary fibrosis (PF). The presence of digital ulcers at baseline was a predictor for the development of arrhythmias (OR: 3.7, p=0.05) and the presence of arrhythmias at baseline for the development of pulmonary hypertension (PH) (OR: 5.4, p=0.039). Cox proportional hazard models multivariate analysis revealed that independent predictors of mortality were: male gender (HR: 3.3, p=0.023), diffuse type (HR: 8.7, p=0.004), PF at baseline (HR: 2.7, p=0.05), PH based on echocardiography at baseline (HR: 12.7, p=0.001) FVC <80% (HR: 2.74, p=0.042) and DLCO <60% of predicted value at baseline (HR: 2.97, p=0.019).
Conclusions:
Results from long-term follow-up data from a single centre inception cohort indicate that diffuse SSc subtype, anti-Scl-70 positivity, esophageal involvement and digital ulcers at baseline are independent predictors for the development of PF. Male gender, diffuse subtype, PF, PH and decreased FVC and DLCO at baseline are prognostic factors of mortality.

FRI0411 COADMINISTRATION OF BOSENTAN HAS NO EFFECT ON THE PHARMACOKINETICS OF NINTEDANIB

S. Wind[1], G. Simons[1], J. Bertulis[1], C. Coeck[2]. *[1]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, Germany; [2]SCS Boehringer Ingelheim Comm.V., Brussels, Belgium*

Background: Nintedanib is a potent intracellular inhibitor of tyrosine kinases that has been approved for the treatment of idiopathic pulmonary fibrosis and is being investigated as a treatment for interstitial lung disease associated with systemic sclerosis (SSc-ILD). Bosentan is a dual endothelin receptor antagonist used in the treatment of pulmonary arterial hypertension, which is a common comorbidity of SSc-ILD.
Objectives: To ascertain the effect of bosentan on the pharmacokinetics of nintedanib.
Methods: In an open-label, single-centre study, healthy male subjects aged ≥18 and ≤55 years with a body mass index (BMI) ≥18.5 and ≤29.9 kg/m^2 received a single dose of nintedanib 150 mg alone (period 1) followed by bosentan 125 mg twice daily (bid) for 8 days (bosentan loading dose phase on days 1–6) with a single dose of nintedanib 150 mg on day 7 (period 2). The primary endpoints were the maximum plasma concentration (C_{max}) of nintedanib and the area under the plasma concentration-time curve from time 0 to the last quantifiable concentration ($AUC_{0\text{-}tz}$) of nintedanib. The secondary endpoint was the AUC from time 0 extrapolated to infinity ($AUC_{0-\infty}$) for nintedanib.
Results: Thirteen subjects (12 White; mean [SD] age 35.0 [9.8] years and BMI 24.5 [2.5] kg/m^2) were treated. All subjects completed the planned observation period. Based on C_{max}, $AUC_{0\text{-}tz}$ and $AUC_{0-\infty}$, exposure to nintedanib was similar after a single dose of nintedanib given alone or in combination with multiple doses of bosentan 125 mg bid (Table). Adverse events were reported in 4 subjects (30.8%) on nintedanib alone (period 1), 4 subjects (30.8%) on bosentan 125 mg bid (days 1–6 of period 2) and 2 subjects (15.4%) after administration of bosentan with nintedanib (days 7 and 8 of period 2). All adverse events were mild in intensity.

	Nintedanib 150 mg alone	Nintedanib 150 mg coadministered with multiple doses of bosentan 125 mg bid	Adjusted geometric mean ratio (90% CI)
C_{max} (ng/mL)	21.9	22.7	103.4 (86.1, 124.0)
$AUC_{0\text{-}tz}$ (ng·h/mL)	194.9	192.6	98.9 (91.3, 107.0)
$AUC_{0-\infty}$ (ng·h/mL)	204.3	208.3	102.0 (94.9, 109.6)

Conclusions: Coadministration of bosentan 125 mg bid had no effect on the pharmacokinetics of a single dose of nintedanib 150 mg.

FRI0412 THE POSITIVE EFFECT OF RITUXIMAB IN PULMONARY FIBROSIS OF SYSTEMIC SCLEROSIS

P. Kiryttopoulos[1], T. Michailidis[1], E. Papchianou[1], M. Charalampidis[2], P. Dimitriadis[3], A. Agorastos[4]. [1]*Department of Internal Medicine, General Hospital of Veria, Veria;* [2]*Gastroenterology Department, Theageneio Hospital of Thessaloniki, Thessaloniki;* [3]*Health Center of Alexandria, Alexandria, Greece;* [4]*Oncology Department, St. Thomas Hospital, London, United Kingdom*

Background: Pulmonary fibrosis is one of the gravest manifestations of Systemic Sclerosis (SSc) and conventional DMARDs therapy has not shown any particular positive effect.
Objectives: Our goal was to see whether the elimination pf B - lymphocytes through use of anti – CD20 Mab, Rituximab (RTX) would offer to the improvement of the pulmonary function of SSc patients.
Methods: We studied 23 SSc patients with pulmonary fibrosis, who received treatment with RTX (n=12) or DMARDs treatment (n=11) for 1 to 3 years (1,9 years). Conventional therapy included azathioprine (n=4), mycophenalate (n=6) and methotrexate (n=2). RTX – treated patients were recorded with FVC improvement in the first year of treatment (FVC 81,3 +/- 12,6 vs FVC 87,4 +/- 11,3 out on the onset of the study and at the first year respectively, p=0,02) when on the other hand DMARDs treated patients didn't show any FVC improvement at all.
Results: All RTX – treated patients did not present any lung HRCT deterioration imaging, in contrast to DMARDs – treated patients who were also submitted to lung HRCT each year of the study, all showing signs of CT imaging deterioration. Similar findings, as far as FVC was concerned, were recorded at the 3rd year of the study (RTX patients, n=6 and DMARDs patients, n=11). 3rd year RTX FVC was 92,6 +/-13,2 vs 80,7 +/-11,8 at the onset of the study, p=0,04 when DMARDs treated patients were all presented with worst 3rd year FVC compared to their primary FVC, p<0,01.
Conclusions: Our small cohort of SSc patients with pulmonary fibrosis shows that it is possible that rituximab may be proven helpful to at least prevent the deterioration of the interstitial pulmonary fibrosis of Systemic Sclerosis. The pathophysiology of this particular fibrosis and the possible molecular role of B-lymphocytes in the inversion of this procedure need yet to be furtherly explored.

FRI0413 ACUTE EFFECT OF ILOPROST ON PERIPHERAL CIRCULATION AS ASSESSED BY VIDEOCAPILLAROSCOPY AND 22-MHZ POWER DOPPLER ULTRASONOGRAPHY

T. Schioppo[1,2], A. Orenti[1,3], P. Boracchi[1,3], O. De Lucia[2], A. Murgo[2], P.L. Meroni[1,2], F. Ingegnoli[1,2] on behalf of OPERA study group. [1]*Università degli Studi di Milano;* [2]*ASST Pini-CTO;* [3]*Lab of Medical Statistics, Epidemiology and Biometry GA Maccacaro, Milan, Italy*

Background: Vascular involvement is a hallmark of systemic sclerosis (SSc) and it is responsible for some of the most common complications of the disease such as Raynaud's phenomenon (Rp), digital ulcers (DUs) and pulmonary arterial hypertension. I.V. iloprost (ILO), a prostacyclin analogue, has been shown to be effective in reducing Rp severity, DUs healing and preventing [1].
Objectives: To assess the acute effect of ILO on acral circulation as assessed by nailfold videocapillaroscopy (NVC) and 22-MHz Power Doppler ultrasound (PDUS).
Methods: 44 SSc consecutive patients fulfilling the 2013 EULAR classification criteria were enrolled. Each patient was evaluated before and immediately after I.V. ILO administration (0.5–2.0 ng/Kg/min for 6 consecutive hours). PDUS was performed at the 3rd and 4th finger of the dominant hand after exclusion of ulnar artery occlusion (UAO). In case of UAO non-dominant hand was examined. Ultrasound investigation was performed with Esaote MyLab 70 XVG by means of linear array transducer (10–22 MHz). Power Doppler settings were standardized (Doppler frequency 14.3 MHz, Gain 55%, PRF 750 Hz). PDUS measurements included sagittal scan of nailbed and fingertip qualitatively graded from 1 (no signal) to 4 (marked hyperemia) [2], and resistivity index (RI) of ulnar and radial proper digital arteries. Capillary width (sum of capillary width/mm) was calculated by NVC with magnification 200X performed on two images of the same digits examined by PDUS.
Results: The study population included 44 SSc patients, 40 (90.9%) women, 35 (79.5%) limited cutaneous SSc, median age 60.2 years old and median disease duration 8 years. 19 (43.2%) had history of DUs, among them 15 had experienced more than one DUs and 1 had active DU at the moment of evaluation.
Semiquantitative perfusion score of sagittal scan of nailbed and fingertip pre- and post-therapy are shown in Table 1.
Changes in RI and capillary width pre- and post-infusion are reported in Table 2.
Conclusions: A statistically significant post-infusion rise in RI, fingertip and nailbed PDUS grade were found. Capillary width was also increased, but it was not statistically significant. As such, these novel results indicate that ILO, alongside its clinical effect, is able to enhance vascularization even at the most peripheral levels.

Table 1

	Pre-infusion		Post-infusion		OR (95% CI)
	%	Cumulate %	%	Cumulate %	
Fingertip PDUS					4.21 (2.12–8.35)

FRI0414 CAN ECHOCARDIOGRAPHY REPLACE FOLLOW-UP CARDIAC CATHETERIZATION IN RE-EVALUATION OF PULMONARY ARTERIAL HYPERTENSION? A LONGITUDINAL SINGLE-CENTER STUDY OF 30 CONNECTIVE TISSUE DISEASE PATIENTS

V.-K. Bournia[1], I. Tsangaris[2], L. Rallidis[2], D. Konstantonis[2], A. Anthi[2], S. Orfanos[2], S. Panopoulos[1], P.P. Sfikakis[1]. [1]*First Department of Propedeutic Internal Medicine and Joined Rheumatology Program;* [2]*Pulmonary Hypertension Clinic, Attikon University General Hospital, Medical School, National and Kapodistrian University of Athens, Athens, Greece*

Background: Transthoracic echocardiography (TTE) is well validated for initial assessment of connective tissue disease patients with suspected pulmonary arterial hypertension (PAH). However, in patients with PAH confirmed by the gold-standard method of right heart catheterization (RHC) the role of TTE in their follow-up is less known.
Objectives: To test the hypothesis that TTE can replace follow-up RHC in connective tissue disease-associated PAH.
Methods: This retrospective study included 30 consecutive patients with systemic sclerosis (n=24) and mixed connective tissue disease (n=6) (mean age±SD: 60±12 years, 87% women), in whom PAH was suggested by TTE and further confirmed by a baseline RHC [pulmonary artery systolic pressure (PASP): 56.8±19.1, range 25–90mmHg; pulmonary vascular resistance (PVR): 5.9±3.8, range 0.7–14.5 Wood units; cardiac output: 4.4±1.3, range 2–7.8 L/min). All 30 patients underwent a second RHC and TTE at follow-up, after 11±6 (range 4–29) months. Ten patients had a 3rd follow-up RHC and TTE 22±7 (range 15–37) months from baseline, thus producing in all 50 pairs of baseline and follow-up measurements. By considering follow-up RHC as the gold-standard, we examined whether clinically meaningful hemodynamic changes (i.e.>15% change from baseline) in either RHC-derived PASP or PVR could be predicted by the corresponding changes from baseline in follow-up TTE. RHC and TTE were always performed, each, by the same examiner.
Results: In 68% of comparisons between baseline and follow-up, the latter TTE measurements could safely replace RHC in terms of PASP estimation. Using Mc Nemars test we confirmed that the two methods did not differ significantly (Table 1). When in addition to changes in PASP, PVR changes were also considered, follow-up TTE could again safely replace the second RHC in 70% patient retests (Table 2). Of note, baseline hemodynamic values or TTE measurements did not differ between patients in whom TTE could replace RHC and those in whom the results of the two methods at follow-up were divergent.

Table 1. McNemars test comparing PASP estimated by repeat TTE to that measured by repeat RHC shows no difference between the two methods

Repeat TTE	Repeat RHC	
	Stable or improved PASP	Deteriorated PASP (>15%)
Stable or improved PASP	25	9
Deteriorated PASP (>15%)	7	9

P=NS (0.8).

Conclusions: In a study where operator-dependent methodological errors are limited we found that the majority of connective tissue disease patients with PAH

Table 2. McNemars test comparing PASP estimated by repeat TTE to hemodynamic parameters measured by repeat RHC when PVR is also considered

Repeat TTE	Repeat RHC	
	Stable or improved PASP and PVR	Deteriorated PASP or PVR (>15%) or PVR (>15%)
Stable or improved PASP	24	10
Deteriorated PASP (>15%)	5	11

P=NS (0.3).

can be safely monitored in the long-term by TTE. Further studies to help identify those patients at need for follow-up RHC are warranted.

FRI0415 CAPILLAROSCOPIC ABNORMALITIES CORRELATE WITH ORGAN DAMAGE IN CHINESE PATIENTS WITH SYSTEMIC SCLEROSIS

W.Y. Yeung[1], C.C. Mok[2], K.L. Lee[1]. *[1]Department of Medicine, Pamela Youde Nethersole Eastern Hospital; [2]Department of Medicine, Tuen Mun Hospital, Hong Kong, -*

Objectives: To study the nailfold capillaroscopic patterns and microangiopathy evolution score (MES) and correlate with the severity of organ damage in Chinese patients with systemic sclerosis (SSc)
Methods: Patients who fulfilled the 2013 ACR criteria for SSc were studied. A full physical examination was performed. Blood was taken for SSc autoantibodies, along with a full lung function test and echocardiogram. The extent of skin involvement was assessed by the modified Rodnan skin score (mRSS). Organ damage of SSc was assessed by the Medsger disease severity scale. A Nailfold capillaroscopic examination was performed by a trained nurse blinded to the medical history of the patients. The following parameters were obtained: (1) capillaroscopy patterns (early, active and late); (2) Degree of enlarged capillaries, giant capillaries, capillary haemorrhages, capillary density, disorganization of vascular array and capillary ramification assessed by a semi-quantitative method; and (3) MES score (sum of capillary density, disorganization of vascular array and capillary ramification). Correlation among the capillaroscopic patterns, individual capillaroscopic parameters and the MES with organ damage was performed by the Spearman's rank correlation test.
Results: A total of 138 Chinese patients were studied (91.3% women; age 56.36±11.81 years). The median disease duration was 8.14±6.21 years. 39 (28.3%) patients had DcSSc and 99 (71.7%) had LcSSc. Anti-centromere, anti-Scl 70 and anti-RNA polymerase III antibodies were present in 28.6%, 28.5% and 5.6% of the patients respectively. Organ damage was present in all patients, most common being skin (84%), lung (79%), peripheral vascular (74%) and GI tract (46%). The median mRSS was 6 (IQR 2–12). A total of 27 patients (19.7%) had early SSc pattern on capillaroscopy, 40 (29.2%) had active pattern and 68 (49.6%) had late pattern. The median MES score was 3.02 (IQR 1.76–5.25). Patients with late SSc pattern on capillaroscopy had significantly longer disease duration and were more likely to have organ damage in the general, peripheral vascular and lung domains compared to those not having late SSc patterns. The total MES score correlated significantly with organ damage scores in the muscle (Rho 0.188; p=0.029), GI tract (Rho 0.169; p=0.048) and lung (Rho 0.265; p=0.006) domains. Regarding individual components of the MES score, capillary density correlated significantly with scores in the peripheral vascular (Rho 0.460; p<0.001), skin (Rho 0.343; p<0.001), joint/tendon (Rho 0.220; p=0.011), muscle (Rho 0.295; p=0.001), GI tract (Rho 0.188; p=0.028) and lung (Rho 0.238; p=0.015) damage domains. Enlarged capillaries correlated significantly with scores in the muscles (Rho -0.205; p=0.017) and lung (Rho -0.213; p=0.029) damage domains. Giant capillaries and microhaemorrhages correlated significantly with scores in the peripheral vascular (Rho 0.239; p=0.005 and Rho 0.228; p=0.007 respectively) damage domains. Disorganization of capillary array correlated significantly with scores in the lung (Rho 0.253; p=0.009) damage domain. Capillary ramifications correlated significantly with the scores in the kidney (Rho 0.171; p=0.048) damage domains.
Conclusions: In Chinese patients with SSc, capillaroscopic patterns and components of the microangiopathy evolution score were associated with severity of organ damage.

FRI0416 CHARACTERISTICS AND CAPILLAROSCOPIC FINDINGS OF SYSTEMIC SCLEROSIS PATIENTS WITH SEVERE PERIPHERAL VASCULAR INVOLVEMENT RECEIVING SPECIFIC VASODILATOR TREATMENT

Y. Yalçınkaya, A.U. Ünal, Z. Ertürk, U. Gazel, S. Kaymaz, A. Aksoy, P. Atagündüz, N. İnanç, H. Direskeneli. *Department of Internal Medicine, Division of Rheumatology, Marmara University, School of Medicine, Istanbul, Turkey*

Background: Severity of peripheral vascular involvement (PVI)is known as an important determinig cause of morbidity in sytemic sclerosis (SSc). Different vasodilating agents have been found to reduce severity and contribute to healing of digital ulcers (DU)in SSc.
Objectives: We aimed to evaluate the characteristics and capillaroscopic patterns of the patients with severe PVI under different vasodilator therapeutic regimens.
Methods: The patients were grouped as "severe PVI" if score of PVI is ≥2 (PVT=2,digital pitting scars; PVT=3, digital tip ulcerations and PVT=4, digital gangrene; Medsger) and "non-severe PVI" if score of PVI is ≤1 (PVI=0,no Raynaud's; PVI=1, Raynaud's requiring vasodilators). We included patients with severe PVI who received cyclic iloprost and bosentan and/or sildenafil and compared to non-severe PVI. Nail fold video-capillaroscopy (NVC)was assessed qualitatively (Cutalo et al., early, active and late patterns).
Results: Severe PVI group more frequently had diffuse cutaneous form, contractures, lung disease, anti-Scl70 positivity and high acute phase response and exposed to immunosuppressives (table-1).

Table 1. Demographics and characteristics of SSc Patients

	Non-severe PVI n=32	Severe PVI group 2 n=22	p
Age (year)/female (%)	44±15/ 88%	48±12/ 87%	NS
Duration of Raynaud's/nonRaynaud's (year)	9±9/5±5	12±10/9±9	NS
Diffuse Cutaneous involvement	5 (16%)	10 (45%)	P=0,039
Anti-Scl70 (+)	7 (22%)	11 (50%)	P=0,024
Interstitial lung disease	7 (22%)	14 (64%)	P=0,001
Flexion contractures	3 (9%)	10 (45%)	P=0,008
Echo PAP>40 mmHg	2 (6%)	4 (18%)	NS
High acute phase response	12 (38%)	18 (82%)	P=0,002
FVC ≤80%/	3 (9%)	12 (55%)	P<0,001
DLCO ≤80%	10 (31%)	14 (64%)	P=0,011
Immunosuppressives- CYC (pulse)	5 (16%)	9 (41%)	P=0,018
– Azathioprin	8 (25%)	10 (46%)	P=0,030
– Mycphenolate mofetil	2 (6%)	10 (46%)	P<0,001
– Rituksimab	1 (3%)	6 (27%)	P=0,027
– Steroids (PRD<10 mg/d)	11 (34%)	17 (77%)	P=0,001

NS = not significant.

Scores of telangiectasia, skin, activity and severity were lower in non-severe group. NVC late pattern was frequent and early pattern was rare in severe PVI groups. Forty-one% (9/22) of patients received second oral agent for PVI. Monotherapy and combination groups had similar scores (table-2).

Table-2: Capillaroscopy Patterns among SSc groups

	non-severe PVI n=32	severe PVI n=22	Cyclic iloprost+ bosentan n=10	Cyclic iloprost+ bosentan+sildenafil n=9
NVC -normal	3(9%)	0	0	0
-early pattern	12(38%)**	2(9%)	1(10%)	1(11%)
-active pattern	10(31%)	2(9%)	2(20%)	0(0%)
-late pattern	8(25%)	18(82%)*	7(70%)	8(89%)
Telangiectasia score (Shah)	3,7±2,5**	6±3,7	4,8±3,2	7,1±4,2
Modified Rodnan skin score	5,8±5*	13,5±8,7	13,6±9,3	13,2±7,6
Activity score (Valentini)	0,9±0,9*	2,1±1,2	2,2±1,3	2,2±1,2
Severity score (Medsger)	3,5±1,7*	7,5±2,4	7,8±2,3	7,4±2,7

**p<0,001, **p<0,05 when severe and non-severe PVI compared*

Conclusions: NVC late pattern was frequent in severe PVI group with long disease duration, exposed to intensive immunosuppresives and received specific vasodilators for PVI. Disease activity and severity were higher in severe PVI group. One third of the severe group required oral combination therapy for PVI. Monotherapy and combination groups were similar in terms of severity. NVC is a useful method to monitor digital ischemia and severe organ involvement in SSc.

FRI0417 EXERCISE-INDUCED PULMONARY HYPERTENSION IN SYSTEMIC SCLEROSIS PATIENTS: TRANSCRIPTOME ANALYSIS OF PERIPHERAL BLOOD AT THE EARLY STAGE OF THE DISEASE

Y. Koyama[1], S. Fuke[2], Y. Sato[3], T. Higuchi[1]. *[1]Center for Autoimmune Diseases, Division of Rheumatology; [2]Division of Cardiology, Japanese Red Cross Okayama Hospital, Okayama; [3]DNA Chip Research Inc., Tokyo, Japan*

Background: Pulmonary arterial hypertension (PAH) is prominent as a vascular involvement in systemic sclerosis (SSc), which remains a leading cause of death in spite of current best treatments. As the pulmonary vascular disease (PVD) can be well compensated for, more than a half of the pulmonary circulation is impaired before early PAH is detected. Although recent studies focused on molecular basis of the PVD, the underlying mechanisms have not been fully elucidated, especially at the early stage of the disease.
Objectives: To detect the subclinical PVD, and to explore the changes in transcriptome of peripheral blood at the early stage of SSc associated PAH.
Methods: Total of 74 cases without PAH symptoms (NYHA I) with either Raynaud phenomenon (RP: n=61), skin sclerosis (n=43) or SSc-related autoantibody (anti-RNP: n=10, centromere: n=36, topoisomerase-1: n=2, RNA polymerase III: n=2) were enrolled. To detect the latent PAH, exercise Doppler echocardiography (DE) with Master's two-step stress was carried out. Systolic PAP (sPAP) was determined by maximum velocities of tricuspid regurgitation jets, and exercise induced pulmonary hypertension (exPH) group was segregated from normal response group (exN) with using the definition of a sPAP greater than 40 mm Hg during exercise, or a exercise increase in sPAP by greater than 20 mm

Hg[1)]. For transcriptome analysis, total RNAs from whole peripheral blood cells were extracted with using PAXgene miRNA kit. After constructing single-stranded, strand-specific libraries, multiplex sequencing was done. After quantifying the expressions of transcripts, differentially expressed genes (DEGs) between exPH and exN group were selected by paired T-test ($P<0.05$). And then, hierarchical clustering analysis and pathway enrichment analysis (PathVisio) were performed.
Results: There were no significant differences between exPH and exN group in the result of total skin score, serum BNP, tests of pulmonary function and thermography after 0℃-stress. Positive SSc-related autoantibody was a risk factor for exPH (odds ratio, 1.41); especially, positive anti-RNP seemed to be prominent (odds ratio, 3.21). Based on the 817 DEGs between exPH and exN group, the hierarchical clustering showed major 4 clusters, and one of them consisted of only cases in exPH group. When we focused on 117 genes reported to be directly implicated in the development of PAH[2)], it is noteworthy that 4 of them including TGF-β induced protein were differentially expressed. Pathway analysis of transcriptome revealed that 22 pathways, such as hypertrophy model, lung fibrosis and Wnt/B-catenin signaling, were differently enriched between exPH and exN group.
Conclusions: The paradigm of SSc-PAH management should ideally be aimed at detecting early PVD and starting treatment prior to fulfilling the criteria for PAH. Although detection of early PVD in SSc patients remains a major challenge, exercise DE seemed to be a good, non-invasive method for screening. It is noteworthy that expression changes in some of known PAH-related genes were detected from peripheral blood of exPH patients. It shows the possibility that the therapeutic intervention at early stage of the disease may alter the clinical course.

FRI0418 FACTORS ASSOCIATED WITH STEROID-FREE REMISSION IN PATIENTS WITH INFLAMMATORY MYOPATHIES. A RETROSPECTIVE ANALYSIS OF A SINGLE-CENTER COHORT

Y. Sato[1], K. Kobayashi[1], K. Minegishi[1], S. Ohno[1], H. Nakajima[2]. *[1]Center for Rheumatic Diseases, Yokohama City University Medical Center; [2]Department of Stem Cell and Immune Regulation, Yokohama City University Graduate School of Medicine, Yokohama, Japan*

Background: The inflammatory myopathies are a heterogeneous group of connective tissue diseases characterized by muscle weakness and inflammation. Corticosteroids are the standard main treatment for inflammatory myopathies. However, steroid therapy often causes a wide range of side effects. Although immunosuppressive drugs are used as steroid-sparing agents in an effort to prevent disease recurrence, the appropriate duration of steroid use remains unclear.
Objectives: We investigated whether steroid therapy can be safely withdrawn in patients with inflammatory myopathies followed in a single center.
Methods: We retrospectively reviewed clinical charts of 71 consecutive patients (age 51.9±15.7 y.o., female 69%) who met Bohan and Peter criteria for polymyositis (PM)/dermatomyositis (DM) and modified Sontheimer's criteria for clinically amyopathic dermatomyositis (ADM), respectively. Steroid free remission was defined as a 3-month consecutive period of no disease activity without corticosteroid treatment. Factors associated with steroid free remission were examined.
Results: Of 71 identified patients, 29 patients (40%) were DM, 15 patients (21%) were PM, 9 patients (13%) were overlap myositis, and 18 patients (25%) were ADM. Thirty-seven patients (52%) had muscle weakness, 5 patients (7%) had malignancies and 43 patients (61%) had signs of interstitial lung disease. With a mean follow-up of 6.6±5.0 years, 9 patients (13%) died during follow-up period. The remaining 62 patients were treated with corticosteroids alone or in combination with immunosuppressants. Steroid-free remission was achieved in 21 of 62 patients (34%) patients with a mean time to steroid withdrawal of 5.5±4.0 years. Six of 21 patients (29%) relapsed 1.7±1.7 years after steroid withdrawal. There were no differences in onset of age, disease duration, positive ANA, positive Anti Jo-1 antibodies, serum creatine kinase levels, maximum dose of corticosteroids, skin, joint and lung involvement between steroid-free group and non-steroid-free group. Elevated inflammatiory markers were associated with long-term steroid use (p=0.038). Concominant immunosuppressants were more frequently used in non-steroid-free group than steroid-free group (p=0.002).
Conclusions: Steroid-free remission might be achieved in some patients with inflammatory myopathies.

FRI0419 THE PREDICTIVE PROGNOSTIC FACTORS FOR CLINICAL COURSE OF POLYMYOSITIS/DERMATOMYOSITIS-ASSOCIATED INTERSTITIAL LUNG DISEASE

Y. Sugiyama[1], R. Yoshimi[1], M. Tamura[1], N. Hamada[1], H. Nagai[1], N. Tsuchida[1], Y. Soejima[1], Y. Kunishita[1], D. Kishimoto[1], H. Nakano[1], R. Kamiyama[1], K. Minegishi[2], Y. Asami[1], Y. Kirino[1], S. Ohno[2], H. Nakajima[1] on behalf of Y-CURD Study Group. *[1]Department of Stem Cell and Immune Regulation, Yokohama City University Graduate School of Medocine; [2]Center for Rheumatic Diseases, Yokohama City University Medical Center, Yokohama, Japan*

Background: Interstitial lung disease (ILD) and concomitant infectious diseases are the predominant causes of death in polymyositis/dermatomyositis (PM/DM). We have already reported that hypocapnea and ILD lesion in upper lung fields are independent prognostic factors. Micro RNA is a non-coding RNA, which has a certain function such as transcriptional regulation. miR-1 has been reported to be associated with myocyte differentiation and to decrease in muscle tissue from patients with inflammatory myopathies.
Objectives: Here we investigated the association of serum miR-1 level with clinical course of PM/DM-associated ILD (PM/DM-ILD).
Methods: We retrospectively analyzed clinical baseline, serum miR-1 level, initial therapeutic regimens, total amounts of PSL, clinical outcomes, and episode of infection of patient with PM/DM-ILD who had received initial treatment at six hospitals associated with Yokohama City University from 2003 to 2016. The serum miR-1 level was measured by quantitative real-time PCR.
Results: One hundred sixteen (PM 22, DM 51, and clinically amyopathic DM 43) patients were included. The mean age was 56±15 years and 83 were female. As initial therapies, oral PSL, methylprednisolone (mPSL) pulse, intravenous cyclophosphamide (IVCY), and oral calcineurin inhibitor therapies were performed in 113 (97%), 80 (69%), 48 (41%) and 80 (69%), respectively. Forty-one patients had a serious infection at 51±38 days from initiation of immunosuppressants and 10 died of infections. Old age, low $PaCO_2$ and albumin, high LDH and KL-6, high score of ILD, high initial dose of PSL, mPSL pulse, IVCY, calcineurin inhibitor and combination therapy were extracted as risk factors for infection by univariate analyses. A multivariate logistic regression analyses revealed that combination therapy (p=0.012, OR 2.83), old age (p=0.024, OR 2.12), high initial dose of PSL (p=0.024, OR 2.69), low albumin (p=0.031, OR 3.56), and low $PaCO_2$ (p=0.038, OR 2.67) were independent risk factors for infection. Serum samples were obtained from total of 14 patients and 13 healthy controls. Serum miR-1 levels in PM/DM-ILD patients before treatment were significantly higher than those in healthy controls (p=0.047). Also serum miR-1 levels were significantly higher in PM/DM-ILD patients with concomitant infectious diseases as compared to patients without infectious diseases (p=0.043). We further divided the PM/DM-ILD cases into two groups by the serum miR-1 level. The higher miR-1 group showed poorer effectiveness of ILD treatment (p=0.040), and lower lymphocyte count (p=0.013) as compared to the lower miR-1 group.
Conclusions: Appropriate monitoring is important for PM/DM-ILD, especially in older patients with malnutrition or decreased respiratory function. miR-1 can be a new biomarker for predicting treatment response and concomitant infectious diseases during treatment for PM/DM-ILD.

Spondyloarthritis - etiology, pathogenesis and animal models

FRI0420 ASSOCIATION OF SUPRESSOR OF CYTOKINE SIGNALING -3 (SOCS-3) EXPRESSION WITH INTERLEUKIN-23 RECEPTOR (IL-23R) SINGLE NUCLEOTIDE POLYMORPHISMS (SNPS) IN ANKYLOSING SPONDYLITIS (AS)

M.A. Sánchez[1], R. Villares[2], J. Polo y La Borda[3], J. Campos[3], J.M. Rodríguez-Frade[2], J. Sanz[3], B.J. Robles Flores[3], A. Royuela[4], P. Lucas[2], M. Mellado[5], J. Mulero[3]. *[1]Rheumatology, Instituto de Investigación Biomédica Hospital Universitario Puerta de Hierro Majadahonda, Majadahonda (Madrid); [2]Immunology and Oncology Department, Centro Nacional de Biotecnología. CNIC, Madrid; [3]Rheumatology; [4]Clinical Biostatistics Unit, Instituto de Investigación Biomédica Hospital Universitario Puerta de Hierro Majadahonda; [5]Immunology and Oncology Department, Centro Nacional de Biotecnología. CNIC, Majadahonda (Madrid), Spain*

Background: Nowadays genetic-association studies have discovered new genes, other than *HLA-B27*, as *IL-23R* associated with AS. The signalling pathway trough IL-23R is negatively regulated by the SOCS proteins. However, the reports regarding the roles of SOCS in AS are very rare at present.[1,2]
Objectives: The aim of this study is to assess the gene expression of *SOCS-1*,

-2, -3 and *-6* in peripheral blood mononuclear cells (PBMCs) in relation with *IL-23R* SNPs previously associated with AS.
Methods: We studied 74 patients (64,8% males) recruited from the Rheumatology Unit of the Puerta de Hierro Hospital diagnosed of AS following the Modified New York Criteria. The study cohort included patients with a mean age of 55.2±11, 2 years. Total RNA was extracted from PBMCs using the Nucleospin RNA kit (MN) and reverse transcribed into cDNA. mRNA expression was assessed by real-time quantitative RT-PCR using specific primers and Power SYBRGreen PCR Master Mix (Applied Biosystems).SNP genotyping [rs1129026 (G/A), rs10489629 (T/C), rs1343151 (G/A) rs2201841 (C/T), rs1004819 (C/T) y rs11209032 (A/G)] was performed using the Sequenom MassARRAY platform. In 17 cases there were two samples from the same patient. These samples were obtained from two scheduled visits and 99 samples were analyzed so. To determine the effect of independent variables on levels of *SOCS* genes expression, we fitted population-averaged models by generalized linear models, nested by patient, using the *xtgee* command of Stata v.12. *P*-values of <0.05 were considered statistically significant.
Results: Cellular *SOCS-1*,*-2* and *-6* expression did not show significant differences between the risk alleles carriers and the protective alleles carriers in any of the *IL-23R* SNP studied. *SOCS-3* increased significantly in protective alleles carriers of the *IL-23R* intronic SNP rs10489629-C (CC>CT>TT; *P*=0.028), the *IL-23R* non-synonymous SNP (Arg381Gln) rs11209026_A (AG>GG; *P*=0.047) and the *IL-23R* intronic SNP rs1343151-A (AA>AG>GG, *P*=0.005).
Conclusions: Higher *SOCS-3* expression levels for AS patients carriers of protective alleles of the *IL-23R* rs10489629-A, rs11209026-A and rs1343151-A as compared to carriers of risk genotypes could influence the pathogenesis of this disease.

FRI0421 DYSREGULATED MIR-125 PROMOTES JOINT ANGIOGENESIS IN PSA THROUGH ALTERED BIOENERGETICS

S. Wade[1], N. Ohnesorge[2], M. Biniecka[3], S. Merrigan[2], T. McGarry[1], M. Canavan[1], D.J. Veale[3], B. Kennedy[2], U. Fearon[1]. *[1]Molecular Rheumatology, Trinity Biomedical Sciences Centre; [2]Conway Insitute, University Collage Dublin; [3]St Vincents University Hospital, Dublin, Ireland*

Background: Psoriatic arthritis (PsA) is characterised by an early vascular phase which is essential in perpetuating pannus growth, immune responses and disease progression. Recently, numerous studies have highlighted the emerging importance of endothelial cell metabolism in controlling angiogenesis. Herein, we propose microRNA, miR-125, modulates EC bioenergetics and orchestrates joint angiogenesis as characterised using *ex-vivo and in-vitro* tissue/cell assays and a novel *in-vivo* zebrafish model.
Objectives: To examine the relationship between miR-125, angiogenesis and cellular metabolism in the PsA synovium.
Methods: Primary PsA synovial fibroblasts (PsA FLS) and microvascular endothelial cells (HMVEC) were transfected with anti-miR-125a. Angiogenic mechanisms were quantified using tube formation assays, invasion by Transwell Matrigel chambers, migration by wound repair and metabolic gene expression by RT-PCR. Real-time analysis of extracellular acidification rates (ECAR) and oxygen consumption rates (OCR) of anti-125 treated HMVEC was assessed using the XF-24 Flux Analyzer (Seahorse Bioscience). To determine if altered metabolism is observed *ex vivo*, glycolysis/oxidative phosphorylation markers (GAPDH/PKM2/GLUT1/ATP), and angiogenic factors (FactorVIII/VEGF/ANG2) were quantified by immunohistology. MiRNA levels were quantified in synovial tissue (ST) and PBMC by RT-PCR and compared to clinical marker and immunohistochemical analysis. The angiogenic effects of miR-125 were assessed *in vivo* using GFP-tagged zebrafish embryos treated with anti-125 morpholinos, or vitamin D3 analog, calcitrol, to monitor vascular development.
Results: An increase in tube formation, cellular invasion and/or migration mechanisms ($p<0.05$) were demonstrated in anti-miR-125a transfected HMVEC and FLS supernatant. Inhibition of miR-125 significantly decreased basal, maximal and spare respiratory capacity ($P<0.009$) with a concurrent decrease in ATP synthesis ($P<0.008$). Increased glycolysis was further confirmed by the observed elevation of glycolytic genes: HK2, GSK3A, PDK1, HP6G (ns) and 3PO target and stimulator of glycolysis, PFKFB3 ($P<0.05$). *In vivo* synovial expression of miR-125 was significantly decreased in PsA versus OA synovial tissue and was associated with increased PsA macroscopic and microscopic vascularity. This was paralleled by a significant increase in the vascular expression of glycolytic markers, PKM2, GLUT1 and ATP5B in PsA compared to OA synovium. Finally, anti-125 morpholinos treated Zebrafish displayed increased vascular sprouting. In contrast, Calcitriol significantly reduced vascular development and increased the expression of miR-125, promoting miR-125 as a potential mechanism for orchestrating angiogenic development *in vivo* and in response to pharmaceutical agents
Conclusions: Our data demonstrates decreased expression of miR-125 in PsA synovium and *in-vivo* models was strongly associated pro-angiogenic mechanisms. Elevated glycolysis following miR-125 inhibition may enables endothelial cells to meet the increased energy and biosynthetic demands for new vessel formation. Correcting these deficiencies and their resulting metabolic shift, either by conventional pharmacological or as novel drug targets, may provide therapeutic benefit, especially in early disease.

FRI0422 ESTROGEN ATTENUATES THE DISEASE ACTIVITY OF SPONDYLOARTHRITIS IN SKG MICE

H. Jeong[1], E.-K. Bae[2], Y.H. Eun[1], I.Y. Kim[1], E.-J. Park[3], J. Lee[1], E.-M. Koh[1], H.-S. Cha[1]. *[1]Samsung Medical Center; [2]Samsung Biomedical Research Institute, Seoul; [3]Jeju National University Hospital, Jeju, Korea, Republic Of*

Background: Ankylosing spondylitis is a male-predominant disease, and the male gender is also associated with more severe radiographic damage. Estrogen modulates immune-related processes such as T cell differentiation and cytokine production.
Objectives: This study aimed to evaluate the role of estrogen in the disease activity of spondyloarthritis (SpA). The effect of estrogen on the inflammatory cytokines was evaluated.
Methods: The effects of estrogen on the development of arthritis were evaluated by performing an ovariectomy and E2 pellet implantation in the zymosan-treated SKG mouse. Clinical arthritis scores were measured and PET-CT was performed to quantify joint inflammation. Total RNA was extracted from the hindpaws and forepaws and the expression of TNFα, IL-6, IFNγ, IL-4, IL-17A, IL-23, Dkk1, and SOST was measured by QuantiGene 2.0 plex assay.
Results: Zymosan exposure triggered SpA-like diseases in SKG mice, including peripheral arthritis, spondylitis, dactylitis, enteritis, and psoriatic skin lesions. E2-treated mice showed remarkable suppression of arthritis clinically and little infiltration of inflammatory cells in the Achilles tendon and intervertebral disc. ^{18}F-FDG uptake was significantly lower in the E2-treated mice. The expression of TNFα, IFNγ, IL-17A, Dkk1, and SOST was significantly reduced in E2-treated mice compared with sham and ovariectomized mice.
Conclusions: Estrogen suppressed arthritis development in SpA model of SKG mouse. Results of the study suggest that estrogen may have an anti-inflammatory effect on the disease activity of SpA.

FRI0423 ANTIBODIES TO TYPE II COLLAGEN: A NOVEL TOOL FOR THE SPONDYLOARTHRITIS DIAGNOSIS?

C. Vinci[1,2], M. Infantino[3], P. Pozzilli[2], V. Grossi[3], M. Manfredi[3], F. Bandinelli[4], F. Li Gobbi[4], A. Damiani[4], R. Strollo[2], M. Benucci[4], A. Nissim[1]. *[1]Biochemical Pharmacology, Queen Mary University of London, London, United Kingdom; [2]Endocrinology and Diabetes, Campus Biomedico, Rome; [3]Immunology and Allergology Laboratory Unit; [4]Rheumatology Unit, San Giovanni di Dio Hospital, Florence, Italy*

Background: Spondyloarthritis (SpA) are an inflammatory joint disease with chronic, progressive, axial inflammation of the spine and the sacroiliac joints. Diagnosis of SpA is done criteria by clinical symptoms, radiology and MRI or ultrasound following ASAS criteria. AS is similar to rheumatoid arthritis (RA) and psoriatic arthritis (PsA) as they are all inflammatory joint disease. Nevertheless they show considerable different pathology. [1]
Objectives: The aim of our study is to test whether a novel assay that we developed for RA can be used for SpA diagnosis. We have previously showed that antibodies to oxidative post-translationally modified collagen type II (oxPTM-CII) are present specifically in RA patients whether ACPA positive or negative. [2]
Our study intends to investigate the reactivity to oxPTM-CII in SpA patients in comparison to early undifferentiated arthritis (EUA) and PsA patients.
Methods: oxPTM-CII were generated using ribose and various reactive oxidants, and then they were analysed by SDS-PAGE. Binding to native and oxPTM-CII was evaluated by ELISA and Western Blotting. We used a cohort of sera from 67 patients with SpA, 54 patients with PsA, 49 patients with EUA. As control we used 19 patients with fibromyalgia (FM) and 70 healthy subjects. The specificity of the binding was further assessed by competitive ELISA and western blot.
Results: We detected stronger reactivity to SpA compared to PsA and even EUA serum samples. Hence specific binding to oxPTM-CII was seen in the 52% of SpA sera compared to 12% in PsA and 10% in EUA. There was no binding in samples from FM and healthy individuals. A group of the most reactive SpA samples was evaluated by western blot confirming a strong binding to several fragments or aggregates of oxPTM-CII.
Conclusions: For the first time we demonstrated that anti-ROS-CII may become a biomarker for SpA diagnosis.

FRI0424 EQUAL PRESENCE OF CIRCULATING MAIT CELLS IN AXIAL SPA PATIENTS WITH ONLY AXIAL INVOLVEMENT AND AGE- AND SEX-MATCHED HEALTHY CONTROLS

S. Arends, W. Abdulahad, A. Boots, B. Doornbos-van der Meer, E. Brouwer, A. Spoorenberg. *Rheumatology and Clinical Immunology, University Medical Center Groningen, Groningen, Netherlands*

Background: Previous studies indicated a potential role for mucosal-associated invariant T (MAIT) cells in the pathogenesis of ankylosing spondylitis (AS).[1,2] Active peripheral arthritis and extra-articular manifestations may influence the presence of circulating MAIT cells in AS.
Objectives: To investigate circulating MAIT cells in a homogenous group of axial spondyloarthritis (SpA) patients with only axial involvement in comparison to age- and sex-matched healthy controls (HC). Secondly, to explore the association of MAIT cells with symptom duration and disease activity.
Methods: Consecutive axial SpA patients from the Groningen Leeuwarden axial SpA (GLAS) cohort without active peripheral arthritis, inflammatory bowel disease, psoriasis or uveitis were included. Patients with active infections or current use of biologics were excluded to rule out possible influence on the presence of circulating MAIT cells. Disease activity was assessed using ASDAS, BASDAI, and serum CRP levels.
The frequencies and absolute numbers of circulating MAIT cells were examined in peripheral blood of all studied samples by 5-color flow cytometry. Immediately after sampling, EDTA-blood was stained with anti-CD3, anti-CD8, anti-TCRVa7.2, anti-CD161, and anti-TCRgd. After staining, the cells were washed, fixed, and analyzed immediately on FACS. MAIT cells were identified phenotypically as $CD3^+CD8^+TCR\gamma\delta^-V\alpha7.2^+CD161^{high}$ cells.
Results: Of the 41 included axial SpA patients, mean age was 46±16 years, 73% were male, mean symptom duration was 23±14 years, and 78% were HLA-B27 positive. Mean ASDAS was 2.6±1.0, mean BASDAI was 4.4±2.5, and median CRP was 3 (range 2–30). 70%, 54% and 37% of axial SpA patients had ASDAS $\geq$2.1, BASDAI$\geq$4 or CRP$\geq$5, respectively. HC had exactly the same age and sex distribution.
Both the percentages and absolute numbers of circulating MAIT cells were comparable between axial SpA patients and HC (Figure 1). In axial SpA patients, absolute numbers of MAIT cells correlated negatively (rho=-0.339) with symptom duration. No significant associations were found between MAIT cells and disease activity, except for a negative correlation (rho=-0.332) between frequency of MAIT cells and BASDAI (Table 1). There were no significant differences in MAIT cells between axial SpA patients with and without active disease according to ASDAS, BASDAI or CRP.

Table 1. Association of percentages and absolute numbers of MAIT cells with symptom duration and assessments of disease activity in axial SpA patients (n=41), Spearman correlation coefficients

	% CD8+ MAIT	nr CD8+ MAIT
Symptom duration (yrs)	-0.248	-0.339*
$ASDAS_{CRP}$	-0.221	0.053
BASDAI (0–10)	-0.332*	-0.126
CRP (mg/l)	-0.137	0.030

*P-value <0.05.

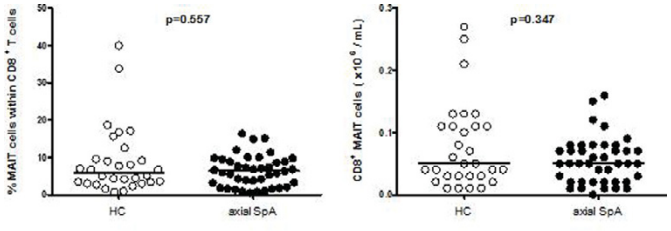

Figure 1. Percentages and absolute numbers of circulating CD8+ MAIT cells in axial SpA patients (n=41) and matched healthy controls (n=30), Mann-Whitney U tests.

Conclusions: In this homogeneous group of axial SpA patients with only axial disease, the presence of circulating MAIT cells did not differ from age- and sex-matched HC. No strong association was found between circulating MAIT cells and symptom duration or disease activity.

FRI0425 ANALYSIS OF CELLULAR COMPOSITION AND CYTOKINE EXPRESSION IN THE SUBCHONDRAL BONE MARROW IN ANKYLOSING SPONDYLITIS

E.E. Kenngott[1], J. Bleil[1], R. Maier[2], J. Sieper[1], U. Syrbe[1]. *[1]Rheumatology Campus Benjamin Franklin, Charité Universitätsmedizin Berlin; [2]Experimental Rheumatology, Deutsches Rheuma-Forschungszentrum, Berlin, Germany*

Background: Ankylosing spondylitis (AS) is characterized by inflammation within the sacroiliac joints and at the spine including vertebral bodies and facet joints. In AS, bone destruction is followed by new bone formation leading to ankylosis of joints and syndesmophyte development. Histological studies of bone material from AS patients showed subchondral bone marrow changes, namely the transition of the bone marrow into granulation tissue which facilitates subchondral bone destruction but also promotes local bone formation [1, 2]. Currently, it is unclear what promotes the transition of the bone marrow into the granulation tissue.
Objectives: The aim of this study was to look for changes in the subchondral bone marrow in joints from AS patients that may precede and promote transformation into granulation tissue. Therefore, we analyzed the cellular composition of the bone marrow and determined local cytokine expression at subchondral regions of AS facet joints.
Methods: Facet joints were acquired from AS patients undergoing polysegmental correction surgery and compared to joints from autopsy controls. We performed immunohistochemical stainings to determine the number of T cells (CD3) and B cells (CD20), macrophages (CD68, CD163), monocytes (CD14), dendritic cells (DC; CD1a, DCsign) and myelopoietic cells (MPO). To correct for putative differences in fat cell content, software assisted image analysis was used to calculate the area of bone marrow covered by fat cells and the number of nucleated cells (DAPI) as well as myeloid cells. Cytokine expression was determined by mRNA in situ hybridization (TNF, IFNg) or immunohistochemistry (TGFβ, IL-10).
Results: We observed no difference in the number of adaptive immune cells, i.e. CD3+ T and CD20+ B cells, between AS and control joints and found no difference in T/B cell aggregates. Furthermore, no difference in the number of macrophages (CD163+, CD68+) and DCs (CD1a+, DCsign+) was found. The only difference in cellular composition appeared to be a slight trend towards a higher percentage of myelopoietic MPO+ cells/DAPI+ cells in AS joints compared to control joints. The overall number of DAPI+ cells as well as the fat content of the bone marrow was not different between AS and control joints.
Concerning cytokines, TNF mRNA expression was in general low but significantly increased ($p<0.05$) in AS versus control joints. No difference was found for IFNg. The number of TGFβ expressing cells was similar in AS and control joints while the number of IL-10 positive cells was decreased ($p<0.01$) in AS joints.
Conclusions: The results show a shift from pro-inflammatory to anti-inflammatory cytokine expression within subchondral bone marrow sites in AS joints while no major change in the cellular distribution of the major leukocyte subsets is found. The shift in cytokine milieu may contribute to transformation of the bone marrow into granulation tissue. It would be interesting to determine the cellular source of local cytokines, such as of IL-10.

FRI0426 NO DEMONSTRABLE EFFECT OF IL-23 RECEPTOR VARIANTS ON CLINICAL MEASURES AND IL23/ IL-17 LEVELS IN ANKYLOSING SPONDYLITIS

J. Nossent[1,2], S. Johnsen[3], G. Bakland[2,4]. *[1]School of Medicine, University of Western Australia, Crawley, Australia; [2]Bone and Joint Group, Arctic University, Tromso; [3]Norwegian University of Life Sciences, Ås; [4]Rheumatology, University Hospital North Norway, Tromso, Norway*

Background: IL23 binding to IL23 receptor (IL23R) is necessary for the maturation of Th17 cells and generation of proinflammatory IL17 and TNF in AS. IL23R variants have considerable impact on AS susceptibility in genome-wide association studies.
Objectives: To describe the effect of genotypic IL23R variants on proinflammatory cytokines and disease measures in AS.
Methods: Cross sectional cohort study of patients with established AS (n=334, 90% B27 +, mean age at study 45 years) included in a disease registry. IL23R genotyping for nonsynonymous SNP's (rs11209026 (protective allele A) and rs11209032 (risk allele A) was done by Taqman RT-PCR, while IL23, IL17, IL6 and TNF levels determined by sandwich ELISA and compared with age and gender matched healthy controls (n=72). Genotypic associations with clinical and serological features were analyzed with nonparametric methods.
Results: There was no significant difference between in AS patients and controls

regarding IL23 (276 vs 262 pg/ml, p>0.4) and IL17 levels (184 vs 233 pg/ml, p>0.2). Only 22 (6.6%) AS patients carried the protective rs11209026 A allele, while 206 (61.7%) carried the rs11209032 A risk allele (p=0.03). There was no demonstrable influence of individual genotypes (A vs G, AA vs AG vs GG) or haplotypic combinations on BASFI, spinal function tests, CRP, ESR, IL-23 or IL-17 levels (all p>0.3)

Conclusions: While there is a high prevalence of the IL-23R rs11209032 A risk allele in Caucasian AS patients, this has no demonstrable bearing on clinical disease measures or serum IL-23 and IL-17 levels.

FRI0427 FIRST DESCRIPTION OF GAMMA DELTA T CELLS AT NORMAL HUMAN ENTHESIS

R.J. Cuthbert[1], E. Fragkakis[2], R. Dunsmuir[2], P. Giannoudis[1], E. Jones[1], D. McGonagle[1]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]Department of Spinal surgery, The Leeds teaching Hospitals NHS Trust, Leeds, United Kingdom*

Background: Recent animal studies have suggested that γδT-cells accumulate at enthesis, secrete IL-17 and are responsible for driving the spondyoarthritis (SpA) phenotype resulting from IL-23 overexpression in mice (1, 2). In humans examination of the immunological profile of enthesis has been hampered by lack of tissue. Recently, we used a novel strategy to show that group 3 innate lymphoid cells are present at the human enthesis (3). Here we extend our methodology to examine the broader immunological profile of human enthesis and to determine if γδT-cells are also present.

Objectives: To characterise γδT-cells at human enthesis and adjacent peri-entheseal bone

Methods: Human etheseal soft tissue (EST) and peri-entheseal bone (PEB) was harvested from normal spinous process in patients undergoing elective spinal orthopaedic procedures. Interspinous EST was dissected from PEB and enzymatically digested, followed by isolation of mononuclear cells. Flow cytometry was then used to determine the proportion of B-cells (CD45+, CD19+) NK cells (CD45+, CD3-, CD56+) and T-cells (CD45+, CD3+). T-cells were then sub divided based on expression of CD4 (T-helper cells), CD8 (Cytotoxic T-cells) and TCRγδ (γδT-cells). All entheseal data was compared to age-matched peripheral blood from healthy controls.

Results: Entheseal digests contained on average a lower proportion of T-cells compared to peripheral blood (p=0.018). However, the proportion of T-cells not expressing either CD4 or CD8 was greater in entheseal tissues (p=0.021), this population was largely composed of γδT-cells. As a proportion of T-cells γδT-cells were 6 fold more numerous in EST compared to peripheral blood (p=0.024), and PEB had 3 fold more. 37% of EST γδT-cells expressed CCR6 this compared to 26% and 34% in PEB and peripheral blood respectively.

Conclusions: γδT-cells are present in normal human enthesis and γδT-cells constitute a greater proportion of the T-cell pool compared to peripheral blood, making it likely that they represent a tissue resident population. Additionally, we observed a very similar proportion γδT-cells that expressed CCR6, a functional marker for IL-17 production, as was observed in mice (2). This is the first description of γδT-cells at the human enthesis and offers tentative confirmation of findings in mouse models where these cells play a key role in SpA pathogenesis.

FRI0428 THE JAK1-SELECTIVE INHIBITOR, FILGOTINIB, INHIBITS INFLAMMATION PATHWAYS OBSERVED IN AN IL23-INDUCED PSORIATIC ARTHRITIS MOUSE MODEL

R. Blanqué[1], M. Ongenaert[2], C. David[1], C. Robin-Jagerschmidt[1], A. Cauvin[1], C. Saccomani[1], P. Clement-Lacroix[1], S. Dupont[1], R. Galien[1]. *[1]Galapagos SASU, Romainville, France; [2]Galapagos NV, Mechelen, Belgium*

Background: Psoriatic arthritis (PsA) is a heterogeneous chronic inflammatory disease characterized by musculoskeletal involvement and extra-skeletal manifestations such as psoriasis, uveitis and Inflammatory Bowel Disease (IBD). The importance of several pro-inflammatory cytokines, in addition to TNFa, IL-12 and IL-23 which are targets of current treatments, suggests that novel therapies may benefit patients. The JAKs (a family of 4 non-receptor tyrosine kinases) are crucial for the signaling of many pro-inflammatory cytokines. In this regard, the JAK1-selective inhibitor filgotinib (GLPG0634, GS-6034) has shown efficacy in patients with rheumatoid arthritis (RA), a disease that shares some hallmarks with PsA, as well as in Crohn's disease (CD), making this molecule a potential therapy for PsA.

Objectives: To gain insight into filgotinib mode of action using a PsA preclinical model by analysing the gene expression signature of filgotinib in mouse phalanges and colon tissues from an IL23-induced PsA mouse model.

Methods: Spondyloarthopathy was induced by hydrodynamic injection of IL-23 enhanced Episomal Expression Vector (EEV). Animals were treated with filgotinib or vehicle from day 10 (therapeutic mode) and sacrificed after 16 days of treatment. RNAs were extracted from the phalanges and the proximal colon, and transcriptome assays were performed using the Agilent SurePrint G3 mouse chip. Data analysis was performed using empirical Bayes methods and linear models (limma BioConductor package).

Results: In mice, IL-23 induced changes in the transcriptome in both phalanges and colon that were marked by effects on genes related to the IL-23/T_H17 axis. Microarray analysis performed on mouse phalanges and colon revealed that filgotinib partially reversed the impact of IL-23 on gene expression in colon and in phalanges. In both tissues, filgotinib signature was different but some impacted biological programs were similar. A consistent interferon signature was counteracted by filgotinib in both tissues with decreased expression of common genes such as Apobec3, Gbp8, Iigp1 and Oas3. Several markers of inflammation or associated with IL-23 activitywere also decreased with common on Kynu and Cd96 gene expression in both tissues. Of interest, filgotinib repression on inflammatory gene expression was stronger in colon compared to phalanges (Il1b, Clec4e). Moreover expression of some genes involved in gut homeostasis that were induced by IL-23 were decreased by filgotinib in the colon, notably Fpr2 (receptor for formyl peptides) and Mmp7. In phalanges, gene expression associated with IL-23-induced disease was also reversed by filgotinib treatment. Il19, Mtcl1 and Tlr1 which are key mediators in psoriasis, or Rankl that is involved in bone remodeling in PsA were differently regulated by IL-23 and filgotinib.

Conclusions: Systemic expression of IL-23 in mice generated a PsA phenotype that was associated with altered gene expression in diseased tissues. A strong interferon signature was reversed by filgotinib as were several inflammation and disease markers. Together with the previous Phase 2 clinical results in RA and CD, these data support the study of filgotinib for the treatment of PsA patients.

FRI0429 DYSREGULATION OF THE SPLICING MACHINERY IN LEUKOCYTES FROM ANKYLOSING SPONDYLITIS PATIENTS IS ASSOCIATED TO DISEASE PATHOGENESIS

Y. Jimenez-Gomez[1], C. Lopez-Pedrera[1], S. Pedraza-Arévalo[2], M. del Río-Moreno[2], M.C. Ábalos-Aguilera[1], P. Ruiz-Limon[1], C. Perez-Sanchez[1], M.C. Castro[1], N. Barbarroja[1], I. Arias-de la Rosa[1], P. Font[1], A. Escudero[1], J.P. Castaño[2], R.M. Luque[2], E. Collantes-Estevez[1]. *[1]IMIBIC/Reina Sofia University Hospital/Cordoba University; [2]IMIBIC/Reina Sofia University Hospital/Cordoba University; CIBERobn and ceiA3, Cordoba, Spain*

Background: Ankylosing spondylitis (AS) is a chronic inflammatory disease, of unknown aetiology, associated to the development of several comorbidities such as atherosclerosis. Splicing is a post-transcriptional process involved in the RNA maturation. Recent studies have revealed that a pathological dysregulation of the splicing machinery or spliceosome is associated to several human diseases. Yet, the spliceosome alterations have not been described in AS.

Objectives: 1) To analyze whether dysregulation of the spliceosome is present in AS. 2) To evaluate the association between the alteration of this process and the clinical, inflammatory, oxidative, and atherogenic profiles present in this pathology.

Methods: Fourteen AS patients and 14 healthy donors (HDs) were included in the study. Disease function and activity status were analyzed using the BASFI and BASDAI. The expression of selected components of the major-(n=12) and minor-spliceosome (n=4), and splicing factors (n=28) was evaluated in purified monocytes, lymphocytes and neutrophils from patients and HDs (n=14 each) by Fluidigm methodology. Oxidative stress, inflammation and atherogenesis were evaluated by flow cytometry and RT-PCR. Endothelial function was determined by the post occlusive hyperaemia test using Laser-Doppler.

Results: Compared to HDs, a significant dysregulation in the expression of relevant splicing factors and spliceosome components was found in all the leukocyte subtypes from AS patients, being neutrophils which displayed higher number of altered molecules. Interestingly, a specific altered profile of major- and minor-spliceosome members, and splicing factors was observed when compared lymphocytes (U4, U6, NOVA1, RMB17), monocytes (PRP8, SF3B TV2, CELF4, ESRP2, RBM3, SAM68 TV1, SRSF10, TIA1) and neutrophils (U11, U2, U2AF2, U11, CA 150, ESRP1, PSF, PTB, SRM160).

Correlation studies revealed that disease activity (CRP, ESR, BASDAI) was associated to the alteration of a vast number of spliceosome components in the three subtypes of analyzed leukocytes. In addition, the BASFI index correlated with the expression of splicing factors ESRP1, SRSF1 and TRA2B in neutrophils. The inflammatory, atherogenic and oxidative profile of AS leukocytes was related to the expression of a number of spliceosome molecules in the three leukocyte subsets, although neutrophils exhibited the highest number of deregulated spliceosome components related to inflammation (STAT3, TNF-α, IL-1α, IL-1β, IL-5) and cell adhesion (ICAM-1, SELL, THBS4, CDH5). Finally, endothelial dysfunction correlated with the expression of several components of the major-spliceosome and splicing factors in monocytes and neutrophils.
Conclusions: 1) AS patients display a dysregulation of the splicing machinery components associated to disease function and activity. 2) The expression of spliceosome members in the different leukocyte subsets is related to the inflammatory, oxidative and proatherogenic profile of AS patients.
Alteration of the spliceosome may provide new biomarkers for diagnosis and clinical monitoring of AS

FRI0431 ALTERED EXPRESSION OF CIRCULATING MICRORNAS IS RELATED TO DISEASE ACTIVITY AND STRUCTURAL DAMAGE IN ANKYLOSING SPONDYLITIS PATIENTS

P. Font, C. Perez-Sanchez, P. Ruiz-Limon, C. Lopez-Pedrera, M.C. Castro-Villegas, M.C. Ábalos-Aguilera, N. Barbarroja, I. Arias-de la Rosa, M.D. Lopez-Montilla, A. Escudero-Contreras, C. Lopez-Medina, E. Collantes-Estevez, Y. Jimenez-Gomez. *Rheumatology Service, IMIBIC/Reina Sofia University Hospital/Cordoba University, Cordoba, Spain*

Background: Ankylosing spondylitis (AS) remains difficult to diagnose before irreversible damage to sacroiliac joint is noticeable. MicroRNAs (miRNAs) are a group of single-stranded non-coding RNAs of 20–25 nucleotides in length that can potentially regulate every aspect of cellular function. Recent studies have demonstrated that miRNAs can be detected in the circulation and serve as potential biomarkers of various inflammatory pathologies.
Objectives: To evaluate whether AS pathogenesis is related to the aberrant expression of plasma miRNAs.
Methods: The expression profile of 800 miRNAs in plasma was determined in pooled samples from AS patients and healthy donors (HDs) (n=3 each) using the nCounter technology. Next, candidate miRNAs were validated by real time RT-PCR in a cohort of AS patients and HDs (n=26 each). In parallel, the expression of validated miRNAs was examined in a cohort of 24 psoriatic arthritis (PsA) patients. To evaluate their relevance in the AS pathogenesis, an analysis was performed by using the web-based bioinformatics tool *Ingenuity Pathways Analysis* (IPA). Association and correlation studies of altered miRNAs with clinical and analytical profile of the AS patients were also performed. AS activity was defined as CRP >5 mg/L and/or BASDAI ≥4 and ESR >20 mm/h. Structural damage was evaluated by mSASSS.
Results: In discovery phase, nine miRNAs were differentially expressed (fold change ≥2) in the plasma of AS patients *vs.* HDs. After validation, higher expression levels of miRNA (miR)-146a-5p, miR-125a-5p, miR-151–3p and miR-22–3p, and lower of miR-150–5p and miR-451a were found in AS *vs.* HDs. Interestingly, higher miR-146a-5p, miR-125a-5p, miR-151–3p and miR-22–3p expression levels in AS than in PsA patients were further observed. The areas under the curve, generated to assess the accuracy of miRNAs as diagnostic biomarkers for AS, ranged from 0.717 to 0.798; the six-miRNAs signature reached 0.947. Bioinformatics analysis revealed that miRNAs targeted inflammatory and bone remodeling genes, underlying their potential role in this pathology. Indeed, correlation studies showed an association between these six miRNAs and potential target proteins associated to AS pathophysiology. In addition, miR-146a-5p, miR-146a-5p, miR-125a-5p and miR-22–3p expression was increased in active *vs.* non-active patients. Moreover, miR-150–5p and miR-451a expression was related to the presence of syndesmophytes in AS patients, underlying their association with structural damage.
Conclusions: 1) Several miRNAs are found differentially expressed in plasma from AS patients vs. HDs and other chronic inflammatory pathologies as PsA, indicating that these miRNAs may be considered potential biomarkers for AS diagnose. 2) The differential expression of certain miRNAs is associated to disease activity and structural damage. Overall, this study identified a six-plasma miRNAs signature that could be attractive candidates as non-invasive biomarkers for the AS diagnosis, and may help to elucidate the disease pathogenesis.

Spondyloarthritis - clinical aspects (other than treatment)

FRI0430 DUAL TRAJECTORIES OF DISEASE ACTIVITY AND HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH ANKYLOSING SPONDYLITIS

A. van Tubergen[1], M. Imkamp[1,2], A. Boonen[1], S. Arends[3,4], M. Dougados[5], R. Landewé[6], S. Ramiro[7], F. van den Bosch[8], D. van der Heijde[7], F. Wink[4], A. Spoorenberg[3,4], V. Lima Passos[2]. *[1]Maastricht University Medical Center; [2]University Maastricht, Maastricht; [3]University Medical Center Groningen, Groningen; [4]Medical Centre Leeuwarden, Leeuwarden, Netherlands; [5]Hôpital Cochin, Paris, France; [6]Amsterdam Medical Center, Amsterdam; [7]Leiden University Medical Center, Leiden, Netherlands; [8]Ghent University Hospital, Ghent, Belgium*

Background: The ultimate goal of managing Ankylosing Spondylitis (AS) is to improve and maintain the patient's health-related quality of life (HRQoL). To reach this goal, rheumatologists target towards low disease activity, as this is the main modifiable factor. To date, there is insufficient insight into (1) the co-evolution of disease activity and HRQoL, and (2) the heterogeneity in such trajectories among patients.
Objectives: To explore the heterogeneous character of AS by identifying different temporal patterns of co-dependence between disease activity and HRQoL over 8 years follow-up.
Methods: Data from Outcome in AS International Study (OASIS; n=161) and Groningen Leeuwarden AS (GLAS; n=264) cohorts were used. All patients had an established diagnosis of AS. In GLAS, all patients started a biological. HRQoL and disease activity were measured bi-annually using ASQoL and ASDAS-CRP

Figure 1. Joint trajectory latent classes of ASQoL - ASDAS

A-B Spaghetti plots of observed, subject-specific ASQoL and ASDAS lines over a period of 8 years, colored according to their final latent class assignment. Note that each class is represented by both an ASQoL and an ASDAS trajectory.

C-D Estimated average trajectories' lines, corresponding 95% confidence bands and baseline prevalence.

Abstract FRI0430 – Table 1. Baseline characteristics of patients within each ASQoL-ASDAS trajectory

Characteristics	Trajectory 1 (N=55)	Trajectory 2 (N=105)	Trajectory 3 (N=86)	Trajectory 4 (N=124)	Trajectory 5 (N=55)	p-value
Age – yr	43.9±12.4	46.0±12.7	40.9±10.7	47.9±11.3	45.1±13.7	<0.01*
Male sex (%)	46 (83.6)	71 (67.6)	62 (72.1)	83 (66.9)	29 (52.7)	0.01*
Smoking – yes (%)	16/42 (38.1)	23/85 (27.1)	26/74 (35.1)	44/98 (44.9)	20/46 (43.5)	0.13
HLAB27 – positive (%)	50/54 (92.6)	73/103 (70.9)	72/82 (87.8)	94/119 (79.0)	44/55 (80.0)	0.01*
Symptom duration – yr	20.3±10.9	21.4±12.1	17.0±10.9	22.2±13.1	21.3±12.6	0.04*
(Bridging) syndesmophytes present (%)	16/39 (41.0)	45/73 (61.6)	38/70 (54.3)	64/90 (71.1)	18/34 (52.9)	0.02*
Start biological (%)	15/54 (27.8)	41/101 (40.6)	81/86 (94.2)	85/120 (70.8)	35/55 (63.6)	<0.01*

respectively. Patients were classified into latent groups with individuals following a similar course of disease activity and HRQoL. These trajectories were estimated by Group-Based Trajectory Modelling. Next, the trajectories were profiled by comparing the latent groups with respect to baseline factors with ANOVA and Chi-square test.

Results: Five dual trajectories were revealed (Figure): 1. Low impact of AS on patient (13%): stable low ASQoL and ASDAS inactive disease; 2. Moderate impact (24%): stable moderate ASQoL and ASDAS high disease; 3. Improving impact (21%): major improvement in ASQoL and ASDAS; 4. High impact (29%): moderately severe ASQoL with very high but improving ASDAS; 5. Very High Impact (13%): persistently severe ASQoL with high ASDAS. Low impact of AS was mainly characterized by male gender and HLA-B27; improving impact by younger age, short symptom duration, and biological intake; high impact by higher age, long symptom duration, and (bridging) syndesmophytes (Table).

Conclusions: We identified five dual trajectories of disease activity and HRQoL, each demonstrating a clear mutual relationship. These trajectories and their profiles provide insight into the heterogeneity of the impact of AS on patients' health and overall functioning.

FRI0432 CLINICAL WORSENING ACCORDING TO THE PATIENT IS INFREQUENT IN AXIAL SPONDYLOARTHRITIS: RESULTS OF THE ASAS-FLARE STUDY IN 1169 PATIENTS

A. Moltó[1], B. Meghnathi[1], L. Gossec[2], R. Landewé[3], D. van der Heijde[4], M. Dougados[1] on behalf of ASAS-FLARE study group. *[1]Paris Descartes University, Medicine Faculty; APHP, Rheumatology B Department, Cochin Hospital; [2]Sorbonne Universités, UPMC Univ Paris 06; AP-HP, Pitié Salpêtrière Hospital, Department of rheumatology, Paris, France; [3]Department of Clinical Immunology & Rheumatology, Amsterdam Rheumatology Center, Amsterdam and Zuyderland Medical Center, Heerlen; [4]Department of Rheumatology, Leiden University Medical Centre, Leiden, Netherlands*

Background: Prevalence of flares/worsening of the disease in axSpA is not well known, with prevalences ranging from 10 to 40%.

Objectives: To evaluate the prevalence of disease worsening according to the patient's perception in an axSpA population with stable disease and its correlation with disease activity parameters.

Methods: Study: International multicentric (20 countries) longitudinal (2 visits: 1 week – 6 months) observational in 2016, under the guidance of ASAS. Patients: axSpA patients with stable disease according to the rheumatologist. Data on disease characteristics were collected at baseline, and data on disease activity were collected at both visits. Disease worsening was defined at the follow-up visit by the patient using the MCID question ("*Think about all the ways your spondyloarthritis has affected you during the last 48 hours. Compared to the last visit how did you feel during the last 48 hours? Improved/No change/Worse")*. If patients answered "worse", they marked if they considered themselves in an acceptable symptoms state (PASS) and whether they considered treatment intensification was necessary. Analyses were descriptive and changes in disease activity were calculated according to patient-reported worsening.

Results: Among the 1639 patients included, 1169 patients had complete data. Patients were predominantly males (64.8%), had a mean age and disease duration of of 41.7 (SD 12.4) and 12.6 (9.9) years, respectively. History of X-ray sacroiliitis, MRI sacroiliitis and HLAB27+ were present in 944 (80.8%), 471 (40.6%) and 807 (69.0%) patients, respectively. 56% (n=655) patients were receiving a biologic treatment. At the baseline visit, mean BASDAI (0–10) was 3.1 (2.3), mean ASDAS 2.3 (1.0) and mean CRP 8.4mg/L (14.5). Mean interval between both visits was 91.2 (51.0) days. At the follow-up visit, 590 (50.5%), 388 (33.2%) and 191 (16.3%) patients considered their condition had improved, not changed and worsened, respectively. Among the 191 patients reporting a worsening, 123 (64.4%) considered their symptom status unacceptable, and 127 (66.5%) judged their state required treatment intensification. BASDAI, ASDAS and CRP significantly increased in patients considering themselves worsening (Table).

	Worsening	Not worsening**	*p*
Change in BASDAI (0–10)*	1.3 (1.8)	-0.5 (1.5)	<0.005
Change in ASDAS*	0.7 (0.8)	-0.3 (0.8)	<0.005
Change in CRP (mg/l)*	4.5 (14.1)	-2.0 (13.2)	<0.005

*Change is calculated as the absolute change between the visits; ** including improvement and no change in status.

Conclusions: in this real-life study of stable axSpA, worsening, as defined by the patient, was not frequent, but was significantly associated with increase in disease activity measures, including objective parameters such as CRP and not only patient-reported outcomes.

FRI0433 HIGH PREVALENCE OF HIDRADENITIS SUPPURATIVA IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

S. Arends[1,2], A. Rondags[3], F. Wink[2], B. Horváth[3], A. Spoorenberg[1,2]. *[1]Rheumatology and Clinical Immunology, University Medical Center Groningen, Groningen; [2]Rheumatology, Medical Center Leeuwarden, Leeuwarden; [3]Dermatology, University Medical Center Groningen, Groningen, Netherlands*

Background: Axial spondyloarthritis (SpA) is associated with several extra-articular manifestations such as the skin disease psoriasis. On the other hand, SpA was found to be more prevalent (3–4%) in patients with another skin disease: hidradenitis suppurativa (HS).[1] HS is a chronic, recurrent, debilitating inflammatory skin disease that involves deep-seated painful nodules in the inverse body regions, with an average prevalence of 1% in the European population and a female predominance (ratio 3:1).[2] Thus far, the prevalence of HS in axial SpA is not exactly known.

Objectives: To investigate the prevalence of HS in patients with axial SpA.

Methods: A self-screening questionnaire with validated questions concerning HS signs and symptoms including prototypical pictures was send to all participating patients from the Groningen Leeuwarden axial SpA (GLAS) cohort in 2016. All patients fulfilled the ASAS axial SpA criteria. Self-reported HS symptoms were verified by checking medical records and/or verification by phone, defined as diagnosis of HS by a dermatologist.

Results: In total, 588 questionnaires were send to the GLAS patients, of which 459 were returned and could be included in the final analysis (response rate 78%). Of the included patients, mean age was 50±13 years, 63% were male, mean symptom duration was 23±13 years, and 78% were HLA-B27 positive.

The questionnaire data showed a high self-reported HS prevalence of 11%. HS symptoms were confirmed by doctor's diagnosis in the large majority of these patients (41/50; 82%), resulting in an estimated HS prevalence of 9%.

The next step will be the comparison of patient characteristics and clinical assessments between axial SpA patients with and without HS.

Conclusions: The present observational cohort study shows that HS is a common skin disease in patients with axial SpA.

FRI0434 POOR QUALITY OF LIFE IN PATIENTS WITH SPONDYLOARTHRITIS IS NOT EXPLAINED BY STRUCTURAL DAMAGE. DATA FROM REGISPONSER

C. López-Medina, P. Font-Ugalde, J.L. Garrido-Castro, M.C. Castro-Villegas, J. Calvo-Gutiérrez, R. Ortega-Castro, A. Escudero-Contreras, E. Collantes-Estévez on behalf of REGISPONSER working group. *Rheumatology, Hospital Universitario Reina Sofía de Córdoba/ Imibic/ Universidad de Córdoba, Córdoba, Spain*

Background: In recent years it has become increasingly important the evaluation of the global impact of the disease in patients with Spondyloarthritis (SpA) through the use of the Patient-reported Outcomes (PROs) (1). One of the most used PROs is the Ankylosing Spondylitis Quality of Life (ASQoL) questionnaire, which refers to Health-Related Quality of Life (HRQoL). Since this is a subjective and multifactorial outcome (2), our goal is to detail the most important factors which are related with the Quality of Life (QoL) in these patients.

Objectives: To evaluate QoL in patients with SpA and to define its association with disease-related factors and patient's features.

Methods: A cross-sectional multicenter study which includes 2229 patients with SpA selected from the national Spondyloarthropaties Spanish Registry (REGISPONSER). The main outcome was the assessment of QoL performed through the ASQoL questionnaire. Subsequently, we studied its relation with different factors organized into 5 groups: sociodemographics, emotional, functionality, disease-related factors and disease activity. Univariate logistic regressions and a multiple linear regression (considering ASQoL as a qualitative dichotomous and quantitative variable respectively) were performed to relate QoL with the studied covariates.

Results: The mean ASQoL score in the entire population studied was 6.09±5.12. The average age was 47.74±13.26 years old and 698 (31.31%) were women.

In univariate logistic regressions, significant differences ($p<0.05$) were seen in many variables included in the 5 groups: poor QoL (ASQoL$\geq$9) is related with gender (female), age, mental and physical component from SF-12 questionnaire, disease duration, inflammatory back pain (IBP), alternating buttock pain, BASRI (Bath Ankylosing Spondylitis Radiographic Index), BASFI (Bath Ankylosing Spondylitis Functional Index), BASDAI (Bath Ankylosing Spondylitis Disease Activity Index), ESR (Erythrocyte Sedimentation Rate) and global patient's VAS (Visual Analogue Scale), among others.

Finally, multivariate linear regression showed that 61.1% of the variability of ASQoL (R^2 =0.611, $p<0.001$) is explained by sex (female), physical component and 2nd item form SF-12 questionnaire (related to functionality), 6th and 7th items form SF-12 (both related to mental status), global patient's VAS, BASFI and BASDAI.

Conclusions: Poor QoL in SpA patients can be explained by high disease activity

and by a deterioration in functionality and mental status. However, clinical form of SpA, disease duration and structural damage in spine do not explain this decrease of QoL.

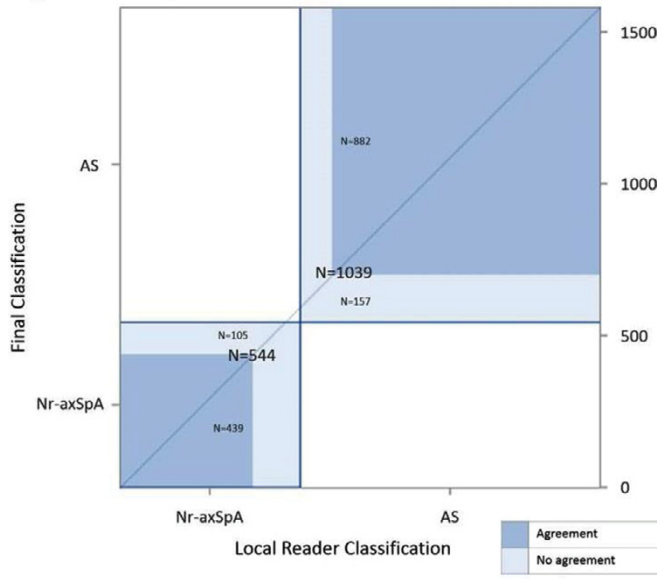
FRI0435 COMPARISON BETWEEN CENTRAL AND LOCAL ASSESSMENT OF RADIOGRAPHIC SACROILIITIS IN PATIENTS WITH RECENTLY DIAGNOSED AXIAL SPONDYLOARTHRITIS IN PROOF STUDY

D. Poddubnyy[1], R.D. Inman[2], J. Sieper[1], H. Haibel[1], M. Hojnik[3]. *[1]Charité Universitätsmedizin Berlin, Berlin, Germany; [2]Toronto Western Hospital, Toronto, Canada; [3]AbbVie, Ljubljana, Slovenia*



Background: High inter-reader variability of radiographic sacroiliitis assessment has been reported in a number of previous studies, suggesting its low reliability for the diagnosing and classification of axial spondyloarthritis (axSpA).

Objectives: To compare the results of local versus central scoring of radiographic sacroiliitis in a large multinational cohort of patients (pts) with recently diagnosed axSpA.

Methods: PROOF is a prospective observational study evaluating clinical and radiographic outcomes in axSpA pts in rheumatology clinical practice in 29 countries. Pts with axSpA fulfilling ASAS classification criteria were eligible if diagnosed ≤1 year prior to study enrolment. Radiographs of sacroiliac joints (SIJ) collected at baseline were graded according to the modified New York (mNY) criteria (0–4 for each SIJ). Pts with sacroiliitis of grade ≥2 bilaterally or grade ≥3 unilaterally were classified as ankylosing spondylitis (AS); otherwise pts were classified as non-radiographic axSpA (nr-axSpA). All available radiographs were assessed first by a local reader (LR) and then by a central reader (CR1), who was blinded to the results of the LR. In the case of a disagreement in the classification (AS or nr-axSpA), the radiograph was evaluated by the 2nd central reader (CR2), who was blinded to the previous assessments and the final classification was made based on the decision of 2 out of 3 readers.

Results: Of the 2126 pts enrolled in PROOF, 1583 were included in this analysis based on evaluable radiographs of the SIJ. Based on the LR judgment, 987 pts were classified as AS and 596 as nr-axSpA, while 1158 were classified as AS and 425 as nr-axSpA according to CR1. Following CR1 assessment, 1146 (72.4%) pts retained their LR classification, while 437 (27.6%) pts were classified differently. Of the 437 pts with discrepant classification assessed by CR2, 175 (40%) retained their initial LR classification and 265 (60%) were re-classified. The agreement between the CR1 and CR2 (kappa=0.24 [95% CI: 0.17–0.32]) was lower than between LR and CR1 (kappa=0.38 [95% CI: 0.33–0.42]). Finally, 1039 pts were classified as AS and 544 as axSpA; 1321 (83.5%) pts retained their initial classification and 262 (16.5%) were re-classified (157 from nr-axSpA to AS and 105 from AS to nr-axSpA). There was a substantial agreement between local and final central classification (kappa=0.64 [95% CI: 0.60–0.68], Figure). Importantly, pts initially classified by a LR as nr-axSpA (157/596, 26.3%) had significantly higher odds (odds ratio=3.0 (95% CI: 2.3–3.9) of being re-classified compared with pts classified as AS (105/987, 10.6%).

Figure. Final Classification of Patients with axSpA in Relation to Their Initial Local Classification in the PROOF Study Based on the Assessment of the Radiographic Changes in the Sacroiliac Joints.

AS = ankylosing spondylitis; nr-axSpA = non-radiographic axial spondyloarthritis.

Conclusions: In the PROOF study, the agreement between local and central classification of pts with axSpA (nr-axSpA vs AS) based on the grading of SIJ radiographs by mNY criteria was reasonably good. Pts locally classified as nr-axSpA were three times more likely to be re-classified compared with AS pts, which may be related to difficulty in the assessment of less advanced structural changes.

FRI0436 CHRONIC PAIN IN PATIENTS WITH ESTABLISHED AXIAL SPONDYLOARTHRITIS AND ASSESSMENT OF PAIN SENSITIVITY BY COMPUTERIZED PNEUMATIC CUFF PRESSURE ALGOMETRY: RESULTS FROM THE SPARTAKUS COHORT

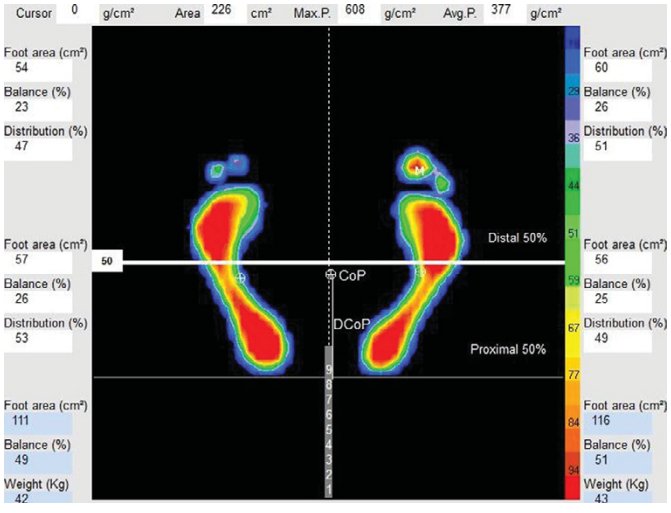
E. Mogard[1], T. Olofsson[1], A. Bremander[2], S. Bergman[3], L.-E. Kristensen[4], J. Kvistgaard Olsen[4], J.K. Wallman[1], E. Lindqvist[1]. *[1]IKVL, Department of Rheumatology, Lund University, Lund; [2]School of Business, Engineering and Science, Halmstad University, Halmstad; [3]Primary health care unit, Department of Public Health and Community Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [4]The Parker Institute, Department of Rheumatology, Copenhagen University Hospital Fredriksberg and Bispebjerg, Copenhagen, Denmark*

Background: Pain is a common symptom in all arthritides, and remains a problem also with better treatment options. In axial spondyloarthritis (ax-SpA), data on chronic pain remain scarce.

Objectives: To study pain distribution, duration and intensity in ax-SpA, and relate this to disease status and measurement of pressure pain sensitivity.

Methods: Consecutive patients (n=115) with clinical ax-SpA diagnoses (ankylosing spondylitis (AS) or undifferentiated axial spondyloarthritis (USpA)) were examined and answered pain questionnaires. Patients were categorised as having no chronic pain (NCP), chronic regional pain (CRP) or chronic widespread pain (CWP). Pressure pain sensitivity was assessed by computerized pneumatic cuff pressure algometry (CPA) on the dominant lower leg, and pain threshold, pain tolerance and temporal summation (assessed by the temporal summation index, TSI) were recorded. Differences in disease status and pressure pain sensitivity between patients with CWP versus NCP were assessed (Chi-square or Mann-Whitney U-test). Pressure pain sensitivity was also compared between patients with/without unacceptable pain levels (VAS pain >40 versus ≤40; Mann-Whitney U-test).

Results: Fifty percent of patients reported CWP, irrespective of clinical diagnosis (AS 47%, USpA 53%), and more women than men reported CWP (59% versus 37%, p<0.001). Only 18% of all patients reported NCP. Overall, higher disease



Mean (SD) unless indicated	All cases n=115	Non chronic pain (NCP) n=20	Chronic regional pain (CRP) n=38	Chronic widespread pain (CWP) n=57	NCP vs CWP p value

AS/USpA (ICD-10) n	60/55	13/7	19/19	28/29	0.299
VAS pain, 0–100	37 (27)	15 (18)	32 (26)	49 (24)	<0.001
VAS global	38 (26)	19 (22)	32 (26)	48 (22)	<0.001
VAS fatigue	40 (28)	23 (23)	33 (28)	51 (26)	<0.001
BASDAI	3.5 (2.3)	1.6 (1.6)	3.0 (2.0)	4.9 (2.1)	<0.001
BASFI	2.5 (2.4)	1.1 (1.4)	1.8 (2.3)	3.7 (2.4)	<0.001
BASMI	3.1 (1.6)	2.9 (1.6)	2.9 (1.9)	3.3 (1.4)	0.255
ASDAS-CRP	2.1 (1.0)	1.2 (0.7)	1.8 (0.9)	2.7 (0.8)	<0.001
Pain threshold ,kPa	30.1 (14.4)	33.7 (18.1)	30.7 (11.5)	27.8 (14.8)	0.216
Pain tolerance, kPa	62.1 (26.5)	71.6 (29.5)	63.0 (25.0)	56.8 (25.6)	0.069
TSI	0.60 (0.59)	0.53 (0.46)	0.60 (0.57)	0.63 (0.66)	0.189

activity, pain intensity, worse fatigue, global health and function were observed among patients with CWP compared to those with NCP. There was a trend towards lower pain tolerance in patients with CWP compared to NCP (Table). Lower pain tolerance and higher TSI scores were observed among patients reporting VAS pain >40 versus those with VAS pain scores ≤40 ((mean (SD)) 51.9 (21.2) versus 68.1 (28.1), p=0.007; 0.73 (0.60) versus 0.55 (0.59), p=0.045).
Conclusions: In this population-based, cross-sectional study of established ax-SpA, chronic widespread pain was common, affecting 50% of the patients and generally associated with higher disease activity and worse function. CPA shows promising results regarding assessment of pain sensitivity, although larger studies are needed for more conclusive results.

FRI0437 EFFECTS OF ANKYLOSING SPONDYLITIS ON PLANTAR PRESSURE DISTRIBUTION

E. Mesci [1], N. Mesci [2], A. İçağasıoğlu [1]. *[1]Physical Therapy and Rehabilitation, Istanbul Medeniyet University Göztepe Education and Research Hospital; [2]Physical Therapy and Rehabilitation, Haydarpaşa Numune Education and Research Hospital, Istanbul, Turkey*

Background: It is considered that postural changes that occur in patients with ankylosing spondylitis (AS) are biomechanically compensated for by contribution from movements of hip, knee and ankle joints [1]. The effects of this phenomenon on the foot, the most distal segment of the kinetic chain, have not been fully elucidated.
Objectives: In the present study, our aim was to investigate possible changes in plantar load distribution in AS patients.
Methods: The study enrolled 30 AS patients diagnosed as per modified New York criteria and 30 healthy controls matched for age, gender and body mass index. Bath Ankylosing Spondylitis Metrology Index (BASMI), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Bath Ankylosing Spondylitis Functional Index (BASFI) scores were obtained for all patients. Using a foot pressure platform, the distance from the center of pressure (CoP) to the posterior heel line was measured in centimeters (cm) in both groups (DCoP) (figure 1). Percent total plantar load distribution over the proximal half and distal half of the foot was calculated.
Results: Mean DCoP distance was significantly shorter in AS patients 9.65±0.96 cm) in comparison to that of control group (10.41±0.89 cm) (p=0.011). While the percent total plantar pressure applied on proximal half of the foot was 60.46±7.62% in AS patients, it was only 55.95±6.21% in the control group (p=0.031). However, AS patients had less percent pressure applied on the distal half of the foot (39.53±7.62%) versus control patients (44.04±6.21%) (p=0.031). The mean ratio of the percent pressure distribution over the proximal half of the foot to the percent pressure distribution over the distal half of the foot was significantly greater in AS patients (1.64±0.62) compared to control group (1.31±0.35) (p=0.037).

Conclusions: Plantar pressure distribution seems to be displaced towards the heel in the sagittal plane due to biomechanical changes in patients with ankylosing spondylitis. This points out to the significance of the lower extremities in the compensation of postural changes in AS patients.

FRI0438 RISK FACTORS FOR UVEITIS IN PATIENTS WITH ANKYLOSING SPONDYLITIS: A RETROSPECTIVE COHORT STUDY

E.E. Lee, M.J. Kim, E.Y. Lee, Y.W. Song, E.B. Lee. *Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic Of*

Background: The uveitis is one of the most common extra-articular manifestation of ankylosing spondylitis (AS), occurring in 20–30% of the patients with AS. But it is not clear which factors are associated with the occurrence of uveitis in patients with AS.
Objectives: To evaluate the risk factors for uveitis in patients with AS.
Methods: A total of 1061 Korean patients who were diagnosed with AS at Seoul National University Hospital between January 2004 and December 2015 were evaluated in this study. Using electronic medical record review, the information on the occurrence of uveitis after AS diagnosis and the other demographic and clinical characteristic were obtained, which included age, gender, disease duration, previous history of uveitis, smoking status, Bath ankylosing spondylitis activity index, HLA-B27 positivity and level of serum inflammatory markers. After dividing the patients into those who experienced uveitis after AS diagnosis (uveitis group) and those who did not (non-uveitis group), the potential risk factors for the occurrence of uveitis were evaluated using univariable and multivariable logistic regression analysis. Receiver operating curve analysis was performed.
Results: Among the 1061 patients, 837 (78.9%) were male and their mean (SD) age was 27.9 (6.2) years. During the observation of 4231 patient-year, uveitis occurred in 142 (13.4%) patients (uveitis group). Patients in the uveitis group had longer disease duration than those in the non-uveitis group (10.0±6.6 vs. 8.2±6.2 years, p=0.003). The proportion of the patients with prior uveitis before diagnosis of AS or HLA-B27 positivity were higher in the uveitis group than those in the non-uveitis group. (58.5% vs. 12.1%, 95.7% vs.83.7%, respectively) There were no significant differences in ESR and CRP between the two groups. In the multivariable analysis, two most significant risk factors for new-onset uveitis was the prior uveitis before the diagnosis of AS (OR=11.18 [95% confidence interval (CI): 7.09–17.63]) and HLA-B27 positivity (OR=9.15 [95% CI: 1.23–68.41]). The area under the curve (AUC) of the final multivariable model was 0.809 (95% CI: 0.77–0.85).

Table 1. Risk factors for uveitis in patients with AS (n=1061)

	Uveitis group (n=142)	Non-uveitis group (n=919)	p-value
Males, n (%)	104 (73.2)	733 (79.8)	0.076
Age on symptom onset (years)	28.51±11.56	27.82±11.95	0.541
Disease duration (years)	10.03±6.60	8.22±6.21	*0.003
History of uveitis, n (%)	83 (58.5)	111 (12.1)	*<0.001
Smoking, n (%)	35 (25.0)	184 (20.3)	0.086
ESR (mm/h)	38.84±31.07	28.10±27.33	*0.001
CRP (mg/L)	1.93±2.70	1.60±2.61	0.216
HLA-B27, n (%)	135 (95.7)	764 (83.7)	*<0.001
†BASDAI	6.44±1.71	6.59±1.68	0.500

†BASDAI in AS patients who exposed to TNF inhibitors.

Multivariate analysis showed that history of uveitis and the presence of HLA-B27 as the final risk factors for the occurrence of uveitis.
Conclusions: Prior uveitis before the diagnosis of AS and HLA-B27 positivity were associated with the occurrence of uveitis. These results can be useful to predict occurrence of uveitis in patients with AS.

FRI0439 PSYCHIATRIC DISORDERS ASSOCIATED WITH ANKYLOSING SPONDYLITIS

F.G. Yurdakul, Y. Garip, R. Koçak Ulucaköy, E. Almaz, A. Uçkun, H. Bodur. *Physical Medicine and Rehabilitation, Ankara Numune Training and Research Hospital, Ankara, Turkey*

Background: Ankylosing spondylitis (AS) is an inflammatory rheumatic disease characterized by spinal and/or peripheral involvement, enthesitis, dactylitis, and several extra-articular manifestations. Chronic inflammation often leads to reduced spinal mobility and functional disability. The frequency of fatigue, sleep disturbance, and psychological problems has increased in AS patients (1,2).
Objectives: Although there are studies investigating depression and anxiety frequency in AS patients, different psychiatric disorders such as impulsivity, alexithymia and eating disorders have not been evaluated. The aim of this study is to investigate the frequency of different psychiatric disorders in AS patients, and to evaluate the relationship between these disorders with disease activity and functional status.
Methods: Patients with AS (n=70) and healthy controls (n=56) were included in the study. The *Ankylosing Spondylitis Disease Activity Score* (*ASDAS*), Bath Ankylosing Spondylitis Functional Index, Bath Ankylosing Spondylitis Metrology

Index (BASMI), pain visual analog scale, Beck depression scale, Beck anxiety scale, Barrat impulsiveness scale, Toronto alexithymia scale, Eating attitude test, fatigue, Ankylosing spondylitis quality of life, and Nothingam health profile were administered.

Results: The frequency of depression, anxiety and non planning impulsiveness were higher in patients with AS than in healthy controls ($p<0.05$), although no difference was found in terms of alexithymia, fatigue, and eating attitude. Depression and anxiety were correlated with high disease activity, fatigue, impaired physical functioning, and lower quality of life in the patients with AS. Non planning impulsiveness was correlated with fatigue and lower quality of life while there was no correlation with disease activity and functional impairment. BASMI scores were not associated with psychiatric disorders.

Table 1. Demographic characteristics and Psychiatric disorders in Ankylosing spondylitis and healthy controls

	Ankylosing spondylitis patients (n=70)	Healthy controls (n=56)	p
Age (year)	42.85±10.46	44.75±10.04	0.363
Male (%)	57.14%	51.78%	0.548
Beck depression score	13.88±8.99	9.78±8.34	0.006*
Beck anxiety score	14.58±10.02	10.53±8.99	0.014*
Barrat impulsiveness - attentional score	15.68±3.25	15.21±2.72	0.590
Barrat impulsiveness - motor score	19.62±4.28	18.92±4.23	0.301
Barrat impulsiveness - non planning score	26.00±4.57	24.78±3.77	0.021*
Toronto alexithymia score	54.84±12.86	54.32±11.12	0.644
Eating attitude score	21.74±11.18	22.01±13.24	0.488

*$P<0.05$.

Conclusions: Depression and anxiety were associated with disease activation, while impulsivity frequency was increased independently of disease activity. Reducing in the quality of life and functional competence due to the psychiatric disorders indicates that, AS patients may require a psychological care approach during the follow up.

FRI0440 PRESENCE OF BONE MARROW EDEMA ON MAGNETIC RESONANCE IMAGING OF THE SACROILIAC JOINTS IN MILITARY RECRUITS BEFORE AND AFTER 6 WEEKS OF INTENSIVE PHYSICAL TRAINING

G. Varkas[1,2], M. de Hooge[1], T. Renson[1], P. Carron[1,2], S. De Mits[3], G. Souverijns[4], D. Elewaut[1,2], F. Van den Bosch[1,2]. *[1]Department of Rheumatology, Ghent University Hospital; [2]VIB Inflammation Research Centre; [3]Department of Rehabilitation Sciences and Physical Therapy, Ghent University, Gent; [4]Department of Radiology, Jessa Ziekenhuis, Hasselt, Belgium*

Background: Studies have shown an increase of bone marrow edema (BME) on magnetic resonance imaging (MRI), especially in feet and ankles of professional athletes and in minimally active healthy controls after mechanical stress [1]. Although this has been described for several joints and across different sport activities, information concerning BME in the sacroiliac joints (SIJ) has not been studied. In axial spondyloarthritis (AxSpA), the presence of 1 BME lesion (characteristics typical for AxSpA) on 2 consecutive slices or 2 BME lesions on 1 slice is sufficient to fulfill the definition of a positive MRI as defined by ASAS. Although this definition should only be applied on MRI of symptomatic patients with suspicion of SpA, it is unknown whether BME lesions in healthy controls could meet this definition and therefore incorrectly be interpreted as BME in the context of SpA.

Objectives: Study the effect of intense physical training in healthy subjects on the presence of BME on MRI-SIJ, by investigating whether healthy subjects meet the ASAS definition of a positive MRI and whether this is modulated by mechanical stress.

Methods: Twenty-two military recruits underwent a MRI-SIJ before and after 6 week of intense and uniform physical training. BME lesions were scored by 3 trained readers (MdH, GV and TR) blinded for time sequence and clinical findings. Additionally, the agreement with the definition of a positive MRI defined by ASAS was evaluated. Regarding the number of lesions and fulfillment of the ASAS definition of positive MRI, a consensus was made by agreement of 2 out of 3 readers.

Results: In total, 86.4% (19/22) asymptomatic recruits were male (mean age of 25.0±0.8 years). At baseline, 40.9% (9/22) of recruits presented with at least one BME lesion, whereas this number increased to 50.0% (11/22) at week 6. Indeed, 3 recruits developed BME over time, whereas in one recruit the BME lesions disappeared over time. The mean number of BME lesions was 1.0 (±0.3) at baseline, compared to 1.9 (±0.7) at week 6. Median (25th, 75th percentile) BME lesions were 0.0 (0.0, 2.25) and 0.5 (0.0, 3.0) at respectively baseline and week 6 (P=0.109). Mean change in BME lesions was 0.9 (±0.6). When applying the ASAS definition of a positive MRI, BME was present in 22.7% (5/22) of recruits at baseline, and this increased to 36.4% at follow up, of which an additional 4 initially MRI negative recruits became MRI positive and one recruit no longer fulfilled the definition.

Conclusions: In this small exploratory study we could not find a statistically significant difference in BME on MRI-SIJ after 6 weeks of training. However, over 1/5 of asymptomatic recruits displayed BME lesions, that would meet the ASAS definition of a positive MRI, increasing to more than 1/3 at follow up. Thus, in young active patients, the interpretation of BME lesions should be cautious.

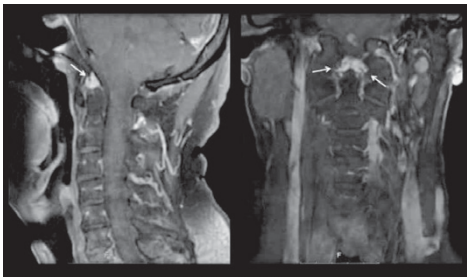
FRI0441 NECK PAIN IN ANKYLOSING SPONDYLITIS: FOCUS ON ACTIVE INFLAMMATION AT THE CRANIOCERVICAL JUNCTION ON MRI



G. Slobodin[1], I. Rosner[1], A. Awisat[1], D. Rimar[1], A. Shpigelman[2], D. Militianu[3]. *[1]Rheumatology; [2]Orthopedic Surgery, Bnai Zion Medical Center; [3]Radiology/Muskulosceletal Imaging, Rambam Medical Center, haifa, Israel*

Background: A wide spectrum of structural changes in the elements of craniocervical junction in patients with ankylosing spondylitis (AS) has been recently described in a retrospective study using computed tomography [1]. The clinical significance of these findings requires further elaboration.

Objectives: To explore and describe inflammatory MR imaging findings in the craniocervical junction in patients with AS and neck pain.

Methods: Eighteen patients with AS and continuing neck pain, as well as 9 patients with fibromyalgia of the same age and similar level of severity of neck pain, who served as a control group, underwent relevant rheumatologic examination, X-ray of cervical spine and MRI study, which included STIR, CUBE T2, FSE and FSE FAT SAT sequences before and after administration of gadolinium.

Results: In the AS group, 12 males and 6 females diagnosed by 1984 New York criteria, of median age 40.5 years (range 31–61 years) and median disease duration of 8 (range 1–35) years, with 13 under treatment with anti-TNF agents were studied. All patients suffered from neck pain, with median VAS of 7 (range 2.5–10). Range of neck spine motion was limited in all but 3 patients. Seven of 18 patients had evidence of cervical syndesmophytes on X-ray. In addition to expected findings of syndesmophytes, active inflammatory lesions were seen in MR imaging in two of 18 patients with AS and in none with fibromyalgia (Fig. 1). Both AS patients with positive MRI were on anti-TNF therapy during the study and did not have syndesmophytes at the cervical spine as also by X-ray films.

Sagittal and coronal FSE T1 FAT SAT images after gadolinium injection showing enhancement of apical and alar ligaments

Conclusions: Active inflammation of both entheses and joints of the craniocervical junction was demonstrated by MRI in some patients with AS and persistent neck pain. Active lesions at the craniocervical junction should be included in the differential diagnosis of neck pain in AS.

FRI0442 IDENTIFICATION OF ENTHESITIS AT THE ACHILLES TENDON INSERTION IN PATIENTS WITH ANKYLOSING SPONDYLITIS USING DIGITAL RADIOGRAPHY

I. Sung, S.-J. Kim. *Orthopedic Department, Hanyang University Medical Center, SEOUL, KOREA, Seoul, Korea, Republic Of*

Background: Posterior heel pain is a common symptom in the foot and ankle region, with many different causes that need to be distinguished by differential diagnosis. Among them is ankylosing spondylitis (AS), in which enthesitis of

the heel is common and occasionally is responsible for their initial symptom to seek clinics. An early or timely recognition of active enthesitis of AS from simple radiographs comes to be relevant issue.

Objectives: The purpose of current study is to assess measurement reliability and diagnostic validity for detecting the digital radiographic findings of enthesitis at the Achilles tendon insertion in patients with AS.

Methods: Current study is a blinded, matched, cross-sectional study with 44 patients (65 feet) having clinical enthesitis at the Achilles tendon insertion (Group I), and 44 healthy controls (65 feet) (Group II). Suggested findings of enthesitis including retrocalcaneal recess obliterations from retrocalcaneal bursitis, increased thickness in shadow of the Achilles tendon and posterior soft tissue at its insertion from the swellings of those soft tissues were assessed on digital radiographs of standing hindfoot lateral view, and their measurement reliabilities were determined. To investigate diagnostic validities, diagnostic odds ratio, sensitivity, specificity, positive likelihood ratio (PLR), and negative likelihood ratio (NLR) were estimated for radiographic findings of retrocalcaneal recess obliterations (RRO). For the thickness of the Achilles at its insertion (TAI) and swollen posterior soft tissue, the receiver operating characteristic (ROC) curve analysis was done.

Results: There were no significant differences between two groups in mean age, BMI and sex ratio. Intra- and inter-observer reliability of all measurements showed high degree of agreements (0.786 to 0.941). The diagnostic odds ratio of RRO for detecting enthesitis was 66.0. The sensitivity, specificity were 67.7%, 96.9%, and PLR, NLR were 22.0, 0.33, respectively. The mean TAI of Group I and II were 6.7mm±1.79, 5.01mm±0.81, respectively (p-value$<$0.001). Area under the ROC curve of the TAI was 0.806, and the optimal cut-off value predicting enthesitis was 5.47mm, and its sensitivity and specificity were both 72.3%.

Conclusions: Retrocalcaneal recess obliteration and thickened shadow of Achilles tendon at its insertion and swollen posterior soft tissue on digital radiographs of standing hindfoot lateral view are regarded as the easy and useful findings for enthesitis of the posterior heel. For searching enthesitis at the Achilles insertion in patients with AS, such findings from simple radiographs showed high measurement reliability and validity.

FRI0443 THE EFFECT OF FIBROMYALGIA ON DISEASE ACTIVITY IN PATIENTS WITH ANKYLOSING SPONDYLITIS

I. Shapoval, M. Stanislavchuk, K. Zaichko, L. Perebetiuk. *Internal Medicine, National Pirogov Memorial Medical University, Vinnytsya, Ukraine*

Background: Ankylosing spondylitis (AS) is a chronic inflammatory rheumatic disease that affects the axial skeleton and characterized by pain, stiffness and fatigue [4]. One of the frequent concomitant condition in patients with AS is fibromyalgia (FM). FM shares some common symptoms with AS. According to the many reports concomitant FM in patients with AS has been found in 5.7 - 41.3% cases [1, 2, 3, 5]. Due to the fact that pain is a major component of the disease activity scores of the AS (Ankylosing Spondylitis Disease Activity Index (BASDAI) and Ankylosing Spondylitis Disease Activity Score (ASDAS)), concomitant FM can significantly modify the disease activity in patients with AS.

Objectives: The aim of this study was to evaluate the effect of FM on disease activity in patients with AS.

Methods: Diagnosis of AS was identified according to the modified New York criteria (1984). FM was diagnosed by ACR criteria (1990). Disease activity was assessed by BASDAI and ASDAS.

Results: 80 patients with AS were included into study (15 females and 65 males), age (M ± SD) 41.64±11.4 years. Nineteen patients (23.8%) met the criteria for FM. Patients with AS and AS+FM were representative for age and disease duration. In both groups, ESR (37.7±18.8 and 39.00±19.6 mm/h) was comparable, while ASDAS and BASDAI were significantly different. The disease activity according to both scores was higher in patients with AS+FM. According to the BASDAI in patients with AS disease activity was 5.20±1.4 whereas in patients with AS and FM - 7.14±1.7; according to the ASDAS-ESR difference in disease activity was slightly lower, but remained significant (3.6±0.8 vs 4.2±0.9).

Conclusions: The obtained data indicates that concomitant FM is a frequent condition in patients with AS. Presence of FM in patients with AS significantly modifies the disease activity determined by ASDAS. The ASDAS-ESR is more appropriate for determining the disease activity comparing to BASDAI, because included in calculation ESR diminish the distorting effect of FM.

FRI0444 INCIDENCE OF INFLAMMATORY BOWEL DISEASE EVENTS IN ADALIMUMAB CLINICAL TRIALS ACROSS INDICATIONS

J.R. Curtis[1], D. Elewaut[2], S. Chen[3], M. Hojnik[4], N. Naveh[5], J.K. Anderson[3]. *[1]Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, United States; [2]VIB Inflammation Research Center, University of Gent, Gent, Belgium; [3]AbbVie Inc., North Chicago, United States; [4]AbbVie, Ljubljana, Slovenia; [5]AbbVie, Hod HaSharon, Israel*

Background: Adalimumab (ADA) is approved for treatment of Crohn's disease (CD) and ulcerative colitis (UC); therefore, it is postulated that new onset or flare of inflammatory bowel disease (IBD) is a rare occurrence in ADA clinical trials for non-IBD indications.

Objectives: The purpose of this analysis was to determine the rates of IBD adverse events (AEs) in ADA clinical trials, particularly in spondyloarthritis (SpA) patients (pts) who are at higher risk of IBD as a feature of SpA.

Methods: The rates of IBD AEs in 73 phase 2–4 interventional ADA clinical trials in rheumatoid arthritis (RA), polyarticular juvenile idiopathic arthritis (pJIA), pediatric enthesitis-related arthritis, uveitis (non-infectious intermediate, posterior, or pan-uveitis), hidradenitis suppurativa (HS), adult and pediatric psoriasis (Ps), psoriatic arthritis (PsA), non-PsA peripheral SpA (pSpA), non-radiographic axial spondyloarthritis (nr-axSpA), and ankylosing spondylitis (AS) were analyzed (trials in UC, CD, and intestinal Behcet's disease [BD] were excluded). The search criteria for IBD events included the following standardized MedDRA queries preferred terms: inflammatory bowel disease (IBD), ulcerative colitis (UC), Crohn's disease (CD), IBD-not otherwise specified (NOS), and ulcerative proctitis. The incidence rates (IR) for events of IBD (combined new onset and flare) in interventional clinical trials of ADA are reported as events per 100 pt-years (PY). 95% confidence intervals (CI) were based on exact Poisson confidence limits.

Results: ADA was administered to 23735 pts, representing 36404.6 PY of exposure. Overall, the IR for IBD events in all interventional ADA trials included in this analysis was 0.1/100PY (Table). The rates of IBD events varied across therapeutic indications from $<$0.1 to 0.8/100PY. There were no reports of IBD events in pediatric pts. The IR for IBD events in RA, uveitis, HS, and Ps trials were $<$0.1, 0.2, 0.4, and $<$0.1/100 PY. In SpA, the overall rates of IBD were 0.5/100 PY, while the rates were 0, 0.8, 0.5, and 0.7/100 PY in PsA, non-PsA pSpA, nr-axSpA, and AS, respectively. 2216 pts with axSpA (AS: 2026, nr-axSpA: 190) were exposed to ADA; in AS, 14 IBD events (7 new onset and 7 flares) were reported in 12 pts (7 new onset and 5 flares), while in nr-axSpA, 2 IBD events were reported in 1 pt (2 flares).

Table. Incidence of IBD events in patients from ADA clinical trials.

Indication	N (PYs)	All IBD AEs, n[§]	IR/100 PY (95% CI)
All ADA trials[†]	23735 (36404.6)	40	0.1 (0.1 – 0.2)
Rheumatoid Arthritis	15152 (24813.0)	16	<0.1 (0.0 – 0.1)
Uveitis	387 (538.8)	1	0.2 (0.0 – 1.0)
Hidradenitis suppurativa	733 (836.3)	3	0.4 (0.1 – 1.1)
Psoriasis	3500 (5268.7)	1	<0.1 (0.0 – 0.1)
All SpA[‡]	3218 (3919.9)	19	0.5 (0.3 – 0.8)
PsA	837 (997.5)	0	0.0 (0.0 – 0.4)
Non-PsA pSpA	165 (390.7)	3	0.8 (0.2 – 2.2)
All axSpA[?]	2216 (2531.7)	16	0.6 (0.4 – 1.0)
nr-axSpA	190 (412.2)	2	0.5 (0.1 – 1.8)
AS	2026 (2119.5)	14	0.7 (0.4 – 1.1)

[§]No IBD events were reported in pediatric patients.
[†]All ADA adult and pediatric patients in all interventional studies excluding Crohn's disease, ulcerative colitis, and intestinal Behcet's disease.
[‡]All ADA patients in all interventional studies of PsA, non -PsA pSpA, nr-axSpA, and AS.
[?]All ADA patients in all interventional studies of nr -axSpA and AS.
Abbreviations: IBD = inflammatory bowel disease; ADA = adalimumab; PY = patient years; AEs = adverse events; IR = incidence rates; CI = confidence interval; SpA = spondyloarthritis; PsA = psoriatic arthritis; pSpA = non-PsA peripheral spondyloarthritis; axSpA = axial spondyloarthritis; nr-axSpA = non-radiographic axSpA; AS = ankylosing spondylitis.

Conclusions: The rates of IBD AEs in ADA clinical trials were generally low across all indications, with all events occurring in adult pts. In AS pts, who are at increased risk of manifesting IBD, the rates of IBD for pts treated with ADA (0.7/100 PY [95% CI, 0.4–1.1]) were similar to published placebo rates pooled

across multiple clinical trials (1.3/100 PY [95% CI, 0.2–4.8]).[1] In pts at risk for IBD requiring biologic therapy, ADA is a reasonable therapeutic option based on the observed low IBD event rates in ADA clinical trials and its demonstrated efficacy in treating UC and CD pts.

FRI0445 FAECAL CALPROTECTIN, BUT NOT ANTI-SACCHAROMYCES CEREVISIAE ANTIBODIES, IS LINKED TO WORSE DISEASE STATUS IN AXIAL SPONDYLOARTHRITIS PATIENTS WITHOUT INFLAMMATORY BOWEL DISEASE: RESULTS FROM THE SPARTAKUS COHORT

T. Olofsson[1], E. Mogard[1], K. Andréasson[1], J. Marsal[2], M. Geijer[3], L.-E. Kristensen[1,4], E. Lindqvist[1], J.K. Wallman[1]. *[1]Department of clinical sciences Lund, Rheumatology; [2]Department of clinical sciences Lund, Gastroenterology, Lund University, Lund; [3]Department of Radiology, Faculty of Medicine and Health, Örebro University, Örebro, Sweden; [4]The Parker Institute, Department of Rheumatology, Copenhagen University Hospital, Frederiksberg and Bispebjerg, Copenhagen, Denmark*

Background: Inflammatory bowel disease (IBD) is a common comorbidity in axial spondyloarthritis.
Objectives: To study faecal calprotectin (F-calprotectin) levels and anti-*Saccharomyces cerevisiae* antibodies (ASCA) and their associations with disease status and gastrointestinal (GI) symptoms in axial spondyloarthritis.
Methods: Consecutive patients with a clinical axial spondyloarthritis diagnosis were examined and classified as non-radiographic axial spondyloarthritis (nr-axSpA; Assessment of SpondyloArthritis international Society [ASAS] criteria; n=26) or ankylosing spondylitis (AS; modified New York criteria; n=45). Only patients without known IBD were included. F-calprotectin and ASCA IgA and IgG antibodies in serum were measured by commercially available enzyme-linked immunosorbent assay kits (Calpro AS; ORGENTEC Diagnostika).
Results: Elevated levels of F-calprotectin (≥50 mg/kg) were observed in 15% of nr-axSpA and 40% of AS patients (non-significant difference, with reservation for small groups). Overall, worse mean disease activity/disability scores were observed among patients with elevated versus normal F-calprotectin levels (Table), whereas no association was seen between F-calprotectin and GI symptoms. Similar results remained after exclusion of patients with monoclonal antibody type anti-TNF therapy. Elevated levels of ASCA IgA were observed in 8%/2% of nr-axSpA/AS patients, and IgG in 28%/26%. Only 2 subjects were ASCA double positive. Neither disease activity/disability measures nor GI symptoms were associated with ASCA status.

	Nr-axSpA (n=26)	AS (n=45)	F-Calprotectin <50 mg/kg (n=38)	F-Calprotectin ≥50 mg/kg (n=18)	p-value*

VAS global	41 (21)	35 (25)	32 (25)	45 (16)	0.023
VAS pain	40 (23)	37 (28)	34 (26)	42 (23)	0.142
VAS fatigue	41 (28)	39 (27)	34 (28)	46 (21)	0.056
BASDAI	3.5 (1.7)	3.5 (2.6)	3.1 (2.3)	4.2 (2.3)	0.076
BASFI	1.9 (1.4)	3.0 (2.9)	2.2 (2.2)	3.9 (3.1)	0.029
ASDAS-CRP	2.0 (0.8)	2.2 (1.1)	1.8 (0.9)	2.6 (0.9)	0.034
CRP, mg/L	3.1 (3.0)	4.7 (4.6)	3.0 (2.7)	5.7 (5.5)	0.157
F-calprotectin, mg/kg	45 (64)	84 (117)	21 (13)	172 (129)	NA
ASCA IgA, E/ml	3.7 (7.3)	2.1 (1.9)	2.9 (5.8)	3.0 (3.8)	0.175
ASCA IgG, E/ml	10 (20)	6.5 (6.3)	6.9 (6.8)	11 (24)	0.854
Often stomach pain, y/n	17 (65%)	25 (56%)	23 (61%)	11 (61%)	0.967
Frequent defecation, y/n	7 (27%)	9 (20%)	9 (24%)	5 (28%)	0.741
Frequent diarrhoea, y/n	12 (46%)	12 (27%)	12 (32%)	8 (44%)	0.348

N (%) or mean (SD). *Chi^2/Mann-Whitney U-test for comparison of categorical/continuous variables between the F-calprotectin groups. Missing data: ASCA IgA/IgG 4%, F-calprotectin 21%. y/n, yes/no; 3m, 3 months; NA, not applicable.

Conclusions: Elevated levels of F-calprotectin and ASCA IgG antibodies are both common in axial spondyloarthritis patients without IBD, and elevated F-calprotectin may be a marker of more severe spondyloarthritis. Neither F-calprotectin nor ASCA levels were associated with self-reported GI symptoms.

FRI0446 PREVALENCE AND CHARACTERISTICS OF SPONDYLOARTHRITIS ACCORDING TO ASAS CRITERIA IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE – RESULTS FROM THE SPICE COHORT

J. Haschka[1,2], S. Hirschmann[3], A. Kleyer[1], M. Englbrecht[1], J. Zimmermann[1], F. Faustini[1], D. Simon[1], C.P. Figueiredo[1], A. Cavallaro[1,4], C. Muschitz[2], R. Kocijan[2], H. Resch[2], R. Atreya[3], J. Rech[1], M.F. Neurath[3], G. Schett[1]. *[1]Department of Internal Medicine 3, University of Erlangen-Nuremberg, Erlangen, Germany; [2]Medical Department 2, St. Vincent Hospital, The VINFORCE Study Group, Vienna, Austria; [3]Department of Internal Medicine 1, University of Erlangen-Nuremberg, Erlangen, Germany; [4]Div. of Rheumatology, Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil*

Background: Musculoskeletal symptoms are considered as one of the most frequent extra-intestinal manifestation in Inflammatory Bowel Disease (IBD) patients with a prevalence of up to 40% involving axial and/or peripheral joints. Data on the prevalence of musculoskeletal disease, in particular of SpA are limited and vary considerably due to different criteria the studies have used to define musculoskeletal disease in IBD patients.
Objectives: To define the prevalence of axial and peripheral spondyloarthritis (SpA) according to Assessment of Spondyloarthritis International Society (ASAS) in patients with Crohn's disease (CD) and ulcerative colitis (UC).
Methods: The SPICE cohort (Spondyloarthritis in Inflammatory Bowel Disease Cohort Erlangen) comprises prospectively recruited colonoscopy- proven Crohn's Disease (CD) or Ulcerative Colitis (UC) patients, who received a pre-defined and standardized musculoskeletal assessment by the rheumatologist. Duration and activity of gastrointestinal and rheumatic disease (axial and peripheral) was documented and fulfillment of ASAS classification criteria for axial and peripheral SpA was tested.
Results: 102 IBD patients (62 with CD and 40 with UC) with a median (IQR) disease of 11.0 (18.0) years were assessed. 38.2% fulfilled ASAS criteria for SpA with no difference between CD and UC. ASAS axial SpA criteria were fulfilled by 12%, ASAS peripheral SpA criteria by 31.4% of the IBD patients. Inflammatory back pain was present in 24.5% with MRI signs of sacroiliitis in 48% of IBD patients with inflammatory back pain. Disease activity according to ASDAS-CRP was moderate to high in 91% of the patients with axial SpA. Peripheral arthralgia was present in 71.6%, while arthritis was found in 18.6% of the IBD patients.
Conclusions: Both major forms of IBD show a similar burden of musculoskeletal disease. More than one third of inflammatory bowel disease patients show axial or peripheral SpA according to ASAS criteria. Peripheral SpA is more commonly found than axial SpA.

FRI0447 SEVERITY OF SACROILIITIS AND ERYTHROCYTE SEDIMENTATION RATE ARE ASSOCIATED WITH A LOW TRABECULAR BONE SCORE IN YOUNG MALE PATIENTS WITH ANKYLOSING SPONDYLITIS

K.Y. Kang. *Division of Rheumatology, Internal Medicine, Catholic University of Korea, Seoul, Korea, Republic Of*

Background: The trabecular bone score (TBS) is a novel method used to evaluate bone microarchitecture. To date, the risk factors associated with a low TBS in AS are unknown and no study has examined the association between TBS and vertebral fracture in ankylosing spondylitis (AS) patients.
Objectives: To examine factors related to a low trabecular bone score (TBS) and the association between TBS and vertebral fracture in patients with (AS).
Methods: One hundred patients (all male, aged <50 years) who fulfilled the modified New York criteria for the classification of AS were enrolled. The TBS and bone mineral density (BMD) were assessed using dual-energy X-ray absorptiometry (DXA). Clinical variables, inflammatory markers, and the presence of vertebral fracture were also assessed. Spinal radiographic progression was measured using the Stokes AS spine score (SASSS). Multivariate linear regression analysis was performed to identify factors associated with TBS.

Results: The mean TBS at the lumbar spine was 1.38±0.13. The TBS showed a negative correlation with disease duration and inflammatory markers, and a positive correlation with BMD at the lumbar spine, femoral neck, and total hip. It also showed a negative correlation with sacroiliitis grade. BMD at the lumbar spine positively correlated with SASSS, whereas TBS showed a negative correlation. A significant decrease in TBS values was observed in patients with spinal radiographic progression (p=0.001). Multivariate analysis showed that ESR and sacroiliitis were independently associated with TBS (p=0.006 and <0.001, respectively). Ten patients had morphometric vertebral fractures. The mean TBS was lower in patients with vertebral fracture than in age-matched patients without fracture (p=0.028).
Conclusions: The TBS in young male patients with AS is associated with the ESR and severity of sacroiliitis. The TBS may be useful as a tool for assessing osteoporosis in AS.

FRI0448 EVALUATION OF SUPPURATIVE HIDRADENITIS IN PATIENTS WITH CHRONIC ARTHRITIS TREATED WITH FULL AND TAPERED BIOLOGICAL DISEASE-MODIFYING ANTIRHEUMATIC DRUGS

L. Valor, D. Hernández-Flórez, T. del Río, J.G. Ovalles B, J. Martínez Barrio, I. Janta, B. Serrano, J.C. Nieto, M. Correyero Plaza, L. Garcia Montoya, C. González, F.J. López-Longo, I. Monteagudo. *Hospital General Universitario Gregorio Marañón, Madrid, Spain*

Background: Suppurative Hidradenitis (SH) is an inflammatory skin disease which often responds poorly to treatment. It is a disorder of the apocrine glands (axillary, inguinal and anogenital regions) that can result in infection, inflamed nodules, cysts, abscesses and sinus tracts. There is a 1–4% incidence of SH in patients with spondyloarthropathies and inflammatory bowel disease, possibly due to innate immune system deregulation. The use of biological disease-modifying antirheumatic drugs (bDMARD), specifically tumor necrosis factor inhibitors, has been useful in cases when other therapies fail.
Objectives: To evaluate the prevalence of SH using the SH-questionnaire in bDMARD-treated chronic arthritis patients.
Methods: This cross-sectional study included 325 patients diagnosed with chronic arthritis. Patients were recruited consecutively from the Biological Therapy Unit of the Hospital General Universitario Gregorio Marañón and evaluated from January to March of 2015. All patients had been undergoing full or tapered bDMARD treatment for at least 1 year and none had any history of SH. Those patients deemed to be in clinical remission were on tapered bDMARD dosage. All patients self-completed the validated SH-questionnaire (1) which was considered positive when one answer was affirmative and when lesions presented in >1 anatomical location. Patient pathologies were subclassified into 2 groups: i) peripheral arthritis (PerAR) which includes rheumatoid arthritis (RA), psoriatic arthritis (PsA) and peripheral spondyloarthropathies (PerSpA); ii) axial spondyloarthropathies (AxSpA). Clinical evaluation was performed by the same physician for all patients. Demographic, clinical and laboratory variables were recorded and disease status was assessed through the relevant clinical index, i.e.DAS28-ESR, DAS28-CRP, SDAI, CDAI, BASDAI, BASFI, ASDAS-CRP.
Results: SH-positive was observed in 25/325 (7.7% vs. 92.3%) patients. Of these 25 patients, 12 (48%) were female and 13 (52%) male. Mean age was 52 years (SD±12.9) and mean time since diagnosis was 14 years (SD±9.3). Twenty-four out of 25 patients were undergoing anti-TNF treatment (ETN=10, GOL=7, ADL=6, CTZ=1). Eighty-four per cent of patients were undergoing full bDMARD dosage with the remaining 16% on tapered. By subset pathology, 13 SH positives were PerAR type and 12 were AxSpA (5.8% vs. 11.8%, p=0.062). On analysis of PerAR subtypes, we found 6 patients had PsA and 5 RA. Evaluating clinical disease activity, we found 9/13 patients in the PerAR group to be in clinical remission according to DAS28-ESR and CDAI (p=0.02 for both). Additionally, we found only 4/12 patients in remission in the AxSpA group as defined under BASDAI, BASFI and ASDAS-CRP (p=0.006, p=0.005, p=0.004, respectively).
Conclusions: We found more SH-positives in the AxSpA than in the PerAR group, which is consistent with published data. A bDMARD tapered dosage was related to SH-positivity which might be linked to persistent and undetectable chronic inflammation.

FRI0449 ANALYSIS OF THE CANADIAN ADALIMUMAB POST-MARKETING OBSERVATIONAL EPIDEMIOLOGICAL STUDY ASSESSING EFFECTIVENESS IN ANKYLOSING SPONDYLITIS (COMPLETE-AS): ASSOCIATION BETWEEN BASELINE EXTRA ARTICULAR MANIFESTATIONS AND PATIENT-REPORTED OUTCOMES

L. Bessette[1,2], B. Haraoui[3], M. Khraishi[4], W. Bensen[5], V.P. Remple[6,7]. *[1]Faculty of Medicine, Université Laval; [2]Centre Hospitalier de l'Université Laval, Quebec; [3]Centre Hospitalier de l'Université de Montréal, Montreal; [4]Faculty of Medicine, Memorial University of Newfoundland, St. John's; [5]Division of Rheumatology, McMaster University, Hamilton; [6]School of Population and Public Health, University of British Columbia, Vancouver; [7]AbbVie Corp., Montreal, Canada*

Background: Ankylosing spondylitis (AS) is an immune mediated inflammatory disease. Although characterized by axial and peripheral joint manifestations, extra articular manifestations (EAMs) are a common clinical feature. EAMs have been found to negatively impact health outcomes including quality of life and work capacity.
Objectives: The aim of this analysis was to describe the prevalence of EAMs at baseline and assess their association with patient-reported outcomes (PROs) in a Canadian routine clinical care setting.
Methods: COMPLETE-AS is an ongoing observational study expected to enroll 1120 AS patients from 60–80 sites across Canada. All patients enrolled between June/2011 - October/2015 were included in this analysis. Eligible patients are anti-TNFα naïve adults, with active AS as per the judgment of the treating physician, who require change in current AS treatment. Baseline disease parameters assessed were EAMs (collected from medical chart, physician assessment or patient report), disease activity (BASDAI) and functional status (BASFI); baseline PROs assessed were related to mental health (BDI-II), work limitations (WLQ), and quality of life (QoL; SF-36 Physical (PCS) and Mental (MCS) component summaries). Multivariate linear regression models adjusting for baseline BASDAI and BASFI assessed the impact of EAMs on PROs.
Results: A total of 569 patients were included in the current analysis. Mean (SD) age and duration of disease was 43.3 (13.4) and 5.9 (9.8) years, respectively. The majority of patients enrolled were male (57.1%), Caucasian (86.1%), HLA $B27^+$ (67.0%), and RF^- (93.7%). The most common baseline EAM reported was enthesitis (15.3%), followed by psoriasis (13.0%), inflammatory bowel disease (IBD; 9.1%), and uveitis (3.2%). EAM combination 1 (EAM1: all EAMs) and EAM combination 2 (EAM2: excluding psoriasis), was reported by 33.2%, and 23.7% of patients, respectfully.
Regression analysis adjusting for baseline BASDAI and BASFI, found enthesitis, EAM1, and EAM2 to be significant negative predictors of SF-36 PCS scores ($p<0.05$). Individual EMAs were not found to impact PROs, except for uveitis, found to be a negative predictor of SF-36 PCS scores for which a statistical trend was identified ($p<0.15$). No association between EAMs and SF-36 MCS, BD-II or WLQ scores were found.
Conclusions: In a Canadian routine clinical care setting, a substantial proportion of AS patients requiring a change in treatment report EAMs. Patients with EAMs were found to have significant reduction in baseline QoL specifically related to physical functioning.

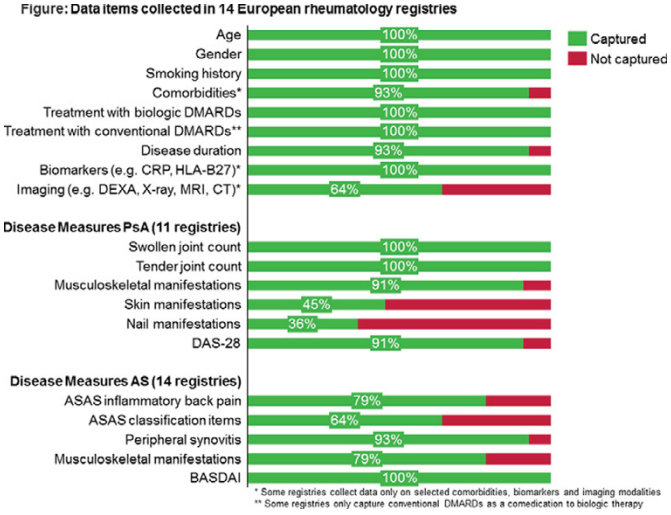
Hauge[1], J. Gomez-Reino[11], F. Díaz-González[12], M. Tomsic[8], K. Pavelka[9], F. O'Shea[5], C. Sullivan[5], M. van de Sande[13], I.E. van der Horst-Bruinsma[13], G.J. Macfarlane[14], G.T. Jones[14], B. Gudbjørnsson[15], T.K. Kvien[16] on behalf of EuroSpA Study Group. *[1]DANBIO, Glostrup, Denmark; [2]ARTIS, Stockholm, Sweden; [3]SCQM, Geneva, Switzerland; [4]ROB-FIN, Helsinki, Finland; [5]ASRI, Dublin, Ireland; [6]Biobadaser, Barcelona, Spain; [7]reuma.pt, Almada, Portugal; [8]biorx.si, Ljubljana, Slovenia; [9]ATTRA, Prague, Czech Republic; [10]GISEA, Bari, Italy; [11]Biobadaser, Santiago; [12]Biobadaser, Santa Cruz de Tenerife, Spain; [13]ARC, Amsterdam, Netherlands; [14]Bsrbr-As, Aberdeen, UK; [15]ICEBIO, Reykjavik, Iceland; [16]Nordmard, Oslo, Norway*

Background: High quality data from prospective, real life patients with spondy-

loarthritis (SpA) is needed to strengthen patient-level research in non-experimental clinical settings. A research network collaboration of registries collecting data on patients with SpA, "EuroSpA" offers opportunities to enhance research capabilities in the real world setting.

Objectives: To assess patient numbers, data extent and completeness in European SpA registries and establish an international research collaboration and common data set to address key data gaps for SpA patients treated in routine clinical practice.



Methods: The "EuroSpA" research network collaboration was established between registries collecting data on SpA patients. A survey was conducted via email and follow-up interviews April-December 2016 to assess patient numbers, data availability and completeness in participating registries. Our survey tool was based on key variables identified through literature review and expert interviews.

Results: 14 European rheumatology registries submitted information on their data covering approximately 63479 SpA patients, including patients with psoriatic arthritis (PsA), ankylosing spondylitis (AS) and non-radiographic axial spondyloarthritis (nr-axSpA) (Table).

Table 1. Approximate patient numbers in each SpA registry

Registry	Approximate patient numbers		
	PsA	AS	Nr-axSpA
ARC (Netherlands)		310	80
ARTIS (Sweden)	10000	10000	
ASRI (Ireland)		630	
ATTRA (Czech Republic)	800	2200	150
BIOBADASER (Spain)	500	500	20
Biorx.si (Slovenia)	350	600	
BSRBR-AS (Britain)		1500	650
DANBIO (Denmark)	7800	3900	3400
GISEA (Italy)	2400	1200	600
ICEBIO (Iceland)	376	343	
NOR-DMARD (Norway)	1600	1100	120
Reuma.pt (Portugal)	1600	2700	
ROBFIN (Finland)	1900	1900	400
SCQM (Switzerland)	1900	1400	550
Total	29226	28283	5970

Data coverage was comprehensive for comorbidities, demographic and treatment variables, but limited for imaging and in PsA for skin and nail manifestations (figure).

Conclusions: A European research collaboration network of SpA registries, "EuroSpA", including ≈ 63500 SpA patients enables the collection of key patient variables and strengthens research through increased patient numbers and cross-country comparative research. While core disease activity measures for SpA patients are widely collected, an enhanced standardized core dataset could strengthen future collaboration.

FRI0451 SEX DIFFERENCES IN DISEASE ACTIVITY ACCORDING TO COMPOSITE INDICES IN SPONDYLOARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

M. Blasco-Blasco[1], I. Castrejón[2], V. Joaní[3], E. Eliseo[4], M. Ruiz-Cantero[1,5].
[1]Public Health, University of Alicante, Alicante, Spain; [2]Rheumatology, Rush University Medical Center, Chicago, United States; [3]Rheumatology, Alicante University General Hospital; [4]Rheumatology, Miguel Hernández University; [5]Ciberesp, Alicante, Spain

Background: The Bath Ankylosing Spondylitis (AS) Disease Activity Index (BASDAI), an index of only patient-self-report measures, and AS Disease Activity Score (ASDAS)[1], which adds patient global estimate and laboratory tests to BASDAI elements are widely used in Spondyloarthritis (SpA). Both indices are specifically designed to evaluate disease activity AS patients. Some studies have shown worse BASDAI in women, but sex-related differences by ASDAS remain unclear [2,3].

Objectives: To analyze reports of sex-stratified disease activity measures -BASDAI and ASDAS- in patients with SpA.

Methods: Data sources included PubMed (1950 to December 2016), Embase, Web Of Science, and manual searches of references lists. We included observational studies and randomized trials comparing disease activity scores, specifically BASDAI and ASDAS, between men and women with SpA. Studies quality was determined in line with the STROBE statement for observational studies and CONSORT statement for RCT, considering <50% positive items as low quality. Randomized effects were performed to report the mean difference (95% confidence interval) by gender, and heterogeneity was measured via I^2 statistic in order to check the results robustness.

Results: From 672 identified studies 18 cross-sectional studies, 3 cohort, 2 case-control studies, and 1 RTC reported sex-stratified BASDAI and ASDAS. ASDAS was evaluated in 3,758 patients (36.5% women) in 9 studies, and BASDAI included 12,329 patients (34.3% women) in 24 studies. In a metanalysis of mean difference BASDAI including 19 studies the mean difference was 0.56 (95% CI: 0.47, 0.66) and I^2=43%, indicating a significantly higher disease activity in women (Figure). In a metanalysis of 7 studies ASDAS the mean difference was 0.06 (95% CI: -0.04, 0.16) and I^2=41%, not showing statistically significant differences.

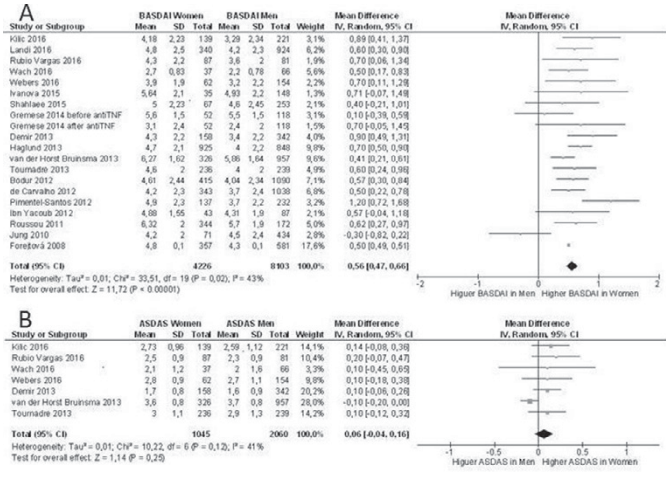

Figure. (A) Mean difference to BASDAI in men vs woman. (B) Mean difference to ASDAS in men vs woman

Conclusions: We identified relevant sex differences in disease activity according to BASDAI with higher disease activity in women, but not according to ASDAS. In SpA, women present more peripheral arthritis and higher pain, which may influence the BASDAI score, mainly based on patient-self-report measures. It is important to recognize these differences that may influence management decisions based on disease activity measures.

FRI0452 IMPACT OF A TRAINING PROGRAM AND EARLY REFERRAL ON DIAGNOSTIC DELAY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: RESULTS FROM THE SPANISH ATLAS

M. Garrido-Cumbrera[1], D. Galvez-Ruiz[1], V. Navarro-Compan[2], J. Gratacós-Masmitja[3], C. Blanch Mur[4], E. Collantes-Estevez[5], P. Zarco-Montejo[6], O. Braçe[1]. *[1]Universidad de Sevilla, Seville; [2]H. la Paz, Madrid; [3]H. Parc Tauli, Sabadell; [4]Novartis, Barcelona; [5]Universidad de Córdoba, Cordova; [6]H. Fundación Alarcón, Madrid, Spain*

Background: In patients with axial spondyloarthritis (axSpA), diagnosis delay (DD) postpones the initialisation of the most appropriate treatment with irreversible consequences on physical function, mobility and quality of life of patients. DD is also responsible for increased health costs resulting from incorrect referrals, visits to inappropriate health professionals and poorly planned diagnostic tests. Many initiatives have been undertaken in recent years in an attempt to reduce DD but their influence is still unknown.
Objectives: i) To determine diagnosis delay in patients with ax-SpA in Spain; ii) To assess the pre-diagnosis care process; iii) To analyse the possible beneficial effects on DD of a training programme for primary care physicians and early referral to rheumatology units.
Methods: A sample of 680 patients diagnosed with ax-SpA was interviewed during 2016 as part of the Atlas in Spain. This project aims to improve early diagnosis and to promote the use of effective treatments in ax-SpA patients. Collected data included: socio-demographics, medical visits prior to diagnosis, date for first symptoms and diagnosis and disease characteristics. This information was used to determine the DD and the possible beneficial effects on DD of a training programme for primary care physicians and early referral to rheumatology units. A descriptive analysis was performed, stratifying the results according to the start of the symptoms (before and after 2009). The ESPeranza Program (a Spanish prospective multicentre national health programme aimed at facilitating early diagnosis of patients with ax-SpA) started in 2009.
Results: 53% of the patients included were females. Mean scores (standard deviation) were 45.7 (10.8) years for age and 12.4 (11.2) for disease duration. 77.1% were HLA-B27+. Visits to health professionals prior to diagnosis included: primary care physicians (88.5%), orthopaedic surgeons (71.7%), rheumatologists (70.4%), and physiotherapists (47.6%). The mean number of consultations prior to diagnosis was 2.6; 3.0; 2.0 and 3.4, respectively.
Patients stated the onset of the first ax-SpA symptoms was at mean 24.4 years of age, with diagnosis at mean 32.9 years of age, translating into a mean DD of 8.5 years. For 25% of patients DD was >12 years, whereas a DD of <2 years was found in only 25% of respondents. Mean DD for patients whose first symptoms appeared before 2009 was 9.5 years, whereas for patients whose first symptoms appeared after that date it was significantly reduced to 2.5 years.
Conclusions: The mean delay in diagnosis ax-SpA in Spain is above 8 years. Patients make a large number of visits to a variety of specialist physicians before they are diagnosed, which could point to proof of wrong referrals by primary care. However, DD has fallen drastically (to a mean 2.5 years) since the implementation of the ESPeranza Program in 2009, suggesting that training primary care physicians have substantial beneficial effects on patients with ax-SpA and the care process.

FRI0453 CLINICAL AND THERAPEUTIC CHARACTERIZATION OF A COLOMBIAN COHORT WITH SPONDYLOARTHROPATHIES

M.A. Alzate[1], F. Ramirez[2], F. Vargas[2], D. Hernandez-Parra[1], J.C. Salazar-Uribe[3], P. Ortiz-Salazar[1], R. Pineda[1] on behalf of Artmedica IPS, Medellin, Colombia. *[1]Clinical information group; [2]Rheumatology division, Artmedica IPS; [3]School of Statistics, Faculty of Sciences, National University of Colombia, Medellin, Colombia*

Background: Spondyloarthropathies (SpAs) are a group of auto-inflammatory diseases, with overlapping symptoms, that include ankylosing spondylitis (AS), psoriatic arthritis (PsA), undifferentiated spondyloarthritis (Und SpA), enteropathic arthritis, and reactive arthritis (1).
Objectives: To characterize the disease in a large Colombian cohort with SpAs, assessing differences in its classification, clinical manifestations, laboratory results, radiographic changes, and treatment, according to the type of SpA.
Methods: A cross-sectional study was conducted in 621 patients with SpAs, in whom sociodemographic, clinical and therapeutic characteristics were analyzed based on the type of diagnosis. Statistical association was examined by means of Chi-square tests, Fisher's exact test, Mann-Whitney test, and logistic regression analyses. In all cases, a p value <0.05 was considered significant.
Results: Out of the 621 patients included, AS was observed in 54,7%, PsA in 35,7%, and Und SpA in 9,5%. AS was positively associated to male gender (OR 2.05 95%IC 1.5–2.8), younger age at onset, axial involvement (OR 23.2 95%IC 15.2–35.5), uveitis (OR 3.8 95%IC 2.25–6.57), radiographic sacroilitis (OR 6.95 95%IC 3.02–16.02), and HLA-B27 positivity (OR 2.3 95%IC 1.5- 3.5). PsA was associated to female gender, older age at onset, arthritis, and peripheral involvement. According to the therapeutic approach, more use of conventional DMARD therapy was found in PsA and Und SpA, while more use of biology therapy in AS.

Table 1. General characteristics of patients with SpAs

	All N=621		AS N=340		PsA N=222		Und SpA N=59		p-value
	N	%	N	%	N	%	N	%	
Mean (SD)									
Age, year	49.3 (12.4)		45.2 (12.5)		56.7 (11.8)		45.9 (12.9)		**<0.0001**

FRI0454 M-SASSS AND CERVICAL SEGMENT C7-D1. SHOULD THE ORIGINAL SCORE BE MODIFIED?

M.J. Moreno-Martinez[1], M.J. Moreno-Ramos[2], L.F. Linares-Ferrando[2]. *[1]Rheumatology, H. Rafael Mendez; [2]Rheumatology, H. U.Virgen de la Arrixaca, MURCIA, Spain*

Background: Ankylosing Spondylitis is characterized by axial involvement. m-SASSS is the radiographic score that is used to evaluate the radiographic progression of the disease. It evaluates different lesions in the lumbar segment and in the cervical segment (from C2-C3 to C7-D1), both with a lateral x-ray.
Theoretically, the C7-D1 intervertebral segment should not be evaluated through a simple lateral radiograph, but with x-rays in special positions.
Objectives: To evaluate the importance of the assessment of the C7-D1 intervertebral segment in patients with Ankylosing Spondylitis.
Methods: The patients come from a Spondyloarthritis Unit (Hospital Virgen of the Arrixaca, Murcia, Spain). All patients are diagnosed with Ankylosing Spondylitis (New York Modified Criteria)
The usual radiographic study was performed to calculate the m-SASSS (lateral cervical and lateral lumbar). We value the alterations found at level C7-D1 of patients and controls.
We compared the alterations found in patients with ankylosing spondylitis with control patients. These came from different rheumatology units, had no inflammatory pathology and had two lateral radiographs at different time periods. We collected demographic data (both from patients and from controls) and from clinical patients (analytical, activity and metrology).
Results: We included 47 patients (81% male and 19% female) with a mean age of 48 (± 8) years and a mean duration of symptoms of 18 (± 8.5) years. The mean time between the two radiographic studies was 3 (± 1.5) years. The control group was made up of 61 people (40, 7% men) with a mean age of 50 years (± 11).
The mean age of the control group was higher than patients (p=0.001).
The C6-C7 intervertebral level could be assessed radiographically with the lateral cervical radiograph in 93,2% of the patients and in 85, 2% of controls, and the C7-D1 level was only assessed in 22, 7% of the patients and 50% of the controls. We analyzed whether the assessment of intervertebral level C7-D1 could be influenced by other variables such as sex, age or duration from the symptoms without finding a statistical result.
The 88, 5% of patients had a lower border of C7 normal or with squaring, erosion or sclerosis. Only 1 patient had syndesmophyte and 2 patients had a bridge between vertebrae. On the upper border of D1, 85, 5% of patients had normal or type-1 lesions (squarin, sclerosis or erosion), there wasn't syndesmophytes and 2 patients had a bridge (Table)

	Injury	Prevalence (%)
Lower border of C7 (n=26)	Normal	65,5%
	Sclerosis, squaring, erosion	23%
	Syndesmophyte	4%
	Bridge	7,5%
Upper border of D1 (n=14)	Normal	57%
	Sclerosis, squaring, erosion	28,5%
	Syndesmophyte	0%
	Bridge	14,5%

Conclusions:
- The cervical segment C7-D1 is not usually valuable through a lateral cervical radiograph.
- Most of our patients with Spondylitis have no significant lesions in this segment.
- It is recommended to modify the m-SASSS index by removing the assessment of the cervical segment C7-D1.

FRI0455 RADIOGRAPHIC PROGRESSION OF HIP ARTHRITIS IN PATIENTS WITH ANKYLOSING SPONDYLITIS TREATED WITH TNF INHIBITORS

M. Konsta[1,2], M.T. Nurmohamed[2], A. Iliopoulos[1], J,C. van Denderen[2], I. Visman[2], P.P. Sfikakis[1], I.E. van der Horst-Bruinsma[2]. *[1]First Department of Propaedeutic Internal Medicine, Rheumatology Department, Joined Rheumatology Program, National and Kapodistrian University of Athens, Medical School, Athens, Greece; [2]Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands*

Background: Although there is debate whether treatment with TNF inhibitors (TNFi) in AS may not inhibit spinal radiographic progression, the effect on hip involvement may be different (1,2).
Objectives: To estimate the impact of long-term TNFi treatment on radiographic progression of hip arthritis in AS, by adding a quantitative scoring method, previously applied in hip osteoarthritis, to the BASRI-hip score.
Methods: Consecutive TNFi-naïve AS patients (fulfilling the modified New York criteria) who were eligible for TNFi treatment were included. Hip involvement was assessed clinically (pain, reduced range of motion and intermalleolar distance) and radiographically. X-rays of the pelvis and lateral cervical and lumbar spine were obtained at 3 time points: at baseline two and seven years after the start of TNFi. Both hips were scored using: a) BASRI-hip score (BASRI-h score $\geq$2 is classified as definitive hip involvement), b) mean joint space width (MJSW), estimated by measurement of 3 distinct points of interbone distance: 2mm inner of the external end of the acetabulum, vertical line through femoral head center, head-neck center line (1). Spinal X-rays were scored were scored blindly, by 2 independent readers using the mSASSS. The significance of changes was tested by mixed models for longitudinal data.
Results: 262 AS patients (188 men, age: 49.8±12 years, disease duration: 24.4±12 years) under TNFi treatment were included. Definite hip involvement at baseline was detected in 95/262 (36%) patients, who had significantly higher BASRI-hip score [2 (2–2.5) median (IQR) vs. 0.5 (0–1) $p<0.0001$] and lower MJSW (3.6±0.7 vs. 4.5±0.7, $p<0.0001$), compared to those without. In patients with hip arthritis at baseline, both BASRI-h score and MJSW remained unchanged during follow up. In patients without hip arthritis, the BASRI-hip score remained unchanged after 2.5±0.7 years, but increased significantly after 7±2.3 years compared to baseline. In contrast, the MJSW in patients without hip arthritis remained unchanged at the three time points. The mSASSS raised significantly during the follow-up period, regardless of hip involvement (see table).

Variables	Baseline	After 2.5±0.7 years	After 7±2.3 years	P
All pts (n=262)				
BASRI-hip, mean±SD	1.15±1	1.14±1	1.2±1	<0.0001
MJSW (mm), mean±SD	4.17±0.8	4.16±0.8	4.12±0.7	NS
mSASSS, median (IQR)	6 (1–24.5)	8 (1–30)	11 (2–30)	<0.0001
Pts with hip involvement (n=95)				
BASRI-hip, median (IQR)	2 (2–2.5)	2 (2–2.5)	2 (2–2.5)	NS
MJSW (mm), mean±SD	3.59±0.7	3.58±0.7	3.53±0.7	NS
mSASSS, median (IQR)	12 (2.5–36)	17 (3–40.5)	15.5 (3–37.5)	<0.0001
Pts without hip involvement (n=167)				
BASRI-hip, mean±SD	0.49±0.5	0.5±0.53	0.58±0.57	<0.0001
MJSW (mm), mean±SD	4.5±0.7	4.47±0.6	4.44±0.6	NS
mSASSS, median (IQR)	4 (0–18)	7 (1–25)	9 (2–27)	<0.0001

Conclusions: One third of the AS patients suffer from radiographic hip involvement, which seems to stabilize during long-term anti-TNF treatment. Assessment of MJSW may contribute to detect minor changes in contrast to BASRI-hip score' rough estimation.

FRI0456 AGE AT SPONDYLOARTHRITIS DIAGNOSIS AND RISK OF CARDIOVASCULAR COMORBIDITY: RESULTS FROM THE COMOSPA STUDY

M.H. Derakhshan[1], N.J. Goodson[2], J. Packham[3], R. Sengupta[4], H. Marzo-Ortega[5], A. Molto[6], S. Siebert[1] on behalf of BRITSpA and COMOSPA investigators. *[1]Institute of Infection, Immunity & Inflammation, University of Glasgow, Glasgow; [2]Academic Rheumatology Department, University of Liverpool, Liverpool; [3]Haywood Rheumatology Centre, Keele University, Keele; [4]Royal National Hospital for Rheumatic Diseases, Bath; [5]NIHR, Leeds Teaching Hospitals Trust and LIRMM, University of Leeds, Leeds, United Kingdom; [6]Paris Descartes University, Hôpital Cochin, Paris, France*

Background: Spondyloarthritis (SpA) and chronic inflammatory diseases are associated with a number of cardiovascular comorbidities. It is unknown whether age at SpA diagnosis is associated with cardiovascular outcomes in later life.
Objectives: To examine the relationship between "younger age at SpA diagnosis" and risk of various cardiovascular comorbidities.
Methods: COMOSPA is a large worldwide cross-sectional study comprising 3984 patients from 23 countries evaluating comorbidities in patients with SpA (1). We evaluated the association between "younger age at SpA diagnosis" (defined in 5-year blocks) and cardiovascular comorbidities using uni-variable and multi-variable binary logistic regression. Each model comprised one cardiovascular co-morbidity as dependent and "age at SpA diagnosis" as predictor adjusted for age, sex, BMI, history of smoking, alcohol, NSAIDs, DMARDs, biologics, steroids and other relevant factors
Results: The data of 3923 patients (64% male) were available for analysis. Current age ranged from 18 to 100 with median (IQR) of 42 (32–53) years. The median (IQR) age at SpA diagnosis was 33 (25–43) years. Main reported cardiovascular-related comorbidities were hypertension (22.4%), ischemic heart disease (IHD) (2.6%), stroke (1.3%) and diabetes mellitus (5.5%).
The risk of hypertension, after adjustment for potential confounding factors was associated with younger age at SpA diagnosis (OR=1.10, 95% CI: 1.05 -1.16), indicating 10% higher risk of hypertension for each 5 year younger age at time of SpA diagnosis (Table). Confounding variables showing significant association with hypertension were current age (OR=1.12, 95% CI: 1.10–1.13, $p<0.001$), male gender (OR=1.47, 95% CI: 1.20–1.80, $p<0.001$), current BMI (OR=1.09, 95% CI: 1.07–1.11, $p<0.001$), ever use of steroids (OR=1.24, 95% CI: 1.03–1.50, $p=0.027$) and ever use of synthetic DMARDs (OR=1.28, 95% CI: 1.05–1.57, $p=0.017$), but not ever use of NSAIDs or biologic DMARDs.
The other cardiovascular comorbidities were not associated with "younger age at SpA diagnosis" after adjustments for relevant confounding factors in multivariable analyses (Table)

Table 1. Association between "younger age at SpA diagnosis" and the risk of cardiovascular disease

	Univariable		Multivariable	
	OR (95% CI)	p value	OR (95% CI)	p value
Hypertension	0.76 (0.74 -0.79)	<0.001	1.10 (1.05 -1.16)	<0.001
IHD	0.74 (0.69 -0.80)	<0.001	0.99 (0.91 -1.086)	0.854
Stroke	0.79 (0.71 -0.87)	<0.001	0.98 (0.86 -1.11)	0.736
Diabetes Mellitus	0.78 (0.74 -0.82)	<0.000	0.95 (0.88 -1.02)	0.172

Conclusions: Younger age of SpA diagnosis is associated with increased risk of developing hypertension but not other cardiovascular comorbidities in this study. The explanation for this association is not clear and does not appear to be due to increased NSAID exposure.

FRI0457 THE ROLE OF SERUM HMGB1 IN BONE REMODELİNG AND OSTEOPOROSIS IN A GROUP OF ANKYLOSING SPONDYLITIS PATIENTS

M. Calis[1], I. Cuce[2], I. Gunturk[3], E. Cuce[1], C. Yazici[4]. *[1]Department of Physical Medicine and Rehabilitation, Erciyes University, Faculty of Medicine, Kayseri; [2]Department of Physical Medicine and Rehabilitation, Adıyaman University Training and Education Hospital, Adıyaman; [3]Institute of Health Sciences, Biochemistry, Erciyes University; [4]Department of Medical Biochemistry, Erciyes University, School of Medicine, Kayseri, Turkey*

Background: Ankylosing spondylitis is characterized by new bone formation and bone loss, associated with inflammation, which are mediated by cytokine-signaling pathways. High mobility group box 1 (HMGB1) protein, is a nonhistone nuclear protein, which is secreted by inflammatory cells, is also defined as a bone-active

cytokine. Recent studies have shown that RANKL induces HMGB1 release and it is required for RANKL-induced osteoclastogenesis in vitro and in vivo.
Objectives: To investigate the relationship of serum HMGB1 levels with RANKL/Osteoprotegerin (OPG) axis and clinical and radiographic parameters in patients with AS.
Methods: In this cross-sectional study, serum samples for total HMGB1, sRANKL and OPG were detected from 54 tumour necrosis factor (TNF) inhibitor naive patients with AS according to the modified New York criteria [mean age 34.9 years (S.D. 7.1); duration of symptoms 8.6 years (S.D. 4.2); male gender 38 patients (70.4%)] and 26 healthy controls. ESR, CRP, Bath AS Disease Activity Index (BASDAI), Bath AS Functional Index (BASFI) were assessed for each patient. Bone mineral density was measured using dual-energy X-ray absorptiometry (DXA) at lumbar spine (L2–L4) and proximal femur. Lumbar spine radiographs were scored using the modified Stoke AS Spine Score (mSASSS).
Results: Serum HMGB1 levels were relatively higher in patients with AS than HCs however no statistically significant in each other. Serum HMGB1 levels correlated with CRP (rho=0.368 and *P*=0.006), ASDAS-CRP (rho=0.358 and *p*=0.008) and BASDAI (rho=0.334 and *p*=0.014) and BASFI (rho=0.355 and *p*=0.008) in patients with AS. CRP and ASDAS-CRP showed more correlated to HMGB1 serum levels than BASDAI. There was no significant correlation between HMGB1 levels with sRANKL, OPG, mSASSS and spine or femur BMD values. In addition, serum OPG levels and the ratio of sRANKL to OPG from AS patients were significantly higher than those of HCs.

Table 1

	AS patients (n=54)	Healthy controls (n=26)	*p*
Age (yrs)	34.9±7.1	33.3±4.0	N/A
Body mass index (kg/m^2)	26.3±4.7	26.3±2.8	N/A
Disease duration (yrs)	8.6±4.2	–	N/A
ESR (mm/hr)	22.0±8.5	–	N/A
CRP (mg/L)	11.5±8.9	–	N/A
HMGB1 (ng/ml)	337.1±166.1	286.3±126.1	N/A
sRANKL (ng/ml)	148.6±31.4	137.2±46.9	N/A
OPG (ng/ml)	285.5±68.9	317.8±51.8	0.02
sRANKL/OPG	0.6±0.2	0.4±0.1	<0.001

Conclusions: This study showed that levels of HMGB1 in the sera of AS patients, are increased compared to healty controls. Serum HMGB1 levels are related to BASDAI, ASDAS-CRP, BASFI and CRP in patients with AS. Different results in the literature on serum HMGB1 levels as well as our results support the hypothesis that HMGB1 plays a role in the pathogenesis of AS. According to our knowledge, it is the first trial evaluating association between serum HMGB1 levels with sRANKL-OPG axis, bone mineral density and new bone formation in AS patients and it seems not to be related for these conditions.

FRI0458 ASSESSMENT OF BONE MINERAL DENSITY IN PATIENTS WITH EARLY AXIAL SPONDYLOARTHRITIS FROM CORSAR COHORT: 2 YEARS FOLLOW UP

O. Rumyantseva, T. Dubinina, A. Demina, D. Rumiantceva, S. Erdes, E. Agafonova, S. Krasnenko, E. Gubar. *Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Bone loss in patients (pts) with early axial spondyloarthritis (axSpA) is insufficiently studied and may be associated with disease activity.
Objectives: To assess the bone mineral density (BMD) in pts with early axSpA base on data from 2 years follow up of CORSAR cohort.
Methods: The research included 65 pts with axSpA (criteria ASAS 2009) with disease duration <5 years and age at onset <45 years. Pts at least 2 years follow up, 32 (49,2%) male, pts mean age was 28,5 (5,8) y., average disease duration 24,1 (15,4) mo, 60 (92,3%) pts were HLA-B27 positive. At baseline all pts were NSAID-naïve, DMARD-naïve, anti-TNF-naïve. For 2 years all pts taking NSAIDs at therapeutic doses, part of the pts received sulfasalazine and anti-TNF. BMD was measured using dual energy x-ray absorptiometry (DXA) of the femoral neck (FN) and lumbar spine (LS) (L2–4) at baseline and after 1 year, and 2 years follow up. BMD reduction was defined as Z score $\leq$ -2 (at least one site).
Results: Low BMD at baseline founded in 9 (13,8%) pts, in 10 (15,3%) pts after 1 year and in 5 (7,7%) pts after 2 years follow up. There were no significantly differences between the mean values of BMD at baseline and after 2 year, data are shown in the Table.

Table 1. BMD at baseline and after 1 and 2 years follow up

	Baseline	1 years after baseline	2 years after baseline	p
BMD LS mean (s.d)	-0,759 (1,13)	-0,679 (1,11)	-0,627 (1,11)	0,541
BMD FN mean (s.d)	-0,527 (0,91)	-0,633 (0,95)	-0,477 (1,00)	0,792

Conclusions: Low BMD was quite rare (14%) in patients with early axSpA. Small frequency of BMD reduction in the Russian cohort of axSpA patients after 2 years of study is probably due to disease activity decrease on anti-inflammatory therapy.

FRI0459 DEVELOPMENT AND VALIDATION OF A SPANISH TOOL FOR SEMI-AUTOMATIC QUANTIFICATION OF SACROILIAC INFLAMMATION BY MAGNETIC RESONANCE IN SPONDYLOARTHRITIS (SCAISS)

P. Zarco[1], R. Almodóvar[1], A. Bueno[2], L.M. Molinero[3]. *[1]Unit Rheumatology; [2]Unit Radiology, Hospital Universitario Fundación Alcorcon; [3]Ingeniera ALCE, Madrid, Spain*

Background: Different systems to quantify inflammatory changes in sacroiliac MRI have been developed.[1, 2] These systems include the Spondyloarthritis Research Consortium of Canada (SPARCC), the Berlin, the Aarhus-Puhakka, and Aarhus-Madsen, the Leeds, the MR Imaging of Seronegative SpA (MISS), Leeds, Sieper/Rudwaleit and Hermann/Bollow scoring systems. In addition, the use of these quantification methods is restricted to clinical trials, since their use in clinical practice is limited due to their complexity, need for trained personal, and prolonged procedural time. The development of computers and data processing software has led to significant advances in methods for image analysis. With the objective to improve interobserver quantification of sacroiliitis while maintaining a practical perspective, our group has developed a semi-automated method to measure bone marrow edema (BME) in MRI images from sacroiliac (SI) joints.
Objectives: The aim of this study is to analyze the validity and reliability of the method.
Methods: The development of the method to quantify inflammation in SI joints involved software selection from a list of potential programs, process-mapping based on discussion, and tuning. Once developed, feasibility (time spent) interobserver reliability (intraclass correlation coefficient), and construct validity (convergent validity) were analysed. Two rheumatologists and a radiologist independently quantified sacroiliitis from SI images from 12 patients with a diagnosis of axial SpA by the new method, and by non-automated methods to rate sacroiliitis (SPARCC* and Berlin). Convergent validity, reliability and feasibility were calculated. (* In the present study, for simplicity reasons and in order to make it closer to the developed technique, the authors modified the SPARCC method by using a single coronal section instead of the standard six consecutive ones).
Results: The interobserver reliability was high, with intraclass correlation coefficients for global score of 0.81 (95% CI: 0.59–0.94). Convergent validity was good, with high correlation with the Berlin (rho between 0.797 and 0.913) and the SPARCC methods (rho between 0.566 and 0.897). Mean time employed in the reading procedure was 30 seconds.
Conclusions: The developed semi-automatic technique permits a fast and valid calculation of overall BME lesion at the SI joint on MRI images.

FRI0460 EXTRA-ARTICULAR MANIFESTATIONS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: A CROSS SECTIONAL STUDY FROM SOUTHERN DENMARK

R.A. Andreasen[1,2], R. Christensen[1], L.E. Kristensen[1], T. Ellingsen[3,4], H.C. Horn[3], I.M.J. Hansen[2,5]. *[1]Rheumatology, The Parker Institute, Bispebjerg and Frederiksberg Hospital, Copenhagen; [2]Rheumatology, OUH, Svendborg Hospital, Svendborg; [3]Rheumatology; [4]Patient data Explorative Network (OPEN), Odense University Hospital; [5]Department of Clinical Research, University of Southern Denmark, Odense, Denmark*

Background: Axial (ax) spondyloarthritis (SpA) is a heterogenous group of chronic rheumatic diseases. Ax-SpA is subdivided into two groups referred to as nonradiographic and radiographic (i.e. AS) respectively. Next to the spinal and articular symptoms, many patients with SpA also have extra-articular manifestations (EAM) which contribute to reduced quality of life [1]. SpA appears to be more frequent in men than woman in its axial presentations, and in reference to the prototype of the disorder, AS, three male cases are documented for every female case. However, since the introduction of the new ASAS criteria for ax-SpA these differences are no longer so apparent[2]. Nevertheless, little is known of the differential clinical expression of SpA between males and females.
Objectives: The objective of this study was to compare patients with AS and

nr-axSpA stratified by gender, using standardized clinical tools (including patient-reported outcomes (P-ROs)) and C-reactive protein (CRP) level as a biomarker for inflammation.
Methods: Ax-SpA patients were included prospectively and underwent an examination program at one visit. We used ASAS criteria and the modified New Yorker criteria for classification. Information on demography and PROs was obtained. A trained physician performed a clinical examination, and BASMI and the The Spondyloarthritis Research Consortium of Canada Enthesitis Index (SPARCC) was used to enthesitis count. Chi-square and t-tests were used for categorical and continuous variables respectively to test the null hypothesis.
Results: Eighty patients with ax-SpA were included. Table 1 shows the results (mean ± SD or relative frequency) for the comparison of demographic and disease characteristics between clinical subgroups.

	Non-radiographic axSpA males n= 20	AS males n=23	*P*-value	Non-radiographic axSpA females n= 29	AS females n= 8	*P*-value
Mean age, years (S.D.)	41.5 ± 15.4	50.6 ± 9.9	0.03	44.0 ± 11.1	47.8 ± 17.3	0.46
HLA-B27 pos. (%)	11 (55)	21 (91)	0.012	13 (45)	8 (100)	0.013
Peripheral arthritis (%)	9 (45)	12 (52)	0.98	14 (48)	7 (88)	0.10
Mean BASDAI (S.D.)	2.5 ± 2.1	2.9 ± 1.9	0.52	4.7 ± 2.2	2.8 ± 2.0	0.043
Mean BASFI (S.D)	2.1 ± 2.2	2.6 ± 2.2	0.53	3.8 ± 2.1	2.4 ± 2.7	0.12
Mean BASMI (S.D)	1.2 ± 1.1	2.7 ± 1.6	0.0012	1.3 ± 1.2	1.5 ± 1.9	0.78
Mean CRP, mg/L (S.D)	6.9 ± 9.6	10.6 ± 17.1	0.20	2.6 ± 2.1	10.6 ± 15.5	<0.001
Mean Pain, VAS 0-100 mm, (S.D)	27.2 ± 23.0	28.6 ± 23.4	0.29	44.9 ± 23.9	25.9 ± 20.1	0.013
Anterior uveitis (%)	3 (15)	10 (43)	0.05	5 (17)	3 (38)	0.33
Psoriasis (%)	8 (40)	9 (39)	0.97	13 (45)	1 (13)	0.12
IBD (%)	3 (15)	3 (13)	0.61	6 (21)	0 (0)	0.31
Mean SPARCC score (entesitis)	1.2 ± 1.3	1.0 ± 1.4	0.63	2.0 ± 1.9	0.8 ± 1.5	0.0092

Conclusions: For the PROs, BASDAI and pain were higher in females diagnosed with nr-axSpA, and the CRP was significantly lower in this group. Peripheral and EAMs were slightly equally prevalent in AS and nr-axSpA in men and women except for uveitis, which is slightly more prevalent in AS. Our data show that AS patients were more frequently male than nr-axSpA patients. These results are in line with previous studies showing that male patients with axial SpA have more structural damage on radiographs than female patients. Among women, this study indicate that pain is more pronounced in non-radiographic axSpA than in AS, potentially revealing that chronic widespread pain (e.g. fibromyalgia) might interfere with the diagnostic accuracy of the non-radiographic axSpA subgroup. However, despite the absence of radiographic changes, patients with nr-axSpA have a burden of illness, with self-reported disease activity and functional impairments comparable with those of patients with structural changes consistent with AS.

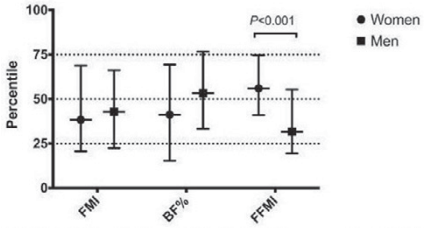
FRI0461 MUSCLE WASTING IN MALE TNF-α BLOCKER NAÏVE ANKYLOSING SPONDYLITIS PATIENTS: A COMPARISON OF GENDER DIFFERENCES IN BODY COMPOSITION WITH DUAL-ENERGY X-RAY ABSORPTIOMETRY

S.E. Ibáñez Vodnizza[1,2], I.M. Visman[3], J.C. van Denderen[3], W.F. Lems[3,4], M.T. Nurmohamed[3,4], I.E. van der horst-Bruinsma[4]. *[1]Rheumatology department, Clínica Alemana de Santiago; [2]Rheumatology department, Hospital Padre Hurtado, Santiago, Chile; [3]Amsterdam Rheumatology and immunology Center, Reade; [4]Amsterdam Rheumatology and immunology Center, VU University Medical Center, Amsterdam, Netherlands*



Background: Female Ankylosing Spondylitis (AS) patients have different disease characteristics compared to males. This might be explained by differences in body composition (BC), as women have higher total body fat mass, and adipose tissue can produce adipokines and participate in inflammatory and immunological processes.
Objectives: To assess gender differences in BC measured by Dual-Energy X-ray Absorptiometry (DXA) in a cohort of AS patients naïve to TNF-α blockers, and compare the BC with the reference population.
Methods: AS patients (Modified New York Criteria), 18 years old or older, who had a whole body DXA analysis before TNF-α blockers were included. Demographic information and disease activity measures (ASDAS and BASDAI) were reported. Fat Mass (FM) was reported as total FM (sum of trunk, arms, legs, and head), BF% (ratio FM/Total body mass), and Fat Mass Index (FMI= FM kg/height m^2). Fat Free Mass (FFM), calculated as lean mass + bone mineral content, and its index (FFMI kg/m^2) were reported. BF%, FMI, and FFMI percentiles, according to the reference population tables, stratified by age and gender, were also reported.
Results: Seventy consecutive patients were included, 60% were men. Baseline demographic characteristics were similar in men and women. Women had significantly higher BF% and FMI, and lower FFMI as absolute values (table 1). The FFMI percentile was markedly low in men (31.7%) (Figure 1). After multivariate analysis, an ASDAS-CRP >3.5 was related with lower FFM in the whole group (β-coefficient -5.1, 95% CI -10.2 to -0.1, P=0.047). ASDAS >3.5 was related to lower fat content in men and to higher fat content in women. The same relationships were found for BASDAI ≥4.

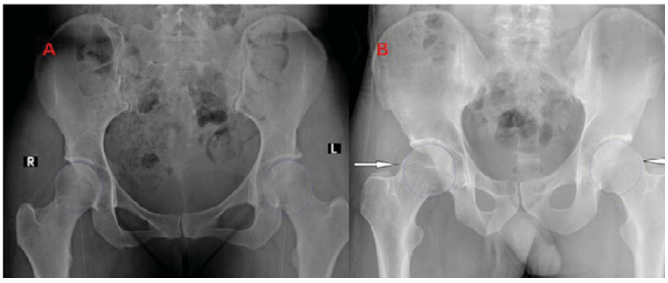
Table 1. Body composition characteristics

	All (N=70)	Male (N=42)	Female (N=28)	*P*
Age (median years, IQR)	42 (16)	44.2 (15.2)	40.7 (17.6)	NS
BMI (median, IQR)	25.6 (5)	25.9 (4.8)	24.2 (9)	NS
Underweight (%)	0	0	0	–
Normal (%)	48.6	45.2	53.6	NS
Overweight (%)	35.7	47.6	17.9	0.011
Obese (%)	15.7	7.1	28.6	0.021
Fat Mass, kg (mean, SD)	26 (9.3)	23.9 (8.7)	29.2 (9.6)	0.018
Fat Free Mass, kg (mean, SD)	51.1 (9.9)	56.8 (7)	42.5 (7.1)	<0.001
Body Fat % (mean, SD)	33.3 (8.9)	28.9 (7.3)	40 (6.7)	<0.001
Fat Mass Index (median, IQR)	8.5 (3.6)	8 (4)	9.7 (6)	0.001
Fat Free Mass Index (median, IQR)	17 (2.5)	17.7 (1.8)	15.1 (1.8)	<0.001

BMI = Body Mass Index, NS = not significant.

Figure 1: FMI, BF% and FFMI percentiles according to reference population tables

FMI= Fat Mass Index, BF%= Body fat percentage, FFMI= Fat Free Mass Index. Dot lines represent 25th, 50th and 75th percentile of reference population.



Conclusions: Muscle wasting, measured as low FFMI compared to the reference population, was found in male TNF-α blocker naïve AS patients, especially in those with active disease. Women had higher volumes of body fat than men, but near the median of the reference population. The relationships between fat content and disease activity support the complex association between adipose tissue and inflammation.

FRI0462 THE PISTOL-GRIP DEFORMITY IS MORE FREQUENT IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

O. Tosun[1], D. Solmaz[2], O. Gercik[3], G. Karaca[4], A. Tosun[5], M. Ozmen[3], F.E. Topal[6], S. Akar[3]. *[1]Radilogy, Katip Celebi University Faculty of Medicine, Izmir; [2]Rheumatology, Katip Celebi University Faculty of Medicine, izmir; [3]Rheumatology, Katip Celebi University Faculty of Medicine, Izmir; [4]Radiology; [5]Physical Medicine and Rehabilitation, Katip Celebi University Faculty of Medicine, izmir; [6]Emergency Medicine, Katip Celebi University Faculty of Medicine, Izmir, Turkey*

Background: Femoroacetabular impingement (FAI) is characterized by early pathologic contact of the proximal femur with the acetabulum. Pincer impingement is the acetabular cause of FAI.Whereas cam deformity seen as a flattening of the anterior contour of the head/neck junction or an osseous hump leading a decreased femoral head/neck offset. Patient with FAI presents with a hip or a trochanteric painusually in the sitting position or during or after activity. It might also be an important cause of hip osteoarthritis (OA).
Objectives: Therefore in this study we evaluated the frequency of pistol-grip deformity (PGD), described as the most characteristic feature of cam-type FAI, in axial spondyloarthritis (axSpA) patients as a potential alternative cause of hip or trochanteric pain.
Methods: A total 180 patients (107 [59%] male, mean age 41.9±12.8 years) with axSpA according to ASAS criteria and 198 patients (120 [61%] male, mean age 40.5±14.8 years) admitted to the emergency department (mostly due to trauma) and who had pelvic X-ray were included in the study.Patients with hip OA, hip prosthesis, acetabular protrusion or who have radiographs taken improper technique were excluded. An experienced radiologist assessed all anteroposterior pelvic radiographs. PGD was determined by demonstration of spherical or non spherical shape of femur head on AP pelvic radiography.
Results: The axSpA group consists 135 ankylosing spondylitis and 45 non-radiographic axSpA patients. The mean duration of symptoms was 13.8±11.3

years in axSpA patients. Radiographic findings of cam abnormality (figure) were significantly more frequent in axSpA patients in comparison with control subjects (30/150 [20%] vs 17/193 [9%] and *P*=0.004). Cam-type radiographic abnormality was only present 2 female control subjects and none of female axSpA patients. FAI was significantly correlated with the presence of HLA-B27 (r=0.213 and *P*=0.048), smoking (r=0.194 and *P*=0.018), height (r=0.283 and *P*=0.001) and gender (r=0.443 and *P*<0.001).

Conclusions: Our results showed that radiographic findings compatible with PGD were frequent in axSpA patients. In addition to repetitive injury tothe proximal femoral physis, new bone formation may be responsible for increased FAI in axSpA.In axSpA patients with hip or trochanteric pain, FAI may be kept in mind as an alternative explanation of the symptoms.

FRI0463 OPTIMIZING THE ASSESSMENT OF SPONDYLOARTHROPATHY AMONG OPHTHALMOLOGISTS –A REGIONAL SURVEY

S. Goel[1], P. Kumar[2], A. Moorthy[2]. [1]*Medical student, University of Leicester;* [2]*University Hospitals of Leicester NHS Trust, UK, Leicester, United Kingdom*

Background: Spondyloarthropathy (SpA), is an under diagnosed clinical condition with an average delay in diagnosis of upto 8 years. The delay occurs due to non-specific symptoms which occur in young patients who are unlikely to present to healthcare services as well as presentations to different specialties as a result of extra-articular manifestations.
30% of Ankylosing Spondylitis (AS) patients have acute anterior uveitis (AAU) at some point due to the common link with HLA B-27. Uveitis may precede the diagnosis of Ankylosing Spondylitis (AS) by several years. Previous studies have shown that up to 40% (1) people with AAU have undiagnosed SpA, and are not routinely seen in rheumatology services due to lack of symptom and risk recognition. Early diagnosis in this group is essential to reduce the delay in diagnosis and improve the outcome of SpA.
Objectives: 1.To identify the current assessment of inflammatory back pain, in patients with recurrent AAU, by local ophthalmologists. 2. To identify ways to improve cross specialty referral and reduce delay in the diagnosis of SpA.
Methods: This is a prospective, questionnaire based semi qualitative study. The target population includes specialist ophthalmology trainees, consultants and GPs with a special interest in ophthalmology across the East Midlands. The questionnaire was piloted locally at a regional uveitis meeting. The improved questionnaire was then electronically communicated to ophthalmologists across East Midlands. The data was collated and analyzed using smartsurvey software.
Results: We received 61 responses (response rate =51%), of which 57 (n=57) were analysed. The respondents largely comprised doctors working at university hospitals (74%) and consultants (45%)
17% of the respondents were not confident with taking an inflammatory back pain history. Of the remaining 83%, only 67% respondents would normally think to ask about the main symptoms of back pain related to AS. Thus 44% respondents were not competent in taking an inflammatory back pain history.
With regards to their clinical practice, only 54% of respondents would routinely ask about symptoms of SpA in patients with recurrent AAU, even though 79% would test for HLA-B27. Furthermore, according to 42% of respondents they would never refer a recurrent AAU patient to a rheumatologist.
Most respondents felt that work pressure was the most likely reason for deficit of proper SpA assessment and referrals, followed by lack of support by guidelines
Conclusions: Our survey demonstrates a clear knowledge deficit among ophthalmologists regarding inflammatory back pain and the importance of assessing it in recurrent AAU patients. This can be improved by educating ophthalmologists about SpA in conferences and developing local guidelines about patients with HLA B-27 recurrent AAU related to assessment and referral.

FRI0464 ARTERIAL WALL INFLAMMATION IS NOT AFFECTED BY ANTI-IL17 TREATMENT IN PATIENTS WITH PERIPHERAL SPONDYLOARTHRITIS

L.J.J. Van Mens[1], S.L. Verweij[2], A.W.R. van Kuijk[3], E.S.G. Stroes[2], D.L. Baeten[1,4]. [1]*AMC, Amsterdam Immunology and Rheumatology Center;* [2]*Vascular medicine, Academisch Medisch Centrum;* [3]*Reade, Amsterdam Immunology and Rheumatology Center, Amsterdam, Netherlands;* [4]*UCB, Brussels, Belgium*

Background: Patients with spondyloarthritis (SpA), a chronic inflammatory disease, have an increased cardiovascular risk, which is partly due to increased inflammatory activity in the arterial wall.
IL-17A blockade with secukinumab is an effective treatment for SpA. The role of IL-17A in atherogenesis is controversial, some studies suggest that IL-17A is pro-atherogenic, while others indicate that IL-17A is athero-protective. So, it is not known wat the effect is of treatment with IL-17A blockade on inflammatory activity in the arterial wall.
Objectives: To assess the effect of 3 months treatment with secukinumab on arterial wall inflammation in SpA patients with peripheral disease (pSpA).
Methods: We included 20 patients with clinical pSpA in a 12 week open-label trial. Treatment consisted of 300 mg secukinumab once a week during the first 4 weeks and then every 4 weeks thereafter. EULAR DAS response was used to define a responder/non responder state. To measure arterial wall inflammation we performed a 18-fluorodeoxyglucose positron emission tomography with computed tomography (^{18}F-FDG PET/CT) imaging in 18 patients at baseline and week 12, which is a validated method to quantify arterial wall inflammation. Arterial wall inflammation is measured in both the ascending aorta and carotids, maximal FDG uptake is shown as the maximal target-to-background ratio (TBR_{max}).
Results: 18 patients with pSpA (age 44±12, 72% male) and without a previous cardiovascular event underwent imaging. Overall, three months treatment with secukinumab resulted in a significant improvement of disease activity with 17/18 patients achieving a EULAR DAS response (9 good and 8 moderate responders). Correspondingly, CRP levels decreased significantly (baseline: 3.2 [1.2–12.40] mg/dl vs. wk 12: 2.0 [1.1–5.8] mg/dl, p=0.011). Importantly, treatment with secukinumab did not affect cholesterol levels (total cholesterol baseline: 5.1±1 mmol/l v.s wk 12: 5.5±1 mmol/l, p=0.167; LDL-c baseline: 3.2±0.8 mmol/l v.s wk 12: 3.5±0.9 mmol/l, p=0.219). Additionally, arterial wall inflammation as measured by PET-CT did not change over the course of the 12 weeks treatment with secukinumab (aorta TBR_{max} baseline: 3.3±0.9 vs. wk 12: 3.3±0.7, p=0.861; carotid TBR_{max} baseline: 1.88±0.6 vs. wk 12: 1.76±0.4, p=0.067).
Conclusions: This pilot study in 18 patients with pSpA without any preexisting CV events showed that treatment with secukinumab for 3 months has no effect on arterial wall inflammation as measured by PET-CT. Further research in larger patient groups, over a longer period of treatment, and with different measurements remains warranted to fully elucidate the effect of IL-17A blockade on vascular inflammation.

FRI0465 ANGLES OF SACRUM INCLINATION EFFECT ON RADIOLOGIC IMAGING READING IN SPONDYLOARTHRITIS (THE ANTELOPE-DESIR STUDY)

M. Herbette[1], L. Deloire[2], F. Garrigues[2], L. Gossec[3], A. Simon[4], A. Feydi[5], F. de Bruin[6], M. Reijnierse[6], D. van der Heijde[7], D. Loeuille[8], P. Claudepierre[9], T. Marhadour[1], A. Saraux[1] on behalf of DESIR cohort. [1]*Rheumatology;* [2]*Radiology, CHU Brest and Université Bretagne Occidentale, Brest;* [3]*Rheumatology, Pitié -Salpétriere, Paris;* [4]*Neurosurgery, CHU Brest and Université Bretagne Occidentale, Brest;* [5]*Radiology, CHU Cochin, Paris, France;* [6]*Radiology;* [7]*Rheumatology, Leiden, Leiden, Netherlands;* [8]*Rheumatology, CHU, Nancy;* [9]*Rheumatology, CHU Creteil, Paris, France*

Objectives: To assess the impact of spinal angles on clinical and imaging features of suspicion of axial spondyloarthritis (axSpA).
Methods: The DESIR cohort is a prospective longitudinal cohort study of adults aged 18–50 with inflammatory back pain (IBP) ≥3 months, ≤3 years. Baseline lateral lumbar radiography of patients included in DESIR cohort were read by two central blinded fellow readers (and a rheumatologist spine specialist in case of discrepancy) for Sacral Horizontal Angle (SHA), Lumbosacral angle (LSA) and total Lordotic Angle (TLA) measures. On the basis of literature, patients were classified depending on whether they had TLA more or less than 50°, SHA more or less than 40° or LSA more or less than 15°. Associations between angles and baseline clinical variables, presence of X-Rays (New York) and MRI (ASAS and MORPHO proposal definition) sacroiliitis, presence of spinal signs of spondyloarthritis (mSASSS, BASRI-total, SPARCC scores), presence

of spinal degenerative MRI signs on X-rays (yes or no) and MRI (presence of Modic abnormalities, Pfirrmann score, Canal stenosis, Extrusion, High intensity zone Facet osteoarthritis) according to central reading (two readers) and axSpA diagnostic confidence (according to local clinician's confidence on a 0–10 visual analog scale) were assessed by univariate analysis using the chi-square test (or Fisher's exact test where appropriate) and the Mann-Whitney test. Adjustment for multiple testing was performed according to Bonferroni method.

Results: Of 708 patients, data were available for 677, 675 and 672 for SHA, LSA and TLA, measures with a mean value of 39.2°, 14.5° and 51.5° respectively. Clinical features and diagnostic confidence did not differ between the SHA, LSA and TLA groups. More sacroiliitis imaging, according to ASAS (41.4% versus 32.0%) and MORPHO definition (48.6% versus 39.3%), were reported in TLA<50° group but the differences did not reach statistical significance. Radiological scores were low with a mean value of 0.49 (±1.83), 0.30 (±0.78) and 4.9 (±9.0) for mSASSS, BASRI-total and SPARCC score, respectively, and no inter-group difference was found. In L5S1, more grade 3 and 4 Pfirrmann class and MODIC discopathy (types 1 and 2) were observed for SHA <40°, and TLA <50° (p<0.001) whereas the difference did not reach the significance level for LSA<15° (p=0.05) (table).

Level	L5/S1					
Angles	SHA		LSA		TLA	
	<40	>40	<15	>15	<50	>50
Number of patients	328	300	313	313	270	353
Pfirmann class =3	**99 (30.2)**	**53 (17.7) ****	92 (29.3)	58 (18.5)*	**83 (30.7)**	**68 (19.3) ****
High Intensity Zone	61 (18.6)	35 (11.7)*	60 (19.2)	36 (11.5)*	40 (14.8)	56 (15.9)
Disc protrusion	37 (11.3)	22 (7.3)	27 (8.6)	30 (9.6)	34 (12.6)	24 (6.8)*
Disc extrusion	29 (8.8)	17 (5.7)	28 (8.9)	18 (5.8)	24 (8.9)	22 (6.2)
Canal stenosis	8 (2.4)	2 (0.7)	2 (0.7)	7 (2.2)	7 (2.6)	3 (0.8)
MODIC 1 signal	12 (3.7)	5 (1.7)*	15 (4.8)	2 (0.6)*	13 (4.8)	4 (1.1)*
MODIC 2 signal	7 (2.1)	1 (0. 3)*	2 (0.6)	1 (0.3)*	5 (1.8)	3 (0.4)*
Facet joint osteoarthritis	1 (0.3)	2 (0. 7)	1 (0.3)	2 (0.6)	1 (0.4)	2 (0.6)

Conclusions: Lumbar spine morphology is not associated with any clinical variable, presence on X-Rays or MRI of spinal signs of spondyloarthritis or sacroiliitis. At the L5S1 level, a more horizontal SHA and a reduction of TLA is associated with more degenerative radiological lumbar spine manifestations.

FRI0466 REAL-LIFE PERFORMANCE OF THE ASAS HEALTH INDEX IN ROUTINE CARE OF PATIENTS WITH SPONDYLOARTHRITIS

U. Kiltz, T. Wiatr, X. Baraliakos, K. Fedorov, J. Braun. *Rheumatology, Rheumazentrum Ruhrgebiet, Herne, Germany*

Background: The measurement properties of the ASAS Health Index (ASAS HI) which has been developed to measure health and functioning of patients with spondyloarthritis (SpA) have been evaluated in a cohort study. Its association with structural changes has not been examined to date.

Objectives: To investigate the relationship between clincial data, function and health as assessed by the ASAS HI in patients with axial SpA (axSpA) and to study the influence of structural spinal changes on this instrument.

Methods: Patients fullfilling ASAS classification criteria for axSpA were recruited prospectively. Information was collected on clinical assessments (ASAS HI, NRS pain, BASDAI, ASDAS, BASFI, BASMI), laboratory parameters and spinal x-rays. Images were scored using mSASSS by two independent readers. The relationship between ASAS HI and other health outcomes was evaluated by Spearman correlation.

Results: A total of 150 patients (57 nr-axSpA and 93 AS patients) were included: 68.7% male, mean (SD) age 46.4 (14.1), symptom duration 18.7 (13.5) and diagnosis since 11.4 (11.8) years, and HLA-B27 positive in 82.0%. Values of clinical assessments were ASAS HI 7.4 (4.1), BASDAI 4.7 (2.3), ASDAS 2.7 (1.1), BASMI 3.3 (1.8), pain 5.7 (2.7), and BASFI 4.7 (2.6). Elevated CRP levels were found in 34.8% of the patients. Radiographs of the sacroiliac (SI) joint and the spine were available in 138 patients, 38.0% of which had syndesmophytes and 7.5% had a bamboo spine. The median (IQR) mSASSS value was 4.3 (IQR 1.0–22.1) in AS und 0.2 (IQR 0.0–1.4) in nr-axSpA patients. Patients received a treatment with NSAIDs (62.7%), DMARDs (20.9%) and/or biologics (49.4%). Significant correlation of ASAS HI was found for BASFI (r=0.8), BASDAI (r=0.7), ASDAS (r=0.5) and BASMI (r=0.5, and, all p<0.05). No correlations were found for ASAS HI and radiographic damage (mSASSS r=0.2, occurrence of syndesmophytes r=0.01, occurrence of bamboo spine r=0.2) and CRP levels (r=0.07). Stratifying patients by symptom duration (cut-off 3 years) did not affect these results.

Conclusions: Established measures of function and spinal mobility correlate well with the ASAS HI in patients with axSpA. The influence of structural changes as measured by mSASSS on the ASAS HI was limited in this study, probably due to relatively low mSASSS scores at baseline,. Further study in more and more severe patients is needed to study the association of physical activity, spinal mobility, function and radiographic damage in axSpA.

FRI0467 DEVELOPMENT AND PRELIMINARY VALIDATION OF THE COMPUTED TOMOGRAPHY SACROILIAC STRUCTURAL SCORE (CT-SSS) FOR ASSESSMENT OF STRUCTURAL LESIONS IN AXIAL SPONDYLOARTHRITIS

W.P. Maksymowych[1,2], M. Raynal[3], D. Loeuille[3], M.-A. D'Agostino[4], J. Paschke[2], R.G. Lambert[5]. *[1]Medicine, University of Alberta; [2]CaRE Arthritis, Edmonton, Canada; [3]Rheumatology, CHRU de Nancy, Vandœuvre-lès-Nancy; [4]Rheumatology, Université Paris Ouest, Paris, France; [5]Radiology, University of Alberta, Edmonton, Canada*

Background: Computed tomography (CT) is considered the imaging benchmark for the assessment of certain structural lesions in the sacroiliac joints (SIJ) of patients with axial spondyloarthritis (axSpA). Availability of low dose radiation techniques may lead to more widespread use, potentially as a structural endpoint in clinical trials research.

Objectives: We aimed to validate a new CT-based scoring method, the CT Sacroiliac Structural Score (CT-SSS), for assessing structural lesions in the SIJ.

Methods: CT scans of the SIJ from 44 patients (26 females, mean age 49.4 years, mean symptom duration 9.1 years) were reconstructed in the semicoronal plane parallel to the superior border of the sacrum and scoring of lesions was confined to this plane. Structural lesions were scored in consecutive slices in SIJ quadrants (erosion, sclerosis) or SIJ halves (ankylosis) on a dichotomous basis (present/absent) using the same anatomical principles as developed for the SPARCC MRI SIJ inflammation and structural scores. The most anterior slice is defined as visible joint ≥1cm vertical height and when <3 cm is defined as having only upper iliac and sacral quadrants. A visible joint ≥3cm vertical height is defined as having 4 quadrants. At the posterior aspect of the SIJ, there is a natural separation of iliac and sacral cortical bone by structures in the ligamentary portion. Scoring is terminated when <1cm of iliac and sacral bone is appositional. Two readers independently scored CT scans without a prior calibration exercise and using direct online data entry onto a schematic of the SIJ. Reliability was assessed by kappa statistics, intra-class correlation coefficient (ICC), and Bland-Altman limits of agreement.

Results: Scoring was feasible (5–10 minutes per scan) and both ankylosis (ICC=0.95) and erosion (ICC=0.81) were reliably scored (Table). Sclerosis was less reliably scored (ICC=0.39). Presence/absence of ankylosis was reliably detected irrespective of whether this was based on a single slice (κ=0.77) or 3 consecutive slices (κ=0.81). Reliable detection was lower for erosion (κ=0.50 for 1 or 3 slices) and sclerosis (κ=0.44 and 0.48 for 1 and 3 slices, respectively). Bland-Altman graphs illustrate reliability across the range of scores for ankylosis and erosion.

Table 1. Descriptive and Reliability data for CT-SSS score

	Mean (SD) score		Median (IQR) score		ICC	95% L of A
	R1	R2	R1	R2		
Erosion	4.4 (9.7)	6.5 (11.5)	0 (25.5)	0 (21)	0.95	-10.7, 13.5
Ankylosis	7.5 (14.1)	6 (13.6)	0 (12)	0 (12)	0.81	-16.2, 12.2
Sclerosis	6.6 (14.4)	7.4 (18.2)	0 (20)	0 (24.5)	0.39	-34.5, 33.0

IQR interquartile range L of A Limits of Agreement.

Conclusions: The CT-SSS method is feasible and reliable for scoring ankylosis and erosion with minimal calibration. Sclerosis requires further standardization and calibration.

FRI0468 RADIOGRAPHIC HIP INVOLVEMENT IN PATIENTS WITH ANKYLOSING SPONDYLITIS. A STUDY OF ITS PREVALENCE AND DETERMINING FACTORS

X. Michelena, M. López de Recalde, H. Borrell, J. Lluch, P. Juárez, I. Morales, M. Pascual, J.-M. Nolla, X. Juanola. *Department of Rheumatology, Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Barcelona, Spain*

Background: Hip involvement in Ankylosing Spondylitis (AS) is the most frequent extraspinal manifestation and a common cause of disability and limited mobility, often ending with hip replacement. There are few studies analysing the radiographic changes of the hip and their relationship with other disease variables.

Objectives: To determine the factors associated with radiographic hip involvement and its prevalence.
Methods: A cross-sectional study was performed based on patients with AS, excluding the patients with associated psoriasis or inflammatory bowel disease. To assess radiographic hip involvement, we scored the last anteroposterior pelvic radiograph performed using the *Bath Ankylosing Spondylitis Radiology Index* (BASRI). Demographic, clinical, laboratory and radiographic data were collected and analysed. We considered the presence of hip disease with a BASRI-hip grade of at least 2. Statistical analysis: A descriptive study was performed. To compare differences we used a 1-way ANOVA test and Pearson chi-square. The statistical analyses were done using SPSS 24.0. $p \leq 0.05$ was considered statistically significant.
Results: 215 patients were identified, with a mean age of 52±13.6 years and 76.7% of the patients were male. The age at onset was 25.29±8.22 years. 86.4% of the patients were HLA-B27-positive. Regarding their treatment, 27.9% were under biological therapy. A hip replacement was needed in 14 patients (0.7%), with 6 of them requiring a bilateral hip replacement. The mean BASDAI score, BASFI score and ASDAS CRP index were 4.01±6.31; 4.73±8.8 and 2.17±1.01 respectively.
The table shows the comparison between the two groups based on the presence of hip involvement (BASRI hip $\geq$2). Statistically significant differences were observed in the age, age at onset and presence of peripheral arthritis. Patients with hip involvement had higher scores in BASFI score, ASDAS CRP and ESR. Axial radiographic involvement assessed with axial BASRI score and total SASSSm was associated with hip disease and a significant association was seen between hip involvement and metrological parameters.

	No hip disease n=154 (71.6%)	Hip disease n=61 (29.4%)	P-value
Age* (years)	49.5±13.63	58.16±11.53	<0.001
Age at onset* (years)	26.14±8.4	23.16±7.38	0.017
Male sex, n (%)	113 (73.4)	52 (85.2)	0.063
HLAB27+, n (%)	132 (85.7)	52 (85.2)	0.790
Peripheral arthritis, n (%)	33 (21.4)	25 (41.0)	0.004
Uveitis, n (%)	40 (26.0)	13 (21.3)	0.475
Biological treatment, n (%)	41 (27.0)	19 (31.1)	0.54
BASDAI*	3.84±7.29	4.47±2.14	0.527
BASFI*	3.79±7.15	7.23±11.81	0.012
ASDAS CRP*	2.07±1.01	2.45±0.95	0.014
ASDAS ESR*	1.89±0.90	2.52±1.92	0.002
Schober's index* (cm)	3.61±1.55	2.43±1.69	<0.001
Chest expansion* (cm)	4.97±1.84	3.67±2.02	<0.001
Cervical rotation* (cm)	72.03±19.73	49.18±28.01	<0.001
Lateral flexion* (cm)	12.96±5.18	7.85±4.1	<0.001
Occiput to wall distance* (cm)	2.49±4.36	8.45±8.38	<0.001
Intermalleolar* (cm)	100.22±21.22	82.37±17.91	<0.001
Axial BASRI*	5.31±3.10	8.53±3.38	<0.001
Total SASSSm*	10.24±16.07	30.67±27.31	<0.001

*Mean ± SD.

Conclusions: Radiographic hip involvement assessed with BASRI score is prevalent and it is related with the age at onset, disease activity and the presence of peripheral arthritis. These patients present more disability, less mobility and greater axial radiographic involvement.
Disclosure of Interest: None declared

FRI0469 DIFFERENCES BETWEEN ANKYLOSING SPONDYLITIS PATIENTS WITH AND WITHOUT RADIOGRAPHIC HIP INVOLVEMENT IN CHINA

X. Zheng, Q. Wei, J. Gu. *Department of Rheumatology and Immunology, The Third Affiliated Hospital of Sun Yat-sen Universiy, GuangZhou, China*

Background: Hip involvement, defined by clinical examination or imaging techniques, is a problem of great concern in Ankylosing Spondylitis (AS) patients as it leads to functional impairment and poor outcomes. It has been shown that early age at disease onset, peripheral manifestation and severe axial disease are risk factors, but other characteristics do not show consistency through studies and data is scarce so far.
Objectives: We aim to describe the phenotype differences between AS patients with and without radiographic hip involvement and to identify potential risk factors for hip involvement.
Methods: AS patients fulfilling the Modified New York Criteria and whose pelvic X-rays have been assessed by at least one radiologist and one rheumatologist were included. Radiographic hip involvement was defined by features of osteophytes around the femoral neck, erosions of the acetabulum, axial migration of the femoral head or hip joint space narrowing. The medical records were retrospectively reviewed and collected. Demographic and disease characteristics were compared by descriptive and bivariate statistics using SPSS v19.0 and stata v12.1 package.
Results: Totally 261 AS patients with hip involvement and 429 patients without hip involvement were analyzed. Statistical significance were found between these 2 groups regarding age at disease onset, gender, BMI, disease duration and presence of peripheral arthritis, with all p value$\leq$0.001. Male patients showed strong risk effect on hip involvement with the odds ratio (OR) around 3.27. Meanwhile, the hip-involved group had lower body mass index (BMI), which may relate to long disease duration or high inflammation level. No significant difference of HLA-B27 positivity, family history and other factors were observed (Table 01). Binary logistic regression results showed that age at disease onset, gender, BMI and disease duration were associated with hip involvement in AS ($p<0.001$). As for the symptoms, among 69 hip-involved and 75 non-involved AS with corresponding records, 83% hip-involved and 35% non-hip-involved patients complained of typical inguinal pain (OR=8.95, 95% CI=3.85~21.37, $p<0.001$).

Table 1

	AS with hip involvement (n=261)	AS without hip involvement (n=429)	*p* value
Age, m (SD)	28.57 (8.66)	28.01 (8.53)	0.41
Age at disease onset, m (SD)	18.28 (5.74)	22.31 (6.87)	<0.001
Men, n (%)	240 (91.95)	336 (77.78)	<0.001
BMI, m (SD)	20.35 (3.47)	21.31 (3.30)	<0.001
Disease duration, median (interquartile range)	108.00 (120.00)	48.00 (72.00)	<0.001
HLA-B27 positive, n (%)	230 (90.20)	370 (88.94)	0.61
Family history positive, n (%)	72 (27.80)	100 (23.53)	0.22
Inflammatory low back pain, n (%)	235 (90.38)	381 (88.81)	0.52
Peripheral arthritis, n (%)	118 (45.21)	140 (32.86)	0.001
Dactylitis, n (%)	9 (3.45)	9 (2.10)	0.28
Uveitis, n (%)	28 (10.73)	48 (11.21)	0.84
Enthesitis, n (%)	56 (21.62)	89 (21.04)	0.86
Axial pattern, n (%)	132 (50.57)	249 (58.04)	0.056

Conclusions: Compared to AS patients without hip involvement, the radiographic hip-involved group are younger age at disease onset, more frequently men and complaining of typical inguinal pain, have lower BMI and longer disease duration. AS patients having these concomitant risk factors should undergo further hip assessment in clinical practice.

FRI0470 CIGARETTE SMOKING HAS A DOSE-DEPENDENT RELATIONSHIP WITH DISEASE ACTIVITY AND CORRELATES WITH MORE FUNCTIONAL LIMITATION AND WORSE HEALTH ASSESSMENT IN THE PATIENTS WITH ANKYLOSING SPONDYLITIS

Y. Jiang, Z. Liao, Z. Lin, M. Yang, Y. Zhang, Q. Li, J. Gu. *Rheumatology, the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Background: Ankylosing spondylitis (AS) is a chronic inflammatory disease that mainly affects the axial skeleton by causing inflammatory and osteoproliferative changes in the sacroiliac joints and spinal structures [1]. Cigarette smoking is associated with poor outcome in patients with established and early AS [2].
Objectives: Our study was to investigate the relationship between cigarette smoking and pain, disease activity, functional limitation, and health assessment in Chinese patients with AS.
Methods: Patients with AS (n=683) from China took part in a cross-sectional survey. Smoking status was obtained by a standardized questionnaire, involving smoking status (non-smokers, exsmokers, current smokers), the age when starting smoking, cigarette numbers a day and smoking status of family numbers. The Bath AS Disease Activity Index (BASDAI), the Bath AS Functional Index (BASFI), visual Analogue scale of pain, Health Assessment Questionnaire for Spondyloarthropathy (HAQ-S) were analyzed in terms of smoking status and relationship with pack-year history.

Table 1. Demographic features and clinical and laboratory results of the patients with AS and comparison between patients with different smoking status

Variable	All patients N=683	Non-smokers N=407	Ex-smokers N=108	Current smokers N=168	*P*(1:3)	*P*(2:3)	*P*(1:2)
Age (years)	27.33±8.67	26.04±8.65	27.65±8.74	30.24±7.98	0.000	0.001	0.069
Disease duration (years)	6.47±6.47	5.73±6.08	6.81±6.54	8.05±7.05	0.000	0.094	0.071
Morning stiffness (VAS)	3.12±2.86	2.84±2.87	2.87±2.53	3.96±2.89	0.000	0.003	0.739
Overall Pain (VAS)	3.97±2.77	3.78±2.83	3.96±2.70	4.44±2.61	0.005	0.150	0.440
Nocturnal back pain (VAS)	2.93±2.96	2.63±2.90	2.89±2.73	3.68±3.11	0.000	0.049	0.216
ESR (mm/h)	20.94±21.71	20.80±22.61	19.65±20.92	22.11±19.98	0.311	0.150	0.407
CRP (mg/dl)	18.4±26.01	17.33±28.14	18.4±22.76	20.98±22.26	0.001	0.126	0.340
BASDAI	3.36±2.03	3.21±2.05	3.30±1.79	3.76±2.07	0.002	0.065	0.437
BASFI	5.21±9.21	1.47±2.07	1.54±1.98	1.55±1.63	0.018	0.379	0.251
HAQ	0.21±0.33	0.20±0.33	0.19±0.30	0.23±0.33	0.130	0.313	0.213

P(1:3) refers to p value of the The Mann-Whitney U test and t test between non-smokers and current smokers.

Results: Of all the 683 patients, 168 are current smokers, while 108 were ex-smokers and 407 patients never smoked. Mean scores of degree and duration of morning stiffness, overall pain, nocturnal back pain, overall back pain, CRP, BASDAI and BASFI score were all higher in the current smoker group compared to those who had never smoked ($P<0.05$). In Spearman correlation analysis, pack years of smoking in current smokers were significantly associated with disease duration, morning stiffness (VAS) and duration, nocturnal back pain, overall back pain, CRP, and BASDAI ($P<0.01$), and overall pain, BASFI and HAQ-S ($P<0.05$).
Conclusions: Cigarette smoking has a dose-dependent relationship with disease activity and correlates with more functional limitation and worse health assessment in patients with AS.

FRI0471 PSYCHOLOGICAL DISORDERS, SLEEP DISTURBANCE AND STRESSFUL LIFE EVENTS IN THE PATIENTS WITH ANKYLOSING SPONDYLITIS

Y. Jiang, M. Yang, Y. Zhang, Z. Liao, Z. Lin, Q. Lv, J. Qi, Q. Wei, S. Cao, J. Gu. *Rheumatology, the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China*

Background: Ankylosing spondylitis (AS) is a chronic inflammatory rheumatic disease that may result in pain, functionally limitation and even less life expectancy. Psychological symptoms not only have a substantial negative impact on the quality of life, but also on the course and outcome of the chronic disorder [1]. AS patients may also suffer from various sleep problems, and pain intensity, anxiety, and depression correlated significantly with poorer sleep quality [2]. Stressful life events have a substantial association with psychological disorders, and there is some evidence indicating that even early life stress constitutes a major risk factor for the subsequent development of mental disorder [3].
Objectives: Our study was to investigate psychological disorders, sleep disturbance and stressful life events in Chinese patients with AS, and to assess the correlation between each two disorders.
Methods: AS patients diagnosed with the modified New York criteria for AS were enrolled from several provinces all over China. Participants were required to complete a set of questionnaires and examinations, including demographic and clinical information, Zung self-rating anxiety scale (SAS), Zung self-rating depression scale (SDS), the Social Readjustment Rating Scale (SRRS) and the Pittsburgh Sleep Quality Index questionnaire (PSQI). The Statistical Package for Social Sciences (SPSS) software version 21 was used for all data management and analysis. The relations between psychological variables, stressful life events, sleep quality and other parameters were examined with Spearman correlation analysis.
Results: Of all the 2772 AS patients, 79.1% were male patients. 79.5% were employed. 48.4% were married. Mean age was 28.99±8.87. Mean disease duration was 6.84±6.78. Mean SAS score was 49.32±18.75. 31.6% of the patients had anxiety, of which 10.8% had severe anxiety. Mean SDS score was 54.97±16.67. 59.3% had suffered from depression, of which 11.3% had severe depression. Mean PSQI score was 6.48±4.32. 31.0% of the patients were poor sleepers. SRRS score was 129.33±145.06. 35.3% had stimulus of psychological and social elements (SPSE), while 14.4% came across severe SPSE. SAS scores were associated with age, age onset, SDS scores, SRRS scores positively and years of education negatively ($P<0.01$). SDS scores were associated with age, SAS scores, SRRS scores positively and years of education negatively ($P<0.01$). SRRS scores also correlated of less sleep efficiency ($P<0.05$).
Conclusions: A large number of AS patients were found to have anxiety, depression, sleep disturbance and stressful life events. These problems correlated with each other. Clinicians should pay more attention to psychological disorders and sleep problems in AS patients.

FRI0472 EXTRA-RHEUMATOLOGICAL FEATURES ARE FREQUENTLY ASSOCIATED WITH PERIPHERAL RHEUMATOLOGICAL FEATURES IN AXIAL SPONDYLOARTHRITIS AND INFLUENCE THE CHOICE OF THE ANTI-TNF IN DAILY PRACTICE. AN ANALYSIS OF 519 PATIENTS

A. Moltó, A. Etcheto, L. Gossec, S. Perrot, N. Boudersa, P. Claudepierre, N. Roux, F. Berenbaum, A. Martin, L. Sparsa, P. Coquerelle, M. Soubrier, M. Dougados. *Predict-SpA Study Group, Paris, France*

Background: Axial involvement is the predominant feature of axSpA but both extra-articular (EAM)and peripheral manifestations (including synovitis and dactylitis) can be concomitantly observed.
Objectives: To evaluate whether the EAM are associated with peripheral rheumatological features in axSpA and whether these EAM influence the choice of the anti-TNF.
Methods: *Study design:* Prospective, multicenter, cross-sectional study in France (baseline visit of the Predict-SpA trial). *Patients:* definite axSpA according to the rheumatologist, requiring an anti-TNF. *Data collected:* Past or present signs/symptoms of EAM (psoriasis, uveitis and Inflammatory Bowel disease (IBD)), peripheral (arthritis, enthesitis and dactylitis) SpA features, and the anti-TNF prescribed by the treating rheumatologist (according to usual practice). Statistical analysis: the frequency of peripheral involvement and the type of anti-TNF (e.g. monoclonal antibodies vs soluble receptor) were compared in patients with versus (vs) without EAM.
Results: Of the 519 patients (females: 46%, age: 42±12 years, HLA B27 positive: 65%, X-Ray sacroiliitis: 56%, inflammation on MRI of the sacro Iliac Joint: 56%), 386 were biologic naïve. A past history or current symptoms of psoriasis, uveitis and IBD was observed in 19%, 17% and 5% respectively and a past history or current symptoms of arthritis, enthesitis and dactylitis in 27%, 54%, 11%, respectively
In patients with vs without psoriasis, the % of arthritis, enthesitis and dactylitis were 40% vs 25% (p=0.004), 67% vs 50% (p=0.002) and 18% vs 10% (p=0.026), respectively
In patients with vs without uveitis, the % of arthritis, enthesitis and dactylitis were 31% vs 27% (p=0.445), 57% vs 53% (p=0.200) and 13% vs 11% (p=0.772),respectively
In patients with vs without IBD, the % of arthritis, enthesitis and dactylitis were 36% vs 27% (p=0.440), 68% vs 53% (p=0.180) and 21% vs 11% (p=0. 152), respectively
Monoclonal antibodies were prescribed as the first biologic in 206 out of the 386 patients (53%).This percentage was 56% vs 58% and vs 52% in patients with a current presence of psoriasis vs any history of psoriasis but currently absent and vs without any history of psoriasis, respectively; p=0.785. This percentage was 100% vs nd% (n=0) and vs 53% in patients with a current attack of uveitis vs any history of uveitis but currently inactive and vs without any history of uveitis, respectively; p=0.032. This percentage was 100% vs 50% (n=2) and vs 53% in patients with a current active IBD vs any history of IBD but currently inactive and vs without any history of IBD, respectively; p=0.064.
Conclusions: In this study focused on ax SpA patients, both peripheral rheumatological clinical features and EAM were frequently observed. The peripheral rheumatological manifestations were more frequently observed in case of concomitant psoriasis. Monoclonal antibodies were the preferred anti-TNF in case of a past history (even currently quiescent) of uveitis or IBD in daily practice.

FRI0473 PATIENT-PHYSICIAN DISCORDANCE IN GLOBAL ASSESSMENT IN 401 EARLY AXIAL SPONDYLOARTHRITIS (AXSPA) PATIENTS FROM THE DESIR COHORT: WHAT IS THE EFFECT ON OUTCOMES AT 3 YEARS?

C. Desthieux[1], A. Molto[2], A. Saraux[3], B. Fautrel[1], L. Gossec[1]. *[1]Rheumatology, Paris 06 University and Pitié-Salpêtrière Hospital; [2]Rheumatology, Paris Descartes University and Cochin Hospital, Paris; [3]Cavale Blanche University Hospital, Brest, France*

Background: Discordance between patients' and physicians' ratings of disease activity is frequent. We have previously shown this discordance occurs in around 28% of visits in early axSpA though repeated discordance (over several visits) is less frequent (1).
Objectives: To assess in patients with early axSpA, the impact at 3 years of repeated discordance on treatment prescription, functional incapacity and remission.
Methods: DESIR (Devenir des Spondyloarthropathies Indifférenciées Récentes) is a French, multicenter, longitudinal cohort of patients with early inflammatory back pain suggestive of axSpA (2). Patient and physician global assessment

(respectively PGA and PhGA) were rated on a 0–10 numeric scale, every 6 months during 2 years then at 3 years. Only patients with all data available for PGA and PhGA for each of the 6 visits were included. Repeated discordance was defined as an absolute difference |PGA–PhGA|≥3/10 for at least 3 of the 6 visits (i.e., at least half of the visits). Univariable and multivariable logistic models were used to determine if repeated discordance was associated at the 3 years timepoint, with prescription of TNFi, functional incapacity defined as HAQ>0.5, and remission defined as ASDAS-CRP<1.3.

Results: Of 401 patients, mean age 34.6±8.7 years, mean symptoms duration 17.8±10.7 months, 219 (54.6%) were female and mean ASDAS-CRP at baseline 2.7±1.0. At 3 years 140 (34.9%) patients had been prescribed a TNFi, 172 (43.2%) had HAQ>0.5 and 89 (25.1%) were in remission. Over the 6 visits, mean PGA was higher than mean PhGA with a mean absolute difference of 0.8±2.2 points. Discordance concerned 110 (27.4%) patients at baseline and repeated discordance concerned 92 (22.9%) patients. In multivariable logistic regression, after adjusting on the others significant factors (which included MRI sacro-iliitis, HLA-B27 and ASDAS-CRP at baseline), repeated discordance was associated with more functional incapacity (61% vs 38%, odds ratio, OR 2.85 [95% CI 1.49–5.62]) and less remission (10% vs 30%, OR 0.38 [0.15–0.85]) but not more TNFi use (34% vs 35%, 1.39 [0.78–2.54] p=0.27).

Conclusions: In early axSpA, repeated discordance concerned 22.9% of patients confirming the frequency of this situation. Repeated discordance was associated with worse outcomes at 3 years, even after adjustment of other factors including baseline ASDAS, indicating for the first time that discordance may indeed reflect an unsatisfactory management of medical care leading to worse outcomes. Future studies should concentrate on understanding the reasons of patient-physician discordance for disease activity in axSpA.

FRI0474 DOES AXIAL SPONDYLOARTHRITIS PHENOTYPE CORRELATE WITH IMAGING MORPHOTYPE?

X. Baraliakos[1], A. Szumski[2], H.E. Jones[3], L. Gensler[4]. *[1]Ruhr University, Bochum, Germany; [2]inVentiv Health, Princeton; [3]Pfizer, Collegeville; [4]University of California, San Francisco, United States*

Background: Traditionally, radiographic imaging was used to describe morphological differences between various types of axial SpA (axSpA). The advent of MRI has advanced understanding of disease, enabled earlier diagnosis and visualization of structural changes, and facilitated the identification of non-radiographic axial SpA (nr-axSpA). The magnitude of the pathologic changes in the axial skeleton is used to quantify inflammatory and structural outcomes of clinical trials and treatment of patients with axSpA.

Objectives: To examine the MRI morphology of sacroiliitis (SI) and vertebral corner lesions in patients with primary (1°, no psoriasis) and secondary (2°, with psoriasis) axSpA.

Methods: This posthoc analysis was performed on data from patients with axSpA enrolled in the EMBARK trial (NCT01258738). Only patients with baseline MRI lesions were included. Symmetric and asymmetric SI, structural lesions, and corner inflammatory lesions were analyzed in 1° axSpA vs 2° axSpA patients. Data were analyzed using one-way analysis of variance for continuous parameters, chi-square tests, or Fisher's exact tests for categorical parameters.

Results: The baseline demographics and disease characteristics between the 122 patients with 1° axSpA and 19 with 2° axSpA were similar. Asymmetric sacroiliitis was seen in significantly fewer 1° (43%) vs 2° (68%) axSpA patients. There were no differences in mean SpondyloArthritis Research Consortium of Canada (SPARCC) scores between 1° and 2° axSpA for any of the 4 SI joint (SIJ) quadrants. However, the lower iliac quadrants had the highest SPARCC SIJ score and the upper iliac quadrants had the lowest SPARCC SIJ scores. When analyzing the 4 spine quadrants (lower/upper anterior and lower/upper posterior), 1° patients had higher total SPARCC spine scores than 2° patients for all 4 quadrants at baseline. Collapsing the 4 quadrants shows that 1° axSpA patients had higher SPARCC MRI of the entire spine (23 discovertebral units [DVU]; mean=5.7) compared with 2° axSpA patients (mean=2.7).

Conclusions: We found 1° axSpA patients had more symmetric sacroiliitis and extensive spinal bone marrow edema compared with 2° axSpA patients. In addition, women appeared to have more asymmetric sacroiliitis. These data may help physicians accurately diagnose patients and decide best treatment options.

FRI0475 ANTI-CD74 ANTIBODIES AS DIAGNOSTIC BIOMARKER FOR EARLY AXIAL SPONDYLOARTHRITIS: DATA FROM THE SPONDYLOARTHRITIS CAUGHT EARLY (SPACE) COHORT STUDY

J.J. de Winter[1], M.G. van de Sande[1], N. Baerlecken[2], I.J. Berg[3], R. Ramonda[4], D. van der Heijde[5], F.A. van Gaalen[5], T. Witte[2], D.L. Baeten[1]. *[1]AMC, Amsterdam, Netherlands; [2]MHH, Hannover, Germany; [3]Diakonhjemmet Hospital, Oslo, Norway; [4]UniPD, Padua, Italy; [5]LUMC, Leiden, Netherlands*

Background: Diagnosis of axSpA is often delayed with 5–10 years. A robust biological disease marker is lacking and could decrease the current diagnostic delay. Two studies showed that serum anti-CD74 IgG antibodies are increased in SpA[1,2].

Objectives: To explore the value of anti-CD74 antibodies as diagnostic biomarker for axSpA in patients with early, chronic back pain.

Methods: We tested the prevalence of anti-CD74 IgG and IgA antibodies in patients from the SPondyloArthritis Caught Early (SPACE) cohort by enzyme-linked immunosorbent assay (ELISA). Patients from the SPACE cohort have chronic back pain for >3 months and ≤2 years with an onset <45 years.

Results: We included 560 patients of the SPACE cohort, of whom 274 patients were diagnosed with axSpA by a rheumatologist at baseline. Anti-CD74 IgG levels did not differ between patients with and without axSpA (p=0.152, Table 1). Median anti-CD74 IgA levels (tested with either casein or BSA as a blocking buffer) were higher in patients with axSpA (both p<0.0001). Despite these differences at the group level, the diagnostic value of the anti-CD74 IgA antibodies was limited as shown by ROC analysis. The optimal cut off according to ROC analysis was an optical density (OD) of 0.875, providing a sensitivity of 38.3% and a specificity of 77.6%. In line with previous reports, further analysis revealed that total IgA levels were elevated in early axSpA patients vs. non-SpA early back pain patients (p=0.008). When correcting the level of anti-CD74 IgA for the level of total IgA, the differentiating capacity of anti-CD74 disappeared for casein but remained intact for BSA (casein: p=0.731, BSA: p=0.038). Additional analyses using the ASAS classification criteria rather than a clinical diagnosis of axSpA, a strict combination of clinical diagnosis and ASAS classification criteria (excluding patients fulfilling the ASAS axSpA criteria without a clinical diagnosis and vice versa) (Table 1) and using the clinical diagnosis at 1 year of follow-up yielded similar results.

	Axial SpA (baseline)			ASAS axSpA criteria (baseline)			Diagnosis and ASAS axSpA positive (baseline)		
	Yes (n=274)	No (n=286)	*P*-value	Yes (n=224)	No (n=351)	*P*-value	Yes (n=108)	No (n=177)	*P*-value
anti-CD74 IgA (casein, OD)	0,73	0,57	**<.0001**	0,74	0,58	**<.0001**	0,78	0,55	**<.0001**
anti-CD74 IgA (BSA, U/mL)	19,92	14,02	**<.0001**	22,55	14,20	**<.0001**	21,82	13,47	**<.0001**
anti-CD74 IgG (OD)	0,50	0,52	0,152	0,49	0,52	.054	0,50	0,52	0,075
anti-CD74 IgA (IC, OD)	0,59	0,6	0,653	0,54	0,62	.112	0,54	0,61	0,383
IgA total (g/dL)	3,94	3,39	**0,008**	3,79	3,51	.084	3,92	3,38	**0,017**
ratio IgA (casein) / IgAtotaal	0,17	0,17	0,731	0,17	0,17	.614	0,18	0,17	0,435
ratio IgA (BSE) / IgAtotaal	4,35	3,56	**0,038**	4,37	3,70	.070	4,37	3,39	**0,036**
ratio IgA IC / IgAtotaal	0,18	0,18	0,387	0,18	0,18	.388	0,17	0,19	0,294

Table 1. Levels of IgG and IgA anti-CD74 antibodies, total IgA and anti-CD74/total IgA ratios in patients from the SPACE cohort. Values are expressed as median and compared using Mann-Whitney U testing. Diagnosis and ASAS axSpA positive: patients diagnosed as axSpA and fulfilling the ASAS axSpA criteria vs. patients not diagnosed as axSpA and not fulfilling the ASAS axSpA criteria.

Conclusions: Serum anti-CD74 IgA antibody levels, but not serum anti-CD74 IgG levels, are elevated in patients with axSpA versus non-SpA with back pain of <2 years duration. However, ROC analyses revealed that these numerical differences are of limited diagnostic value in these patients with early back pain.

Abstract FRI0474 – Table 1

Parameter	Total (n=141)	1° axSpA with			2° axSpA with			P value

FRI0476 ANTI-CD74 ANTIBODIES: DIAGNOSTIC PROPERTIES IN LOW HLA-B27 EARLY AXIAL SPONDYLOARTHRITIS

N.R. Ziade[1], F. Fayad[1], I. Mallak[2], G. Merheb[3], T. Witte[4], X. Baraliakos[5].
[1]Rheumatology; [2]Radiology, Hotel Dieu de France, Beirut; [3]Rheumatology, ND Secours, Jbeil, Lebanon; [4]Medicine, Hannover University, Hannover; [5]Rheumatology, Rheumazentrum Ruhrgebiet, Herne, Germany

Background: Axial spondyloarthritis (AxSpA) is a severe and potentially debilitating disease, where earlier diagnosis lead to a better prognosis. Although HLA-B27 antigen is strongly associated with AxSpA, this marker may have a low sensitivity in some Middle-Eastern countries. Recent European studies showed a strong association between antibodies against CD74 and AxSpA with a sensitivity of 85.1%, specificity of 92.2%, and positive likelihood ratio (LR) of 10.8. The diagnostic properties of anti-CD74 may have a particular interest in non-European countries with low HLA-B27 such as Lebanon.
Objectives: In this prospective study, we tested the diagnostic properties of IgG and IgA anti-CD74 as an early diagnostic marker for AxSpA, compared with HLA-B27, in Lebanon, which is known as one of the countries with the lowest HLA-B27 prevalence ever reported.
Methods: Sera of AxSpA patients and healthy blood donors (HBD) were analyzed for HLA-B27 genes (PCR) and for IgG and IgA anti-CD74 (ELISA). The patients were recruited from rheumatology clinics across Lebanon. Clinical assessment and sera sample collection were performed at a center specialized in AxSpA (Hotel-Dieu de France University hospital, Beirut). Inclusion criteria were: age 18–45 years, Lebanese, symptom duration <3 years, AxSpA as per ASAS criteria (imaging arm), no prior biologic therapy. Interpretation of the radiographic images was performed centrally and blindly. Clinical and laboratory assessments of the disease were performed in all AxSpA patients. Comparison between groups was performed with the Fisher exact test and Student's test. For the diagnostic properties of HLA-B27 and anti-CD74, ROC curves were calculated.
Results: 29 AxSpA patients and 75 HBD were tested. AxSpA patients were slightly older (31.3 and 27.4 yo, respectively, p=0.02). Male gender was slightly predominant (51.7% and 53.6%, respectively). 93% had all characteristics of IBP as per ASAS criteria. 62.1% had non radiographic AxSpA. Mean disease duration was 25.2 months (SD 15.9), mean BASDAI 4.5 and mean ASDAS 3.25. 58.6% had extra-articular manifestations (28% enthesitis, 24% psoriasis, 21% peripheral arthritis, 10% IBD and 7% uveitis). 27.6% had familial history of SpA (21%), psoriasis (10%) and Crohn's disease (3.4%). HLA-B27 status was positive in 10 AxSpA patients and in 2 HBD (Sensitivity 34.5%, Specificity 97.2%, Positive LR 12.24). In the ROC analysis, IgG4 anti-CD74 showed the best diagnostic properties for AxSpA (AUC 0.939, cut-off value 0.55). Using this cut-off value, positive values of IgG anti-CD74 were found in 27 axSpA patients and 5 HBD (Sensitivity 93.1%, Specificity 93.3%, positive predictive value 84.4%, negative predictive value 97.2%). Positive LR was 13.97. Anti-CD74 was positive in 58.6% HLA-B27 negative AxSpA (Fig1).

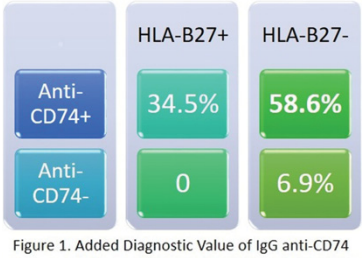

Figure 1. Added Diagnostic Value of IgG anti-CD74 compared to HLA-B27 in Early Axial Spondyloarthritis

Conclusions: In this study in a population with low HLA-B27 prevalence, IgG anti-CD74 antibodies showed higher diagnostic value than HLA-B27 for AxSpA. This is of special interest in populations with low HLA-B27 prevalence, especially on the background of diagnosing AxSpA when using the clinical arm of the ASAS classification criteria.

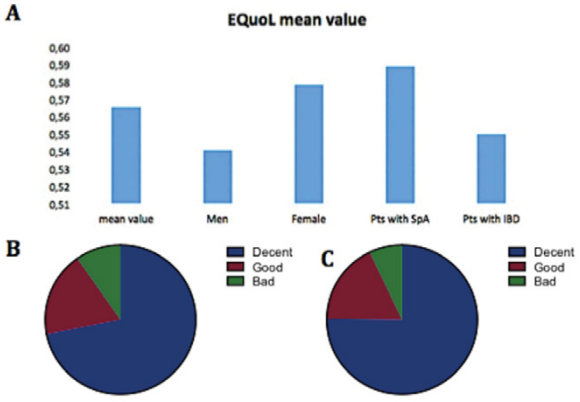
FRI0477 PROSPECTIVE OBSERVATIONAL STUDY ON THE EVALUATION OF QUALITY OF LIFE IN PATIENTS AFFECTED BY ENTEROPATHIC SPONDYLOARTHRITIS

M.S. Chimenti[1], P. Conigliaro[1], B. Polistena[2], P. Triggianese[1], A. Ruffa[3], C. Canofari[1], F. Cedola[1], S. Onali[3], M. Balan[1], E. Calabrese[1], C. Petruzziello[3], F. Spandonaro[2], G. Monteleone[1], L. Biancone[3], R. Perricone[1]. *[1]Department of system medicine, Rheumatology, Allergology and Clinical Immunology; [2]Department of Economic and Finance; [3]Department of system medicine, Gi Unit, Dpt, University of Rome Tor Vergata, Rome, Italy*



Background: Enteropathic Spondyloarthritis (ESpA) belongs to the group of Spondyloarthritis (SpA) tipically associated with inflammatory bowel disease (IBD) as Crohn's Disease (CD) and Ulcerative Colitis (UC). Joint pain is the most common (22–33%) and significant extra-intestinal manifestation in patients with IBD and its management requires reumatological and gastroenterological competence in collaboration. No data concerning the Health-related quality of life (HRQoL) have been evaluated in patients affected by ESpA.
Objectives: Prospective study was performed in a combined GastroIntestinal and RHEumatologic "GI-Rhe" clinic, in order to evaluate: 1) prevalence and characteristics of articular manifestations in a group of IBD patients; 2) quality of life, state of health and well-being in ESpA patients.
Methods: Patients affected by IBD who presented muscolo-skeletal pain between February 2013 and September 2016 (CD 264 and UC 142) were enrolled. New diagnosis, disease management, adverse events as well as laboratory evaluations were assessed every 3 months during the follow-up. Disease activity, function and quality of life in ESpA patients were assessed by ASDAS-CRP, HAQ-S and EuroQol questionnaire.
Results:

Table 1

	IBD-SpA (N=212)	IBD non-SpA (N=215)
Age (years)	47±13.1	48.3±14.8
Male (n/%)	134/63.2	131/60.9
CD (n/%)	141/66.5	122/56.7
UC (n/%)	71/33.5	93/43.3
SpA disease duration (months)	37±75	NA
IBD disease duration (months)	162.2±115.3	166.6±14.8
CRP (mg/dL)	1.2±8.6	1.2±5.1
CDAI >150 (n/%)	26/18.4*	10/8.2*
Mayo score >3 (n/%)	11/15.5*	0/0*
HAQ-S	0.5±1.3	NA
ASDAS	2.1±1	NA

Data are expressed as mean ± SD. *IBD-SpA versus IBD-non SpA.

A total of 427 patients were evaluated for joint involvement (Table 1). The prevalence of SpA in IBD patients was 49.6% (n=212: UC 71 (43.3%), CD 141 (53.4%)), suggesting that the majority of patients with IBD who complain arthralgia may have a concomitant SpA. Other rheumatologic diseases were detected in the study population in 215 patients defined as IBD non-SpA. There was a significantly higher prevalence of active intestinal disease in patients with SpA with respect to IBD-non SpA (CD: CDAI>150 in 18.4% vs 8.2% p=0.004; UC: Mayo score >3 in 15.5% vs 0%, p=0.0004). The evaluation of the EuroQoL demonstrated a mean value of 0.59 in IBD-SpA patients and of 0.55 in IBD non-SpA (Figure 1A). In IBD-SpA, the health related status was: decent 69.8%, good 17.9% and bad 9.4%. In IBD-non SpA, the health related status was: decent in 74.8%, good in 17.7% and bad in 7% of patients. In both groups, none of the patients had a neither exceptional nor great perception of QoL. No significant differences were observed between the two groups (Figure 1B-C).

Distribution of the health state in the study population

Conclusions: The joint clinic facilitates diagnosis and management of SpA and IBD. Although IBD-SpA patients showed higher IBD disease activity than IBD-non SpA one, both groups of patients have a good health related QL.

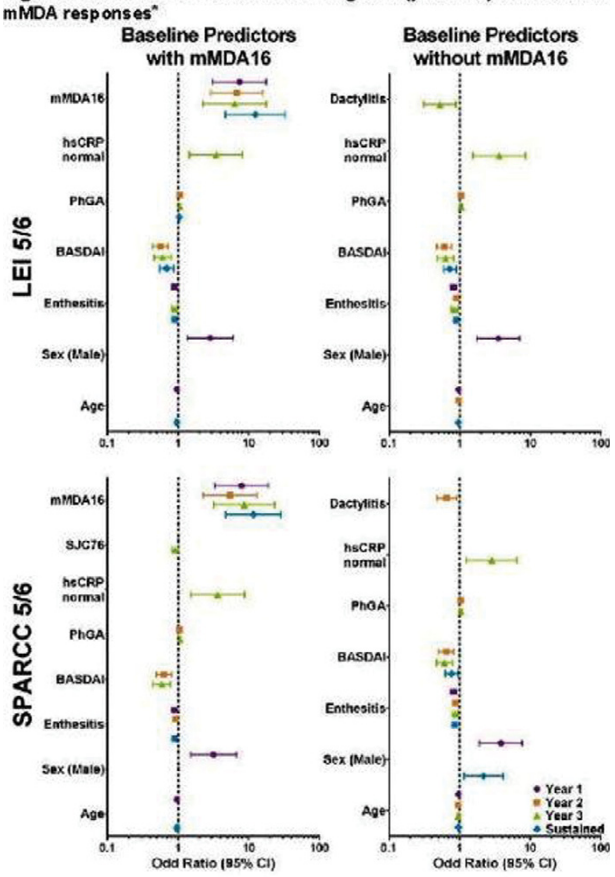
FRI0478 SUBCHONDRAL BONE SCLEROSIS ON COMPUTED TOMOGRAPHY – DOES IT HAVE ANY VALUE IN THE DIAGNOSIS OF INFLAMMATORY SACROILIITIS OR IS IT A NON-SPECIFIC FINDING?

O. Azmat[1], R.G. Lambert[1], Z. Jibri[1], W.P. Maksymowych[2]. [1]*Radiology;* [2]*Medicine, University of Alberta, Edmonton, Canada*



Background: Sclerosis in the sacroiliac joints (SIJ) on radiography and computed tomography (CT) is common but widely considered a non-specific finding of sacroiliitis due to an association with degeneration and osteitis condensans ilii, despite little formal study. Availability of low dose radiation CT may lead to more widespread use for diagnostic evaluation.
Objectives: We standardized the definition of sclerosis on CT and then aimed to determine whether this lesion could be reliably detected and its diagnostic utility.
Methods: 215 CT scans were obtained from patients with a history of low back pain. 107 patients had a clinical diagnosis of spondyloarthritis (SpA) and 108 patients were clinically proven not to have SpA. Groups were age and gender matched (140 males, 75 females, mean age was 45 years). Three musculoskeletal radiologists, blinded to patient demographics and diagnosis, scored the CTs after standardization of lesion definitions and calibration. Erosions, sclerosis, and ankylosis were graded by size and number of articular surfaces/ joints involved. Sclerosis was considered definite if located along the cartilaginous compartment, measured >5mm in all 3 planes, and present >5mm from the joint surface. Discrepant scores were arbitrated and inter-reader reliability calculated by intra-class correlation coefficient (ICC). Diagnostic utility of CT lesions was determined by calculating sensitivity and specificity for the clinical diagnosis and by logistic regression.
Results: ICC for sclerosis and erosion for each articular surface ranged from 0.65–0.76 and 0.71–0.78, respectively. ICC for ankylosis was 0.87–0.89. Sclerosis occurred in 87 (81%) cases with SpA and 25 (23%) controls. For a single articular surface the specificity for sacroiliitis ranged between 88–94%, for any two articular surfaces 95–100%, for all 4 articular surfaces 100%. Sensitivity ranged from 14% (4 articular surfaces) to 55% (either ilium). Erosion and ankylosis had a similar specificity range of 91–100% and 92–93%. The odds ratio was 4.9 for presence of definite sclerosis, and 12.6 for bilateral joint involvement. The odds ratio increased to 84.2 for bilateral erosion and 22.8 for bilateral ankylosis.
Conclusions: When sclerosis measures >5mm in three planes and is located >5mm from a joint perimeter, it has high specificity for sacroiliitis, regardless of how many articular surfaces are involved, with similar specificity to erosion and ankylosis.

FRI0479 PREDICTORS OF LONG-TERM MODIFIED MINIMAL DISEASE ACTIVITY RESPONSE IN PERIPHERAL SPONDYLOARTHRITIS PATIENTS TREATED WITH ADALIMUMAB

L.C. Coates[1], S. Abraham[2], W. Tillett[3], P.J. Mease[4], S. Ramiro[5], T. Wu[6], X. Wang[6], A.L. Pangan[6], I.-H. Song[6]. [1]*University of Leeds and Leeds Teaching Hospitals NHS Trust, Leeds;* [2]*NIHR/Wellcome CRF, Imperial College Healthcare NHS Trust, London;* [3]*Royal National Hospital for Rheumatic Diseases and University of Bath, Bath, United Kingdom;* [4]*Swedish Medical Center and University of Washington, Seattle, United States;* [5]*Leiden University Medical Center, Leiden, Netherlands;* [6]*AbbVie Inc., N Chicago, United States*

Background: There is a lack of validated outcome measures in non-psoriatic peripheral spondyloarthritis (pSpA). Therefore, a modified version of the minimal disease activity (mMDA)[1] was developed and validated. Identification of factors that predict long-term mMDA response in pSpA patients (pts) can facilitate decisions regarding treatment initiation and maintenance.
Objectives: The purpose of this analysis was to determine predictors of long-term mMDA response following adalimumab (ADA) treatment in pSpA pts from the ABILITY-2 study.
Methods: ABILITY-2[2] was a phase 3 randomized, double-blind trial evaluating the efficacy and safety of 40 mg ADA every other week versus placebo (PBO) over 12 weeks (wks) followed by open-label (OL) ADA for 144 wks in pts with pSpA. This post-hoc analysis included pts who received at least one dose of ADA during the PBO-controlled period or OL extension. The mMDA for pSpA was defined as achieving at least 5 out of the following 6 criteria: 1) TJC78 ≤1; 2) SJC76 ≤1; 3) pt pain visual analog scale (VAS) ≤15 of 100 mm; 4) pt global activity (PtGA) VAS ≤20 of 100 mm; 5) HAQ-DI ≤0.5; and 6) tender entheseal points ≤1 (Leeds Enthesitis Index [LEI] or Spondyloarthritis Research Consortium of Canada [SPARCC] Enthesitis Index). In this post hoc analysis, multiple logistic regression with stepwise variable selection was used to determine predictors of long-term (yrs 1–3) and sustained (defined as mMDA for at least 24 consecutive wks) mMDA responses. Variable selection of baseline (BL) pt demographics and disease characteristics were performed with and without mMDA response at wk 16 (mMDA16) as a candidate. In pts achieving mMDA at wk 16, ADA exposure ranged between 4 and 16 wks.
Results: In pSpA pts treated with ADA, mMDA (5/6 LEI or SPARCC) was achieved by almost 41%, 49%, and 50% of pts at yrs 1, 2, and 3, respectively and sustained mMDA response was achieved by 42% of pts. Regardless of mMDA definition, achieving mMDA response at wk 16 (up to 16 wks of ADA) was a robust positive predictor of attaining both long-term mMDA at yrs 1–3 and sustained mMDA (Figure). In the model examining the BL predictors (model without mMDA16), age, BL enthesitis and BL BASDAI scores were most commonly selected as negative predictors for achieving long-term and sustained mMDA. Other selected predictors included BL dactylitis, physician's global assessment, hsCRP, and male sex; however, these predictors were not consistently selected for all time points or sustained mMDA.
Conclusions: Early mMDA response is a stronger and more consistent predictor of long-term mMDA, whether at 1, 2, or 3 yrs or sustained over time, than BL

Figure. Odds Ratio for Predictors of Long-term (years 1-3) and Sustained mMDA responses*

*Only variables selected by stepwise selection model are shown (model selected variables are significant at P<.05)
mMDA16 = modified minimal disease activity response at week 16; LEI = Leeds enthesitis index; SPARCC = Spondyloarthritis Research Consortium of Canada enthesitis index; hsCRP = high sensitivity C-reactive protein; PhGA = physician's global assessment of disease activity; BASDAI = Bath ankylosing spondylitis disease activity index; SJC76 = swollen joint count (76 joints); CI = confidence interval.

Abstract FRI0478 – Table 1

Sclerosis of articular surface (s) involved	Specificity (95% CI)	Sensitivity (95% CI)
Single articular surface	Either ilium: 87% (82–91) – 91% (87–95)	Either ilium: 46% (39–52) - 51% (44–58)
	Either sacrum: 93% (89–96) – 94% (90 – 97)	Either sacrum: 19% (14–25) - 21% (16–26)
Any 2 articular surfaces	96% (94–99) – 99% (98–100)	10% (6–14) - 41% (35–48)
All 4 articular surfaces	99% (8–100)	14% (9 – 19)
Erosion of articular surface (s) involved	Specificity (95% CI)	Sensitivity (95% CI)
Single articular surface	Either ilium: 90% (85–94)	Either ilium: 77% (71–83)
	Either sacrum: 94% (91–98)	Either sacrum: 65% (58–72)
Any 2 articular surfaces	96% (93–99) – 100% (100–100)	24% (18–31) – 67% (60–74)
All 4 articular surfaces	100% (100–100)	38.1% (31–45)
Ankylosis of articular surface (s) involved	Specificity (95% CI)	Sensitivity (95% CI)
Single joint	92% (88 – 95)	60% (53–66)
Both joints	93% (89 – 96)	58% (51–64)

characteristics. The 5/6 versions of mMDA could be an appropriate treatment target in pSpA pts.

FRI0480 SCORING SYNDESMOPHYTES ON CT SPINE IMAGES OF PATIENTS WITH RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS FROM THE SENSITIVE IMAGING OF AXIAL SPONDYLOARTHRITIS (SIAS) COHORT

F. de Bruin[1], R. van den Berg[1], X. Baraliakos[2], J. Braun[2], F. van Gaalen[1], M. Reijniersе[1], D. van der Heijde[1]. *[1]LUMC, Leiden, Netherlands; [2]Rheumazentrum, Herne, Germany*

Background: Low dose Computed Tomography (CT) could potentially be more sensitive than radiographs in the follow up of patients with axial spondyloarthritis (axSpA).

Objectives: Our first goal was to develop a scoring method for the spine and test its interreader variability and frequency of progression in the various parts of the spine.

Methods: Patients (pts) of the Sensitive Imaging of Axial Spondyloarthritis (SIAS) cohort fulfilled the modified New York (mNY) criteria, had ≥1 syndesmophyte in cervical or lumbar spine on radiographs and ≥1 inflammatory lesion on MRI-spine. Baseline and 2 years follow up low-dose CT scans (approximately 2–3 mSV) were performed. Syndesmophytes were scored in the coronal and sagittal planes for all "corners" per view, thus scoring 8 'quadrants' per vertebral unit (VU). Syndesmophytes were scored as absent (score 0), <50% of the intervertebral disc height (IVDH) (score 1), ≥50% of the IVDH but no bridging (score 2) or as "bridging the IDVH" (score 3). Score range 0–552. Two readers, blinded for clinical information and time order, scored the CT scans paired by patient. Scores of the 2 readers were compared using heatmaps. Interreader variability was assessed by (two-way average) ICC and smallest detectable change (SDC) for the whole spine and per segment.

Results: In total, 56 pts (84% male, mean age 48.6) were included. The heatmap (fig 1) presents the similarity in basseline and change scores per reader per VU (VU on the y-axis). Ankylosis (score 3) is most prevalent in the thoracic spine, and syndesmophytes in general are least prevalent in the cervical spine.

Both readers use almost the entire possible range, pick up a similar magnitude of change and have high ICCs. Most change is present in the thoracic spine. A change ≥SDC is seen in 33.9% of the patients.

Conclusions: A fine-grained scoring system for CT spine was developed. Scoring syndesmophytes with good accuracy on CT images was feasible, picking up changes over a 2-year period in a high percentage of patients, especially in the thoracic spine, which is insufficiently visible on radiographs.

FRI0481 INTERPLAY BETWEEN PATIENT GLOBAL ASSESSMENT, PAIN AND FATIGUE AND INFLUENCE OF OTHER CLINICAL DISEASE ACTIVITY MEASURES IN PATIENTS WITH ACTIVE SPONDYLOARTHRITIS

O.R. Madsen[1,2], E.L. Egsmose[1,2]. *[1]Department of Rheumatology, Copenhagen University Hospital Rigshospitalet Gentofte, Hellerup; [2]The DANBIO registry, Copenhagen University Hospital Rigshospitalet Glostrup, Glostrup, Denmark*

Background: The Assessment of SpondyloArthritis international Society (ASAS) has selected core sets of variables to include as standardised end points in clinical trials and clinical practice. These core sets include fatigue, pain and patient global assessment (PaGl) as key patient-reported outcome measures (ref.). However, although associations between fatigue, pain and PaGl have been examined to some extent on the group level, studies focusing on the agreement between these patient-reported measures in individual patients are missing. A better understanding of how tight the measures are bounded in individuals may improve our ability to deal with them in the daily clinic.

Objectives: To examine associations on the group level and agreements on the individual patient level between fatigue, pain and PaGl as scored on visual analogue scales (VAS) in the daily clinic by patients with active spondyloarthropathy (SpA).

Methods: Data on 118 SpA patients with active disease planned to initiate treatment with a biological agent were extracted from the Danish registry for biological treatment in rheumatology (DANBIO). Data included fatigue, pain and PaGl, BASDAI and BASFI assessed on VAS-scales (0–100) and age, CRP and physician global assessment. Associations between variables were examined using simple and multiple regression analysis (all mentioned variables including sex was incorporated as independent variables). Agreements between PaGl, pain and fatigue on the individual patient level was examined by Bland-Altman analyses yielding 95% lower and upper limits of agreement (LLoA and ULoA) between intra-individual assessments. The difference between the scores on the group level was expressed as the bias.

Results: Mean age was 42.9±12.6 years, mean BASDAI 56.0±19.0, mean CRP mg/dL12.9 and mean PaGl 65.7±22.6. No significant differences in BASDAI, fatigue, pain, PaGl were demonstrated between men (n=76) and women. Fatigue, pain and PaGl were significantly but only moderately inter-correlated with high standard errors of estimation (SEE): Fatigue vs. PaGl (r =0.57, p<0.0001, SEE =21.4), fatigue vs.pain (r =0.55, p<0.0001, SEE =21.6), and pain vs. PaGl (r =0.81, p<0.0001, SEE =15.1). In multiple regression analyses, pain was independently predicted by PaGl (beta =0.52, p<0.0001) and BASDAI (beta =0.36, p<0.0001) [R =0.82, SEE =14.1, p<0.0001], PaGl by pain (beta =0.54, p<0.0001) and BASDAI (beta =0.33) [R =0.81, SEE =12.7, p<0.0001]), and fatigue by BASDAI (beta =0.44, p<0.0001) and PaGl (beta =0.23, p<0.05) [R =0.63, SEE =20.2, p<0.0001]. Biases between the patient-reported VAS-scores were small but intra-individual differences were substantial: LLoA and ULoA [bias] for fatigue vs. PaGl were -45.5 and 43.5 [-0.97], for fatigue vs. pain -42.3 and 52.9 [5.3], and for

Abstract FRI0480 – Table 1. SDC and interreader variability between readers on timepoint 1, timepoint 2 and for the difference between the timepoints (syndesmophyte growth)

Segment (max score)	Time point	Median and range reader 1	Median and range reader 2	SDC (inter-reader)	No. of patients with growth ≥SDC (%) (n=58)	ICC
Whole spine (552)	Time 1	144 (16–428)	135 (6–447)			0.99 (0.94–1.00)
	Time 2	157 (18–428)	146 (8–461)			0.98 (0.92–0.99)
	Change	9 (-11–96)	8 (-6–93)	12.4	19 (32.8)	0.75 (0.49–0.88)
Cervical (144)	Time 1	8 (0–140)	8 (0–128)			0.96 (0.92–0.98)
	Time 2	8 (0–140)	8 (0–128)			0.98 (0.95–0.99)
	Change	0 (-12–38)	0 (-9–38)	5.41	9 (15.6)	0.85 (0.75–0.91)
Thoracic (264)	Time 1	84 (2–250)	72 (0–264)			0.97 (0.92–0.99)
	Time 2	93 (2–256)	81 (0–264)			0.97 (0.85–0.99)
	Change	6 (-6–94)	6 (-12–93)	12.4	15 (25.9)	0.85 (0.75–0.92)
Lumbar (144)	Time 1	32 (0–140)	36 (0–140)			0.91 (0.79–0.96)
	Time 2	34 (0–144)	39 (0–144)			0.99 (0.98–1.00)
	Change	2 (-10–14)	1 (-4–12)	4.51	14 (24.1)	0.56 (0.26- 0.73)

pain vs. PaGl -35.7 and 23.3 [-6.3]. LLoA and UloA remained constant over the whole range of the VAS-scales.
Conclusions: In patients with SpA, fatigue, pain and PaGl scores were poorly associated and only poorly explained by other potential explanatory variables. On the individual level, disagreements between the scores were substantial. The findings emphasize the complexity of understanding patient-reported outcome measures and their diverging interplay across individuals.

Psoriatic arthritis

FRI0482 INSULIN RESISTANCE IN PATIENTS WITH PSORIATIC ARTHRITIS

A. Abogamal[1], E. Mahmoud[2], S. Abdulhakiem[1], S. Abdelatif[1], A. Abdelaziz[3]. *[1]Rheumatology; [2]Enocrinology; [3]Clinical Pathology, Alazhar Faculty of Medicine, Cairo, Egypt*

Background: inflammation and, levels of inflammatory markers, CRP and other cytokines are important for enhancing insulin resistance in PsA patients.
Inflammation and, levels of inflammatory markers, CRP and other inflammatory cytokines are important players for enhancement and develpoment of insulin resistance in psoriatic arthritis patients.
Objectives: To investigate the relation between insulin resistance and psoriatic arthritis presence and disease activity.
To investigate the relation between insulin resistance and disease activity in patients with psoriatic arthritis.
Methods: *Patients Inclusion criteria:* all patients in this study had psoriatic arthritis with disease duration 5 years or more. All under conventional DMARDs treatment in the form of methotrexate 12.5 mg/wk, hydroxychloroquine 400mg/day. With no treatment with glucocorticoids, 3 months prior to enrollment in the study and no previous treatment with biologics. All patients were Postmenopausal females with 3 or more years since menopause.
Exclusion Criteria: DM, ischemic heart disease, hypertension, or any other chronic diseases, Smoking, on medications Medications that affect blood lipids, or body composition and metabolic functions. Postmenopausal females who were on hormonal replacement therapy.
Grouping: G I: Included 50 postmenopausal females with psoriatic arthritis. G II: Included 25 normal postmenopausal females, as a control group.
Methods: 1. Full medical history and Complete clinical examination 2. Anthropometric measurements: Body mass index (BMI), Waist-hip ratio (WHR). 3. The following laboratory investigations were done: C-reactive protein (CRP), Fibrinogen, Fasting insulin. 4. Measures of insulin resistance: Homeostasis model assessment of insulin resistance (HOMA-IR): (a) HOMA 1-IR: It is calculated according to the following equation: Fasting insulin (μU/ml) x FBS (mg/dL)/405. (2). Insulin resistance was defined as HOMA-IR >3. 8. (3), (4). (b) HOMA 2-IR: it is the updated (or computer) model with nonlinear solutions, which also uses paired fasting glucose and insulin values, were calculated using the computer model (HOMA calculator version 2.2).
Results: Comparing means of age, BMI, and WHR of both groups' shows no significant difference, which indicates that both groups was matched and valid for comparison. G I have significantly higher values than the control group in the laboratory parameters Insulin, CRP and Fibrinogen as $p>0.05$, and the insulin resistance parameters (HOMA1, HOMA2). G I was significantly higher than the control group as $p>0.05$. Significant positive correlation also found between *Index for Psoriatic Arthritis (DAPSA)* and insulin, HOMA1, and HOMA2.
Conclusions: Psoriatic arthritis is associated with increased risk of insulin resistance. PsA activity is strongly associated with developing insulin resistance in psoriatic arthritis patients.

FRI0483 WORK CAPACITY AND QUALITY OF LIFE IN A COHORT OF PATIENTS WITH EARLY PSORIATIC ARTHRITIS IN ARGENTINA

F. Colombres[1], H. Berman[2], A. Spindler[2], W. Spindler[2], J.A. Maldonado Cocco[3], M.C. Orozco[4], E. Schneeberger[4], A. Ortiz[5], S. Paira[5], M. Zalazar[6], O. Rillo[6], D. Baenas[7], A. Alvarellos[7], T. Alvarellos[7], M. Garcia[8], A. Salas[8], V. Duarte[9], F. Romanini[9], L. Ferreyra Garrott[10], E. Soriano[10], L. Galindo[11], G. Castelli[12], C. Borlenghi[12], A. Berman[2]. *[1]Hosp. Avellaneda; [2]Centro Medico Privado de Reumatologia, SAN M, de Tucuman; [3]Fundación Reuma, Argentina; [4]Instituto Rehab. Psicofisica, Buenos Aires; [5]Hosp.Cullen, Santa Fe; [6]Hosp. Pirovano, Buenos Aires; [7]Hosp. Privado Cordoba, Cordoba; [8]Hosp. San Martin, la Plata; [9]Hosp. Rivadavia; [10]Hosp. Italiano, Buenos Aires; [11]U.N.T., SAN M, de Tucuman; [12]Pfizer Argentina, Buenos Aires, Argentina*

Objectives: To evaluate work capacity and quality of life in patients with early Psoriatic Arthritis (PsA).
Methods: Multi-center study in which patients with recent onset of PsA (disease duration <3 years) who met the CASPAR criteria established by the Early Spondyloarthritis Committee (CONEART) were enrolled. Work loss and lost workdays within six months prior to the baseline visit attributable to their baseline condition were evaluated, as well as quality of life, measured by PsAQol. Statistical analysis: descriptive statistics, Spearman's correlation, multiple linear regression model.
Results: 108 patients with a PsA diagnosis were enrolled. 53% (57/108) were male, of a mean age of 48.4 (SD 12.5). The mean PsA disease duration was 17.6 (SD 9.8) months. 4/60 patients (6.6%) were positive for HLA-*B27*. BASDAI 4.81±2.66; BASFI 3.75±2.70; PsAQoL 7.24±6.44; HAQ-A 0.72±0.61, physician global activity assessment (by Visual Numeric Scale, VNS) 3.76±2.33, and pain assessment (VNS) 5.22±2.98. The average days lost due to the condition within the past 6 months was 8.6 (SD 32.1), it was significantly associated with the presence of enthesitis, number of swollen joints, worse BASDAI, BASFI, lower level of education, and higher pain and physician global activity assessment ($p<0.0001$). Five patients lost their job due to PsA. 12% of the patients had a disability certificate and the possession of one, according to the logistic regression model, was associated with a longer PsA disease duration (OR 1.09, p=0.02). A poorer quality of life was significantly correlated to the physician assessment of disease activity ($p<0.001$) and pain ($p<0.01$) using a linear regression model.
Conclusions: In this cohort of patients with early PsA, the deterioration of work capacity expressed in lost workdays was associated with disease activity parameters and functional disability. The physician global activity assessment and pain were the main factors associated with the impact on patient's quality of life. Having a disability certificate was associated with longer disease duration. Although this is an early cohort of PsA patients, a worsening in quality of life and work disability was observed.

FRI0484 IMPACT OF PSORIATIC ARTHRITIS ON PATIENT-REPORTED OUTCOMES IN 5 EUROPEAN UNION COUNTRIES

A.B. Gottlieb[1], J. Gratacos[2], A. Dikranian[3], L. Fallon[4], B. Emir[5], T. Smith[5], L. Aikman[6], L. Chen[5]. *[1]Department of Dermatology, New York Medical College, Valhalla, NY, United States; [2]University Hospital Parc Tauli Sabadell, Barcelona, Spain; [3]Cabrillo Center for Rheumatic Diseases, San Diego, CA, United States; [4]Pfizer Canada, Montreal, QC, Canada; [5]Pfizer Inc, New York, NY, United States; [6]Pfizer Ltd, Sandwich, United Kingdom*

Objectives: This non-interventional, cross-sectional, descriptive, exploratory analysis aimed to characterise patients (pts) with psoriatic arthritis (PsA) in the 2016 National Health and Wellness Survey (NHWS) and determine the impact of treatment, or no treatment, on pt-reported outcomes.
Methods: The NHWS was a self-administered, web-based, voluntary, confidential questionnaire. Stratified randomised sampling provided a representative sample of EU adults in France, Germany, Italy, Spain and UK. Respondents completing the arthritis module and reporting PsA diagnosis were stratified by: advanced therapies (tumour necrosis factor inhibitors, interleukin antagonists, phosphodiesterase-4 inhibitors) ± other drugs; other therapies (eg conventional synthetic disease-modifying antirheumatic drugs, glucocorticoids, topical medications); or no current treatment. Short Form-36 health survey (SF-36), Work Productivity and Activity Impairment questionnaire and Patient Health Questionnaire-9 (PHQ-9) responses were summarised descriptively.
Results: NHWS was completed by 80,600 adults; 947 completed the arthritis module and self-reported PsA diagnosis. Of these, 65 (7%) reported receiving advanced therapies, 274 (29%) other therapies and 608 (64%) no current treatment. Age and gender were generally balanced between the groups (mean 51–56 years; 51–64% female). More patients on advanced therapies had a body mass index ≥30 (41%) vs other therapies (34%) and no current treatment (26%). Pts on advanced therapies reported more comorbidities (mean 2.2) vs pts on other therapies (mean 1.8) and pts with no current treatment (mean 1.7). More pts on advanced therapies were current smokers (49%) vs pts on other therapies (30%) and pts with no current treatment (32%). Prior to treatment with advanced or other therapies, 94% and 82% self-reported moderate or severe PsA, falling to 58% and 59%, respectively, after treatment, compared with 36% of pts with no current treatment. SF-36 scores and PHQ-9 scores did not widely vary across groups (Table 1). Regardless of treatment groups, pts reported >20% work loss, >45% overall work impairment and >45% activity impairment (Table 1).
Conclusions: More than 60% of pts reporting PsA diagnosis reported no current

Table 1. Mean (SD) outcome scores by treatment type

	Advanced therapies N=65	Other therapies N=274	Not treated N=608
SF-36 MCS	38.0 (11.0)	40.1 (11.6)	39.8 (10.5)
SF-36 PCS	36.0 (9.9)	37.6 (9.6)	43.9 (8.4)
PHQ-9 total score[a]	7.7 (7.0)	9.1 (6.8)	7.8 (7.1)
WPAI domain scores[b]			
% work missed	26.8 (29.7)	27.8 (35.4)	20.8 (27.8)
% impairment at work	55.8 (31.1)	42.8 (29.6)	44.5 (29.3)
% overall work impairment	61.4 (34.2)	49.0 (33.2)	51.1 (32.6)
% activity impairment	62.0 (26.1)	57.8 (26.5)	48.3 (28.9)

[a]N = 22, 45, 137 for advanced therapies, other therapies, not treated, respectively

[b]N for WPAI % work missed = 33, 113, 338, respectively for advanced therapies, other therapies, not treated; N for WPAI % impairment at work and overall work impairment = 33, 99, 328, respectively, for advanced therapies, other therapies and not treated

MCS, mental component summary; PCS, physical component summary; PHQ-9, Patient Health Questionnaire-9; SD, standard deviation; SF-36, Short Form-36 health survey; WPAI, Work Productivity and Activity Impairment questionnaire

treatment. Regardless of treatment group, pts reported >20% work loss and >45% work impairment. Among treated pts, >50% reported moderate or severe PsA, suggesting a need for overall better management of PsA to reduce the disease impact and improve quality of life. Our results are limited by self-reported PsA diagnosis, which may differ from physician-reported PsA diagnosis, and the survey being conducted in the EU only, which may differ from other parts of the world. Further statistical analyses are needed to determine differences between groups and correlation to other health indicators.

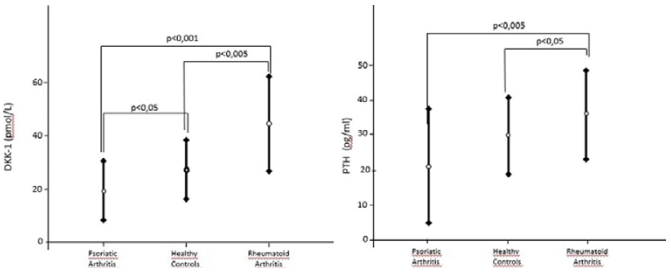
FRI0485 IN PERIPHERAL PSORIATIC ARTHRITIS DKK-1 AND PTH ARE LOWER THAN IN RHEUMATOID ARTHRITIS AND HEALTHY CONTROLS

A. Fassio, L. Idolazzi, O. Viapiana, C. Benini, E. Vantaggiato, M. Rossini, D. Gatti. *Rheumatology, Aoui Verona Reumatologia, Verona, Italy*

Background: The recent characterization of the canonical WNT pathway in the regulation of bone modeling and remodeling provided important insights for our understanding of the pathophysiology of bone involvement in chronic arthritis [1]. Dkk-1 and sclerostin are the main regulators of WNT/b-catenin signaling, regulating both bone formation and resorption [2]. In a previous our study we showed that in patients with Rheumatoid Arthritis (RA) Dkk-1 is significantly increased and associated with the presence of typical erosions and lower BMD [3].



Objectives: we decided to perform this study in order to compare the serum levels of WNT-pathway regulators alongside bone turnover markers (BTM) and Parathyroid Hormone (PTH) between a group of female patients with PsA and healthy controls (HC) or patients with Rheumatoid Arthritis (RA).

Methods: this is a cross-sectional study including 18 patients with PsA classified with the CASPAR criteria, 35 HC, and 28 patients with RA classified with the ACR/EULAR 2010 criteria. Intact N-propeptide of type I collagen (PINP), C-terminal telopeptide of type I collagen (CTX-I), Dickkopf-related-protein 1 (Dkk-1), sclerostin, PTH and 25OH-Vitamin D serum levels were dosed. All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and/or national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards. Informed consent was obtained from all individual participants included in the study.

Results: the PsA group showed significantly lower Dkk-1 levels when compared to the HC and RA groups. Dkk-1 in the RA group was also significantly higher than in the HC group. A similar trend was documented also for PTH, however a statistically significant difference was observed only when we comparing the PsA vs RA group (table 1, figure 1). No other statistically significant differences in the other markers were found.

Table 1. Values of bone turnover markers (CTX-I, PINP), Dkk-1 and sclerostin of PsA, RA patients and control group (mean ± SD)

	PsA	RA	HC	P (ANOVA)
PINP ng/ml	42,80±16,670	39,19±21,38	42,49±11,52	NS
CTX-I ng/ml	0,21±0 ,17	0,32±0,21	0,28±0,10	NS
Dkk-1 pmol/l	19,45±11,30	44,51±17,81	27,29±11,48	<0,001
Sclerostin pmol/l	30,82±11,25	30,75±10,25	34,23±17,29	NS
PTH pg/ml	21,12±16,63	35,83±13,02	29,69±11,43	<0,005

Conclusions: this study demonstrated for the first time that Dkk-1 levels in PsA are lower than HC, in contrast with RA where they are higher. These results might contribute to explain the different bone involvement of the two different diseases.

FRI0486 INTRAVENOUS GOLIMUMAB IN ADULT PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: EFFICACY AND SAFETY THROUGH WEEK 24

A. Kavanaugh[1], M.E. Husni[2], D.D. Harrison[3], L. Kim[3], K.H. Lo[3], E.C. Hsia[4]. *[1]University of California, San Diego; [2]Cleveland Clinic, Cleveland; [3]Janssen Research & Development, LLC, Spring House; [4]Janssen Research & Development, LLC/University of Pennsylvania School of Medicine, Spring House/Philadelphia, United States*

Objectives: The GO-VIBRANT study was designed to evaluate the safety and efficacy of intravenous (IV) golimumab (GLM) in adult patients (pts) with active PsA (biologic-naïve).

Methods: GO-VIBRANT is a Phase 3, multicenter, randomized, double-blind, placebo (PBO)-controlled trial. Biologic-naïve active PsA pts were randomized (1:1) to IV GLM 2mg/kg at weeks (wk) 0, 4, and every 8 wks thereafter or PBO at wks 0, 4, 12, and 20 with crossover to GLM at wk24. The primary endpoint was ACR20 response at wk14. Multiplicity-controlled endpoints were ACR50, ACR70, PASI 75, change from baseline in HAQ-DI, enthesitis, dactylitis, SF-36 PCS/MCS scores at wk14; and ACR50 and change from baseline in total modified vdH-S (structural damage) score at wk24. Efficacy analyses were based on randomized treatment. Adverse events (AE) through wk24 are reported here. Investigators remain blinded through wk60.

Results: 480 pts were randomized (PBO: 239; GLM: 241). The study met its primary and all controlled secondary endpoints. At wk14, significantly greater proportions of GLM pts vs PBO achieved ACR20 (75.1% vs. 21.8%). Also, GLM treatment resulted in significant change from baseline HAQ-DI score (-0.60 vs. -0.12), ACR50 (43.6% vs. 6.3%), PASI 75 (59.2% vs. 13.6%), ACR70 (24.5% vs. 2.1%), change from baseline in enthesitis and dactylitis scores (-1.8 vs. -0.8 and -7.8 vs. -2.8, respectively), and change from baseline in SF-36 PCS and SF-36 MCS scores (8.65 vs. 2.69 and 5.33 vs. 0.97, respectively) (all p<0.001) at wk14. At wk24, significantly greater proportions of GLM pts vs. PBO pts achieved ACR 50 (53.5% vs. 6.3%, p<0.001). At wk24, there was significantly less progression of structural damage for GLM pts vs PBO as measured by change from baseline in total modified vdH-S score (-0.36 vs. 1.95; p<0.001). ACR20 was significantly higher with GLM than PBO as early as wk2 (45.6% vs. 7.5%; p<0.001). 27.0% of GLM pts (vs. 4.2% PBO) achieved Minimal Disease Activity by wk14. Due to the difference in response rates in GLM vs. PBO treated pts, the number needed to treat for ACR20 at wk14 was 1.9 in a post-hoc analysis (Table). Through wk24,

46.3% of GLM pts and 40.6% of PBO pts had ≥1 AE; 2.9% vs. 3.3% of pts, respectively, had ≥1 serious AE. Two deaths, 2 malignancies, and 1 demyelinating event were reported. The most common treatment-emergent type of AE was infection (20.0% of GLM pts vs. 13.8% of PBO pts). No opportunistic infection or tuberculosis was reported through wk24. The rate of infusion reactions was low at <2%; none was serious or severe.

Table. Clinical Response

	Placebo	Golimumab 2 mg/kg	P-values
Patients randomized, n	239	241	
Clinical efficacy at wk14			
ACR20/50/70, (%)	21.8/6.3/2.1	75.1/43.6/24.5	p<0.001
PASI 75, n (%)*	27/198 (13.6%)	116/196 (59.2%)	p<0.001
Change from BL in HAQ-DI (n) Mean (SD)	222 -0.12 (0.47)	233 -0.60 (0.53)	p<0.001
Change from BL in enthesitis** (n) Mean (SD)	173 -0.8 (1.98)	182 -1.87 (1.75)	p<0.001
Change from BL in dactylitis** (n) Mean (SD)	115 -2.8 (7.03)	130 -7.8 (8.57)	p<0.001
Minimal Disease Activity, n/N (%)	10/239 (4.2%)	65/241 (27.0%)	p<0.001
Number Needed to Treat (95% CI)		1.9 (1.64, 2.18)	
Clinical efficacy at Week 24			
ACR50, n (%)	15 (6.3%)	129 (53.5%)	
Imaging data at Week 24			
Change from BL in vdH-S score (N) Mean (SE)	237 1.95 (0.264)	237 -0.36 (0.144)	p<0.001
HRQoL at wk14			
Change from BL in SF-36 PCS score (n) Mean (SD)	222 2.69 (5.92)	233 8.65 (7.60)	p<0.001
Change from BL in SF-36 MCS score (n) Mean (SD)	222 0.97 (7.64)	233 5.33 (9.95)	p<0.001

*Among pts with ≥3% BSA involvement, **Among pts with finding at baseline, BL:baseline

Conclusions: In pts with active PsA, IV GLM demonstrated significant and clinically meaningful improvements of disease activity and physical function, skin psoriasis clearance, HRQoL, reduction in dactylitis and enthesitis, and inhibition of structural damage progression. GLM was well-tolerated through wk24; the safety profile was consistent with other anti-TNF therapies, including SC GLM.

FRI0487 APREMILAST IS ASSOCIATED WITH LONG-TERM (4-YEAR) DAS-28 (CRP) REMISSION AND IMPROVEMENTS IN SKIN DISEASE: RESULTS FROM A PHASE III STUDY IN DMARD/BIOLOGIC-EXPERIENCED PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS

C.J. Edwards[1], F.J. Blanco[2], J. Crowley[3], M. McIlraith[4], M. Paris[4], N. Delev[4], L. Teng[4], C.A. Birbara[5]. *[1]University Hospital Southampton, Southampton, United Kingdom; [2]INIBIC-Hospital Universitario A Coruña, Galicia, Spain; [3]Bakersfield Dermatology, Bakersfield; [4]Celgene Corporation, Summit; [5]University of Massachusetts Medical School, Worcester, United States*

Background: Treatment goals for long-term control of skin and joint symptoms in active psoriatic arthritis (PsA) include clinically important changes in DAS-28 (CRP), achievement of remission in DAS-28 (CRP), reduction in swollen joint count (SJC), and decrease in skin disease.[1] PALACE 3 included PsA patients with active joint disease and an active skin lesion at the time of enrollment.

Objectives: Report the impact of apremilast (APR) on PsA manifestations over 4 years.

Methods: Patients were stratified by baseline (BL) DMARD use (yes/no) and psoriasis involvement of the body surface area (<3%/≥3%) and randomized (1:1:1) to placebo (PBO), APR 30 mg BID (APR30), or APR 20 mg BID (APR20). After the 24-week PBO-controlled phase, all patients were treated with APR30 or APR20 and could enroll in the long-term extension. Efficacy assessments were conducted through Week 208.

Results: 505 patients were randomized and received ≥1 dose of study medication (PBO: n=169; APR30: n=167; APR20: n=169). A total of 91% (227/249) of patients starting the fourth year of APR therapy completed the Week 208 visit. Patients treated with APR30 demonstrated sustained decreases in disease activity at Week 208, as shown by mean change from BL in DAS-28 (CRP) of –1.66; 80.3% achieved good/moderate EULAR response and 50.4% achieved DAS-28 (CRP) remission. Sustained effect on inflammation at Week 208 was also demonstrated by mean/median percent changes in SJC, a marker of inflammatory activity, of –77.4%/–100.0% (Table); 64.8% of patients had an SJC of 0 or 1. Decreases in disability and maintenance of functionality were shown by sustained improvements in Health Assessment Questionnaire-Disability Index (HAQ-DI) scores (Table). A continued effect on skin disease was shown by decreases in skin involvement, as measured by the Psoriasis Area and Severity Index (PASI); 54.7% of APR30 patients had BL PASI >5 and 27.3% had BL PASI >10; at Week 208, 64.5% had PASI <3 and 77.4% had PASI ≤5. PASI-75 and PASI-50 response rates also demonstrated clinically significant relief (Table). In patients treated with APR20, similar findings were observed at Week 208. No new safety concerns were identified through 208 weeks of APR30 therapy. During Weeks >156 to ≤208 of APR30 exposure, the only adverse event (AE) occurring in ≥5% of patients was nasopharyngitis; most AEs were mild or moderate in severity. Serious AEs occurred in 7.2% of APR30 patients over Weeks >156 to ≤208, similar to rates in earlier study periods. Few discontinuations due to AEs (0.7%) occurred over Weeks >156 to ≤208. The APR20 safety profile was similar to that of APR30.

Outcomes at Week 208	
	APR30 n=129*
DAS-28 (CRP), mean change	−1.66
DAS-28 (CRP) <2.6, n/m (%)	64/127 (50.4)
SJC, mean/median % change	−77.4/−100.0
TJC, mean/median % change	−64.4/−86.6
HAQ-DI (0-3), mean change	−0.42
HAQ-DI MCID ≥0.30/≥0.35, n/m (%)	63/129 (48.8)
ACR20, n/m (%)	85/128 (66.4)
ACR50, n/m (%)	51/128 (39.8)
ACR70, n/m (%)	31/127 (24.4)
PASI-75, n/m (%)§	28/62 (45.2)
PASI-50, n/m (%)§	42/62 (67.7)

Data as observed. *The n reflects the number of patients treated with APR30, regardless of when APR was started (BL, Week 16, or Week 24) and who had data available at Week 208; actual number of patients available for each end point may vary. §Examined among patients with psoriasis involvement of the body surface area ≥3% at BL. APR30=apremilast 30 mg BID; DAS-28=28-joint count Disease Activity Score; CRP=C-reactive protein; SJC=swollen joint count; TJC=tender joint count; HAQ-DI=Health Assessment Questionnaire-Disability Index; MCID=minimal clinically important differences; ACR20/50/70=20%/50%/70% improvement in modified American College of Rheumatology response criteria; n/m=number of responders/number of patients with sufficient data for evaluation; PASI-75/50=≥75%/≥50% reduction from BL Psoriasis Area and Severity Index score; BL=baseline.

Conclusions: Over 208 weeks, APR demonstrated sustained and clinically important improvements in PsA signs and symptoms, including physical function and associated psoriasis, among patients continuing the study. APR was generally well tolerated with an acceptable safety profile.

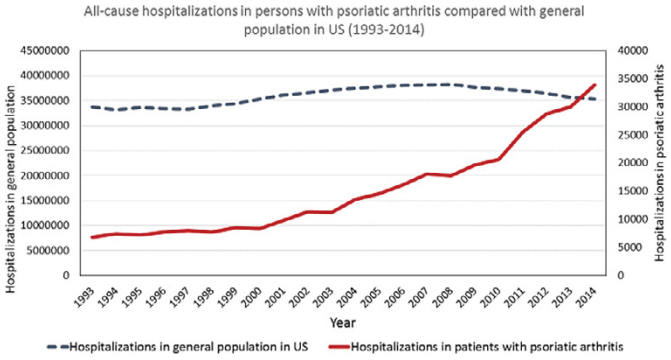
FRI0488 PSORIATIC ARTHRITIS IN THE UNITED STATES: INCREASING ALL-CAUSE HOSPITALIZATIONS 1993–2014

G. Singh[1], C. Moise[2], A. Mithal[3], R. Ionescu[2], A. Mithal[4]. *[1]Gastroenterology and Hepatology, Stanford University, Palo Alto, United States; [2]Disciplina Medicina Interna si Reumatologie, Spitalul Clinic "Sf. Maria", Bucharest, Romania; [3]Student; [4]Epidemiology, ICORE, Woodside, United States*



Background: Psoriatic arthritis (PsA) is a rare disease, with an estimated prevalence of 0.02 – 0.42% in Europe and US (1). PsA is often regarded as a mild disease, but recent data suggest an increase in comorbidities and mortality, possibly related to systemic inflammation (1).

Objectives: To study all-cause hospitalizations in patients with PsA in the United States (US) from 1993 to 2014.

Methods: The Nationwide Inpatient Sample (NIS) is a stratified random sample of all US community hospitals. It is the only US national hospital database with information on all patients, regardless of payer, including persons covered by Medicare, Medicaid, private insurance, and the uninsured. We examined all inpatient hospitalizations in NIS from 1993 to 2014 with a primary or secondary diagnosis of PsA, and compared them to total all-cause US hospitalizations during the same period. US population estimates and projections for the resident US population were obtained from the US Census Bureau.

Results: There were 789.8 million all-cause hospitalizations in 6.4 billion person-years of observation from 1993 to 2014 (123.4 hospitalizations per 1,000 person-years). During this time-period, 332,496 hospitalizations occurred in patients with PsA (5.2 per 100,000 person-years). All-cause US hospitalizations increased from 33.7 million in 1993 to 35.4 million in 2014, an increase of 4.8% over 22 years (Figure, dotted blue line). All-cause hospitalizations in PsA patients have increased from 6,866 in 1993 (2.6 per 100,000 person-year) to 33,875 in 2014 (10.6 per 100,000 person-years, a dramatic increase of over 393% (p<0.0001, Figure solid red line). In 2014, hospitalizations in PsA patients accounted for 163,630 hospital days at a total national cost of over US$1.66 billion.

Conclusions: All-cause hospitalizations in patients with PsA in the US have significantly increased by 393% in the last 22 years, almost 80-fold of the 4.8% increase in US population all-cause hospitalization rate in the same time-period. This calls for an increase need for identification and management of serious co-morbid conditions in patients with PsA.

FRI0489 CERTOLIZUMAB PEGOL IS ASSOCIATED WITH LONG-TERM IMPROVEMENTS IN PATIENT-REPORTED OUTCOMES IN PSORIATIC ARTHRITIS: 4-YEAR OUTCOMES FROM THE RAPID-PSA STUDY

D. Gladman [1], R. Fleischmann [2], K. Harris [3], L. Peterson [4], P.J. Mease [5].
[1] University of Toronto and Krembil Research Institute, Toronto Western Hospital, Toronto, Canada; [2] UT Southwestern Medical Center and Dallas Metroplex Clinical Research Center, Dallas, United States; [3] UCB Pharma, Brussels, Belgium; [4] UCB Pharma, Raleigh; [5] Swedish Medical Center and University of Washington, Seattle, United States

Background: Psoriatic arthritis (PsA) is a heterogeneous inflammatory disease that has a substantial impact on patients' (pts) physical and emotional wellbeing.[1] Certolizumab pegol (CZP) is an Fc-free, PEGylated anti-TNF that has been shown to improve patient-reported outcomes (PROs) in pts with PsA over 96 weeks (wks) of treatment in the RAPID-PsA study (NCT01087788).[2]
Objectives: To investigate whether initial improvements in PROs observed with CZP treatment were maintained over 4 years in the RAPID-PsA study.
Methods: RAPID-PsA was double-blind and placebo-controlled to Wk24, dose-blind to Wk48, and open-label to Wk216. Pts were aged ≥18 years, with a diagnosis of active PsA, and had failed treatment with ≥1 DMARD. Pts originally randomized to CZP (400mg at Wks0,2,4 [loading dose] followed by either 200mg every 2 wks [Q2W] or 400mg every 4 wks [Q4W]) continued on their assigned dose during the open-label period. PROs assessed included Patient's Global Assessment of Arthritis Pain (PtAAP; visual analog scale), fatigue (numeric rating scale), Health Assessment Questionnaire-Disability Index (HAQ-DI), Short Form-36 Physical and Mental Component Summary (SF-36 PCS/MCS), Psoriatic Arthritis Quality of Life (PsAQoL), and Dermatology Life Quality Index (DLQI; assessed in the subgroup of pts with ≥3% body surface area affected by psoriasis at baseline [BL]). Data are reported as the mean change from BL (CFB) for pts randomized to CZP at Wk0, with last observation carried forward (LOCF) imputation for Wk24, and LOCF imputation and observed case (OC) values for Wk216.
Results: Of 273 pts randomized to CZP at Wk0, 248 (91%) completed Wk24 and 183 (67%) completed Wk216. Improvements observed to Wk24 of treatment were generally maintained over 4 years (to Wk216) in all PROs assessed, regardless of prior anti-TNF exposure (Table). Similar improvements were observed in both CZP dose regimens for all PROs examined, including PtAAP (CFB at Wk216 in the 200mg Q2W group [with LOCF imputation]: -30.5, in the 400mg Q4W group: -33.8); fatigue (-2.3, -2.3); HAQ-DI (-0.50, -0.49); SF-36 PCS (8.73, 8.77); SF-36 MCS (3.91, 3.28); PsAQoL (-4.6, -4.4); and DLQI (-8.4, -6.8).
Conclusions: Early improvements with CZP treatment were maintained over 4 years in all PROs assessed in the RAPID-PsA study. Similar improvements were observed in pts with and without prior anti-TNF exposure, and in both CZP dose regimens.

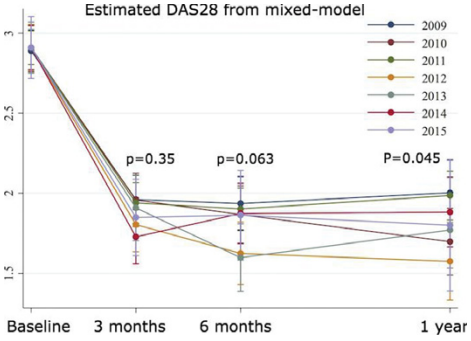
FRI0490 REAL-LIFE EFFECTIVENESS OF TNF INHIBITORS IN PSORIATIC ARTHRITIS: ARE CHANGING NATIONAL POLICIES ON CHOICE OF TNF INHIBITOR REFLECTED IN RESPONSE TO TREATMENT?



E.K. Kristianslund [1], K.M. Fagerli [1], E. Lie [1], A. Wierød [2], S. Kalstad [3], E. Rødevand [4], F. Krøll [5], P. Mielnik [6], T.K. Kvien [1], I.C. Olsen [1]. *[1] Department of Rheumatology, Diakonhjemmet Hospital, Oslo; [2] Department of Rheumatology, Drammen Hospital, Drammen; [3] Department of Rheumatology, University Hospital of North Norway, Tromsø; [4] Department of Rheumatology, St. Olavs Hospital, Trondheim; [5] Revmatismesykehuset, Lillehammer; [6] Department of Rheumatology, Førde Central Hospital, Førde, Norway*

Background: Tumour necrosis factor inhibitors (TNFi) are essential in the treatment of psoriatic arthritis (PsA). Whether the effectiveness of the five different TNFi differs is not known, as they have not been directly compared. In Norway the national authorities consider the TNFi to be equivalent, and since 2009 the least expensive drug in an annual national tender has been preferred in the publicly funded healthcare system. This has led to substantial year-to-year differences in chioce of first TNFi, the system has acted as an unbiased factor distributing patients between different agents across years.
Objectives: Comparing response to TNFi during the first year of treatment of PsA over years with highly varying uptake of different TNFi.
Methods: From the NOR-DMARD register we included the 715 biologics-naïve patients with PsA who started their first TNFi from 2009 through 2015. The preferred TNFi in national recommendations were: 2009 adalimumab, 2010 golimumab, 2011 and 2012 etanercept, 2013 golimumab, 2014 certolizumab, 2015 certolizumab/biosimilar infliximab (CT-P13). The estimated Disease Activity Score 28 joints (DAS28) at 3, 6 and 12 months after treatment start was compared between treatment years using a mixed-model, adjusted for baseline disease activity, age, sex and treatment centre.
Results: Demographics, choice of TNFi and baseline characteristics are listed for each year 2009–2015 in Table 1. The preferred drug was started in 56–91% of patients. There was a trend towards lower disease activity at baseline over time. There were no significant differences in DAS28 at 3 and 6 months between treatment years, but a difference was found at 1 year (figure).
Conclusions: The results from this innovative analytic approach indicate similar effectiveness of different TNFi in PsA, and consequently supports the practice of selecting agent based on cost and feasibility of use. However, there are potential differences after 1 year. The interpretation of this is challenging, especially as there is a marked difference in outcomes between the years 2011 and 2012, where the distribution of type of TNFi was similar.

Abstract FRI0490 – Table 1

	2009	2010	2011	2012	2013	2014	2015	p-value

FRI0491 EFFECT OF THE TIGHT CONTROL TREAT-TO-TARGET STRATEGY ON THE DYNAMICS OF ACTIVE MRI SACROILIITIS IN THE RUSSIAN COHORT OF EARLY PERIFERAL PSORIATIC ARTHRITIS PATIENTS (PRELIMINARY RESULTS OF AN ONGOING OPEN-LABEL REMARCA STUDY)

E.E. Gubar, E.Y. Loginova, T.V. Korotaeva, D.E. Karateev. *V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Axial involvement in early psoriatic arthritis (ePsA) patients (pts) is often poorly diagnosed. Magnetic resonance imaging (MRI) of sacroiliac joints (SIJs) helps to better define spinal involvement and is used as an outcome measure to evaluate treatment of axial disease with TNF blockers. Treat-to-target (T2T) strategy was studied in various manifestations of PsA except axial involvement.
Objectives: to assess the effect of tight control T2T strategy on the 12-months dynamics of active MRI sacroiliitis (MRI-SI) in peripheral ePsA pts.
Methods: 89 treatment-naive pts (M/F–42 /47) with active peripheral ePsA, according to CASPAR criteria were included; mean age 36.5±10.9 yrs., disease duration 12.1±10.1 mo., disease activity index (DAS) 5.2±2.8, C-RP 16.1 [6.6; 31.0] mg/l, ESR 22.5±19.2 mm/h. At baseline and every 3 mo. of therapy all pts underwent standard clinical examination of PsA activity. All patients were evaluated for the presence of inflammatory back pain (IBP) by ASAS criteria. In pts having IBP, disease activity was also measured by BASDAI. At baseline MRI of SIJs was performed in 79 pts, both with and without IBP, on Signa Ovation 0.35T. Bone marrow edema (BME) on MRI (STIR), considered as active MRI sacroiliitis (MRI-SI), was evaluated by an independent reader. MRI of SIJs was repeated after 12 mo. in 20 pts who had completed a year of therapy having MRI-SI at baseline. Positive dynamics was indicated by the disappearance of BME on MRI (STIR). The main goal of T2T strategy was to reach remission or low/minimal disease activity (LDA/MDA). LDA was considered at DAS<1.6 or DAS28<2.6, remission was considered at DAS<1.6 or DAS28<2.6. At baseline all pts were treated with methotrexate (MTX) subcutaneous (s/c). The dose of MTX was escalated by 5 mg eow from 10 mg/wk to 20–25mg/wk. If the patient did not achieve LDA/MDA or remission after 3 mo. of MTX mono-therapy (MoT), combination therapy (CoT) with MTX+ adalimumab (ADA) 40 mg (s/c) eow was started. All pts were treated with NSAIDs: nimesulide 100–200mg or eterikokxib 60–90 mg per day.
Results: IBP was found in 58 out of 89 pts (65.1%). Disease activity by BASDAI in pts with IBP was 4.5±1.6. At baseline MRI-SI was observed in 28 out of 79 (35.4%) pts. Among the group of 20 pts who had completed a year of therapy having MRI-SI at baseline, 16 (80%) pts after 12 mo. of therapy demonstrated positive dynamics. Among these 16 pts, 8 (50%) pts underwent MoT and 8 (50%) pts underwent CoT. In the CoT-group pts received ADA for 6–9 mo. After 12 mo. of therapy, BME of SIJs on MRI still remained in 4 out of 20 (20%) pts. Among these 4 pts 2 pts underwent MoT and 2 pts underwent CoT (both pts received ADA for 3 mo., 9 th-12th mo. of therapy).
Conclusions: tight control T2T strategy in the Russian cohort of peripheral ePsA pts, demonstrated positive dynamics of active MRI-SI in 80% of pts after 12 months of therapy irrespective of the treatment used. These preliminary results demonstrate that tight control T2T strategy is effective not only in peripheral arthritis but also in axial involvement in ePsA. To confirm its effectiveness the strategy still needs to be verified on larger cohorts of pts.

FRI0492 OBESITY IS HIGHLY OVERREPRESENTED AMONG SWEDISH PATIENTS WITH PSORIATIC ARTHRITIS COMPARED WITH THE GENERAL POPULATION

E. Klingberg[1], A. Bilberg[1], B. Eliasson[2], I. Larsson[3]. *[1]Department of Rheumatology and Inflammation Research, Sahlgrenska Academy at University of Gothenburg; [2]Department of Medicine; [3]Department of Gastroenterology and Hepatology, Sahlgrenska University Hospital, Göteborg, Sweden*

Background: Patients with psoriatic arthritis (PsA) are at increased risk of developing cardiovascular disease.
Objectives: To determine the prevalence of cardiovascular risk factors among patients with PsA followed at a Swedish Rheumatology Clinic in comparison with the general population (GP).
Methods: A questionnaire including weight, height, smoking habits, hypertension, diabetes and hyperlipidemia was sent to all PsA patients registered at the Rheumatology Clinic at Sahlgrenska University Hospital, Gothenburg (N=982). Obesity was defined as body mass index (BMI) ≥30 kg/m^{2}and overweight as BMI 25–29.9 kg/m^2. Comparison with the Swedish GP was made using data from the National public health survey, "Health on equal terms", which is sent yearly to 20 000 citizens by the Public Health Agency of Sweden.
Results: 686 (70%) of the PsA patients with mean age 56±11yrs (mean: SD), 52% women, responded.Higher prevalence of self-reported obesity and several cardiovascular risk factors was found in the PsA patients compared with the GP: Obesity 28.7% [GP 15% (95% C.I. 14.5–15.9%)], current smoking 10.5% [GP 9% (8.2–9.3%)], former smoking 43.4% [GP 23% (22.3–24.0%)], never smoking 48.8% [GP 63% (61.9–63.9%)], treatment of hypertension 32.9% [GP 20% (19.6–21.2%)] and diabetes 8.3% [GP 6% (5.4–6.3%)] Treatment of hyperlipidemia was reported by 15.0% [GP no data] and overweight by 36.2% [GP 36% (34.5–36.5%)]. Data stratified by age and sex is shown in the table. (Numbers are % and 95% C.I.)
Conclusions: Obesity was highly overrepresented among the PsA patients. It is imperative to take action against weight gain in overweight patients and promote weight loss in obese patients with PsA, since obesity may be involved in the pathogenesis of the disease and may fuel disease activity.

FRI0493 DISEASE ACTIVITY TOGETHER WITH DEPRESSION CONTRIBUTES TO WORK DISABILITY IN PSORIATIC ARTHRITIS

F. Farkas[1], N. Ikumi[1], A. Szentpetery[1], B. Kirby[2], O. FitzGerald[1]. *[1]Department of Rheumatology; [2]Department of Dermatology, St. Vincent's University Hospital, Dublin, Ireland, Dublin, Ireland*

Background: Work disability (WD) is an important functional outcome measure in inflammatory arthritis, which has been studied comprehensively in rheumatoid arthritis and ankylosing spondylitis, however limited data are available in psoriatic arthritis (PsA)[1]. Depression and anxiety are well known comorbidities in psoriasis and PsA with higher prevalence in PsA[2].
Objectives: The aim of this study was to compare 1) patient-reported outcomes (PROs), including depression/anxiety scores; 2) physician-assessed measures and 3) disease activity using minimal disease activity (MDA) and Composite Psoriatic Disease Activity Index (CPDAI) in PsA patients with and without WD.
Methods: Consecutive patients with PsA fulfilling the CASPAR criteria were enrolled. Patients on disability pension, those with early retirement due to arthritis, those unemployed, away from work due to sick leave were considered as having WD. Patients have completed questionnaires on physical function and health-related quality of life and they were assessed for depression/anxiety using the Hospital Anxiety and Depression Scale (HADS-A and HADS-D) and Penn State Worry Questionnaire (PSWQ). Patients underwent musculoskeletal and skin assessments. Disease activity was compared between work-disabled and employed patients using MDA and CPDAI. Mann-Whitney, Chi-square tests and linear regression model were used to perform statistical analysis.
Results: 100 PsA patients were recruited, 18 were natural retirees, leaving 82 patients available for analysis. Thirty-one (17 male, age 50.9±9.97 years) participants of working age had work disability versus fifty-one (29 male, age 49.1±8.65 years) employed patients. Work-disabled patients had significantly higher HADS-D score (5.07±3.01 vs. 2.57±2.64; p<0.001) and significantly worse PROMs, including HAQ, PsAQoL, EQ-5D, BASDAI, BASFI, ASQoL, BRAF-NRS, pain and general health VAS. HADS-A and PSWQ scores were similar in both groups. Leeds enthesitis index and ESR were significantly higher (p=0.008; p=0.04, respectively) in patients with WD compared to those employed; furthermore the % of patients with CPDAI>4, suggesting moderate to severe disease activity were significantly higher (51.6% vs. 28%; p=0.032) in the WD group. There was no significant difference in MDA status between the two groups. Multiple regression analysis revealed significant relationship between HADS-D scores and CPDAI (B=0.566; p=0.03).
Conclusions: Consistent with previous studies we have observed that the WD rate is high (37.8%) among patients with PsA. This is the first study assessing the relationship between depression and disease activity using CPDAI in PsA patients with work disability. We have found significantly higher HADS-D score and higher % of patients with CPDAI>4 in the WD group compared to those employed. Significant relationship was revealed between depression and CPDAI, which suggests that disease activity together with depression contributes to work disability in PsA.

FRI0494 SECUKINUMAB PROVIDES RAPID AND SUSTAINED PAIN RELIEF IN PSORIATIC ARTHRITIS: 2-YEAR RESULTS FROM THE FUTURE 2 STUDY

I.B. McInnes[1], P.J. Mease[2], G. Schett[3], B. Kirkham[4], V. Strand[5], N. Williams[6], T. Fox[7], L. Pricop[8], S. Jugl[7], K.K. Gandhi[8] on behalf of the FUTURE 2 study group. *[1]University of Glasgow, Glasgow, United Kingdom; [2]Swedish Medical Center and University of Washington, Seattle, United States; [3]University of Erlangen-Nuremberg, Erlangen, Germany; [4]Guy's & St Thomas' NHS Foundation Trust, London, United Kingdom; [5]Stanford University School of Medicine, Palo Alto; [6]RTI Health Solutions, Durham, United States; [7]Novartis Pharma AG, Basel, Switzerland; [8]Novartis Pharmaceuticals Corp., East Hanover, United States*

Background: Pain remains a major clinical challenge in the treatment of psoriatic arthritis (PsA). Secukinumab (SEC) has demonstrated significant efficacy in PsA patients (pts), across a range of quality of life related outcome measures.[1,2]
Objectives: This *post-hoc* analysis evaluated change in pain scores from baseline (BL) to Week (Wk) 104 in PsA pts receiving SEC in the FUTURE 2 study.
Methods: FUTURE 2 study design has been reported.[2] Mean change from BL in pain VAS and SF-36 bodily pain domain scores were evaluated using mixed-effect model for repeated measures (MMRM) through Wk 16 and as observed through Wk 104. Proportion of pts reporting improvements ≥clinically meaningful differences in pain VAS (mean change from BL ≥20%) was assessed. Results are reported for SEC 300 and 150mg in overall population and stratified by prior use of TNF inhibitor (TNFi; TNFi-naïve vs. inadequate responder/intolerant [TNFi-IR]). EQ–5D-3L pain item scores (no-, moderate- or extreme-pain/discomfort) were assessed as proportions.
Results: Mean changes from BL in pain VAS were greater with SEC vs. placebo (PBO) by Wk 3 (least squares mean [LSM]: -16.9, -12.6 with SEC 300 and 150mg, respectively vs. -5.75 with PBO; $P<0.05$), and Wk 16 (LSM: -24.0 and -23.0 for SEC 300 and 150mg, respectively vs. -8.41 with PBO; $P<0.05$). Mean changes were sustained through Wk 104 (-26.1 and -25.9 with SEC 300 and 150mg, respectively). In both SEC groups, >50% pts reported improvements of ≥20% by Wk 3 and this increased through Wk 104. Similarly, SF-36 bodily pain domain scores improved from BL by Wk 4 and 16 with SEC vs. PBO, exceeding minimum clinically important differences of 5.0 (Wk 4: LSM: 16.2 and 16.3 for SEC 300 and 150mg, respectively vs. 5.9 with PBO; $P<0.05$ and Wk 16: LSM: 21.1 and 22.0 for SEC 300 and 150mg, respectively vs. 6.9 with PBO; $P<0.05$). Improvements in pain were consistent in TNFi-naïve and TNFi-IR pts; and of greater magnitude in the naïve subgroup (table). Based on the EQ–5D-3L pain/discomfort item, 99% pts reported moderate to extreme pain or discomfort at BL. At Wk 4, the proportion of pts with no pain or discomfort was greater for the SEC 300mg (15%) and 150mg (10%) vs. PBO (5%) and increased through Wk 104 to 28% and 16% with SEC 300 and 150mg, respectively.

Table 1. Summary of results by TNFi status at baseline

	TNFi-naïve			TNFi-IR		
	SEC 300mg	SEC 150mg	PBO	SEC 300mg	SEC 150mg	PBO
N	67	63	63	33	37	35
Pain VAS						
Wk 16	-27.8*	-25.1†	-11.3	-18.2‡	-21.1§	-4.4
Wk 104	-29.6	-28.3	–	-19.3	-20.4	–
SF-36 bodily pain						
Wk 16	23.8*	25.4*	8.6	18.3§	17.9§	5.2
Wk 104	24.2	22.2	–	24.5	14.0¶	–

*$P<0.0001$; †$P<0.001$; §$P<0.01$; ‡$P<0.05$ vs. PBO. *P*-values and LS mean change at Wk 16 from MMRM analysis. Mean change at Wk 104 from observed data in n=57 (300mg) and 53 (150mg) for TNFi-naïve and n=29 (300mg) and 24 (150mg) for TNFi-IR; ¶n=26.

Conclusions: SEC provides rapid and sustained pain relief through 104 wks in pts with PsA as assessed by multiple clinically relevant patient-reported measures of pain. Improvements were reported by pts regardless of their prior TNFi therapy status.

FRI0495 USE OF MELATONIN IN PATIENTS WITH PSORIATIC ARTHRITIS VIOLATIONS OF EMOTIONAL STATUS

I. Blaginina[1], O. Rebrova[1], N. Bludova[1], O. Volman[2]. *[1]Internal Medcine, SI "Lugansk State Medical University"; [2]Lugansk Clinical Regional Hospital, Lugansk, Ukraine*

Background: The ability of melatonin to reduce the activity of the sympathetic nervous system tone and of pituitary-adrenal system ensures its anti-stress properties. It can be used to reduce psycho-emotional manifestations of chronic pain in patients with psoriatic arthritis (PsA).
Objectives: To evaluate the effect of combined therapy with the use of melatonin on the expression of psycho-emotional disorders, and pain in patients with PsA.
Methods: High levels of anxiety and depressive disorders were established in the survey on Spielberger Anxiety Scale and on Hamilton Rating Scale for Depression (HRDS) in 43 patients with PsA (≥5 SJC and ≥5 TJC; CRP ≥0.3 mg/dL). The quality of life was studied by questionnaire Medical Outcomes Study Short Form (SF-36); the severity of morning stiffness, pain, patient's health status (EWS) - using the 100-mm visual analog scale (VAS). All patients were receiving a stable dose of MTX for at least 6 months. They were divided into two groups; 1 group (n=22) additionally received 3 mg of melatonin at bedtime for 2 months of observation
Results: At the end of the observation period the frequency and the level of

severity of depression by HRDS (p=0.0098), and the index of personal anxiety (P=0.009) in group 1 decreased. In the 2nd group above mentioned parameters have not changed. On the 1 group data of SF-36 evaluation: the physical health component has improved - the increase of RP and BP 57.4% and 37.8% from the baseline; vital activity and role functioning due to emotional state, have also increased by 35.6% and 43.5%, respectively. In the 2nd group (n=22) investigated parameters have not undergone significant changes in dynamics. In the 1 receiving melatonin group TJC and SJC have decreased by 15% and 22% (p=0.0079, p=0.0022, respectively) and their dynamics in the 2nd group was less significant (p=0.013 and p=0.017, respectively). Also, patients in group 1 have highly significant (p<0.001) reduction in the severity of morning stiffness and joint pain, and in the 2nd group the changes were less significant (respectively, p=0.043, p=0.016). Positive dynamics of CRP in group 1 was more significant (p=0.003), than it was in 2 patients' group (p=0.033).

Conclusions: In the group of patients treated with melatonin was noted improvement in general condition (a significant improvement in the parameters of the physical components of health, reduction of depressive and psycho-vegetative disorders) and also more significant decrease of the intensity of pain and of morning stiffness duration, of TJC and SJC, than in not treated with melatonin patients. Inclusion of Melatonin in the comprehensive PsA therapy promotes not only reduction of depression symptoms and sleep disorders, but also reduces the severity of the chronic pain manifestations and, consequently, improves the quality of life of patients with this disease

FRI0496 COMPARING TOFACITINIB SAFETY PROFILE IN PATIENTS WITH PSORIATIC ARTHRITIS IN CLINICAL STUDIES WITH REAL-WORLD DATA

J.R. Curtis[1], H. Yun[1], O. FitzGerald[2], K. Winthrop[3], V.F. Azevedo[4], G. Burmester[5], W.F.C. Rigby[6], K.S. Kanik[7], R. Rojo[7], S. Menon[7], C. Wang[7], P. Biswas[8], T. Hendrikx[9], N. Palmetto[8]. *[1]University of Alabama at Birmingham, Birmingham, AL, United States; [2]Department of Rheumatology, St Vincent's University Hospital, Dublin, Ireland; [3]Oregon Health and Science University, Portland, OR, United States; [4]Universidade Federal do Paraná, Curitiba, Brazil; [5]Charité - University Medicine Berlin, Berlin, Germany; [6]Geisel School of Medicine at Dartmouth, Lebanon, NH; [7]Pfizer Inc, Groton, CT; [8]Pfizer Inc, New York, NY; [9]Pfizer Inc, Collegeville, PA, United States*

Background: Tofacitinib is an oral Janus kinase inhibitor under investigation for the treatment of psoriatic arthritis (PsA). Two Phase 3 studies have been completed (NCT01877668; NCT01882439) and a long-term extension (LTE) study is ongoing (database not locked; NCT01976364).

Objectives: To compare incidence rates (IR) for adverse events (AEs) of special interest in a tofacitinib cohort from the Phase 3 PsA trials with real-world experience in a comparison cohort from the US Truven MarketScan database.

Methods: The tofacitinib cohort included adult patients (pts) from 2 Phase 3 studies with ≥6 months PsA diagnosis who met ClASsification of Psoriatic ARthritis (CASPAR) criteria, had active plaque psoriasis, and active arthritis (≥3 swollen and ≥3 tender/painful joints) and who were treated with tofacitinib. Pts were grouped by those who received tofacitinib 5 (N=238) or 10 mg (N=236) twice daily (BID) in the 2 Phase 3 studies, and all pts who received ≥1 dose of tofacitinib in the 2 Phase 3 studies or the LTE (tofacitinib all doses, N=783). The comparison cohort (N=5799) comprised pts with moderate to severe PsA, defined by ≥1 inpatient or ≥2 outpatient 696.0 diagnosis codes on 2 unique calendar days (≥1 by a rheumatologist) between Oct 2010 and Sep 2015, initiating therapy with a systemic agent for PsA. Key Phase 3 study exclusion criteria were applied to the comparison cohort. IRs for serious infection events (SIEs), herpes zoster (HZ), malignancies (excluding non-melanoma skin cancer [NMSC]), NMSC and major adverse cardiovascular events (MACE) were compared.

Results: Mean age, gender and diabetes history were generally similar between the tofacitinib and comparison cohorts (48.7–49.5 years, 42.4–49.2% male, 12.2–15.7% with diabetes history). Overall more pts treated with tofacitinib had prior experience with corticosteroids (15.7–28.2%), conventional synthetic disease-modifying antirheumatic drugs (100%) and tumour necrosis factor inhibitors (48.1–55.9%) vs the comparison cohort (11.9%, 46.6% and 36.6%, respectively). IRs for SIEs were lower for the tofacitinib vs the comparison cohort (Table 1). The tofacitinib cohort had a higher rate of HZ vs the comparison cohort (Table 1). IRs for malignancies and MACE were similar between cohorts (Table 1).

Conclusions: IRs of AEs of special interest reported in tofacitinib PsA Phase 3 studies were generally comparable to those in a general PsA population comprising pts receiving a range of biologic agents, except HZ, which was higher for pts treated with tofacitinb but similar to the incidence observed with tofacitinib treatment in other indications.

Background: Psoriatic arthritis (PsA) is a multifaceted disease.

Objectives: We aimed to evaluate change in medication over time guided by joints, skin, enthesis, low back pain and dactylitis in newly diagnosed PsA patients

Methods: Newly diagnosed PsA patients were included in the Dutch Early south-west Psoriatic Arthritis cohoRt (DEPAR) study between August 2013 and March 2016. Initial drug treatment and escalation of therapy were described for all patients. Drivers of treatment changes in the first year were evaluated by mixed

Table 1 Multivariable mixed effects ordered ordinal logistic regression of treatment change over time in early PsA

	Odds Ratio	95% CI

ordered ordinal regression with outcome treatment change and variables joints (66/68 count), skin (PASI), entheses (LEI and MASES), dactylitis (LDI) and axial disease (BASDAI)

Results: 323 patients had had baseline assessment in March 2016. Their average age was 50.0 years (SD 13.8) and 49% were male. 80% patients had arthritis (19% monoarthritis, 39% oligoarthritis and 23%polyarthritis), 9% had an enthesitis subtype, 2% axial disease and 9% dactylitis. Initial treatment consisted of methotrexate (MTX) (52%), in 7% of other synthetic disease modifying antirheumatic drugs (sDMARDs) and due to treatment of psoriasis 3% biologicals. Within the different phenotypes MTX was most frequently started in polyarthritis (84%) followed by oligoarthritis (63%), monoarthritis (33%) and other phenotypes (5%). At 12 months 70% (n=148) stayed on the initial drug. Of those switched, 9 started MTX, within the initial MTX users (n=74) almost equal percentages stopped, switched to metoject or biological (4%). A smaller percentage (2%) switch to leflunomide. Changes in medication were driven by swollen joint count and the presence of dactylitis (Table 1)

Conclusions: MTX was initiated in about half of the early PsA patients. The majority of patients were kept on the initial treatment strategy in first year. Failure on initial drug led to variation in subsequent drugs with additional start of other sdmards, switch subcutaneuous MTX, to other sdmards or to biological dmards. Treatment change was driven by Swollen Joint Count and presence of Dactylitis. Skin, Enthesis and Axial disease did not play a role in escalating treatment.

FRI0498 OUTCOMES ASSOCIATED WITH ACHIEVEMENT OF VARIOUS TREATMENT TARGETS IN PATIENTS WITH PSORIATIC ARTHRITIS RECEIVING ADALIMUMAB

J. Smolen[1], D. Aletaha[1], D.D. Gladman[2], Y. Zhang[3], F. Ganz[4]. *[1]Medical University of Vienna, Vienna, Austria; [2]University of Toronto, Toronto Western Hospital, Toronto, Canada; [3]AbbVie, Inc., North Chicago, United States; [4]AbbVie, Inc., Baar, Switzerland*

Background: Various instruments are currently used for disease activity and outcome assessment in psoriatic arthritis (PsA). Some measures attempt to incorporate the total spectrum of psoriatic disease manifestations [eg, minimal disease activity (MDA)] while others focus on arthritis assessments [eg, disease activity index for PsA (DAPSA)]. Whether in patients (pts) with PsA it is sufficient to primarily consider joint disease aspects remains unclear.

Objectives: To compare DAPSA remission and low disease activity (LDA) with MDA and very low disease activity (VLDA) for the presence of residual abnormalities of the respective composing variables.

Methods: This post hoc analysis included pts with PsA receiving adalimumab (ADA) in one of two multicenter studies: ADEPT was a 24-week (wk), randomized, double-blind, placebo-controlled trial; ACCLAIM was a 12-wk, open-label study conducted in Canada in care settings that reflected usual practice. Frequencies of DAPSA remission/LDA and MDA/VLDA were summarized, and the individual PsA manifestations within these states were assessed. DAPSA was summed from the following continuous variables: swollen (66) and tender (68) joints, pt global assessment (PtGA, cm), pt pain (PP, cm), and C-reactive protein (CRP, mg/dL). DAPSA remission was defined as $\leq$4 and DAPSA LDA as $>$4 and $\leq$14. MDA criteria were as follows: $\leq$1 tender, $\leq$1 swollen joint, $\leq$1 entheseal point, PP $\leq$15mm, PtGA $\leq$20mm, HAQ $\leq$0.5, and PASI $\leq$3. MDA was calculated as fulfilling 5 of the 7 criteria, and VLDA calculated as fulfilling all 7 criteria. Data were as observed.

Results: Among 151 pts receiving ADA in ADEPT, 33 (22%) each achieved DAPSA remission and LDA at wk 24, and 20 (14%) and 11 (7%) achieved MDA and VLDA, respectively. Pts achieving DAPSA LDA appeared to mirror those in MDA, with the exception of experiencing numerically higher PP, PtGA, and PASI scores at wk 24 (Table). Pts in DAPSA LDA did experience numerically lower SJC when compared with the MDA achievers, and, like MDA achievers, displayed little residual enthesitis. Only VLDA, but not MDA, could match the stringency of DAPSA remission, a finding that was confirmed through analysis of the ACCLAIM cohort.

Table. Mean Values of DAPSA and MDA Components Following 12 or 24 Weeks of Adalimumab in ACCLAIM or ADEPT, Respectively

	DAPSA LDA (>4 – ≤14)		DAPSA Remission (≤4)		MDA (5 of 7 criteria)		VLDA (all 7 criteria)	
Variable	ADEPT n=33	ACCLAIM n=37	ADEPT n=33	ACCLAIM n=7	ADEPT n=20	ACCLAIM n=32	ADEPT n=11	ACCLAIM n=9
TJC, 0–78	3.1 ± 2.96	2.0 ± 1.80	0.3 ± 0.73	0.1 ± 0.38	3.4 ± 5.85	5.1 ± 5.49	0.1 ± 0.30	0.2 ± 0.44
SJC, 0–76	1.7 ± 2.00	2.4 ± 2.53	0.7 ± 1.36	0.3 ± 0.49	4.0 ± 7.97	4.8 ± 4.31	0.1 ± 0.30	0.2 ± 0.44

CRP, mg/dL	0.4 ± 0.77	1.0 ± 0.99	0.2 ± 0.18	1.1 ± 0.79	0.3 ± 0.30	1.0 ± 1.27	0.2 ± 0.16	1.6 ± 0.97
PASI	2.5 ± 5.24	1.7 ± 1.47	0.6 ± 1.40	1.3 ± 0.58	0.7 ± 0.59	2.0 ± 3.02	0.3 ± 0.34	1.2 ± 0.55
HAQ-DI	0.4 ± 0.46	0.3 ± 0.47	0.1 ± 0.39	0.2 ± 0.34	0.2 ± 0.40	0.2 ± 0.35	0.0 ± 0.12	0.0 ± 0.09
Enthesitis	0.1 ± 0.40	0.1 ± 0.28	0.1 ± 0.24	0.1 ± 0.38	0.2 ± 0.37	0.2 ± 0.37	0.0 ± 0.00	0.1 ± 0.33
ΔmTSS, 0–570	−0.1 ± 1.30	N/A	−0.2 ± 0.70	N/A	−0.5 ± 2.20	N/A	−0.1 ± 0.51	N/A

All values are mean ± SD, unless otherwise indicated.

DAPSA, disease activity index of psoriatic arthritis; MDA, minimal disease activity; VLDA, very low disease activity; TJC, tender joint count based on 78 joints; SJC, swollen joint count based on 76 joints; mm, millimeter; VAS, visual analog scale; PtGA, patient global assessment of disease activity; CRP, C-reactive protein; mg, milligram; dL, deciliter; PASI, psoriasis activity score index; HAQ-DI, health assessment questionnaire disability index; mTSS, modified total Sharp score.

However, VLDA allowed for numerically higher residual PP and PtGA levels when compared with DAPSA remission. Importantly, residual enthesitis did not differ among pts achieving DAPSA remission or VLDA. Irrespective of disease activity assessment, pts receiving ADA displayed little to no radiographic progression.

Conclusions: In the ADEPT and ACCLAIM cohorts, pts who achieved DAPSA remission or VLDA demonstrated similar outcomes with respect to the individual components of both scores, despite the omission of several of these within the DAPSA. Given the DAPSA's continuous nature, its use may offer a good alternative to fulfillment of the VLDA criteria, but these results require confirmation in different pt populations.

FRI0499 REAL-WORLD STUDY ON THE PATTERNS AND COST OF TREATMENT FAILURE IN PATIENTS WITH PSORIATIC ARTHRITIS USING US CLAIMS DATA

K. Price[1], E. Alemao[1], L. Burns[1], Z. Guo[1], V. Anupindi[2], S. Goday[3]. *[1]Bristol-Myers Squibb; [2]Mu Sigma, Princeton, United States; [3]Mu Sigma, Bangalore, India*

Background: Current treatments for psoriatic arthritis (PsA) are associated with a range of limitations, e.g. side effects, safety concerns and inadequate efficacy. The economic burden of biologic (b)DMARD failure among patients (pts) with PsA is thought to be substantial,[1] but there is a need to quantify this formally.

Objectives: To evaluate PsA treatment failure (i.e. discontinuation and switching rates) in a US managed care setting and its economic consequences.

Methods: Pts aged $\geq$18 years with 2 diagnosis codes for PsA and 1 claim for a bDMARD from 1 Jan 2007 to 31 Mar 2015 in the Truven Health MarketScan® Database (Commercial and Supplemental Medicare) were eligible for the study. Pts were considered incident if they did not have a PsA diagnosis or a bDMARD prescription during 1 year prior to first PsA diagnosis in the study period, and as prevalent otherwise. Pts had a 1-year follow-up from first PsA diagnosis in the study period. The percentages of pts discontinuing a drug, switching to another drug or continuing on the same drug for 1 year from first date of treatment were reported. Healthcare costs for 1 year from initiation of the first bDMARD, (medical and drug costs associated with treatment failures) were reported as cost per-pt-per-month (PPPM), and a generalized linear model was used to analyse the cost after controlling for various demographic variables.

Results: Of the 18,632 pts treated with a bDMARD, 1298 (6.97%) were incident and 17,334 (93.03%) prevalent. Almost half (n=8994; 48.27%) of the pts continued on the index bDMARD for 1 year. Treatment failed for the remaining pts, with 7852 (42.14%) discontinuing, and 1630 (8.75%; overlap $\leq$30 days between drugs) and 156 (0.84%; overlap $>$30 days) switching. In the prevalent group, 8754 (50.50%) pts continued on the index drug, 7043 (40.63%) discontinued, and 1399 (8.07%; overlap $\leq$30 days) and 138 (0.79%; overlap $>$30 days) switched to another drug. Among incident pts, only 240 (18.49%) continued, 809 (62.33%) discontinued, and 231 (17.80%; overlap $\leq$30 days) and 18 (1.38%; overlap $>$30 days) switched to another drug. Pts with an overlap $>$30 days were excluded from the analysis. Overall, pts who switched had a higher PPPM total cost ($3317) than those who discontinued ($2650; $p<0.0001$) or continued ($2708; $p<0.0001$). Similar results were observed in the prevalent and incident groups, respectively, with pts who switched incurring a higher PPPM total cost ($3241 and $3779) compared with those who discontinued ($2583 and $3237; both $p<0.0001$) or continued ($2700 and $3080; both $p<0.0001$). Increasing age (per year) was associated with a 0.57% higher total cost in the incident group ($p=0.002$) and with a 0.49% higher cost in the prevalent group ($p<0.0001$). Among prevalent pts, females had a 3.08% higher cost than males ($p=0.0069$). The Charlson Co-morbidity Index score predicted a higher cost ($p<0.0001$) among prevalent but not incident pts.

Conclusions: In a US claims study population of pts with PsA, rates of treatment failure as defined by switching or discontinuation were high. Follow-up costs for pts who switched were higher than for pts who continued or discontinued their medication. Baseline age, female sex and co-morbidities were associated with higher treatment costs.

FRI0500 AVOIDANCE OF PHYSICAL ACTIVITY LEADS TO REDUCED INFLAMMATORY ENTHESITIS ON ULTRASOUND

K. Wervers[1], I. Herrings[1], J.J. Luime[1], M. Moed[1], I. Tchetverikov[2], A.H. Gerards[3], J.M.W. Hazes[1], M. Vis[1]. [1]*Rheumatology, Erasmus MC, Rotterdam;* [2]*Rheumatology, Albert Schweitzer Hospital, Dordrecht;* [3]*Rheumatology, Vlietland Hospital, Schiedam, Netherlands*

Background: Enthesitis is one of the manifestations of psoriatic arthritis (PsA), but no clear definition for the diagnosis exists. To further evaluate the added value of sonographic evaluation of entheses in diagnosing enthesitis, more knowledge on factors associated with sonographic enthesitis is needed.
Objectives: We aim to evaluate which clinical characteristics are associated with sonographic enthesitis changes in a cross-sectional PsA population.
Methods: established PsA patients were asked to participate, irrespective of enthesitis complaints. Patients were interviewed on history of musculoskeletal complaints (MSC), more specifically if they had complaints during activities and whether they avoided physical activities (during exercise, work, household tasks, hobbies, chores). Tenderness was determined in the MASEI entheses and those in the Leeds Enthesitis Index (LEI) and Maastricht Ankylosing Spondylitis Enthesitis Score (MASES). Previously we showed that a modified Madrid Sonographic Enthesitis Index (MASEI, i.e. excluding knee enthesis thickness and scoring PD-signal semi-quantitatively) distinguishes entheses of PsA patients from those of healthy volunteers (1). A sonographist unaware of clinical findings scored the modified MASEI. Multivariable linear regressions of structural (erosions, calcifications, structure) and inflammatory (thickness, bursitis and PD) modified MASEI scores were performed (transformed for a better distribution). Variables included age, gender, PsA duration, medication use (non/nsaids vs. sDMARDs vs. bDMARDs), LEI + MASES and avoidance (no vs. yes).
Results: 84 PsA patients participated (45 males, mean age 55, median disease duration 8 years). Median modified MASEI was 12 (IQR 7.25–17), with a structural component score of 7 (3–10) and inflammatory component score of 6 (3.5–8.5). 8 patients used no medication or NSAIDs only, 36 used sDMARDs and 40 used bDMARDs. 45 patients reported avoiding activities. In a multivariable analysis, inflammatory modified MASEI was negatively associated with avoidance (i.e. fewer inflammatory changes in patients reporting avoidance) and positively associated with age, BMI and use of biologics. Structural MASEI was positively associated with age only.

Table 1. Univariable and multivariable linear regression analysis of inflammatory and structural summary scores of MASEI

	inflammatory modified MASEI				structural modified MASEI			
	Univariable		Multivariable		Univariable		Multivariable	
age	**0.018**	[0.005;0.031]	**0.015**	[0.002;0.029]	**0.034**	[0.017;0.051]	**0.032**	[0.013;0.051]
gender (female vs. male)	0.156		0.162		0.122		0.102	
BMI	0.030		**0.031**	[0.002;0.060]	0.041		0.039	
medication use								
none/nsaids vs. sDMARDs	0.365		0.349		0.690		0.463	
none/nsaids vs. bDMARDs	0.484		**0.588**	[0.076;1.100]	0.588		0.462	
sqrt(disease duration)	0.085		-0.021		**0.246**	[0.030-0.462]	0.110	
LEI + MASES	-0.006		-0.005		0.016		-0.005	
avoidance (no vs. Yes)	**-0.415**	[-0.710;-0.119]	**-0.40**	[-0.697;-0.094]	-0.012		0.131	

Data shown as β [95%-CI]

Conclusions: Avoiding physical activities is associated with fewer inflammatory changes of the entheses. More inflammatory changes are seen in older or overweight patients and patients on biologicals, in the latter possibly due to more active disease.

FRI0501 REAL-WORLD USE OF SECUKINUMAB IN PATIENTS WITH PSORIATIC ARTHRITIS IN THE UNITED STATES: PATIENT PROFILE AND DOSING REGIMEN USE

K. Oelke[1], G. Chun[2], Y. Li[2], X. Liu[3], J.B. Palmer[2]. [1]*Rheumatic Disease Center, Glendale;* [2]*Novartis Pharmaceuticals Corporation, East Hanover;* [3]*KMK Consulting, Inc, Morristown, United States*

Background: As of January 15, 2016, secukinumab became the first fully human anti–interleukin-17 monoclonal antibody approved for the treatment of patients with psoriatic arthritis (PsA) in the United States. Secukinumab may be administered with or without loading of 150 mg or 300 mg (patients with concomitant moderate to severe psoriasis only) at weeks 0, 1, 2, 3 and 4 followed by maintenance dosing every 4 weeks. The use of a loading regimen of secukinumab in a real-world setting of patients with PsA has not been evaluated since its approval in the United States.
Objectives: To better understand the real-world use of secukinumab by describing the demographic, clinical and treatment characteristics (loading vs no loading) of secukinumab-treated patients with PsA.
Methods: Retrospective data from the Symphony Health Solutions Lx commercial claims database were used to identify patients who had ≥1 secukinumab claim between 01/15/2016 and 06/30/2016. Patients who were included in the analysis were aged ≥18 years, had ≥1 ICD-9 code of 696.0 or ICD-10 code of L40.5 for PsA and had ≥1 pharmacy or medical claim in the 12 months prior to their first secukinumab claim (index date). Patient demographics and secukinumab dosage were examined at the index date. Clinical characteristics, comorbidities and treatment history in the 12 months prior to the index date were identified and presented by use vs no use of loading.
Results: A total of 764 patients met the inclusion criteria. The mean (SD) age was 50.7 (11.6) years, 58.5% of patients were female and 39.8% of patients were from the south. The most common specialties prescribing secukinumab to patients with PsA were rheumatologists (52.1%) and dermatologists (30.0%). A total of 608 patients (79.6%) received loading and 156 (20.4%) did not; at the index date, the majority of patients received secukinumab at the 300-mg dose in the loading (73.2%) and no loading (84.6%) groups. Patient demographics, clinical characteristics and treatment history were generally comparable between groups (Table 1). However, more patients with loading had prior oral corticosteroid (OCS; 30.9% vs 20.5%), targeted synthetic disease-modifying antirheumatic drug (tsDMARD; 24.7% vs 17.3%) and biologic (64.3% vs 59.6%) use compared with those without loading. The most prevalent comorbidities were psoriasis (58.8%), hypertension (34.4%) and hyperlipidemia (26.8%). A higher proportion of patients with loading had hypertension (35.2% vs 31.2%), rheumatoid arthritis (RA; 15.3% vs 10.9%), fatigue (13.5% vs 9.0%) and anxiety (13.3% vs 8.3%) and a lower proportion had psoriasis (57.4% vs 64.1%) compared with those without loading.

Table 1. Demographics, clinical characteristics and treatment history of patients with PsA treated with secukinumab with or without a loading dose of 150 mg

	Overall (n = 764)	Loading (n = 608)	No Loading (n = 156)
Age, mean (SD), years	50.7 (11.6)	50.9 (11.9)	49.9 (10.5)

Depression	125 (16.4)	98 (16.1)	27 (17.3)
Obesity	117 (15.3)	96 (15.8)	21 (13.5)
Rheumatoid arthritis	110 (14.4)	93 (15.3)	17 (10.9)
Fatigue	96 (12.6)	82 (13.5)	14 (9.0)
Anxiety	94 (12.3)	81 (13.3)	13 (8.3)

csDMARD, conventional synthetic disease-modifying antirheumatic drug; NSAID, nonsteroidal anti-inflammatory drug; PsA, psoriatic arthritis; tsDMARD, targeted synthetic disease-modifying antirheumatic drug.

Conclusions: This US claims-based study found the majority (≈ 73%) of secukinumab-treated patients with PsA were initiated with a loading regimen. Most patients initiated the 300-mg dose regardless of loading. A higher proportion of patients with loading had prior OCS, tsDMARD and biologic use, as well as hypertension, RA, fatigue and anxiety compared with those without loading, suggesting patients who initiated with loading had more refractory disease. These results provide the first insights into real-world use of secukinumab with and without loading in patients with PsA in the United States.

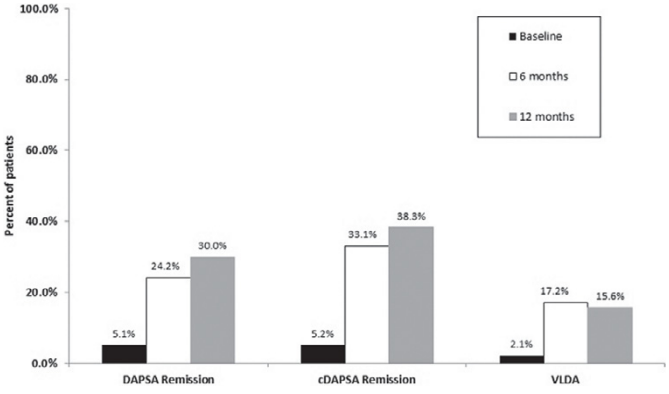
FRI0502 IXEKIZUMAB REDUCES DISEASE ACTIVITY IN ACTIVE PSORIATIC ARTHRITIS PATIENTS WHO HAD PREVIOUS INADEQUATE RESPONSE TO TUMOUR NECROSIS FACTOR-INHIBITORS

L.C. Coates[1], P. Mease[2], M.E. Husni[3], E. Lespessailles[4,5], D.H. Adams[6], O. Benichou[6], L. Kerr[6], P. Helliwell[1]. *[1]University of Leeds, Leeds, United Kingdom; [2]Swedish Medical Center and University of Washington, Seattle; [3]Cleveland Clinic, Cleveland, United States; [4]Orléans University; [5]Department of Rheumatology, C.H.R. Orléans, Orléans, France; [6]Eli Lilly and Company, Indianapolis, United States*

Background: Psoriatic arthritis (PsA) is a chronic immune-mediated inflammatory disease associated with psoriasis, peripheral arthritis, enthesitis, dactylitis, and spondylitis. Ixekizumab (IXE), a monoclonal high affinity antibody that selectively targets interleukin-17A, has improved disease activity and physical function in bDMARD-naïve patients with active PsA.[1] Herein, results are presented from a phase 3 trial (SPIRIT-P2; NCT02349295) with IXE in patients with active PsA and previous inadequate response to tumour necrosis factor-inhibitors (TNF-i).
Objectives: To explore the impact of IXE, as assessed by composite endpoints that incorporate multiple disease domains including peripheral arthritis, skin disease, enthesitis, dactylitis, spinal disease, functioning, and global disease assessment, up to 24 weeks (wks).
Methods: In this phase 3, multicentre, double-blind study, 363 adult patients with active PsA and a history of inadequate response to TNF-i were randomly assigned at a 1:1:1 ratio to subcutaneous administration of 80-mg IXE either every 4 wks (Q4W; N=122) or every 2 wks (Q2W; N=123) following a 160-mg starting dose at Wk 0 or placebo (PBO; N=118). TNF-i inadequate response was defined as lack of efficacy to one or two TNF-i or intolerance to TNF-i. Response to treatment and disease activity were measured at Wks 12 and 24 by the following composite endpoints: minimal disease activity with skin component measured with the Psoriasis Area and Severity Index (MDA) or the static Physician Global Assessment of psoriasis (mMDA) and Composite Psoriatic Disease Activity Index (CPDAI) as well as traditional measures by Psoriatic Arthritis Response Criteria (PsARC). Treatment comparisons were made by a logistic regression model for categorical data with missing values imputed by nonresponder imputation (NRI); a mixed model for repeated measures analysis was used for continuous data.
Results: At Wks 12 and 24, significantly more patients receiving IXEQ4W or IXEQ2W achieved MDA, mMDA, and PsARC compared with patients receiving PBO (Table). Results for MDA were similar to mMDA results within each treatment group at each time point. CPDAI total scores for patients receiving IXEQ4W or IXEQ2W were significantly improved compared with results for patients receiving PBO.

Table: Summary of Composite Endpoints at Weeks 12 and 24

			PBO (N=118)	IXEQ4W (N=122)	IXEQ2W (N=123)
MDA	Week 12	n (%)	6 (5.1)	31 (25.4)***	21 (17.1)**
	Week 24	n (%)	4 (3.4)	34 (27.9)***	29 (23.6)***
mMDA	Week 12	n (%)	6 (5.1)	31 (25.4)***	23 (18.7)**
	Week 24	n (%)	4 (3.4)	34 (27.9)***	29 (23.6)***
PsARC	Week 12	n (%)	28 (23.7)	61 (50.0)***	64 (52.0)***
	Week 24	n (%)	24 (20.3)	68 (55.7)***	58 (47.2)***
CPDAI	Week 12	Change from baseline	-0.9 (0.4)	-3.0 (0.4)***	-2.8 (0.3)***
		Effect Size	--	-2.1 (-2.8 to -1.5)	-1.9 (-2.6 to -1.3)
	Week 24	Change from baseline	-1.0 (0.4)	-3.7 (0.4)***	-3.4 (0.4)***
		Effect Size	--	-2.7 (-3.5 to -2.0)	-2.4 (-3.2 to -1.7)



Change from baseline is least square mean (SE); Effect size is least square mean difference versus PBO (95% CI). **p<.01; *** p<.001.

Conclusions: Treatment with either IXEQ2W or IXEQ4W provides improvement in disease activity across multiple symptom domains, as measured by various composite endpoints, in patients with active PsA and who had a previous inadequate response to TNF-i.

FRI0503 VALIDATION OF NEW POTENTIAL TARGETS FOR REMISSION IN PSORIATIC ARTHRITIS IN PATIENTS TREATED WITH GOLIMUMAB

L.C. Coates[1], P. Rahman[2], E. Psaradellis[3], A. Karellis[3], E. Rampakakis[3], B. Osborne[4], C. Tkaczyk[4], A.J. Lehman[4], F. Nantel[4]. *[1]Leeds University, Leeds, United Kingdom; [2]Memorial University, St-Johns, NL; [3]JSS Medical Research, Montreal, QC; [4]Janssen Inc, Toronto, ON, Canada*

Background: Treat to target recommendations in psoriatic arthritis (PsA) stated that the target of treatment should be remission or inactive disease. At that time, no definitions of remission or inactive disease existed and the only validated target available was the minimal disease activity (MDA) criteria. Since then, other potential targets have been developed including very low disease activity (VLDA) and the Disease Activity in PsA (DAPSA) score remission.
Objectives: Using an existing dataset allowing calculation of DAPSA and clinical cDAPSA scores and the VLDA criteria, the objectives were to calculate the proportion of patients achieving these criteria, their prognostic value and the overall patient impact of these disease states.
Methods: BioTRAC is an ongoing, prospective registry of inflammatory arthritis patients initiating treatment with infliximab, golimumab (GLM) or ustekinumab. PsA patients treated with GLM were included. Data collected at baseline, 6 and 12 months (mts) were used. DAPSA remission was defined as: TJC + SJC + PtGA + Pt pain + CRP $\leq$4. cDAPSA Remission was defined as: TJC + SJC + PtGA+ Pt pain $\leq$4. Very low disease activity (VLDA) was achieved when all 7 MDA criteria were satisfied: TJC28$\leq$1, SJC28$\leq$1, PASI$\leq$1, Pain (VAS) $\leq$15mm, PtGA (VAS) $\leq$20mm, HAQ $\leq$0.5 and tender entheseal points $\leq$1. Correlation between DAPSA, cDAPSA and VLDA were based on tetrachoric analysis.
Results: A total of 188 patients (53.2% female gender) were included with a mean (SD) disease duration of 5.46 (6.91) years. DAPSA remission was achieved in 5.1%, 24.2% and 30.0% of patients at baseline, 6 mts and 12 mts, respectively. Those patients had a significant reduction in the number of TJC, SJC, enthesitis and dactylitis ($p<0.043$). cDAPSA remission was achieved in 5.2%, 33.1% and 38.3% of patients at baseline, 6 mts and 12 mts, respectively. Those patients had a significant reduction in the number of TJC, SJC and enthesitis only ($p<0.002$). VLDA was achieved in 2.1%, 17.2% and 15.6% of patients at baseline, 6 mts and 12 mts, respectively and those patients had a significant reduction in the number of TJC, SJC, enthesitis and PASI ($p<0.002$). The overall correlation for DAPSA or cDAPSA remission vs. VLDA achievement were both at 0.999 (Asymptotic Standard Error <0.027) although this is likely driven by the high number of patients who are not in either state. 75% and 53.3% of patients in DAPSA and cDAPSA remission, respectively, also achieved VLDA ($p<0.001$). In contrast, patients who did not achieve neither cDAPSA nor DAPSA never achieved VLDA. Nonetheless, patients in remission had significantly greater HAQ scores ($p<0.03$) if they had remaining dactylitis or active skin disease (BSA$\leq$10%; cDAPSA only).

Conclusions: DAPSA, cDAPSA and VLDA represent new potential target for remission in PsA with VLDA being the most stringent criteria. There was a high level of correlation between these scores although residual activity in dactylitis and skin despite DAPSA remission has some impact on patients' function.

FRI0504 APREMILAST EXPANDS IL-10-PRODUCING REGULATORY B CELLS, AND DECREASES TH1 AND TH7 CELLS IN PSORIATIC ARTHRITIS AND PSORIASIS

A. Mavropoulos[1], E. Zafiriou[2], A. Varna[1], E. Papadopoulou[2], I. Alexiou[1], A.-V. Roussaki-Schulze[2], D.P. Bogdanos[1], L.I. Sakkas[1]. *[1]Rheumatology and Clinical Immunology; [2]Dermatology, University of Thessaly, School of Health Sciences, LARISSA, Greece*

Background: IL-10-producing regulatory B cells (Bregs), also known as B10 cells, are decreased and inversely correlate with IFN-γ- and IL-17-producing NK and T cells in patients with psoriatic arthritis (PsA) and psoriasis (Ps) (1–3)
Objectives: To assess whether or not apremilast, a PDE4 inhibitor recently approved for the treatment of Ps and PsA, is able to induce IL-10-producing B cells and decrease Th1 cells and Th17 cells in vivo
Methods: PBMCs and magnetically purified B cells were isolated from 21 patients (7 PsA, all responders; 14 Ps, 9 responders) at baseline and post-apremilast treatment (at 3 and 6 months in responders; at 3 months in non–responders, as they switched to biologicals). Phenotypic analysis of CD3, CD19, CD24, CD27, CD38 and intracellular expression of cytoplasmic IL-10, IFN-γ, IL-17 after bacterial CpG (ODN2006) and PMA/ionomycin stimulation was examined by flow cytometry
Results: At 6 months, apremilast significantly increased IL-10-producing Bregs (IL-10+CD19+, B10 cells) compared to baseline and 3 months. B10 cells increase was confined mainly to the transitional Bregs (CD19+CD24highCD38high) rather than memory Bregs (CD19+CD27+CD24high). IFNγ+CD3+ (Th1) and IL-17+CD3+ (Th17) T cells were significantly decreased at 3 and 6 months ($p<0.05$, for both). There was an inverse correlation between percentages of B10 cells and IFN-γ-producing CD3+ cells. The percentage of B10 cells were not changed post-treatemnt in non-responders.
Conclusions: Our data suggest that apremilast may exert its therapeutic effect through the expansion of IL-10-producing Bregs and the decrease of IFN-γ- and/or IL-17-producing T cells

FRI0505 RESIDUAL DISEASE ACTIVITY IN PSORIATIC ARTHRITIS TRIGGERS TREATMENT ADJUSTMENT IN ONLY A QUARTER OF PATIENTS IN DAILY CLINICAL PRACTICE

L.J.J. Van Mens[1], S. Atiqi[1], I.A. Fluri[1], M.G.H. van de Sande[1], A.W.R. van Kuijk[2], D.L. Baeten[1,3]. *[1]AMC; [2]Reade, Amsterdam Immunology and Rheumatology Center, Amsterdam, Netherlands; [3]UCB, Brussels, Belgium*

Background: With expanding therapeutic possibilities for the treatment of psoriatic arthritis (PsA) it will be increasingly important to determine residual disease and define when to adjust treatment. The rationale behind treatment decisions in current daily clinical practice and the relation with residual disease activity has not been reported in literature.
Objectives: To assess the current clinical practice on defining residual disease and the subsequent treatment decisions made in PsA patients.
Methods: This cross sectional study included 142 consecutive PsA patients who visited the outpatient clinic. The treating rheumatologist scored disease activity and his opinion on the presence of residual disease and the subsequent treatment decisions made. Patients scored patient disease activity scores.
Results: Of the 142 patients, 52 patients were considered without residual disease by the treating rheumatologist. These patients indeed show low disease activity on all measured domains, and all patients were considered in remission or low disease activity according to CDAI composite score.
90 of the 142 patients were considered to have residual active disease by their treating rheumatologist. Disease activity was present across all measured domains and 48/90 patients were considered in moderate (39) or high (9) disease activity defined by CDAI. There were no differences between the groups with or without residual disease activity in gender, disease duration, comorbidity, current treatment duration or number of previously used cDMARDS. Residual disease activity was more frequently reported in patients treated with a cDMARD only or a 2nd TNFi.
Of the 90 patients with residual disease, in 21 (23%) treatment adjustment was initiated. Treatment adjustments consisted of: addition or adjustment of analgesic treatment in 6 pts (29%); local or intramuscular corticosteroid therapy in 5 pts (24%); switch of cDMARD to another cDMARD in 4 pts (19%); referral to a paramedic in 2 pts (10%); switch to a 2nd or 3rd TNFi in a patient already using TNFi treatment in 2pts (10%); addition of a cDMARD to current TNFi 1 pt (5%); and start of a TNFi with current use of cDMARD only in 1pt (5%). Treatment changes were considered less frequent in those patients treated with a 2nd TNFi. No differences were seen in disease activity and demographics between those with or without a treatment adjustment.
Reasons not to adjust therapy mostly reported were: complaints were seen as only minor (39/69, 57%). The most frequent other reasons reported were: it was the patients' preference not to adjust medication (10/69, 14%); "we have no other options left" (5/69, 7%); lack of compliance (due to side effects) (5/69, 7%).
Conclusions: Residual disease resulted in treatment adjustment in only a quarter of patients. Not adjusting treatment could not be explained by comorbidities, or a lack of treatment options in a majority of the patients. Our data indicate that future implementation of a treat-to-target approach in PsA does not only require a data-driven consensus on the optimal target to use but also active coaching of physicians and patients to promote treatment adjustments in clinical practice.

FRI0506 HLA PROFILES AND THEIR ASSOCIATIONS WITH DISEASE PHENOTYPES IN A CANADIAN PSORIATIC ARTHRITIS (PSA) COHORT

M. Khraishi[1], C. Molta[2], Z. Khraishi[3], A.M. Lewis[4]. *[1]Rheumatology, Memorial University of Newfoundland, St. John's, Canada; [2]Rheumatology, MainLine Rheumatology Lankenau Medical Center, Philadelphia, United States; [3]University of Western Ontario, London; [4]Epidemiology, Memorial University of Newfoundland, St. John's, Canada*

Background: PSA is a chronic disease with known genetic predisposition that affects 0.3% to 1% of the general population.Certain HLA allelles were reported to be more predominant in PSA and to be associated with certain manifestations.
Objectives: To determine HLA alleles prevalence in PSA patients and their association with clinical features and the severity of PSA in these patients
Methods: Two cohorts of early (established PSA)were followed prospectively.Clinical and laboratory data were collected at 6 months intervals, included PASI scores, nail involvement, joint counts, patient reported outcomes, comorbidities, inflammatory parameters and HLA Class I typing. Statistics utilized IBM SPSS v.23. Frequencies,means,medians and 2-tailed Pearson correlation were calculated.As the majority of our patients have Irish ancestry,we utilized HLA prevalence from an Irish population based data
Results: The cohorts included 265 patients. Of those, one hundred thirty five patients had their HLA analysis done. Fifty one percent of the patients were male, the mean age at onset of PSA 43.07 (19–76) years. Mean age of PSO diagnosis was 33.47 years. Sixty four percent had polyarticular involvement at base line and 17% had documented axial involvement.
Forty two haplotypes were reported in our cohort of those: HLA B27 was present in 33% of the patients (as compared to 6.77% in an Irish control population). HLAA1 was present in 31%, B8 in 21%,B57 in 6.6%B44 in 24.5%, B51 in 10%B58 in 5.6%, HLA B62 in 7%, HLA Bw4 in 43.6%and Bw6 in 46.5%.
The following associations were found to be significant: HLAB49 was negatively associated with age of onset of PSA with a Pearson correlation of -0.610 (P 0.007), also, HLA A23 had a correlation of -0.232 (P 0.016)
B44 was associated with increased total number of comorbidities, Pearson correlation was 0.332 (P 0.0001)
HLA B22 was associated with more severe PASI score with a correlation of 0.488 (P 0.000)
Of note that the only case in the cohort with Crohn's disease had HLA B12 which was previously reported in spondylitis
135 patients were studied,51% were male. The mean age of PSA onset was 43.07 yearsand 33.4 for PSO. 64% had polyarticular disease while 17% had axial involvement. 42 alleles were studied, of those, HLA B27 was present in 33% of patients (vs.6.77% controls) HLAA1 in 31%, B8 in 21%,B57 in 6.6%,B44 in 24.5%,B51 in 10%,B58 in 5.6%, HLA B62 in 7%, HLA Bw4 in43.6%, Bw6 in 46.5%. The following associations were significant: HLAB49& HLA A23 were associated with age of onset of PSA (correlation of -0.610 (P.007) and -0.232 (P.016) respectively. HLA B44 was associated with increased number of comorbidities (correlation 0.332 (P.0001),HLA B22 was associated with severe PASI score (correlation of 0.488 (P.000).The only case in our cohort with Crohn's disease had HLA B12 (previously reported in spondylitis)
Conclusions: The majority of patients had polyarticular involvement.HLABw6 and HLA Bw4 were the most frequent allelles. We found high percentage of patients with HLAB27, HLAA1 vs controls.HLA B27 prevalence was higher in patients with axial involvement but it did not reach significance in our cohort.HLA B44 was strongly associated with increased comorbidities (previous reports suggested protective effect of this allelle).HLA B22 was associated with more severe PASI scores.
Disclosure of Interest: None declared

FRI0507 THE RELATIONSHIP BETWEEN 10-YEAR CARDIOVASCULAR RISK SCORES AND DISEASE ACTIVITY IN PATIENTS WITH PSORIATIC ARTHRITIS

N. Ikumi[1], F. Farkas[1], A. Szentpetery[1], B. Kirby[2], O. FitzGerald[1].
[1]Rheumatology; [2]Dermatology, St. Vincent's University Hospital, Dublin, Ireland

Background: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis associated with an increased prevalence of cardiovascular (CV) disease[1]. This increase may in turn be due to a higher prevalence of traditional CV risk factors as well as to persistent inflammatory musculoskeletal and skin disease[2]. Disease activity in PsA may be assessed by the Composite Psoriatic Disease Activity Index (CPDAI) across 5 domains of involvement: peripheral joints, skin, entheses, dactylitis and spinal manifestations. Long-term CV risk is evaluated using several methods for general population.

Objectives: (1) To describe CV risk factors and 10-year CV risk scores among patients with PsA; and (2) to correlate with baseline CPDAI in this longitudinal study

Methods: PsA patients fulfilling the CASPAR criteria were enrolled consecutively from Rheumatology clinics. Fasting bloods were obtained for glucose, insulin, lipids. Patients underwent thorough physical examination, joint and skin assessments and completed questionnaires on health, depression/anxiety and quality of life. Four different CV risk scores were calculated: (1) Framingham Coronary risk score (FCS); (2) American College of Cardiology and American Heart Association (ACC/AHA) 10-year atherosclerotic cardiovascular disease (ASCVD) algorithm; (3) Systematic Coronary Risk Evaluation (SCORE) algorithm; and (4) QRISK2 (2016). CPDAI was calculated with CPDAI cutoff $\leq$4 representing low/minimal disease activity (LDA) or remission. CPDAI $>$4 represented active disease requiring treatment change.

Results: 100 PsA patients were recruited with mean age 52.4 (±10.5) (male 55%). Mean disease duration for PsA was 17.9 (±10) years. 58 patients (age 52.4±9.6, male 60.3%) had CPDAI$\leq$4 (LDA Gp) and 41 patients (age 52.4±11.9, male 48.8%) had CPDAI$>$4 (active Gp) at baseline. There were significantly more patients with BMI$\geq$35 in active Gp, but mean BMI, waist/hip ratio, blood pressure, fasting glucose, insulin, lipids, and patients taking NSIADs, oral corticosteroid, Methotrexate and/or biologics treatment were otherwise similar compared to LDA Gp. Skin (Psoriasis Area Severity Index (PASI); Dermatology Life Assessment Questionnaire (DLQI)) assessments together with levels of inflammatory markers such as C-reactive protein (CRP) were also similar in both groups. More active Gp had enthesitis (58.5%) and acute dactylitis (14.6%) (P$<$0.01 and 0.02, respectively). The mean FCS, ASCVD, SCORE and QRISK2 were similar in both groups (8.5±7.1% vs. 6.2±6.9%, P=0.11; 8.9±8.5% vs. 7.8±7.9%, P=0.54; 2.2±2.6% vs. 2.0±2.7%, P=0.81; 11.2±9.2% vs. 11.3±11.%, P=0.97, LDA Gp and active Gp respectively). Interestingly, there were more smokers in LDA Gp (60.3% vs 39.0%; p=0.04) and this likely accounts for the higher number of LDA Gp patients with FCS$>$10%.

Conclusions: We found similar prevalence of traditional CV risk factors and similar 10-year CV risk scores in PsA patients regardless of their CPDAI. Further correlation with measures of disease activity over time will be required.

FRI0508 THE EFFECT OF CERTOLIZUMAB PEGOL ON EXTRA-ARTICULAR MANIFESTATIONS OF PSORIATIC ARTHRITIS OVER 4 YEARS OF TREATMENT IN PATIENTS WITH AND WITHOUT PRIOR ANTI-TNF EXPOSURE

O. FitzGerald[1], R. Fleischmann[2], A. Kavanaugh[3], B. Hoepken[4], L. Peterson[5], D. Gladman[6]. *[1]St. Vincent's University Hospital and Conway Institute for Biomolecular Research, University College Dublin, Dublin, Ireland; [2]UT Southwestern Medical Center and Dallas Metroplex Clinical Research Center, Dallas; [3]UC San Diego School of Medicine, la Jolla, United States; [4]UCB Pharma, Monheim, Germany; [5]UCB Pharma, Raleigh, United States; [6]Krembil Research Institute, Toronto Western Hospital, Toronto, Canada*

Background: Extra-articular manifestations (EAMs) of psoriatic arthritis (PsA) include nail psoriasis, dactylitis, and enthesitis, which can significantly impact patients' (pts') quality of life.[1] In the RAPID-PsA trial (NCT01087788), certolizumab pegol (CZP) improved the signs and symptoms of EAMs in pts with PsA over 96 weeks (wks).[2]

Objectives: To report improvements in EAMs of PsA in pts treated with CZP over 4 years, both with and without prior anti-TNF exposure.

Methods: The RAPID-PsA trial was double-blind and placebo-controlled to Wk24, dose-blind to Wk48, and open-label (OL) to Wk216. Pts had active PsA and had failed $\geq$1 DMARD. Pts originally randomized to CZP (200mg Q2W or 400mg Q4W, following 400mg loading dose at Wks0, 2, 4) continued their assigned dose in the OL period. We present EAM data for those pts originally randomized to CZP, with involvement of the particular EAM at baseline (BL), and both with and without prior anti-TNF exposure. EAMs assessed include nail psoriasis (modified Nail Psoriasis Severity Index [mNAPSI], BL involvement = BL mNAPSI $>$0), enthesitis (Leeds Enthesitis Index [LEI], BL involvement = BL LEI $>$0), and dactylitis (Leeds Dactylitis Index [LDI], BL involvement = $\geq$1 digit affected with a difference in circumference $\geq$10% compared to the opposite digit). Also presented are the proportions of pts with BL involvement of each EAM who achieved total resolution of the respective EAM on follow-up (a score of 0 for mNAPSI, LEI, or LDI). Observed values are reported, combined for pts receiving either CZP dose regimen.

Results: A total of 409 PsA pts were randomized; 273 received CZP from Wk0. Among CZP-randomized pts, 197 had nail psoriasis at BL (159 without, and 38 with, prior anti-TNF exposure), 172 had enthesitis (133 without, and 39 with, prior anti-TNF exposure), and 73 had dactylitis (56 without, and 17 with, prior anti-TNF exposure). Although relatively few pts were anti-TNF experienced, a large proportion of pts both with and without prior anti-TNF exposure with BL involvement went on to achieve total resolution of the respective EAM following 48 wks of CZP treatment (Table). Among pts completing the study, the proportions achieving total resolution were maintained or further increased from Wk48 to Wk216 (Table). Mean scores of all EAMs assessed showed improvements by Wk48 of CZP treatment in pts both with and without prior anti-TNF exposure, which were maintained to Wk216 in pts completing the study (Table).

Table: Improvements in extra-articular manifestations of PsA over 216 weeks of CZP treatment in patients with and without prior anti-TNF exposure (observed values)

	Week 0 CZP dose combined (N=273)			
	Baseline	Week 48	Week 96	Week 216
Number of patients observed **Mean score (standard deviation)** **Patients with total resolution, n (%)**				
Nail psoriasis (mNAPSI) [a]				
Anti-TNF naïve (n=159)	159 3.4 (2.1) –	139 1.1 (1.5) 71 (51.1)	129 0.7 (1.3) 84 (65.1)	109 0.4 (0.8) 80 (73.4)
Anti-TNF experienced (n=38)	38 2.9 (1.8) –	33 0.9 (2.1) 22 (66.7)	29 0.6 (1.1) 19 (65.5)	23 0.5 (0.7) 14 (60.9)
Enthesitis (LEI) [b]				
Anti-TNF naïve (n=133)	133 3.0 (1.7) –	116 0.8 (1.5) 83 (71.6)	104 0.7 (1.3) 74 (71.2)	85 0.5 (1.0) 65 (76.5)
Anti-TNF experienced (n=39)	39 2.9 (1.6) –	33 1.2 (2.1) 23 (69.7)	27 0.8 (1.4) 19 (70.4)	25 0.5 (1.2) 20 (80.0)
Dactylitis (LDI) [c]				
Anti-TNF naïve (n=56)	56 50.9 (64.7) –	48 0.0 (0.0) 44 (91.7)	46 0.0 (0.0) 42 (91.3)	41 0.3 (2.1) 38 (92.7)
Anti-TNF experienced (n=17)	17 52.5 (42.7) –	14 12.6 (25.3) 11 (78.6)	11 0.0 (0.0) 9 (81.8)	9 4.2 (12.7) 8 (88.9)

EAMs were assessed in patients with involvement of the respective EAM at baseline. [a] Patients with mNAPSI >0 at baseline; [b] Patients with LEI >0 at baseline; [c] Patients with LDI >0 at baseline, defined as having at least 1 digit affected and with a difference in circumference ≥10% compared to the opposite digit.

Conclusions: PsA patients treated with CZP for up to 4 years, both with and without prior anti-TNF exposure, exhibited sustained improvements in the extra-articular manifestations of PsA.

FRI0509 SAFETY AND EFFICACY OF TOFACITINIB, AN ORAL JANUS KINASE INHIBITOR, UP TO 24 MONTHS IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: INTERIM DATA FROM OPAL BALANCE, AN OPEN-LABEL, LONG-TERM EXTENSION STUDY

P. Nash[1], L.C. Coates[2], A.J. Kivitz[3], P.J. Mease[4], D.D. Gladman[5], J.A. Covarrubias-Cobos[6], D. Fleishaker[7], C. Wang[7], E. Kudlacz[7], S. Menon[7], T. Hendrikx[8], K.S. Kanik[7]. *[1]Department of Medicine, University of Queensland, St Lucia, Brisbane, Australia; [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom; [3]Department of Rheumatology, Altoona Center for Clinical Research, Duncansville, PA; [4]Swedish Medical Center and University of Washington, Seattle, WA, United States; [5]Department of Medicine, University of Toronto, Toronto Western Hospital, Toronto, ON, Canada; [6]Unidad Reumatologica Las Americas S.C.P, Mérida, Yucatán, Mexico; [7]Pfizer Inc, Groton, CT; [8]Pfizer Inc, Collegeville, PA, United States*

Background: Tofacitinib is an oral Janus kinase inhibitor under investigation for psoriatic arthritis (PsA). Interim data (database not locked) from ≤24 months' participation (3 years' total treatment duration) for patients (pts) with active PsA in an ongoing, open-label, long-term extension study (LTE; NCT01976364 OPAL Balance) is reported.

Objectives: To evaluate the safety, tolerability and efficacy of tofacitinib in pts with active PsA.

Methods: Eligible pts from 2 pivotal Phase 3 tofacitinib PsA studies (NCT01877668 OPAL Broaden, NCT01882439 OPAL Beyond) could enter a 3-year LTE ≤3 months after completing the qualifying study or discontinuing for non study-drug-related reasons. Pts were to receive tofacitinib 5 mg twice daily (BID) for 1 month, after which an increase to 10 mg BID or reduction back to 5 mg BID was permitted at any time for efficacy or safety reasons. Concomitant treatment with a single conventional synthetic disease-modifying antirheumatic drug (csDMARD) was allowed but not required. Primary endpoints were incidence and severity of adverse events (AEs) and change from baseline in laboratory values. Efficacy was a secondary endpoint.

Results: 680/685 enrolled pts were treated. 608 (89.4%) remained at data cut-off. Mean (range) duration of tofacitinib exposure in this LTE was 206 (3–741) days. 661 (97.2%) pts took a csDMARD on Day 1, and 73 (11.0%) later discontinued csDMARD. To Month 24, 860 AEs were reported in 367 (54.0%) pts, 41 (6.0%) pts had serious AEs and 24 (3.5%) pts discontinued due to AEs. Special interest AEs included 6 serious infections (0.9%), 10 herpes zoster events (1.5%) including 1 serious event, 2 major adverse cardiovascular events (0.3%) and 2 malignancies (0.3%). There were 3 deaths (not attributed to treatment, as assessed by the investigator) due to metastatic pancreatic carcinoma, acute cardiac failure and pulmonary embolism. No GI perforation, inflammatory bowel disease or uveitis cases were reported. One AE of latent TB was reported. One pt met discontinuation criteria for laboratory values due to increased serum creatinine >50% and >0.5 mg/dL over the average of screening and baseline creatinine. Small mean decreases in absolute lymphocyte and neutrophil counts, and small mean increases in serum lipid markers, were observed; 18 (2.6%) pts started new lipid-lowering medication during the LTE (80 [11.8%] pts were on lipid-lowering drug at baseline). Efficacy was maintained in the LTE (Table 1).

Table 1. Summary of efficacy through to Month 15[a]

	Tofacitinib (all patients) (N=680)				
	Month 3	Month 6	Month 9	Month 12	Month 15
ACR20, n/N1 (%)	421/606 (69.5)	326/470 (69.4)	219/307 (71.3)	109/154 (70.8)	48/66 (72.7)
ACR50, n/N1 (%)	264/607 (43.5)	217/469 (46.3)	160/308 (52.0)	77/153 (50.3)	31/66 (47.0)
ACR70, n/N1 (%)	154/608 (25.3)	140/471 (29.7)	92/308 (29.9)	48/153 (31.4)	19/67 (28.4)
ΔHAQ-DI, mean (SD) [N1]	-0.5 (0.6) [606]	-0.5 (0.6) [472]	-0.5 (0.6) [308]	-0.5 (0.6) [154]	-0.5 (0.6) [67]
PASI75 response rate, n/N1 (%)[b]	219/387 (56.6)	180/304 (59.2)	113/202 (55.9)	55/100 (55.0)	31/45 (68.9)
ΔLEI, mean (SD)[c] [N1]	-1.6 (1.8) [399]	-1.5 (1.8) [312]	-1.6 (1.8) [204]	-1.4 (2.0) [102]	-1.8 (2.1) [48]
ΔDSS, mean (SD)[c] [N1]	-6.9 (7.8) [330]	-6.8 (8.3) [254]	-6.9 (7.2) [164]	-6.9 (6.6) [83]	-7.3 (7.4) [39]
ΔPain, mean (SD)[d] [N1]	-25.3 (26.8) [604]	-26.3 (28.0) [471]	-28.7 (28.9) [308]	-28.7 (29.2) [154]	-31.4 (29.1) [67]

Baseline values represent those at the start of the qualifying study

Only evaluable pts at a visit of interest were included in the analysis and missing values were not imputed

[a]Efficacy data is reported to Month 15 as sample sizes were too small beyond this time point; [b]Among patients with baseline BSA ≥3% and PASI >0; [c]Among patients with baseline score >0; [d]Patient's assessment of arthritis pain measured using VAS (mm)

Δ, change from baseline; ACR, American College of Rheumatology; ACR20/50/70, ACR20%/50%/70% response rate; BSA body surface area; DSS, Dactylitis Severity Score; HAQ-DI, Health Assessment Questionnaire Disability Index; LEI, Leeds Enthesitis Index; N, number of patients in full analysis set; N1, number of evaluable patients at a visit; n, number of responders; PASI75, Psoriasis Area Severity Index 75% improvement; PsA, psoriatic arthritis; SD, standard deviation; VAS, visual analogue scale

Conclusions: Over 24 months in the LTE, the safety profile of tofacitinib in pts with active PsA was generally similar to that of the pivotal Phase 3 studies. No new safety signals were identified. Efficacy was maintained over time.

FRI0510 CORRELATION OF THE ROUTINE ASSESSMENT OF PATIENT INDEX DATA (RAPID-3) WITH OTHER PSORIATIC ARTHRITIS COMPOSITE DISEASE ACTIVITY MEASURES IN PATIENTS RECEIVING ADALIMUMAB

P.J. Mease[1], S. Chen[2], F. Ganz[3], W. Tillett[4]. *[1]Swedish Medical Center and University of Washington, Seattle; [2]AbbVie, Inc., North Chicago, United States; [3]AbbVie, Inc., Baar, Switzerland; [4]Royal United Hospitals Bath NHS Foundation Trust, Bath, United Kingdom*

Background: There is increased interest across rheumatologic disease to utilize patient (pt)-reported outcomes (PROs) in disease assessment. Several measures entirely derived from PROs, such as the 3-component routine assessment of pt index data (RAPID-3), have been shown to be closely correlated with physician rheumatoid arthritis assessments using traditional composite scores.[1]

Objectives: To assess the correlation between the RAPID-3 and other psoriatic arthritis (PsA) composite indices [eg, disease activity index for PsA (DAPSA), minimal disease activity (MDA)] in pts with PsA receiving adalimumab (ADA) or placebo (PBO).

Methods: This post hoc analysis used data from the ADEPT trial, which included pts with active PsA despite prior DMARD therapy who were randomized to receive ADA or PBO for 24 weeks (wks). Mean RAPID-3 was summarized by visit for each treatment group. Correlations between RAPID-3 and DAPSA over time were assessed through Pearson and Spearman coefficient. Pts were categorized at wk 24 according to DAPSA [Remission: ≤4; low disease activity (LowDA): >4 – ≤14; moderate disease activity (ModDA): >14 – ≤28; high disease activity (HighDA): >28) and MDA [achievement of 5 of 7 or the more stringent 7 of 7 criteria (very low disease activity [VLDA]): yes, no], and assessed for the numbers of pts in each respective RAPID-3 disease activity state (Remission: ≤3; LowDA: >3 – ≤6; ModDA: >6 – ≤12; HighDA: >12). The Kappa statistic was used to describe the agreement between the numbers of pts in respective disease activity categories by RAPID-3, DAPSA, and MDA. Data were as observed.

Results: Amongst the 151 and 162 pts randomized to receive ADA and PBO, respectively, both groups exhibited HighDA when assessed by RAPID-3 [13.1 for both groups; 55% (ADA) and 54% (PBO) in HighDA]. At wk 24, mean RAPID-3 remained in HighDA for the PBO group (12.6), whereas it decreased to a state of LowDA (6.8) in those receiving ADA. Following 24 wks of treatment, 39% and 24% in the ADA group were in remission by RAPID-3 and DAPSA, respectively. Fewer pts in the PBO group were in remission by either definition at wk 24 (8% and 3%, respectively). At baseline, there was moderate correlation between RAPID-3 and DAPSA in both treatment groups (ADA: 0.512; PBO: 0.510). At wk 24, the correlations in both treatment groups increased, with the correlation observed in the ADA group outpacing the PBO group (ADA: 0.721; PBO: 0.590). Similarly, disease activity categorizations by RAPID-3 correlated with DAPSA and MDA categorizations (Table).

Conclusions: In a PBO-controlled trial of ADA in pts with PsA, there was good correlation between disease activity captured by pt's self-assessment, via the RAPID-3, and physician assessment, underscoring the potential utility of pt-derived measures in assessing disease activity.

FRI0511 SECUKINUMAB DEMONSTRATES CONSISTENT SAFETY OVER LONG-TERM EXPOSURE IN PATIENTS WITH PSORIATIC ARTHRITIS AND MODERATE-TO-SEVERE PLAQUE PSORIASIS: UPDATED POOLED SAFETY ANALYSES

P.J. Mease[1], I.B. McInnes[2], K. Reich[3], P. Nash[4], M. Andersson[5], K. Abrams[6], L. Pricorp[6], T. Fox[5]. *[1]Swedish Medical Center and University of Washington, Seattle, United States; [2]University of Glasgow, Glasgow, United Kingdom; [3]Dermatologikum Hamburg and Georg-August-University Göttingen, Hamburg, Germany; [4]University of Queensland, St Lucia, Australia; [5]Novartis Pharma AG, Basel, Switzerland; [6]Novartis Pharmaceuticals Corp., East Hanover, United States*

Background: Pooled safety data from secukinumab psoriasis (PsO) and psoriatic arthritis (PsA) clinical trial programs after ~1 year of exposure have been reported.[1,2]

Objectives: To report updated longer-term secukinumab exposure safety data from PsO and PsA studies (data cut-off: 25 June 2016).

Methods: The PsO data pool consisted of 9 Phase III studies in moderate-to-severe plaque PsO and PsA pool consisted of 3 Phase III studies in active PsA. Secukinumab doses differed in the studies and included intravenous (up to 10 mg/kg) or subcutaneous (s.c.; 75–300 mg) loading, followed by s.c. maintenance dosing (300, 150 or 75 mg). Placebo patients were re-randomised to secukinumab at 12–24 weeks depending on study design. Only data for approved secukinumab 300 and 150mg doses were included in analysis. Exposure adjusted incident rates (EAIR) were used to adjust for differences in exposure.

Results: In both PsO and PsA, the most frequently reported adverse events (AEs) with secukinumab were non-serious infections of the upper respiratory tract, headache and arthralgia (Table). The EAIRs of AEs of special interest with secukinumab including Crohn's disease, *Candida* infections, serious infections, inflammatory bowel disease, major adverse cardiac events and neutropenia (reported in the Table) were similar in both PSO and PsA indications, and comparable to those reported previously.[1,2] No cases of tuberculosis (new onset or reactivation) were reported.

Table 1. Summary of pooled safety of secukinumab in PSO and PsA

	PSO Any secukinumab N=3893	PsA Any secukinumab N=1128
Total exposure, patient-years)	7769.0	1907.0
Min–max exposure (days)	1–1526	16–1464
Death, n (%)	7 (0.2)	4 (0.4)
AE's by EAIR: AE per 100 Pt-years (95% CI)		
Any AE	196.9 (190.3, 203.6)	173.7 (162.5, 185.5)
Any serious AE	7.2 (6.6, 7.8)	8.5 (7.2, 10.0)
Frequent AEs[1]		
Nasopharyngitis	18.2 (17.1, 19.3)	13.7 (12.0, 15.7)
Headache	6.3 (5.7, 6.9)	4.8 (3.9, 5.9)
Upper respiratory tract infections	6.2 (5.6, 6.8)	11.2 (9.6, 12.9)
Arthralgia	5.1 (4.6, 5.6)	4.3 (3.4, 5.3)
AEs of special interest		
Candida infections	2.1 (1.8, 2.4)	2.3 (1.6, 3.1)
Serious infections	1.4 (1.2, 1.7)	1.8 (1.3, 2.5)
Inflammatory Bowel Disease	0.3 (0.2, 0.4)	0.5 (0.2, 0.9)
Crohn's disease	0.1 (0.0, 0.1)	0
Ulcerative colitis	0.2 (0.1, 0.3)	0.1 (0.0, 0.4)
MACE	0.3 (0.2, 0.5)	0.3 (0.1, 0.6)
Neutropenia	0.4 (0.3, 0.5)	0.7 (0.4, 1.2)

[1] Adverse events in the secukinumab group that occurred with an IR >5.0 during the entire safety period in either of the spooled groups; AE, adverse event; EAIR, exposure adjusted incidence rate per 100 patient-years; MACE, major adverse cardiac event; N, number of patients in the analysis.

Conclusions: The safety profile of secukinumab was similar for PsO and PsA patients supporting its long-term use in these chronic conditions. Secukinumab long-term exposure safety data is consistent with that previously reported with shorter-term exposure, including being well tolerated, and without any new safety signals identified.

FRI0512 APREMILAST, AN ORAL PHOSPHODIESTERASE 4 INHIBITOR, IS ASSOCIATED WITH LONG-TERM (156-WEEK) IMPROVEMENTS IN BASDAI IN PSORIATIC ARTHRITIS PATIENTS: POOLED RESULTS FROM 3 PHASE III, RANDOMIZED, CONTROLLED TRIALS

P.J. Mease[1], H. Marzo-Ortega[2], A. Poder[3], F. Van den Bosch[4], J. Wollenhaupt[5], E. Lespessailles[6], M. McIlraith[7], L. Teng[7], S. Hall[8]. *[1]Swedish Medical Center and University of Washington School of Medicine, Seattle, United States; [2]NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals and University of Leeds, Leeds, United Kingdom; [3]Clinical Research Centre Ltd, Tartu, Estonia; [4]UZ Gent, Gent, Belgium; [5]Schön Klinik Hamburg Eilbek, Hamburg, Germany; [6]University of Orléans, Orléans, France; [7]Celgene Corporation, Summit, United States; [8]Monash University, CabriniHealth, Melbourne, Australia*

Background: In PALACE psoriatic arthritis (PsA) studies, the Bath Ankylosing Spondylitis Disease Activity Index score (BASDAI) was used as an exploratory measure in a subset of patients (pts) considered by investigators to have axial involvement, although PsA spondylitis was not confirmed by imaging.

Objectives: Report the impact of apremilast 30 mg BID (APR) treatment on BASDAI over 156 wks using pooled PALACE 1–3 data of pts with active PsA despite prior conventional DMARDs and/or biologics.

Methods: APR treatment outcomes were evaluated in a subset of pts with baseline (BL) BASDAI ≥4 ("subset") over 156 wks.
Results: BL BASDAI ≥4 was reported for 454/1493 (30%) pts. Mean PsA duration was similar between the subset and rest of the PALACE 1–3 population (n=1039); mean BL psoriasis body surface area (BSA) and percentage of pts with BSA ≥3% were slightly higher. The subset had higher mean BL values vs the rest of PALACE 1–3 pts for C-reactive protein (1.12 vs 0.93), pain VAS (63.6 vs 53.8 mm), pt's global assessment of disease activity (62.2 vs 53.5 mm), and physician's global assessment of disease activity (PhGA; 59.0 vs 53.0 mm) and markedly worse mean HAQ-DI (1.41 vs 1.08), SF-36v2 Physical Functioning (30.6 vs 35.8), and FACIT-F (25.7 vs 31.8) scores. Despite disease activity differences, BL concomitant oral DMARDs were similar in both groups: 1 DMARD in 61.0% (subset) vs 57.8% (rest of PALACE 1–3 pts); methotrexate was the most common DMARD. In the subset, 73.6% had been treated with only oral DMARDs prestudy (44.9% with only 1); 25.1% had prior biologic use. Mean BL BASDAI in the subset was 6.6 with APR and 6.4 with placebo (PBO). Mean BL BASDAI question 2 score, referring directly to spinal and hip pain, was 6.7. APR resulted in greater mean improvement in BASDAI vs PBO at Wk 16 (–1.53 vs –0.91; *P*=0.0173) and Wk 24 (Table). As early as Wk 16, a 19% mean decrease in the question 2 score was seen with APR vs an increase with PBO. Other disease measures significantly improved early in treatment, including HAQ-DI, fatigue, PhGA, and mPsARC (Table). Long-term improvement was seen across measures, with mean BASDAI reductions of 2.18 at Wk 52 and 2.19 at Wk 156 (Table) and question 2 reductions of 1.94 and 2.28, respectively; treatment resulted in a shift toward lower BASDAI across the subset, with a significant proportion reaching BASDAI <4.

Outcomes at Wk 24, Wk 52, and Wk 156 in Pts With BASDAI ≥4 at BL

	Wk 24		Wk 52	Wk 156
	APR n=156	PBO n=151	APR n=125	APR n=127
BASDAI, mean BL	6.6	6.4	6.6	6.6
BASDAI, mean change from BL	−1.64*	−0.74	−2.18	−2.19
Swollen joint count, mean change	−5.5*	−2.4	−8.5	−10.6
HAQ-DI, mean change	−0.301*	−0.117	−0.464	−0.448
SF-36v2 PF, mean change	4.98*	1.76	7.06	8.21
Pain VAS, mean change, mm	−12.6*	−7.9	−22.1	−21.9
FACIT-F, mean change	4.38*	1.29	6.77	6.31
Pt's global assessment of disease activity, mean change (VAS mm)	−10.9	−5.7	−19.8	−21.2
PhGA, mean change (VAS mm)	−22.1§	−7.4	−34.3	−40.2
Proportion meeting mPsARC, %	46.2§	23.8	77.9	84.1

The n may vary slightly for the end points at each time point. For Wk 24, the n represents the number of pts randomized at BL in the subset; last-observation-carried-forward methodology and non-responder imputation rule were applied to pts who early escaped at Wk 16 or had missing value at Wk 24 for continuous data and binary response, respectively. For Wk 52, the n represents the number of pts randomized to APR at BL in the subset, with an outcome measure at Wk 52. For Wk 156, the n represents the number of pts who were randomized to APR (at BL, Wk 16, or Wk 24), with an outcome measure at Wk 156.
*P<0.05; §P<0.0001 vs PBO, based on an analysis of covariance model for the change from BL, with treatment group, BL DMARD use (yes/no), and study as factors and BL value as the covariate, and the Cochran-Mantel-Haenszel test for binary response, adjusting for BL DMARD use and study. Pt's global assessment of disease activity APR 30 mg BID vs PBO at Wk 24: P=0.0590.
BASDAI=Bath Ankylosing Spondylitis Disease Activity Index score; APR=apremilast 30 mg BID; PBO=placebo; BL=baseline; HAQ-DI=Health Assessment Questionnaire-Disability Index score; SF-36v2 PF=36-item Short-Form Health Survey version 2 Physical Functioning domain score; VAS=visual analog scale; FACIT-F=Functional Assessment of Chronic Illness Therapy-Fatigue score; PhGA=physician's global assessment of disease activity; mPsARC=modified Psoriatic Arthritis Response Criteria; DMARD=disease-modifying anti-rheumatic drug.

Conclusions: In this post hoc analysis of pooled data, pts reporting BASDAI ≥4 at BL appear to experience greater disease burden, including disability, pain, and fatigue; effective treatment strategies may not have been available. APR treatment resulted in long-term improvements in BASDAI and other measures in pts with clinically suspected axial disease.

FRI0513 LONG-TERM (156 WEEKS) IMPROVEMENTS IN PHYSICAL FUNCTION OF DMARD-NAÏVE AND DMARD/BIOLOGIC-EXPERIENCED PSORIATIC ARTHRITIS PATIENTS TREATED WITH APREMILAST: DATA FROM A LARGE DATABASE OF 4 PHASE III CLINICAL TRIALS

P.J. Mease[1], A. Wells[2], J. Wollenhaupt[3], S. Hall[4], F. Van den Bosch[5], E. Lespessailles[6], M. McIlraith[7], D. Nguyen[7], L. Teng[7], C.J. Edwards[8].
[1]Swedish Medical Center and University of Washington School of Medicine, Seattle; [2]Rheumatology and Immunotherapy Center, Franklin, United States; [3]Schön Klinik Hamburg Eilbek, Hamburg, Germany; [4]Monash University, CabriniHealth, Melbourne, Australia; [5]UZ Gent, Gent, Belgium; [6]University of Orléans, Orléans, France; [7]Celgene Corporation, Summit, United States; [8]University Hospital Southampton, Southampton, United Kingdom

Background: Improving and preserving patient (pt) physical function is an important goal for psoriatic arthritis (PsA).
Objectives: To evaluate apremilast's (APR) effects on physical function/functional status for up to 3 yrs in DMARD/biologic-experienced (PALACE 1–3 [PAL1–3] pooled data) and DMARD-naive (PALACE 4 [PAL4]) pts with active PsA.
Methods: Pts were randomized (1:1:1) to placebo (PBO), APR 30 mg BID (APR30), or 20 mg BID (APR20) at baseline (BL). The primary endpoint was at Wk16; a long-term extension is ongoing. A detailed study design has been previously presented. Assessed were mean change from BL HAQ-DI scores and proportions of pts reaching HAQ-DI MCID and reaching scores ≤1.0 (below clinically significant disability), ≤0.5 (minimal disability), and ≤0.25 (general population). Wk16 data were analyzed by LOCF. Wk156 data are as observed. Mean change and MCID outcomes are for all pts receiving APR30 at any time during the study; disability level data are for pts randomized to APR30 at BL.
Results: PAL1–3 (biologic/DMARD-experienced) and PAL4 (DMARD-naïve) pts had similar BL SJC/TJC and DAS-28 (CRP), indicating active PsA. PAL1–3 pts had longer mean duration of PsA and psoriasis, higher PASI scores, and greater corticosteroid use at BL. Despite differences, BL physical disability was clinically significant in both populations (mean HAQ-DI, PAL1–3: 1.2; PAL4: 1.1). Marked disability at BL was seen in some pts randomized to APR30, with HAQ-DI scores up to 2.63–2.88. More PAL1–3 vs PAL4 APR30 pts had BL HAQ-DI >1.0 (60% vs 54%), >1.5 (marked difficulty/need for assistive devices, 31%vs 21%), and >1.75 (major disability, 19% vs 10%), highlighting need for early, effective treatment (tx). Few APR30 pts had BL scores ≤0.5 (18–22%) or ≤0.25 (10–14%). At Wk16, physical function significantly improved with APR30 vs PBO (mean HAQ-DI change, PAL1–3: –0.23 vs –0.08; PAL4: –0.21 vs 0.03; both P<0.0001) and more APR30 vs PBO pts reached HAQ-DI MCID ≥0.30 and ≥0.35. As early as Wk16, overall disability levels also shifted; more APR30 vs PBO pts achieved HAQ-DI ≤1.0 (PAL1–3: 56% vs 48%; PAL4: 60% vs 52%). At Wk156, marked achievement of HAQ-DI ≤1.0, ≤0.5, and ≤0.25 was observed in both populations (Table). LOCF analyses confirmed Wk156 results.

Pts Achieving Improvement in Physical Function by HAQ-DI Level at Wk156*

	PAL1-3	PAL4
Pts Achieving HAQ-DI Disability Threshold, %	**APR30 n=279§**	**APR30 n=94§**
≤1.0[1]	62	65
≤0.5[2]	38	45
≤0.25	28	42
Pts Achieving HAQ-DI MCID Levels, %	**APR30 n=413‡**	**APR30 n=143‡**
≥0.30[3]‖	48	48
≥0.35[4]¶	48	48

HAQ-DI ≤1.0=disability not clinically significant; HAQ-DI ≤0.5=disability remission. HAQ-DI=Health Assessment Questionnaire-Disability Index; MCID=minimal clinically important difference.
*Wk156 data are based on data as observed. §Analysis in pts randomized to APR30 from BL. ‡Analysis in pts randomized to APR30 at any time (BL, Wk16, or Wk24). †Accepted threshold for HAQ-DI MCID in PsA at time of initiation of studies.[3] ¶Currently accepted threshold based on updated research.[4]
1. Sokka T, et al. *Arthritis Rheum.* 2003;48:59-63. 2. Coates LC, et al. *Ann Rheum Dis.* 2010;69:48-53. 3. Mease PJ, et al. *Ann Rheum Dis.* 2004;63(Suppl 1):391. 4. Mease PJ, et al. *J Rheumatol.* 2011;38:2461-2465.

Conclusions: With APR30 tx, physical disability improved early; functionality was maintained for up to 3 yrs. Most pts achieved HAQ-DI ≤1.0; many attained minimal/mild physical impairment. Over 40% of pts receiving APR30 earlier in the tx paradigm had functional ability similar to population norms after 3 yrs; shorter disease duration and no prior DMARD/biologics use in this population suggests that earlier APR tx may increase the likelihood of maximal functionality for some pts.

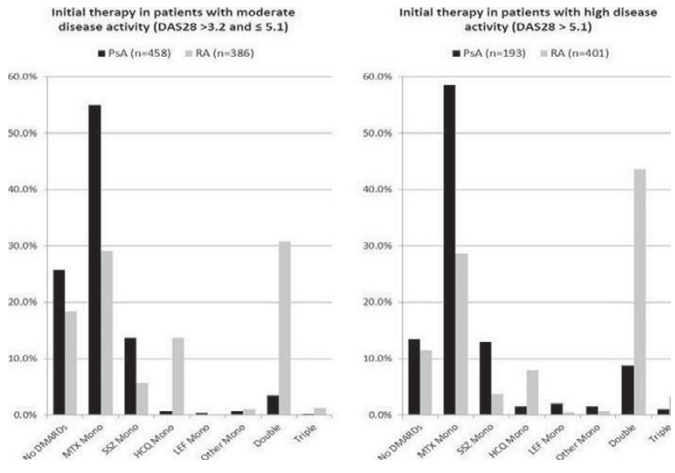
FRI0514 PSORIATIC ARTHRITIS IS ASSOCIATED WITH DIAGNOSTIC DELAY AND WORSE OUTCOME AT THREE MONTHS WHEN COMPARED TO RHEUMATOID ARTHRITIS: RESULTS FROM THE UK NATIONAL AUDIT FOR INFLAMMATORY ARTHRITIS



R. Holland[1], A. Davis[2], A. Green[2], A. Nightingale[2], R. Charlton[2], E. Cullen[3], N. McHugh[1]. *[1]Royal National Hospital for Rheumatic Diseases; [2]University of Bath, Bath; [3]Celgene Ltd, London, United Kingdom*

Background: Psoriatic arthritis (PsA) is underdiagnosed in primary care, and can be difficult to distinguish from osteoarthritis. Accumulating evidence suggests that diagnostic delay is associated with poorer functional outcome despite treatment.
Objectives: To develop a better understanding of the diagnostic delay and burden of disease in patients with PsA, and to investigate management within the first three months of diagnosis.
Methods: Data were analysed on all participants with a final diagnosis of PsA from The National Clinical Audit for Rheumatoid and Early Inflammatory Arthritis, undertaken by the British Society for Rheumatology and commissioned by the Healthcare Quality Improvement Programme, recruited between 1/2/2014 and 30/10/2015. Data were collected from patients and clinicians at baseline and three months. 1016 participants with PsA (mean age 49.4±14.5 years; 54% female) were matched 1:1 by age and sex with participants with Rheumatoid Arthritis (RA).
Results: Patients with PsA had a significantly longer delay to presentation and diagnosis than those with RA ($p<0.02$, Table 1), and this remained significant when adjusted for age, sex, ethnicity and social status.
PsA patients had lower median tender (4.0 vs 7.0) and swollen (3.0 vs 5.0) joint counts and lower mean baseline ESR (21.9 vs 27.8 mm/hr) and CRP (16.2 vs 24.2 mg/L) values than patients with RA ($p<0.01$ for all comparisons), and this remained significant when adjusted for potential confounders. Mean baseline scores for the Inflammatory Arthritis Impact of Disease (IAID) questionnaire were lower in patients with PsA (5.34±2.25 vs 5.94±2.35 in RA, lower scores indicating less impact), although this was not statistically significant when adjusted for demographics and disease activity (p=0.36). There was no significant difference between physical function at baseline between the groups (median HAQ 0.88 PsA vs 1.13 RA, p=0.70).
At follow-up, patients with PsA had significantly higher mean IAID scores (4.32±2.60 vs 3.78±2.56, $P<0.05$). In those with paired results, the mean improvement in IAID score was 1.32 (95% CI 0.99–1.65) in PsA vs 2.37 (95% CI 2.07–2.67) in RA. In patients with high disease activity at baseline (DAS28 >5.1) a good EULAR response was seen in only 21.4% in PsA vs 30.3% in RA. There was a marked difference in the DMARDs initially prescribed, and the differences remained significant when only those with a DAS28 score indicating moderate or high disease activity at presentation were analysed, as shown in Figure 1.
Conclusions: This study demonstrates that patients with PsA have a longer delay to diagnosis between both symptom onset and presentation to primary care, and referral to secondary care and diagnosis than those with RA. Despite similar disease impact and physical function at diagnosis, patients with PsA are less likely to receive combination DMARD treatment, and have increased disease burden at three months.

Table 1. Median delay in weeks

	PsA		RA	
	Unadjusted	Adjusted*	Unadjusted	Adjusted*
Symptoms to GP Presentation	8.9	8.9	7.1	6.6
GP Presentation to Referral	5.3	5.4	4.3	4
GP Presentation to Diagnosis	12.4	12.1	9.9	9.7
Symptoms to Diagnosis	29.0	28.6	21.4	21.6

*Adjusted for age, sex, ethnicity and deprivation Index; $p<0.02$ for all between group comparisons.

FRI0515 CLASSIC CARDIOVASCULAR RISK FACTORS AND MINIMAL DISEASE ACTIVITY IN PSORIATIC ARTHRITIS: RESULTS OF A SPANISH MULTICENTER STUDY

R. Queiro[1], J.D. Cañete[2], C. Montilla[3], M.A. Abad[3], M. Montoro[3], S. Gómez[3], A. Cábez[3], J.C. Torre Alonso[3], J.A. Román Ivorra[3], J. Sanz[3], J. Salvatierra[3], J. Calvo Alén[3], A. Sellas[3], F.J. Rodriguez[3], A. Bermúdez[3], M. Romero[3], M. Riesco[3], J.C. Cobeta[3], F. Medina[3], A. Aragón[3], M.L. García[3], A. Urruticoechea[3]. *[1]Rheumatology, Hospital Universitario Central de Asturias, Oviedo; [2]Rheumatology, HU, Clinic and IDIBAPS, Barcelona, Spain; [3]Affiliation not provided*

Background: Some cardiovascular risk factors (CVRF) have been related to poorer responses to biological therapy[1]. We aimed to evaluate the potential link between the MDA response and the presence of CVRF in patients treated with traditional and/or biological DMARDs.
Objectives: The objective has been to evaluate the potential association between classic CVRF and the probability of reaching an MDA response in PsA patients.
Methods: Cross-sectional study carried out at 25 rheumatology outpatient clinics in patients who fulfilled the Classification for Psoriatic Arthritis (CASPAR) criteria with at least one year disease duration, and treated with biological or conventional synthetic (cs) DMARDs according to routine clinical practice in Spain. Patients were considered in MDA if they met at least 5/7 of the MDA criteria[2]. The relationship between MDA and CVRF was evaluated by uni and multivariate analyses.
Results: 227 patients were included, 133 (58.6%) were in MDA state (52% on anti-TNFα monotherapy, 24% on csDMARD monotherapy, 24% on anti-TNFα in combination with csDMARD). Among the classic CVRF, tobacco (crude OR: 0.54), sedentary lifestyle (crude OR: 1.95), hyperuricemia (crude OR: 2.01) and obesity (crude OR: 1.54) were related to the likelihood of MDA in the univariate model ($p<0.25$). The only CVRF related to the MDA response in the multivariate analysis was a sedentary lifestyle (OR 3.13, 95% CI: 1.50–6.53; p=0.002). We did not find any association between the number of CVRF and the MDA response.
Conclusions: Contrary to what has been found in other studies, in this cross-sectional multicenter study we could not find any relationship between traditional CVRF (except for sedentary lifestyle) and MDA. In any case, patients with psoriatic disease should be encouraged to maintain healthy lifestyle habits.

FRI0516 ASSESSMENT OF DISEASE REMISSION BY POWER DOPPLER ULTRASONOGRAPHY IN PATIENTS WITH PSORIATIC ARTHRITIS

S. Monov[1], R. Shumnalieva[1], D. Monova[2], A. Kopchev[1]. *[1]Department of Internal Medicine, Clinic of rheumatology, Medical University - Sofia; [2]Medical Institute-MVR, Medical University-Sofia, Sofia, Bulgaria*

Background: Treatment strategies nowadays are targeting clinical remission or low disease activity. In some patients with psoriatic arthritis (PsA) clinical findings defer from the ultrasonographic evidence of inflammation which raise the need for revising the remission criteria in the clinical practice.
Objectives: The aim of our study was to estimate the presence of subclinical synovitis by power Doppler ultrasonography (PDUS) in PsA patients, who were considered as being in clinical remission defined by DAS28-ESR (Disease activity score of 28 joints – erythrocyte sedimentation rate) for at least 6 months during the treatment course.
Methods: 64 PsA patients in clinical remission based on DAS28 – ESR <2.6 were included in the study. The patients were examined by two independent rheumatologists. The affected joints were assessed by PDUS (MyLab 60, Esaote) for the presence of synovial hypertrophy (SH) and synovitis scored from 0 to 3 based on the presence and intensity of PD signal. Disease activity was determined by the presence of SH ≥2 degree and a positive PD signal.
Results: We found a persistent synovitis in 23 (35.9%) of the PsA with clinical remission of the peripheral joint involvement. Active synovitis was also found in 7

(10.9%) of the patients with DAS28 <2.6 which were on systemic corticosteroid (CS) treatment regimen.
Conclusions: The presence of active synovitis on PDUS in a significant part of the studied PsA patients (35.9%) which were considered as being in clinical remission for at least 6 months showed that these kind of patients need to be closely followed-up and adequately treated. The systemic CS treatment does not exclude the presence of disease activity in PsA. Further studies for assessment of the synovitis will establish correct criteria for defining and monitoring the disease activity in PsA.

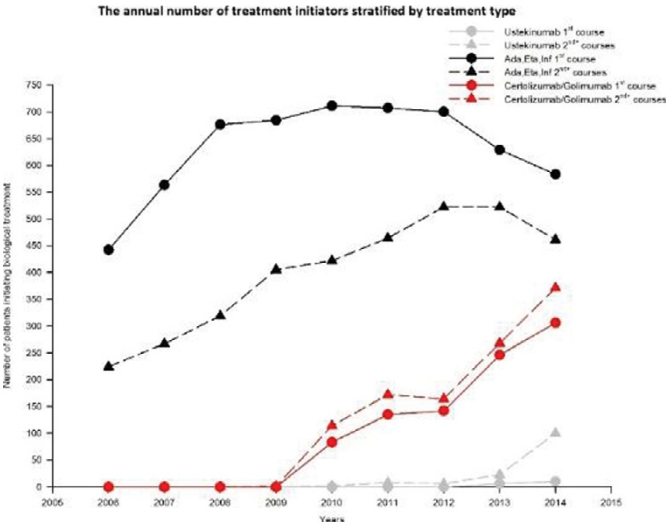
FRI0517 QUALITY OF LIFE IN PATIENTS WITH EARLY PSORIATIC ARTHRITIS



S. Monov, A. Kopchev. *Clinic of Rheumatology, Department of Internal Medicine, Medical University, Sofia, Sofia, Bulgaria*

Background: Psoriatic arthritis (PsA) is a chronic systemic inflammatory disease. Affecting skin, joints, entheses and dactylitis, its impact on health-related quality-of-life (HRQoL) could be substantial.
Objectives: The aim of this study was to describe HRQoL in newly diagnosed PsA patients taking into account skin involvement, swollen joints, tender enthuses and dactylitis.
Methods: HRQoL was assessed by 8 subscales of the Short-Form 36 (SF-36) questionnaire (0–100, higher score represents a better HRQoL). Patients were classified in arthritis subtypes (i.e. mono-, oligo- or polyarthritis) by rheumatologist. Entheses were evaluated using the Leeds Enthesitis Index (LEI) and Maastricht Ankylosing Spondylitis Enthesitis Score (MASES; positive if tender entheses >1). Psoriasis was evaluated using the Psoriasis Area Severity Index (PASI; mild: 0–7; moderate/severe: >7) and dactylitis using the Leeds Dactylitis Index (LDI).
Results: 87 patients (48 male, 39 female, mean age 47,6±15,3) with PsA (21 had monoarthritis, 49 - oligoarthrit and 17 - polyarthritis) completed the SF-36 were included in the study. Psoriasis was mild in 63 (72,41%) patients and moderate/severe in 12 (13,79%) patiients. At least one digit with dactylitis was present in 10 (11,49%) of the patients. A tender enthesis was present in 39 (44,83%) of patients. Mean scores of the subdomains in the SF-36 were similar across the different arthritis groups, with slightly worse scores for polyarthritis compared to mono- and oligoarthritis. However, when stratifying these groups for the presence of a tender enthesis, HRQoL decreased substantially for all groups across all subdomains of the SF-36, with a median difference of 12,9 points. Irrespective of joint involvement, a tender enthesis decreased the mean scores of all subdomains significantly compared to the non-tender enthesis group ($p<0,05$). Severity of psoriasis and presence of dactylitis did not lead to significantly different SF-36 values compared to those not affected.
Conclusions: Having tender entheses impacts HRQoL severly in both its physical and mental dimensions in incident untreated PsA.

FRI0518 PRESCRIPTION PATTERNS OF TUMOUR NECROSIS FACTOR INHIBITOR AND USTEKINUMAB IN PSORIATIC ARTHRITIS: A NORDIC POPULATION-BASED COHORT STUDY

T.S. Jørgensen[1], L. Dreyer[1], B. Guðbjörnsson[2], M.L. Hetland[1], B. Glintborg[1], J. Askling[3], K. Chatzidionysiou[3], D. Di Giuseppe[3], L. Jacobsson[3], J.K. Wallman[3], E.K. Kristianslund[4], I.C. Olsen[4], K. Fagerli[4], E. Lie[4], D. Nordström[5], K. Aaltonen[5], J. Joensuu[5], T.J. Love[2], A.J. Geirsson[2], L.E. Kristensen[1]. *[1]On behalf of the DANBIO registry, Copenhagen, Denmark; [2]On behalf of the ICEBIO registry, Reykjavik, Iceland; [3]On behalf of the SRQ registry, Stockholm, Sweden; [4]On behalf of the NOR-DMARD registry, Oslo, Norway; [5]On behalf of the ROB-FIN registry, Helsinki, Finland*

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disorder associated with skin and joint manifestations, several extra-articular symptoms, various comorbidities, and disability. The emergence of tumour necrosis factor inhibitor (TNFi) therapy has dramatically changed the course of disease. Over the past decade new TNFi therapies have emerged (certolizumab pegol and golimumab), and recently ustekinumab and secukinumab have also become available for PsA.
Objectives: The objective of this study was to assess the relative use of biological agents (bDMARDs) in PsA from 2006 through 2014, using data from the Nordic Rheumatology registers.
Methods: Based on data from the observational registers DANBIO, ICEBIO, NOR-DMARD, ROB-FIN, and SRQ registers, PsA patients initiating treatment with bDMARDs as a first or subsequent biological therapy were identified. Adalimumab, etanercept and infliximab were grouped as “first generation TNFi therapies”; certolizumab pegol and golimumab were grouped as “second generation TNFi”. Treatments with ustekinumab during the study period were also identified. Descriptive statistics for prescription patterns of bDMARD therapy were calculated.
Results: A total of 11,458 treatment initiations were identified (DANBIO 3,068, ICEBIO 357, NOR-DMARD 1,113, ROB-FIN 708, SRQ 6,212). 54% of the patients were female. Overall, 5,695 patients initiated a first generation TNFi, 912 a second generation TNFi, and 16 ustekinumab, as their first course of biological treatment. The corresponding numbers for those initiating a second (or more) biological treatment were 3,606, 1,090 and 139 patients, respectively. The figure displays the annual number of treatment initiations stratified by treatment type. The total yearly number of first course biological treatment increased significantly throughout the period ($p<0.001$), and this was also the case for patients switching therapy ($p<0.001$), indicating a previously unmet need for biological therapies in the Nordic population. The annual number of patients initiating first generation TNFi both as first and subsequent course of therapy decreased significantly towards the end of the study period ($p<0.001$). This drop was more than offset by a rapid increase in initiation of second generation TNFi treatments ($p<0.001$). Ustekinumab was primarily used as second or subsequent course of therapy in PsA. The same pattern was seen when stratified for country (data not shown).

Conclusions: Across the Nordic countries the prescription pattern for biological therapies for PsA has changed significantly over time. After 2012 initiation of the first generation TNFi is decreasing both as first and second course therapy, whereas second generation TNFi are increasing both as first and second course of biologic intervention. Collaboration across registers will allow for robust assessment of the uptake of newer biological therapies.

FRI0519 EFFECT OF BIOLOGICS ON FATIGUE IN PSORIATIC ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW WITH META-ANALYSIS

T. Reygaerts[1,2], S. Mitrovic[1], B. Fautrel[1], L. Gossec[1]. *[1]Service de Rhumatologie, Pitie-Salpétrière Hospital, Paris, France; [2]Service de Rhumatologie et de Médecine Physique, Erasme Hospital, Bruxelles, Belgium*

Background: Fatigue is an important aspect of disease both in rheumatoid arthritis (RA) and in psoriatic arthritis (PsA) and is of high priority for patients. In RA, a recent Cochrane meta-analysis found a small effect of biologics on fatigue (standardized mean difference, SMD, 0.43; 95% confidence interval, CI: 0.38–0.49).(1) Little is known about this effect in PsA.
Objectives: To assess the effect of biologics on fatigue in PsA randomised controlled trials (RCTs) and to compare this effect with the effect in the same trials, on pain, through a systematic literature review (SLR) and meta-analysis (MA).
Methods: SLR up to January 2017 in PubMed, Embase and Cochrane trials database and in recent congress abstracts, using key words related to PsA and biologics. All RCTs in PsA of any biologic therapy, assessing fatigue (whatever the

score used), with data available for fatigue were included. Data were collected by 2 regarding levels of fatigue (6 trials used FACIT, 1 VAS) and pain (if available) at baseline and at the timepoint closest to 24 weeks after the biologic introduction. A MA was performed using RevMan and SMDs were calculated for each trial and each study dose, for fatigue and for pain. A SMD <0.5 is usually considered small, between 0.5 and 0.8 moderate and >0.8 as important.

Results: After screening 295 publications, 7 RCTs were included in the meta-analysis and assessed TNF blockers (N=3: adalimumab N=2, certolizumab pegol, N=1), secukinumab (N=2), apremilast (N=1) and ustekinumab (N=1) with or without methotrexate, compared to placebo. The studies included 2340 PsA patients: weighted mean age ± standard deviation (SD), 48.7±1.3 years, disease duration 7.7±1.3 years, 53.3% were females. At baseline, joint disease activity was high (weighted mean swollen joint count: 13.0±3.1, HAQ-DI: 1.2±0.1, PASI: 10.4±3.3). Fatigue levels were high at baseline (weighted mean FACIT score: 29.2±1.5). The pooled SMD for fatigue was 0.44 (95% CI -0.35, 0.54) and it ranged 0.04 to 0.71 across drugs and trials with a small to moderate effect (Graph). In 6 of the same studies, the pooled SMD for pain was 0.62 (95% CI 0.52, 0.73) and ranged 0.46 to 0.84.

Conclusions: Biologics had a mild to moderate effect on fatigue at 24 weeks in PsA RCTs. No notable differences across drugs were apparent. Effect sizes were higher on pain with a moderate effect. This effect seems similar to effects noted in RA in the Cochrane meta-analysis (1).These results confirm fatigue may be multifactorial in PsA; biologics bring some improvement at the group level but other treatment modalities should be further explored also.

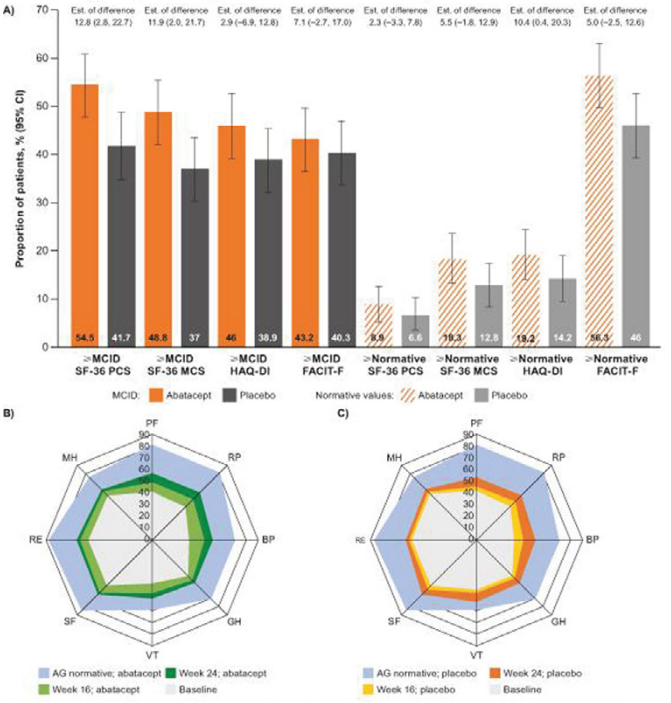
FRI0520 IMPROVED PATIENT-REPORTED OUTCOMES IN PSORIATIC ARTHRITIS PATIENTS TREATED WITH ABATACEPT: RESULTS FROM A PHASE III TRIAL

V. Strand[1], E. Alemao[2], T. Lehman[2], A. Johnsen[2], S. Banerjee[2], H. Ahmad[2], P. Mease[3]. *[1]Stanford University, Stanford; [2]Bristol-Myers Squibb, Princeton; [3]Swedish Medical Center and University of Washington, Seattle, United States*

Background: In the Phase III ASTRAEA study (NCT01860976), abatacept (ABA) significantly increased ACR20 responses, with benefits on other musculoskeletal symptoms in patients (pts) with active psoriatic arthritis (PsA).[1] As PsA impacts HRQoL, assessing treatment (tmt) effect using patient-reported outcomes (PROs) is important.

Objectives: To explore the effect of ABA tmt using PROs in intent-to-treat and *post hoc* analyses of ASTRAEA.

Methods: Pts were randomized (1:1) to SC ABA 125 mg weekly or placebo (PBO) for 24 weeks (W). At W16, pts without ≥20% improvement in joint counts started open-label ABA. Adjusted mean changes from baseline (BL) to W16 (all pts) and W24 (responder analysis) in Short Form-36 (SF-36; physical and mental component summary [PCS, MCS] and individual domains using spydergrams), pain VAS and HAQ-DI scores, Dermatology QoL Index (DLQI) and FACIT-Fatigue scale (FACIT-F) were evaluated in the total population and subgroups stratified by BL CRP level and prior TNFi use. Proportions of pts reporting improvements ≥minimal clinically important difference (MCID) in SF-36 summary (≥2.5) and domain (≥5.0), FACIT-F (≥40) and HAQ-DI (<–0.22) scores and ≥normative values in SF-36 summary (≥50) and domains, FACIT-F (<40) and HAQ-DI (<0.5) at W16 were analysed in the total population.



Results: In the total population, improvements in all PROs were numerically greater for ABA (n=213) vs PBO (n=211) at W16 and W24 and significant for SF-36 PCS at W16 and HAQ-DI at W24 (Table). At W16, improvements in all SF-36 domains were numerically greater with ABA, and significant for physical function, bodily pain and vitality. A higher proportion of pts receiving ABA vs PBO reported improvements ≥MCID in SF-36 PCS, MCS, SF-36 domains, FACIT-F, HAQ-DI (Fig) and DLQI (not shown) at W16. The proportion of pts whose scores were ≥normative values at W16 was higher with ABA vs PBO in SF-36 PCS, MCS, FACIT-F and HAQ-DI scores. At W24, improvements in SF-36 domain scores accrued in both groups, with numerical differences in favour of ABA except in social function. Improvements in PROs were greater with ABA tmt in BL CRP>upper limit of normal (ULN) vs CRP≤ULN and in TNFi-naïve vs -exposed subpopulations.

Table 1. Change from Baseline in PROs at 16 and 24 Weeks

PRO	Week 16 (total population)		Week 24 (responder analysis)	
	Abatacept	Placebo	Abatacept	Placebo
SF-36	*n=202*	*n=186*	*n=124*	*n=97*
PCS	3.76 (0.55)*	2.02 (0.57)	5.11 (0.64)	3.69 (0.71)
MCS	2.42 (0.70)	1.15 (0.73)	2.56 (0.83)	2.62 (0.92)
HAQ-DI	*n=202*	*n=187*	*n=124*	*n=98*
	–0.25 (0.04)	–0.15 (0.04)	–0.33 (0.04)*	–0.20 (0.05)

FRI0521 SECUKINUMAB PROVIDES SUSTAINED IMPROVEMENTS IN WORK PRODUCTIVITY AND HEALTH RELATED QUALITY OF LIFE IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: 2-YEAR RESULTS FROM FUTURE 1 AND FUTURE 2

V. Strand[1], O. FitzGerald[2], L.C. Coates[3], J.A. Walsh[4], J.D. Cañete[5], V. Bhosekar[6], L. Pricop[7], K. Gandhi[7], S. Jugl[8]. *[1]Stanford University School of Medicine, Palo Alto, CA, United States; [2]St. Vincent's University Hospital, Dublin, Ireland; [3]University of Leeds, Leeds, United Kingdom; [4]University of Utah, Salt Lake City, United States; [5]Hospital Clinic de Barcelona e IDIBAPS, Barcelona, Spain; [6]Novartis Healthcare, Hyderabad, India; [7]Novartis Pharmaceuticals Corporation, East Hanover, NJ, United States; [8]Novartis Pharma AG, Basel, Switzerland*

Background: Patients (pts) with PsA experience significant impairment of work productivity (WP) and health-related QoL (HRQoL). Secukinumab (SEC) has previously been shown to rapidly improve symptoms, physical function and HRQoL in pts with active PsA.[1,2]

Objectives: To assess the impact of SEC on WP and HRQoL through 2 years (yrs) in TNF inhibitor (TNF)-naïve PsA pts and those with an inadequate response or intolerance to TNF inhibitors (TNF-IR).

Methods: 606 and 397 pts were randomized to SEC or placebo (PBO) in FUTURE 1 (10 mg/kg IV followed by 150 or 75 mg SC) and FUTURE 2 (300, 150 or 75 mg SC), respectively. PBO pts were re-randomized to SEC at Wk 16/24. WP was assessed using the WP and Activity Impairment–General Health (WPAI-GH) questionnaire. WPAI-GH includes 6 questions to measure absenteeism, presenteeism, work productivity and impairments in unpaid activity because of health problems during the preceding 7 days. HRQoL was assessed using the PsAQoL questionnaire, encompassing 20 statements that pts rate as true or false on the day of completion. Across both trials, approximately 68% of pts were TNF-naïve and 32% were TNF-IR. Observed data are presented from the full analysis set and in subgroups stratified by prior TNF exposure. Only data with approved doses of SEC (300 and 150 mg) are shown.

Results: In FUTURE 1, 88 of 202 in the SEC 150 mg group were employed and working at baseline (BL); 61 of 100 and 59 of 100 were employed and working at BL in the SEC 300 mg and 150 mg groups of FUTURE 2, respectively. Improvements in all elements of WPAI were reported with SEC 300 and 150 mg in the overall population at Wk 16; responses were sustained through Wk 104 (Table). The greatest improvements were seen in presenteeism (–10.0), work productivity (–10.3) and activity impairment (–14.1), which corresponded to improvements from BL of approximately 29%, 26% and 30%, respectively in the overall population of FUTURE 1 at Wk 104; similar improvements were seen in FUTURE 2 at Wk 104 (300 mg: –14.4 [42%], –11.2 [33%] and –17.7 [38%]; 150 mg: –16.8 [50%], –16.8 [45%] and –18.5 [38%]). Sustained improvements in all elements of WPAI were also evident with SEC in TNF-naïve and TNF-IR pts in both FUTURE 1 and FUTURE 2. Improvements in PsAQoL were reported as early as Wk 4 and sustained through Wk 104. At Wk 104 of FUTURE 2, PsAQoL scores had improved by approximately 46% from BL with SEC 300 mg and 49% with SEC 150 mg in the overall population. Similar improvements were seen in TNF-naïve (47% and 51%, respectively) and TNF-IR pts (45% and 45%, respectively). Consistent results were reported in FUTURE 1. The efficacy of SEC was consistent regardless of concomitant MTX use.

Conclusions: SEC provided sustained improvements in WP and PsAQoL in pts with PsA for up to 104 wks, regardless of prior TNF exposure.

Table. WPAI-GH and PsAQoL outcomes in FUTURE 1 and FUTURE 2 through Week 104

FRI0522 THE ASSOCIATION BETWEEN OCCUPATIONAL-RELATED MECHANICAL STRESS AND RADIOGRAPHIC DAMAGE IN PSORIATIC ARTHRITIS

W. Zhou[1], R. Cook[2], V. Chandran[1,3], D.D. Gladman[1,3], L. Eder[1,4]. *[1]Department of Medicine, University of Toronto, Toronto; [2]Department of Statistics and Actuarial Science, University of Waterloo, Waterloo; [3]Centre for Prognosis Studies in the Rheumatic Diseases, University Health Network; [4]Women's College Research Institute, Women's College Hospital, Toronto, Canada*

Background: Mechanical stress is thought to play a role in the development of psoriatic arthritis (PsA).

Objectives: To determine the association between occupational-related mechanical factors and the severity of radiographic peripheral and axial joint damage in patients with PsA.

Methods: A retrospective cohort study was conducted in patients with long-standing PsA (>10 years duration). Patients were asked to report all paid employment since the age of 18. The key predictor variables included various occupational-related mechanical exposures. For each job, the Occupational Information Network (O*NET) was used to rate the level of exposure to 11 workers abilities and 16 occupational exposures. The outcomes of interest were the extent of radiographic damage in the peripheral and axial joints, as measured by the modified Steinbrocker score (mSS), and the modified Stokes Ankylosing Spondylitis Spine Score (mSASSS). The association between the predictor and outcome variables was assessed by linear multivariable regression models after adjusting for age, sex, PsA duration and lifestyle habits.

Results: 307 eligible patients were analyzed. Univariate analysis identified severeal occupational factors associated with radiographic damage (Table 1–2). In the multivariable regression analysis prolonged repetitive hand movements

Table 1. Linear Regression Analysis – The association between high level of work-related exposure and modified Steinbrocker score

Exposure	Univariate analysis		Multivariable Reduced Model*	
	β (95% CI)	P value	β (95% CI)	P value
Sitting	-15.7 (-29.2, -2.3)	0.02	-11.9 (-25.4, 1.6)	**0.085**
Hands handle	23.1 (4.4, 42)	**0.02**		
Repetitive hands motions	33 (11.7, 54.4)	0.002	29.5 (8.2, 50.8)	**0.007**
Twisting/Bending	18.8 (1.4, 36.2)	0.03		
Minor burns	21.5 (2.7, 40.4)	0.03		
Awkward body position	17.7 (-1.1, 36.5)	0.06		

Table 2. Linear Regression analysis – The association between workers' abilities and modified Steinbrocker score

Exposure	Univariate analysis		Multivariable Reduced Model*	
	β (95% CI)	P value	β (95% CI)	P value
Manual dexterity	2.5 (0.4, 4.6)	0.02		
Arm-hand steadiness	2.7 (0.6, 5.0)	0.01		
Finger dexterity	5.3 (1.4, 9.2)	**0.008**	5.4 (1.6, 9.2)	**0.005**
Trunk strength	2.0 (-0.3, 4.4)	0.09		
Wrist-finger speed	3.2 (-0.4, 6.8)	0.08		
Extent flexibility	1.9 (-0.3, 4.2)	0.10		

*Each model was adjusted for age, sex, duration of PsA, smoking, BMI, Biologics therapy (ever), DMARDs therapy (ever).

was associated with a higher peripheral joint damage score (by mSS, adjusted β=29.5, 95% CI 8.2, 50.8, p=0.007, Table 1), while the association between prolonged time spent sitting and lower mSS was of borderline significance (p=0.085, Table 1). Additionally, occupations that required higher finger dexterity were associated with higher mSS (adjusted β=5.4, 95% CI 1.6, 9.2, p=0.005, Table 2). Regarding axial damage, occupations that involved prolonged walking/running were associated with a higher mSASSS score (adjusted β=4.4, 95% CI 0.1, 8.7, p=0.04). PsA duration was independently associated with both peripheral and axial joint damage (p<0.001).

Conclusions: High level of occupation-related mechanical stress is associated with increased radiographic peripheral joint damage. These findings support the potential role of micro-trauma in the pathogenesis of PsA.

FRI0523 SHORT-TERM EFFICACY AND SAFETY OF NEW BIOLOGICAL AGENTS TARGETING THE IL-6, IL-12/23 AND IL-17 PATHWAYS FOR ACTIVE PSORIATIC ARTHRITIS: A NETWORK META-ANALYSIS OF RANDOMISED CONTROLLED TRIALS

W. Dongze, Y. Jiang, L.-S. Tam. *Department of Medicine & Therapeutics, The Prince of Wales Hospital, the Chinese University of Hong Kong, Hong Kong, China*

Background: IL-6, IL-12/23 and IL-17 inhibitors have been found to be highly effective for both skin and joint manifestations of psoriatic arthritis (PsA). Nonetheless, reliable evidence of the comparative benefits and harms for these interventions is absent for treatment selection in daily practice.

Objectives: To investigate the comparative efficacy, safety and tolerability of IL-6, IL-12/23 or IL-17 inhibitors and the proportion attributable to overall treatment for patients with active PsA.

Methods: Randomized controlled trials (RCTs) evaluating the efficacy, safety and tolerability of IL-6, IL12/23 or IL17 inhibitors at weeks 24 were identified by a comprehensive systematic literature review (PROSPERO 2016: CRD42016048166). Quality of evidence was assessed following the Grading of Recommendations, Assessment, Development and Evaluations (GRADE) approach. Treatment effects were evaluated based on the intention-to treat efficacy rates (ACR20, ACR50), safety parameters (any adverse effect [AE], serious adverse effect [SAE]) and tolerability (discontinuation due to AE [DAE]). Pair-wise meta-analyses and Bayesian network meta-analyses using the random-effects model were performed to estimate pooled odds ratios (ORs) and 95% credible interval (CrI). A subgroup analysis was performed to investigate the effects of prior anti-TNF exposure on the efficacy of ustekinumab and secukinumab.

Results: Six trials were identified which included 2411 participants and 11 treatments. All trials were of generally high quality according to Cochrane compliant rules and GRADEpro assessment. Direct comparisons of each biologic showed that secukinumab, ustekinumab and ixekizumab demonstrated superior efficacy over placebo with respect to all efficacy outcomes (ACR20 and ACR50). Regarding safety and tolerability, ixekizumab has a higher incidence of adverse events while ustekinumab were more tolerable compared with placebo. Mixed treatment comparisons showed that secukinumab (300mg monthly) had the highest efficacy in achieving ACR20 and ACR50; whereas clazakizumab (200mg monthly), ustekinumab (45mg 12 weekly), secukinumab (150mg monthly) had the lowest probability of having AE, SAE, DAE, respectively. Considering the overall risk-benefit profile of IL-6, IL12/23, IL17 inhibitors in the treatment of active PsA, secukinumab (150mg monthly) may offer an optimal balance for active PsA patients (Figure 1). When considering ACR 20 response, subgroup analysis revealed that anti-TNF naïve patient respond significantly better than placebo for all dosages of secukinumab and ustekinumab used. In contrast, only higher dose of secukinumab and ustekinumab were significantly more effective than placebo in anti-TNF failure patient.

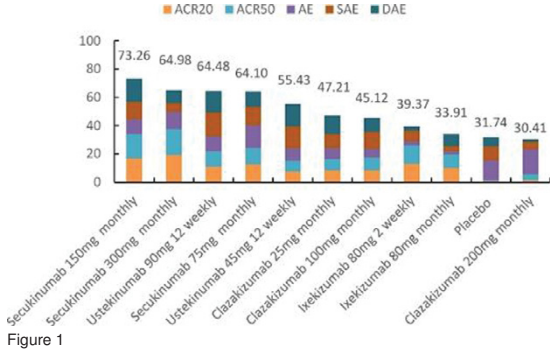

Figure 1

Conclusions: In conclusion, from the available evidence, secukinumab and ustekinumab were found to be the safest and most efficacious short-term treatments for active PsA amongst all the new biologics targeting the IL-6, IL-12.23 and IL-17 pathways.

Osteoporosis

FRI0524 CAROTID ATHEROSCLEROSIS IS ASSOCIATED WITH COMPROMISED VOLUMETRIC BONE MINERAL DENSITY AND MICROSTRUCTURES IN PATIENTS WITH INFLAMMATORY ARTHRITIS

T.H. Cheng[1], Q. Shang[1], E.K.M. Li[1], P.C.H. Wong[1], E.W.L. Kun[2], M. Li[1], T.K.Y. Li[1], T.Y. Zhu[3], A.P.W. Lee[1], L. Qin[3], L.S. Tam[1]. *[1]Department of Medicine and Therapeutics, the Chinese University of Hong Kong; [2]Department of Medicine & Geriatrics, Tai Po Hospital; [3]Department of Orthopaedics and Traumatology, the Chinese University of Hong Kong, Hong Kong, Hong Kong*

Background: Carotid Atherosclerosis is associated with compromised volumetric bone mineral density and microstructures in patients with inflammatory arthritis

Objectives: The aim of this study was to explore the relationship between volumetric bone mineral density (vBMD)/microstructural features and presence of carotid plaque (CP) in patients with inflammatory arthritis.

Methods: 175 inflammatory arthritis patients (81 [46%] PsA, 94 [54%] RA; 70 [40%] males; age: 53±12 years) were recruited into an ongoing prospective study assessing the relationship between inflammation, osteoporosis and carotid atherosclerosis. Carotid plaque and intima-media thickness (IMT) were measured by carotid ultrasound. Areal BMD (aBMD) was measured by dual energy X-ray absorptiometry (DXA). Microstructure features and vBMD of distal radius were measured using high-resolution peripheral quantitative computed tomography (HR-pQCT).

Results: No patients had established cardiovascular disease (CVD). Data from 172 patients at baseline were analyzed for this cross-sectional study. Patients were sub grouped according to the presence or absence of carotid plaque (CP+ group, n=68 [40%]) and CP- group, n=132 [60%]). CP+ group were older (59±10 vs 49±11, $p<0.001$), more likely to be male (54% vs 31%, $p=0.002$), had higher systolic blood pressure (130±19 vs 124±17 mmHg, $p=0.034$) and CVD risk (15.7±14.2 vs 7.9±8.6, $p<0.001$) according to the Framingham Risk Score (FRS) then the CP- group. aBMD, vBMD and microstructure were significantly compromised in the CP+ group. Distal radius aBMD, distal radius total vBMD, trabecular (Tb) vBMD, Tb thickness, cortical (Ct.) vBMD, Ct. thickness and bone volume fraction were 5% ($p=0.004$), 12% ($p<0.001$), 8% ($p=0.007$), 8% ($p=0.004$), 4% ($p=0.007$), 10% ($p=0.001$) and 8% ($p=0.007$) lower in the CP+ group. The differences remained significant after adjustment for gender, disease type and FRS (Table 1).

Table – Distal radius vBMD/microstructure and presence of plaque

	Carotid plaque		*p* value	Adjusted *p* value*
	No (n=104)	Yes (n=68)		
Total radius				
aBMD, g/cm^2	.575 ± .087	.547 ± .091	0.095	0.004
Distal radius				
Total vBMD, mmHA/cm^3	353.8 ± 77.8	315.3 ± 69.7	0.001	<0.001
Trabecular BMD, mmHA/cm^3	141.5 ± 46.2	131.4 ± 38.8	0.138	0.007
Bone volume fraction	.118 ± .039	.110 ± .032	0.142	0.007
Trabecular thickness, mm	.077 ± .017	.071 ± .013	0.019	0.004
Cortical vBMD, mmHA/cm^3	902.6 ± 58.0	870.0 ± 63.5	0.001	0.007
Cortical Thickness, mm	.882 ± .177	.792 ± .211	0.009	0.001

* Adjusted for gender, disease type and Framingham Risk Score

Conclusions: Inflammatory arthritis patients with carotid plaque had lower aBMD, vBMD and compromised bone microstructure in the distal radius even after adjustment for gender, disease type and FRS, suggesting that inflammation may be the common link for both conditions.

FRI0525 ASSOCIATION OF DYSMOBILITY SYNDROME WITH FRACTURE RISK IN THE MROS COHORT

B. Buehring[1,2], B.L. Lewis[1], K.E. Hansen[1], S.R. Cummings[3], N.E. Lane[4], N. Binkley[1], K.E. Ensrud[5], P.M. Cawthon[3]. *[1]Department of Medicine, University of Wisconsin-Madison, Madison, United States; [2]Rheumazentrum Ruhrgebiet, Herne, Germany; [3]California Pacific Medical Center Research Institute, San Francisco; [4]University of California - Davis, Sacramento; [5]University of Minnesota, Minneapolis, United States*

Background: Osteoporosis, obesity and sarcopenia are risk factors for fractures and their combination has a negative effect on musculoskeletal health (MSKH). We proposed a score-based approach to define this combination as "dysmobility syndrome (DS)". DS increases mortality in the NHANES cohort but no data exist on fracture risk. The most widely used fracture risk calculator, the WHO FRAX® tool, does not include several measures of MSKH such as physical function, muscle mass or falls. In this analysis of the Osteoporotic Fractures in Men (MrOS) cohort, we examine whether individuals with impaired MSKH/DS have a higher incidence of fragility fractures and whether this composite score confers additional risk for fracture, beyond risk estimates provided by FRAX®.

Objectives: In this analysis of the Osteoporotic Fractures in Men (MrOS) cohort, we examine whether individuals with impaired MSKH/DS have a higher incidence of fragility fractures and whether this composite score confers additional risk for fracture, beyond risk estimates provided by FRAX®.

Methods: The MrOS cohort was utilized in this study. The score-based approach to define DS includes six factors with one point assigned to each: appendicular lean mass/height2 $<$7.26 kg/m^2, body fat $>$30%, T-score $\leq$-2.5, grip strength $<$30 kg, gait speed $<$1.0 m/s, and falls in last 12 months. A score $\geq$3 indicated DS. We use odds ratios and cox proportional hazard models to analyze risks of major osteoporotic fracture (MOF). Men were censored at the time of fracture or last follow up. We determined the hazards of fracture using presence of dysmobility syndrome, the FRAX® score, and the FRAX® score in quartiles. We used the program R (www.r project.org) to perform all analyses.

Results: 5827 men ages 74±6 years with a mean BMI of 27.4±3.8 kg/m^2 had complete data necessary for this analysis. 391 males (6.7%) met criteria for DS. 571 (10%) experienced a MOF including 245 (4%) hip fractures. DS increased the hazards of major osteoporotic (HR 3.31, 95% CI, 2.58, 4.23) and hip (HR 3.48, 95% CI 2.41, 5.03) fractures. In adjusted models, DS and elevated FRAX® risk each increased the hazards of major osteoporotic and hip fracture. Interaction models showed no significant interaction between the presence of DS and FRAX® score for major osteoporotic (p=0.184) or hip (p=0.177) fractures.

Table 1. Cox Proportional Hazard Models for Fracture

Models	Major Osteoporotic Fracture 571 events Hazard Ratio (95% CI)	Hip Fracture 245 events Hazard Ratio (95% CI)
Dysmobility Index[a]	3.31 (2.59, 4.23)	3.48 (2.41, 5.03)
FRAX Score above treatment threshold	3.56 (2.51, 5.07)	5.52 (4.28, 7.11)
Dysmobility Index *and* FRAX Score	3.14 (2.45, 4.02) 3.17 (2.22, 4.51)	2.21 (1.52, 3.21) 5.14 (3.97, 6.65)

CI, Confidence Interval.

Conclusions: DS was associated with increased MOF fracture incidence even after adjusting for quartiles of FRAX® risk in this cohort of older men. Our study suggests that using a composite assessment of MSKH in addition to already available tools such as FRAX® may improve identification of individuals at high fracture risk. Additional analyses are necessary to examine whether this approach can better distinguish between those who will fracture and who will not and whether the results can be reproduced in women.

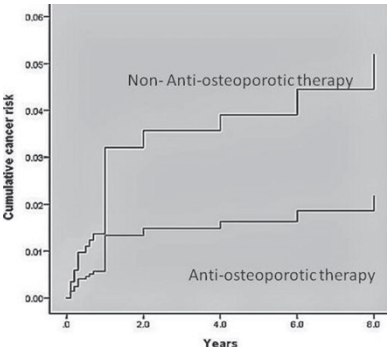
FRI0526 ANTI-OSTEOPOROTIC THERAPY DECREASE CANCER RISK IN PATIENTS WITH OSTEOPOROTIC VERTEBRAL FRACTURES

Y.-C. Chen, C.-H. Ko. *Rheumatology, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, Province of China*

Background: Some studies had looked at the long-term effect of anti-osteoporotic therapy on risks of different cancers in the general population. But epidemiological studies have consistently reported a reduced risk of breast cancer in bisphosphonate users. so there is little data to establish definitive conclusions.

Objectives: This study aimed to determine if anti-osteoporotic therapy can influence cancer risk in patients with osteoporotic vertebral fracture.



Methods: This retrospective study reviewed of cases of osteoporosis patients with acute vertebral fractures between 2001 and 2015. Anti-osteoporotic therapy were recorded (alendronate, ibandronate, zolendronic acid, raloxifen, teriparatide, denosumab). We followed these patients to develop cancer. All associated co-morbidities were recorded. Cox regression analysis were performed.

Results: There were 1128 patients with acute vertebral fractures were enrolled, among them 693 patients accepted anti-osteoporotic therapy, 432 were not. The mean age of anti-osteoporotic therapy was 73.86±7.52, while the age of nonanti-osteoporotic therapy was 72.82±10.92 (p=0.059). 15 (2.2%) patients of anti-osteoporotic therapy developed cancer, while 24 (5.6%) patients of non-antiosteoporotic therapy developed cancer (p=0.004). After adjusting for potential confounders, patients with antiosteoporotic therapy still had a lower cancer risk (p=0.038; HR: 0.428, 95% CI: 0.192∼0.955). The cancer risk also increased among smokers (p=0.002; HR: 10.505; 95% CI: 2.375∼46.462).

Table 1. Multivariable cox regression analysis of the hazard ratios for cancer

	Regression coefficient	SE	P value	HR (95.CI)
Anti-osteoporosis	-0.848	0.409	0.038	0.428 (0.192–0.955)
Gender	-0.693	0.584	0.236	0.500 (0.159–1.572)
Age	-0.029	0.016	0.071	0.972 (0.942–1.002)
Smmoking	2.352	0.759	0.002	10.505 (2.375–46.462)
liver disease	2.012	0.487	0.001	7.477 (2.880–19.412)
Kidney disease	-0.338	1.224	0.783	0.713 (0.065–7.859)
Cardiovascular disease	0.856	0.677	0.206	2.355 (0.624–8.882)
Pulmonary disease	0.771	0.597	0.197	2.162 (0.671–6.971)

Abbreviations: HR, hazard ratio; SE, standard error.

Conclusions: In this study, anti-osteoporotic therapy decrease cancer risk. So we could safely use these drugs in osteoporotic management.

FRI0527 LACUNARITY OF TRABECULAR BONE MICROARCHITECTURE, TBLβ, AS A PREDICTOR OF BONE FRAGILITY FRACTURE AND POTENTIAL INDEX OF OSTEOPOROSIS TREATMENT EFFICACY. THE LOTO STUDY

A. Zaia[1], R. Rossi[2], R. Galeazzi[2], P. Scendoni[3]. *[1]Scientific Direction; [2]Medical Imaging and Services, INRCA Italian National Research Center on Aging, Ancona; [3]Rheumatology Division, INRCA Italian National Research Center on Aging, Fermo, Italy*

Background: Bone mineral density (BMD) by dual-energy X-ray absortiometry (DXA) is still the routinely diagnostic approach for osteoporosis. However, BMD alone is not a good predictor of fracture risk while bone microarchitecture emerges as a determinant of bone fragility independent of BMD. High-resolution magnetic resonance imaging (MRI) represents an effective tool for in vivo characterization of trabecular bone microarchitecture (TBA) by noninvasive/nonionizing methods. Nevertheless, texture analysis is not used in clinical practice because of the large number of parameters to be calculated and analyzed.

We previously developed a MRI method to provide one parameter (TBLβ) sensitive to TBA changes in aging and osteoporosis[1]. Fractal lacunarity was chosen for TBA texture analysis as it is able to describe bone network discontinuity and sizes of bone marrow spaces, whose changes are index of increased fracture risk.

Objectives: Clinical validation of the method as a new tool useful in early diagnosis of osteoporotic fracture risk is the strategic aim of LOTO study. One major objective is to verify the potential of TBLβ in discriminating patients with (VF+) and without (VF-) vertebral fractures. TBLβ as a potential marker of osteoporosis treatment efficacy is also investigated.

Methods: An observational, cross-sectional and prospective study on over50s women at risk for bone fragility fractures was designed to validate the method[2]. Sample size was estimated equal to 280 osteopenic/osteoporotic women with/without prior vertebral bone fragility fractures. The main outcome measure is TBLβ as an index of osteoporotic fracture risk. It is calculated by a software prototype of the gray-scale version of our method on L4 axial images acquired by 1.5T MRI spin-echo multislice technique[3].

Results: A complete set of baseline recording, including DXA-BMD, conventional column Rx morphometry, and lumbar spine MRI-spin echo images for TBA characterization, was obtained for 279 out of 309 subjects eligible for the study. Prevalent VF were found in 31.5% subjects, 47.7% of which defined osteopenic at lumbar spine by DXA-BMD and 67% younger than 65 years. Baseline results from ROC analysis show that the contribution of TBA degeneration (TBLβ=40) to prevalent fractures is statistically higher (p=0.032) than BMD (T-score=-2.5). TBLβ results (Table 1) show that the proposed method is able to discriminate between

VF+ and VF- patients (p=0.001). This result is further stressed in untreated T- subjects (p<0.0001). Treatment, any medication (T+), and drug therapy in particular, significantly counteract the difference between VF+ and VF- within groups (Table 1) and between groups with TBLβ values comparable to untreated VF- patients (p=0.319) and statistically higher than untreated VF+ (p=0.014).

Table 1 Lacunarity of trabecular bone microarchitecture, TBLβ, can assess osteoporosis fracture risk and treatment efficacy

Patients	n VF-/VF+ (%)	TBLβ		p
		VF-	VF+	
Overall	191/88 (100)	66±51	46±42	0.001
T-	121/35 (55.9)	67±51	36±29	0.001
T+, any medication	70/53 (44.1)	65±52	52±48	0.091
VitD/Ca supplements *	25/19 (35.8)	56±49	36±24	0.051
Drug therapy*	45/34 (64.2)	70±54	62±56	0.276
Bisphosphonates**	43/27 (88.6)	70±55	60±54	0.225

VF: prevalent vertebral fractures; **T-** without treatment; **T+** with treatment; * % within T+ patients; ** % within drug therapy group; p: statistical significance from one-tail t-test

Conclusions: These promising results stress the usefulness of the method as a diagnostic tool in the assessment of osteoporotic fracture risk and suggest a potential role of TBLβ as a marker of treatment efficacy. More intriguing results are expected from prospective LOTO data.

FRI0528 SUCCESSFUL IMPLEMENTATION OF A PHARMACIST-LED FRACTURE LIAISON SERVICE AT A US VETERAN AFFAIRS (VA) HOSPITAL

B. Buehring[1,2,3], T. Holobyn[3], J. Kotek[4], B. Glynn-Servedio[5], S. Wright[6], K. Hansen[1,3], A. Bridges[1,3]. *[1]William S. Middleton Memorial Veterans Hospital, Madison, United States; [2]Rheumazentrum Ruhrgebiet, Herne, Germany; [3]Department of Medicine, University of Wisconsin-Madison, Madison; [4]Milwaukee VA Medical Center, Milwaukee; [5]Durham VA Medical Center, Durham; [6]VA Great Lakes Health Care System, Westchester, United States*

Background: Worldwide, an osteoporosis (OP) care gap exists for individuals with a fragility fracture (FF). Published data shows that US veterans are no exception. To address the OP care gap, fracture liaison services (FLS) are being implemented with the goal to prevent additional FF.

Objectives: Here we report the patient outcomes after initiating a FLS at a US Veterans Affairs (VA) hospital.

Methods: We identified veterans with a pelvic, hip and/or femur shaft fracture by querying a central database. Veterans with traumatic fractures, active OP medication, recent dual-energy X-ray absorptiometry (DXA) and/or hospice status were excluded. The remaining veterans were contacted via letter and the responsible primary health care team was sent a template letter with OP management recommendations via the electronic medical record. Recommendations included DXA, laboratory evaluation, and pharmacologic and non-pharmacologic interventions. In most cases, trained clinical pharmacists serving as FLS coordinators performed all tasks with an expert physician available for questions. Presented data are based on a review 4 months after recommendations were sent.

Results: The initial query revealed 149 veterans with pelvic, femoral, and/or hip fractures without a recent DXA and/or active OP therapy. Of those, 32 (31 males, 1 female) patients suffered a FF and were included in the FLS intervention. Our review showed that 59% of these had a DXA scan, 35% had their calcium/vitamin D intake reviewed, and 40% had started OP therapy or were referred to an OP specialist. When the primary care team's clinical pharmacist instead of the primary care provider implemented the FLS recommendations (10/32), 100% of the recommendations were addressed. Furthermore, 70% of patients had a bisphosphonate ordered, whereas it was 9% when no pharmacist was involved (p=0.0004).

Conclusions: Our study suggests that a pharmacist-led FLS improves post-FF care in US veterans. We found a high percentage of OP care goals met when patients interacted with clinical pharmacists. This observation might be due to the fact that most pharmacists had dedicated training in OP management and their interaction with the patient focused on their FF. In summary, our data suggests that clinical pharmacists trained in OP management can very effectively implement a FLS intervention.

FRI0529 ANALYSIS OF THE EVOLUTION OF CORTICAL AND TRABECULAR BONE COMPARTMENTS IN THE PROXIMAL FEMUR AFTER SPINAL CORD INJURY BY 3D-DXA

L. Gifre[1,2], L. Humbert[3], A. Muxi[4], L. del Rio[5], J. Vidal[6], E. Portell[6], A. Monegal[1], N. Guañabens[1], P. Peris[1]. *[1]Rheumatology, Hospital Clínic of Barcelona, Barcelona; [2]Rheumatology, Hospital Universitari Germans Trias i Pujol, Badalona; [3]Galgo Medical; [4]Nuclear Medicine, Hospital Clínic of Barcelona; [5]CETIR, Barcelona; [6]Spinal Cord Unit, Guttmann Neurorehabilitation Institute, Badalona, Spain*

Background: Spinal cord injury (SCI) is associated with a marked increase in bone loss and risk of osteoporosis development short-term after injury. 3D-DXA is a new imaging analysis providing volumetric measurements of the cortical and trabecular bone from DXA scans.

Objectives: The aim of this study was to assess the evolution of 3D femoral shape, trabecular macrostructure and cortical bone from DXA scans in patients with recent SCI followed over 12 months.

Methods: 16 males with recent SCI (<3 months since injury) were included. Clinical assessment, bone mineral density (BMD) measurements and 3D-DXA evaluation at proximal femur (analyzing the integral, trabecular and cortical volumetric BMD [vBMD] and cortical thickness) were performed at baseline and at 6 and 12 months of follow-up.

Results: vBMD measured by 3D-DXA significantly decreased at integral, trabecular and cortical compartments at 6 months (-31.1 mg/cm^3, -8.8%, p<0.001; -25.4 mg/cm^3, -11.6%, p=0.001; and -20.4 mg/cm^3, -2.4%, p=0.004), with a further decrease at 12 months, resulting in an overall decrease of -58.9 mg/cm^3 (-16.6%, p<0.001), -47.9 mg/cm^3 (-21.9%, p<0.001) and -42.4 mg/cm^3 (-5%, p<0.001), respectively. Cortical thickness also decreased at 6 and 12 months (-8%, p<0.001; and -11.4%, p<0.001), with the maximal decrease being observed during the first 6 months. The mean BMD loss by DXA at femoral neck and total femur were -17.7% (p<0.001) and -21.1% (p<0.001), at 12-months, respectively. Integral vBMD values at baseline were positively correlated with total femur BMD (r=0.874, p<0.001), however no correlation was observed in the changes in these values at 12-months.

Conclusions: 3D-DXA shows the differentiation of the marked bone loss that occurs at both proximal femoral compartments (cortical and trabecular) short-term after SCI. The present data suggest that 3D-DXA could be a useful complementary assessment tool in SCI patients.

FRI0530 EFECTIVENESS OF AN ORTHOGERIATRIC FRACTURE LIAISON SERVICE COMPARED WITH STANDARD CARE

A. Naranjo[1], S. Fernández Conde[2], S. Ojeda[1], S. Rodríguez[3], L. Torres Hernández[4], I. Bernardos[1], I. Rodríguez[3], V. Kraev[3], C. Hernández Carballo[4], P. Laynez[4]. *[1]Rheumatology, Hospital Univ. Gran Canaria Dr. Negrin, Las Palmas de Gran Canaria; [2]Internam Medicine, Hospital Universitario NS Candelaria, Santa Cruz de Tenerife; [3]Geriatrics, Hospital Univ. Gran Canaria Dr. Negrin, Las Palmas de Gran Canaria; [4]Internal Medicine, Hospital Universitario NS Candelaria, Santa Cruz de Tenerife, Spain*

Background: Our fracture liaison service (FLS) for outpatients has reported to maintain 73% of the patients on antiresorptive 2 years after the fracture. For hip fracture we are concerned about the low capture rate (27%).

Objectives: To analyze the efectiveness of a FLS for inpatients with hip fracture compared with standard care.

Methods: Observational study carried out in two hospitals, one with a FLS (Hospital Negrin) and the other one with standard orthogeriatric care (Hospital Candelaria). The reference population >65 y from H.Negrin and H.Candelaria are 63,382 and 63,249 inhabitants respectively.

We included patient >65 y with fragility hip fracture ocurred between 1th March 2016 and 31th July 2016. Severe dementia, non-fragility fractures and those patients who died during hospital admittance were excluded. All patients underwent hemogram and biochemistry. The densitometry was not performed on any patient. The only difference between hospitals was a dedicated nurse from the FLS H.Negrin who visited inpatients twice a week, interviewed patients, gave education and applied a treatment protocol to be started by Primary Care.

Data recorded were: age, sex, previous fractures and previous treatment for osteoporosis, including calcium, vitamin D, bisphosphonates, denosumab and teriparatide. We also collected the treatment that was included in the discharge report and treatment six month later (checking the electronic prescription).

Results: We included 185 patients (105 from Hospital Candelaria and 80 from Hospital Negrin), mean age 82 y (Table). The percentage of patients receiving a bisphosphonate or equivalent before hospital admittance was similar in both hospitals. However, the percentage after discharge rose by 91% in the hospital with FLS and remain 8% in the hospital with standard care. After six months, 75% of patients from FLS and 15% of patients with standard care had a treatment.

Conclusions: The implementation of an orthogeriatric FLS lead to an increase in treatment for osteoporosis compared with standard care and similar to our outpatient FLS model. The ideal approach to secondary fracture prevention is a FLS model of care in an integrated health care network, overseen by a nurse coordinator.

	Hospital Negrin	Hospital Candelaria	P

FRI0531 DUAL ENERGY X-RAY ABSORPTIOMETRY TESTING IN ELDERLY MEN WITH PROSTATE CANCER INITIATING ANDROGEN DEPRIVATION THERAPY REDUCES SUBSEQUENT FRACTURE RISK

M.E. Suarez-Almazor[1], G.M. Cabanillas Salazar[1], H. Zhao[1], B. Shi[2], J. Kim[3], L. Elting[4]. *[1]General Internal Medicine, MD Anderson Cancer Center; [2]Health Science, The University of Texas School of Public Health; [3]Health Science, University of Texas School of Public Health; [4]Health Science, MD Anderson Cancer Center, Houston, United States*

Background: Androgen deprivation therapy (ADT) is a mainstay therapy for prostate cancer, and a risk factor for bone mineral density (BMD) loss and fractures. Despite this risk, few patients undergo measurement of BMD when initiating ADT. Conceivably, screening for bone loss could lead to identification of patients at risk, and to implementation of bone conserving therapy (BCT), and subsequent decrease in fracture risk.
Objectives: To evaluate the utilization of Dual Energy X-ray Absorptiometry (DXA) testing for measurement of BMD in elderly patients with prostate cancer initiating treatment with ADT, and the effects of testing on subsequent fracture risk.
Methods: We conducted a population-based retrospective cohort study using the Surveillance, Epidemiology, and End Results (SEER) and Texas Cancer Registry (TCR) databases linked to Medicare claims. Medicare is the United States national health insurance program for individuals aged 65 and older. We identified all men over 66 years old with a diagnosis of prostate cancer who received ADT. We identified claims for DXA within 12 months prior, and 12 months after ADT initiation. We assumed that if patients had DXA testing in the year before ADT, this would not be repeated. We then ascertained claims for fractures during follow-up after ADT onset, comparing those who had undergone DXA with those who had not. Statistical analysis included multivariate logistic regression adjusting for demographic and clinical variables.
Results: The cohort included 36,739 men with prostate cancer treated with ADT; 48.3% were over 75 years of age and 75% were white. Only 5.2% of the patients underwent DXA within the window of evaluation. Men were more likely to have DXA id the were white vs. African American, and if the lived in census tracts with higher socio-economic status. When comparing the incidence of fractures, 11.3% of those who underwent DXA had a fracture, compared to 19.4% of those who did not undergo DXA ($p<0.0001$). In the multivariate model an increase in the odds for a fracture was associated with older age, being White, having a prior history of osteoporosis or fracture, were evaluated with DXA.A decrease in the odds for a fracture was associated with having undergone DXA testing (0.70; 95% CI 0.61 – 0.80).
Conclusions: Very few patients with prostate cancer starting ADT undergo DXA despite being at increased risk of fracture. DXA use was associated with socioeconomic status. Our results show that patients who underwent DXA were significantly less likely to have a fracture. Our findings suggest that DXA should be performed in all patients with prostate cancer initiating ADT.

FRI0532 DUAL ENERGY X-RAY ABSORPTIOMETRY TESTING IN WOMEN WITH BREAST CANCER INITIATING THERAPY WITH AROMATASE INHIBITORS REDUCES SUBSEQUENT FRACTURE RISK

M.A. Ursani[1], M. Suarez-Almazor[2], M. Yang[2], H.-F. Lu[2], H. Zhao[2], L. Elting[2]. *[1]Medicine, Section of Allergy, Immunology and Rheumatology, Baylor College of Medicine; [2]Internal Medicine, Rheumatology, The University of Texas M.D. Anderson Cancer Institute, Houston, United States*

Background: Estrogen receptor positive breast cancer is commonly treated with aromatase inhibitors (AI). A well-known adverse effect of this therapy is osteoporosis and related bone fractures. National guidelines have promoted the use of dual energy X-ray absorptiometry (DXA) for screening purposes.
Objectives: To evaluate the association between use of DXA among women with breast cancer treated with AI enrolled in Medicare, and subsequent fracture risk.
Methods: Retrospective cohort study using the Texas Cancer Registry (TCR) and the National Cancer Institute's Surveillance, Epidemiology and End Results (SEER) data linked with Medicare claims. To help estimate the likelihood of performing a DXA, a multivariable logistic regression model was used. Covariates of age, ethnicity, stage, residence area, and socioeconomic variables were controlled for the analyses. The outcome variable a DXA claim within 12 months after the initiation of the AI therapy. Cox regression model to evaluate time to first fracture after initiation of AI.
Results: The total number of cases within the SEER-Medicare database was 15,350 and in the TCR 4,532. Women aged between 66–74 years and Non-Hispanic white were more likely to get DXA than were Hispanic and Non-Hispanic Black.
In TCR, 2714 patients did not get treatment for osteoporosis in the first 12 months after AI therapy initiation. 2989 patients did not receive treatment for osteoporosis within 12 months of obtaining their first DXA scan. 1330 patients who did not undergo DXA were not treated for osteoporosis; and 1384 patients who underwent DXA got treated for osteoporosis.
The duration of AI treatment was negatively associated with the risk of fracture. Women who received DXA scan showed 11% lower risk of fracture than those who were not scanned (HR 0.89 (0.83, 0.94).
Conclusions: National guidelines suggest to obtain a DXA and start bisphosphonate therapy in female breast cancer patients who are treated with AI therapy. Our data suggests that the majority of women in the TCR and SEER database were not treated for osteoporosis within the first 12 months after initiation of AI therapy. Women who received DXA scan showed a lower risk of fracture than those who were not scanned.

FRI0533 INCIDENCE AND RISK FACTORS OF OSTEOPOROTIC FRACTURE IN PATIENTS WITH RHEUMATOID ARTHRITIS: A MULTICENTER COMPARATIVE STUDY OF THE FRAX CRITERIA AND WHO CRITERIA

S.T. Choi[1], S.-R. Kwon[2], H.-A. Kim[3], J.-Y. Jung[3], S.-S. Kim[4], S.-H. Kim[5], J.-M. Kim[5], J.-H. Park[1], C.-H. Suh[3]. *[1]Internal Medicine, Chung-Ang University College of Medicine, Seoul; [2]Internal Medicine, Inha University College of Medicine, Incheon; [3]Internal Medicine, Ajou University College of Medicine, Suwon; [4]Internal Medicine, Ulsan University College of Medicine, Gangneung Asan Hospital, Gangneung; [5]Internal Medicine, Keimyung University College of Medicine, Daegu, Korea, Republic Of*

Background: The fracture risk assessment tool (FRAX) criteria and the bone mineral density (BMD) criteria of the World Health Organization (WHO) are widely used for the assessment of osteoporotic fracture. Rheumatoid arthritis (RA) is the only disease parameter for the evaluation of osteoporotic fracture in the FRAX model, unlike the WHO criteria. However, the input for RA is just a dichotomous variable in FRAX model.
Objectives: In this study, we evaluated the incidence and risk factors of osteoporotic fracture in patients with RA through the comparison of the FRAX criteria and WHO criteria.
Methods: This study is a multicenter study, including 479 RA patients in 5 hospitals and 384 healthy controls, between January 2012 and December 2016. All of the RA patients fulfilled the 1987 American College of Rheumatology (ACR) criteria or the 2010 ACR/European League Against Rheumatism (EULAR) criteria for RA. The FRAX criteria for high risk of osteoporotic fracture, which is a 10-year probability of $\geq$20% for major osteoporotic fracture or $\geq$3% for hip fracture, were calculated by the FRAX tool including the BMD values. The classification of osteoporosis, according to WHO criteria were based on T-score $\leq$ -2.5. We assessed various demographic factors, clinical and laboratory findings of RA, and

medication use for RA and osteoporosis, and then evaluated the incidence and risk factors for osteoporotic fracture.
Results: The mean age of RA patients was 61.7±11.9 years, and 426 patients were female (88.9%) with 353 postmenopausal women (82.9%). The BMD score of L-spine in RA patients was significantly lower than that in healthy control (-2.21±1.41 vs. 0.97±0.11, $p<0.001$). Osteoporotic fracture was detected in 81 (16.9%) patients with RA. In RA patients, 226 (47.2%) patients met the FRAX criteria for high risk of osteoporotic fracture, and 240 (50.1%) patients satisfied the WHO criteria. The result of the FRAX criteria was affected by the female sex, menopause, smoking, drinking, higher dose of glucocorticoid (≥5mg/day), vitamin D use, calcium use and proton pump inhibitor (PPI) use ($p<0.05$). In multiple linear analysis, the FRAX score to 10-year probability of ≥3% of hip fracture was associated with age (β=0.384, $p<0.001$), body weight (β=-0.110, $p=0.038$), erythrocyte sedimentation rate level (β=0.125, $p=0.010$), glucocorticoid dose (β=0.105, $p=0.024$), and PPI use (β= -0.123, $p=0.010$). The independent risk factors for FRAX criteria were age (OR 1.160, $p<0.001$), female sex (OR 3.942, $p=0.010$), body mass index (BMI) (OR 0.869, $p=0.001$), glucocorticoid dose (OR 1.167, $p=0.025$) and PPI use (OR 2.552, $p=0.019$), and those for WHO criteria were age (OR 1.021, $p=0.040$), glucocorticoid dose (OR 1.109, $p=0.046$) and smoking (OR 2.924, $p=0.031$).
Conclusions: Osteoporotic fractures were found in 16.9% of RA patients. The proportion of patients with high risk of osteoporotic fracture was 47.2% in the FRAX model and 50.1% in the WHO model. Age, female sex, lower BMI, higher dose of glucocorticoid, PPI use and smoking were independent risk factors for osteoporotic fracture in RA patients.

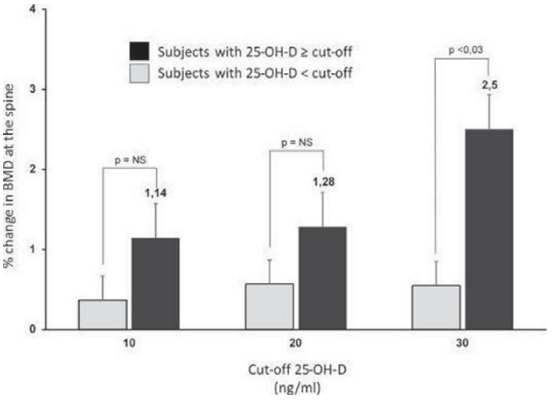
FRI0534 REPEATED OSTEOPOROSIS SCREENING IN RHEUMATOID ARTHRITIS: ARE WE COMPLYING WITH GUIDELINES?

A. Gorman[1], V. Sullivan[2], S. Khan[1], A. Mohammed[1], K. O'Rourke[1].
[1]Rheumatology; [2]Midlands Regional Hospital Tullamore, Tullamore, Ireland



Background: Osteoporosis rates are higher in patients with rheumatoid arthritis (RA). Patients with RA diagnosed with osteoporosis have a 30% increased risk of major fracture [1]. Monitoring response to osteoporosis treatment is recommended however there is no consensus on how frequently this should be performed. The International Society for Clinical Densitometry (ISCD), National Osteoporosis Foundation (NOF) and the American Association of Clinical Endocrinologists (AACE) all recommend repeat Bone Mineral Density (BMD) assessment within two years after initiating osteoporosis treatment to assess response to treatment [2–4]. Furthermore, the NOF and AACE recommend repeat screening every two years after diagnosis [3,4].
Objectives:
- To identify patients with RA and osteoporosis
- To identify if international guidelines are being achieved for reassessment of BMD within two years of treatment commencement in keeping with international guidelines.

Methods: A database of patients with a diagnosis of RA and osteoporosis who attend the Rheumatology department of the Midlands Regional Hospital, Tullamore since January 2013 was reviewed. Outpatient summaries, date of diagnosis, radiology investigations (DEXA scanning), pharmacological treatment and follow up investigations and treatment were documented.
Results: As of August 2016, 770 patients were identified as having RA. 90% of patients had attended the department since 2013. 117 (16.7%) patients were identified as having osteoporosis. Of these, 52.14% of patients were prescribed bisphosphonate therapy, 31.62% denosumab, 9.4% calcium/vitamin D alone, 0.85% other treatment (teriparatide/strontium) and 5.1% were on no treatment. Only 11.9% of these patients had a repeat DEXA scan within two years of starting or changing treatment. 11.1% of patients had repeat DEXA scans booked. The average length of time since a patient's most recent DEXA is 35 months.
Conclusions: Repeat DEXA scanning to assess the response to osteoporosis treatment in people with RA within the timeframe recommended by international guidelines has not been achieved. Patients who fail to respond to osteoporotic treatment are not being identified in a timely manner and therefore are at an increased risk of fractures. The results of this audit will make us more vigilant to identify those patients who are treated for osteoporosis that need repeat DEXA scanning to ensure that treatment is efficacious.

FRI0535 STRONG INFLUENCE OF VITAMIN D STATUS ON BONE MINERAL DENSITY AND BONE TURNOVER MARKERS DURING WEIGHT RESTORATION IN PATIENTS WITH ANOREXIA NERVOSA

A. Giollo[1], L. Idolazzi[1], C. Caimmi[1], A. Fassio[1], F. Bertoldo[2], R. Dalle Grave[3], S. Calugi[3], P.V. Bazzani[3], O. Viapiana[1], M. Rossini[1], D. Gatti[1]. *[1]Rheumatology Unit, Department of Medicine; [2]Internal Medicine Unit, Department of Medicine, University of Verona, Verona; [3]Department of Eating and Weight Disorder, Villa Garda Hospital, Garda, Italy*

Background: Anoressia nervosa (AN) is associated with an increased risk of low bone mineral density (BMD) and fractures as a consequence of an inadequate bone mass peak in adolescence and bone loss in young adulthood. Moreover, recently we have showed that vitamin D (25-OH-D) deficiency is widespread in untreated patients with AN, and there is a strong positive relationship between vitamin D status and BMD in AN. However, if vitamin D status could affect the efficacy of weight restoration in improving bone health in patients with AN is currently unknown.
Objectives: Our aim was to investigate the potential role of vitamin D status in determining the efficacy on bone mineral density (BMD) of weight restoration in AN.
Methods: Bone mineral density assessed by dual-energy x-ray absorptiometry (DXA), vitamin D, N-propeptide of type I collagen (P1NP), C-terminal telopeptide of type I collagen (CTX), intact parathyroid hormone (PTH) were evaluated before and after a 20-weeks intensive weight restoration therapy in patients with anorexia nervosa and secondary amenorrhoea for at least 6-months. The subjects were not receiving medications known to affect bone metabolism.
Results: Ninety-one female patients aged 13–45 years old were evaluated, baseline weight 39.4±5.6 kg and BMI 15.1±1.6 kg/m^2. Weight and BMI were significantly increased in all patients after treatment. The mean BMD values were significantly increased only at the spine (1.0±3.6%, p=0.009). A positive trend was demonstrated between post-treatment 25-OH-D and BMD changes at the spine (p=0.032). However, only the patients with post-treatment 25-OH-D ≥30 ng/ml showed significantly higher increases in BMD at the spine (2.5% vs 0.5% respectively for 25-OH-D ≥30 ng/ml and 25-OH-D <30 ng/ml, p<0.03; Figure 1). Both P1NP and PTH increased, whereas a significant decrease was found in 25-OH-D and CTX ($p<0.05$). Post-treatment CTX levels were inversely correlated with spine BMD. A positive relationship was found between changes in weight and P1NP (R2 =0.27).

Conclusions: In anorexia nervosa, a hypovitaminosis D status counteracts the efficacy of the weight restoration treatment because of an increase in bone resorption mediated by a secondary hyperparathyroidism. Our study strongly support the use of vitamin D supplements for bone health in anorexia nervosa.

FRI0536 THE METHOD OF CALCULATING THE PROBABLE VALUE OF T-SCORE IN PATIENTS WITH MULTIFOCAL ATHEROCALCIFICATION

A.N. Kokov, V. Masenko, S. Semenov, O. Barbarash. *Federal State Budgetary Scientific Institution Research Institute for Complex Issues of Cardiovascular Diseases, Kemerovo, Russian Federation*

Objectives: To determine probable value of T-score for early detection of osteopenic syndrome in patients with multifocal atherosclerosis based on the multislice computed tomography (MSCT) evaluation of vascular calcification.
Methods: 186 male (60±6,7 years) with multifocal atherosclerosis. All the patients underwent the measurement of BMD with X-ray absorptiometry. Moreover, calcium scores (CS) of coronary and brachiocephalic arteries were obtained using Agatston method.
Results: T-score values of lumbar vertebrae -1.07 [-1.54;-0.40], T-score of the proximal femur -2.01 [-2.71;-1.49]. Calcification of the coronary arteries: CS=471.8 [118.2;916,8] and carotid arteries: CS=113.9 [44.5;300.8]. Factors that affect the

probable value of T-score in patients with known rates of calcification of the coronary and carotid arteries were obtained by regression analysis. These factors were equivalent density of coronary calcinoses (p=0,0046), the volume of the carotid calcifications (p=0,0039), the mass of calcifications of the carotid arteries (p=0,0054) and the presence of a stenosis of the carotid arteries (p=0.0001).The predictive model for estimating the probable value of T-score has been is designed using regression coefficients of each of the factors. The value is equal to the Fisher statistic F=9,52, p-value <0.000001, multiple correlation model's coefficient is 0.753.

Conclusions: The results of this study indicate that rates of calcification of the carotid and coronary arteries, resulting in the planned survey on MSCT patients with multifocal atherosclerosis have a high predictive capacity for assessing the probable value of the T-score and early detection of osteopenic syndrome in these patients.

FRI0537 PREVENTION STRATEGY OF OSTEOPOROTIC FRACTURES IN PORTUGAL: AN ANALYSES ON A COHORT OF HIP FRACTURED PATIENTS

A. Daniel[1], M.L. Marques[1], L. Brites[1], C. Torres[2], A. Marques[1], J.A. Pereira da Silva[1]. *[1]Rheumatology Unit, Centro Hospitalar e Universitário de Coimbra; [2]Rheumatology Unit, Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal*

Background: Despite the fact that Portugal has one of the lowest rates of hip fractures in Western Europe, more than 10.000 patients are admitted every year to the Portuguese National Health Service due to hip fragility fractures. The burden of the problem will tend to increase in coming years, unless effective preventive measures are put in place.[1]

Objectives: The aim of our work was to evaluate the percentage of patients under osteoporotic treatment (OT) before and after a hip fracture (HF) and compare these results with the percentage of patients who should be under treatment, according to FRAX model and Portuguese cost-effectiveness guidelines (PG) for OT.[1]

Methods: Patients diagnosed with a HF, between May 1st and October 31st 2013, from a single tertiary hospital, were included in this transversal study. Patients or their primary caregiver were contacted by phone to gather data regarding demographic and clinical features, including risk factors for Osteoporosis (OP) defined by FRAX®. Clinical data was obtained from medical files.

FRAX® without mineral bone density was used to calculate the 10 year fracture risk. For each patient the FRAX® was scored according to data available the day before the present HF (ie the current fracture was not considered as a previous fracture for the purpose of risk prediction). Thresholds for therapeutic intervention were defined according to PG: a 10-year probability of a major osteoporotic fracture (OF) ≥11% and/or a 10 year probability of HF ≥3%[1].

Results: The mean age of the population (n=130) was 81.6±8.6 years, and 69.2% were female. Before the current HF, only 23 (17.7%) of the patients had been prescribed some form of medication for OP: bisphosphonates (n=2), strontium ranelate (n=3) and calcium + vitamin D supplementation (n=13); the other patients or caregivers didn't specify the ongoing medication.

About 65 patients had a previous fracture, of which 8 patients had ≥1 fragility fracture of the hip; 6 had ≥1 symptomatic vertebral fragility fracture and 16 had ≥2 fragility fractures, independently of the site of the fracture. According to PG, all these 30 (26%) patients should be under OT without the need for FRAX® risk calculation.

The mean 10-year major OF probability was 21.2±14% and the mean 10-year HF probability was 13.7±12.9%. According to FRAX®, 104 (80%) of the patients had indication to start OT based on the 10-year risk of major OF and 117 (90%) based on the 10-year risk of HF.

After hospitalization, although all the patients had formal indication for treatment, only 11 (8.5%) patients had received a prescription for OT up to one year after the fracture event.

Conclusions: Similar to other countries, the percentage of patients under OT (before and after HF) in Portugal is extremely low. Risk estimation by FRAX® and application of current PG would allow clinicians to identify these patients and introduce appropriate preventive measures. Continued efforts are needed to promote timely prevention, most especially after the first fragility fracture.

FRI0538 EVALUATION OF FACTORS THAT INCREASE FRACTURE RISK IN BREAST CANCER

A. Anand[1], M. Ghafouri[2], M. Bukhari[1]. *[1]University Hospitals of Morcambe Bay NHS Foundation Trust; [2]Lancaster University, Lancaster, United Kingdom*

Background: Women with breast cancer are at an increased risk of fractures. This is present in patients with both active and treated disease. In addition to established risk factors of fractures, patients with breast cancer are exposed to additional factors that further compromise bone strength. These factors primarily include: the malignancy interfering with bone metabolism and breast cancer treatments inducing bone loss.

Objectives: To evaluate fracture risk in active and treated breast cancer patients, and to understand the role bone mineral density (BMD) plays in predicting fracture risk.

Methods: The study population included breast cancer patients with active and treated disease referred to dual-energy X-ray absorptiometry (DEXA) scanning at the Royal Lancaster Infirmary between 2004–2015. Patients on aromatase inhibitors were excluded because of its' negative effect on oestrogen.

From this population, we collected BMD measurements of the femur and lumbar vertebra. Alongside information on physical characteristics such as age, height, weight, body mass index (BMI), average tissue thickness, lean and fat mass were measured.

To evaluate other precipitating factors known to increase fracture risk we included: smoking status, steroids use, alcohol, family history of fractures, diagnosis of rheumatoid arthritis and secondary osteoperosis.

Data analysis was done on R 3.3.2 software. Odds ratios were calculated using logistic regression and age adjusted models were compared using the likelihood ratio test. Categorical data was analysed using Chi squared and Fischer's exact test, while continuous data was analyzed using t-test.

Results: The study population was a total of 306 patients with a mean age of 63.6 years. 146 of the study group had active disease, while 160 patient were breast cancer survivors. Of the total population 87 (28%) had sustained at least one fracture.

Active breast cancer insignificantly increased fracture risk in comparison to the cancer survivor population (*OR=1.330, 95% CI=0.801–2.218, p=0.271).*

Physical characteristics that significantly increased fracture risk included increased age and decreased average fat percentage (Table 1). BMD reduction in the femoral neck and all vertebrae significantly increased odds of having a fracture (Table 2). External factors such as smoking status, alcohol consumption, family history and steroid use had no significant effect.

Table 1. Physical Characteristics and Fracture Risk

	Odds Ratio	95% Confidence Interval	*p*-value
Age	1.407	1.106–1.803	0.043
BMI	0.832	0.639–1.074	0.159
Average Tissue Thickness	0.929	0.847–1.016	0.108
Average Fat Percentage	0.069	0.005–0.883	0.040
Fat Mass	0.997	0.994–0.999	0.032
Lean Mass	1.003	1.000–1.006	0.032

Table 2. BMD Results from DEXA Scan

	Odds Ratio	95% Confidence Interval	*p*-value
Left Neck of Femur	0.035	0.035–0.309	0.002
Right Neck of Femur	0.063	0.006–0.561	0.013
Lumber Vertebra Total (L1–4)	0.063	0.013–0.285	0.0002

Conclusions: In conclusion, this study emphasizes DEXA measurements are the best predictive tool for fractures in breast cancer patients. Thus further supporting the need for increased BMD surveillance for those diagnosed with breast cancer who are not on aromatase inhibitors.

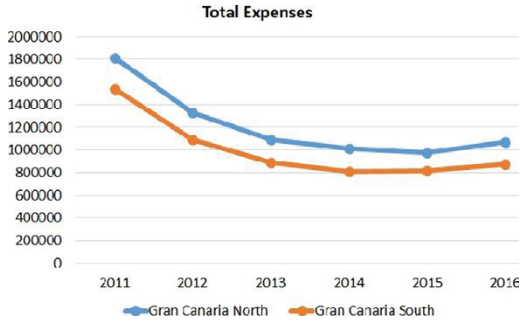
FRI0539 IMPACT OF THE IMPLEMENTATION OF A FRACTURE LIAISON SERVICE IN PHARMACEUTICAL EXPENSES FOR OSTEOPOROSIS

A. Naranjo[1], S. Ojeda[1], S. Rodriguez[2], I. Bernardos[1], A. Molina[1], F. de la Nuez[3], M. Negrin[4]. *[1]Rheumatology; [2]Geriatrics, Hospital Univ. Gran Canaria Dr. Negrin; [3]Rational Drug Use Service, Servicio Canario de la Salud; [4]Met. cuantitativos en Economia, Universidad de Las Palmas, Las Palmas de Gran Canaria, Spain*



Background: In 2012 a Fracture Liaison Service (FLS) was implemented in Hospital Dr Negrin

Objectives: To analyze the economic impact of the FLS on pharmaceutical expenditure for osteoporosis.

Methods: Expenditure on osteoporosis medication (government inpunt) was collected from January 1th, 2011 to October 1th, 2016. The data distinguish group I (calcium and vitamin D), group II (Bisphosphonates, denosumab, SERM, strontium and teriparatide) and total expenditure (sum of groups I and II). Intravenous bisphosphonates were not included.

Gran Canaria island is organized in two health areas; the North and the South areas. The population aged >65 years in the North and South areas in 2016 were

63.535 and 52.453 people, respectively. In the Gran Canaria South area there is no formal FLS.
An estimate of the number of cases of fracture attended in FLS and that was still under treatment in septiembre 2016 was calculated.
Results: The total expenditure on prescriptions for osteoporosis in 2016 (January to September) in the North area was 1,226,702 €, while in the South area it was 1,069,606 € (a 14% higher in the North area). The expenditure in 2016 for group II (bisphosphonates and equivalents) was 799,840 € and 656,301 € respectively (22% higher in the North area). The evolution of the percentage of total expenditure in osteoporosis for the North area in relation to the total of Gran Canaria was the following: 53.6% in 2011; 54.2% in 2012; 54.4% in 2013; 54.3% in 2014; 53.4% in 2014 and 53.4% in 2016 (Figure). For group II drugs, the percentage of 55% for the North area did not change between 2011 and 2016.
The number of drug prescriptions for group I was 7,551 units in the North area and 7,732 in the South area. For group II, the figures were 3,917 units in the North area and 2,873 units in the South area. That is, the prescription of group I drugs in the January-September 2016 period was similar in both areas (2% higher in the South area), while for Group II it was 36% higher in the North area, being this difference stable between 2011 and 2016.
Between 2012 and 2016, 1,297 patients have been evaluated in the FLS, of which 75% have indication of bisphosphonate or equivalents. The average adherence to treatment at 12 and 24 months is 70% (1). The estimate is that approximately 681 patients (17%) of the 3,917 who receive a drug from group II in the North area in October 2016 derivates from the FLS.

Conclusions: The implantation of a FLS, despite supposing around 16% of the percentage of patients treated with bisphosphonates and equivalents in the health area Gran Canaria North derivates from the FLS has not led to an increase in pharmaceutical expenditure for osteoporosis. We believe that one of the reasons for the non-increase in spending is the rational use of drugs for osteoporosis.

FRI0540 EVALUATION OF BONE QUALITY USING THE NEW TRABECULAR BONE SCORE (TBS) TOOL IN RHEUMATOID ARTHRITIS PATIENTS

A. Casabella[1], A. Sulli[1], C. Seriolo[2], G. Botticella[2], L. Molfetta[2], M. Cutolo[1], S. Paolino[1], B. Ruaro[1]. *[1]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS AOU San Martino; [2]Osteoporosis, Bone and Joint Disease Researc Center, CROPO, Di.M.I., University of Genova, Genoa, Italy*

Background: Patients affected by Rheumatoid Arthritis (RA) show an increased risk of low bone mass, as a result of multi-systemic disorders including toxic drug, low vitamin D levels and physical inactivity. Trabecular Bone Score (TBS), is an index extracted from the dual-energy X-ray absorptiometry (DXA) images, that provides an indirect measurement (Score) of bone axial microarchitecture and allows to get information about bone quality (1,2).
Objectives: The aim of this investigation was to evaluate bone quality in RA patients (high risk population) receiving vitamin D supplementation from at least 3 month, using the TBS.
Methods: 108 female patients (mean age 61±8 years) affected by RA and 60 age- matched controls (CNT) (mean age 64±11 years) were enrolled. Bone Mineral Density (BMD, g/cm^2) of the lumbar spine (L1-L4) was analyzed using a DXA scan (GE,Lunar Prodigy). Lumbar spine TBS (TBS iNsight Medimaps) was derived for each spine DXA examination. All patients were evaluated for serum 25 hydroxyvitamin D (25(OH)D) concentrations.
Results: 78 RA patients (80%) presented a bone loss that was significantly lower when compared with control group ($p<0.001$). Likewise, lumbar spine TBS score was found significantly lower in RA patients compared with CNT ($p<0.001$). Finally, RA patients showed lower 25(OH)D concentrations (18.4±1.3 ng/ml) than CNT (26.2±0.9 ng/ml; $p<0.04$).
Conclusions: This study shows in RA patients a reduction of TBS values that seem placed side by side with reduced BMD values and 25(OH)D serum concentrations. Therefore, TBS could become a new and safe diagnostic tool for the quantification of the bone quality and related osteoporosis, in chronic systemic inflammatory rheumatic diseases, such as RA.

FRI0541 RELATIONSHIP BETWEEN CHRONIC PERIODONTITIS AND BONE MINERAL DENSITY IN A CASE-CONTROL STUDY OF PATIENTS WITH RHEUMATOID ARTHRITIS AND NON-INFLAMMATORY JOINT DISEASE

J.L. Garnier Rodríguez[1], J. González Febles[2], S. Dadlani[1], M.A. Gómez[3], A. González Díaz[3], L. Expósito Pérez[4], E. Trujillo[4], M. García González[4], B. Rodríguez-Lozano[4]. *[1]Odontology/Periodontology, Dental Clinic Dr Garnier, Santa Cruz de Tenerife; [2]Periodontology, UCM, Madrid; [3]Nuclear Medicine Department; [4]Rheumatology, Hospital Universitario Canarias, Tenerife, Spain*

Background: The association between two chronic inflammatory diseases such as rheumatoid arthritis (RA) and periodontitis (PD) may be explained by causal and noncausal pathways. A possible mechanism in the increased PD observed in patients with RA is systemic bone loss due to the inflammatory process itself among others factors. Several studies have reported associations between OP and PD, not confirmed in other studies.
Objectives: 1.To determine whether OP is associated with PD and with PD severity.
Methods: Observational cross-sectional, case-control study of RA patients ≥18 y.o. meeting ACR/EULAR 2010 criteria for RA in a Rheumatology Dept. and a control group with a non-inflammatory joint disease, with at least 4 teeth, without dental prophylaxis or antibiotic intake 6 months before. Socio-demographic and anthropometric variables with smoking status,Graffar scale, stress level, annual dental prophylaxis, and co-morbidities such as diabetes mellitus (DM), dyslipidemia (DS), ischemic cardiovascular disease (ICD) and history of low-impact fractures. Dual-energy x-ray absorptiometry (DXA) (g/cm^2) was performed with a DXA LUNAR (GE HealthCare) in lumbar spine and femoral neck. Periodontal Variables included plaque index, bleeding on probing, probing pocket depth, recession, clinical attachment level (CAL). Full mouth CAL and periapical x-rays were taken. CAL was classified according to the European Workshop in 2005 (Tonetti), into level 0 (absence), TL1 (mild), TL2 (severe). Statistical Analysis: t-student test, Kruskal Wallis, Chi-square with Stata 13.1.
Results: We studied 344 patients: 187 RA (147 F/40 M) and 157control (101F/56M). Both groups were comparable in age 54.9 (17.9) y.o., body mass index 27.8 (4.6), stress level, DM and ICD. Differences in gender (>no. of males in controls), socioeconomic status (lower level in RA), >no. of current and former smokers RA (19.2%vs 8.9%/24.6%vs 11.5%),OP (23.4% RA vs 7.8%), DS (hipertrygliceridemia 11.2% RA vs 4.4%). PD was found in 97.3% of RA patients vs 66.2% of controls. DEXA was performed in 303 patients: 163 RA/140 controls that showed OP in 38 (23.3%) and 13 (9.3%) of RA and control groups as well as osteopenia in 47 (32.4%) and 16 (11.3%) respectively ($p<0.001$); 81% of these patients presented PD. There was association between PD and OP/osteopenia, so patients with PD had greater abnormal BMD 88% vs 76.3% with normal BMD; patients without PD showed greater normal BMD with statistically significant difference (23.7% vs 11.1%) (p=0.008).
Conclusions: 1. PD was observed in 81% of the patients evaluated with BMD; of these, 89% had OP/ osteopenia, and among the patients without PD a significant normal BMD predominated. 2. PD was found in 97% of RA patients *versus* 66% of controls; similarly OP was present in 23.3% of RA patients *versus* 9.3% of controls, with the diference being significant. 3. There was no association between BMD and PD severity.

FRI0542 PREVALENCE OF VERTEBRAL BODY DEFORMITIES RELATED TO OSTEOPOROSIS IN PATIENTS WITH NON-TRAUMATIC LUMBAR OR DORSAL ACUTE PAIN

C.A. Guillen-Astete, C. Pijoán-Moratalla, J.R. Quiñones-Torres. *Rheumatology Department, Ramon y Cajal University Hospital, Madrid, Spain*

Background: Presence of vertebral body deformities is considered a relevant issue in order to chose a particular treatment in patients with osteoporosis. However, only remarcable deformities are properly identified and registred while those, less striking can just be unnoticed in radiological studies not related to osteporosis studies. One of the most usual radiographic study of the axial skeleton is the lumbar and dorsal acute pain. This group of patients is, indeed, suitable stablish proportions of any grade of vertebral body deformities according to the Genant scale.
Objectives: The goal of present study is to determine prevalence of vertebral body deformities in postmenopausial patients radiologically assessed due to lumbar or dorsal non traumatic related pain.
Methods: We performed a simple randomization of the registries of female patients with 65 years old or more who consulted due to dorsal or lumbar

non-traumatic acute pain, between 2014 and 2015. All included registries must had a radiological assessment. The gathering of registries concluded after reach 120% of the estimated sample size for a non finite theoretical population, a precision of 3% and a hypothetical estimated prevalence of 7% based on local previous studies of prevalence of vertebral osteoporotic fractures. Vertebral body measures were performed according to Genant scale recommendations from D7 to L5 as far as possible according to the field of study of the radiological chart plate.

Results: 275 randomized registries of dorsal and lumbar pain were included (total=550). Among patients with dorsal pain we identified 62 (22.5%), 30 (10.9%) and 18 (6.5%) vertebral deformities grade I, II and III respectively. Among patients with lumbar pain we identified 31 (11.2%), 49 (17.8%) and 33 (12%) vertebral deformities grade I, II and III respectively. Prevalence of any grade of dorsal vertebral deformity was 40.00% (CI 34.39 – 45.89) and lumbar was 41.09% (CI 95% 35.44 – 46.99). Lumbar vertebral body deformities grade I and II summed 70.7% while dorsal grade I and II summed 83.6%. From the 93 vertebral body deformities grade I, 6.4% were recognized in their clinical histories, 20.2% of the grade II deformities and 92.1% of the grade III deformities, ($P<0.001$).

Conclusions: Although our population sample is circumscribed to symptomatic patients, our results contribute with prevalence of vertebral body deformities in postmenopausal patients grade I and II and who were mostly unnoticed. Proper identification of vertebral body deformities in patients with osteoporosis is crucial to decide treatment strategies in patients with known osteoporosis. Due to that, prevalence studies of this kind are relevant and useful to avoid diagnostic mistakes.

FRI0543 WHICH FACTORS CAN HELP PREDICT FRAGILITY FRACTURES IN PATIENTS DIAGNOSED WITH INFLAMMATORY BOWEL DISEASE? A CASE-CONTROL STUDY

D. Ahmed[1], M. Bukhari[2]. *[1]Lancaster Medical School; [2]Rheumatology, University Hospitals of Morecambe Bay NHS Trust, Lancaster, United Kingdom*

Background: Inflammatory Bowel Disease (IBD) is a known risk factor for developing low bone mineral density (BMD) osteoporosis, due to malabsorption and treatment with steroids. These patients are more susceptible to fragility fractures. Though the percentage of such fractures is low, they can be associated with impaired mortality and morbidity. The difficulty lies in early detection of patients at an increased risk of fractures. Currently the diagnosis of osteoporosis and predictions of fracture risk are calculated assessing patient BMD on dual energy X-ray absorptiometry (DEXA). However, previous studies suggest that despite a decreasing BMD being significantly associated with an increased risk of fracture, its measurement alone is fairly restricted in predicting them; other patient factors must also be brought into consideration (1).

Objectives: To identify specific factors which may assist in the prediction of fragility fractures in a cohort of patients diagnosed with IBD.

Methods: Patients referred to a DEXA scan in the North West of England were identified and those with a referral reason of IBD were studied. Factors measured at BMD scanning include patient age, height, weight, lumbar and femoral head bmd, BMI, smoking history, alcohol use, family history of fractures, steroid exposure, rheumatoid arthritis and secondary osteoporosis. Patients where assorted into cases and controls after adjusting for age and gender. They were then analysed using T tests for continuous variables and Chi squared tests for categorical variables. Univariate and multivariate logical regression models were then utilised to identify factors predicting fractures.

Results: 938 patients were identified of which 721 (76.9%) were female with an average age of 58 as compared to an average age of 53 in men. 274 patients (29%) had fractures of which 238 were females (87%), at an average age of 63 compared to 60 in men. Men were shown to have a greater risk of fractures. Results of the univariate analysis are shown below.

Predictor	All Pts	Pts with Fracture	Pts without Fracture	P-value	Odds ratio (95% CI)
Age at scan	56.8	62.5	54.5	0.00	1.03 (1.03–1.05)
Height	163.7	161.2	164.7	0.21	0.99 (0.96–1.01)
Weight	71.6	70.0	72.2	0.63	0.99 (0.99–1.08)
Alcohol	52	16	36	0.24	1.48 (0.77–2.82)
Smoking	373	109	264	0.69	1.06 (0.79–1.44)
Family History	169	53	116	0.34	1.19 (0.81–1.74)
RA	49	20	29	0.20	1.49 (0.81–2.75)
Secondary op	108	40	78	0.93	1.02 (0.66–1.56)
Left Femoral Neck BMD	0.87	0.82	0.89	0.00	0.11 (0.04–0.31)
Right Femoral Neck BMD	0.92	0.86	0.94	0.00	0.19 (0.62–0.58)
Lumbar Spine BMD	1.22	1.01	1.10	0.00	0.10 (0.44–0.24)
BMI	28.7	26.9	26.6	0.96	0.99 (0.97–1.03)
Steroid	617	134	483	0.00	0.49 (0.36–0.67)

In the multivariate analysis, statistically significant variables were BMI (OR 1.05, 95% CI 1.01–1.08) and steroids (OR 0.49, 95% CI 0.35–0.69) with steroids being protective against fractures.

Conclusions: In the univariate analysis several risk factors are shown to be associated with fractures. These include femoral neck BMD, steroid use, lumbar BMD and the patient age at the time of the scan. The multivariate analysis showed that the biggest predictor after adjusting for age and gender is steroids and BMI with steroids being protective.

FRI0544 CLINICAL AND DEMOGRAPHIC PROFILE OF PATIENTS CONSULTING FOR FRAGILITY FRACTURES IN A HOSPITAL IN COLOMBIA DURING THE YEARS 2014-2016: IMAGE OF THE COLOMBIAN HEALTH SYSTEM

D.G. Fernández-Ávila, D.N. Rincón-Riaño, D. Pinzón, J.M. Gutiérrez. *Rheumatology, Hospital Universitario San Ignacio - Pontificia Universidad Javeriana, Bogotá, Colombia*

Background: Osteoporosis represents a major public health problem due to the seriousness of a patient's main complication: fracture. The lack of the Colombian health system for a structured public policy aiming diagnosis and early intervention generates a high volume of patients having fragility fractures.

Objectives: To describe the clinical and demographic characteristics of patients with fragility fractures seen in our hospital. To describe the risk factors for fragility fractures. To inquire about the patient's knowledge about osteoporosis. To follow each case establishing whether after presenting the complication (fracture), the patient would receive an ambulatory treatment covered by the health insurance.

Methods: Cross-sectional descriptive study

Results: 111 patients mean age of 74.4 years (± 11.3 years), 84 (75.6%) were women. All consulted for osteoporotic fracture. The most frequent type of fracture was hip (51.4%), followed by vertebra (23.4%), wrist (22.5%) and humerus (4.5%). 87.4% (n=97) had no personal history of fracture and only 1% had a history of frailty fracture in a first-degree relative. Risk factors: 7.2% (n=8) used glucocorticoids, 3.6% (n=4) antiepileptics and 3.6% (n=4) warfarin. 21.6% (n=24) were smokers. 77.5% (n=86) had never previously undergone a densitometry despite the fact that, because of their age, they had indicated that this study had previously been performed. Knowledge of osteoporosis by patients: 49.5% (n=55) did not know that osteoporosis was present, 58.6% (n=65) did not know that fracture was the main complication of this disease and 62.2% =69) does not relate to fractures with osteoporosis. All patients were educated and sensitized about osteoporosis and the importance of diagnosis and treatment and they were given an order to perform densitometry at discharge, despite the above 24.3% (n=27) densitometry was performed in the next year of the fracture. As for treatment, 33.3% (n=37) received calcium plus vitamin D. Only 9.9% (n=11) received treatment for osteoporosis (7 patients with bisphosphonate and 4 with denosumab), none received teriparatide osteoformer therapy.

Conclusions: The present study demonstrates the lack of understanding by the Colombian patients about osteoporosis. Despite of clear indications described international guidelines, we have found a the lack of densitometry measurements on our follow up patients. More serious, only 10% of the patients received treatment for osteoporosis and none of them used a osteoformer therapy. This proves the suboptimal follow-up made by the health insurance companies of our country. Urgent educational and public health policies are needed.

FRI0545 COMPARISON OF MINERAL BONE DENSITY IN HIV-INFECTED PATIENTS FOLLOWED IN A SPANISH TERTIARY HOSPITAL WITH THAT OF NON HIV-INFECTED SPANISH POPULATION

F. López Gutiérrez[1], W.A. Sifuentes Giraldo[1], J.L. Casado Osorio[2], M. Vázquez Díaz[1]. *[1]Rheumatology; [2]Infectious Diseases, Ramon y Cajal University Hospital, Madrid, Spain*

Background: Patients with human immunodeficiency virus (HIV) have a higher prevalence of low bone mineral density (BMD) and fractures than the general population, but there are no comparative studies in Spanish population.

Objectives: To assess the BMD in HIV-infected patients followed in a tertiary hospital of Madrid and compare it with the ESOSVAL cohort, which included 11035 patients and is representative of non-HIV population seen in Spanish tertiary centers.

Methods: We performed a cross-sectional study in which BMD values were determined in a prospective cohort that included HIV-infected patients seen our center during the period 2010–2015. Collected data included demography, comorbidities, treatment and densitometric variables.

Results: 93 patients from a total of a total of 924 with BMD data were eligible for the study after discarding those younger than 55 years, because that group is not included in the ESOSVAL cohort. Mean age of patients of our whole cohort was 43.8 years (range: 17–83), 11% were older than 55 years, of whom 83 were men (83%). Most of them were Caucasians, with a mean body mass index 24.1 (range: 14,7–40.6). Median time of HIV infection was 162,6 months (interquartile range [IQR]: 77.7- 283,3), median CD4+ cells nadir was 224 (IQR: 100–332) and median maximun viral load was 4,9 log (IQR: 4,3–5,4); concomitant hepatitis C

virus infection was present in 29%. 25% were treated with tenofovir plus protease inhibitors, and 47% with tenofovir plus a non-nucleoside reverse transcriptase inhibitor. The mean value of BMD in lumbar spine (LS) was 0.93 g/cm^2 (range: 0.84–1.02) and in femoral neck (FN) 0.78 g/cm^2 (range: 0.69–0.86). For the comparison with the ESOSVAL cohort the worst value of T-score in either LS or FN was chosen and patients were classified according to WHO definitions (osteoporosis ≤ -2.5, osteopenia -1 to -2.5); the results are presented in the table. Only the data for the 50–64 and 65–74 years groups were compared because the number of older HIV patients in our center was small. Significant differences were found between the categories of osteoporosis in men in the 65–74 years old group, and that of osteopenia in women in the 55–64 years old group.

	55–64y		*p*-value	65–74y		*p*-value
	HIV+ n=60	ESOSVAL n=2893		HIV+ n=16	ESOSVAL n=1555	
Males						
T-score ≤ -2,5	20%	12.6%	0.08798	44%	11.2%	0.00005*
T-score -1 to -2,5	61%	48.9%	0.02888*	63%	59.2%	0.79102
Females						
T-score ≤ -2,5	31%	21%	0.38845	50%	29,8%	0.37768
T-score -1 to -2,5	82%	50.1%	0.01296*	50%	49,7%	0.99107

Conclusions: We observed a statistically significant increase in prevalence of osteoporosis in HIV-infected men in the 65–74 years group, and in osteopenia HIV-infected men in the 55–64 years group, in concordance with the presumed greater risk derived from a variety of causes (treatment, chronic inflammatory status, comorbidities, etc.). A non significant trend towards an increased prevalence of osteoporosis in the 55–64 years group, and in osteopenia in the 65–74 years group was seen. As for women, there was a statistically significant increase in osteopenia prevalence in the 55–64 years group with HIV and a non significant trend towards increased prevalence of osteoporosis in that age group, whereas no significant increase was observed in the 65–74 years HIV group, presumably due to the small number of patients included in it.

FRI0546 COMPARISON OF MINERAL BONE DENSITY AND RISK FRACTURE ASSESSED BY THE FRAX TOOL IN HIV-INFECTED PATIENTS FOLLOWED IN A SPANISH TERTIARY HOSPITAL WITH THOSE OF NON HIV-INFECTED SPANISH POPULATION

F. López Gutiérrez [1], W.A. Sifuentes Giraldo [1], M. Vázquez Díaz [1], J.L. Casado Osorio [2]. *[1] Rheumatology; [2] Infectious Diseases, Ramon y Cajal University Hospital, Madrid, Spain*

Background: The Fracture Risk Assessment Tool (FRAX) is a validated clinical fracture risk calculator that estimates 10-year risk of both major osteoporotic and hip fractures in the general population. However, its role in patients with human immunodeficiency virus (HIV) infection is still not clear because may underestimate their risk.
Objectives: To assess the bone mineral density (BMD) and 10-year fracture risk according to FRAX in HIV-infected patients followed in a tertiary hospital of Madrid and compare them with the ESOSVAL cohort, which included 11035 patients and is representative of the non-HIV population seen in Spanish tertiary hospitals.
Methods: We performed a cross-sectional study in which FRAX and BMD values were determined in a prospective cohort that included HIV-infected patients seen our center during the period from 2010 to 2015. Collected data included demography, comorbidities, treatment, risk factors required for the FRAX calculation and densitometric variables.
Results: 97 patients from a total of a total of 311 had bone densitometry data and FRAX assessment available and were included in this study. The mean age of the patients was 55.4 years (range: 50–80), 75 were men (77%), most of them were Caucasians (89%), with a mean body mass index of 24.2 (range: 15–32.7). Median time of HIV infection was 194 months (interquartile range [IQR]: 155.2- 259), median nadir of CD4+ cells was 168 (IQR: 81–308) and concomitant hepatitis C virus infection was present in 40%. Among the risk factors included in FRAX calculation, 44% reported smoking, 10% inadequate alcohol consumption and 3% hyperthyroidism; there was no history of steroid therapy or previous fractures and only one had a family history of hip fracture. The mean value of BMD in lumbar spine (LS) was 0.9 g/cm^2 (range: 0.83–0.99) and in femoral neck (FN) 0.74 g/cm^2 (range: 0.65–0.82). For the comparison with the ESOSVAL cohort the worst value of T-score in either LS or FN was chosen and the patients were classified according to WHO definitions; the results are presented in the table.

	Men 50–64y		*p*	Women 50–64y		*p*
	HIV (n=68)	ESOSVAL (n=2983)		HIV (n=21)	ESOSVAL (n=3043)	
T-score ≤-2,5	14%	12.6%	0.606	33%	21%	0.167
T-score -1 to -2,5	56%	48.9%	0.255	52%	50.1%	0.834
FRAX major fracture ≥10	1.8% (0.4–5.1)	0.1% (0–0.2)	0.002*	2,36% (1.3–4.1)	0.6% (0–1)	0.015
FRAX hip fracture ≥3	0.47% (0–3.5)	0.1% (0.-0.3)	0.002*	0.57% (0–2)	0.7 (0.4–1.1)	0.702

Only the data for the 50–64 years group were compared because the number of older HIV patients in our center was small. No significant differences were found between the categories of osteopenia and osteoporosis in both genders, but there was a significant difference with respect to the risk of both major and hip fractures in males, being higher in patients with HIV infection compared to the population of the ESOSVAL cohort.
Conclusions: HIV-infected patients followed in our center do not show significant differences regarding the prevalence of osteopenia and osteoporosis compared to non-HIV Spanish population represented by the ESOSVAL cohort. However, a trend towards a lesser BMD is seen in all HIV infected groups. The fracture risk estimated by FRAX is significantly higher in HIV-infected men probably due to a higher frequency of associated risk factors.

FRI0547 OSTEOPOROSIS AND BONE METABOLISM IN SYSTEMIC SCLEROSIS

Á. Horváth [1], K. Gulyás [1], H.P. Bhattoa [2], G. Szücs [1], Z. Szekanecz [1], S. Szamosi [1]. *[1] Department of Rheumatology; [2] Department of Laboratory Medicine, University of Debrecen, Faculty of Medicine, Debrecen, Hungary*

Background: Systemic sclerosis (SSc) has been associated with bone loss and increased risk for bone fractures. Disease-related factors, age, corticosteroid therapy may be associated with increased bone turnover and bone loss.
Objectives: Here we performed a detailed study on osteoporosis in SSc. We performed bone density assessment by DXA, as well as peripheral forearm quantitative CT (pQCT). In addition, we assessed bone biomarkers and correlated bone- and disease-associated measures.
Methods: Altogether 44 SSc patients (36 women, 8 men; age: 64.1 years; disease duration: 17.6 years) were randomly recruited for the study. Bone density was assessed by DXA at the lumbar spine and femoral neck. pQCT (Stratec) is able to assess total, trabecular and cortical density. We also determined FRAX, levels of vitamin D, as well as bone markers (Ca, PTH, osteoclacin, P1NP, beta-CTX), markers of autoimmunity (ANA, ACA and anti-Scl70) and clinical manifestations of the disease. Statistical analysis was performed by SPSS v22.0.
Results: Vitamin D levels were lower (53.9 +/- 36.8 nM) than the normal range (>75 nM). 34 out of 44 patients (77%) had D-hypovitaminosis. Abnormally increased PTH, P1NP, OC, CTX levels were observed in 10, 7, 2 and 6 patients, respectively. Previous fractures occurred in 19 patients (43%). The vertebral and hip FRAX values were 13.5% and 4%>respectively. By DXA, osteoporosis of the lumbar spine and hip was detected in 10 and 10 patients, while osteopenia were found in 16 and 20 patients, respectively. With respect to pQCT, total and trabecular bone density in SSc patients (248.4 and 150.9 mg/cm^3) was significantly lower than in healthy controls (354 and 193 mg/cm^3, respectively). Higher OC levels were assocated with the diffuse form of SSc (R=0.330, p=0.035). Longer disease duration correlated with lower pQCT total (R=-0.341, p=0.023) and trabecular density (R=-0.336, p=0.026). Interestingly, most bone markers (P1NP, OC, CTX) positively correlated with gastrointestinal manifestations. Furthermore, pQCT total bone density was siognificantly lower in patients with pulmonary involvement, digital ulcer and anti-Scl70+.
Conclusions: A high proportion of SSc patients have osteopenia or osteoporosis, as well as low vitamin D levels. As determined by pQCT, trabecular loss is more common. Both total and trabecular bone loss, as well as bone markers may be associated with disease duration, anti-Scl70 and some organ manifestations. SSc patients should be screened and treated for osteoporosis.

FRI0548 INFLUENCE OF HOMOCYSTEINE AND VERTEBRAL FRACTURES ON PREVALENT ABDOMINAL AORTIC CALCIFICATION IN POSTMENOPAUSAL WOMEN: A MULTICENTRIC CROSS-SECTIONAL STUDY

I. Ghozlani [1], A. El Maataoui [2], M. Ghazi [3], A. Kherrab [3], R. Niamane [3]. *[1] Rheumatology Department, Military Hospital; [2] Chemistry-Biochemistry Department, Faculty of Medicine and Pharmacy, Ibn Zohr University, Agadir; [3] Rheumatology Department, Military Hospital Avicenne, Marrakech, Morocco*

Background: Osteoporosis and cardiovascular diseases are two major public health problems. Both are associated with high morbidity, long-term hospitalization, mortality and loss of independence leading to institutionalization. Vertebral morphometry using dual-energy X-ray absorptiometry (DXA) also known as vertebral fracture assessment (VFA) is a fast, low-radiation technique which produces images that are of sufficient quality to be used to diagnose the presence of vertebral deformity consistent with fracture. VFA has demonstrated utility for vertebral visualization and thus is an important tool for fracture detection in women and men. It has been shown also in many populations that this technique can simultaneously identify abdominal aortic calcification (AAC). Hyperhomocysteinemia, a condition that recent epidemiological studies have shown to be associated with increased risk of vascular disease. A potential role of homocysteine in bone fragility has been considered from the observation of a high prevalence of osteoporosis in subjects with homocystinuria.

Objectives: The main of this study was to examine the relationship between plasma homocysteine (Hcy), asymptomatic osteoporotic vertebral fractures (VFs) using vertebral fracture assessment (VFA) and prevalent abdominal aortic calcification (AAC) in Moroccan postmenopausal women.
Methods: The study cohort consisted of 188 consecutive postmenopausal women with no prior known diagnosis of osteoporosis or taking medication interfering with bone metabolism. Mean age, weight, height, body mass index and plasma homocysteine were determined. Lateral VFA images and scans of the lumbar spine and proximal femur were obtained using a Lunar Prodigy Vision densitometer (GE Healthcare Inc., Waukesha, WI). VFs were defined using a combination of Genant's semiquantitative approach and morphometry. VFA images were also scored for prevalent AAC using a validated 24 point scale.
Results: Fifty-eight (30.9%) patients had densitometric osteoporosis. VFs were identified using VFA in 76 (40.4%) patients: 61 women had grade 1 VFs and 15 had grade 2 or 3 VFs. One hundred twenty nine women (68.6%) did not have any detectable AAC, whereas the prevalence of significant atherosclerotic burden defined as AAC score of 5 or higher, was 13.8%. A significant positive correlation between AAC score and homocysteine was observed. Women with extended AAC, were older, had a lower weight, BMI and BMD, higher homocysteine levels and more prevalent VFs than women without extended AAC. Multiple regression analysis showed that the presence of extended AAC was significantly associated with Age and grade 2/3 VFs and not independently associated with homocysteine levels.
Conclusions: This study did not confirm that homocysteine is important determinant of extended AAC in postmenopausal women. However, this significant atherosclerotic marker is independently associated with VFs regardless of age.

FRI0549 IMPACT OF CHEMOTHERAPY ON BONE MINERAL DENSITY IN POSTMENOPATHIC WOMEN WITH BREAST CANCER IN TREATMENT WITH AROMATASE INHIBITORS

J. Loarce-Martos [1], W.A. Sifuentes Giraldo [1], L.V. Maldonado Romero [1], M. Ahijón Lana [1], C. Velázquez Arce [1], N. Martínez Jañez [2], M. Vázquez Díaz [1]. *[1] Rheumatology; [2] Oncology, Ramon y Cajal University Hospital, Madrid, Spain*

Background: Aromatase inhibitors (AI) been related to an increased risk of bone loss and fractures in women receiving these drugs as adjuvant treatment, but few studies have assessed the impact of prior chemotherapy (CT) on bone mineral density (BMD) loss associated to AI.
Objectives: To assess the impact of CT prior to the initiation of AI on BMD in postmenopausal patients with breast cancer (BC) seen at a Spanish tertiary care hospital.
Methods: We perform a longitudinal study in patients who received AI after initial CT (CT group) or as adjuvant therapy without prior CT (non-CT group) followed up for 12 months. BMD was assessed by DXA in lumbar spine (LS) and femoral neck (FN) at baseline and after 12 months of AI treatment following the usual protocol of our center, with in vitro coefficient of variation of 1% in both locations and estimated minimal significant change (MSC) of 0.0223 g/cm^2 in LS and 0.0288 g/cm^2 in FN. Demographics, neoplastic disease data, and osteoporosis risk factors were also collected.
Results: 69 patients (CT group 39, non-CT group 30) attended at our center between August 2011 and December 2014 were included. Mean age at diagnosis was 59.9±7.7 years, most of them have BC stages I-II (84%). Most frequent AI in both groups was letrozole (95%). Baseline characteristics were similar, except for age at diagnosis that was significantly higher in the non-CT group, these data are presented in the table. Mean BMD at the start of AI was significantly lower in LS in the CT group (0.7793 g/cm^2) than in the non-CT group (0.8483 g/cm^2) (p=0.018), but no difference in FN (CT 0.6764 g/cm^2 and non-CT 0.7077 g/cm^2, p=0.123). A significant difference in LS (CT 0.7685 g/cm^2, non-CT 0.8397 g/cm^2, p=0.003) was found in the comparison of BMD means between the two groups at 12 months but not in FN (CT 0.6598 g/cm^2, non-CT 0.6689 g/cm^2, p=0.369). After 12 months of treatment with AI, mean BMD change in the CT group in LS was -0.0107 g/cm^2 (95% confidence interval [CI] -0.0269, +0.0055, p=0.189) and in FN -0.0165 g/cm^2 (95% CI: -0.0339, +0.0009, p=0.063), while in the non-CT group the means changes were in LS -0.0085 g/cm^2 (95% CI -0.0416, +0.0244, p=0.599) and FN -0.0388 g/cm^2 (95% CI -0.0707, -0.0068, p=0.019). During the study period there was a fracture in each group (CT 2.6%, non-CT 3.3%).

	CT group (n=39)	Non-CT group (n=30)	p-value
Age at diagnosis, years (mean ± SD)	58.2±7.3	62±7.9	0.042*
Age of menarche, years (mean ± SD)	12.5±1.2	12.5±1.1	0.980
Age of menopause, years (mean ± SD)	48±4.2	48.9±4.1	0.394
Age >65 years	13 (33%)	9 (30%)	0.284
Body mass index (mean ± SD)	25.8±6	27.6±4.3	0.184
Osteopenia/osteoporosis before AI	35 (89%)	26 (86%)	0.692
Smoking	5 (13%)	2 (6%)	0.401
Previous fracture	2 (5%)	2 (7%)	0.786
Family history of fracture	2 (5%)	2 (7%)	0.786
Calcium + Vitamin D Supplements	26 (67%)	14 (47%)	0.095
Radiotherapy	27 (69%)	23 (77%)	0.493
Prior tamoxifen	5 (13%)	3 (10%)	0.717
Bisphosphonates	2 (5%)	1 (3%)	0,717

Conclusions: Our results do not demonstrate that CT prior to AI treatment significantly decreased BMD during the first year. Mean change in both LS and FN in CT group was not superior to MSC nor to the change in non-CT group, although they had a significantly lower mean BMD in LS than the latter group and this difference was maintained at the end of the study period.

FRI0550 MALE PATIENTS WITH RHEUMATOID ARTHRITIS HAVE AN INCREASED RISK OF OSTEOPOROSIS: FREQUENCY AND RISK FACTORS

J.-H. Park [1], S.-G. Lee [1], E.-K. Park [1], S.-M. Kweon [1], D.H. Sohn [2], Y.-K. Kim [3], H.-S. Tag [3], G.-T. Kim [3], J.-W. Lee [4]. *[1] Internal Medicine, Pusan National University School of Medicine, Pusan National University Hospital; [2] Microbiology and Immunology, Pusan National University School of Medicine; [3] Internal Medicine, Kosin University College of Medicine; [4] Internal Medicine, Busan St. Mary's Hospital, Busan, Korea, Republic Of*

Background: Osteoporosis is a well-known extra-articular manifestation of rheumatoid arthritis (RA) and almost 2 times higher prevalence of osteoporosis was reported in female patients with RA than in healthy subjects. Accordingly, patients with RA are at increased risk of fragility fractures that lead to significant morbidity and mortality and higher healthcare cost. However, most previous epidemiologic studies regarding osteoporosis in RA have focused on female subjects, and little attention has been given to male patients with RA.
Objectives: To compare the prevalence of osteoporosis between male patients with RA and healthy subjects and to identify the risk factors of osteoporosis in male patients with RA.
Methods: By using a cross-sectional design, we recruited 76 male patients with RA aged 50 years and over and 76 sex-matched and age-matched healthy subjects at a university-affiliated rheumatology centre in South Korea from August 2014 to August 2016. We measured bone mineral density (BMD) at L1–4 levels of the lumbar spine and the hip (femoral neck and total hip) in all the subjects by using dual-energy X-ray absorptiometry (DEXA). We assessed the prevalence of osteoporosis defined as a T-score of ≤-2.5 according to the WHO criteria. We also investigated potential risk factors of decreased BMD and the presence of osteoporosis in male patients with RA using linear and logistic regression analyses, respectively.
Results: The mean age and body mass index (BMI) of the male patients with RA were 64.5 years and 22 kg/m^2, respectively, which were comparable with those of the healthy controls. The overall prevalence of osteoporosis at either the spine or the hip in the male patients with RA was significantly higher than that of the healthy controls (22.4% vs 10.5%, respectively; p=0.049). However, no significant differences in the prevalence of osteoporosis at the spine (19.7% vs 10.5%, respectively; p=0.113) and the hip (3.9% vs 0%, respectively; p=0.245) were found between the patients with RA and the controls. For the male patients with RA, the median disease duration was 37 months, the mean 28-joint Disease Activity Score using erythrocyte sedimentation rate (DAS28-ESR) was 3.28 and the median modified total Sharp score was 6. An increased titre of anti-cyclic citrullinated antibody showed a trend toward lower L1–4 BMD (β=-0.0007, p=0.057) in the multivariable linear regression analysis. In addition, DAS28-ESR of >3.2 was independently associated with the presence of osteoporosis (OR=3.85, 95% CI=1.13–13.17, p=0.032) after adjusting for confounding factors. The patients with RA whose BMIs were ≤22 kg/m^2 had a higher risk of osteoporosis (OR=3.43, 95% CI=1.04 -11.33, p=0.043).
Conclusions: Similar to their female counterparts, the frequency of osteoporosis in male patients with RA had an osteoporosis prevalence of about 2.1 times higher than that of the healthy subjects. Increased DAS28-ESR was an independent risk factor of osteoporosis. Our data suggest that appropriate management for osteoporosis in patients with RA is crucial not only for postmenopausal women, but also for men aged 50 years and over.

FRI0551 USE OF GLUCOCORTICOID IS THE RISK FACTOR FOR INADEQUATE RESPONSE TO THE TREATMENT OF OSTEOPOROSIS BY DENOSUMAB

K. Orita [1], T. Koike [2]. *[1] Orthopaedic Surgery, Shirahama Hamayu Hospital, Shirahama Foundation for Health and Welfare; [2] Orthopaedic Surgery, 2. Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama Foundation for Health and Welfare, Shirahama, Japan*

Background: In treating rheumatoid arthritis (RA), T2T (treat-to-Target) is the most reliable treatment strategy. Recent reports have indicated that reaching normal levels of bone mineral density (BMD) might be important for the prevention of fractures in osteoporosis treatment (reference 1 and 2).From this fact, there might be a possibility that T2T targeting BMD might be feasible also in osteoporosis treatment. In doing so, medicines with the ability to sufficiently increase BMD at a fast speed should be needed. Denosumab (DMAb) specifically inhibits the receptor activator for nuclear factor-kappa B ligand (RANKL) improves BMD rapidly at lumbar or hip. Therefore, DMAb is one of candidate drugs for T2T

practice, and it is very important to know risk factors that attenuate its effect in the treatment of osteoporosis.
Objectives: The aim of this study was to identify risk factors for inadequate response to the treatment of osteoporosis by DMAb.
Methods: Sixty-six patients treated with DMAb were observed retrospectively for one year. The mean age was 74 years, women were 91% and 36 patients with RA were included.We measured BMDs at lumbar and hip by dual-energy X-ray absorptiometry (Hologic Discovery) at baseline and one year later. We evaluated the effects of age, body mass index (BMI), use of glucocorticoide (GC), previous treatment for osteoporosis, BMD at baseline, bone metabolic markers (BAP; bone alkaline phosphatase, uNTx; urinary N-telopeptide), serum Ca and P levels and the previous vertebral fractures for inadequate response to DMAb.We defined the cases who could not gain the increase of BMD over 2% at the lumbar vertebrae and 4% at the hip as inadequate responders by taking the measurement error into account.
Results: Dose of PSL was significantly high in non-responder at non-RA trochanter and RA lumbar BMD (p=0.028, 0.006). BAP was higher in non-responder at RA lumbar BMD (p=0.007). Urinary NTX was significantly low in non-responder at non-RA lumbar and RA trochanter BMD (p=0.026, 0.048). Previous treatment for osteoporosis was significantly high in non-responder at non-RA lumbar, total hip and trochanter BMD (p=0.026, 0.022, 0.003).Multivariate logistic analysis including age, BMI, dose of PSL, BMD at baseline, BAP, uNTX, Ca and P level as confounders revealed that dose of PSL was the significant risk factors for no-response at lumbar BMD (OR0.634, 95% CI 0.433–0.93, p=0.02).
Conclusions: Patients receiving GC might not gain an adequate response to the treatment by DMAb for osteoporosis. Reducing dose of GC or altanative treatment regimen might be necessary.

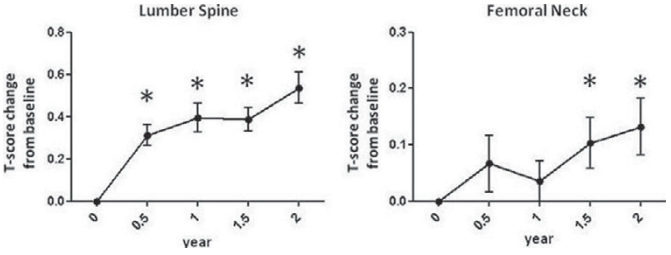
FRI0552 THE CORRELATION BETWEEN EROSION AND BONE MINERAL DENSITY IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH DENOSUMAB AND BIOLOGIC DMARDS: A PROSPECTIVE COHORT STUDY



K. Izumi, Y. Kaneko, T. Hasegawa, T. Takeuchi. *Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan*

Background: We have previously reported the efficacy of denosumab combined with biological DMARDs on radiographic progression in rheumatoid arthritis (RA).
Objectives: The aim of this work was to reveal the relationship between the changes in structural joint damage and in bone mineral density (BMD) in patients with RA who were started on denosumab in addition to biologic DMARDs.
Methods: We prospectively evaluated erosion (ERO) and joint space narrowing (JSN) scores by the van der Heijde-modified Sharp method and T-scores of the lumbar spine (LS) and total hip (TH) by dual energy X-ray absorptiometry scans at baseline and 12 months in the RA patients who were started on denosumab (60 mg every 6 months) for osteoporosis in addition to biologic DMARDs. We compared the 12-month change in ERO or JSN scores (∆ERO; ∆JSN) with the change in T-scores of the LS or TH (∆LS; ∆TH).
Results: Twenty-two patients (1 man and 21 women) at the mean±SD age of 74.4±8.1 at baseline were included in this study. The T-scores of the LS and TH at baseline were -1.38±1.57 and -2.53±0.85, respectively. ∆ERO, ∆JSN, ∆LS, and ∆TH were 0.16±0.49, 0.44±0.66, 0.30±0.39, and 0.20±0.42, respectively. BMD was significantly increased from baseline to 12 months. There was a significant inverse correlation between the ∆ERO and the ∆TH (ρ=–0.473, P=0.03), while there was no correlation between the ∆ERO and the ∆LS (P=0.98) nor correlation between the ∆JSN and the ∆LS (P=0.57) or ∆TH (P=0.25).
Conclusions: The change in erosive joint damage of hands and feet showed a significant relationship with the change in femoral BMD in patients with RA treated with denosumab and biologic DMARDs. BMD was ameliorated along with erosion by denosumab combined with biologic DMARDs, and may be an indicator for joint destruction.

FRI0553 THE EFFICACY OF 2-YEARS DENOSUMAB TREATMENT FOR GLUCOCORTICOID-INDUCED OSTEOPOROSIS (GIOP)

K. Akashi[1], K. Nishimura[2], G. Kageyama[3], S. Ichikawa[1], T. Shirai[1], Y. Yamamoto[1], Y. Ichise[1], H. Yamada[1], I. Naka[1], D. Waki[1], T. Okano[1], S. Takahashi[1], Y. Ueda[1], S. Sendo[1], A. Onishi[1], J. Saegusa[1], A. Morinobu[1]. *[1]Department of Rheumatology and Clinical Immunology, Kobe University Hospital, Kobe,[2]Department of Endocrinology and Rheumatology, Kurashiki Central Hospital, Kurashiki;[3]Department of Rheumatology, Hyogo Prefectual Amagasaki General Medical Center, Amagasaki, Japan*

Background: Osteoporosis is one of the important adverse effects in the glucocorticoids treatment for the patients with rheumatoid arthritis (RA) and connective tissue diseases (CTDs). Although the usefulness of denosmab for primary osteoporosis has been well-established, the efficacy for GIOP remains unclear.
Objectives: This study aimed to clarify the therapeutic effects of denosumab for GIOP.
Methods: We evaluated bone mineral density (BMD) and serum markers of bone metabolism (BAP, NTx, TRACP-5b and P1NP) of patients who had been treated with over 5mg of predonisolone for RA and CTDs, and denosumab for GIOP, for two years in Kobe University Hospital. BMD and serum markers were evaluated every six months for 2 years from the baseline. The changes of those data from baseline were analyzed by Student's t test using GraphPad Prism 5 software and $p<0.05$ was considered statistically significant.
Results: Number of the patients were 53 (male: 4 cases, female: 49 cases), and their characteristics at the beginning of denosumab treatment were as below; age: 64.19±12.0 years old, dose of prednisolon: 10.59±9.97mg/day, BMD of lumber spine: 0.768±0.112g/cm^3, T-score of lumber spine: -2.28±1.01, BMD of femoral neck: 0.540±0.085g/cm^3, T-score of femoral neck: -2.28±0.76. After 2-years denosumab treatment, T-scores of lumber spine (0.54±0.39 gain) and femoral neck (0.13±0.26 gain) were significantly increased from baseline (Figure; mean ± SEM. *:$p<0.05$). In addition, the serum markers of bone metabolism, both absorption and formation, were significantly suppressed with denosumab.

Conclusions: Denosumab can suppress bone metabolic turnover, and increase lumber spine and femoral neck T-scores of GIOP patients.
Disclosure of Interest: None declared

FRI0554 NEW BIOMARKER FOR DIAGNOSIS OF OSTEOPOROSIS IN RHEUMATOID ARTHRITIS PATIENTS

Y. Polyakova, L. Sivordova, Y. Akhverdyan, V. Kravtcov, B. Zavodovsky. *Federal State Budgetary Institution "Research Institute of Clinical end Experimental Rheumatology", Volgograd, Russian Federation*

Background: Bone mineral density and proteins/peptides determination in blood and urine as markers of bone resorption and formation are currently used to diagnose osteoporosis (OP) and metabolic bone diseases. However, these methods have some disadvantages for bone turnover evaluation. Recent evidence suggests that in RA changes in the secretion of hormones of white adipose tissue can be revealed [2]. One of them is Adiponectin possessing anti-inflammatory, anti-diabetic and anti-atherogenic properties [1]. Changes in Adiponectin levels may reflect influence of immune inflammation on bone turnover.
Objectives: To study the clinical and diagnostic value of serum Adiponectin determination in RA patients complicated by OP.
Methods: We examined 88 women with documented diagnosis of RA and mean disease duration of 6.56±0.88 years. We used EULAR/ARA 2010 criteria to diagnose the patients. Female patients with II degree of disease activity (DAS28), Steinbrocker stage II (erosive), rheumatoid factor- and anti-cyclic-citrullinated peptide antibody-positive were prevalent. We excluded patients who had surgery or developed an infection within the last 8 weeks, pregnant and breast-feeding women, those with severe heart, liver or kidney disease, immune deficiency, leukopenia or chronic infection.
A control group of 45 healthy females aged of 25 and 59 years were included in the study. There were no reported findings of joint pain and RA symptoms in the group. The groups were adjusted for age ($p>0.05$) and showed no statistically significant differences.
We measured serum Adiponectin levels (μg/ml) using Human Adiponectin ELISA commercial test systems. We plotted a curve using computer software. We diagnosed OP using dual-energy X-ray absorptiometry with LUNAR DPX PRO (GE, USA).
Results: Serum adiponectin levels in the control group were 12.5±0.9 μg/ml (M±m). Adiponectin levels in healthy subjects measured as M ± 2d, ranged between 0.44 and 24.56 μg/ml. Patients with OP and RA had significantly higher levels of serum Adiponectin ($p<0.001$). Mean serum Adiponectin levels in RA patients who had normal bone density and had no OP were 35.21±0.6 μg/ml. Mean serum Adiponectin levels in RA/OP patients with low bone mineral density were 52.42±0.69 μ g/ml. Adiponectin levels of 44 μg/ml and higher were

associated with osteoporosis. Adiponectin levels of 43.9 μg/ml and lower were associated with normal bone density.
Conclusions: Thus, we revealed that Adiponectin levels depend on osteoporosis presence in RA patients. We suppose that Adiponectin determination may be useful laboratory marker for OP diagnosis.

FRI0555 LEFT VENTRICULAR EJECTION FRACTION AND BONE MINERAL DENSITY AFTER CARDIAC TRANSPLANTATION

L. Bautista Aguilar, A. Salmoral Chamizo, I. Gomez Gracia, R. Jimenez Gasco, P. Font Ugalde, E.C. Lopez Medina, M.L. Ladehesa Pineda, L. Perez Sanchez, A. Escudero Contreras, E. Collantes Estevez. *Rheumatology, Reina Sofia University Hospital/IMIBIC/ University of Cordoba, Cordoba, Spain*

Background: Left ventricular ejectionfraction (LVEF) has beendirectlyassociatedwith BMD in patientswithheartfailure. Nevertheless, no study has linked yet the left ventricular ejection fraction to bone mineral density and fragility fractures in cardiac transplantation.
Objectives: The main aim of this study was to evaluate the possible relationship between LVEF and BMD in heart transplantation and the association of LVEF with 25 OH vitamin D, paratohormone (PTH) and markers of bone remodeling in patients with heart transplantation (osteocalcin, telopeptide C terminal (CTX).
Methods: Seventy nine patients (66 male) were included in this cross-sectional study with a mean age of 55,75±14,81 years, body mass index (BMI) values of 26,95±5,35 kg/m^2 and an average post-transplantation period of 8,46±8,71 years. Transthoracic doppler echocardiography measuring LVEF (%) was calculated for each of patients, as well as bone mass study that included: bone mineral density scans of lumbar spine and hip, spine radiography, biomarkers of bone metabolism (calcium, phosphorus, osteocalcin,CTX,Parathyroid hormone and vitamin D). The association of LVEF with BMD and biomarkers of bone remodeling was determined by performing multiple linear regression analysis adjusted for variables directly related to BMD (age, sex, BMI, post-transplantation period and pharmacological treatment (daily corticoids dose, immunosuppressive treatment).
Results: A total of 79 patients were included in this present study. BMD in osteoporotic range was found in 31.2% of patients (17.7% in spine,16.52% in femoral neck and 13% in hip). Vitamin D deficiency ($\leq$20ng/d) was detected in 68.4% of patients. Vertebral fracture was found in 30.4% and a 2.6% hip fracture. Bivariate analysis showed that the group of patients with FEVI $\leq$65% had a higher proportion of femoral neck osteoporosis (p=0.04), higher proportion of osteoporosis in total hip (p=0.03) and higher percentage of vertebral fractures (p=0.04) compared with group with LVEF$>$65%.
The multiple linear regression analysis indicated that LVEF was independently associated with osteoporosis in spine (B = -5.225, p=0.011), femoral neck osteoporosis (B = -5.411, p=0.015) and vertebral fractures (B = -5.433, p=0.002). In addition, LVEF was associated with osteocalcin levels (B = -0.105, p=0.002).
Conclusions: These results suggest that post-transplantation LVEF may have an influence on bone remodeling. However, further studies are neededin order to consider LVEF as a risk factor for osteoporosis and fractures due to fragility after heart transplantation.

FRI0556 LONG-TERM EFFECTS OF BACK EXTENSOR STRENGTHENING EXERCISES ON QUALITY OF LIFE IN WOMEN WITH OSTEOPOROSIS

S.A. Raeissadat[1], A. Khalili[2], L. Sedighipour[3], M. Heidari Almasi[4]. *[1]Physical Medicine & Rehabilitation Research Center, Modarres hospital; [2]Department of Orthopedic Surgery, Department of Orthopedic Surgery; [3]Physical Medicine & Rehabilitation Research Center, Physical Medicine & Rehabilitation Research Center; [4]Boo-Ali hospital, Tehran, Iran, Islamic Republic Of*

Background: A correlation exists between bone mineral density and physical activity level, suggesting that exercise may increase peak bone mass. Back extensor strength has been of major importance and had a strong effect on quality of life in this population.
Objectives: The aim of the present study was to evaluate the long-term effect of back extensor strengthening exercises on health-related quality of life (QOL) in women with osteoporosis.
Methods: In this randomized clinical trial, 183 women with osteoporosis were treated with pharmacotherapy and weight-bearing and balance-training exercises. The case group additionally performed back extensor exercises at home. Patients filled out the Persian version of the Short Form (SF-36) QOL questionnaire at baseline and 6 months post treatment.
Results: At the end, all physical and mental parameters of the SF-36 questionnaire improved significantly in the case group, except for one subscale of mental health, compared to the control group. In the control group, only some physical health dimensions (bodily pain, role limitation, physical function, vitality), and mental health status as a mental health subscale improved.
Conclusions: considering a major impact of back extensor exercises on improving QOL in women with osteoporosis over the long term, these exercises should be prescribed in routine management of these patients.

FRI0557 DOES WEIGHTED KYPHO-ORTHOSIS (WKO) REDUCE RISK OF FALL IN WOMEN WITH OSTEOPOROSIS? A PRELIMINARY STUDY

S.A. Raeissadat[1], S.M. Rayegani[2], L. Sedighipour[1], M. Hashemi[2], M.H. Bahrami[2]. *[1]Physical Medicine & Rehabilitation Research Center; [2]Physical Medicine and Rehabilitation research center, Tehran, Iran, Islamic Republic Of*

Background: It was suggested that posture training support with spinal orthosis including weighted kyphorthosis can improve balance in patients with osteoporosis.
Objectives: The aim of the present study was to determine the effects of weighted kyphorthosis on improving dynamic balance tests and consequently reducing risk of fall in women with osteoporosis.
Methods: In this Randomized controlled clinical trial, twenty three patients with osteoporosis were included. The patients were assigned into two groups: 1) control group who received 4-week home-based daily exercise program and 2) intervention group (weighted kyphorthosis) who performed exercises and wore weighted kyphorthosis for one hour twice a day. Patients were assessed using computerized balance tests by Balance Master (NeuroCom) (Limits of Stability, Step Quick Turn, Sit to Stand and Walk across tests) before and 4 weeks after start of treatment.
Results: Speed in walk across test was improved significantly in both groups compared to baseline from (77.6±25 cm/s to 91.57±30 cm/s and from 72.60±20cm/s to 88.73±18 cm/s)in case and control groups respectively. Improvement in right turn time in step quick turn, end point excursion and mean of excursion parameters of Limits of Stability was more significant in orthosis group in comparison with control group ($P<0.05$).
Conclusions: Applying WKO together with exercise program improved some computerized balance tests in women with osteoporosis.WKO can be suggested as an effective intervention in postmenopausal women in order to reduce the risk of falling.
Key words: Osteoporosis, balance tests, Weighted KyphOrthoris, posture training support.

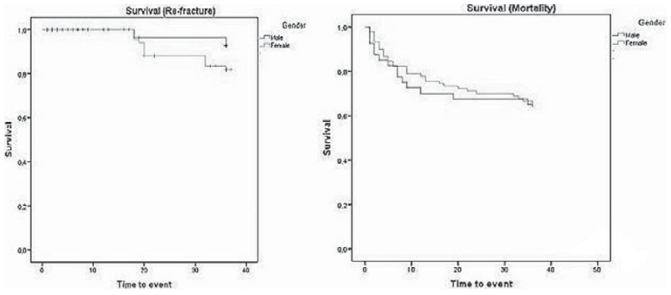
FRI0558 PREDICTORS OF MORTALITY AND RE-FRACTURE AT 1 AND 3YEARS AFTER HIP FRACTURE

L. Brites, M. Marques, A. Daniel, M. Santiago, A. Marques, J. Pereira da Silva. *Rheumatology department, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal*



Background: Osteoporosis is a major health problem, particularly in the elderly, because of fragility fractures and their consequences. Hip fractures (HF) are the most ominous in terms of morbi-mortality.
Objectives: The aim of our work was to establish the current mortality and re-fracture rate at 1 and 3 years after HF, as well as their predictors.
Methods: The study included all patients aged $>$40 years, admitted to Coimbra University Hospital between May and October 2013 with the diagnosis of HF. Demographic and clinical data related to the fracture episode was collected from medical files. Patients or the caregiver were contacted to assess potential risk factors at baseline and major post-fracture events at 1 and 3 years after the index HF. The mortality and re-fracture rate 1 and 3 years after fracture were calculated. Possible predictor variables were tested by cox regression analysis: age, gender,

Table 1. Mortality and refracture predictors

	Mortality		Re-fracture	
	p-value	Exp (b)	p-value	Exp (b)
Gender	0,106	2,052	0,265	3,089
Age	0,002	1,075	0,276	0,953
Katz index	0,116	1,154	0,752	0,918
Physiotherapy	0,020	2,167	0,499	0,638
BMI	0,812	0,991	0,142	0,891
Parent hip fracture	0,015	0,355	0,196	0,322
Current smoking	0,453	0,615	0,394	0,417
Corticotherapy	0,013	0,404	0,639	0,637
Rheumatoid arthritis	0,071	2,848	0,798	1,410
Secondary osteoporosis	0,172	0,566	0,154	0,321
Alcohol intake	0,037	0,370	0,980	348544,658
Charlson index	0,000	1,384	0,835	0,941
Number of re-fractures	0,660	0,781		
Anti-osteoporotic treatment			0,430	0,474

physiotherapy, number of re-fractures, BMI, parent hip fracture, current smoking, corticotherapy, rheumatoid arthritis, secondary osteoporosis, alcohol, history of falls, anti-osteoporotic treatment, Katz index of independence in activities of daily living and Charlson comorbidity index. All FRAX® variables were defined as established in this algorithm.

Results: A total of 130 patients satisfied the inclusion criteria, with a mean age of 82±8,7 years, 69% being female). Mortality rates were of 30% and 41% at 1 and 3 years after HF respectively (Fig.1). Age, physiotherapy, parent fractured hip, corticotherapy, alcohol consumption (>3/day) and Charlson índex were statistically significant predictors of mortality at 3 years in multivariable analysis (Tab.1). Re-fracture rates at 1 and 3 years after the index fracture was 3,8% and 11% respectively (Fig.1). We were unable to identify any statistically significant predictors of re-fracture.

Conclusions: We concluded that HF have a great impact on the older population, leading to high morbidity and mortality. In our study, age, physiotherapy, parent hip fracture, corticotherapy, alcohol consumption and Charlson índex are related with increasing mortality in patients who suffered a fagility HF.

FRI0559 CORRELATION OF THE FRACTURE RISK ASSESSMENT TOOL (FRAX) AND ASYMPTOMATIC MORPHOMETRIC VERTEBRAL DEFORMITIES IN HIV-INFECTED PATIENTS

M. Llop Vilatella[1], C. Medina Quiñones[1], C. Macía Villa[1], W.A. Sifuentes Giraldo[1], M. Vázquez Díaz[1], J.L. Casado Osorio[2]. *[1]Rheumatology; [2]Infectious diseases, Hospital Universitario Ramón y Cajal, Madrid, Spain*

Background: Patients infected with the human immunodeficiency virus (HIV) have a high rate of low bone mineral density (BMD) and is thought to be multifactorial. Some instruments have been developed to estimate the risk of osteoporotic fracture in the general population such as the WHO Fracture Risk Assessment Tool (FRAX), which allows calculating the 10-year probability of fractures in men and women from clinical risk factors with or without the measurement of femoral neck BMD. The cut-off values for high risk of hip fracture >3% and for major osteoporotic fracture >20%. Although FRAX has been validated in multiple large cohorts, still there are no clear recommendations of its use in HIV-infected patients older than 50 years.

Objectives: To evaluate the utility of FRAX tool in the prediction of risk of vertebral morphometric deformity (MVD) in HIV-infected patients over 50 years old seen in a Spanish tertiary care center.

Methods: We performed a cross-sectional study in HIV-infected patients with age 50 years treated in our centre during the period 2014–2016. Demographics and risk factors were collected through a specific survey. FRAX was calculated adding HIV as a cause of secondary osteoporosis in all patients with and without BMD measured by dual-energy X-ray absorptiometry scan (DXA). The MVD were assessed using the Genant's semiquantitative method. The sensitivity and specificity of the test were assessed and correlations made with the presence of MVD.

Results: A total of 121 patients were included, 34 women (28%), with a mean age of 54.1 years (range: 50–75). MVD was detected in 25 cases (21%). The patients presented with a mean BMI of 23.7 kg/m^2, 33% were smokers, 7% had a consumption of ≥3 doses of alcohol per day, 9% had a family history of hip fracture but no patient presented with previous history of fracture, corticoid treatment or rheumatoid arthritis. The mean FRAX score for major osteoporotic fracture without BMD was of 2.29 (1.1–8.5), there were 2 patients above 7 and any above 10; the mean FRAX score for hip fracture without BMD was of 0.64 (0.1–3.9), 2 patients were above 3. With DXA, osteoporosis in femoral neck was detected in 8% and in the lumbar spine in 30%, while femoral neck osteopenia was detected in 64% and in the lumbar spine in 45%. Including DXA data, the mean FRAX score for major osteoporotic fracture was 2.52 (0.2–8.2), 2 patients were above 7, and for hip fracture the mean FRAX score was 0.67 (0.01–4.4), with 2 patients above 3. The values of FRAX with DXA or without DXA were very similar, with a variation of -0.4 for the mean value of major osteoporotic fracture and +0.03 for the mean value of hip fracture. In ROC curve, a value above 1 in FRAX for hip fracture with DXA, detected 9 MVD of 29 patients (sensitivity 38%, specificity 80%), a value above 2 detected 4 MVD of 10 patients (sensitivity 17%, specificity 93%) and a value of 3 detected 1 MVD of 2 patients (sensitivity 4%, specificity 99%).

Conclusions: The FRAX tool does not identify properly the HIV-infected patients older than 50 years with MVD as well as the patients who need DXA. An alternative could be to perform X-rays of thoracic and lumbar spine as a screening method in HIV-infected patients with risk factors.

FRI0560 PREDICTORS OF FRACTURES IN FEMALE PATIENTS WITH ANOREXIA

M. Rahm, M. Bukhari. *Rheumatology, Royal Lancaster Hospital, Lancaster, United Kingdom*

Background: Anorexia Nervosa (AN) is an eating disorder characterised by extremely low body weight and body image distortion. It is more common in females and is expected to become increasingly more prevalent. Numerous studies have found AN to have a detrimental effect on bone health. The evidence shows that anorexia is associated with reduced bone mass and strength which increases fracture risk. Few staudes have looked at other predictors of fracture in these patients.

Objectives: The aim of this study was to determine whether further predictors of fracture could be found in female patients suffering from anorexia nervosa (AN).

Methods: Female patients with anorexia refereed for a bone mineral density (BMD) DEXA scan from June 2006 to October 2014 were identified. This cohort of patients was split into two subgroups depending on their fracture status. Demographics collected on scanning and factors such as age at DEXA scan, height, weight, body fat percentage, BMI, lumbar spine L1-L4 BMD and femoral neck BMD were used to compare the fracture group against the controls. Categorical variables such as smoking, comorbidities (Rheumatoid arthritis), alcohol, family history and steroid use were compared using chi squared test and the T test was used tompare continous variables. Logistic regression models were used to model fractures unadjusted and adjusting for age at scan.

Results: A total of 193 female patients with anorexia were included: 45 (23.3%) had sustained a fracture. The results of statistical analysis are shown in Table 1. The data showed there is a significant association with having a low femoral neck BMD and increased fracture risk OR 0.036 (95%, CI 0.003, 0.497). The case group was also significantly taller OR 1.061 (95%, CI 1.009, 1.117) and older P value 0.0027 (95% combined CI 39.193, 42.682). There was no correlation with any of the categorical variables and fracture risk, see Table 2 for results.

Table 1. Results of statistical analysis of continuous variables

Characteristic	Significance (P value)	Cases with fractures	Control group
Age at scan (years)	0.0027	45.71 ±SD10.36	39.49 ± SD12.46
Height (cm)	0.021	165.08 ± SD7.45	162.66 ± SD6.82
Weight (kg)	0.129	58.16 ± SD13.68	53.73 ± SD11.83
Body Fat (%)	0.536	16.36 ± SD11.75	13.62 ± SD10.28
BMI	0.601	21.24 ± SD4.31	20.31 ± SD4.43
Lumbar spine (L1-L4) (g/cm^2)	0.053	0.98 ± SD0.18	1.03 ± SD0.14
Femoral neck BMD (g/cm^2)	0.013	0.81±SD0.15	0.86±SD0.14

Table 2. Results of statistical analysis of categorical variables

Characteristic	Cases with fracture (45)	Control group (148)	Significance (P value)
Smoker	28.9% (13)	34.46% (51)	0.445
RA	2.22% (1)	0.68% (1)	0.349
Alcohol	8.89% (4)	8.78% (13)	0.524
Family history	31.11% (14)	22.97% (34)	0.403
Steroid	15.56% (7)	8.78% (13)	0.197

Conclusions: This study demonstrates that fractures in female patients with anorexia are more likely to occur in those who are taller, older at DEXA scan and in those who have a lower femoral neck BMD. This would inidcate that cortiocal bone loss and taller stature are indepent risks in this cohort. Further work using vitamin D levels as a risk should be performed.

FRI0561 SAFETY OF DENOSUMAB IN POST-MENOPAUSAL OSTEOPOROSIS AND IN CANCER: A SYSTEMATIC REVIEW AND META-ANALYSIS

M. Aubailly[1], T. Barnetche[2], B. Combe[1], C. Gaujoux-viala[3], C. Lukas[1], J. Morel[1], H. Che[1]. *[1]CHU lapeyronie, Montpellier; [2]CHU bordeaux, Bordeaux; [3]CHU Nîmes, Nîmes, France*

Background: Denosumab is a RANK ligand antibody (1) used for the treatment of post-menopausal osteoporosis (OP) and prevention of bone metastases complications (2,3).

Objectives: The aim of this meta-analysis was to assess the safety of Denosumab.

Methods: Data sources included MEDLINE, EMBASE, Cochrane Library, and recent abstracts from ACR and EULAR congresses were searched until March 2016. Randomized controlled trials comparing the safety of Denosumab to placebo or bisphosphonates (BP) in postmenopausal OP and in cancer (either cancer with bone metastases or with hormone therapy) were selected. Data were

extracted by one investigator, confirmed by another, and pooled in meta-analysis using Review Manager software (Cochrane collaboration).
Results: 6136 articles were of potential interest, and 19 met the inclusion criteria. 7 articles compared the safety of Denosumab to BP in post-menopausal OP. There was no significant difference when comparing Denosumab with bisphosphonates in any adverse events (AAE) (RR=0.98, 95% CI=0.95–1.01) serious adverse event (SAE) (RR=1.04, 95% CI=0.81–1.33). Regarding Denosumab versus placebo in post-menopausal OP, 7 studies were included and there was no significant difference in AAE (RR=0.98, 95% CI=0.94–1.01), SAE (RR=1.03, 95% CI=0.96–1.11), however cellulitis was more frequently found with Denosumab (RR=8.03, 95% CI=1.44–44.79). No cases of osteonecrosis of the jaw (ONJ) had been reported. 5 articles were pooled to compare Denosumab with BP in patients with bone metastases and no significant difference was found in AAE (RR=0.99, 95% CI=0.98–1.00), SAE (RR=0.99, 95% CI=0.95–1.03), and ONJ (RR=1.40, 95% CI=0.92–2.13). 4 articles were selected concerning patients treated with placebo or Denosumab in breast and prostate cancer without bone metastases. Although no significant difference was found in AAE (RR 1.01, 95% CI=0.99–1.03), use of Denosumab was associated with a significantly increased risk of hypocalcemia (RR 5.20, 95% CI=1.34–20.13) and of cholecystitis (RR 3.43, 95% CI=1.01–11.69).
Conclusions: In post-menopausal OP, Denosumab had a relatively good safety profile although significantly more cellulitis occurred when compared with placebo. For patient with cancer, Denosumab was associated with more hypocalcemia and cholecystitis than placebo.

FRI0562 PROPORTION OF HIP AND NON-HIP MAJOR FRACTURES: COSTS AND QUALITY OF LIFE

M.L. Marques, A. Marques, A. Daniel, L. Brites, J.A.P. da Silva. *Rheumatology Department, CHUC, Coimbra, Portugal*

Background: FRAX® country specific risk estimates are a mainstay of current treatment decisions and public health policies in osteoporosis. Because the registries of major non-hip fractures (NHF) is poor in most countries, this estimate is based on the gender- and age-specific ratio of hip fractures (HF) to NHF observed in a prospective population-based study performed in Malmo, Sweden[1]. FRAX® presumes, therefore, that the ratio of incidence and cost of hip/major osteoporotic fractures is similar, in every country, to that observed in Sweden. This major assumption has seldom been questioned.
Objectives: This retrospective single-centre observational study aimed to assess the proportion of HF vs. NHF and the impact of wrist and vertebral fractures, in terms of costs and health-related quality of life (HrQoL), 1 year after the fracture in Portugal.
Methods: We revised the records of all patients observed in an emergency department through a period of 3 months and included those aged 50+ diagnosed with a fragility (low energy) HF or NHF. A telephone interview was conducted in a randomly selected subsample of patients from each type of fracture 1 year after fracture. A questionnaire with socio-demographic data, resource consumption over 1st year and HrQol (EQ-5D) was applied to patients or their caregivers. Direct and indirect costs were estimated from a societal perspective.
Results: In the study period, 1760 patients were observed by the orthopaedics emergency team. Of these, 435 patients had suffered a fracture (129 fragility HF, 152 NHF and 154 fractures that were not considered low-trauma and were therefore excluded). Humerus fractures were also excluded, to mirror the Swedish study. The randomly selected subsample of patients consisted of 66 NHF (55 with wrist and 11 with clinical vertebral fractures). Patients were mostly females in all types of fractures (58% to 82%). The mean age at fracture was higher in HF (81.6±8.59 vs. 69.1±10.06). Falls were the cause of fracture in 97% of cases. Inpatient care was provided to 100% of HF patients vs. 25.8% of NHF patients. The proportion of fractures, average fracture-related costs for the 1st year, and the mean impact upon HrQoL are shown in Table 1.
Conclusions: The proportion HF/NHF observed in Portugal is similar to the Swedish reference values (0.44/0.56). The highest cost were attributed to hip fractures in both countries, followed by vertebral fractures and lastly by wrist fractures. The HrQoL mean loss was higher for vertebral fractures in both countries. The reported costs of vertebral fractures are much higher than in Portugal which may significantly affect the calculation of cost-effectiveness thresholds for intervention.

FRI0563 USE OF TERIPARATIDE AS A CALLUS ACCELERATOR IN NONUNION OF LOWER LIMB

M. Muratore[1], O.E. Casilli[1], V. Russi[2], P. Pichierri[2], L. Meccariello[2], L. Quarta[1], E. Quarta[1], G. Rollo[2], M. Filipponi[2]. *[1]U.O. Reumatologia- P.O. "V. Fazzi" Lecce; [2]U.O. Ortopedia- P.O. "V. Fazzi" Lecce, LECCE, Italy*

Background: The use of teriparatide in fracture management by high-energy trauma with loss of bone substance and muscle and skin with possible nerve/vascular lesions is poorly documented. The aim of our study is to evaluate how the intermittent administration of teriparatide may affect the bone consolidation newly generated and compression in patients with bone loss and my-skin during treatment reconstruction with the technique of resection Ilizarov-lengthening.
Objectives: In large trauma or in the outcomes of these,in which there is loss of bone substance and muscle and skin the technique of reconstruction of Ilizarov (1 mm/day) is used; the main problem is the long time required to reach complete healing with optimal bone consolidation newly generated and the compression outbreak of ensuring the mechanical strength necessary to be able to remove the external fixator (1). The rationale of this study, therefore, was to evaluate the influence of treatment with teriparatide, administered subcutaneously 1 dose 1 time/day from a pre-filled syringe of 20mcg and for a period of three months, the evolution radiographic, on the healing time and the external fixator removal and on the functional recovery quality in multiple trauma patient.
Methods: In our prospective study, we evaluated two groups of patients: Group 1: 9 patients treated with PTH during bone transport; Control Group 2: 10 patients treated with bone transport.
Results: The group 1 compared to the 2 (control group) showed a bone radiographic progression slower newly-generated in the first month of administration of teriparatide; subsequently it was observed an acceleration of bone maturation but not uniform; after about 3 months, the bone maturation accelerates further also at the level of the compression outbreak if already in compression, allowing the removal of the fixator about 1.5 months earlier than the estimated time. This is due to the reduction of the time allowed for "elongation stage" bone that physiologically is around 1mm/day, thus ensuring an optimal functional recovery.
Conclusions: The action of teriparatide (2) on bone healing is derived from increased differentiation of cells responsible for bone callus formation, chondrocytes and osteoblasts, mediated in part by increased activation of genes that produce the Wnt, Osterix and Runx2, all fundamental elements in the osteoblastogenesis. Although the sample examined is small for the specificity of the described treatment, the data reported showed that the intermittent administration of teriparatide is able to accelerate the timing for the "elongation stage" bone and therefore the bone healing and reconstructive treatment times in serious loss of substance.

FRI0564 **128 PATIENTS WITH SUBACUTE SYMPTOMATIC FRAGILITY VERTEBRAL COMPRESSION FRACTURES: HIGH INCIDENCE OF MORTALITY, FALLING, MONOCLONAL GAMMOPATHY OF UNCERTAIN SIGNIFICANCE AND MYELOMA, PERNICIOUS ANEMIA AND VITAMIN B-12 DEFICIENCY: IS THIS A PROFILE OF AN OSTEOPOROTIC OR AN AGED POPULATION?**

M. Lovy[1], N. Ben-Shlomo[2], J. Udkoff[3]. *[1]Desert Oasis Healthcare, Palm Springs, California, United States; [2]Ben-Gurion Medical School, Beer Sheva, Israel; [3]University of California, San Diego Medical School, San Diego, California, United States*

Background: Epidemiological studies have identified risk factors for falling and fractures. However there is a paucity of observational studies[1,2] of patients with symptomatic fragility vertebral compression fractures (VCF). These studies were not done in community based populations and did not evaluate the contribution of falling.
Objectives: To study factors contributing to both osteoporosis and falling in a cohort of community based patients with symptomatic subacute fragilty VCF.
Methods: We saw 128 patients with symptomatic subacute fragility VCF in our community based outpatient fracture clinic over a two year period. We performed a complete history and physical, review of past medical records and radiographs, complete blood count, sedimentation rate, chemistry profile, TSH, urinalysis, vitamin B-12, PTH, 25-OH vitamin D, and serum protein electrophoresis (SPE). We performed testosterone level, methylmalonic acid, antiparietal cell antibody and intrinsic factor antibody in select cases. We recorded diseases including diabetes, COPD, cardiac, neurological for each patient.
Results: There were 92 females aged 45–98 years (mean 77.7), 36 males aged 39–94 years (mean 77.6). Factors contributing to falling included peripheral neuropathy-61, use of sedatives-43, blindness-12, foot drop-6, dementia-3, Parkinson's-3, hyponatremia-2. VCF were precipitated by falls in 94 patients, of which 87 occurred at home. VCF occurred with lifting in 8 patients, bending in 3, and were spontaneous in 23. Use of steroids was reported in 18 patients and associated with mulitple ($>$3) fractures ($p<0.0008$). Blindness (p=0.022) and multiple fractures (p=0.049) were found more often among females. Males were more likely to have peripheral neuropathy (p=0.056) and 3 or more medical conditions ($P<0.008$). Age correlated with the number of diseases ($p<0.0001$). Diagnosis based on laboratory studies included vitamin D insufficiency-29, vitamin D deficiency-12, pernicious anemia-6, vitamin B-12 deficiency-8, monoclonal gammopathy of uncertain significance (MGUS)-10, myeloma-2, hypogonadism-12, and iatrogenic hyperthyroidism-3. Ankylosing spondylitis and lymphoma were diagnosed in one patient each. The average age of those that died was 83.9 years compared to 76.8 of the remaining group (p=0.033).
Conclusions: Conditions that increase with age and are associated with an increased risk of falling and fracture include neurological diseases, visual loss, use of steroids and sedatives, MGUS, myeloma, pernicious anemia and vitamin B-12 and vitamin D deficiencies. These were all common in our cohort with subacute symptomatic fragility VCF. Accordingly we recommend vitamin B-12 levels and SPE in the evaluation of all patients with VCF. These findings support the emphasis on interventions to reduce the risk of falling in the elderly and to recognize and treat these age-related conditions in an attempt to mitigate the risk of VCF.

FRI0565 **FRAGILITY FRACTURES IN PATIENTS ON DEPO-PROVERA ARE NOT ASSOCIATED WITH USUAL RISK FACTORS FOR FRACTURE**

M. Dey, M. Bukhari. *University Hospitals of Morecambe Bay NHS Foundation Trust, Lancaster, United Kingdom*

Background: Depo-Provera is one of the most widely-used contraceptives. The side-effects includes loss in bone mineral density (BMD), increasing fracture risk (1,2). It is not known if conventional fracture risk factors impact fracture risk in these patients.
Objectives: We set out to determine if the usual risk factors for fracture are associated with increased risk of fragility fractures in patients exposed to Depo-Provera.
Methods: Patients referred for bone densitometry at a scanner in North West of England were analysed. Femoral and vertebral BMD, height, weight and body mass index (BMI) were recorded, in addition to: age, diagnosis of rheumatoid arthritis, smoking status, alcohol consumption, family history of fractures, history of secondary osteoporosis, corticosteroid use, total average proportion fat, average tissue thickness, fat mass, and lean mass. Patients with exposure to Depo-Provera were selected for analysis. Initially patients with and without a fracture were compared using Chi-squared test and T-test. Logistic models were fitted univariately and adjusted for age to analyse association between traditional risk factors and fracture.
Results: 304 females (103 currently and 201 previously on Depo-Provera) were included. 62 (20.4%) had sustained had least one fragility fracture. There was no significant difference in fracture risk between those currently and previously on Depo-Provera (p=0.176 95% CI). Decreased left femoral BMD significantly impacted fracture risk (p=0.035 95% CI). All other factors investigated did not significantly increase fracture risk in this cohort.(see table below)

Predictor	All (n=304)	Patients with fracture (n=62)	Patients without fracture (n=242)	*p*-value	Odds ratio (95% CI)
Age at scan (years)	36.7	41.5	39.2	0.083	1.028 [0.10, 1.06]
Height (m)	163.2	163.3	163.2	0.924	1.002 [0.96, 1.04]
Weight (kg)	73.0	76.9	72.1	0.078	1.012 [0.10, 1.03]
Femoral BMD (left) (g/cm^2)	0.966	0.932	0.975	0.035	0.100 [0.01, 0.82]
Femoral BMD (right) (g/cm^2)	0.972	0.945	0.979	0.112	0.177 [0.02, 1.47]
Lumbar spine BMD (L2) (g/cm^2)	1.115	1.099	1.119	0.364	0.432 [0.07, 2.62]
BMI (kg/m^2)	27.4	28.8	27.0	0.068	1.037 [0.10, 1.08]
Average proportion fat	0.274	0.299	0.267	0.069	9.071 [0.86, 101.12]
Average tissue thickness (cm)	17.6	18.3	17.5	0.080	1.076 [0.99, 1.17]
Fat mass (g)	275.2	302.7	268.1	0.053	1.002 [0.10, 1.00]
Lean mass (g)	724.8	697.3	731.9	0.053	0.998 [0.10, 1.00]
Alcohol (no. of patients)	23	8	15	0.102	2.235 [0.78, 5.96]
Smoking (no of patients)	154	31	123	1.000	0.968 [0.53, 1.76]
Family history (no. of patients)	77	17	60	0.744	1.145 [0.57, 2.22]
Rheumatoid arthritis (no. of patients)	11	3	8	0.702	1.485 [0.25, 6.43]
Secondary operation (no. of patients)	48	10	38	1.000	1.032 [0.43, 2.29]
Corticosteroids (no. of patients)	67	18	49	0.169	1.609 [0.80, 3.14]

Conclusions: Our study suggests that fragility fractures in patients taking Depo-Provera are not associated with the usual risk factors for fractures. To our knowledge, this is the first study demonstrating fracture risk in such patients to be independent of conventional risk factors. This therefore indicates an as yet unidentified mechanism of increased fracture risk. Study limitations include the small number of fractures and lack of data on length of treatment with Depo-Provera. Further research is needed into the mechanisms by which the drug gives rise to increased fracture risk, independent of other factors.

FRI0566 **TERIPARATIDE AND ALENDRONATE IMPROVED BONE LOSS AND HYPERALGESIA IN A MOUSE MODEL OF OSTEOPOROSIS**

N. Nagao, H. Wakabayashi, S. Kato, G. Miyamura, Y. Naito, A. Sudo. *Department of Orthopaedic Surgery, Mie University Graduate School of Medicine, Mie, Japan, Tsu, Japan*

Background: Osteoporosis may cause not only fractures but also chronic back pain in elderly women. Teriparatide (TPTD) and alendronate (ALN) are widely used in clinical for treatment of osteoporosis. Several studies have demonstrated that TPTD and ALN treatments improved skeletal pain in osteoporosis patients.
Objectives: We investigated the effect of TPTD and ALN on pain-related behavior in ovariectomized (OVX) mice. And we investigated expression of inflammatory cytokines treated OVX mice.
Methods: 8-week-old female ddY mice were OVX and assigned to 4groups; SHAM-operated mice treated with vehicle (SHAM), OVX mice treated with vehicle (OVX), OVX mice treated with TPTD (TPTD) and OVX mice treated with ALN (ALN). Mice were started treatment immediately after surgery. For 4 weeks, mice were injected subcutaneously with vehicle or 40μg/kg ALN twice a week or 40μg/kg TPTD 5 times a week.
The bilateral distal femur metaphyses were analyzed three-dimensionally by μCT 4 weeks after surgery (each group; n=8).
Mechanical sensitivity was tested using von Frey filaments 4 weeks after surgery. To evaluate the 50% withdrawal threshold, seven von Frey filaments with forces of 0.07, 0.16, 0.4, 0.6, 1.0, 1.4 and 2.0 g were applied to the middle of the plantar surface. Data was collected using the up-down method.
To evaluate expression of interleukin-1β (IL-1β), IL-6 and tumor necrosis factor-α (TNF-α), mice were anesthetized and the bilateral hindlimb bone excised. We performed quantitative polymerase chain reaction (q-PCR) from hindlimb bone.
Results: μCT analysis of the distal femur metaphysis showed that bone volume/tissue volume (BV/TV) and trabecular number (Tb.N) were significantly less in the OVX group than in the SHAM group, whereas trabecular separation (Tb.Sp) was significantly greater in the OVX group than in the SHAM group. In the TPTD and ALN group, BV/TV and Tb.N were significantly greater than in the OVX group, whereas Tb.Sp was significantly less than in the OVX group. And in the ALN group, BV/TV and Tb.N were significantly greater than in the TPTD group, but Tb.Sp was no significance.
The 50% withdrawal threshold was significantly lower in the OVX group than in the SHAM group, and it was significantly higher in the TPTD and ALN group than in the OVX group. And the 50% withdrawal threshold was no significance between the TPTD and ALN group.
The expression levels of TNF-α was increased in the OVX group compared with those in the SHAM group. Other cytokines were not increased significantly in the

OVX group. In the TPTD and ALN group, the expression levels of TNF-α was significantly degreased than the OVX group. And the expression levels of TNF-α was no significance between the TPTD and ALN group.
Conclusions: In this study, TPTD and ALN treatments prevented bone loss in OVX mice. Mechanical hyperalgesia in hindlimbs tended to be decreased in the OVX group compared with the TPTD and ALN group. ALN treatment was more effective in bone formation compared with TPTD treatment, whereas pain relief was no significance between TPTD and ALN treatment. These results suggest that TPTD treatment was more effective in osteoporosis patients with skeletal pain.

FRI0567 DIFFERENCES IN ADCHERENCE TO OSTEOPOROSIS MEDICATIONS IN PATIENTS WITH RHEUMATIC DISEASES: A 3-YEAR RETROSPECTIVE COHORT STUDY

O. Nikitinskaya, N. Toroptsova. *Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Patients with rheumatic diseases (RD) have an increased risk of developing osteoporosis (OP) compared with healthy population due to chronic inflammation, low physical activity and using some kind of medications. Persons with RD and OP require prolonged osteoporosis treatment due to increased risk of fracture.
Objectives: To evaluate adherence and persistence with different osteoporosis medications in RD patients with OP during 3 years.
Methods: We conducted a retrospective study of 204 patients (82% women, mean age 54±11 years) with RD (93 – rheumatoid arthritis, 48 – systemic sclerosis, 39 – systemic lupus erythematosus and 24 – ankylosing spondylitis), whom OP was diagnosed in 2013. In 2016 we revised there medical charts for collection information on the osteoporosis treatment and performed telephone contact for patient's self-reporting.
Results: 196 (96%) patients started the OP treatment. Among them 26% - alendronate, 24% received alfacalcidol or supplements of calcium and vitamin D only, 16% - stroncium ranelate, 12% - ibandronate, 9% zoledronic acid, 8% - calcitonin and 5% - denosumab.
8 (4%) patients didn't start the drug treatment at all, 72 (35%) patients were persisted less than 12 months, 47 (23%) – 2 years and 77 (38%) – 3 years. Mean persistence was 2.1, 2.4, 1.6, 1.7, 1.9, 2.0 years for alendronate, alfacalcidol, stroncium ranelate, ibandronate, zoledronic acid, denosumab, respectively. 61 (31%) persons were switched from one antiosteoporotic medication to another due to side effects, inconvenient dose regimen or other reasons. Persistence to oral therapy was better among women than men ($p<0.05$), especially on daily regimen. Discontinuers were less likely than persistent subjects to visit rheumatologist and BMD measurement each year for control of treatment ($p<0.05$). Patients with ankylosing spondylitis were less persistent than persons with other RD. Presence of OP fractures in anamnesis had no significant influence on adherence. 8 (4%) patients had fractures during retrospective period, among them 6 - received only supplements of calcium and vitamin D, 1 - zoledronic acid once and 1 – without OP therapy.
Conclusions: Only 1/3 of patients with RD received antiosteoporotic drugs during 3 years. Visits to rheumatologist and BMD measurements increased subject's persistence. Improving the quality of medical care can be achieved through education and motivation of patients for a long-term treatment of OP.

FRI0568 ECHOSOUND APPROACH FOR SHORT-TERM FOLLOW-UP OF THE DENOSUMAB EFFECT ON BMD RECOVERY AGAINST AROMATASE INHIBITOR IMPACT IN BREAST CANCER PATIENTS

P. Pisani[1], M. Muratore[2], F. Conversano[1], E. Casciaro[1], M. Di Paola[1], R. Forcignanò[3], M. Ciccarese[3], G. Surico[3], L. Quarta[2], E. Quarta[2], D. Costanza[2], R. Franchini[1], R. Tarparelli[4], S. Casciaro[1]. *[1]1National Research Council, Institute of Clinical Physiology; [2]2OU of Rheumatology Galateo Hospital, San Cesario di Lecce, ASL-LE; [3]3OU of Oncology Vito Fazzi Hospital, ASL-LE; [4]4Echolight Spa, LECCE, Italy*

Background: The Aromatase Inhibitors (AIs)-based therapy used in breast cancer patients to profoundly lower estrogen levels seems to enhance the loss of bone mineral density (BMD) and to increase the fragility fracture rate [1]. Several clinical studies demonstrated that, in breast cancer patients that received the adjuvant AIs, the subcutaneous administration of Denosumab-based therapy significantly increased BMD values and reduced the rate of clinical fractures.
Objectives: To monitor the short-term Denosumab and AIs therapeutic effects on BMD in breast cancer patients through an innovative echographic approach, the EchoSound technology [2].
Methods: 154 breast cancer patients selected for receiving the adiuvant AIs therapy were recruited. All the patients underwent spinal and femoral dual X-ray absorptiometry (DXA) examinations before AIs therapy administration starting (time T0). After AIs treatment starting, enrolled patients were divided into 2 groups: 105 patients received only the AIs treatment (Group A), whereas the remaining 49 patients (Group B) received also an additional Denosumab treatment, in order to contrast the BMD reduction induced by AIs administration. Follow-up measurements were conducted at two different time points: 12 (T1) and 18 (T2) months from AIs treatment starting. At time T1, patients underwent both DXA examinations and EchoSound echographic scans, whereas at time T2 only the echographic scans were performed, since DXA cannot be used for short-term follow-ups.
Results: At time T1, the following results were obtained on lumbar spine: Group A showed a BMD decrement, which was equal to -2.07%±1.66% ($p<0.01$) according to DXA and to -2.22%±0.89% ($p<0.01$) according to EchoSound; Group B showed a BMD increase of 4.06%±1.49% ($p<0.01$) and 4.31% ±0.62% ($p<0.01$) as measured by DXA and EchoSound scans, respectively. At time T2, Group A showed a further BMD decrement, resulting in a total decrease of -3.95%±1.09% ($p<0.01$) with respect to T0 values; on the contrary, in Group B Denosumab treatment produced an additional BMD increment, resulting in a total BMD increase of 4.98%±1.03% ($p<0.01$) in the same 18-month period. Similar results were obtained for femoral neck BMD: a total BMD decrease of -2.37%±0.97% ($p<0.01$) during the whole treatment period was observed in Group A, whereas a total BMD increment of 3.53%±0.43% ($p<0.01$) was measured in the same period in Group B.
Conclusions: By using the EchoSound technology the short-term follow-up of the positive Denosumab effects on BMD reduction in patients treated with adjuvant AIs was feasible and accurate. This approach can be also useful to monitor the therapy effectiveness in patients undergoing specific anti-osteoporotic treatments.

FRI0569 EVALUATION OF BONE MICROARCHITECTURE IN SYSTEMIC SCLEROSIS PATIENTS: RELATIONSHIPS BETWEEN TRABECULAR BONE SCORE (TBS) AND DISEASE SEVERITY

S. Paolino[1], E. Gotelli[1], A. Sulli[1], B. Ruaro[1], M. Ghio[1], C. Pizzorni[1], E. Alessandri[1], V. Tomatis[1], C. Seriolo[2], L. Molfetta[2], M. Cutolo[1], A. Casabella[1]. *[1]Department of Internal Medicine, University of Genova, IRCCS AOU San Martino, Genoa, Italy, Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy; [2]Department of Internal Medicine, University of Genova, Genoa, Italy, Osteoporosis, Bone and Joint Disease Research Center, CROPO, Genoa, Italy*

Background: Systemic sclerosis (SSc) is a rare connective tissue disorder characterized by an increased synthesis and deposition of extracellular matrix in the skin and internal organs (1). Several studies described SSc as potential risk factor for osteoporosis, however, to date the bone quality in SSc is unclear (2). Trabecular bone score (TBS) has been recently proposed as an indirect measure of bone microarchitecture (3).
Objectives: The aim of this study was to assess bone microarchitecture in SSc patients and possible association with disease severity and microangiopathy.
Methods: Twenty-three female SSc patients (mean age 63.2±12.8 SD years, mean disease duration 92.8±66 SD months, mean Raynaud's Phenomenon duration 142.6±126.1 SD months) were enrolled after written informed consent. The assessment of disease severity was performed using the Medsger's severity scale (4). Bone Mineral Density (BMD) measurements at L1-L4, femoral neck and total hip, were performed using DXA Prodigy Densitometer (GE Lunar). TBS was derived for each spine DXA examination using the TBS index (TBS iNsight Medimaps). Nailfold videocapillaroscopy (NVC) was used to assess the microangiopathy based on nailfold video capillaroscopic pattern (NVC) analysis and the microangiopathy evolution score (MES) (5–6). Using the FRAX (Fracture Risk Assessment Tool) we also evaluate the 10-year risk of hip and major joints osteoporotic fracture.
Results: A positive correlation was observed between TBS and Medsger's general organ score (r=0.5; p=0.01); no other correlations were found between TBS and Medsger's score. Interestingly, TBS was positively and significantly correlated with modified Rodnam skin score (mRss) (p=0.01). When the patients were divided in two groups considering skin involvement by mRss, TBS was found significantly higher into the group with mRss >15 compared to the group with mRss <15 (1.255±0.08 vs 1.163±0.03; p=0.01) No correlations were found between NVC patterns/MES and bone quality assessment (TBS) or bone density assessment (BMD), only a significant correlation, as expected, was observed

between MES and skin involvement (mRss) (p=0.05). On the other hands, FRAX, the major osteoporotic fracture risk, positively correlates with Medsger's kidney disease severity (p=0.04) and Medsger's lung disease severity (p=0.04); in addition, FRAX, for hip fracture risk, seems to correlate significantly with Medsger's lung involvement severity (p=0.04).

Conclusions: This study demonstrates in SSc patients a relationship between clinical disease severity (organ fibrosis/failure) and altered bone microarchitecture (TBS). In addition, skin involvement was found significantly correlated with altered quality of the trabecular bone architecture (TBS) and a significant increase of osteoporotic fracture risk (FRAX) was found correlated with kindey and lung involvement.

FRI0570 OSTEOPOROSIS AND BREAST CANCER: OUTCOMES AT A SPECIALIZED OSTEOPOROSIS CLINIC FOLLOWING A STRUCTURED ASSESSMENT

S. Lopez-Salguero[1], J.C. Ordoñez[1], L. Ranieri[1], M. Andrés[1,2], J. Ponce[3], I. Ibero[1]. [1]*Rheumatology, Hospital General Universtiario Alicante;* [2]*Departamento de Medicina Clínica, Universidad Miguel Hernández de Elche;* [3]*Oncology, Hospital General Universtiario Alicante, Alicante, Spain*

Background: Women with breast cáncer (BC) are at risk for the development of bone loss and osteoporosis (OP) mainly due to adjuvant therapies. Aromatase inhibitors (AI) therapy fully suppresses estrogen synthesis, further exacerbating the increased bone resorption and leading to an excess fracture risk. Thus, a close monitoring of bone mineral metabolism is recommended.

Objectives: The aim of the present study was to analyze bone health status and clinical characteristics of women BC referred by oncologist to a specialized clinic and their outcomes during follow-up.

Methods: Retrospective analysis of consecutive female patients with recent BC and low bone mineral density (BMD) referred to the osteoporosis outpatient clinic for assessment, as agreed with oncologists. A descriptive analysis of epidemiological, clinical, laboratory, imaging, and dual energy x-ray absorptiometry (DEXA) data is presented, both at baseline and last visit. 95% confidence intervals (95% CI) were estimated for rate of fragility fractures (FF) at baseline and during follow-up.

Results: A total number of 156 female patients have been assessed up to January 2017; median aged 60.7 (SD±10.6) years old, 89% postmenopausal. BC was mainly non-methastasic (117; 75%), and 110 (70%) patients were on aromatase inhibitors (14 on anastrozole, 89 on letrozole, and 7 on exemestane). 36 patients (23%) were active smokers, and 17 (11%) had stopped smoking. At baseline, 37 patients (24.2%, 95CI% 20–37) had previous FF, mostly vertebral (19) or non-vertebral (13), and three cases had suffered from multiple FF. BMDs were at osteoporotic range at the lumbar spine (median T-score -2.6 p25/75 -2.2, -3.2) and osteopenic at both the femoral neck and hip (mediant T-score -1.9 p25/75 -1.1, -2.3). Regarding antiosteoporotic therapies, bisphosphonates were prescribed in 110 cases (70.5%), denosumab in 24 (15.3%), and raloxifene in two cases (1.2%); in the others (12.8%) only calcium plus vitamin D supplementation was recommended. A total of 107 patients were followed a median of 2.13 years (p25–75 1.23–3.18). During follow-up, new FF occurred in 13 patients (12.1%, 95% CI 6–19), that were vertebral in 8, non-vertebral in 4, both in one case, while no hip FF were detected.

Conclusions: outcomes of a structured assessment of female patients with BC and low BMD are reported here. Despite this, 12% of cases developed a new FF, highlighting the need for special attention to this singular, secondary form of osteoporosis.

FRI0571 OSTEOPOROSIS AND BREAST CANCER: CAN FRAX-BASED RISK FACTORS ACCURATELY PREDICT FURTHER FRACTURES AT THIS SETTING?

S. Lopez-Salguero[1,1], J.C. Ordoñez[1], L. Ranieri[1], M. Andrés[1,2], J. Ponce[3], I. Ibero[1]. [1]*Rheumatology, Hospital General Universtiario Alicante;* [2]*Departamento de Medicina Clínica, Universidad Miguel Hernández de Elche;* [3]*Oncology, Hospital General Universtiario Alicante, Alicante, Spain*

Background: Women with breast cáncer (BC) are at risk for the development of bone loss and osteoporosis (OP) mainly due to adjuvant therapies, as aromatase inhibitors (AI). Thus, it would be of special interest in this group of patientes, to know at baseline wich factors can predispose to develope fragility fractures (FF) during follow-up, in order to optmize vigilance and treatment.

Objectives: The purpose of this study is to analyze wich risk factors at baseline that can predict the appereance of a new FF in women with BC and OP.

Methods: Retrospective analysis of consecutive female patients with recent breast cancer (BC) and low bone mineral density (BMD) referred to the osteoporosis outpatient clinic for assessment, as agreed with oncologists. Fort he purpose of this anaylisis, only patients with follow-up data (at least six months after baseline visit) were selected. FRAX tool [1]-derived risk factors (age, BMI, DEXA, previous fracture, parent fractured hip, smoking, alcohol, glucocorticoids, rheumatoid arthritis, secondary OP) were taken as explicative variables. Student's t and chi-2 tests were used to perform comparisons base don the appereance of new FF in the study period.

Results: A total number of 156 female patients have been assessed up to January 2017. Of the 107 patients in follow-up (68.5%; median time in follow-up 2.1 years p25–75 1.2–3.2). Median age was 62.07 years old (SD±10,35), being 89% of them postmenopausal. 73 (68,2%) were on AI therapy (10 anastrozole, 59 letrozole and 4 exemestane). At baseline, 29 patients (27.1%) showed a FF (15 vertebral; 10 non vertebral; 2 hip; 2 multiple fracture). Antiosteoporotic treatment was recommended in 95 patients (88.7%). During follow-up, 13 FF were seen (12,1%; CI95% 6–19); being 8 of them vertebral, 4 not vertebral, and one multiple fracture; no new hip FF was seen.

After comparison of the different risk factors according to the development of a new FF, no significant association was found (see table).

Table 1

	New fragility fracture		p
	NO (n=94)	YES (n=13)	
Age (years old), mean ±SD	62.0±10.7	62.1±9.9	0.956
BMI (kg/m^2), mean ±SD	26.5±7.1	23.1±10.0	0.213
Follow-up duration (months) median ±SD	28.6±19,4	30.6±12.8	0.723
DEXA at lumbar spine (T-score) median ±SD	-2.7±0,8	-2.9±0.6	0.256
GFR (ml/min) mean ±SD	91.7±16.0	97.2±11.2	0.282
Menopause (%)	93.4	91.6	0.822
Previous fracture (%)	27.1	38.4	0.512
Parent fractured hip (%)	11.0	25.0	0.125
Smoking (%)	10.0	8.3	0.721
Glucocorticoids (%)	9.9	7.7	1.000
Rheumatoid arthritis (%)	3.2	0	1.000
Aromatase inhibitor (%)	70.9	69.2	0.897
Antiosteoporotic treatment (%)	88.4	92.3	0.676

Conclusions: In this study no relationship between FRAX-based risk factors and the development of new FF in women with OP and BC was found. As new FF occurred in 12% of cases, it highlights the need for special attention to this singular, secondary form of OP.

FRI0572 IDENTIFYING WOMEN AND MEN AT HIGH FRACTURE RISK BY LEVERAGING THE ELECTRONIC MEDICAL RECORDS TO ESTIMATE FRAX TREATMENT THRESHOLDS

S. Amin, E. Atkinson, S. Khosla. *Mayo Clinic, Rochester, United States*

Background: In the busy clinic, identifying individuals at high fracture (fx) risk who warrant intervention can be a challenge. There are several medical conditions that increase the risk for bone loss and falls which are recorded in the electronic medical record (EMR).

Objectives: We explored whether we could exploit data available in the EMR to estimate FRAX treatment thresholds to help passively identify patients who would benefit from further bone mineral density screening and management.

Methods: We studied 912 women and men, previously recruited for our bone health studies, in whom FRAX scores (with and without BMD) had been determined and comprehensive medical diagnoses were available through the medical linkage system of the Rochester Epidemiology Project. All diagnoses were categorized by the Clinical Classification Software (CCS) system whereby over 14,000 ICD-9-CM diagnoses are reduced to 568 clinically meaningful categories. If a subject had at least two diagnoses in a CCS category that were at least 30 days apart and within 5 years of their FRAX assessment, the subject was treated as having that CCS code. We used Gradient Boosting Machine (GBM) to create models that would predict the treatment thresholds for the FRAX 10-year risk for major osteoporotic (OP) fx (>20%) and hip fx (>3%), based on available diagnoses. Models were fit using age, sex and CCS category from 80% of the data, retaining 20% for validation.

Results: Of the 564 (62%) women and 348 (38%) men, the mean ± SD age was 61±16 yrs. There were no significant differences in subject characteristics used for FRAX calculation or FRAX scores between the training and validation sets. The c-statistic for GBM models predicting treatment thresholds for FRAX, calculated with BMD, for major OP fx and hip fx were 0.95 and 0.96, respectively, for the training set, and 0.88 and 0.94 for the validation set. Similar results were observed for FRAX scores without BMD.

Conclusions: FRAX treatment thresholds may be reasonably estimated from data available in the EMR to help identify to the clinician those at highest risk

for fracture who would warrant further evaluation. Further work to implement and validate these findings in the EMR system would be necessary.

FRI0573 OSTEOCYTES ARE INVOLVED IN THE PATHOGENESIS OF OSTEOPOROSIS IN CHRONIC CHOLESTASIS. EFFECTS OF BILIRUBIN AND BILE ACIDS ON OSTEOCYTIC CELL LINES

S. Ruiz-Gaspà, A. Parés, A. Combalia, P. Peris, A. Monegal, N. Guañabens. *Liver and Metabolic Bone Diseases Units, CIBERehd-Hospital Clínic, University of Barcelona, Barcelona, Spain*

Background: Mechanisms underlying osteoporosis in chronic cholestasis are complex and poorly understood. In this setting, osteoporosis mainly results from low bone formation, related to the effects of retained substances of cholestasis, such as bilirubin and bile acids. Thus, in "in vitro" studies, unconjugated bilirubin and serum from jaundiced patients decrease osteoblast viability, differentiation and mineralization. However, the influence of cholestasis on osteocytes, the most ubiquitous cells of the skeleton, is unknown.
Objectives: The aim of this study was to analyze the direct effects of increased molecules of cholestasis, such as bilirubin (Bil) and lithocholic acid (LCA), and the potential protective effect of ursodeoxycholic acid (UDCA) on the osteocytes.
Methods: MLO-Y4 and MLO-A5 osteocyte cell lines treated at different times and concentrations with Bil, LCA and UDCA were used to determine: 1) Viability: WST colorimetric method; 2) Differentiation: quantification of alkaline phosphatase (AP) activity; 3) Mineralization: Alizarin red staining quantification; and 4) Apoptosis: quantification of DNA fragmentation and caspase-3 activity.
Results: LCA (100μM) and Bil (50μM) significantly decreased viability in MLO-Y4 from 72 hours (10%) and 48 hours (11%), respectively ($p \leq 0.01$), and Bil decreased viability (49%) in MLO-A5 from 96 hours ($p < 0.01$). Bil decreased AP activity by 47% after 96 hours, under conditions of differentiation in MLO-Y4 ($p \leq 0.01$). There were no effects on AP activity in MLO-A5. After 14 days, Bil was associated with a significant mineralization decrease, as high as 87%, in MLO-A5 ($p \leq 0.02$). Moreover, Bil and LCA increased apoptosis in MLO-Y4, determined by DNA fragmentation (242% and 119%, respectively) and caspase-3 activity (190% and 251%, respectively) ($p \leq 0.01$) after 24 hours. In contrast, UDCA (100 μM) increased viability after 72 hours (11%) and decreased the deleterious effects of LCA or Bil ($p \leq 0.02$). UDCA increased AP activity in MLO-Y4 after 72 hours under growth conditions ($p = 0.018$), and after 24 hours under differentiation conditions ($p \leq 0.01$).
Conclusions: Bilirubin and lithocholic acid have damaging effects on osteocytic cells decreasing viability, differentiation and mineralization, and increasing apoptosis, effects that are neutralized by the UDCA. These results indicate that substances retained in cholestasis impair osteocytic functions, and therefore may be involved in the pathogenesis of osteoporosis in cholestatic diseases.

FRI0574 QUALITY OF LIFE ASSESMENT IN POSTMENOPAUSAL OSTEOPOROSIS

S. Novkovic[1], G. Stanojevic[2]. *[1]Institute of rheumatology; [2]Health Center "Zvezdara", Belgrade, Serbia*

Objectives: To compair two questionaires:a specific one-Osteoporosis Quality of Life Questionnaire (OQLQ) and a general one-Short Form-36 (SF-36),in women with decreased mineral bone density (BMD) and vertebral fractures,and to estimate which one is more useful for everyday work.
Methods: Cross-section study included 50 menopausal women with osteoporosis (OP), who were assessed with the general questionaire,and all known risk factors for osteoporosis were confirmed. Osteodensitometry scan (DXA) was performed on lumbar spine,and based both on T index value and BMD the subjects were divided in two groups:first grour (women with OP, n=25),second group (women with fractures of spinal vertebra due to OP,regardless of BMD, n=25, and with at least 4 months since the last fracture).The quality of life was assessed by two questionaires:a specific one OQLQ- consists of 30 questions divided into 5 areas,which are evaluated from 1 to 7 (the lower the score the more sever function damage and worse quality of life) and the general questionnaire SF-36-containing 36 questions divided into 8 areas (scores from 0 to 100, where the lower value is also a poorer quality of life).Questionnaires were converted to get two summarized scales,so as to obtain the total score for:physical (PCS) and mental functions (MCS).The two questionnaires were compared using appropriate statistical methods in SPSS.
Results: There was no significant differencev between groups regarding: mean age (first=63.3±6.0, second=64.9±7.8),mean age at the start of the menopause (first=46.8±5.3, second=48.2±4.2 years), mean duration of menopause (first=16.4±6.9, second=17.1±6.9 year),but there was statistically significant difference between the number of risk factors for OP (first=1.8±1.2, second=2.8±0.9, $p < 0.01$).Statistically significant between group difference ($p < 0.01$) in mean BMD and T score (first-BMD 0.807±0.057gr/cm^2,T scor -3.12±0.49SD, second- BMD 0.931±0.172 gr/cm^2,T score -2.09±1.45SD).The following DXA values were measured in the second group:8 patients-normal,6-osteopenia,11-osteoporosis,with average number of fractures 2.6±0.8.There was statistically significant between group difference in values of PCS OQLQ questionnaire (first=2.99, 42.7%, second=2.30, 32.8%, $p < 0.01$),as well as in values of MCS OQLQ (first=3.18, 45.4%, second=2.17, 31.0%, $p < 0.01$).Statistically significant difference was also observed regarding values of PCS SF-36 (first=42.2, 42.2%, second=32.5, 32.5%, $p < 0.01$),while regarding MCS SF-36 questionnaire there was no significant between group difference (first=40.2, 40.2%, second=33.3, 33.3%, $p > 0.05$).Mutual comparison of two questionnaires demonstrated correspondence and statistically significant decline in the quality of life in a group with fractures when it comes to PCS and MCS at OQLQ questionnaire and did not record between group difference in MCS SF-36 questionnaire.
Conclusions: It was demonstrated that the specific questionnaire provided more accurate information in all areas of quality of life,with general questionnaire failing to record between group differenc in the field of mental functions.Based on the proven value as an instrument of measurement,its simplicity,accuracy and ease of administration,OQLQ questionnaire is more appropriate for routine use in women with decreasing bone quality and fractures of vertebrae due to osteoporosis.

FRI0575 SAFETY OF DENOSUMAB IN A MONOCENTRIC COHORT OF KIDNEY TRANSPLANT RECIPIENTS

S. Doddoli, P. Lafforgue, T. Pham. *Bouches Du Rhones, Aix Marseille Unversity, APHM, Marseille, Marseille, France*

Background: The safety of Denosumab, a fully human monoclonal antibody against RANKL, which was developed for treatment of osteoporosis and prevention of fractures, remains unclear in kidney transplanted patients.
Objectives: Our aim was to assess its clinical and biological tolerance in this specific population.
Methods: *Design:* Prospective observational monocentric cohort. *Inclusion criteria:* kidney transplant recipient who received at least one subcutaneous injections of 60 mg denosumab; age $\geq$18 years.
Safety assessment: the following variables were collected every 6 months: infection, reaction at the injection site, plasmatic parameters of renal function and mineral metabolism (estimated glomerular filtration rate, serum creatinine, calcium, 1–25 [OH] vitamin D, PTH).
Results: Patients were recruited from April 2014 to September 2015. All patients received immunosuppression therapy including prednisolone $\geq$5 mg/d. The main baseline characteristics of the 37 kidney transplant recipients were the following [mean]: male: 41%, age: 60.5 years, BMI: 24,1, transplantation duration: 7.1 years, osteopenic patients: 36%, osteoporosis patients: 64%, total lumbar spine T-score: -2.04 SD, total hip T-score: -2.7 SD, T-score femoral neck: 0.676 g/cm^2, serum creatinine: 132.8 mmol/L, calcium: 2.33 mmol/L, 1–25 [OH] vitamin D: 93.5 nmol/L, PTH 95: ng/l. All patients were prescribed vitamin D and calcium supplementation.
During the mean 12-month follow-up period, there were no unexpected adverse event [AE] or severe adverse event, no graft failure and no deaths. No patient experienced fracture. Only one patient presented an infectious AE with recurrent cutaneous abscess. Renal function remained stable with no difference in serum creatinine between baseline and 12 months for the majority of the kidney transplant recipients. However, 9 recipients experienced a decrease in renal function with a mean increased in serum creatinine of 32.5micromol/L between baseline and 12 months. Serum calcium was stable, no hypocalcaemia was observed. Among patients with normal baseline PTH, two presented hyperparathyroidism during the follow-up period. Among the 11 patients with baseline hyperparathyroidism, 7 had an increased PTH level between baseline and 12 months. None were initiated on cinacalcet.
Conclusions: Our results suggest that denosumab is safe in kidney transplant recipients. We did not observe an increase in the infection rates, nor hypocalcemia. However, several patients experienced a decrease in their renal function or an increased hyperparathyroidism.
Disclosure of Interest: None declared

FRI0576 COMPARING TREATMENT INDICATION BY FRAX AND BMD ALONE IN RHEUMATIC PATIENTS ON LONG-TERM GLUCOCORTICOID IN HONG KONG

S.L. Lau[1], M.L. Yip[2], L.-S. Tam[1], K.L. Lee[3] on behalf of The Hong Kong GIOP Study Group. *[1]Department of Medicine & Therapeutics, The Chinese University of Hong Kong; [2]Department of Medicine and Geriatrics, Kwong Wah Hospital; [3]Department of Medicine, Pamela Youde Nethersole Eastern Hospital, Hong Kong, Hong Kong*

Background: Bone mineral density (BMD) may underestimate fracture risk since most patients with fracture had osteopenia or normal BMD. The WHO Fracture Risk Assessment Tool (FRAX) incorporated BMD and clinical risk factors (CRF) to estimate the 10-year probability of major osteoporotic fractures (MOF) and hip fracture. FRAX has been adopted by various guidelines to assess the need for therapeutic intervention. Whether FRAX is superior to BMD in identifying high-risk patients in need of anti-osteoporotic treatment is worth exploring.

Objectives: To compare the ability of FRAX and BMD alone in discriminating patients with and without fracture, and their effectiveness in identifying anti-osteoporotic treatment needs

Methods: 1300 rheumatic disease patients on long-term glucocorticoid were screened for vertebral fracture by radiograph from 7 rheumatology clinics. 220 ambulatory patients (110 with vertebral fracture and 110 without vertebral fracture) were recruited and assessed on CRF with FRAX questionnaire, BMD at the lumbar spine, total hip and femoral neck by dual-energy x-ray absorptiometry (DXA). The ten-year probability of MOF and hip fracture (FRAX score) with and without femoral neck BMD were calculated with the WHO FRAX tool.

Results: Both groups of patients were matched in gender, disease type and cumulative glucocorticoid dose ($p>0.1$). Patients in the fracture group were older (63±14 vs 59±12 years, $p<0.01$), of lower body mass index [22.7±3.5vs 24±3.7kg/m^2, $p<0.05$], with a higher prevalence of previous fracture [38 (34.5%) vs 5 (4.5%), $p<0.01$], use of vitamin D [77 (70%)vs 54 (49.1%), $p<0.01$] and bisphosphonates [23 (20.9%) vs 7 (6.4%), $p<0.01$]. A receiver operating characteristic (ROC) curve analysis was performed to determine the ability of FRAX score with or without BMD and BMD alone to discriminate fracture status (Table 1). BMD at the femoral neck and FRAX score with BMD were able to provide adequate discrimination with their area under curve (AUC) >0.70. With regards to treatment indication, only 53/110 (48.2%) of the patients with vertebral fracture were identified as having osteoporosis (T-score ≤ -2.5 at hip/spine) by DXA. In contrast, FRAX with BMD were able to identify 71/110 (64.5%) of the fracture patients whom treatment criteria were met, with a power of 0.97 and effect size of 0.38 (a medium effect) at the 0.05 level.

Table 1. Area under ROC curve on discriminating fracture

		AUC	95% Confidence Interval
BMD at Femoral Neck		0.709	0.640-0.778*
BMD of Total Hip		0.693	0.623-0.763*
BMD of Lumbar Spine		0.654	0.581-0.727*
FRAX with BMD	MOF	0.705	0.635-0.775*
	Hip fracture	0.720	0.651-0.789*
FRAX without	MOF	0.681	0.610-0.752*
BMD	Hip fracture	0.687	0.616-0.758*

*p<0.001

Conclusions: In rheumatic patients on long-term glucocorticoid, FRAX score was more effective in identifying patients with intervention needs than BMD alone. It is suggested that FRAX should be used as a routine assessment to identify patients, even asymptomatic, indicated for anti-osteoporotic treatment.

FRI0577 CLINICAL CHARACTERISTICS OF SPONTANEUS FRACTURES IN THE BEDRIDDEN PATIENTS UNINTENTIONALLY CAUSED BY CAREGIVERS

T. Kashiwagura[1], Y. Kimura[1], I. Wakabayashi[2], M. Fujii[1], K. Nozaka[3], N. Miyakoshi[3], Y. Shimada[3]. *[1]Department of Orthopedic Surgery; [2]Department of Rehabilitation Medicine, Akita City Hospital; [3]Department of Orthopedic Surgery, Akita University Graduate School of Medicine, Akita, Japan*

Background: The number of bedridden patients in our super-aging society is increasing. We previously studied fractures occurring in bedridden patients during daily activities with caregiver assistance (dry baths, range of motion exercises, transfer to wheelchair, changing diapers, and so forth) and non-traumatic fractures detected by pain, swelling, subcutaneous bleeding, deformity, and so on. These minimal trauma or spontaneous fractures were defined as "*spontaneus fractures in the bedridden patients unintentionally caused by caregivers*". Despite efforts to draw attention to preventing these injuries, the incidence of such fractures has been increasing. Spontaneus fractures caused by caregivers are characterized by the presence of untreated osteoporosis, contracture or spasticity near the lesion, institutionalization or hospitalization, repeated fractures, femur fracture, and other unknown causes.

Objectives: Spontaneus fractures caused by caregivers frequently occur without any noticeable trauma and at present, predicting the risk of occurrence is difficult. This study aimed to explore the usefulness of bone metabolism markers in predicting the risk for spontaneus fractures caused by caregivers.

Methods: Study subjects were selected from a pool of 28 patients (3 men; 25 women) with 33 spontaneus fractures caused by caregivers who were treated in our hospital between April 2006 and July 2016. Patients were selected based on the following inclusion criteria: no renal dysfunction (eGFR ≥60) and those who had undergone measurement of bone metabolism markers. Finally, 12 women with a mean age at onset of 90.6 (76–100) years were enrolled in the study. The following markers were evaluated: the bone formation markers bone type alkaline phosphatase and intact procollagen type 1 amino-terminal propeptide; the bone resorption markers tartrate-resistant acid phosphatase (TRACP)-5b, urinary deoxypyridinoline (DPD), and serum N-telopeptide; and the bone quality markers undercarboxylated osteocalcin (ucOC), urinary pentosidine (Pen), and homocysteine (Hcy).

Results: Low levels of bone metabolism markers were not observed in these subjects. However, TRACP-5b levels were high in six subjects while urinary DPD levels were abnormally high in all subjects with a mean value of 23.3 (9.2–41.4) nmol/mmol creatinine (Cr). With regards to bone quality markers, levels of Hcy and ucOC were high in two and three subjects, respectively; while Pen levels were abnormally high in ten subjects with a mean value of 0.183 (0.0774–0.3115) μg/mg Cr.

Conclusions: The majority of subjects with spontaneus fractures caused by caregivers had untreated osteoporosis and some had repeated fractures, indicating that early treatment of osteoporosis is important. Assessing osteoporosis in bedridden patients is challenging as measurement of bone density is often difficult due to spinal deformity and contracture. Our results suggest that among the bone metabolism markers, DPD and Pen may be useful predictors for the risk of spontaneus fractures caused by caregivers.

FRI0578 ODONTOID FRACTURES IN THE ELDERLY: AN UNKNOWN OSTEOPOROTIC FRACTURE?

L.L. Natella[1], N. Bronsard[2], J. Allia[2], L. Hekayem[3], L. Euller-Ziegler[1], F. De Peretti[2], V. Breuil[1]. *[1]Rheumatology/University of Nice, Rheumatology/ University of Nice; [2]Department of Orthopedic Surgery; [3]Emergency Room Department, University of Nice, nice, France*

Background: Current WHO definition of osteoporosis excludes cervical fractures. However, in atraumatic odontoid fractures, mainly reported by orthopedic surgeons, bone status has not been described yet [1].

Objectives: To investigate bone status in elderly patients sustaining a low energy odontoid fracture.

Methods: We conducted a prospective study from January 2016 to January 2017 in patients >65 years old, hospitalized in Nice University hospital for low energy odontoid fracture. An evaluation of bone status was proposed within 3 months after fracture event. Evaluation included demographic data, clinical risk factors of osteoporosis, bone mineral density (BMD) at spine and hip and vertebral fracture assessment (VFA) by dual X-ray absorptiometry and serum analysis to detect secondary osteoporosis.

Results: 38 patients were hospitalized for odontoid fracture: 8 patients <65 years always after a major trauma (mean age 37.1±14.5 y) and 30 patients ≥65 years including 3 after a high energy impact. 27 odontoid fractures followed a low energy impact: 18 women and 9 men, mean age 83.8 y. (±10.7). 8 patients died before bone status assessment (5 men and 3 women), 6 died during hospitalization with a mean delay of 3.5 days (±1.87) and 2 after discharge (1 month and 5 month). 3 patients refused bone status evaluation, 5 were lost to follow-up and 1 is awaiting evaluation. Finally 10 patients had bone status evaluation, all women, mean age 84.2 y. (±8.9). None had parental history of hip fracture, 1 had an early menopause, 1 received aromatase inhibitors for breast cancer and 2 had a history of steroid therapy (>3 months). 3 patients had previously received hormone replacement therapy, 1 received bisphosphonate for 5 years and 4 had calcium + vitamin D supplements. Lumbar spine mean T-score was -1.45 (±1.08), femoral neck: -2.37 (±0.040) and total hip: -1.99 (±0.6). VFA analysis revealed 4 unknown vertebral fractures. The table summarizes population bone status: 8 patients out of 10 fulfilled diagnostic criteria of osteoporosis, including 6 with previous fractures. 2 patients with T-score > -1.DS didn't have hip BMD assessment because of bilateral hip replacement but had previous major osteoporotic fractures. No

Lowest T-score	No fracture (n)	Previous minor osteoporotic fracture (n)	Previous major osteoporotic fracture (n)
T-score > -1 DS	0	0	**2** (1 patient: 2 femoral neck fracture, 1 patient: pelvic and humeral fractures. Both patients had vertebral fracture on VFA)
-1 DS > T-score ≥ -2.5	1	1 (1 wrist)	**2** (1 patient: humeral and vertebral fracture on VFA, 1 patient: 5 ribs fractures)
T-score < -2.5	**2**	**1** (2 wrist fractures)	**1** (vertebral fracture on VFA)

secondary osteoporosis was detected. Serum vitamin D concentration was <30 ng/ml in 5 patients, including 2 with concentration <10 ng/ml.

Conclusions: Our study reveals that odontoid fractures mainly occur in elderly osteoporotic patients after a low energy impact. Although WHO osteoporosis definition excludes cervical fractures, odontoid fracture may be considered as an osteoporotic fracture. Further studies are required to confirm these results.

FRI0579 INFLUENCE OF ORAL PREDNISOLONE ON EFFECT OF DENOSUMAB ON OSTEOPOROSIS IN PATIENTS WITH JAPANESE RHEUMATOID ARTHRITIS; 24 MONTHS OF FOLLOW-UP ~A MULTICENTER REGISTRY STUDY~

Y. Kanayama[1], Y. Hirano[2], N. Takahashi[3], S. Asai[3], N. Ishiguro[3], T. Kojima[3] on behalf of TBCR-BONE study group. *[1]Orthopedic Surgery and Rheumatology, Toyota Kosei Hospital, Toyota; [2]Rheumatology, Toyohashi Municipal Hospital, Toyohashi; [3]Orthopedic Surgery, Nagoya University Graduate School of Medicine, Nagoya, Japan*

Background: Denosumab (DMB) is a fully human monoclonal antibody to the RANKL that blocks its binding RANK, inhibiting the development and activity of osteoclasts, decreasing bone resorption, increasing bone density and reducing fracture risk. Osteoporosis (OP) is more frequent in patients with rheumatoid arthritis (RA) than in the general population due to active systemic inflammation as well as the use of glucocorticoid and immobility. However efficacy of DMB is not clear in patirnts with glucocorticoid- induced OP in RA. Therefore we investigated the influence of oral prednisolone on effect of DMB in patients with Japanese RA from initiation to 24 months at this time.

Objectives: This prospective study investigated the efficacy of DMB for 24 months on glucocorticoid- induced OP in RA patients.

Methods: Patients with a diagnosis of RA according to the 2010 ACR/EULAR criteria who had been prescribed DMB from Tsurumai Biologics Communication Registry (TBCR)-BONE between October 2013 and October 2015 were enrolled. The final study cohort of 63 patients received continuous DMB therapy more than 24 months. The DMB dose was 60mg at once every 6 months. In all cases native or activated vitamin D has been used. We reviewed the results for 24 months about the increase and decrease of bone mineral density (BMD) of lumbar spine (LS) and total hip (TH) by DEXA and bone turnover markers, intact n-terminal propeptide type I procollagen (PINP) and tartrate-resistant acid phopshatate form 5b (TRACP-5b).

Results: In the patients receiving oral prednisolone group (n=23, GC+) and not receiving group (n=40, GC-), the number of female was each 21 (91%) and 39 (98%) cases (p=0.548). The mean age was 69.8±7.0 and 71.0±7.3 years old (p=0.622); disease duration was 16.0±8.9 and 15.7±12.6 years (p=0.592); the body mass index was 20.7±3.5 and 19.7±3.0 (p=0.335) and the FRAX was 34.2±19.1 and 24.6±13.9 (p=0.040). Clinical findings related to RA and OP at baseline were as follows; CRP 1.2±1.4 and 0.5±1.0 mg/dl (p=0.009); DAS-CRP 3.16±1.17 and 2.50±1.27 (p=0.025); m-HAQ 1.24±0.90 and 0.82±0.82 (p=0.065); P1NP 60.1±38.6 and 56.9±33.5 μg/l (p=0.711); TRACP-5b 513±257 and 505±202 mU/dL (p=0.689); LS-BMD 0.87±0.18 and 0.80±0.14 g/cm^2(p=0.074) and TH-BMD 0.60±0.11 and 0.59±0.08 g/cm^2 (p=0.457). The rate of decreased P1NP from baseline to 6, 12, 18 and 24 months were each -25.6% vs -41.6% (p=0.129) at 6 month, -8.0% vs -42.6% (p=0.031) at 12 month, -19.5% vs -27.5% (p=0.235) at 18 month and -13.8% vs -33.8% (p=0.134) at 24 month and TRAC-5b were -26.5% vs -38.7% (p=0.710) at 6 month, -22.0% vs -35.1% (p=0.229) at 12 month, -25.2% vs -28.1% (p=0.792) at 18 month and -20.6% vs -27.3% (p=0.663) at 24 month in the GS+ vs GS- group. The rate of increased LS-BMD from baseline to 6, 12, 18 and 24 months were each 4.1% vs 4.6% (p=0.671) at 6 month, 5.3% vs 7.0% (p=0.361) at 12 month, 8.1% vs 8.1% (p=0.438) at 18 month and 10.0% vs 7.7% (p=0.104) at 24 month and TH-BMD were 3.3% vs 2.7% (p=0.690) at 6 month, 1.4% vs 3.8% (p=0.804) at 12 month, 6.4% vs 4.0% (p=0.259) at 18 month and 5.7% vs 4.3% (p=0.945) at 24 month in the GS+ vs GS- group (Fig.1,2).

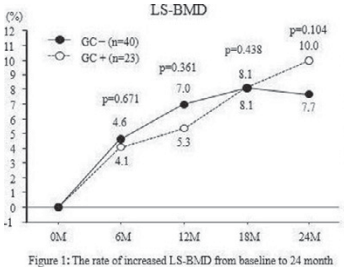

Figure 1: The rate of increased LS-BMD from baseline to 24 month

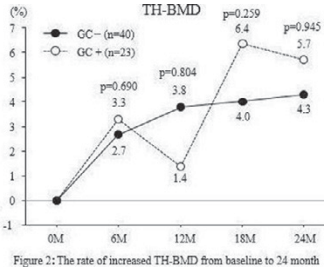

Figure 2: The rate of increased TH-BMD from baseline to 24 month

Conclusions: DMB was effective in OP of RA patients. Oral prednisolone use did not influence the efficacy of DMB for 24 months.

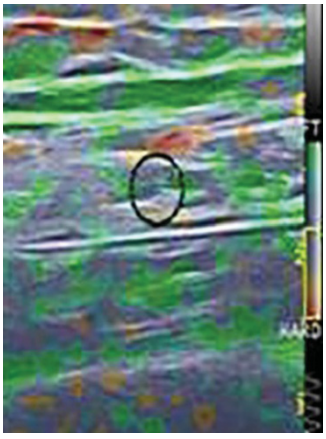
FRI0580 PREDICT SARCOPENIA BY SONOELASTOGRAPHY OF QUADRICEPS MUSCLE IN OSTEOPOROTIC PATIENTS

Y.-C. Chen, C.-H. Ko. *Rheumatology, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, Province of China*

Background: Reduced muscle mass had associated with high mortality. So it is urgent for simple techniques to early detection sarcopenia. Our objective was to examine the validity of sonoelastography to predict sarcopenia in osteoporotic patients.



Objectives: To evaluate the association of sonoelastography and dual-energy X-ray absorptiometry in patients with sarcopenia and osteoporosis.

Methods: We conducted an observational study in Kaohsiung Chang Gang Memorial Hospital. Sarcopenia was determined using a dual-energy X-ray absorptiometry. Osteoporosis was defined through estimated bone mass (BM). Sonoelastography was performed over mid thigh over quadriceps muscle. We measure hardness and elastography ratio of quadriceps over subcutaneous fat tissue. ROC analysis was used to find best cut-off point.

Results: A total 47 (23 sarcopenia, 24 non-sarcopenia) osteoporotic patients were enrolled. The mean age was 71.04±9.64 years, and most patients (88.9%) were women. Sonoelastography showed sarcopenia patients had more soft than non-sarcopenia patients, furthermore the elastography ratio of quadriceps over subcutaneous tissue was lower than non-sarcopenia patients. When the cut points determined by receiver operating characteristic (ROC) curve analysis were applied, The best cut-point of hardness was 42.5 (sensitivity, 0.969; 1-specificity, 0.066), while the best cut-point of quadriceps over subcutaneous tissue was 70.5% (sensitivity, 1.00; 1-specificity, 0.079).

Characteristics of study patients

Variables	Sarcopenia (n=23)	Non-sarcopenia (n=24)	*P*-value
Age (years)	71.04 ±9.64	70.82±8.624	0.316
Body mass index (kg/m^2)	23.80±3.45	23.83±4.56	0.977
Gender (Female %)	22 (75.9%)	78 (84.8%)	0.624
EX2/1	0.37±0.15	1.36±0.57	**<0.001**
Hard%	15.44±13.15	76.70±20.12	**<0.001**

Conclusions: Sonoelastography was easily applicable in patients with sarcopenia and osteoporosis. Using hardness content and elastography ratio of quadriceps over subcutaneous ratio render more information of muscle character. Early detection of sarcopenia with sonoelastography in patients with osteoporosis afford future trend of preventive medicine in geriatric patients.

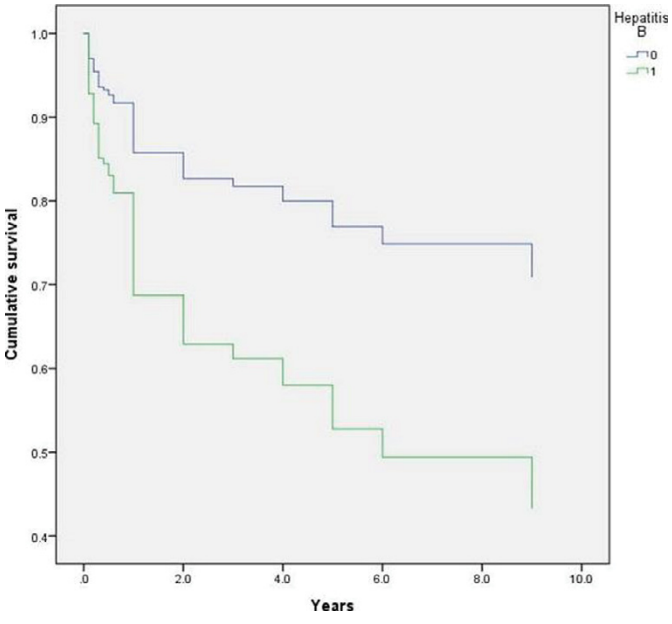
FRI0581 HEPATITIS B INCREASE MORTALITY IN PATEINTS WITH OSTEOPOROTIC VERTEBRAL FRACTURES



Y.-C. Chen, C.-H. Ko. *Rheumatology, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, Province of China*

Background: Hepatitis B virus (HBV) is a major cause of chronic liver diseases worldwide, particularly cirrhosis and hepatocellular carcinoma, and the most important liver disease in Taiwan. However, little is known the impact of hepatitis b on osteoporotic patients.
Objectives: This study aimed to determine if hepatitis b can increase the risk of mortality in patients with osteoporotic vertebral fracture.
Methods: This retrospective study reviewed of cases of osteoporosis patients with acute vertebral fractures between 2001 and 2008. All associated co-morbidities were recorded. Kaplan-Meier and cox regression analysis were performed.
Results: There were 432 patients with acute vertebral fractures. The mean age of 72.85±9.28. 31 (7.2%) patients had chronic hepatitis b. Using the Kaplan-Meier curve, hepatitis b had a significant effect on mortality ($p<0.001$, by log rank text). After adjusting for potential confounders, patients with hepatitis b still had a high mortality rate (p=0.019; HR: 2.436∼5.136) 2.137, 95% CI: 1.156∼5.136). The mortality rate also increased among smokers (p=0.026; HR: 3.6043.891; 95% CI: 1.056∼12.301).

Table 1. Multivariable Cox regression analysis of the hazard ratios for adjacent fracture

Variables	Regression coefficient	P value	HR (95CI)
Gender	-0.127	0.764	0.88 (0.383–0.022)
Age	0.004	0.785	1.004 (0.976–1.032)
Smoking	1.282	0.041	3.604 (1.056–12.301)
Alcohol consumption	-0.701	0.396	0.496 (0.098–2.508)
Body mass index (kg/m^2)	0.024	0.446	1.024 (0.964–1.088)
Hepatitis B	0.891	0.019	2.436 (1.156–5.136)
Diabetes	-0.185	0.538	0.831 (0.461–1.498)
Hypertension	-0.271	0.31	0.762 (0.451–1.288)
Stroke	-0.696	0.248	0.499 (0.153–1.625)
Kidney disease	0.809	0.145	2.246 (0.758–6.656)
Cardiovascular disease	0.037	0.946	1.038 (0.351–3.069)
Pulmonary disease	-0.971	0.349	0.379 (0.050–2.883)

Abbreviations: HR, hazard ratio; SE, standard error.

Conclusions: In this study, hepatitis b increase mortality in osteoporotic vertebral fracture patients. So we should pay attention to this group in osteoporotic management.

[1]Rheumatology, University Hospitals of Geneva, Geneva, Switzerland; [2]Rheumatology, Pitié Salpetrière University Hospital, Paris, France; [3]Department of Medicine 3, Rheumatology and Immunology, Universitätsklinikum Erlangen, Erlangen, Germany; [4]Division of Immunology and Allergy, CHUV, Lausanne, Switzerland; [5]Rheumatology, Charité Universitatsmedizin, Berlin; [6]Asklepios Klinikum, Hamburg, Germany; [7]CHRU de Lille - Hopital Claude Huriez, Lille; [8]Department of Rheumatology, University and CHU of Montpellier, Montpellier; [9]Rheumatology, Hopital Pellegrin, Bordeaux; [10]CHU de Nantes, Nantes; [11]University Hospital of Strasbourg, Strasbourg, France; [12]Klinik fur Innere Medizin, Rheumatologie und immunologie, Medius Klinik, Kirchheim unter Teck; [13]Rheumatology, University of Lübeck, Lübeck; [14]Medizinische Klinik und Poliklinik IV, LMU, Muenchen, Germany; [15]Ab2 Bio, Lausanne, Switzerland

Background: Adult Onset Still's Disease (AOSD) is a severe systemic autoinflammatory disease. Elevated interleukin (IL)-18 levels correlate with AOSD disease activity, suggesting a central role
Objectives: To examine the safety and efficacy of IL-18 blockade in AOSD with the administration of Tadekinig alpha, a recombinant human IL-18 binding protein
Methods: Patients (Pts) with AOSD according to Yamaguchi criteria were included if they had been previously treated for at least one month with corticosteroids (CS). The pts received either 80 mg (group 1) or 160 mg (group 2) Tadekinig alpha sc three times weekly for 12 weeks. Oral CS and/or conventional DMARDs were allowed at stable dose in combination with Tadekinig alpha. After 3 wks, group 1 pts qualified as non responders (CRP levels did not decrease by ≥50% from baseline values or absence of temperature normalization) could be up-dosed to 160 mg for an additional 12 weeks. The primary endpoint was safety and secondary endpoints included early signs of efficacy
Results: 23 pts were included (10 and 13 in group 1 and group 2, respectively). 6 pts of group 1 were up-dosed to 160 mg. Baseline characteristics and safety and efficacy results are described in Table 1. Most adverse events (AEs) (47) were considered as mild or moderate. Three serious AEs (SAE) were reported including two that were considered not related to the study drug and one possibly related according to the investigator (toxic optic neuropathy). Four premature discontinuations were related to AEs, including 3 cases of injection site reactions and 1 SAE. Systemic response as defined by ≥70% decrease of serum C-reactive protein (CRP) or normalization of CRP and ferritin levels was obtained in 2/10 and 6/13 pts of groups 1 and 2, respectively in the ITT analysis, and in 2/9 and 6/9 pts of groups 1 and 2, respectively, in the PP analysis.

Table 1. Baseline characteristics and safety and efficacy results

	Group 1 (80 mg) (N=10)	Group 2 (160 mg) (N=13)
Age, median (IQR)	49.5 (34.3–58.8)	35 (30–58)
Median disease duration, months (IQR)	25.5 (8.7–44.2)	11.6 (2.1–37.6)
Pts with previous conventional DMARDs	6	7
Pts with previous biological DMARDs	4	5
Pts with SAEs	2	1
Discontinuations due to AEs*	1	3
Discontinuations due to lack of response*	1	2
Arthritis improvement (≥20% reduction in tender and swollen joint count)**	3/9	4/10
Skin rash resolution**	6/7	2/5
CRP level reduction by ≥70%**	2/10	6/13
Normalization of ferritin levels**	0/7	1/5

*Number of Pts, **Denominator corresponds to Pts with clinical manifestations or abnormal values at baseline.

Conclusions: IL-18 blockade by Tadekinig alpha has an acceptable safety profile and is efficacious, in particular at the 160 mg dosage, in patients with refractory AOSD

FRI0583 IGG4-RELATED DISEASE AMONG PATIENTS PREVIOUSLY DIAGNOSED WITH IDIOPATHIC RETROPERITONEAL FIBROSIS. A NATIONWIDE DANISH STUDY

N. Lomborg[1], M. Jakobsen[2], C.S. Bode[3], P. Junker[4]. *[1]Department of Rheumatology; [2]Department of Pathology, Vejle Hospital, Vejle; [3]Department of Pathology; [4]Department of Rheumatology, Odense University Hospital, Odense, Denmark*

Background: IgG4-related disease (IgG4-RD) is a recently recognized systemic disease of unknown etiology and prevalence [1]. Retrospective single center series have provided evidence that 13–63% of patients with idiopathic retroperitoneal fibrosis (IRPF) could be reclassified as IgG4-RD. Since immunesuppressants or B-cell targeted therapies may halt or reverse progression, early diagnosis and treatment is important to prevent terminal fibrosis.
Objectives: To estimate the occurrence of IgG4 related retroperitoneal fibrosis (RPF) in Danish patients diagnosed with IRPF.
Methods: The National Danish Pathology Register was searched for biopsy codes relating to retroperitoneal tissue and inflammation from 01.01.2004 through 31.12.2013. Patients below 18 years of age, secondary causes, malignancies, infections, and specimens with multinucleated giant cells or granulomas were excluded. Among 724 candidate cases 68 were identified with IRPF. Among these 25 were left out due to small tissue samples, unavailable patient files or lack of consent. Clinical, laboratory data and imagings were reviewed. Paraffin-embedded tissue blocks were retrieved from 18 pathology departments. Four sections were prepared and stained with hematoxylin-eosin, Weigerts elastin and IgG4 immunostaining. Histopathologic features suggesting an IgG4-RD background were recorded (table). Cut-off levels for IgG4 positive cells at $\geq$30 per HPF and IgG4: total IgG ratio at $\geq$40% were applied. Patients were categorized as IRPF, definite or possible IgG4-RD according to international consensus [2]. Intergroup comparisons were done using Mann-Whitney U test or Chi square test.
Results: Forty three patients (29 males), median age 56 years were included among which 19 (44%) met the criteria for IgG4-RD comprising 7 with definite, 12 with possible IgG4-RD and 24 with IRPF. Biopsies were available from all participants. Extraretroperitoneal manifestations, standard laboratory measures and serum IgG4 (in 5 individuals) did not differ significantly between RPF subsets. Patients with an IgG4: total IgG ratio $\geq$40% had significantly more histopathologic features of IgG4-RD compared to a ratio $<$40% (table). Patients with $\geq$30 IgG4 positive cells per HPF had higher numbers of tissue eosinophils than those with lower IgG4+ cell counts.

Table 1. Histopathologic findings in RPF biopsies (N=43) according to IgG4: total IgG ratio

	IgG4/IgG ratio $\geq$40% N=21	IgG4/IgG ratio $<$40% N=22	p-value
Lymphoplasmacytic infiltrate	21	13	0,002
Storiform fibrosis	12	3	0,004
Obliterative phlebitis	5	1	0,078
Phlebitis without obliteration	4	2	0,378
Increased numbers of eosinophils	13	6	0,030

Conclusions: A total of 44% of IRPF patients was diagnosed with IgG4-RD, 16% with definite and 28% with possible IgG4-RD. This estimate may be conservative because specimens with multinucleated giant cells or granulomas were excluded. The closer association of IgG4: total IgG ratio $\geq$40 vs. lower ratios with histopathologic findings supports a direct pathogenic role by IgG4 bearing cells or IgG4 in IgG4 RPF.

FRI0584 RHEUMATIC AND MUSCULOSKELETAL DISORDERS RELATED TO IMMUNE CHECKPOINT INHIBITORS IN CANCER PATIENTS: A PROSPECTIVE SINGLE-INSTITUTION STUDY

K. Marie[1], L. Rouxel[1], R. Veillon[2], F. Martin[2], C. Dutriaux[3], A. Pham-Ledard[3], S. Prey[3], M. Beylot-Barry[3], M. Gross-Goupil[4], B. Bannwarth[1], C. Richez[1], N. Mehsen-Cetre[1], T. Schaeverbeke[1]. *[1]Rheumatology, Hôpital Pellegrin; [2]Pneumology, Hôpital Haut-Lévêque; [3]Onco-dermatology; [4]Medical Oncology, Hôpital Saint-André, Bordeaux, France*

Background: Immune checkpoint inhibitors (ICI) targeting cytotoxic T-lymphocyte-associated protein 4 (CTLA-4) and programmed cell death protein 1 (PD-1) axis have been a major advance in cancer immunotherapy. By enhancing T cell activity, unprecedented long-lasting tumour responses are observed in selected cancers but some patients experience immune related adverse events (irAE).
Objectives: To evaluate the prevalence and type of rheumatic and musculoskeletal disorders in patients receiving ICI at a single institution (University Hospital of Bordeaux, France).
Methods: All cancer patients with musculoskeletal disorders while receiving ICI were referred to our rheumatology department. For each referred patient, an experienced rheumatologist performed a comprehensive clinical evaluation. Blood tests (inflammatory markers, serum creatine kinase, autoantibodies) and imaging (X-rays, ultrasound) were obtained according to clinical findings. HLA-DR phenotyping was also performed for some patients to search for shared epitope.
Results: From September 2015 to December 2016, 329 patients received ICI (anti CTLA-4: n=38; anti PD-1: n=251; anti PD-L1: n=29; combination anti CTLA-4/anti PD-1: n=11) and 21 patients were referred to our rheumatology department (6.4%). Mean age was 65 years and cancer types included melanoma (n=10), non small cell lung cancer (n=9), Merkel carcinoma (n=1) and renal carcinoma (n=1). All musculoskeletal disorders occurred in patients receiving anti PD-1 (nivolumab: n=12; pembrolizumab: n=6) or anti PD-L1 (avelumab: n=2; atezolizumab: n=1), with a median exposure time of 90 days (range: 1–650 days). There were two distinct clinical presentations: 1) inflammatory arthritis (IA) mimicking either rheumatoid arthritis (n=5) or polymyalgia rheumatica (n=8) and, 2) non-inflammatory musculoskeletal conditions (n=8). Of note, one patient was anti-CCP positive but negative for RF. Shared epitope HLA-DRB1 *01:01 was present in 4 patients. Eleven patients required corticosteroid therapy with a median dose of 15mg/day (range: 7–30 mg/day). Non-inflammatory disorders were easily managed with NSAIDs, analgesics and/or physiotherapy. ICI treatment was temporarily discontinued in one patient only, in line with the clinical trial protocol. To date, there was a partial or complete tumour response to ICI in 10 patients whereas 3 had stable disease and 7 had progressive disease. Tumour response or stable disease was observed in 11 of 12 patients with IA but only in 2 of 8 patients with non-inflammatory conditions.
Conclusions: In our series, patients with immune-related IA mimicking rheumatoid arthritis and polymyalgia rheumatica were responsive to low-to-moderate dose of prednisone and did not require ICI discontinuation. Furthermore, tumour response was frequently observed in such patients.

FRI0585 FREQUENT, UNUSUALLY SEVERE, LONG LASTING, LOCAL AND SYSTEMIC PNEUMOCOCCAL VACCINE REACTIONS IN PATIENTS WITH CRYOPYRIN-ASSOCIATED PERIODIC SYNDROMES (CAPS): RESULTS OF A PROSPECTIVE REGISTRY BASED STUDY

V.K. Jaeger[1], H.M. Hoffmann[2], T. van der Poll[3], H. Tilson[4], J. Seibert[5], A. Speziale[5], G. Junge[5], K. Franke[6], E. Vritzali[5], P.N. Hawkins[7], J. Kuemmerle-Deschner[8], U.A. Walker[1]. *[1]University Hospital Basel, Basel, Switzerland; [2]University of California at San Diego and Rady Children's Hospital, San Diego, United States; [3]University of Amsterdam, Amsterdam, Netherlands; [4]University of North Carolina, Chapel Hill, United States; [5]Novartis Pharma AG, Basel, Switzerland; [6]QuintilesIMS, Real World Insights, NC, United States; [7]University College London, London, United Kingdom; [8]University Hospital Tübingen, Tübingen, Germany*

Background: Pneumococcal, tetanus and influenza vaccinations are recommended for patients with Cryopyrin-Associated Periodic Syndromes (CAPS) when treated with immunosuppressive medication.
Objectives: This study aims to report the safety of pneumococcal and other vaccinations administered to CAPS patients.
Methods: All CAPS patients followed in the β-CONFIDENT (Clinical Outcomes and Safety Registry study of Ilaris® patients) registry between 07/2010 and 12/2015 were analysed if they had received a vaccination. The β-CONFIDENT registry is a global, long-term, prospective, observational registry, capturing and monitoring CAPS patients treated with canakinumab [1].
Results: 68 CAPS patients (56% female, age range 3.5–73 years) had received a total of 159 vaccine injections, 107 injections against influenza, 19 pneumococcal vaccinations (15 pneumococcal polysaccharide vaccines [PPV], 2 pneumococcal conjugate vaccines [PCV], 2 unknown), 12 against tetanus/diphtheria antigens and 21 other vaccinations.
A reaction was observed in 22 vaccine injections (14%) administered to 18 patients. 13 vaccine reactions (68% of all pneumococcal vaccine injections) occurred in 12 patients receiving pneumococcal vaccines. 12 PPV injections (80% of all PPV injections) elicited a vaccine reaction while none was elicited by the PCV injections The high frequency of pneumococcal vaccine reactions contrasted with that of the reactions to other vaccine types: only 17% and 7% of the tetanus/diphtheria and influenza vaccinations, respectively, elicited a vaccine reaction. The odds ratios to react to the pneumococcal vaccines compared to influenza and tetanus/diphtheria vaccines were 31.0 (95% confidence interval (CI) 8–119) and 10.8 (95% CI 2–74).
Vaccine reactions after pneumococcal vaccinations were more severe and lasted significantly longer compared to the reactions after other vaccinations. Fever was elicited by almost half of all PPV injections. All symptoms after pneumococcal vaccination were observed very rapidly, usually within hours. Unlike the symptoms observed after influenza and tetanus/diphtheria vaccination, which resolved rapidly, the symptoms related to PPV were much more prolonged and in some cases lasted more than 3 weeks. In 2 patients, pneumococcal vaccination also elicited symptoms consistent with systemic inflammation due to CAPS reactivation. All 5 vaccine related serious adverse events were associated with pneumococcal vaccination.

Conclusions: Pneumococcal vaccines, unlike other vaccines, frequently trigger severe local and systemic inflammation in CAPS patients. Clinicians must balance potential benefits of pneumococcal immunisation against safety concerns.

FRI0586 INTERLEUKIN (IL)-1 INHIBITION WITH ANAKINRA AND CANAKINUMAB IN BEHÇET'S DISEASE RELATED UVEITIS: A MULTICENTER RETROSPECTIVE OBSERVATIONAL STUDY

C. Fabiani[1], A. Vitale[2], G. Emmi[3], G. Lopalco[4], L. Vannozzi[3], S. Guerriero[4], S. Gentileschi[2], D. Bacherini[3], R. Franceschini[2], B. Frediani[2], M. Galeazzi[2], F. Iannone[4], G.M. Tosi[2], L. Cantarini[2]. *[1]Humanitas Research Hospital, Rozzano, Milan; [2]University of Siena, Siena; [3]University of Florence, Florence; [4]University of Bari, Bari, Italy*

Objectives: To evaluate the role of interleukin (IL)-1 inhibitors anakinra (ANA) and canakinumab (CAN) in the treatment of Behçet disease (BD)-related uveitis

Methods: multicenter retrospective observational study including 19 consecutive BD patients (31 affected eyes) receiving treatment with anti-IL-1 agents. Data were analyzed at baseline, at 3 and 12 months. Primary end-point: reduction of ocular inflammatory flares (OIF). Secondary end-points: improvement of Best Corrected Visual Acuity (BCVA); reduction of macular thickness defined by optical coherence tomography (OCT) and of vasculitis identified with fluorescein angiography (FA); evaluation of statistically significant differences between patients treated with IL-1 inhibitors as monotherapy, subjects also administered with disease modifying anti-rheumatic drugs (DMARDs) and/or corticosteroids as well as between patients administered with IL-1 inhibitors as first line biologic treatment and those previously treated with TNF-α inhibitors

Results: at 12 months OIF significantly decreased from 200/100 patients/year to 48.87/100 patients/year ($p<0.0001$). The frequency of retinal vasculitis identified by FA significantly decreased between baseline, 3-month and 12-month follow-up visits ($p<0.0001$ and $p=0.001$, respectively). OIF rate was significantly higher in patients co-administered with DMARDs (81.8/100 patients/year) than in patients undergoing IL-1 inhibitors as monotherapy (0.0/100 patients/year) ($p=0.03$). No differences were identified on the basis of corticosteroid use and between patients administered with IL-1 inhibitors as first-line biologic approach or second-line. Steroid dosage was significantly decreased at 12-month visit compared to baseline ($p=0.02$).

Conclusions: treatment with IL-1 inhibitors is effective in the management of BD-related uveitis and provides a long-term control of ocular inflammation in refractory and long-lasting cases.

FRI0587 DIFFERENT FACTORS ARE RELATED TO RECURRENCE OF EXISTING ORGAN INVOLVEMENT AND NEW DEVELOPMENT OF ORGAN INVOLVEMENT IN IGG4-RELATED DISEASE

I. Mizushima, S. Tsuge, Y. Fujisawa, S. Hara, F. Suzuki, K. Ito, H. Fujii, K. Yamada, M. Kawano. *Division of Rheumatology, Kanazawa University Hospital, Kanazawa, Kanazawa, Japan*

Background: IgG4-related disease (IgG4-RD) is a recently recognized systemic inflammatory disorder that can affect many organs [1]. In IgG4-RD, relapse including recurrence of existing organ involvement (REOI) and new development of organ involvement (NDOI) easily occurs during the clinical course, and its predictors have been suggested [2, 3]. However, differences between risk factors of REOI and those of NDOI have not been clarified.

Objectives: This study aimed to clarify the respective risk factors of REOI and NDOI in IgG4-RD.

Methods: We retrospectively investigated factors related to REOI and NDOI in 86 IgG4-RD patients whose follow-up period was more than 12 months. For assessment of factors related to REOI and NDOI, we performed uni- and multivariate Cox regression analysis. On stepwise multivariate analysis, we applied the variables with $P<0.1$ in univariate analysis and the predictors of relapse suggested in past reports (age, sex, serum IgG4, IgG, and IgE levels, eosinophil counts, and RF positivity) [2, 3], and used the forward selection method (including factors presenting with $P<0.05$).

Results: The patients comprised 57 men and 29 women (mean age 65.9 years). Mean follow-up period was 63.1 months (range 14–150). At diagnosis, their mean serum IgG4 level was 718 mg/dL (range 10.7–3,610). Seventy-one patients were treated with glucocorticoid (GC). REOI was detected at 52.3 months (range 1.0–120) after the diagnosis in 20 patients, including 4 not receiving GC at that time. On the other hand, NDOI was detected at 37.6 months (range 5.0–120) after the diagnosis in 15 patients, including 8 not receiving GC then. In multivariate Cox regression analysis, blood eosinophil counts [per 100/μL, hazard ratio (HR) 1.072, 95% confidence interval (CI) 1.018–1.129, $P=0.008$] and continuation of GC (vs discontinuation or observation without GC, HR 0.245, 95% CI 0.076–0.793, $P=0.019$) had a significant impact on the time to NDOI, whereas age (per year, HR 0.942, 95% CI 0.899–0.986, $P=0.011$) and ANA positivity (vs negativity, HR 6.632, 95% CI 1.892–23.255, $P=0.003$) had a significant impact on the time to REOI.

Conclusions: The present study suggests that the risk factors of REOI and NDOI in IgG4-RD are different.

FRI0588 INTERIM RESULTS OF A PHASE 2 STUDY OF XMAB®5871, A REVERSIBLE B CELL INHIBITOR, IN IGG4-RELATED DISEASE

J.H. Stone[1], Z.S. Wallace[1], C.A. Perugino[1], A.D. Fernandes[1], P.S. Patel[1], P.A. Foster[2], D.J. Zack[2]. *[1]Massachusetts General Hospital Rheumatology Unit, Harvard, Boston; [2]Clinical Development, Xencor Inc., Monrovia, United States*

Background: IgG4-related disease (IgG4-RD) is an immune-mediated condition causing fibro-inflammatory lesions that can lead to irreversible organ damage. No approved therapies for IgG4-RD exist. We report the use of a novel monoclonal antibody, XmAb5871, in IgG4-RD. XmAb5871 is a humanized anti-CD19 antibody with an Fc portion engineered for increased affinity (up to 400-fold over native IgG_1) to FcgRIIb, the only Fc receptor on B cells. Co-ligation of CD19 and FcgRIIb leads to inhibition of B lineage cells bearing these targets. Reversible inhibition of B cell function without B cell ablation is one potential advantage of this approach.

Methods: The trial is an open-label investigation of XmAb5871 in active IgG4-RD, defined by an IgG4-RD Responder Index (RI) of ≥3. XmAb5871 (5 mg/kg) is administered IV every 14 days for 12 doses. The primary outcome measure is the proportion of patients on day 169 (2 weeks following the last dose) with a decrease in the IgG4-RD RI of 2 or more points compared to baseline. Glucocorticoids are permitted but not required at entry and must be discontinued by two months. Other immunosuppressive medications are not allowed. Imaging and mechanistic studies are performed at baseline and at selected intervals.

Results: Fifteen patients were enrolled between March 2016 and January 2017. As of October 31, 2016, 12 patients had received at least one infusion of XmAb5871. The median age of the 12 patients is 58 years (range: 43 to 78 years). Two-thirds of the patients are male. Nine of the 12 patients had elevated serum IgG4 concentrations at baseline with a mean serum IgG4 of 499 mg/dL (range: 25–2415; normal <86 mg/dL). The median baseline IgG4-RD RI score was 10 (range: 2–30), with active inflammatory disease in at least one organ system (median 4, range: 1–10). The organs most commonly affected were lymph nodes (75% of patients), submandibular glands (67%), parotid glands (58%), and lacrimal glands (50%). Four patients (33%) had kidney involvement and 3 (25%) had heart/pericardium findings. Nine of 11 patients (82%) have had an initial response to XmAb5871 therapy of at least a three-point reduction in the IgG4-RD RI within two weeks of the first dose. As of Oct 31st, 2016, five patients attained disease remission (an IgG4-RD RI of 0 and no prednisone treatment after 2 months) during the study. Efficacy outcomes will be updated as more patients complete the study. One patient had been on glucocorticoid treatment for 2 years and was on prednisone of 15 mg/day at baseline, but was able to discontinue prednisone by 2 months after starting treatment. Three patients experienced minor, transient gastrointestinal side-effects during the 1st infusion. One patient had infusion-related GI symptoms on the 5thinfusion and subsequently developed rash and arthritis. She was found to have anti-drug antibodies and has discontinued the study. Mechanistic studies show that both peripheral B cells and plasmablasts decrease substantially following therapy in the majority of patients. Studies of the mechanism of this decrease and functional B cell assays are under way.

Conclusions: XmAb5871 is tolerated well in patients with active IgG4-RD and is a promising treatment approach for IgG4-RD.

FRI0589 CANCER IS FREQUENT IN PATIENTS WITH ANTICENTROMERE PATTERN

C. Vázquez-Triñanes[1], V. Alende[2], E. González[3], R. Lorenzo[4], T. Caínzos[5], L. González[6], S. Rodríguez[6], B. Sopeña[2] on behalf of Círculo de estudio de las enfermedades autoinmunes de Galicia (CEAG). *[1]Systemic Autoimmune Diseases and Thrombosis Unit, H. Álvaro Cunqueiro, Vigo; [2]Hospital Clínico Universitario de Santiago, Santiago; [3]Complejo Hospitalario de Ourense, Ourense; [4]H. Álvaro Cunqueiro, Vigo; [5]Hospital Arquitecto Marcide, Ferrol; [6]H. Povisa SA, Vigo, Spain*

Background: Anti-centromere pattern (ACA) is infrequently seen among antinuclear antibodies (ANA) detected by indirect immunofluorescence (IFI). ACA is associated with systemic autoimmune diseases (SAD), especially systemic sclerosis (SSc). Some studies had recently related ACA with cancer, mostly with breast and lung cancer [1]. However, most published series of patients with ACA lack information about cancer occurrence. A prevalence of cancer of 11.1% was the only reported data, on a series of 45 unselected patients with ACA [2]
Objectives: Our aim was to study the prevalence of cancer in the largest series of patients with ACA, with a long follow-up. Our second objective was to make a cohort to calculate the incidence of cancer and to try to identify risk markers of cancer in these patients
Methods: We included consecutive patients with at least 2 positive determinations of ANA with ACA by IFI on Hep2 cells between January 1st of 2011 and June 30th of 2015 in 6 Galician hospitals. The authors reviewed each patient's chart to determine the presence of cancer and its type among numerous variables. Then, patients with cancer at the moment of the first positive determination of ANA with ACA were excluded. We checked the presence of any tumour in patients of this cohort at the end of follow-up to calculate the incidence of cancer. Finally, we compared patients with and without cancer by multivariate analysis, with the SPSS 20.0. The ethics committees of each hospital approved the study and patients gave their consent
Results: 369 patients with ACA were studied, of which 333 were women (90.2%), with a mean age of 64.7 years (range: 22–92). The mean follow-up from the first positive ACA determination was 67.6 months. 283 patients (76.7%) had a SAD: 46.3% SSc (79% of whom were lc-SSc), 8.13% primary biliary cholangitis, 7.05% Sjögren's syndrome, 4.6% autoimmune hepatitis and 11 other SAD (polyarthritis, SLE, Raynaud phenomenon, sarcoidosis, mixed connective tissue disease, etc). 45 of these patients (15.9%) had any overlap syndrome. 39 patients had cancer at some time (10.6%), 3 of them with 2 types of cancer. The most frequent were: breast in 9 (23.1%), lung in 5 (11%), NHL in 5 (11%) and colorectal in 4 (10.3%). Cancer preceded the diagnosis of ACA in 19 patients (48.7%), with a mean time to diagnosis of 9.1 years (range 1–18). In the cohort of 350 patients with ACA the incidence was 1.14 per 100 patients per year (n 20). The mean time to diagnosis of cancer was 7.3years (range 1–27). The oldest age was the only risk marker of cancer identified (70.8±13.29 years vs. 63.9±14.32, p 0.005). There were no differences in the other variables analysed including sex, tobacco, diagnosis of SAD, capillaroscopy pattern, ANA titrations and mortality
Conclusions: Cancer was frequent in patients with ACA, with a prevalence of 10.6% and incidence of 1.14 per 100 patients per year. The only risk marker of cancer identified in this population was the oldest age

FRI0590 SOLUBLE INTERLEUKIN-2 RECEPTOR LEVELS REFLECT DISEASE ACTIVITY IN IGG4-RELATED DISEASE AND PRIMARY SJÖGREN'S SYNDROME

M. Akiyama, T. Sasaki, Y. Kaneko, H. Yasuoka, K. Suzuki, K. Yamaoka, T. Takeuchi. *Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan*

Background: Soluble interleukin-2 receptor (sIL-2R) is known as an indicator for activation status of lymphocytes and could be a potential biomarker for disease activity of lymphoproliferative disorders and autoimmune diseases.
Objectives: The aim of this study was to examine the association of sIL-2R with disease activity in patients with IgG4-related disease (IgG4-RD) and primary Sjögren's syndrome (pSS).
Methods: Consecutive 45 patients with active, untreated IgG4-RD, 117 patients with pSS, and 10 patients with sicca syndrome (subjects with xerostomia with neither anti-SSA/SSB antibodies nor lymphocytic infiltration by lip biopsy) were enrolled. Disease activity of IgG4-RD and pSS was determined based on the IgG4-RD responder index (IgG4-RD RI) score and the EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) score, respectively. The association of sIL-2R with disease activity was analyzed.
Results: The levels of sIL-2R and serum IgG were significantly higher in both IgG4-RD (709U/mL, and 1988mg/dL) and pSS (464U/mL, and 1851mg/dL) compared to sicca syndrome (276U/mL, and 1255mg/dL). Serum levels of IgG4, IgE, and circulating eosinophil counts were significantly higher in IgG4-RD (552mg/dL, 732IU/mL, and 366/mm^3) compared to pSS (37mg/dL, 216IU/mL, and 157/mm^3) and sicca syndrome (45mg/dL, 132IU/mL, and 137/mm^3). On the other hand, the levels of serum IgA and IgM were significantly higher in pSS (312mg/dL, and 112mg/dL) compared to IgG4-RD (182mg/dL and 81mg/dL) and sicca syndrome (228mg/dL and 78mg/dL). The levels of serum C-reactive protein, lactate dehydrogenase, CH50, CC chemokine ligand (CCL17)/thymus and activation-regulated chemokines (TARC) were not different among the three groups. In patients with IgG4-RD, the baseline IgG4-RD RI scores significantly correlated with the levels of sIL-2R (ρ=0.715, $p<0.0001$), serum IgG (ρ=0.672, $p<0.0001$) and IgG4 (ρ=0.632, $p<0.0001$), but not serum IgE levels (ρ=0.290, p=0.082) and circulating eosinophil counts (ρ=0.149, p=0.335). In patients with pSS, the ESSDAI scores significantly correlated with the levels of sIL-2R (ρ=0.615, $p<0.0001$) and serum IgG (ρ=0.627, $p<0.0001$), but not the levels of serum IgA (ρ=0.169, p=0.073) and IgM (ρ=0.133, p=0.157). Furthermore, the number of affected organs positively correlated with sIL-2R levels in both IgG4-RD (ρ=0.725, $p<0.0001$) and pSS (ρ=0.559, $p<0.0001$). Receiver operating characteristic curve analysis demonstrated that sIL-2R was the most distinguishable biomarker for the presence of extra-dacryosialadenitis lesions in patients with IgG4-RD, compared to serum IgG and IgG4, with a cut-off value of 424 U/mL (AUC=0.917, $p<0.0001$), and in patients with pSS with 513 U/mL (AUC=0.894, $p<0.0001$). The sIL-2R levels in patients with IgG4-RD decreased significantly after glucocorticoid treatment. Notably, the cases which could be followed up at disease relapse or exacerbation showed the re-elevation of sIL-2R levels.
Conclusions: Soluble IL-2R level is a biomarker for disease activity, in particular for the extent of organ involvements and extra-dacryosialadenitis lesions in patients with IgG4-RD and pSS. Furthermore, sIL-2R level could be useful for longitudinal disease monitoring in patients with IgG4-RD.

FRI0591 RISK FACTORS FOR DISEASE RELAPSE IN IGG4-RELATED DISEASE FOLLOWING GLUCOCORTICOIDS TREATMENT

T. Sasaki, M. Akiyama, Y. Kaneko, H. Yasuoka, K. Suzuki, K. Yamaoka, T. Takeuchi. *Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan*

Background: IgG4-related disease (IgG4-RD) is a fibroinflammatory disease characterized by elevated serum IgG4 and infiltration of IgG4$^+$ plasma cells at affected sites. The patients with IgG4-RD respond well to glucocorticoids (GCs), but one-third of the patients experience disease relapse during tapering of GCs (1). The risk factors for disease relapse following treatment are unclear.
Objectives: The aim of this study was to identify the risk factors of disease relapse following reduction of GCs therapy.
Methods: Consecutive, newly diagnosed patients with IgG4-RD who were followed over 6 months after treatment with GCs in our department were enrolled. The patients were divided into two groups according to the presence or absence of disease relapse. Disease relapse was defined as the appearance of new lesions or the re-enlargement of involved organs that required dose-increase of GCs. Patient characteristics and laboratory findings at diagnosis were compared and receiver operating characteristic curve analysis was performed to identify the relevant predictive factors of disease relapse.
Results: A total of 34 patients were included and all patients were treated with GCs alone as initial treatment. Ten patients (29.4%) experienced relapses during GCs dose tapering which was at 16.0 months (median) after GCs initiation. No difference was found in age, sex, body weight, and disease duration between the two groups. The observation periods and the initial/last GCs dose were also not different. However, serum IgG4 (939 vs 450 mg/dl, p=0.008), serum IgG4/IgG ratio (0.35 vs 0.24 p=0.046), soluble IL-2 receptor (907 vs 677 U/ml, p=0.032) and number of organ involvement (4.3 vs 3.0, p=0.028) were significantly higher in patients with relapse than those without, while the level of IgA (135 vs 205 mg/dl, p=0.015) and IgM (60 vs 91 mg/dl, p=0.038) were significantly lower in the patients with relapse. IgG4 decreased to a comparable level in both groups after GCs treatment (200 vs 91 mg/dl, p=0.124), but increased in the relapse group afterward (387 vs 115 mg/dl at last observation, p=0.048). The predictive values (sensitivity, specificity) at IgG4-RD diagnosis for relapse were as follows; serum IgG4 570 mg/dl (90.0%, 75.0%), IgG4/IgG 0.31 (70.0%, 79.2%), soluble IL-2 receptor 470 IU/ml (100.0%, 54.5%), the number of affected organs of four (80.0%, 70.8%), IgA 100 mg/dl (50.0%,100.0%) and IgM 60 mg/dl (80.0%,75.0%) (Figure 1).
Conclusions: Higher serum IgG4, soluble IL-2 receptor, and the number of affected organs and lower levels of serum IgA and IgM at baseline indicate

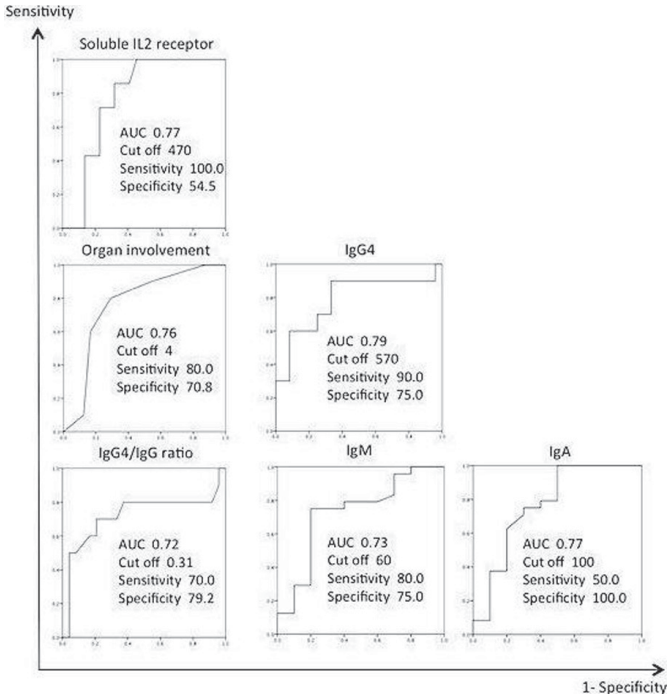

Figure 1

the higher likelihood of disease relapse following GCs therapy in patients with IgG4-RD.

FRI0592 CLINICAL, ANALYTICAL AND RADIOLOGICAL CHARACTERISTICS IN A COHORT OF PATIENTS WITH SARCOIDOSIS

A. Ruiz Román[1], C. Aguilera Cros[1], M. Arcila Durán[1], M. León Luque[1], M. Lisbona Muñoz[1], J.P. Sanchez Serrano[2], J.A. Rodriguez Portal[3], J. Povedano Gomez[1]. *[1]Rheumatology, Hospital Virgen del Rocio, Sevilla; [2]Breeding and Genetics, Irta, Caldas de Montbui; [3]Pneumology, Hospital Virgen del Rocio, Sevilla, Spain*

Background: Sarcoidosis is a systemic granulomatous disease, frequently affecting lungs, eyes and skin, although it may damage other organs, among them the musculoskeletal system

Objectives: To describe the clinical characteristics and radiological pattern in a cohort with predominantly pulmonary sarcoidosis, and to determine the relationship between the levels of angiotensin converting enzyme (ACE), pulmonary radiological stage and sarcoidosis course (chronification or remission)

Methods: Data from 2328 patients in an Interstitial Lung Diseases consultation during the first half of 2016 were analyzed. Out of these, 50 had sarcoidosis.The delay in the diagnosis of sarcoidosis was defined as the difference in years between the diagnostic suspicion and diagnosis of sarcoidosis.

Chi square tests were used, assuming an error of the first species not higher than 0.05, in order to: 1. Study the association between angiotensin converting enzyme (ACE) levels and binary variables (extrapulmonary symptoms, radiological stage and evolution of S) 2. Determine the association between evolution, the radiological stage and the presence of extrapulmonary symptoms.

Results: We included 29 (58%) women and 21 (42%) men, (mean age of 44±11.7 years). Initial diagnosis: 88% S, 8% lymphoma and 4% tuberculosis. Of the 44 diagnosed cases of S, 24 were on the first visit, 11 the following year and 1 seven years later. Of the 4 lymphomas, 2 were diagnosed of S that same year and the other 2 were diagnosed the following year. Of the 2 tuberculosis, one was diagnosed of S in one year and the other at 4 years.

The most frequent extrapulmonary manifestations were cutaneous 24%, followed by the articular, cardiac and ocular in 10%, neurological 8% and renal 4%. In 6% of patients, the first clinical manifestation of the disease was bilateral arthritis of the ankles, The ACE title is increased in 62% of patients, normal in 34%. The mean and standard deviation of the title of patients with an increased ACE value was 150.5 and 53.4 IU/L, respectively. In all patients, x-ray and high resolution tomography were performed, with stage 2 being the most frequent (44%), followed by 3 (20%), 0 and 1 (14%) and 4 (8%). Histological confirmation was obtained by transbronchial biopsy (66%), cutaneous (12%) or lymph node biopsy (12%) in 90% of the patients. 90% of patients have been treated with oral glucocorticoids and 42% associate immunosuppressive therapy.

The ACE levels showed no statistical association with any of the variables studied, although a very clear association (p=0.04754) was observed between the course of the disease and the presence of extrapulmonary symptoms: from the 25 patients without extrapulmonary symptoms, only in 35% of cases the process become chronic.

Conclusions: Our results, in general, coincide with what is published in the literature. In our cohort, initial diagnosis of S was relatively high (28/50 =56%), while misdiagnosis was relatively low (6/50 =12%). The level of ACE does not seem to be clearly associated with the presence of extrapulmonary symptoms, nor with the course of S. However, the presence of extra-pulmonary symptoms seems to lead to a chronification

FRI0593 ASSOCIATION OF THYMOMA WITH AUTOIMMUNE DISEASES IN A SERIES OF 83 CASES

A. González García[1], W.A. Sifuentes Giraldo[2], J.L. Morell Hita[2], J.L. Patier de la Peña[1]. *[1]Internal Medicine; [2]Rheumatology, Ramon y Cajal University Hospital, Madrid, Spain*

Background: Thymoma is the most common neoplasm originated from the thymus gland and accounting for 50% of anterior mediastinal tumors. Within its clinical manifestations are included the loss of self-tolerance and the development of autoimmunity.

Objectives: To study the frequency of autoimmune diseases (AD) in patients with thymoma and to describe their clinical characteristics and outcome.

Methods: We performed a retrospective observational study of a cohort of patients diagnosed with thymoma and followed-up in our center between January 1985 and September 2016. The variables evaluated included demographics, thymoma characteristics, clinical and analytical manifestations of autoimmunity, treatment and outcome.

Results: A total of 83 patients were included, 56.6% of them women, with a mean age at diagnosis of the thymoma of 58.4±15.8 years (range: 16–94), 31.3% of which corresponded to type I The classification of Masaoka, 39.1% to II, 17.2% to III and 10.9% to IV. There were one or more AD associated in 41 cases (49.4%). The most frequent diagnoses were myasthenia gravis (19), systemic lupus erythematosus (SLE) (4), subacute cutaneous lupus erythematosus (1), Sjögren's syndrome (1), rheumatoid arthritis (1), spondyloarthritis (1), sarcoidosis (1), hemolytic anemia (2), pernicious anemia (1), aplastic anemia (1), cutaneous limited systemic sclerosis (1), urticaria-vasculitis, erythroblastopenia (1), recurrent pericarditis (1), thyroid disease (2) and lichen planus (1). The diagnosis of AD preceded to thymoma in 38.2% of cases and was later in the remaining cases. In 4 cases there was also a concomitant primary immunodeficiency (variable common immunodeficiency 3, CD4 immunodeficiency 1). The most frequently identified autoantibodies were anti-acetylcholine receptor (14/41, 34.1%), anti-striated muscle (3/41, 7.3%), ANA (11/41, 26.8%), (3/41, 7.3%), rheumatoid factor (3/41, 7.3%), anti-thyroid (3/41, 7.3%), antiphospholipids (2/41, 9%) and anticentromere (1/41, 2.4%). In the comparison of patients with and without associated AD, no significant differences were found regarding age, sex or Masaoka classification. There were 6 deaths, 4 in group with associated AD and 2 in the group without AD, but without significant difference (p=0.3797).

Conclusions: In the analyzed population of patients with thymoma of our center, almost half of them developed AD, which in a major group preceded the diagnosis of neoplasia. The spectrum of autoimmunity associated with thymoma was quite broad, including organ-specific AD such as myasthenia gravis (which is most frequently described in the literature) and autoimmune cytopenias, but also to systemic AD, the most common being SLE. The autoimmunity study should be included in the assessment of the patient with thymoma as it could contribute to the early diagnosis of associated AD.

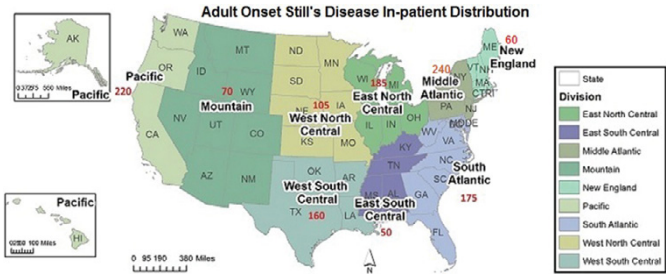
FRI0594 A CASE OF MOSAICISM IN TNF ASSOCIATED PERIODIC SYNDROME (TRAPS)

A. Kontzias[1], C. Calabrese[1], Y.-W. Cheng[2]. *[1]Rheumatology and Immunology; [2]Laboratory Medicine, Cleveland Clinic, Cleveland, United States*

Background: Tumor necrosis factor receptor (TNFR)–associated periodic syndrome (TRAPS) is an autosomal-dominant disease caused by gain-of-function mutations in the TNFRSF1A gene, which encodes the 55-kd TNFR type I (TNFRI) protein. Mosaicism has been recently idenitfied in a single patient.[1] A 60 year old male presented with a 6 year history of intermittent fever as high as 103.5, lasting 3–4 weeks with associated peritoneal symptoms, arthralgias, myalgias, lymphadenopathy, bilateral episcleritis, erythematous rash in his torso. Prednisone up to 60 mg daily only partially alleviated his symptoms and colchicine was ineffective.

Objectives: To explore the role of mosaicism in a patient with adult onset TRAPS phenotype.

Methods: DNA was extracted from the patient's whole blood, saliva and hair root. The TNFRSF1A gene was analyzed by Sanger sequencing in all tissues, and next-generation sequencing in whole blood. In silico molecular modeling was performed to predict the structural and functional consequences of the tumor necrosis factor receptor (TNFR) type I protein mutation.
Results: Sanger sequencing and next-generation sequencing methods revealed differential tissue presence of a misense mutation at c.265 T>C p.Phe89Leu (F89L) Chr12(GRCh37):g.6442960A>G ex3 rs104895245. The mutant allele was present in whole blood and buccal mucosa and absent in hair root, supporting the presence of somatic TNFRSF1A mosaicism. In silico prediction modeling with SIFT and PolyPhen2 suggested that this mutation led to numerous structural rearrangements which resulted in changes in the protein surface profile. The patient had a complete response to treatment with canakinumab an interleukin-1 beta blocker, with resolution of symptoms and normalization of acute-phase protein levels.



Conclusions: This is the second reported case of TNFRSF1A mosaicism in a patient with TRAPS, which was attributable to a de novo mosaic missense mutation in the TNFRSF1A gene. (c.265 T>C) p.Phe89Leu (F89L) The clinical picture in this patient, including the complete response to IL-1 blockade, was typical of that found in TRAPS. This case suggests that adult onset TRAPS phenocopies may be attributed to somatic (or postzygotic) mutations.

FRI0595 EPIDEMIOLOGY AND COMPLICATIONS OF HOSPITALIZED PATIENTS WITH ADULT ONSET STILL'S DISEASE IN UNITED STATES: A NATIONWIDE ESTIMATE

B. Mehta[1], W. Briggs[2], P. Efthimiou[3,4]. *[1]Rheumatology, HSS; [2]New York Presbyterian/ Brooklyn Methodist Hospital, New York, United States; [3]Rheumatology, New York Presbyterian/ Brooklyn Methodist Hospital; [4]Medicine, Weill Cornell Medicine, New York, United States*

Background: There is a dearth of epidemiological studies in the US and worldwide on Adult Onset Still's Disease (AOSD). Currently, there is no consensus on its incidence and prevalence in different populations. Most studies report a majority of patients below the age of 35.[1]
Objectives: To describe the demographics, complications and mortality of hospitalized patients with AOSD in United States.
Methods: All adult (>18 years) hospitalized patients in 2013 from a nationwide inpatient sample (NIS) database were captured. AOSD patients were identified using the ICD-9 code 714.2 that was in use in 2013. Patients also coded for Rheumatoid Arthritis, Lupus, Myositis, Polymyalgia Rheumatica, Ankylosing Spondylosis and Psoriatic Arthritis were excluded. This was done in order to truly capture patients with strictly AOSD. NIS is the largest all- payer inpatient care database in the United States with approximately 8 million hospitalizations each year. Discharge weights were used to enable nationwide estimates. Descriptive statistics were represented as means/medians for continuous and as frequencies and percentages for categorical variables.
Results: In 2013, 1410 US patients were coded with the ICD-9 code 714.2 and, after excluding concomitant rheumatic disease diagnoses as per protocol, 1265 AOSD patients were analyzed. AOSD patients had a mean age of 53.8 (SD - 18.1) years and a median age of 54 years. 70.4% were females. The racial/ethnic distribution showed that 61.6% white, 13.9% African American and 17.3% Hispanic patients were affected. 56.9% were hospitalized in urban teaching hospitals. The Mid-Atlantic census division had the highest number of patients – 240 (Figure). 35 (2.8%) of patients developed Macrophage Activating Syndrome (MAS). 30 (2.4%) patients had other severe complications of AOSD like disseminated intravascular coagulation (DIC) and thrombotic thrombocytopenic purpura (TTP). Median length of stay was 4 days and median hospital charges were $31,400 (Table). There were 35 inpatient deaths (mortality 2.8%): 71.4% of deaths were in females, 50% in Asians, and 71.4% were in patients in the 54- 67 age group.

Variables	N=1265	Percentage
Age (mean age in years (standard deviation))	53.9 (18)	
Female Sex	890	70.4%
White	730	61.6%
Black	165	13.9%
Hispanic	205	17.3%
Asian	50	4.2%
Bed Size of the Hospital		
Small	140	13.7%
Medium	270	26.5%
Large	610	59.8%
Location/teaching status of hospital		
Rural	100	9.8%
Urban non-teaching	340	33.3%
Urban teaching	580	56.9%
Macrophage Activating Syndrome	35	2.8%
Other complications - (DIC and TTP)	30	2.4%
In-hospital death	35	2.8%
Length of stay (Median no of days)	4 days	
Total Hospital Charges (Median in dollars)	$ 31,400	

Conclusions: In hospitalized American AOSD patients, the average age was higher than previously thought. This may indicate an aging population with a higher number of comorbidities that justify hospitalization. Mortality increased with age and was higher among women and Asians. To our knowledge, this is the largest epidemiological study of AOSD today in the USA.

FRI0596 ANAKINRA TREATMENT IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER: A SINGLE-CENTER EXPERIENCE (CASE SERIES)

B. Ergezen, S. Ugurlu, H. Ozdogan. *Division of Rheumatology, Department of Internal Medicine, Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey*

Background: Approximately in 5 to 10% of FMF patients there is insufficient response and/or intolerance to colchicine treatment. Several reports have pointed out the efficacy of IL-1 blockade in colchicine resistant FMF subgroup.
Objectives: To review the patients followed in our center with FMF who received Anakinra, an anti-IL-1 receptor antagonist, in terms of outcome and side effects.
Methods: 43 FMF patients who were treated with Anakinra were retrospectively

reviewed with regard to indication, effect on disease activity and acute phase response, adverse events and patient global assessment.
Results: There were 43 patients with FMF (20 M/ 23 F) who were treated with Anakinra for various indications (colchicine resistant recurrent febrile attacks in 39, colchicine related side effects in 3, both in 1). The mean age of the patients was 31.73±9.56 years. The mean duration of the disease was 19.90±10.52 years. There were various co-existing pathologies among this study group like Ankylosing Spondylitis (4), Psoriasis (1), Behçet's disease (1), Gout (1), Vasculitis (1), Adult-onset Still's disease (1), Polyarthritis Nodosa (1) and Celiac disease (1). The mean colchicine dose was 1.84±0.31 mg/d. As for the dosage, 35 patients were on 100 mg/day, 6 were 100 mg on alternate days, 2 were on 200 mg/day. The mean duration of anakinra treatment was 10.76±13.64 months. After the initiation of anakinra 29 patients became attack-free, 9 patients reported more than 50% decrease, 3 patients less than 50% decrease, and 2 patients no change in the frequency of the attacks. Mean patient global assessment decreased from 7.55±2.34 to 2.82±2.63 under Anakinra treatment ($p<0.001$).
As for the adverse events, eight patients (%18) had allergic reactions under Anakinra treatment (severe disseminated rash in 1 patient and severe injection site reaction in 4 patients and tolerable injection side reaction in 3) which necessitated termination of treatment in 5 patients. Anakinra was stopped because of genital warts and urinary tract infection in one other patient. Worsening of psoriatic lesions was observed in another patient. There were no adverse events in the remaining 41 patients during the course of treatment. On the other hand, treatment was terminated due to inadequate response in 11 (25%), remission in 2 and patient preference in 3 patients. Nineteen patients are still on Anakinra treatment for 10.09±14.51 months.
Conclusions: Anakinra is an effective and relatively safe alternative treatment in FMF patients with inadequate response or intolerance to colchicine, however approximately one fourth of the patients stop anakinra for insufficient response.
Disclosure of Interest: None declared
DOI: 10.1136/annrheumdis-2017-eular.5436

FRI0597 FATIGUE IN FAMILIAL MEDITERRANEAN FEVER (FMF) AND ITS RELATIONS WITH OTHER CLINICAL PARAMETERS

C. Unal Ertekin[1], T. Duruoz[1], D. Karali[2], F. Ulutatar[2]. *[1]PM&R Department, Rheumatology Division; [2]PM&R Department, Marmara University, School of Medicine, Istanbul, Turkey*

Background: Fatigue is a common problem in patients with rheumatic disease. It may cause disability and poor quality of life (1). Although fatigue and its determinants are studied in several rheumatic diseases, there is no study in Familial Mediterranean Fever (FMF).
Objectives: The aim of this study is to investigate fatigue in FMF patients as a disabiling symptom and its associations with clinical and demographic variables.
Methods: FMF patients were recruited into the study according to FMF Tel Hashomer criteria (2). Control group composed of healthy individuals. Patients who were pregnant or who had concomitant medical illnesses such as cancer, fibromyalgia, or psychiatric conditions such as psychosis or bipolar disorder were excluded. Age, gender, disease duration, education, marital status were noted as demographic features. Number of attacks in the last year, type of attack, involvement of joints, dosage of colchicine, genotype, amyloidosis, and severity of FMF was assessed with PRAS score, visual analogue score of pain (VAS-pain) and VAS-fatigue were used as clinical parameters. Pittsburgh Sleep Quality Index (PSQI), Multidimensional Assessment of Fatigue (MAF), Nottingham Health Profile (NHP), Fatigue Severity Scale (FSS), Fatigue Impact Scale (FIS) and Hospital Anxiety and Depression Scale (HADS) were filled out by both control and study group. Assessment of normality was analyzed with Shapiro-Wilk test. Differences in the mean scores of control and study group were compared with independent samples Mann-Whitney U and Kruskal-Wallis test. Relationship between continuous variables was assessed with Spearman's correlation coefficient (rho).
Results: 61 FMF patients and 61 age, gender (44 female, 17 male in each group) matched controls were enrolled into the study. Mean age of FMF and control group were 35.5±11.8 and 35.8±11.7 years, respectively. The mean disease duration was 82.5±81.7 months. Difference between mean of VAS-pain, VAS-fatigue, PSQI total score, MAF, all subsets of NHP, FSS, FIS, HADS scores of FMF patients were significantly higher than control group ($p<0.0001$). The correlations between scales assessing fatigue and other outcome measures in FMF patients was shown in Table.

Spearman'sCorrelation (rho)	VAS.fatigue	MAF	FSS	FIS
PSQI.TotalScore	0.49***	0.53***	0.38**	0.50***
NHP.EnergyLevel	0.43***	0.65***	0.54***	0.55***
NHP.Pain	0.58***	0.66***	0.56***	0.67***
NHP.EmotionalReaction	0.40**	0.54***	0.48***	0.65***
NHP.Sleep	0.32*	0.24	0.12	0.31*
NHP.SocialIsolation	0.27*	0.39**	0.50***	0.54***
NHP.PhysicalAbilities	0.51***	0.64***	0.56***	0.69***
HADS.Anxiety	0.43***	0.55***	0.52***	0.75***
HADS.Depression	0.30*	0.42***	0.42***	0.57***

***=p<0.001; **=p<0.01; *=p<0.05.

Conclusions: This study has shown that fatigue in FMF is associated with a number of psychological, sleep, quality of life and disease related factors. FMF group had increased pain, fatigue, sleep disturbance and decreased quality of life compared to control group. FMF patients with fatigue may benefit from pharmacological and psychological interventions which target these factors.

FRI0598 CHARACTERIZATION OF PATIENTS WITH AN INITIAL DIAGNOSIS OF UNDIFFERENTIATED CONNECTIVE TISSUE DISEASE. OBSERVATIONS FROM A LONGSTANDING MONOCENTRIC COHORT

C. Sepúlveda[1,2,3], A.V. Taulaigo[2,3], F. Carreiro[2,3,4], M.F. Moraes-Fontes[2,3]. *[1]Serviço de Medicina, Centro hospitalar Médio Tejo, Abrantes; [2]Unidade de Doenças Auto-imunes/Medicina 7.2, Hospital de Curry Cabral, Centro Hospitalar de Lisboa Central; [3]NEDAI - Núcleo de Estudos de Doenças Autoimunes da Sociedade Portuguesa de Medicina Interna, Lisbon; [4]Serviço de Medicina, Hospital do Divino Espírito Santo, Ponta Delgada, Azores, Portugal*

Background: Evolution from Undifferentiated Connective Tissue Disease (UCTD) to a defined Autoimmune Disease (AID) remains unexplained and usually occurs in the first 3 to 5 years.
Objectives: To determine the frequency and predictors of differentiation from UCTD to AID in a selected cohort of patients originally labelled as UCTD within the first 3 years of follow-up.
Methods: Demographic and clinical features were retrieved: (i) retrospectively, from the AID's Unit current database in December 2016 (n=195), including Systemic Lupus Erythematosus (SLE), incomplete SLE, Sjögren's Syndrome (SS), Systemic Sclerosis (SSc), VEDOSS and Mixed Connective Tissue Disease (MCTD); and (ii) from a prospectively UCTD database created in January 2012 (n=48). Inclusion criteria for the latter pertains to ANA positive patients, not fulfilling any of the existing classification criteria for AID and without severe organ involvement [1]. Patients with cutaneous lesions suggestive of lupus, inflammatory myopathies, erosive arthritis, systemic sclerosis and certain auto-antibody profiles were excluded *a priori* from the definition of UCTD as these are thought to herald defined conditions, as previously defined [2]. Definition of stable UCTD includes patients with at least one clinical manifestation of AID, positive ANA result and disease duration of at least 3 years [3]. Comparisons between stable UCTD and progressing patients were made using Wilcoxon Rank Sum and Chi square tests, p values of <0.05 were considered statistically significant.
Results: Each individual patient was analysed for differentiation into AID at yearly intervals. Overall, the main features of the prospective UCTD cohort were arthralgia (79%), rash (31%), arthritis (19%), sicca symptoms (19%), photosensitivity (17%) and Raynaud (13%). Prospective analysis in the UCTD cohort revealed differentiation in 4/48 patients (8.3%): into rheumatoid arthritis (n=2), psoriatic arthritis (n=1) and SLE (n=1). The main difference between stable UCTD and those that progressed to AID was the presence of arthritis (p=0.003). Median age of onset and symptom duration was similar between both groups. Retrospective analysis yielded very few patients presenting as UCTD (n=5/195): 2/106 SLE; 1/13 incomplete SLE; 1/43 SS; 1/19 SSc; 0/7 VEDOSS and 0/7 MCTD with no distinguishing features.
Conclusions: Very few patients differentiated in the UCTD cohort after 3 years of follow-up and in our retrospectively studied cohort, in accordance to a previous study [4]. Apart from arthritis, there were no other predicting factors for differentiation to AID. UCTD at disease onset seems to be a rare event.

FRI0599 A RETROSPECTIVE OVERVIEW OF CLINICAL FEATURES, SEROLOGY AND HISTOLOGY OF IGG4 RELATED DISEASE IN HONG KONG: A DATASET OF 108 PATIENTS FROM FOUR REGIONAL HOSPITALS

C.P. Tang[1], K.L. Lee[1], K.W. Lee[2], W.L. Ng[3], M.C. Wan[4], K.Y. Yuen[5]. *[1]Medicine, PYNEH; [2]Medicine, HKSH; [3]Medicine, UCH; [4]Medicine, RH; [5]Medicine, QMH, HK, Hong Kong*

Background: IgG4 related disease (IgG4RD) is a spectrum of immune mediated disease with multiple organs involvement characterized by organ enlargement, function loss or obstructive symptoms (1, 2).
Objectives: In this retrospective study, clinical, serological and histological features of IgG4RD patients over the past ten years from four regional hopsitals were reviewed.

Methods: Four regional hospitals participated with study period from 1/1/2006 to 30/6/2016. IgG4RD patients were classifed into definite, probable and possible IgG4RD according to Japanese Comprehensive Diagnostic Criteria for IgG4RD (3).
Statistical analysis: Association between the individual categorical covariates and the different organ involvement were analyzed by Fisher's exact test.
Results: 108 patients were included. There were 81 male patients and 27 female patients and the male to female ratio is 3:1. The mean age of diagnosis was 62.8 year old. 57 patients were diagnosed as definite IgG4RD (53%), 14 patients as probable IgG4RD (13%) and 37 patients as possible IgG4RD (34%). Salivary glands involvement was the commonest, (M=45.7% vs F=33.3%), followed by pancreas (M=28.4% vs F=18.5%) and biliary system in male (M=24.7% vs F=11.1%) and orbital in female (M=23.5% vs F=18.5%). 53% patients also had multi organ involvement.
104 patients had serum IgG4 level checked and it was raised in 94 patients (90.4%). 77 patients (74.0%) had IgG4 level above twice upper limit of normal. IgG4 level was normal in 10 patients. 98% and 86.3% patients with multi organ involvement had IgG4 level >135mg/dL (p=0.016) and >270mg/dL (p=0.007) respectively. In the hepatobiliary group (n=36), 30 patients had blood checked for Ca19.9 level and it was raised in 17 patients (56.7%), with the highest level 14127 U/ml.
71 histological reports were available. Lymphoplasmacytic infiltration was a consistent features in all specimens (100%). Eosinophilic infiltration was seen in 19 specimen (27%). Fibrosis was seen in 44 specimens (63%). Sialadenitis and dacryoadenitis were associated with dense fibrosis. Obliterative phlebitis was seen in 7 specimens (10%). IgG4/IgG ratio was reported in 61 specimens. 53 specimens had IgG4/IgG ratio greater than 40% per high power field which accounted for 86.9% of the specimens.
Conclusions: Most patients were male with the peak diagnosis at age 50 to 70. Salivary gland and pancreas were the most common organ involved. Most patients had a raised IgG4 level and most histological specimens showed a raised IgG4/IgG ratio on immunostaining. IgG4 level twice the upper limit of normal was quite specific for the disease and was associated with multi organ involvement.

FRI0600 THE EFFICACY OF DIFFERENT COLCHICINE DOSES IN TREATMENT OF FAMILIAL MEDITERRANEAN FEVER PATIENTS

E. Uguztemur, S. Çelik, S. Sadri, E. Aşçı, G. Ergun, Ö. Velipaşalar, S. Yılmaz-Öner, C. Bes, N. Alpay-Kanıtez. *Bakırköy Dr.Sadi Konuk Research and Training Hospital, Istanbul, Turkey*

Background: Recommended colchicine dose in familial mediterranean fever (FMF) is 1–1.5 mg/day in adults. If necessary it can be increased up to 3 mg/day by clinical monitoring. In the final FMF recommendation report of the EULAR, it was reported that after 5 years of stable disease, in appropriate patients, the dose of colchicine may be reduced by close follow-up. However, the number of clinical trials supporting this recommendation is not enough.
Objectives: In this study, demographic and clinical characteristics of FMF patients whose disease under control and treated with different doses of colchicine were compared.
Methods: Among the all FMF patients attending to the rheumatology outpatient clinic between April and September 2016, only the patients in non-attacks period at least for the last 1 month were included to the study. Clinical and laboratory findings, MEFV gene mutations, drug compliance of the patients and duration and doses of the colchicine treatment were recorded. The 'international severity scoring system for familial mediterranean fever' (ISSF) score was calculated to determine disease severity. The patients who were under the control (less than 4 attacks per year and ISSF score ≤2) divided to three gruops. These gruops were the patients taking low dose (average daily dose of colchicin <1 mg), median dose>1 mg/day and<1.5 mg/ day and standard dose ≥1.5 mg/colchicine treatment at least for 3 years. Patients treated with DMARDs or biological therapy were excluded from the study.
Results: Of the 162 FMF patients enrolled into the ongoing cohort, 86 patients were excluded from the study due to 57 patients had active disease, 19 had not yet completed 3 years of colchicine treatment and 10 patients received biological or DMARD treatment. The remaining 76 patients (25 male, 51 female) met the study criteria. The mean age was 32±11.5 years and the disease duration was 18.2±10.9 years. Amyloidosis or organ failure was not detected in any of these patients. Because of various reasons (drug side effect, treatment incompatibility, physician advice), 16 patients (21%) were treated with low dose colchicine (group A), 30 patients (39%) with moderate dose of colchicine (group B) and the remaining 30 patients (39%) with standard dose colchicine (group C). There were no statistically significant differences in demographic, clinical or laboratory data among these 3 subgroups.
Conclusions: Disease control in FMF is important to prevent amyloidosis and improve the quality of life. Recent studies contribute to the determination of treatment goals. Reducing the colchicine dose may increase drug compliance in this lifelong treatment. In our study, there was no difference between the treatment groups in amyloidosis, MEFV gene mutation or subclinical inflammation. These findings suggest that the dose of colchicine maybe reduced in inactive patients who determineted by the number of annual episodes and the ISSF score.

FRI0601 HYPERFERRITINEMIC SYNDROME IN A GENERAL UNIVERSITARY HOSPITAL

F. Pierini, I.J. Gandino, J.M. Martinez Perez, S. Ruta, M. Scolnik, E.R. Soriano. *Rheumatology Section, Medical Services, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina*

Background: Hyperferritinemia is associated with severe inflammatory conditions, such as rheumatic diseases with systemic inflammatory responses, and multiorgan dysfunction syndromes.
Objectives: To determine which diseases are associated with hyperferritinemia in a tertiary hospital; to compare ferritin levels between these different entities and to evaluate relationship between levels of ferritin and mortality in these patients.
Methods: A retrospective study was carried out in which all patients over 18 years with at least one determination of serum ferritin equal to or greater than 1000 ng/ml were identified in the laboratory database of our hospital between 1/1/2006 and 6/30/2016. Corresponding electronic medical records were reviewed and demographic data and clinical data were collected. Mortality was assessed at the end of follow-up. Descriptive statistical analysis and logistic regression analysis were performed in order to identify variables associated with mortality.
Results: A total of 1979 patients were included, 1235 men (62.4%) with a mean age of 63.2 years (SD 17.2). Only 36 patients (1.8%) presented a rheumatologic diagnosis as the only cause of high levels of ferritin, with Still's disease (n=8) and systemic Vasculitis (n=9) being the main diagnoses. Table 1 shows patients' characteristics grouped according to whether the elevation of ferritin was associated with a rheumatic disease or not. Median serum ferritin and transferrin saturation in both groups were similar (see Table 1). Mortality was lower for rheumatologic causes (5.9% vs 37.2%, p<0.001). Variables that were associated with mortality in multivariable logistic regression analysis were: maximum ferritin value (OR 1,0004, 95% CI 1,0003–1,0004, p<0.001) and age (OR 1.03, 95% CI 1.02–1.04, p<0.001), whereas the diagnosis of a rheumatic disease was a protective factor (OR 0.11, 95% CI 0.03–0.47, p=0.003). ROC curve for ferritin and mortality showed an area under the curve of 0.59 (95% CI 0.58–0.62). Ferritin levels greater than 3000 ng/ml showed a specificity of 89.2% and a sensitivity of 19.7% for mortality, regardless of cause of ferritin elevation.

Table 1. Patients' characteristics grouped by cause of Hyperferritininemia (Rheumatologic or not)

	Rheumatic disease (n=35)		Other causes of ferritin elevation (n=1944)		p
Female, n (%)	13 (37.1)		731 (37.6)		0.96
Mean age, years (DS)	62.5 (17.1)		52.4 (21.1)		<0.001
Diagnostic	Vasculitis	9	Solid cancer	497	
	Still's disease	8	Infections	336	
	Rheumatoid arthritis	4	Onco-hematologic disease	302	
	SLE	3	Chronic renal insufficiency	236	
	Seronegative arthritis and psoriatic arthritis	3 3	Hepatic disease	188	
	Others	3	Others	152	
	Gout	2	Hematologic disease	128	
	Juvenile idiopathic arthritis	1	Cardiovascular	57	
	Myositis	1	Sepsis	46	
	IgG 4	1	Iron overload	2	
Serum ferritin, median (IQR)	1622 (1264- 3639)		1460 (1200–2140)		0.07
Tranferrin saturation, %, median (IQR)	38 (19–50)		33 (18–55)		0.83
Follow-up time, years, median (IQR)	5.2 (1,2–10.2)		5.7 (1.2–8.9)		0.97
Mortality, n (%)	2 (5.9)		698 (37.2)		<0.001

Conclusions: Rheumatic diseases, represents a very small percentage of the causes of elevation of ferritin above 1000 ng/ml, and were associated with lower mortality than the non-rheumatic causes. Serum ferritin levels were significantly associated with increased mortality regardless of the underlying cause.

FRI0602 NATIONAL RECOMMENDATIONS ON THE USE OF IMMUNOMODULATORY DRUGS IN PATIENTS WITH NON-INFECTIOUS NON-MALIGNANT ANTERIOR UVEITIS

G. Espinosa[1], S. Muñoz-Fernandez[2], J.M. García Ruiz de Morales[3],

J.M. Herreras[4], M. Cordero-Coma[5]. *[1]Department of Autoimmune Diseses, Institut Clinic de Medicina i Dermatologia, Hospital Clinic, Barcelona; [2]Rheumatology, Hospital Universitario Infanta Sofia, Madrid; [3]Immunology, Complejo Asistencial Universitario de León, Leon; [4]Ophtalmology, Hospital Clínico Universitario de Valladolid, Valladolid; [5]Ophtalmology, Complejo Asistencial Universitario de Leon, Leon, Spain*

Background: Anterior uveitis (AU) is the most common pattern of uveitis, that migh lead to important ocular complications including blindness. Immunomodulatory drugs have been used in order to prevent recurrences of uveitis. Nevertheless, it is not clear which drug could be preferred in each patient.
Objectives: To generate recommendations on the use of immunomodulators in adult patients with non-infectious, non-neoplastic anterior uveitis (AU) based on best evidence and experience.
Methods: Delphi methodology was followed. A multidisciplinary panel of 5 experts (2 ophtalmologists, one immunologist, one rheumatologist, one internist) was established, who, in the first nominal group meeting, defined the scope, users, and chapters of the document. A systematic literature review was performed to assess the efficacy and safety of immunomodulators in patients with non-infectious, non-neoplastic AU. All of the exposed above was discussed in a second nominal group meeting and 33 recommendations were generated. Recommendations agreement grade was tested also in 25 additional experts. Recommendations were voted from 1 (total disagreement) to 10 (total agreement). We defined agreement if at least 70% voted $\geq$7. The level of evidence and grade or recommendation was assessed using the Oxford Centre for Evidence-based Medicine Levels of Evidence.
Results: The 33 recommendations were accepted. They include specific recommendations on patients with non-infectious, non-neoplastic UA, as well as different treatment lines. Methotrexate (MTX) or Sulfasalazine were recommended as a first line drugs in refractory cases to topic treatments in patients with AU and spondyloarthritis, inflammatory bowel disease, psoriasis, idiopathic HLA-B27 positive or negative AU. Etanercept was recommended for patients with TRAPS syndrome, and for those with other autoinflammatory syndromes canakinumab o anakinra. In case of bilateral sarcoidosis, relapsing polychondritis or TINU syndrome, MTX was recommended along with systemic steroids. For patients with a flare of AU and Behçet disease, systemic steroids along with azathioprine or a calcineurin inhibitor were recommended. The indication of an immunomodulatory drug in patitnes with multiple sclerosis was considered to be decided with a neurologist. For patients refractory to all exposed above and or intolerant, depending on AU type, a change to another classical immunomodulatory drug or to an anti-TNF was recommended (adalimumab, infliximab, certolizumab or). Except for patients with TINU, etanercept was not recommended because current evidence does not support the use of it to prevent AU flares.
Conclusions: In patients with non-infectious, non-neoplastic AU, these recommendations on the use of immunomodulators might be a guide in order to help in the treatment decision making, due to the lack of robust evidence or other globally accepted algorithms.

FRI0603 CLINICAL IMPLICATIONS OF ULTRASONOGRAPHY IN MONITORING DISEASE ACTIVITY OF RELAPSING POLYCHONDRITIS: THE ASSESSMENT OF AURICULAR CHONDRITIS IN 3 CASES

H. Nishikawa, Y. Taniguchi, Y. Terada. *Kochi Medical School, Nankoku, Japan*

Background: Relapsing polychondritis (RP) is a rare systemic inflammatory disorder and might often be refractory. Therefore, the discover of imaging modality would be required on diagnosis and treatment of RP.
Objectives: To assess the clinical implications of ultrasonography (US) in monitoring disease activity of relapsing polychondritis (RP).
Methods: Three cases of a 78-year-old man with RP, a 74-year-old woman with RP associated with optic perineuritis and a 42-year-old woman with RP associated with uveitis were assessed by US before and after treatments.
Results: Ultrasonography (US) of the auricle before treatment showed low-echoic swollen auricular cartilage with increased power Doppler signals (PDS) in all cases. US findings corresponded to the above-mentioned biopsy findings. After treatment with prednisolone combined with methotrexate, the auricular swelling completely resolved in all cases. Then, US findings also showed dramatic reductions in swelling of cartilage with the decrease in PDS.
Conclusions: US imaging can be used to differentiate between inflammation, vascular lesions, and tumors in the ear pinna. RP could be differentiated from the damage of repeated trauma (i.e. rugby) with producing subperichondrial serous effusion. As in the present cases, US imaging of the external ear and auricular cartilage in RP also facilitates evaluation of auricular lesions and monitoring of disease activity, especially when we consider the treatment response and the timing of drug tapering.

FRI0604 SUCCESSFUL TREATMENT OF ARTHRITIS INDUCED BY CHECKPOINT INHIBITORS WITH ANTI–INTERLEUKIN-6 RECEPTOR ANTIBODY: A CASE SERIES

S.T. Kim[1], A. Diab[2], M. Uemura[2], S. Garcia[3], P. Hwu[2], J. Tayar[1]. *[1]Rheumatology; [2]Melanoma Medical Oncology, MD Anderson Cancer Center; [3]Rheumatology, Baylor College of Medicine, Houston, United States*

Background: Immune checkpoint inhibitors (CPIs) have significantly improved outcomes for patients with various cancers. However, CPIs are associated with immune-related adverse events (irAEs). Two to three percent of patients receiving a CPI develop arthritis. In general, severe irAEs are treated with a high-dose steroid and a tumor necrosis factor inhibitor (TNFi), usually infliximab; however, TNFi treatment is sometimes contraindicated and, furthermore, entails a theoretical concern of impairing antitumor immunity. Therefore, evidence showing the clinical benefits of non-TNFi biologics in the treatment of irAEs is of immediate interest.
Objectives: We described the effects of anti-IL-6R antibody for the treatment of arthritis-irAE.
Methods: Three patients receiving CPI developed arthritis and were treated with anti-IL-6R antibody. Patients were followed up to 15 months.
Results: All patients had metastatic melanoma (Table 1). No patient had a

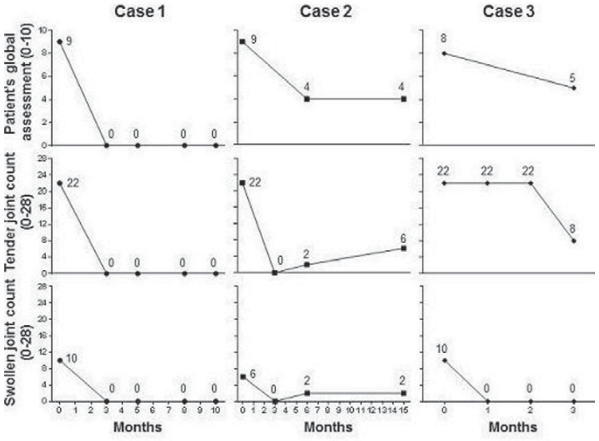

Figure 1. Serial measurement of the patient's global assessment, tender joint count, and swollen joint count before (0 month) and after anti-IL-6R antibody treatment

Abstract FRI0604 – Table 1. Patient demographic and clinical characteristics

Patient	1	2	3
Age, years	71	65	46
Sex	Male	Male	Female
Race	Caucasian	Caucasian	Caucasian
Tumor	Metastatic melanoma	Metastatic melanoma	Metastatic melanoma
CPI	Anti-CTLA4 antibody	Anti-PD-1 antibody	Anti-PD-1 antibody
Onset of arthritis-irAEs (days after initiation of CPI)	100	19	49
Pattern of arthritis	Symmetric polyarthritis involving small joints	Symmetric polyarthritis involving small and large joints	Symmetric polyarthritis involving small joints
History of autoimmune disease prior to CPI treatment	No	No	No, but known positive ANA
Autoantibody results	ANA, CCP neg RF: 27 (UNL: 15.9)	ANA, CCP, RF neg	CCP, RF, Ro, dsDNA neg ANA 1:640 (homogenous) La pos
Discontinuation of CPI treatment due to arthritis-irAE	N/A	No	Yes
Duration of anti-IL-6R antibody therapy, months	12	15	3
Tumor response to CPI as of December 2016 (RECIST 1.1)	Complete remission	Progressive disease	Progressive disease

CPI, immune checkpoint inhibitor; UNL, upper normal limit; ANA, antinuclear antibody; CCP, anti-cyclin citrullinated antibody; RF, rheumatoid factor; Ro, anti-SSA antibody; dsDNA, anti–double-stranded DNA antibody; La, anti-SSB antibody; N/A, not applicable.

history of autoimmune disease at the time of initiation of CPI treatment. One patient developed arthritis 8 weeks after the completion of anti-CTLA-4 antibody treatment. Two patients were receiving anti-PD-1 antibody when they developed arthritis. Patient 2 continued to receive anti-PD-1 antibody despite of arthritis-irAE while patient 3 discontinued anti-PD-1 antibody due to arthritis-irAE. The pattern of arthritis was symmetric polyarthritis involving small and large joints. Patient 1 had a positive rheumatoid factor (unknown baseline) and patient 3 had a positive ANA (known positive prior to CPI treatment). All patients were treated with anti-IL-6R antibody, which was well tolerated. All patients experienced a 40–100% reduction in global assessment, swollen joint count, and tender joint count, and these effects were maintained for up to 15 months of treatment (Figure 1). As of December 2016, all patients were alive; one patient was in complete remission and two patients had experienced progression of their melanoma.

Conclusions: These three cases suggest that anti-IL-6R antibody is an effective alternative to TNFi for the treatment of arthritis-irAE.

FRI0605 THE USE OF HAND PERFUSION SCINTIGRAPHY TO ASSESS RAYNAUD'S PHENOMENON ASSOCIATED WITH HAND-ARM VIBRATION SYNDROME

K.A. Lee [1], H.W. Chung [2], S.-H. Lee [1], H.-R. Kim [1]. *[1]Internal Medicine; [2]Nuclear Medicine, Konkuk University Medical Center, Seoul, Korea, Republic Of*

Background: Raynaud's phenomenon (RP) is a prominent manifestation of hand-arm vibration syndrome (HAVS). Previous studies have evaluated the diagnostic validity and characteristics of hand perfusion scintigraphy. However, no study to date has classified or differentiated the findings of this technique based on the aetiology of RP.

Objectives: This study aimed to evaluate the hand perfusion scintigraphic features of hand-arm vibration syndrome (HAVS) and to compare these with the features of primary and secondary Raynaud's phenomenon (RP) associated with connective tissue disease (CTD).

Methods: Hand perfusion scintigraphy was performed in 57 patients with primary RP, 71 patients with HAVS-related RP, and 36 patients with CTD-related RP. We calculated 6 ratios by using the time-activity curve and static blood pool images, the chilled to ambient hand and wrist ratios of the first peak height, initial slope, and blood pool uptake. We analysed 3 morphologic characteristics: slow progress pattern, paradoxically increased uptake pattern in the time-activity curve, and the inhomogeneous radioactivity uptake in the blood pool image.

Results: All of the 71 patients with HAVS-related RP were mine workers. The onset of RP after exposure to vibration was at 21.8±7.3 years, with 26.3±7.0 years of vibration exposure time. The chilled to ambient hand ratios of the first peak height and the initial slope were significantly lower in patients with HAVS-related occupational RP than in patients with primary RP. The presence of a paradoxically increased uptake pattern was significantly lower in HAVS than in primary RP.

Table 1. Comparison of the 6 quantitative variables of patients with Raynaud's phenomenon

Parameter		HAVS	Primary RP	CTD	P value
First peak height ratio	Hand	0.90±0.89[c]	1.50±1.50[c]	1.03±1.12	0.034[a]
	Wrist	0.72±0.31	0.87±0.57	0.80±0.46	0.161[a]
Initial slope ratio	Hand	0.75±0.63[d]	1.43±1.26[d]	1.06±1.29	0.002[a]
	Wrist	0.87±0.83	0.87±0.71	0.84±0.86	0.981[b]
Blood pool uptake ratio	Hand	0.85±0.39	1.10±0.72	0.87±0.67	0.071[a]
	Wrist	0.72±0.18	0.73±0.40	0.73±0.24	0.982[b]

Data are presented as mean ± standard deviation. HAVS: hand-arm vibration syndrome; CTD: connective tissue disease. [a]Significant using analysis of variance (ANOVA). [b]Significant using Welch test. [c]Primary > HAVS (P=0.015 by multiple comparisons), [d]Primary > HAVS (P =0.001 by multiple comparisons).

Table 2. Comparison of presence of the 3 scintigraphic characteristics in the chilled hand of the patients

Characteristics	HAVS (n=71)	Primary RP (n=57)	CTD (n=36)	P value
Slow progression pattern	61 (86.0)	51 (89.5)	32 (88.9)	0.809
Inhomogenous radio-activity uptake pattern	17 (24.0)	18 (31.6)	8 (21.2)	0.513
Paradoxically increased uptake pattern	15 (19.7)[a]	27 (43.9)[a]	10 (27.8)	0.012

Data are presented as number (%). HAVS: hand-arm vibration syndrome; CTD: connective tissue disease. [a]Primary > HAVS (P=0.004) on the basis of Chi-square test.

Conclusions: There were significant differences in hand perfusion scintigraphic features between primary RP and HAVS. These results suggest that the underlying pathophysiology of the two diseases differs; thus, different criteria might be applied for their evaluation

FRI0606 CHARACTERISTICS AND TREATMENT OF NEW ONSET ARTHRITIS AFTER CHECKPOINT INHIBITOR THERAPY

L.A. Christ [1], S. Mönch [1], S. Hasmann [1], I. Goldscheider [2], M. Heppt [2], C. Berking [2], F. Berger [3], C. Dechant [1], A. Skapenko [1], H. Schulze-Koops [1], J. Leipe [1]. *[1]Division of Rheumatology and Clinical Immunology, Department of Internal Medicine IV, University of Munich; [2]Department of Dermatology and Allergology; [3]Department of Radiology, University of Munich, Munich, Germany*

Background: The recent introduction of biologic agents targeting immunologic checkpoints (immunologic checkpoint inhibitors (ICI)) established immunotherapy as a highly effective cancer therapy. ICI that trigger an anti-tumor response by activation of T cells, may also cause immune-related adverse events (irAEs). Characterization of rheumatic adverse events such as arthritis and data on treatment of irAEs are scarce.

Objectives: To characterize patients with new-onset arthritis under ICI therapy and to assess the efficacy and safety of treatment that aimed to balance anti-tumor and anti-inflammatory therapy.

Methods: In this prospective observational study, patients with melanoma receiving ICI therapy who experienced arthralgias were evaluated for the presence of musculoskeletal inflammation. Data on demographics, ICI regime, time of onset and response to therapy of musculoskeletal irAEs, imaging, joint count, CRP/ESR, and immune serology were collected. Further, response to anti-inflammatory therapies including NSAR, glucocorticoids (GC) and methotrexate was assessed.

Results: Of 7 patients with arthralgias after initiation of ICI therapy, all had objective signs of musculoskeletal inflammation. Arthritis was demonstrated in 6 patients, 3 oligoarthritis (SpA pattern), 2 polyarthritis (RA pattern), 1 monoarthritis. PMR-like disease with typical ultrasound findings was evident in 1 case. The time from start of ICI therapy to onset of synovitis symptoms varied from 1 to 259 days without a timely association to other irAEs. Upon first visit in our clinic, CRP levels were elevated in 6 of the patients (5.5 to 107 mg/l) while immune serology was positive only in one patient (high titer RF and ACPA). Interestingly, in this patient low RF and ACPA titers had been detected when she presented with arthralgias without synovitis five years prior. This patient developed highly active RA one day after the first infusion of nivolumab. Retrospective analysis of cancer staging imaging studies revealed good sensitivity for PET-CT in the detection of synovitis, as opposed to contrast-enhanced CT. The baseline mean overall disease burden (assessed by VAS for pain, 0–10) was 7.6±0.8 and was significantly reduced after 3 months of anti-inflammatory treatment to 1±1.4. Initially, all patients were treated with systemic and four patients also with intraarticular GC. Four of 7 patients flared on GC treatment upon tapering and were given methotrexate. Remission was achieved in all and prednisolone could be tapered. Patients were followed for a median of 152 days, and no safety signal with regard to tumor reappearance was detected.

Conclusions: All patients with arthralgias upon ICI therapy had arthritis or PMR-like disease suggesting a need for increased awareness for musculoskeletal irAE. Inflammatory manifestations were associated with high disease burden and not self-limiting. While GC therapy is effective, flares were frequent after tapering and, thus, potential side-effects including attenuation of the anti-tumor efficacy of ICI are a concern. This is the first report on the efficacy and safety of methotrexate as a GC-sparing agent in ICI-induced arthritis.

Objectives: To assess the long term efficacy and optimization of Infliximab (IFX) in refractory Uveitis of Behçet Disease (BD)

Methods: Multicentre study of Uveitis associated-BD refractory to conventional immunosupressive drug. Ocular inflammation was evaluated with "SUN criteria" (Am J Ophthalmol 2005;140:509–516) and the macular thickening with OCT. Results are expressed as mean±SD or median [IQR] (comparison, Wilcoxon test)

Results: We studied 100 patients/180 affected eyes (54M/46W), mean age 40.7±10.1. The ocular pattern was panuveitis (n=62), posterior (27) and anterior uveítis (11). Before IFX they received iv MP (28), cyclosporine (75), azathioprine (56), metotrexate (43) and others (33). IFX dose ranged between 3–5mg/kg/4 or 8 weeks. In patients in remission IFX was optimized (n=28) or stopped (n=20).

FRI0608 STUDY OF ARTICULAR SARCOIDOSIS IN A TERTIARY CARE HOSPITAL

M. Garijo Bufort[1], E. Vallejo Pascual[2], C. Moriano Morales[1], M. Retuerto Guerrero[1], C. Iñiguez Ubiaga[1], A. Crespo Golmar[1], A. López Robles[1], C. Álvarez Castro[2], E. Diez Álvarez[1], M. Martín Martínez[1], T. Pérez Sandoval[2].
[1]Rheumatology Department of the University Health Care Complex of León; [2]University of Leon, León, Spain

Background: Sarcoidosis is a systemic granulomatous disease, being the joint involvement a poorly studied manifestation.
Objectives: To describe the clinical and demographic characteristics of patients with sarcoidosis, paying particular attention to the joint involvement and its possible relationship with other extra-articular manifestations, as well as the treatment recieved.
Methods: A retrospective, observational study that included 104 patients who were admitted to the Hospital of León between January 2011 and December 2015 with main or secondary diagnosis of sarcoidosis; according to clinical onset, imaging tests and/or anatomopathological study. The variables studied were: age at the time of diagnosis, sex, type of joint involvement, forms of extra-articular involvement, serologic parameters and drugs received. Statistical analysis was performed using SPSSv22.0, $p<0.005$.
Results: 57.7% of the patients included in the study were women with a mean age of 53.42±18.4 years. At the systemic level, 35% of them presented fever, 66.3% lymphadenopathy and 4.8% splenomegaly. 97.1% of the patients presented pulmonary involvement, with stage II being the most common (46.2%). Only 8 patients had cardiac abnormalities. Ocular involvement was observed in 10.6%, predominating uveitis. The most common renal manifestation was hypercalciuria in 6.7%. The presence of neurological involvement was exceptional, detecting 3 cases of neurosarcoidosis. In the cutaneous involvement (2.9%), erythema nodosum predominated (17.3%). The CRP levels were normal in 44.3% (<5mg/dl) and high levels of CRP were found in 25.3% of the sample (>30mg/dl). 62.6% presented pathological figures of ACE. The joint involvement was present in 38.5% of the patients (14.4% in the form of arthralgia, 2.9% as periarthritis, 13.5% as acute arthritis, 4.8% as chronic arthritis and 2.9% as sacroiliitis). The 19,23% debuted as Löefgren syndrome, being seen an association between the presence of acute arthritis and erythema nodosum *(p0,000).* The mean age observed in patients with acute arthritis was lower than the one of the other patients with other joint manifestations (*p0.044)* and a statistically significant relationship was observed between the absence of joint and ocular involvement *(p0,011).* Regarding the treatment of joint manifestations, 30.77% of the cases were resolved with NSAIDs, 46.15% with corticosteroids in a monotherapy and 15.38% required an immunosuppressant. In our study, most patients treated with corticosteroids did not show articular nor ocular involvement *(p0,018),* although when analysing the ocular involvement separately, many received corticoid treatment (42.86%). Only one patient required Adalimumab for refractory uveitis and another presented anti-TNFα-induced sarcoidosis (Infliximab).
Conclusions: The pulmonary involvement is the predominant one in patients with sarcoidosis. The acute arthritis occurs in younger patients and is associated with the onset of erythema nodosum. The joint involvement is usually not severe and, although it has not been demonstrated, it seems that the use of corticosteroids predominates in the extra-articular manifestations. Only 1 in 4 patients showed an increase of acute phase reactants.

FRI0609 USEFULNESS OF FDG-PET/CT IMAGING AND SEROLOGICAL BIOMARKERS TO PREDICT RELAPSE IN IGG4-RELATED DISEASE

M. Kato, H. Ozaki, T. Kameda, M. Izumikawa, S. Nakashima, H. Shimada, R. Wakiya, A. Kondo, N. Kadowaki, H. Dobashi. *Department of Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine, Faculty of Medicine, Kagawa University, Kita-gun, Japan*

Background: IgG4-RD shows relapses frequently. It is important to search to the factors to predict relapse. Recent research has shown the usefulness of FDG-PET/CT for IgG4-RD because it is more sensitive than conventional imaging to detect organ involvement of the disease. It has been suggested that FDG-PET/CT is also useful for monitoring therapeutic response of IgG4-RD.
Objectives: We investigate the usefulness of FDG-PET/CT imaging and serological biomarkers to predict relapse in IgG4-RD.
Methods: We analyzed 24 patients with IgG4-RD treated for more than 1 year between 2008 and 2016 in our facility. The diagnosis for IgG4-RD was based on comprehensive diagnostic criteria for IgG4-RD. All cases underwent FDG-PET/CT at least once, and laboratory data were collected from their medical records retrospectively. Levels of serum C-reactive protein (CRP), eosinophil/leukocyte ratio, serum IgG, IgG4, IgA, IgM, IgE, sIL2-R and serum compliment were investigated.
Results: The patients had a mean age of 67.9 years (range: 50–87 years). In the cases with high FDG uptake on FDG-PET/CT, they had a greater number of organ involvements, higher serum IgG and sIL-2R levels. Eight patients experienced relapses following treatment. Higher serum IgG predicted relapses of IgG4-RD. FDG-PET/CT findings at baseline were not associated with relapse. FDG-PET/CT was performed in 13 patients after initiation of treatment and 4 patients had a relapse. There were no significant reduction of abnormal FDG uptake in 6 patients, and 4 of 6 patients relapsed.
Conclusions: In this study, we examined the factors to predict relapse in IgG4-RD. Patients with higher serum IgG were regarded as a risk of relapse, but FDG-PET/CT findings at baseline were not associated with relapse. FDG-PET/CT reexamined after initiation of treatment is useful to predict relapse of IgG4-RD.

FRI0610 PROBLEMS IN THE DIAGNOSIS OF FAMILIAL MEDITERRANEAN FEVER IN TURKEY

M. Erdoğan, Y. Özgüler, G. Karatemiz, S.N. Esatoğlu, G. Güzelant, E. Dinçes, S. Uğurlu, G. Hatemi, H. Özdoğan, E. Seyahi. *Internal Medicine, Division of Rheumatology, Cerrahpaşa Medical Faculty, University of Istanbul, Istanbil, Turkey*

Background: The diagnosis of FMF (Familial Mediterranean Fever) can be missed or delayed even in a country like Turkey, one of the most prevalent places for FMF (1).
Objectives: We compared the duration of delay in diagnosis before and after year 2000, and assessed the problems related with the diagnosis of FMF.
Methods: We studied 143 (102 F, 41 M) consecutive patients with FMF seen at the rheumatology outpatient clinic, between November 2016 and January 2017. Patients completed a self-administered questionnaire that assesses initial symptoms, previous diagnosis and treatments received before the formal diagnosis of FMF. Patients were divided in 2: as Group 1, which includes 70 patients seen for the first time by a physician before 2000 and Group 2, which includes 73 patients seen after 2000.
Results: The median age of the patients was 34 years [IQR:27–45]. The F/M ratio was 2.4. The initial symptom was abdominal pain in the majority (n=134, 89%), followed by fever (n=114, 75%), arthritis (n=66, 44%), pleuritic pain (n=21, 14%), arthralgia (n=11, 7%) and other complaints (n=14, 9%).
The median age at initial symptom was 10 years (IQR:6–23). The median delay in diagnosis was 8 years [IQR:2–15]. This was significantly shorter in Group 2 (median: 4 years [IQR:0–11]) than that observed in Group 1 (median: 10 years [IQR:6–17]), as shown in Table.
A total of 110 patients (73%) were diagnosed with one or more diseases or syndromes other than FMF. These were appendicitis (n=50, 45%), gastrointestinal diseases (n=44, 40%), acute rheumatic fever (n=36, 33%), inflammatory

arthritis (n=18, 16%), gynecological diseases (n=11, 10%) kidney stones (n=9, 8%) and others (n=34, 31%). As shown in Table, the frequency of patients with misdiagnosis, was significantly lower in Group 2 (66%) compared to Group 1 (84%).
A total of 59 patients (39%) received other long-term treatments, mainly monthly penicillin (n=28), prior to colchicine. There were 41 surgical interventions in 36 patients (24%), before the diagnosis of FMF, the most common being appendectomy in 31, gyneacological operations in 5, cholecystectomy in 3 and others in 2 occasions. It was noted that, the frequency of surgical operations was significantly decreased in Group 2 (12%) compared to Group 1 (27%) (Table).
The presence or absence of MEFV mutations was assessed in 69 patients (46%) before the diagnosis or after to reinforce the diagnosis. As expected, this was significantly more frequent in Group 2 (59%) compared to Group 1 (33%) (Table).
Seventy patients (46%) were diagnosed as FMF only after someone else in the family (n=44) or a friend (n=26) had a similar diagnosis. The frequency of these patients was similar when Group 1 and 2 were compared.

Table: Demographic and clinical characteristics of Group 1 (patients seen before 2000) and Group 2 (patients seen after 2000)

	Group 1, (n=70)	Group 2, (n=73)	P
Male/Female, n	22/48	19/54	Non significant
Current age, med [IQR] years	40[31-51.5]	32[24.5-38]	<0.001
Delay in diagnosis, med [IQR] years	10 [6-18]	4 [0-11]	<0.001
Misdiagnosed patients, n (%)	59 (84)	48 (66)	0.011
Surgery before diagnosis, n (%)	19(27)	9(12)	0.026
Assessment of MEFV mutations, n (%)	23 (33)	43 (59)	0.005
Diagnosed as FMF after someone else, n (%)	27(39)	38(52)	0.1

Conclusions: Although there is considerable decrease in delayed diagnosis of FMF, there is still significant amount of misdiagnoses after the year 2000, even in a geography where FMF is highly prevalent.
Table: Demographic and clinical characteristics of Group 1 (patients seen before 2000) and Group 2 (patients seen after 2000)

FRI0611 ASSESSMENT OF PANNICULITIS CLINICAL OUTCOMES: RISK FACTORS FOR RECURRENCE AND PREDICTORS OF SLOW REGRESSION OF INDURATIONS

N. Savushkina, O. Egorova, B. Belov. *V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: Currently there's no clear understanding of the clinical course and outcomes of panniculitis with predominant involvement of subcutaneous adipose tissue (SAT), which is often associated with the involvement of locomotor system and viscera. Consistent elaboration of both is of paramount importance, as it may give a deeper insight into clinical and curative factors which may have impact on the disease prognosis.
Objectives: To assess clinical outcomes of panniculitis (risk factors for recurrence and predictors of slow regression of indurations).
Methods: 186 pts (172 females, 14 males) aged 43,5±14,5 years with different types of Pn, who were at the record of V. A. Nasonova Research Institute of Rheumatology during 2009–2015 yy. Disease duration varied from 1 week to 20 years. General clinical examination and lab tests (serum levels of α1-antitrypsin, amylase, lipase, ferritin, creatine phosphokinase (CPK), rheumatoid factor) (RF), ANF, anti-DNA, ANCA), bacteriological and serological tests, radiological examination (chest CT scan), ultrasound examinations of skin and subcutaneous fat (SF) around the nodules, tuberculin skin test and histopathology of nodular skin samples were performed at baseline. Patients were re-tested during the follow up (FUP) when necessary.
Results: Female middle-aged patients prevailed in the study group with the disease duration from 1 week to 25 years. *Saucer*-like depressions as a Pn - specific phenomenon was documented in 28,5% cases. The estimated risk of *saucer*-like depressions was higher in patients who manifested Pn at the age of >40 years (OR 4,9, 95% CI 2,3–10,4; $p<0,0001$); this subgroup also showed lesion proneness to confluence and forming of irregular shape conglomerates (OR 2,9, 95% CI 1,45–5,7; $p=0,002$), tendency to forming large size >3 cm lesions (OR 4,96, 95% CI 2,2–10,97; $p<0,0001$), and the disease lasting over 3 months (OR 24,9, 95% CI 9,2–67,4; $p<0,0001$). All pts were re-examined within 1–6 years. Median time to onset of nodules regression was 2 [1;6] months. Recurrences were documented in 66 (35,5%) pts during the follow up. Logistic regression was used for multivariate statistical analysis in order to identify the potential predictors of delayed (>3 months) nodules regression and recurrence risk factors. Used model identified the following predictors of delayed nodules regression (i.e., disease regression): age >40 years (OR 2,58; CI 1,02–6,5; $p=0,04$), and presence of saucer-like depressions (OR 5,05; CI 1,2–21,7; $p=0,03$). The sensitivity of used statistical model was 70%, specificity – 71%, positive predictive value - 74%. Disease duration >3 months (OR 4,7; CI 2,0–10,6; $p=0,0002$) was identified by our model as the predictor of recurrences with 60% sensitivity, 78% specificity, and 59% positive predictive value.
Conclusions: Pn tends to regress more slowly in pts aged over 40 and in pts having saucer-like depressions. Trend to recurrences is not so evident in Pn, although probability of recurrence increases in pts with longer disease duration at the time of initiation of therapy.

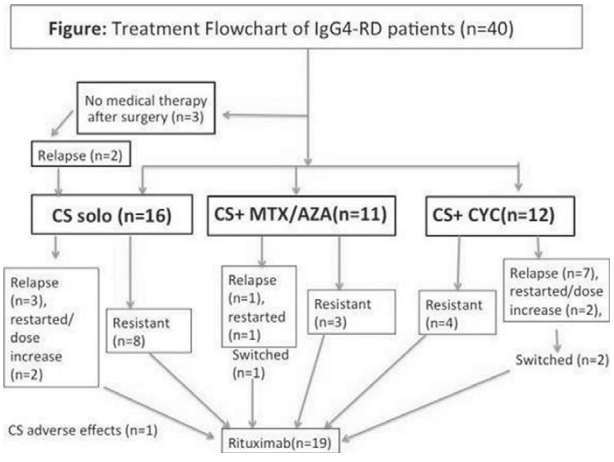
FRI0612 IGG4-RELATED DISEASE IN EASTERN MEDITERRANEAN: CLINICAL FEATURES AND OUTCOMES OF A LARGE COHORT



O. Karadag[1], A. Erden[1], A.S. Ayhan[2], E.C. Bolek[3], U. Kalyoncu[1], B. Armagan[1], A. Sari[1], L. Kilic[1], A. Akdogan[1], T. Hazirolan[4], B. Akdogan[5], S.A. Bilgen[1], D.E. Baydar[2], S. Kiraz[1], I. Ertenli[1]. *[1]Department of Rheumatology; [2]Department of Pathology; [3]Department of Internal Medicine; [4]Department of Radiology; [5]Department of Urology, Hacettepe University Faculty of Medicine, Ankara, Turkey*

Background: Since majority of IgG4-related disease (IgG4-RD) patients in the literature are from Far East and United States, there is a lack of large series from other parts of the world.
Objectives: We aimed to identify the clinical characteristics and outcome of Turkish IgG4-RD patients from a tertiary center.
Methods: In step 1, clinical and histopathological features of patients having any disease under the clinical spectrum of IgG4-RD were retrospectively reviewed. For step 2, patients prospectively diagnosed are enrolled into the study. Patients fulfilling the "definite" diagnosis according to comprehensive diagnostic criteria were recruited (enrolled (n=52), excluded (n=47).
Results: Median age was 51.1 years and no gender predominance was observed (Male/female: 26/26). Retroperitoneal fibrosis is the most frequent presentation;

Table 1. Distribution of clinical findings and organ involvement (n=52)

Constitutional symptoms, n (%)	
Fatigue	31 (59.6)
Tiredness	16 (30.7)
Night sweats	15 (28.8)
Weight loss	14 (26.9)
Fever	13 (25)
Retroperitoneal fibrosis, n (%)	23 (44.2)
Lymphadenopathy, n (%)	20 (39.2)
Any cardiovascular involvement, n (%)	15 (28.8)
Periaortitis	12 (23.1)
Pericardium	5 (9.6)
Coronary periarteritis	4 (7.7)
Abdominal aort aneurysm	1 (1.9)
Orbital pseudotumor, n (%)	12 (23.1)
Orbitalmass/proptosis	6 (11.5)
Extraocular muscles	6 (11.5)
Pancreas, n (%)	12 (23.1)
Major salivary glands, n (%)	11 (21.2)
Lacrimal glands, n (%)	9 (17.3)
Mediastinal fibrosis, n (%)	6 (11.5)
Ear, nose, sinuses, n (%)	5 (9.6)
Lung fibrosis, n (%)	5 (9.6)
Skin , n (%)	4 (7.7)
Pleura, n (%)	4 (7.7)
Gall bladder and Biliary ducts, n (%)	4 (7.7)
Thyroid, n (%)	3 (5.8)
Liver, n (%)	3 (5.8)
Kidney (mass) , n (%)	3 (5.8)
Pachymeningitis, n (%)	2 (3.8)

Breast involvement: (n=1), tubulointerstitial nephritis (n=1).

others were lymphadenopathy, orbital pseudotumor, pancreas and salivary glands in decreasing order (Table). Twenty-four (46.1%) of patients had localized involvement. Corticosteroids were mainstay of treatment in 92.5% of patients, and in 57.5% with any immunosuppressive agents as first line treatment. Rituximab has been used for cases resistant to previous treatment or with relapses in 19 (47.5%) of patients. A complete response was achieved in 52.5% of patients and partial response (<50% of regression) in 40%. Two patients deceased due to IgG4-RD attributed problems and no malignancy was observed (median follow up: 18 months).
Conclusions: We observed similar features with previous European cohorts however no male predominance was seen. Even though conventional immunosuppressives were used in more than half of patients, treatment had switched to rituximab ~50% patients owing to resistance or relapses.

FRI0613 H-FERRITIN AND PRO-INFLAMMATORY CYTOKINES ARE INCREASED IN THE BONE MARROW OF ADULT PATIENTS AFFECTED BY MACROPHAGE ACTIVATION SYNDROME

P. Ruscitti[1], P. Cipriani[1], F. Ciccia[2], P. Di Benedetto[1], A.R. Lizzi[3], V. Liakouli[1], O. Berardicurti[1], F. Carubbi[1], G. Guggino[2], G. D'Andrea[3], G. Triolo[2], R. Giacomelli[1]. *[1]Division of Rheumatology, Department of Biotechnological and Applied Clinical Science, School of Medicine, University of L'Aquila, L'Aquila; [2]Division of Rheumatology, Department of Internal Medicine, University of Palermo, Palermo; [3]Department of Biotechnological and Applied Clinical Science, School of Medicine, University of L'Aquila, L'Aquila, Italy*

Background: During macrophage activation syndrome (MAS), an inflammatory life-threatening syndrome, extremely high levels of serum ferritin may be observed [1]. Ferritin is an intracellular iron storage protein comprising 24 subunits that may be divided in heavy (H) subunits and light (L) subunits, based on their molecular weight [2]. The H-/L-subunits ratio may change, depending on the specific tissue and the physiologic status of the cell. In the normal condition, ferritin enriched in L subunits (L-ferritin) has been found in the liver and in the spleen, whereas the ferritin enriched in H subunits (H-ferritin), may be mainly observed in the heart and kidneys [2].
Objectives: We investigated the tissue expression of both H-and L-ferritin as well as the macrophage subsets expressing these molecules, in the inflammatory BM infiltrate of MAS patients. In addition, the co-expression of IL-1β, TNF, IFN-γ and H- or L ferritin, within the inflammatory cells, was assessed. Finally, we explored if the imbalance between H-ferritin and L-ferritin as well as the number of ferritin positive cells may be considered helpful bio-markers to assess the severity of these patients.
Methods: We analysed the bone marrow (BM) biopsies, by immunofluorescence of 10 adult MAS patients affected by rheumatic disease to assess the presence of: i. both H- and L-ferritin; ii. the number of CD68+/H-ferritin+ and CD68+/L-ferritin+; iii. the tissue pro-inflammatory cytokines, IL-1β, TNF, IFN-γ; and we correlated these data with clinical and laboratory data. Furthermore, the presence of ferritins was assessed in the sera of the same patients by western blot analysis.
Results: We observed an increased tissue expression of H-ferritin and of pro-inflammatory cytokines (IL-1β, TNF, IFN-γ). Western blot analysis, in the sera, of H-ferritin mirrored data on the tissue. Furthermore, an increased number of CD68+/H-ferritin+ cells and an infiltrate of cells co-expressing H-ferritin and IL-12, suggesting an infiltrate of M1 macrophages, were observed.
Tissue H-ferritin levels correlated with the decreased counts of WBC (p=0.01) and PLT (p=0.0001); with the increased values of serum ferritin (p=0.012) and C-reactive protein (CRP) (p=0.0058); and with the tissue expression of IL-1β (p=0.006). The number of the CD68+/H-ferritin+ cells correlated with the decreased counts of WBC (p=0.03) and PLT (p=0.0007), and with the increased serum ferritin levels (p=0.0088) and CRP (p=0.049). The analyses concerning tissues L-ferritin as well as the number of CD68+/L-ferritin+ cells and the same parameters failed to show any significant result.
Conclusions: We observed an increased tissue expression of H-ferritin associated with an increased expression of IL-1β. Interestingly, in the BM inflammatory infiltrate an increased number of CD68+/H-ferritin+ cells was shown. Of note, tissue expression of H-ferritin as well as the number of CD68+/H-ferritin+ significantly were associated with the hematological involvement of the disease, suggesting possible bio-markers to assess the severity of these patients.

FRI0614 FREQUENCY OF ORGAN MANIFESTATIONS IN CHRONIC SARCOIDOSIS

R. Bergner[1], K. de Groot[2], G.A. Müller[3], P. Korsten[3]. *[1]Medizinische Klinik A, Klinikum Ludwigshafen, Ludwigshafen; [2]Medizinische Klinik III, Sana Klinikum Offenbach, Offenbach; [3]Klinik für Nephrologie und Rheumatologie, Universitätsmedizin Göttingen, Göttingen, Germany*

Background: Chronic sarcoidosis is a systemic disease of unknown etiology, characterized by the histological finding of granulomas in involved organ systems. The most often affected organ is the lung with approximately 90–95%. Systematic data of organ manifestations other than the lung are scarce and show a wide range from 1–2% up to 50% depending on the series.
Methods: We analyzed data of newly diagnosed chronic sarcoidosis in 3 tertiary hospitals. We analyzed data on organ manifestations (OM), type of OM and laboratory findings. The certainty of OM was classified as grade 0 (not investigated), grade 1 (no sign of OM), grade 2 (clinical sign of OM), grade 3 (signs of OM in laboratory findings or imaging) and grade 4 (histological proven OM), respectively.
Results: We included 151 patients with biopsy-proven chronic sarcoidosis. Mean age was 50.8±15 years with a male predominance (87 [57.2%] vs. 65 [42.8%] patients).
Except for 3 patients, all demonstrated pulmonary involvement. The predominant type of lung involvement was type I (mediastinal lymph node enlargement) in 54.2% and type II (mediastinal lymph node enlargement and interstitial involvement) in 27.7%.
96.5% of patients were investigated for an affection of the kidneys, 97.3% for hepatic, 92.7% for skin involvement, 68.8% for ocular manifestations, 67.5% for ear, nose, throat (ENT) manifestations and 92% for cardiac manifestations, respectively.
Grade 3 (imaging/laboratory) and grade 4 (histology) findings were seen in the kidneys in 7.6/22.8%, in the liver in 13.3/11.9%, in the heart in 10.6/0.7%, in the eyes in 6.6/
Conclusions: OM in chronic sarcoidosis are more frequent than suggested in the current literature, especially renal and hepatic. About 20% of patients with chronic sarcoidosis suffered from moderate to severe CKD due to sarcoidosis, which is a major organ complication contributing to overall morbidity.
We recommend a systematic screening for OM in all patients with chronic sarcoidosis as it is performed in other systemic rheumatic disease.

Objectives: To evaluate the temporal association between the diagnosis of neoplasia and sarcoidosis in a large cohort of Spanish patients with sarcoidosis.
Methods: In January 2016, the Autoimmune Diseases Study Group (GEAS-SEMI) created a national registry (SARCOGEAS) of patients with sarcoidosis. Sarcoidosis was diagnosed with the criteria proposed by the ATS/ERS/WASOG 1999 statement, and extrathoracic disease by the 2014 WASOG instrument. Diagnosis of neoplasia was recorded before and after the diagnosis of sarcoidosis.
Results: The cohort included 1082 patients (82% biopsy-proven, 618 women, mean age 47yrs). Association with neoplasia was detected in 135 (13%) patients who developed 140 neoplasms (110 solid and 30 hematological neoplasia). The neoplasia more frequently reported were breast (n=18), lymphoma (n=16), non-melanoma skin (n=15) and colon (n=15). Association with neoplasia was more frequent in patients born in Spain (97% vs 86%, p<0.001, OR 4.06), older patients (55 vs 46yrs, p<0.001, OR 1.03) and those with bone marrow involvement (14% vs 4%, p<0.001, OR 3.64). Patients in whom cancer preceded the diagnosis of sarcoidosis had a higher frequency of sarcoidosis diagnosed incidentally (20% vs 4%, p=0.011) and a lower frequency of ocular sarcoidosis (3% vs 16%, p=0.016). Patients with associated hematological neoplasia had a higher frequency of ENT (13% vs 1%, p=0.009) and bone marrow (33% vs 9%, p=0.002) involvements in comparison with patients with associated solid neoplasia.
Conclusions: Association between sarcoidosis and cancer was found in 13% of patients (80% solid and 20% hematologic malignancies). Elderly patients and those born in Spain were at high risk of having associated cancer. Asymptomatic

sarcoidosis was more frequently observed in those patients with a previous history of neoplasia, while the association with hematological neoplasms was linked to a higher frequency of sarcoidosis involving ENT and bone marrow.

FRI0616 EYE MANIFESTATIONS OF PATIENTS WITH MUCKLE-WELLS SYNDROME

S. Cekic[1], O. Yalcinbayir[2], S.S. Kilic[1]. [1]*Pediatric Rheumatology;* [2]*Ophtahlmatology, Uludag University Medical Faculty, Bursa, Turkey*

Background: CAPS is a rare autoinflammatory disease associated with mutations in the *CIAS1* gene, encoding for NLRP3 that result in overactivation of the inflammasome and systemic inflammation. Muckle-Wells syndrome (MWS) is a rare autosomal dominant disease which causes episodic fever attacks, sensorineural deafness, recurrent hives, arthritis and eye involvement.
Objectives: Here we present the findings of eye involvement in a family whose 11 members have MWS.
Methods: Clinical data was collected during the course of ongoing patient care.
Results: We evaluated the clinical features of 11 patients who were referred to a tertiary care center. The median age of the patients was 25 years (range: 9–65). The ratio of females /males was 1.2 (6/5). All patients had arthritis with exacerbation on exposure to cold and recurrent episodes of pink eye. The median age of onset of ocular involvement was 8 years (2–45). We observed severe eye involvement in 36% of our cases, including band keratopathy, severe damage of corneal stroma and neovascularization. Corneal involvement and clouding was detected in four patient. Two of those had the diagnosis of keratoconus as well. Patients with keratoconus had corneal scarring due to corneal hydrops verified with corneal topography. The other two patients with corneal clouding had bant keratopathy. One of those patient was a 17 year old girl who had recurrent uveitis with hypopyon which necessiated the use of intravitreal dexamethasone implant. She also had posterior synechia of the iris to the lens. The other eye of that patient had signs of phthisis bulbi. The other patient with bant keraopathy was 46 years old male who had optic atrophy and tractional fibrovascular membranes at the posterior pole of the eye. Anakinra was used for treatment of 5 cases, and canakinumab of 3 cases. It was observed that the frequency of conjunctivitis decreased after anti IL-1 therapy. There was no mutation detected in the study of MEFV (all exons), TNFRSF1A (exons 2 to 7), MVK (all exons), NLRP3 (all exons), NOD2 (exons 4, 8 and 9) and PSTPIP1 (exons 10 and 11) genes.
Conclusions: In this study, it has been shown that eye findings related to MWS can vary from conjunctivitis to severe uveitis. We want to emphasize that ocular involvement in MWS should be carefully assessed, since it can lead to visual impairment.

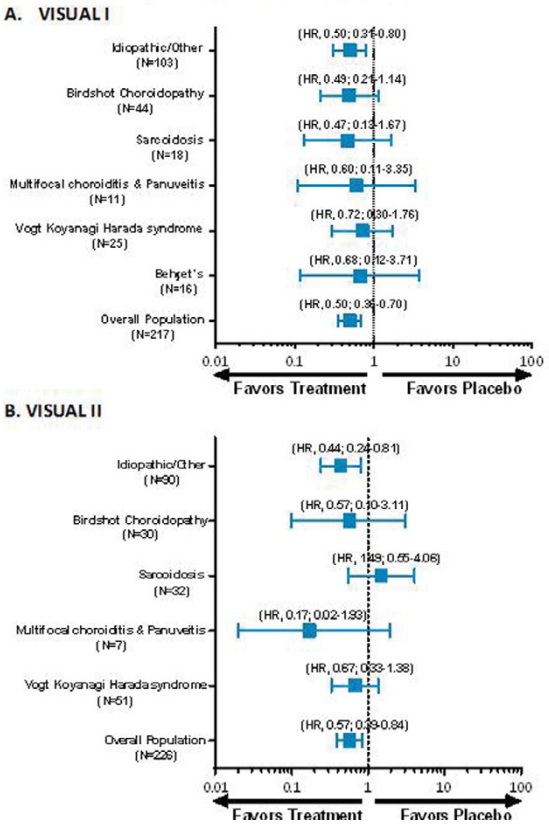
FRI0617 DIAGNOSTIC SENSITIVITY OF CUTOFF VALUES OF IGG4-POSITIVE PLASMA CELL NUMBER AND IGG4-POSITIVE/CD138-POSITIVE CELL RATIO IN TYPICAL MULTIPLE LESIONS OF PATIENTS WITH IGG4-RELATED DISEASE

S. Tsuge, I. Mizushima, Y. Fujisawa, S. Hara, F. Suzuki, K. Ito, H. Fujii, K. Yamada, M. Kawano. *Division of Rheumatology, Department of Cardiovascular and Internal Medicine, Kanazawa University hospital, Kanazawa, Kanazawa, Japan*



Background: Immunoglobulin G4-related disease (IgG4-RD) is a recently recognized systemic inflammatory disease with multi-organ involvement [1]. Diagnostically, two of the most important hallmarks of IgG4-RD are high IgG4-positive plasma cell (PC) counts and high IgG4/IgG ratios in affected organs. Although the International consensus statement (ICS) on the pathology of IgG4-RD adopted different IgG4-positive PC counts among affected organs for the diagnosis to differentiate IgG4-RD mimickers from IgG4-RD [2], histological and immunohistochemical findings of the specimens from not only one but multiple organs in the same patient has not been evaluated.
Objectives: This study aimed to investigate the diagnostic sensitivity of the cutoff values of IgG4-positive PC number and IgG4-positive/CD138-positive cell ratio proposed by the International consensus statement (ICS) on the pathology of IgG4-RD in typical multiple lesions of patients with IgG4-RD.
Methods: We evaluated IgG4-positive PC number and IgG4-positive/CD138-positive cell ratio in 35 samples from 16 IgG4-RD patients having more than two typical lesions of IgG4-RD.
Results: We evaluated twelve submandibular, eleven ophthalmic, four skin, four kidney, two pancreatic, and one bronchus and prostate lesion each in 16 patients with typical clinical, serological, and radiographic features. Concerning IgG4+ PC number per high power field, most ophthalmic (8/11), kidney (4/4), pancreatic (2/2), and bronchial lesions (1/1) fulfilled the cutoff value of ICS, whereas many of the submandibular (5/12) and skin lesions (0/4) did not. In contrast to the absolute number, almost all lesions fulfilled the cutoff value of IgG4+/CD138+ cell ratio. In five cases, only one or two lesions in the same patient fulfilled the cutoff value of ICS, while the others did not.
Conclusions: These results suggest that ICS criteria have different sensitivities among the affected organs in diagnosing IgG4-RD.

FRI0618 ADALIMUMAB IN NON-INFECTIOUS UVEITIS – EFFICACY ACROSS DIFFERENT ETIOLOGIES IN THE VISUAL I AND VISUAL II TRIALS

P.T. Merrill[1], A. Vitale[2], M. Zierhut[3], E. Forton[4], H. Goto[5], M. Kron[6], S. Tari[7], S. Pathai[8]. [1]*Rush University Medical Center, Chicago;* [2]*University of Utah, Salt Lake City, United States;* [3]*University of Tuebingen, Center of Ophthalmology, Tuebingen, Germany;* [4]*University of Montreal, Montreal, Canada;* [5]*Tokyo Medical University, Tokyo, Japan;* [6]*AbbVie Deutschland GmbH & Co KG, Ludwigshafen, Germany;* [7]*AbbVie Inc., North Chicago, United States;* [8]*AbbVie Ltd, Maidenhead, United Kingdom*

Background: There is increasing interest in understanding the efficacy of adalimumab across different etiologies of uveitis. No prospective analysis has been conducted to date to determine the efficacy of adalimumab among non-infectious uveitis patients with different etiologies.
Objectives: To assess adalimumab (ADA) efficacy in active and inactive, non-infectious uveitis across different etiologies in patients who were recruited as part of the VISUAL program.
Methods: Exploratory data analyses from two global phase 3, double-masked trials: VISUAL I (patients with active uveitis despite ≥2 weeks of prednisone 10–60 mg/day) and VISUAL II (patients with inactive disease dependent on 10–35 mg/day of prednisone to maintain inactivity) were performed. Patients received placebo (PBO) or ADA subcutaneously (80 mg week 0, followed by 40 mg every other week from week 1 up to 80 weeks). In VISUAL I, all patients received a prednisone burst followed by taper to 0 mg by week 15. In VISUAL II, prednisone taper to 0 mg was mandatory by week 19. The primary endpoint was time to treatment failure (TF) at or after week 6 for VISUAL I; and at or after week 2 for VISUAL II[1,2]. For this analysis, patients were categorized into different uveitis etiologies which they presented at study entry. Hazard ratios (HR) for time to TF were obtained for each uveitis etiology.
Results: The efficacy of ADA was significantly greater than PBO in the largest subgroup of patients with Idiopathic/other uveitis (VISUAL I: 103 and VISUAL II: 90) etiology in both VISUAL I[1] and VISUAL II trials. All other subgroups showed

Figure: Hazard ratios of time to treatment failure by uveitis etiologies.
VISUAL I (A) and VISUAL II* (B) clinical trials.

a trend in favor of ADA, except for Sarcoidosis subgroup in the VISUAL II trial (Figure). Overall safety for both trials has been previously reported [1,2].

Conclusions: These exploratory analyses from the VISUAL I and VISUAL II trials show significantly higher efficacy in ADA-treated patients over PBO in "idiopathic/other" diagnoses of patients with both active and inactive non-infectious uveitis. Furthermore, across different uveitis etiologies, these analyses suggest that ADA-treated patients had a prolonged time to treatment failure compared to PBO.

FRI0619 COMPARING CANAKIMUMAB AND ANAKINRA IN YOUNG GREEK WOMEN WITH RESISTANT RECURRING PERICARDITIS

P. Kiryttopoulos [1], T. Michailidis [1], E. Papchianou [1], M. Charalampidis [2], P. Dimitriadis [3], A. Agorastos [4], T. Mpektsis [1]. *[1]Department of Internal Medicine, General Hospital of Veria, Veria; [2]Gastroenterology Department, Theageneio Hospital of Thessaloniki, Thessaloniki; [3]Health Center of Alexandria, Alexandria, Greece; [4]Oncology Department, St. Thomas Hospital, London, United Kingdom*

Background: Resistant – recurring pericarditis (RRP) is often associated with autoinflammatory syndromes. Conventional therapy with glucocorticoids and colchicine is often enough unsuccessful, thus nowadays the use of anakinra in such cases is becoming common every – day practice.

Objectives: Our goal was to determine whether RRP was associated with gene mutations relevant with autoinflammatory diseases and then compare the effectiveness of canakimumab and anakinra.

Methods: We studied 18 patients with RRP (all women, from 14 to 36 years old) determing the existence of mutation from the infevers database (25 genes, from MEFV and TNFRSF1A to MVK and SLC 29A3, all related with autoinflammatory diseases). All the patients were proven positive to one of the above mutations (all heterozygous) and then treatment with anakinra (n=9, 100mg sc once daily) and canakimumab (n=9, 150mg sc q4wk) was administered.

Results: During the study (3 years), all anakinra patients stopped receiving per os glucocorticoids and were free of any new pericarditis episodes. 3 of them (33%) stopped any treatment after a year of anakinra therapy and none was presented with any skin reactions.

On the contrary, all canakimumab patients were not able to free themselves of the glucocorticoid treatment, since at least one new episode of pericarditis to each patient was recorded. Two of them were free of pericarditis the last year of the study (though being treated with 2,5mg prednisolone per os daily).

Statistically speaking, the use of IL-1R antagonist in recurrent – resistant pericarditis associated with autoinflammatory mutations was proven much more successful ($p<0,01$) than the use of the IL-1b Mab.

Conclusions: Though the sample of patients (n=18) was too small in order to set us able to reach any safe conclusions, it is quite possible that anakinra may be one effective solution that can prevent the long term administration of corticoids to patients with recurrent pericarditis Canakimumab was not recorded with similar positive results.

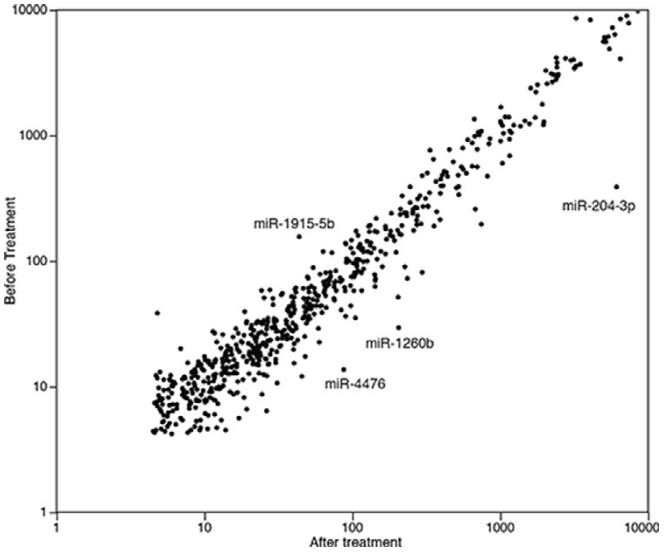
FRI0620 MIR-204-3P INHIBITS THE PRODUCTION OF TLR4-RELATED CYTOKINES IN FAMILIAL MEDITERRANEAN FEVER BY TARGETING THE PIK3 SIGNALING PATHWAY



T. Koga [1,2], K. Migita [3], M. Umeda [1], F. Nonaka [4], S.-Y. Kawashiri [1], N. Iwamoto [1], K. Ichinose [1], M. Tamai [1], H. Nakamura [1], T. Origuchi [1], K. Eguchi [5], A. Kawakami [1]. *[1]Department of Immunology and Rheumatology, Unit of Advanced Preventive Medical Sciences, Nagasaki University Graduate School of Biomedical Sciences; [2]Center for Bioinformatics and Molecular Medicine, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki; [3]Fukushima Medical University School of Medicine, Fukushima Medical University School of Medicine; [4]Department of Internal Medicine, Sasebo City General Hospital; [5]Center for Rheumatic Disease, Sasebo Chuo Hospital, Sasebo, Japan*

Background: MicroRNAs (miRNAs) are endogenous small RNAs and post-transcriptionally regulate gene expression by pairing with target. There has been emerging evidence showing the association of aberrantly expressed circulating miRNAs in the serum with the pathogenesis or progression of diseases including cancer and autoimmune disease. Although a number of circulating miRNAs associated with inflammation have been identified, the roles of them in patients with FMF and the underlying mechanism remain to be elucidated.

Objectives: The aim of this study was to identify a serum miRNAs profile and potential biomarkers in FMF and clarify their gene targets for understanding the pathogenesis of autoinflammatory diseases.

Methods: We performed miRNA microarray in the serum from FMF in attack and in remission. We subsequently examined the expression of miRNAs that varied before and after the attack in macrophages derived from THP-1 cells stimulated with toll-like receptor (TLR) ligands. Macrophages derived from THP-1 cells transfected with pre-miRNA and anti-miRNA were stimulated with TLR ligands for 24 hours. We collected the supernatants for the quantification of inflammatory cytokine production. To identify the target genes, we overexpressed its miRNA and performed Agilent expression microarray. Transfection with reporter construct and pre-miRNA and anti-miRNA was performed to confirm suppression of target mRNA.

Results: We found that miR-204–3p was greatly decreased in the serum from FMF patients in attack. In vitro study, the expression of miR-204–3p was suppressed by LPS stimulation in macrophages derived from THP-1 cells. Inhibition of miR-204–3p significantly induced the production of TLR4-related cytokines whereas overexpression of miR-204–3p inhibited their production. Bioinformatic analysis showed that miR-204–3p is predicted to target genes implicated in TLR pathway through regulation of PIK3 signaling. Reporter assay revealed that miR-204–3p directly suppressed the luciferase activity of 3'UTR of PIK3CG reporter construct.

Conclusions: These data suggest that serum miR-204–3p has a potential as a useful biomarker among patients with FMF and that miR-204–3p plays a critical role as a suppressor to regulate the production of TLR4 related cytokines by targeting PIK3 signaling pathway.

FRI0621 PREVALENCE OF DIFFERENT ORBITAL ANATOMIC STRUCTURES AFFECTION IN IGG4-RELATED OPHTHALMIC DISEASE: SINGLE CENTER EXPERIENCE

V. Vasilyev [1], E. Sokol [1], T. Safonova [2], S. Palshina [1], N. Kokosadze [3], A. Kovrigina [4]. *[1]Nasonova Research Institute of Rheumatology, Moscow, Russia; [2]Research Institute of Ophthalmic diseases; [3]N.N. Blochin Russian Cancer Research Center; [4]Hematology Research Center, Moscow, Russian Federation*

Background: According to 2009 Japanese nationwide survey of IgG4-related disease (IgG4-RD), orbit is the leading site of affection [1]. However diagnostic criteria and nomenclature of IgG4-RD were developed a few years later [2,3].

Objectives: To evaluate the peculiarities of clinical, laboratory, histological and immunohistochemical presentation of IgG4-related ophthalmic disease (IgG4-ROD).

Methods: During 2004 – 2016, 82 patients were diagnosed with IgG4-RD 53 of whom had IgG4-ROD (men – 17, women - 36). The diagnoses of IgG4-RD and IgG4-ROD were established using comprehensive diagnostic criteria [2,3]. In all patients full clinical, ophtalmological, dental and serological (rheumatoid factor, C-reactive protein, IgG, IgG4, IgM, IgA, ANA, anti-Ro/La, C3/C4 complement) examination was carried. In all cases diagnosis was verified pathomorphologicaly with immunohystochemical staining (anti-CD 138, CD 68, IgG, IgG4, κ-chain, λ-chain), but only in 43 patients the diagnosis of IgG4-RD was established on orbital tissues biopsy. Some patients at baseline were tested on B-cell clonality

in tissue (on frozen tissue section or paraffin embedded) by PCR analysis of immunoglobulin V-D-J genes heavy chain rearrangements (FR1, FR2, FR3); monoclonal secretion was tested in serum protein electrophoresis.

Results: 40 patients with IgG4-ROD had orbital lesions at the onset of the disease and 13 developed them after 2 - 9 years from the onset. The frequency of different orbital anatomic structures involvement see in table 1. 15 (28%) patients had isolated orbital lesions while 38 (72%) had systemic IgG4-RD with simultaneous involvement of 2 - 7 other organs. 6 (14%) patients had unilateral orbital lesions. 23 (53%) patients with IgG4-ROD had associated IgG4-related sialoadenitis and nasal lesions. Most common pathomorphological features of IgG4-ROD see in table 2. The most common laboratory features of IgG4-ROD were elevation of: total serum IgG (44%), serum IgG4 (88%), serum IgE (61%) and monoclonal serum secretion (23%).

Table 1. Prevalence of different orbital anatomic structures affection in IgG4-ROD (n=43)

Anatomicstructure	N,%
Lacrimal gland	93
Extraocular muscules	85,5
Fibroinflammatory lesions of eyelids	32,5
Retrobulbar infiltration	32,5
Optic nerve thickening	32,5
Trigeminal involvement	21
Nasolacrimal duct	4,5

Table 2. Pathomorphological features in IgG4-ROD (n=43)

Pathomorphological feature	N, %
Lymphoplasmatic infiltrate	93
Dense fibrosis	93
Lymphoid follici formation	69
Tissue eosinophilia	32,5
Obliterative phlebitis	14
Vasculitis	7
IgG4/IgG > 40%	90,5
MALT-lymphoma of lacrimal gland	2,3
AL-amyloidosis	2,3

Conclusions: In our cohort of IgG4-RD patients orbit is the leading site of the disease (64.5% of patients) and the disease onset (75% of patients). The majority of patients have bilateral orbital lesions (89%) and systemic course of the disease with other organ involvement (72%). Most often affected orbital anatomicstructures are lacrimal glands, extraocular muscles, retrobulbar infiltration with optic nerve thickening and fibroinflammatory lesions of eyelids. MALT-lymphoma of lacrimal gland and local AL-amyloidosis can complicate the long history of IgG4-ROD. Monoclonal serum secretion and B-cell clonality in the tissue in 23% of patients can potentially act as a background for lymphoma formation.

FRI0622 A RETROSPECTIVE COHORT STUDY ABOUT THE CLINICAL CHARACTERISTICS OF IGG4-RELATED DISEASES

X. Wu, C. Wang, Y. Miao, Y. Huang, L. Dong. *Department of Rheumatology and Immunology, Tongji Hospital of Tongji Medical College, Huazhong University of Science and Technology, Wuhan, Hubei, China*

Background: Immunoglobulin (Ig) G4-related disease (IgG4-RD) is an increasingly recognized systemic autoimmune disease in the past decade, and encompasses a wide spectrum of disorders previously considered to be unrelated, but with common pathologic, serologic, and clinical features.There have been several hundred literatures on IgG4-RD published in the past few years, however, we still cannot well characterize this complicated disease, including clinical features, treatments as well as mechanisms, which promotesus to further describe this disease.

Objectives: To describe the clinical presentations, laboratory features, imaging manifestations, treatments and evolutions in a cohort of 34 Chinese patients with immunoglobulin G-related diseases (IgG4-RD).

Methods: A retrospective study was performed in Wuhan Tongji Hospital. Electronically stored records of clinical, laboratory, imaging, and histological features were reviewed. The diagnoses were made according to comprehensive diagnostic criteria for IgG4-RD. Disease activity was assessed by IgG4-RD Responder Index (RI).This study was approved by the Ethical Committee of TongjiHospital (TJ-C20150603). All patients were contacted, and consents were obtained from all the participants.

Results: We found that among the whole 34 patients enrolled in this study (median age=51 years, male/female ratio=1.4/1), 65.2% tested patients had a declined HDL level, 82.3% tested patients had an elevated IgG4 level, and lymph node was the most frequently involved organ. 18F-FDG PET/CT had high sensitivity in providing information about the organ distribution of IgG4-RD. The IgG4 level and IgG4-RD RI in the multi-organs affected patients were significantly higher than that in the localized ones. Most patients were prescribed with glucocorticoids (GCs) alone or combined with disease modifying antirheumatic drugs (DMARDs), the majorities responded well, while some relapsed. Patients given rituximab (RTX) obtained good responses.

Table 1. The overall prognosis of 19 patients who were followed up

Prognosis	GCs	GCs + DMARDs	Surgery + GCs	Surgery + DMARDs	Antifungal therapy	MMF	Total, n
Remission, n	5	1	2	0	0	1	9
Recurrence, n	3	4	0	0	0	0	7
Worsen/Persistence, n	0	1	0	1	1	0	3
Total, n	8	6	2	1	1	1	19

Abbreviations: GCs, glucocorticoids; DMARDs, disease-modifying anti-rheumatic drugs; MMF, mycophenolate mofetil.

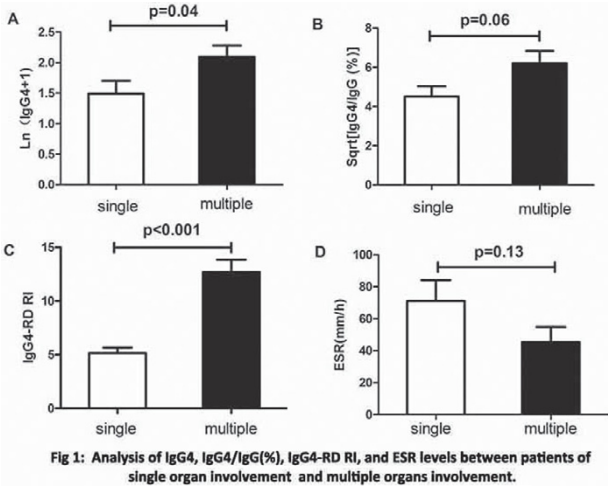

Fig 1: Analysis of IgG4, IgG4/IgG(%), IgG4-RD RI, and ESR levels between patients of single organ involvement and multiple organs involvement.

Conclusions: It was concluded that 18F-FDG PET/CT can be an effective tool to detect involved lesions of IgG4-RD. The addition of DMARDs to the initial GCs therapy in the remission induction stage may not bring much benefit. The most appropriate dosage schedule of RTX needs to be further investigated. Patients with younger age, longer duration of disease, higher IgG4 level and IgG4/IgG ratio may more commonly experience recurrence.

FRI0623 [18F]FLUORIDE PET-CT IMAGING OF BONE FORMATION IN ANKYLOSING SPONDYLITIS BEFORE AND AFTER 12 WEEKS OF ANTI-TNF TREATMENT

S. Bruijnen[1], N. Verweij[1], L. van Duivenvoorde[1], N. Bravenboer[2], D. Baeten[1], C. van Denderen[1], I. van der Horst-Bruinsma[1], A. Voskuyl[1], P. van de Ven[3], J. Bot[4], B. Boden[4], A. Lammertsma[4], O. Hoekstra[4], P. Raijmakers[4], C. van der Laken[1]. *[1]Rheumatology, Amsterdam Rheumatology and immunology Center; [2]Clinical Chemistry; [3]Epidemiology and Biostatistics; [4]Radiology & Nuclear Medicine, VU University Medical Center, Amsterdam, Netherlands*

Background: Excessive bone formation is an important hallmark of ankylosing spondylitis (AS). Recently, it has been demonstrated that axial bony lesions in AS patients can be visualized using [^{18}F]fluoride PET-CT. This technique may also provide opportunities to monitor changes in bone formation in axial AS lesions during therapy.

Objectives: To assess (1)changes in [^{18}F]fluoride uptake in axial lesions of AS patients before and 12 weeks after treatment with TNF-inhibitors (TNFi) and (2)whether [^{18}F]fluoride uptake on PET is related to focal bone formation in spine biopsies.

Methods: Twelve TNFi naive AS patients (female 7/12; age 39±11years) with high disease activity (BASDAI 5.5±1.1) were included. [^{18}F]fluoride PET-CT scans were performed before initiation of TNFi therapy. In 2 patients, biopsies were obtained from PET identified spine lesions for histologic analysis. Of the remaining 10 patients, a second [^{18}F]fluoride PET-CT scan was performed after 12 weeks of TNFi treatment. PET scans were scored visually for positivity by two blinded expert readers. Subsequently, [^{18}F]fluoride uptake was quantified in PET positive (PET^{+}) lesions using the standardized uptake value corrected for individual integrated whole blood activity concentrations (SUV_{AUC}). Clinical response to TNFi was defined according to ASAS20 at 24 weeks.
Results: At baseline, in all patients at least one axial PET^{+} lesion was found. In spine, 6/10 patients showed 84 lesions (range 2–30;63% thoracic spine, primarily costovertebral joints) and in the SI joints in 9/10 patients were PET^{+} (Fig A). Histological analysis of PET^{+} lesions in the spine confirmed local osteoid formation, which was nearly absent in PET negative lesions. Quantitative PET analysis revealed significantly lower [^{18}F]fluoride uptake in spine lesions at baseline in responders than in non-responders. This difference remained after 12 weeks of treatment (mean difference in SUV_{AUC}: -0.5, 95% CI:[-0.7,-0.2], p=0.001). After 12 weeks of TNFi treatment, [^{18}F]fluoride uptake in clinical responders decreased significantly in the costovertebral (mean difference SUV_{AUC}: -1.0, 95% CI: [-1.3,-0.7]) and SI joints (mean difference in SUV_{AUC}: -1.2, 95% CI: [-2.3,-0.2]) (fig B) in contrast to non-responders (mean difference in SUV_{AUC}: -0.4, 95% CI: [-2.3,1.6] and +0.4, 95% CI: [-0.6, 1.4], respectively). [^{18}F]fluoride uptake in other spinal lesions such as bridging syndesmophytes showed heterogeneous response without a significant decrease in [^{18}F]fluoride accumulation over time at a group level.

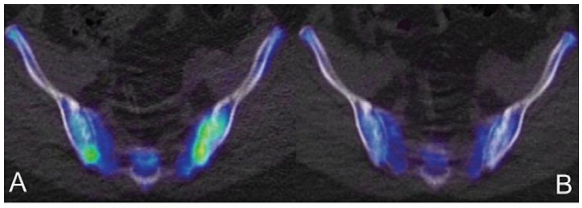

Figure: Example of [^{18}F]fluoride uptake in both SI joints at baseline (A) and a clear decrease of uptake after 12 weeks of TNF-I (B).

Conclusions: [^{18}F]fluoride PET-CT enables non-invasive visualization of (changes in) lesions with bone formation of the whole spine and SI joints in clinically active AS patients, which is confirmed by histological signs of osteoid formation. Part of these lesions, in particular costovertebral lesions in spine and SI joints, decreased in clinical responders to TNFi (and not in non-responders), whereas other spinal lesions remained unchanged at a group level.

FRI0624 STRUCTURAL MRI-BASED CONNECTOMICS IN SLE: A PILOT STUDY

G.A. Ramirez [1,2], E.P. Bozzolo [1], P. Preziosa [3], M.A. Rocca [3], L. Moiola [3], L.A. Coletto [2], E. Tombetti [1,2], P. Rovere-Querini [1,2], M. Filippi [2,3], A.A. Manfredi [1,2]. *[1] Unit of Allergy, Immunology, Rheumatology and Rare Diseases, IRCCS Ospedale San Raffaele; [2] Università Vita-Salute San Raffaele; [3] Institute of Experimental Neurology and Unit of Neurology, IRCCS Ospedale San Raffaele, Milano, Italy*

Background: Neuropsychiatric manifestations are common in patients with systemic lupus erythematosus (SLE). Furthermore, subclinical brain damage occurs in an even higher fraction of patients. However, little is known about the effect of these phenomena on brain connectivity. MRI-based connectomics relies on graph analysis of structural and functional images to detect alterations of the topographic organization of the brain and has been successfully employed to dissect network disassembly in neuroinflammatory diseases such as multiple sclerosis (MS) and Devic's syndrome.
Objectives: To investigate the topographic organization of the brain of patients with SLE with and without neuropsychiatric manifestations.
Methods: Thirty-two patients with SLE (12 with overt neuropsychiatric involvement as per ACR criteria) were enrolled and compared with 32 healthy controls (HC) and 32 patients with relapsing-remitting MS, all matched for sex, age and disease duration (where applicable). Diffusion tensor (DT) and dual-echo MRI scans were obtained. Structural connectivity matrices between 116 cortical and subcortical brain regions were estimated and global and nodal network metrics were calculated.
Results: Conventional MRI revealed that patients with SLE had significantly higher T2-lesional volumes when compared to controls ($p<0.0001$). Patients with definite NPSLE had a higher lesion burden (p=0.006). Network strength, transitivity and global efficiency were all significantly impaired in patients with MS and SLE when compared to HC ($p<0.0001$). MS and SLE were also characterized by higher average path length when compared to HC ($p<0.0001$). Global structural alterations were more significant in MS patients than in patients with SLE (p from 0.005 to 0.01 at multiple comparison). However, antiDNA-positive patients (n=24) showed a more severe phenotype when compared to antiDNA-negative patients (p from 0.026 to 0.041) and did not differ significantly from patients with MS. When regional hubs were analysed, patients with SLE and MS showed a reduced strength compared to HC (p from <0.0001 to 0.001 at multiple comparison). Hub strength impairment was more pronounced in MS when compared to SLE and preferentially involved hubs located in fronto-temporo-parieto-occipital cortices, subcortical nuclei (including the thalamus, caudate nucleus and putamen) and cerebellum (p from 0.001 to 0.05 at multiple comparison). No significant associations were found between global structural parameters, clinical diagnosis of neuropsychiatric SLE, other SLE sub-phenotypes, presence of antiphospholipid antibodies, antiphospholipid syndrome and SLE-related damage burden.
Conclusions: Structural alterations of global and regional brain connectivity occur in patients with SLE, irrespectively of the clinical phenotype. AntiDNA-positive patients are characterized by a more severe phenotype, which is similar to that of patients with relapsing-remitting MS.

FRI0625 IMPROVEMENT OF JOINT INFLAMMATION AS ASSESSED BY MRI AND POWER DOPPLER ULTRASOUND (PDUS) IN AN OPEN LABEL STUDY IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS TREATED WITH SECUKINUMAB (PSARTROS)

E. Kampylafka, I. D'Oliveira, C. Linz, V. Lerchen, M. Englbrecht, A. Kleyer, J. Rech, G. Schett, A.J. Hueber. *Department of Internal Medicine 3 – Rheumatology and Immunology, Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and Universitätsklinikum Erlangen, Ulmenweg 18, 91054 Erlangen, Germany, Erlangen, Germany*

Background: Secukinumab, an anti-interleukin 17A monoclonal antibody, showed significant improvement of signs and symptoms of psoriatic arthritis (PsA) in FUTURE 1 study. Available studies used conventional radiography, not allowing a deeper imaging analysis of the inflammatory changes during application.
Objectives: To assess short term efficacy of secukinumab on inflammation and structural damage according to change in OMERACT-EULAR ultrasound score and the MRI PsAMRIS score in PsA patients.
Methods: PsA patients with active disease (TJC and SJC $\geq$3), were included in the 24 week open label prospective PSARTROS study and treated with subcutaneous secukinumab 300 mg once weekly over 4 weeks, then once every 4 weeks. Baseline 1,5T MRI hand scans and ultrasound imaging of 28 joints were performed at baseline and after 24 weeks of treatment. MRI was scored according to PsAMRIS, ultrasound for synovial hypertrophy and Doppler activity according to OMERACT scores. Statistical significance was set at $p\leq0.05$.
Results: 20 patients, mean age 52±9.9 years, 60% female, mean disease duration 6.7±5.9 years, 50% naïve for biological therapy, were included in the study. Three patients were early discontinued (recurrent pharyngitis, lack of efficacy, withdrawal of consent), and were not included into the longitudinal analysis. Baseline DAS28 was 5.03±0.96, baseline DAPSA was 32.2±12. 1. On baseline MRI, all patients had at least one inflammatory sign (synovitis: 90%, osteitis: 20%, periarticular inflammation: 25%, flexor tenosynovitis: 35%, bone proliferation: 30%, erosions: 60%). Baseline composite PsAMRIS score

A- Baseline coronal T1W fs pos-Gd image shows synovial and periarticular thickness and enhancement (arrow), indicating active synovitis and periarticular inflammation.
B- Follow up image after 24 weeks treatment shows resolution of the periarticular inflammation and only residual synovial enhancement.

was 11.6±12.8 and baseline PsAMRIS synovitis score was 3.7±3.3. Baseline ultrasound synovial hypertrophy and Doppler activity were 6.2±4.5 and 3.5±4.0, respectively. Specific MRI and ultrasound scores were significantly correlated with DAS28 and DAPSA at baseline. Clinical disease activity parameters significantly improved at follow up (DAS28: 2.94±0.95, $p<0.001$; DAPSA: 8.8±5.8, $p<0.001$). PsAMRIS synovitis score (2.5±2.4) as well as composite PsAMRIS score (8.8±10.0) decreased longitudinally with secukinumab treatment (p=0.034 and p=0.039, respectively). There was no progression in erosion or proliferation scores between baseline and follow-up. Synovial hypertrophy and Doppler activity in ultrasound also significantly improved with secukinumab treatment (2.3±3.5; p=0.009 and 1.8±2.7; p=0.003, respectively). A significant percentage of patients reaching minimal disease activity showed residual signs of synovitis in the MRI and US (66% and 50%, respectively).

Conclusions: Secukinumab significantly improves MRI and ultrasound signs of joint inflammation in patients with PsA.

FRI0626 ANALYSIS OF CORRELATION AND CAUSES FOR DISCREPANCY BETWEEN QUANTITATIVE AND SEMI-QUANTITATIVE DOPPLER SCORES IN SYNOVITIS IN RHEUMATOID ARTHRITIS

H. Rezaei[1], E. af Klint[1], H.B. Hammer[2], L. Terslev[3], M.-A. D'Agostino[4], Y. Kisten[5], L. Arnaud[5]. *[1]Rheumatology department, Institute of Medicine, Karolinska University Hospital, Stockholm, Sweden; [2]Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; [3]Center for Rheumatology and Spine Disease, Rigshospitalet, Copenhagen, Denmark; [4]Rheumatology, APHP, Hôpital Ambroise Paré, Saint-Quentin en Yvelines, Paris, France; [5]Unit of Clinical Therapy Research, Inflammatory Diseases (ClinTRID), Institute of Medicine, Karolinska Institutet, Stockholm, Sweden*

Background: Doppler US is used for the evaluation of synovitis in RA. The amount of Doppler signals are measured in the synovial tissue according to either semi-quantitative (SQS) or quantitative scoring (QS) methods. None of the SQS has been chosen by consensus so far, and this creates some heterogeneity in US in clinical practice and research. Conversely, a major strength of the QS is to allow objective measurement of Doppler pixels using a continuous numeric scale.

Objectives: This study aimed to evaluate the association between $SQS^{1,2}$, and QS^3 in RA patients with active disease. Additionally, to elucidate the reasons for potential discrepancies between SQS and QS assessments, in order to better understand the intrinsic limitations of these methods,

Methods: Adult patients with RA and inadequate clinical response to anti-rheumatic therapy were examined with US. Dorsal US of the wrists, MCP and MTP 2–5 were performed. US images with sign of synovitis were collected and the QS was measured. Five assessors blinded to the QS evaluated the images independently, according to either SQS method. Association between QS and SQS was studied using correlations and multilevel models taking into account the clustering of ratings at the rater, patient and joint levels.

Based on the cut-offs, the discrepant cases were extracted, and each participant was asked to re-grade his/her own discrepant cases, blinded to the initial SQS grading and original QS, and to provide an explanation for the discrepancy. Then, discrepant images and explanations provided were reviewed in consensus and classified into a limited number of categories

Results: Analysis of the 1190 ratings revealed a strong correlation (ρ=0.89, $p<0.0001$) and significant associations ($p<0.0001$) between QS and SQS. Correlations between QS and SQS according to Szkudlarek et al. (ρ=0.87, $p<0.0001$) or Hammer et al. (ρ=0.91, $p<0.0001$) were similar. A total of 239 (20.1%) images were given a SQS grade that did not match that expected based on initial QS, using predefined cutoffs. Main explanations for discrepancies were different perceived ROI (40.7%) and Doppler pixel count near cutoffs between SQS grades (32.3%).

Conclusions: We showed that both SQS methods correlated well with QS to assess synovitis, but SQS methods are intrinsically limited when the Doppler pixel count is close to the cutoffs between the SQS grades. Analysis discrepancies between these methods may help further revision of criteria used to assess disease activity with MSUS in RA.

FRI0627 ULTRASOUND HAND EXAMINATION IS MORE SENSITIVE IN DIAGNOSING HAND OSTEOARTHRITIS THAN CONVENTIONAL RADIOGRAPHY: COMPARISON BETWEEN DIFFERENT ULTRASONOGRAPHIC SCORES

S. Hussain[1,2], P. Sivakumaran[1,2], C. Ciurtin[2]. *[1]University College London Medical School; [2]Department of Rheumatology, University College London Hospitals NHS Foundation Trust, London, United Kingdom*

Background: Hand osteoarthritis (OA) diagnosis is based on a combination of clinical, imaging features and assessment of risk factors, together with clinical associations and outcomes (1). In a real-life context, clinicians face difficulty in differentiating between OA and other hand arthropathies, particularly when the clinical examination is equivocal (e.g. no obvious bony enlargement with the characteristic distribution for hand OA).

Objectives: This is the first study to investigate the usefulness of a standardised ultrasound (US) examination protocol for hand joints in diagnosing hand osteoarthritis (OA) and the correlations between several US scores and clinical, inflammatory and radiographic parameters, aiming to explore which type of investigations are the most useful for diagnosing hand OA.

Methods: We conducted a cross-sectional study including 62 patients, ultimately diagnosed with hand OA based on the ACR diagnosis criteria (2). We compared the 34 joint score of the hand, with smaller, pre-defined joint scores including two scores of 22 and 12 joint each, and another 10 and 6 joint scores for OA. We correlated the US findings with radiographic scores (2108 joints).

Results: Radiographic osteophyte scores correlated very well with the predefined US scores detailed above (R=0.381 to 0.645, $P<0.05$), despite having a low sensitivity for detection of osteophytes (58.6%), and an even lower sensitivity for detection of erosions (38.4%) when compared with the 34 joint US score. There was a good correlation between different US scores (R =0.53 to 0.97, $P<0.05$), apart from the 6 joint score excluding the proximal interphalangeal joints (R= -0181 to 0.207, $P>0.05$).

Conclusions: US examination of the hands can facilitate the diagnosis of hand OA in patients who do not fulfil the ACR criteria, by identifying the presence of osteophytes with the particular distribution and number required for diagnosis in a proportion of patients that was three times higher than that of patients diagnosed based on clinical examination and hand radiography alone.

FRI0628 ULTRASOUND SHOWS SIGNS OF INFLAMMATION IN MOST PATIENTS WITH RHEUMATOID ARTHRITIS IN LONGSTANDING CLINICAL REMISSION, IRRESPECTIVE OF CONVENTIONAL SYNTHETIC OR BIOLOGIC DMARD THERAPY

U. Møller Døhn, C.H. Brahe, M.L. Hetland, V. Fana, S. Krabbe, M. Ammitzbøll-Danielsen, M. Østergaard, L. Terslev. *Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Denmark*

Background: None of the currently accepted remission criteria in rheumatoid arthritis (RA) incorporate inflammation on imaging. Signs of inflammation on ultrasound (US) and magnetic resonance imaging are frequently seen in RA patients in clinical remission.(1–3) It is not known whether patients in longstanding clinical and radiographic remission obtained through a DAS28 driven treat to target (T2T) strategy by conventional synthetic disease modifying anti-rheumatic drugs (csDMARD) or by biologic (bDMARD) therapy differ with respect to US detected synovitis.

Abstract FRI0626 – Table 1

Cut-offs between grades*	Sensitivity and specificity in the different statistical models							
	Raw data		Model 1		Model 2		Model 3	
	Sensitivity	Specificity	Sensitivity	Specificity	Sensitivity	Specificity	Sensitivity	Specificity
Grade 0–1	1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.0
Grade 1–2	0.94	0.72	0.99	0.85	0.99	0.82	0.96	0.77
Grade 2–3	0.90	0.84	0.99	0.92	0.99	0.91	0.98	0.92

*Cut-off between grade 0 (G0) and G1: 0%; between G1 and G2: 10%; between G2 and G3: 50%.

Objectives: In RA patients in longstanding clinical and radiographic remission, achieved by a DAS28-driven T2T strategy, to investigate if US signs of inflammation differs between RA patients, treated with csDMARD or bDMARD (+/- csDMARD).
Methods: Eighty-seven patients with RA in longstanding clinical (continuous DAS28<2.6 for the preceding year) and radiographic (no progression for at least 1 year) remission, were included in the study. US of elbows, wrists, MCP2–5, knees, ankles and MTP2–5 were performed using a GE LOGIQE9 US unit. Each joint was scored for grey-scale synovitis (GSS) and synovial color Doppler activity (CDA) by a 0–3 semi-quantitative score. Ultrasound remission was defined in two ways: either no (GSS=0 and CDA=0) or minimal (GSS≤1 and CDA=0) inflammation in any of the 24 assessed joints.
Results: Clinical characteristics and US findings are shown in the table. All 87 patients fulfilled DAS28 remission criteria at entry and CDAI remission was fulfilled in 76% and 79% in the csDMARD and bDMARD group, respectively. Complete absence of any signs of US inflammation (GSS=0 and CDA=0) was seen in 0% and 14% in the csDMARD and bDMARD groups, respectively (p=0.01), while minimal US inflammation (GSS≤1 and CDA=0) was seen in 33% and 40% (NS). CDA in at least one joint was seen in the majority of patients in both groups, 58% and 57% respectively.

Table 1

	csDMARD (n=45)	bDMARD (n=42)	
Females	28 (62%)	28 (67%)	NS
Age (years)	64 (31–82)	57 (25–82)	NS
Disease duration	6 (1–44)	12 (0–54)	p<0.01
IgM-RF/anti-CCP positive	25 (56%)/25 (56%)	28 (67%)/33 (79%)	NS/p<0.05
Erosive disease	23 (51%)	34 (81%)	<0.01
Tender joint count	0 (0–1)	0 (0–1)	NS
Swollen joint count	0 (0–2)	0 (0–2)	NS
C-reactive protein (mg/L)	4 (1–13)	5 (4–26)	p<0.01
DAS28	1.7 (1.1–2.4)	2.0 (1.6–2.5)	p<0.01
CDAI	1.4 (0–5.3)	1.8 (0–7.7)	NS
GSS-score (0–72)	4 (1–18)	6 (0–18)	NS
CDA-score (0–72)	0 (0–12)	0 (0–7)	NS
US minimal inflammation (GSS≤1 & CDA=0)	15 (33%)	17 (40%)	NS
US no inflammation (GSS=0 & CDA=0)	0 (0%)	6 (14%)	p=0.01

Values are given as numbers (percentages) and median (range). Fisher's exact or Mann-Whitney test used for comparisons.

Conclusions: The majority of RA patients, in this cohort of patients in longstanding clinical and radiographic remission obtained through a DAS28 driven T2T strategy, had signs of inflammation as assessed by US, irrespective of receiving biologic treatment or not. For patients in clinical remission, the consequences of sustained US inflammation still have to be investigated.

FRI0629 MAGNETIC RESONANCE IMAGING (MRI) INFLAMMATION OF THE FEET DEMONSTRATES SUBCLINICAL INFLAMMATORY DISEASE IN CUTANEOUS PSORIASIS PATIENTS WITHOUT CLINICAL ARTHRITIS

A.J. Mathew[1], P. Bird[2], A. Gupta[3], R.E. George[3], D. Danda[1]. *[1]Clinical Immunology & Rheumatology, Christian Medical College, Vellore, India; [2]University of New South Wales, Sydney, Australia; [3]Dermatology, Christian Medical College, Vellore, India*

Background: Up to 40% of patients with cutaneous psoriasis may develop psoriatic arthritis (PsA). Early detection of PsA by advanced imaging techniques results in better response to therapy. There are very few studies evaluating the MRI appearance in feet of patients with psoriasis and PsA.
Objectives: This study sought to evaluate inflammation at the small joints of feet in a subset of psoriasis patients without clinical arthritis, using an office-based extremity MRI (eMRI) as compared to the findings in overt PsA patients.
Methods: Patients with psoriasis were recruited from Dermatology and Rheumatology clinics of a tertiary care institution in southern India were divided into those without arthritis (PsO) and PsA groups. All consenting patients underwent non-contrast eMRI of the right foot. Demographic and physical examination details were recorded. PsO patients completed the early arthritis in psoriasis (EARP) questionnaire. Two trained readers scored the MRI inflammation (synovitis, tenosynovitis, osteitis) using a modification of the PsAMRI scores (PsAMRIS). [1] Inter-reader agreement was assessed in a random subset of 42 cases using intra-class correlation coefficient (ICC). Proportion of patients with any sign of MRI inflammation was noted. Mann-Whitney U test was used to compare inflammation scores of PsO with PsA patients. Clinical variables were compared with inflammation scores for any association.
Results: A total of 83 patients (30 PsA and 53 PsO) with 75% males and mean age of 42.2±11.6 years were included. ICC for all three variables between the readers was very good (>0.8). There was no statistical difference between the median eMRI inflammatory scores in PsA and PsO patients (p=0.493). Evidence of inflammation was present in 64% and 67% patients in the PsO and PsA groups, respectively (Table 1). Higher NAPSI scores were associated with presence of MRI inflammation (p=0.022).

Table 1. PsAMRIS variables for MRI inflammation of foot in PsO and PsA subgroups

Variable	PsO (n=53)	PsA (n=30)
Synovitis	34 (64%)	19 (63%)
Osteitis	2 (4%)	2 (7%)
Flexor tenosynovitis	9 (17%)	8 (27%)
Inflammation	34 (64%)	20 (67%)

Conclusions: This study corroborates a high proportion of psoriasis patients with subclinical disease of the small joints of foot. Patients with nail involvement had a higher risk of subclinical disease. The cohort is being assessed longitudinally to determine the clinical utility of MRI feet in predicting subsequent development of PsA in patients with psoriasis.

FRI0630 CAN WHOLE BODY MRI AT BASELINE IDENTIFY DEFINITE INFLAMMATORY ARTHRITIS PATTERNS IN UNDIFFERENTIATED ARTHRITIS?

J.E. Freeston[1,2], K.S. Mankia[1], M.-A. D'Agostino[1,3], R. Hodgson[2], A. Grainger[2,4], I. Matsuura[1], N. Larkman[4], P.G. Conaghan[1], P. Emery[1]. *[1]LIRMM, University of Leeds; [2]NIHR Leeds Musculoskeletal Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; [3]Université Versailles Saint Quentin en Yvelines, APHP Ambroise Paré, Boulogne, France; [4]Radiology, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

Background: When diagnosing inflammatory arthritis (IA) early, focal joint imaging may not reflect the overall inflammatory burden/distribution. Whole body MRI (WBMRI) offers the potential to feasibly scan most joints in a single session.
Objectives: The aims were (i) to describe the WBMRI pattern of disease in early IA (ii) to identify patterns associated with subsequent definite IA.
Methods: Patients were recruited with early inflammatory joint symptoms and/or signs of IA. Clinical data included age, gender, symptom duration, CRP, HLA-B27, RF, CCP Ab and tender/swollen joint counts. Using 3T WBMRI, T2-weighted fat suppressed spine/SIJ images pre contrast and 3D VIBE Dixon images of peripheral joints and entheses post IV contrast were acquired. Images were consensus scored for inflammation/erosion at the spine, SIJ, GHJ, SCJ, wrist, MCP, PIP, hip, knee, ankle, mid/hind foot, MTP and IP joints plus shoulder, ASIS, greater trochanter, knee, Achilles and plantar fascia entheses. Subjects were clinically classified at baseline and 1 year as undifferentiated arthritis (UA), CCP+RA, CCP-RA or Spondyloarthropathy (SpA). Clinicians were unaware of the MRI findings.
Results: 39 patients (23 female) were recruited; mean age 43 years, median symptom duration 18 months (7, 24), TJC 5 (2,11), SJC 1 (0,3) and CRP 2 (2,2). At baseline, 14 were classified as definite disease (RA or SpA) and 25 (14 female) as UA with mean age 40 years, median symptom duration 16.5 months (9.8, 24.3), TJC 3 (1,8), SJC 0 (0,1), CRP 2 (2,2) and 3 (12%) were HLA-B27 positive. The distribution of WBMRI findings in the classified (i.e. definite IA) group was predominantly small joint and tendon-based in the CCP+ RA group, large joint based with 50% having SIJ disease in the CCP- group and similar findings in the SpA group. In the non-classified group (i.e. pUA and rUA), the distribution in pUA was both axial and peripheral, involving joints and entheses, with 25% having SIJ disease. In comparison, findings in the rUA group were similarly distributed but less frequent with no cases of SIJ disease. After 1 year of clinical/laboratory follow-up, 8 were identified as pUA, 6 rUA, 7 CCP+RA, 6 CCP-RA and 12 as SpA. Table 1 shows WBMRI disease distribution by 1 year diagnostic category. The inclusion of affected WBMRI sites in the diagnostic work-up would have appropriately classified 6 further cases of definite SpA, 3 from the pUA and 3 from the CCP-RA groups.

Site of Disease Activity at Baseline on MRI

	Clinical Diagnostic category at 1 year				
	pUA (n=8)	rUA (n=6)	CCP+ RA (n=7)	CCP– RA	SpA (n=12)
Axial	1 (13%)	1 (17%)	0 (0%)	1 (17%)	0 (0%)
SIJ	2 (25%)	0 (0%)	0 (0%)	3 (50%)	4 (33%)
Large Joints	3 (38%)	4 (67%)	4 (57%)	6 (100%)	6 (50%)
Small Joints	6 (75%)	2 (33%)	7 (100%)	5 (83%)	6 (100%)
Tendons	3 (38%)	1 (17%)	5 (71%)	5 (83%)	4 (33%)
Entheses	6 (75%)	3 (50%)	4 (57%)	5 (83%)	8 (67%)

Key: pUA = Persistent UA, rUA = Resolved UA, RA = Rheumatoid arthritis, SpA = Spondyloarthropathy.

Conclusions: In the persistent UA group and CCP-RA group, WBMRI findings at baseline already showed a definite pattern of spinal disease. Therefore the use of WBMRI findings at presentation in addition to clinical assessment would allow clinicians to classify a proportion of patients earlier.

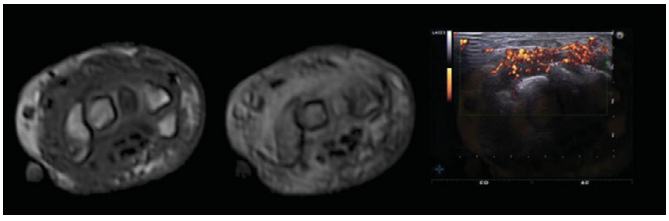
FRI0631 PREDICTIVE VALUE OF POWER DOPPLER ULTRASONOGRAPHY (PDUS) IN THE DIAGNOSIS OF EARLY RHEUMATOID ARTHRITIS

L. Mayordomo[1], C. Jurado[2], M.L. Velloso[1], A. Gutierrez-Leonard[3], P. González-Moreno[4], J.L. Marenco[1], C. Almeida[5]. *[1]Rheumatology Department; [2]Radiology Dp, Hospital Universitario Valme; [3]Physioterapy, HVR; [4]Rheumatology Department, HVM; [5]Research and Statistics Dp, Hospital Universitario Valme, SEVILLA, Spain*

Background: There is a short window of opportunity for early diagnosis and treatment of rheumatoid arthritis, that may be crucial for reaching remission and a low rate of radiographic progression. High resolution power doppler ultrasonography (PDUS) is helpful in early detection of synovitis and allows an accurate classification of patients with joint inflammation.
Objectives: To establish wether the presence of basal power doppler signal in patients with very early arthritis may be helpful in order to establish the risk of final diagnosis of rheumatoid arthritis according ACR criteria 1987 at a year of follow up.
Methods: We studied the presence of ultrasonographic Power Doppler (PD) signal on 28 joints (shoulders, elbows, wrists, MCPs, PIPs, knees) and 44 joints (28 joints and in addition hips, ankles, tarsus, and MTPs), with a mid-range equipment GE L5, in 70 patients with suspected early arthritis The patients were included with at least one of the following inclusion criteria: a) Swelling in 2 or more joints b) pain in MCPs, MTPs and/or the wrists c) morning stiffness of more than 30 minutes with <12 months of duration of the symptoms. Presence or not basal erosions (score ≥2 in at least one joint by modified Sharp method) for each patient were registered (65 patients with basal hands and feet radiology available). Presence of RF and ACPA positive were recorded as well. At one year follow-up was established whether patients met criteria for RA according1987 ACR or not. Statistical study: Chi-square, Fisher exact test, p univariant and Odds Ratio calculation.
Results: The presence of basal power doppler signal in ≥1 joints of 44 (PD44) in baseline visit shows statistically significant association to RA diagnosis at 12 months by ACR 1987 classification criteria, p=0.003, OR=5,43 (1,71–17,24) but the presence of at least one joint with power doppler signal of 28 joints (PD28) did not (p=0.051). Presence hypertrophic synovium with PD44 or not, in at least one joint (HSORPD44) was associated to RA diagnosis as well p=0.024; OR 10,24 (1,12–93,28). RF was positive in 18/70 (25,71%) and was associated to RA diagnosis (p 0.003, OR 8,31 (1,74–39,64), as well as FR/ACPA, positive in 20/70 (28,57%), p=0.001 OR 10 (2,10–47,58). PD44 in addition to positive RF was associated to RA p=0.003, OR 12,93 (1,59–104,94). Presence of basal radiographic erosions (BRE) was associated to RA, p=0.001 OR 7,72 (2,2–26,8). PD44 in addition to BRE was significantly associated to RA p=0.0005, OR 29,33 (3,61–238,37). PD28 in addition to RF or BRE was significantly associated to RA respectively p 0.0005 OR 24,20 (2,98–196.34) and p=0.003 OR 12,93 (1,59–104,94).



BASAL		RA YES	p (univariate)	OR	CI 95%
PD 44	YES	38/52 (73,1%)	0.003	5,43	(1,71-17,24)
	NO	6/18 (33,3%)			
PD44+FR	YES	15/16 (93,9%)	0.003	12,93	(1,59-104,94)
	NO	29/54 (53,7%)			
PD44+BAS EROS n=65	YES	24/25 (96%)	0.0005	29,33	(3,61-238,37)
	NO	18/40 (45%)			
HSORPD 44	YES	43/64 (67,19%)	0.024	10,24	(1,12-93,28)
	NO	1/6 (16,6%)			
BAS EROS n=65	YES	26/30 (86,7%)	0.001	7,72	(2,2-26,8)
	NO	16/35 (45,7%)			
FR	YES	18/20 (90%)	0.003	8,31	(1,74-39,64)
	NO	26/50 (52%)			
FR/PCC	YES	20/22 (90,9%)	0.001	10	(2,10-47,58)
	NO	24/48 (50%)			

Conclusions: The presence of at least one joint with power doppler signal of 44 joints (PD44) on baseline visit may help to predict the RA diagnosis at 12 months of follow up according to criteria ACR 1987, in patients with early RA. PD 44 in addition to classic RA factors (RF and basal radiographic erosions) increased the risk final of RA, till more than three times in case of concomitant basal PD44 and radiographic erosions.

FRI0632 MRI-US FUSION IMAGES FOR RHEUMATOID ARTHRITIS: CAN DOPPLER SUBSTITUTE FOR GADOLINIUM?

F. Barbieri[1], A. Muda[2], S. Migone[2], V. Prono[2], I. Mussetto[2], N. Romano[2], A. Fischetti[3], V. Tomatis[1], S. Paolino[4], M. Cutolo[4], G. Garlaschi[2], M.A. Cimmino[1]. *[1]Dipartimento di Medicina Interna, Clinica Reumatologica; [2]Sezione di Radiologia; [3]Università di Genova; [4]Clinica Reumatologica, Genova, Italy*

Background: MRI is increasingly used to objectively assess disease activity and damage in patients with rheumatoid arthritis (RA), especially in clinical trials. The preferred scoring method is the RAMRIS, which implies the use of gadolinium, an intravenous contrast agent, to assess synovitis.
Objectives: We evaluated in a small preliminary study if the fusion of MRI and US Power Doppler (PD) images could avoid gadolinium.
Methods: 12 patients (10 women) affected by RA, with at least one involved wrist, were studied. Mean age was 58.8±9.1 years and mean disease duration was 54.5±56.1 months. Disease activity (DAS 28-CRP) was evaluated on the day of the examinations.
MRI was performed on a extremity-dedicated machine (Oscan 0.3 T, Esaote, Genova Italy) and US by MyLab Twice ultrasound scanner with a virtual navigator software (Esaote, Genova, Italy). T3Dt1 sequences were used in the fusion images (parameters: TR/TE/NEX 38/16/1, matrix 192*192*39, FOV 160*160*60, thickness 0.6 mm). US scans were performed sagittally on the radio-lunate joint and axially on the proximal carpal bones of the dorsal wrist with B-mode and PD (PRF 500–750Hz; WF: 3; maximum gain with probe's calibration in air). Magnetic position sensor linked to the US transducer (13 MHz) and low magnetic field transmitters were used to allowed fusion images.
MRI synovitis was scored by the RAMRIS and with the contrast-enhanced dynamic method resulting in rate of early enhancement (REE) and relative enhancement, (RE). The US score was the Global OMERACT-EULAR Synovitis Score (GLOESS) and its individual parts.
Results: Inter-reader agreement for PD by weighted kappa was 0.75 (75%CI 0.53–0.96) for the sagittal and 1 (75%CI 1–1) for the axial view. It was 0.85 (75%CI 0.69–0.98) for MRI synovitis.
There was a correlation between DAS28 and the MRI synovits score (r=0.59, p=0.04), REE (r=0.60, p=0.04), and RE (r=0.58, p=0.05), US Doppler in the long (r=0.75, p=0.005) and in the axial axes (r=0.86, p=0.01), but not with B-mode synovial effusion (r=0.56, p=0.056). The GLOESS correlated with DAS28 (r=0.66, p=0.019), but not with RAMRIS synovitis, erosions or BME nor with REE. The MRI wrist synovitis score did not correlate with the Doppler score on the sagittal and axial views, nor with US B mode score. This was true also for the three individual MRI slices of the wrist, the REE and the RE. The figure shows from the left the pre-contrast axial MRI image, the post-contrast and the fusion images.

Conclusions: Although both MRI and Doppler are good indicators of disease activity in RA, they seem not to be interchangeable. This may be due to the fact that MRI and US show different features of synovitis or, alternatively, that MRI comprised the whole wrist whereas US visualized only its dorsal area. Although our preliminary data do not support the use of fusion images, these should be investigated on larger number of patients with a more extended PD approach.

FRI0633 WHICH ARE THE ULTRASOUND LESIONS UNDERLYING DACTYLITIS?

A. Nzeusseu Toukap[1,2], T. Kirchgesner[3], F. Lecouvet[1,3], P. Navarro[2], B. Vande Berg[1,3], A. Durnez[2], M.S. Stoenoiu[1,2]. *[1]Institut de Recherche Expérimentale et Clinique (IREC), Université catholique de Louvain; [2]Rheumatology department; [3]Radiology department, Cliniques Universitaires Saint-Luc, Brussels, Belgium*

Background: Dactylitis, defined as a diffuse swelling of a digit is a hallmark feature of peripheral spondyloarthritis (SpA), particularly in psoriatic arthritis, with a prevalence between 16% and 48[1].
Objectives: This study aims to assess the frequency of the pathological lesions in dactylitis using ultrasonography (US) and to evaluate their association with patient-reported tenderness.
Methods: Thirty-four dactylitis from 20 consecutive patients suffering from peripheral spondyloarthritis were examined by ultrasound. At US examination, the entire digit was scanned both on dorsal and palmar/plantar sides. The following US pathological lesions were scored: soft tissue thickness, soft tissue edema, soft tissue vascularization, synovitis of metacarpophalangeal (MCP)/metatarsophalangeal (MTP), of proximal interphalangeal (PIP) and of

distal interphalangeal (DIP) joints, inflammatory involvement of both flexor (tenosynovitis) and extensor (paratenonitis) tendons, nail bed vascularization, synovio-entheseal complex at DIP level, enthesitis of flexor tendon, and bone proliferation. Grey-scale (GS) and power-Doppler (PD) synovitis and tenosynovitis were assessed according to OMERACT scores (0–3). Nail bed vascularization was scored 0 to 3. The other US lesions were scored 0 (absent) or 1 (present), both in GS and PD. The standard (HAQ) questionnaire, tender and swollen joint count, patient-reported tenderness, global disease activity scored by physician and by patient were assessed in all patients.

Results: Twelve (60%) patients presented hand and 8 (40%) patients foot dactylitis. Twelve (60%) patients had single dactylitis. Eight patients presented with multiple dactylitis: 4 dactylitis in 1 patient, (5%), 3 dactylitis in 4 patients (20%) patients and 2 dactylitis in 3 (15%) patients. Soft tissue thickening was present in all 34 dactylitis. MCP/MTP joint synovitis was present in 28 digits (82%), PIP joint synovitis in 23 digits (68%) and DIP joint synovitis in 17 digits (50%). Extensor paratenonitis was observed in 21 digits (62%) and flexor tenosynovitis in 20 digits (59%). Enthesitis of extensor tendons was present in 21 digits (62%) and enthesitis of flexor tendon in 5 digits (15%). Osteoproliferation was present in 21 digits (62%). The frequency of synovitis, tenosynovitis and enthesitis did not differ significantly between tender (n=25) and non-tender (n=9) dactylitis. A significant association between tenderness and the presence of power Doppler (χ^2:17.9, $p<0.01$) and of edema in the soft tissue was observed (χ^2:11.5, $p<0.01$).

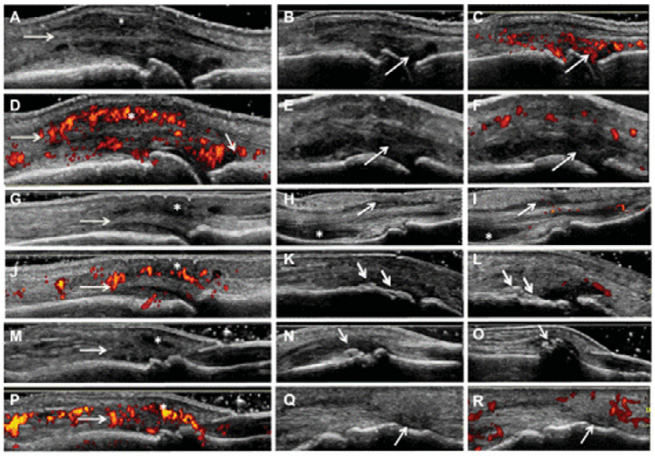

Figure. Ultrasound lesions in dactylitis. Longitudinal scans of digital extensor tendons in GS (A,G,M) and in PD (D, J, P) US showed extensive peritendinous inflammation. Note the tendon thickening (A,G,M), the loss of fibrillar pattern (A,G) and hypoechogenicity (A,M) of the extensor tendon. Digital extensor tendonitis or paratenonitis at the MCP joint (A,D), at the PIP joint (G,J) and at the synovio-entheaseal complex at the DIP joint (M,P) (arrows in panels A,D,G,J,M,P indicate digital extensor tendon and asterisks indicate anechoic or hypoechoic material around the dorsal extensor tendon with PD signals). Longitudinal US scans of MCP and PIP joints in GS (B,E) and PD C,F) mode. PD positive (C) and PD Doppler negative (F) synovitis at the MCP joint (B,C) and at the PIP joint (E,F). Note the pericapsular PD signals in panel F (arrows in panels B,C,E,F indicate synovial hyperthrophy) with (C) or without (F) PD signals. Longitudinal scans of digital flexor tendon (H,I) at the PIP joint. Tenosynovitis of flexor digital tendon is depicted in GS (H) and PD (I) mode. Note the hypoechoic thickened tissue (arrows) with fluid (asterisk) inside the tendon sheath (H) with few synovial and intra-tendinous PD signals (I). Osteoproliferation at the PIP joint (K,L) and at the DIP joint (N,O) depicted in longitudinal scans. Enthesitis of digital flexor tendon is depicted in GS (Q) and PD (R). The latter finding is rare (arrows indicate enthesitis).

Conclusions: Dactylitis is a multi-compartment digit disease, and anatomical lesions are more heterogenous than previously described. A significant amount of joint, tendon and entheseal inflammation persists in non-tender dactylitis. Patient-reported tenderness is associated with the presence of edema and/or power Doppler inside the soft tissue.

FRI0634 DO ANTHROPOMETRIC FACTORS INFLUENCE MEDIAN NERVE SIZE IN HEALTHY INDIVIDUALS? AN ULTRASOUND AND VOLUMETRY STUDY

A. O'Neill, P. Gardiner, D. McCormick, E. Savage, D. Small. *Rheumatology, Western Health and Social Care Trust, Londonderry, United Kingdom*

Background: Some (but not all) ultrasound studies of median nerve dimensions at the wrist have suggested that anthropometric factors such as height and weight are among the possible sources of variability in the normal population but this has not been systematically studied[1].

Objectives: The purpose of our study was to establish if hand and wrist volume or other standard anthropomorphic factors influenced median nerve size in normal subjects using standard ultrasonographic techniques. If median nerve size is predictably related to anthropomorphic factors, adjusted normal reference ranges would improve the diagnostic precision of the test for carpal tunnel syndrome.

Methods: We studied 30 healthy subjects: 14 females and 16 males. We measured their height, weight, arm span, finger span and wrist circumference. Ultrasonography of the median nerve was carried out at the entrance to the carpal tunnel and at a second level 2 cm proximal to the wrist using an Esaote MyLab Class C ultrasound with a 12–18MHz linear probe. The wrist was marked at the distal wrist crease and 2cm proximally. Hand and wrist volume were measured using water displacement volumetry.

Results: The intra-rater reliability of volumetry measurements was excellent for both hand and wrist volumetry with a Cronbach alpha of 0.99 and 0.88 respectively. The intra-rater reliability for median nerve measurements was excellent with a Cronbach alpha of 0.96. The median nerve dimensions were not significantly different between male and female subjects, nor between the dominant and non-dominant hands. The mean median nerve cross sectional area (CSA) at the distal wrist crease was 10.68 mm^2 and at a point 2cm proximal to this it was 10.18 mm^2. The mean difference in CSA between these two points was 0.5 mm^2. The median nerve CSA was not significantly related to height, weight or hand size. It was not correlated with hand or wrist volume. No significant differences were found in relation to hand dominance or gender.

Spearman's correlation between median nerve CSA (distal, right wrist) and anthropometric factors

	Rho	p
Height	0.063	0.73
Weight	0.290	0.11
BMI	0.094	0.47
Arm Span	0.115	0.38
Finger Span	0.024	0.85
Wrist Circumference	0.095	0.46
Hand Volume	0.102	0.44
Wrist Volume	0.244	0.19

Conclusions: Anthropometric factors including BMI, hand/wrist volume were not found to be closely related to median nerve size in normal individuals.

FRI0635 DESCRIPTION OF VIDEOCAPILLAROSCOPY OF THE LABIAL MUCOSA IN COMPARISON WITH NAILFOLD VIDEOCAPILLAROSCOPY IN SCLERODERMA

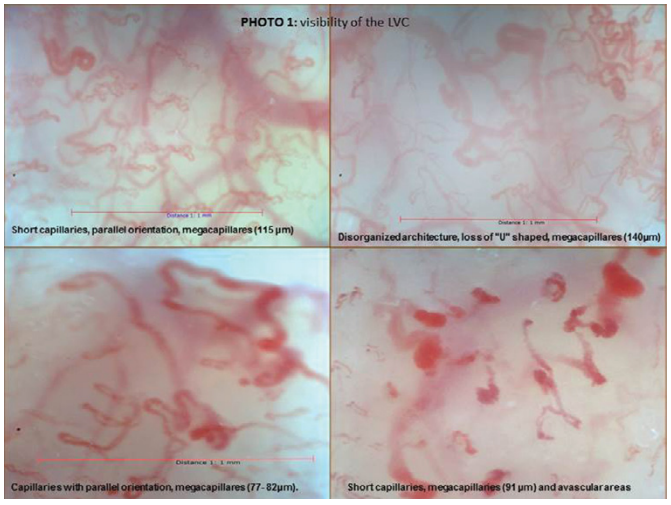
A.M. Beron, S. Sapag duran, H. Laborde, G. Medina, M. Garcia Carrasco, G. Nasswetter, D. Dubinsky. *Rheumatology, Clinical Hospital "Jose de San Martin", University of Buenos Aires., CABA, Argentina*

Background: Capillary bed of labial mucosa may be a potentially useful area for assessing abnormalities on the microcirculation. Videocapilaroscopy of the labial mucosa (LVC) in 12/13 scleroderma (SCL) patients showed capillaries disturbance such as great disorganization and anarchic orientation(1).

Objectives: To describe LVC features in SCL and compare them with healthy controls. (HC). To compare nailfold videocapillaroscopy (NVC) with LVC in HC and SCL patients.

Methods: ≥16 years old patients with SCL (ACR-EULAR 2013) were included consecutively since June to July 2016. Smoking patients were excluded. For the evaluation of the LVC we performed a general displaying and then we studied following areas: a-central (1 cm from the frenulum), b-lateral right and left (both 2 cm from the frenulum) and c-labial border. For evaluation of the NVC, 200x images were obtained from 2nd to 4th fingers both hands and was classified according Cutolo in early, active, late patterns(2). For assesment through LVC: photographs (200x) for each subject were taken. We define quantitative characteristics as means of: capillary diameter, length and density. The average of these parameters was obtained from the evaluation of capillaries included in 1 mm^2 of at least 2 continuous images. In addition, the visibility of the subpapillary venous plexus, architecture, dilatation of capillaries, presence of megacapillaries and avascular areas were qualitatively evaluated (photo 1). Each image was reviewed by two experienced observers. We conducted the same process describe above for each healthy control subject.

Results: Twenty two patients were included (18 female, age 47±11 ys) with SCL (limited 17, diffuse 5); NVC pattern: early 8, active 11, late 3. Healthy subjects 12 (11 female, age: 34±10 years).



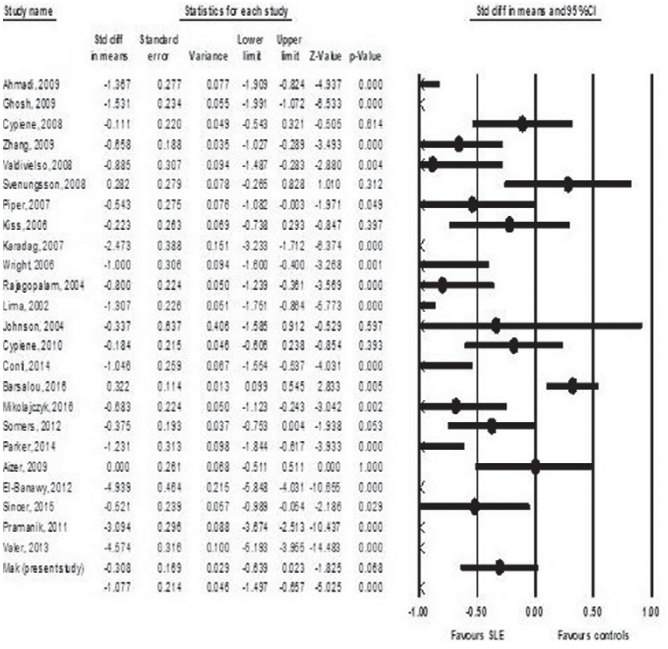
Average capillary density: 17±4.13 (13–26) in SCL vs 21±3.65 (16–28) in HC (p 0.00).

Average capillary diameter: 43±13.54 (17–83) SCL vs 19±1.67 μm (16–21) HC (p 0.02).

Mean capillary length: 185±34 μm (125–248) SCL vs 237±42 μm (178–313) HC (p 0.00).

In 22 SCL patients were observed dilated capillaries in 20 (90%), megacapillaries (≥70 μm) in 10 (45%) and 7 (32%) showed disturbed architecture with lost areas of the normal U-shape and changes in the parallelism of the main axis of the

capillaries. About subpapillary venous plexus in SCL: 7 (32%) were prominent and only one had capillary hemorrhage. In contrast, none of the controls presented these alterations. (p 0.0).
According to the 3 NVC patterns the following averages were observed in the LVC:
Early Pattern (n: 8): diameter 36.93±10.84 μm; Long 191.21±47.58 μm; Density 18.12±5.33 μm.
Active Pattern (n: 11): diameter 48.80±14.80 μm; Length 184.11±29.91 μm; Density 16.72±3.25 μm.
Late Pattern (n: 3): diameter 36.27±10; Long 178.03±28.8 μm, density 19.33±4.16 μm.



Conclusions: We found that LVC in SCL patients show significant microvascular changes with respect to HC. In addition, all NVC patterns described in SCL showed similar alterations in LVC. Therefore, LVC could be a complementary or alternative method to NVC since it is easily accessible, has good visibility and is not influenced by local mechanical or chemical stimuli that can affect the nail bed.

FRI0636 ENDOTHELIAL DYSFUNCTION IN SYSTEMIC LUPUS ERYTHEMATOSUS – A CASE-CONTROL STUDY AND AN UPDATED META-ANALYSIS AND META-REGRESSION

A. Mak[1], N.Y. Kow[1], H. Schwarz[2], L.L. Gong[3], S.H. Tay[1], L.H. Ling[3]. *[1]Medicine; [2]Physiology; [3]Cardiology, National University of Singapore, Singapore, Singapore*

Background: Endothelium-dependent flow-mediated dilation (ED-FMD), a biophysical marker of endothelial dysfunction, is apparently impaired in patients with systemic lupus erythematosus (SLE). However, such observation is inconsistent because of the lack of standardization of the methodology of ED-FMD measurement and inclusion of patients with different comorbidities amongst different studies.
Objectives: Firstly, we evaluated if ED-FMD is indeed impaired in SLE patients naïve of cardiovascular disease and its traditional risk factors. Secondly, we aimed to determine if the putative contribution of SLE to endothelial dysfunction is in fact confounded by demographic-, disease- and treatment-related factors.
Methods: We assessed and compared the brachial artery ED-FMD (baED-FMD) using the Prosound Alpha-10 ultrasound system® between SLE patients without cardiovascular disease and cardiovascular risk factors and healthy controls (HC) matched for age, gender and body mass index (BMI). Exclusions were pregnancy, a history hypertension, diabetes mellitus, chronic kidney disease, cardiovascular and cerebrovascular diseases, and statin therapy. SLE-related disease activity and organ damage in the SLE patients were assessed using SELENA-SLEDAI and SLICC/ACR DI, respectively. With inclusion of our own data from this case-control study, we performed a comprehensive meta-analysis of case-control studies which compared baED-FMD between SLE patients and HC by determining the effect size of baED-FMD as standard mean difference (SMD). Demographic and clinical factors associated with the effect size were explored by mixed-model meta-regression.
Results: Seventy one SLE patients and 71 HC were studied, and there were 6 men in each group. The mean±SD age and BMI of SLE patients and HC were 39.21±13.4 and 40.37±12.9 years, and 22.54±5.1 and 22.86±4.2 kg/m^2, respectively. In SLE patients, the mean±SD daily prednisolone dose, SELENA-SLEDAI and SLICC/ACR DI were 13.43±14.4mg, 6.52±5.4 and 0.17±0.4, respectively. SLE patients had significantly lower baED-FMD than HC (3.72±2.8% vs 4.63±3.1%, p=0.032). In the SLE group, no association between baED-FMD and age, gender, BMI, blood pressure, duration of SLE, serum C3, C4 and anti-dsDNA levels, SELENA-SLEDAI, SLICC/ACR DI and daily prednisolone dose was found. Similarly, no association was noted between baED-FMD and age, gender and BMI in the HC group. Meta-analysis of 25 case-control studies involving 1,313 SLE patients and 1,012 HC with the random effects model revealed significantly lower baED-FMD in SLE patients compared to HC (SMD -1.077, p<0.001) (see Fig for forest plot). The presence of diabetes mellitus (p=0.04747), higher diastolic blood pressure (p=0.04419) and renal involvement (p=0.02721) were associated with more discrepant baED-FMD between both groups.

Conclusions: SLE patients naïve of cardiovascular disease and its traditional risk factors have impaired endothelial function. While SLE-related disease activity and organ damage are not apparently related to endothelial dysfunction, the presence of diabetes mellitus, renal disease and diastolic hypertension are potential contributors to endothelial dysfunction in SLE patients.

FRI0637 DIAGNOSTIC PERFORMANCE OF THE NEW OMERACT CRITERIA FOR CPPD IDENTIFICATION BY US: CORRELATION WITH SYNOVIAL FLUID ANALYSIS

A. Adinolfi[1], V. Picerno[1], A. Scanu[2], C. Toscano[1], C.A. Scirè[3], G. Carrara[4], B. Frediani[1], A. Iagnocco[5], N. Damjanov[6], L. Punzi[2], G. Filippou[1]. *[1]University of Siena, Siena; [2]University of Padova, Padova; [3]University of Ferrara, Ferrara; [4]SIR-Epidemiology Unit, Milan; [5]University of Turin, Turin, Italy; [6]University of Belgrade, Belgrade, Serbia*

Background: Ultrasonography (US) has demonstrated to be an accurate tool for the diagnosis of calcium pyrophosphate deposition disease (CPPD) (1). Recently, the OMERACT "US in CPPD" subtask force, has created new definitions for CPPD identification by US, that demonstrated to be reliable at the knee joint, bridging a gap afflicting the old definitions (2). On the other hand, synovial fluid analysis (SFA) is considered to be an accurate and valid method for diagnosing CPPD.
Objectives: The aim of this study wasto evaluate the association between US, using for the first time the new OMERACT US criteria for CPPD, and SFA findings for identifying patients affected by CPPD.
Methods: We enrolled all the consecutive patients, aged more than 60 years old, referred to our outpatient clinic from September 2016 to December 2016, for knee pain and that presented knee effusion of any grade. Patients with suspected chronic inflammatory conditions were excluded.
All the subjects underwent an US exam (EsaoteMyLab 70) of the clinically involved knee, performed by an expert sonographer that applied the new OMERACT criteria for the diagnosis of CPPD at the fibrocartilage (menisci) and hyaline cartilage of the affected knee (2).
Subsequently, a US-guided arthrocentesis was performed, and the synovial fluid was collected and analyzed by a compensated polarized light microscopy (AxioLab A.1 [Zeiss]) by an expert observer in order to assess the presence of CPP crystals. Both observers were blinded to clinical and to each other findings. The Chi-squared test was used to correlate the US and SFA findings.
Results: 49 patients (28 women) were enrolled in the study, with a mean age of 70,29yo (SD±10,93). 28 subjects were affected by CPPD at SFA and 26 patients

were identified as affected by CPPD at US. In 4 patients, the SFA was positive and the US was negative, while in 2 patients the SFA was negative and the US positive. Using the chi-squared test, a very strong association was found between the exams, with a p-value $<$0,0001.

Conclusions: The new OMERACT US criteria for CPPD identification have already demonstrated to be reliable, considering the good to high kappa values yielded in previous multi-observer studies (2). This preliminary study, indicates that the new criteria seem to be also accurate for diagnostic purposes as they strongly correlate with the SFA for the presence of CPPD in knee joints. Further validation studies that will be able to assess the diagnostic accuracy of US are already in the research agenda of the OMERACT group "US in CPPD".

FRI0638 COMPARISON OF ULTRASOUND AND MRI IN THE DIAGNOSIS OF PROXIMAL AND DISTAL BICEPS TENDON PATHOLOGY

D. Huguet, C. Darrieutort-Laffite, B. Le Goff. *Hopital Hotel Dieu Et Hme, Nantes Cedex 1, France*

Background: Disorders of the long head of the biceps brachii tendon (LHBt) are commonly recognized as a source of shoulder pain. Ultrasound (US) is thought to be of limited value in the diagnosis of partial-thickness tear and non-tear abnormalities of the LHBt because of the difficulty to assess its intra-articular proximal portion. Brasseur recently described that placing the arm in extension/external rotation increased LHBt intra-articular portion visibility.

Objectives: The goal of this study was to determine if the systematic assessment of the intra-articular portion of the tendon, from the rotator interval to its glenoid insertion, with the arm placed in extension/external rotation could increase US sensitivity.

Methods: This was a cross-sectional study. All patients referred for the treatment of a rotator cuff disease (rupture, tendinopathy, calcific deposit) with an available MRI were included. US was performed blinded from the results of the clinical or MRI using a Sonosite Edge with a 6–13 MHz probe. LHBt was studied at different level: in the bicipital groove, at the rotator interval, over the upper pole of the humerus head to its insertion on the superior glenoid tubercule. To increase the visibility of the proximal portion, we placed the arm in extension/external rotation as described by Brasseur [1]. Diagnosis of tendinopathy were tendon enlargement, hypoechogenicity and an increase in the interfibrillar distance. Subluxation or dislocation of the LHBt was defined as a partial or total loss of contact between the tendon and its groove. Tearing of tendon was defined as discontinuity or absence of tendon fibers. Fluid collection was defined as an anechoic ring around the tendon $>$2 mm. Abnormalities of the LBHt on MRI was retrieved from the report. LBHt abnormalities detected on arthroscopy were used as the gold standard.

Results: We included 129 patients, 57 female (44%), and mean age 54 years (33–73). Seventy-five (58%) had a rotator cuff tear and 54 (42%) a tendinopathy. Arthroscopy found LHBt pathological changes in 39% of the case. The summary of the findings obtained with MRI, US (distal and proximal) and arthroscopy are summarised in table 1.

Table 1

LHB	MRI	US distal	US proximal	Arthroscopy
Normal	99	90	111	78
Subluxation	15	6		9
Effusion	12	30		
Tear	3	3	6	6
Flattened			12	2
Thickening				30
Nodular				1
Inflammatory				3

We calculated the sensitivity/specificity of MRI and US (at the proximal and distal level) in the detection of LHBt changes using arthroscopy as gold standard (Table 2).

Table 2

	Sensitivity	Specificity	PPV	PNV
MRI	52%	96%	90%	73%
US proximal	59%	88%	77%	77%
US distal	29%	96%	83%	67%

Conclusions: US has a good specificity but a poor sensitivity in the detection of LHB tendon changes even when a systematic and carreful study of the proximal part of the tendon is undertaken. If detection of distal changes of the tendon in the inter-tubercular groove seems feasible with US, the involvement of the more proximal, intra-articular part of the tendon remains challenging. MRI sensitivity remains also poor. Overall, arthroscopy still remains the gold standard to detect LHB tendon intra-articular pathology.

FRI0639 COULD BE THE ULTRASOUND STUDY OF PATIENTS WITH TROCHANTERIC PAIN USED TO CHOSE AN SPECIFIC THERAPEUTIC APPROACH?

C.A. Guillen-Astete, M. Teran-Tinedo. *Rheumatology Department, Ramon y Cajal University Hospital, Madrid, Spain*

Background: Previous studies on tendinopathies of the hand (Quervain's tendinitis) and enthesis knee (anserine syndrome) have shown that some sort of ultrasound findings could predict the therapeutic response to specific treatments. Globally, acute inflammatory (power Doppler, synovial effusion) US findings predicts a better response to steroids injection than the chronic US findings (enthesophytosis, bone cortical irregularities).

Objectives: The aim of present study is to determine the probability of therapeutical success of different treatment approaches according to the presence of some specific US findings, in patients with trochanteric pain.

Methods: The image and clinical charts of patients who were assessed due to trochanteric pain between June 2015 and June 2016 in our clinic were reviewed. From those registries, dichotomic data about US findings were collected: Superficial bursitis, deep bursitis, cortical irregularities, enthesophytosis and power Doppler signal. The follow up data were collected from the electronic app or paper control form at day 6 to 9 from the original consultation. Successful treatment was interpreted as at least a reduction of 50% of the basal visual pain scale (rated from 1 to 10). Correlations with US findings were performed using single or composite variables.

Results: One hundred and twenty six registries of patients with trochanteric pain were included. From all of them, 119 belongs to female patients (94.4%). The global US findings were as follows: 43 superficial bursitis, 39 deep bursitis, 47 cortical irregularities, 32 enthesophytosis and 6 power Doppler signal. Thirty seven steroids injection, 64 prescriptions of non steroideal antinflammatory drugs (NSAIDs) and 66 prescriptions of transdermal NSAIDs were performed.

Therapeutic success was achieved in 76.8% of patients who underwent an steroid injection in whom superficial or deep bursitis were identified in the US, and in 79.9% of patients who were treated with transdermal NSAIDs in whom enthesophytosis of cortical irregularities were identified.

By the other hand, patients treated with steroids injections in whom chronic US findings were achieved showed a failure treatment rate of 54.4%. For those in whom any kind of bursitis were identified the failure treatment rate of transdermal NSAIDs was 65.5%. Oral NSAIDs treatments were success in 35% of patients with any kind of bursitis and in 70% of patients with cortical irregularities or enthesophytosis.

Into the composite variables study we find that the treatment with steroid injection in patients with any kind of bursitis with independence of the presence of any chronic US findings had a Relative Risk (RR) of success of 2.66 compared to transdermal NSAID and a RR of 2.26 compared with oral NSAD treatment ($P<0.001$ y $P<0.01$, respectively). The only independent factor that demonstrated a 100% success treatment rate was the presence of power Doppler signal treated using steroid injection.

Conclusions: US findings are useful predictors of therapeutic response in patients with trochanteric pain. In general terms, we found that patients with US acute findings have an increased probability of treatment success when treated with steroid injection while those with US chronic findings have an increased probability of success when treated with NSAIDs (transdermal or systemic).

FRI0640 STRUCTURAL DAMAGE PROGRESSION IN LUPUS ARTHRITIS: A PROSPECTIVE OBSERVATIONAL STUDY

C. Tani [1], A. Delle Sedie [1], D. D'Aniello [2], C. Stagnaro [1], L. Carli [1,3], R. Vagelli [1], F. Balestri [1], S. Accogli [4], D. Caramella [4], M. Mosca [1]. *[1]Rheumatology Unit, University of Pisa; [2]Emergency Department, Azienda Ospedaliero Universitaria Pisana, Pisa; [3]GenOMeC PhD, University of Siena, Siena; [4]Diagnostic and Interventional Radiology, University of Pisa, Pisa, Italy*

Background: Joint involvement is one of the main causes of chronic pain and disability in SLE patients (pts); despite arthritis in SLE is usually considered mild, joint erosions and deformities can be observed with significant impact on patient's quality of life. Imaging techniques are more sensitive than joint count in detecting synovitis and early joint damage.

Objectives: This study was aimed at evaluating the progression of joint damage in SLE and at evaluating predictive factors for damage accrual

Methods: Consecutive SLE pts with active hand-wrists synovitis (detected by joint

count and/or ultrasounds) were enrolled in this 5-years prospective observational study. Clinical assessments as well as joint ultrasound (US) and MRI were performed at baseline and after 5 years. Each patient underwent a non-dominant hand–wrist US examination using a Logiq 9 with a linear probe operating at 14 MHz. Synovitis was defined as the presence of synovial hypertrophy and/or the presence of power Doppler signal (PD). A non-dominant hand–wrist MRI study with a 0.3 T extremity dedicated machine to evaluate the presence of bone erosions (BE) and bone marrow edema (BME) was also performed. Coronal and axial T1-weighted gradient-echo images and coronal STIR images were acquired. The images acquired were scored according to the RAMRIS scoring system for RA by a trained radiologist unaware of the clinical picture and diagnosis.

Results: Fifty-seven pts were enrolled (female 91.2%, mean age 44±12.2 years, mean disease duration 15.9±9 years);43 (75.4%) completed the follow-up, 3 died (5.2%) and 11 (19.4%) were lost to follow-up. At baseline, 7 (12.3%)satisfied criteria for Jaccoud arthropathy (JA) and 7 (12.3%) had a recent onset arthritis (<1 year of duration). 22 pts (28.6%) showed clinical signs of synovitis, 56 (98.2%) presented positive hand-wrists US (synovitis) and in 14 (24.6%) PD signal was also recorded. Six pts (11.76%) already showed erosions at standard X-Ray, while MRI revealed at least one BE in 30 and 54 patients respectively, for a cumulative mean erosive burden of 9.2 erosions (range 1–63). After 5 years of follow-up, 34 pts consented to repeat the assessment; 11 (33%) had JA and 18 (29%) were still presenting clinical signs of synovitis; 28 pts (82.3%) showed synovitis at US with PD in 7 cases (20.5%). The final mean erosive burden resulted 12.3 (range 2–82) with a significant increase from the baseline evaluation (p=0.001). Overall, 16 pts accrued joint damage. Interestingly, erosion progression was observed also in 12 pts with negative joint count but positive US at baseline. The presence of PD at US and BME at baseline was associated with higher erosive burden at follow-up (p=0.03 and p=0.02 respectively)

Conclusions: Arthritis in SLE can be persistent over time and progress to joint damage even in a short tem period despite treatment; normal joint count at physical examination but US findings of synovitis can be associated with erosion progression over time. The presence of PD at US and bone marrow edema at MRI are associated with a more severe damage progression. US and MRI can be a valid help for the clinician to identify patients at higher risk of severe damage to be treated with a more aggressive therapeutic strategy targeting arthritis.

FRI0641 WRIST INFLAMMATION AS ASSESSED BY MAGNETIC RESONANCE IMAGING IS ASSOCIATED WITH PATIENT-REPORTED PHYSICAL IMPAIRMENT, GLOBAL DISEASE ACTIVITY AND PAIN IN EARLY RHEUMATOID ARTHRITIS: LONG-TERM RESULTS FROM TWO RANDOMIZED CONTROLLED TRIALS

D. Glinatsi[1], J.F. Baker[2], M.L. Hetland[1,3], K. Hørslev-Petersen[4,5], B.J. Ejbjerg[6], K. Stengaard-Pedersen[7], P. Junker[8], T. Ellingsen[8], H.M. Lindegaard[8], I. Hansen[7], T. Lottenburger[9], J.M. Møller[10], L. Ørnbjerg[1], A. Vestergaard[11], A.G. Jurik[7,12], H.S. Thomsen[3,10], T. Torfing[8], S.M. Bisgaard[1], M.B. Axelsen[1], M. Østergaard[1,3]. *[1]Rigshospitalet, Glostrup, Denmark; [2]Corporal Michael J. Crescenz VA Medical Center, Philadelphia, PA, United States; [3]University of Copenhagen, Copenhagen; [4]King Christian 10th Hospital for Rheumatic Diseases, Gråsten; [5]University of Southern Denmark, Odense; [6]Slagelse Hospital, Slagelse; [7]Aarhus University Hospital, Aarhus; [8]Odense University Hospital, Odense; [9]Vejle Hospital, SLB, Vejle; [10]Copenhagen University Hospital Herlev, Herlev; [11]Hvidovre University Hospital, Hvidovre; [12]Aarhus University, Aarhus, Denmark*

Background: Studies in established rheumatoid arthritis (RA) have shown that radiographic progression is associated with increasing health assessment questionnaire (HAQ) score. However, most studies have failed to demonstrate this association at the early stage of the disease. In addition, little is known about how specific pathologies, e.g. joint inflammation, tenosynovitis and joint damage, contribute to different patient-reported outcomes (PROs).

Objectives: To examine the association between MRI wrist inflammation and damage with PROs in patients with early RA.

Methods: MRIs of the wrist and hand were obtained from 210 early RA patients participating in two investigator-initiated, randomized, controlled studies (CIMESTRA/OPERA), which aimed at achieving inflammatory control by use of conventional and/or biologic drugs combined with intra-articular injection of glucocorticoids. The image-sets were assessed according to the RA MRI scoring system (RAMRIS) for inflammation (synovitis, tenosynovitis, osteitis) and damage (bone erosions, joint space narrowing) at baseline (n=210), 1 (n=206) and 5 (n=113) years follow-up. Data from the two studies were pooled and assessed for associations between MRI features and HAQ, patient global visual analogue scales (VAS-PtGlobal) and VAS pain using Spearman correlation for status and change scores, univariate and multivariable linear regression analyses for change scores and generalized estimating equations for status and change scores. MRI features were further tested for trends against specific hand-related HAQ questions using the Jonckheere trend test.

Results: MRI inflammation, but not damage, showed statistically significant associations with HAQ, VAS-PtGlobal and VAS pain for status and change scores, independently of swollen joint count and level of C-reactive protein. Synovitis and tenosynovitis were the MRI features most consistently associated with PROs, particularly VAS-PtGlobal and VAS pain (Table 1). MRI synovitis and tenosynovitis mean scores increased with the level of difficulty to cut meat and open a milk carton (p<0.01), and similar patterns were seen for other hand-related HAQ items. As an additional analysis, the metacarpophalangeal joints were included in the analyses, but this did not strengthen the associations between MRI pathology and PROs.

Table 1 Univariate and multivariable generalized estimating equations

Association between magnetic resonance imaging (MRI) parameters and patient-reported outcomes for status scores and change scores. All generalized estimating equations (GEE) were adjusted for age and sex. MRI parameters with a univariate p-value ≤0.10 were included in multivariable GEE analysis where C-reactive protein levels and swollen joint counts were incorporated. *Log-transformed for status scores. Abbreviations: HAQ: Health assessment questionnaire, JSN: Joint space narrowing, VAS: Visual analogue scale, PtGlobal: Patient global.

Conclusions: MRI-assessed inflammation, but not damage, in the early RA wrist is associated with patient-reported physical impairment, global disease activity and pain, and the amount of wrist inflammation influences physical hand function.

FRI0642 THE POTENTIAL VALUE OF POSITRON EMISSION TOMOGRAPHY (PET)-SCAN IN SYSTEMIC SCLEROSIS FOR THE QUANTITATIVE ASSESSMENT OF INTERSTITIAL LUNG DISEASE

D.M. Peelen[1], B. Zwezerijnen[2], E.J. Nossent[3], L.J. Meijboom[4], O.S. Hoekstra[2], C.J. van der Laken[1], A.E. Voskuyl[1]. *[1]Rheumatology; [2]Nuclear Medicine; [3]Pulmonology; [4]Radiology, VU University Medical Center, Amsterdam, Netherlands*

Background: Interstitial lung disease (ILD) in systemic sclerosis is treated by immunosuppressive drugs (e.g. cyclophosphamide), aimed at reduction of inflammatory response. Differentiation between inflamed and non-inflamed fibrotic tissue might help to develop treatment stratification, with the aim of improving the prognosis of (subgroups of) SSc-ILD patients. ^{18}F-Fluoro-Dexoxyglucose Positron Emission Tomography (^{18}F-FDG PET) scan might be a promising tool to detect inflamed lung areas, as formerly shown in a semi-quantitative setting.[1, 2]

Objectives: This study aims to investigate the potential role of ^{18}F-FDG PET –scan for the quantitative assessment of metabolically active SSc related ILD.

Methods: ^{18}F-FDG PET -scans of 22 patients with systemic auto-immune disease, including 9 with SSc, 9 with systemic lupus erythematosus (SLE) and 4 with primary Sjögren's syndrome (pSS), were retrospectively analyzed. FDG-uptake was quantitatively measured within 2cm-sized Regions of Interest (ROI's) at apical, medial and basal lung levels. A total of 22 ROI's were drawn in each patient. SUVmean values of all ROI's were corrected by the medial SUVmean bloodpool value. Subsequently, the average of 6 posterior basal SUVmean values

was divided by the average of 6 posterior apical SUVmean values (basal/apical ratio). High Resolution Computed tomography (HRCT)-scans and Pulmonary Function Tests (PFT) were examined to confirm the diagnosis of ILD and to specify the pattern of fibrosis.

Results: Mean age of patients was 69.4 (SSc-ILD), 62.5 (SSc without ILD), 38.9 (SLE) and, 49.3 (pSS). In SSc patients, the mean disease duration was 5.0 (SSc-ILD) and 4.4 (SSc without ILD) years. Diffuse cutaneous sclerosis was present in 2 SSc-ILD and 1 SSc without ILD patients, while other SSc patients were diagnosed with limited cutaneous SSc. ILD was present in 5 out of 9 SSc patients as confirmed by HRCT and PFT. ILD was active in 3 out of 5 SSc-ILD patients. Posterior basal/apical SUVmean ratios of SSc-ILD patients were significantly increased compared to SSc patients without ILD (p=0.016), and compared to SLE and pSS patients without ILD (p=0.001 and p=0.016, respectively), which is shown in Figure 1.

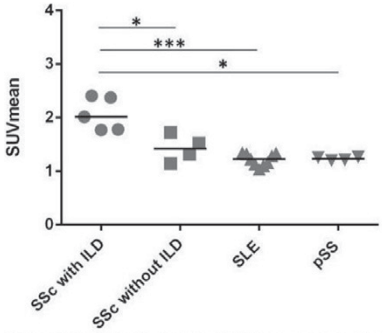

Figure 1: Basal/Apical ratio of SUVmean scores (corrected for bloodpool) in systemic autoimmune patients.
*= p<0.05, ***= p<0.001 (Mann-Whitney test), —— = median

Conclusions: Our findings demonstrate that ^{18}F-FDG PET -scan is potentially useful for the quantitative assessment of active ILD lesions in SSc patients. The technique may therefore provide opportunities to select the patients with inflammatory regions in ILD that are most likely to respond to immunesuppression.

FRI0643 ENTHESITIS AND FOOT DISABILITY IN PATIENTS WITH ANKYLOSING SPONDYLITIS

A. Serce, A. Bal, D. Dulgeroglu, A. Cakci. *Physical Medicine and Rehabilitation, Diskapi YB Education and Resarch Hospital, Ankara, Turkey*

Background: Enthesitis is a primary clinical feature of ankylosing spondylitis (AS). Lower extremity enthesopathy may cause foot pain and functional disability. Detection of enthesitis by using physical examination may be insufficient. Musculoskeletal ultrasonography is a noninvasive and low-cost method for detecting enthesitis readily.

Objectives: The aims of this study were to evaluate enthesitis by using musculoskeletal ultrasonography and foot disability in patients with AS, to compare healthy controls, and to determine the correlation of enthesitis score and foot function with disease activity and functional status.

Methods: In this study, 101 patients with AS and 42 healthy controls were examined for enthesal site abnormalities by using gray-scale ultrasonography. The findings were assessed by using the Glasgow Ultrasound Enthesitis Scoring System (GUESS). The foot function index (FFI), which comprised of pain, disability, and activity limitation subscales, was measured in all the patients with AS and healthy controls for assessment of foot function. Disease activity and functional status were assessed using the Bath AS Disease Activity Index (BASDAI) and Bath AS Functional Index (BASFI), respectively, in patients with AS.

Results: The median GUESS score was 8.00 (1.00–23.00), and, the median total FFI and scores in all the pain, disability, and activity limitation subscales were 14.70 (0.00–75.20), 16.60 (0.00–82.80), 16.10 (0.00–84.40), and 4.00 (0.00–60.00), respectively in patients with AS. The GUESS score, total FFI, and all the subscales scores were significantly higher in the patients with AS than in the controls (p=0.00). GUESS score showed no correlation with BASDAI and BASFI. In patients with AS, total FFI and scores for all subscales showed positive correlations between BASDAI and BASFI, respectively (p=0.00, *r*=0,66; p=0.00, *r*=0,0,50; p=0.00, *r*=0,59; p=0.00, *r*=0,31; p=0.00, *r*=0,60; p=0.00, *r*=0,54; p=0.00, *r*=0.57; p=0.00, *r*=0.50).

Conclusions: The severities of enthesitis and foot disability were higher in patients with AS. Patients with AS may undergo ultrasonographic examination for enthesal foot involvement. Foot disability is related with disease activity and function. Foot involvement and disability should be evaluated comprehensively and managed properly.

FRI0644 SUBCLINICAL ULTRASONOGRAPHIC CHANGES OF THE ANTERIOR CHEST WALL JOINTS IN ANKYLOSING SPONDYLITIS AND RHEUMATOID ARTHRITIS AND THEIR ASSOCIATION WITH CHEST EXPANSION

F.I. Abdelrahman [1], M.A. Mortada [1], A.B. Abdul_Sattar [1], A.A. El Sammak [2]. *[1]Rheumatology and Rehabilitation; [2]Radiology, Zagazig University, Zagazig, Egypt*

Background: Anterior chest wall (ACW) joints can be involved during the course of Rheumatoid arthritis (RA) and ankylosing spondylitis (AS), however, its clinical implications appear to be underestimated by the rheumatology community.

Objectives: To determine the prevelance and types of subclinical ultrasonographic changes in the ACW joints in RA and AS patients and their association with the chest expansion.

Methods: The study was conducted on 132 sternoclavicular joints (SCJ) and 66 manibrusternal joints (MSJ) in 66 subjects (22 AS, 22 RA, and 22 control). Ultrasound (US) assessments were performed to detect synovitis, erosions, ankylosis, osteophytes, or doppler signals. Chest expansion was measured. In RA group, Disease Activity Score (DAS28) and Health Assesment Questionare Disability Index (HAQDI) were recorded. In AS group, Ankylosing Spondylitis Disease Activity Score (ASDAS), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Bath Ankylosing Spondylitis Functional Index (BASFI) were recorded.

Results: US detected subclinical changes of ACW joints in (74.2%) of RA, (77.3%) of AS, and (21.2%) of control groups. There was a highly significant difference between total US changes in RA (74.2%) and control (21.2%) ($p<0.001$) and also between AS (77.3%) and control (21.2%) ($p<0.001$). Non of our control had neither erosions nor ankylosing in MSJ. MSJ ankylosing was signficantly higher in AS (77.3%) than RA (18.2%) ($p<0.001$). MSJ ankylosing was highly associated with limited chest expansion in both RA and AS ($P<0.001$). All patients (100%) in both groups (RA and AS) with MSJ ankylosing by US had limited chest expansion. In RA group, ultrasonographic changes were found to be higher with smoking, longer disease duration and high DAS28. In AS group, ultrasonographic changes were found to be higher with older age, male sex, smoking, longer disease duration and high BASDAI and BASFI.

Table 1. Comparison between RA and AS as regard ultrasonographic changes of anterior chest wall joints

	RA n (%)	AS n (%)	χ^2	p value
SCJ synovitis	34 (77.3)	24 (54.5)	5	**0.02***
SCJ PD activity	14 (31.8)	12 (27.3)	0.2	0.6
SCJ erosion	32 (72.3)	28 (63.6)	0.8	0.4
SCJ osteophyte	4 (4.5)	6 (13.6)	0.4	0.5
MSJ ankylosing	4 (18.2)	14 (63.6)	9.2	**0.002***
MSJ erosion	9 (40.9)	4 (18.2)	2.7	0.09
MSJ osteophyte	1 (0.5)	1 (0. 5)	0	1

*n: number; χ^2: chi-square test; PD: Power Doppler signals.

Conclusions: US detected subclinical changes of ACW joints in a high percentage of RA and AS patients. No erosions or ankylosing in MSJ were Found in the healthy individuals. MSJ ankylosing is more in AS than RA. Relatively, ankylosing of MSJ by US is highly associated with limited chest expansion in RA and AS. Up to the best of our knowledge, our study was the first study that detected subclinical changes of ACW joints in RA and AS by US.

FRI0645 NAILFOLD CAPILLAROSCOPY IN DIABETES MELLITUS TYPE 2

G. Maldonado[1], C. Paredes[2], R. Guerrero[1], C. Ríos[1]. [1]*Universidad Espíritu Santo;* [2]*Universidad Espiritu Santo, Guayaquil, Ecuador*

Background: Diabetes mellitus (DM) is characterized by chronic hyperglycemia states and the development of specific microvascular disorders such as retinopathy and nephropathy. Conventional methods are usually used to study the vascular compromise of this entity, however, the use of capillaroscopy for the evaluation of capillary microarchitecture is not frequently used.
Objectives: The objective of this study was to identify vascular alterations in patients with type II diabetes mellitus and to determine the relationship between capillaroscopic findings and clinical manifestations.
Methods: Observational, descriptive and prospective of patients with diabetes mellitus II selected by inclusion and exclusion criteria. Subjects presenting signs/symptoms or history of any collagen disease, trauma presence in the nailfold due to cosmetic treatment or nail polish, were excluded. The capillaroscopy was performed by an experienced rheumatologist in a room with an ambient temperature of 20–23oC. The fourth and fifth fingers of the nondominant hand were chosen. The capillaries were observed using a 10x magnification capillaroscope (Dino-Lite) and photographs of the last distal row of capillaries were taken. The following capillaroscopic parameters were considered: capillary diameter (ectasia and giant capillaries), crosslinked capillaries, capillary tortuosity, ramified capillaries, avascular zones, hemorrhages, dominant morphology, subpapillar venous plexus visibility, cuticulitis and SD pattern. The images were analyzed by an experienced rheumatologist. Data was analyzed using SPSS. The non-parametric correlations were performed by tau_b Kendall and values were considered statistically significant when $p>0.01$ and they had two tails.
Results: 65 patients were included in the study, with a mean age of 57 years [39–80], of which 75% [49] were women and 25% [16] men. The capillaroscopic findings were evident in 83% of the study population. The most frequent alterations were tortuous capillaries in 63% [41], cross-linked capillary in 59% [38], avascular areas in 48% [34], ectasias in 31% [25]. In smaller frequency, giant capillaries 14% [9], arborified capillaries 11% [7], no haemorrhages, no SD pattern. The capillaroscopic findings representing vascular damage were greater in patients with Diabetes Mellitus than in the control group (Figure 1). Moreover, the capillary morphology in the control group was open versus tortuous in patients with DM. Those patients with capillaroscopic alterations had a longer time of evolution of the disease with an average of 12.8 years, compared to those who did not present alterations that had a mean evolution of the disease of 8.5 years, which shows that those capillaroscopic alterations represent progressive endothelial damage. In addition, an association between the presence of retinopathy and capillary damage at the nail bed level was demonstrated ($p>0.001$).

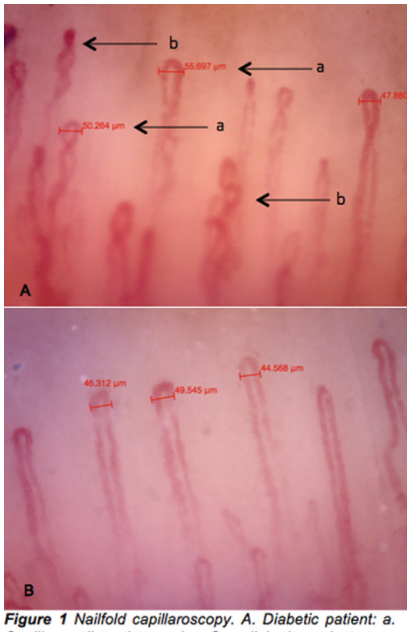

Figure 1 *Nailfold capillaroscopy. A. Diabetic patient: a. Capillary distention b. Crosslinked and tortous capillaries. B. Healthy subject, normal capilaroscopy. Original photos: Génessis Maldonado.*

Conclusions: Capillaroscopy has proven to be a non-invasive, reproducible and reliable technique for the evaluation of vascular microarchitecture within a large group of rheumatic diseases of the scleroderma spectrum. However, it has been shown that it can be used for evaluation other diseases outside the field of Rheumatology such as diabetes, being a tool that should be known by primary care physicians and healthcare workers.

FRI0646 THREE-DIMENSIONAL NAIL IMAGING BY OPTICAL COHERENCE TOMOGRAPHY: A NOVEL BIOMARKER OF RESPONSE TO THERAPY FOR NAIL DISEASE IN PSORIASIS AND PSORIATIC ARTHRITIS

G. Abignano[1,2], P. Laws[3], F. Del Galdo[1,2], H. Marzo-Ortega[1,2], D. McGonagle[1,2]. [1]*Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds;* [2]*NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds Teaching Hospitals NHS Trust;* [3]*Department of Dermatology, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

Background: Nail disease is a common feature of psoriasis and psoriatic arthritis (PsA) and can impact quality of life significantly. The assessment of nail disease, unlike skin disease, is challenging with no tissue biomarkers feasible. Commonly used clinical outcomes include the Nail Psoriasis Severity Index (NAPSI) or the modified NAPSI system which are subjective. Optical Coherence Tomography (OCT) can detect changes in psoriatic nails and is a potential tool to assess response to therapy (1).
Objectives: To evaluate OCT imaging changes in cases with nail psoriasis following 6 month-therapy with Apremilast, a PDE4 inhibitor with known efficacy for nail disease in psoriasis and PsA.
Methods: Forty fingernails from four psoriatic patients were imaged at baseline and after 6 month-treatment with Apremilast 30 mg bd using Vivosight OCT scanner (Michelson Diagnostics Ltd., Kent, UK). Three OCT scans were collected from each fingernail (1 transverse and 2 longitudinal – proximal and distal) totalling 240 scans available for analysis. OCT scoring of the forty fingernails, at baseline and six months later, was carried out for changes including: 1. leukonychia/white spots; 2. pitting/localized surface irregularities; 3. diffuse surface waving; 4. onycholysis; 5. subungual hyperkeratosis. OCT score was arbitrarily calculated based on the absence (=0) or presence (=1) of each feature on the three scans of the corresponding fingernail (range 0–15). Macroscopic nail features were scored at baseline and 6 months later using the NAPSI scoring system by a Dermatologist blinded to OCT findings and compared with OCT score. Data were expressed as median (range). Comparison between baseline and follow up measurements was performed using Wilcoxon matched-pairs signed rank test. Difference between two groups and correlation were calculated using Mann-Whitney test and Spearman's test respectively. Statistical analysis was carried out using GraphPad Prism software V.7.0.
Results: Based on NAPSI, twenty-eight/40 fingernails (70%) improved or remained stable after 6 months with the median NAPSI per nail falling from 3.5 (0–7) to 0 (0–6) ($p<0.0001$). The OCT evaluation showed that the entire gamut of nail changes exhibited improvement or stabilization in thirty-three/40 (82.5%) nails after 6 months with median OCT score per nail falling from 8 (3–14) to 4 (1–9) ($p<0.0001$). Difference of the change (Δ) of OCT score between baseline and follow-up significantly correlated with Δ-NAPSI ($r=0.71$, $p<0.0001$).
Conclusions: OCT is able to identify all common psoriasis related nail pathology and changes after treatment. Further studies with larger numbers are needed to validate its potential role as a biomarker for nail disease.

FRI0647 COLOR DOPPLER AS A VALUABLE PROCEDURE FOR EARLY DIAGNOSIS OF OCULAR VASCULAR CHANGES IN BEHÇET'S DISEASE

H.H. Al Sherbeni[1], S. Metawie[1], R. Abdel salam[2], H. Azizi[3]. [1]*Rheumatology and Rehabilitation;* [2]*Ophthalmology;* [3]*Radiology, Faculty of Medicine- Cairo University, Cairo, Egypt*

Background: Ocular involvement is a common and serious manifestation of Behçet's disease (BD). It occurs in about 70% of the patients and is associated with a high risk of blindness (Kaçmaz et al., 2008).
Color Doppler is used for imaging retrobulbar vasculature. It measures the peak systolic velocity (PSV) and end diastolic velocity (EDV), from which the resistance index (RI) is calculated in the ophthalmic artery (OA), central retinal artery (CRA), and posterior ciliary artery (PCA) to detect any abnormality in the retrobulbar vessels (Nagaoka, 2006).
Objectives: To determine and compare the orbital Color Doppler haemodynamic parameters of Behçet's patients with those of healthy subjects and to evaluate the OA, CRA, PCA flow velocities and resistance indices (RIs).
Methods: This study included thirty patients suffering from Behçet's disease satisfying at least 3 of the criteria of BD according to the International Study Group for Behçet's disease in 1990. 20 age/sex-matched healthy subjects served as a control group. All patients were subjected to history taking, clinical examination, full ophthalmological examination, routine laboratory investigations and Color Doppler ultrasound (CDU) examination.
Results: The patients' age ranged from 18 to 45 years with a mean of 31.0±7.5. Their disease duration ranged from 0.25 to 20 years with a mean of 5.71±5.84. There were diminished blood flow velocities of the OA, CRA and PCA as the peak systolic velocity (PSV) and end diastolic velocity (EDV) of these arteries were lower than normal while resistance flow indices (RIs) were higher than normal.

Table 1. Results of ocular Doppler ultrasound over right (RT) and left (LT) sided arteries

		RT sided arteries					LT sided arteries

FRI0648 CONCORDANCE BETWEEN THE TUBERCULIN SKIN TEST AND INTERFERON GAMMA RELEASE ASSAY FOR DIAGNOSING LATENT TUBERCULOSIS INFECTION IN PATIENTS WITH CHRONIC INFLAMMATORY ARTHRITIS

I. Aktas [1], F. Unlu Ozkan [1], T. Nazligul [1], H. Kuzu Okur [2]. *[1]Department of Physical Medicine and Rehabilitation; [2]Department of Chest Disease, Fatih Sultan Mehmet Education and Research Hospital, Istanbul, Turkey*

Background: Biologic therapies have led to a dramatic change in the management of rheumatologic diseases. Although biologic agents provide profound clinical benefits, various adverse events are associated with their use particularly an increased risk of the reactivation of latent tuberculosis. Therefore, screening for latent tuberculosis infection (LTBI) is imperative before initiating biologic agents[1]. Although tuberculin skin test (TST) is the most common test for detecting LTBI, Bacillus Calmette-Gue'rin (BCG) vaccination and non-tuberculosis Mycobacterium infections, can lead to false positive TST results. Interferon-gamma release assay (IGRA) measures the immune response to tuberculosis specific antigens that do not cross react with BCG, and therefore, do not cause false positive reactions in BCG recipients. Its positiveness indicates the presence of tuberculosis infection either latent or active[2].

Objectives: We aimed to prevent the unnecessary anti-tuberculosis prophylaxis in patients whom biologic therapy is planned by evaluating the concordance between the TST and IGRA.

Methods: Patients who have been receiving biologic therapy due to chronic inflammatory arthritis were enrolled in this study. Demographic and clinical data, TST and IGRA results were recorded. The agreement between IGRA and TST results was evaluated by Kappa coefficient.

Results: A total of 35 patients were included; 15 (42.8%) were male and mean age was 43.74±12.72 years. Of the 22 TST positive patients, 13 (37.1%) were IGRA negative. Of the 13 TST negative patients, 3 (8.6%) were IGRA positive. Nine (25.7%) patients were positive for either of the two tests and 10 (28.6%) patients were negative for both tests. There was statistically significant discordance between two tests (p:0.021; $p<0.05$) (Table 1). While positive rate of TST was 62.9%, positive rate of IGRA was 34.3% and Kappa consistency coefficient between two tests was 15.4% (p:0.283; $p>0.05$).

Table 1. Agreement between IGRA and TST results

IGRA	TST		Total	p
	Negative n (%)	Positive n (%)	n (%)	
Negative	10 (28.6)	13 (37.1)	23 (65.7)	**0.021**
Positive	3 (8.6)	9 (25.7)	12 (34.3)	
Total	13 (37.1)	22 (62.9)		

Conclusions: It is very common in rheumatology practice to administer anti-tuberculosis prophylaxis according to the TST. IGRA may reduce the number of patients in whom tuberculostatics are prescribed, especially in BCG recipients in endemic populations, resulting in a benefit of avoiding possible side effects. Furthermore, IGRA is also important for detecting the cases of LTBI that would be missed by TST. Confirmation in larger studies is necessary.

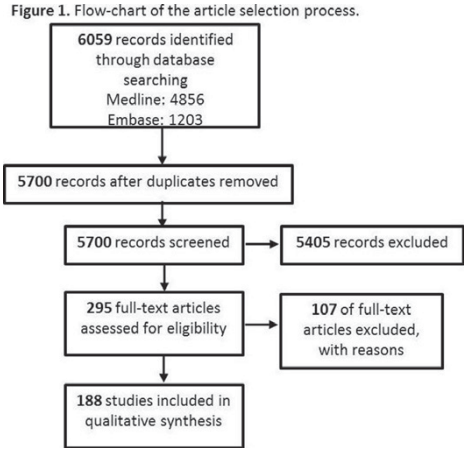
FRI0649 STANDARDIZED PROCEDURES FOR ULTRASOUND IMAGING IN PAEDIATRIC RHEUMATOLOGY: PROGRESS OF A EULAR TASK FORCE

I. Janta [1], P. Collado Ramos [2], J. Vojinovic [3], E. Naredo [4], L. Carmona [5]. *[1]Rheumatology, Hospital General Universitario Gregorio Marañón; [2]Rheumatology, Rheum-Pediatric Unit, Hospital Universitario Severo Ochoa, Madrid, Spain; [3]Pediatric Rheumatology, Clinical Center, Faculty of Medicine, University of Nis, Nis, Serbia; [4]Rheumatology, Joint and Bone Research Unit, Hospital Universitario Fundación Jiménez Díaz and Autónoma University; [5]Instituto de Salud Musculoesquelética, Madrid, Spain*



Background: Musculoskeletal ultrasound (MSUS) is a useful imaging technique in paediatric rheumatic diseases (PRD). US has several advantages over other imaging techniques: it is non-invasive, radiation free, rapid, highly accepted by the patients and does not require sedation for scanning in younger children. However, MSUS examination is incriminated to be an operator dependent technique. Moreover, the variability of normal sonoanatomy in children, due to ossification, makes the acquisition and interpretation of MSUS images difficult. The variability in background and experience of ultrasonographers in different countries requires an international multidisciplinary effort for an optimal standardization of MSUS performance in PRD.

Objectives: To perform a systematic literature review on guidelines for MSUS for children published by international societies and articles on how to perform MSUS scanning in children. This represents the first step for an EULAR taskforce, which objective is to develop EULAR Standardized Procedures for Ultrasound Imaging in Pediatric Rheumatology through a consensus process among rheumatologists, paediatric rheumatologists, and radiologists highly experienced in the performance, teaching and research in paediatric MSUS in rheumatologic disease.

Methods: The objective was reformulated according to the PICO-adapted approach, as follows: body parts, ultrasound, and scanning procedures. For each component several synonyms were used. Search limits were applied for animal studies and age. The literature search was performed in Medline and Embase from databases inception to 1st June 2016. References identified were imported into a bibliographic manager and duplicates were removed. To identify eligible studies the remaining articles were assessed by title and abstract. Only articles in English were retained. From the selected studies, data about the examined area, patient position, probe placement, scanning method, landmarks and pathologies using a predefined data collection form.

Results: The literature search resulted in 6059 articles, of which 4856 were captured in Medline and 1203 in Embase. Figure 1 shows the the study flow-chart for article selection. After removing duplicates and scanning titles and abstracts, 295 articles remained for detailed review. After full-text review, 107 articles were excluded. The main reason for article exclusion after full-text review was the lack of standardized examination. Of the remaining articles, 2 described shoulder structures, 14 elbow structures, 5 wrist structures, 9 hand structures, 25 hip

Figure 1. Flow-chart of the article selection process.

structures, 41 knee structures, 14 ankle structures and 2 foot structures. The number of structures described for each joint part was as follows: 3 shoulder, 13 elbow, 2 wrist, 4 hand, 7 hip, 25 knee, 14 ankle, 1 foot.
Conclusions: Several anatomical structures are lacking standardized MSUS examination in children.

FRI0650 NON OMERACT -EXPERT RHEUMATOLOGISTS SONOGRAPHERS AND INTER-ULTRASOUND MACHINE RELIABILITY OF THE OMERACT ULTRASOUND SCORING IN RHEUMATOID ARTHRITIS IN A CLINICAL-BASED SETTING: A BELGIAN STUDY

J.-P. Hauzeur[1], M.-J. Kaiser[2], J. Bentin[3], J.-P. Brasseur[4], B. André[2], P. Carron[5], E. Deflandre[2], C. Naveau[6], C. Ribbens[2], C. Rinkin[2], R. Wittoek[5], M.-A. D'Agostino[7], V. De Maertelaer[8] on behalf of The Belgian Group of Ultrasonography in Rheumatology. *[1]Rheumatology, CHIREC, Braine l'Alleud; [2]Rheumatology, CHU Liège, Liege; [3]Rheumatology, CHU Brugmann, Brussels; [4]Rheumatology, CHU Mont-Godinne, Yvoir; [5]Rheumatology, Ghent University Hospital, Ghent; [6]Rheumatology, GHDC, Charleroi, Belgium; [7]Rheumatology, hôpital Ambroise Paré, Boulogne-Billancourt, France; [8]Biostatistics and Medical Informatics & IRIBHM, School of Medicine, ULB, Brussels, Belgium*

Background: The OMERACT Ultrasound scoring system (USSS) of joint in RA has been shown to be reliable and sensitive to change when used in clinical trial setting. However it is unclear whether this reliability is also achieved in clinical daily practice among Rheumatologists performing US in a non-research setting and using different machines.
Objectives: To assess agreement between non-research sonographers in scoring synovitis using the OMERACT USSS and using the scoring of an OMERACT expert as gold standard. To assess the reliability of the USSS by using different US machines.
Methods: First an OMERACT US expert presented the scoring method and supervised a training session. The wrist, MCP 2 and 3 joints of the left hand (dorsal aspect) of 3 RA patients were then successively evaluated by 9 Rheumatologists with 3 different US machines: Hitachi Arietta = H, GE Logic E9 = G, Esaote MyLab 7= E. The USSS included B-mode acquisition of synovial hypertrophy (SH), joint effusion (JE) and bone erosion (BE), and Power-Doppler (PD) activity. JE, SH and BE were scored binary; SH and PD were score semi quantitatively (0 to 3), by both the 9 participating Rheumatologists and the OMERACT US expert. The agreement between each participant with the scoring of the OMERACT US expert was quantified by proportions. The inter-US machine reproducibility was assessed by kappa statistics for discrete variables and weighted kappa's for ordinate.
Results: The 3 joints of 3 patients each were evaluated on the 4 US items (SH, JF, BE, PD) on a different US machine. So 27 values were obtained for each joint within each item. The percentages of exact agreement (PEA) between these 27 values and the scores of the OMERACT US expert were calculated and ranged between 33% (9/27) for SH-MCP3, 37% for JF-MCP2 and PD-Wrist, 41% for SH-wrist, 48% BE-MCP3, 52% PD-MCP3, 56% PD-MCP3, 59 JF-wrist and BE-MCP2, 63% JF-MCP3, 67% SH-MCP2 and 78% (21/27) for BE-wrist. For the inter-US machines reproducibility, kappa between the 3 machines was calculated on 9 data (3 patients x 3 joints). The reliability was low for detecting JE $\leq$0.211. Acceptable reliability among machines was found for SH, BE and PD (table 1).

Table 1

		H/G	H/E	E/G
Kappa values	JF	0,211	0,143	0,211
	SH	0,529	0,602	0,584
	PD	0,455	0,709	0,434
	BE	0,628	0,615	0,550
Corresponding P-values	JF	0,357	0,588	0,357
	SH	<0,001	<0,001	<0,001
	PD	0,001	<0,001	<0,001
	BE	0,002	0,003	0,004

Conclusions: Non OMERACT-expert Rheumatologists can apply the USSS, and this score works well across different machines. The difference among machines and sonographers is mostly captured by the low reliability of JE. The OMERACT USSS could be used by sonographers in their everyday clinical practice to evaluate the activity of RA patients. Further studies in clinical-based settings will allow to define more precisely the applicability of this scoring system.

FRI0651 OBSERVATIONAL REPRODUCIBILITY STUDY OF UCO-TRACK©, AN AUTOMATIZED MEASUREMENT OF MOBILITY, IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

J. Garrido[1], E. Collantes[2], J. Mulero[3], B. Flores[3], P. Zarco[4], R. Mazzucchelli[4], M. Domínguez-González[4], L. Carmona[5], L. Cea-Calvo[6], M. Arteaga[6], R. Curbelo[5]. *[1]I. Mamónides; [2]H Reina Sofía, Córdoba; [3]H Puerta de Hierro; [4]H Fundación Alcorcón; [5]I. Salud Muscular; [6]Medical Affairs, Merck Sharp & Dohme, Madrid, Spain*

Background: The classical measures of spinal mobility for the assessment of patients with axial spondyloarthritis (SpA), such as BASMI, are subject to inter-observer variability.
Objectives: We assessed the reproducibility of the UCOASMI index (University of Córdoba Ankylosing Spondylitis Metrology Index), a composite index of cervical and spinal mobility obtained with the UCOTrack© motion analysis system (an innovative 3D motion capture system based on video-images) [1], in patients with axial SpA.
Methods: An observational study of repeated measures was carried out in 3 Spanish centers with the technology available (H. Reina Sofía, Córdoba, H. Puerta de Hierro, Madrid and H. Fundación Alcorcón, Madrid). For the assessment of intra-observer reliability, 30 patients (10 per center) were evaluated twice, 3–5 days apart. For the inter-observer reliability, 9 patients were evaluated in the 3 centers by 3 observers (window 3–7 days). The Intraclass Correlation Coefficients (ICC) for UCOASMI and classical metrology measurements were calculated.
Results: We included 30 patients (73% men, mean age 52 [SD 9], mean BASDAI 3.3 [SD 2]). The table shows the intra- and inter-observer reliability values. The reproducibility of UCOASMI was very high, with inter-observer ICC 0.99, and intra-observer ICC 0.97, 0.97 and 0.99, higher than most conventional measurements. The Schober test and cervical rotation showed lower reproducibility (inter-observer ICC between 0.58 and 0.68) and variable intra-observer ICC.
Conclusions: The reproducibility of the UCOASMI, obtained through the UCOTrack© motion analysis system in the 3 centers, was very high, in contrast to the lower reproducibility of the Schobert test and other measures of classical metrology. The reliability of this system opens the door to using this technology to monitor SpA patients and in future research studies.

FRI0652 MEDIAN NERVE ULTRASOUND FINDINGS AND CLINICAL CORRELATIONS IN PATIENTS WITH SYSTEMIC SCLEROSIS: A COMPARATIVE ANALYSIS WITH MATCHED CONTROL SUBJECTS

J. Sousa-Neves[1], M. Cerqueira[1], D. Santos-Faria[1], J. Leite Silva[1], A. Raposo[2], C. Afonso[1], F. Teixeira[1]. *[1]Rheumatology, Hospital Conde de Bertiandos, ULSAM, Ponte de Lima; [2]Rheumatology, Centro Hospitalar Trás-os-Montes e Alto Douro, Vila Real, Portugal*

Background: Median nerve (MN) entrapment in the carpal tunnel seems to be common in patients with Systemic Sclerosis (SSc). Ultrasound (US) evaluation of MN in SSc patients was performed in some previous studies but conclusions were not linear (1).
Objectives: To compare specific MN US parameters of patients with SSc and a group of age and sex matched controls. To understand if specific clinical variables correlate with US parameters assessed in the group of SSc patients.

Abstract FRI0651 – Table 1

	Inter-observer reliability	Intra-observer reliability		
	ICC (95% CI)	Observer 1 ICC (95% CI)	Observer 2 ICC (95% CI)	Observer 3 ICC (95% CI)
UCOASMI	0.99 (0.98–1.00)	0.99 (0.98–1.00)	0.97 (0.94–1.00)	0.97 (0.93–1.00)
Conventional Metrology				
BASMI	0.50 (0.11–0.89)	0.78 (0.54–1.00)	0.61 (0.21–1.00)	0.99 (0.97–1.00)
Right lateral flexion	0.83 (0.64–1.00)	0.94 (0.87–1.00)	0.91 (0.80–1.00)	0.96 (0.91–1.00)
Left lateral flexion	0.88 (0.75–1.00)	0.96 (0.92–1.00)	0.93 (0.85–1.00)	0.97 (0.94–1.00)
Right tragus-wall distance	0.97 (0.95–1.00)	0.96 (0.91–1.00)	0.91 (0.81–1.00)	0.99 (0.98–1.00)
Left tragus-wall distance	0.97 (0.95–1.00)	0.96 (0.91–1.00)	0.90 (0.78–1.00)	0.98 (0.97–1.00)
Schöber test	0.68 (0.39–0.97)	0.64 (0.27–1.00)	0.98 (0.97–1.00)	0.95 (0.89–1.00)
Intermaleolar distance	0.87 (0.73–1.00)	0.93 (0.85–1.00)	0.82 (0.61–1.00)	0.98 (0.97–1.00)
Right cervical rotation	0.65 (0.33–0.96)	0.82 (0.61–1.00)	0.94 (0.87–1.00)	0.98 (0.97–1.00)
Left cervical rotation	0.58 (0.22–0.94)	0.91 (0.81–1.00)	0.75 (0.47–1.00)	0.98 (0.97–1.00)

Methods: We conducted a cross-sectional study comparing MN US parameters of SSc patients followed up at our Rheumatology Unit and control subjects. Exclusion criteria included body mass index (BMI)>30, previous wrist trauma and known diagnosis of carpal tunnel syndrome. Forty-eight out of 62 SSc patients and 45 healthy age and sex matched controls were enrolled. Subjects were consecutively evaluated in our Department. A General Electric LOGIQ S8 US with a 15 MHz linear transducer was used for assessment. MN cross-sectional area (MNA) and perimeter (MNP) of both sides of each person were measured at the level of the carpal tunnel inlet. For comparative analysis, the mean MNA and MNP of combined right and left side were used. Patients' relevant clinical and demographic data were collected. Modified Rodnan skin score (mRSS), hand mobility (HAMIS) and SSc Severity Scale (SScSS) were also assessed. Statistical analysis included Chi-Square test, Mann-Whitney U-test, Kruskal-Wallis and Spearman correlation coefficient. P value <0.05 was defined as statistically significant.

Results: A total of 186 MN were assessed by US. Both groups had the same proportion of diabetes and history of tunnel carpal surgery (p=0.803 and p=0.339, respectively). Median of MNA and MNP were significantly higher in SSc patients (7.5 mm^2 [6.6 to 9.5] and 13.8 mm [12.4 to 15], respectively) (median [interquartile range]) compared with controls (7.0 mm^2 [6 to 8] and 12.9 mm [11.7 to 14], respectively) (p=0.021 and p=0.018, respectively). Higher mRSS correlated with higher MNA (Spearman's rho=0.335, p=0.02) and MNP (rho=0.336, p=0.02). Values of MNA and MNP did not correlate with age, disease duration, HAMIS and SScSS, and were similar according to categories of gender and subset of disease (p>0.05). However, median of MNA and MNP were significantly different between the 3 phases of skin involvement (p=0.007 and p=0.009, respectively), being higher in patients in the oedematous phase (median MNA of 9.25 mm^2 [7.5 to 11.5] and median MNP of 14.5 mm [13.5 to 16.9]).

Conclusions: Our study confirmed an increased MNA and MNP in SSc patients in comparison with healthy age and sex matched controls. Patients in the oedematous phase of skin involvement and patients with higher skin thickness assessed by mRSS showed higher MNA and MNP values.

FRI0653 SALIVARY GLAND ULTRASOUND IS RELATED TO AUTOIMMUNITY IN PRIMARY SJÖGREN SYNDROME

J.C. Nieto-González[1], F.J. López-Longo[1], E. Estrada[2], E. Naredo[3].
[1]Rheumatology, Hospital G.U. Gregorio Marañón; [2]Psychology, Universidad Camilo José Cela; [3]Rheumatology, Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain

Background: Primary Sjögren syndrome (pSS) is a systemic autoimmune disease involving exocrine glands, mainly ocular and salivary glands. Salivary gland ultrasound (SGU), of submandibular and parotid glands, in pSS is characterized by hypo/anechoic rounded areas within gland parenchyma, losing the normal homogeneity of the glands (typical SGU)[1]. SGU is a reliable imaging technique for assessing gland echostructure in pSS[2].

Objectives: The aim of our study is to evaluate the relation between typical SGU and clinical and laboratory data in pSS

Methods: We performed SGU to 100 patients with pSS from our rheumatology department selected randomly from a database. We used a semiquantitative score from 0 to 3. Grades 0 and 1 were considered as normal and grades 2 and 3 were considered as typical for pSS. We retrospectively collected demographics (age, gender, disease duration), clinical (extra-glandular manifestations, parotid swelling and lymphoma) and laboratory data (ESR, CRP, rheumatoid factor (RF), antinuclear antibodies (AAN), anti-SSA and anti-SSB antibodies). We divided the patients into 3 groups depending on their autoimmunity profile. Complete seropositive group were patients with RF, AAN and antiSSA or antiSSB positives simultaneously or sequentially. Simple seropositive group were patients with any positive autoantibody (RF/AAN/antiSSA or antiSSB) but not all of them together. Finally, patients without positive autoantibodies were included in the seronegative group

Results: We excluded 7 patients because they were diagnosed with secondary SS. From 93 pSS patients analyzed, 32 (frequency 34.5%) had a typical SGU. Demographics, extra-glandular manifestations and lymphomas were similar between patients with typical SGU and patients with normal SGU. Parotid swelling and longer disease duration were associated with a typical SGU (p<0.05). Patients with positive autoantibodies (AAN, RF, antiSSA and antiSSB) had more frequently a typical SGU. Complete seropositive group had the highest frequency of typical SGU, followed by simple seropositive group. All seronegative patients had a normal SGU. SGU relation with autoimmunity is shown in table 1

	Total	Typical SGU	Normal SGU	*p*
n (%)	*n*=93	*n*=32	*n*=61	
Complete seropositive group	36 (38.7)	25 (78.1)	11 (18.0)	**<0.001**
Simple seropositive group	44 (47.3)	7 (21.9)	37 (60.7)	**<0.001**
Seronegative group	13 (14)	0	13 (21.3)	**<0.001**
AAN + (n:90)	70 (76.9)	31 (96.9)	39 (66.1)	**0.001**
RF + (n:92)	55 (59.1)	28 (87.5)	27 (44.3)	**<0.001**
Anti-Ro + (n:86)	46 (52.9)	27 (84.4)	19 (34.5)	**<0.001**
Anti-La + (n:86)	28 (33.3)	19 (63.3)	9 (16.7)	**<0.001**

Conclusions: Longer disease duration and parotid swelling were associated with typical SGU. Typical SGU was associated with positive autoimmunity, moreover all seronegative patients had a normal SGU

FRI0654 ULTRASOUND DETECTED PATHOLOGY IN THE ENTHESIS OF THE LOWER LIMB IN AN AGE STRATIFIED COHORT OF ASYMPTOMATIC SUBJECTS -A PROSPECTIVELY DESIGNED DESCRIPTIVE CROSS-SECTIONAL STUDY

J. Guldberg-Møller[1], S.M. Nielsen[1], M.J. Koenig[2], S. Torp-Pedersen[3], L. Terslev[4], A. Torp-Pedersen[1], R. Christensen[1], H. Bliddal[1], K. Ellegaard[1].
[1]The Parker Institute, Frederiksberg; [2]Department of radiology, Herlevand Gentofte Hospital, Gentofte; [3]Department of radiology, Righhospitalet; [4]Rigshospitalet, Glostrup, Denmark

Background: Ultrasound (US) examination of the entheses is increasingly used to document pathological changes in e.g. psoriasis arthritis and spondyloarthritis. Grey-scale (GS) US is used to assess morphological changes and Doppler US to assess increased blood flow.

The OMERACT expert group has agreed on the following elementary components when assessing the entheses on US examination; hypoechogenicity, increased thickness, enthesophytes/ calcifications, erosions, and Doppler activity (1).

Little is known about US assessment of the entheses in asymptomatic persons, thus the frequency and distribution of the above components between genders and age groups is uncertain.

Objectives: To investigate the frequency of enthesitis components in the entheses of the lower limb in a group of healthy subjects.

Methods: We recruited 64 subjects (32 women and 32 men), eight women and eight men in four decades, from 20 to 59 years. None of the subjects had previous or present signs of tendon or joint disease in the lower extremities. None of the participants took any kind of medication.

All subjects were examined by a rheumatologist and blood samples were collected to rule out any clinical signs of tendon or joint disease e.g. swollen and tender

	Age 20-29 (n=8/8)		Age 30-39 (n=8/8)		Age 40-49 (n =8/8)		Age 50-59 (n =8/8)		Total (n=64)

F, female; M, male. All empty fields have the value 0.

entheses or increased inflammatory markers in the blood. The dominant leg was examined with US using a Logiq 9 (GE Medical, Milwaukee, WI, USA) with a ML 6–15 MHz transducer and a fixed pre-set with Doppler settings optimised for inflammatory flow. Both GS and Doppler examination were made.
The entheses were examined for hypoechogenicity, increased thickness, enthesophytes/ calcifications, erosions, and Doppler activity.
Results: No subjects had clinical signs of tendon or joint disease. Seven displayed various degrees of hypermobility and seven had various degrees of flatfoot; some in combination. None of the blood tests indicated any pathology.
On US erosions were only seen in one Achilles insertion (not shown in table). The Doppler activity was not measured in plantar fascia due to attenuation of the heel fad pad. All other US pathology present is seen in the table below.
Conclusions: Only minor pathological findings in the entheses of the lower limb were present in an age stratified cohort of healthy persons. The changes most frequently seen were bony changes in the insertion of the quadriceps and Achilles tendons. A weak tendency toward more pathological findings was seen in this cohort among men, compared to women, and additionally, with increasing age.
The findings suggest that US can be used to diagnose/examine subjects for pathological changes of the entheses although with caution regarding enthesophytes of the quadriceps and Achilles tendon.

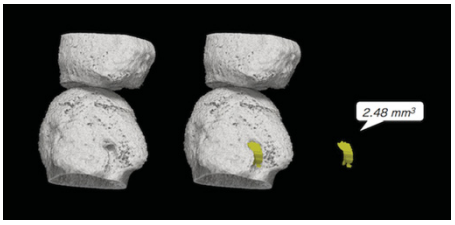
FRI0655 ULTRASOUND FINDINGS OF FEEDING VESSELS AND BONE SURFACE IRREGULARITY IN WRIST JOINTS OF HEALTHY CONTROLS

K. Misaki[1], K. Ikeda[2], K. Inoue[1]. *[1]Rheumatology, Kita-Harima Medical Center, Ono; [2]Chiba University, Chiba, Japan*

Background: Musculoskeletal ultrasound (MSKUS) is capable of visualizing synovitis and bone damage such as erosion. In particular, synovial vascularity as measured by power Doppler (PD) is correlated to rheumatoid arthritis disease activity, and PD signal reveals the prevalence of subclinical synovitis overlooked on physical examination. It is frequently difficult to distinguish bone erosion from normal concave surface of the bone. It is necessary for us to know these normal structures well in evaluating disease activity by using MSKUS. Here we examine the normal feeding vessels and bone surface irregularity in wrist joints.
Objectives: To clarify the distribution of feeding vessels in wrist joints and lunate surface irregularity of healthy controls by using MSKUS
Methods: The dorsal side of the bilateral wrists was scanned in 2 perpendicular planes with 2D-probe in healthy volunteers. The distribution and bilaterality of feeding vessels in the capsule and the extensor tendon sheath of wrist joint, and the evaluation of bone surface irregularity at lunate were validated.
Results: The distribution and bilaterality (Blt) of feeding vessels in healthy volunteers (n=30) were as follows:
Above-trapezoid (Rt:100.0%, Lt:100.0%, Blt:100.0%), intra-extensor digitorum tendon sheath (Rt:86.7%, Lt:66.7%, Blt:43.3%), intra-extensor digiti minimi tendon sheath (Rt:30.0%, Lt:30.0%, Blt:10.0%), above-capitate (Rt:23.3%, Lt:30.0%, Blt:10.0%), above-triangular fibrocartilage complex (Rt:16.7%, Lt:30.0%, Blt:6.7%), distal radial side of the radio-carpal joint (Rt:20.0%, Lt:23.3%, Blt:0.0%), distal end of the ulna (Rt:10.0%, Lt:16.7%, Blt:0.0%), dorsal side of the lunate (Rt:6.7%, Lt:0.0%, Blt:0.0%), palmar side of the extensor digitorum tendon sheath (Rt:0.0%, Lt:3.3%, Blt:0.0%). Feeding vessels from vascular channels were depicted at lunate (Rt:53.3%, Lt:46.7%, Blt:43.3%), the distal side of the radius (Rt:20.0%, Lt:16.7%, Blt:3.3%), triquetrum (Rt:10.0%, Lt:16.7%, Blt:0.0%) and capitate (Rt:6.7%, Lt:10.0%, Blt:0.0%). The frequency of the bone surface irregularity at lunate in healthy volunteers (n=47) and the transverse diameter (TD) (Mean±S.D.) of those were Rt longitudinal plane:57.4% (TD1.26±0.33mm), Rt transverse plane: 51.1% (TD1.20±0.31mm), Lt longitudinal plane: 68.1% (TD1.06±0.28mm), and Lt transverse plane: 42.6% (TD1.29±0.31mm). Bilateral evaluation of those was 53.2%.



Conclusions: MSKUS evaluation in wrist joints revealed various normal vessels and bone surface irregularity of lunate. It is necessary to distinguish a normal pattern from a pathological pattern in MSKUS examination.

FRI0656 SEMIAUTOMATIC ANALYSIS OF EROSION VOLUME BY HR-PQCT IN PATIENTS WITH RHEUMATOID ARTHRITIS

K. Chiba[1], N. Iwamoto[2], M. Osaki[1], A. Kawakami[2]. *[1]Department of Orthopedic Surgery; [2]Department of Rheumatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan*

Background: HR-pQCT is a high resolution CT dedicated to human extremities. It has been used mainly for osteoporosis, while in more recent years it has been applied to research in rheumatoid arthritis (RA).
Objectives: The purpose of this study is to develop a method to quantify the volume of erosions in RA patients semiautomatically using second generation HR-pQCT.
Methods: Twenty patients with RA (70±8 years, 15 female, 5 male) participated in this study. The second and third MCP joints were scanned using HR-pQCT (XtremeCT II, Scanco Medical, Switzerland) at the voxel size of 61μm.
The erosion volume was measured semiautomatically using the dedicated software (TRI/3D-BON, Ratoc System Engineering, Tokyo).
All concave regions on the bone surface around the MCP joints were extracted automatically by subtracting the bone region from the smoothed bone model. Erosions were selected manually by a medical doctor based on certain criteria. The volume of the erosions were measured by voxel counting.
Results: In a total of 37 joints (3 joints were excluded due to severe deformities), 40 erosions were detected by HR-pQCT (phalanx side: 9 erosions, metacarpal side: 31 erosions). The average volume of the erosions was 1.84mm^3, minimum 0.08mm^3, and maximum 16.3mm^3.

Conclusions: The semiautomatic method to quantify the volume of erosions at MCP joints in RA patients by HR-pQCT was developed.
The opinion as to whether concave regions are pathological erosion or physiological concave, vascular channel or recess of osteophyte is occasionally difficult and should be performed by an experienced tester.

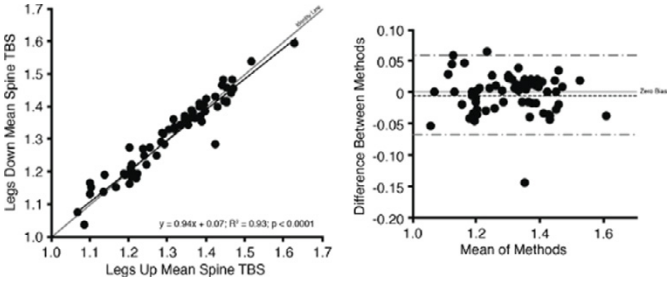
FRI0657 COMPARATIVE STUDY OF PAROTID ULTRASONOGRAPHY AND PAROTID GLAND ECT IN PREDICTING THE PATHOLOGICAL BIOPSY OF THE SALIVARY GLAND IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

C. Xiaomei, L. Cong, W. Lijun, L. Cainan, S. Yamei. *Department of Rheumatology and Immunology, People's Hospital of Xinjiang Uyghur Autonomous Region, urumqi, China*



Objectives: To investigate the value of Parotid Ultrasonography and parotid gland radionuclide imaging in predicting salivary gland biopsy of primary Sjögren's syndrome (pSS).
Methods: Sixty - five patients with primary Sjogren 's syndrome and 38 patients with non - Sjogren' s syndrome were enrolled in the Department of Rheumatology and Immunology, Xinjiang Uygur Autonomous Region People 's Hospital from October, 2015 to June, 2016. All patients were accpted the check of Parotid Ultrasonography, Parotid Gland ECT and labial gland biopsy. The data were analyzed statistically.
Results: The sensitivity and specificity of Parotid Ultrasonography in pSS were 65% and 76%, respectively. The area under the ROC curve was 0.936±0.024 for the diagnosis of pSS. The positive predictive rate of parotid gland ultrasonography was 84.0% and the negative predictive rate was 94.4%. Parotid scintigraphy in pSS in the sensitivity of 80.0%, specificity of 69.1%. The positive predictive rate of parotid gland radionuclide imaging for labial gland biopsy was 78.9% and the negative predictive rate was 87.5%. The diagnostic value of Parotid

Ultrasonography in pSS group is superior to that of parotid gland radionuclide imaging, which can effectively reduce the complication of invasive operation.
Conclusions: The diagnosis of pSS by parotid gland ultrasonography is superior to that of parotid gland radionuclide examination. For patients with atypical clinical manifestations who are negative for anti-SSA and/or anti-SSB antibodies, there is no need for a labial biopsy of the labial glands to reduce the number of complications associated with unwanted invasive procedures.

FRI0658 LEG ELEVATION DOES NOT SUBSTANTIALLY AFFECT TBS RESULTS

D. Krueger[1], E. Siglinsky[1], D. Tran[2], L. Del Rio[3], N. Binkley[1]. *[1]Osteoporosis Clinical Research Program, University of Wisconsin, Madison, United States; [2]R&D, Medimaps, Merignac, France; [3]CETIR Grupo Médico, Barcelona, Spain*

Background: Lumbar spine dual energy X-ray absorptiometry (DXA) scans are typically acquired with the patient's legs elevated on a positioning block thereby flattening the normal lumbar lordosis. With GE densitometers it is also possible to acquire lumbar spine scans with the legs down. BMD values obtained with legs down vs. legs elevated does minimally differ, however it is unknown if leg elevation affects trabecular bone score (TBS) results.
Objectives: The purpose of this study is to assess the effect of leg position on TBS.
Methods: Lumbar spine (L1-L4) DXA scans were acquired in legs up and legs down positioning using GE Healthcare Prodigy and iDXA densitometers. The "OneScan" feature mode was not used. These scans were analyzed with enCORE software v 12.3 or 14.1. All scans were re-processed using Medimaps TBS Calculator v2.3 or TBS iNsight v3.0.2 to obtain TBS results. Linear regression and Bland-Altman analyses were performed to compare TBS results in the legs up vs. legs down position.
Results: Sixty-four women, mean age and BMI 65.1 years (range 28.2–86.6) and 26.4 kg/m^2 (range 18.1–34.8) were studied on three Prodigy densitometers. Fifty women, mean age and BMI 68.6 years (range 15.2–92.5) and 26.2 kg/m^2 (range 19.9–35.1) were studied on a iDXA densitometer. With Prodigy and standard legs up positioning, the L1-L4 BMD ranged from 0.738–1.549 g/cm^2 and was highly correlated with legs down positioning, R^2 =0.99. TBS results ranged from 1.072–1.632 and were also highly correlated, R^2 =0.93 with a mean bias of -0.005 TBS units between leg positions (Figure). With iDXA and standard legs up positioning, the L1-L4 BMD ranged from 0.753–1.622 g/cm^2 and was highly correlated with legs down positioning, R^2 =0.97. TBS results ranged from 1.040–1.455 and were also highly correlated, R^2 =0.90 with a mean bias of 0.00 TBS units between leg positions (data not shown).

Conclusions: Leg positioning minimally affects TBS results with GE Healthcare Prodigy and iDXA densitometers but the difference from legs up to legs down is likely of no clinical significance.

FRI0659 INCLUSION OF THE ASSESSMENT OF CERVICAL FACET JOINTS IN THE M-SASSS SCORE IN PATIENTS WITH ANKYLOSING SPONDYLITIS. IMPROVING SENSITIVITY TO CHANGE

M.J. Moreno-Martínez[1], M.J. Moreno-Ramos[2], L.F. Linares-Ferrando[3]. *[1]Rheumatology, H. Rafael Mendez; [2]H. Virgen de la Arrixaca, MURCIA, Spain; [3]Rheumatology, H. Virgen de la Arrixaca, MURCIA, Spain*

Background: Ankylosing Spondylitis is characterized by axial involvement, especially of sacroiliacs and the vertebral bodies, although we also know that other such as facet joints (Fj) are affected. These joints can be seen with a simple x-ray, especially in the cervical spine. Despite their involvement, the different rates of radiographic progression do not assess their alteration.
Objectives: To evaluate the sensitivity to the change of the m-SASSS radiographic score by including the assessment of the cervical Fj.
Methods: The patients come from a Spondyloarthritis Unit (Hospital U. Virgen de la Arrixaca de Murcia, Spain). All patients are diagnosed of Ankylosing Spondylitis (New York Modified Criteria)
The usual radiographic study was performed to calculate the m-SASSS and a lateral cervical radiograph at two different times to calculate the difference between the scores. The score used for Fj (only one score is given for each intervertebral segment) is:
– 0: normal.
– 1: pinching (narrowing of joint space).
– 2: sclerosis in the joint margins.
– 3: joint fusion.
We will analyze the mean of the two m-SASSS radiographic score, with (m-SASSS + Fj) and without the inclusion of the Fj, and the difference between those means. We will also analyze the correlation with the rest of the radiographic scores and with the clinical patient's parameters.
Results: We included 47 patients (81% male and 19% female) with a mean age of 48 (± 8) years and a mean duration of symptoms of 18 (± 8.5) years. The mean time between the two radiographic studies was 3 (± 1.5) years.
In the following table we show the difference of means of the radiographic scores over time:

	First mean (standard deviation)	Last mean (standard deviation)	Significance (p)
Radiographic evaluation of FJ	6±5,2	8,8±6,8	0,0001
m-SASSS	9,3±11,6	10,1±11,7	0,1
m-SASSS+Fj	15,4±13,4	19,3±13,5	0,0001

After comparing Δ mSASSS with Δ mSASSS+Fj, we found significant differences in favor of inclusion: 2.6 (± 2) vs 4.9 (± 4.7), p=0.04.
Conclusions: The inclusion of the evaluation of cervical Fj improves sensitivity to change of m-SASSS.

FRI0660 IMPACT OF ULTRASOUND IN TREATMENT DECISION OF RHEUMATOID ARTHRITIS

M. Gutierrez[1], C. Pineda[1], R. Espinosa[2], C. Hernandez[1], L. Ventura[1], C. Lozada[1], L.H. Silveira[3], G. Rodriguez[2], E. Cruz[2], A. Vargas[3], C. Bertolazzi[2], A.C. Lozada[1]. *[1]Division of Musculoskeletal and Rheumatic Disorders; [2]Instituto Nacional de Rehabilitacion; [3]Instituto Nacional de Cardiologia, Mexico City, Mexico*

Background: Ultrasound (US) is an important tool to support the clinician in the diagnosis and treatment monitoring of rheumatoid arthritis (RA). The EULAR recommended it for the follow up of RA patients. In spite of the evidence supporting the value of US, the real impact in treatment decisions is not clearly defined.
Objectives: To investigate the impact of US findings in the treatment decisions of rheumatologists in patients with RA in a real-life setting. Additionally, to verify the US findings that play a role in change of treatment, types of changes and their distribution.
Methods: RA patients were included. As a first step, the rheumatologist performed a clinical examination (including DAS28) and recorded the treatment approach suggested according his clinical evaluation (i.e. starting, changing or stopping pharmacological medication as well as local injection). In the same day, after the clinical assessment, the patients were sent for an US examination using the 7-joint score, which was performed by an independent rheumatologist sonographer who reported the US findings to the same rheumatologist that previously evaluated clinically the patient. This last decided, according to the US findings to maintain or change the previous suggested therapy. Additionally, the clinical rheumatologist reported the reasons which induced to change or not the treatment after the US examination
Results: A total of 128 RA patients were included [female 117 (91.4%), male 11 (8.59%)], with mean ± SD disease duration of 9.88±8.22 years. Ninety-four patients (73.4%) had active disease according the DAS 28, whereas 34 (26.5%) were considered in remission.
US findings influenced a change in the treatment in 56 cases (43.7%) (47 with clinical active disease and 9 in remission). Among the main reasons that induced a change in the treatment based on the US examinations were: grade of synovitis (25%), higher number of synovitis than clinical examination (16.6%) and presence of power Doppler (PD) (16.7%). The most frequent treatment changes were increasing dose or start a new combination of DMARDs [39 patients (69.5%)]. The multiple logistic regression analysis showed that synovitis of 2nd metacarpophalangeal joint (MCPj) was the US finding with more influence in the decision to change treatment (p=0.016).

With respect to distribution, 122 patients (95.3%) had al least one joint with US synovitis and 76 patients (59.3%) had at least one joint with PD. The wrist, 2nd MCPj and 2nd metatarsophalangeal joint (MTPj) were the most affected in terms of synovitis whereas the 5th MTPj showed more erosions (37.7%) and the extensor fingers tendons showed more tenosynovitis (23.02%).
Conclusions: US demonstrated to play an important role in the treatment decision of RA patients. The impact was more frequent in patients with active disease but also affected the decision in patients considered in clinical remission.

FRI0661 CAPILLAROSCOPY IN PATIENTS WITH SILICA EXPOSURE. A CASE CONTROL STUDY

M. Freire[1], A. Perez-Gonzalez[1], V. Arnalich[2], D. Boveda-Ruiz[1], A. Salgado[3], J.J. Blanco-Perez[2]. *[1]Unidad de Enfermedades Autoinmunes Sistémicas y Trombosis; [2]Servicio de Neumología, Complejo Hospitalario Universitario de Vigo; [3]Unidad de apoyo a la investigación, Instituto de Investigación Biomedica de Ourense-Pontevedra-Vigo, Vigo, Spain*

Background: Exposure to silica dust has been associated with different autoimmune diseases and immunological abnormalities in which microvascular involvement is very common, as systemic sclerosis, systemic lupus erythematosus, rheumatoid arthritis or dermatomyositis.
Objectives: To show capillaroscopic findings in patients exposed and not exposed to silica and to analyze the differences between both groups.
Methods: A case control design was made. Cases (Si+) were subjects exposed to silica (with and without silicosis). Controls (Si-) were healthy subjects not exposed to silica. Capillaroscopy was made with both Zuzi® Optical stereo microscope with Optikam® camera adapted and with USB Digital Microscope Video epiluminiscence Dino-Lite ® in each patient. The capillaroscopic alterations were evaluated according to a semiquantitative method. Background data on CVRF and variables related to capillaroscopy were collected. A comparative study was done.
Results: Capillaroscopy was performed on 61 Si+ and 12 Si- subjects. Mean age of Si+ was 52.6 years (SD: 7.3) and 54 years (SD: 6.6) in Si-. There were no significant differences in CVRF: hypertension (13.1% Si+ and 8.3% Si-), diabetes mellitus (3.3% Si+ and 8.3% Si-) and tobacco exposure (18.0% Si+ and 25.0% Si-). It was observed capillary dilation in 24 (33.9%) Si+ and only in 3 (25.0%) Si-. The dilation score was mild in all Si- while in Si+ was mild in 41.7%, moderate in 37.5% and extreme in 12.5%. 42.7% of Si + had a degree of tortuosity higher than 33% (score 2) whereas in all Si- the degree of tortuosity was <33% (score 1). Capillaroscopic general pattern showed differences between both groups: it was normal in 24 (42.1%) Si+ and 9 (75%) Si-; slightly irregular in 30 (52.6%) Si+ and 3 (25%) Si- and unstructured in 3 Si+ (5.3%) and in none Si-.
Conclusions: The current study shows significant differences between the capillaroscopy of subjects exposed and not exposed to silica, with a trend in more frequency and severity of capillary dilatation, greater frequency of tortuosity in a severe degree and more frequent irregular capillaroscopic pattern in the exposed patients.

FRI0662 ASSESSMENT OF BONE DENSITY, STRUCTURE, AND CORTICAL INTERRUPTIONS OF FINGER JOINTS IN PATIENTS WITH RHEUMATOID ARTHRITIS USING HIGH-RESOLUTION PERIPHERAL QUANTITATIVE CT

M. Peters[1], A. Scharmga[1], A. van Tubergen[1], D. Loeffen[1], R. Weijers[1], B. van Rietbergen[1,2], P. Geusens[1], J. van den Bergh[1]. *[1]MUMC, Maastricht; [2]TU/e, Eindhoven, Netherlands*

Background: Rheumatoid arthritis (RA) is characterized by peri-articular bone loss. In patients with RA, lower bone density and structural integrity, and an increased number of erosions compared to healthy controls (HCs) has been demonstrated using High-Resolution peripheral Quantitative CT (HR-pQCT) (1,2). To further characterize RA-related changes, we recently introduced a method for quantifying small cortical interruptions in finger joints (3).
Objectives: To investigate the cortical and trabecular bone density, structure, and cortical interruptions in MCP joints in early and late RA patients compared to HCs using HR-pQCT imaging.
Methods: The 2nd and 3rd MCP joint of 70 subjects (mean age 53.1 (SD 9.2) years) were evaluated by HR-pQCT (82μm isotropic voxel size): 38 HCs, 10 early RA (diagnosis ≤2 years ago) and 22 late RA (diagnosis ≥10 years ago). Images were analyzed for cortical interruptions, and for cortical and trabecular bone density and structure. Descriptives were analyzed per joint by one-way ANOVA with Bonferroni post-hoc testing or Kruskal-Wallis with Mann-Whitney post-hoc testing, as appropriate.
Results: Significant differences with respect to all parameters were found across the groups (Table 1). In early and late RA, the percentage of joints with at least 1 interruption was higher, and number of trabeculae, cortical thickness, total density and cortical density were lower than in HC. In addition, in late RA, number of interruptions, interruption volume and trabecular separation were higher, and trabecular density was lower than in HC. Bone loss at the cortical and trabecular bone was primarily observed at the rim of the joint (Figure 1, arrows).

Table 1. Comparison of cortical interruptions, and bone density and structure parameters across early RA patients, late RA patients and HCs

	HC	Early RA	Late RA	p-value
Cortical interruption parameters	n=82	n=39	n=73	
Percentage of joints ≥1 interruption, %	69.5	89.7 *	82.2	0.025
Number of interruptions	1.50 (1.49)	2.64 (2.95)	5.22* (6.32)	<0.001
Interruption volume, mm^3	1.49 (5.16)	2.05 (6.76)	39.31* (78.51)	<0.001
Bone density parameters	n=50	n=31	n=68	
Total vBMD, mg HA/cm^3	327.3 (35.3)	295.8* (38.9)	286.4* (65.1)	<0.001
Trabecular vBMD, mg HA/cm^3	202.1 (20.6)	185.0 (21.6)	177.3* (42.0)	<0.001
Cortical vBMD, mg HA/cm^3	685.8 (42.8)	643.7* (58.2)	634.0* (73.3)	<0.001
Bone structure parameters	n=50	n=31	n=68	
Trabecular number, mm^1	1.68 (0.31)	1.45* (0.29)	1.52* (0.37)	0.004
Trabecular thickness, μm	102.3 (15.3)	109.1 (17.8)	98.6 (14.7)	0.009
Trabecular separation, μm	513.9 (116.9)	608.4 (132.3)	611.4* (220.6)	0.007
Distribution of trabecular separation, μm	550.6 (287.0)	728.5 (306.1)	689.4 (368.8)	0.029
Cortical thickness, μm	440.0 (99.2)	363.2* (90.2)	357.5* (132.8)	<0.001

Values are displayed as mean (SD) or otherwise described. *Significantly different from HC, $p<0.05$. [1]p-value obtained across the groups. vBMD, volumetric bone mineral density.

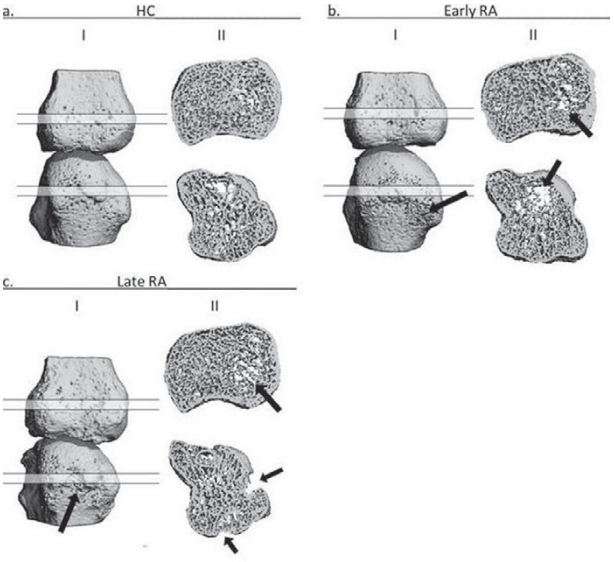

Figure 1. Typical examples of MCP joints; (a) HC, (b) early RA patient, and (c) late RA patient. The total 3D reconstructions are shown (I.) with corresponding 20slices thick axial slices (II). The arrows indicate locations of loss of trabecular and/or cortical structure in the early and late RA patients compared to the HC.

Conclusions: Bone density and structural integrity were impaired in early and late RA patients compared to HCs whereas the number of cortical interruptions is increased. The assessment of such parameters using HR-pQCT is, therefore, a promising tool for the follow-up of bone involvement in MCP joints in patients with RA.

FRI0663 EVALUATION OF A FLUOROENZYME IMMUNOASSAY (ELIA-CTD) IN THE SCREENING OF PATIENTS SUSPECTED FOR AUTOIMMUNE CONNECTIVE TISSUE DISEASES

M. Elkhalifa[1], R. Abdulhadi[1], H. Ramadan[1], S. Barrientos[1], S. Saleh[1], O. Suhial[2], A.W. Al-Allaf[2]. *[1]Laboratory Medicine & Pathology; [2]Medicine, Hamad Medical Corporation, Doha, Qatar*

Background: Detection of auto-antibodies directed against nuclear antigens (antinuclear antibodies or ANA) have important diagnostic and prognostic implications in connective tissue diseases (CTD). The conventional indirect immunofluorescence assay on HEp-2 cell line (ANA-IIF) is the most commonly used method to detect ANA. The ANA-IIF can be labor intensive and suffers from lack of specificity.

Objectives: To evaluate the utility of a new fluoroenzyme Immunoassay "EliA-CTD" as an alternative for screening patients suspected for autoimmune connective tissue diseases.
Methods: Sixteen Hundread (1600) consecutive patients' sera submitted for anti-nuclear antibodies were tested using the ANA-IIF (Diasorin S.P.A, Saluggia, Italy) and the new EliA-CTD screen (Phadia GmbH, Frieiburg, Germany). ANA testing was ordered by both primary and secondary care physicians. The EliA-CTD screening assay is a fluoroenzyme immunoassay which is performed on the Phadia-250 automated platform. The EliA–CTD assay contains ANA-targeted recombinant antigens including dsDNA, Sm-D, Rib-P, PCNA, U1-RNP (70, A, C), SS-A/Ro, SS-B/La, Centromere B, Scl-70, Fibrillarin, RNA Polymerase III, Jo-1, Mi-2, and PM-scl. The test results are expressed as ratio, with >1.0 considered positive. For ANA-IIF, the cut off for positive results was 1:40 or greater. Additionally, further testing for dsDNA and other extractable nuclear antigens (ENA) was undertaken on a subset of sera that were ANA-IIF+ or whenever there was discrepancy between the two methods.
Results: The overall agreement between the two methods was 84.2%. Three hundread and eight (308) out of 1600 (19.3%) samples tested positive by ANA-IIF positive as compared to 101/1600 (6.6%) for the EliA-CTD assay. Additional testing showed that 105 samples were positive for ENA including dsDNA. Of those, 101 were EliA-CTD positive and 81 were ANA-IIF positive. By incorporating the ENA results, the calculated sensitivity and specificity for the EliA-CTD were 97.1% and 99.7% respectively with positive and negative predictive values for the EliA-CTD assay of 96.1% and 99.8%, respectively. The corresponding sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) for the ANA-IIF assay at different dilutions is shown below:

Titer	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
≥1:40	77.7	84.8	26.0	98.2
≥1:80	60.3	95.3	32.4	98.4
≥1:160	57.4	97.4	41.3	98.4
≥1:320	46.5	98.7	48.8	98.5

Conclusions: The new automated EliA-CTD assay shows superior sensitivity and specificity compared to the conventional labor intensive ANA-IIF. The EliA-CTD can be used as an upfront screening tool for connective tissue diseases. Depending on the clinical details, any EliA-CTD positive results could be reflexly followed by additional testing including ANA-IIF testing to elucidate the titer and pattern.

FRI0664 INFLUENCE OF JOINT PATHOLOGY ON OPTICAL SPECTRAL TRANSMISSION IMAGING, ASSESSING INFLAMMATION IN HAND AND WRIST JOINTS OF RHEUMATOID ARTHRITIS PATIENTS

N. Besselink[1], P. van der Meijde[1], A. Marijnissen[1], P. Meijer[2], W. Rensen[2], J. van Laar[1], F. Lafeber[1], J. Jacobs[1]. *[1]Rheumatology and Clinical Immunology, University Medical Centre Utrecht, Utrecht; [2]Hemics BV., Eindhoven, Netherlands*

Background: Rheumatoid arthritis (RA) patients benefit from treat-to-target strategies, aiming for remission or low disease activity[1]. Clinical disease activity measures like the Disease Activity Score (DAS28) have questionable reproducibility and lack sensitivity for low disease activity states; MRI and ultrasound (US) are sensitive, but scanning multiple joints is time-consuming. Optical spectral transmission (OST) is stronger than DAS28 associated with inflammation assessed by both US and MRI[2]. OST measures the blood-specific absorption of light transmitted through tissue, which is reduced in presence of joint inflammation, but also influenced by other joint pathology.
Objectives: Evaluating the influence of joint pathology on the misclassification of joint inflammation, in the hand and wrist joints of RA patients, determined by OST, as compared to US, the reference standard.
Methods: Fifty RA patients with at least one swollen joint, generally with low disease activity were included in this cross-sectional study. Assessments were US, OST, and DAS28, performed according to established guidelines[3] by separate experienced examiners, blinded for other study outcomes. US joint inflammation was defined as a gray-scale score>1 or a power Doppler score>0 (scales 0–3), assessed in MCP, (P)IP, and wrist joints. Using US as reference, diagnostic performance of OST in detecting inflammation at joint level was evaluated using receiver operating characteristic (ROC) analyses; at patient level, DAS28 and OST were correlated to US. Joint pathology potentially influencing misclassification of OST (erosions, osteophytes, tendon (sheet) inflammation, abnormal vasculature, and triangular fibrocartilage complex injuries) were evaluated for significance in a multivariate nominal logistic regression model.
Results: OST performed well at joint level, separately for the MCP (ROC-AUC:0.85), PIP (ROC-AUC:0.79) and wrist (ROC-AUC:0.72) joints and for all joints together (ROC-AUC:0.83). On patient level, DAS28 correlated poorly with US (r=0.29), but OST correlation was good (r=0.72). The presence of joint pathologies per misclassification group is shown in table 1. In the regression model, inflammation in MCP and PIP joints had a higher risk of false negative misclassification in the presence of dorsal bone erosions (OR:3.5, 95% CI:1.7–7.3), volar erosions (OR:5.0, 95% CI:1.8–14.1), flexor tenosynovitis (OR:2.5, 95% CI:1.4–4.5), osteophytes (OR:1.9, 95% CI:1.2–2.8), and extensor tendonitis (OR:3.7, 95% CI:1.6–8.5), and a higher risk of false positive misclassification in the presence of osteophytes (OR:2.3, 95% CI:1.6–3.2).

Table 1: Frequency of joint pathologies, per misclassification group.

Misclassification	Erosions dorsal		Erosions volar		Osteophytes		Flexor tenosynovitis		Extensor tendonitis		Vascular pattern		TFCC	
	Absent	Present	Absent	Present	Absent	Present	Absent	Present	Absent	Present	Absent	Present	Absent	Present
True positives & true negatives	1546 84.4%	34 66.7%	1569 84.2%	12 63.2%	1265 86.6%	315 74.8%	1502 84.3%	79 78.2%	1556 84.3%	25 65.8%	1349 84.6%	231 80.5%	121 65.4%	2 50.0%
False negatives	116 6.3%	13 25.5%	122 6.5%	7 36.8%	85 5.8%	44 10.5%	114 6.4%	15 14.9%	121 6.6%	8 21.1%	109 6.8%	20 7.0%	13 7.0%	1 25.0%
False positives	169 9.2%	4 7.8%	173 9.3%	0 0.0%	111 7.6%	62 14.7%	166 9.3%	7 6.9%	168 9.1%	5 13.2%	137 8.6%	36 12.5%	51 27.6%	1 25.0%
Total	1831	51	1864	19	1461	421	1782	101	1845	38	1595	287	185	4

Conclusions: OST is a sensitive and specific technique to assess inflammation in hand and wrist joints of RA patients with low disease activity, nonetheless, joint pathology like erosions, tendonitis, and osteophytes increase the risk of misclassification of inflammation by OST.

FRI0665 ANTI-HETEROGENOUS NUCLEAR RIBONUCLEOPROTEINS (ANTI- HNRNP) AND OTHER AUTOANTIBODIES FOR DETECTION OF EROSIVE ARTHROPATHY IN SYSTEMIC LUPUS ERYTHEMATOSUS WITH JOINT INVOLVEMENT IN COMPARISON BY JOINT X-RAY

S.Y. Hussein[1], N.A. Fathi[1], S.H. Goma[1], N.A. Mohammed[2], E. Mosad[3]. *[1]Physical Medicine, Rheumatology & Rehabilitation, Faculty of Medicine, Assiut university, Egypt; [2]Diagnostic Radiology, Assiut University Hospital; [3]Clinical Pathology, South Egypt Cancer Institute, Assiut, Egypt*

Background: Joint involvement in SLE is very common, affecting 90% of patients at some stage in the course of their disease (1).Arthritis featuring prominent radiological erosion in SLE is less common; however, in a small subset of patients an erosive pattern similar to RA develops (2).
Anti- heterogenous nuclear ribonucleoprotein A2 (anti-hnRNP-A2) occur in about one-third of patients with RA but rarely in other arthritides such as OA, PsA or reactive arthritis. Interestingly, in SLE patients anti-hnRNP-A2 autoantibodies were found to be significantly associated with erosive arthritis (3).
Objectives: To investigate joint involvement in SLE and its relationship with autoantibodies to the hnRNP Ab A1 and A2, rheumatoid factor (R.F), Antinuclear antibody (A.N.A) and Anti-double stranded DNA (Anti-DSDNA) and correlation with articular involvement by joint x-ray.
Methods: Case series study comparing diagnosis of arthritis by hand and wrist x-ray with anti-hnRNP A1 and A2 in Fourty SLE patients aged 17–60 years old with disease duration 1–17 years complaining of arthralgia or arthritis. A controlled group of 21 clinically normal persons, age and sex matched and blood

Table 1. Comparison of serological features in SLE patients with and without erosive arthritis (EA)*

Characteristic	SLE patients with EA	SLE patients without EA	Total	P value
Rheumatoid Factor, N (%)[b]	5 (50)	6 (20)	11 (27.5)	0.079
ANA, N (%)[b]	8 (80)	14 (46.7)	22 (55)	0.069
Anti-double stranded DNA, N (%)[b]	9 (90)	13 (43.3)	22 (55)	0.011*

Table 2. Comparison of radiological findings of hand X-ray in SLE patients with and without erosive arthritis (EA)*

Characteristic	SLE patients with EA	SLE patients without EA	Total	P value
Juxta-articular osteoporosis, N (%)	9 (90)	21 (70)	30 (75)	0.204
Narrowing of joint space, N (%)	9 (90)	9 (30)	18 (45)	0.001*
Subchondral cysts, N (%)	4 (40)	1 (3.3)	5 (12.5)	0.010*
MCP sublaxation, N (%)	7 (70)	3 (10)	10 (25)	0.001*
Interruption of cortical surface, N (%)	7 (70)	1 (3.3)	8 (20)	<0.0001*
New bone formation, N (%)	1 (10)	0	1 (2.5)	0.250
AVN, N (%)	0	1 (3.3)	1 (2.5)	0.750

samples are drawn and centrifuged. RF and auto-antibodies to nuclear antigens anti-nuclear antibodies (ANA) and anti-double stranded DNA were determined in all the patients. All patients underwent X-rays of the hands and wrists.
Results: Anti-hnRNP A1 showed highly significant difference between study and control. Anti-hnRNP A2 showed significant difference between study and control.
Conclusions: This study showed a high frequency of erosive arthropathy and autoantibody to both hnRNP antigens might become useful marker for joint involvement in SLE patients and identify SLE patients prone to develop joint damage

FRI0666 INCREASED PREVALENCE OF SUBCLINICAL ATHEROSCLEROSIS IN MODERATE-SEVERE PLAQUE PSORIATIC PATIENTS

N. Vegas-Revenga, J. Martín-Varillas, S. Armesto, M. Drake, V. Portilla, P. Fuentevilla, J. Rueda-Gotor, B. Atienza, L. Domínguez-Casas, C. Fernández-Díaz, R. Blanco, M. González-Gay, A. Corrales. *HUMV, Santander, Spain*

Background: Recent studies suggest that plaque psoriasis may be a risk factor for major adverse cardiac events. This has important therapeutic implications for cardiovascular (CV) risk stratification and prevention in patients with severe psoriasis. For that reason surrogate markers of subclinical atherosclerosis and CV mortality such as carotid plaques (CP) have been studied by carotid US examination.
In most studies of psoriasis done before, the results have shown an increased prevalence of carotid plaques, but it is not always the rule.
Objectives: To compare the prevalence of CP between patients with moderate-severe psoriasis and the general population.
Methods: A cross-sectional study that included 40 patients with moderate-severe psoriasis (PASI>10, BAS>10%), that fulfilled definitions for initiating treatment with a biological agent and 40 age-, sex- and traditional CV risk factors-matched healthy control subjects. Patients with history of CV events, diabetes mellitus, and chronic kidney disease or body max index (BMI)>35 were excluded. Carotid ultrasonography was performed by a MyLab 70 scanner (Esaote; Genoa, Italy), then carotid plaque was defined according to the Manheim Consensus Conference criteria. Statistical analysis: Qualitative data were expressed as number and percentages and quantitative data as mean (SD). Student's t test or Mann-Whitney U were used to compare continuous variables, as appropriate. Chi2 test or Fisher test were used for qualitative variables.
Results: The main data of the patients are summarized in the Table. It is important to highlight that it is based on a young population (mean age<40 years). The two groups did not present significant differences except for high sensitivity C-reactive protein (hsCRP)
As expected given the age of the group, CV risk measured by SCORE was low (0%) with a mean of 0.2 us 0.15. No patient had a high-very high CV risk as measured by SCORE (≥5%).
Patients with psoriasis had a long-standing disease (17.05±11.63 years). The presence of carotid plaques was found in a total of 10 patients with plaque psoriasis (25%), 5 of them had bilateral plaques) and one in the control group (2.5%) without bilateral plaques), p<0.003.

Variable	Plaque Psoriasis (n=40)	Controls (n=40)	P
Age: Mean (SD)	37,68 (11.83)	38.63 (11.83)	0.75
Sex (Male): n (%)	18 (45)	18 (45)	1.0

FRI0667 THE RECALL SURVEY: CAN ULTRASOUND AFFECTS CLINICIANS' DECISIONS ABOUT CHANGING TREATMENT IN RA?

O. Epis[1], P. Macchioni[2], A. Delle Sedie[3], M. Canzoni[4], E. Filippucci[5], A. Iagnocco[6], S. Tropea[7], C.F. Bonali[8]. *[1]Rheumatology Unit, Ospedale Niguarda Milano, Milano; [2]Rheumatology Unit, Reggio Emilia Hospital, Reggio Emilia; [3]Rheumatology Unit, Università di Pisa, Pisa; [4]Local Health Unit (ASL) Rome 1, Rome; [5]Rheumatology Department, Università Politecnica delle Marche, Jesi (AN); [6]Academic Rheumatology Unit, Università degli Studi di Torino, Torino; [7]ASP7, Busacca Hospital, Ragusa; [8]Rheumatology Unit, Ospedale San Paolo, Bari, Italy*

Background: In Rheumatoid Arthritis (RA) treatment response is assessed using standard clinical disease activity measure. However ultrasound (US) is able to show subclinical synovitis in patients (pts) with RA who are in clinical remission (CR); further studies are still required to delineate the impact of US findings in the management of RA pts in daily clinical practice.
Objectives: to investigate the influence of US on the clinicians' treatment choices in pts with RA.
Methods: in 2015 an educational event (RECALL Survey) focused on the added value of US in RA pts was held in 22 rheumatology centers in Italy.In every center, the local rheumatologists provided RA pts to be examined by US. Pts signed an informed consent and a brief history of them was collected by the local rheumatologists (previous and current therapy, DAS28, HAQ score). Bilateral US examinations of wrists, metacarpophalangeal (MCP) and metatarsophalangeal (MTP) joints were performed by rheumatologists expert in US, to assess synovitis (joint effusion, synovial proliferation, and power Doppler (PD) signal), and bone erosions, using a Logiq E R7, General Electrics, with a 4.2–13 MHz linear probe. All US findings were scored using a 4 degree semiquantitative scoring system.
Results: 465 pts were evaluated. Clinicians, after US evaluations, changed therapy in 23.7% of pts, did not change therapy in 35.5% of pts.In general changes of therapy tended to be made by clinicians when joint effusion or power Doppler signal were present (table 1–2). The presence of erosion did not influence the clinicians' decisions.

Table 1. Changes of therapy and joint effusion

		Joint Effusion		
		Score ≤0	Score >0	Total
Change in therapy	No	86	79	165
	Yes	11	99	110
	Total	97	178	275

Table 2. changes of therapy and Power Doppler

		Power Doppler Signal		
		Score ≤0	Score >0	Total
Change in therapy	No	129	36	165
	Yes	24	86	110
	Total	153	122	275

Conclusions: Ultrasound may be an useful tool in daily rheumatologic practice to help clinicians make decisions about how to treat patients with RA. US results, especially joint effusion and Power Doppler signal, may influence the choice of clinicians to modify a patient's treatment regime.

FRI0668 SONOGRAPHIC AND ANATOMICAL DESCRIPTION OF THE SUBTALAR JOINT

P. Mandl[1], D. Bong[2], P.V. Balint[3], H.B. Hammer[4], M. Miguel[5], E. Naredo[6], I. Möller[2] on behalf of Anatomy for the Image. *[1]Rheumatology, Medical University of Vienna, Vienna, Austria; [2]Rheumatology, Universitat de Barcelona, Instituto Poal de Reumatologia, Barcelona, Spain; [3]Rheumatology, National Institute of Rheumatology and Physiotherapy, Budapest, Hungary; [4]Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; [5]Pathology and Experimental Therapeutics, Universitat de Barcelona, Barcelona; [6]Rheumatology, Joint and Bone Research Unit. Hospital Universitario Fundación Jiménez Díaz and Autónoma University, Madrid, Spain*

Background: The subtalar joint is commonly affected in many rheumatic and musculoskeletal diseases; however, subtalar joint involvement is often neglected or missed during clinical examination due to the fact that the joint is difficult to examine and most clinicians have a limited understanding of its anatomy.
Objectives: To provide a detailed anatomical and US description of the subtalar joint, a single joint that, anatomically, is divided into two separate compartments: the anterior subtalar joint (ASTJ) and the posterior subtalar joint (PSTJ).
Methods: Cadaver specimens of the ankle and foot were examined in detail by ultrasound (US) by rheumatologist experts in musculoskeletal US. The ASTJ of all

the specimens were injected with colored latex while the PSTJs were respectively injected with 1ml of latex of a contrasting color under US guidance. Following the injections, the joints were frozen and cut into 2 centimeter sections from medial to lateral in the sagittal plane. Sections were examined independently by three authors for the presence of latex within the ASTJ, PSTJ and, also, to look for the presence of extra-articular latex extravasation or the spread of latex to adjacent articulations by means of a communication with the ankle joint or the adjacent portion of the subtalar joint.

Results: Six cryopreserved intact ankle-foot specimens from three male and three female cadavers (two right and four left), with a mean age of 74 years (range, 66–80 years) were studied. A recommended list of standardized scanning technique which allows sonographers to evaluate both compartments of the subtalar joint (ASTJ and PSTJ) from the medial, lateral and posterior aspect were developed. All of the specimens (6/6, 100%) contained the appropriate colored latex in the appropriate subtalar joint compartment with minimal leakage into the surrounding soft tissues (Figure 1). Of note, five of the six (5/6, 83%) specimens revealed communication between the PSTJ and the posterior tibiotalar joint. There was no communication between the ASTJ and the tibiotalar joint, nor was there evidence of spread of the latex, i.e. communication, from one subtalar joint compartment to the other.

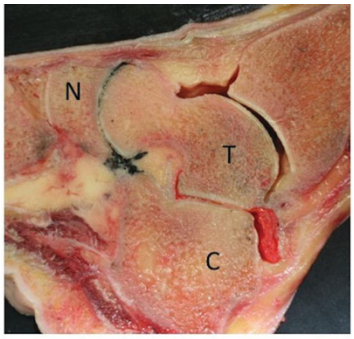

Figure 1. Anatomical specimen showing the anterior subtalar joint (filled with green latex) and the posterior subtalar joint (filled with red latex); C: calcaneus, N: navicular, T: talus

Conclusions: Lack of communication between the ASTJ and the PSTJ and the communication between the PSTJ and the posterior recess of the tibiotalar joint are compatible with other studies. Our study highlights the importance of employing cadaver specimens in musculoskeletal ultrasound, and presents a number of options for US imaging of both the ASTJ and PSTJ that also provide access to these distinct compartments for the purpose of aspiration and injection.

FRI0669 VALIDITY OF SEVEN-JOINT VERSUS SIMPLIFIED TWELVE-JOINT ULTRASONOGRAPHY SCORING SYSTEMS IN ASSESSMENT OF RHEUMATOID ARTHRITIS ACTIVITY

R. El-Gohary[1], A. Ahmed[1], A. Khalil[2], H. El-Gendy[1], K. Gado[1]. *[1]Internal Medicine, Rheumatology & Clinical Immunology Subspeciality, Kasr Alainy; [2]New Kasr El-Aini Teaching Hospital, Cairo, Egypt*

Background: Musculoskeletal ultrasonography imposes itself as reliable tool for the disease activity assessment of rheumatoid arthritis (RA) being more sensitive than clinical in detection of synovitis. There is no consensus on the exact joint number should be examined. Naredo et al. developed reduced 12-joint count[1] while Backhaus et al. scored only seven small joints[2]. Although both were found to reflect disease activity it is suitable in a busy clinic to assess the lowest joint count.

Objectives: To investigate the validity of 7-joint ultrasonography (US7) scores in assessment of disease activity in Egyptian RA patients compared with simplified 12-joint ultrasonography (US12) scores and correlate both to composite disease activity indices.

Methods: Fifty Egyptian RA adult patients diagnosed according to the ACR1987 criteria were subjected to detailed history, 28 tender & swollen joint counts (TJC, SJC). The disease activity was assessed by calculating DAS28-CRP, SDAI and CDAI. The Ultrasonographic assessment was performed using a LOGIQP6 with 10–13 MHz broadband linear array transducer by one well-trained blinded rheumatologist. The synovial hypertrophy on GS & PD images were graded using a semi-quantitative 0–3 scale. The simplified US12 was performed as originally described[1]. However the GS & PD synovitis were computed in two separate scores instead of one. The US7 was performed at the clinically dominant side as described by Backhaus et al[2]. Two Sum-US7 scores were added; Sum (GS)-US7 after grading the GS-tenosynovitis and Sum (PD)-US7. Ultrasonography inter/intraobserver reliability was evaluated on 40 stored images using randomization and blinded techniques.The study was approved by the local ethics committee.

Results: The studied population had mean disease duration of 89±60 months. 62% were using more than one DMARD. They showed moderate disease activity as defined by DAS28, SDAI and CDAI (mean 3.7±1.4, 19.9±14.9 & 17.9±13.3 respectively). The GS-scores showed no correlation with disease activity parameters. PD-US12, PD (synovitis)-US7 and Sum (PD)-US7 significantly correlated with the SJC, CRP levels (P values 0.03, 0.04 and 0.01) and DAS28 (P values 0.02, 0.009 and 0.001), furthermore Sum (PD)-US7 correlated with SDAI and CDAI (P values 0.013& 0.042 respectively). Correlation coefficient between the different ultrasonographic scores showed no differance. The ultrasonography reliability showed significant agreement ($P<0.001$). Kappa values were 0.80 & 0.96 for GS & PD interobserver reliability and 0.96 & 1.0 for GS & PD intraobserver reliability.

Conclusions: Our results confirm the validity of PD-scores in assessment of disease activity. However they make the significance of GS questionable. The Sum-(PD) US7 seems to perform better than the original one, it was strongly correlated with CRP and with the three disease composite indices. The studied scores correlated with each other favoring the use of less time consuming US7score.

FRI0670 THE COURSE OF SUBCLINICAL JOINT INFLAMMATION DURING PROGRESSION FROM ARTHRALGIA TO CLINICALLY DETECTABLE ARTHRITIS, A LONGITUDINAL MRI STUDY

R.M. Ten Brinck, H.W. van Steenbergen, L. Mangnus, A.H. van der Helm-van Mil. *Rheumatology, Leiden University Medical Centre, Leiden, Netherlands*

Background: Subclinical joint inflammation in the phase of arthralgia preceding RA can comprise synovitis, bone marrow edema (BME) and/or tenosynovitis. It is unknown in what time order the different tissues in a joint become inflamed or progress with inflammation. It has been postulated that synovitis is an initial process that is succeeded by bone involvement ("outside-in hypothesis" presuming that synovitis precedes BME and erosions). Alternatively, it is suggested that inflammatory cells in the bone marrow migrate via bone pores to the synovium, promoting synovitis ("inside-out", then BME precedes synovitis). Thirdly, these processes can occur or progress simultaneously. Serial MRI studies can reveal time-relationships. This longitudinal MRI study on patient-level determined the course of joint inflammation during progression from arthralgia to clinical arthritis.

Objectives: To increase the comprehension on the course of MRI-detected subclinical joint inflammation during progression from arthralgia to clinical arthritis, both in ACPA-positive and ACPA-negative arthritis patients.

Methods: We longitudinally followed 29 patients that all progressed from Clinically Suspect Arthralgia to clinical arthritis. 1.5T MRI on hand and foot joints was performed at presentation with arthralgia and subsequently at the development of clinical arthritis. MRIs were evaluated for BME, synovitis and tenosynovitis (summed in the total inflammation score) and erosions by three readers (ICCs 0.98, 0.96 and 0.97) that were blind to clinical data and the order in time. Analyses were repeated in arthritis patients that fulfilled the 2010 criteria for rheumatoid arthritis, and in ACPA-positive and ACPA-negative patients separately.

Results: At presentation with arthralgia the mean age was 43 years, 72% was female, and 28% was ACPA-positive. Median duration to clinical arthritis was 17 weeks. At the time of arthritis development 65% fulfilled the 2010-criteria. During progression from arthralgia to clinical arthritis the median total inflammation score increased from 4.5 (IQR 2.8–7.8) to 6.0 (IQR 2.0–13.5), p=0.01. The BME score increased over time (p=0.04), as did the synovitis score (p=0.002). The tenosynovitis and erosion scores increased as well, though not statistically significant (p=0.10 and p=0.07 respectively). Analyses within the patients that developed 2010-RA revealed that BME (p=0.047), synovitis (p=0.005) and tenosynovitis (p=0.004) all increased significantly, in contrast to the erosion score. At presentation with arthralgia, BME and synovitis scores were higher in ACPA-positive than in ACPA-negative patients; during progression to clinical arthritis the different types of inflammation increased similarly in ACPA-positive and ACPA-negative patients.

Conclusions: During progression from arthralgia to clinically evident rheumatoid arthritis, BME, synovitis as well as tenosynovitis progress simultaneously.

FRI0671 ULTRA-HIGH FIELD MRI AND BIOMECHANICAL INVESTIGATION OF VERTEBRAL BONE MICROARCHITECTURE

S. Guis[1], D. Guenoun[2], A. Fouré[3], M. Pithioux[4], T. Le Corroller[2], J.P. Mattei[1], V. Pauly[5], M. Bernard[3], P. Chabrand[4], P. Champsaur[2], D. Bendahan[3].
[1]Rheumatology 1; [2]Radiology, Aix Marseille Université, AP-HM; [3]CRMBM, UMR 7339; [4]Ism UMR 7287, CNRS; [5]Statistic department, AP-HM, Marseille Cedex 9, France

Background: Fracture risk prediction in patient relies chiefly on bone mineral density (BMD) measurement. However, the decreased bone strength characteristic of osteoporosis is dependent not only on BMD, but also on other factors, most notably bone microarchitecture.
Objectives: The purpose of this study was to investigate bone microarchitecture variables of cadaveric vertebrae using ultra-high field MRI (7 Tesla).
Methods: Twenty four vertebrae (L2, L3, L4) from eight cadavers were studied using 7 Tesla MRI. Their Bone Mineral Density (BMD) were investigated using dual energy X Ray absorptiometry. Then, all specimens underwent mechanical compression tests to failure and the failure load (in Newton) and constraint (in Mpa) were measured. Bone Volume Fraction (BV/TV), Trabecular Thickness (Tb.Th), and Trabecular Spacing (Tb.Sp) were measured in MR images using a Digital topological analysis (Bone J). Measurements were performed by two observators in order to characterize the inter-rater reliability. Statistical analyses were performed using SPSS. Correlations between variables were analyzed using Spearman correlations and Stepwise regression. A p value of 0.05 was considered as significant.
Results: The inter-rater reliability for bone microarchitecture parameters quantification was good. Tb.Th and Tb.Sp measured using high-field MRI were 0.52±0.18 and 0.48±0.10 respectively while the BV/TV fraction was 0.52±0.13. The mean BMD was 0.86±0.20 g/cm^2. The failure load and the constraint measured during the compression tests were 2600±1267N and 1.57±0.81 Mpa respectively. Interestingly, the variables measured during the mechanical tests were significantly
The failure load and constraint measured during the compression tests were significantly correlated with the BMD. Regarding the bone indices quantified using high-field MRI, a significant linear relationship was observed between the trabecular spacing and the BMD (R^2=0.23, p=0.01 and the constraint values to failure (R^2=0.18, p=0.04). A stepwise regression with backward elimination demonstrated that combining BV/TV and BMD improved the relationship with the constraints from an adjusted R^2=0.384 for BMD alone to an adjusted R^2=0.41 for BMD + BV/TV.
Conclusions: In the present study, we demonstrated for the first time that the variables characterizing the vertebral bone microarchitecture quantified using ultra-high field MRI were significantly correlated with biomechanical parameters. In addition, we illustrated that the vertebral bone strength was better described by a variable combining BMD and trabecular bone spacing.

FRI0672 ASSESSMENT OF THE NAIL BED IN PSORIATIC ARTHRITIS (PSA) BY ULTRASOUND (US) AND MRI

S. Paramalingam[1], A. Taylor[2], H. Keen[2,3]. *[1]Rheumatology, Sir Charles Gairdner Hospital; [2]Rheumatology, Fiona Stanley Hospital; [3]School of Medicine, University of Western Australia, Perth, Australia*

Background: PsA can be difficult to distinguish from osteoarthritis (OA) and the treatments vary greatly. Nail involvement can occur in about 15–50% patients with psoriasis[1], which may aid differentiation from OA. If US can reliably detect nail bed changes in early disease then it might be helpful in differentiating PsA from OA
Objectives: This study aims to investigate the nail bed changes seen in patients with PsA and OA using US and MRI, and to determine the impact of nail bed changes on quality of life (QOL).
Methods: Patients who fulfilled the CASPAR PsA or 1990 ACR OA classification criteria were recruited. At baseline, clinical assessment included patient and physician's visual analogue scale (VAS), tender and swollen joints, patient's Leeds Enthesitis Index and quality of life specific to nail psoriasis (NPQ10). Nail abnormalities on the dominant hand such as onycholysis, pitting, nail bed hyperkeratosis and nail bed crumbling were documented. Using US, each nail (1–5) was scored dichotomously for pitting/irregularity, loss of normal trilaminar appearance of the nail. Each nail was scored semi quantitatively for power doppler (PD) signal (0–3) in the nail bed, nail matrix and dermis, and assigned a total PD score. All patients had an MRI of the dominant 2nd to 5th finger.
Results: 14 patients were recruited; demographics, clinical and US detected nail changes are documented in Table 1. Clinical nail changes were not seen in the OA group, but were relatively common in the PsA group. In the PsA group, 54% of nails had US detected structural abnormalities; 12% pitting and 52% loss of trilaminar layer. Only 20% of OA nails had US detected abnormalities. There was a strong relationship between the presence of clinical nail change and US structural changes (chi square 10.769 df 1 p=0.001) but not PD signal score. There was no relationship between clinical or US detected nail scores and NPQ10, patient or physician VAS, swollen joint count or Leeds Enthesitis Index. MRI analysis is pending.

Table 1

	Total (n=14)	PsA (n=10)	OA (n=4)
Age (median (IQR))	56.5 (52.2–63.2)	55.0 (48.0–63.2)	61.0 (55.2–73.5)
Patient VAS (median (IQR))	29.0 (12.5–54.8	39.5 (19.8–54.8)	11.0 (3.8–54.2)
Physician VAS (median (IQR))	35.3 (20.5–57.5)	42.5 (24.5–57.5)	24.0 (4.8–53.8)
NPQ10 (median (IQR))	6.5 (1.8–10.0)	7.0 (5.2–10.2)	1.5 (0.2–5.8)
Swollen joint count (median (IQR))	2.0 (0.0–4.2)	1.5 (0.0–5.2)	2.5 (0.5–5.8)
Leeds Enthesitis index (median (IQR))	1.0 (0.0–2.0)	1.0 (0.0–2.0)	0.5 (0.0–1.8)
Percentage of nails with clinical abnormalities	27.7%	40.0%	0.0%
Percentage of nails with US structural abnormalities	44.3%	54.0%	20.0%
Percentage of nails with PD signal	97.1%	96.0%	95.0%

Conclusions: In this small prospective study, structural abnormalities detected by US appear to correlate well against clinical structural findings, but PD signal does not. No relationship was found between US findings and other clinical parameters. US structural abnormalities may be a better differentiator of PsA and OA than PD signal. MRI validation of these results is pending.

FRI0673 CLINICAL REMISSION IN TOCILIZUMAB-USING RHEUMATOID ARTHRITIS PATIENTS CAN BE OVERESTIMATED: A CROSS SECTIONAL STUDY USING ULTRASOUND SONOGRAPHY

S. Nakabo[1], Y. Tsuji[2], M. Inagaki[2], H. Tsuji[1], T. Nakajima[1], M. Hashimoto[3], M. Furu[3,4], M. Tanaka[3], H. Ito[4], T. Fujii[1,5], Y. Fujii[2], T. Mimori[1]. *[1]Department of Rheumatology and Clinical Immunology; [2]Human Health Sciences Clinical Physiology and Ultrasound Labo; [3]Department of the Control for Rheumatic Diseases; [4]Department of Orthopaedic Surgery, Graduate School of Medicine, Kyoto University, Kyoto; [5]Department of Clinical Immunology and Rheumatology, Wakayama Medical University, Wakayama, Japan*

Background: Several clinical remission (CR) criteria of rheumatoid arthritis (RA) contain acute-phase reactants [C-reactive protein (CRP), and erythrocyte sedimentation rate (ESR)] as their components. However, it is known that they can be underscored by the usage of tocilizumab (TCZ). This may cause overestimation of CR. On the other hand, ultrasound sonography (US) provides objective information independent of acute-phase reactants and assessment by physician and patient, and can detect synovitis in RA patients in CR, which is called sonographic residual synovitis (SRS).
Objectives: To assess whether CR of TCZ-using RA patients are overestimated, by using US.
Methods: We recruited 402 RA patients. Bilateral 2–5 MCP, wrist, ankle, and 2–5MTP joints were scanned by using the Aplio500 (TOSHIBA) with a 12 MHz transducer. Power Doppler (PD) images were obtained by Superb Micro-vascular Imaging (SMI). Gray scale (GS) and PD images were scored using a 0–3 semi-quantitative scale. Clinical information was obtained from the Kyoto University Rheumatoid Arthritis Management Alliance (KURAMA) database, which is based on the assessments by physicians who were blind to the US results. The patients were divided into 4 groups based on their treatment: tumor necrosis factor alpha inhibitors (TNFi), TCZ, abatacept (ABT), and non-biologic (non-Bio) users. Two patients treated by tofacitinib were excluded because the number was too small to analyze. The Boolean (BL)-based, Simplified Disease Activity Index (SDAI)-based, Clinical Disease Activity Index (CDAI)-based, and Disease Activity Score (DAS)28-ESR-based CR criteria were assessed using SRS.
Results: A total of 400 RA patients were analyzed. The number of patients in each treatment group is shown in the Table. When the BL-based, SDAI-based, and DAS28-ESR-based CR criteria were used, SRS in TCZ group was significantly stronger than the other groups (Fig 1–3). On the other hand, when CDAI-based CR criteria was used, the difference was not significant among 4 groups (Fig

FRI0674 USING HIGHER IMAGE RESOLUTION OF MAGNETIC RESONANCE IMAGING OF THE CERVICAL SPINE IDENTIFIES MORE INFLAMMATORY AND STRUCTURAL LESIONS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

S. Krabbe[1], M. Østergaard[1], J. Møller[2], I.J. Sørensen[1], B. Jensen[1], O.R. Madsen[1], S.J. Pedersen[1]. *[1]Center for Rheumatology and Spine Diseases, Rigshospitalet, Copenhagen; [2]Department of Radiology, Herlev Hospital, Herlev, Denmark*

Background: The vertebrae of the cervical spine are rather small and it may be difficult to assess if small areas with signal intensity changes represent the bones, joints or entheses, or derive from the surrounding blood vessels.
Objectives: To investigate if image resolution affects the assessment of inflammatory and structural lesions of the cervical spine.
Methods: Forty-nine patients with axial spondyloarthritis according to the ASAS criteria started anti-TNF treatment and had "standard" resolution (std-res) and "high" resolution (high-res) MRI sequences of the cervical spine performed at baseline and after 48 weeks. 3 patients had follow-up scan already after 6–24 weeks due to study exclusion.
Std-res: STIR sequence: Voxel size 5.0 mm^3 (slice thickness 4.0, spatial resolution 1x1.25); T1W sequence: voxel size 4.5 mm^3 (slice thickness 4.0, spatial resolution 0.9x1.25).
High-res: STIR sequence: Voxel size 3.1 mm^3 (slice thickness 3.5, spatial resolution 0.8x1.11); T1W sequence: voxel size 1.4 mm^3 (slice thickness 3.0, spatial resolution 0.6x0.76).
Images were assessed in known chronology by an experienced axSpA MRI reader (SJP) blinded to clinical data. High-res and std-res were read in random order. MRI lesions of inflammation, fat and new bone formation were defined according to the Canada-Denmark working group [1,2]. Erosions were not assessed.
Results: Inflammatory lesions: In 9 of 43 patients (21%), inflammatory lesions were detected in the cervical spine at baseline at std-res, while this was detected in 14 of 43 patients (33%) at high-res. Using high-res, as compared to std-res, 6 patients were reclassified from negative to positive for inflammation, 1 patient was reclassified from positive to negative, and 8/28 patients remained classified as positive/negative, p=0.13 by Exact McNemar test. The mean inflammation score was significantly higher at high-res compared to std-res (1.7 (SD 4.5) vs. 0.8 (SD 2.7), p=0.04 by paired t-test).
Fat lesions: 11 of 43 patients (26%) had fat lesions in the cervical spine at baseline using std-res, while 10 of 43 patients (23%) had this using high-res. The mean fat score was significantly higher at high-res compared with std-res (1.6 (SD 3.5) vs. 0.8 (SD 1.8), p=0.02 by paired t-test).
Bone spurs/ankylosis: 11 of 43 patients (26%) had bone spurs/ankylosis of the cervical spine at baseline at std-res, while 10 of 43 patients (23%) using high-res. The mean new bone formation score was significantly higher at high-res compared with std-res (2.7 (SD 6.1) vs. 1.4 (SD 3.5), p=0.01 by paired t-test).
Responsiveness: Standardized response mean for inflammation score at std-res was 0.15, and at high-res 0.14. Structural lesions remained largely unchanged in all patients.
Conclusions: More patients were classified as having inflammatory lesions in the cervical spine when using high-res MRI, compared to std-res. Likewise, mean scores of inflammatory lesions, fatty lesions and new bone formation were significantly higher compared with std-res. Further studies are needed to investigate the clinical significance of these findings as well as the frequency of these minor lesions in healthy controls.

FRI0675 OBTAINING SYNOVIAL BIOPSIES FROM THE WRIST IN PATIENTS WITH NEWLY DIAGNOSED UNTREATED AND LONGSTANDING RHEUMATOID ARTHRITIS FOLLOWED BY INTRAMUSCULAR GLUCOCORTICOID AND METHOTREXATE INITIATION IS SAFE AND THE GLUCOCORTICOID TREATMENT SIGNIFICANTLY REDUCES DISEASE ACTIVITY

S.A. Just[1], C. Nielsen[2], E.K. Hejbøl[3], H.D. Schrøder[3], I.M.J. Hansen[4], T. Barington[2], H.M. Lindegaard[1]. *[1]Rheumatology; [2]Clinical Immunology; [3]Clinical Pathology, Odense University Hospital, Odense; [4]Medicine, Svendborg Hospital, Odense University Hospital, Svendborg, Denmark*

Background: The minimal invasive ultrasound-guided synovial biopsy (USG-SB) method has been shown to be safe and tolerable. The method has accelerated the research field of using synovial biopsies focusing on early diagnosis, disease stratification, biomarker studies and in the future optimal treatment selection for the individual patient. Here synovial biopsies obtained from patients with early arthritis before therapy initiation are essential. A major issue in newly diagnosed RA patients but also in RA patients with longstanding active RA, is to combine an effective fast working treatment with safely obtaining synovial tissue without delaying treatment initiation. In the EULAR early arthritis recommendations, prompt treatment initiation is recommended by combining glucocorticoid bridge therapy with disease-modifying antirheumatic drugs (DMARD). It is therefore essential that accepting synovial biopsy, does not delay start of fast remission-inducing treatment. Especially if synovial biopsies by the USG-SB method in the future shall be used systematically for detailed disease stratification and personalized treatment decisions.
Objectives: Safety of using intramuscular glucocorticoid injection (IGI) immediately after the USG-SB procedure in patients with newly diagnosed untreated RA or longstanding active RA, and the effect of IGI on disease activity after 4 weeks.
Methods: Wrist synovial biopsies were taken) at inclusion and after 6 months from 22 patients with newly diagnosed, untreated RA and 15 with longstanding RA (>5 years). After biopsies patients were offered an IGI of 2 ml of methylprednisolone acetate (Depo Medrol) 40mg/ml. Early RA patients were also started on methotrexate. Disease activity scores in 28 joints (DAS28) were recorded at day of biopsy and again after 4 weeks. Safety data were obtained after 5 days (telephone), 2 weeks (questionnaire) and at first clinical evaluation (4 weeks) after biopsy. Patient-reported outcomes (PRO) with pain, swelling and stiffness of biopsied joint were obtained at day of biopsy and after two weeks.
Results: At present time, all patients have undergone first biopsy and 18/37 second biopsy. At the EULAR congress complete data will be presented. 68% of all patients accepted IGI after first biopsy currently 39% after second procedure. Patients accepting IGI after first biopsy did not have higher DAS-28 (early RA group (p=0.15), longstanding RA (p=0.06)). Time to first follow-up was not significantly different for patients accepting IGI (early RA group (p=0.17), longstanding RA (p=0.05)). Two weeks after biopsy, PRO was not significantly different when comparing IGI vs non-IGI treated. For all patients, DAS-28 was significantly reduced in the group receiving IGI at first clinical evaluation after synovial biopsy (p=0.004, without IGI ΔDAS28: -0.5, with IGI ΔDAS28: -1.7).
Conclusions: Start of treatment with IGI combined with DMARD after obtaining synovial biopsies by the USG-SB procedure from patients with early untreated RA and longstanding RA is safe, and reduces disease activity more than without IGI.

FRI0676 A PROPOSAL FOR A SIMPLE ULTRASOUND METHOD FOR THE DIAGNOSIS OF EARLY RHEUMATOID ARTHRITIS

T. Serban[1,2], I. Satulu[3], O. Vutcanu[1], M. Milicescu[1,2], C.M. Mihai[1,2], M. Bojinca[1,2]. *[1]Internal Medicine and Rheumatology, "Dr. I. Cantacuzino" Clinical Hospital; [2]Internal Medicine and Rheumatology, "Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania; [3]Rheumatology, Kalmar County Hospital, Kalmar, Sweden*

Background: At this point, the classification criteria for rheumatoid arthritis (RA) are well known and generally applied in clinical practice. (1) Ultrasound (US) assessment can help in distinguishing the patients with early RA (ERA) within the patients with early inflammatory arthritis (EIA).
Objectives: The aim of this study was to develop an US method for the diagnosis

of ERA in a population of EIA patients from an Early Arthritis Research Center (EARC).
Methods: We have assessed all patients with EIA referred to our EARC between 2012–2016. Patients who were diagnosed with other diseases except EIA or ERA, or in whom symptom duration exceeded 12 months, were excluded from the analysis. Every patient underwent clinical, laboratory and ultrasound evaluation. For the proposed US diagnostic method we have evaluated bilaterally 3 joints: wrists, MCP II and III and 2 tendon regions: the extensor ulnaris carpis tendon and the flexor tendons of the fingers. The presence/absence of synovitis/tenosynovitis either in gray-scale or power-Doppler scale was scored in a binary mode as 1/0. In order to simplify the scanning protocol, we considered the flexor tendons of the fingers as a singular structure for each hand which meant that that the presence of US abnormalities in at least one flexor tendon was scored as 1. Thus, the maximum score obtainable in both hands was 10. We analyzed the performance of the proposed US method for the diagnosis of ERA using ROC curve analysis.
Results: Of 253 patients referred to our EARC, 73 satisfied the inclusion criteria; among them, 43 fulfilled the EULAR/ACR criteria for RA (ERA patients), while the other 30 were considered to have undifferentiated EIA. The demographic, clinical and US data of the 73 patients are displayed in the table below. 34/43 ERA patients (76.7%) had a duration of symptoms less or equal to 3 months which classifies them as very ERA (VERA).

Table 1. Demographic, clinical, laboratory and US data of the study patients – data are either n (%), mean ± SD or median (IQR)

Parameters	EIA (n=30)	ERA (n=43)	p
Gender (Female)	17 (56.7%)	27 (62.8%)	0.816
Age	41.70±15.58	55.47±13.71	<0.001
Mean duration of symptoms	3.16±3.22	3.54±3.58	0.556
CRP (mg/l)	7.85 (1.99–26.20)	18.62 (3.57–14.68)	0.848
ESR (mm/h)	26.00 (10.00–44.75)	34.53 (14–51)	0.238
RF (IU/ml)	10.00 (7.85–14.56)	142.75 (35.14–201.74)	<0.001
ACPA (IU/ml)	5.00 (0.5–5.00)	153.96 (46.20–212.00)	<0.001
DAS28	4.00 (3.35–5.05)	4.89 (4.31–5.60)	<0.001
SDAI	17.82 (12.28–26.37)	27.96 (20.92–34.61)	<0.001
US evaluation	0 (0–3)	5 (3–7)	<0.001

In ROC analysis, a cut-off of the US score of 4 had best results for sensitivity and specificity (73.3% and 82.1%, respectively), with an area under the curve of 0.812. The US score correlated with the levels of RF, ACPA, DAS28 and SDAI ($p<0.001$), but not with those of acute phase reactants ($p>0.05$). The time needed for performing the ultrasound examination was less than 10 minutes.
Conclusions: The proposed US method proves to be reliable in identifying patients with ERA. The binary mode of US evaluation allows even persons with little training in US examination to diagnose patients. As the costs and time needed for US evaluation are low, the method is valuable in clinical practice for a rapid assessment of patients with EIA.

FRI0677 ROLE OF NAILFOLD VIDEOCAPILLAROSCOPY AND 22-MHZ DOPPLER ULTRASOUND IN THE ASSESSMENT OF SYSTEMIC SCLEROSIS-RELATED DIGITAL VASCULOPATHY

T. Schioppo[1,2], A. Orenti[1,3], P. Boracchi[1,3], O. De Lucia[2], A. Murgo[2], P.L. Meroni[1,2], F. Ingegnoli[1,2] on behalf of OPERA study group. *[1]Università degli Studi di Milano; [2]ASST Pini-CTO; [3]Lab of Medical Statistics, Epidemiology and Biometry GA Maccacaro, Milan, Italy*

Background: Microvascular damage plays a critical role in the initiation and perpetuation of systemic sclerosis (SSc). A comprehensive approach should investigate both superficial and deep layers of peripheral microcirculation. In addition to nailfold videocapillaroscopy (NVC), a well-established technique to evaluate outer skin layer vessels, power Doppler ultrasound (PDUS) has been recently used to study microcirculation in the inner levels [1].
Objectives: To study the severity of microvascular involvement in patients with SSc by using both NVC to measure capillary density (outer layer at the nailfold area) and PDUS to detect perfusion (deeper layers at the nailfold and pulp area).
Methods: 100 SSc consecutive patients fulfilling the 2013 EULAR classification criteria were enrolled. PDUS was performed at the 3rd and 4th finger of the dominant hand after exclusion of ulnar artery occlusion (UAO). In case of UAO non-dominant hand was examined. Ultrasound investigation was performed with Esaote MyLab 70 XVG by means of linear array transducer (10–22 MHz). Power Doppler settings were standardized (Doppler frequency 14.3 MHz, Gain 55%, PRF 750 Hz). PDUS measurements included sagittal scan of nailbed and fingertip qualitatively graded from 1 (no signal) to 4 (marked hyperemia) [2], and resistivity index (RI) of ulnar and radial proper digital arteries. Capillary density (number/mm) was calculated by NVC with magnification 200X performed on two images of the same digits examined by PDUS.
Results: 100 SSc patients, 87 (87%) women, 86 (86%) limited cutaneous SSc, median age 62.2 years old, median disease duration 8 years were evaluated. 7 (7%) patients had UAO. Concordance between fingertip and nailbed perfusion as assessed by PDUS is reported in Table 1.

Table 1

		Nailbed PDUS				Sum
		Grade 1	Grade 2	Grade 3	Grade 4	
Fingertip PDUS	Grade 1	15	19	3	1	38
	Grade 2	13	13	6	6	38
	Grade 3	3	5	10	10	28
	Grade 4	2	8	15	71	96
	Sum	33	45	34	88	200

Concordance between fingertip and nailbed perfusion as assessed by PDUS is equal to 0.7398. The lower 97.5% confidence interval limit is 0.6433.
Association between capillary density, and fingertip and nailbed perfusion as assessed by PDUS is shown in Table 2.

Table 2

	Capillary density	p-value of the difference between the mean of the category, with respect to reference (grade 1)
Fingertip PDUS		
Grade 1	2.895	
Grade 2	3.763	0.038
Grade 3	3.500	0.181
Grade 4	3.844	0.007
Nailbed PDUS		
Grade 1	3.212	
Grade 2	3.433	0.597
Grade 3	3.294	0.854
Grade 4	3.949	0.049

Conclusions: To our knowledge, this is the first study to correlate NVC and PDUS finding in SSc patients. Fingertip and nailbed PDUS grade concordance was found to be satisfactory. The mean capillary density tends to be greater with respect to grade 1. This is particularly evident comparing grade 4 and grade 1. As such, these two imaging techniques provide different and potentially complementary information on SSc-related peripheral microvascular involvement. There is potential clinical utility in these observations that has yet to be unlocked fully.

FRI0678 ULTRASOUND-GUIDED SYNOVIAL NEEDLE BIOPSY: SINGLE CENTER EXPERIENCE OF AN EMERGING, MINIMALLY INVASIVE TECHNIQUE IN CLINICAL PRACTICE AND RESEARCH

V.C. Romao[1,2], J. Polido-Pereira[1,2], R. Barros[1], E. Vieira-Sousa[1,2], R. Luís[3], E. Vitorino[3], F. Saraiva[1], J.E. Fonseca[1,2]. *[1]Rheumatology Department, Hospital de Santa Maria, CHLN; [2]Rheumatology Research Unit, Instituto de Medicina Molecular, Faculty of Medicine, University of Lisbon; [3]Pathology Department, Hospital de Santa Maria, CHLN, Lisbon, Portugal*

Background: Synovial biopsy remains an important tool in clinical practice and research for the study of synovitis. Ultrasound-guided needle biopsy (USNB) has recently emerged as a minimally invasive technique, which enables collection of high quality synovial tissue with very good patient tolerance.
Objectives: To report the experience with USNB in our department, since its introduction in late 2013.
Methods: We reviewed the clinical files of all patients who had an USNB in our department. Degree of US joint synovitis was evaluated on a semi-quantitative scale (0–3) in terms of synovial thickness (ST) and power Doppler (PD). Since 2015, we assessed patient tolerance and acceptance of the procedure using a standardized questionnaire, which includes visual analogue scales (VAS) of pain, stiffness and swelling of the biopsied joint. Changes in US and VAS scores were assessed using the Wilcoxon signed-rank test.
Results: Forty-eight patients had 53 USNB, mostly for diagnostic purposes (79%), performed by 4 different operators - Figure 1. All types of joints were biopsied, mostly medium sized (26 wrists, 7 ankles), but also large (3 knees, 4 shoulders, 6 elbows, 3 hips) and small (1 sternoclavicular, 1 naviculocuneiform, 1 metacarpophalangeal and 1 proximal interphalangeal) joints, 2 bursae (subacromial) and 1 tendon sheath. USNB was repeated in the same joint (wrist) twice in 3 patients and three times in one patient. Procedures were well tolerated, with 67% of patients classifying it as easy or very easy, 78% reporting no or only mild discomfort and 77% considering likely/very likely to accept to repeat the biopsy. An increase in analgesic medication in the days following the biopsy was reported by 13 out of 44 questioned patients. After a median of 8 days following the procedure, a significant decrease was observed in VAS scores of pain, stiffness and swelling of the biopsied joint, although 23%, 23% and 31% of the patients reported small increases in these scores (median 9.5, 11 and 10mm, respectively). There was no significant change in US scores pre- and post-biopsy, with only 3 and 2 patients having an increase in ST or PD scores, respectively. Biopsies were overall safe, with 6 minor immediate adverse events (11%). There were no cases of haemartrosis, joint/periarticular

infection or neurovascular damage. Two patients reported transient limitation of the 5th and 1st digit extension following a biopsy of the wrist and 1st extensor compartment tendon sheath, respectively, with no detectable tendinous ruptures on US; 1 patient had a muscular hematoma of the extensor muscles of the forearm following an elbow biopsy.

	Patient & Biopsy characteristics (N=53)		
Age / Female	56 ± 18 years / 34 (64%)		
Diagnosis	21 RA, 13 UA, 8 septic, 5 crystal, 3 PsA, 1SpA, 2 other		
Disease duration	5.3 ± 7.1 years		
DAS28	4.3±1.2		
Clinical indication	42 diagnostic (79%), 11 research (21%)		
Joint size	16 large, 30 medium, 4 small, 2 bursa, 1 tendon sheath		
Infection confirmed	3/42 (7%)		
Immediate tolerance	29% very easy, 38% easy, 24% tolerable, 9% difficult		
Discomfort during procedure	36% no disc., 42% mild disc., 11% moderate disc., 5.5% mild pain, 5.5% intense pain		
Increase pain medication	13 (30%) in days following procedure		
Likelihood to repeat biopsy	41% very likely, 36% likely, 9% maybe, 14% unlikely		
Immediate AE	5 minor local bleeding, 1 transitory forearm extensor paralysis due to anesthesia		
Other AE	2 transient digit extension limitation (D5, D1), 1 muscular hematoma forearm		
	Pre-biopsy	**Post-biopsy**	**p-value**
VAS pain biopsied joint (mm)	62±25	46±29	0.001*
VAS stiffness biopsied joint (mm)	59±30	37±31	0.004*
VAS swelling biopsied joint (mm)	61±26	44±28	0.007*
US synovial thickness score	2.5±0.6	2.2±0.8	0.092
US Power Doppler score	1.0±1.2	1.0±1.1	0.414

*p-value significant at <0.05. AE, adverse events; D1, digit 1; D5, digit 5; DAS28, disease activity score 28 joints; disc., discomfort; PsA, psoriatic arthritis; RA, rheumatoid arthritis; SpA, spondyloarthritis; UA, undifferentiated arthritis; US, ultrasound; VAS, visual analogue scale.

Conclusions: In our center, USNB has proved to be an effective technique for collection of synovial membrane that can be used for diagnostic and research purposes. The vast majority of the procedures were well tolerated, without significant worsening of local joint symptoms or synovitis, and safe, without major adverse events. Importantly, patients' concordance to repeat a USNB was mostly high.

FRI0679 WHOLE SPINE AND SIJ MRI OF PSORIATIC ARTHRITIS PATIENTS: DESCRIPTIVE STUDY OF THE SPINE, AND SACROILIAC JOINTS INVOLVEMENT IN A CROSS SECTIONAL LARGE COHORT

V. Furer[1], M. Stark[2], H. Matz[3], D. Levartovsky[4], J. Wollman[4], I. Wigler[4], H. Sarbagil-Maman[4], D. Paran[1], I. Kaufman[4], M. Anouk[4], S. Borok[4], R. Zemah[4], A. Broyde[4], G. Flusser[5], I. Druckmann[5], O. Elkayam[1], I. Eshed[6]. *[1]Rheumatology, Tel Aviv Medical Center, Sackler School of Medicine; [2]Tel Aviv Medical Center, Tel Aviv, Israel; [3]Dermatology; [4]Rheumatology; [5]Radiology, Tel Aviv Medical Center, Tel Aviv; [6]Radiology, Sheba Medical Center, Sackler School of Medicine, Ramat Gan, Israel*

Background: Detection of axial disease has important implications. Data on the structural changes of the spine and SIJ in PsA is mainly based on plain XR and MRI of SIJ. The prevalence and distribution of spinal changes in PsA as detected by MRI is largely unknown.

Objectives: To evaluate acute and structural changes in spine and SIJ by whole spine MRI performed in a consecutive clinical cohort of PsA.

Methods: Adult PsA (CASPAR criteria) patients were enrolled in the study. All underwent clinical exam, CRP, HLA-B27 tests, and MRI of the entire spine and SIJ. Spinal sagittal T1-W, STIR and semi-coronal T1-W and T2-W with fat saturation sequences of the SIJ were performed. The spine was scored for the presence of syndesmophytes, bone marrow edema (BME)/fatty corners and enthesitis. SIJS were scored (Berlin score) for the presence of BME, fatty replacement, erosions, sclerosis, and ankylosis. Findings were further categorized into active sacroiliitis (ASAS[1]), structural sacroiliitis, and spinal findings compatible with SpA (≥3 BME or ≥4 fatty corners[2]). All MRIs were evaluated by an experienced musculoskeletal radiologist, blinded to clinical data. Data were analyzed by SPSS Version 20.0.

Results: Ninety six patients completed the study.(Table1) Active/structural/total sacroiliitis was detected in 26%/11.5%/37.5% of patients, respectively. Spinal SpA was demonstrated in 15.6%.(Table 2) Isolated spinal changes were detected in 2.1% of the cohort. Presence of inflammatory back pain (IBP) by ASAS correlated with the prevalence of active sacroiliitis (p 0.024) and SpA (axial/SIJ) (p 0.003). The extent of psoriasis severity (PASI) correlated with both SIJ and whole spine SpA changes. (*p 0.02 for both*) Gender differences or biologic therapy did not affect the prevalence of SIJ or spine involvement.

Table 1. Demographic and clinical data

Age (mean, yr)	50±13
Gender M:F	50:46
Psoriasis/PsA duration (mean, yr)	19±13.6/9±8
PASI	3.9±8.9
ASDAS-CRP	2.2±1
Back pain (%)/Inflammatory back pain by ASAS (%)	70%/30%
HLA-B27 (%)	4.4%
Current DMARD Tx (%)/Current biologic Tx (%)	45%/35%

Table 2. Whole spine MRI findings

	N (%) patients
Active Inflammatory Lesions	
≥1 BME corner	22 (23%)
≥1 posterior elements enthesitis	4 (4%)
Structural Lesions	
≥1 corner erosion	10 (10.4%)
≥1 fatty corner	30 (31%)
≥1 syndesmophytes	30 (31%)
Distribution of inflammatory lesions:	
Cervical 2.1%, Thoracic 18.8%, Lumbar 14.6%	
Distribution of structural lesions:	
Cervical 10.4%, Thoracic 32.3%, Lumbar 25%	

Conclusions: In the present PsA cohort, active and structural sacroiliitis was more prevalent vs typical spinal SpA changes. In particular, there was a paucity of SpA changes in the cervical spine. The most prominent axial findings included fatty corners and syndesmophytes. IBP presence and extensive skin disease correlated with SpA axial and SIJ changes.

FRI0680 SYNOVIAL INTENSITY MEASURED BY ULTRASONOGRAPHY AS AN INDICATOR FOR JOINT INFLAMMATION IN RHEUMATOID ARTHRITIS PATIENTS UNDER TREATMENT

Y. Kondo, K. Suzuki, Y. Inoue, K. Sakata, C. Takahashi, M. Takeshita, Y. Kaneko, K. Yamaoka, T. Takeuchi. *Department of Internal Medicine, Division of Rheumatology, Keio University School of Medicine, Shinjuku, Tokyo, Japan*

Background: Ultrasonography (US) is a useful modality that can directly visualize RA joint inflammation. Recently, brightness of thickened synovium is considered to associate with local synovitis. However the accuracy of US findings with the local pathophysiology remains uncertain since synovial biopsy could be heterogeneous depending on the biopsy site and can be influenced by various medications. On another front, synovial fluid (SF) is homogenous, easy to access and contains abundant inflammatory cytokines and growth factors, which play an important role in the local pathogenesis of RA. However, the association between SF proteins and joint US findings is not clear.

Objectives: To clarify whether synovitis detected by US including synovial hypertrophy, vascularity and brightness reflect local joint molecular pathophysiology.

Methods: Forty-four RA patients were recruited. All patients were performed standardized US examination of knee joint. US images were evaluated by semi-quantitative scoring (synovial hypertrophy; grey scale (GS) US, vascularity; power Doppler (PD) US) and quantitative analysis by using Image J (National Institutes of Health, MD, Maryland USA). The average of the pixels of synovial tissue area (GS quant), PD signal area (PD quant) and mean gray values of synovium (Brightness) in 3 areas of the knee joint were calculated. US guided SF aspiration was performed on the same day and concentrations of cytokines and growth factors were measured by Cytometric Beads Array. (BD Biosciences, NJ, USA)

Results: Median age, disease duration and DAS28-ESR were 64 years, 1.5 years and 5.2 respectively. Mean GSUS and PDUS were 2.3 and 2.0. Nineteen patients were untreated. US inflammatory findings especially PD quant were well correlated with corresponding SF IL-6, IL-8, IL-1β and IL-10.(range of rho;0.40–0.72, $p<0.05$) synovial brightness also inversely correlated with SF VEGF (rho=-0.41, $p<0.05$). When we analyzed untreated and treated RA patients separately, GS quant did not correlate with any SF cytokines in treated group although, PD quant and brightness both significantly correlated with SF IL-6 and VEGF ($p<0.05$). Next, we divided the treated patients into 4 groups according to median of brightness and GS quant to compare the SF IL-6 levels. This analysis showed that SF IL-6 levels were influenced by synovial brightness rather than its hypertrophy. ($p<0.05$)

Conclusions: Our results suggest that not only US PD signals but also synovial brightness is a useful indicator for joint inflammation rather than synovial hypertrophy itself in treated RA patients.

FRI0681 **CLINICAL VALIDATION STUDIES OF THE 2012 CLASSIFICATION CRITERIA FOR EARLY RHEUMATOID ARTHRITIS (ERA) IN A DOMESTIC MULTI-CENTER COHORT**

Y. Li[1,2], W. Fan[3], H. Chen[4], P. Yu[5], H. Miao[1], K. Li[3], J. Xu[4], L. Cui[5], G. Zhang[1], K. Xu[1], L. Zhang[1], R. Li[2]. *[1]Shanxi Academy of Medical Sciences Shanxi Dayi Hospital, Taiyuan; [2]Rheumatology and Immunology, Peking University People's Hospital, Beijing; [3]Xinxiang Central Hospital, Xinxiang; [4]the Third Hospital of Hebei Medical University, Shijiazhuang; [5]Kailuan General Hospital, Tangshan, China*

Background: Recently, a new classification criteria for early rheumatoid arthritis (ERA) have been developed.
Objectives: To evaluate the value of 2012 classification criteria for early rheumatoid arthritis (ERA), 2010 ACR/EULAR classification criteria, and 1987 ACR classification criteria in the diagnosis of early RA.
Methods: Early arthritis patients with age more than 16 years, disease duration no more than 1 year, Cat least one joint swelling and tenderness were enrolled in a multicenter, open, cross-sectional study cohort. The patients were diagnosed as RA or other none RA disease by 2 trained experienced rheumatologists. Detailed recorded the clinical and laboratory parameters include disease duration, morning stiffness duration, RF, anti-CCP, ESR, CRP etc.The sensitivity and specificity of three RA classification criteria were compared by McNemar test, The areas under the ROC curve (AUC) of each RA classification criteria were analyzed using MedCalc software.
Results: A total of 310 patients were randomly enrolled in this study, including 182 ERA and 128 non-RA. The sensitivity (88.5%) of ERA criteria were much higher than that of 1987 ACR criteria (45.6%, χ^2=75.013, P<0.0125), and not significantly different with the 2010 ACR/EULAR criteria (91.8%, χ^2=1.042, P>0.05). The specificity of ERA criteria (91.4%) were similar to those of 2010 ACR/EULAR criteria (87.5%, χ^2=1.8, P>0.05) and 1987 ACR criteria (96.1%, χ^2=3.1, P>0.05). The AUC of ERA criteria was 0.962 (95% CI: 0.934, 0.980), which was slightly better than that of the 2010 ACR/EULAR criteria [0.959 (95% CI: 0.931, 0.978), Z=0.380, P=0.7038], and much higher than that of the 1987 ACR criteria [0.885 (95% CI: 0.845, 0.919), Z=4.517, P<0.0001].

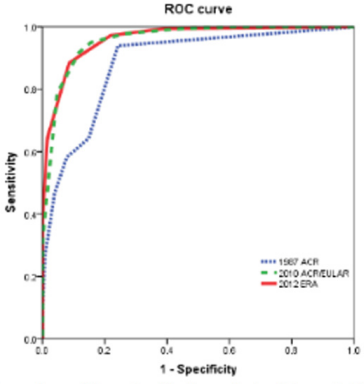

Fig.1 Comparison of three classification criteria of rheumatoid arthritis

Conclusions: Overall evaluation, the diagnostic value of ERA criteria is better than 1987 ACR and 2010 ACR/EULAR criteria in early rheumatoid arthritis. Compared to 2010 ACR/EULAR classification criteria, ERA criteria is obviously more simple and practical.

FRI0682 **FOLLOW-UP OF TREATMENT RESPONSE WITH DYNAMIC DOPPLER ULTRASOUND IN RAYNAUD'SPHENOMENON**

U. Toprak[1], Z. Ozbalkan[2], M. Edugan[3], S. Parlak[4], S.C. Sandıkci[2], T. Kaya[4], S. Saylisoy[5]. *[1]Department of Radiology, Suleyman demirel University, Isparta; [2]Department of Rheumatology, Ankara Numune Education and Research Hospital, Ankara; [3]Department of Rheumatology, Istanbul University, Capa School of Medicine, Istanbul; [4]Department of Radiology, Ankara Numune Education and Research Hospital, Ankara; [5]Department of Radiology, Eskisehir Osmangazi University, School of Medicine, Eskisehir, Turkey*

Background: This study aims to investigate the role of flow parameters obtained by dynamic Doppler ultrasound in the objective follow-up of treatment response in Raynaud's phenomenon (RP) cases.
Methods: The study included newly diagnosed 33 patients with primary RP (PRP), 31 patients with secondary RP (SRP), and 26 healthy controls. The control group was evaluated with Doppler once, while the patients before treatment and on the third month of thet reatment. Baseline and post-cold provocation diameter (BD, CPD, mm) andflowvolume (BFV, CPFV, mL/min); post-coldprovocationflowstarting time (FST, min), and flowv olume normalizing time (FVNT, min) were recorded. Statistical analysis: for disturubution of thes ex of the groups: chi-square test, for analysing age distrubution among the groups One-way ANNOVA; for analysing the pre and post treatment doppler results: Wilcoxon test and fo rcomparison of the PRP and SRP post treatment values to control group; Krusal Wallis test were used. A p value less than 0,05 was considered statistically significant.
Results: Before-after treatment, there was no significant improvement in the BD in both PRP and SRP groups (0.79±0.17–0.82±0.19 vs. 0.66±0.13–0.68±0.14 PRP vs. SRP, respectively), while FST did not significantly improve in the PRP group (1.15±2.27–0.61±1.41 vs 3.13±4.81–1.58±2.36) (p>0.05). A significant improvement was observed in baseline flow volüme (3.08±2,96 vs 3.91±3.39 (p: 0,002),flow volume normalization time (7.24±7.60 vs 3.84±3.39) (p: 0,0001), after cold provocation flow volume (1.18±1,26 vs 2.17±2.16) (p: 0,0001), after cold provocated diameter (0.63±0.15 vs 0.70±0.16) (p: 0,005) in PRP group after treatment.
In SRP group, only baselined iameter changes were not influenced by the treatment, all other post treatmen tparameters were impoved in all SRP cases including baseline flow volume (2.14±1.94 vs 2.80±2.15) (p:0,009), after cold provocation diameter (0.56±0.15 vs 0.63±0.13) (p: 0.004), after cold provocation flow volume (1.07±1.40 vs 1.46±1.67) (p: 0,004), flow starting time (3.13±4.81 vs 1.58±2.36) (p: 0,021) and flow volume normalisation time (9.58±8.49 vs 4.32±3.56) (p: 0,0001).
There was an improvement in parameters after the treatment in both RP groups comparing by the control groups (p<0.01).
Conclusions: Doppler ultrasound is an objective, cost-effective, safe (does not include radiation), and easy-to-use method in thefollow-up of RP patients on macrovascular level with or without cold provocation before and after treatment.

Epidemiology, risk factors for disease or disease progression

FRI0683 **CAUSES OF DEATH IN 350 PATIENTS WITH SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES (SARD)**

J.G. Ovalles-Bonilla[1,2], O. Fernández[3], J. Martínez-Barrio[1], L. Valor[1,2], D. Hernández[1,2], I. Janta[1], B. Serrano[1], C. Sáenz[1], R. González[1], M. Correyero[1], L. García[1], A. López[1], A. Silva[1], J.C. Nieto[1], C. González[1,4], I. Monteagudo[1], F.J. López-Longo[1,4]. *[1]Rheumatology, Hospital General Universitario Gregorio Marañón; [2]Instituto de Investigación Sanitaria Gregorio Marañón, Madrid; [3]Rheumatology, Hospital Universitario de Basurto, Bilbao; [4]Facultad de Medicina, Universidad Complutense de Madrid, Madrid, Spain*

Background: The major SARD have an increased mortality compared to the general population. It is well known that the main causes of death in Systemic Lupus Erythematosus (SLE) are infections (INF), cardiovascular events (CV), neoplasia

(NEO) and disease activity. However, the compared mortality of Mixed Connective Tissue Disease (MCTD), Systemic Sclerosis (SSc), Poly/Dermatomyositis (PM/DM), overlap syndromes (OS), Sjögren's syndrome (SS), Antiphospholipid syndrome (APS), systemic vasculitis (SV), and undifferentiated or incomplete Connective Tissue Disease (UCTD) is poorly described.
Objectives: To analyze the causes of death and the autoantibodies (AAB) profile among the SARD.
Methods: This was a single center, prospective and observational study. Mortality by all causes and relationship with AAB profile were analyzed in patients diagnosed of SLE, MCTD, SSc, PM/DM, OS (simultaneous or sequential criteria of 2 or more SARD), SS, APS, SV and UCTD or incomplete SARD (at least one clinical criterion of the classification criteria and a related antibody of any of the SARD). Data were obtained from the "Systemic Autoimmune Rheumatic Diseases Registry" of a tertiary referral hospital from 1986 to 2016. Patients with rheumatoid arthritis were excluded. The SARD registry counts with the institutional review board approval.
Results: 1750 patients were included, of whom 1453 (83%) were women. Five hundred fifty six SLE, 125 SSc, 111 PM/DM, 91 OS, 90 MCTD, 250 SS, 71 APS, 211 SV, 117 UCTD and 128 losses to follow-up, the global follow up rate was 92.7%. A global mortality of 350 (20%) cases was observed: 101 INF (28,8%), 89 CV (25,4%), 51 NEO (14,5%), 45 due to disease activity (12,8%), 41 other causes (11,7%) and 23 from unknown causes (6,5%). Table 1 shows detailed mortality causes compared by diseases. A higher mortality was associated ($p<0,05$) with older patients (71 years, 20–96), SV (OR 3,65), male patients (OR 1,95), SSC/PM/DM (OR 1,76), MCTD (OR 1,6) and OS (OR 1,43). AAB to pANCA (OR 4,43), anti-topoisomerase I (OR 3,64), myositis-specific AAB (OR 3.0), cANCA (OR 2,19) and anticardiolipin (OR 1,89) were associated with poorer survival. A higher survival rate was observed in patients with SLE (OR 1,7), SS (OR 1,69) and UCTD (OR 15,57) ($p<0,05$).

CAUSES	SLE, %	SSC, %	MCTD, %	SV, %	PM/DM, %	OS, %	SS, %	APS, %
CV	**30,86**	**27,02**	**42,3**	25,55	18,18	16,12	17,64	21,4
INF	27,16	21,62	3,84	**36,66**	**33,33**	**45,16**	23,52	21,4
NEO	14,81	13,51	15,38	8,88	18,18	9,67	**26,47**	14,28
ACTIVITY	9,87	18,91	19,23	11,11	12,12	19,35	11,76	**28,57**
OTHER	8,64	13,51	11,53	15,55	9,09	3,22	8,82	0.00
UNKNOWN	8,64	5,40	7,69	2,22	9,09	6,45	11,76	14,28

Conclusions: The main causes of death among SARD patients are CV (MCTD, SLE, and SSC), severe infections (OS, SV, and PM/DM), disease activity (APS) and neoplasia (SS). A higher mortality is observed among ANCA positive SV, anti-topoisomerase I positive SSC, MCTD, OS, anticardiolipin and myositis-specific positive patients.

FRI0684 EARLY TREATMENT WITH METHOTREXATE IMPROVES ALL-CAUSE AND CARDIOVASCULAR SURVIVAL AMONG AN INCEPTION COHORT OF SENIORS WITH RHEUMATOID ARTHRITIS

J. Widdifield[1], J.M. Paterson[2], A. Huang[2], S. Bernatsky[1] on behalf of CANAIM.
[1]Mcgill University, Montreal; [2]Institute for Clinical Evaluative Sciences, Toronto, Canada

Background: We previously observed that incident RA patients have an increased risk of all-cause and cardiovascular disease (CVD) mortality relative to the general population in Ontario.[1]
Objectives: To evaluate the effect of treatment and other factors on all-cause and CVD mortality among incident senior RA patients.
Methods: We studied incident RA patients within the population-based Ontario Rheumatoid Arthritis Database (ORAD) who were diagnosed after their 65th birthdate (ensuring comprehensive drug coverage) between 2000 and 2013. Patients are included in ORAD if they received 3 physician billing RA diagnosis codes (with at least one provided by a MSK specialist) over 2 yrs OR at least 1 hospital RA diagnosis code. All patients were followed from cohort entry (when all case definition criteria were met) until death, out-migration, or end of study period (Dec 2013). Two multivariable Cox regression models were performed to estimate hazard ratios (HRs) for each outcome (all-cause and CVD mortality, separately), exploring the effects of both baseline/early treatment (within the year preceding index date) and time-varying medication exposures over the entire duration of follow-up (for methotrexate, other DMARDs, anti-TNFs, COXIBS, NSAIDs, glucocorticosteroids, statins, antihypertensives), baseline comorbidities (within 3 yrs prior to index date), time-varying development of extra-articular manifestations (as proxy for disease severity), healthcare use, and demographics (age, sex, rurality, SES).
Results: 28,172 incident RA patients were followed for 141,072 person years. During follow-up, 8,848 (31%) patients died with 1,419 (5%) deaths due to CVD, corresponding to an all-cause rate of 62.7 deaths (95% CI 61.4,64.0), and 10.1 deaths due to CVD (95% CI 9.5,10.6) per 1,000 patient-years, respectively. In our multivariable analysis focused on all-cause mortality, early treatment with methotrexate [HR 0.90 (95% CI 0.85,0.96)] and other DMARDs [HR 0.92 (95% CI 0.87,0.97)] were associated with a lower mortality risk. For CVD mortality, early treatment with methotrexate was associated with lower risk estimates [HR 0.71 (95% CI 0.60,0.83)], which was not clearly seen with other DMARDs [HR 0.94 (95% CI 0.82, 1.08)]. Use of COX-II inhibitors and NSAIDs at baseline were associated with lower HR for all-cause and CVD mortality risk, though we were unable to detect clear associations with greater use during follow-up. Greater cumulative exposure to glucocorticosteroids, comorbidities, and extra-articular manifestations of RA were associated with increasing risk of all-cause and CVD mortality.
Conclusions: Patients with early exposure to methotrexate had a lower risk of all-cause and CVD mortality. Our findings support the hypothesis that early treatment, by reducing inflammation, may help improve survival in RA. However, residual confounding cannot be ruled out.

FRI0685 THE PRESENCE OF RHEUMATOID FACTOR IS ASSOCIATED WITH LOWER BONE MASS IN KOREAN HEALTH SCREENING MALE SUBJECTS WITHOUT CLINICALLY APPARENT ARTHRITIS

J. Hwang[1], J.K. Ahn[2], Y.H. Eun[3], E.-J. Park[4], J. Lee[3], E.-M. Koh[3], H.-S. Cha[3].
[1]Department of Internal Medicine, National Police Hospital; [2]Department of Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine; [3]Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul; [4]Department of Medicine, Jeju National University Hospital, Jeju, Korea, Republic Of

Background: Close relationship between the immune and skeletal systems has been recognized through the bone loss in rheumatoid arthritis (RA). Rheumatoid factor (RF) is present in approximately 70–80% of RA patients, which is an autoantibody directed against the Fc component of IgG and associated with osteoporosis and reduced bone mineral density (BMD) in RA. RF is also found nonspecifically in chronic inflammatory condition such as sarcoidosis, hepatitis B or C, and tuberculosis. However, the influence of RF to bone loss is scarcely known in subjects without any specific medical problem.
Objectives: This cross-sectional study aimed to investigate the association between the presence of RF and BMD in Korean healthy male subjects without any history of joint disease.
Methods: Of the 84,344 males who had undergone a comprehensive health checkup program in 2012, 1,390 healthy subjects were recruited, whose BMD and RF results were available. Subjects with history of diabetes, kidney disease, thyroid disease, and malignancy, and taking medicine regarding these diseases, osteoporosis, and arthritis were excluded based on self-reported questionnaire. The RF titer $\geq$20 IU/ml was considered positive. BMD was categorized into 3 groups based on T-score; normal (T-score $\geq$ -1.0), osteopenia (-1.0 $>$ T-score $>$ -2.5) and osteoporosis (T-score $\leq$ -2.5). The association between the presence of RF and BMD was assessed by multiple linear regression analysis.
Results: Of 1,390 males, the mean age was 52.8±10.9 years (range, 22 – 83) and RF was positive in 64 subjects (4.6%). Demographics including smoking history, alcohol consumption, the frequency of vigorous exercise and body mass index (BMI), and laboratory data were not different between RF-positive and –negative subjects except hepatitis B surface antigen, which was more frequently seen in RF-positive subjects (15.6% vs. 4.3%, p =0.001). Low bone mass (osteopenia and osteoporosis) of lumbar spine was more prevalent in subjects aged 50 or more compared with those younger than 50 years (28.0% vs. 10.7%, p $<$0.001) while no differences of femur neck and total hip. RF-positive subjects had significantly lower BMD compared to RF-negative subjects in lumbar spine (1.10±0.18 g/cm^{2}vs. 1.17±0.16 g/cm^2, p =0.002) but neither in femur neck nor total hip. In subjects with higher titer RF ($\geq$40 IU/ml), the mean BMD of lumbar spine was significantly decreased than those with lower titer RF (one-way ANOVA, F(3, 1190) =3.527, p =0.015). After adjusting for multiple confounders such as age, BMI, glomerular filtration rate, serum concentration of calcium, phosphorus, and uric acid, and lifestyle factors (drinking, smoking, and physical exercise), RF positivity was negatively associated with BMD at lumbar spine (B = -0.055 and SE =0.027, p =0.039).
Conclusions: Our results provide epidemiological evidence that the presence of RF could have an unfavorable impact on bone density in apparently healthy male subjects. Additional studies to elucidate the osteoimmunological mechanism of RF are warranted.

FRI0686 NEGATIVE ASSOCIATIONS FOR FASTING BLOOD GLUCOSE, CHOLESTEROL AND TRIGLYCERIDE LEVELS WITH THE DEVELOPMENT OF GIANT CELL ARTERITIS

K. Jakobsson[1,2], L.T. Jacobsson[1,3], A.J. Mohammad[4,5], K.J. Warrington[6], E.L. Matteson[6], C. Turesson[1,2]. *[1]Department of Clinical Sciences, Malmö, Lunds University; [2]Department of Rheumatology, Skåne University Hospital, Malmö; [3]Department of Rheumatology & Inflammation Research, The Sahlgrenska Academy, University of Gothenburg, Institute of Medicine, Gothenburg; [4]Department of Rheumatology, Skåne University Hospital, Lund, Sweden; [5]Vasculitis and Lupus Clinic, Addenbrooke's Hospital, Cambridge, United Kingdom; [6]Division of Rheumatology, Mayo Clinic College of Medicine and Science, Rochester, Minnesota, United States*

Background: Giant cell arteritis (GCA) is the most common vasculitis among patients age >50 years in north European countries. Although ethnic factors and age clearly play a role, the etiology of the disease is largely unknown. Studies of predictors are therefore of major interest. A meta-analysis of observational studies demonstrated that patients with GCA have a significantly reduced prevalence of diabetes at the time of diagnosis (1).
Objectives: To investigate metabolic features prior to diagnosis of GCA in a nested case-control study.
Methods: Individuals who developed GCA after inclusion in a population-based health survey (the Malmö Preventive Medicine Project; N=33346) were identified by linking the health survey database to the local patient administrative register and the national patient register. A structured review of medical records was performed. Four controls for every validated case, matched for sex, year of birth and year of screening, were selected from the database. Fasting blood samples had been obtained and analyzed using standard methods as part of the health survey. Potential predictors of GCA were examined in conditional logistic regression models.
Results: There were 76 cases with a confirmed clinical diagnosis of GCA (61% female; 65% biopsy positive; 95% fulfilled the ACR criteria for GCA). The mean age at diagnosis was 70 years, and the median time from screening to diagnosis was 20 years (range 2–32). The cases had significantly lower fasting blood glucose (fB-glucose) at baseline screening compared to controls [mean 4.7 vs 5.1 mmol/l, odds ratio (OR) 0.49 per mmol/l; 95% confidence interval (CI) 0.30–0.79]. Current smokers had a reduced risk of GCA (OR 0.35; 95% CI 0.18–0.70). The negative association between baseline fB-glucose and GCA remained significant in analysis adjusted for smoking (OR 0.46 per mmol/l; 95% CI 0.28–0.76). Both cholesterol (mean 5.6 vs 6.0 mmol/l) and triglyceride levels (median 1.0 vs 1.2 mmol/l) were lower among the cases at baseline screening, with significant negative associations with subsequent GCA in crude and smoking-adjusted (ORs with 95% CIs 0.66 per mmol/l; 0.46–0.94 for cholesterol, 0.33 per mmol/l; 0.16–0.69 for triglycerides) models. The effect of fB-glucose on the risk of GCA was stronger in men compared to women (smoking-adjusted ORs per mmol/l 0.11; 95% CI 0.03–0.37, and 0.77; 95% CI 0.50–1.18, respectively). Apart from this, results were similar in women and men.
Conclusions: Development of GCA was associated with lower fB-glucose, lower cholesterol and triglyceride levels at baseline, all adjusted for current smoking. These findings are in line with the previous findings of a reduced prevalence of diabetes mellitus at the time of diagnosis of GCA (1). This suggests that metabolic factors influence the development of GCA.

FRI0687 BODY MASS INDEX, SMOKING, SOCIOECONOMIC STATUS AND THE RISK OF GIANT CELL ARTERITIS

K. Jakobsson[1,2], L.T. Jacobsson[1,3], A.J. Mohammad[4,5], K.J. Warrington[6], E.L. Matteson[6], C. Turesson[1,2]. *[1]Department of Clinical Sciences, Lunds University; [2]Department of Rheumatology, Skåne University Hospital, Malmö; [3]Department of Rheumatology & Inflammation Research, The Sahlgrenska Academy, University of Gothenburg, Institute of Medicine, Gothenburg; [4]Department of Rheumatology, Skåne University Hospital, Lund, Sweden; [5]Vasculitis and Lupus Clinic, Addenbrooke's Hospital, Cambridge, United Kingdom; [6]Division of Rheumatology, Mayo Clinic College of Medicine and Science, Rochester, Minnesota, United States*

Background: Few studies have examined predictors of giant cell arteritis (GCA). A negative association between body mass index (BMI) and development of GCA has been reported (1, 2). There is limited information on the impact of smoking and socioeconomic factors on the risk of GCA.
Objectives: To further investigate the relation between BMI and GCA, and also assess the role of smoking and socioeconomic factors in this context.
Methods: Two population based health-surveys, The Malmö Preventive Medicine Program (MPMP) and the Malmö Diet Cancer Study (MDCS), performed in the same catchment area between 1974 and 1996. In the MPMP, 33346 subjects (33% women), and in the MDCS, 30447 subjects (60% women) were included. Both surveys included standard physical examinations and self-administered questionnaires. Subjects were classified as blue-collar workers or white-collar workers, using the Socioeconomic Index (SEI) based on self-reported job titles in the Swedish national censuses.
Individuals who developed GCA after inclusion in the two health surveys were identified by linking the health survey databases to local and national patient registers. A structured review of the medical records was performed. Four controls for every validated case, matched for sex, year of birth and year of screening, were selected from the corresponding databases. Potential predictors of GCA were examined in conditional logistic regression models. This is an extension of a previous study, adding more incident cases (2).
Results: A total of 138 cases with a confirmed clinical diagnosis of GCA (median age at diagnosis 71 years; 72% female; 66% biopsy-positive; 94% fulfilled the ACR criteria for GCA) were included. The median time from screening to diagnosis was 15 years (range 0–32).
The cases who subsequently developed GCA had significantly lower BMI at baseline (24.3 vs 25.3 kg/m^2, odds ratio (OR) 0.91 per kg/m^2; 95% confidence interval (CI) 0.86–0.97) and were less likely to be current smokers when entering the health survey (OR 0.56; 95% CI 0.33–0.94). There was no difference in the proportion with low level of formal education between cases and controls (OR 1.27; 95% CI 0.66–2.44). Blue-collar workers tended to be less likely to develop GCA than white-collar workers (OR 0.53; 95% CI 0.28–1.00). This association reached statistical significance in women (OR 0.32; 95% CI 0.13–0.81) but not in men (OR 0.87; 95% CI 0.35–2.16). In multivariate analysis, including both variables and the SEI, the impact of BMI (OR 0.85; 95% CI 0.74–0.96) and smoking (OR 0.26; 95% CI 0.12–0.60) remained significant.
Conclusions: In this study, the negative association between BMI and subsequent GCA was confirmed, and there was an independent protective effect of smoking. Socioeconomic status, reflected by occupation later in life rather than level of formal education, may also influence the risk of developing GCA.

FRI0688 PRERA (PREDICTING RHEUMATOID ARTHRITIS): PRELIMINARY FINDINGS FROM AN ON-GOING PROSPECTIVE STUDY OF SEROPOSITIVE AND SERONEGATIVE INDIVIDUALS AND THEIR RISK FOR DEVELOPING RA

M. Mayr[1], M. Hucke[1], V. Nell-Duxneuer[1], T. Stamm[1], G. Steiner[1], T. Perkmann[1], E. Hitzelhammer[2], J. Smolen[1], K. Machold[1], H. Radner[1]. *[1]Rheumatology, Medical University of Vienna; [2]Health Centers of The Vienna General Health Insurance, Wien, Austria*

Background: A characteristic feature of RA is the presence of autoantibodies (AAB), such as rheumatoid factor (RF) and antibodies against citrullinated peptides (ACPA). RF and ACPA are not only diagnostically helpful but are also prognostic indicators for progression of joint destruction.
Objectives: This is an on-going prospective study to investigate the prevalence of AAB in healthy individuals presenting to community health centres and to subsequently determine the incidence of RA in AAB-positive individuals compared to AAB-negative persons over five years considering the presence of certain risk factors.
Methods: Blood drawn at the time of the screening examination was anonymously analyzed for the presence of AAB. AAB positive and age and sex matched AAB negative individuals (2 for each AAB positive subject) were enrolled for further assessment at the central outpatient clinic and examined every 6 months over 5 years. Assessment included laboratory testing (AAB, acute phase parameters), questionnaires on nutrition, lifestyle and general health, 28 joint counts (SJC28, TJC28), the health assessment questionnaire (HAQ), and visual analogue scales for pain and global health. Risk factors were analysed by clusters according to EULAR recommendations for terminology of individuals at risk of RA: hereditary, environmental, systemic autoimmunity and unclassified arthritis and the number of clusters per individual was reported at baseline (1). The primary outcome was the development of RA; individuals lost to follow up were telephone-interviewed for signs and symptoms of RA.
Results: 4858 sera were obtained from which 148 (3%) were seropositive (14 ACPA, 124 RF, 10 both). 113 individuals (2,3%) were followed over 5 years. 37 (32,7%) were seropositive of whom 32 (28,3%) were RF-positive, 2 (5,4%) were ACPA-positive and 3 (8,1%) positive for both. We found no significant differences in demographics and risk factors between seropositive and seronegative individuals at baseline (Table 1). The number of risk clusters per individuals is reported in

Risk Factors		Seronegative (*n*=76)	Seropositive (*n*=37)
Age		54,8 (±12,3)	57,6 (±10,3)
Genetic	Sex (% female)	50 (66%)	23 (62%)
	Family history	11 (14%)	3 (8%)
Environmental	Smoking	20 (26%)	8 (22%)
	BMI >25kg/m^2	37 (49%)	14 (38%)
	Low education	20 (29%)	16 (49%)
Unclassified Arthritis	SJC28	0 (0–2)	0 (0–2)
	TJC28	0 (0–2)	0 (0–3)
	Patient Global	8,9 (±16,8)	5,1 (±10,7)
	HAQ	0,07 (±0,17)	0,05 (±0,15)
	hsCRP	0,29 (±0,46)	0,21 (±0,27)

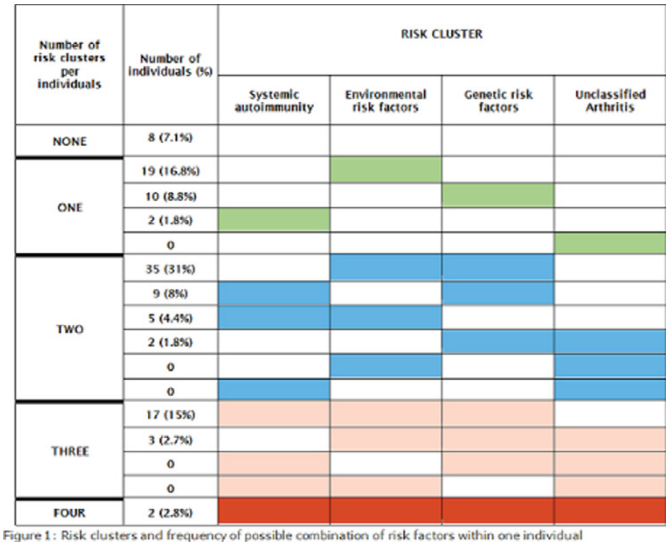

Figure 1: Risk clusters and frequency of possible combination of risk factors within one individual

figure 1. Until now, 43 people were followed for 5 years; additional 52 telephone interviews were conducted. No evidence of RA (clinically or by history) was found.
Conclusions: By now none of the followed individuals had any evidence of inflammatory joint disease based on patient-telephone interviews conducted and completed 5-year follow-up examinations. We were unable to find evidence for practical value of routine AAB screening in healthy individuals without clinical signs of inflammatory joint diseases.

FRI0689 LIPID PEROXIDATION AS RISK FACTOR FOR ENDOTHELIAL DYSFUNCTION IN ANTIPHOSPHOLIPID SYNDROME (APS) PATIENTS

L. Stojanovich, N. Stanisavljevic, A. Djokovic, M. Zdravkovic. *Internal medicine department, University Hospital Center Bezanijska Kosa, Belgrade, Serbia*

Background: APS pathophysiology is not clear enough yet since it has been implicated that aPL can activate cells (endothelial cells, monocytes, platelets), interfere with hemostatic reactions and activate complement reactions [1,2].
Objectives: The aim of this study was to evaluate oxidative stress markers and it relations to endothelial damage as risk factor for thrombosis in patients with primary (PAPS) and secondary (SAPS) antiphospholipid syndrome (APS) in correlation to traditional risk factors.
Methods: Flow mediated (FMD) and nitroglycerine (NMD) induced dilation of the brachial artery were studied in 140 APS patients (90 PAPS, 50 SAPS) and 40 controls matched by age, sex and conventional risk factors for atherosclerosis. Markers of oxidative stress: lipid hydroperoxydes (LOOH), advanced oxidation protein products (AOPP), total sulfhydryl grups (tSHG) and paraoxonase 1 activity (PON1) were determined by spectrophotometric method.
Results: Oxidative stress dominate in APS patients. LOOH and AOPP correlate to lipid fractions ($p<0.05$), unlike PON1, tSHG that correlated to antiphospholipid antibody positivity ($p<0.05$). FMD was lower in APS patients comparing to controls ($p<0.001$). Cholesterol is independent variable for FMD impairment in control group (p=0.011); LOOH in PAPS (p=0.004); LOOH, aCL and triglycerides in SAPS patients (p=0.009, p=0.049 and p=0.012, respectively).Combined predictive of aCL and LOOH is better for FMD impairment than LOOH alone in both PAPS and SAPS patients (AUC 0.727, p=0.001, 95% CI 0.616–0.837 and AUC 0.824, $p<0.001$, 95% CI 0.690–0.957, repectively).
Conclusions: Endothelial dysfunction is doubtlessly present in APS patients with oxidative imbalance as additional risk factor among other risk factors for clinical event. Anticardiolipin antibodies affect endothelial dependent vasodilatation in SAPS patients. We demonstrated synergistic effect of aCL and LOOH as risk for endothelial impairment in both PAPS and SAPS patients.

FRI0690 RISK OF FRACTURE AMONG PATIENTS WITH GOUT: A POPULATION-BASED COHORT STUDY

A. Abdul Sultan[1], R. Whittle[1], S. Muller[1], E. Roddy[1,2], C. Mallen[1], M. Blagojevic-Bucknall[1], T. Helliwell[1], S. Hider[1,2], Z. Paskins[1,2]. *[1]Research Institute for Primary Care & Health Sciences, Keele University, Staffordshire; [2]Haywood Academic Rheumatology Centre, Staffordshire and Stoke-on-Trent Partnership Trust, Stoke-on-Trent, United Kingdom*

Background: Gout is the most common type of inflammatory arthritis, affecting 2.4% of adults in the UK and is associated with a number of co-morbidities. Our understanding of the association between gout and fracture risk is limited with previous studies offering conflicting results.
Objectives: To determine the risk of fracture among gout patients and assess the potential impact of urate-lowering therapy (ULT) on fracture risk.
Methods: Utilising primary care records from Clinical Practice Research Datalink we identified patients with gout between 1990 and 2004 who were followed up until 2015. Each gout patient was individually matched to 5 individuals without gout based on age, sex, and registered practice. Absolute rate (AR) of fracture and hazard ratios (HR) were calculated using Cox regression models. We further stratified our analysis by age, gender and ULT prescription.
Results: We matched 35,857 patients with incident gout to 148,407 controls. Overall, we found no increased risk of fracture among gout patients compared to controls. However, men with no evidence of ULT had higher absolute risk of fracture compared to controls (AR=39 versus 26 per 10,000 person-years) corresponding to a 23% (HR=1.23; 95% CI 1.12–1.36) increased risk. The risk was particularly high for vertebral (HR=1.50; 95% CI 1.20–1.87) and wrist fracture (HR=1.45; 95% CI 1.21–1.74). Those treated with ULT had a 12% (HR=0.88; 95% CI 0.79–0.98) lower risk of fracture. Similar findings were not observed for women.
Conclusions: We found higher risk of vertebral and wrist fractures among men with gout not prescribed ULT. Those prescribed ULT had lower risk of fracture compared to the general population. Further research is needed to understand the role of ULT in fracture prevention.

FRI0691 ASSOCIATION BETWEEN PERIODONTITIS AND THE RISK OF PALINDROMIC RHEUMATISM: A NATIONWIDE, POPULATION-BASED, CASE-CONTROL STUDY

H.-H. Chen[1], W.-C. Chao[1], Y.-M. Chen[1], D.-Y. Chen[2]. *[1]Department of Medical Research; [2]Department of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan, Province of China*

Background: Some patients with palindromic rheumatism (PR) may develop a chronic connective tissue disease, mainly rheumatoid arthritis (RA). About one to two-thirds of PR patients developed RA during a period of follow-up. Periodontitis (PD) has been found to be associated with RA risk. However, the association between PD and PR risk is unknown.
Objectives: To estimate the association between a history of PD and the risk of incident PR.
Methods: This study used a nationwide, administrative database to identify PR cases and non-PR controls. After exclusion of individuals with rheumatoid arthritis, systemic lupus erythematosus, Sjögren's syndrome, systemic sclerosis, dermatomyositis or polymyositis before the first PR diagnosis date (index date), we identified 4,421 newly-diagnosed PR cases from 2007 to 2012 and randomly selected 44,210 non-PR controls matched (1:10) for sex, age, and the year of the index date. After adjusting for comorbid diabetes mellitus, we estimated odds ratios (ORs) with 95% confidence intervals (CIs) by conditional logistic regression analysis to quantify the association between a history of PD and the risk of PR. The influences of the lag time and severity of PD were examined by calculating ORs for subgroups of patients based on time interval between the last PD-related visit and the index date and PD-related cumulative cost and visit number.
Results: This study showed an association between a history of PD and newly diagnosed PR (OR, 1.51; 95% CI, 1.41–1.61). The association remained significant after variation of PD definitions. The magnitude of the association was

Table 1. Univariable and multivariable conditional logistic regression analyses for the association between periodontitis defined by various definitions and the risk of palindromic rheumatism

	Univariable OR (95% CI)	Multivariable OR (95% CI)
Various periodontitis exposure definitions		
Periodontitis (ICD9: 523.3–5)	1.50 (1.41–1.60)	1.51 (1.41–1.61)
Chronic periodontitis (ICD9: 523.4)	1.36 (1.20–1.54)	1.37 (1.21–1.55)
Acute or chronic periodontitis (ICD9: 523.3–4)	1.56 (1.46–1.67)	1.57 (1.46–1.68)
Gingival and periodontal diseases (ICD9: 523)	1.56 (1.46–1.66)	1.56 (1.47–1.67)

greater in those who had shorter lag time between the last date of PD diagnosis and PR index date and those who had a higher number of visits for PD or greater cumulative cost of PD-related visits.

Conclusions: This study demonstrated a time- and dose-dependent association between PD exposure and PR risk.

FRI0692 ALLOPURINOL AND THE RISK OF VENTRICULAR ARRHYTHMIAS IN THE ELDERLY: A STUDY USING U.S. MEDICARE DATA

J. Singh, J. Cleveland. *University of Alabama at Birmingham, Birmingham, United States*

Background: Recent studies have shown that hyperuricemia and gout, a condition with hyperuricemia associated with joint inflammation and/or renal manifestations, are associated with a higher risk of coronary artery disease (CAD), acute cardiovascular events including myocardial infarction (MI) and stroke, and cardiovascular mortality. Emerging data suggest that gout and hyperuricemia may also be associated with cardiac arrhythmias such as atrial fibrillation

Objectives: To assess whether allopurinol use is associated with a reduction in the risk of ventricular arrhythmias (VA).

Methods: We used the 5% random sample of Medicare beneficiaries from 2006–2012 to examine new allopurinol use and the risk of incident VA. Multivariable Cox regression analyses were adjusted for demographics (age, race, gender), comorbidity, cardiac medications and conditions associated with VA. We calculated hazard ratios (HR) and 95% confidence intervals (CI).

Results: Of the 28,755 episodes of new allopurinol use, 2,538 were associated with incident VA (8.8%). Among patients with incident VA, 54% were male, 78% were White, and the mean Charlson-Romano comorbidity score was 4.8. The crude incidence of VA per 1,000,000 person-days declined as the duration of allopurinol use increased: 1–180 days, 151; 181 days-2 years, 105; and >2 years, 85. In multivariable-adjusted analyses, compared to non-use, allopurinol use was associated with lower HR of VA of 0.82 (95% CI, 0.76 to 0.90). Compared to allopurinol non-use, longer allopurinol use durations were significantly associated with lower multivariable-adjusted HR for VA: 1–180 days, 0.96 (95% CI, 0.85 to 1.08); 181 days to 2 years, 0.76 (95% CI, 0.68 to 0.85); and >2 years, 0.72 (95% CI, 0.60 to 0.87). Multiple sensitivity analyses adjusting for cardiac conditions, anti-arrhythmic drugs and alternate definitions confirmed our findings with minimal/no attenuation of estimates.

Conclusions: Allopurinol use and use duration >6 months were independently associated with a lower risk of VA. Future studies need to assess the pathophysiology of this potential benefit.

FRI0693 SYNOVIAL CHANGES DETECTED BY ULTRASONOGRAPHY AND THEIR ASSOCIATION WITH OSTEOARTHRITIS-RELATED KNEE PAIN: A 1-YEAR PROSPECTIVE COHORT STUDY

A. Sarmanova[1,2], M. Hall[2,3], G.S. Fernandes[1,4], A.M. Valdes[1,2], D.A. Walsh[1,2], M. Doherty[1,2], W. Zhang[1,2]. *[1]Division of Rheumatology, Orthopaedics and Dermatology, The University of Nottingham; [2]Pain Centre, Arthritis Research UK; [3]School of Health Sciences, The University of Nottingham; [4]Centre for Sports, Exercise and Osteoarthritis, Arthritis Research UK, Nottingham, United Kingdom*

Background: Recently an important role for synovial pathology in the initiation and progression of knee osteoarthritis (OA) has been emphasised. Our previous cross-sectional study showed that synovial changes on US associated with knee pain (KP), but the association was confounded by radiographic severity [1]

Objectives: To examine whether these synovial changes associate with KP changes over 1 year.

Methods: 220 participants with early KP (<3yrs duration) identified from the Knee Pain and Related Health in the Community (KPIC, n=9514) survey in Nottingham, UK formed the cohort for this study. All participants had bilateral US and radiographic examination at baseline, and US was repeated after 1 year. KP was defined as pain in or around the knee on most days for at least a month, and KP severity was measured using a numerical rating scale (NRS 0–10). Change in KP severity was defined according to a Patient Global Impression of Change. Synovial changes (effusion, hypertrophy and Power Doppler (PD) signal) were measured by two observers (inter-observer concordance correlation was 0.8 (0.6 to 0.9) for effusion and 0.7 (0.5 to 0.9) for synovial hypertrophy). Standardised radiographs (semi-flexed weight-bearing and flexed skyline views) were scored using the Nottingham Line Drawing Atlas (NLDA). Radiographic OA was defined as definite joint space narrowing (grade 2) plus definite osteophyte (grade 2) in any compartment. An absolute change in effusion/synovial thickness/pain scores was calculated by subtracting the baseline measure from the follow-up measure within individuals. A correlation analysis was used to examine the association between changes in pain and changes in US values. Potential baseline predictors for KP worsening were examined using multivariate logistic regression analysis.

Results: Of 220 participants in this cohort, 165 (75%) had US measurements at baseline and follow-up (mean age 61yrs; 61% women; 24% ROA). The mean NRS score decreased from 4.44 to 3.01 mm. The mean depth of the effusion and synovial hypertrophy changed from 4.01 mm to 5.37 mm, and from 1.82 to 2.45 mm, respectively. There was no correlation between changes in pain on NRS and changes in US-detected synovial change (Figure 1).

At 1 year follow-up, 58% reported that their KP had improved from baseline, 16% reported worsening, and 27% reported no change in KP. After adjustment for age, gender and BMI baseline US features did not predict worsening pain, whereas ROA did (OR=4.06 95% CI 1.55 to 10.61).

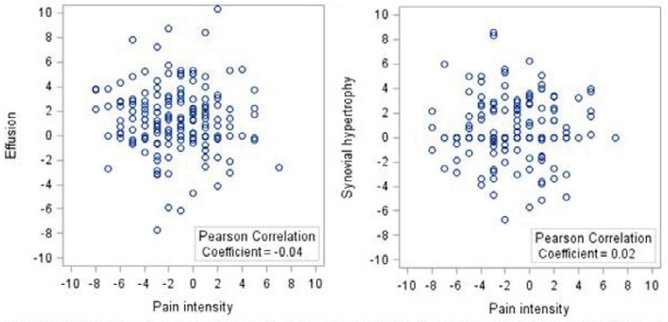

Figure 1. Correlation between changes from baseline in US features (in mm) and knee pain intensity (NRS 0-10)

Conclusions: This cohort study showed that US-detected knee "synovitis" was not a predictor of change in OA symptoms, whereas baseline radiographic OA severity was. It suggests that synovial changes detected by US might reflect aspects of OA pathology discrete from mechanisms driving OA pain change.

FRI0694 PREVALENCE OF RHEUMATIC DISEASE IN AN ADULT POPULATION FROM COLOMBIA. A COPCORD METHODOLOGY STUDY

A.M. Santos[1], J.C. Rueda[1], J.-I. Angarita[1], R. Giraldo[1], E. Forero[2], I. Pelaez-Ballestas[3], J.G. Ballesteros Muñoz[4], E.-L. Saldarriaga[1], J. Ramirez[5], C. Toro[5], J. Londono[6]. *[1]Reumatología, Universidad de la Sabana, Chia; [2]Medicina Interna, Reumatología, Universidad del Norte, Barranquilla, Colombia; [3]Departamento de Reumatología, Hospital General de México, Ciudad de México, Mexico; [4]Departamento de Medicina Interna, Hospital San José; [5]Asociación Colombiana de Reumatología; [6]Reumatología, Universidad de la Sabana-Hospital Militar Central, Bogotá, Colombia*

Background: Rheumatic diseases are the leading cause of permanent disability. In our country are the fourth cause of consultation in health institutions. The COPCORD model constitutes an effective tool in the determination of the prevalence of diseases. Globally, this model has been carried out in Asia, Europe and in some countries of Latin America. In Colombia the epidemiology of rheumatic diseases is not known globally; this would be the first national study that uses the data collection questionnaire using the COPCORD instrument

Objectives: To estimate the prevalence of rheumatic disease and related factors in a Colombian population over 18 years of age in six Colombian cities
Methods: A Cross-sectional analytical study was designed in people older than 18 years. A probabilistic stratified sampling method using three stages. The first stage of sampling was the selection of cartographic sectors in each city. The second stage of sampling was the blocks of each sector. The third stage of sampling was the homes of each block. All household members were surveyed. The sample size was calculated to be 6,528 people (2336 from Bogotá, 1220 from Medellín and Cali each, 746 from Barranquilla, 503 from Bucaramanga and Cúcuta each). The COPCORD questionnaire adapted for Colombia, was applied in the first stage by standardized interviewers. Positive cases were reviewed at home by a first year rheumatology fellow. To assess whether it is a rheumatic disease; the positive cases for a probable rheumatic disease were reviewed by a second year rheumatology fellow and reviewed again with laboratory and image studies by a certified rheumatologist to establish the definitive diagnosis
Results: 3,146 men and 3,547 women were included. Pain in the last 7 days not associated with trauma was reported in 3,213 (48%) participants. The most frequent sites were knees (right 31%, left 29%), hands (right 25%, left 24%), lumbar spine (18%) and shoulders (right 16%, left 14%). Table 1 depicts the prevalence of rheumatic diseases in Colombia

Table 1. Prevalence of Rheumatic Disease in Colombia

	Prevalence (%)	Variation Coefficient	CI 95%
Osteoarthritis	10,81	6	9,68–12,06
Gout	0,56	26	0,33–0,92
Fibromyalgia	0,72	22	0,47–1,11
Soft Tissue Rheumatism	25,82	6	11,60–19,93
Mechanic Low Back Pain	7,24	7	6,28–8,34
Inflammatory Low Back Pain	0,65	28	0,38–1,12
Spondyloarthritis	0,39	51	0,08–0,48
Rheumatoid Arthritis	1,49	15	1,12–1,98
Systemic Lupus Erythematosus	0,05	56	0,02–0,16
Sjögren Syndrome	0,08	61	0,02–0,27
Dermatomyositis	0,03	100	0,00–0,23
Scleroderma	0,02	100	0,00–14
CHIKV infection	6,68	8	5,73–7,78

CI: confidence interval; CHIKV: chikungunya virus.

Conclusions: Our study shows a similar prevalence to those worldwide in scleroderma, dermatomyositis, systemic lupus erythematosus, and spondyloarthritis. A lower prevalence was observed in Sjögren Syndrome, fibromyalgia, gout and osteoarthritis. A slightly higher prevalence of rheumatoid arthritis was observed in our population. The high prevalence of rheumatoid arthritis and soft tissue rheumatism should increase awareness in our governmental health entities given their long term disability risk

FRI0695 SERIOUS INFECTION ACROSS BIOLOGIC TREATED PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS FROM A NATIONAL REGISTRY

A.I. Rutherford[1], S. Subesinghe[1], R. Byng-Maddick[2], K. Hyrich[3], J.B. Galloway[1]. *[1]Academic Rheumatology Department, King's College London; [2]Rheumatology, Homerton Hospital, London; [3]Arthritis Research UK Centre for Epidemiology, University of Manchester, Manchester, United Kingdom*

Background: Infection is a complication of biologic therapy in RA.
Objectives: To describe the incidence and pattern of serious infection within the British Society for Rheumatology Biologics Register (BSRBR-RA) by drug.
Methods: The BSRBR-RA is a prospective observational study designed to evaluate the safety of biologics. Adverse events are coded using MedDRA defintitions. This analysis included patients with RA starting a biologic. They were considered at risk from their start date until 3 half-lives after stopping their biologic, death, first serious infection, or completion of three years of therapy, whichever came first. Event rates were compared across biologics using Cox proportional hazards with adjustment for age, gender, disease severity and duration, smoking, seropositivity, polypharmacy and baseline steroid usage.
Results: 19,282 patients were included in the analysis with combined follow-up time of 46,771 years. At baseline the mean age was 57 years, 76% female, mean disease duration 12.3 years and mean DAS28 6.1. 22% were current smokers and 64% had a positive rheumatoid factor. The incidence of serious infection for each biologic and hazard ratios for serious infections including by subclass are tabulated.
A sensitivity analysis limiting to 1st biologic exposure only did not significantly alter the estimates. A second sensitivity analysis limiting to new starters from 2010 found certolizumab still had a lower point estimate but findings were no longer significant (HR 0.79, CI 0.54–1.16).
Conclusions: Although the incidence of serious infection was lowest with certolizumab it is difficult to draw strong conclusions about comparative safety from observational studies due to channelling bias and unmeasured confounding. Rituximab and tocilizumab both had higher unadjusted rates of infection but in the adjusted model the rate was no different suggesting that patient factors as opposed to the drug itself were responsible for the observed difference.

FRI0696 IMPACT OF ADALIMUMAB THERAPY ON BRACHIAL ENDOTHELIAL FUNCTION AND LARGE ARTERY STIFFNESS IN PATIENTS WITH RHEUMATOID ARTHRITIS

A.L. Demoux[1], K. Aissi[1], B. Chaudier[2], S. Carijn[3], P.-Y. Chouc[3], H. De Baillou[3], P. Rossi[1]. *[1]Internal medicine department, public hospital of Marseille; [2]Internal Medicine Deprtement, Laveran Hospital; [3]CONCERTO Association, Marseille, France*

Background: Anti-TNF alpha treatment may improve endothelial function and mechanical properties of large artery stiffness in patients with inflammatory rheumatic diseases, however studies remain controversial.
Objectives: To study the effect of TNF alpha blockage with adalimumab for 24 weeks on brachial endothelial function and sub-clinical markers of atherosclerosis in patients with inflammatory rheumatic diseases.
Methods: A total of 26 patients (14 males, 12 females; mean age, 47±11 years) with inflammatory rheumatic diseases (16, rheumatoid arthritis; 9, ankylosing spondylitis, 1, psoriasic rheumatism), resistant to disease-modifying antirheumatic drugs, were studied before the first infusion of adalimumab and again after 24 weeks of treatment. Endothelial function was assessed by measuring flow mediated dilatation using an ultrasound Doppler technique on the brachial artery. Other markers of sub clinical atherosclerosis were assessed by arterial stiffness via aortic pulse wave velocity, augmentation index and central blood pressure, and carotid intima-media thickness. Data for body mass index, disease activity using DAS-PCR and BASDAI, C-reactive protein, fasting glycaemia, and lipid profile were collected before treatment and after 24 weeks.
Results: 24 weeks of adalimumab therapy resulted in a reduction of disease activity score and serum levels of C-reactive protein. No significant differences were found in body mass index, total cholesterol, triglycerides and fasting glycaemia. Brachial blood pressure and heart rate remained similar, as well as carotid intima-media thickness. After 24 weeks of treatment with adalimumab, flow mediated dilatation improved significantly; central systolic and diastolic blood pressure decreased significantly; however central pulse pressure, augmentation index and aortic pulse wave velocity remained unchanged.
Conclusions: In patients with inflammatory rheumatic diseases, treatment with adalimumab for 24 weeks resulted in a significant improvement of endothelial function and central arterial pressure.

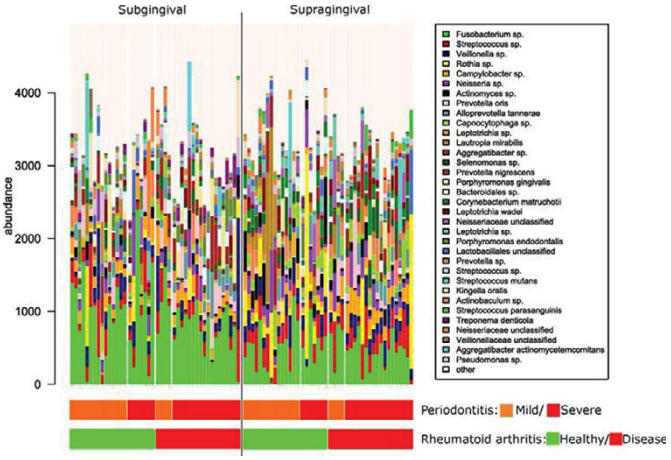
FRI0697 FRENCH NATIONWIDE SURVEY OF CHRONIC PAIN PERCEPTION IN 1739 PATIENTS WITH CHRONIC INFLAMMATORY RHEUMATISM



A.-P. Trouvin[1], C. Beller[2], P. Preiss[2], S. Perrot[3]. [1]*Rheumatology, Hopitaux Universitaire Paris Centre - Cochin;* [2]*Association AFPric;* [3]*Pain Center, Hopitaux Universitaire Paris Centre - Cochin, Paris, France*

Background: Pain is a major symptom in chronic inflammatory rheumatism. Pain intensity doesn't always correlate with disease activity and it can persist even when RA seems in clinical and biological remission. Little is known about the patients' perception of their treatment efficacy on pain, of pain influence in their life and their expectations for pain management. A French patients association (AFPric) conducted a national survey to explore patient's point of view on pain in their rheumatism.
Objectives: Describe in patients with chronic inflammatory rheumatism, their perception of treatment efficacy on pain, the impact of pain in their life and their expectations on pain care, in a nationwide survey.
Methods: A nationwide survey with a 20-item questionnaire was conducted. The questions were developed by patients and rheumatologists in focus groups. Questionnaires were e-mailed to every member of the association (9065 members). Answers were collected until the 17th July 2016. Answers were anonymous.
Results: One thousand thirty nine patients (response rate 19.2%) answered the questionnaire with 1510 women (86.8%), mean age was 59 years [18–85 years]. For more than half (58%) of the patients, their rheumatism had more than 10 years of evolution. Rheumatoid arthritis was the main rheumatism with 1377 patients (87%). Among the 1194 patients (76%) under conventional DMARDs 46.4% considered the cDMARDs efficacy on pain was between 70 and 100%, on the other hand for 17.7% of the patients, cDMARDs efficacy on pain was less than 30%. Among the 744 patients (47.6%) receiving a biological DMARD, 66.2% considered bDMARDs efficacy on pain was between 70 and 100% and 10% considered it was 30% or less. Among the 658 patients (42.3%) receiving oral corticosteroids, 56.6% considered corticosteroids' efficacy on pain between 70 and 100% and 12% considered it was less than 30%. Patients were asked to rate the weight of pain among their symptoms, for 38% of the patients pain represents 70 to 100% of the symptoms of their rheumatism, for 31.7% it represents 40 to 60% and for 30.3% 30% or less. The mean weight is 51.55% Almost half of the patients (46.8%) consider that their pain is underestimated by health professionals. For 37.2% of the patients, their current treatments are not appropriate for their current pain intensity. Finally 528 (35.7%) patients are not satisfied with pain management offered by health professionals, 90% of them think that pain management is too standardized and 80% think that functional impact of chronic pain is not taken in consideration. Among the expectations, 95% of the patients wish a tailored pain management by their rheumatologist, 82.9% wish to participate to support groups with health professionals specialized in pain care.
Conclusions: This nationwide survey on pain among chronic inflammatory rheumatism patients shows that even in the biological DMARDs era, pain is the main concerning symptom for the patients. It is striking in this large cohort that almost half of the patients consider their pain insufficiently taken care of.

FRI0698 PREVOTELLA AND ALLOPREVOTELLA SPECIES CHARACTERIZE THE ORAL MICROBIOME OF EARLY RHEUMATOID ARTHRITIS

B. Wolff[1], S. Boutin[2], H.-M. Lorenz[3], H. Ueffing[1], A. Dalpke[2], D. Wolff[1]. [1]*Department of Conservative Dentistry, School of Dental Medicine, University Hospital Heidelberg;* [2]*Dept. of Infectious Diseases-Medical Microbiology and Hygiene, University Hospital Heidelberg;* [3]*Division of Rheumatology, Department of Medicine V, Ruprecht Karls University, Heidelberg, Germany*

Background: We previously showed that in this early rheumatoid arthritis (ERA) cohort with a mean disease duration of <6 months, a clinically significant loss of clinical attachment loss as surrogate of alveolar bone loss is detectable compared with a matched healthy control cohort (1). Evidence is accumulating that distinct pathogens residing in reservoirs such as the oral cavity, the lung or the gut may play a role in driving the pathogenesis of RA (2–3).
Objectives: To characterize the oral microbiome associated with ERA.
Methods: 16S amplicon sequencing was used to analyze 88 samples of the supragingival and subgingival microbiome of 22 patients with ERA and 22 matched healthy controls. Oral and periodontal status, clinical activity of ERA and periodontitis, and socio-demographic parameters were used as explanatory variables in the next generation DNA sequencing analysis.
Results: Overall, a total of 4.702.161 16S RNA high-quality sequences were yielded. Using a distance-based similarity of >97% for species-level operational taxonomic unit (OTU) assignment, a total of 1054 OTUs were identified (Fig 1). The oral microbiota was equally rich and diverse in ERA and control group. Subgingivally, *Prevotella oris, Prevotella oralis, Prevotella nigrescens, Alloprevotella rava* and *Alloprevotella tannerae* were associated with early RA independent of severity of periodontitis.

Conclusions: Prevotella and Alloprevotella species were enriched in patients with early RA independent of severity of periodontitis. Further studies are needed to test a causal relationship of these species with onset and/or disease progression of RA.

FRI0699 DETERMINANTS OF 12-MONTHS PERSISTENCE IN ANKYLOSING SPONDYLITIS PATIENTS INITIATING SUBCUTANEOUS TNF-ALPHA INHIBITORS

B. Fautrel[1], M. Belhassen[2], C. Hudry[3], M.-C. Woronoff[4], N. Gouyette[5], A. Clément[5], E. Van Ganse[6], F. Tubach[7]. [1]*Sorbonne Universités, UPMC Univ Paris 06; AP-HP, Rheumatology Department, Pitié Salpétrière University Hospital, Paris, France., Paris;* [2]*Hesper 7425, Health Services and Performance Research, University Claude Bernard Lyon 1; PELyon, Pharmacoepidemiologie Lyon, Lyon;* [3]*AP-HP Hôpital Cochin, Paris;* [4]*CHU Besançon, Université Franche-Comté, Comue Ubfc, UMR INSERM 1098, Besançon;* [5]*Merck Sharp & Dohme, Paris;* [6]*Hesper 7425, Health Services and Performance Research, University Claude Bernard Lyon 1, PELyon, Pharmacoepidemiologie Lyon, Lyon;* [7]*APHP, Hôpital Pitié-Salpêtrière, Département de Biostatistiques, Santé publique et Information médicale, APHP, Centre de Pharmacoépidémiologie (Cephepi); INSERM, UMR 1123 ECEVE; Université Pierre et Marie Curie Paris 6, Sorbonne Universités, Paris, France*

Background: Biotherapies such as subcutaneous tumour necrosis factor-alpha inhibitors (SC-TNFis) have transformed the management of inflammatory joint diseases such as ankylosing spondylitis (AS). The assessment of SC- TNFis persistence and its determinants is needed.
Objectives: The objective of this study was to describe treatment persistence in real-world settings, and identify the determinants of persistence among AS patients initiating treatment with an SC-TNFi.
Methods: The French national health insurance scheme database lists all outpatient and inpatient healthcare consumption for individuals covered by the general health insurance scheme. Using French claims data, AS was diagnosed using Long Term Disease status and hospital admission, based on ICD-10 codes. Patients were then identified through prescription filled for adalimumab (ADA), etanercept (ETA), certolizumab pegol (CZP) and golimumab (GLM) between 2012/07/01 and 2013/12/31. A patient was considered as non-persistent in the event of a prolonged interruption of the therapy lasting 91 days or more. Persistence was estimated with Kaplan Meier analysis. Determinants of persistence in the 12 months before initiation were identified using Cox models.
Results: A total of 9,098 patients with AS were identified. In the descriptive analyses of the 12 months persistence, differences were observed for AS patients, with raw/non-adjusted persistence rates of 33.2% for CZP, 49.3% for ETA, 52.4% for ADA and 54.5% for GLM. Results of the Cox model are presented, including hazard ratio for biotherapy, adjusted on sex, age, socio-economic status, and criteria on disease severity. The variables biotherapy, socio-economic status and hospital admission for IRMD did not meet the proportionality hypothesis of risks,

and were corrected by the addition of a variable integrating the interaction with time.

Table 1. Determinants of 12-month non-persistence (Cox model)

	Hazard Ratio	IC 95%		P-value
SC-TNFis				
GLM	1.000	–	–	–
CZP	2.707	2.139	3.426	**<0.0001**
ETA	1.915	1.665	2.203	**<0.0001**
ADA	1.418	1.286	1.565	**<0.0001**
Sex				
Male	1.000	–	–	–
Female	1.377	1.300	1.458	**<0.0001**
Age	0.995	0.993	0.997	**<0.0001**
Deprived socio-economic status: Yes vs No	1.543	1.288	1.849	**<0.0001**
Number of comorbid conditions (per additional condition)	1.150	1.113	1.187	**<0.0001**
Biotherapy line (per additional line)	1.176	1.124	1.231	**<0.0001**
DMARD dispensation: Yes vs No	0.943	0.875	1.015	0.1182
Sulfasalazine dispensation: Yes vs No	0.996	0.915	1.084	0.9257
Long term oral steroids: Yes vs No	0.915	0.806	1.039	0.1719
Hospital admission for IRMD	0.883	0.792	0.984	**0.0249**
Visits to rheumatologist				
0	1.000	–	–	–
1–4	0.925	0.800	1.070	0.2959
>4	0.958	0.829	1.108	0.5645
Interaction with time				
Interaction biotherapy * time	1.001	1.001	1.001	**<0.0001**
Interaction socio-economic status * time	0.999	0.998	1.000	0.0132
Interaction hospital admission for IRMD * time	1.001	1.000	1.001	0.0335

Conclusions: Non-persistent patients were more likely female, with deprived socio-economic status, multiple comorbid conditions, and multiple line of biotherapy. Age, hospital admission for IRMD and treatment with GLM (compared to CZP, ETA and ADA) decreased the risk of non-persistence. Further analyses are needed to assess the impact of non-persistence.

FRI0700 PHYSICAL ACTIVITY DECREASED SIGNIFICANTLY BUT MODERATELY DURING WEEKS WHERE PATIENTS REPORTED FLARES: A 3-MONTH STUDY OF 170 RHEUMATOID ARTHRITIS (RA) OR AXIAL SPONDYLOARTHRITIS (AXSPA) PATIENTS WEARING AN ACTIVITY TRACKER

C. Jacquemin[1], H. Servy[2], A. Molto[3], J. Sellam[4], V. Foltz[1], F. Gandjbakhch[1], C. Hudry[5], S. Mitrovic[1], B. Fautrel[1], L. Gossec[1]. *[1]Rheumatology, La Pitié Salpêtrière Hospital, Paris; [2]Sanoia, e-Health services, Gardanne; [3]Rheumatology, Cochin Hospital; [4]Rheumatology, Saint Antoine hospital; [5]Rheumatology, Private practice, Paris, France*

Background: RA and axSpA natural history comprises periods of low disease activity and flares. There is much interest in the concept of flares. Studies have indicated flares may alter patient quality of life, however, there are few data linking flares to quantifiable outcomes.

Objectives: The objective was to assess longitudinally the association between patient-reported flares and physical activity assessed objectively using an activity tracker.

Methods: This prospective multi-center observational study (ActConnect) included patients with definite RA (ACR/EULAR criteria) or axSpA (ASAS criteria) owning a smartphone. Physical activity was assessed continuously over 3 months by the number of steps using an activity tracker, and flares were self-assessed weekly using a specific flare question ("has your disease flared up during the last 7 days?")[1] with a categorical response according to: no flare, 1 to 3 days flare, or >3 days flare. The relationship between flares and physical activity for each week (time point) was assessed by linear mixed models adjusted on rheumatic disease, sex, age, obesity, biologics and employment status.

Results: 170/178 patients (91 RA and 79 axSpA patients; 1553 time points) were analyzed: mean age 45.5±12.4 years, mean disease duration 10.3±8.7 years; 60 (35.3%) were males and 90 (52.9%) received biologics. Disease was well-controlled (mean DAS28: 2.3±1.2; mean BASDAI: 3.3±2.1). Physical activity was moderate (mean steps/day, 7067±2770). Flares were frequent (25.5% of the questionnaires); most (76.8%) were of short duration. Flares, in particular >3 days flares, were independently associated with less weekly physical activity (p=0.02–0.03), leading to a relative decrease of physical activity of 12–21% and an absolute decrease ranging from 836 to 1462 steps/day (Table 1).

Conclusions: Flares were frequent in these low-disease patients, though most flares were of short duration. Flares were related to a moderate decrease in physical activity, confirming objectively the functional impact of patient-reported flares.

FRI0701 DOES PARITY INFLUENCE JOINT DAMAGE PROGRESSION IN WOMEN WITH RHEUMATOID ARTHRITIS?

D. Alpizar-Rodriguez[1], F. Förger[2], D. Courvoisier[1], C. Gabay[1], A. Finckh[1] on behalf of Physicians of the Swiss Clinical Quality Management Program for Rheumatoid Arthritis. *[1]Rheumatology, Department of Medical Specialities, Geneva University Hospitals (HUG), Geneve; [2]Inselspital, Bern, Switzerland*

Background: Disease activity and severity of rheumatoid arthritis (RA) appear to be worse in women than in men [1]. The role of parity on disease activity is controversial, since pregnancy is characterized by a lower disease activity, but the postpartum period by an increase in activity [2]. Radiographic joint damage progression represents the cumulative effect of disease activity and allows us to study the long term effect of parity.

Objectives: To study the impact of parity on radiographic progression in women with RA.

Methods: This is an observational cohort study of RA patients included in the Swiss Clinical Quality Management in Rheumatoid Arthritis (SCQM-RA). Patients enrolled are followed-up yearly and have x-rays assessments at regular intervals. Information about female hormonal factors, such as pregnancies, breastfeeding, menstrual cycles and hormonal treatment were retrospectively retrieved using a questionnaire. For this analysis we included women with at least two x-rays and full information on reproductive factors. The primary outcome was the rate of radiographic progression (Ratingen erosion score) and the secondary outcome was functional disability progression (Health Assessment Questionnaire-Disability Index (HAQ-DI)). We compared the rate of progression between parous and nulliparous women using a multilevel regression model for longitudinal data,

Table 1. Characteristics of women SCQM

General and disease characteristics	Parous n=438	Nulliparous n=288
Age, years, median(IQR)	49 (40-57)*	45 (34-57)
Body mass index, kg/m², median(IQR)	24 (22-28)*	23 (21-27)
Ever smoking, n(%)	281 (64)	163 (57)
Alcohol consumption, n(%)	144 (33)	88 (31)
Disease duration, years, median(IQR)	0.4 (0.1-4.5)	0.4 (0.1-4.7)
ACPA positive, n(%)	294 (67)	201 (70)
Rheumatoid factor, n(%)	295 (67)*	217 (75)
DAS 28, median(IQR)	3.8 (2.8-5.0)	4.0 (2.9-5.1)
HAQ-DI, median(IQR)	0.8 (0.3-1.3)	0.6 (0.3-1.3)
Erosion score, %, median (IQR)	2.0 (0.5-4.9)	1.1 (0.1-4.7)
DMARD treatment, n(%)	332 (77)	223 (77)
Biologic treatment, n(%)	48 (11)	37 (13)
Glucocorticoid use, n(%)	120 (27)	72 (25)
Number of pregnancies, median (IQR)	2 (1-3)	-
Ever breastfeeding, n(%)	303(69)	-

*p-value <0.05, T-student or Kruskal-Wallis test for continuous variables and Chi-squared or Fisher's exact test for categorical variables. ACPA: anticitrullinated protein antibodies; DAS 28: 28-joint Disease Activity Score ESR; HAQ-DI: Health Assessment Questionnaire–Disability Index; DMARD: disease-modifying antirheumatic drugs.

Abstract FRI0700 – Table 1. Physical activity according to flare status in 170 RA and axSpA patients

	No flare (N=1157 assessments)	Flare (N=396 assessments)	p†	Flare ≤3 days (N=304 assessments)	p‡	Flare >3 days (N=92 assessments)	p‡
Number of steps per day	7197 (±2810)	6688 (±2618)	**0.03**	6792 (±2597)	0.17	6347 (±2670)	**0.02**
Range of absolute reduction of steps per day in flare	–	500–3504[a]	–	931–2794[b]	–	836–1462[c]	–
Range of relative reduction of steps per day in flare (%)	–	6.9–48.7[a]	–	13.5–40.6[b]	–	12.2–21.3[c]	–

The mean physical activity levels according to flare status are indicative data from pooled assessments. Results are expressed in mean (±standard deviation). †Linear mixed model with flare yes/no as the explanatory variable. ‡Linear mixed model with no/<3 days/>3 days flares as the explanatory variable. [a]Range considering flare duration from 1 to 7 days. [b]Range considering flare duration from 1 to 3 days. [c]Range considering flare duration from 4 to 7 days.

adjusting for potential confounders, such as age, disease duration, DAS 28 and treatment. In a subanalysis we explored if the x-ray progression was more severe during the active parous period, operationally defined as the 10 years following the first pregnancy or miscarriage.
Results: A total of 726 women were analysed, of which 438 (60%) were parous, with a median number of pregnancies of 2 (IQR: 2–3), a mean of 4.8 x-rays per patient and 10.9 years of follow-up. Baseline patients and disease characteristics were balanced, but parous women were older than nulliparous (median of 49 vs 45 years, p=0.001) (Table 1). During follow-up, erosion progression did not differ significantly between parous and nulliparous women (p=0.94). In a subanalysis, the radiographic progression during the active parous period was not different [0.6% (95% CI: 0.5 to 0.8) vs 0.5% (95% CI: 0.4 to 0.7) by year, respectively, p=0.28]. The decrease of the HAQ-DI score overtime was not different between parous and nulliparous women (p=0.21), and it was not different during the active parous period [-0.02 (95% CI: -0.03 to - 0.01) vs -0.02 (95% CI:- 0.03 to - 0.01) by year, respectively, p=0.67]. We did not find differences in radiographic progression or HAQ-DI score between women with a single pregnancy and multiparous women.
Conclusions: In women with RA, the progression of structural damage and of functional disability did not differ between parous and nulliparous women. Among parous women, the active parous period was not associated with more radiographic damage progression. Although postpartum period is associated with increase in disease activity, our results suggest that parity does not have a negative long term impact on structural damage.

FRI0702 2-YEAR OUTCOME OF 1077 PATIENTS WITH RECENT-ONSET INFLAMMATORY ARTHRITIS

E.S. Norli[1,2], G. Hetland Brinkmann[2,3], T.K. Kvien[2], O. Bjørneboe[1], A. Julsrud Haugen[3], H. Nygaard[4], C. Thunem[5], E. Lie[2], M.D. Mjaavatten[2].
[1]Rheumatology, Martina Hansens Hospital, Sandvika; [2]Rheumatology, Diakonhjemmet Hospital, Oslo; [3]Rheumatology, Østfold Hospital Trust, Grålum; [4]Rheumatology, Lillehammer Hospital of Rheumatic diseases, Lillehammer; [5]Rheumatology, Betanien Hospital, Skien, Norway

Background: Recent-onset inflammatory arthritis (IA) may represent a broad range of diseases. Few studies have examined the full spectrum of diagnostic outcomes in an unselected cohort of recent-onset IA patients.
Objectives: To describe the disease spectrum and 2-year outcome of recent onset IA in a large multicenter study in Norway.
Methods: Data from the Norwegian Very Early Arthritis Clinic (NOR-VEAC), a 2-year longitudinal observational study of 1118 patients (age 18–75 yrs) with inflammatory arthritis of ≤16 weeks duration, were used. Exclusion criteria were arthritis due to crystal deposits, trauma, osteoarthritis and septic arthritis. Herein we included all patients with follow-up information. Descriptive methods were applied to describe the whole range of diagnostic outcomes (clinical diagnoses made by the treating rheumatologist), as well as disease persistency (defined as disease modifying anti-rheumatic drug (DMARD) use and/or persistent joint swelling) vs resolution of disease for each clinical diagnosis. Patients with temporary DMARD use were classified as no-DMARD users if they were observed for ≥1 year after DMARD cessation. If a patient dropped out of the study before 2 years, the last outcome information was used in a last observation carried forward approach.
Results: 1077 patients (96.3%) were included in the current analyses, of these 64.9% had 2-year follow-up data. Duration of joint swelling before inclusion [median (25–75 perc.)] was 34 (13–66) days, mean (SD) age 46.1 (14.8) years, 54.7% were females, 16.9% anti-CCP positive, and 21.9% anti-CCP and/or RF positive. Presentation as mono-, oligo- (2–4 swollen joints), and polyarthritis (≥5 swollen joints) had approximately the same frequency, 32.5, 35.7 and 31.8%, respectively.
After 2 years 33.0% used DMARDs, and a further 9.3% had joint swelling without DMARD use. The arthritis resolved in the remaining 57.6%. The final clinical diagnoses and their respective outcomes are shown in Figure 1. The most common final diagnoses were undifferentiated arthritis (UA) (39.9%), rheumatoid arthritis (RA) (22.7%), reactive arthritis (17.1%), psoriatic arthritis (6.0%) and sarcoid arthropathy/Löfgren's syndrome (6.2%). A final diagnosis of sarcoid arthropathy, reactive arthritis and UA carried the best prognoses, with resolution of arthritis without DMARDs in 91.0, 85.9 and 73.7%, respectively. Patients presenting with polyarthritis developed persistent disease more often than patients with oligo- or monoarthritis (67.6%, 34.9 and 26.0%, respectively) (p<0.001).
Conclusions: Among 1077 patients with IA of ≤16 weeks duration, UA was the most common diagnosis after 2 years, 22.7% were diagnosed with RA and 6.0% with psoriatic arthritis. The arthritis resolved without DMARDs in the majority of the patients. This is, as far as we know, the first study to describe the whole range of diagnostic outcomes in an unselected cohort of recent-onset arthritis, as well as the persistency of disease according to each diagnosis.

FRI0703 NEW INCIDENT CASES OF RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS AND POLYMYALGIA RHEUMATICA IN A CITY OF CENTRAL ITALY: RESULTS OF THE CAMPO-RE STUDY

A. De Socio, F.M. Perrotta, E. Lubrano. *Medicina e scienze della salute, Università degli studi del Molise, Campobasso, Italy*

Background: few studies reported the incidence of rheumatic disease in Italy using the most recent classification criteria.
Objectives: The aim of the CAMPO-RE study was to assess the new incidence cases of Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) and Polymyalgia Rheumatic (PMR) attending a primary rheumatologic outpatient's clinic of new institution, integrated in the community of Campobasso, a small town in the centre of Italy.
Methods: Campobasso has a population of 49,501 inhabitants (1st January 2016) and Public Health is managed from a single health authority in the entire area. In Italy, all citizens are registered with a National Health System of General Practitioner Physicians (GPP). Between 1st June 2014 to 31st May 2016 all consecutive adult patients, sent by GPP of the municipality of Campobasso with any diagnosis of musculoskeletal symptoms/signs complains were evaluated in a single rheumatology outpatient clinic of our Academic Unit, that represent the first and unique reference for the GPP about rheumatic diseases in the territory. Subjects were classified using the EULAR criteria for RA, the CASPAR criteria for PsA and the 2012 ACR classification criteria for PMR. New incident cases were calculated using the number of cases as the numerator and population based on 1st January census of the municipality of Campobasso as the denominator.
Results: 1003 adult patients, sent by GPP with articular or musculoskeletal complains were visited in our clinic. Of these, 409 patients inhabitants of the municipality of Campobasso were evaluated for the study. During the 2-years study period we diagnosed 18, 19 and 12 new cases of RA, PsA and PMR respectively, with a new incident cases rate of 18.18, 19.19 and 12.12/100,000/year on the whole population of Campobasso municipality. Age-related incident cases were also calculated (table 1).

Table 1. Annual incident cases of rheumatoid arthritis (RA), psoriatic arthritis (PsA) and polymyalgia rheumatica (PMR) trough two-years observation period in the town of Campobasso

Disease	Number of patients	Male/female	Incident cases (number/ 100,000 pt/year), total	Male (number/ 100,000 pt/year)	Female (number/ 100,000 pt/year)
RA	18	4/14	18.18	4.04	15.15
18–29 yr	1	0/1	7.69	–	16.1
30–49 yr	3	1/2	11.08	7.53	15.14
50–65 yr	7	1/6	31.16	9.52	50.15
>65 yr	7	1/6	32.08	10.86	47.56
PsA	19	10/9	19.19	10.1	9.1
18–29 yr	0	–	–	–	–
30–49 yr	6	3/3	22.66	22.61	22.71
50–65 yr	11	5/6	48.97	47.61	50.15
>65 yr	2	2/0	9.17	21.72	–
PMR	12	3/9	12.12	2.02	10.10
18–29 yr	0	–	0	0	0
30–49 yr	0	–	0	0	0
50–65 yr	0	–	0	0	0
>65 yr	12	3/9	54.99	32.58	71.34

Conclusions: The results of our study could contribute to better define the new incident cases of these rheumatic disease classified with the new classification

criteria. The incidences of RA, PsA and PMR seem to be similar to those reported in previous study[1–3].

FRI0704 ANALYSIS OF RISK FACTOR FOR PREGNANCY OUTCOMES IN 142 PREGNANCIES COMPLICATED WITH CONNECTIVE TISSUE DISEASE

H. Shimada[1], K. Kanenishi[2], T. Kameda[1], M. Izumikawa[1], S. Nakashima[1], H. Ozaki[1], R. Wakiya[1], A. Kondo[1], N. Kadowaki[1], H. Dobashi[1]. *[1]Department of Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine; [2]Department of Perinatology and Gynecology, Faculty of Medicine, Kagawa University, Kagawa, Japan*

Background: Recently, many connective tissue disease (CTD) patients wish to become a mother because immunosuppressants and biologics enable to improve the outcome of underlying CTD and quality of life respectively. However, Pregnancies in CTD patients often have problems including underlying disease exacerbation, some complications during pregnancy especially in preterm birth, light for date (LFD) and premature rapture of membrane (PROM). Previous study identified that high clinical activities with hypocomplementemia and positive anti-dsDNA antibody were at highest risk for pregnancy loss and preterm delivery in SLE[1)]. It is unclear whether these problems are associated with the activity of underlying CTD or immunosuppressant treatment.
Objectives: We examine the issue of pregnancy and delivery complicated with CTD by the analysis of the cases in our institution.
Methods: We investigated the risk factors of preterm birth, LFD (light for dates) and perinatal complication from exacerbation of underlying disease, anti SS-A antibody, antiphospholipid antibody, doses of corticosteroid, immunosuppressants or biologics before pregnancy in 142 cases which were delivered in our institution.
Results: In 23 among all cases underlying diseases were exacerbated, and these occurred more often in PM/DM (60%), MCTD (33.3%), RA (15.3%) and SLE (13.3%). In SLE, SS, MCTD and PM/DM, preterm births and LFD were closely related to disease exacerbation and dose of corticosteroid, pulse therapy, and these were extracted as risk factors for these perinatal complications. Preterm birth was also associated with low complement (CH50) and high titer of anti-dsDNA antibody, and LFD was associated with high titer of anti-dsDNA antibody before pregnancy. However, there was no significant association with these factors in threatened premature delivery and PROM. In RA, perinatal complications were not influenced by methotrexate and biologics before pregnancy. However, only LFD was related with doses of corticosteroid during pregnancy.
Conclusions: We extracted disease exacerbation and dose of corticosteroid, pulse therapy during pregnancy and also low complement, high titer of anti-double stranded DNA antibody before pregnancy as risk factors of pregnancy outcomes. In pregnancy complicated with CTD, we need to control the disease activity strictly, however, we should consider the increase or pulse therapy of corticosteroid carefully.

FRI0705 PROGRESSION OF CHRONIC DAMAGE IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS AFTER 5-YEAR FOLLOW-UP: DATA FROM A LARGE MONOCENTRIC COHORT

I. Leccese, F. Ceccarelli, C. Perricone, L. Massaro, E. Cipriano, S. Truglia, F. Miranda, F.R. Spinelli, C. Alessandri, G. Valesini, F. Conti. *Lupus Clinic, Reumatologia, Dipartimento di Medicina Interna e Specialità Mediche, Sapienza Università di Roma, Rome, Italy*

Background: The prevention of chronic damage represents one of the most important target in the management of patients affected by Systemic Lupus Erythematosus (SLE). About 50% of patients develop chronic damage, especially in the early disease phase, due to disease activity, treatment adverse events and comorbidities. Longitudinal studies demonstrated a progressive increase of damage, evaluated by using SLICC Damage Index (SDI).
Objectives: Moving from these evidences, we aimed at evaluating the progression of chronic damage in a monocentric SLE cohort with at least 5-year follow-up and identifying the factors associated with damage progression.
Methods: We analyzed 658 SLE patients diagnosed according to the ACR 1997 revised criteria, referring to a dedicated outpatient clinic. For the present analysis, we evaluated only patients with a minimum follow-up of 5 years and at least one visit per year. Clinical and laboratory data were collected in a standardized, computerized and electronically-filled form, including demographics, past medical history, comorbidities and concomitant treatments. In all patients, chronic damage was determined by using SDI, with the evaluation of 12 organ systems. Disease activity was evaluated by SLEDAI-2K. Furthermore, we calculated the number of flares during the follow-up, defined as an increase in SLEDAI-2K score $\geq$4 from the previous visit, with a minimum interval of 2 months between visits.
Results: According with the inclusion criteria, we analyzed data deriving from 198 SLE patients (17 M/181 F, mean±SD age 46.8±12.1 years, mean±SD disease duration 131±99.7 months). At the first visit 60 patients (30.3%) showed SDI$>$0; in particular SDI=1 was identified in 65%, SDI=2 in 18.3%, SDI=3 in 10%, SDI=4 in 6.7%). At baseline, the presence of chronic damage was significantly associated with age ($P<0.0001$) and disease duration (P=0.001). After 5 years, we registered the progression of chronic damage in 69 patients (34.8%), with a significant increase of SDI values (baseline: median SDI 0.0, IQR 0–1; follow-up SDI: median 0 IQR 0–2, P=0.009). SDI progression resulted significantly more frequent in subjects with damage at baseline (55.0%) in comparison with free-damage patients (26.1%, P=0.0001, Fisher exact test). The progression of chronic damage was significantly associated with neuropsychiatric involvement (P=0.01), disease activity in terms of number of flares during the 5-year follow-up (P=0.001), concomitant anti-phospholipid syndrome (P=0.02) and arterial hypertension (P=0.001).
Conclusions: In our study, we observed a progression of chronic damage in almost 30% of SLE patients after 5 years. In particular, the presence of previous chronic damage seem to be a risk factor for new damage development. Moreover, the lack of disease control and the presence of comorbidities allows damage progression. Taken together, the results of this study underline the need of a better management of SLE patients in order to prevent damage accrual.

FRI0706 HLA-DRB1 ALLELES ARE ASSOCIATED WITH MARKERS OF ENDOTHELIAL INJURY IN FIRST-DEGREE RELATIVES OF RHEUMATOID ARTHRITIS PATIENTS

J.M. Hughes-Austin[1], M. Corr[2], G.S. Firestein[2], V.M. Holers[3], K.D. Deane[3], J.M. Norris[4], J.H. Ix[5,6]. *[1]Orthopaedic Surgery; [2]Rheumatology, Allergy, Immunology, UC San Diego, la Jolla; [3]Rheumatology; [4]Colorado School of Public Health, University of Colorado, Aurora; [5]Medicine, UC San Diego; [6]Nephrology, VA San Diego, la Jolla, United States*

Background: Rheumatoid arthritis (RA) patients experience higher cardiovascular disease (CVD) risk and CVD-related mortality. MHC class II HLA-DRB1 alleles, or the shared epitope (SE), has also been linked to endothelial dysfunction in RA patients. It is not known whether this association exists in individuals who are RA-free, but who are at higher risk due to being a first-degree relative (FDR) of an RA patient.
Objectives: To determine the association between HLA-DRB1 alleles (*0401, *0404, *0405, *0408) and markers of endothelial injury in FDRs of RA patients, a population free of RA and RA-related medications.
Methods: From the Studies of the Etiology of RA, SERA, (a multicenter prospective study of preclinical RA, started in 2002), 113 FDRs who had been positive for any of 5 RA-related autoantibodies (Abs): rheumatoid factor (RF), RF isotypes – IgM, IgG, IgA, or anti-cyclic citrullinated peptide (anti-CCP2) on at least one of their visits, and 100 FDRs who had never been Ab positive were selected, frequency matched on age, sex, and field center site. No FDR met the 1987 ACR Criteria or 2010 EULAR/ACR Criteria for RA. In cross-sectional testing of single samples from baseline, the following were measured: endothelial injury markers: soluble intracellular adhesion molecule-1 (sICAM), soluble vascular cell adhesion molecule-1 (sVCAM) and E-selectin; and high resolution HLA-DRB1 typing for the*0401, *0404, *0405, and *0408 alleles using real-time polymerase chain reaction. ANCOVA was used to evaluate associations between HLA-DRB1 alleles, sVCAM, sICAM, and E-selectin, adjusting for age, sex, race, body mass index (BMI), Ab status, ever smoking, and current statin use.
Results: Among 213 FDRs, age was 50±18 yr, BMI was 27±6, 75% were women, 83% were Caucasian, 35% ever smoked, 11% were currently taking statins, and 38% were SE positive. sVCAM was significantly higher by 135ng/mL in FDRs with the HLA-DRB1*0404 allele (p=0.009) compared to FDRs without the *0404 allele (Table 1). E-selectin was higher by 23ng/mL in FDRs with the HLA-DRB1*0405

Table 1. Differences in levels of endothelial injury markers by HLA-DRB1 alleles in FDRs of RA patients

	n (%)	ICAM (ng/mL)	p-value	VCAM (ng/mL)	p-value	E-selectin (ng/mL)	p-value
SE Positive	81 (38)	11.6 (8.8)	0.19	55.7 (32.5)	0.09	3.7 (2.2)	0.09
401	55 (26)	2.6 (10.0)	0.80	-14.1 (37.0)	0.70	0.4 (2.5)	0.86
404	23 (11)	21.1 (13.9)	0.13	135.4 (50.9)	0.009	6.4 (3.4)	0.06
405	2 (1)	55.1 (44.0)	0.21	186.0 (163.1)	0.26	22.9 (10.8)	0.03
408	6 (3)	-6.6 (25.4)	0.79	7.1 (94.1)	0.94	8.1 (6.2)	0.19

*n=213 (92 Ab+, 121 Ab–).

allele (p=0.03) compared to FDRs without the *0405 allele. Being positive for the SE was not significantly associated with sICAM, sVCAM, or E-selectin levels.
Conclusions: In RA-free FDRs, having an HLA-DRB1*0404 or HLA-DRB1*0405 allele was associated with markers of endothelial injury. Therefore, the genetic predisposition to RA could contribute to parallel development of atherosclerosis during the preclinical period of RA.

FRI0707 DRUG LEVELS AND ANTIDRUG ANTIBODIES IN THE DEVELOPMENT OF PARADOXICAL PSORIASIS AND PALMOPLANTAR PUSTULOSIS

J. Ruwaard[1], E. van der Vlugt[1], P. Brevet[1], L. Berkhout[2], T. Rispens[2], M. Nurmohamed[1], G.J. Wolbink[1,2]. [1]*Amsterdam Rheumatology and immunology Center | Reade;* [2]*Department of Immunopathology, Sanquin Research and Landsteiner Laboratory Academic Medical Centre, Amsterdam, Netherlands*

Background: The pathogenesis of psoriasis and palmoplantar pustulosis induced by Tumor Necrosis Factor inhibitors (TNFi) is largely unknown. Only one study, in 9 inflammatory bowel disease patients, investigated the relation with infliximab drug levels in the development of psoriasis or palmoplantar pustulosis and demonstrated no relation with of trough concentrations in these events (1). However, psoriasis and palmoplantar pustulosis were not studied separately.
Objectives: To study the differences in drug levels and antidrug antibodies (ADA) of TNFi in rheumatoid arthritis (RA) and ankylosing spondylitis (AS) patients who developed de novo psoriasis, palmoplantar pustulosis and those who did not develop skin adverse events.
Methods: In this retrospective study data was collected from the observational cohorts of Reade of consecutive RA and AS patients in whom TNFi was started. At every visit, serum samples were collected. We quantified the samples before/on time of event of the patients who developed psoriasis or palmoplantar pustulosis, for the patients with no skin adverse events (control group) at 24 or 28 weeks. Drug levels and ADA were measured with an Enzyme-linked immunosorbent assay and antibody binding test respectively.
Results: A total of 830 TNFi naive patients with RA and AS were included, of whom 21 developed psoriasis (n=11) or palmoplantar pustulosis (n=10). These patients were only observed in the adalimumab and etanercept cohorts. Sixteen patients with an event and 585 patients in the control group had serum samples available to quantify drug levels and ADA. No statistical significant differences were found in drug levels of adalimumab and etanercept for both RA and AS patients (table 1). Moreover, no statistical significant differences were observed in the detection of ADA between the three groups. However, no ADA were detected in patients who developed psoriasis or palmoplantar pustulosis compared to the overall 13.9% of the RA patients and 25.5% in AS patients.

Table 1. Differences in drug levels and detection of anti-drug antibodies between palmoplantar pustulosis, psoriasis and control group

		Druglevels adalimumab (μg/ml; median (IQR)		Drug levels etanercept (μg/ml); median (IQR)		Anti-drug antibodies adalimumab, no. (%)
RA						
Palmoplantar pustulosis	n=3	7,6 (0,01–12,0)	n=1	4,4	n=3	0 (0)
Psoriasis	n=3	8,5 (6,5–10,0)	n=2	2,3 (1,5–3,1)	n=2	0 (0)
Control group	n=153	7,4 (4,0–10,0)	n=89	2.7 (1.9–3.9)	n=151	21 (13,9)
p-value		0,992		0,380		0,674
AS						
Palmoplantar pustulosis	n=3	9,0 (6,5–10,0)	n=1	1,7	n=3	0 (0)
Psoriasis	n=1	10, 0	n=2	1,3 (0,8–1,7)	n=1	0 (0)
Control group	n=46	8,5 (3,7–11,3)	n=99	2.6 (1.4–4.0)	n=47	12 (25,5)
p-value		0,754		0,406		0,754

RA: rheumatoid arthritis; AS: ankylosing spondylitis; Control group: patients who did not develop skin adverse events; IQR: interquartile range; no. number of patients. p-value <0,05 was considered statistically significant.

Conclusions: Patients who develop paradoxical psoriasis and palmoplantar pustulosis have adequate drug levels and no ADA were detected.

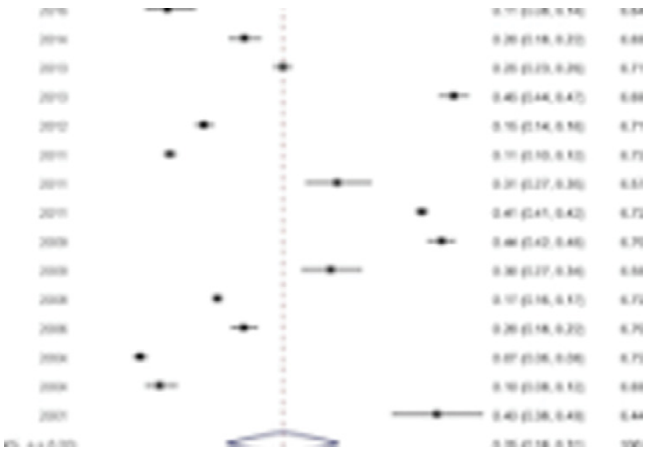
FRI0708 NEUROPATHIC PAIN IS A WEAK PREDICTOR OF NEW ONSET CHRONIC WIDESPREAD PAIN



J. McBeth[1], M. Mulvey[2], A. Rashid[1], J. Anderson[1], K. Druce[1]. [1]*Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester;* [2]*Leeds University, Leeds, United Kingdom*

Background: Regional pain (e.g. back pain) predicts incident chronic widespread pain (CWP), the clinical hallmark of fibromyalgia. Up to 20% of patients with CWP have neuropathic pain (NP). People with CWP and NP report similar pain characteristics including allodynia (pain in response to normal touch), have common risk factors (age, sex, body mass index, smoking and socioeconomic status) and a shared genetic predisposition. Whether NP is a risk factor for CWP is not known.
Objectives: To test the hypothesis that among persons free of CWP, NP would increase the risk of developing CWP.
Methods: In a population based study participant's pain reports were coded and those free of CWP (ACR criteria: pain lasting ≥3 months in the axial skeleton and contralateral body quadrants) identified. Participants also completed the Douleur Neuropathique 4 (DN4) (which has 7 sensory descriptors of pain (burning, painful cold, electric shocks, tingling, pins and needles, itching, and numbness), scores ≥3 indicating NP); demographics (date of birth, sex, English Index of Multiple Deprivation, occupational status); Hospital Anxiety and Depression (HAD) scale; Estimation of Sleep Problem Scale (ESPS); self-reported pain medications (summed to give a total count); and signed consent. Participants were classified as no pain, having some pain that wasn't neuropathic (NP-; DN4 score <3), or neuropathic pain (NP+; DN4 score ≥3). A follow-up questionnaire mailed 12 months later gathered pain data using the methods in the baseline survey. Based upon their pain reports at follow up participants were classified as "new CWP" for those who reported pain that satisfied the criteria for CWP, or "not CWP". Logistic regression estimated the odds of developing new CWP in the NP-, and NP+ groups compared to the no pain group. Results were expressed as odds ratios (OR) with 95% confidence intervals (CI). Population attributable fractions (PAF) estimated the % of new CWP that would be avoided if participants were not exposed to NP- or NP+.
Results: A total of 1162 participants who were free of CWP, completed the DN4 and provided pain data at follow up. Of those 523 (45.0%) had no pain at baseline, 562 (48.4%) had NP- and 77 (6.6%) had NP+. New onset CWP was reported by 153 (13.2%) participants; 19 (3.6%) of the no pain group, 108 (19.2%) of the NP- group, and 26 (33.8%) of the NP+ group. After adjusting for age and sex, compared to the no pain group, the NP- group was 3 times (OR 2.9, 95% CI (2.0, 4.2)) and the NP+ group 4 times (3.9 (2.3, 6.4)) more likely to have new CWP at follow up. These relationships were attenuated but persisted after adjustments for demographics, HAD, ESPS and medication use (NP- (2.9 (1.9, 4.3); NP+ (2.1 (1.1, 4.0)). The PAF was 41.3% (95% CI (25.2, 54.0)) for NP- and 6.0% (0.1, 11.6) for NP+. All of the individual DN4 characteristics except painful cold and itching predicted new CWP with PAF's ranging from 1.6% (0.1, 3.8) for pins and needles to 5.0% (1.1, 8.8) for burning.
Conclusions: NP predicts a small number of new onset CWP cases. CWP is highly prevalent in the general population and effective treatment of pain not of NP origin will have a significant impact on population levels of CWP.

FRI0709 PREVALENCE OF RHEUMATIC DISEASES BASED ON COPCOPRD STUDIES: A SYSTEMATIC REVIEW

J. Moreno-Montoya[1], J. Rodriguez-Amado[2], R. Burgos-Vargas[3], I. Pelaez-Ballestas[3]. [1]*Universidad del Bosque, Bogota, Colombia;* [2]*Research Associate of South Florida, Miami, United States;* [3]*Rheumatology Unit, Hospital General de Mexico, Mexico, Mexico*

Background: Despite many efforts, to date there has been no focused attempt to derive a robust estimate of the prevalence of rheumatic diseases (RDs) to quantify how this is influenced by other factors than them examined in every local study, however, the problems magnitude is rising and due the demographic transition and the increase in the life expectancy
Objectives: To determine, through a systematic review and meta-analysis, the prevalence of RDs in the adult general population and explore its heterogeneity
Methods: MEDLINE, EMBASE, BIREME, LILLACS and Web of Science were searched using a search strategy combining key words and related database-specific subject terms to identify relevant cross-sectional based on COPCORD methodology studies. Also was developed a manual search. Included articles were assessed for risk of bias and quality based on the STROBE statement. Prevalence figures for RDs were analyzed according to female percentage of sampled individuals, mean age and sample size. A mixed effect model was used to obtain the combined prevalence and a meta-regression to estimate the effects of other variables
Results: 44 out from 127 papers were included in English, Spanish or Portuguese. Estimates for any RDs prevalence ranged from 7.2% to 62.3% (26.9%; 95% CI 18.3%>25.6%). For rheumatoid arthritis (RA), the prevalence varied between 0.2% and 6.2% (1.04%; 95% CI 0.4%>1.6%); fibromyalgia (FM) had a mean prevalence of 2.1% (95% CI 1.0%>3.2%) and osteoarthritis: 13.5% (95% CI: 10.6%>16.4%). SLE (systematic lupus erythematosus) was the less frequent condition with average prevalence of 0.14% (95% CI: 0.005%>0.28%). The random-effects pooled prevalence for any RDs was 25% (95% CI: 18.0%, 31.1%). Prevalence was higher in studies with bigger sample size (random effect coefficient: 0.0014, p=002). There was evidence of relevant heterogeneity in the analysis (p<0,001) and for RDs, RA and FM the sample size was positively associated to the perceived heterogeneity. No effects were found for SLE
Conclusions: It was found significant variation among the prevalence across this

review, in particular, related to the sample size used in each study. Two facts must be accounted for, first the statistical difficulties associated to the estimation of small prevalence and the consequent heterogeneity of the estimates, and, second, the limited number of studies included in this meta-analysis. Nonetheless, there is evidence about big heterogeneity what can correspond to non-observed variables, in particular, life-styles, and environmental or genetic traits.

FRI0710 MONOSODIUM URATE CRYSTAL DEPOSITION ASSOCIATED WITH THE CHANGE OF RADIOGRAPHIC GRADE AT THE SACROILIAC JOINT IN AXIAL SPA: A DUAL-ENERGY CT STUDY

J. Zhu[1], A. Aiwu Li[2], E. Jia[2], Y. Zhou[3], J. Xu[2], S. Chen[2], Y. Huang[2], X. Xiao[4], J. Li[2]. *[1]Department of Rheumatology, Nanfang Hospital, Southern Medical University; [2]Department of Internal Medicine of Traditional Chinese Medicine, College of Traditional Chinese Medicine, Southern Medical University; [3]Department of Obstetrics, Guangdong Women and Children Hospital; [4]Department of Radiology, Nanfang Hospital, Southern Medical University, Guangzhou, China*

Background: Previous studies have revealed that ankylosing spondylitis (AS), as the progenitor of axial spondyloarthritis (AxSpA), has been characterized by the insidiously progressive nature of sacroiliitis and spondylitis. Dual-energy computed tomography (DECT) has recently been used to analyse the deposition of monosodium urate (MSU) crystals with higher sensitivity and specificity. However, it remains unclear whether the existence of the MSU crystal deposits detected by DECT at the sacroiliac joint in patients with AxSpA also contributed to the existing structural damage.

Objectives: We performed this study to show the DECT MSU crystal deposits in AxSpA patients without coexisting gout and to ascertain whether the MSU crystal deposits at the sacroiliac joint in those patients increased the risk of the structural joint damage.

Methods: One hundred and eighty-six AxSpA patients without coexisting gout were recruited. The plain radiographs of the sacroiliac joint were obtained, along with the DECT scans at the pelvis and the clinical variables. All statistics based on the left or right sacroiliac joint damage grading (0–4) were calculated independently. Bivariate analysis and ordinal logistic regression was performed between the clinical features and radiographic grades at the sacroiliac joint.

Results: At painful joints or skeleton regions, large quantities of MSU crystal deposits were found in 186 patients with AxSpA, as depicted in green with DECT. The average MSU crystal volume at the left sacroiliac joint, the right sacroiliac joint, and the pelvis were 0.902±1.345, 1.074±1.878, and 5.272±9.044 cm^3, values which were correlated with serum uric acid concentrations (r=0.727, 0.740, 0.896; $p<0.001$). At the left and right sacroiliac joint, the presence of MSU crystal deposits (=11.451, 43.684; $p<0.01$) and the volumes of MSU crystals (Z=9.198, Z=34.607; $p<0.05$) were statistically different among groups divided by the ASDAS scores. In bivariate analysis, wide clinical variables were associated with the changes in sacroiliac joint damage. When others factors were adjusted in the ordinal logistic models, the AxSpA duration, total back pain, BASFI score, and volume of MSU crystallization were the risk factors for the radiographic grade at the left sacroiliac joint (AOR=1.187, 1.428, 3.837, 2.018; $p<0.05$). The same risk factors were obtained for the right sacroiliac joint, except for total back pain. Additionally, the simplified models excluded the repeated variables; the AxSpA duration, BASFI score, and the volume of MSU crystallization at both sides of sacroiliac joint served as risk factors for the radiographic grade (left-AOR=1.180, 3.800, 1.920; right-AOR=1.190, 3.034, 1.418; $p<0.01$).

Conclusions: Large quantities of MSU crystal deposits detected by DECT were found in AxSpA patients without coexisting gout. In addition to AxSpA duration and BASFI score, the MSU crystal deposits at the sacroiliac joint in those patients independently increased the risk of structural joint damage.

FRI0711 DISCORDANCE OF THE FRAMINGHAM CARDIOVASCULAR RISK SCORE AND THE 2013 AMERICAN COLLEGE OF CARDIOLOGY/AMERICAN HEART ASSOCIATION RISK SCORE IN SYSTEMIC LUPUS ERYTHEMATOSUS AND RHEUMATOID ARTHRITIS

K. Jafri[1], A. Ogdie[2], P. Katz[1], J. Yazdany[1], G. Schmajuk[1,3]. *[1]Rheumatology, University of California, San Francisco, San Francisco; [2]Rheumatology, University of Pennsylvania, Philadelphia; [3]Rheumatology, Veterans Affairs Medical Center, San Francisco, United States*

Background: Systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) are associated with an increased risk of cardiovascular (CV) disease, and multipliers to traditional 10-year CV risk scores, such as a EULAR-recommended 1.5 multiplier in RA, have been proposed to capture this increased CV risk. The discordance between CV risk assessment by the Framingham risk score, a modified Framingham risk score (with a 1.5 multiplier), and the more recent 2013 American College of Cardiology/American Heart Association (ACC/AHA) risk score has not been well-studied in patients with rheumatic diseases.

Objectives: To determine the proportion of discordant 10-year Framingham risk scores and 2013 ACC/AHA risk scores in subjects with SLE and RA, both with and without a 1.5 multiplier to the Framingham risk score, and to assess demographic, CV, and rheumatologic clinical characteristics associated with discordant risk scores.

Methods: A cross-sectional study was conducted using SLE and RA subjects drawn from the University of California, San Francisco, Arthritis, Body Composition, and Disability project. 10-year Framingham risk scores, modified Framingham risk scores (with a 1.5 multiplier), and 2013 ACC/AHA risk scores were calculated. As per Adult Treatment Panel-III (ATP-III) recommendations, a subject with a Framingham risk score (or modified Framingham risk score)$\geq$10% was defined as high-risk by that score, whereas a subject with a Framingham risk score (or modified Framingham risk score)$<$10% was defined as low-risk. A subject with a 2013 ACC/AHA risk score$\geq$7.5% was defined as high-risk by that score, whereas a subject with a 2013 ACC/AHA risk score$<$7.5% was defined as low-risk. A subject with a discordant risk score was defined as one who had a Framingham risk score (or modified Framingham risk score) that characterized him/her as low-risk and a 2013 ACC/AHA risk score that characterized him/her as high risk. Associations of demographic, CV, and rheumatologic characteristics with discordant risk scores were analyzed using chi-squared tests for categorical variables and using independent t-tests for continuous variables.

Results: 11 (7.0%) of the 157 SLE subjects and 11 (11.5%) of the 96 RA subjects had discordant CV risk scores with low Framingham risk scores but high ACC/AHA risk scores. When the 1.5 multiplier was applied to the Framingham risk score, the number of subjects with discordant risk scores did not significantly change. Rheumatologic disease duration, CRP levels, African-American race, diabetes, current use of anti-hypertensive medication, higher age, and higher systolic blood pressure were all significantly associated with discordant risk scores.

Conclusions: Approximately 10% of SLE and RA subjects had discordant 10-year CV risk scores with low Framingham risk scores but high ACC/AHA risk scores, even when a 1.5 multiplier was applied to the Framingham risk score. Prospective studies are needed to address the ability of different CV risk assessment tools, such as the 2013 ACC/AHA risk score, Framingham risk score, and modified risk scores, to predict CV events in rheumatologic patients, especially those with risk factors associated with discordant risk scores.

FRI0712 DRIVERS OF UNREFRESHING SLEEP IN PEOPLE WITH MUSCULOSKELETAL PAIN

K.L. Druce, J. McBeth. *Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester, United Kingdom*

Background: Waking feeling unrefreshed is associated with poor health outcomes including an increased risk of cardiovascular death. Pain is a robust predictor of waking feeling unrefreshed. Pain is a complex disorder and it is not clear whether the pain itself, or associated somatic symptoms, mental health conditions and lifestyle factors, predicts waking unrefreshed.

Objectives: To investigate whether reporting pain was an independent predictor of waking unrefreshed among people with musculoskeletal pain.

Methods: Participants in a population study completed the Estimation of Sleep Problems Scale (ESPS), which indicates the number of days in the past month participants have experienced unrefreshing sleep, problems with sleep onset, maintenance and night awakenings. Pain assessments (body map and duration $>$3 months) were used to classify participants as having no pain, acute pain, chronic pain and CWP (ACR criteria: pain lasting $\geq$3 months in the axial skeleton and contralateral body quadrants). Participants also reported demographics (date of birth, sex, English Index of Multiple Deprivation); somatic symptoms (Chalder Fatigue Scale (CFQ 11) and Inflammatory Bowel Syndrome (IBS)); mental health (Hospital Anxiety and Depression (HAD) scale); disability (Stanford Health Assessment Questionnaire (HAQ)) and lifestyle factors (average number

of alcoholic drinks per week, smoking status and Rapid Assessment of Physical Activity (RAPA)). Univariable ordinal logistic regression tested the relationship between pain and waking unrefreshed. The model was then cumulatively adjusted for sleep, somatic symptoms, mental health, disability and lifestyle domains. All models were age, sex and deprivation adjusted. The results of a complete case analysis were comparable to those which used multiple imputation for missing data and the results of the complete case analyses are shown. Results were expressed as odds ratios (OR) with 95% confidence intervals (CI).

Results: Of 1913 people who had complete data, 1376 (72%) woke unrefreshed on at least one day in the past month (41% 1–7 days; 31% ≥8 days). Compared to those with no pain, people with acute pain and chronic pain were two (OR 2.0, 95% CI (1.5–2.6) and 2.2 (1.9–2.7), respectively) times more likely to wake unrefreshed; those with CWP were five (5.0 (4.0–6.3)), times more likely to wake unrefreshed. Following adjustment for all other variables, the relationship between reporting chronic pain (1.5 (1.2–1.8)) or CWP (1.9 (1.4–1.5)) and waking unrefreshed was attenuated, but remained statistically significant. The reporting of acute pain was not an independent predictor of waking unrefreshed (1.4 (0.98–1.9)). Problems with sleep onset (≥8 days vs 0: 2.9 (2.0–4.1)) and maintenance (≥8 days vs 0: 5.9 (4.1–8.4)), night awakenings (≥8 days vs 0: 2.5 (1.7–3.7)), IBS (2.2 (1.2–4.0)), currently smoking (vs never: 1.5 (1.02–2.1)) and engagement in activities such as stretching and yoga (vs none: 0.8 (0.6–0.97)), physical (1.3 (1.2–1.3)) but not mental (0.99 (0.9–1.1)) fatigue, and anxiety (definite vs no: 2.4 (1.8–3.1)), but not depression (definite vs no: 1.5 (0.8–2.6)), were associated with waking unrefreshed.

Conclusions: This study suggests that among people with chronic pain, the risk of waking feeling unrefreshed may be reduced through interventions that target factors such as smoking cessation, IBS management, physical fatigue and anxiety.

FRI0713 LOW BONE MINERAL DENSITY IS THE MAIN CONTRIBUTOR TO FALLS-RELATED HEALTH BURDEN IN THE EUROPEAN ELDERLY

L. Sanchez-Riera[1], N. Wilson[2], D. Prieto-Alhambra[3], C. Cooper[4], K. Dreinhöfer[5], A. Woolf[6], L. March[2], P. Halbout[7]. *[1]University Hospital Bristol NHS Foundation Trust, Bristol, United Kingdom; [2]Institute of Bone and Joint Research, University of Sydney, Sydney, Australia; [3]Oxford NIHR Musculoskeletal Biomedical Research Unit, University of Oxford, Oxford; [4]MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton, United Kingdom; [5]Center for Musculoskeletal Surgery, Charité Universitätsmedizin, Berlin, Germany; [6]Institute of Health Research, University of Exeter Medical School, Exeter, United Kingdom; [7]International Osteoporosis Foundation, Nyon, Switzerland*

Background: Falls are the leading injury type in elderly populations and a major health burden and cause of death globally. Most of such burden is due to bone fractures. In the Global Burden of Diseases (GBD) Initiative, the attributable burden of falls due to low bone mineral density (BMD) was analysed through its relationship with fractures.

Objectives: To measure the percentage of disability-adjusted life years (DALYs), years lived with disability (YLDs) and deaths due to falls attributable to low BMD in European population for the year 2015.

Methods: The estimates followed the Counterfactual Risk Assessment Methodology used in the GBD study (1). Systematic review was performed seeking population-based studies with femoral neck (FNBMD) measured by Dual-X-Ray-Absorptiometry in people 50 years and over. Age- and sex- specific levels of mean +/-SD FNBMD (g/cm^2) were extracted from eligible studies, and this was used as the exposure variable. The age and sex-specific 99th percentile from non-Hispanic whites in the National Health and Nutrition Examination Survey (NHANES) 2009–2010 was used as theoretical minimum risk factor exposure distribution, to estimate the potential impact fraction (PIF) of FNBMD for fractures. Relative risks of FNBMD for fractures were obtained from a previous meta-analysis (2). Coded hospital data was used to calculate the fraction of falls-related deaths due to fractures. Disability levels were established by applying disability weights to each type of fracture. Then, PIFs were applied to obtain attributable deaths and disability due to low BMD.

Results: The percentage of falls-related preventable deaths attributable to low BMD is around 9% in the 50–54 age group, increasing to 84% in those aged 80 years and over. Total health burden (DALYs) and disability attribution (YLDs) also increase with age, from 19% and 25% in 50–54 years old, respectively, to 61% and 44% and population aged 80 years and above, respectively. Low BMD constitutes the most important preventable risk factors for falls-related DALYs from 50 years and above, followed by alcohol, occupational risk and smoking.

Conclusions: Low BMD is a major preventable risk factor that explains a very remarkable proportion of falls health burden in Europe, in particular in those aged 70 years and above. This is a growing concern, given the population trajectories, and requires urgent attention.

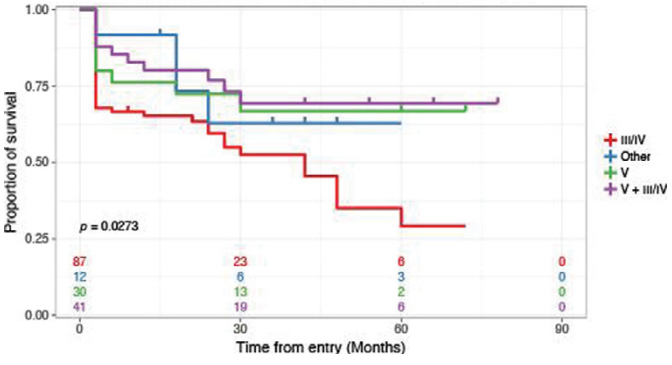
FRI0714 LUPUS NEPHRITIS AND PROGNOSIS. EFFECT OF MEMBRANOUS AND OTHER COMPONENTS OF THE HISTOLOGY

M.U. Martinez Martinez[1], C. Vallín-Orozco[1], H.E. Esparza-Holguin[1], G. Aguilera-Barragán Pickens[1], D. Martínez-Galla[2], C. Abud-Mendoza[1]. *[1]Unidad de Investigaciones Reumatológicas; [2]Renal Pathology, Hospital Central "Dr. Ignacio Morones Prieto", Universidad Autónoma de San Luis Potosí, San Luis Potosi, Mexico*

Background: In 1983 Austin et al. informed a series of prognostic factors (including histology) associated with the development of renal failure in patients with lupus nephritis (LN). Differences in actual therapies may have different hazard ratios of renal failure than the described by Austin et al.[1]

Objectives: To evaluate histological factors associated with a decline in kidney function (DKF) in patients with SLE.



Methods: We evaluated all the patients in whom a kidney biopsy was performed. DKF was defined as a glomerular filtration rate (GFR) of less than 60 ml/min/m^2 in two determinations in the follow-up. Histology was graded according to Austin et al.[1] (activity and chronicity) by a renal pathology specialist. Factors associated with the development of DKF were evaluated through Kaplan-Meier curves and Cox regression analysis (bivariate and multivariate).

Results: At this moment, we have followed 170 patients with LN and kidney biopsy, 130 (76.5%) women, mean age at kidney biopsy was 29.7±13.2 years; classes of LN were: 71 patients (41.8%) class IV, 30 (17.6%) class V, 22 (12.9%) class III/V, 19 (11.2%) class IV/V, 16 (9.4%) class III, and other classes 12 patients; 135 patients (79.5%) have a minimum follow-up of 12 months. There were statistically significant differences in four groups of LN: pure proliferative (classes III or IV), the combination with membranous (III/IV±V), pure membranous (V) or other classes (Figure1).

Table 1. Factors associated with a DKF

Histological feature	Bivariate HR (CI)	Bivariate p-value	Multivariate HR (CI)	Multivariate p-value
Glomerular abnormalities				
Cellular proliferation	1.01 (0.83–1.22)	0.920	NA	NA
Karyorrhexis	0.94 (0.76–1.17)	0.566	NA	NA
Celular crescents	1.09 (0.96–1.22)	0.179	0.95 (0.82–1.10)	0.501484
Hyaline thrombi	0.85 (0.64–1.12)	0.248	0.65 (0.47–0.90)	0.008837
Leukocyte infiltration	1.23 (0.97–1.57)	0.0848	1.03 (0.77–1.40)	0.815447
Glomerular sclerosis	1.79 (1.41–2.26)	<0.001	1.67 (1.23–2.25)	0.000838
Fibrous crescents	1.71 (1.27–2.29)	<0.001	1.55 (1.11–2.16)	0.009917
Membranous	0.50 (0.30–0.85)	0.0105	0.48 (0.27–0.88)	0.017001
Tubulointerstitial abnormalities				
Interstitial cell infiltration	1.31 (1.13–1.56)	<0.001	1.18 (0.95–1.47)	0.126099
Interstitial fibrosis	0.80 (0.92–1.70)	0.162	0.74 (0.47–1.16)	0.194012
Tubular atrophy	1.33 (1.02–1.74)	0.035	1.10 (0.47–1.17)	0.613154

Figure 1. Decline of kidney function according classes of LN

In the bivariate analysis, factors statistically significant associated with the development of DKF were: glomerular sclerosis, fibrous crescents, interstitial cell infiltration and tubular atrophy; having membranous component resulted as a "protector" factor for the development of DKF. The Cox regression model included all the factors with a p-value less than 0.25 in the bivariate analysis; independent factors associated with increased HR of DKF were glomerular sclerosis and fibrous crescents; however, hyaline thrombi and presence of membranous nephritis were associated with a decreased HR of DKF. (Table 1).

Conclusions: We describe factors associated with a DKF. We found that the proliferative LN in combination with membranous have a better prognosis than pure proliferative LN. Our study could help to evaluate the effects of therapies in LN.

FRI0715 BEING A WOMAN AND HAVING KNEE OSTEOARTHRITIS INCREASES THE LIKELIHOOD OF COMORBIDITIES

M. Herrero Barbero[1], S. Gimenez[2], J. Vergara[3], E. Viles I Lladó[4], H. Martinez[4], G. Rodríguez Roca[5], L. Sánchez[6], J.A. Díaz Muñoz[7], J.F. Frias[8], A. Castaño[9], J.J. Jiménez Díaz[10], Á. Rodríguez de Cossío[11], R. Belenguer[12], J.L. Llisterri[13], J. Vergés Milano[6,14] on behalf of EMARTRO. *[1]Plaça Francesc Macià 7, Bioiberica, Barcelona; [2]Unidad de Gestión Clínica el Limonar, Malaga; [3]Centro de Salud Huercal, Almería; [4]Bioiberica S.A., Barcelona; [5]Centro de Salud la Puebla de Montalbán, Toledo; [6]Bioiberica, Barcelona; [7]Centro de Salud Ávila Rural, Ávila; [8]Hospital Universitario Virgen de las Nieves, Granada; [9]Centro de Salud Corella, Navarra; [10]Centro de Salud Los Cubos, Burgos; [11]Centro de Salud San Martin de la Vega, Madrid; [12]Centro de Salud Algemesí; [13]Centro de Salud Ingeniero Joaquín Belloch, Valencia; [14]Osteoarthritis Fundation International, Barcelona, Spain*

Background: Osteoarthritis (OA) is the most prevalent joint disease and the leading cause of disability from 60 years onwards. In fact, 14,8% of the Spanish population has OA.

Objectives: This study aimed to determine if there is a differential profile and greater comorbidity in women affected by symptomatic knee OA compared to a control group without OA.

Methods: The EMARTRO study was designed as an observational, multicenter, transversal study to compare probability of suffering a comorbidities based on presence of symptomatic knee OA visited by GPs. Sociodemographic, anthropometric, clinical parameters and clinical variables of interest were recorded. The probability of suffering comorbidities in each study group was estimated using the Odds Ratio estimation with conditioned logistic regression models. The HAD scale, the Goldberg health questionnaire were administered to patients and the concomitant medication was also registered. The comparison between groups was done using t-Student, Chi-square and Mann-Whitney.

Results: A total of 897 women were included with a mean (SD) age of 67.4 (6.8) years.

Osteoarthritic women were obese and had a higher BMI compared with control group, 31.2 (5.5) vs 27.5 (4.3) ($p<0.0001$), respectively. Regarding blood pressure, no differences were found in the systolic BP ($p=0.0646$) but in the diastolic, women with OA also had higher values, 77.9 (9.1) vs 75.8 (8.9) mmHg ($p=0.0005$).

In general terms, the presence of OA doubled the probability of having concomitant conditions with respect to controls [OR=2,220 (95% CI: 1,449–3,400) p=0,0002]. Likewise, women with syntomatic knee OA were more likely to have hypertension [OR=1.697 (95% CI 1.299–2.217), $p=0.0001$], venous peripheral vascular disease [OR=2.148 (95% CI 1.547–2.984), $p<0.0001$] and gastroesophageal reflux (OR=1.890 (95% CI 1.297–2.754), $p=0.0009$).

Regarding the mental health of the patients, according to the Goldberg scale, 41% of the patients with OA elicited psychopathology vs 17.8% in controls, $p<0.0001$. As for the HAD scale, there were more cases of anxiety ($p<0.0001$) and depression in the OA women ($p<0.0001$).

The greater burden of physical and mental comorbidity in the OA patients was accompanied by a higher consumption of concomitant medications ($p<0.0001$).

Conclusions: The results of the present study indicate that in patients with knee OA, being female is a risk factor for the development of concomitant pathologies. Also, the increased likelihood of suffering from hypertension, venous peripheral vascular disease and gastroesophageal reflux should determine chronic medications for the treatment of osteoarthritis.

FRI0716 RISK STRATIFICATION IN YOUNG PATIENTS WITH ACUTE MYOCARDIAL INFARCTION USING THE ADJUSTED GLOBAL ANTIPHOSPHOLIPID SYNDROME SCORE (AGAPSS)

M. Radin[1], K. Schreiber[2], P. Costanzo[3], I. Cecchi[1], D. Roccatello[1], S. Baldovino[1], M. Bazzan[3], M. Cuadrado[4], S. Sciascia[1]. *[1]Department of Clinical and Biological Sciences, Center of Research of Immunopathology and Rare Diseases- Coordinating Center of Piemonte and Valle d'Aosta Network for Rare Diseases, Torino, Italy; [2]Department of Thrombosis and Haemophilia, Guy's and St Thomas' Hospital, London, United Kingdom; [3]S. Giovanni BoscoHospital, Torino, Italy; [4]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom*

Background: Young adults with acute myocardial infarction are a critical group to examine for the purpose of risk factors stratification and modification [1].

In the setting of underlying systemic autoimmune diseases, premature cardiovascular disease deserves even more attention in these conditions, such as antiphospholipid syndrome (APS), the most common acquired thrombophilia.

Objectives: In this study we aimed to assess the clinical utility of the adjusted Global AntiphosPholipid Syndrome Score (aGAPSS)[2] for the risk stratification of acute myocardial infarction in a cohort of young APS patients with thrombotic events.

Methods: The analysis included 83 consecutive APS patients (≤50 years old) who presented with arterial or venous thromboembolic events. Data on cardiovascular risk factors and antiphospholipid antibodies (aPL) positivity were retrospectively collected. The aGAPSS was calculated for each patient by adding the points corresponding to the risk factors, based on a linear transformation derived from the β regression coefficient as follows: 3 for hyperlipidaemia, 1 for arterial hypertension, 5 for aCL IgG/IgM, 4 for anti-b2 glycoprotein I IgG/IgM and 4 for LA.

Results: Demographic, clinical and laboratory characteristics of the cohort are summarized in Table 1. Higher aGAPSS values were observed in patients with acute myocardial infarction when compared to the others [mean aGAPSS 11.9 (S.D. 4.15, range 4–18) Vs. (mean aGAPSS 9.2, S.D. 5.1, range 1–17); T test: $p<0.05$]. Significantly higher aGAPSS values were also seen in patients with acute coronary syndrome compared to patients with a history of peripheral or cerebrovascular arterial thrombotic events [mean aGAPSS 11.9 (S.D. 4.15, range 4–18) Vs. (mean aGAPSS 6.7, S.D. 5.7, range 1–17); T test: $P<0.005$]. When separating for cardiovascular risk factors and aPL positivity, hypercholesterolemia was significantly higher in the group that developed myocardial infarction compared with patients with a history of any thrombosis and patients with a history of peripheral or cerebrovascular arterial thrombotic events (Chi square test: $p<0.0001$ and $p<0.0001$) and significantly higher rate of multiple positivity

Patients Characteristics	All (n=83)	%
Female sex	75	90
Age, mean (S.D.), years	44,6 (11,3)	
Disease duration, mean (S.D.), years	11,4 (7,8)	
Caucasians, n	82	93

Venous thrombosis, n	44	50
Acute Myocardial Infarction	13	15
PAPS, n	31	35
SLE and APS, n	44	50
Arterial Hypertension, n	27	31
Hyperlipidemia, n	16	18
LA, n	38	43
aCL IgG/M, n	65	74
IgG	60	68
IgM	35	40
Anti-Beta2GPI IgG/IgM, n	44	50
IgG	39	44
IgM	12	14
Triple aPL positivite	27	31

Table 1. Demographic, clinical and laboratory characteristics of the cohort

	Acute myocardial infarction (13)	Arterial and/or venous thrombosis (70)
Hyperlipidemia	10	9
Arterial Hypertension	4	22
LA	8	31
aCL IgG/M	11/6	51/30
Anti-Beta2GPI IgG/IgM	8/2	31/11
Triple aPL positivite	5	22

Table 2. Patients cardiovascular risk factors and aPL positivity between groups

for LA, aCL (IgG/IgM), anti-β2GPI antibodies (IgG/IgM) were present in the group that developed myocardial infarction (Chi square test: $p<0.05$ for all aPL) (Table 2).

Conclusions: The aGAPSS is based upon a quantitative score and could aid risk stratifying APS patients younger than 50 years for the likelihood of developing coronary thrombotic events and may consequently guide pharmacological treatment for high-risk patients.

FRI0717 POSITIVE CONVERSION OF TUBERCULOSIS SCREENING RESULTS AND INCIDENCE OF ACTIVE TUBERCULOSIS INFECTION IN PATIENTS RECEIVING BIOLOGIC TREATMENT

M.-C. Park[1], H.W. Kim[1], S.H. Han[2]. *[1]Division of Rheumatology; [2]Division of Infectious Diseases, Yonsei University College of Medicine, Seoul, Korea, Republic Of*

Background: Previous studies reported active tuberculosis infections can occur during biologic treatment in patients with negative baseline LTBI screening. Current recommendations suggesting the annual testing for latent tuberculosis infections are mainly issued for patients with rheumatoid arthritis (RA) receiving anti-TNF inhibitors and there are lacking evidence for patients receiving non-TNF biologic agents and for patients with ankylosing spondylitis (AS) or psoriatic arthritis (PsA).

Objectives: This study was performed to investigate the conversion rate of initially negative tuberculosis screening test results during biologic treatment and the usefulness of repeated screening test for detecting unexpected tuberculosis infection in patients with RA, AS, and PsA.

Methods: A total of 95 patients (43 with RA, 50 with AS, and 2 with PsA) who had negative baseline interferon γ releasing assay (IGRA) results, which were assessed using QuatiFERON-TB Gold in tube (QTF-GIT), prior to initiation of biologic treatment were enrolled in this study. All patients received biologic agents for the treatment of their diseases and rescreening with QTF-GIT were performed in all patients after median 12 months from baseline test. Clinical characteristics were compared between converters and non-converters and incidence of active tuberculosis infection was evaluated.

Results: Patients were treated with different biologics (23 with etanercept, 50 with adalimumab, 5 with infliximab, 4 with golimumab, 1 with certolizumab pegol, 3 with abatacept, and 9 with tocilizumab). Positive conversions of initially negative IGRA were found in 13 (6 patients with etanercept, 4 patients with adalimumab, 2 patients with tocillizumab and 1 patient with abatacept) of 95 patents (13.7%) after initiation of biologic treatment. Age over 50 years and diagnosis of RA were more common in converters. Multivariate analysis showed that age over 50 was an independent risk factor for IGRA conversion with OR 4.36 (95% CI 1.10 - 17.34, p=0.036). During biologic treatments, active tuberculous infections were found in 3 of 13 converters (23.1%)

Conclusions: Although initial screening test showed negative results, the serial follow-up of tuberculosis screening test should be considered during biologic treatment in patients with rheumatic diseases to prevent unexpected tuberculosis infection.

FRI0718 PREVALENCE AND PATTERN OF COMORBIDITIES IN CHRONIC RHEUMATIC AND MUSCULOSKELETAL DISEASES: THE COMORD STUDY

N.R. Ziade[1,2], F. Fayad[1,2], B. Khoury[3], M. Zoghbi[4], G. Merheb[5], G. Abi karam[1,2], K. Mroue[6], J. Missaykeh[7]. *[1]Rheumatology, Hotel Dieu de France; [2]Rheumatology; [3]Medicine; [4]Family Medicine, St-Joseph University, Beirut; [5]Medicine, ND des Secours, Jbeil; [6]Rheumatology, Zahra University Hospital, Beirut; [7]Rheumatology, Monla Hospital, Tripoli, Lebanon*

Background: Rheumatic and musculoskeletal diseases (RMD) frequently coexist with other conditions, resulting in multimorbidity, which may compromise arthritis management and lead to diminished quality-of-life and increased mortality. In 2016, EULAR published "Points to consider for reporting, screening for and preventing selected comorbidities in chronic inflammatory rheumatic diseases", used to guide this study.

Objectives: The primary objective is to evaluate the prevalence and pattern of comorbidities in selected RMD in Lebanese patients. The secondary objective is to evaluate the gap between recommendations and routine comorbidities' screening.

Methods: COMORD is an observational, cross-sectional, multicentric national study. Consecutive RMD patients (Rheumatoid Arthritis (RA), Osteoarthritis (OA), Systemic Lupus Erythematous (SLE), Axial Spondyloarthritis (AxSpA) and Peripheral Spondyloarthritis (pSpA)) as diagnosed by the rheumatologist) were recruited at 6 practices from university hospitals and private clinics in Lebanon. Six axes of comorbidities (Cardiovascular, Malignancies, Infections, Gastrointestinal, Osteoporosis, Depression) were investigated using a case report form (patient interview). Optimal comorbidities screening was defined according to current recommendations and compared with monitoring in practice. Prevalences were presented descriptively. The number of comorbidities was correlated with predictive factors using Poisson Regression. Finally, Latent Class Analysis (LCA) was used to identify patterns of multimorbidity. All analysis were performed on IBM SPSS Statistics 23 and XLSTAT 18.07.

Results: 515 patients were recruited (196 RA, 161 OA, 75 AxSpA, 45 SLE, 40 pSA). Mean age was 56y, 76% were female. There was no difference in the disease distribution between centers. The most common comorbidities were cardiovascular risk factors and diseases, followed by depression and osteoporosis. The number of comorbidities was significantly associated with age ($p<0.001$), obesity ($p<0.001$) and biotherapies (p 0.05). LCA analysis identified 3 main clusters of multimorbidity: OA, RA, AxSPA (Fig 1). The most optimal screening was found for cardiovascular risk factors (84%). DXA was prescribed in 69% of correct indications. As for malignancies, mammograms and pap smears were the most optimally prescribed (36% and 28%). Colonoscopy and dermatology visit were prescribed in 22% and 18%. Correct vaccination (influenza and pneumococcal) was found in 17% and 8%. Predictive factors for optimal screening were age, university setting, social coverage, disease duration and biotherapy.

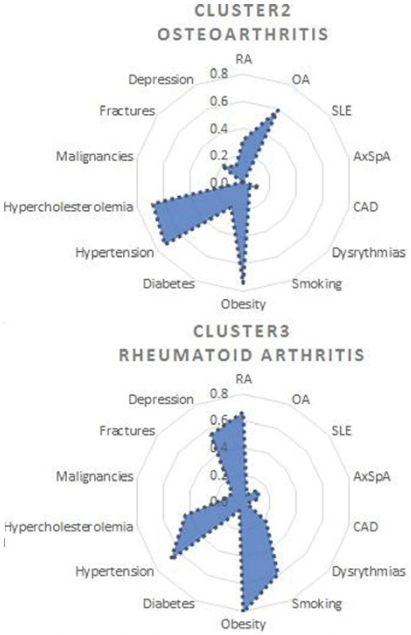

Figure 1. Identified Multimorbidity Clusters by Latent Class Analysis

Conclusions: Comorbidities are prevalent in RMDs and follow specific multimorbidity patterns, with a predominance for cardiovascular, depression and osteoporosis. They are more frequent with age and obesity. Optimal screening needs to be improved.

FRI0719 BURDEN OF HEPATITIS E VIRUS INFECTION IN PATIENTS WITH RHEUMATIC DISEASES

P. Jacques[1,2], E. Padalko[3], E. Verheugen[1,2], L. Cattoir[3], X. Verhelst[4], E. Nys[3], S. Van Gucht[5], V. Hutse[5], V. Suin[5], D. Elewaut[1,2]. *[1]Rheumatology, University Hospital; [2]VIB, Ghent University; [3]Clinical Chemistry, Microbiology and Immunology; [4]Gastroenterology, University Hospital, Ghent; [5]National Reference Centre for Viral Hepatitis, Scientific Institute of Public Health, Brussels, Belgium*

Background: Hepatitis E virus (HEV) is considered an emerging pathogen in developed countries, potentially causing chronic hepatitis.
Objectives: This cross-sectional analysis was undertaken to determine the seroprevalence of HEV in patients with autoimmune or inflammatory arthritis. This subgroup of patients is often treated with immune suppressive drugs, and is generally considered more susceptible to infections.
Methods: Serum samples were obtained from 449 consecutive patients consulting at the department of Rheumatology between October and November 2015. Patient characteristics with respect to diagnosis and treatment were collected. HEV IgM and IgG were measured by ELISA (Wantai Hepatitis E Virus IgG and IgM ELISA, Sanbio BV). Positive or borderline samples were further analyzed for HEV RNA (RealStar® HEV RT-PCR Kit, Altona Diagnostics NRC WIV).
Results: A total of 449 patients were included, 211 men and 238 women. HEV IgG was positive in 82 samples (18.26%), 6 were borderline, and 5 were non-determinable (not enough serum). IgM was positive in only 2 samples (0.45%). These 2 patients had normal liver function tests. Additional PCR was performed on all positive and borderline samples, which turned out negative in all samples. Of the 88 IgG positive and borderline samples, 86 patients had a known diagnosis of chronic inflammatory arthritis, of which 50 patients had previously been diagnosed with rheumatoid arthritis, 18 with spondyloarthritis, 8 with psoriatic arthritis. Fifty patients were treated with biologics (37 TNF inhibitors), 43 patients were treated with methotrexate (mean dose 12.5mg weekly), and 20 were treated with corticosteroids (mean daily dose 5.5mg prednisolone equivalent).
Conclusions: In a consecutive cohort of patients with known diagnosis of autoimmune or inflammatory arthritis, seroprevalence of HEV IgG was 18,2%. No active HEV infection could be detected. We found this to be comparable to a historical cohort of healthy patients from the departments of Orthopedics and obstetrics[1], where prevalence of HEV IgG was 14%.

FRI0720 CHARACTERISTICS OF PATIENTS WITH GOUT TREATED TO SUA TARGET THAT CONTINUE TO EXPERIENCE FLARES: DATA FROM FRANCE, GERMANY, ITALY, SPAIN, UK AND US

R. Morlock[1], D.C. Taylor[2], S. Baumgartner[3]. *[1]YourCareChoice, Ann Arbor; [2]Health Economics and Outcomes Research, Ironwood Pharmaceuticals, Cambridge; [3]drB Consulting, Spokane, United States*

Background: Gout is a common form of inflammatory arthritis. Treatment guidelines recommend a target serum urate (sUA) ≤6mg/dL. ACR and EULAR treatment guidelines indicate sUA targets may need to be surpassed to achieve treatment benefits in a subset of patient that continue to flare and/or have tophi.
Methods: Data were assessed from a survey of physicians about gout disease management. Patient results were confirmed through in-depth chart audits assessing diagnosis, comorbid conditions, disease severity and laboratory assessments. Disease severity was measured using a physician global assessment, flare counts, joint damage and presence of tophi. Type and dose of XOI, length of current treatment, compliance, physician type and patient socio-demographic factors were identified. Descriptive and multivariate statistics were used to describe patients having ≥2 flares per year (excluding treatment-related flares) in patients achieving target sUA ≤6 mg/dL.
Results: Overall, 251 rheumatologists and 250 primary care physicians were interviewed and provided data from 2505 patients with gout; 82% were male and the average age was 58 years (SD=12). 1823 (73%) patients were treated with an XOI, of these 813 (44%) had a least one assessment of sUA ≤6 mg/dL over a 12-month period. Of the 813 patients reaching sUA target, 307 (37.8%) reported ≥2 flares in the last year. On average, patients at sUA goal with ≥2 flares had been treated over 38.8 months on their current XOI and patients with ≤1 flare had been treated for 40.7 months. Patients at sUA ≤6 mg/dL treated with an XOI and reporting ≥2 flares a year were more likely to have tophi (32.9% vs. 19.2%; p<0.01), alcoholism (22.8 vs. 10.7; p<0.01), CVD (24.8 vs. 17.6%; p=0.014), depression (14.3 vs. 9.3; p=0.027), and diabetes mellitus (23.8 vs. 16.8; p=0.015) compared to patients with ≤1 flare a year. A backward stepwise multivariate model predicting patients classified as controlled (sUA ≤6 mg/dL) and continuing to flare (≥2 flares in the last year) found the physician-reported and chart-documented comorbidities of chronic kidney disease (OR 1.9; p<0.01), alcoholism (OR 2.4; p<0.01), diabetes mellitus (OR 1.5; p<0.05), and have tophi (1.7; p<0.01) to be associated with having higher flare rates despite achieving sUA ≤6 mg/dL. There was no difference by the type of XOI or physician.
Conclusions: Of the patients achieving target sUA level of ≤6 mg/dL, 62% have ≤1 flare; however, over a third reported ≥2 in a 12-month period. Patients with multiple flares were more likely to have higher urate burden in the form of tophi, chronic kidney disease, alcoholism, and diabetes mellitus comorbid conditions. Frequent flares and greater tophaceous burden may require treating more aggressively to an sUA level of 5 mg/dL or lower as recommended by treatment guidelines.

FRI0721 SLEEP DISORDERS IN PATIENTS AT THE FIRST ACCESS TO A RHEUMATHOLOGY OUTPATIENT CLINIC

R. Tirri, D. Capocotta, R. Ferrara. *Department of internal and experimental Medicine, Unit of Rheumatology of Univerity of study of Campania "Luigi Vanvitelli", Naples, Italy*

Background: Sleep disturbances are frequently found in patients affected by rheumatic conditions (1). Chronic pain, the most common manifestation of these conditions is associated to poor sleep (2).
Objectives: Our primary objective was to evaluate prevalence of excess daytime sleepiness and impaired sleep quality in a patient population at the first access to a Rheumatology outpatient clinic. Secondary objective was evaluation of pain and others factors well known to be associated to sleep disorders.
Methods: 961 out of 1454 (mean age was 52.6 years; 14.3% were male) consecutive patients admitted for the first time to an Italian Rheumatology Outpatient Clinic, between December 2014 and November 2016, accepted to answer a self-administered questionnaire study. We considered the following parameters: pain intensity on visual analogic scale ranging from 0 to 100 according to commonly used classification (3), patient's assessment of General Health (GH), Epworth Sleepiness Scale (ESS), Pittsburgh Sleep Quality Index (PSQI), Health Assessment Questionnaire (HAQ), and Body Mass Index (BMI). Smoke habits were also considered.
Results: 70 patients showed both sleep disorders (7.3%),624 patients had only impaired sleep quality (64.9%), 25 showed isolated excessive daytime sleepiness (2.6%). 242 patients did not have any sleep disorders (25.2%). We found that the presence of both ESS≥10 and PSQI≥5 was correlated to moderate-severe pain VAS pain≥40, BMI≥35, HAQ≥1 and GH≥50 with a statistical significance (respectively p=0.004; p=0.032; p=0.0004; p=0.0001). A correlation with GH≥50 in the patient group with only PSQI≥5 was detected (p=0.03). Smoke habits did not correlate with sleep disturbance measures investigated. No other correlations were found in the other groups.
Conclusions: Thus excess daytime sleepiness and impaired sleep quality may be a target of therapeutic intervention in the treatment of rheumatic conditions. Further studies are needed to generalize results and suggestions.

FRI0722 CROSS-SECTIONAL ASSOCIATIONS BETWEEN DEMOGRAPHIC, JOB RELATED, HEALTH RELATED AND PSYCHOSOCIAL FACTORS AND THREE DIFFERENT MEASURES OF PRESENTEEISM: RESULTS FROM EULAR-PRO AT-WORK PRODUCTIVITY STUDY

S. Leggett[1], D. Lacaille[2], A. Boonen[3], C. Mihai[4], S. Talli[5], S. Hagel[6], S. Dadoun[7], S. Ramiro[8], A. Bosworth[9], G. Sakellariou[10], S. Verstappen[1,11] on behalf of EULAR-PRO at-work productivity co-investigators. *[1]Arthritis Research UK Centre for Epidemiology, University of Manchester, Manchester, United Kingdom; [2]University of British Columbia, Vancouver, Canada; [3]Maastricht UMC, Maastricht, Netherlands; [4]Dr. Ion Cantacuzino Hospital, Bucharest, Romania; [5]East Tallinn Central Hospital, Tallinn, Estonia; [6]Lund University and Skane University hospital, Lund, Sweden; [7]APHP Pitie-Salpetriere Hospital, Paris, France; [8]Leiden UMC, Leiden, Netherlands; [9]NRAS, Maidenhead, United Kingdom; [10]IRCCS Policlinico San Matteo Foundation, Pavia, Italy; [11]NIHR Manchester Musculoskeletal BRU, Central Manchester NHS Trusts, Manchester, United Kingdom*

Background: Several measures of at-work productivity loss (i.e. presenteeism)

exist, varying in concept, recall period, and attribution[1]. As a consequence, the contribution of contextual factors may vary which has important implications when considering these factors in studies evaluating the impact of inflammatory arthritis (IA) and osteoarthritis (OA) on presenteeism.

Objectives: To determine demographic, job related and health related factors associated with three different global measures of presenteeism in patients with IA or OA.

Methods: This large cross-sectional international EULAR-PRO study (n=8 countries) includes patients with RA, PsA, AS or OA in paid employment. Data collection included: demographics, job characteristics, health related and psychosocial factors. Patients also completed three global measures of presenteeism, varying in content, attribution and recall period. The Work Productivity Scale–Arthritis (WPS-A) measuring the affect of arthritis on productivity during the last 7 days, the Work Productivity and Activity Impairment Questionnaire (WPAI) measuring interference of arthritis on work productivity in the last month, and the Work Ability Index (WAI) a generic scale measuring current ability to work. For interpretation purposes the scale of the WAI was reversed in this study. Due to skewed data, univariable median regression analyses were performed to assess the association between independent variables with each individual presenteeism instrument.

Results: 503 patients with IA/OA were recruited in this study with a mean age of 47 (SD10) yrs and disease duration of 12.6 (SD10) yrs. Except for male patients reporting a lower WPS-A score, no other demographics were significantly associated with presenteeism (table). Being neutral/unsatisfied about the job, not being able to organize one's own work, reporting higher VAS well-being and disability scores, and experiencing reduced quality of life were all significantly associated with higher presenteeism, a result observed for all three instruments. Furthermore, those with higher anxiety and depression scores also reported having more problems at work due to ill health. Discrepancies between instruments were especially observed between the WPAI (affect of ill health on productivity)/WPS-A (interference ills health on productivity) and WAI (generic scale on ability to work) in relation to job demands, receiving help from colleagues and the option to postpone work.

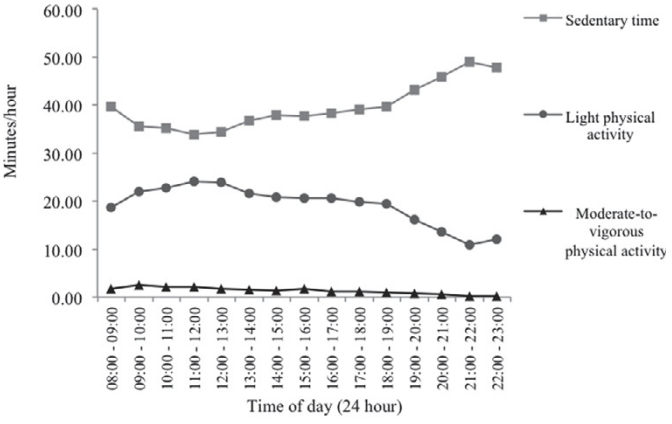
FRI0723 TEMPORAL PATTERNS OF SEDENTARY BEHAVIOUR AND PHYSICAL ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

S.A.M. Fenton[1,2], J.L. Duda[1], J.J. Veldhuijzen van Zanten[1,2], G.S. Metsios[3], P.C. Rouse[4], C.-A. Yu[5], G.D. Kitas[2]. *[1]School of Sport Exercise and Rehabilitation Sciences, University of Birmingham, Birmingham; [2]Rheumatology, Russells Hall Hospital, Dudley; [3]Faculty of Education, Health and Wellbeing, Institute of Sport, Wolverhampton; [4]Department for Health, University of Bath, Bath; [5]School of Biomedical Sciences, University of Leeds, Leeds, United Kingdom*



Background: Rheumatoid Arthritis (RA) is associated with increased risk of cardiovascular disease (CVD). Recent evidence suggests sedentary behaviour (waking behaviour ≤1.5 metabolic equivalents whilst sitting/lying) may contribute towards the progression of RA outcomes, including heightened CVD risk (1). Sedentary behaviour occupies the majority of waking hours among people with RA (1). However, the proportion of time spent sedentary is likely to fluctuate over the course of the day, with periods of high sedentarity representing more optimal opportunity for intervention, and thus potentially higher intervention efficacy.

Objectives: The aims of this study were; 1) to explore temporal patterns of sedentary behaviour (and physical activity) among RA patients, and 2) to examine associations between temporal sedentary patterns and predicted 10-year risk of CVD.

Methods: Patients with RA (N=97) wore a GT3X accelerometer for 7 days to assess habitual sedentary time (<100 counts/min) and physical activity (PA; light =100–2019, moderate-to-vigorous = ≥2020 counts/min). Accelerometer data were analysed separately for each hour (valid hour criteria; 60-minutes of data on ≥3 days, including a weekend day). To evaluate 10-year risk of CVD (Q-risk2), patients reported their medical history, provided a fasted blood sample and underwent assessments of blood pressure and body-mass index.

Results: Temporal patterns of sedentary time and PA are reported in Figure 1. Sedentary time declined throughout the morning (08:00–12:00). During the afternoon, sedentary time increased by 4.5 minutes (12:00–18:00; M =34.36±8.86 to M =39.06±7.91). A more marked increase in sedentary time was observed during leisure time (18:00–22:00; M =39.61±7.59 to M =47.90±6.30). Repeated measures analysis of variance (ANOVA) revealed sedentary time was significantly higher during leisure time (M =46.20±5.46) compared to the morning (M =36.88±5.61), and afternoon (M =38.50±6.07) [N =28, $F(2,26)=43.48$, $p=<0.01$]. Significant differences remained after accounting for employment status (i.e., employed vs. unemployed/student, $F(2,23)=1.40$, $p=0.27$). Patients who accumulated M = ≥45.31 sedentary minutes during their leisure time (18:00–23:00, median split), had significantly higher 10-year risk of CVD (M =22.23±13.83) compared to those accruing M=<45.31 sedentary minutes (M=8.09±7.62) [$t(41)=3.92$, $p=<0.01$]. Finally, hourly patterns for light PA were the reverse of those observed for sedentary time. Hourly MVPA engagement was consistently <3 minutes (peak MVPA at 09:00–10:00, M =2.47±4.16).

Figure 1. Temporal patterns of sedentary time, light and moderate-to-vigorous physical activity

Note: Valid data available at each time point ranged from N = 49 (08:00) to N = 71 (13:00). A total of N = 41 participants provided complete data across all hours during the morning (08:00 – 12:00) and leisure time (18:00 – 23:00). N = 64 participants complete data during the afternoon (12:00 – 18:00).

Conclusions: Interventions targeting leisure time sedentary behaviour (18:00–23:00), relative to more occupational sedentary behaviour (08:00–18:00), may offer the greatest potential for sedentary time reduction and associated improvements of CVD risk profile. Due to inverse patterns of engagement, replacing leisure time sedentary behaviour with light PA may offer an effective intervention approach.

FRI0724 PREDICTORS OF PRESENTEEISM AND ABSENTEEISM IN PATIENTS COMMENCING TREATMENT WITH METHOTREXATE MONOTHERAPY OR BIOLOGIC THERAPY FOR RHEUMATOID ARTHRITIS

S. Leggett[1], M. Lunt[1], A. Barton[2], K. Hyrich[1], K. Walker-Bone[3], S.M. Verstappen[1] on behalf of RAMS and BRAGGSS co-investigators. *[1]Arthritis Research UK Centre for Epidemiology; [2]Arthritis Research UK Centre for Genetics and Genomics, The University of Manchester, Manchester; [3]Arthritis Research UK/MRC Centre for Musculoskeletal Health and Work, The University of Southampton, Southampton, United Kingdom*

Background: The adverse effects of RA on absenteeism (i.e. days absent from work) and presenteeism (at-work productivity loss) are increasingly recognised as an important issue. Research suggests the reasons are multifactorial with many factors such as disease severity, quality of life, and depression possibly contributing to poor work outcomes in patients with RA.
Objectives: To identify predictors of presenteeism and absenteeism over one year in patients with RA commencing treatment with methotrexate (MTX) or biologics for the first time.
Methods: Patients recruited to the Rheumatoid Arthritis Methotrexate Starters study (RAMS) or the Biologics in Rheumatoid Arthritis Genetics and Genomics Study Syndicate (BRAGGSS), and in full or part-time paid employment were included in this analysis. Demographic (e.g., age), clinical (e.g., DAS28), and psychological data (e.g., Hospital Anxiety and Depression scale (HADS)) were collected at baseline. Patients were followed up at six months and one year in both cohorts. Absenteeism in the last month (days missed), and presenteeism (*0 = no interference – 10 = complete interference)*, were measured at all three points using the RA specific Work Productivity Survey (WPS-RA). Patients with at least one follow-up post baseline were included in this analysis. Due to excessive zeros in the WPS-RA, a repeated measure zero inflated negative binomial regression (ZINB) was used to test the association between baseline demographic, clinical and psychological variables and presenteeism and absenteeism over one year.
Results: Data was available for 191 patients in BRAGGSS and 308 in RAMS. In BRAGGSS, the mean age was 51 years (SD 9.5), median symptom duration was 8 years (IQR 5–13); 78% female. In RAMS, the mean age was 52 years (SD 9.6), median symptom duration was 8.5 months (IQR 5–23); 66% female. At baseline, 26% (BRAGGSS) and 27% (RAMS) reported ≥1 days absent from work, and the median presenteeism scores were 5 (IQR 3–7) and 4 (IQR 1–7) for BRAGGSS and RAMS respectively. Presenteeism scores significantly improved over 1 year in both cohorts (BRAGGSS: median 2 [IQR 0–5], RAMS: median 2 (IQR 0–4) Kruskal-Wallis $p<0.001$)), as did absenteeism for both cohorts although non-significant. The ZINB revealed similar predictive patterns in both cohorts for presenteeism and absenteeism (Table 1). For example, for every 0.06 increase in EQ-5D (clinically important difference), the odds of being in the zero presenteeism group (i.e., no at-work productivity loss) over one year increased by a factor of 1.2 in BRAGGSS, and was similar in RAMS. In RAMS, a one unit increase in VAS fatigue decreased the odds of having no absenteeism over one year by a factor of 0.97.

Table 1. Demographic, clinical, and psychological predictors of presenteeism and absenteeism over one year.

	RAMS				BRAGGSS

*Adjusted for age, gender, and disease duration.
*p<0.05.
¶ Relative change in count part of ZINB model, assuming non-zero score.
§ Odds ratio for being in zero scoring group of ZINB model.
≠ A unit increase of 0.06 (a minimal clinically important difference in EQ-5D scores)

Conclusions: The results from this analysis support the notion of a multifactorial relationship between RA and work outcomes. The results suggest that greater quality of life and psychological well-being, amongst other factors, can predict improvements in presenteeism and absenteeism at one year in patients on either MTX or biologics for RA.

FRI0725 PREDICTION OF INTERSTITIAL LUNG DISEASE IN MIXED CONNECTIVE TISSUE DISEASE

S. Reiseter[1], R. Gunnarsson[2], T.M. Aaløkken[3], M.B. Lund[4], J. Corander[5], Ø. Molberg[6]. *[1]Institute of Clinical Medicine, University of Oslo; [2]Dept. of Rheumatology; [3]Dept. of Radiology and Nuclear Medicine; [4]Dept. of Respiratory Medicine, Oslo University Hospital; [5]Institute of Basic Medical Sciences; [6]Institute of Clinical Medicine, University of Oslo, Oslo, Norway*

Background: Mixed Connective Tissue Disease (MCTD) is characterized by high levels of autoantibodies against U1 small nuclear ribonucleoprotein (RNP) and clinical manifestations also found in Systemic Sclerosis, Systemic Lupus Erythematosus, Rheumatoid Arthritis and Polymyositis. Interstitial Lung Disease (ILD) is a severe complication in MCTD and has been reported to affect between 35% and 85% (1) in different cohorts.
Objectives: Here we present a predicting model of ILD in an unselected nationwide MCTD cohort aiming to assist clinicians in identifying MCTD patients with ILD.
Methods: 135 patients with high resolution computed tomography (CT) available for systematic evaluation were included from our nationwide MCTD cohort. Abnormal CT findings of ground glass attenuation and reticular patterns were defined as ILD. Pulmonary function tests were performed within 2 months of the HRCT examination. Serum levels of anti-RNP and Ro-52 autoantibody were determined by line immunoassay (ANA Profile 5 Euroline Blot test kit, Euroimmun, Lübeck, Germany). Logistic regression analyses were used to find the predictive factors of ILD. Variables at a significant level of $P<0.25$ where considered a candidate in the prediction model by manual backward elimination procedure in addition to age and gender.
Results: Results: 52 patients (38%) had evidence of ILD on HRCT. The predictive model is shown in Table 1. $P=0.55$ for goodness of fit test and $P=0.80$ for area under ROC curve.

	Univariable			Multivariable		
	OR	95% CI	P value	OR	95% CI	P value
DLCO <60	5.8	2.3–14.6	<.001	4.6	1.5–13.6	0.006
Anti-RNP antibodies titer >200	3.0	1.5–7.1	0.003	4.9	1.8–13.3	0.003
Never arthritis	5.4	2.1–13.6	<.001	3.3	1.1–9.9	0.033
Age group* at HRCT	1.0	1.0–1.0	0.015	1.6	1.1–2.2	0.012
Anti-Ro52 antibodies present	2.6	1.2–5.9	0.021			
FVC <75	3.0	1.1–8.2	0.040			
ESR >30	2.3	1.0–5.0	0.043			
Sclerodactily	2.0	0.94–4.0	0.071			
Male gender	1.6	0.71–3.5	0.268			

*Patients were divided in 6 age groups (<25 years, 26 to 35 years, 36 to 45 years, 46 to 55 years, 56–65 years and above 65 years). FVC = Forced Vital Capacity % of predicted, DLCO = diffusing capacity of the lung for carbon monoxide % of predicted, RNP = Ribonucleoprotein, ESR = erythrocyte sedimentation rate.

Conclusions: Risk factors of ILD in MCTD are DLCO less than 60% of predicted, high titer RNP antibodies, no previous arthritis and increasing age.

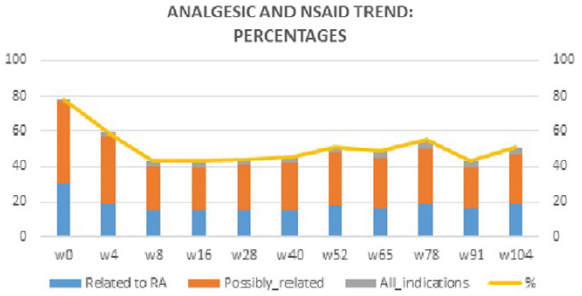
FRI0726 LONG TERM USE OF ANALGESICS AND NSAIDS IN EARLY RA: LESSONS FROM THE CARERA STUDY

S. Pazmino[1], R. Westhovens[1,2], V. Stouten[1], J. Joly[2], K. Van Der Elst[2,3], P. Verschueren[1,2] on behalf of CareRA study group. *[1]Skeletal Biology and Engineering Research Centre, KU Leuven Department of Development and Regeneration; [2]Rheumatology, University Hospitals Leuven; [3]Skeletal Biology and Engineering Research Centre, KU Leuven Department of Public Health and Primary Care, Leuven, Belgium*



Background: One might consider pain accompanying musculoskeletal conditions as a separate illness entity deserving specific treatment. A subgroup of early Rheumatoid Arthritis (RA) patients has remaining pain despite adequate disease control and this might be reflected in the use of analgesics and NSAIDs.
Objectives: To investigate the usage of analgesics and antiphlogistics prospectively in the pragmatic randomized controlled CareRA trial and describe the users of such drugs taking into account body mass index (BMI), VAS pain and DAS28CRP.
Methods: This study utilized data from the CareRA trial, a 2-year prospective investigator-initiated multicentre pragmatic RCT in patients with early RA (≤1 year) comparing different early intensive treat to target strategies, including glucocorticoid (GC) bridging, aiming for remission in all participants.
All concomitant medication for each patient was recorded, including: name, dose, frequency/timing, continuous/intermittent use, start/end date and indication (possibly/definitely RA-related or other). Meaningful sub-classifications were made (analgesics, cox2-selective and non-selective NSAIDs). We defined two subgroups with prolonged analgesic/NSAID use till w104: the pre-induction group starting before/at baseline (BL) and the post-induction group starting w28-w52, after GC step-down.
Results: From the CareRA cohort (n=379), 90% were on analgesics/NSAIDs at some time during the study and 84% had already started before inclusion (mean 24 weeks). In general, we observed a decreasing trend in the use of analgesics/NSAIDs, with a slight increase after GC step-down. Overall, 266 patients used non-selective and 131 cox2-selective NSAIDs, 154 paracetamol and 85 opioids.
Of the total population, 15, 5% (53 patients) started long-term analgesics/NSAIDs before/at BL (pre-induction group) and 13% (45 patients) from w28-w52 (post-induction group).

A detailed distribution of on-demand/daily analgesic/NSAID use is provided in the table below.

Table 1

Group of long-term users	NSAIDs		Paracetamol	Opioids	Combined therapy
	Non-selective	Selective COX2			
Pre-induction (n=53)	26% (17%/d)	11% (4%/d)	45% (8%/d)	9% (6%/d)	9% (2%/d)
Post-induction (n=45)	33% (16%/d)	20% (7%/d)	33% (4%/d)	13% (7%/d)	0%

Proportionally more patients were using NSAIDs in the post-induction group and paracetamol in the pre-induction group.
Mean DAS28CRP (BL-w104) in the pre-induction group was 3.11 (±0.70) and mean VAS pain 32.7 (±16.3). In this group 62.3% had sustained low disease activity while taking continuous analgesics/NSAIDs. Results in the post-induction group were comparable.
Analgesic/NSAID use was not significantly associated with mean (BL-w104) BMI, DAS28CRP or VAS pain.

Conclusions: Analgesics/NSAID intake in early RA was high (90%) and remarkably about 30% continued using these drugs, despite overall low disease activity. This high consumption might be explained by the ambiguous nature of arthritis-related pain and the lack of differentiation between nociceptive and non-nociceptive pain. Therefore pain management in early RA deserves more attention.

FRI0727 IMPACT OF MATERNAL SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES ON NEONATAL OUTCOMES: A POPULATION-LEVEL ANALYSIS

S.O. Keeling, A. Savu, P. Kaul. *Department of Medicine, University of Alberta, Edmonton, Canada*

Background: The impact of systemic autoimmune rheumatic diseases (SARDS) on peripartum outcomes is not well described at a population level despite the potential for active disease in this period.
Objectives: We examined the association between SARDs and neonatal outcomes in a contemporary pregnancy cohort in the province of Alberta, Canada.
Methods: The patient population consisted of women giving birth between January 1, 2005 to December 31, 2014 (n=312,081). For women with multiple gestations during the period, one birth event was randomly selected. Women with SARDs included any of the following: systemic lupus erythematosus, systemic sclerosis, myositis and sjogren's syndrome, diagnoses based on the presence of International Classification of Disease version 9/10 codes in outpatient or inpatient records. Baseline characteristics, comorbidities, medication use (available for all births after January 1, 2009), and neonatal outcomes among women with and without SARDs were compared.
Results: Compared to women with no SARDs (n=311,755), women with SARDs (n=326, 0.1%) were slightly older (SARDs 31.3 vs No SARDs 29.3 years ($p<0.01$)) but did not differ in terms of rural residence, ethnicity, median household income or nulliparity. However, rates of pre-term delivery, emergent cesearian section, induction, hypertensive disorders/eclampsia and mortality were higher among women with SARDs than those with no SARDs (Table 1). Offspring of women with SARDs had lower birth weights, were more likely small for gestational age (SGA), and had longer stays in neonatal ICU (Table 1). Among women with SARDs, prescription rates in the 270 days prior to delivery were highest for anti-malarials (Table 2). After multivariable adjustment, both NSAIDS use (OR (95% CI): 5.24 (1.57, 17.52), $p<0.01$) and steroid use (OR (95% CI): 3.15 (1.31, 7.59), $p<0.01$) were significantly associated with a higher risk of preterm delivery.
Conclusions: Women with SARDs are at an increased risk of adverse outcomes during pregnancy. The association between corticosteroid and NSAID use and preterm delivery requires further investigation. Our findings suggest the need for closer monitoring and coordinated care with obstetrics and perinatology in these high risk women.

Table 1. Maternal and Neonatal Outcomes in SARDs vs No SARDs Mothers*

Outcome	No SARDs # (%)	SARDs # (%)	P-value
Pre-term Delivery	22205 (7.1)	58 (17.8)	<0.01
C-section (Emergent)	51132 (16.4)	82 (25.2)	<0.01
Hypertensive disorders	20029 (6.4)	47 (14.4)	<0.01
Small for gestational age	35047 (11.2)	68 (20.9)	<0.01
Congenital Anomaly	5810 (1.9)	11 (3.4)	0.05
Mean days in neonatal ICU	0.8 (5.0)	2.3 (9.6)	<0.01

*Sensitivity analysis utilizing primiparious SARDs vs NonSARDs women confirmed similar results.

Table 2. Unadjusted Effect of Medication Use During Pregnancy on Maternal and Neonatal Outcomes

Outcome	Steroids	NSAIDS	Antimalarials
# (%) SARDS patients on medication	33 (16.3)	13 (6.4)	51 (25.1)

FRI0728 OSTEOARTHRITIS AND GOUT: REAL-WORLD EVIDENCE EVALUATING PATIENT CHARACTERISTICS, TREATMENT PATTERNS, AND HEALTHCARE UTILIZATION

S. Krasnokutsky Samuels[1], M. Pillinger[1], S. Kabadi[2], D.C. Taylor[3], R. Morlock[4]. *[1]New York University, New York; [2]AstraZeneca Pharmaceuticals, Gaithersburg; [3]Ironwood Pharmaceuticals, Cambridge; [4]YourCareChoice, Ann Arbor, United States*

Background: Gout and osteoarthritis (OA) are common in the United States, but little is known about potential associations of OA and hyperuricemia/gout with clinical outcomes.
Objectives: This study examined variations in gout severity, management, and healthcare utilization among gout patients with and without OA.
Methods: Data were assessed from a survey of US physicians and patient chart audits. Participating physicians managed the care of ≥50 patients with gout annually; chart audits were of their most recent 5 consecutive adult patients with confirmed gout. Gout severity was measured by physician global assessment, flares, organ/joint damage, and tophi. Treatment characteristics, presence of clinician-confirmed OA, and sociodemographic factors were identified. Descriptive and multivariate (stepwise logistic regression) statistics analyzed the differences among gout patients with and without clinician-confirmed comorbid OA, and assessed urate-lowering therapy (ULT) use and gout control.
Results: Overall, 1159 charts of gout patients were abstracted (230 w/ OA, 929 w/o; 81% male; 71% white); the proportion of patients aged ≥61 was greater for those with gout and OA than those with gout but without OA (63% vs 32%; $P<0.001$). Patients with gout and OA had longer mean duration of gout (63 vs 41 months), were more likely to have tophi (44% vs 19%), joint damage (31% vs 11%), and clinician-rated severe gout (31% vs 12%) than those without OA (all $P<0.01$). Patients with gout and OA were also more likely to receive ULT (89% vs 70%; $P<0.01$), and among those receiving ULT, OA patients treated with allopurinol received a higher average daily dose (325 mg vs 296 mg; $P=0.031$). Gout patients with OA were more likely to have additional comorbidities (cardiovascular disease, kidney disease, COPD, depression, diabetes, hyperlipidemia, hypertension, obesity, prostate problems [men]) and have chronic pain than those without OA (all $P<0.05$). Gout patients with OA reported more office visits (4.0 vs 3.5), were more likely to have an emergency department visit (17% vs 9%), and were more likely to require surgery for gout in the past 12 months (3% vs 0.3%) (all $P<0.01$). In both groups, ULT use was associated with better gout control, but the specific factors predictive of ULT use and disease control varied between those with and without OA.
Conclusions: Gout patients with OA were more likely to have a greater impact on health system spending, with additional comorbidities and more severe gout than those without OA. These data suggest that gout patients with OA constitute a less healthy group in need of more careful monitoring and more aggressive gout management.

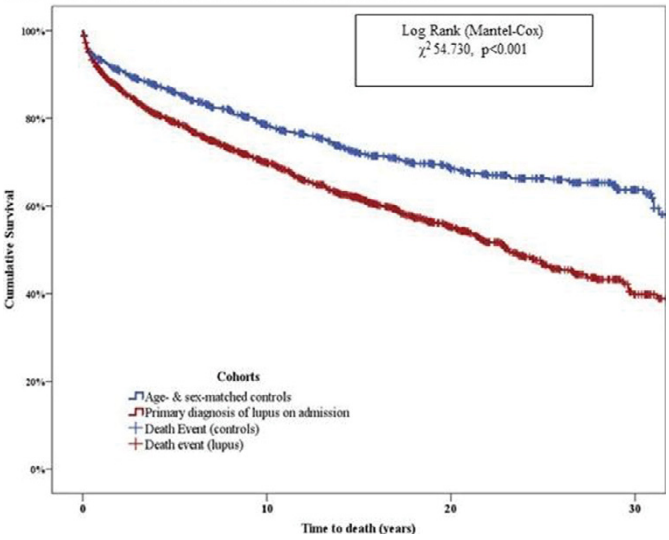
FRI0729 **DEFINITION OF REMISSION AND MINIMAL DISEASE ACTIVITY IN PSORIATIC ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW**

T. Gudu[1,1], R. Ionescu. *Rheumatology, Sf Maria Hospital, UMF Carol Davila, Bucharest, Bucharest, Romania*



Background: In psoriatic arthritis (PsA) a state of minimal disease activity (MDA) or remission are the target of treatment [1], but due to the heterogeneity of disease manifestations, it is still an unmet need. Coates et al [2] have developed and validated a composite score for MDA that encompasses most disease domains. However, for disease remission there is no accepted definition, with studies "borrowing" measures from rheumatoid arthritis or using their own criteria.
Objectives: The objective of this study was to analyse existing data on the definition of MDA and remission in studies on PsA.
Methods: A systematic literature review was performed. Studies evaluating remission or minimal disease activity in PsA either as a primary or secondary outcome, published between 2007–2017, were identified using the terms ("psoriatic arthritis") AND ("remission" OR "low disease state" OR "low disease activity" OR "minimal disease state" OR "minimal disease activity"). Studies assessing disease activity in general, without specifically mentioning remission or MDA were not included; reviews and case-reports were also excluded.
Results: Two hundred and thirty-five publications were identified, of which 56 were included in the final analysis. The majority were observational studies (85.5%) and there were no qualitative studies identified. In total, 10843 PsA patients were analysed: 8779 in observational studies and 2064 in interventional studies; 4823 patients fulfilled the CASPAR criteria [3] and 6667 (31 studies) were taking a biologic drug at their inclusion. The majority of the studies assessed either MDA (65.5%) or remission (60%), but only 14 studies (25.5%) assessed both of the two outcomes. MDA or remission were mainly used as a secondary outcome (52.7% of the studies).
MDA was assessed mainly in observational studies (61.7%) and in almost all cases (88.9% of the studies) the definition used was the one proposed by Coates et al [2]. Remission was also assessed mainly in observational studies (63.8%). The most used definition (57.6%) was based on the disease activity score (DAS28), with values less than 2.6 considered as "remission". Articular involvement was assessed in all cases, whilst skin psoriasis, dactylitis and enthesites were rarely included in the definition of remission (15.15% each). Physician's assessment was taken into consideration in almost a third of the studies (27.3%), but the patient's assessment (pain or global evaluation) was included in more than half of the studies (69.7%). However, other patient reported outcomes were sparsely used (i.e., fatigue and morning joint stiffness were included in only one study) or not all reported (e.g, social participation, work productivity, depression).
Conclusions: Whilst for MDA there is a standardised definition which is widely used, there is no accepted definition for remission. In defining remission, domains other than articular are seldom used and although patient's opinion is usually evaluated, it rarely includes domains other than pain or global assessment. The concept of remission remains un unmet need in PsA.

FRI0730 **THE NEED FOR HOSPITAL ADMISSION FOR SYSTEMIC LUPUS ERYTHEMATOSUS IN WESTERN AUSTRALIA LEADS TO A DOUBLING OF THE ALL-CAUSE MORTALITY RISK AS SEEN IN CONTROLS, ESPECIALLY FOR MEDICARE RELIANT AND MALE PATIENTS**

W.D. Raymond[1], D. Preen[2], C. Inderjeeth[1,3], H. Keen[4,5], J. Nossent[1,6]. *[1]School of Medicine & Pharmacology; [2]School of Population Health, University of Western Australia; [3]Rehabilitation and Aged Care, Sir Charles Gairdner Hospital; [4]Rheumatology, Fiona Stanley Hospital; [5]School of Medicine, Murdoch University; [6]Rheumatology, Sir Charles Gairdner Hospital, Perth, Australia*

Background: Hospitalisation for Systemic Lupus Erythematosus (SLE) is a significant event.
Objectives: We aimed to understand the factors leading to an incident admission and its impact on long term outcome in SLE patients in Western Australia (WA).
Methods: Using whole-population data linkage of hospital admissions, cancer registrations and death records in WA from 1980 to 2015, we performed a retrospective comparative analysis for all patients admitted with a first ever primary diagnosis of SLE (ICD-9-CM 695.4, 710.0, ICD-10-AM L93.0 & M32). For SLE patients, we analysed annual incident hospitalisation rates and compared patient characteristics, all-cause mortality and cancer risk (by Kaplan-Meier and Cox regression) versus age- and gender-matched controls free of rheumatic disease.
Results: The incident hospitalisation rate for SLE (mean 20.9/million/year (CI: 11–35) showed little variation. SLE patients were younger, more likely to be Indigenous, uninsured, have kidney and cardiovascular disorders and to die during their first hospitalisation (Table 1). Cancer risk was equivalent, but a first admission for SLE doubled the risk of subsequent death (OR=1.99, CI: 1.5– 2.7, p<0.001) (Figure 1/Table 2). Medicare reliance (OR 1.7, CI: 1.4 – 1.9, p=0.001) and male gender (OR 1.4, CI: 1.0 – 1.8, p<0.04) were the strongest independent predictors of death.

Figure 1: Kaplan-Meier survival analysis of all-cause mortality for SLE patients and age- and sex-matched controls (free of rheumatic disease) from index hospitalisation.

Conclusions: Hospitalisation rates for SLE in WA have not decreased over 25 years. Once hospital-based management for SLE was required, the risk of all-cause mortality doubled compared to age and gender-matched controls. This risk was greatest in Medicare reliant or male SLE patients and not due to increased cancer risk.

FRI0731 **ASSESSING THE RISK OF RAPID RADIOLOGIC PROGRESSION IN HUNGARIAN RHEUMATOID ARTHRITIS PATIENTS**

G. Szücs[1], J. Gaál[2], P. Géher[3], E. Gömöri[4], A. Kovács[5], L. Kovács[6], K. Nagy[7], E. Posta[8], L. Tamási[9], E. Tóth[10], E. Varga[11], A. Domján[1], Z. Szekanecz[1]. *[1]Department of Rheumatology, University of Debrecen, Faculty of Medicine; [2]Department of Rheumatology, Kenézy County Hospital, Debrecen; [3]Department of Rheumatology, Hospital of Hospitaller Brothers of St. John of God, Budapest; [4]Department of Rheumatology, Pándy Hospital, Gyula; [5]Department of Rheumatology, Hospital of State Railways, Szolnok; [6]Department of Rheumatology, University of Szeged, Szeged; [7]Department of Rheumatology, Ferenc Markhot Hospital, Eger; [8]Department of Rheumatology, András Jósa Hospital, Nyiregyháza; [9]Department of Rheumatology, Semmelweis Teaching Hospital, Miskolc; [10]Department of Rheumatology, Ferenc Flór Hospital, Kistarcsa; [11]Department of Rheumatology, Markusovszky Hospital, Szombathely, Hungary*

Background: Prognosis of rheumatoid arthritis (RA) should be assessed early during the disease course. Rapid radiological progression (RRP) has been defined as a ≥% unit increase in van der Heijde-Sharp score within a year. The matrix risk model has been developed by Vastesaeger et al in 2009. This tool calculates RRP based on non-radiographic indicators such as baseline CRP, RF and swollen joint count.
Objectives: We wished to test the matrix prediction model int he very first Hungarian cohort study.
Methods: In this non-interventional, cross-sectional retrospective study carried out in 11 Hungarian arthritis centres, we assessed high risk (≥40%) of RRP in biologic-naive RA patients with active disease. In order to obtain a representative sample, patients were selected from each centre by a random technique. RRP was calculated according to the matrix model described by Vastesaeger et al. As a secondary endpoint, we compared methotrexate (MTX) responders vs non-responders with respect to RRP.
Results: We screened data of 1843 RA patients. Finally, data obtained from 1356 patients could be used for RRP prediction and MTX responsiveness. The mean age of patients was 55.5 years, 84.7% were women. The mean disease duration was 8.4 years. At the time of the assessment, mean CRP was 17.7 mg/l, RF was 139,3 IU/ml, mean DAS28 was 5.00 and mean swollen joint count was 6.56. High risk ((≥40%) of RRP could be determined in 18.2% of patients. Among continuous variables other than those used for calculation of RRP risk, RA patients with the risk of RRP≥40% (n=247) had significantly lower age than those with RRP<40% (n=1109) (53.33±12.31 vs 56.02±13.50 years; p=0.001). With respect to binary variables, the risk of RRP≥40% was significantly associated

with non-response to MTX (OR: 17.82), male gender (OR: 1.53), ACPA positivity (OR: 2.11), the presence of erosions (OR: 1.37) and current smoking (OR: 1.66). Binary logistic regression analysis revealed that MTX non-response (OR: 16.84), male gender (OR: 1.67) and ACPA positivity (OR: 2.18) were independent predictors of high-risk RRP (≥40%). With regards to MTX responsiveness, binary logistic regression analysis confirmed that both male gender (OR: 5.20) and the presence of erosions (OR: 7.98) were independent predictors of high RRP risk in the MTX responder subpopulation.

Conclusions: In the first bioloigc-naive Hungarian RA cohort assessed for RRP, RRP occurs in almost one-fifth of the patients. These patients differ from others in various clinical and serological parameters. RRP has also been associated with non-response to MTX.

Innate immunity in rheumatic diseases

SAT0001 LACK OF OBESITY-RELATED FEATURES IN ADIPOCYTES AND INFLAMMATORY CELLS IN THE INFRAPATELLAR FAT PAD (IFP)

A. Ioan-Facsinay[1], A. de Jong[1], I. Klein-Wieringa[1], S. Andersen[1], J. Kwekkeboom[1], L. Herb-van Toorn[1], B. de Lange-Brokaar[1], D. van Delft[2], J. Garcia[3], W. Wei[3], H. van der Heide[2], Y. Bastiaansen-Jenniskens[3], G. van Osch[3], A.-M. Zuurmond[4], V. Stojanovic-Susulic[5], R. Nelissen[2], R. Toes[2], M. Kloppenburg[2]. *[1]Rheumatology; [2]Leiden University Medical Center, Leiden; [3]Erasmus MC, University Medical Center, Rotterdam; [4]TNO, Leiden, Netherlands; [5]Janssen, Pharmaceutical Companies Johnson & Johnson, Springhouse, United States*

Background: Obesity is associated with the development and progression of osteoarthritis (OA), both for weight-bearing and non-weight bearing joints. Several lines of research indicate that obesity-related systemic factors, such as adipose tissue-derived factors, could be involved in this association. The infrapatellar fat pad (IFP) is an adipose tissue depot localized in the knee joint. and could mediate obesity-associated effects. However, it is currently unknown whether and how obesity affects IFP.
Objectives: To investigate the presence of obesity-related features in adipocytes and infiltrating immune cells in the IFP of OA patients.
Methods: Knee OA patients (N=155: 68% women, mean age 65 years, mean (SD) BMI 29.9 kg/m^2 (5.7)) were recruited: IFP volume was determined by MRI in 79 knee OA patients, while IFP and subcutaneous adipose tissue (SCAT) were obtained from 106 patients undergoing arthroplasty. Crown-like structures (CLS) were determined using immunohistochemistry. Adipocyte size was determined by light microscopy and histology. Stromal vascular fraction (SVF) cells were characterized by flow cytometry.
Results: IFP volume (mean (SD) 23.6 (5.4) mm^3) was associated with height, but not with BMI or other obesity-related features such as waist circumference, fat percentage and waist to hip ratio. The volume of IFP adipocytes did not correlate with BMI, in contrast to SCAT adipocytes. Few CLS were observed in IFP and their number did not differ between individuals with high and low BMI. Moreover, high BMI was not associated with higher infiltrating immune cell numbers in IFP, nor with changes in immune cell populations. Likewise, no molecular differences were observed in FCM-secreted factors between high and low BMI, except for an increased TNFa secretion in obesity. Since obesity is usually associated with a shift towards pro-inflammatory macrophages in conventional adipose tissue, we have extensively characterized IFP macrophages. Surprisingly, CD206 and CD163, usually associated with an anti-inflammatory phenotype were the most abundantly expressed surface markers on macrophages (81% and 41% respectively). In contrast, cytokine profiles revealed a pro-inflammatory phenotype of the total macrophage population, with cells producing predominantly IL-6 and TNFα, but little IL-10. Interestingly, the CD163+ macrophages were bigger and had a more activated and pro-inflammatory phenotype than their CD163- counterparts. However, no association with BMI could be observed for different macrophage populations or their cytokines.
Conclusions: BMI-related features usually observed in SCAT and visceral adipose tissue could not be detected in IFP of OA patients, a fat depot implicated in OA pathogenesis.

SAT0002 INNATE LYMPHOID CELLS (ILCS) ARE DIFFERENTIALLY DISTRIBUTED IN INFLAMMATORY AND NON-INFLAMMATORY JOINT DISEASES

I. Meunier[1], I. Marois[2], M. Richter[3], G. Boire[4]. *[1]Meakins-Christie Laboratories, McGill University, Montréal; [2]Université de Sherbrooke, Sherbrooke, Canada; [3]Medicine; [4]Medicine, Division of Rheumatology, Université de Sherbrooke, Sherbrooke, Canada*

Background: Innate lymphoid cells (ILC) are immune cells of the lymphoid lineage not expressing specific antigen receptors.They are classified into three subsets: *ILC1* (including Natural Killer (NK) cells and ILC1) secrete IFN-γ and TNF-α; *ILC2* secrete IL-4, IL-5, IL-9, IL-13, and amphiregulin; *ILC3* (including Lymphoid Tissue Inducer (LTi) and NK cell activating receptor (NCR+ ILC3) secrete IL-17A and IL-22.
Objectives: To enumerate the different subsets of ILCs in peripheral blood and synovial fluids of patients with inflammatory and non-inflammatory joint effusions.
Methods: Patients with confirmed synovial effusion presenting at the Centre hospitalier universitaire de Sherbrooke (CHUS) signed an informed consent form. Cells from joint effusions were separated by Ficoll-density gradient centrifugation, stained for ILC, and analysed using a BD FACS Aria III flow cytometer. For cytokine detection, cells were stimulated for 6h with PMA/ionomycin prior to cell staining. The distribution of ILC subtypes according to various diagnoses is presented in cells/ml and ratios of ILC subtypes per ml of synovial fluid relative to peripheral blood. The protocol was approved by the CRC-CHUS ethics committee.
Results: Synovial fluids and blood from 57 patients with various diagnoses were analyzed. The highest concentrations (cells/mL) of ILC cell subtypes found in the synovial fluids/peripheral blood were: ILC1: 7/4; ILC2: 70/3; LTi: 4x10^4 (in RA)/8x10^4 (in OA); NCR+ ILC3: 1.3x10^5 (in JIA)/5.8x10^4; NK: 5/1.
Synovial fluids relative to peripheral blood frequently presented ratios of ILC cell subtypes $\leq$1, suggesting little preferential homing in the joints. However, synovial fluids (relative to blood) were enriched 45 and 7 times for NCR+ ILC3 in Juvenile Idiopathic Arthritis (JIA) and spondylarthropathy patients, respectively, and 8 and 6 times for LTi in Psoriatic Arthritis and Rheumatoid Arthritis (RA) patients, respectively. We observed marked heterogeneity in ILC numbers within patients with the same inflammatory joint diseases. Part of this heterogeneity was associated with the presence of concomitant joint degenerative disease and low cell numbers in the synovial fluids.
Conclusions: 1. LTi and NCR+ ILC3 subtypes are the ILC most abundant in synovial fluids.
ILC1 and NK cells are rare in synovial fluids and unlikely to be involved in pathogenesis; ILC2 remain infrequent, even when enriched in synovial fluid relative to peripheral blood (e.g. in JIA, RA and gout).
2. Relative to their concentrations in peripheral blood, LTi and NCR+ ILC3 subtypes are markedly enriched in synovial fluids of patients with autoimmune-mediated diseases, notably LTi in RA and Psoriatic Arthritis, and NCR+ ILC3 in spondylarthropathy and JIA. The abundance of these IL-17 secreting cells in synovial fluids from these diseases is especially intriguing.
3. We observed significant heterogeneity within patients with the same clinical diagnosis.
4. The pathophysiological implications of the differential distribution of subtypes of ILC cells across diseases and within clinical diagnoses remain unclear.

SAT0003 SINGLE-NUCLEOTIDE POLYMORPHISMS ASSOCIATED WITH P2X7R FUNCTION REGULATE THE ONSET OF GOUTY ARTHRITIS

J. Tao, M. Cheng. *Department of Rheumatology & Immunology, Anhui Provincial Hospital Affiliated to Anhui Medical University, hefei, China*

Background: Gout is an inflammatory disease, considered to be caused by the increased production of IL-1β stimulated by monosodium urate (MSU) crystals. However, some hyperuricemia patients, even gouty patients with tophi in the joints, never have gout attack, indicating some other pathogenic pathways participating in the secretion of IL-1β rather than MSU in the pathogenesis of acute gouty arthritis. ATP-P2X7R-IL-1β axis may be one of them.
Objectives: The purpose of this study is to explore the role of ATP in the pathogenesis of gout, and the association between ATP receptor (P2X7R) function associated single nucleotide polymorphisms and gout arthritis.
Methods: The non-synonymous SNPs loci of P2X7R in Chinese people were screened, to compare the frequencies of different alleles and genotype distribution of selective SNPs in 117 gouty patients and 95 hyperuricemia patients. Then peripheral white blood cells were purified from the peripheral blood of randomly selected 43 gout patients and 36 hyperuricemia patients from the total. After culturing the cells with MSU or MSU+ATP, supernatants were collected and the concentrations of IL-1β were detected by enzyme linked immunosorbent assay (ELISA).
Results: 1. Eight SNPs loci including rs1653624, rs10160951, rs1718119, rs7958316, rs1621388, rs16950860, rs208294, rs17525809 and rs2230912 were screened and detected, and rs1653624, rs7958316 and rs17525809 were demonstrated associated with gout arthritis. 2. After the stimulation with MSU+ATP, the concentrations of IL-1β in supernatants of gouty patients were significantly higher than that in hyperuricemia groups [(131.08±176.11)pg/ml vs (50.84±86.10)pg/ml]. Furthermore, gouty patients carrying susceptibility genotype AA or AT of rs1653624 had significant higher concentration than that carrying non-susceptibility genotype TT [(104.20±164.25)pg/ml vs (21.90±12.14)pg/ml]. However, no differences were found while stimulated with MSU alone.
Conclusions: ATP promotes the pathogenesis of gouty arthritis by increasing the secretion of IL-1 β, and its receptor (2X7R) function associated single nucleotide polymorphisms may be related to gouty arthritis, which indicates that ATP-P2X7R signaling pathway plays a significant regulatory role in the pathogenesis of gout.

SAT0004 NEW AUTOANTIGEN (JKTBP) PART OF STRESS GRANULES CLOSES THE SENSITIVITY GAP IN RHEUMATOID ARTHRITIS

B. Marklein, M. Jenning, K. Muenzer, G. Burmester, K. Skriner. *Department of Rheumatology and Clinical Immunology, Charité University Medicine, Berlin, Germany*

Background: Rheumatoid arthritis triggers the formation of prion-like stress granules. To investigate which members of the heterogeneous nuclear ribonucleoprotein (hnRNP)-family, components of functionally important subcellular

particles are targeted by autoantibodies from RA and other systemic rheumatic diseases.
Methods: Using a protein macroarray we identified JKTBP in humans and animal models of inflammatory rheumatic diseases. Bacterially expressed recombinant JKDBP proteins were used to confirm the obtained data. Epitope, TLR7/9 and MyD88 dependency was determined by ELISA. JKTBP expression in cultivated cells and synovial tissue was analysed by indirect immunofluorescence, immunoblot and immunohistochemistry.
Results: Anti-JKTBP autoantibodies were detected in 46% of the patients with systemic lupus erythematosus (n=103), in 20–30% of the patients with rheumatoid arthritis (n=286), in 10% of the patients with mixed connective tissue disease (n=20) or spondyloathropathy (n=20), and in <10% of patients with other autoimmune disorders (n=382). Sera positive to JKTBP as well as hnRNP-B1, revealed nearly two thirds of the RF IgM/ CCP2-seronegative patients as early RA patients. Combining sensitivities to all autoantigens tested (JKTBP, AUF1, hnRNP-B1), it was possible to identify 92% of the early RA patients (n=91). In the MRL/lpr mouse model of SLE, mice deficient of MyD88 or TLR7/9 lacked anti-JKTBP autoantibodies, whereas mice deficient of SIGIRR/TIR8 showed enhanced anti-JKTBP autoantibody production. These results show that autoantibody generation against JKTBP, AUF1, hnRNP-B1 is dependent on TLR 7 and TLR9 like rheumatoid factor different to TLR 7 dependent generation of snRNPs. For all tested autoantigens either their titter or generation are dependent on the activation of innate immunity genes MyD88 and SIGIRR/TIR8 gene.
In localization, experiments anti-JKTBP autoantibodies specifically stained stress granules (SG) in the cytoplasm. Immunohistochemical studies revealed JKTBP to be highly expressed in SG in the cytoplasm of RA synovial tissue different from OA and normal control tissue
Conclusions: These data identify SG as targeted particle in RA and JKTBP as a novel autoantigen in RA, SLE patients and mouse models of inflammatory rheumatic diseases. In combination with the hnRNPs AUF1 and hnRNP-B1, JKTBP autoantibodies close the sensitivity gap in RA left by rheumatoid factor and anti-CCP2 antibodies.

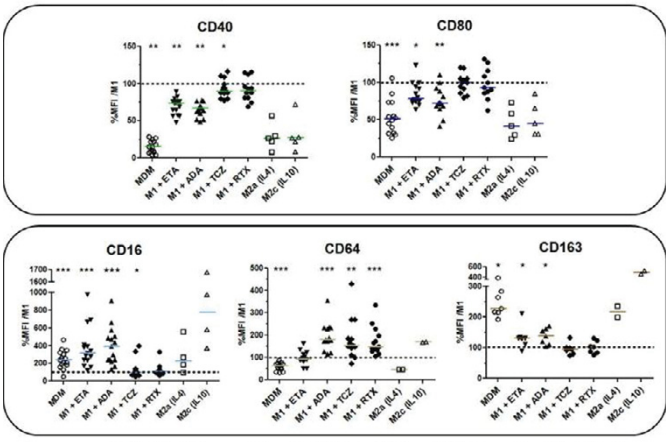
SAT0005 DNA METHYLATION INHIBITORS PRODUCE SUSTAINED REMISSION OF ARTHRITIS IN MICE AND PROMOTE REGULATORY T CELL RESPONSES

W. Tseng[1,2], I.-S. Huang[1], F. Clanchy[1], K. McNamee[1], D. Perocheau[1], P. Ericsson[3], H.-O. Sjogren[3], Z. Xue[3], L. Salford[3], A. Sundstedt[4], R.O. Williams[1]. *[1]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford University, The Kennedy Institute of Rheumatology, Oxford, United Kingdom; [2]Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital, Keelung, Taiwan, Province of China; [3]Department of Clinical Sciences, Lund University, The Rausing Laboratory; [4]Idogen, Lund, Sweden*



Background: Dysfunction of Tregs results in a breakdown of immunological tolerance and has been implicated in the pathogenesis of autoimmune diseases, including systemic lupus erythematosus, rheumatoid arthritis (RA) and type 1 diabetes. Treg function is regulated by epigenetic factors and we have previously reported the presence of Tregs expressing an aberrant DNA methylation profile in RA.
Objectives: The aim of this study was to assess the potential utility of DNA methylation inhibitors for the treatment of RA, using collagen-induced arthritis (CIA) as an animal model.
Methods: DBA/1 mice were immunised with bovine type II collagen emulsified in complete Freund's adjuvant. The mice were treated with zebularine (400 mg/kg), decitabine (1 mg/kg) or psammaplin A (10 mg/kg) for 4 days, starting on the day of arthritis onset. Treatment was then stopped and the disease was monitored up to day 10 of arthritis. The expression of Treg genes was measured in lymph nodes on day 10 by qPCR. To assess the effect of DNA methylation inhibitors on generation of Tregs, naïve $CD4^+CD25^-$ T cells were cultured with mitomycin C treated APCs plus IL-2, TGFβ and anti-CD3 in the presence or absence of DNA demethylating agents and numbers of $CD4^+FoxP3^+$ Tregs were determined by FACS after 72h.
Results: Treatment with zebularine resulted in a sustained reduction of arthritis severity, accompanied by an increase in the expression of Treg associated genes, *Foxp3, Ctla4 and Tgfb1*, in draining lymph nodes. Treatment with decitabine produced a more profound reduction in disease severity whereas the therapeutic effect of psammaplin A was more transient. All three DNA methylation inhibitors could convert $CD4^+CD25^-$ T cells into $CD4^+FoxP3^+$ Tregs in a dose-dependent manner *in vitro*.
Conclusions: This study has shown that pulse treatment with DNA demethylating drugs produces a sustained reduction in the severity of arthritis and promotes the generation of Tregs. The findings raise the possibility that epigenetic drugs can be used on a short-term basis for re-setting tolerance and boosting Treg responses in human autoimmune disease.

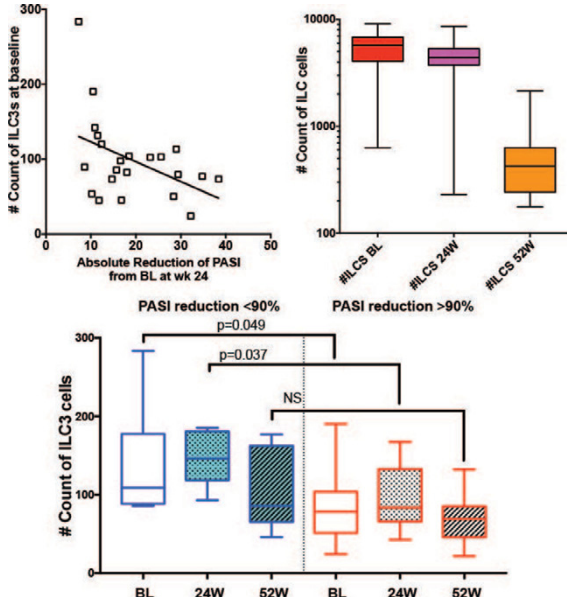
SAT0006 ANTI-TNF AGENTS INDUCE MACROPHAGES WITH PRO-RESOLVING PHENOTYPE

Y. Degboe[1,2], B. Rauwel[2], M. Baron[2], J.-F. Boyer[1,2], A. Cantagrel[1,2], A. Constantin[1,2], J.-L. Davignon[1,2]. *[1]Centre de Rhumatologie, CHU Purpan; [2]CPTP, INSERM UMR 1043, Toulouse, France*

Background: Macrophages contribute to the rheumatoid arthritis (RA) pathogenesis. They can display various states of activation or " polarization ", characterized by distinct functions in inflammation, and reversibility depending on their environment [1]. M1 polarization corresponds to the "classical", pro-inflammatory activation as identified in RA. M2 "alternative" polarizations display pro-resolving or wound-healing properties.
Data concerning the effects of RA biological drugs (bDMARDs) on macrophage polarization are scarce.
Objectives: To assess in vitro modulation of macrophage polarization by RA bDMARDs.
Methods: Blood monocytes from 14 healthy donors were positively sorted by CD14+ magnetic selection. Macrophages were Derived from Monocytes (MDM) by 5 days of culture in the presence of MCSF, and activated or not for 24h as M1 pro-inflammatory MDM (by LPS + IFNγ) or as M2 alternative MDM (by IL10 or IL4). MDM were cultured with or without bDMARDs.
We evaluated 2 anti-TNF agents (etanercept (ETA), adalimumab (ADA)), 1 anti-IL6R agent (tocilizumab (TCZ)), and 1 anti-CD20 agent (rituximab (RTX)) used as control monoclonal antibody. bDMARDs effects were assessed separately on differentiation and activation phases by flow cytometric analysis of membrane markers. Functional aspects of polarization were assessed by analysis of cytokine production in supernatants (cytometric bead array) and phagocytosis (flow cytometry).
MDM cultured in the presence of bDMARDs were compared to untreated MDM by a Wilcoxon matched pairs test.
Results: We first validated *membranous polarization markers* in our culture model: CD40 and CD80 as M1 (LPS + IFNγ) markers; CD16, CD163 and CD64 as M2 (IL10) markers, CD206 and CD200R as M2 (IL4) markers.
Anti-TNF significantly modulated surface polarization markers of *MDM* obtained after differentiation. CD40 decreased with both anti-TNFs. CD16 increased with ADA, whereas opposite effects on CD64, decrease with ETA, increase with ADA, were observed. CD206 increased with ADA. CD200R increased with both anti-TNF. We observed a significant increase in CD64 with TCZ. RTX induced no modulation except an increase in CD64.
Concerning the effect of bDMARDs on *M1 activation* (M1 MDM) shown in Figure, anti-TNF agents induced a significant decrease in M1 markers and a significant modulation in M2 (IL10) markers. We observed a decrease in CD40 and CD80, an increase in CD16, CD163, a decrease in CD64 with ETA and an increase with ADA. TCZ induced a slight but significant decrease in CD40 and an increase in CD64. RTX only affected CD64 as observed for differentiation.
In *M2 (IL4) et M2 (IL10) activated MDM*, anti-TNF agents induced a similar trend toward M2 (IL10) phenotype.
Anti-TNF agents led to a significant decrease in *TNFα, IL6, IL12 and IL10 levels* measured in cell culture supernatant after M1 MDM. TCZ mainly affected IL6 and TNFα productions. No significant effect was observed with RTX.

Normalized polarization surface markers on M1 MDM



Data were normalized to M1 MDM (represented as a dotted line) for each donor. Statistical comparison of M1 MDM without bDMARD (dotted line) versus M1 MDM with bDMARD, using a Wilcoxon matched pairs test → * p < 0.05 ; ** p<0.005 ; *** p<0.0005

Phagocytosis was superior in M2 (IL10) and M2 (IL4) activated MDM than in M1 MDM. Anti-TNF agents but not TCZ or RTX induced an increase of phagocytosis in M1 MDM.
Conclusions: Anti-TNF agents upregulate M2 alternative pro-resolving markers and downregulate M1 inflammatory markers in macrophages. Our results need to be extended by transcriptional analysis and evaluated in RA patients.

SAT0007 GROUP 3 INNATE LYMPHOID CELLS NUMBERS IN PERIPHERAL BLOOD PREDICT USTEKINUMAB (STELARA) THERAPY RESPONSIVENESS IN PSORIATIC DISEASE CASES WITH SUBCLINICAL IMAGING ENTHESOPATHY

Y.M. El-Sherbiny[1,2], L. Savage[1], M. Wittmann[1,2], P. Emery[1,2], M. Goodfield[3], D. McGonagle[1,2]. *[1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; [2]National Institute of Health Research Leeds Musculoskeletal Biomedical Research Unit; [3]Department of Dermatology, Leeds Centre for Dermatology, Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom*

Background: Ustekinumab[1] targets the common p40 sub-unit of interleukin-12 (IL-12/interleukin-23 (IL-23). In patients treated with Ustekinumab for psoriasis where patients were selected on the basis of subclinical imaging enthesopathy, we have noted an improvement in subclinical imaging enthesopathy (Savage LJ et al submitted), raising the possibility that it may be possible to find a biomarker for predicting response to therapy in psoriatic disease. Innate lymphoid cells may be centrally involved in the pathogenesis of psoriatic skin and joints disease[2], since they express IL-23R receptor and are associated with IL-17/IL-22 production.
Objectives: This work was performed to test the hypothesis that peripheral blood ILC perturbations may be useful in defining response in psoriasis cases with imaging confirmed subclinical enthesopathy.
Methods: Peripheral blood collected at baseline (before therapy, 24weeks, 54 weeks) from patients in the MUSTEK trial (Ustekinumab in psoriasis cases who had ultrasound imaging confirmed subclinical enthesopathy) (n=23). Cellular immunophenotyping was performed density gradient separated PBMCs. Innate lymphoid cells were identified as lineage negative (CD3- TCR$\gamma\delta$- TCR$\alpha\beta$- CD19- CD14- CD11c- CD1a- CD303- FcεRI- CD34- CD123-) with positive expression of CD45, CD127. ILC2 cells were identified as Lineage- CD127+ and CRTH2 positive, while ILC3 were identified as Lineage- CD127+, CRTH2 – and CD117 (c-Kit) positive and further subdivided of NKp44+ and NKp44-. ILC1 were identified as lineage- CD127+ CD117-and CRTH2-. For data analysis we separated cases into PASI>90% or PASI <90% responders. The subclinical enthesopathy scores also fell significantly under therapy (Savage LJ data submitted)
Results: No correlation was found with total ILCs (ILC1,2, AND 3) (R=0.104, p=321, Spearman R) and therapy response. While, The absolute numbers of baseline ILC3s was inversely correlated in with the reduction in the PASI score (R -0.404, p=0308, Spearman R). The ILC3s also fell progressively under therapy. All the patients respond with reduction of PASI score mean 92.6% (range 65.8–100%), Interestingly, those patients with reduction below 90% of PASI score has a significantly higher absolute numbers of ILC3+ cells in peripheral blood at the baseline than PASI (n=6/23) than super-responder group (n=17/23)
Conclusions: Only peripheral blood ILC3s, but not other ILCs changes, correlate with the PASI score (disease activity), Furthermore, excellent responders (PASI reduction >90%) showed strong correlated with higher ILC3 population at the baseline. This may help to use ILC3 enumeration as predictive parameter for ustekinamab clinical therapeutic response and may be relevant to assessing novel biomarkers for subclincal arthropathy in psoriasis.

SAT0008 DRUG THERAPY ENHANCES TOLEROGENIC PROPERTIES OF DENDRITIC CELLS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Kurochkina[1], M. Tikhonova[2], T. Tyrinova[2], O. Leplina[2], A. Sizikov[1], A. Sulutian[1], L. Konenkova[1], O. Chumasova[1], A. Ostanin[2], E. Chernykh[2]. *[1]Department of Rheumatology; [2]Laboratory of Cellular Immunotherapy, Federal State Budgetary Scientific Institution Research Institute of Fundamental and Clinical Immunology, Novosibirsk, Russian Federation*

Background: Dendritic cells (DCs) are known to contribute to the pathogenesis of rheumatoid arthritis (RA) through presentation of cartilage glycoprotein, production of proinflammatory cytokines and activation of Th1/Th17 responses. Along with stimulating activity, DCs may exhibit suppressive functions via capacity to induce T cell apoptosis/anergy and to generate regulatory T cells. Since these DCs have potential to control autoreactive T-lymphocytes, the enhancing of tolerogenic properties of DCs seems to be a new important strategy in treatment of RA. The experimental research in animals and human in vitro studies revealed the capacity of anti-rheumatic drugs to inhibit stimulating activity and to enhance tolerogenic functions of DCs. However, data concerning the in vivo influences of drug therapies on DC functions in RA patients are not available.
Objectives: The aim of our study is to investigate, whether drug therapies influence the properties of monocyte-derived DCs generated in the presence of IFNα (IFN-DCs) in RA patients, and if the effect of disease-modifying anti-rheumatic drugs differ from that of biological/pulse steroid therapy.
Methods: Thirty nine patients with RA with high and moderate activity of disease were recruited in this study. All patients fullfield ACR/EULAR criteria (2010). Nineteen patients received methotrexate, leflunomide, sulfasalazine or their combination (RA1). Twenty patients were at pulse therapy (methylprednisolone 500mg No. 3) or biological drugs (adalimumab or rituximab) (RA 2). All studies were performed after receiving informed consent. DCs were generated from blood monocytes culturing for 5 days with GM-CSF and IFN-α in the absence and presence dexamethasone, applied on third day. LPS as maturation stimuli was added on fourth day. The expression of CD14, CD83, CD 86, B7H1, HLA-DR, TLR-2 on the surface of DCs was measured by flow cytometry. The functions of DCs were evaluated by measuring cytokine production and DC allostimulatory activity in mixed lymphocyte culture.
Results: Both DC-RA1 and DC-RA2 where shown to display impaired maturation evidenced by elevated expression of CD14 and decreased number of mature (CD14-CD83+) DCs. Wherein, DCs-RA2 demonstrated several additional differences, including increased number of intermediate CD14+CD83+ cells (compared with donors DCs), higher expression of inhibitory molecule B7-H1 (PD-1L) (compare with donors DCs and DCs-RA1) and tendency to lower expression of CD86 and higher expression of TLR-2. Besides, DCs-RA2 produced higher concentrations of IL-6 and had 2-fold lower allostimulatory activity then DCs-RA1. These differences together with phenotypic changes suggested more pronounced tolerogenic properties of DCs-RA2. Despite the revealed DC differences in RA1 and RA2 patients both types of DCs preserved in vitro sensitivity to dexamethasone, that suppressed the production of TNF-α and reduced allostimulatory activity.
Conclusions: The data obtained indicate that, IFN-DCs from RA patients at drug treatments are characterized by tolerogenic properties, which are more pronounced in patients with biological or pulse steroid therapy.

SAT0009 DISTRIBUTION AND INTRACELLULAR SETTITNG OF GRANULYSIN IN WOMEN WITH KNEE OSTEOARTHRITIS

G. Laskarin[1], T. Kehler[2], M. Dominovic[3], V. Persic[4], M. Rogoznica[4], D. Rukavina[1]. *[1]Medicinski fakultet Sveučilišta u Rijeci, Rijeka; [2]Specialized Hospital "Thalassotherapia-Opatija"; [3]Medicinski fakultet Sveučilišta u Rijeci; [4]Tth Opatija, Opatija, Croatia*

Background: The role of the cell-mediated immune response is recently recognized in osteoarthritis (OA) (1). Granulysin (GNLY) is mediator of cellular immunity and cytotoxic molecule expressed in T and NK cells in regulatory (15 kDa) and cytotoxic (9 kDa) forms (2). Cytotoxic 9 kDa form of GNLY mediates apoptosis of eukaryotic cells (3) and might be responsible for silent unscheduled apoptosis of joint tissue cells in patients with OA without clinically recognized

systematic immune reaction, as measured by erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) (4). We investigate GNLY distribution and intracellular setting in peripheral blood lymphocytes of patients with OA.

Objectives: Women with knee OA (17), and age and sex appropriated control (17) were tested. All of them signed informed consent before sampling of peripheral blood (PB).

Methods: Medical history, clinical examination, X-ray and routine laboratory testing (ESR, CRP) were used for diagnosing OA. Peripheral blood mononuclear cells (PBMC) were isolated by gradient density centrifugation and used for multiple, simultaneous intracellular [total GNLY, 9 kDa GNLY, 15 kDa GNLY and Lysosomal-associated membrane protein-1 (LAMP-1)] and surface antigens (CD3 and CD56) detection by immunofluorescence. Data were analyzed by flow cytometry or confocal microscopy.

Results: In OA and control samples the percentage of total GNLY+ cells and GNLY expressing NK and T cells did not significantly differ and correlate with ESR and CRP. The frequency of GNLY+ cells was always higher in natural killer (NK) then in T cells and 9 kDa GNLY dominated over 15 kDa GNLY. However, 9 kDa GNLY co-localized more with the marker of cell degranulation, LAMP-1 in polarized granules of OA patients when compared to the control or to the 15 kDa GNLY.

Conclusions: The increase in the expression of cytotoxic (9 kDa) over regulatory (15 kDa) GNLY form in PBMC and its intracellular setting in polarized exocytic granules suggests the involvement of activated GNLY$^+$ lymphocytes in the immunopathogenesis of knee OA, indispensable of ESR and CRP.

SAT0010 THE DAMP PROTEIN S100A8/A9 IS CRUCIALLY INVOLVED IN MYELOID-DERIVED SUPPRESSOR CELL (MDSC) DIFFERENTIATION AND FUNCTION IN COLLAGEN-INDUCED ARTHRITIS

M. Kuhlencord, Y. Kusche, S. Zenker, T. Vogl, J. Roth. *Institute of Immunology, Münster, Germany*

Background: Over the last years, the differentiation and activation of MDSC under tumor conditions has been studied extensively. Various tumor-derived factors have been identified in promoting the accumulation of this suppressive cell population. Recent findings determined the two alarmins S100A8 and S100A9 as important factors in the differentiation of MDSC during tumor conditions. However, little is known about the S100A8/A9 driven expansion and activation, as well as the relevance of these cells in autoimmune diseases such as rheumatoid arthritis.

Objectives: We therefore analyzed the mechanisms involved in S100A8/A9 driven MDSC accumulation and their functional importance in a mouse model of rheumatoid arthritis.

Methods: To investigate the effect of S100A8/A9 on MDSC differentiation, bone marrow cells from wild type (wt), S100A9 knockout (A9ko) and S100A9 transgenic (A9tg) mice were analyzed. Accumulation of MDSC and their phenotypical characterization was performed by FACS analysis and functional characterization including arginase activity, NO- and ROS-production and T cell proliferation assays.

The role of S100A8/A9 and MDSC in arthritis was investigated using the collagen-induced arthritis (CIA) mouse model. Accumulation of MDSC in different organs was analyzed by FACS and systemic S100A8/A9 levels were measured by ELISA. Ex vivo functional analysis of purified MDSC was performed to assess the potential of these MDSC to inhibit T cell responses.

Results: Our in vitro studies reveal that, in the presence of S100A8, myeloid progenitor cells differentiate to immature cells that phenotypically as well as functionally resemble MDSC. These cells are characterized by co-expression and up-regulation of arginase activity, NO- and ROS-production, and exhibit strong suppressive effects on the proliferation of both CD4- and CD8-positive T cells. Furthermore, accumulation of MDSC by extracellular S100A8 was found to be mediated via the Toll-like receptor 4 signaling pathway. In addition, lack of intracellular S100A8/A9 results in a decreased number of MDSC as well as a reduced suppressive activity of these cells, implying a dual role of these proteins for MDSC differentiation and function.

Investigating the role of S100A8/A9 and MDSC in a mouse model of CIA, a clear correlation between disease scores, MDSC numbers and systemic S100A8/A9 levels was observed. Furthermore, disease activity was reduced in wt and A9tg mice compared to A9ko mice and was in line with an increased accumulation of MDSC in the lymph nodes. Next to an enhanced suppressive activity of MDSC isolated from lymph nodes of wt and A9tg mice, these MDSC promoted the accumulation of regulatory T cells (Treg) whilst suppressing the differentiation of TH17 cells. In contrast, MDSC isolated from lymph nodes of A9ko mice had no effect on Treg differentiation and did not inhibit TH17 emergence.

Conclusions: Our in vitro results clearly show a S100A8/A9 dependent accumulation of cells that phenotypically as well as functionally resemble MDSC also under non-tumor conditions. In vivo data strongly support the importance of these findings. By influencing MDSC accumulation and function, S100A8/A9 is critically involved in regulating the disease outcome in rheumatoid arthritis, implying an important role of S100A8/A9 derived MDSC in regulating immune reactions during autoimmune diseases.

SAT0011 THE ACTIVATION OF MUSCARINIC ACETYLCHOLINE RECEPTORS INFLUENCES THE ONTOGENY OF NEUTROPHILS

S. Sommerlatte[1], L. Kappes[1], S. Pitann[1], G. Marschner[1], H. Heidecke[2], P. Lamprecht[1], A. Mueller[1], T. Lange[1], O. Cabral-Marques[1], G. Riemekasten[1]. *[1]Rheumatology, University of Lübeck, Lübeck; [2]CellTrend GmbH, Luckenwalde, Germany*

Background: There is growing evidence that nervous and immune system communicate with each other through soluble mediators.[1] Immune cells such as neutrophils express muscarinic acetylcholine receptors (mAChR), which are neuroimmune receptors and highly prevalent in the nervous system.[2] Aberrant neutrophil functioning plays an important role in various autoimmune diseases. Dysregulation of neutrophil immune responses such as oxidative burst and migration is one of the key mechanisms leading to tissue damage in autoimmune diseases.[3] However, the impact of mAChR activation on neutrophils remains contradictory.

Objectives: We aimed to determine effects of muscarinic receptor activation on development and functions of neutrophils.

Methods: Neutrophils were isolated from peripheral blood of healthy donors by dextran sedimentation. After one hour in the absence or presence of the natural ligand acetylcholine (Ach) (10nM-100μM) or the muscarinic agonist oxotremorine-m (oxo-m) (10nM-100μM), neutrophil respiratory burst was analyzed by dihydrorhodamine (DHR) flow cytometry assay and migration assessed by transwell assay in response to N-formylmethionyl-leucyl-phenylalanine (fMLP). Cells that migrated were quantified by flow cytometry. To analyze the effects mAChR activation on the development of neutrophils, HL-60 cells were incubated in the presence of DMSO (1%), oxo-m (100μM) or DMSO plus oxo-m. After 6 days, cells were harvested and expression of maturation markers (CD15, CD63 and CD16) as well as mAChR (M1-M5) were measured by flow cytometry.

Results: We observed no effects of mAChR activation on the respiratory burst of neutrophils. However, both ACh and oxo-m inhibited neutrophil migration in a dose-dependent manner, but with peculiar differences. By increasing acetylcholine concentrations, we observed a reduction of neutrophil migration in a directly proportional manner. On the other hand, while the lowest dose (10nM) of oxo-m inhibited migration most effectively, the increase of oxo-m showed inversely proportional effects on neutrophil migration. Thus, we aimed to investigate, if the highest dose of oxo-m has a different effect on neutrophils ontogeny. In agreement with the results obtained with neutrophils, the incubation of HL-60 cells with the highest dose of oxo-m showed no effect on oxidative burst and migration and induced no changes in the expression of mAChRs (M1-M5), CD16 and CD63 in HL-60 cells. However, we observed that it resulted in significantly increased surface levels of the neutrophilic lineage marker CD15.

Conclusions: Our data indicate a differential activation of mAChR affecting different steps of neutrophil ontogeny. Considering this finding, abnormalities in the activation of muscarinic receptors as have been observed in autoimmune diseases might contribute to neutrophil dysfunction and need further investigation.

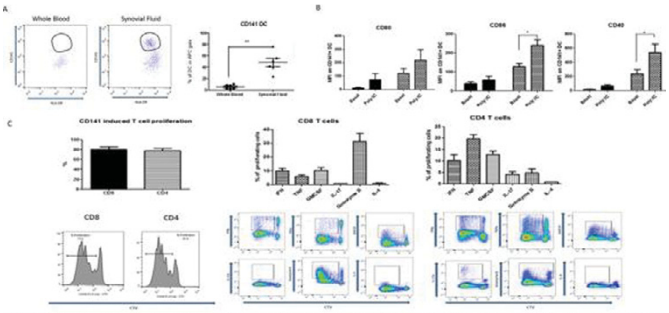
SAT0012 S100A8/A9 INCREASES THE MOBILIZATION OF LY6C HIGH MONOCYTES TO THE SYNOVIUM DURING EXPERIMENTAL OSTEOARTHRITIS

N. Cremers[1], E. Geven[2], A. Blom[2], M. van den Bosch[2], P. van der Kraan[2], P. van Lent[2]. *[1]Experimental Rheumatology; [2]Radboud university medical center, Nijmegen, Netherlands*



Background: It is increasingly recognized that part of the pathology in osteoarthri-

tis (OA) is driven by a low-grade inflammation in the synovium. Pro-inflammatory cytokines released locally during OA, such as S100A8/A9 which are expressed for prolonged periods when compared to IL-1β, IL-6, and TNF-α, may recruit monocytes from the bone marrow (BM) to the joint. In mice, two functionally distinct monocyte populations are described: (i) pro-inflammatory Ly6C^{high} monocytes; and (ii) patrolling Ly6C^{low} monocytes.
Objectives: The objective of our study is to investigate the role of S100A8/A9 in the recruitment of the different monocyte populations during early collagenase-induced OA (CiOA).
Methods: S100A8 was intra-articularly injected into the knee joint of naïve wild type C57BL/6 (WT) mice to investigate their direct role in recruitment of monocytes. CiOA was induced by unilateral intra-articular collagenase injection in WT, and S100A9KO mice to investigate the role of S100A8/A9 in more detail. At CiOA day 7, WT and S100A9KO mice were sacrificed together with age-matched saline-injected control mice (n=6/group), and expression of several monocyte cell markers, chemokines, and adhesion molecules were measured in the synovium and BM, in which the cells were also analyzed by FACS. Monocytes were identified as (B220/CD90/CD49b/NK1.1/Ly6G)^{low}CD11b^{high}(F4/80/MHCII/CD11c)^{low}, which were further divided into subsets based on their Ly6C expression.
Results: Injection of S100A8 into the knee joints of naïve mice led to a significantly elevated expression of monocyte-related markers (Ly6C, CCR2, and CX3CR1) and monocyte attracting chemokines (MCP-1, CX3CL1, MIP1α, and KC) within the synovium after 1 and 3 days, suggesting that S100A8/A9 is directly involved in the attraction of monocytes. At CiOA day 7 in WT mice, numbers of Ly6C^{high}, but not Ly6C^{low} monocytes, were strongly increased (7.6-fold) in the synovium as compared to saline-injected control joints. In contrast, S100A9KO mice showed a significant increase in Ly6C^{low} monocytes (2-fold), whereas the number of Ly6C^{high} monocytes remained unaffected. Concurrently, a strong upregulation of several chemokines (MCP1, CX3CL1, KC, and MIP1α) was observed locally in the synovium, of which only the Ly6C^{low} mobilization marker CX3CL1 was significantly higher in S100A9KO mice, corresponding with the increased Ly6C^{low} monocytes in the synovium of S100A9KO mice. This could however not explain the local increased number of Ly6C^{high} monocytes at CiOA day 7 in WT mice, and therefore we next investigated the main source of the monocytes, which is the BM. We observed a decrease of 14% of myeloid cells (consisting partly of Ly6C^{high} monocytes) in the BM of WT mice at CiOA day 7, whereas there were no changes in the BM of S100A9KO mice, suggesting that S100A8/A9 affects the release of myeloid populations from the BM. In line with that, expression of adhesion molecules (LFA-1, VCAM, VE-cadherin, PECAM1, and L-selectin) was lower at CiOA day 7 in the BM of S100A9KO mice when compared to WT mice.
Conclusions: Local induction of OA leads to S100A8/A9 production, and subsequently to the mobilization of Ly6C^{high} monocytes into the joint, driving OA pathology.

SAT0013 THE PATHOGENIC ROLE OF MYELOID CD141+ DENDRITIC CELLS IN INFLAMMATORY ARTHRITIS

M. Canavan[1], T. McGarry[1], K. Killick[2], B. Moran[3], D. Cluxton[3], C. Orr[4], H. Convery[4], S. Wade[1], S. Wade[1], R. Mullan[5], J. Fletcher[3], D.J. Veale[4], U. Fearon[1]. *[1]Molecular Rheumatology, Trinity College Dublin, Dublin; [2]Systems Biology Ireland, Conway Institute of Biomolecular and Biomedical Research, UCD, Dublin 4; [3]Immune Regulation in Human Disease, Trinity College Dublin, Dublin; [4]The Centre for Arthritis and Rheumatic Diseases, St Vincents University Hospital, Dublin 4; [5]Rheumatology Department, The Adelaide and Meath Hospital, Dublin, Ireland*

Background: Dendritic cell (DC) are a heterogeneous group of antigen presenting cells that can be subdivided into CD1c$^+$ & CD141$^+$ DC. CD141$^+$ DC are a rare population of DC that were first discovered in 2010 in human peripheral blood. Due to their rarity very little is known about the function of these cells in other tissue in or indeed disease. These newly described DC subset have thus never been described in Inflammatory Arthritis (IA) or any of the rheumatic diseases.
Objectives: To identify CD141 DC in IA synovium and functionally assess if these cells play a pathogenic role in IA.
Methods: CD141$^+$DC were magnetically purified from synovial fluid mononuclear cells (SFMC) and peripheral blood mononuclear cells (PBMC) stimulated and stained with a panel of fluorochrome conjugated antibodies for multicolour flow cytometry. CD141$^+$ DC isolated and purified from IA synovial fluid were subsequently cocultured with allogenic CD3$^+$ T cells for 6d after which intracellular cytokine production was assessed by flow cytometry. Supernatants from this DC-T cell cocultures were used to treat synovial fibroblasts & the expression of adhesion molecules, cytokines & MMPs was measured. Finally using sorted populations of CD141$^+$ DC from SFMC and PBMC, RNA sequencing was performed and differentially expressed genes and interaction network analysis were identified using the DeSeq2 R package, Ingenuity® Pathway Analysis (IPA) and InnateDB and Cytoscape.
Results: Within IA synovial fluid (SF), CD141$^+$ DC are significantly enriched compared to WB & express higher levels of the costimulatory activation markers CD80 CD86 and CD40. Following coculture of these SF CD141$^+$ DC with CD3$^+$ T cells, CD141$^+$ DC induce both CD8$^+$ & CD4$^+$ T cell proliferation. SF CD141$^+$ DC induce Granzyme B production from CD8$^+$ T cells & TNFα, IFNγ & GMCSF from CD4$^+$ T cells. The IA synovium consists of a complex interplay of multiple cell types. Therefore next we examined the effect of this CD141$^+$ DC-T cell interaction on the key invasive cells in the synovium – synovial fibroblasts. Supernatants from CD141 activated T cells were cultured with fibroblasts & induced expression of ICAM-1, IL-6, IL-8, MMP1 & MMP3. SF CD141 expressed significantly higher levels of the the hypoxia marker TREM1, activation of which induces further expression of CD80, CD86 and CD40. Coculture of these TREM1 activated CD141 with CD3$^+$T cells increases IFNγ and IL-17a production. Finally RNASeq analysis revealed that there are 2089 differentially expressed genes between SF CD141$^+$DC & WB CD141$^+$DC. These genes are involved in a number of key pathways such as energy metabolism, chemokine & cytokine signalling. Principal Component Analysis (PCA) revealed that CD141$^+$ DC with the synovium are distinctly different from blood CD141$^+$ DC

A) CD141 DC are enriched in the IA synovium compared to peripheral blood. B) IA CD141 from synovial fluid (SF) express higher expression of activation markers and respond to TLR engagement. C) CD141 DC isolated from IA SF induce CD4+ and CD8+ T cell proliferation and cytokine secretion

Conclusions: CD141$^+$ DC are enriched in the IA joint in an active state. RNASeq analysis revealed they are distinct from blood CD141$^+$DC and our *in vitro* data would support the hypothesis that these CD141$^+$DC contribute to synovial inflammation and joint destruction.

SAT0014 THE MUTATED RNA SPLICING PROTEIN HNRNP-A3 IS A NOVEL AUTOANTIGEN IN SYSTEMIC RHEUMATIC DISEASES A LINK TO WARBURG EFFECT IN RA

B. Marklein[1], M. Hansson[2], G. Steiner[3], G. Burmester[1], K. Skriner[1]. *[1]Department of Rheumatology and Clinical Immunology, Charité University Medicine, Berlin, Germany; [2]Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockhom, Sweden; [3]2Division of Rheumatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria*

Background: The present study was undertaken to investigate novel anti-hnRNPs autoantibodies in rheumatic diseases.
Objectives: Novel mutated hnRNP A3 was cloned out of RA synovial tissue linking it directly to Warburg effect and lactate production in RA. Increased lactate production in RA synovia and tumors is klinked to alternative splicing process from PKM1 to PKM2 hnRNPs dependent.
Methods: After immunobloting and 2D-gel-eletrophoresis of a semipurified hnRNP fraction two protein spots were sequenced and identified to be highly similar to hnRNPA3. The hnRNP A3 variants were cloned from RA synovial tissue, which identified the isoforms found on protein level. 3700 RA sera were screened for the presence of mutated anti-hnRNP A3 autoantibodies using recombinant proteins and peptides thereof. Binding of RNA to hnRNP A3 (MA3) and mutated citrullinated A3 peptides (MCA3) the epitope recognition was investigated. Expression of hnRNP A3 in synovial tissue was analysed by
Results: Autoantibodies to MA3 protein were detected in 13% of RA (n=215) patients, in 9% SLE (n=154), in 27% of MCTD patients (n=44/10) and in less than 5% of 129 patients with other rheumatic disorders but not at all in healthy controls on immunoblot. When using renaturated MA3 on ELISA 22% of RA patients were detected and 87% of these patients had erosive arthritis. Same modification as in cancer cells were identified in synovial tissue and verified by MS and DNA sequencing. Using 2–3 citrullinated MCA3 peptides up to 81% of patients (n=150) with established and 67% (n=2926) of patients with an early RA with a specificity of 97% were detected. In early RA 27% and 25% in established RA of CCP2 negative and 93% of CCP2 positive patients were identified.
By combining with the already established CCP2 and the new MCA3, 72% of early patients are positive. MCA3 autoantibodies predominantly occur ($p<0.001$) in an erosive, severe course of disease and approximately 60% of these patients receive a TNF alpha blocker within a year. MRL Lpr/lpr sera were hnRNP-A3 reactive and the antibody generation is Toll 7 and 9 dependent. Anti-hnRNP-A3-antibodies are directed to conformational RNA binding epitopes. Expression of hnRNP-A3 revealed the antigen to be overexpressed in RA synovial tissue.
Conclusions: Mutated hnRNP-A3 is as a novel Toll7/9 dependent autoantigen in systemic rheumatic diseases. These mutated proteins are major components of RNA and DNA containing alternative splicing complexes leading to the Warburg effect and and autoantibodies predominantly occurre in an erosive, and severe courses of RA.

SAT0015 ANCA-ASSOCIATED VASCULITIS- AND SYSTEMIC LUPUS ERYTHEMATOSUS-INDUCED NEUTROPHIL EXTRACELLULAR TRAPS HAVE INTRINSICALLY DIFFERENT FEATURES

L.S. Van Dam[1], T. Kraaij[1], S.W. Kamerling[1], M.C. Avramut[2], C.R. Jost[2], A.J. Koster[2], H.U. Scherer[3], C.D. Pusey[4], A.J. Rabelink[1], C. van Kooten[1], Y.K. Teng[1]. *[1]Nephrology; [2]Molecular Cell Biology; [3]Rheumatology, LUMC, Leiden, Netherlands; [4]Renal and Vascular Inflammation, Imperial College, London, United Kingdom*

Background: Neutrophil extracellular traps (NETs) are immunogenic, extracellular DNA structures that harness important autoantigens to be recognized by the adaptive immune system. NETs are thought to play a pivotal role in the pathogenesis of many systemic autoimmune diseases including ANCA-associated vasculitis (AAV) and systemic lupus erytematosus (SLE). However it is still unclear how and if NETs can act as a common pathway in the pathophysiology of these clinically divergent autoimmune diseases.
Objectives: To investigate the characteristics of NETs induced by sera of AAV and SLE patients.
Methods: The present study involved 101 AAV patients, 59 SLE patients and 10 healthy controls. Healthy neutrophils were stimulated with 10% serum of these patients to induce NETs. Quantity of NET induction was measured by a novel, highly-sensitive NET quantification assay using 3D-confocal laser scanning microscopy[1]. Qualitative characteristics of NETs were investigated by immunofluorescence microscopy that detected co-localisation of several established autoantigens and NET-markers on AAV- and SLE-induced NETs, including citrullinated histon-3 (CitH3), neutrophil elastase (NE), high mobility group box-1 (HMGB1), myeloperoxidase (MPO) and proteinase-3 (PR3). Additionally, the morphology and kinetics of AAV- and SLE-induced NETosis were visualized by live imaging and electron microscopy.
Results: Quantifying ex vivo NET induction demonstrated that AAV sera induced significant more NETs (median [Q1 - Q3]: 20.74 [9.56 – 74.14]), compared to SLE sera (5.02 [1.88 – 14.33]). Also qualitatively, NETs induced by AAV or SLE sera were distinct. In both cases, NETs showed co-localisation of MPO and PR3 with extracellular DNA. However, AAV-induced NETs had significantly higher Cith3 expression than SLE-induced NETs. Interestingly, the opposite was observed for other markers as HMGB1 was exclusively expressed on SLE-induced NETs and NE was also higher expressed on SLE-induced NETs compared to AAV-induced NETs. Intriguingly, the distinction between AAV and SLE NETs was further corroborated by live imaging demonstrating differences in morphology and chronology of NET induction: in SLE NET-clusters were induced within the 1st hour while in AAV non-clustered NETs composed of long, thin DNA-fibres were induced in 2–4 hours through lytic expulsion.
Conclusions: The present study demonstrates that NET induction in AAV and SLE results in quantitative and qualitative distinct NETs indicating that NET formation in AAV and SLE is likely based on intrinsically different processes. These data increase our understanding of the pathophysiologic relevance of NETs and how they could be considered as a common pathway underpinning different autoimmune diseases.

SAT0016 A NEW SUBSET OF NK CELLS, WITH ENHANCED CYTOTOXIC FUNCTION, IS INCREASED IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

D.D.J. Cruz González[1], L. Baranda-Cándido[2], C. Abud-Mendoza[2], J. Alcocer-Varela[3], R. González-Amaro[1], D. Gómez-Martin[3], A.E. Monsiváis-Urenda[1]. *[1]Medicina Translacional y Molecular. Centro de Investigación en Salud y Biomedicina; [2]Departamento de Reumatología. Hospital Central "Ignacio Morones Prieto", Facultad de Medicina. Universidad Autónoma de San Luis Potosí, San Luis Potosí; [3]Departamento de Reumatología e Inmunología, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Ciudad de México, Mexico*

Background: Natural killer cells (NK cells) are granular lymphocytes that belong to innate immunity, its major function is the lysis of virus-infected or tumoral cells. These functions are regulated by activating (NKG2D, NKp46, NKP30, NKG2C, CD161) and inhibitory receptors like KIRs and NKG2A. The role of NK cells in autoimmunity is poorly understood; it is well known that in systemic lupus erythematosus (SLE) patients there are decreased levels of NK cells. NK cells can modulate the adaptive immunity through its interaction with dendritic cells (DCs); the activation or killing of DC by NK cells depends of the ratio NK:DC. However, the interactions NK:DC in SLE have not been well studied. A new subset of NK cells with DCs characteristics has been reported in a model of lupus mice; however, the possible increment of NK cells with DC like phenotype in SLE has not been reported.
Objectives: To analyze the phenotype of circulating NK cells as well as its function in SLE patients.
Methods: Sixty SLE patients and fifty-five controls were included in this study. Diagnosis was made according to ACR criteria. Activity of disease was measured by SLEDAI index. The expression of NKG2A, ILT2, NKG2D, NKG2C, NKp30, NKp46, CD161, CD134, CD80, CD86, HLA-DR, CD11c+ was evaluated in NK cells (CD3-CD56+) from peripheral mononuclear cells. NK cell function was assessed by the percentage of monocyte-derived DC lysis by NK cells.
Results: Diminished levels of circulating NK cells were found in SLE patients ($p=0.0439$) compared to healthy subjects. NK cells from SLE showed higher levels of the inhibitory receptor ILT2+($p=0.0024$), and the costimulatory molecules CD86+ ($p=0.0136$) and CD134+($p=0.0238$); in addition, SLE patients displayed a higher expression of MHC-class II molecule, HLA-DR+ ($p<0.0001$). Interestingly, higher levels of atypical NK cells CD11c+HLA-DR+ ($p=0.0075$) were found in SLE patients compared with healthy subjects. Furthermore, we found that SLE patients showed a significate increased level of monocyte derived-DC lysis by NK cells.
Conclusions: In this study, we show for the first time that NK cells in SLE have an altered phenotype, expressing receptors, which are characteristic of dendritic cells (CD134, CD86 and HLA-DR). The expression of these receptors may provide NK cells with the ability to activate T cells, which together with their higher capacity to lyse immature or tolerogenic DCs could contribute to SLE pathogenesis. It is known that NK cells could have a dual role in autoimmune diseases, here we propose that the lysis of DC mediated by NK cells could be important to modulate the disease activity in SLE patients. Even more, in this report we identify a new subset of NK cells, CD11c+ HLA-DR+, reported previously in a mouse lupus model. It is essential to highlight that these NK cells with DC-like phenotype could be crucial for the development of SLE.

Adaptive immunity (T cells and B cells) in rheumatic diseases

SAT0017 INVESTIGATING NOVEL AUTOANTIBODIES IN PATIENTS WITH GRANULOMATOSIS WITH POLYANGIITIS

M.C. Baker, N. Lingampalli, W. Robinson. *Rheumatology, Stanford University, Palo Alto, United States*

Background: Granulomatosis with polyangiitis (GPA) is a disease characterized by inflammation in small blood vessels, leading to significant organ damage and ultimately great morbidity and mortality. The presence of anti-neutrophil cytoplasmic antibodies (ANCAs) is a hallmark of the disease, and thought to directly play a role in pathogenesis by activating primed neutrophils. The two major antigens that ANCAs are believed to recognize are myeloperoxidase (MPO) and proteinase 3 (PR3). Although anti-MPO antibodies are directly pathogenic when transferred or induced in animal models, the evidence is less clear for PR3. Clinically, it is debated whether levels of anti-PR3 correlate with disease activity. Therefore, we believe that anti-PR3 antibodies are not the primary drivers of disease in patients with PR3+ ANCA-vasculitis (i.e. GPA), and that novel autoantibodies may play a role in disease pathogenesis.
Objectives: The objective of this work is to identify the human autoantigen targets of novel autoantibodies identified in GPA, and to test their association with disease. The goal is to discover novel autoantigens that will ultimately lead to new diagnostics and therapeutics.
Methods: Cell-barcode-enabled antibody repertoire sequencing was performed on blood plasmablasts (antibody-producing cells formed during an immune response) from five PR3+ ANCA-vasculitis patients with GPA treated with rituximab in the RAVE trial. Phylogenetic trees were bioinformatically created in order to identify clonal families of plasmablasts. Antibodies representing clonal families of plasmablasts were recombinantly expressed and are being tested using human protein arrays and ELISAs to determine their antigen specificity.
Results: All five PR3+ ANCA-vasculitis patients sequenced from the RAVE trial achieved complete remission but subsequently flared. Plasmablasts were isolated at the baseline flare, at remission and at the post-rituximab flare. Phylograms of the antibody repertoires revealed clonal families of affinity-matured antibodies that share heavy and light chain VJ usage. A total of 24 representative antibodies were selected for recombinant expression, including representative antibodies derived from clonal families: (1) shared across patients at baseline flare and/or post-rituximab flare (n=5), (2) present at baseline flare and post-rituximab flare (n=7) [persistent clone or same clone came back], (3) present at baseline flare or post-rituximab flare (n=6), (4) present in remission and post-rituximab flare (n=5) [achieves remission despite clone presence], (5) present in remission (but not flare) (n=1) [patient in remission despite clone presence]. None of the 24 antibodies bind PR3 in an ELISA and thus these antibodies do not represent

ANCAs. Antigen discovery to determine the targets of these recombinant plasmablast antibodies is ongoing.
Conclusions: Plasmablasts from patients with GPA in the RAVE trial were sequenced and antibody repertoires were generated. Clonal families of plasmablasts, including those expressing antibodies possessing shared CDR sequences across multiple patients, were identified and recombinantly expressed. None of the 24 antibodies bound to PR3, suggesting these are not ANCAs and are potentially novel autoantibodies. Identification of the antigen targets of these antibodies is ongoing.

SAT0018 EFFECTS OF ANTI-TNF ALPHA THERAPY ON B CELLS IN RHEUMATOID ARTHRITIS (RA) PATIENTS

O. Pala[1], A. Diaz[2], B. Aubourg[1], E. Greidinger[1], B.B. Blomberg[2], D. Frasca[2]. *[1]Rheumatology; [2]Microbiology&Immunology, University of Miami, Miami, United States*

Background: Our laboratory has previously characterized defects in humoral B cell responses of aged mice and humans. These defects include: the reduction in activation-induced cytidine deaminase (AID), required for the generation of optimal antibody responses, and the reduction in the percentage/number of the subset of switched memory B cells (1). AID and switched memory B cells have been proposed to be effective predictive biomarkers of vaccine responses (2). Moreover, we have shown that aging is characterized by increased systemic inflammation which induces intrinsic B cell inflammation, measured by intracellular (ic) TNF-α, and this significantly decreases the capacity of the same B cells to make protective antibodies in response to vaccination (3). Other marker of B cell intrinsic inflammation is micro-RNA (miR) expression, particularly miR-16 and miR-155, which is increased in elderly B cells and negatively correlated with B cell function (4).
Objectives: Our goal for this study was to evaluate B cell phenotype and function in RA patients treated Methotrexate (MTX), alone or together with anti-TNF-α. We hypothesized that patients treated with anti-TNF-α will show improved B cell function due to reduction in icTNF-α.
Methods: We recruited 9 RA patients, 5 patients on MTX and 4 on MTX/anti-TNF-α. We measured the relevant B cell subsets in blood (Naïve, switched memory, IgM memory and late memory) by flow cytometry. Staining was performed with antibodies specific for CD19, CD27 and IgD. In addition, we isolated blood B cells using magnetic beads, and measured the expression of miR-16 and miR-155 on blood B cells by qPCR.
Results: Preliminary data showed that the percentages of switched memory (IgD-CD27+) B cells are significantly higher ($p<0.003$) in patients undergoing MTX/anti-TNF-α therapy. We also observed a significant decrease in naïve B cell percentages ($p<0.028$). Preliminary results also showed a decrease in the mRNA expression of both miR-16 and miR-155 in patients on combination therapy compared to MTX alone.
Conclusions: These results support the hypothesis that therapy with anti-TNF-α is beneficial for improving B cell function in RA patients, as compared to MTX therapy alone. Future experiments will seek to evaluate intrinsic B cell TNF levels in these patients and correlate them with measurements of B cell function. Treatment with anti-TNF-α may be able to block the excessive amounts of systemic TNF-α and in turn B cell intrinsic TNF-α which could improve the antibody responses and the risk of infections in RA patients undergoing therapy.

SAT0019 ESTROGEN INFLUENCES THE SIALYLATION PROFILE AND INFLAMMATORY PROPERTIES OF ANTIBODIES – A POTENTIAL EXPLANATION FOR THE SEX DIFFERENCES AND INCREASED RISK FOR RA IN POSTMENOPAUSAL WOMEN

C. Engdahl[1,2], J. Raufer[1], U. Harre[1], A. Bondt[3], R. Pfeifle[1,4], G. Krönke[4,5], H.U. Scherer[6], H. Forsblad[2,7], G. Schett[1]. *[1]Department of Internal Medicin 3, Clinical Immunolgy, Erlangen, Germany; [2]Department of Rhemtology and Inflammation reserch, CBAR, Institue of Medicine, Gothenburg, Sweden; [3]Department of Rheumatology, Lediden University Medical Center, Leiden, Netherlands; [4]Nikolaus-Fiebiger Center for Molecular Medicine, FAU Erlangen-Nuremberg, Erlangen; [5]Department of Internal Medicin 3, Clinical Immunolgy, Gothenburg, Germany; [6]Department of Rheumatology, Lediden University Medical Center, Leiden, Netherlands; [7]Department of Public Health and Clinical Medicine, Rheumatology, Umeå University, Umeå, Sweden*

Background: Rheumatoid arthritis preferentially affects women. RA has its peak over 50 years coincidencing with the decrease in sex hormones in menopause. Recently, the transition from asymptomatic autoimmunity to RA has been shown to essentially depend on the glycosylation status of antibodies affecting the binding affinity to Fc gamma receptors[1]. Hence a decrease in the sialylation of antibodies resulting from a decrease in the activity of the sialylation enzyme β-galactoside α2,6-sialylltransferase (St6Gal1) was shown to trigger the onset of RA.
Objectives: To test whether estrogen influences the glycosylation status of antibodies and St6Gal1 expression explaining why postmenopausal women are particularly prone to develop RA
Methods: In the experimental part we tested the influence of estrogen on antibody glycosylation and St6Gal1 expression. Ovariectomized mice, which were either left without estrogen supplementation or were supplemented with estrogen (hormone replacement), were immunized with ovalbumin (OVA) to induce antibody production. Immunoglobulin G (IgG) levels were analyzed by ELISA and the glycosylation of the Fc-part of total and OVA-specific IgG was determined by lectin ELISA and MALDI-TOF, respectively. St6Gal1 expression in plasma cells was determined by RT-PCR and FACS. Inhuman part we measured the effects of estrogen treatment on autoantibody levels and IgG glycosylation in a cohort of postmenopausal RA patients over 2 years[2].
Results: Ovariectomy and loss of estrogens was associated with a lower sialylation of OVA-specific IgG. Conversely estrogen treatment significantly increased the sialylation level of newly formed OVA-specific and totals IgG as well as enhanced the expression of St6Gal1 enzyme in plasma cells suggesting a shift towards an anti-inflammatory pattern of IgG. These results were confirmed with estrogen treated postmenopausal RA patients showing that hormone replacement therapy significantly increased antibody glycosylation, while in a control RA population not exposed to estrogens no such increase in sialylation of IgG was found. Estrogens however, did not influence the CCP autoantibody levels.
Conclusions: These findings indicate that estrogen regulates St6Ga1 and increases the glycosylation of IgG. Lack of estrogen decreases IgG glycosylation and results in pro-inflammatory properties of IgG which may explain the increase prevalence of RA in postmenopausal women.

SAT0020 THE CITRULLINOME IN TISSUE AND BIOFLUIDS OF HUMAN AND MOUSE ORIGIN

T.B.G. Poulsen[1], D. Damgaard[2], T.B. Bennike[1], M.K. Meyer[3], K.J. Elbæk[1], V. Andersen[4], S. Birkelund[1], C.H. Nielsen[2], A. Stensballe[1]. *[1]Department of Health Science and Technology, Aalborg University, Aalborg; [2]Center for Rheumatology and Spine Diseases, Copenhagen University Hospital, Rigshospitalet, Institute for Inflammation Research, Rigshospitalet, Institute for Inflammation Research, Copenhagen; [3]Department of Rheumatology, North Denmark Regional Hospital, Hjørring; [4]IRS-Center Sonderjylland, Hospital of Southern Jutland, Aabenraa, Denmark*

Background: Protein citrullination is fundamental to several essential processes in apoptosis and antimicrobial defense, however, also linked to multiple pathogenic endpoints. This post-translational modification (PTM), by conversion of arginine to citrulline residues, is mediated by peptidylarginine deiminase (PAD) enzymes found in specific cells and tissues. In polymorphonuclear cells (PMNs) these enzymes enable NETosis, a specialized form of programmed necrosis and the formation of NETs (neutrophil extracellular traps). Also, these enzymes are expressed in the synovium of patients with rheumatoid arthritis (RA) thereby triggering the production of autoantibodies against citrullinated proteins (ACPAs).
Objectives: Our objective was to optimize methodology for characterization of this PTM and determine the citrullinome in tissue and biofluids of human and mouse origin in clinical relation to rheumatoid arthritis (RA), osteoarthritis (OA), Spondyloarthritis (SpA) as well as presence of ACAPs and NETs
Methods: Synovial fluid (SF) and plasma was collected from patients diagnosed with RA, OA, SpA (n=120). Inflammation levels patients were characterized with plasma C-reactive protein (CRP), and circulating anti-CCP levels as well as 10 most relevant proinflammatory cytokines. Intestinal tissue (colon mucosa) from RA patients (n=10) and joint lysate from collagen-induced arthritis mouse model (n=24). All samples were analyzed by citrulline specific sample preparation and high-end mass spectrometric analysis [1,2]. Follow-up studies were performed by multiple techniques including confocal microscopy and cell-free DNA measurement.

Results: The proteome analysis of SF allowed deepest proteome analysis so far (Proteoforms >1300) as well as a number of citrullinated sites. The three patient groups could be differentiated by cluster analysis and the occupancy of each modified site calculated. The investigation of the intestinal tissue enabled identification of 223 citrullinated peptides from 121 proteins. Three of the peptides were unique to RA. The list of citrullinated proteins was enriched in extracellular and membrane proteins and included known targets of anticitrullinated protein antibodies (ACPAs). Investigation of collagen-induced arthritis mouse model enabled differential analysis of the proteome as response to treatment and determination of the PTMs associated with this model.
Conclusions: Our deep proteome based analysis of tissue and biofluids have enabled an extended catalogue of citrullinated proteins and sites relevant to improved disease subtyping as well as a source of citrullinated sites for future studies.

SAT0021 HUMAN CD4 T CELLS AND SYNOVIAL FIBROBLASTS COOPERATE TO PROMOTE INFLAMMATION IN THE RA SYNOVIAL JOINT

A. Petrasca[1], G. Jameson[1], T. McGarry[2], D.J. Veale[3], U. Fearon[2,3], J.M. Fletcher[1,2]. *[1]School of Biochemistry and Immunology; [2]School of Medicine, Trinity Biomedical Sciences Institute, Trinity College Dublin; [3]Department of Rheumatology, St. Vincent's University Hospital, Dublin, Ireland*

Background: Rheumatoid arthritis (RA) is a chronic autoimmune disease characterised by synovial tissue proliferation and degradation of articular cartilage. Activated synovial fibroblasts proliferate and express matrix-degrading proteases, adhesion molecules and proinflammatory cytokines, which contribute to cartilage and joint destruction. Moreover, synovial cell activation correlates with infiltration of inflammatory lymphocytes and monocytes which in turn contribute to synoviocyte activation, thus further exacerbating inflammation.
Objectives: The functional relationship linking fibroblasts and T lymphocytes in this complex microenvironment has yet to be characterised. Therefore, we established an *in vitro* model to examine the outcomes of co-culturing activated human CD4 T cells with RA synovial fibroblasts.
Methods: Co-culture assays were carried out using immortalised K4IM RA synovial fibroblasts or synovial fibroblast cells derived from arthroscopy biopsies of RA patients. Human CD4 T cells were stained with a proliferation-tracking dye and co-cultured with pre-seeded synovial fibroblasts for 5 days. The resulting cell cultures and supernatants were examined for proliferation, cytokine production, secretion of matrix metalloproteinases and expression of adhesion molecules.
Results: We found that CD4 T cells and K4IM cells reciprocally induced an increased expression of adhesion molecules ICAM and VCAM. Furthermore, co-culture of CD4 T cells and synovial fibroblasts resulted in proliferation of CD4 T cells expressing increased levels of the proinflammatory cytokines IFN-γ and IL-17a and RANKL after 5 days. Lastly, co-culture of T cells and synovial fibroblasts resulted in secretion of IL-6, IL-8, IFN-γ and IL-17a and matrix metalloproteinases MMP-1 and MMP-3.
Conclusions: These results indicate that CD4 T cells work mutually with synoviocytes to create an inflammatory microenvironment likely to promote joint destruction. Future studies will characterise the role of glucose metabolism in these cells and investigate if metabolism is intrinsically coupled to effector functions in these cells.

SAT0022 EPIGENOME-WIDE ASSOCIATION STUDY OF RHEUMATOID ARTHRITIS IDENTIFIES DIFFERENTIALLY METHYLATED LOCI IN B CELLS

A. Julià[1], D. Absher[2], M. López-Lasanta[1], N. Palau[1], A. Pluma[1], L. Waite Jones[2], J.R. Glossop[3], W.E. Farrell[3], R.M. Myers[2], S. Marsal[4]. *[1]Grup de Recerca de Reumatologia, Vall Hebron Research Institute, Barcelona, Spain; [2]Absher Lab, HudsonAlpha Institute for Biotechnology, Huntsville, United States; [3]Keele University, Institute for Science and Technology in Medicine, Staffordshire, United Kingdom; [4]Grup de Recerca de Reumatologia, Vall Hebron Research Institute, Alabama, Spain*

Background: Epigenetic regulation of immune cell types could be critical for the development and maintenance of autoimmune diseases like Rheumatoid Arthritis (RA). B cells are highly relevant in RA, since patients express autoantibodies and depleting this cell type is a successful therapeutic approach. Epigenetic variation, such as DNA methylation, may mediate the pathogenic activity of B cells.
Objectives: In this study, we performed an epigenome-wide association study (EWAS) for RA with three different replication cohorts, to identify disease-specific alterations in DNA methylation in B cells.
Methods: Genomic methylation in isolated B lymphocytes was assayed on the Illumina HumanMethylation450 BeadChip, assaying >450,000 different CpG sites. Differential methylated positions (DMPs) were identified in a discovery cohort using a single-point analysis using logistic regression, as well as a pathway-level analysis using a newly developed permutation-based method. A discovery cohort of 50 RA patients and 75 healthy controls from Spain was used to identify the most differentially methylated regions after multiple test correction. Using an independent sample of 15 patients and 15 controls from the same population we performed a replication analysis of the most significant CpG sites and pathways. Using an additional case-control sample of 24 individuals from the UK we provided further evidence of association of the DMPs with RA. Finally, in silico datta from a cohort of systemic lupus erythematosus patients (SLE, n=47) and controls (n=56) from the US, we tested the association of the associated DMPs.
Results: A total of 64 CpG sites were found to be differentially methylated in RA patients compared to controls in the discovery stage after multiple test correction ($q<0.05$). Six biological pathways were also differentially methylated in RA B cells. Analysis of these epigenetic changes in the independent Spain cohort replicated the association of 10 CpG sites located on 8 genes and 2 intergenic regions. Differential methylation at the *CBL* signaling pathway was also replicated. Using the UK case-control cohort, association between RA risk and methylation levels at *CD1C* (P=2.26x10^{-9}) and *TNFSF10* (P=1.67x10^{-8}) loci was further validated. Most of the replicated DMPs associated with RA were also found to be associated with differential methylation in SLE B cells.
Conclusions: Our results highlight genes that may drive the pathogenic activity of B cells in RA and suggest shared methylation patterns with SLE.

Klatzmann[7], L. Musset[8], T. Poynard[9], P. Cacoub[10], D. Saadoun[10]. *[1]Internal Medicine and Clinical Immunology; [2]INSERM, UMR_s 959, FRE3632, Hôpital Pitié-Salpêtrière; [3]Biological Hematology, Groupe Hospitalier Pitié-Salpêtrière, Paris; [4]Hepatology, Hôpital d'Orléans, Orléans; [5]Internal Medicine, Centre hospitalier universitaire Purpan, Toulouse; [6]Hepatology, CHU Cochin; [7]INSERM, UMR_s 959, FRE3632; [8]Immunology, UF d'Immunochimie et d'autoimmunité; [9]Hepatology; [10]Internal Medicine and Clinical Immunology, CHU Pitié-Salpêtrière, Paris, France*

Objectives: Interferon-free direct-acting antiviral (DAA)-based therapy has proven to be very effective in patients with hepatitis C virus-cryoglobulinemia vasculitis (HCV-CV). However, their mechanisms of action and their effects on cellular immunity remain poorly defined.
Methods: 27 HCV-CV patients treated with DAA therapy, 12 healthy donors (HD) and 12 HCV were included. We investigated the effects of DAA-based therapy on cellular and cytokine abnormalities in HCV-CV patients by flow cytometry, cytokine Multiplex and enzyme-linked immunosorbent assay.
Results: Compared with HD and HCV, pre-DAA abnormalities in HCV-CV patients included a decreased percentage of $CD4^+CD25^{hi}FoxP3^+$ regulatory T cells ($P<0.01$) with increases in $IgM^+CD21^{-/low}$ memory B cells ($P<0.05$), $CD4^+IFN\gamma^+$ ($P<0.01$), $CD4^+IL17A^+$ ($P<0.01$) and $CD4^+CXCR5^+IL21^+$ follicular helper T cells (Tfh) ($P<0.01$). $IgM^+CD21^{-/low}$ memory B cells were negatively correlated with regulatory T cells (Tregs) (P=0.03), and positively correlated with Tfh (P=0.03) and serum cryoglobulin levels (P=0.01). DAA-based therapy was associated with an increase in Tregs frequency (1.5% ± 0.18% versus 2.1% ± 0.18%), and decreased $IgM^+CD21^{-/low}$ memory B cells and Tfh percentage (35.7% ± 6.1% versus 14.9% ± 3.8%, and 12% ± 1.3% versus 8% ± 0.9%, respectively). B lymphocyte stimulator receptor 3 and programmed death-ligand 1 staining expression on B cells increased in HCV-CV after DAA-based therapy (MFI 37±2.4 versus 47±2.6, $P<0.01$; and 29±7.3 versus 48±9.3, $P<0.05$ respectively).
Conclusions: Our results indicate that DAA-based therapy effectively normalizes many of the disturbances in peripheral B and T lymphocyte homeostasis of HCV-CV patients.

SAT0024 ALTERATIONS OF PERIPHERAL BLOOD B-CELL SUBSETS IN EARLY RHEUMATOID ARTHRITIS

E. Suponitskaya, A. Avdeeva, A.A. Aleksankin, E. Gerasimova, E. Aleksandrova, T. Popkova, A.N. Novikov, D.K. Karateev. *Institute of Rheumatology, Moscow, Russian Federation*

Background: Alterations of B-cell subpopulation have been described in the

peripheral blood of rheumatoid arthritis (RA) patients (pts), but differences between B-cell subsets distributions in early and late onset RA (LORA) are still unclear [1,2].

Objectives: To examine B-cell subsets in peripheral blood of healthy donors, early (disease duration <6 months) RA (ERA) and LORA pts by flow cytometry, and to analyze the association between B-cell subsets and RA activity.

Methods: 24 active ERA pts (20F/4M); median age 54 years (range) (38–64); disease duration 5 months (4–6); DAS28 score 5.2 (4.7–5.9); RF+75%, ACCP+ 87.5% and 20 LORA pts (16F/4M); median age 58 years (range) (44–62); disease duration 12 years (4.5–17.5); DAS28 score 5.3 (4.6–6.2); both RF+ and ACCP+ 80%, were assessed for B-cell subpopulations and laboratory data: ESR, CRP. LORA pts were treated with DMARDs (anti-TNF-α, Methotrexate), glucocorticoids, and NSAIDS; ERA pts received NSAIDS only. CD19+B cells, memory B cells (CD19+CD27-), non-switched memory B cells (CD19+IgD+CD27+), switched memory B cells (CD19+IgD-CD27+), naïve (CD19+IgD+CD27-), double-negative (CD19+IgD-CD27-), transitional (CD19+IgD+CD10+CD38++CD27-) B cells, and plasmablasts (CD19+CD38+++IgD-CD27+CD20-) were analyzed using multicolor flow cytometry.

Results: The median percentages (range) of non-switched memory B cells (CD19+IgD+CD27+) were lower in ERA and LORA RA cohorts compared to donors: 3.0% (1.6–5.5) and 6.2% (2.4–10.2) vs 7.4% (3.7–11.1), respectively, $p<0.05$ for both cases. In LORA pts, the median percentages (range) and absolute numbers of switched memory B cells (CD19+IgD+CD27-) were higher compared to both ERA pts and donors: 24,1% (14,0–42.3) vs 8,3% (4.4–12.9) and 12.8% (9.3–17.0); and 0.03 (0.02–0.05) vs 0.01 (0.006–0.02) and 0.02 (0.01–0.04), respectively; $p<0.05$ for all cases. The median percentages of naïve B cells (CD19+IgD+CD27-) were significantly higher in ERA pts compared to LORA pts and healthy donors: 75.3% (69.7–83.6) vs 54.3% (39.7–69.1) and 64.7% (57.6–72.4), respectively, $p<0.05$ for both cases.

In ERA pts, we found a significant correlation between absolute numbers of non-switched memory B cells (CD19+IgD+CD27+), RF and anti-CCP: r=0.50 and 0.45, respectively, $p<0.05$ for both cases. In LORA pts, the percentage of memory B cells (CD19+CD27+) correlated positively with ESR (r=0.58), $p<0.05$; a positive association was observed between the absolute numbers of switched memory B cells (CD19+IgD-CD27+), CRP (r=0.48) and RF (r=0.49), $p<0.05$ for all cases.

Conclusions: in ERA pts, immunophenotyping showed increased frequencies of naïve B cells and decreased frequencies and absolute numbers of switched memory B cells compared to LORA cohort.

SAT0025 MIR 106A, MIR 19A-B, MIR 20A AND MIR21A REGULATE Vγ9Vδ2 FUNCTIONS PARTICIPATING IN THE INFLAMMATORY RESPONSES OCCURRING IN RHEUMATOID ARTHRITIS

G. Guggino[1], F. Ciccia[1], V. Orlando[2], L. SAieva[2], P. Ruscitti[3], P. Cipriani[3], I. Chalcarz[4], R. Alessandro[4], R. Giacomelli[3], F. Dieli[4], N. Caccamo[4], G. Triolo[4]. *[1]DIBIMIS; [2]DIBIME, University of Palermo, palermo; [3]University of L'Aquila, L'Aquila; [4]University of Palermo, Palermo, Italy*

Background: miRNAs are non-coding RNAs which have significant roles in regulating gene expression. The miR17-92 cluster appears to be a key factor in the inflammatory pathways activated during RA.

Objectives: In this study we aimed to evaluate miR17–92 expression and functions in γδ T cell subsets in RA patients, γδ T cells, in fact produce pro-inflammatory cytokines such as IFN-g, IL-6 and IL-8 that may contribute to the inflammatory responses in RA.

Methods: Heparinized peripheral blood from 10 early RA untreated patients and 10 healthy donors was obtained for this study. Polyclonal Vγ9Vδ2 T cell lines were generated first by magnetic isolation followed by sorting (FACSAria) and further analysed by flow cytometry to define their phenotype and their pattern of cytokine production. Expression analysis of miRNA17–92 cluster was performerd by RT-PCR and after identification of relevant miRNA involved in RA, mRNA expression of miRNA target genes was studied.

Results: A remarkable change in the distribution of Vγ9Vδ2 T cell functional subsets with an expansion of effector subsets and a reduction of naïve cells, was observed in the peripheral blood of RA patients, as compared to healthy donors, which were accompanied by modifications in proinflammatory cytokine expression. Particularly, $T_{EM\ (effector\ memory)}$ and $T_{EMRA\ (effector\ memory\ terminally\ differentiated)}$ cells resulted the major souce of IL-6 and IL-8. A significant correlation between miRNA expression and levels of IL-6 and IL-8 was found. The comparative analysis of miRNA expression among Vγ9Vδ2 T cell subsets, between RA patients and healthy controls showed a downregulation of miR106a-5p and miR20a-5p and an upregulation of miR 21a-5p among Vγ9Vδ2 T_{EM} cells; a downregulation of miR19–3p among Vγ9Vδ2 T_{EM} and $Tc_{M\ (central\ memory)}$ cells was also found. This miRNA expression regulated IL-8 and IL-6 gene transcription contributing to the survival of the pro-inflammatory pool reducing the expression of the PDCD4 gene.

Conclusions: Our results provide evidence of a role of miR106a, miR19–3p, 20a and 21a in the regulation of Vγ9Vδ2 T cells function in RA patients and suggest the possibility that the miR17–92 family and γδ T cells participate to the pathogenesis of RA.

SAT0026 SIGNALLING THROUGH INSULIN-LIKE GROWTH FACTOR 1 RECEPTOR CONTRIBUTES TO IL-6 PRODUCTION AND SUPPORTS T CELL DEPENDENT INFLAMMATION IN RHEUMATOID ARTHRITIS

M. Erlandsson[1], M. Nadali[2], S. Töyrä Silfverswärd[2], M.N. Svensson[2], I.-M. Jonsson[2], K.M. Andersson[3], M.I. Bokarewa[2]. *[1]Rheumatology and Inflammation Research; [2]Dept of Rheumatology and Inflammation Research; [3]Dept. of Rheumatology and Inflammation Research, Gothenburg University, Gothenburg, Sweden*

Background: Insulin-like growth factor (IGF) 1 receptor is essential for cell energy metabolism. It plays a key role linking glucose and lipid metabolism of active cells and may turn pathogenic in uncontrolled tissue growth in tumours. In rheumatoid arthritis (RA), the IGF-1R signalling is activated supporting expansion of the inflamed synovia.

Objectives: The aim of the present study was to understand the place of IGF-1R expression and signalling for development of adaptive immune responses in the setting of prospective RA cohort and in experimental arthritis.

Methods: Clinical associations of IGF1R expression in leukocytes of the peripheral blood were studied in 84 female RA patients with mean disease duration 8 years, all treated with methotrexate. Consequences of the IGF1R signalling inhibition for arthritis were studied in mBSA immunised Balb/c mice treated with NT157 compound promoting degradation of the insulin receptor substrates IRS-1/2.

Results: In RA patients, high expression of IGF1R in leukocytes was associated with systemic inflammation as verified by higher transcription factor NF-kB (p=0.033), serum levels of IL-6 (p=0.006) and erythrocyte sedimentation rate (p=0.003), and higher pain perception (VAS, p=0.019). Additionally, women with high IGF1R were often in need of combined DMARD treatment (p=0.045). Phosphorylated IGF1R and STAT3 enrich T cells infiltrate in RA synovia. Treatment with NT157 rendered no metabolic consequences to mouse body weight and serum glucose levels. NT157 inhibited the phosphorylation of IGF1R and STAT3 in synovia, and alleviated arthritis and erosions in mice. It also reduced IGF1R+ T cell population in spleen and despaired ERK and Akt signalling. This limited the ability of mBSA-specific T cells to produce IL-6 (p=0.013), IFNg (p=0.024) and IL-17 (p=0.0097). The reduction of IL-6 and IL-17 levels was associated with changed RoRgt/FoxP3 balance.

Conclusions: IGF1R signalling contributes to severe RA by triggering T cell dependent inflammation in arthritis. Inhibition of IGF1R on the level of insulin receptor substrates alleviates arthritis by restricting IL-6 dependent formation of Th17 cells and may open for new treatment strategies in RA.

SAT0027 IMMUNOMODULATORY EFFECTS OF MGD010, A DART® MOLECULE TARGETING HUMAN B-CELL CD32B AND CD79B

W. Chen, S. Shankar, J. Lohr, X.-T. Yao, H. Li, X. Chen, J. Muth, N. Gal-Edd, E. Bonvini, S. Johnson, N. Pandya, P.A. Moore, J. Wigginton. *Macrogenics, INC., Rockville, United States*

Background: B-cell targeted therapeutics have proven efficacious in the treatment of autoimmune diseases, generating impetus to develop alternate strategies that provide activity with rapid onset and no B-cell depletion. To this end, MGD010, a bispecifc DART® molecule, was designed to exploit the inhibitory function of the checkpoint molecule, CD32B, (FcγRIIb) via its simultaneous co-ligation with the BCR component, CD79B. Initial phase 1 studies performed in healthy subjects demonstrated MGD010 was well tolerated in a single-dose, dose escalation to up to 10 mg/kg, with no evidence of peripheral B-cell activation or depletion. MGD010 exhibited pharmacokinetic properties of an antibody-based molecule, with dose-dependent B-cell occupancy saturating at >1mg/kg and diminished propensity for ex-vivo BCR-induced B-cell activation (1). To further understand the potential for MGD010 to modulate ongoing immune responses, the impact of MGD010 on the immune response to Hepatitis A (HAV) vaccination, a T-cell dependent neo-antigen challenge, was evaluated in normal healthy subjects.

Objectives: To determine effects of MGD010 on humoral and cellular immune responses in normal healthy volunteers.

Methods: This was an open label, placebo controlled cohort-expansion in normal healthy volunteers. Subjects (n=8 per group) were randomly assigned to receive an IV administration of a single dose of 3 or 10 mg/kg MGD010 or placebo. All subjects received a single intramuscular dose of hepatitis A vaccine (HAV) (1.0 mL or ~50U) 24 hours after administration of MGD010 or placebo. Subjects were monitored for adverse events for 56 days after administration of drug or placebo. Analyses included peripheral lymphocyte

counts and immunophenotyping, determination of serum immunoglobulin levels, seroconversion rate of HAV and quantification of serum HAV IgG concentration.
Results: Twenty-four (24) healthy subjects were enrolled for the study and 23 completed the study. One subject discontinued prior to completion due to inability to follow study procedures. There were no severe adverse events in subjects who received 3 or 10 mg/kg MGD010. The only serious adverse event reported in t in a subject who had received placebo and was not drug related. There were no CTCAE grade 3 or higher adverse events related to MGD010. Consistent with prior observations (1), ex vivo flow cytometric analysis confirmed dose-dependent MGD010 binding to peripheral B cells without B-cell depletion, accompanied with decreased surface BCR and CD40 expression as well as a moderate decrease in total serum IgM levels. Reduced HAV seroconversion rates were observed in subjects treated with MGD010 as compared to placebo, with significantly lower HAV-specific IgG levels in subjects treated with MGD010 compared with placebo group ($P < 0.05$).
Conclusions: These studies demonstrate that by pharmacologically exploiting the activity of the checkpoint molecule CD32B in combination with the BCR CD79B component, a single dose administration of either 3 or 10 mg/kg MGD010 delivers an immunomodulatory effect that effectively counters B-cell function. Together with a good safety profile, these data provide compelling rationale for further developing MGD010 as a therapeutic modality for autoimmune diseases.

SAT0028 AIOLOS OVEREXPRESSION IN SYSTEMIC LUPUS ERYTHEMATOSUS B-CELL SUBTYPES AND BAFF INDUCED MEMORY B-CELL DIFFERENTIATION ARE REDUCED BY CC-220 MODULATION OF CEREBLON ACTIVITY

G.E. Ringheim, J. Kosek, L. Capone, P.H. Schafer, Y. Nakayama. *Inflammation and Immunology, Celgene Corporation, Summit, United States*

Background: Systemic Lupus Erythematosis (SLE) is an autoimmune disease characterized by alterations in B-cells, autoantibody production, and elevations in circulating B-cell activating factor (BAFF). Aiolos single nucleotide polymorphisms and elevations in Aiolos mRNA are associated with SLE susceptibility. CC-220 is a Cullin Ring Ligase 4 Cereblon (CRL4CRBN) E3 Ubiquitin Ligase Modulator that induces ubiquitination and degradation of Aiolos and Ikaros transcription factors. We investigated the effects of CC-220 in B-cells from SLE patients to assess its impact on Aiolos protein levels and B-cell proliferation, differentiation, and antibody production.
Objectives: Determine the protein levels of the B-cell transcription factors Aiolos and Ikaros in B-cell subtypes of SLE patients and assess the impact of the cereblon modulator CC-220 on Aiolos and Ikaros protein degradation, proliferation, and plasmablast differentiation.
Methods: Peripheral blood mononuclear cells (PBMC) were measured for levels of circulating B-cell subtypes, B-cell activation state, and Aiolos and Ikaros protein levels by flow cytometry. Cell types were defined as: $CD27^-IgD^+$ naive, $CD27^+IgD^-$ switched memory, $CD27^+IgD^+$ nonswitched memory, and $CD27^-IgD^-$ double negative B-cells and $CD20^-CD38^+$ plasmablasts. Measurements of BAFF, IL-2 and IL-21 from plasma and IgG and IgM were done by ELISA. Plasmablast differentiation was induced by BAFF, IL-2, and IL-21 co-stimulation of B-cell cultures for 5 days in the absence and presence of CC-220.
Results: Plasma samples from SLE patients were found to have higher circulating BAFF, similar IL-2 levels, and reduced IL-21 levels relative to healthy individuals. Alterations in circulating B-cell subtypes occur in SLE patients including reduction of memory and elevations of naive and double negative B-cells. Alterations in biomarkers associated with chronic B-cell activation, including elevation of CD95 and reduction of CD21 and CD23 were also observed. Assessment of the B-cell differentiation transcription factors Aiolos and Ikaros in SLE B-cells showed that Aiolos, but not Ikaros is elevated in naive, switched memory, nonswitched memory, and double negative B-cells. CC-220 treatment reduced Aiolos and Ikaros protein levels in both SLE and healthy individuals in all four B-cell subtypes measured. CC-220 treatment was associated with reduced B-cell proliferation, plasmablast differentiation, and secretion of IgG and IgM in cells co-stimulated with BAFF, IL-2 and IL-21. Similarly, CC-220 reduced the expression of genes involved in B-cell differentiation including IRF-4, Xbp-1, Blimp-1, and IgJ indicating an early blockade in B-cell differntiation.
Conclusions: Our observations that SLE is associated with alterations of circulating B-cell subtypes and their activation state, Aiolos overexpression in B-cells, and increases in circulating BAFF support the hypothesis that B-cells play a significant role in SLE pathology. Moreover, these observed changes suggest that B-cells may be predisposed towards plasmablast differentiation and antibody production in SLE. CC-220 administration reduced Aiolos and Ikaros protein levels in B-cells and reduced proliferation, plasmablast differentiation and antibody production at clinically obtainable drug concentrations (<10 nM).

SAT0029 B CELL DEPLETION AFFECTS CD8 T CELLS IN ANCA-ASSOCIATED VASCULITIS

A. Néel[1,2], M. Bucchia[3], M. Néel[2], M. Rimbert[2,4], C. Agard[1], M. Hourmant[5], G. Tilly[2], M. Yap[6], F. Perrin[1], J. Graveleau[1], P. Godmer[7], S. Brouard[2], C. Bressollette[8], F. Fakhouri[2,5], M. Hamidou[1,2], N. Degauque[2]. *[1]Internal Medicine, Nantes University Hospital; [2]U1064, INSERM; [3]Pediatrics; [4]Immunology; [5]Nephrology, Nantes University Hospital; [6]INSERM, Nantes; [7]Internal Medicine, CH Bretagne Atlantique, Vannes; [8]Virology, Nantes University Hospital, Nantes, France*

Background: In anti-neutrophil cytoplasmic antibodies associated vasculitis (AAV), several clues suggest that the efficacy of B cell depletion therapy lies beyond the suppression of ANCA-producing cells and may involve the suppression of B-T cell crosstalk. However, little if any data are available regarding the impact of rituximab on CD4, regulatory T and CD8 T cells in this setting.
Objectives: To compare the effect of conventional immunosuppressants (CIS) and rituximab (RTX) on 3 T cells compartments in AAV. To assess the impact of patients B cells and that of B cell depletion on CD8 T cell cytokine production.
Methods: Thorough cross-sectionnal immunophenotypic analysis of CD4, regulatory T and CD8 cells of 53 patients with AAV, using polychromatic flow cytometry. A multiplex Luminex immunoassay was used to measure Cytokine/chemokine production of in vitro stimulated CD8 T cells. Active untreated AAV patients' B cells and/or CD8 T cells were cocultures for 72h with Staphylococcal Enterotoxin (Autologous and criss-cross experiments), and CD8 T cells cytokine production was then measured by flow cytometry.
Results: Among CD4 T cells, we found that frequency of naïve and memory subsets and the expression of CCR5, CCR4 and CD161 were not influenced by maintenance treatment type. Similarly, total Treg frequency and Treg subsets including CD161+, Helios+, resting (CD45RA+) and memory (CD45RA-FoxP3hi) Tregs were comparable among RTX and CIS treated patients. By contrast, the type of maintenance treatment markedly influenced the CD8+ T cell compartment. Patient under B cel depletion therapy had less TEMRA (CD45RA+CCR7-) and more TEM cells than those receiving CIS, and ressembled those in long term remission off therapy. CMV seropositivity did not explained the observed diifferences. Longitudinal data confirmed that B cell depletion significantly decreased TEMRA (CD45RA+CCR7-) CD8 T cell frequency ($p<0.001$), whereas CIS had the opposite effect. Furthermore, we found that in vitro stimulated CD8 T cells from B cell depleted patients produced less pro-inflammatory cytokine/chemokine than those from patients treated with CIS. In coculture with B cells and SEB, patients CD8 cells coculture produced higher level of inflammatory cytokines than those from controls, but only when they were stimulated with patients' B cells.
Conclusions: B cell depletion therapy has a significant impact on the CD8 T cell compartment in terms of phenotype and function. B cell can promote pro-inflammtory function of CD8 T cell in vitro. CD8 T cell are found in vasculitis lesions. These observations raise the question whether the disruption of B cell help to CD8 T cells could contribute to the dramatic efficacy of RTX. Further studies are needed to demonstrate the implication of patients' CD8 T cell in tissue damage.

SAT0030 BREACH OF AUTOREACTIVE B-CELL TOLERANCE BY POST-TRANSLATIONALLY MODIFIED FOREIGN PROTEINS

J. Dekkers[1], M. Verheul[1], J. Stoop[1], B. Liu[1], A. Ioan-Facsinay[1], P. van Veelen[1], A. de Ru[1], G. Janssen[1], M. Hegen[2], S. Rapecki[3], T. Huizinga[4], L. Trouw[4], R. Toes[4]. *[1]Rheumatology, LUMC, Leiden, Netherlands; [2]Pfizer, Boston, United States; [3]UCB, Slough, United Kingdom; [4]LUMC, Leiden, Netherlands*

Background: Autoimmunity in Rheumatoid arthritis (RA) patients is characterized by a spectrum of anti-modified protein antibodies (AMPA) directed against post-translationally modified (PTM) proteins. The best-known AMPA in RA are anti-citrullinated protein antibodies (ACPA). Much less is known about the occurrence and aetiology of other AMPA responses in RA such as autoantibodies directed to malondialdehyde-acetaldehyde (MAA) adducts, acetylated antigens, and carbamylated proteins. Anti-carbamylated protein (anti-CarP) autoantibodies recognize carbamylated proteins containing a homocitrulline, a PTM structurally similar to citrulline. With the presence of various AMPA responses in RA, PTM proteins have been implicated in the breach of autoreactive B-cell tolerance

leading to the formation of these autoantibodies. At present it is unkown how AMPA are generated and how autoreactive B-cell responses against PTM proteins are induced.
Objectives: To investigate how PTM proteins, more specifically carbamylated proteins, could contribute to a breach of B-cell tolerance.
Methods: Serum reactivity towards five different carbamylated proteins was determined for 160 RA-patients and 40 healthy individuals. Anti-CarP antibody cross-reactivity was studied by inhibition experiments. Mass spectrometry was performed to identify carbamylated self-proteins in human rheumatic and osteoarthritic joint tissue. Mice were immunized with carbamylated- or non-modified foreign (OVA) and self-antigens (mouse Albumin). Sera of immunized mice and monoclonal antibodies were analyzed for antigen reactivity.
Results: We show that anti-CarP antibodies in RA are highly cross-reactive towards multiple carbamylated proteins, including modified self- as well as modified non-self proteins. Immunization with carbamylated foreign proteins (Ca-OVA) induced a strong anti-CarP response against both carbamylated foreign- and self-proteins. Similar to murine serum anti-CarP antibodies, murine monoclonal anti-CarP antibodies were highly specific and cross-reactive to multiple carbamylated (auto)antigens. Although citrulline greatly resembles homocitrulline residues in structure, murine anti-CarP antibodies differ in antigen recognition profile from ACPA as they are able to discriminate between citrullinated and homocitrullinated forms of the same protein. Interestingly, we were able to identify carbamylated-albumin, in RA synovial tissue, indicating that albumin is present in carbamylated form locally in the inflamed joint.
Conclusions: Self-reactive AMPA-responses can be induced by exposure to foreign proteins containing PTM. Our findings show that autoreactive B-cell responses against PTM self proteins can be induced by exposure to PTM foreign proteins and provide new insights on the breach of autoreactive B-cell tolerance by foreign proteins.

SAT0031 DETECTION AND ISOLATION OF ANTIGEN SPECIFIC B CELLS IN PATIENTS WITH RHEUMATOID ARTHRITIS

J. Nilsson[1], M. Bergquist[1], K. Önnheim[1], I.-L. Mårtensson[1], J. Viljanen[2], E. Lönnblom[3], B. Xu[3], O. Sareila[3], J. Kihlberg[2], R. Holmdahl[3], I. Gjertsson[1]. *[1]Rheumatology and Inflammation Research, Gothenburg University, Göteborg; [2]Department of Chemistry, BMC, Uppsala University, Uppsala; [3]Medical Inflammation Research, Dept of medical Biochemistry and biophysics, Karolinska Institute, Stockholm, Sweden*

Background: The majority of autoimmune diseases, e.g. rheumatoid arthritis (RA), are characterized by autoantibodies that are produced by B cells. We have identified several novel post-translationally modified epitopes in collagen type II (CII), a major cartilage constituent that are autoreactive. In mouse models, autoantibodies that bind to these epitopes can either induce or protect against inflammatory arthritis. However, very little is known about the frequencies or phenotype the B cells that produce these autoantibodies in humans.
Objectives: The aim of this project is to study the B cells that produce autoantibodies reactive to CII-epitopes in patients with RA.
Methods: Clinical data and peripheral blood were collected from patients with RA (n=100). Titres of CII-reactive serum-autoantibodies were determined by Luminex. The different subsets of B cells that expressed a CII-reactive B cell receptor (BCR) were analysed and isolated in patients with positive (n=10) or negative (n=5) titres for autoantibodies recognizing the CII-epitopes cyc48 (CII-F4-R-Cit) and cyc49 (CII-F4-Cit-R) as well as in healthy controls (n=3) using flow cytometry.
Results: In patients with detectable autoantibodies to cyc48 and cyc49, their titres were 13761±3815 and 5585±1992 (mean ± SEM), respectively. The corresponding titres in the patients negative for these autoantibodies were 122±55 and 234±75. In autoantibody-positive patients, the frequencies of cells expressing a BCR reactive for cyc48 and cyc49 in different subsets were: transitional cells 0.88±0.18% and 1.33±0.33%; naïve cells 0.09±0.0008% and 0.13±0.06 and memory cells 0.31±0.25 and 0.30±0.12%. All frequencies were well above those detected in patients without cyc48/49 titres and in healthy controls. A higher proportion (p=0.03) of the cyc48/49 positive patients were treated with methotrexate compared to cyc48/49 negative patients, no other clinical differences were recorded. CII-reactive single B cells were isolated in order to clone the BCR
Conclusions: In patients with manifest RA there is a relatively high and detectable frequency of transitional B cells that express a joint-specific BCR, which suggests that the deletion of autoreactive B cells in the bone marrow in RA patients is defective. As there is a decrease in the proportion of naïve CII-specific B cells, a substantial amount of the autoreactive cells are deleted in the periphery. However, peripheral B-cell tolerance is incomplete, as CII-specific B cells are enriched in the pool of memory B cells.

SAT0032 EX VIVO ANALYSIS OF AUTOANTIGEN-SPECIFIC T CELL RESPONSES USING A MULTI HLA-CLASS II TETRAMER APPROACH

C. Gerstner[1], H. Uchtenhagen[1,2], A. Dubnovitsky[3,4], W. Kwok[2], E.A. James[5], V. Malmström[1]. *[1]Rheumatology Unit, Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden; [2]Translational Research program, BRI at Virginia Mason, Seattle, United States; [3]Department of Clinical Neurosciences; [4]Science for Life Laboratory, Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden; [5]Tetramer Core, BRI at Virginia Mason, Seattle, United States*

Background: HLA class II tetramers allow the direct *ex vivo* enumeration and phenotypic characterization of antigen-specific T cells and have proven a useful tool in different settings, e.g. allergy and vaccination.
In rheumatoid arthritis (RA), many candidate auto-antigens have been characterized and are believed to play a role in the disease.
Objectives: Based on flow cytometry we developed a multi HLA-class II tetramer approach that renders it possible to look at numerous specificities simultaneously and is sufficiently sensitive at the same time as auto-reactive T cells are likely to be rare. We focused on validated citrullinated T cell epitopes previously studied in RA, namely a-enolase, fibrinogen and CILP.
To test the robustness and sensitivity of our multi-tetramer assay, we performed repeated experiments on PBMCs of HLA-DRB1*04:01-positive healthy controls as well as HLA-DRB1*04:01-positive RA patients.
Results: First, we examined the sensitivity of the panel by assessing PBMC from healthy donors and we could detect low frequencies of auto-reactive T cells in these samples (1–10 per million CD4), mostly displaying a naïve phenotype, which was in sharp contrast to influenza-specific T cells in the same donors which were 10–20 fold higher in numbers and of memory phenotype. Next, we tested the robustness of the panel by running technical repeats of all healthy donor samples, which yielded similar frequencies. Thereafter, we focused on RA patient PBMC obtained from repeated blood draws (2–4 weeks apart). Also in these samples, frequencies ranged between 1–10 tetramer-positive cells per million CD4+ T cells, i.e. similar as in healthy controls. Moreover, not all T cell specificities were present in all patients. Still, we found the frequencies to be stable in the repeated blood draws in approximately half of the individuals, implicating that frequencies close to 1 cell per million CD4+ T cells is borderline of what we can stably detect. Importantly, the patient samples utilized were not taken from time points of active disease, where we hypothesize frequencies to be elevated. This may be the case also in synovial fluid and as a proof of principle, we assessed synovial fluid samples of HLA-DRB1*04:01+ RA patients and were able to detect auto-reactive T cells at frequencies comparable to the ones found in peripheral blood.
Conclusions: In conclusion, we developed a sensitive tetramer panel allowing the simultaneous enumeration and phenotypic characterization of antigen-specific T cells in *ex vivo* samples from RA patients that can be used for monitoring and in-depth studying of these cells during the course of disease and treatment in individual patients.

SAT0033 SMOKING CONTRIBUTES TO EXHAUSTED STATE OF CD4+ T CELLS IN RHEUMATOID ARTHRITIS

C. Wasén, M. Turkkila, M. Erlandsson, K.M. Andersson, M. Brisslert, S. Töyrä Silfverswärd, M.I. Bokarewa. *Department of Rheumatology and Inflammation Research, University of Gothenburg, Gothenburg, Sweden*

Background: Rheumatoid arthritis (RA) has recently been linked to an exhausted state of $CD4^+$ T cells in peripheral blood of patients [1]. Exhaustion of $CD4^+$ T cells limits their proliferation and increases cell death. In $CD8^+$ T cells smoking counteract exhaustion, which may lead to increased cytotoxic activity exemplified by targeting of cells with high expression of the anti-apoptotic protein survivin [2]. Exhaustion of $CD4^+$ T cells coincides with expression of interferon (IFN) response genes [3], referred to as the IFN signature. The development of the IFN signature has been suggested to predate RA [4].
Objectives: We investigated how smoking affect the $CD4^+$ T cell population in peripheral blood of RA patients with focus on the exhaustion marker programmed cell death-1 (PD-1).
Methods: Blood samples were collected from RA patients and healthy women with different smoking status and analysed for PD-1 and survivin expression using flow cytometry and qPCR. Sorted Th17 cells from peripheral blood were analysed for expression of 18 genes up regulated during exhaustion [3], herein referred to as the exhaustion set, and serum levels of survivin were assessed by ELISA. Peripheral blood CD4+ cells were analysed for their expression of seven IFN response genes [4]. The role of survivin in the formation of exhausted $CD4^+$ T cells was studied in collagen-induced arthritis (CIA), where mice were treated with nicotine or vaccinated with survivin peptides.
Results: High frequency of exhausted $PD\text{-}1^+CD4^+$ cells was found in smoking RA patients. The numbers of $PD1^+CD4^+$ cells correlated inversely with the PD-1 expression by cytotoxic $CD8^+CD107^+$ cells (r=-0.62, p=0.01). Additionally, the frequency of $PD\text{-}1^+CD4^+$ cells increased with reduction of the $CD4^+$ population (r=-0.71, p=0.002). The IFN signature was found exclusively among smoking RA patients. The patients with the IFN signature all had $CD4^+$ cells with low survivin

production. Th17 cells from RA patients with high serum survivin were enriched in genes of the exhaustion set. $CD4^+$ cells with high survivin expression were negative for PD-1, while PD-1^{hi} cells had low expression of survivin. In CIA mice the survivin^{hi}PD-1^- $CD4^+$ cells were reduced by nicotine treatment (p=0.03) or survivin vaccination (p=0.009).

Conclusions: Smoking associates with exhaustion of $CD4^+$ T cells in RA by increasing the frequency of PD-1^+CD4^+ cells and supporting the IFN signature. Balancing T cell exhaustion and preventing the IFN signature are potential future treatment strategies for RA.

SAT0034 ANALYSIS OF THE T-CELL SUBSET COMPOSITION IN ANKYLOSING SPONDYLITIS PATIENTS WITH LONG-STANDING ANTI-TNF THERAPY

S. Dulic[1], Z. Vásárhelyi[2], A. Bajnok[3], B. Szalay[4], G. Toldi[2], L. Kovács[1], A. Balog[1]. *[1]University of Szeged Departement of Rheumatology, Szeged; [2]First Department of Obstetrics and Gynecology; [3]First Department of Pediatrics; [4]Department of Laboratory Medicine, Semmelweis University, Budapest, Hungary*

Background: Ankylosing spondylitis (AS) is a chronic, progressive, immune-mediated inflammatory disease, driven primarily by Th1 and Th17 cells. Anti-TNF therapies are successfully used in AS to achieve and maintain remission. However, their influence on the composition of the T-cell repertoire is not clear, and, in particular, the few published studies involve mostly patients with anti-TNF treatment of short duration.

Objectives: We aimed to characterize the changes in several T cell subsets after long-term anti-TNF treatment in AS patients.

Methods: Twenty-two AS patients on long-term anti-TNF therapy were evaluated (15 anti-TNF-responders and 7 non-responders). A wide range of cell subtypes were analysed with flow cytometry and compared with therapy-naïve and short-term data.

Results: Key findings include decreased proportions of naive CD4 and CD8 cells, increased frequencies of Th1 and Th17 cells and higher Th1/Th2 and Th17/Treg ratios in the long-term anti-TNF-treated patients (responders, non-responders and total), which was found to be significant not only when compared with healthy controls, but also with therapy-naive and short-term anti-TNF-treated AS patients. We have found several alterations within the various activated T-cell subsets – increase in CD4HLADR cells in responders, in CD8HLADR cells in the whole AS group and in responders, and in CD4CD25 cells in responders, and decrease in CD4CD69 cell percentages in long-term treated patients – becoming evident only after long-term anti-TNF-therapy.

Conclusions: This study provides a comprehensive assessment of the impact of anti-TNF therapy on the T cell repertoire in AS, and indicate that these therapies induce profound changes within T-cells. Changes in T cell phenotype seem to develop progressively during therapy, even in inactive disease, and reflect an ongoing effector T-cell differentiation and activation, and a normalization of Treg development.

SAT0035 INHIBITION OF PROTEIN KINASE C THETA BY THE SELECTIVE INHIBITOR CC-90005 INDUCES T CELL ANERGY

E.M. Hur, L. Capone, J. Kosek, P.H. Schafer, G.E. Ringheim. *Translational Development, Celgene Corp., Summit, United States*

Background: Protein Kinase C theta (PKC-θ), a member of the PKC family of serine/threonine kinases, is essential in T cell receptor (TCR) signaling and T cell activation [1]. Inhibition of PKC-θ activity may provide new therapeutic options for autoimmune diseases with a T effector cell dependent pathology. CC-90005 is a highly selective small molecule inhibitor of PKC-θ.

Objectives: Evaluate the impact of specific PKC-θ inhibition on T-cell activation and anergy using the highly selective inhibitor CC-90005.

Methods: Human peripheral blood mononuclear cell (PBMC) or isolated T cell cultures were pre-treated with CC-90005 (0.1–10 μM) and stimulated for various times up to 24 h with anti-CD3 and anti-CD28 activation of the TCR, followed by a washout incubation period (1 h-24 h). Cells were then re-stimulated in the presence or absence of CC-90005 and cultured a further 24–96 h. T cell activation was assessed by CD25 and CD69 cell surface expression, thymidine incorporation, and cytokine production.

Results: Upon TCR stimulation, CC-90005 significantly inhibited CD25 and CD69 expression and T cell proliferation in PBMC and isolated T cells. Similarly, CC-90005 inhibited the production of Th1, Th2, Th17 and other pro-inflammatory cytokines. Furthermore, the inhibitory effects of CC-90005 on T cell activation persisted after washout in stimulated T cells, indicating an induction of an anergic cell state. CC-90005 anergy induction was shown to require only short initial exposures of as little as 2 h and to maintain anergy for as long as 48–96 h post CC-90005 washout. However, T cells pre-treated with the inhibitor in the absence of concomitant TCR stimulation were able to respond to stimulus after as little as 1 h washout, indicating a rapid recovery of PKC-θ activity and T-cell function. CC-90005 upregulated an anergy-related E3 ubiquitin ligase, Gene related to anergy in lymphocytes (GRAIL) in T cells. Elevated expression level of GRAIL was maintained in unresponsive T cells after washout, suggesting that GRAIL was a possible downstream mediator of CC-90005 effect on T cell anergy.

Conclusions: CC-90005, a specific inhibitor of PKC-θ, significantly inhibits TCR-mediated T cell activation, proliferation, and cytokine production. Moreover, inhibition of these T-cell functions persists after drug withdrawal and restimulus of T-cells, but only if the primary T cell activation event occurrs in the presence of CC-90005. Thus, CC-90005 induces a functional unresponsiveness anergic state in T cells if present during TCR activation, which may have long-term therapeutic benefit in the treatment of T-cell mediated autoimmune and allergic inflammatory conditions.

SAT0036 IL-17+CD8+ T CELLS ENRICHED IN THE SYNOVIAL FLUID OF PSA/SPA PATIENTS EXHIBIT A PRO-INFLAMMATORY CYTOKINE PHENOTYPE

K.J.A. Steel[1], E. Chan[2], B.W. Kirkham[2], L.S. Taams[1]. *[1]Centre for Inflammation Biology and Cancer Immunology (CIBCI), Division of Immunology, Infection & Inflammatory Disease (DIIID), King's College London; [2]Department of Rheumatology, Guy's & St Thomas' NHS Trust, London, United Kingdom*

Background: Seronegative spondylarthropathies (SpA) share common clinical and immunological characteristics, including a common association with MHC class I, suggesting a role for CD8+ T cells. In contrast, rheumatoid arthritis (RA) is associated with MHC class II. We previously showed that IL-17+CD8+ T cells are increased in the synovial fluid (SF) of patients with psoriatic arthritis (PsA) but not RA, compared to peripheral blood (PB). This study extends this analysis to other SpA types, and phenotypes the SF IL-17+CD8+ T cells to further elucidate their potential pathogenic role.

Methods: Paired PB and SF were collected from patients with RA, PsA and other SpA types (ankylosing spondylitis (AS), reactive arthritis (ReA), enteropathic arthritis (EA) and peripheral SpA (p-SpA)) from Guy's Hospital Rheumatology clinic with informed consent. PB from healthy controls (HC) was collected at King's College London. PBMC and SFMC were isolated and stimulated *ex vivo* with PMA/ionomycin in the presence of golgistop before analysis of surface marker and cytokine expression by flow cytometry.

Results: The percentage of IL-17A+CD8+ T (Tc17) cells was increased in the SF of PsA (median 0.9%, p=0.0012, n=13) as well as other SpA patients (0.34%, p=0.0009, n=14), but not RA patients (0.07%, p=0.3, n=7) compared to matched PB (median 0.10%, no significant differences between disease and control PB). The percentage of SF IL-17A+CD4+ T (Th17) cells was increased in patients with SpA (2.14%, p=0.004, n=14), RA (2.31%, p=0.016, n=7) and to a lesser extent PsA (0.97%, p=0.057, n=13), compared to PB (median 0.61%, no significant differences between disease and control PB).

Phenotypically, most SF IL-17A+CD8+ T cells expressed CCR6 (median 88%, n=7) and CD161 (75%, n=8), known markers of IL-17+CD4+ T cells. A high percentage also expressed CD103 (69%, n=9), which was not observed in the synovial IL-17A+CD4+ T cells (2%, n=10). A high frequency of IL-17A+CD8+ T cells co-expressed a range of pro-inflammatory cytokines including IFN-γ (72%, n=12), GM-CSF (58%, n=7), TNF-α (48%, n=12) and to a lesser extent IL-21 (20%, n=6) and IL-22 (5%, n=6). IL-10 was usually co-expressed at very low levels (1%, n=7), although 2 samples showed co-expression of IL-10 (33%, n=2). CCR6, CD161, GM-CSF and IL-21 were not significantly co-expressed by either IL-17A negative CD8+ or IFNg+CD8+ (Tc1) T cells from the SF, indicating this may be a co-expression profile specific to IL-17 expressing T cells.

Conclusions: These findings confirm the presence of an IL-17A+CD8+ T cell subset in the SF of PsA patients and extend this to other SpA types. The expression of the integrin CD103 by these cells indicates they may represent a tissue resident memory (Trm) population in the synovial joint. In addition to IL-17A, the co-expression of several pro-inflammatory cytokines combined with low expression of IL-10, suggests a pro-inflammatory role for these cells.

Rheumatoid arthritis - prognosis, predictors and outcome

SAT0037 THE EFFECTS OF B CELL DIRECTED THERAPY ON DISEASE RELEVANT BIOMARKERS IN SUBJECTS AT RISK OF RHEUMATOID ARTHRITIS

D. Gerlag[1], M. Safy[2], K. Maijer[2], T. Ramwadhdoebe[2], S. Tas[2], N. de Vries[2], M. Starmans-Kool[3], A. van Tubergen[4], M. Janssen[5], S. Eyre[6], L. Klareskog[7], K. Zwinderman[2], P.-P. Tak[2]. *[1]Amsterdam Rheumatology and Immunology Center; [2]Academic Medical Center, University of Amsterdam, Amsterdam, the Netherlands, Amsterdam; [3]Zuyderland Medical Center, Heerlen; [4]Maastricht Medical Center, Maastricht; [5]Rijnstate Hospital, Arnhem, Netherlands; [6]Arthritis Research UK Centre for Genetics and Genomics, Manchester, United Kingdom; [7]Karolinska Institute, Stockholm, Sweden*

Background: Exploration of the mechanism underlying the delay of development of clinical signs of seropositive rheumatoid arthritis (RA) observed after B cell directed therapy in individuals at risk of developing autoantibody positive RA may offer insights into the mechanism of disease and may assist the development of preventive strategies.
Objectives: To explore the effects of a single infusion of rituximab (anti-CD20 antibody) on the observed delay of the onset of clinically manifest arthritis in individuals at risk of developing autoantibody positive RA.
Methods: In a study of 81 subjects positive for both anti-citrullinated protein antibodies (ACPA) and rheumatoid factor (RF) with arthralgia who never had clinically manifest arthritis and never used disease-modifying antirheumatic drugs, a 55% reduction of the risk of developing arthritis was observed 12 months after receiving a single iv infusion of 1000 mg rituximab when compared to placebo. In this group there was a delay in the development of arthritis of 12.0 months (12 months placebo vs 24 rituximab group) at the 25% quartile (75% free of arthritis) of the cumulative arthritis-free survival. Explorative analysis of disease-related biomarkers was performed in subgroups to better understand the mechanisms of the observed delay of clinical disease onset.
Results: Baseline levels of ESR (mm/h; HR 1.03; p=0.016), the total number of B cells in peripheral blood (HR 1.48; p=0.047), the presence of anti-alpha-enolase 1 (anti-CEP1) antibodies (HR 3.71; p=0.004) and the percentage of regulatory B cells (HR 1.04; p=0.002) were related to arthritis development over time. Importantly, genetic analysis of 100 RA associated SNPs showed that the top SNP associated with arthritis development in the rituximab-treated group (OR=7, MAF in cases 60% compared to 17% in unaffected) was in the PLCL2 gene, described to play a role in B cell signaling[1]. In individuals treated with rituximab, B cell numbers and subtypes mainly of the memory and regulatory compartment as well as serum levels of IgM-RF ($p<0.0001$), IgA-RF (p=0.003), total IgM (p=0.001), and anti-CCP (p=0.035) showed statistically significant changes over time compared to individuals who received placebo. Exploratory analysis showed trends for multiple biomarkers in the B cell compartment that appeared predictive of the development of arthritis.
Conclusions: A single infusion of 1000 mg rituximab significantly affects B cell numbers and subsets of memory and regulatory B cells as well as a reduction of disease-related antibodies and immunoglobulin levels in individuals at risk of RA. The changes coincide with a decrease in risk and a delay in development of arthritis in this population. PLCL2 gene polymorphism was associated with arthritis development in rituximab-treated individuals.

SAT0038 SERUM B LYMPHOCYTE CHEMOATTRACTANT PROTEIN 13 (CXCL 13) AND MUSCULOSKELETAL ULTRASONOGRAPHIC FINDINGS IN EARLY RHEUMATOID ARTHRITIS

E. Baraka, S. Egila, G. Hamad, M. Khalil. *Rheumatology, Rehabilitation and Physical medicine, Benha Faculty of Medicine, Benha University., Cairo, Egypt*

Background: Patients in clinical remission may continue to have synovitis detected by the musculo skeletal ultrasonography (MSUS).Recently,B-lymphocyte chemoattractant chemokine (CXCL13) has reported to be upregulated and risen to be a possible new marker of disease inflammation in RA
Objectives: to detect early synovitis by grey scale and power Doppler MSUS, measure serum levels of CXCL13 and to correlate these levels with both clinical and ultrasonographic disease activity in early RA patients
Methods: RA was assessed by the modified disease activity score (DAS28).Hands and feet plain radiography were evaluated by Laresn score. A semi-quantitative score (0–3) was used to score synovial effusion (SE), synovial proliferation (SP) and power Doppler (PD) signals by MSUS in 6 synovial sites in 3 joints bilaterally: wrist (dorsal radiocarpal recess). 2nd MCPJ (dorsal and palmar side) and knee (suprapatellar recess) according to the European Leauge Against Rheumatism guidelines. A total MSUS score is the sum of scores for SE, SP and PD signals of the six joints in each patient (0–54).Quantitative detection of serum (CXCL13) levels of all subjects was done by ELISA.
Results: The mean serum CXCL13 values were highly significantly higher in fifty RA patients than in 30 age and sex matched control subjects with a mean of (388.86±283.63 pg/ml) and (62.96±32.5 pg/ml) respectively ($p<0.001$) and were significantly positively correlated with morning stiffness durations ($p<0.001$), Tender Joint Counts ($p<0.001$), Swollen Joint Counts ($p<0.001$), VASs ($p<0.001$), ESR 1st h values ($p<0.001$) and the platelets count ($p<0.05$), negatively correlated with disease durations ($p<0.05$) and HB concentrations ($p<0.05$) and showed no differences according to presence of extra-articular manifestations or CRP, RF or ACCP seropositivity.($p>0.05$). In our RA patients' group, MSUS detected either synovial effusion and /or synovial hypertrophy with or without PD signal in 132 (65%) joints out of 203 clinically silent joints and and detected erosions in 93/300 joints (31%) compared to 27/300 joints (9%) detected by x ray.the serum CXCL13 levels were highly significantly positively correlated with the total MSUS score for each patient ($p<0.001$),SP and SE gradings ($p<0.001$) and ($p<0.05$) and were significantly higher in RA patients with MSUS detected erosions but were not correlated with either PD gradings (p=0.11) or Larsen scores ($p>0.05$).
Conclusions: MSUS is more sensitive than clinical assessment and conventional radiology in detecting synovitis and erosions in RA. Serum CXCL13 levels correlated with MSUS and DAS 28 scores and can be used as a marker for activity and severity of RA.Screening early RA patients by MSUS for more precise evaluation of synovitis activity, severity and better management of the disease and follow up patients to detect if elevated CXCL13 affect RA disease progression or patient disability are recommended.

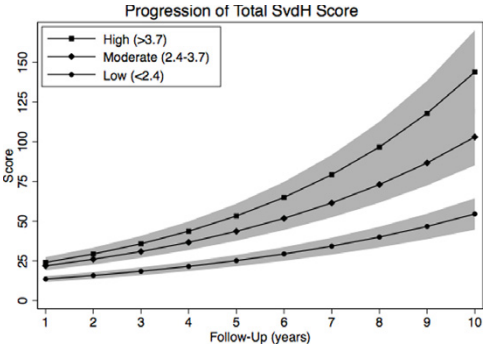
SAT0039 LARGE TENDER JOINTS HAVE THE GREATEST IMPACT ON LONGITUDINAL TRAJECTORIES OF FUNCTION IN EARLY RHEUMATOID ARTHRITIS

S.H.L. Lim[1], O. Schieir[2], S. Bartlett[3], G. Boire[4], B. Haraoui[5], E. Keystone[2], D. Tin[6], C. Thorne[6], J. Pope[7], V. Bykerk[8], C. Hitchon[1] on behalf of Canadian Early Arthritis Cohort Canada (CATCH) Investigators. *[1]University of Manitoba, Winnipeg; [2]University of Toronto, Toronto; [3]McGill University, Montreal; [4]Universite de Sherbrooke, Sherbrooke; [5]Institut de Rhumatologie de Montreal, Montreal; [6]Southlake Regional Health Center, Newmarket; [7]Western University, London, Canada; [8]Hospital for Special Surgery, New York, United States*



Background: Physical function remains suboptimal in patients with early rheumatoid arthritis (ERA) despite adequate disease control. Hence, factors impacting function need further evaluation. Large weight bearing joints are more likely to impact overall function than small non-weight bearing joints although the magnitude of impact may be task dependent. By weighting large joints more than small joints, the Lansbury Articular Index (LAI) may have stronger associations with function than standard joint counts that give equal weight to small and large joints.
Objectives: 1) To compare the correlations of weighted and non-weighted arthritis joint measures with physical function over time; and 2) to determine the impact of large compared to small joint involvement on the trajectory of HAQ in ERA.
Methods: ERA participants had <1 year symptom duration at enrolment in a multicentre Early Arthritis Cohort and were followed prospectively. Arthritis activity measures (DAS28, tender 28 joint count (TJC28), swollen 28 joint count (SJC28), function (Health Assessment Questionnaire; HAQ) were captured at each visit. The LAI weighted 28 joint count (LT28) and swollen joint count (LS28) were calculated based on the standard 28 joint sites. Correlations of trajectories were calculated using joint modeling for each of the following: DAS28, TJC28,SJC28,LS28 LT28 with the HAQ (2 trajectories/model). Unadjusted effects of large joints (shoulders, elbows, hips knees, ankles) and hand joints (time-varying) on the HAQ trajectory were estimated with a series of generalized estimating equations (GEE). GEE models were adjusted for baseline age, sex and education.
Results: ERA subjects (n=2125, 73% female; baseline mean (SD) age 53 (15) years, DAS28 5.1 (1.4)), were followed for median (IQR) 24 (10,48) months. At their last visit 44% were in remission ($DAS28<2.6$). HAQ over time was highly correlated with the following: DAS28 (r=0.83), LT28 (r=0.83), and TJC28 (r=0.85) and moderately with the LS28 (r=0.59) and SJC28 (r=0.61) trajectories. Each increase in joint involvement was associated with increase in HAQ: large tender joint (0.110 (95% CI 0.102–0.116)); large swollen joint (0.109 (0.099–0.120)); tender hand joint (0.036 (0.032–0.039)); swollen hand joint (0.035 (0.032–0.039)).

In multivariable modeling, after adjusting for age, sex, and education, large joints had greater effects (tender 0.074 (0.065–0.084), swollen 0.027 (0.014–0.04)) on HAQ than hand joints (tender 0.013 (0.009–0.017), swollen 0.008 (0.003–0.013)).
Conclusions: Both Lansbury and standard joint count trajectories correlate similarly with HAQ in ERA. The weighting of large joints in LAI was insufficient to reflect the full impact of large joint involvement in ERA probably because HAQ questions emphasize large joint activities. The effects of large joint swelling may be under recognized due to difficulty in measuring hip, shoulder or elbow swelling. Overall, tender joints had a greater impact on function than swollen joints and large tender joints had the most impact on function.

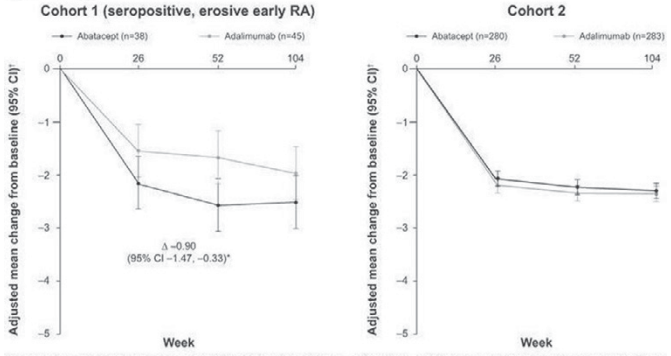
SAT0040 ASSESSING 5-YEAR RADIOGRAPHIC PROGRESSION IN RHEUMATOID ARTHRITIS PATIENTS WITH MODERATE DISEASE: FINDINGS FROM A UK MULTI-CENTRE PROSPECTIVE OBSERVATIONAL STUDY

L. Carpenter[1], S. Norton[2], E. Nikiphorou[3], K. Jayakumar[4], D.F. McWilliams[5], J. Dixey[6], P. Kiely[7], D.A. Walsh[5], A. Young[4] on behalf of ERAS and ERAN. *[1]Life and Medical Sciences, University of Hertfordshire; [2]Psychology Department, Institute of Psychiatry; [3]Department of Rheumatology, Whittington Hospital NHS Trust, London; [4]Department of Rheumatology, St Albans City Hospital, St Albans; [5]Arthritis UK Pain Centre, University of Nottingham, Nottingham; [6]Department of Rheumatology, New Cross Hospital, Wolverhampton; [7]Department of Rheumatology, St Georges University Hospitals NHS Foundation Trust, London, United Kingdom*

Background: Early, intensive treatment to achieve remission, or at least low disease target (Treat-to-Target, T2T), is advocated to prevent and/or reduce structural joint damage and disability in early Rheumatoid Arthritis (RA). A recent study shows how patients with moderate disease exhibit similar rates of functional disability and orthopaedic surgical interventions to those patients with high disease[1]. To our knowledge, no study has looked at longitudinal observational data to investigate the progression of structural joint damage in these patient sub-groups.
Objectives: To investigate the long-term progression of radiographic joint damage in patients with sustained moderate disease activity.
Methods: Demographic, clinical, laboratory and radiographic data from the Early Rheumatoid Arthritis Study (ERAS) was available for 1,465 patients. Radiographic damage was scored using the modified Sharp/van der Heijde (SvdH) method. The original three variable 44 joint count Disease Activity Score (DAS-44) was used. Mean DAS-44 over the first 5 years was estimated for patients with at least two DAS-44 scores. Patients were stratified based on EULARs thresholds of low ($<$2.4), moderate (2.4–3.7) and high ($>$3.7) disease. Mixed-effects negative binomial regression modelled patients' radiographic progression over 5 years, whilst controlling for key confounders, including age at onset, sex, rheumatoid factor status and baseline functional disability.
Results: A total of 1,110 patients with 3,751 observations over the 5 year period (mean =3.4 observations per patient) were analysed. 396 (36%), 363 (33%) and 351 (32%) patients were classified in the low, moderate and high DAS-44 groups respectively. The low group had lower SvdH scores at 1 year compared to the moderate group (12.9 vs. 19.2, $p<0.001$). Furthermore, the low group also experienced half the annual rate of change over the 5 years compared to the moderate group (3.6 vs. 7.4, p=0.002). In contrast, the high group had similar SvdH scores at year 1 compared the moderate group (20.4 vs. 19.2, p=0.884), but increased annual progression over the 5 years (10.0 vs. 7.4, p=0.010). Despite the increased annual progression rate, the difference in SvdH scores between the moderate and high groups remained non-significant at 5 years.
Conclusions: Sustained moderate disease over the first five years of RA indicates similar levels of radiographic progression compared to sustained high disease.



This study provides support on the importance of tight treatment control with early and aggressive therapy according to T2T principles. Preventing sustained moderate disease activity states can help reduce radiographic progression and consequently joint destruction, minimising the risk of disability in the long-term.

SAT0041 EFFICACY OF ABATACEPT VERSUS ADALIMUMAB IN PATIENTS WITH SEROPOSITIVE, EROSIVE EARLY RA: ANALYSIS OF A RANDOMIZED CONTROLLED CLINICAL TRIAL (AMPLE)

R. Fleischmann[1], M. Weinblatt[2], H. Ahmad[3], M. Maldonado[3], E. Alemao[3], J. Ye[3], M. Schiff[4]. *[1]University of Texas Southwestern Medical Center, Dallas; [2]Brigham and Women's Hospital, Boston; [3]Bristol-Myers Squibb, Princeton; [4]University of Colorado, Denver, United States*

Background: Patients (pts) who are anti-citrullinated protein antibody (ACPA) positive tend to develop more severe erosive disease than ACPA-negative pts.[1] The presence of seropositivity and erosions have been noted in EULAR treatment guidelines as poor prognostic factors to identify pts with RA who require early and aggressive clinical intervention.[2] Since the disease in pts with seropositive, erosive early RA is mostly driven by immunological features, response to RA therapy may vary based on therapeutic mechanism of action (MOA).
Objectives: To investigate the efficacy of abatacept (ABA) vs adalimumab (ADA) in pts with seropositive, erosive early RA.
Methods: AMPLE (NCT00929864)[3] was a 2-year, Phase IIIb study in which biologic-naïve pts with RA were randomized 1:1 to either SC ABA 125 mg weekly or SC ADA 40 mg biweekly, both with background MTX. This *post hoc* analysis of AMPLE compared clinical outcomes between treatment groups in a subpopulation of pts with specified baseline criteria: disease duration $\leq$6 months, RF or ACPA seropositivity and $>$1 radiographic erosion. Disease activity and patient-reported outcomes were evaluated at Weeks 26, 52 and 104. Endpoints were compared between ABA and ADA groups using chi-square test for categorical variables, analysis of covariance model (ANCOVA) controlling for baseline covariates and DAS28 (CRP) stratification for continuous variables.
Results: Of 318 and 328 pts in the ABA and ADA groups, respectively, 38 and 45 pts had all specified baseline characteristics (Cohort 1) and 280 and 283 pts had an absence of at least 1 of the specified characteristics (Cohort 2). Overall, the baseline characteristics, including anti-cyclic citrullinated peptide titres, were well balanced between the groups, with the exception of weight. For Cohort 1, adjusted mean change (95% CI) from baseline DAS28 (CRP) with ABA vs ADA was –2.18 (–2.61, –1.75) vs –1.56 (–2.01, –1.11) at Week 26, –2.58 (–2.99, –2.17) vs –1.68 (–2.10, –1.25) at Week 52 and –2.50 (–2.97, –2.03) vs –2.0 (–2.49, –1.50) at Week 104. Similar trends of increased efficacy with ABA vs ADA were observed for changes from baseline CDAI, SDAI, HAQ-DI, pain and fatigue; no differences in radiographic progression were observed. For Cohort 2, no differences in clinical outcomes between ABA and ADA groups were observed. Given the differences in baseline weight between ABA and ADA groups in Cohort 1, sensitivity analyses that excluded pts $>$100 kg and adjusted for baseline weight were performed and demonstrated minimal effect of weight on treatment efficacy.
Conclusions: This *post hoc* analysis seems to indicate a trend of increased efficacy for abatacept in pts with seropositive, erosive early RA compared with the TNF inhibitor adalimumab. Given the small sample size, additional pre-specified randomized studies are needed to compare the benefit of biologic DMARDs with different MOAs in pts with early, rapidly progressing RA.

SAT0042 SEVERITY OF RADIOGRAPHIC DESTRUCTION ON PERIPHERAL JOINTS IS A STRONG INDEPENDENT RISK FACTOR FOR CAROTID ATHEROSCLEROSIS

J.S. Eun, E.S. Lee, J.W. Kang, J.H. Kim, J.Y. Kang, G.B. Bae, N.R. Kim, S.J. Lee, E.J. Nam, Y.M. Kang. *Kyungpook National University School of Medicine, Daegu, Korea, Republic Of*

Background: In our previous study, we identified that cumulative inflammatory burdern contributes to the development of carotid atherosclerosis through a synergistic interaction with conventional cardiovascular (CV) risk factors in patients with rheumatoid arthritis (RA). However, it is controversial whether the presence of joint destruction which result from inflammatory burden may be a risk factor for carotid atherosclerosis.
Objectives: To investigate whether intima-media thickness (IMT) and plaques of carotid artery are influenced by radiographic joint destruction in patients with RA.
Methods: A total of 186 patients with RA were included in the present study. Plain X-ray of joints were used to assess the severity of joint destruction. We developed a new radiographic scoring system, named Rheumatoid Arthritis-Radiographic Severity Score (RA-RSS), which scores 21 joint groups with the modified Steinbrocker method. The following joint groups were included: 2 proximal interphalangeal (PIP) joint group, 2 metacarpophalangeal (MCP) joint group, 2 wrist joint group, 2 elbow joint group, 2 shoulder joint group, 1 atlantoaxial joint group, 2 hip joint group, 2 knee joint group, 2 ankle joint group, 2 tarsometatarsal (TMT) joint group, and 2 metatarsophalangeal (MTP) joint group. The grade was determined by the worst changes in each joint group of PIP, MCP, TMT, and MTP joints. RA-RSS grades are assigned as follows: 0 = No radiographic changes; 1 = mild destruction of bone and cartilage; 2 = moderate destruction of bone and cartilage or joint deformities; 3 = Severe destruction of bone and cartilage or bony ankylosis (Score ranges from 0–63). We performed carotid ultrasound to detect the presence of carotid atherosclerosis.
Results: Among 186 patients who were graded using RA-RSS, 110 patients had carotid plaques (59.1%). RA-RSS was significantly higher in patients with plaques compared to patients without plaques (11.2±8.79 vs. 7.6±7.72, p=0.004). Patients were divided into two groups by the cut-off value of plaque development as determined using receiver operating characteristic (ROC) curves: 115 (61.8%) patients with RA-RSS $<$10 and 71 (38.2%) with RA-RSS $\geq$10. There was a significant difference between the groups with respect to the presence of plaques (48.7% vs. 76.1%, $p<0.001$), while there was no difference in mean carotid IMT (0.87±0.19 vs. 0.88±0.14, p=0.684). The mean age, the presence of conventional CV risk factors, Korean version of the modified HAQ (mKHAQ), DAS28-ESR, and RA-RSS $\geq$10 were significantly associated with plaque development. Multivariate logistic regression analysis showed that RA-RSS $\geq$10 (OR 2.94 [95% CI 1.48–5.84]) and the presence of conventional CV risk factors (OR 2.30 [95% CI 1.21–4.35]) were independent risk factors for plaque development.
Conclusions: The present study shows that radiographic destruction over peripheral joints, which directly reflects cumulative inflammatory burden, is a strong independent risk factor for plaque development that is associated with CV events and mortality.

SAT0043 FACTORS AFFECTING THE NEED FOR ORTHOPAEDIC SURGERY IN PATIENTS WITH RHEUMATOID ARTHRITIS. RESULTS FROM 1010 PATIENTS DIAGNOSED WITH RA FROM 1972-2009

B.-T.S. Fevang[1,2], A.M. Fenstad[3], O.N. Furnes[3,4], T.W. Nystad[1,3]. *[1]Dept. of Rheumatology, Haukeland University Hospital; [2]Dept. of Clinical Sciences, University of Bergen; [3]The Norwegian Arthroplasty Register, Haukeland University Hospital; [4]Department of Surgical Sciences, University of Bergen, Bergen, Norway*

Background: Surgery still comprises a necessary part of treating RA patients, when medication fail to prevent joint destruction. Orthopaedic corrective procedures are considered a reliable and objective proxy for a destructed joint, and is an important outcome measure in RA.
Objectives: To investigate how patient characteristics, time of diagnosis and treatment affect the need for orthopaedic surgery in patients with rheumatoid arthritis (RA).
Methods: We reviewed the medical history of 1544 patients diagnosed with RA at Haukeland University Hospital in Bergen, Norway from 1972 to 2009, of which 1010 (mean age 57, 69% women) were included in the study. Relevant orthopaedic procedures were obtained from the Norwegian Arthroplasty Register and the hospital's administrative patient records. 693 procedures (joint synovectomies 22%, arthrodeses 21%, prostheses 41% and forefoot procedures 12%) were performed in 315 patients. Survival analyses were completed to evaluate the impact of age, sex, radiographic changes and year of diagnosis, on the risk of undergoing surgery.
Results: Patients diagnosed in 1972–1985 and 1986–1998 had a relative risk (RR) of 2.4 and 2.2 ($p<0.001$) respectively, of surgery compared to patients diagnosed in 1999–2009. Radiographic changes at diagnosis and female sex were also significant risk factors. Disease activity at baseline did not affect the outcome. Anti-rheumatic medication was significantly different in the three time periods.

Variable category	5 years[a]	10 years[a]	RR	95% CI	p-value
Gender, male	13	22	1		
female	19	30	1.35	1.02–1.77	0.035
Age (years)					
<69	15	27	1		
≥70	22	31	1.04	0.77–1.42	0.78
Radiolographic changes at diagnosis					
No arthritis	12	21	1		
Possible arthritis, or MR findings only	19	26	1.01	0.66–1.57	0.92
Arthritis	23	34	1.46	1.10–1.94	0.008
Osteoarthritis	35	55	2.81	1.94–4.05	<0.001
Time period					
1999–2009	12	18	1		
1986–1998	25	38	2.16	1.62–2.87	<0.001
1972–1985	15	37	2.38	1.71–3.31	<0.001

[a]5- and 10-year survival, in percent.

Conclusions: Patients with early years of diagnosis had greatly increased risk of having an RA related procedure performed. This is probably due to the year of diagnosis being a proxy for the type and intensity of medical treatment.

SAT0044 A 10-YEAR FOLLOW UP STUDY OF EARLY SERONEGATIVE ARTHRITIS DIAGNOSED AT AN ADULT AGE

K. Paalanen, J. Asikainen, T. Rannio, P. Hannonen, T. Sokka. *Rheumatology Department, KSSHP, JyväskylÄ, Finland*

Background: Up to 20–30% of patients enrolled into RA cohorts and clinical trials are seronegative. However, in studies examining predictors, prognosis, and response to treatment, seropositive and seronegative groups of patients seem to behave differently. Only a few studies have focused on the long term follow up of seronegative arthritis.
Objectives: To investigate long-term outcomes of patients with seronegative arthritis during a 10-year follow-up period including clinical outcomes and reclassification of diagnosis when applicable.
Methods: A total of 1046 patients were classified as early RA in 1997–2005 at single rheumatology center and scheduled for a ten year follow-up, including 434 seronegative patients who are subjects of the present analysis. Follow-up examinations were carried out for at least 2 years and then at 5 and 10 years by the treating specialist including complete clinical examination and patient reported outcomes. In addition, case –reviews were performed, with re-classification of the cases when applicable
Results: Among the 434 seronegative patients (69,4% women, mean age 58), 271 subjects were seen for the 10 year visit with the mean disease activity DAS28 of 2,3 (SD 1,02) and the mean HAQ of 0,71 (SD 0,72). Out of the remaining 146 patients, 88 had died and 53 did not attend the 10-year visit due to altered diagnosis, refusal or comorbidity. Five patients had dropped out and files of 17 patients were missing. During the follow-up of 10 years, 12/434 (2,7%) patients could be classified as seropositive or erosive RA: 4 turned seropositive (2 for ACPA and 2 for RF [>2x normal level]) and 8 developed erosions typical for RA. Reclassification revealed 70 (16,1%) cases of polymyalgia rheumatica, 47 (10,8%) cases of osteoarthrosis without evidence of inflammatory disease, 47 (10,8%) cases of psoriatic arthritis, 39 (9,0%) cases of spondylarthritis and 16 (3,7%) cases of plausible reactive arthritis. Few cases were reclassified as gout (11 cases (2,5%)) and pseudogout (3 cases (0,7%)). Also paraneoplastic arthritis (6 cases (1,4%)), juvenile arthritis (5 cases (1,2%)), hemochromatosis (2 cases (0,5%)), ankylosing spondylitis (2 cases (0,5%)) and temporal arteritis (2 cases (0,5%)) were revealed during follow up. One case of each reflex sympathetic dystrophy, trauma-induced arthritis, meniscal injury, optional Nasu Hakola disease, microscopic polyangiitis (MPA), granulomatous polyangiitis (GPA), antisynthetase syndrome and colitis ulcerosa were also found. The remaining 147 patient (33,8%) could not be reclassified in any clear cut diagnosis. A total of 44 of these undifferentiated cases had transient arthritis, 43 cases had features of seronegative spondylarthritis and 57 cases remained totally unspecified, while three patients had features of inflammatory connective tissue disease (SLE and Sjögren's syndrome), but they did not meet available classification criteria. In addition, files of 17 (3,9%) patients were missing from the analyses.
Conclusions: Over a 10-year period, 97% of seronegative patients remained seronegative and did not develop RA-like erosions. Reclassification revealed significant heterogeneity in the diagnosis of seronegative RA. Therefore, seronegative arthritis should not be studied as a homogenous disease entity.

SAT0045 11 YEARS' FOLLOW-UP OF A DANISH 2-YEAR TREAT-TO-TARGET RANDOMIZED CONTROLLED TRIAL IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS: BASELINE PREDICTORS OF FUNCTIONAL AND RADIOGRAPHIC OUTCOMES

M.L. Hetland[1,2], K. Stengaard-Petersen[3], P. Junker[4], H. Lindegaard[4], T. Ellingsen[4], J. Pødenphant[5], H. Skjødt[6], A. Vestergaard[7], B. Ejbjerg[8], S. Jacobsen[9], N.S. Krogh[10], M. Østergaard[2], K. Hørslev-Petersen[11]. *[1]DANBIO; [2]COPECARE, Rigshospitalet, Glostrup; [3]Department of Rheumatology, University Hospital, Aarhus; [4]Department of Rheumatology, University Hospital, Odense; [5]Department of Rheumatology, Gentofte Hospital, Gentofte; [6]Department of Rheumatology, Rigshospitalet, Glostrup; [7]Department of Radiology, Hvidovre Hospital, Hvidovre; [8]Department of Rheumatology, Slagelse Hospital, Slagelse; [9]Department of Rheumatology, Rigshospitalet; [10]ZiteLab, Copenhagen; [11]Kong Christian X's Gigthospital, Gråsten, Denmark*

Background: Few RCTs have investigated long-term (>10 years (yrs)) outcomes of goal-directed synovitis suppression in early rheumatoid arthritis (RA). The CIMESTRA trial was a 2-year double-blinded Danish multicenter study on aggressive treatment with csDMARDS (methotrexate (MTX) versus MTX and cyclosporine) in combination with intra-articular glucocorticoids (1+2). Disease control after 2 yrs was excellent with ≈50% in remission and halted radiographic progression in both groups. We present 11 yr follow-up data.

Baseline predictors of:			
-Functional status (HAQ_{10}-)*	**Coefficient**	**95% CI**	**p-value**
DAS28 (per unit increase)	0.10	0.02-0.18	0.02
Anti CCP (positive)	0.24	0.02-0.46	0.03
-Radiographic progression (ΔTSS_{0-10}-)*	**Coefficient**	**95% CI**	**p-value**
Anti CCP (positive)	7.69	0.91; 14.47	0.03
MRI bone marrow edema (per unit increase)	0.87	0.19; 1.55	0.01

: Initial baseline variables in the HAQ_{10}- (§) and ΔTSS_{0-10}-(#) multivariable linear models before backward selection were: Total Sharp-van der Heijde-Score (TSS)[§#]; Health Assessment Questionnaire score[§]; Disease Activity Score (28-joint count, 4 variables)[§]; age[§]*; anti CCP[§]*; gender[§]*; MRI erosion score[§]*; MRI synovitis score[§]*; MRI bone marrow edema[§]*. CI, confidence interval; CCP, cyclic citrullinated peptide (dichotomized value); MRI, magnetic resonance imaging.

Objectives: The aims were to 1) investigate the clinical and radiographic status and 2) identify baseline predictors of functional status and erosive progression.
Methods: Of 160 patients (pts) included, 130 pts also had MRI of the wrist performed at baseline. 17 pts had died since baseline. All living pts were contacted and 120 signed informed consent to participate in a 11 yrs' follow-up visit assessing e.g. treatment, disease activity (DAS28, CRP, 4 variables), physical function (HAQ), X-ray of hands and feet. Baseline MRI was scored by OMERACT rheumatoid arthritis MRI scoring (RAMRIS) system, X-rays by Sharp-van der Heijde total Sharp Score (TSS). Multivariable linear regression analyses of a panel of baseline variables (see foot note in table) with backward selection were performed with HAQ at 11 yrs (HAQ_{11}) and radiographic progression since baseline (ΔTSS_{0-11}) as dependent variables.
Results: 120 of 160 pts (75%) completed the 11 yrs visit. 96 pts with available baseline MRI and X-rays of both time points were included in the prediction models. Withdrawal analysis comparing the 160 pts with the 40 and 64 pts who were not included showed similar baseline characteristics except for higher DAS28 and HAQ score for withdrawers. Follow-up was after 11.6 yrs (10.7–12.2) (median (IQR)). Pts were 63 yrs (55–72) and 70% females. 20% received biologics (+/- csDMARD), 53% csDMARD alone, 27% were in drug free remission. DAS28 was 2.0 (1.5–2.6); pain score: 1 cm (0.3–3); pt. global: 1.1 cm (0.2–2.9); swollen joint count (28SJC): 0 (0–0); tender joint count (28TJC): 0 (0–1). 76% of pts were in DAS28 remission; HAQ-score was 0.25 (0–0.75); ΔTSS_{0-11}(median (IQR)):4 (0–13); ΔTSS_{0-11}(mean±SD): 10.9±16.9). The annual progression rate since baseline was median (IQR):0.4 (0–1.1); mean±SD:0.96±1.52. Multivariable linear regression analyses are shown in Table.
Conclusions: 11 years after diagnosis 75% were in DAS28 remission. HAQ-score was low, and mean radiographic progression was <1 TSS unit/year. High DAS28 and positive anti-CCP at baseline were independent predictors of poorer functional status. Baseline MRI bone marrow edema and anti-CCP positivity were independent predictors of radiographic progression.

SAT0046 TNF ANTAGONIST DRUG SAFETY ASSESSMENT BY PHARMACOVIGILANCE SIGNALING AND POST-MARKETING ADVERSE EVENT REPORTS

M. Cavaco[1], F. Araujo[2,3], J. Eurico Fonseca[4,5], J. Goncalves[1]. *[1]iMed – Research Institute of Medicines, Faculdade de Farmacia Universidade de Lisboa, Lisboa; [2]Rheumatology Unit, Hospital de Sant'Ana, Cascais; [3]Institute of Microbiology; [4]Instituto de Medicina Molecular, Faculdade de Medicina da Universidade de Lisboa, Lisbon; [5]Rheumatology Department, Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria, Lisbon Academic Medical Centre, Lisboa, Portugal*

Background: TNF antagonists have been equally effective in the treatment of immunoinflammatory diseases. However, differences in their characteristics and the introduction of biosimilars may be associated with different safety profiles.
Objectives: The main goal of this study is to compare the safety of infliximab (IFX), etanercept (ETN), and adalimumab (ADA), as well as of IFX-biosimilar.
Methods: We assessed the adverse events reported in the EudraVigilance database between 2004 and 2016. The MEdDRA® system was used to classify the adverse events according to the primary system organ class. For a direct

comparison of the data obtained, the adverse events reported for each drug were normalized using the number of treatments for the same period. The reporting odds ratio (ROR) and its 95% confidence intervals (CI) were calculated regarding the different categories of adverse events. The incidence of serious adverse events, serious infections, withdrawals due to adverse events and deaths were also calculated.

Results: The EudraVigilance database contains 851 882 adverse events reported for IFX, ETN, and ADA. During this period, the different TNF antagonists have shown almost the same safety profile. The reported adverse events were classified by systems organ class (SOC) and the most frequent were administration site conditions (28.8%) and infections and infestations (11.2%), Safety was not statistically different. The comparison between IFX originator and its biosimilar did not show statistically significant differences in safety (ROR 1.08 [0.80, 1.46]) during the initial 3-years after launch for both drugs. However, a small non-significant increase in immune reactions during administration was reported for IFX-biosimilar, which might reflect increasing attention for this class of drugs.

Conclusions: The comparison of reference IFX and IFX-biosimilar did not demonstrate statistically significant differences in safety. This pharmacovigilance study provides the first analysis of TNF antagonists from the EudraVigilance database and offers a framework for safety comparison between originators and biosimilar TNF antagonists.

SAT0047 PREDICTING MAINTENANCE OF RESPONSE BASED ON DISEASE CHARACTERISTICS AND EARLY CLINICAL RESPONSE IN RHEUMATOID ARTHRITIS PATIENTS UPON WITHDRAWAL OF ADALIMUMAB

J.S. Smolen[1], P. Emery[2], H. Zhang[3], X. Wang[3], J. Suboticki[3], I. Sainsbury[3], A. Kavanaugh[4]. *[1]Medical Univ of Vienna, Vienna, Austria; [2]Leeds Inst of Rheumatic & Musculoskeletal Medicine, Leeds, United Kingdom; [3]AbbVie, N Chicago, IL; [4]Univ of California, San Diego, CA, United States*

Background: Some patients (pts) with rheumatoid arthritis (RA) achieve low disease activity (LDA) after treatment with adalimumab (ADA) plus methotrexate (MTX) and can maintain LDA after ADA withdrawal[1]. However, others experience a flare in disease activity. The factors associated with loss or maintenance of response are not understood.

Objectives: To identify pt disease characteristics and early clinical responses, which predict maintenance of LDA upon ADA withdrawal in individual RA pts.

Methods: Data from the OPTIMA trial were used in this *post hoc* analysis. In period 1 (P1), pts were treated for 26 weeks (wks) with ADA+MTX or placebo (PBO) +MTX. Pts on ADA+MTX who achieved DAS28-CRP <3.2 at wks 22 and 26 (responders) were randomized to ADA withdrawal, or ADA+MTX continuation up to Wk 78. Responders to PBO+MTX in P1 continued on PBO+MTX up to Wk 78 (PBO continuation). Data from the ADA withdrawal arm were used to predict LDA at Wk 78 by DAS28-CRP (≤3.2) or SDAI (≤11). Potential factors including baseline (BL) disease characteristics and Wk 26 responses, including DAS28-CRP, SDAI, ACR score components, modified total sharp score (mTSS) and joint space narrowing score (JSN), were screened by the LASSO method[2], which performs variable selection by penalizing unduly complicated models, with/without incorporating the speed of DAS28-CRP or SDAI response as an individual predictor. Logistic regression on the LASSO-selected factors yielded coefficients used to derive individual scoring equations and prediction scores for Wk 78 outcomes (fig footnote). Prediction score cutoffs were established by the regression tree method[3]. The results were validated in data from the PBO continuation arm.

Results: For the prediction of DAS28-CRP LDA at Wk 78, BL physician global assessment (PhGA) and health-assessment questionnaire-disability index (HAQ-DI), and Wk 26 DAS28-CRP, HAQ-DI, JSN and CRP were selected by LASSO, and used to calculate the prediction score. Including speed of response did not affect the predictors chosen. Out of 9 pts predicted not to have DAS28-CRP LDA at Wk 78, 0 had LDA (NPV=100%) (fig 1). Out of 66 pts predicted to have DAS28-CRP LDA at Wk 78, 63 predictions were correct (PPV=96.5%). Results were comparable for most cutoff categories in the validation arm (PPV=82%); however, no pts were predicted to have a non-response at Wk 78. For the prediction of SDAI LDA at Wk 78, the NPV was 86% (1/7 predictions incorrect); PPV was 95% (39/41 predictions correct); in the validation arm, the PPV was 82%.

Conclusions: DAS28-CRP LDA at 78 wks could be individually predicted for up to 63% pts in OPTIMA who withdrew ADA/continued PBO+MTX with 96.5% accuracy, based on demographics and clinical outcomes at 6 months. This instrument could help identify pts who may be able to maintain LDA upon ADA withdrawal.

SAT0048 THE PATTERN OF ACPA REACTIVITIES IN ANTI-CCP POSITIVE INDIVIDUALS WITH NON-SPECIFIC MUSCULOSKELETAL SYMPTOMS AT RISK OF DEVELOPING RA

A. Hensvold[1], Y. Kisten[1,1], V. Joshua[1], M. Hansson[1], L. Mathsson-Alm[2], A. Karlsson[1], H. Rezaei[1], E. af Klint[1], G. Fei[1], A. Catrina[1]. *[1]Karolinska University Hospital and Karolinska Institutet, Stockholm; [2]ThermoFisher Scientific, Uppsala, Sweden*

Background: There is today a paucity of prospective studies to describe the natural longitudinal history of anti-ccp positive individuals developing RA or not developing RA. Further no study to investigate the detailed ACPA reactivities in such a setting is currently available.

Methods: Individuals at risk of developing RA were included in a cohort at Karolinska University Hospital, Stockholm. Examinations of peripheral joints was repeated at one year follow-up visit or at any time the patients experienced worsening of their symptoms. Peripheral blood samples were available at inclusion (n=70). Serum was run on a microarray based on the ImmuoCAP ISAC system testing for ACPA reactivities toward 13 different citrullinated peptides (fillagrin, fibrinogen, alpha-enolase, vimentin, histone) (1).

Results: Individuals referred from primary care with musculoskeletal complaints and positive anti-ccp test were systematically investigated as part of routine care at our rheumatology clinic. Individuals lacking self-reported history of suspect arthritis, clinical arthritis according to rheumatologist and signs of synovitis on ultrasound examination were included in a clinical Risk-RA program with life-style coaching and personalized information on the risk of developing RA. Seventy individuals, with a mean age of 48 years (SD 15) and 86% females, were included in the program. Twenty (29%) individuals developed arthritis during a medium follow up time of 7 months (range 1–25 months).

Number of ACPA reactivities at baseline was significant higher among those developing (in mean 6 reactivities) as compared to those not developing arthritis (in mean 4 reactivities). A increased proportion of individuals were showing reactivity towards citrullinated (cit) vimentin (vim) 60–75, fibrinogen (fib) 573 and enolase (eno) (CEP-1) among those developing arthritis (80% for anti-cit-vim 45% for anti-cit-fib and 60% for anti-cit eno) as compared to those not developing arthritis (41% for anti-cit-vim, 30% for anti-cit-fib and 52% for anti-cit-eno). Increased level of anti-cit-vim and anti-cit-eno antibodies was also observed at inclusion for those individuals developing arthritis as compared to those not developing arthritis.

Conclusions: We describe here the pattern of ACPA reactivities in anti-CCP positive individuals with non-specific musculoskeletal symptoms at risk of developing RA and without clinical and ultrasonograph signs of synovitis and report that 30% of these patients will develop arthritis during a short follow-up. Number, frequency and titers of specific ACPA reactivities appear to be enriched already at inclusion among those patients that developed arthritis during follow-up.

SAT0049 21ST CENTURY STATE OF RHEUMATOID ARTHRITIS MANAGEMENT IN THE UK

A.L. Tan[1], M. Buch[1], D. O'Reilly[2], T. Sheeran[3], A. Bishop-Bailey[4], G. Nock[4], S. Chitale[5], P. Emery[1]. *[1]NIHR Leeds Musculoskeletal Biomedical Research Unit, Chapel Allerton Hospital, Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds; [2]West Suffolk NHS Foundation Trust, West Suffolk Hospital, Bury Saint Edmunds; [3]Rheumatology, Cannock Chase Hospital, Royal Wolverhampton Trust, Cannock; [4]pH Associates, pH Associates, Marlow; [5]Rheumatology, Peter Maddison Rheumatology Centre, North Wales, Llandudno, United Kingdom*

Background: The rheumatoid arthritis (RA) Treat to Target (T2T) recommendations[1] defined in 2010 aimed to support clinicians to achieve optimal therapeutic outcomes for their patients.
Objectives: 38 hospitals prospectively audited management of newly diagnosed RA patients to determine compliance with the T2T recommendations and therapeutic outcomes achieved.
Methods: From April 2012 to September 2016 and upon diagnosis of RA, data on disease history, management and clinical outcomes were collected prospectively in a web based tool. Follow up to date provides data for up to 24 months from diagnosis (baseline).
Results: 1571 patients were recruited in 38 centres, with 12 months' follow up for 713 patients and of these 269 also had 24 months' follow up. 1021 (65%) patients were female and 1360 (87%) had a treatment target documented at baseline (1235 [79%] disease activity score 28 (DAS28) remission and 125 [8%] low disease activity state (LDAS)). DAS28 remission is defined as DAS28 <2.6, LDAS is defined as DAS28 ≥2.6<3.2. Median baseline DAS28 scores were 4.9 and 5.3 for patients having a DAS28 remission and LDAS target, respectively. The table shows DAS28 scores at baseline, 12 and 24 months, and disease management received for the subset of patients with available DAS28 scores at the relevant time points, stratified by those who did/did not achieve their remission target and those with/without sustained remission at 24 months. Of the 108 patients eligible to receive biologic therapy, according to NICE guidance, 39 (36%) received a biologic within their first 24 months of treatment.

	Patients with 12 months follow up (n=713)		Patients with 24 months follow up (n=269)	
	In remission at 12 months [n=276]	Not in remission at 12 months [n=239]	Sustained remission at 24 months [n=32]	Remission not sustained at 24 months [n=96]
% patients compliant with TTT standards				
N (%) with baseline target set (remission or LDAS)	244 (88%)	183 (77%)	29 (91%)	76 (79%)
N (%) with >4 visits in the first year of management	207 (75%)	175 (73%)	31 (97%)	81 (84%)
N (%) with >4 DAS scores in the first year of management	180 (65%)	155 (65%)	24 (75%)	48 (50%)
N (%) with dual therapy within 6 months of diagnosis	148 (54%)	154 (64%)	17 (53%)	53 (55%)
Disease scores				
median baseline DAS28 (n with available score)	4.6 [n=226]	5.1 [n=193]	4.5 [n=26]	5.3 [n=67]
median 12 month DAS28 (n with available score)	1.9 [n=276]	3.9 [n=239]	1.9 [n=23]	2.9 [n=63]
median 24 month DAS28 (n with available score)	2.1 [n=43]	3.4 [n=43]	1.6 [n=32]	3.0 [n=96]

Conclusions: The results suggest that more patients with a target set at baseline are in remission at 12 months and at 24 months than those without a target set. Number of visits, number of DAS28 scores and starting dual therapy within 6 months do not appear to affect the proportion of patients in remission at 12 months, but active management in the first 12 months (>4 visits, >4 DAS28 scores) does appear to be associated with more patients in remission at 24 months. Thus we conclude that treating RA early and aggressively, in line with the T2T guidelines, leads to sustained clinical improvement.

SAT0050 EARLY RESPONSE TO CERTOLIZUMAB PEGOL IN RHEUMATOID ARTHRITIS PREDICTS OUTCOME: DATA FROM A PROSPECTIVE OBSERVATIONAL STUDY

A. Saraux[1], R.M. Flipo[2], F. Fagnani[3], J. Massol[4], B. Combe[5], P. Huot-Marchand[6], J.M. Joubert[7], J. Dunkel[8], G. Cukierman[7]. *[1]C.H.U. la Cavale Blanche, Brest; [2]C.H.U. Hôpital Roger Salengro, Lille; [3]Cemka Eval, Bourg-la-Reine; [4]Phisquare, Besançon; [5]C.H.U. Lapeyronie, Montpellier; [6]MAPI, Lyon; [7]UCB Pharma, Colombes, France; [8]UCB Pharma, Monheim, Germany*

Background: Treat-to-target strategies for rheumatoid arthritis (RA) require reliable clinical markers of treatment response in order to adapt therapy. Markers of early treatment failure can be used to ensure that patients (pts) are not unnecessarily exposed to ineffective therapy. Data from interventional clinical trials suggest that early clinical measures of disease activity (such as CDAI, DAS28 or HAQ-DI) after 12 weeks (wks) of treatment can reliably predict treatment failure at 1 year (yr).[1–3] However, it is unknown how such indicators perform in real-world settings.
Objectives: To evaluate the performance of clinical markers of early treatment failure (Wk12) as predictors of treatment failure at 1yr in everyday clinical practice.
Methods: Data from a 1yr interim analysis of the ECLAIR study were used: a longitudinal, prospective, observational, multicentre study of pts with RA starting treatment with certolizumab pegol (CZP) in France. Pts were evaluated at study entry and thereafter at 3-monthly routine consultations. Disease activity was assessed at each visit using CDAI, DAS28 and HAQ-DI. At Wk12, pts with missing data or no longer taking CZP were excluded from the analyses. Linear interpolation, LOCF or NRI were used to impute missing data at 1yr, including data from pts who left the study early. Different definitions for treatment non-response were applied based on CDAI or ΔDAS28 and ΔHAQ-DI relative to pre-treatment values. Non-response at Wk12 was defined as CDAI>10, ΔDAS28<1.2 or ΔHAQ-DI<0.22. Then, failure at 1yr was defined as CDAI>22, DAS28>3.2 and HAQ-DI>0.5. Positive predictive values (PPV; proportion of treatment failures at 1yr in Wk12 non-responders) were used to evaluate the predictive performance of each tool.
Results: Overall, 792 pts were enrolled and data from 730 pts analysed. Performance of CDAI at predicting treatment failure at 1yr was assessed in 532 pts (198 data values missing at Wk12). Response and failure rates at Wk12 and 1yr are presented (see Table). The PPV for CDAI was 88.8%, indicating that almost 9/10 pts identified as non-responders at Wk12 fail to respond at 1yr. Specificity was also high (96.0%), indicating that <5% of pts who achieved CDAI response at 1yr were non-responders at Wk12. Similar analyses performed for DAS28 and HAQ-DI produced PPVs of 69.0% and 75.4%, respectively.

Table: Response and failure rates of CZP-treated patients at Week 12 and 1 year

	CDAI at 1 year		
CDAI at Week 12	**>22 (Failure)**	**≤22 (Response)**	**Total**
>10 (Non-response)	79	10	89
≤10 (Response)	205	238	443
Total	284	248	532
	Sensitivity=27.8%, Specificity=96.0%, PPV=88.8%, NPV=53.7%		
	DAS28 at 1 year		
ΔDAS28 at Week 12	**>3.2 (Failure)**	**≤3.2 (Response)**	**Total**
<1.2 (Non-response)	136	61	197
≥1.2 (Response)	102	135	237
Total	238	196	434
	Sensitivity=57.1%, Specificity=68.9%, PPV=69.0%, NPV=57.0%		
	HAQ-DI at 1 year		
ΔHAQ-DI at Week 12	**>0.5 (Failure)**	**≤0.5 (Response)**	**Total**
<0.22 (Non-response)	175	57	232
≥0.22 (Response)	154	110	264
Total	329	167	496
	Sensitivity=53.2%, Specificity=65.9%, PPV=75.4%, NPV=41.7%		

CDAI: Clinical Disease Activity Index; DAS28: Disease Activity Score; HAQ-DI: Health Assessment Questionnaire-Disability Index; NPV: Negative predictive value; PPV: Positive predictive value.

Conclusions: The PPV describing the performance of early CDAI measure as a

predictor of treatment failure at 1yr among CZP-treated RA pts was high; 88.8% of pts identified as non-responders at Wk12 will represent a treatment failure at 1yr. Simple tools such as CDAI, assessed during routine consultations, may be reliable markers to predict treatment failure without need for complementary biological tests.

SAT0051 CITRULLINATION OF ADENOSINE DEAMINASE ISOFORMS IN RHEUMATOID ARTHRITIS

S. Sharoyan[1], L. Karapetyan[1], R. Harutyunyan[2], S. Mardanyan[1], A. Antonyan[1]. [1]*H.Ch. Buniatian Institute of Biochemistry of Armenian NAS;* [2]*"Yerevan" Medical Center, Yerevan, Armenia*

Background: One of the most important discoveries in rheumatology is the characterization of citrulline containing auto-antigens [1]. The identification of citrullinated proteins as auto-antigens and the development of new assay based on the detection of anti-citrullinated protein antibodies (ACPAs) become a breakthrough in the diagnosis and treatment of rheumatoid arthritis (RA). Mitsui and coauthors *in vitro* identified adenosine deaminase (ADA) as an ACPA antigen [2]. Earlier we have reported the enhance of ADA activity in synovial fluids (SFs) of RA patients [3].This increasing was in correlation with the ratio of small isoenzyme (SADA) to the large (LADA) [4].The comparison of citrullination states of SADA and LADA can be a clue for understanding the mechanism of SADA/LADA increase in RA, which is important both in diagnosis and treatment of the disease.

Objectives: The objectives of this study were a) to separate SADA and LADA isoforms from SFs of RA patients and b) to compare their citrullination degree.

Methods: The SADA and LADA isoforms from SFs of RA patients were separated and purified using gel-filtration and ion-exchange chromatography [4]. The citrullination degree of the isoforms was measured in the colorimetric assay with diacetylmonoxime (DAMO) [6] using the absorbance at 530 nm and free L-citrulline as a standard.

Results: The SF samples of 20 RA patients with initial ADA activity in the range 35–190 IU/L were used. Earlier we demonstrated a negligible level of SADA at initial ADA lower of this interval. In the samples with medium initial activity (35–55 IU/L), SADA/LADA ratio was $\approx$ 1/2. In those with high ADA activity (100–190 IU/L) this ratio was $\approx$ 4. The separation and purification of LADA from 10 SFs revealed that it is not citrullinated in any case. In SADA from SFs with medium ADA activity, we failed to register the citrullination. In SADA from SFs with the initial ADA activity $\geq$100 IU/L, the significant citrullination ($\approx$ 0.6 μmol/mg of protein) was registered.

Conclusions: The obtained results evidence that SADA from SFs with high ADA activity can serve as new citrulline containing ACPA antigen. This finding can be a base of developing new strategy (e.g. seeking specific inhibitors) for treatment of RA patients because citrullination enhances the ADA activity [2], hampering the increase of adenosine by methotrexate.

SAT0052 HIGH CHANCE OF COMPREHENSIVE DISEASE CONTROL (CDC) IN VERY EARLY AND NORMAL WEIGHT RHEUMATOID ARTHRITIS PATIENTS TREATED ACCORDING TO THE TREAT TO TARGET STRATEGY

A.L. Fedele, L. Petricca, B. Tolusso, S. Alivernini, C. Di Mario, G. Di Sante, G. Ferraccioli, E. Gremese. *Institute of Rheumatology, Fondazione Policlinico Universitario A. Gemelli, Rome, Italy*

Background: The ultimate goal for Rheumatoid Arthritis (RA) management is the simultaneous achievement of all clinical, functional and structural efficacy, i.e. comprehensive disease control (CDC) [1].

Objectives: To evaluate the effective chance and the consequences of CDC achievement in real world practice of Early Arthritis Clinic (EAC).

Methods: A total of 349 early rheumatoid arthritis (ERA) patients with a disease duration of less than 12 months were enrolled in the study. ERA patients fulfilled the 2010 ACR criteria for RA and were followed according to the treat-to-target strategy. Subjects with symptom duration less than 3 months were defined as having "very early RA" (VERA). The mean follow-up (FU) was 38.2±32.8 months. At baseline, and every three months, the ACR/EULAR core data set variables were recorded. At baseline and every year hand and foot radiographs were examined according to modified Total Sharp score (mTSS). At each visit, clinical improvement and remission were evaluated according to EULAR criteria. The achievement of CDC (28-joint Disease Activity Score using C reactive protein $<$2.6, Health Assessment Questionnaire $<$0.5 and change from baseline in mTSS $\leq$0.5) was assessed every year of follow-up.

Results: At the twelfth month of FU 148 (42.4%) ERA patients achieved CDC, while at the time of last FU 228 (65.3%) subjects reached this target.

Patients achieving CDC at the 12th month of FU were younger (*p=0.05*), in higher percentage male (*p=0.004*), and with a normal weight (body mass index, BMI $<$25) (*p=0.003*) and had a shorter disease duration, comprising a greater number of VERA (*p=0.01*), compared to subjects not achieving disease control. There were no differences concerning autoantibody positivity and presence of erosions at onset between the two analyzed cohorts. Adjusting the analysis for age, the variables that arose as independent predictors of CDC at the 12th month of FU were a disease duration less than 3 months [OR (95% CI): 1.97 (1.23–3.14)] and a normal BMI [OR (95% CI): 2.05 (1.32–3.21)].

In our cohort, 105 (30.1%) ERA patients were treated with biological disease modifying anti-rheumatic drugs (bDMARDs) over time. Biotechnological therapy was less frequently started by subjects in CDC, both after 12 months (*p=0.003*) and at the time of last FU (*p$<$0.0001*). At the multivariate analysis, not achieving CDC at the 12th month of FU [OR (95% CI): 2.69 (1.59–4.57)] and a BMI $\geq$25 [OR (95% CI): 2.05 (1.23–3.42)] were the variables significantly associated to bDMARD therapy over time.

Conclusions: The simultaneous achievement of symptom control, inhibition of radiographic progression and normalization of function, is a feasible target in real word EAC. Having a VERA and a normal weight are associated to a high chance of "deep" remission.

SAT0053 THE INCIDENT IMMUNOLOGICAL STATUS PREDICTS DRUG-FREE DISEASE FLARE IN RHEUMATOID ARTHRITIS PATIENTS ACHIEVING STRINGENT CLINICAL AND ULTRASONOGRAPHIC CONTROL OF THE PERIPHERAL INFLAMMATORY PROCESS

A. Manzo, S. Bugatti, F. Benaglio, B. Vitolo, G. Sakellariou, R. Caporali, C. Montecucco. *Rheumatology and Translational Immunology Research Laboratories (LaRIT), Division of Rheumatology, IRCCS Policlinico San Matteo Foundation/University of Pavia, Pavia, Italy*

Background: The development of predictive tools to evaluate health risks and design personalized health plans in patients with rheumatoid arthritis (RA) achieving remission still represents a major unmet need. In this perspective, the relative weight of clinical, ultrasound and immunological assessment of disease characteristics for predicting recurrence of the inflammatory process under drug-free conditions remains unclear.

Objectives: To investigate the predictive value of baseline clinical remission stringency, synovial power Doppler (PD) ultrasound indices and the incident autoimmune status, as predictors of flare under drug-free conditions after a DAS28-driven treatment strategy with methotrexate (MTX) in early RA.

Methods: 85 RA patients achieving stable remission and candidate to MTX withdrawal were recruited according to the following criteria: 1) introduction of MTX within 12 months from symptoms' onset, 2) at least 24 months of MTX treatment with a DAS28-driven protocol targeting low disease activity (LDA), 3) DAS28$<$2.6 for $\geq$6 months in the absence of corticosteroids. Following treatment suspension, patients were monitored at three months' intervals across 24 months through clinical, ultrasound (hands-feet-axillary lymph nodes), radiographic and immunologic screenings (ACPA-RF status, CXCL13 circulating levels [1–2] and FACS analysis for quantification of Ki67+/regulatory T-B cell subsets). Treatment was re-introduced in case of DAS28$\geq$3.2 or stable LDA.

Results: At baseline, 84% of the patients were in remission according to the SDAI (<3,3) with 44% of the cases showing SDAI remission and absence of PD signal in hands and feet (SDAI<3,3 and PD=0). Despite stringent remission, 48% of the patients showed an episode of flare during follow-up with a peak incidence between 6 and 9 months after drug withdrawal. With the exception of a mild protective role of SDAI remission, none of the investigated clinical and ultrasound parameters (alone or in combination) showed a significant impact on clinical evolution across 24 months. ACPA IgG levels showed instead a strong, inflammation-independent predictive value for disease recurrence, an observation that was confirmed in the overall cohort (HR: 3.39 [1.7–6.64], p=0.0006, Cox regression) and, invariably, across progressive clinical and/or ultrasound remission thresholds (SDAI remission, SDAI remission-PD=0). Sub-analyses focused on short-term events (0–6 months after DMARDs withdrawal), identified the systemic level of CXCL13 at baseline as the strongest predictor of early disease recurrence in ACPA IgG positive individuals.

Conclusions: The systemic immuno-type of patients in remission is the major determinant of drug-free disease recurrence, over and above drug-induced achievement of stringent clinical and ultrasonographic control of the peripheral inflammatory process.

SAT0054 RISK FACTORS FOR ACUTE EXACERBATION OF RHEUMATOID ARTHRITIS-ASSOCIATED INTERSTITIAL PNEUMONIA

A. Yashima, H. Yamashita, R. Kamei, K. Suga, M. Nakano, S. Yamada, Y. Takahashi, H. Kaneko. *Division of Rheumatic Diseases, National Center for Global Health and Medicine, Tokyo, Japan*

Background: Acute exacerbation (AE) is recently recognized as deterioration of respiratory status in idiopathic pulmonary fibrosis. It is reported that AE also occurs in other interstitial lung diseases (ILD) such as collagen vascular diseases associated ILD (CVD-ILD). However, the characteristics and risk factors of AE in CVD-ILD are not clearly identified.

Objectives: To clarify the characteristics of patients with rheumatoid arthritis-associated interstitial pneumonia (RA-IP) and to investigate the risk factors associated with AE and its survival of RA-IP.

Methods: We examined the clinical features of 60 RA-IP patients admitted to our hospital between July 2010 and September 2016. We compared the characteristics between patients who developed AE (AE group) and those who didn't (non-AE group), and between patients who survived after AE (alive group) and those who died after AE (dead group), and identified variables significantly associated with AE occurrence and survival using Cox hazards analyses.

Results: Thirty-six (60%) were female. Twenty-two (36.7%) developed AE and seven of them (11.7%) died with the mean follow-up period of 2.7 years. The mean age at RA diagnosis was 61.1±16.3 years in AE group and 61.5±13.1 years in non-AE group. Sex, smoking habit and high-resolution computed tomography (HRCT) pattern were not significantly different between two groups. Although there was no significant difference, more patients in AE group received methotrexate (MTX) treatment than those in non-AE group (40.9% vs. 18.9%, *p*=0.08), and MTX use was significantly associated with occurrence of AE in a Cox hazard analysis (Hazard ratio [HR] 1.09, 95% confidence interval [CI] 1.01–1.18). Further, age (median 70 vs. 82 years, *p*=0.002) and matrix metalloproteinase-3 (MMP-3) level (median 84.8 vs. 205.6 ng/mL, *p*=0.03) on admission were significantly higher in dead group than in alive group. Univariate analyses revealed that age ≧ 75 years (HR 10.53, 95% CI 1.26–88.15), MMP-3 ≧ 200 ng/mL (HR 15.58, 95% CI 1.38–175.8), and 3L or more oxygen use (HR 8.46, 95% CI 1.02–70.49) on admission were associated with death (Table 1).

Table 1. Risk factors for AE mortality based on univariate Cox hazard analyses

	HR	95% CI	*p* value
Age ≥75 years	1.19	1.05 to 1.36	0.008
Sex, male	1.65	0.37 to 7.41	0.51
HRCT, UIP pattern	3.82	0.74 to 19.8	0.11
KL-6 ≥700 U.mL	1.32	0.24 to 7.22	0.75
LDH ≥400 IU/L	0.40	0.05 to 3.32	0.40
MMP-3 ≥200 ng/mL	15.58	1.38 to 175.80	0.03
O_2 ≥3 L	9.46	1.02 to 70.49	0.05

UIP, usual interstitial pneumonia; KL-6, Krebs von den Lungen-6; LDH, lactate dehydrogenase.

Conclusions: Our data suggest that MTX use relates to the occurrence of AE, and age, MMP-3 level, and oxygen volume on admission relate to AE survival in patients with RA-IP.

SAT0055 BARICITINIB SHOWED RAPID AND GREATER REDUCTION IN PAIN COMPARED TO ADALIMUMAB OR PLACEBO IN PATIENTS WITH RHEUMATOID ARTHRITIS

P. Taylor[1], B. Zhu[2], C. Gaich[2], X. Zhang[2], A.M. DeLozier[2], D. Schlichting[2], H. Patel[2], F. Durand[2], B. Fautrel[3]. *[1]University of Oxford, Oxford, United Kingdom; [2]Eli Lilly and Company, Indianapolis, United States; [3]University Pierre et Marie Curie, Paris, France*

Background: A rapid and meaningful reduction in pain is important to quality of life in patients (pts) with rheumatoid arthritis (RA). Baricitinib (bari) is a selective inhibitor of Janus kinase (JAK)1/JAK 2 in development for pts with active RA.[1]

Objectives: To evaluate the effect of bari treatment on pain reduction compared to adalimumab (ADA) or placebo (PBO) in pts with inadequate response to methotrexate (MTX) or biologic disease-modifying antirheumatic drugs (bDMARDs).

Methods: In RA-BEAM (NCT01710358), 1305 patients with inadequate response to MTX were randomised 3:3:2 to PBO QD, bari 4 mg once daily (QD), or ADA 40 mg biweekly.[2] In RA-BEACON (NCT01721044), 527 pts with inadequate response or intolerance to bDMARDs were randomised 1:1:1 to PBO or bari (2 or 4 mg) QD.[3] This post-hoc analysis reports the pts' assessment of pain using a visual analogue scale (VAS, range: 0 to 100 mm). The proportion of pts who achieved pain improvement of ≥30%, ≥50%, and ≥70% of their baseline pain at 1, 2, 4, 8, 12, 16, 20, and 24 weeks of treatment were compared between treatment groups using logistic models adjusted for geographic region, baseline pain score, baseline joint erosion status (RA-BEAM only), and history of bDMARD at screening (RA-BEACON only). Missing data were imputed using modified last observation carried forward.

Results: Mean baseline pain scores were 60, 62, and 61 for PBO, bari 4 mg, and ADA, respectively, in RA-BEAM and 65, 62, and 66 for PBO, bari 2 mg, and bari 4 mg, respectively, in RA-BEACON. A significantly greater proportion of pts treated with bari 4 mg achieved ≥30% and ≥50% pain improvement as early as week 1 compared to PBO (both studies) and as early as week 4 compared to ADA (RA-BEAM) (Table). A significant pain improvement of ≥70% was achieved at week 12 for pts treated with bari 4 mg compared to PBO (both studies) and ADA (RA-BEAM). Pain improvement of ≥30%, ≥50%, and ≥70% with bari 2 mg was significant compared to PBO by week 12 (RA-BEACON). Significant improvements in pain for bari vs PBO and bari vs ADA were sustained through week 24.

Table 1. Percent Pain Improvement in RA-BEAM and RA-BEACON

	RA-BEAM			RA-BEACON		
	PBO (N=488)	Bari 4 mg (N=487)	ADA (N=330)	PBO (N=176)	Bari 2 mg (N=174)	Bari 4 mg (N=177)
Pain Improvement ≥30%						
Week 1	27	48***	47***	20	25	32**
Week 4	37	67***†	60***	29	38	50***
Week 12	47	73***†	64***	31	43*	58***
Week 24	49	74***	69***	34	44*	57***
Pain Improvement ≥50%						
Week 1	13	26***	28***	6	9	17**
Week 4	22	48***‡	37***	15	25*	30***
Week 12	31	57***†	49***	17	31**	35***
Week 24	32	61***†	52***	20	32**	45***
Pain Improvement ≥70%						
Week 1	4	12***	11***	2	3	6
Week 4	8	26***	21***	6	11	14*
Week 12	14	37***‡	28***	7	19***	18**
Week 24	16	41***‡	32***	9	22***	29***

*p≤0.05 vs PBO; **p≤0.01 vs PBO; ***p≤0.001 vs PBO; †p≤0.05 vs ADA; ‡p≤0.01 vs ADA; p-values based on logistic regression model. ADA = adalimumab; Bari = baricitinib; PBO = placebo.

Conclusions: Bari-treated pts reported significantly greater and more rapid reductions in pain severity as measured by the pain VAS compared to PBO or ADA; improvements were sustained through 24 weeks. The results were similar regardless of the pt population.

SAT0056 RHEUMATOID ARTHRITIS MAGNETIC RESONANCE IMAGING SCORE (RAMRIS) CAN PREDICT DAS-28 THERAPY RESPONSE AFTER 6 MONTHS: RESULTS OF THE GERMAN ARTHROMARK COHORT

P. Sewerin[1], S. Vordenbäumen[1], C. Schleich[2], R. Sengewein[1], R. Brinks[3], G. Pongratz[3], J. Lesch[1], L. Le[4], U. Mansmann[4], M. Schneider[1], B. Ostendorf[1] on behalf of ArthroMark Studygroup. *[1]Department for Rheumatology; [2]Department for diagnostic and interventional Radiology; [3]Hiller-Research-Center for Rheumatology, University Hospital Duesseldorf, Düsseldorf; [4]Institute for Medical Information Sciences, Biometry and Epidemiology, Ludwig Maximilian University of Munich, Munich, Germany*

Background: Remission is the ultimate goal in rheumatoid arthritis (RA). The absence of rheumatoid factors (RF) and /or anti-citrullinated protein (CCP) antibodies, no bone erosions on conventional x-rays, the presence of low disease activity, and early therapeutic intervention are established good prognostic markers. Magnetic resonance imaging (MRI) is a well evaluated imaging technic and is increasingly used in daily practice. In this study, we prospectively investigated the prognostic performance of high-field MRI and serological biomarkers 6 months after initiation of methotrexate in patients with early RA (eRA)

Objectives: To evaluate the value of high-resolution MRI of the hand as a prognostic marker for EULAR-response and remission after 6 month of MTX therapy in early RA patients

Methods: Prospective cohort study on the ArthroMark cohort using 3T MRI of the hand at baseline (V0) before initiating an MTX-therapy in eRA patients, after 3 months (V3) and after six months (V6). 28 patients (Ø 56.8 years) with RF and/or CCP positive RA and a disease duration <6 months (mean16.3 weeks) fulfilling the 2010 ACR/EULAR criteria were examined. EULAR core set of variables were recorded: patient's global assessment of overall disease activity; number of tender and swollen joints, ESR and CRP. The following biomarkers were assessed by ELISA: Dkk-1, Osteoprotegerin, IL-22, MMP-3, TNF-Alpha and Neuropeptide-Y. Remission was defined as DAS28 <2.6 according to the ACR/EULAR remission criteria. MRI-scans were analysed by using OMERACT RA-MRI scoring system (RAMRIS). To adjust for intrapersonal correlation, we calculated generalized linear mixed models with time being recognized as a confounder in pretests.

Results: A low RAMRIS subscore for erosions (p=0.019) or total RAMRIS score predicted response at V3 (p=0.03). No significant results were found for the other imaging markers assessed for response prediction at either V3 or V6. Concerning remission, low levels of RANKL at baseline were significantly associated with EULAR remission at V6 (p=0.033). The other markers assessed did not show significant results at either V3 or V6.

In multivariate analyses, response was predicted more accurately with the inclusion of either RAMRIS (p value LR-test =0.035), RAMRIS synovitis subscore at MCP-2 (p-value LR-test =0.035) or a combination of the two (p-value LR-test =0.042). Remission was more accurately predicted when RANKL was considered with low RANKL improving the chance of remission. In contrast to response-prediction, MRI did not significantly add to the prediction model for remission.

Conclusions: Low RAMRIS scores or RAMRIS synovitis subscores at MCP-2 were predictive for therapy response after 6 months in our generalized mixed model. Baseline RANKL was able to significantly predict remission. Our data suggests that MRI and/or biomarkers may aid response prediction and facilitate patient selection for intensified therapy in the future.

SAT0057 PROSPECTIVE OBSERVATIONAL REAL-LIFE STUDY (STRATEGE) SHOWS THE EFFICACY OF TREAT-TO-TARGET STRATEGY AND METHOTREXATE MONOTHERAPY OPTIMIZATION IN PATIENTS WITH ESTABLISHED RHEUMATOID ARTHRITIS

R.-M. Flipo[1], C. Gaujoux-Viala[2,3], C. Hudry[4,5], E. Zinovieva[6], H. Herman-Demars[6] on behalf of STRATEGE study observers. *[1]Rheumatology Department, Lille University Hospital Roger Salengro, Lille; [2]Rheumatology Department, Nîmes Hospital, Nîmes; [3]Montpellier University, Montpellier; [4]Rheumatology Institute; [5]Rheumatology Department, Cochin Hospital; [6]Medical Department, Nordic Pharma, Paris, France*

Background: Current guidelines consider MTX as initial gold standard treatment for patients (pts) with RA. They also propose various strategies for MTX inadequate responders, among which the most frequent are optimization of MTX therapy (alone or in combination with csDMARDs or bDMARDs).

Objectives: The objective of the trial was to explore the strategies applied in daily practice in RA pts with inadequate response to MTX.

Methods: STRATEGE was a prospective, observational, multicenter study. Main inclusion criteria were: confirmed RA (ACR 1987 or ACR/EULAR 2010 criteria) and treatment by MTX monotherapy with clinical, structural, functional and/or therapeutic evolution leading to therapeutic management modification. Data were obtained at 2 time-points: baseline and 6-month follow-up.

Results: Between Sept 2014 and July 2015, 176 rheumatologists, at 90% with private practice, included 854 pts, 801 of which composed the analyzable baseline set. Pts baseline characteristics were [mean (SD)]: age: 57.4 (13.7) yrs; RA duration: 5.3 (6.7) yrs; DAS28: 4.0 (1.1), with the following distribution: <2.6 for 10%, >3.2 for 74% and >5.1 for 16%; HAQ: 1.1 (0.84); and extra-articular features and erosive disease for respectively 10.5% and 39.9% of pts. All pts were receiving MTX monotherapy, orally for 67.6% and at mean (SD) dose of 14.2 (4.1) mg/wk for oral and 16.6 (3.8) mg/wk for parenteral administration. Concomitant treatment included corticosteroids for 45.8% of pts, at a mean (SD) dose of 8.2 (6.3) mg/d, and folic acid for 90.0%. After the inclusion visit, MTX prescription has been identically maintained (dose and route) for 28.1% of pts, interrupted for 1.9% and modified for 70.0%. Changes included dose increasing for 50.2%, dose tapering for 1.8% and a route modification for 21.4% (88.2% oral -> parenteral). After inclusion visit, MTX oral versus (vs) parenteral balance was respectively 49.8% at mean (SD) dose 16.2 (4.0) mg/wk vs 45.8%, 18.0 (3.9) mg/wk. Biologic treatment was initiated for 14.6%, in association with MTX for 95.7%. Other csDMARD treatment was initiated for 1.2% in monotherapy and for 3.6% in association with MTX. The reasons for treatment modification were mainly active RA (72.0%), worsening of clinical and biologic parameters (31.4%), radiographic progression (14.5%), remission not achieved (12.4%), steroid dependence (11.3%), and MTX intolerance 5.0%. Six-month follow-up results show that all the active treatment strategies were significantly and equally successful in improving disease activity (Table).

Table 1

	N	DAS28 Baseline	DAS28 (M6)	D DAS28	*p*
MTX unchanged (Ref.)	126	3.4 (1.3)	2.5 (1.0)*	-0.8 (1.2)	–
MTX optimization	519	4.0 (1.0)	2.9 (1.2)*	-1.1 (1.3)	0.10
bDMARDs	117	4.6 (1.1)	3.2 (1.1)*	-1.4 (1.3)	0.22
csDMARDs	39	4.3 (1.2)	3.1 (1.3)*	-1.3 (1.4)	0.37

Data presented: mean (SD). *$p<0.0001$ (M6 *vs* baseline), ANCOVA, adjusted for DAS28 at baseline.

Conclusions: Consistently with all current guidelines, results of the large prospective observational study STRATEGE reveal an important place held by initial MTX treatment optimization before initiation of a biotherapy and emphasize the importance of treat-to-target strategy.

SAT0058 EFFECTS OF BARICITINIB ON PATIENTS WHO STOP METHOTREXATE MONOTHERAPY AND SWITCH TO BARICITINIB MONOTHERAPY

R. Fleischmann[1], T. Takeuchi[2], M. Schiff[3], D. Schlichting[4], L. Xie[4], M. Issa[4], I. Stoykov[4], J.R. Lisse[4], P. Martinez-Osuna[4], T. Rooney[4], C.A. Zerbini[5]. *[1]U Texas SW Medical Center, Dallas, United States; [2]Keio University, Tokyo, Japan; [3]Univ Colorado Hospital Rheum, Colorado; [4]Eli Lilly and Company, Indianapolis, United States; [5]Univ Sao Paolo, Sao Palo, Brazil*

Background: Baricitinib (bari) is a reversible oral Janus kinase (JAK) inhibitor with selectivity for JAK1/JAK2 in development for treatment of patients (pts) with active rheumatoid arthritis (RA). In the 52-week (wk) Phase 3 RA-BEGIN study of MTX-naïve pts, there were 3 arms: bari 4 mg once daily (QD), methotrexate (MTX) up to 20 mg weekly (QW), and the combination of bari plus MTX (bari+MTX). Nonresponders were rescued from week 24 onwards by receiving bari+MTX, regardless of original treatment. Bari monotherapy showed superior efficacy compared to MTX monotherapy and similar clinical efficacy to bari+MTX.

Objectives: Efficacy and safety were evaluated in pts from RA-BEGIN who switched from MTX or bari+MTX therapy to bari monotherapy upon entering the long-term extension (LTE) study (RA-BEYOND).

Methods: In RA-BEGIN, 588 pts were randomised 4:3:4 to MTX, bari monotherapy 4 mg, or bari+MTX. At Wk 52, pts could enter the LTE; all pts received bari 4 mg monotherapy. MTX could be added in the LTE by investigator decision. Seventy-seven percent of pts (451/588) enrolled in the LTE, of whom 423 had not been rescued in RA-BEGIN. This post hoc analysis evaluated clinical efficacy of pts who continued bari monotherapy compared to those in whom MTX was added within the first 24 wks of the LTE.

Results: Of these 423 pts, 200 (47%) remained on monotherapy at Wk 24 of the LTE and 223 pts started on MTX before wk 24. Most (193) had initiated MTX within 4 wks of starting the LTE study, evenly balanced from the 3 original arms of RA-BEGIN. Across study arms, pts who had MTX added in the LTE had worse disease control upon entry and during the LTE. Through 24 wks, statistically significant improvement in disease state was observed in the MTX-to-bari group regardless of whether or not MTX was added back. In the bari-to-bari monotherapy group, the addition of MTX led to lowered disease activity, which was statistically significant. No statistically significant changes in disease activity were observed in the pts who were switched from bari+MTX to bari monotherapy regardless of additional MTX therapy (Table 1). Exposure-adjusted incidence rates for total treatment-emergent adverse events, including non-serious infections, were lowest in the MTX-to-bari group. Clinically significant or consistent differences in SIE,

SAEs, or AEs leading to study drug discontinuation were not seen in any of the arms, whether MTX was added or not.

Serious infections	+MTX	0	2 (3.0) [7.7]	1 (1.1) [2.8]
	-MTX	2 (3.0) [6.9]	1 (1.8) [4.2]	0

Abbreviations: AEs=adverse events; Bari=baricitinib; EAIR=exposure adjusted incidence rate; LTE=long-term extension; MTX=methotrexate; SAE=serious adverse event; TEAE=treatment-emergent adverse event.
Results are subdivided into those patients placed back on MTX (+MTX) and those who remained true Bari monotherapy (-MTX). Analyses are based on a September 1, 2016 data cutoff. Data are n (%) [EAIR].

Conclusions: Switching from MTX to bari monotherapy, maintaining bari monotherapy was associated with improvements in depths of disease control during the initial 24 wks post-switch. Disease control did not significantly change after withdrawal of MTX from combination therapy. Pts who entered the LTE with suboptimal disease control after treatment with bari monotherapy may benefit from the addition of MTX. Discontinuation of MTX in pts treated with combination during the index study was associated with maintenance of response. There were no differences in important measures of safety including events that are serious or led to discontinuation.

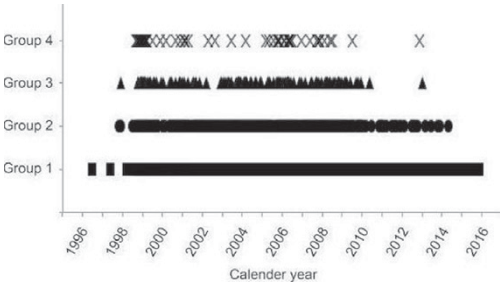
SAT0059 HIGH RADIOGRAPHIC PROGRESSION IS RARE AND GETS LESS FREQUENT IN RA PATIENTS OF THE SWISS SCQM COHORT FROM 1998 TO 2015

S. Mueller[1], R. Thalmann[1], H. Schulze-Koops[2], N. Graf[3], J. von Kempis[1].
[1]Division of Rheumatology, Kantonsspital St. Gallen, St. Gallen, Switzerland; [2]Rheumaeinheit, Klinikum der Universität München, Campus Innenstadt, Munich, Germany; [3]Graf Biostatistics, Winterthur, Switzerland



Background: The primary goal of current therapeutic strategies in RA is to control disease activity and at the same time to prevent radiographic progression. A disconnect between a missing radiographic progression and higher disease activity under treatment with biologic agents has been discussed. In general, analyses of radiographic progression in RA rather focus on radiographic non-progression or repair and high radiographic progression in spite of therapy has, to our knowledge not been analysed in detail in the last years, neither in RCTs nor in cohort studies.

Objectives: To analyse the occurrence of high radiographic destruction and it's development in the era of biologic treatment.

Methods: We included all RA patients from the Swiss registry SCQM with at least two subsequently scored radiographs. Radiographic destruction was scored with the Ratingen erosion score and calculated by dividing the change of Ratingen scores by time (>6 months) between two subsequent radiographs. To analyse high radiographic progression we looked for the height and time of the highest (peak) radiographic progression in every individual patient for the analysis. The individual peak radiographic progression was analysed in groups as change of Ratingen scores/year: 0-≤10, 10-≤20, 20-≤30, >30 (groups 1–4). The time point of the individual peak radiographic progression was analysed per group (follow up 1998 – 2015). The baseline disease characteristics were compared using standard descriptive statistics (Kruskal-Wallis or Chi-square tests).

Results: 4'033 patients were included into the analysis. 3'049 patients had a peak radiographic progression between 0 and ≤10/year, 773 between 10 and ≤20, 150 between 20 and ≤30, and 61 of >30. All patient groups were within the same age range (mean: 56.5 – 60.5 years). Rheumatoid factor and ACPA were more frequent in patient groups with higher peak radiographic progression (RF: 73.6, 80.0, 88.9, 90.0; ACPA: 66.8, 73.4, 74.3, 82.1, groups 1–4, respectively). When the rate of radiographic progression before and after peak progression was analysed, 69.7%, 74.7%, 76.9%, and 93.3% of the patients had a radiographic progression of 25% or lower as compared to peak progression before and 76.1%, 81.8%, 91.1%, and 93.8% after this peak progression, respectively for patients in groups 1 to 4 (Figure A).

The disease activity, as assessed by DAS 28, was significantly higher in all patient groups before peak progression and lower thereafter (Figure B, p<0.001). Average HAQ-DI scores increased after peak radiographic progression in group 4 (Figure C, p=0.005) whereas it is stable or even decreases among the patients of the other patient groups.

Conclusions: High peak radiographic progression is a rear phenomenon that gets less frequent in patients over the last years of observation. This may be an effect of modern therapy. Among the patients with high radiographic progression, (1) a greater delay between diagnosis and first symptoms was found and (2) the use of biologic agents was less frequent. These data suggest that the decreasing frequency of very high radiographic peak progression in the Swiss RA patients reflect a more effective therapeutic approach in the last years.

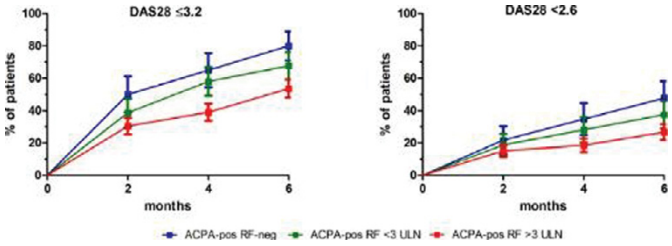
SAT0060 RESPONSE TO CONVENTIONAL SYNTHETIC DMARDS DIFFERS DEPENDING ON RHEUMATOID FACTOR LEVELS IN ANTI-CITRULLINATED POSITIVE PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

S. Bugatti, A. Manzo, G. Zanframundo, F. Benaglio, G. Sakellariou, C. Montecucco, R. Caporali. *Rheumatology and Translational Immunology Research Laboratories (LaRIT) and Early Arthritis Clinic, Division of Rheumatology, University of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia, Italy*



Background: In rheumatoid arthritis (RA), several autoantibody characteristics, including specifities, levels and isotypes, may influence their pathogenic properties and impact on clinical presentation and outcomes of the disease (1, 2). In particular, classical IgM rheumatoid factor (RF) may boost inflammation triggered by anti-citrullinated protein antibodies (ACPA) (3).

Objectives: To investigate whether RF impacts on disease characteristics and response to therapy in ACPA-positive early RA patients treated with conventional synthetic disease modifying drugs (csDMARDs).

Methods: 574 early RA patients consecutively enrolled in our Early Arthritis Clinic between 2005 and 2014 were included. Patients had symptoms' duration <12 months, were glucocorticoid- and DMARD-naïve, and fulfilled RA criteria at inclusion. IgM RF and IgG ACPA were determined in baseline sera by immunonephelometry and a second-generation EliA CCP assay respectively. Autoantibody levels were considered high when >3 times the upper limit of normal (ULN). Patients were treated with incremental doses of methotrexate according to a treat-to-target strategy aiming at low disease activity (LDA, DAS28 ≤3.2). The associations between autoantibody specifities and levels and the achievement of LDA and disease remission (DAS28 <2.6) over 6 months were investigated by Cox regression.

Results: 360 patients tested RF and/or ACPA positive (31.9% single RF-positive, 10.3% single ACPA-positive, 57.8% ACPA and RF double-positive) and were

selected for outcome analyses. Among seropositive patients, both LDA and remission were less frequently achieved in case of RF-positivity. Relevantly, in ACPA-positive patients (n=273), the co-occurrence of RF dose-dependently influenced clinical outcomes. After 6 months of treatment, LDA and disease remission were achieved respectively by 69.6% and 47.8% of single ACPA-positive, 68.8% and 37.5% of ACPA-positive RF-low, and 57% and 27.6% of ACPA-positive RF-high patients (chi-square for trend p=0.18 for LDA, p=0.05 for remission). After adjusting for confounders (age, gender, symptoms' duration, baseline disease activity, use of prednisone, recruitment period), high levels of RF independently predicted failure to achieve LDA with an HR (95% CI) of 0.61 (0.39 to 0.95) and failure to achieve remission with an HR (95% CI) of 0.63 (0.35 to 0.99) (Figure 1). In contrast, ACPA levels did not show any significant predictive value, neither for thresholds of >3 ULN nor of >100 U.

Conclusions: Among ACPA-positive RA patients, disease characteristics may vary in association with the extent of overall humoral autoimmunity. In particular, the concomitant presence of high levels of IgM RF seems associated with lower response rates to csDMARDs. Collectively, these findings highlight the importance of further subclassifying patients with autoantibody-positive RA in order get deeper insights into disease mechanisms and clinical outcomes.

SAT0061 HAQ SCORE IS AN INDEPENDENT PREDICTOR OF SUSTAINED REMISSION IN PATIENTS WITH RHEUMATOID ARTHRITIS

S.-S. Lee[1,1], J.-H. Kang, J.-E. Kim, K.-E. Lee, D.-J. Park. *Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic Of*

Objectives: We compared remission rates, according to different definitions of remission in rheumatoid arthritis (RA) and investigated the potential predictors of sustained remission at the 2-year follow-up.

Methods: We obtained data on 291 RA outpatients, seen from July 2009 to September 2012. Sociodemographic data and answers to questionnaires were collected in face-to-face interviews. Remission was defined according to the Disease Activity Score in 28 joints (DAS28)-ESR, DAS28-CRP, Simplified Disease Activity Index (SDAI), Clinical Disease Activity Index (CDAI), and ACR/EULAR Boolean definition. Sustained remission was defined as when the patient continued in remission at two consecutive annual assessments. Predictors of sustained remission according to the DAS28-CRP were assessed by univariate and multivariate analyses.

Results: For the 291 RA patients, the remission rates of RA were 17.9% (DAS28-ESR), 54.3% (DAS28-CRP), 10.3% (SDAI), 10.0% (CDAI), and 5.8% (Boolean). On follow-up for 2 years, the sustained remission rates of RA were 46.5% (DAS28), 55.0% (DAS28-CRP), 37.5% (SDAI), 32.0% (CDAI), and 30.8% (Boolean). RA patients who achieve sustained remission according to the DAS28-CRP were younger, and had more education, higher monthly income, lower Health Assessment Questionnaire (HAQ) score, lower physician global assessment, lower patient global assessment, lower patient pain assessment, and higher EQ-5D. In multivariate analysis, only the HAQ score predicted sustained remission according to DAS28-CRP (OR=0.257, 95% CI 0.067–0.980, p =0.047).

Conclusions: The remission rates of RA patients differed according to the definition of remission, and the highest sustained remission rate was classified by the DAS28-CRP. A lower HAQ score was an independent predictor of sustained remission over 2 years, according to the DAS28-CRP.

SAT0062 14-3-3ETA PREDICTS JOINT DAMAGE PROGRESSION AND FLARING AFTER ADALIMUMAB DISCONTINUATION

S. Hirata[1,2], A. Marotta[3], K. Hanami[2], Y. Tanaka[2]. *[1]Hiroshima University Hospital, Hiroshima; [2]University of Occupational and Environmental Health, Kitakyushu, Japan; [3]Augurex Life Sciences Corp, Vancouver, Canada*

Background: The HONOR (humira discontinuation without functional and radiographic damage following sustained remission) study was designed to investigate the possibility of patients discontinuing adalimumab (ADA) therapy for 1 year without flaring (DAS28-ESR ≥3.2). 14–3-3η is a mechanistic serum marker that is modifiable over the disease course, does not correlate with CRP and is a predictor of radiographic progression even in patients who achieve clinical remission. The uncoupling of inflammation and joint damage processes in RA underscores a risk of premature discontinuation of biologic treatment when aiming to achieve sustained remission. Serum markers that could indicate which patients are at risk of flare and continued joint damage despite clinical remission are highly desirable.

Objectives: In this study, serum 14–3-3η was investigated as a predictor of joint damage and flares in the HONOR cohort.

Methods: Serum 14–3-3η levels were measured in 62 Japanese patients, 51 of which were from the HONOR study at baseline, 1-year after treatment initiation, at discontinuation and at the time of flare. Of the 62 patients, 46 (74%) patients achieved sustained drug-free remission up to 1 year following ADA discontinuation. Sharp van der Heidje (SHS) scores were available at therapy initiation, discontinuation, and at 52 weeks following. Relationships between continuous variables were assessed using uni- and multi-variable Gaussian linear regression models and logistic regression.

Results: At baseline and discontinuation, median (QR) 14–3-3η levels were 0.28 ng/ml (0.07–2.11) and 0.22 ng/ml (0.04–1.28) respectively, with 26 (59%) of 44 and 29 (54%) of 54 patients being positive (≥0.19 ng/ml) at the corresponding time-points. Paired t-test revealed that levels of 14–3-3η were significantly different between baseline and discontinuation, p=0.030. Level of 14–3-3η at baseline was positively associated with SHS at 12 months and at the time of flare, p=0.038. Bivariable modeling revealed that baseline 14–3-3η together with the change in 14–3-3η had a significant interacting effect on SHS at 12 months and the time of flare, p=0.02. Higher baseline 14–3-3η levels together with an increase in levels at the time of discontinuation was strongly associated with an increased SHS. Adding CRP, flare, sustained remission through 12 months, MTX dose at initiation and at ADA discontinuation did not improve predictive effects of 14–3-3η with SHS. Baseline 14–3-3η levels alone was not associated with flares at 12 months (p=0.15) however when combined with CRP, a significant interaction was present (p=0.03). Specifically, patients with a low CRP, and a high 14–3-3η level had a higher likelihood of flaring versus those with a low 14–3-3η, 22% versus 12%.

Conclusions: Baseline 14–3-3η and increases in its levels are associated with worse radiographic outcomes in patients who achieve clinical remission and discontinue ADA. To reduce the risk of flare in patients who are candidates for discontinuation of ADA, CRP and 14–3-3η measurements should be considered in combination as markers of flare prediction.

SAT0063 A PROSPECTIVE STUDY ON COMPARISON OF COMPOSITE INDICES WITH ULTRASOUND FOR DETECTING REMISSION AND PREDICTION OF FLARE IN 2 YEARS

M.O. Olmez[1], E.K. Gunal[2], S.B. Ureyen[3], H. Keskin[2], A.B. Ozturk[4], H.G. Yeter[5], E. Cobanoglu[5], S.Z. Aydin[3]. *[1]Internal Medicine; [2]Rheumatology, Istanbul Medeniyet University School of Medicine, Istanbul, Turkey; [3]Rheumatology, University of Ottawa, Faculty of Medicine, Ottawa, Canada; [4]Allergy and Immunology; [5]Koc University, School of Medicine, Istanbul, Turkey*

Background: Treat-to-target (T2T) approach suggests using a composite index when following patients with rheumatoid arthritis (RA) without identifying which one to use.

Objectives: In this prospective study we aimed to compare the accuracy of different indices for RA patients in remission taking Ultrasound Global Synovitis Score (GLOESS) as a gold standard and their predictive value for flares in 2 years.

Methods: RA patients who were considered to be in clinical remission according to the clinician were recruited. Disease activity was assessed using DAS28-CRP, CDAI, SDAI and RAPID-3 and 38 joints per patient were scanned by US and scored according to GLOESS. The total GLOESS scores were calculated for 38 joints and also for 28 joints by excluding the MTP joints. The number of joints with ≥2 GLOESS was calculated. Flare data was collected in 3 subsequent visits in the following 2 years, whenever available.

Results: Ninety-six consecutive patients (80.2% females) were recruited. Patients were more frequently categorized as being in remission using DAS28 (80%) compared to CDAI (50%), SDAI (45.2%) and RAPID 3 (37.5%). Patients that were in remission according to CDAI had lower GLOESS scores on 28 joints (p=0.05) and had less joints with ≥2 signals (p=0.04) (table). For SDAI patients in remission had significantly less number of joints with grade 3 signals (p=0.03) and tend to have lower GLOESS scores on 28 joints as well as lower number of joints with ≥2 signals (p=0.06). None of the US scores were able to differentiate different disease states according to DAS28-CRP or RAPID. Flare data was available in 76 patients, 22 of whom had flares. Patients that had flare had higher GLOESS scores on 28 joints at baseline (p=0.05) and tend to have higher number of joints with grade 3 signals (p=0.06). Although numerically higher, none of the clinical indices were able to predict flares based on remission status (remission vs non remission: CDAI: 22.5% vs 36.1, p=0.2; SDAI: 22.9 vs 36.8, p=0.2; DAS28: 25.4% vs 50%, p=0.1; RAPID3: 20% vs 34.8%, p=0.2).

Table 1. The distribution of US-GLOESS according to different categories by indices

	GLOESS 38 joints mean±SD	GLOESS 28 joints mean±SD	Joint counts ≥ score 2 mean±SD	Joint counts with score 3 mean±SD
DAS-28				
Remission (n=77)	10.9±7.5	7.8±7.2	3.5±3.1	0.7±1.3
LDA (n=11)	14.5±6.6	10.0±5.4	4.9±3.0	0.9±1.4
VMDA (n=5)	9.6±6.2	5.4±3.5	3.0±2.3	0.80±1.7
CDAI				
Remission (n=48)	10.0±6.9	6.9±6.2	3.02±2.7	0.60±1.0
LDA (n=48)	12.7±7.7	9.1±7.2	4.3±3.3	0.94±1.5
SDAI				
Remission (n=42)	9.9±6.6	6.6±5.9	2.9±2.6	0.5±0.9
LDA (n=50)	12.4±7.8	9.1±7.5	4.2±3.3	0.9±1.5
MDA (n=1)	13.0	4.0	5.0	0
RAPID				
Remission (n=36)	10.3±6.2	6.7±4.6	3.1±2.6	0.5±0.8
Low activity (n=28)	9.6±5.8	6.6±4.6	2.7±2.2	0.3±0.7
MDA (n=30)	14.0±9.4	10.7±9.7	5.1±3.9	1.4±1.9
HDA (n=2)	15±1.4	8.5±2.1	5±1.4	0

LDA: Low disease activity MDA: Moderate disease activity HDA: High Disease activity.

Conclusions: Our results show that CDAI is superior then other clinical indices to assess remission in RA. US has the superiority over clinical indices to predict flares and 28 joint GLOESS is superior to 38 joints.

SAT0064 HIGH MMP3 SERUM LEVELS ARE ASSOCIATED WITH EXTENSIVE STRUCTURAL DAMAGE IN PATIENTS WITH EARLY, TREATMENT NAIVE RHEUMATOID ARTHRITIS (RA): TWO YEARS PROSPECTIVE CLINICAL AND ULTRASONOGRAPHIC STUDY

S.Z. Prodanovic[1], G. Radunovic[2], M. Sefik-Bukilica[3], M. Zlatanovic[4], K. Simic-Pasalic[5], S. Seric[6], N. Damjanov[7]. *[1]Clinical IVb; [2]Deputy of head; [3]Clinical IVa; [4]Clinical III; [5]Clinical VI; [6]Radiology Department; [7]Head of Institute, Institute of Rheumatology, Belgrade, Serbia*

Objectives: To investigate the association of high baseline MMP-3 serum levels with hands and feet joints structural damage progression, estimated by ultrasonography (US), in patients with early, treatment "naïve" RA without X-ray visible erosions.
Methods: Sixty-three pts. (9 males and 54 females; mean age 53.4 yrs 21–81±14.1) with early RA (EULAR/ACR 2010 criteria) and symptom duration of ≤12 months (mean duration of 3.8 months) had baseline serum MMP-3 levels tested. Patients had been DMARDs/glucocorticoid naïve, without visible X-ray erosions at the study entry. The subsequent structural joints damages, that were estimated by high frequency linear probe by ESAOTE My Lab 70 machine, as well as clinical markers of disease activity, in the first 2 years were followed. The presence of bone erosion was analyzed at the wrist, MCP2 and MCP5 joints of both hands, as well as at MTP5 joints according to OMERACT US group definition. In order to estimate progression of preexisting erosion the total volume (TV) of bone erosion were calculated by multiplying three diameters (mm): a-the length of erosion; diameter b- the width and diameter c-the depth of erosion. Anova statistical method was performed in data processing.
Results: 46 pts. had basal serum MMP-3 level higher than normal (MMP-3 positive). The 504 joints were assessed summary by US on each visit. The 122 bone erosions in total (1.9 per patient) were depicted at baseline and 213 bone erosions (4.3 per patient) at follow-up visit in whole group. After 24 months MMP3 positive pts. had significantly higher total number of US erosions than MMP-3 negative (3.8 vs. 2.4, p=0.039). The total volume of bone erosion (mm^3) was higher in MMP-3 positive than MMP-3 negative pts. after 24 months of treatment, but without statistical significance (18.6 vs. 8.9, p=0.07). MMP-3 positive pts. had a significantly higher value of ESR, CRP and DAS28 than MMP-3 negative pts. at the baseline visit (53.6 vs.25.9, p=0.002; 36.6 vs. 9.5, p=0.005; 6.0 vs. 4.8, p=0.002, respectively). All of those parameters were significantly decreased after 24 months in a group of MMP-3 positive compared to MMP-3 negative pts. (p=0.009, p=0.021, p=0.028, respectively).
Conclusions: After 2-year of follow-up, US assessment showed a significantly higher number of new bone erosions in patients with early, treatment "naïve" RA and baseline MMP3 levels higher than normal (MMP3 positive) compared to patients with normal baseline levels of MMP3, as well as a biger TV of bone erosions but not statistically significant. The parameters of RA activity (ESR, CRP, DAS28) significantly correlated with baseline MMP-3 levels of higher than normal.

SAT0065 ACPA AGAINST DIFFERENT CITRULLINATED PEPTIDES IDENTIFY SPECIFIC PHENOTYPES OF RHEUMATOID ARTHRITIS

M. Brink[1], M. Hansson[2], L. Mathson-Alm[3], M. Cornillet[4], J. Rönnelid[3], K. Skriner[5], G. Serre[4], R. Holmdahl[6], L. Klareskog[2], S. Rantapää-Dahlqvist[1]. *[1]Public Health and Clinical Medicine, Rheumatology, Umeå University, Umeå; [2]Rheumatology Unit, Dept of Medicine, Karolinska Institute, Stockholm; [3]Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden; [4]U 1056 Inserm, Univeristy de Toulouse, Toulouse, France; [5]Medicine, Charité University, Berlin, Germany; [6]Medical Inflammation Research, Karolinska Institute, Stockholm, Sweden*

Background: Anti-citrullinated protein/peptide antibodies (ACPA) have been suggested to identify a more severe phenotype of rheumatoid arthritis (RA).
Objectives: In this study in an inception cohort of early RA we have analysed a number of antibodies against different citrullinated and/or mutated peptides using a multiplex platform in relation to the patients disease inflammation and radiological destruction
Methods: Patients with early RA (≤12 m of symptoms) fulfilling the 1987 ARA criteria (n=1022, 692f/330m, mean age56.7±14.0 years) were sampled at the time of diagnosis and assessed using disease activity score (DAS28) at baseline, 6, 12, 18 and 24 months. Radiographs were graded using Larsen score (baseline and *at* 24 m). Plasma sampled at baseline was analysed for presence of antibody reactivities against 21 different citrullinated peptides/proteins; Fibrinogen (Fib) α36–50, Fibα573, Fibα591, Fibα621–635, Fibβ36–52, Fibβ60–74, Fibβ62–78 (72), Fibβ62–78 (74), Filaggrin (Fil307–324), α-Enolase peptide 5–21 (CEP-1), Vimentin (Vim) 2–17, Vim60–75, F4-R-Cit, F4-Cit-Cit, F4- Cit-R), or mutated proteins (Bla26, Pept1, Pept5, PeptZ1, PeptZ2) and type II Collagen citrullinated or not using a custom-made microarray assay based on the ImmunoCAP ISAC system (Phadia AB, Sweden). Cut-off levels were at the 98th percentile of controls (n=477). Anti-CCP2 was analysed using ELISA (Euro Diagnostica, Sweden).
Results: The most frequent appearing ACPA were; Fibβ60–74 (63%), Vim60–75 (56.6%), Fibβ36–52 (55.1%), Fil307–324 (54.9%), CEP-1 (53.7%) and Pept5 (52.0%) besides CCP2 (67.5%). Adding all ACPAs gave additional 13.1% of positivity in the anti-CCP2 negative group, yielding a positivity of 77.5%. The median (IQR) number of positive ACPA-peptide was 8 (11). There was a high degree of correlation between the antibodies, e.g., anti-Fibβ60–74 vs. -Vim60–75, -Fibβ36–52 or anti-CCP2 antibodies and also anti-Fil307–324 vs. -Fibβ36–52, -F4 R-Cit or anti-CCP2 antibodies (rs 0.692–0.79). Positivity for all antibodies was associated with higher ESR (baseline and AUC_{24}). A number of antibodies were associated with both high DAS28 (baseline and AUC_{24}) and radiological findings/progression (anti-CCP2, - Fil307–324, -Vim60–75 and Vim 2–17, and -CEP1 antibodies), whilst some others were more associated with inflammation (DAS28, baseline and AUC_{24}) (anti-Fibβ60–74, -Pept5 and -F4R-cit antibodies) and others more with radiological destruction/progression (anti-Fibβ36–52, -Fibβ74, -PeptZ1, -F4 Cit-R antibodies). Partial least squares regression analyses confirmed the results with significant correlation between radiological progression and antibodies against Vim2–17, Fibβ36–52, CEP1, Fibα621–635, and CCP2 and between DAS28AUC_{24} and Vim60–75, Vim2–17, Fibα621–635 and F4-R-Cit. Patients treated with biologics during the first 24 months (11.2%) were significantly more frequent positive for anti-CCP2, -Vim60-75, -Fibα36–50, -PeptZ1 and -PeptZ2 antibodies vs. being negative.
Conclusions: Analyses at baseline, of the ACPA specificity profiles allowed different patterns of disease activity and radiological progression during the first 24 months of the disease to be identified.

SAT0066 HISTOLOGICAL AND ULTRASOUND SYNOVIAL PREDICTORS OF CLINICAL DIFFERENTIATION TO DEFINED ARTHRITIS IN PATIENTS WITH SERONEGATIVE UNDIFFERENTIATED PERIPHERAL INFLAMMATORY ARTHRITIS

S. Alivernini[1], L. Petricca[1], B. Tolusso[1], L. Bui[2], C. Di Mario[1], M.R. Gigante[1], G. Di Sante[1], R. Benvenuto[2], A.L. Fedele[1], F. Federico[2], E. Gremese[1], G. Ferraccioli[1]. *[1]Institute of Rheumatology; [2]Institute of Pathology, Catholic University of the Sacred Heart, Rome, Italy*

Background: Undifferentiated Peripheral Inflammatory Arthritis (UPIA) is a common diagnosis at the first clinical evaluation in rheumatological settings. However, the likelihood of developing a well-defined rheumatic disease in UPIA patients is still matter of debate.
Objectives: To examine the role of ultrasound (US) and histological parameters in the disease outcome of patients with seronegative UPIA.
Methods: Fourty-two patients with IgA/IgM-Rheumatoid Factor and anti-citrullinated peptide antibodies negative UPIA, naïve to any Disease-Modifying Anti-Rheumatic Drugs, underwent Gray Scale (GSUS) and power Doppler (PDUS) evaluation and US guided synovial tissue biopsy. Synovial expression of CD68, CD3, CD21, CD20 and CD31 was evaluated by immunohistochemistry. IL-6, VEGF-A and VEGF-D peripheral blood (PB) and synovial fluid (SF) levels were measured by ELISA. To exclude Reactive Arthritis, each patient underwent genital and throat swabs. Afterwards, each UPIA patient was treated with chloroquine 250 mg/daily and followed every 3 months for 1 year and classified as having

UPIA, Rheumatoid Arthritis (RA), Spondyloarthritis (SpA) or Psoriatic Arthritis (PsA), respectively.

Results: During the follow-up 6 (14.3%) UPIA reached a defined diagnosis (2 RA, 2 SpA and 2 PsA, respectively). At baseline, UPIA who differentiated had higher GSUS (p=0.01) and PDUS scores (p=0.02) compared to patients who remained as UPIA within 1 year. At baseline, UPIA who differentiated towards defined arthritis had higher histological scores for lining and sublining $CD68^+$ (p=0.005 and p=0.04 for lining and sublining, respectively), sublining $CD3^+$ cells (p=0.002) and $CD31^+$ vessels count (p<0.001) than patients who remained as UPIA. In addition, there were direct correlations between baseline GSUS and PDUS scores with lining $CD68^+$ cells scores (p<0.001 for GSUS and p=0.02 for PDUS scores respectively), sublining $CD68^+$ cells scores (p=0.02 for GSUS and p=0.03 for PDUS scores respectively), sublining $CD3^+$ cells score (p=0.002 for GSUS and p=0.002 for PDUS scores respectively) and $CD31^+$ vessels count (p<0.001 for GSUS and p=0.01 for PDUS scores respectively) in UPIA. Finally, the areas under the receiver operating characteristic (ROC) curves $CD31^+$ vessels count (cut-off value: 24.3), GS score (cut-off value: 1.5) and PDUS score (cut-off value: 1.5) were calculated to assess the best cut-off points to identify the differentiation likelihood during the follow-up in UPIA patients. The logistic regression analysis, demonstrated that having baseline GSUS and PDUS scores ≥1.5 [OR:13.64 (95% CI: 0.98–242.59); p=0.05] and $CD31^+$ vessels count ≥24.3 [OR:51.13 (95% CI: 3.15–829.16); p=0.01] were independent factors associated with the achievement of defined arthritis.

Conclusions: Histological and US assessment may help in the identification of patients with seronegative UPIA with high likelihood of clinical differentiation towards defined arthritis.

SAT0067 FURTHER TREATMENT INTENSIFICATIONS IN UNDIFFERENTIATED AND RHEUMATOID ARTHRITIS PATIENTS ALREADY IN LOW DISEASE ACTIVITY HAVE LIMITED BENEFIT TOWARDS PHYSICAL FUNCTIONING

S.A. Bergstra[1], O. Olivas[2], G. Akdemir[1], N. Riyazi[3], G. Collee[3], J.H. Van Groenendael[4], R.B. Landewé[5,6], C.F. Allaart[1]. *[1]Rheumatology, LUMC, Leiden, Netherlands; [2]Rheumatology, Hospital Universitario 12 de Octubre, Madrid, Spain; [3]Medical Center Haaglanden, The Hague; [4]Reumazorg Southwest Netherlands, Bergen op Zoom; [5]Amsterdam Rheumatology & Immunology Center, Amsterdam; [6]Zuyderland Medical Center, Heerlen, Netherlands*

Background: It is recommended to optimize treatment as long as a predefined treatment target is not met, but should we aim at remission if patients are in low disease activity (LDA)?

Objectives: To assess if RA or undifferentiated arthritis (UA) patients who achieved LDA benefit with better functional ability from treatment intensification aimed at DAS remission.

Methods: In the IMPROVED study 610 patients with early RA (ACR 2010) or UA were "treated to target" aimed at DAS remission, assessed 4-monthly. Initial treatment was methotrexate (MTX) + tapered high dose prednisone. Patients with DAS≤1.6 tapered treatment. Patients with DAS>1.6 were randomized to MTX + hydroxychloroquine + sulphasalazine + prednisone or to MTX + adalimumab. Over 5 years, patients with DAS>1.6 were required to increase, change or restart medication. HAQ was measured 4-monthly. A linear mixed model analysis with random intercept was performed to test the relationship between changes in therapy and HAQ over time. Patients in LDA with DAS>1.6 with and without (i.e. protocol violation) treatment change were compared. ΔHAQ and ΔDAS at each visit compared to the previous visit were calculated. We tested the interaction effect between change in treatment and follow-up time adjusted for possible confounders.

Results: Overall, over 5 years DAS (baseline mean (SD) 3.2 (1.7)) and HAQ (1.2 (0.7)) showed a statistically significant and clinically relevant decrease (ΔHAQ -0.59, 95% CI -0.61, -0.57; ΔDAS -1.77, 95% CI -1.79; -1.75). The number of patients in LDA per visit ranged from 88 to 146, of which 26% to 73% (increasing over time) had no treatment change due to protocol violations. We found a statistically significant but not clinically relevant effect of treatment change on ΔHAQ, corrected for baseline HAQ, age, gender and treatment arm (model 1, β -0.085, 95% CI -0.13, -0.044). When ΔDAS was added (model 2), the effect of treatment change was partly explained by ΔDAS and no longer statistically significant (β -0.022, 95% CI -0.060; 0.015). The effect of treatment intensification on HAQ improvement became less over time, as demonstrated by a statistically significant interaction between change in HAQ and time in follow-up in model 3 (β 0.0098, 95% CI 0.0010; 0.019) (table 1).

Table 1: Linear Mixed Model analysis to assess the effect of treatment intensification on change in HAQ.

	β	P	95% CI
Model 1 (n patients = 479, n visits = 1528)*			
Treatment intensification	-0.085	<0.001	-0.13; -0.044
Follow-up time[b]	0.0057	0.019	0.00094; 0.010
Model 2 (n patients = 476, n visits = 1509)*			
Treatment intensification	-0.022	0.246	-0.060; 0.016
Follow-up time[b]	0.0022	0.313	-0.0021; 0.0066
DAS change	0.23	<0.001	0.21; 0.26
Model 3 (n patients = 476, n visits = 1509)*			
Treatment intensification * follow-up time	-0.10	0.013	-0.18; -0.021
Follow-up time[b]	-0.0034	0.323	-0.010; 0.0033
Treatment intensification * follow-up time	0.0098	0.029	0.0010; 0.019
DAS change	0.23	<0.001	0.21; 0.26

HAQ = health assessment questionnaire, SE = standard error, CI = confidence interval.
*All models were adjusted for age, gender, treatment arm and baseline HAQ.
[b]Follow-up time is added to the model as visit number, with time between visits being 4 months.

Conclusions: Treatment intensification in early RA or UA patients who have already achieved low disease activity is associated with a statistically significant decrease in HAQ, but not with a clinically meaningful improvement in functional ability. The effect on ΔHAQ decreased with increasing follow-up time. Therefore not remission or low disease activity, but good functional ability may be the optimal treatment target at which to steer treatment adjustments. These results suggest that, whereas remission may be the optimal goal, when patients in low disease activity have acceptably low HAQ, further treatment intensification may only have downsides such as side effects and costs.

SAT0068 THE TIME UNTIL PERFORMING TIGHT CONTROL AS A TREAT-TO-TARGET STRATEGY AND THE TOLERABILITY OF METHOTREXATE STRONGLY INFLUENCE THE ACHIEVEMENT OF CLINICAL REMISSION IN RHEUMATOID ARTHRITIS

T. Hagiwara, K. Kamada, N. Namura. *Rheumatology, Takarazuka City Hospital, Takarazuka, Japan*

Background: Clinical remission (CR) is the first targeted outcome of early treatment for rheumatoid arthritis (RA). Therefore, a consensus is needed for achieving CR by using the treat-to-target (T2T) strategy in RA treatment. However, in patients who received long-term insufficient treatment for RA, achievement of CR becomes increasingly difficult, especially if there is delay in the treatment.

Objectives: We aimed to examine factors that hinder successful RA treatment. We believe that making primary-care physicians aware of treatment results will increase the remission rate of RA.

Methods: We examined 388 patients with RA who were observed between January and October 2016 and who had not received new disease-modifying anti-rheumatic drugs (DMARDs) more than 3 months before the observation day. We investigated their age at RA onset, sex, Steinbrocker radiographic stage and functional class, activity level, rheumatoid factor (RF), the anti-cyclic citrullinated peptide antibody and DMARDs prescribed at the first consultation (Prescribed Before), disease activity, status of methotrexate (MTX), glucocorticoids (GCs), and biologic agent use at the last observational day.

First, we analysed the assumed remissions by using the Boolean-based definition (Boolean remission) as a purpose variable for these factors. Furthermore, we examined the odds ratio (OR) and 95% confidence interval (95% CI) by using a multiple logistic regression analysis for the statistically significantly different factors.

As for the time-related factor, we recognized that each factor had distinct multiplex collinear characteristics. Therefore, we adopted the time required for the first consultation as disease duration with the most effective values as the analysis object. The representative factor for the functional assessment adopted class according to the number of effective analyses.

Results: We recognised the statistically significant differences in disease duration, stage, class at the time of the first medical examination, RF, Prescribed Before, and state of MTX and GCs use at the last observation day for the achievement of Boolean remission.

We examined the multiple logistic regression analysis with the previously mentioned results and obtained the following results.

- Disease duration (per 1 year); OR 1.110, 95% CI 1.048–1.175, p<0.001.
- MTX (state; using vs no using); OR 2.522, 95% CI 1.560–4.076, p<0.001.
- Class at 1st interview; OR 1.512, 95% CI 1.126–2.029, p<0.01.
- GCs (state; no using vs using); OR 1.803, 95% CI 0.912–3.565, p=0.090.
- Disease duration (≤1.605y vs >1.605y); OR 2.233, 95% CI 1.437–3.470, p<0.001.
- MTX (state; using vs no using); OR 2.656, 95% CI 1.644–4.291, p<0.001.
- Class at 1st interview; OR 1.589, 95% CI 1.181–2.136, p<0.01.
- GCs (state; no using vs using); OR 1.883, 95% CI 0.956–3.711, p=0.067.

Conclusions: Our results indicated the importance of the time required for consultation facilities with the T2T strategy treatment, tolerability for MTX use, and mild dysfunction at the first interview.

The window of opportunity to achieve remission for patients with RA has less time than expected. Therefore, we recommend that physicians should introduce patients with RA to a rheumatologist following the T2T strategy promptly when the primary care provided by the family physician is insufficient.

SAT0069 A RAPID3-LIKE INDEX DOCUMENTS SUPERIOR EFFICACY OF BARICITINIB TO ADALIMUMAB AND PLACEBO, SIMILAR TO DAS28 AND CDAI IN THE RA-BEAM CLINICAL TRIAL IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. Pincus[1], B. Zhu[2], C.J. Larmore[2], J.D. Bradley[2], N. Patel[2], C.L. Gaich[2], A.E. Koch[2]. *[1]Rush University Medical Center, Chicago; [2]Eli Lilly and Company, Indianapolis, United States*

Background: RAPID3 (Routine Assessment of Patient Index Data) indicates differences in efficacy of active versus control treatments at levels similar to DAS28-ESR (Disease Activity Score 28-Erythrocyte Sedimentation Rate) and CDAI (Clinical Disease Activity Index) in clinical trials of adalimumab, abatacept, certolizumab.
Objectives: To compare improvement according to RAPID3, DAS 28-ESR, and CDAI in the RA-BEAM trial of baricitinib vs adalimumab and placebo.
Methods: Post-hoc analyses were performed of the RA-BEAM trial, in which patients with moderately to severely active rheumatoid arthritis and an inadequate response to methotrexate (MTX) were randomized to baricitinib, adalimumab, or placebo. All patients were to continue stable background MTX and other DMARDs, as well as stable low-dose prednisone and/or NSAIDs, if indicated. A RAPID3-like index was computed from 3 measures: physical function (FN), pain (PN), and patient global assessment (PATGL). FN on a HAQ (Health Assessment Questionnaire) of 20 items [rather than MDHAQ (multidimensional HAQ) of 10 items] was recalculated from 0–3 to 0–10; PN and PATGL (visual analog scales) were recalculated from 0–100 to 0–10, for a 0–30 total score, hence "RAPID3-like". Mean values at baseline and Week 24 for RAPID3-like, DAS28-ESR, and CDAI, and percent change from baseline were computed in the 3 treatment groups. The proportion of patients with high/moderate activity/severity at Week 24 versus low activity/severity/remission, as well as correlations of the 3 indices at Week 24, were calculated. Statistical significance for percent change was analyzed using Wilcoxon tests, after imputation of missing values using modified last observation carried forward (mLOCF); low activity/severity/remission was compared between groups using a logistic model, adjusting for region and baseline joint erosion status after imputation of missing values using non-responder imputation.
Results: Improvement from baseline to Week 24 ranged from 19.2% to 37.0% in placebo patients, 40.0% to 65.9% in baricitinib-treated patients, and 37.6% to 60.9% in adalimumab-treated patients (Table), least in DAS28-ESR, intermediate in RAPID3-like, and highest in CDAI. Changes according to RAPID3-like, DAS28-ESR and CDAI were similar in the 3 treatment groups; baricitinib and adalimumab were superior to placebo according to all indices, and baricitinib was superior to adalimumab according to RAPID3-like and CDAI (Table). Correlations of RAPID3-like with DAS28-ESR and CDAI ranged from r=0.61 to 0.75 and for DAS28-ESR with CDAI from r=0.86 to 0.91 (all $p<0.001$). The proportion of patients with low activity/severity/remission at Week 24 ranged from 9.6% to 19.7% in placebo patients, 31.6% to 49.9% in baricitinib-treated patients, and 33.6% to 47.6% in adalimumab-treated patients. RAPID3-like results were intermediate between DAS28-ESR and CDAI.

Table. Disease Activity/Severity by 3 Indices through Week 24 in RA-BEAM

		Baseline Mean	Week 24 Mean	Week 24 % Change from Baseline	Correlation with DAS28-ESR	Correlation with CDAI	High or Mod at Week 24 n (%)	Low or Remission at Week 24 n (%)

	All (N=1305)				N/A	0.90		
CDAI	Placebo (N=488)	37.6	23.4	-37.0%	0.91	N/A	392 (80.3%)	96 (19.7%)
	Baricitinib (N=487)	38.1	13.0	-65.9%***‡	0.86	N/A	244 (50.1%)	243 (49.9%)***
	Adalimumab (N=330)	38.0	15.0	-60.9%***	0.87	N/A	173 (52.4%)	157 (47.6%)***
	All (N=1305)				0.90	N/A		

***Significant at 0.001 level, Baricitinib or Adalimumab vs.Placebo.
‡‡, ‡Significant at 0.01 and 0.05 levels respectively, Baricitinib vs. Adalimumab.
Abbreviations: CDAI=Clinical Disease Activity Index; DAS28-ESR=Disease Activity Score 28-erythrocyte sedimentation rate; High=high disease activity/severity; Low=low disease activity/severity; Mod=moderate disease activity/severity; N=number of patients; RAPID3-like=Routine Assessment of Patient Index Data 3-like.

Conclusions: RAPID3-like documented greater efficacy of baricitinib versus adalimumab and placebo in the RA-BEAM trial, with results in similar ranges to DAS28-ESR and CDAI. RAPID3 is feasible to provide quantitative, standard medical history data; almost of the time and effort is by the patient rather than a health professional, assuring quantitative data in the infrastructure of usual clinical care.

SAT0070 BARICITINIB VERSUS ADALIMUMAB IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS: ANALYSIS OF PATIENTS ACHIEVING A MODERATE EULAR RESPONSE AT WEEK 4

T.K. Kvien[1], P. van Riel[2], A. Rubbert-Roth[3], R. Blanco[4], S.S. Liu-Leage[5], E. Larsson[5], H. Lund[5], P. López-Romero[5], L. Zaremba-Pechmann[5], P. Emery[6]. *[1]Diakonhjemmet Hospital, Oslo, Norway; [2]Bernhoven, Uden, Netherlands; [3]Uniklinik Köln, Köln, Germany; [4]Hospital Universitario Valdecilla, Santander, Cantabria, Spain; [5]Eli Lilly and Company, Indianapolis, United States; [6]Leeds MSK Biomed/Chapel Allerton Hosp, Leeds, United Kingdom*

Background: Baricitinib (BARI) is a selective inhibitor of Janus kinase,[1] improves disease activity in patients (pts) with rheumatoid arthritis (RA), and is associated with inhibition of structural joint damage.[2–4] Response to BARI observed at week (wk) 4 may be useful to predict future response.[5]
Objectives: To characterise pts with RA who achieved moderate EULAR responses (MERs)[6] at wk 4 and to describe the outcomes through wk 52 while continuing the assigned treatment.
Methods: Pts enrolled in the RA-BEAM study with active RA who had an inadequate response to methotrexate (MTX) were randomised 3:3:2 to placebo (PBO), BARI 4 mg once daily, or adalimumab (ADA) 40 mg biweekly.[1] Pts who showed good or no EULAR responses at wk 4 were excluded. For the MER cohort, the cumulative incidence for first transition to good EULAR response and to no EULAR response from wk 4 through wk 52 was estimated in the presence of competing risks events, which either hinder observation of the events of interest or modify the chance that these events occur.[7] Pts who transitioned from MER to no EULAR response or pts who were rescued or discontinued because of an adverse event or lack of efficacy were counted as no EULAR response; pts who discontinued the study for other reasons (eg, lost to follow-up, death) were censored at the time of discontinuation. No formal statistical tests were performed for these post hoc analyses.
Results: Of 1305 pts who received at least 1 dose of study drug, 683 experienced MERs at wk 4, including 37.3% (182/488), 62.0% (302/487), and 60.3% (199/330) of pts on PBO, BARI, and ADA, respectively. Pts who achieved MERs at wk 4 on BARI and ADA had similar baseline disease activity characteristics (Table 1). The mean age of the MER subgroup was 53 years, and the mean disease duration was 8.7 years. The mean MTX dosage was 15 mg/wk, and 59% of pts were taking concomitant oral glucocorticoids. At wk 4, 27% (131/487) and 11% (54/487) of pts on BARI vs 29% (95/330) and 11% (36/330) of pts on ADA experienced no response or good response, respectively. The cumulative incidence for the first transitions to good EULAR response at wks 12, 24, and 52 was higher in pts who reached MERs at wk 4 on BARI than those on ADA. The cumulative incidence for the first transitions to subsequent no EULAR response was higher in pts who achieved MER at wk 4 on ADA (Figures 1A and 1B, Table 2) than those on BARI.
Conclusions: Among pts achieving early MER on BARI and ADA, subsequent loss of response was less common for pts on BARI than for those on ADA. Transitions to good EULAR response were more common for pts who achieved MERs on BARI than for those on ADA. Mechanistic explanations warrant future study.

Table 1: Baseline Characteristics for Patients with Moderate EULAR Response at Week 4

Characteristic	Baricitinib n = 302*	Adalimumab n = 199*
Background therapy (MTX only), no. (%)	259 (85.8)	173 (86.9)
Background therapy (MTX + other cDMARD), no. (%)	43 (14.2)	26 (13.1)
DAS28-ESR, mean (SD)	6.6 (0.9)	6.5 (0.9)
DAS28-ESR category, no. (%)		
>3.2 to ≤5.1	12 (4.0)	8 (4.0)
>5.1	290 (96.0)	191 (96.0)
Baseline mTSS, mean (SD)	42.0 (50.0)	47.1 (51.9)
HAQ-DI total score, mean (SD)	1.6 (0.7)	1.6 (0.7)

SAT0071 RHEUMATOID ARTHRITIS (RA) REGISTRY IN AKITA PREFECTURE, WHERE AGING IS THE MOST ADVANCED IN JAPAN

T. Aizawa[1], T. Kashiwagura[2], N. MIyakoshi[3], Y. Shimada[3]. *[1]Dept. of Orthopedic Surgery, Kitaakita Municipal Hospital, Kitaakita City; [2]Akita City Hospita; [3]Dept. of Orthopedic Surgery, Akita University Graduate School of Medicine, Akita City, Japan*

Background: The rate of aging (percentage of population aged 65 years and over) in Akita Prefecture is 33.8% (26.6% for the whole of Japan), the highest throughout Japan. The Akita Orthopaedic Group on Rheumatoid Arthritis (AORA) was established in 2010. Since then, patients have been enrolled every year to prepare the registry.
Objectives: To compare patient characteristics as well as clinical effectiveness between the treatments with and without use of methotrexate (MTX) and a biological (BIO) using the data of the AORA registry.
Methods: The subjects were 2,016 patients enrolled in the Akita registry in 2015. The subjects included 403 men and 1,613 women. According to the use of MTX and BIO, 2,016 patients were divided into the group treated with no use of MTX or BIO (group A), that treated with BIO, but no use of MTX (group B), that treated with MTX, but no use of BIO (group C), and that treated with MTX and BIO (group D).
Results: The subjects were grouped into group A (n=673), B (n=153), C (n=805), and D (n=385). MTX was used in 59.0% and BIO was used in 26.7% of all patients. The mean ages were 69.6 years (group A), 65.7 years (group B), 65.6 years (group C), and 62.6 years (group D). The aging rates were 67.9% (group A), 55.6% (group B), 56.8% (group C), and 48.3% (group D), which shows that aging was more advanced in group A.
The rates of patients with a complication of hypertension, diabetes, respiratory disease, cerebrovascular disease, heart disease or malignant tumour were 52.0% (group A), 54.2% (group B), 45.5% (group C), and 40.8% (group D). The incidence of complication was the lowest in group D.
The rates of patients who received one or more of conventional synthetic disease-modifying antirheumatic drugs (cs DMARDs) other than MTX were 79.0% (group A), 42.5% (group B), 39.9% (group C), and 19.2% (group D). Although bucillamine and salazosulfapyridine were frequently used in any group, concomitant use of tacrolimus was remarkable in group A and C, while that of iguratimod was remarkable in groups C and D. The rate of use of a prednisolone (PSL), was significantly higher in group B. The dose of PSL was significantly higher in group A. In regard to BIO, three drugs of etanercept, tocilizumab, and abatacept accounted for 90% in group B. In group D, etanercept and tocilizumab were also frequently used, followed by infliximab, adalimumab, golimumab and abatacept.
In DAS28ESR, the rate of combined low disease activity and remission was significantly higher in group D. The mean values of C-reactive protein (CRP) (mg/dL) were 0.61 (group A), 0.52 (group B), 0.47 (group C), and 0.35 (group D), which shows that the mean value was significantly higher in group A than group D. The mean values of matrix metalloproteinase 3 (MMP3) (ng/dL) were 119.0 (group A), 130.6 (group B), 100.7 (group C), and 88.9 (group D), which shows that the mean value was significantly higher in group A and B than group C and D.
Conclusions: Using the AORA registry, we compared patient characteristics as well as clinical effectiveness between the treatments with and without use of MTX and BIO. Since in group A, neither MTX nor BIO could be used in most patients, one had to practically rely on PSL. The study suggests that remission needs to be achieved prior to increase in complication due to aging.

SAT0072 DOSE REDUCTION OF BARICITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS ACHIEVING SUSTAINED DISEASE CONTROL: RESULTS OF A PROSPECTIVE STUDY

T. Takeuchi[1], M. Genovese[2], B. Haraoui[3], L. Xie[4], R. Klar[5], A. Luisa Pinto Correia[4], T. Rooney[4], S. Otawa[4], J.S. Smolen[6]. *[1]Keio University, Tokyo, Japan; [2]Stanford University Medical Center, Palo Alto, United States; [3]Centre Hospitalier de l'Université de Montréal, Montreal, Canada; [4]Eli Lilly and Company, Indianapolis; [5]Quintiles IMS Holdings, Inc, Durham, United States; [6]Medical University of Vienna, Vienna, Austria*

Background: In patients (pts) with active rheumatoid arthritis (RA) and inadequate response (IR) to DMARDs, ph3 studies demonstrated efficacy of baricitinib (bari) (2mg and 4mg). Larger, more rapid treatment effects were observed for bari 4mg.
Objectives: To investigate the effects of bari dose step-down in pts who achieved sustained disease control with bari 4mg.
Methods: Pts with RA who completed a bari ph3 study could enter a long-term extension (LTE) study. In the LTE, pts who received bari 4mg for ≥15 months and who achieved sustained low disease activity ([LDA]-CDAI score ≤10) or remission (CDAI ≤2.8) at 2 consecutive visits ≥3 months apart were re-randomised in a blinded manner to continue bari 4mg or step down to 2mg. Patients could rescue (to bari 4mg) if CDAI >10. Efficacy and safety were assessed through 48 weeks (wks) following re-randomisation.
Results: Among pts who achieved sustained disease control with bari 4mg, dose reduction to 2mg resulted in significant increases in disease activity at 12, 24, and 48 wks; however, the majority of pts in both groups maintained the state of LDA

Abstract SAT0072 – Table 1

	Pts originating from RA-BEAM, RA-BUILD, RA-BEACON Combined†					
	Week 12		Week 24		Week 48	
	Continued bari 4 mg N=396	Stepped down to bari 2 mg N=394	Continued bari 4 mg N=353	Stepped down to bari 2 mg N=358	Continued bari 4 mg N=245	Stepped down to bari 2 mg N=245
Efficacy measure	NRI after rescue or for missing data					
CDAI LDA ≤10	359/396 (90.7)	326/393 (83.0)**	309/353 (87.5)	269/357 (75.4)***	198/245 (80.8)	167/245 (68.2)**
CDAI remission ≤2.8	158/396 (39.9)	143/393 (36.4)	149/353 (42.2)	127/357 (35.6)	99/245 (40.4)	82/245 (33.5)
	NRI only for missing data (observed data used after rescue)					
CDAI LDA ≤10	359/396 (90.7)	326/393 (83.0)**	314/353 (89.0)	289/357 (81.0)**	212/245 (86.5)	196/245 (80.0)
CDAI remission ≤2.8	158/396 (39.9)	143/393 (36.4)	150/353 (42.5)	133/357 (37.3)	103/245 (42.0)	90/245 (36.7)
Safety measure	Wks 0–48					
n [EAIR/100 PYE]	Continued bari 4mg N=396				Stepped down to bari 2mg N=394	
SDEAE	225 [70.5]				196 [65.4]	
Infection	99 [31.0]				70 [23.3]	
SAE	23 [7.2]				23 [7.7]	
Serious infection	8 [2.5]				4 [1.3]	
AE → discontinuation	9 [2.8]				11 [3.6]	

Efficacy and safety data are n/N (%), and n [EAIR/100 PYE], respectively. †RA-BEAM = MTX-IR pts; RA-BUILD = csDMARD-IR pts; RA-BEACON = bDMARD-IR pts; EAIR = exposure-adjusted incidence rate; NRI = nonresponder imputation; PYE = patient-years of exposure; SDEAE = step-down emergent adverse event. **p≤0.01, ***p≤0.001 vs. continued bari 4mg.

or remission. Rescue rates were 7.3% for bari 4mg, 17.1% for bari 2mg. Most rescued patients could regain LDA or remission. Dose reduction was associated with a lower rate of non-serious infections; rates of SAEs and AEs leading to discontinuation were similar across groups.

Conclusions: These data indicate that 4mg once daily was the most efficacious dose of bari for pts with RA; increases in disease activity were consistently seen with dose reduction from 4mg to 2mg in well-controlled pts. However, after step-down most pts could maintain LDA or remission, or recapture control with return to 4mg if needed. Attempted dose taper may be a reasonable consideration for some pts following induction of sustained disease control with bari 4mg.

SAT0073 MIR-186-5P TARGETING IL-33 GENE AS BIOMARKER TO PREDICT SUBCLINICAL ATHEROSCLEROSIS IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

T.H. Cheng[1], Q. Shang[1], W.Y. Mak[1], M. Li[1], K.Y. Kwok[2], I.C.W. Yim[3], E.K.M. Li[1], P.C.H. Wong[4], V.W.N. Lao[5], H.T. Pang[5], L.S. Tam[1]. *[1]Department of Medicine and Therapeutics, the Chinese University of Hong Kong; [2]Department of Medicine, Queen Elizabeth Hospital; [3]Department of Medicine, Tseung Kwan O Hospital; [4]Department of Medicine and Therapeutics, Prince of Wales Hospital; [5]Department of Medicine and Geriatrics, Kwong Wah Hosptial, Hong Kong, Hong Kong*

Background: Patients with rheumatoid arthritis (RA) die prematurely compared with the general population, primarily because of cardiovascular diseases (CVD). Interleukin-33 (IL-33) is a member of the IL-1 cytokine family which was important in the pathogenesis of RA and development of CVD. Blood IL-33 protein was not detectable in most subjects, even in RA patients. Thus, the usability of IL-33 as a biomarker for CVD is limited. MicroRNAs (miRNAs) are small non-coding RNAs that function as post-transcriptional regulators of gene expression.

Objectives: This study was to ascertain if dysregulated miRNAs targeting *IL-33* gene in early RA (ERA) patients were associated with subclinical atherosclerosis in ERA patients.

Methods: 76 ERA patients were recruited in this cross-sessional study. Potential miRNAs binding to 3'UTR of the *IL-33* gene were predicted by miRanda (www.microRNA.org). 10 miRNAs with highest possibility targeting functional sites of *IL-33* gene were quantified in cell free plasma samples using a $2^{\Delta Ct}$ method. Caenorhabditis elegans miR-39 (cel-miR-39) was used as spike-in control. The results were then log transferd. Carotid plaque (CP) was measured and identified at bilateral common carotid artery, bulb, and proximal internal carotid artery using a high-resolution B mode ultrasound. Receiver-operating characteristic curve (ROC) analysis was performed to determine the discriminating power of the miRNA for the presence of CP.

Results: CPs were identified in 26/76 (34%) subjects (CP+ group). Subjects in the CP+ group were older [58±10 vs 48±11 years old, p=0.001], predominantly male [48 (42.3%) vs 43 (14.0%), p=0.006], with a higher C-reactive protein (CRP) level [24.9±25.0 vs 11.8±13.7 mg/dL, p=0.018] and higher cardiovascular risk [Framingham risk score (FRS): 12.8±11.6 vs 5.7±6.8, p=0.008] (Table 1). All miRNAs were detected in >80% of subjects in both group. Plasma level of miR-186–5p in the CP+ group was significantly higher than that in the CP- group [log miRNA: 3.28±3.21 vs 2.58±1.13 p=0.008]. It was still significant after adjusting age, sex, plasma CRP and FRS (p=0.030) (Table 1). Using multivariate logistic regression, miRNA-186–5p was an independent predictor of the presence of carotid plaque (OR: 1.919, 95% CI=1.096–3.361, p=0.023) after adjustment of FRS and CRP level. [Area under the ROC (AUC) 0.66, 95% CI: 0.60–0.80 p=0.024].

Conclusions: miR-186–5p was an independent predictor for presence of subclinical atherosclerosis and may serve as a novel biomarker for risk stratification in ERA patients with mild to moderate cardiovascular risk.

Table 1 - Characteristics of patients with and without carotid plaque

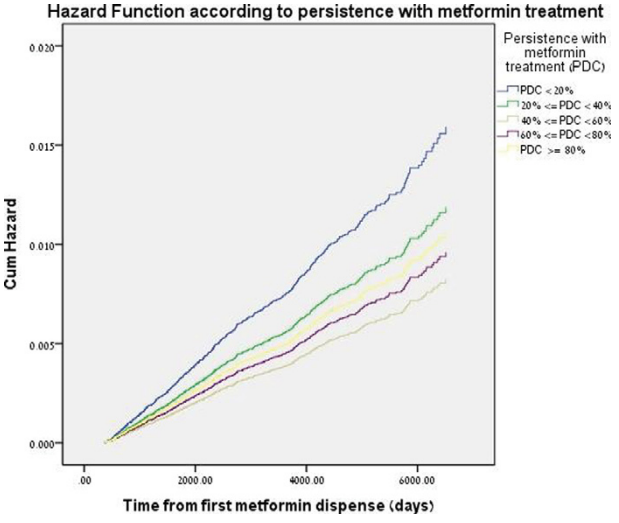
SAT0074 PERSISTENCE WITH METFORMIN TREATMENT AND ONSET OF RHEUMATOID ARTHRITIS



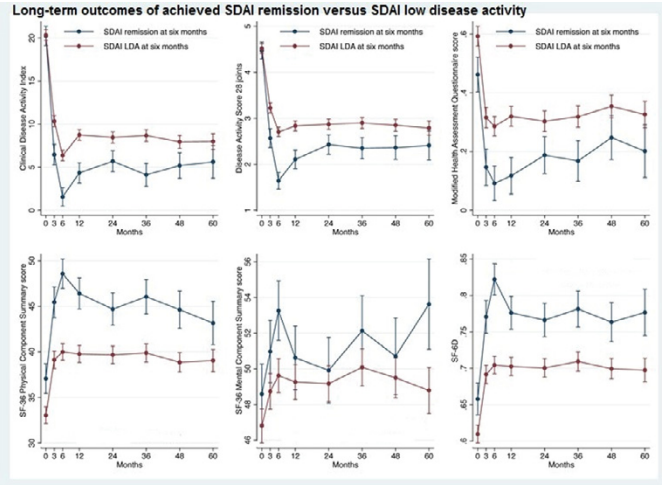
M.E. Naffaa[1], V. Rosenberg[2], G. Chodick[2,3], V. Shalev[2,3], S. Tiosano[3,4], H. Amital[3,4]. *[1]Rheumatology unit, Galilee Medical Center, Nahariya; [2]Maccabi Healthcare Services; [3]Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv; [4]Internal Medicine 'B', Sheba Medical Center, Ramat-Gan, Israel*

Background: Several studies have suggested that metformin, an oral hypoglycemic agent, possess an anti-inflammatory property and may have a role in the treatment of rheumatoid arthritis (RA)[1,2], but little is known on its preventive effects.

Objectives: To examine the association between persistence with metformin and the onset of RA.

Methods: Using the computerized medical database of a large health organization in Israel (Maccabi Healthcare Services, MHS) we have identified incident RA cases among new users of metformin between 1998 and 2014. Included were patients aged 18 or above with one year of follow up before and after the therapy initiation. RA was defined according to physician diagnoses. Participants were followed until the earliest of the following dates: onset of RA, leaving MHS, death, end of follow up (1.1.2016). Persistence with metformin was assessed by calculating the mean proportion of follow-up days covered (PDC) with metformin during the study period.

Results: A total of 113,749 eligible patients were included. During the study follow up period (794,386 person-years) we identified 600 incident cases (incidence rate of 75 cases per 100,000 PY). The incidence of RA in women (111 per 100,000 PY) was higher compared to men (42 per 100,000 PY). In a multivariable model, persistence with metformin (PDC≥80%) was associated with lower risk of RA (hazard ratio (HR) 0.66; 95% confidence interval (CI) 0.53–0.82) compared to non-persistent participants (PDC<20%). Figure 1 shows the hazard function according to persistence with metformin treatment. Similar risk reduction was observed among men but did not reach statistical significance (HR=0.85; 95% CI 0.54–1.32).



Conclusions: In the present study, we observed an association between high persistence to metformin therapy and reduced risk of developing RA in women.

SAT0075 DOES EARLY REMISSION LEAD TO BETTER 5-YEAR OUTCOMES THAN LOW DISEASE ACTIVITY? RESULTS FROM THE REAL LIFE NOR-DMARD STUDY

V. Norvang, I.C. Olsen, E. Lie, E.K. Kristianslund, T.K. Kvien, E.A. Haavardsholm, T. Uhlig. *Department of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway*

Background: When initiating therapy with synthetic disease-modifying anti-rheumatic drugs (sDMARDs) in patients with rheumatoid arthritis (RA), the recommended target is remission or low disease activity (LDA). Limited data exist on the impacts of reaching remission rather than LDA on long-term outcomes.
Objectives: To compare RA-patients who achieved Simplified Disease Activity Index (SDAI) remission versus LDA 6 months after initiating sDMARD therapy, with regard to physical function, Health Related Quality of Life (HRQoL) and disease activity during 5 years of follow-up in a routine clinical setting.
Methods: Data were provided NOR-DMARD, a prospective multicentre longitudinal observational study. We selected DMARD-naïve patients with RA enrolled between December 2000 and April 2009 who had a registered visit with available SDAI status 6 months after initiating sDMARD therapy. Data on each patient were collected at baseline, after 3, 6 and 12 months, and yearly thereafter, including the modified Health Assessment Questionnaire (MHAQ), the Medical Outcomes Study 36-item Short-Form Health Survey (SF-36) with Physical and Mental Components Summary scores (PCS and MCS, respectively) and SF-6D, and assessments that allowed the calculation of the composite disease activity scores SDAI, Clinical Disease Activity Index (CDAI) and the Disease Activity Score based on 28 joint counts (DAS28). Multivariate linear mixed models were used to explore the effect of SDAI status at 6 months on physical function (MHAQ), HRQoL (SF-36 PCS and MCS, SF-6D) and disease activity (SDAI, CDAI, DAS28) during 5 year follow-up. The statistical models were adjusted for age, gender, disease duration and baseline disease activity. Furthermore, we performed mixed model analyses separately for patients in LDA, MDA and HDA at baseline, exploring the impact of SDAI status at 6 months on long-term disease activity in each sub-group.
Results: Of 1148 eligible patients, 867 patients (75.5%) started with methotrexate in monotherapy and 281 (24.5%) started with another sDMARD or sDMARD combination. Patients in SDAI remission (n=145; 16.6%) rather than LDA (n=454; 39.5%) 6 months after initiating therapy had better physical function (MHAQ, estimated mean difference 0.11–0.20, $p<0.02$), higher SF-36 PCS (4.13–8.16, $p<0.003$) and SF-6D (0.06–0.12, $p<0.0001$), and lower disease activity (SDAI, 2.24–5.15, $p<0.05$) for all visits during 5 years of follow-up. Stratified mixed models analyses of patients in SDAI LDA, MDA and HDA at baseline, resulted in an overall significant long-term beneficial effect of achieving remission rather than LDA at 6 months; however, the differences were less distinct for patients who were already in a state of LDA at baseline.

Conclusions: The achievement of SDAI remission 6 months after initiating DMARD-therapy was associated with favourable long-term outcomes compared with the achievement of SDAI low disease activity. The results from the study support that stringent remission is the optimal treatment target in patients with RA.

SAT0076 SERUM LEVEL OF SYNDECAN-4 AND ITS CORRELATION WITH CLINICAL PARAMETERS IN RHEUMATOID ARTHRITIS PATIENTS

X. Ye, J. Zhao, Z. Zhang. *Rheumatology and Clinical Immunology Department, Peking University First Hospital, Beijing, China*

Background: Heparan sulfate proteoglycan syndecan-4 plays an important role in inflammation. However, the role of syndecan-4 in rheumatoid arthritis (RA) has not yet been elucidated.
Objectives: To detect serum level of syndecan-4 in RA patients and investigate its correlation with RA clinical parameters.
Methods: The concentration of serum syndecan-4 was assayed by enzyme-linked immunosorbent assay (ELISA). 43 patients' serum samples from our RA cohort study between 2014 and 2016, and 20 age- and gender-matched osteoarthritis (OA) patients' serum samples were collected and analyzed. Compared the serum syndecan-4 levels in RA patients with DAS28$\geq$3.2 and DAS28$<$3.2 by Wilcoxon signed rank test. The relationships between serum syndecan-4 levels and RA clinical parameters (DAS28, rheumatoid factor (RF), erythrocyte sedimentation rate, C-reactive protein, etc.) were analyzed.
Results: Baseline serum syndecan-4 levels of RA patients were significantly higher than the matched OA patients (1101.56 pg/mL vs 281.41 pg/mL, $p<0.001$). In RA patients who had sera both at the point of DAS28$\geq$3.2 and DAS28$<$3.2 (n=13), we found that the former syndecan-4 levels were higher than the latter (1666.22 pg/mL vs 1378.34 pg/mL, p=0.65). The levels of serum syndecan-4 and RF were significantly and positively correlated in RA patients (r=0.696, p=0.008). Furthermore, there is a tendency that serum syndecan-4 levels were higher in the RF-positive (n=31) than in the RF-negative (n=12) RA patients (1344.43 pg/mL vs 971.27 pg/mL, p=0.078).

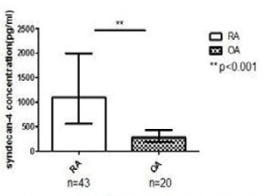

Figure 1. Serum syndecan-4 levels of RA patients and matched OA patients.

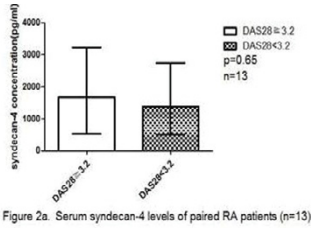

Figure 2a. Serum syndecan-4 levels of paired RA patients (n=13)

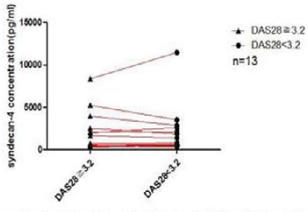

Figure 2b. Serum syndecan-4 levels of paired RA patients (n=13).

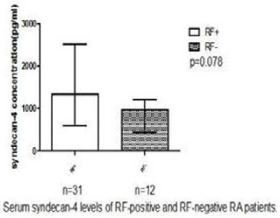

Figure 3. Serum syndecan-4 levels of RF-positive and RF-negative RA patients

Conclusions: Compared with age- and gender- matched OA patients, serum syndecan-4 concentration is significantly higher in RA patients. Serum syndecan-4 level is positively correlated with RF. Syndecan-4 may play an important role in thes pathogenesis of RA. Further investigation is required to study the mechanism of syndecan-4 in RA.

SAT0077 CLINICAL FEATURES AND PERFORIN A91V GENE ANALYSIS IN SO-JIA CHILDREN WITH MACROPHAGE ACTIVATION SYNDROME

X. Chen[1], H. Zeng[2]. *[1]Department of Pediatric Allergy, Immunology and Rheumatolog; [2]Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children's Medical Center, Guangzhou, China*

Objectives: Macrophage activation syndrome (MAS) is a severe, potentially life-threatening syndrome.Here we aim to review the precipitating events,clinical features, treatment, outcome and perforin A91V gene analysis in systemic onset juvenile idiopathic arthritis (SoJIA) children with MAS.

Methods: Retrospective review of cases of MAS from a collected database of fourteen children with SoJIA from 2003 to 2008. Gene-specific polymerase chain reaction (PCR) primers were used to analyze the perforin A91V gene polymorphism.
Results: Fourteen patients (nine boys) were considered to have evidence of MAS, with age ranged from 4 months to 12 years.The primary diagnosis was systemic onset juvenile idiopathic arthritis.No medication was identified as trigger. Eleven had infections prior to MAS,specific infectious agents were identified in four. High fever, new onset hepatosplenomegaly, lymphadenopathy, liver dysfunction,abnormal lipid metabolism and hemophagocytosis were common clinical features.Two cases were with acute respiratory distress syndrome (ARDS),multiple organ failure (MOF) in three and three died. The perforin A91V (NCBI:SNP rs35947132) variant gene was detected in seven systemic onset juvenile idiopathic arthritis compolicated with MAS cases, but no mutation were found. Glucocorticoid, intravenous immunoglobulin, immunoimpressive therapy were effective and HP (Plasmapheresis) used in one serious case was also effective.
Conclusions: MAS is a rare and potentially fatal complication of childhood rheumatoid diseases,especially systemic onset juvenile idiopathic arthritis. Most of our patients were male, and most cases were preceded by infection. Bone marrow studies support the diagnosis. MOF may be a poor prognostic sign.Aggressive early therapy is essential.

SAT0078 MAGNETIC RESONANCE IMAGING OF THE HANDS IN RHEUMATOID ARTHRITIS: UNILATERAL OR BILATERAL?

Y.-Q. Mo[1], Z.-H. Yang[2], H.-N. He[3], J.-D. Ma[1], J.-J. Liang[1], L. Dai[1].
[1]Rheumatology; [2]Radiology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University; [3]Zhongshan School of Medicine, Guangzhou, China

Background: MRI had higher sensitivity of detecting inflammation than physical examination and higher sensitivity of detecting bone damage than X-rays. Physical examination and X-rays are usually performed on bilateral hands of RA patients, however, MRI evaluation of unilateral hand was recommended by OMERACT at the very beginning when RA MRI score (RAMRIS) was validated in the databases only consisting of images of dominant wrists and/or metacarpal phalangeal joints (MCPJs). Recently, high performance of whole-body MRI and multi-channel synergic coil enable simultaneous scan of bilateral hands.
Objectives: To explore the advantages of bilateral hands MRI on RA.

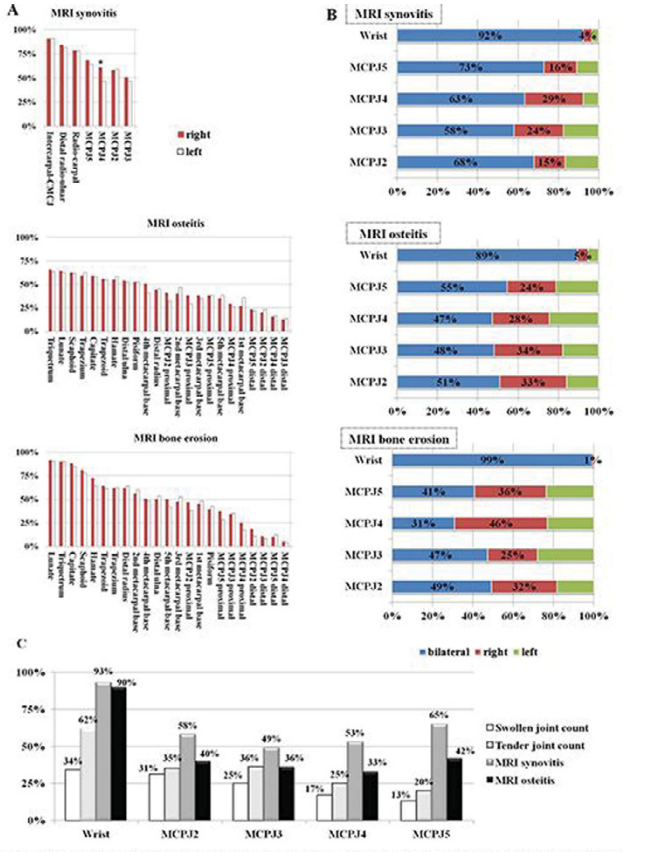

Figure 1 A: The frequencies of MRI synovitis, osteitis and bone erosion per joint or bone in the right and left hands of RA patients separately. B: The percentages of bilateral or unilateral involvement for each joint among patients with MRI synovitis, osteitis and bone erosion. C: The frequencies of joint swelling, tenderness, MRI synovitis and osteitis in wrists and MCPJ2~5 separately among 120 RA patients. MRI synovitis in the wrist included synovitis in distal radio-ulnar joint, radio-carpal joint and intercarpal-CMCJs. MRI osteitis in the wrist included osteitis in eight carpal bones, the distal radius, the distal ulna and five metacarpal bases. MRI osteitis in each MCPJ contained two parts: metacarpal head (proximal) and phalangeal base (distal). * p<0.05.

Methods: Consecutive hospitalized RA patients were recruited from April 2014 to April 2016 at Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University. Together with assessing swelling and tenderness of 28 joints essential for DAS28, bilateral wrists and MCPJ2~5 of each patient were scanned simultaneously on 3.0T MRI system. MRI synovitis, osteitis and bone erosion were scored referred to the definitions and atlas of RAMRIS system.
Results: (1) Among 120 RA patients were included, 79% were female, age (median and IQR, similarly hereinafter) was 52 (44~61) years, disease duration was 48 (12~120) months and DAS28-crp was 5.9 (4.7~6.9). The mean imaging time for the entire MRI examinations including the time of patient positioning and contrast agent injection was 23 minutes. The mean scoring time was 10 minutes for $RAMRIS_{bilateral\ hands}$ and 7 minutes for $RAMRIS_{unilateral\ hand}$. Interreader ICC for $RAMRIS_{bilateral\ hands}$ was 0.852 in synovitis, 0.739 in osteitis and 0.815 in bone erosion.
(2) The frequencies of MRI synovitis, osteitis and bone erosion per joint or bone were shown in figure1A. For MCPJ2~5, 27%~42% of RA patients showed unilateral synovitis, 45%~53% showed unilateral osteitis and 51%~69% showed unilateral bone erosion (Figure1B).
(3) Of wrists with MRI synovitis, 73% were not swollen and 48% were not tender at physical examination. Of wrists with MRI osteitis, 74% were not swollen and 49% were not tender. Similar trend was seen in MCPJ2~5 (Figure1C).
(4) The most clinically involved hands (or dominant hand in case of equally severe involved) were usually chosen for MRI of unilateral hand. Here 70 patients showed more severe involvement in unilateral hand according to patients' complaint and physical examination. However, MRI verified 42%, 40% and 42% of them respectively had more synovits, osteitis and bone erosion in the opposite hand. The other 50 patients had equally severe involvement at physical examination and the dominant hands were chosen. MRI verified 30%, 49% and 33% of them respectively had more synovits, osteitis and bone erosion in the non-dominant hand.
(5) $RAMRIS_{bilateral\ hands}$ was correlated positively with RA disease activity indices, X-ray Sharp/vdH total score and subscores (all $p<0.05$). Moderate correlation was found between $RAMRIS_{bilateral\ hands}$ in synovitis and ESR, CRP, TJC28, SJC28, DAS28, SDAI or CDAI (all $r>0.4$, $p<0.001$). Relatively high correlation was found between $RAMRIS_{bilateral\ hands}$ in bone erosion and X-ray Sharp/vdH total score or erosion subscore (all $r>0.7$, $p<0.001$).
Conclusions: Performing MRI of bilateral hands yields additive information compared with imaging only unilateral hand.

SAT0079 ASSOCIATION OF ALCOHOL CONSUMPTION AND DISEASE ACTIVITY IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS: ANALYSIS OF THE IORRA COHORT

Y. Shimizu[1], E. Tanaka[1], E. Inoue[1,2], M. Ochiai[1], R. Yamaguchi[1], N. Sugimoto[1], A. Nakajima[1], K. Ikari[1], A. Taniguchi[1], H. Yamanaka[1]. *[1]Tokyo Women's Medical University Institute of Rheumatology; [2]National Center for Child Health and Development Center for Clinical Research for Development, Tokyo, Japan*

Background: While the results of several observational studies suggest that light-to-moderate alcohol consumption may decrease the risk for susceptibility to or severity of rheumatoid arthritis (RA) (1–3), findings regarding the effect of alcohol consumption on RA disease activity are conflicting. Furthermore, there are few reports of longitudinal studies regarding the effect of alcohol consumption on RA disease activity. In addition, although alcohol consumption in the Japanese general population was lower than that in European countries, according to the 2011 World Health Organization's Global Status Report on Alcohol and Health, there are few reports specifically concerning alcohol consumption in Japanese RA patients.
Objectives: To examine the longitudinal relationship between alcohol consumption and changes in disease activity in patients with RA using the Institute of Rheumatology, Rheumatoid Arthritis (IORRA) cohort database.
Methods: Subjects were RA patients who participated in the IORRA cohort study between October 2014 and October 2015. Patients were assigned to one of 5 groups according to alcohol-drinking status at baseline: the non-drinking group, drinking group 1 (0 g < amount of drinking per day [Alco-drink] ≦14 g), drinking group 2 (14 g < Alco-drink ≦28 g), drinking group 3 (28 g < Alco-drink ≦50 g), and drinking group 4 (50 g < Alco-drink). Multiple regression analyses were used to examine the relationship between alcohol consumption and baseline DAS28, and change in DAS28 between baseline and 1 year.
Results: Data from a total of 4,695 Japanese patients with RA (female: 86.6%, mean age: 61.3 years old, mean disease duration: 15.2 years, and mean DAS28: 2.5) were analyzed. The number of patients and their characteristics (% female, mean age, mean disease duration, mean DAS28 at baseline/after 1 year) in the non-drinking group, and drinking groups 1, 2, 3, and 4 were 2,735 (92.8%, 64.0 years old, 16.1 years, 2.7/2.7); 646 (89.9%, 58.7 years old, 14.8 years, 2.4/2.5), 497 (82.5%, 56.7 years old, 13.8 years, 2.3/2.3), 444 (71.6%, 56.4 years old, 13.0 years, 2.3/2.3), and 373 (58.2%, 57.5 years old, 13.7 years, 2.2/2.3), respectively. Baseline DAS28 in drinking groups 2 (p=0.02), 3 ($p<0.01$), and 4 ($p<0.01$) was significantly lower than that in the nondrinking group. Multivariate regression analysis revealed that there was no association between alcohol-drinking status and the change in DAS28 at 1 year, after adjusting for DAS28 at baseline.

Conclusions: Although moderate-to-heavy alcohol consumption was associated with lower baseline DAS28 in patients, alcohol drinking status was not associated with change in disease activity, as measured by DAS28, at 1-year follow-up.

SAT0080 CLINICAL SIGNIFICANCE OF SOLUBLE CD163 IN REFRACTORY SYSTEMIC-ONSET IDIOPATHIC ARTHRITIS

Y. Cui[1], H. Zeng[2]. *[1]Department of Pediatric Allergy, Immunology and Rheumatolog; [2]Department of Pediatric Allergy, Immunology and Rheumatology, Guangzhou Women and Children's Medical Center, Guangzhou, China*

Objectives: The present study explored the correlation of soluble CD163 with refractory systemic-onset juvenile idiopathic arthritis (refractory So-JIA) as well as the clinical significanceof soluble CD163 in (refractory So-JIA).
Methods: A total of 33 young patients diagnosed with So-JIA in the active period and 30 young patients diagnosed with So-JIA in the inactive period at Guangzhou Women and Children's Medical Center (Guangzhou, China) from January 2010 to January 2012 as well as 40 age-matched healthy individuals, who had visited the hospital for medical examination in the same time-period were enrolled in the present study. Flow cytometry was used to determine the lymphocyte count and ELISA was adopted for determining the levels of soluble CD163 in serum
Results: The levels of soluble CD163 and their correlation with indexes of disease activity were observed. In patients with So-JIA in the active period, the levels of soluble CD163 and the Tcell count were significantly higher than those in the inactive So-JIA and healthy individuals ($P<0.05$). Furthermore, the levels of soluble CD163 were positively correlated with C-reactive protein, ferritin, erythrocyte sedimentation rate, white blood cell count and immunoglobulin E as indexes of disease activity ($P<0.05$).
Conclusions: Soluble CD163 is a more valuable index for early recognise refractory active So-JIA, which can provide a basis for active period development and clinical observation.

SAT0081 RELATIONSHIP BETWEEN RHEUMATOID FACTOR POSITIVITY AND TREATMENT EFFECT WITH A FIRST BIOLOGIC AGENT IN RHEUMATOID ARTHRITIS: MULTICENTER STUDY USING A MIXED-EFFECT MODEL

Y. Ogawa[1], N. Takahashi[2], N. Ishiguro[2], T. Kojima[2]. *[1]Sakashita Hospital, Nakatsugawa; [2]Nagoya University Graduate School of Medicine, Nagoya, Japan*

Background: Although the presence of rheumatoid factor (RF) may be a risk factor for the onset and progression of rheumatoid arthritis (RA), sufficient literature does not exist to support the clinical relationship between RF positivity and the effects of treatment with biologic disease-modifying antirheumatic drugs (bDMARDS). This multicenter study aimed to explore the association of RF positivity with the effects of bDMARDS treatment in bio-naïve RA patients using a linear mixed-effect model.
Objectives: In a multicenter study, patients are clustered within institutions, therefore results of adjustment models are likely to be biased by random, unobserved between-institution differences. Such bias could lead to inaccurate prediction and interpretation of outcomes. We used a linear mixed-effect model including between-institution variation as a random effect, which would improve the performance of this multicenter study.
Methods: In total, 625 bio-naïve RA patients registered in the Tsurumai Biologics Communication Registry (TBCR), which comprises Nagoya University and 15 affiliated institutions in Japan, who received bDMARDS treatment during the study period (2006–2016) were eligible for inclusion. Demographic information and disease characteristics were assessed at baseline. DAS28 using erythrocyte sedimentation rate was recorded at baseline and following 24 weeks of therapy. In order to predict DAS28 improvement at 24 week, a linear mixed-effect model including between-institution variation as a random effect, controlling for RF positivity, age, sex, stage, methotrexate (MTX) use, prednisolone (PSL) use, tumor necrosis factor inhibitor (TNFi) or non-TNFi, and DAS28 at baseline, was developed.
Results: Of the 625 patients, 513 showed RF positivity and 112 were antibody negative. Mean ± SD age at baseline was 56.9±14.0 years; 509 patients were women (81.4%). The mean ± SD DAS28 score at baseline was 5.19±1.24. Proportion of MTX and PSL use were 79.3% and 58.1%, respectively. Following adjustment for relevant covariates, RF positivity was associated with a decrease biologic treatment effect ($\beta = -0.33\pm0.12$, $p<0.05$). In another model including an additional interaction term of RF status and TNFi or non-TNFi, the influence of RF status on treatment effect was persistent ($\beta = -0.26\pm0.14$, $p<0.1$). These two models had comparable AIC. A model excluding RF positivity term had larger AIC than these two models, suggesting that RF positivity is crucial for predicting the effect of bDMARDS treatment.

Fixed effects

	β coefficient estimate	Std. Error	p value
(Intercept)	0.18	0.42	0.67
RF positivity	-0.33	0.12	<0.05
DAS28 at baseline	0.74	0.041	<0.05
Age	-0.016	0.0037	<0.05
Female gender	-0.35	0.12	<0.05
Non-TNFi use (TNFi as reference)	0.29	0.12	<0.05
Methotrexate use	0.084	0.12	0.51
Prednisolone use	-0.23	0.10	<0.05
Stage	-0.24	0.10	<0.05

Conclusions: In our multicenter study using a linear mixed-effect model including between-institution variation as a random effect, RF positivity, in addition to some well-known variables, was found to be independently associated with decreased effects of bDMARDS treatment in bio-naïve RA patients.

SAT0082 THE INVESTIGATION FOR THE INFLUENCE OF SILASTIC ARTHROPLASTY OF METACARPOPHALANGEAL JOINT ON THE ACTIVE EXTENSION RANGE OF PROXIMAL INTERPHALANGEAL JOINT IN THE RHEUMATOID HAND

Y. Sakuma, M. Nakayama, H. Tobimatsu, H. Imamura, K. Yano, K. Ikari. *Orthopedic Surgery, Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan*

Background: The ulnar deviation (Ud) deformity of the metacarpophalangeal (MCP) joints is a typical deformity in the patients of rheumatoid arthritis (RA). Joint replacement arthroplasty can be indicated for the treatment of severe Ud deformity, silastic prosthesis being widely used with generally good results [1]. There are few, however, previous reports focusing on the relationship between the range of motion (ROM) of the MCP and PIP joints after the surgery.
Objectives: The objective of this study was to investigate the influence of silastic replacement arthroplasty of MCP joint replacement on post-operative extension range of PIP joint of the same finger.
Methods: RA patients who underwent silastic replacement arthroplasty of at least 1 MCP joint except for thumb for the treatment of Ud deformity were reviewed. There were 80 hands of 65 patients, average age of whom was 70.1 (32.4 - 86.1) years old, 56 patients being female and 9 being men. The ROM of the PIP joints before and after surgery was collected from the medical records, and the relationship between the post-operative change of ROM in PIP joints and post-operative ROM of in the MCP joint of same finger was examined. Paired-t test and the correlation coefficient were used for statistical analysis.
Results: The mean active extension range of PIP joints in index to little finger changed from -0.68° (-56.0–30.0) to 0.92° (-52.0–30.0)° [P=0.55], -5.64° (-104.0–30.0) to -8.44° (-56.0–30.0) [P=0.03], -3.44° (-112.0–32.0) to -8.91° (-94.0–40.0) [P=0.08], and -9.81° (-96.0–30.0) to -17.2° (-76.0–30.0) [P=0.07], respectively. There was an indication of a decrease in post-operative extension range of PIP joint except for the index finger. The ROM of the PIP joint was reduced only in the little finger, but was significantly increased in the index and middle finger. Correlation coefficients between the active flexion range of the MCP joint and the active extension range of the PIP joint of index to little finger was 0.34, 0.19, 0.08, and 0.33 respectively, no correlation being found.
Conclusions: Post-operative decline in active extension of the PIP joint might be a compensatory change accompanying a shift of the arc of motion of the

replaced MCP joint to a more extended position [2]. However, since the correlation between extension deficit of PIP join and MCP joint flexion range was not actually observed, it is unlikely that a decrease in the extension of the PIP joint is a result of compensation. There is a possibility that the procedure such as intrinsic tendon release, bone shortening by resection of metacarpal head, and centralization of extensor tendon [3], might influence the postoperative PIP joint motion. It is necessary to pay attention to changes in the ROM of the PIP joint after joint replacement arthroplasty of MCP joint.

SAT0083 TOCILIZUMAB INDUCED CLINICAL REMISSION IN RHEUMATOID ARTHRITIS HAD MORE RESIDUAL DOPPLER SIGNALS IN COMPARISON WITH OTHER BIOLOGICS

Y. Hara[1], Y. Ishida[1], Y. Yamaguchi[1], Y. Yoshimine[1], T. Wibowo[1], Y. Manabe[1], M. Yaga[2], K. Kawamoto[1], H. Nakahara[1], S. Higa[1], T. Igarashi[1], K. Maeda[1], A. Ogata[1]. *[1]Division of Allergy, Rheumatology and Connective Tissue Diseases, Department of Internal Medicine; [2]Respiratory Medicine, Department of Internal Medicine, Ntt West Osaka Hospital, Osaka, Japan*

Objectives: To study the residual Power Doppler (PD) signals for assessing synovitis in CRP negative patients with rheumatoid arthritis (RA) treated with biologics.
Methods: Biologics treated RA patients who were maintained normal CRP for more than 6months (34 TNF inhibitors, 37 Tocilizumab, 23 Abatacept) were assessed by ultrasonography. Residual PD signals were assessed in MCP, PIP, and wrist joints with both hands. We assumed patients who had any PD signals in assessed joints were “residual PD signals”.
Results: All treated patients with biologics maintained normal CRP for a half year (n=94). 35.1% of patients treated with biologics had positive PD signals. The remission rates of DAS28-ESR, CDAI, and Boolean were 68.7%, 62.8%, and 48.9% respectively. 28.1% of patients who achieved DAS28-ESR remission had residual PD signals, 22.0% in CDAI, and 21.7% in Boolean. 23.8% of patients treated by TNF inhibitors who achieved DAS28-ESR remission had residual PD signals, 34.6% in Tocilizumab, and 20.0% in Abatacept. In case of setting the DAS28-ESR remission less than 3.0, 30.2% of patients who achieved DAS28-ESR remission had residual PD signals, 29.0% in less than 2.0, and 12.5% in less than 1.5. The patients who have no tender or swollen joints and the excellent patient oriented global health assessment (VAS score was zero) had fewer residual PD signals (23.4% vs 58.6% in tender joints, 26.7% vs 66.7% in swollen joints, and 13.3% vs 44.4% in patient VAS).

Table 1. Rate of remission and residual PD signals

	All biologics	TNF inhibitors*	Tocilizumab	Abatacept
Patients number	94	34	37	23
Residual PD signals**	33/94 (35.1%)	9/34 (26.4%)	15/37 (40.5%)	9/23 (39.1%)
DAS28-CRP remission				
Achieved***	78/94 (83.0%)	32/34 (94.1%)	31/37 (83.8%)	15/23 (65.2%)
Residual PD signals	22/78 (28.2%)	8/32 (25.0%)	10/31 (32.3%)	4/15 (26.7%)
DAS28-ESR remission				
Achieved	57/94 (68.7%)	21/34 (72.4%)	26/37 (78.8%)	10/23 (47.6%)
Residual PD signals	16/57 (28.1%)	5/21 (23.8%)	9/26 (34.6%)	2/10 (20.0%)
CDAI remission				
Achieved	59/94 (62.8%)	26/34 (76.5%)	23/37 (62.2%)	10/23 (43.5%)
Residual PD signals	13/59 (22.0%)	5/26 (19.2%)	7/23 (30.4%)	1/10 (10.0%)
Boolean remission				
Achieved	46/94 (48.9%)	21/34 (61.8%)	17/37 (45.9%)	8/23 (34.8%)
Residual PD signals	10/46 (21.7%)	5/21 (23.8%)	4/17 (23.5%)	1/8 (12.5%)

*TNF inhibitors (Infliximab (n=6), Etanercept (n=14), Adalimumab (n=7), Golimumab (n=4), Certolizumab pegol (n=3)). ** Residual PD signals: patients who had any PD signals in asessed joints. ***Achieved: remission rate in biologics treated patients who were maintained normal CRP for a half year.

Conclusions: The patients who achieved clinical remission had residual PD signals. Patients with Tocilizumab induced remission had more residual PD signals compared with TNF inhibitor or Abatacept induced remission. More strict criteria of clinical remission may reduce residual PD signals in patients treated by Tocilizumab.

SAT0084 CHARACTERISTICS OF PATIENTS WHO RESPOND POORLY TO REDUCTION OF BIOLOGICAL DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS IN RHEUMATOID ARTHRITIS; RT-4 STUDY POST HOC ANALYSIS

Y. Urata[1], S. Abe[2], B. Devers[2], Y. Nakamura[3], H. Takemoto[4], K.-I. Furukawa[5]. *[1]Department of Rheumatology, Tsugaru General Hospital, Gosyogawara; [2]Marketing Department, Diagnostics Division, Sekisui Medical Co., Ltd., Tokyo; [3]Department of Orthopedic Surgery; [4]Department of Dermatology, Tsugaru General Hospital, Gosyogawara; [5]Department of Pharmacology, Hirosaki University Graduate School of Medicine, Hirosaki, Japan*

Background: A number of studies have shown that reduction of biological disease-modifying anti-rheumatic drugs (bDMARDs) is possible for rheumatoid arthritis (RA) patients in whom bDMARD treatment has induced clinical remission or low disease activity. However, there have been few studies which have evaluated the background characteristics of patients who have difficulty in reducing bDMARDs despite being in clinical remission or having low disease activity.
Objectives: To clarify the characteristics of RA patients who have difficulty with bDMARD reduction despite maintaining clinical remission in the rT-4 study.
Methods: This study is a post-hoc analysis of the rT-4 study. Briefly introducing the rT-4 study: 209 RA patients demonstrating both SDAI remission and MMP-3 normalization using bDMARDs for $\geq$3months were randomly allocated to one of four strategy groups: Standard care (SC group; n=50); SDAI-driven therapy (n=53); MMP-3-driven therapy (n=55); or both SDAI and MMP-3-driven therapy group (Twin; T group; n=51). Dose reduction methodology (every 3 months): ettanercept (ETN) - period between injections increased by one week; tocilizumab (TCZ) - dose reduced by 80mg or period between injections increased by one week; up to a minimum dose of: ETN - 25 mg every 5 weeks; TCZ - 80 mg every 5 weeks or 162 mg every 5 weeks. The dose was reverted to the previous level in the event that the target scores were exceeded, and the lower dose was eventually reattempted after the target was re-achieved. The primary outcome was the difference in the proportion of patients who maintained remission at 12 months among the four groups, compared against a non-inferiority margin of 10%. The results of the rT-4 study revealed that a twin target strategy can achieve effects non-inferior to standard care with regard to maintaining clinical remission. Specifically, subgroup analysis was carried out between the T and SC groups of the rT-4 study. A factor was defined as significant when the difference in the proportion of patients who maintained remission at 12 months in the two groups across subgroups, exceeded 10%.
Results: The requisite margin was recognized only for rheumatoid factor (RF) negativity (35.2%; 95% CIs of 14.4 to 65.0). Others factor were not identified.
Disease activity is likely to be affected by even a small dose reduction of bDMRADS in RA patients who are RF negative, regardless of the presence or absence of anti-citrulline antibody, and it can probably be explained as a nocebo effect. Nocebo effects occur in studies which investigate the effectiveness of drug reduction, and we believe that the nocebo effect is prone to happen in RF-negative patients.
Conclusions: The twin target strategy can be used to reduce the dose of bDMARDs for RA patients while maintaining the effectiveness of said bDMARDs, with the exception of RF negative patients.

SAT0085 A STUDY ON CHARACTERISTICS OF RHEUMATOID ARTHRITIS PATIENTS ACHIEVING DEPRESSION REMISSION WITH 6 MONTHS OF BIOLOGIC AGENT TREATMENT

Y. Miwa[1], N. Yajima[1], T. Isozaki[1], R. Takahashi[1], Y. Miura[1], Y. Ikari[1], M. Hatano[1], T. Hayashi[1], T. Kasama[1], K. Sanada[2] on behalf of ASHURA Registry Group. *[1]Division of Rheumatology, Department of Medicine; [2]Department of Psychiatry, Showa University School of Medicine, Tokyo, Japan*

Background: Approximately 15% of RA patients also suffer from depression, with an odds ratio of 1.42 (95% CI 1.3 - 1.5) compared with healthy people. A previous study reported that biological agents can improve the depressed state associated with RA. Although previous studies have been cross-sectional, there were no reports that analyzed factors that led to depression remission.
Objectives: To examine the relationship between baseline factors and depression remission after six-month biologic agent treatment in rheumatoid arthritis (RA) patients.
Methods: The subjects were 384 RA patients treated with biologic agents. The following patient’s characteristics were investigated: age, gender, number of previous drugs, disease duration, type of biologic agents, baseline steroid dosage, methotrexate dosage and serum matrix metalloproteinase-3 (MMP-3) levels. For evaluation, we used the Simplified Disease Activity Index for RA disease activity; the Health Assessment Questionnaire Disability Index (HAQ-DI) score for activities of daily living; the Short Form-36 for nonspecific health-related quality of life; and Hamilton Depression Rating Scale (HAM-D) scores for depression status. Depression remission was defined by HAM-D$\leq$7 after 6 months of treatment. The subjects were divided into two groups according to the presence or absence of depression, and a retrospective study was performed.
Results: We included 152 patients in the analysis. Two hundred thirty-two

patients were excluded due to primary and secondary failure, complications, loss to 6-month follow-up, incomplete data, etc. Compared with a group of RA patients with depression remission (n=124), a group of patients with no depression remission (n=28) had a younger age (p=0.000), female sex (p=0.039), lower serum MMP-3 levels (p=0.021), lower HAQ-DI (p=0.018), lower HAM-D score (p=0.000), and higher Role/Social component summary score of the SF-36 (p=0.009) by univariate analyses. The binominal logistic analyses findings were as follows: younger age (p=0.0045, odd ratio: 0.94, 95% CI: 0.8–0.98), female sex (p=0.021, odd ratio: 0.21, 95% CI: 0.054–0.79), and lower HAM-D scores (p=0.0073, odd ratio: 0.85, 95% CI: 0.76–0.96).

Conclusions: It was suggested that RA patients who are female, younger in age and have lower depression scores at baseline are more likely to achieve depression remission status with the biologic treatment.

SAT0086 THE ASSOCIATION BETWEEN ELDERLY RHEUMATOID ARTHRITIS PATIENTS USING BIOLOGICS AND ADVERSE EVENTS: RETROSPECTIVE COHORT STUDY

Y. Ikari, Y. Miwa, N. Yajima. *Division of Rheumatology, Department of Medicine, Showa University School of Medicine, Hatanodai Shinagawaku Tokyo, Japan*

Background: In Japan, the definition of the elderly was suggested as being over 75 years old by the Japan Geriatric Society. The effectiveness of biologics in elderly rheumatoid arthritis (RA) patients has been demonstrated in several clinical trials and cohort studies[1]. On the other hand, regarding safety, there are reports that the use of biologics in elderly RA patients is a significant risk for severe infections and that they do not increase the risk of serious infection [2,3]. There is little evidence to support the association between age of RA patients and adverse events caused by biologics.

Objectives: We aimed to examine whether the age of RA patients was associated with adverse events caused by biologics.

Methods: RA patients using biologics were eligible. The participants were collected at Showa University Hospital, Showa University Northern Yokohama Hospital and Showa University Koto Toyosu Hospital from 2005 to 2016 in a retrospective cohort study.

RA patients of 75 years and above compared with RA patients under 75 years.

The primary outcome was the rate of discontinuation due to adverse events caused by biologics. Statistical analysis was Pearson's chi-square test. Multivariable analysis was performed by multi linear analysis. Covariates were sex, glucocorticoids dose, csDMARDs, interstitial pneumonia, diabetes mellitus and chronic kidney disease.

Results: In total, 309 patients were enrolled. The mean age standard deviation was 57.1±15.6years, and 83.4% were women. 174 (56.3%) took glucocorticoid, and the mean glucocorticoid dose was 3.13±3.9mg.The patients over 75 years were 42 patients (13.6%), and those under 75 years were 267 patients (86.4%). The rate of discontinuation due to adverse events caused by biologics was 11/42 (26.2%) in the patients over 75 years and over, and 21/267 (7.9%) in the patients under the age of 75 (Relative Risk 1.24; 95% Confidential Interval (CI) 1.04 to 1.50; P 0.0003). Adverse events were bacterial pneumonia, pneumocystis pneumonia, exacerbation of interstitial pneumonia, urinary tract infection, herpes zoster, cytopenia, eruption, congestive heart failure. In the multivariable analysis adjusting for confounders, the rate of discontinuation in the group aged 75 years and older was significantly higher than that in the group under the age of 75 (regression coefficient 1.35; 95% CI 0.39–2.31; p=0.006).

Conclusions: Our results demonstrated that the rate of discontinuation due to adverse events by biologics was high significantly in RA patients over 75 years and above.

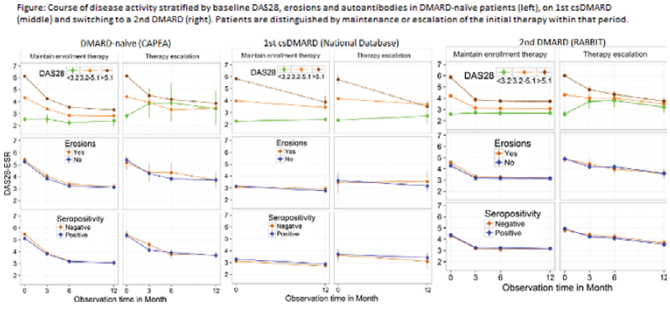
SAT0087 THE RELEVANCE OF POOR PROGNOSTIC FACTORS FOR ACHIEVING LOW DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: A COLLABORATIVE ANALYSIS OF THREE GERMAN COHORTS

Y. Meissner[1], K. Albrecht[1], A. Richter[1], L. Baganz[1], D. Huscher[1], M. Schneider[2], A. Strangfeld[1], A. Zink[1,3]. *[1]German Rheumatism Research Center, Berlin; [2]Heinrich-Heine University, Duesseldorf; [3]Charité University Medicine, Berlin, Germany*

Background: Poor prognostic factors (PPF) are used as decision-criteria for treatment strategies in patients with rheumatoid arthritis (RA). However, their definition is based on the outcome of rapid radiologic progression.

Objectives: To investigate the impact of PPF in RA on achieving low disease activity (LDA) at follow-up.

Methods: We performed a collaborative analysis of three large German RA cohorts. Patients under routine care were either DMARD-naïve (n=991, early arthritis cohort CAPEA), on 1st conventional synthetic (cs)DMARD (n=2,547, National Database of the German Arthritis Centres (NDB)), or switching to a 2nd (n=1,959) or a 3rd DMARD (n=1,854, both biologics register RABBIT). Disease activity based on DAS28, autoantibody positivity (RF+/ACPA+), erosions, disability (HAQ≥1.2) and intake of glucocorticoids (>5mg/d) were evaluated as PPF at baseline. The outcome was DAS28 at 0, 3, 6 and 12 months. With multinomial logistic regression analyses, predictors of either LDA (DAS28<3.2) at 12 months or treatment escalation (adding or switching to cs/biologic (b)DMARD) were investigated.



Results: Patients had a mean age of 57 to 60 years; 63% of DMARD-naïve patients and 71–72% of all others were female. Disease duration was 13 weeks in early RA (CAPEA) and 5–8 years in other cohorts. Patients with more treatment failures had more often PPF (not shown).

The figure shows the course of disease activity stratified by baseline DAS28, erosions and RF/ACPA. Values of DAS28 at baseline did not differ depending on presence/absence of erosions and autoantibodies. In all cohorts, irrespective of maintaining or escalating the initial treatment, patients with or without erosions and autoantibodies had similar DAS28 outcomes, whereas patients with moderate or high baseline DAS28 had higher disease activity during follow-up. The proportion of patients that did not achieve LDA at 12 months was 46% in DMARD-naïve, 34% on 1st DMARD, 47% switching to 2nd and 49% switching to 3rd DMARD.

In the multinomial model, a 1-unit increase in DAS28 was associated with a decreased probability to achieve LDA in all cohorts (table). In contrast, autoantibodies (OR from 0.8 to 1.3) and erosions (OR from 0.8 to 1.6) had no impact on achieving LDA at month 12 or on treatment escalation. The latter applied for DAS28 (OR from 0.9 to 1.5) and HAQ (OR from 0.7 to 1.2) regarding only treatment escalation.

Table 1. Selected OR (95% CI) of multinomial logistic regression

	DMARD-naïve	1st DMARD	2nd DMARD	3rd DMARD
Predictiors of LDA				
Age (by 5 yrs)	0.96 (0.9–1.0)	0.9 (0.8–0.99)	0.95 (0.91–0.99)	0.96 (0.9–1.0)
DAS28 (per 1 unit)	0.8 (0.6–0.9)	0.6 (0.4–0.9)	0.7 (0.6–0.8)	0.6 (0.6–0.7)
HAQ ≥1.2	0.9 (0.6–1.3)	1.1 (0.6–1.9)	0.6 (0.5–0.8)	0.6 (0.4–0.7)
GC >5 mg/d	1.6 (1.2–2.3)	0.6 (0.3–1.3)	1.0 (0.8–1.3)	0.99 (0.8–1.3)
b vs. csDMARD	–	–	1.4 (1.0–1.9)	1.4 (1.0–1.8)
Predictors for treatment escalation				
Age (by 5 years)	0.9 (0.9–0.98)	0.8 (0.7–0.9)	0.9 (0.8–0.9)	0.9 (0.9–0.96)
GC >5 mg/d	1.3 (0.8–1.9)	4.2 (1.6–11.0)	1.5 (1.1–2.0)	1.5 (1.2–2.0)

Conclusions: Although autoantibodies and erosions were associated with treatment failure, their absence did not predict LDA. Instead, baseline disease activity, functional status and glucocorticoid use may be more useful to guide treatment strategies when LDA is the target.

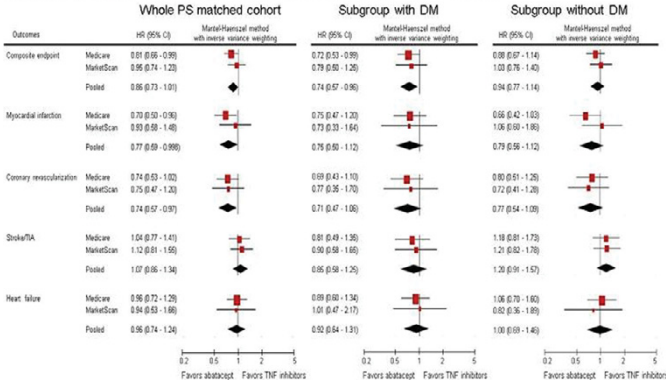
Rheumatoid arthritis - comorbidity and clinical aspects

SAT0088 HDL CHOLESTEROL EFFLUX CAPACITY IN RHEUMATOID ARTHRITIS PATIENTS: CONTRIBUTING FACTORS AND RELATIONSHIP WITH SUBCLINICAL ATHEROSCLEROSIS

B. Tejera Segura[1], M. Macía-Díaz[2], J.D.M. Machado[2], A. de Vera-González[3], A. González-Delgado[3], J.M. Olmos[4], J.L. Hernández[4], F. Díaz-González[1], M.A. González-Gay[5], I. Ferraz-Amaro[1]. *[1]Division of Rheumatology; [2]Pharmacology Department; [3]Central Laboratory Division, Hospital Universitario de Canarias, Tenerife; [4]Division of Internal Medicine; [5]Rheumatology Department, Hospital Universitario Marqués de Valdecilla-IDIVAL, Santander, Spain*



Background: Lipid profiles appear to be altered in rheumatoid arthritis (RA) patients due to disease activity and inflammation. Cholesterol efflux capacity (CEC) has not only been linked to cardiovascular events in the general population, but also to be impaired in RA patients.
Objectives: To analyze whether CEC is related to subclinical atherosclerosis, as determined by the presence of carotid plaque or increased levels of carotid intima-media thickness (cIMT) in RA patients. Secondarily, we aimed to describe the disease-contributing factors that are related to CEC as an expression of the abnormalities in the lipid profile associated with the disease.
Methods: Cross-sectional study that encompassed 401 individuals; 178 patients with RA and 223 sex-matched controls. CEC was measured using an *in vitro* assay, lipoproteins serum concentrations, and standard lipid profile were assessed in patients and controls. Carotid intima-media thickness and carotid plaques were assessed in RA patients. A multivariable analysis was performed to evaluate the relation of CEC with RA-related data, lipid profile and subclinical carotid atherosclerosis.
Results: Mean CEC was not significantly different between RA patients (18.9 ± SD 9.0%) and controls (16.9±10.4%), p=0.11. Demographic variables were not associated with CEC except for a correlation with male gender that was only found in RA patients, but not in controls. Systolic blood pressure inversely correlated with CEC in controls (beta coefficient -0.1 [-0.2–0.0] %, p=0.025). In RA patients, a similar trend was found although a statistically significant difference was not reached. Neither the traditional cardiovascular risk factors nor the cardiovascular co-morbidity-related data were associated with CEC. Similarly, lipid profile did not show any relationship with CEC in patients or controls. ESR tended to be associated with a lower CEC although it did not reach statistical significance. RA patients with low (beta coef. -5.2 [-10.0–0.3] %, p=0.039) and moderate disease activity (beta coef. -4.6 [-8.5–0.7] %, p=0.020) were associated with inferior levels of CEC when compared to patients in remission. CEC was not found to be associated with cIMT in RA patients. However, higher CEC was associated with a protective effect for the presence of carotid plaque in RA patients. This relationship was maintained even after multivariate analysis (OR 0.94 [0.89–0.98], p=0.015).
Conclusions: Our study, which includes the largest series of RA patients ever assessed for CEC, reveals for the first time that CEC is related to subclinical atherosclerosis in RA patients. The fact that CEC is also associated with disease activity reinforces the idea that CEC may be a mediator between disease activity and subclinical atherosclerosis.

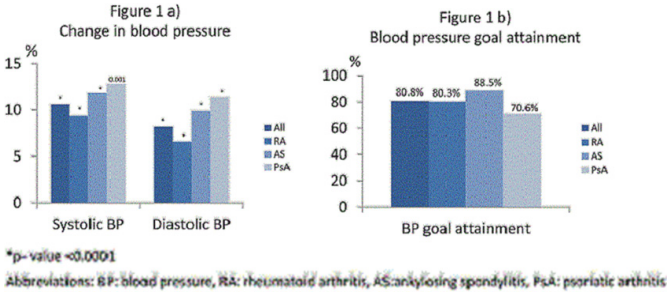
SAT0089 COMPARATIVE CARDIOVASCULAR SAFETY OF ABATACEPT AND TUMOR NECROSIS FACTOR INHIBITORS IN RHEUMATOID ARTHRITIS PATIENTS WITH AND WITHOUT TYPE 2 DIABETES: A POPULATION-BASED COHORT STUDY

E.H. Kang[1,2], Y.P. Jin[1], G. Brill[1], J.P. Lewey[1,3], E.P. Patorno[1], R. Desai[1], S.C. Kim[1]. *[1]Division of Pharmacoepidemiology and Pharmacoeconomics, Harvard Medical School and Brigham and Women's Hospital, Boston, United States; [2]Division of Rheumatology Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Korea, Republic Of; [3]University of Pennsylvania, Philadelphia, United States*

Background: Patients with rheumatoid arthritis (RA) are at high risk of developing cardiovascular disease (CVD) and may benefit from potent disease-modifying anti-inflammatory drugs such as biologics. Since diabetes mellitus (DM) is a major risk factor for CVD, RA patients with DM constitute a high CVD risk subgroup, calling for particular attention. However, there is a lack of knowledge on the comparative cardiovascular safety of different biologics in RA patients with DM.
Objectives: To examine the comparative cardiovascular safety of abatacept versus TNF inhibitors in RA patients with and without DM.
Methods: RA patients enrolled in both public (Medicare) and commercial (Truven MarketScan) health plans in the U.S. who newly initiated abatacept or TNF inhibitors were eligible. The primary outcome of interest was a composite CVD endpoint of myocardial infarction (MI), stroke/transient ischemic attack (TIA), and coronary revascularization. The secondary outcomes included each component of the composite CVD endpoint and heart failure (HF). After 1:1 propensity score (PS) matching between two exposure groups, Cox proportional hazard model was used to estimate the hazard ratio (HR) and 95% confidence interval (CI) for each outcome, comparing abatacept to TNF inhibitors. PS matching was separately done in subgroups with or without baseline DM in each database. PS-matched HRs from the two databases were pooled using an inverse variance–weighted fixed-effect model.
Results: We identified 31,899 Medicare enrollees (6,107 new users of abatacept and 25,792 new users of TNF inhibitors) and 71,956 commercial enrollees (6,942 new users of abatacept and 65,464 new users of TNF inhibitors) with RA. After PS matching, 2,119 pairs with DM and 3,984 pairs without DM were identified in Medicare and 1,371 pairs with DM and 5565 pairs without DM in MarketScan. The PS matched HR (95% CI) for the composite CVD endpoint in the whole cohort was 0.81 (0.66–0.99) in Medicare and 0.95 (0.74–1.23) in MarketScan with a pooled HR (95% CI) of 0.86 (0.73–1.01). In the subgroup with DM, HR (95% CI) for composite CVD endpoint was 0.72 (0.53–0.99) in Medicare and 0.79 (0.50–1.25) in MarketScan with a pooled HR (95% CI) of 0.74 (0.57–0.96). In the subgroup without DM, HR (95% CI) was 0.88 (0.67–1.14) in Medicare and 1.03 (0.76–1.40) in MarketScan with a pooled HR (95% CI) of 0.94 (0.77–1.14). For secondary outcomes (Figure 1), the pooled HR (95% CI) was 0.77 (0.59–1.00) for MI and 0.74 (0.57–0.97) for coronary revascularization in the whole cohort. There was a trend toward a decreased risk, albeit statistically insignificant, for MI and coronary revascularization in each subgroup. There was no significant difference in the risk for stroke/TIA and HF.

Figure 1. Cardiovascular safety of abatacept compared to TNF inhibitors



Conclusions: Among RA patients, abatacept may be associated with a reduced risk of coronary events compared to TNF inhibitors, particularly in patients with DM. The risk of HF was not different between these two groups.

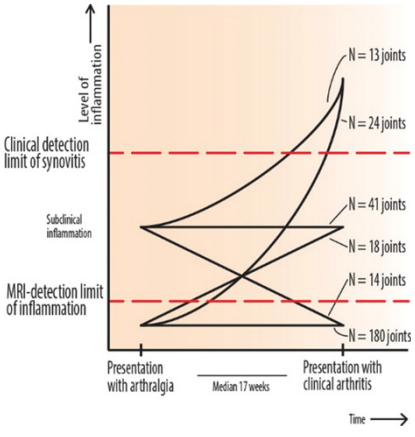
SAT0090 SUCCESS RATE OF BLOOD PRESSURE GOAL ACHIEVEMENT IN INFLAMMATORY JOINT DISEASES

S. Rollefstad, P. Norheim, E. Ikdahl, G. Wibetoe, A.G. Semb. *Preventive Cardio-Rheuma Clinic, Department of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway*

Background: The excess risk of cardiovascular disease (CVD) in patients with inflammatory joint diseases (IJD) is attributable to several risk factors, including a high prevalence of hypertension. However, there is limited knowledge on the effect of antihypertensive treatment (a-HTT) in these patients.
Objectives: Our objective was to initiate a-HTT when indicated and treat to guideline recommended blood pressure (BP) goal in IJD patients. We also aimed to evaluate the effect of a-HTT in this patient population, and which factors were associated with BP goal attainment.
Methods: Patients with IJD (n=765) were referred from a rheumatology outpatient clinic or general practitioners to a preventive cardio-rheuma clinic. All patients underwent a CVD risk evaluation, including BP measurements (performed using and Omron M7 apparatus). Antihypertensive treatment was initiated in accordance with guidelines, and the BP treatment goal was <140/90 mmHg.
Results: Of the 765 IJD patients referred (rheumatoid arthritis n=450, ankylosing spondylitis n=210 and psoriatic arthritis n=105), 104 (13.6%) had an indication for BP lowering, while 224 (29.3%) were already using a-HTT at the first consultation. For those where a-HTT was initiated at baseline (n=104), there was a highly significant change in BP from first to final consultation (Fig 1a). BP goal was achieved in 84 (80.8%) patients (Fig 1b), using mean±SD 3.1±1.7 consultations. Dose adjustments was done in 38 (36.5%) of the patients with median (IQR) a-HTT dose adjustments of 1 (1, 1.25). In 9 (8.7%) patients the



a-HTT was changed. Systolic BP ($p<0.0001$) was significantly associated with BP goal attainment in age- and sex adjusted logistic regression analyses, while the use of anti-rheumatic medication or inflammatory biomarkers at baseline was not. Patients with the lowest systolic BP were more likely to achieve BP goals. For patients already on a-HTT (n=224), only 52.7% had a BP <140/90 mmHg at baseline. After up titration or change of a-HTT, the percentage of patients achieving BP goal in this group increased to 82.6%.
Conclusions: This is to our knowledge the first prospective report on success rate of BP goal achievement in patients with IJD. Approximately 80% reached BP target, which is even a higher proportion than what is shown in the general population. Treatment to BP goal is feasible in patients with IJD, and is not complicated by inflammation or use of anti-rheumatic medication.

SAT0091 IS CLINICAL ARTHRITIS ALWAYS PRECEDED BY SUBCLINICAL INFLAMMATION? A LONGITUDINAL STUDY AT JOINT LEVEL IN PATIENTS WITH ARTHRALGIA THAT DEVELOPED ARTHRITIS

R.M. Ten Brinck, H.W. van Steenbergen, A.H. van der Helm-van Mil.
Rheumatology, Leiden University Medical Centre, Leiden, Netherlands

Background: The clinical phase of Rheumatoid arthritis (RA) is preceded by a phase with subclinical inflammation. MRI can detect subclinical inflammation and, at patient level, this is predictive for the development of clinical arthritis. However, at joint level it is unknown how arthritis develops. It is unknown how frequently joints with subclinical inflammation progress to clinical arthritis, and vice versa, how often joints that developed clinical arthritis had local subclinical inflammation during the preceding phase of arthralgia. A longitudinal MRI study in patients that developed arthritis can unravel if arthritis development is restricted to some locations in which the severity of inflammation increases over time or, alternatively, if the process is more generalized with a weak association between the locations of subclinical inflammation and subsequent clinical arthritis.
Objectives: This longitudinal study at joint level during progression from pre-RA to RA determined the relation between the location of subclinical inflammation and clinical arthritis over time.
Methods: 290 small joints (4 MCPs, 1 wrist, 5 MTPs per person) of 29 patients that presented with arthralgia and developed clinical arthritis were studied with 1.5T MRI at both time-points. MRIs were evaluated for BME, synovitis and tenosynovitis by three readers (ICCs 0.98, 0.96 and 0.97) that were blind to clinical data and the order in time. Subclinical inflammations was defined as presence of BME, synovitis and/or tenosynovitis.
Results: The median time between presentation with arthralgia and clinical arthritis development was 17 weeks. At presentation with arthralgia 68 joints had subclinical inflammation and no significant association was found between joint tenderness and the presence of local MRI-detected subclinical inflammation (OR 0.98; 95% CI 0.48–1.9). Over time, 21% of 68 joints had resolution of subclinical inflammation, 60% had persistent subclinical inflammation and 19% developed clinical arthritis. At arthritis development 37 joints were swollen. Of these, 24 (65%) had no prior subclinical inflammation at the time of presentation with arthralgia (Figure).

Conclusions: This first longitudinal MRI-study on joint level in pre-RA suggested that the majority of joints that developed clinical arthritis had no (long-lasting) preceding phase with subclinical inflammation.

SAT0092 PROGRESSION OF ATHEROSCLEROSIS OVER 5 YEARS IN A COHORT OF EARLY INFLAMMATORY ARTHRITIS PATIENTS: RESULTS FROM THE NORFOLK ARTHRITIS REGISTER

S. Skeoch[1], M. O'Sullivan[1], J. Gwinnutt[1], H. Mirjafari[1], J. Chipping[2], H. Edlin[3], A. MacGregor[2], S. Verstappen[1], D. Symmons[1], I. Bruce[1,4]. [1]*Centre for Epidemiology, University of Manchester, Manchester;* [2]*Norwich Medical School, University of East Anglia, Norwich;* [3]*The Department of Radiology;* [4]*Manchester NIHR Musculoskeletal Biomedical Research Unit, Central Manchester University Hospitals NHS Foundation Trust, Manchester, United Kingdom*

Background: Carotid artery intimal medial thickness (IMT) on ultrasound (US) is a validated measure of subclinical cardiovascular (CV) disease. Rates of IMT progression of 0.001cm/year[1] have been observed in the general population and faster progression is associated with increased CV risk.
Objectives: To describe change in IMT over 5 years in a cohort of early inflammatory arthritis (IA) patients and the association of IMT with estimated CV risk and IA related factors.
Methods: Between 2004 and 2010, patients enrolling in the Norfolk Arthritis Register (a UK inception cohort of IA patients) aged from 16 to 65 years with symptom duration less than 2 years, were invited to take part in the NOAR CVD sub-study. In addition to standard IA disease assessments at 0, 2 and 5 years, traditional CV risk factors were measured at baseline and Framingham based 10-year CV risk score was calculated. IMT was measured in the common carotid arteries at baseline and year 5 using a previously validated US protocol. Patient reported clinical CV events at follow up visits which were then verified by a physician. The associations of baseline CV risk and IA characteristics (tender and swollen joint count, rheumatoid factor, CRP, health assessment questionnaire (HAQ), baseline disease modifying anti-rheumatic therapy use) with baseline IMT (IMT_0) and change in IMT at year 5 (IMT_Δ) were tested using non-parametric statistics. The association of IMT_Δ with IA characteristics over time (cumulative joint counts, change in HAQ) and medication use during follow up (statins, biologic therapy) with IMT_Δ were explored using non-parametric statistics.
Results: 201 patients with a median (IQR) age and symptom duration of 51 (42, 58) years and 10.4 (7.7, 14.4) months respectively were studied. 143 (71%) subjects were female. Median IMT_0 was 0.06 (0.05, 0.07) cm and median IMT_Δ at 5-year follow up period was 0.01 (0, 0.01) cm with an estimated median annual IMT_Δ of 0.002cm. IMT had progressed in 104 (51.5%) patients and regressed in 23 (11.4%) patients by year 5. The median CV risk score at baseline was 5.6 (2.6, 10.7)% and was associated with IMT_0 but not IMT_Δ ($r=0.46, p<0.01$; $r=0.03$, $p=0.73$ respectively). There was no association between baseline IA characteristics and IMT_0 or IMT_Δ. There was a trend towards an association between cumulative swollen joint count and IMT_Δ ($r=0.14$, $p=0.057$) but no association with cumulative tender joint count, change in HAQ, statin or biologic use (all $p>0.05$). CV events occurred in 5 patients during follow up. Of these patients, 3 had IMT progression, 1 had no change and 1 had IMT regression.
Conclusions: Overall, patients with early IA had a higher than expected rate of IMT progression; a significant proportion however had regression in IMT over time. Trajectories of CV risk may vary within the IA population and identifying protective factors will help to better target strategies for CVD prevention in IA.

SAT0093 HIGH TRIGLYCERIDES AND LOW HDL LIPID PROFILE AS A SURROGATE MARKER OF HDL DYSFUNCTION IN RA: POTENTIAL LINKS WITH INFLAMMATION AND OXIDATIVE STATUS

J. Rodríguez-Carrio[1], M. Alperi-López[2], P. López[1], R. López-Mejías[3], S. Alonso-Castro[4], F. Abal[5], F.J. Ballina-García[2], M.Á. González-Gay[3,6,7], A. Suárez[1]. Background: the interactions between inflammation and lipid profile in RA are

poorly understood. The study of lipid profiles in RA has been biased towards lipoprotein levels, whereas those of triglycerides (TG) and lipoprotein functionality have been neglected.

Objectives: since recent findings point to an emerging role for TG and TG-rich lipoproteins (TRL) on inflammation, we aimed to evaluate a combined lipid profile characterized by high TG and low HDL levels ($TG^{high}HDL^{low}$) in RA.

Methods: lipid profiles were analyzed in 113 RA patients, 113 healthy controls (HC) and 27 dyslipemic subjects (DL). A group of 13 biological-naïve RA patients was prospectively followed for 3 months upon TNFα-blockade. Serum levels of inflammatory mediators were assessed by immunoassays. PON1 activity and Total Antioxidant Capacity (TAC) were quantified in serum. PON1 rs662 status was evaluated by RT-PCR

Results: the prevalence of the $TG^{high}HDL^{low}$ profile was similar among RA patients (29/113), HC (30/113) and DL (11/27), linked to higher TRL levels in all groups. However, this profile was associated with increased CRP (p=0.012), TNFα (p=0.004), MCP-1 (p=0.004), IP-10 (p=0.018) and leptin ($p<0.001$) serum levels in RA, where decreased PON1 activity and TAC were found (both $p<0.001$). TRL serum levels were positively correlated to inflammatory mediators, whereas a negative association was found for PON1 activity (r=-0.203, p=0.036). These findings remain after excluding patients with previous CV events or those under statins. No associations were observed in the HC and DL groups. When RA patients were stratified by PON1 rs662 status, these associations were restricted to the low activity genotype (QQ) (TNFα: p=0.002, MCP-1: p=0.013, EGF: p=0.047, IP-10: p=0.018 and leptin: p=0.002), whereas no effect of the lipid profile was observed in those harboring the QR or RR genotypes (all $p>0.050$). As expected, QQ-patients exhibited a lower PON1 activity compared to the other genetic variants (both $p<0.010$). The $TG^{high}HDL^{low}$ prevalence was related to a decreased anti-TNFα usage in the cross-sectional sample (p=0.004). A poor clinical response upon TNFα-blockade was related to an increasing prevalence of the $TG^{high}HDL^{low}$ profile over treatment (p=0.021) and elevated baseline TRL levels (p=0.042).

Conclusions: the $TG^{high}HDL^{low}$ profile is associated with systemic inflammation, increased TRL levels, decreased PON1 activity and a poor clinical outcome upon TNFα-blockade in RA. Overall, these findings support the link between inflammation and lipid profile, oxidative status and TRL having a pivotal role. The $TG^{high}HDL^{low}$ profile can be proposed as a surrogate marker of HDL dysfunction in RA.

SAT0094 METABOLIC AND CARDIO-VASCULAR BENEFITS OF HYDROXYCHLOROQUINE IN PATIENTS WITH RHEUMATOID ARTHRITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

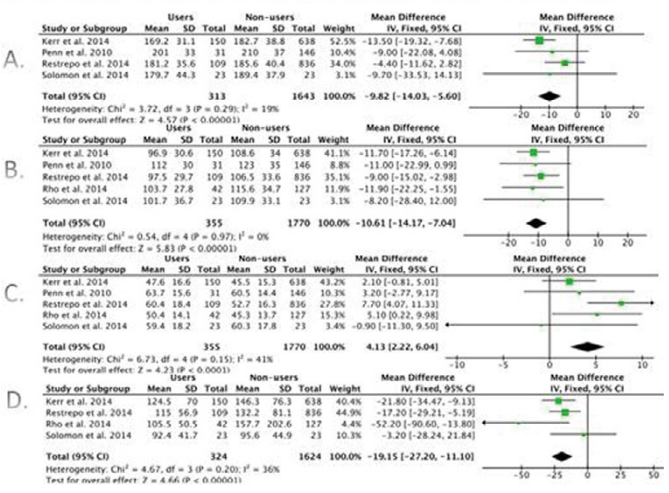
C. Rempenault[1], B. Combe[1], T. Barnetche[2], C. Gaujoux-Viala[3], C. Lukas[1], J. Morel[1], C. Hua[1]. *[1]Rheumatology, University Hospital Lapeyronie, Montpellier; [2]Rheumatology, University Hospital Pellegrin, Bordeaux; [3]Rheumatology, University Hospital Carémeau, Nimes, France*

Background: Cardiovascular disease (CVD) is the leading cause of mortality in rheumatoid arthritis (RA) patients (1). Hydroxychloroquine (HCQ) has been shown to improve major outcomes like survival rates in other inflammatory diseases, like systemic lupus (2).

Objectives: The aim of our study was to assess currently available literature on the cardiovascular impact of hydroxychloroquine (HCQ) in patients with RA.

Methods: We systematically searched literature (via Pubmed, Embase and abstracts from recent ACR and EULAR congresses) for studies evaluating the effects of HCQ, wether in monotherapy or in combination with other conventional synthetic disease modifying antirheumatic drugs (csDMARDs) on cardiovascular outcomes or known risk factors for CVD in RA patients (lipid profiles, diabetes incidence, insulin resistance and incidence of CVD). A meta-analysis was performed with Review Manager Software, with random effects models, whenever methodologically possible and relevant. Data were extracted by one investigator and independently checked by another.

Results: The literature search revealed 185 articles and abstracts of potential interest, and further examination resulted in 16 studies fulfilling required criteria for preplanned analyses regarding the cardiovascular impact of HCQ in RA. For lipid profiles, the mean difference (mg/dL) between HCQ users versus nonusers was -9,82 (95% confidence interval [95% CI] 14.03; 5.60) for total cholesterol, -10.61 [14.17;7.04] for low density lipoprotein, -19.15 [27.20; 11.10] for triglycerides and +4.13 [2.22;6.04] for high density lipoprotein (figure 1); with respectively a decrease (mg/dL) of 13.15 [20.96; 5.34], 12.35 [20.14; 4.36], 12.54 [28.94; 3.86] and an increase of 1.67 [0.96, 4.31] after HCQ initiation. Diabetes incidence was reduced in "HCQ ever users" versus "patients who never used HCQ" with a hazard ratio of 0.59 [0.49; 0.70]. In addition, HCQ seems to decrease insulin resistance and incidence of cardiovascular events but data were too scarce for meta-analysis.



Conclusions: Beside its limited efficacy on disease activity, this study supports the interest of HCQ on lipid profiles, and diabetes incidence, and to a lesser extent on cardio-vascular events and insulin resistance in RA patients. Therefore, this study suggests that HCQ may be of some interest in RA, in combination with other csDMARDS.

SAT0095 INCRETINS-INSULIN AXIS IN PATIENTS WITH RHEUMATOID ARTHRITIS

B. Segura[1], A. de Vera-González[2], A. González-Delgado[2], J.M. Olmos[3], J.L. Hernández[3], R. López-Mejías[4], B. Ubilla[4], M.A. González-Gay[5,6], I. Ferraz-Amaro[1]. *[1]Division of Rheumatology; [2]Central Laboratory Division, Hospital Universitario de Canarias, Tenerife; [3]Division of Internal Medicine; [4]Division of Rheumatology; [5]Division of Rheumatology, IDIVAL, Hospital Universitario Marqués de Valdecilla, Santander, Spain; [6]Cardiovascular Pathophysiology and Genomics Research Unit, School of Physiology, University of the Witwatersrand, Johannesburg, South Africa*

Background: Rheumatoid arthritis (RA) patients have higher levels of resistance to the action of insulin (IR) compared to healthy subjects.The "Incretin effect" consists in a greater release of insulin by the pancreas when there is a gastrointestinal glucose stimulation, compared to an intravenous stimulation. It is known that this effect is altered in patients with IR.

Objectives: To determine if the incretins-insulin axis is altered in patients with RA and if this correlates to IR in patients with RA, as well as if it is explainable by certain features of the disease.

Methods: Cross-sectional study that includes 361 non-diabetic individuals, 151 patients with RA and 210 controls. Serum levels of insulin, C-peptide, Amylin, glucagon-like peptide 1 (GLP-1), gastric inhibitory polypeptide (GIP) and dipeptidyl peptidase 4 (DPP-4) were analyzed in patients and controls. Indexes of resistance and sensitivity to insulin activity were determined by HOMA2.

A "meal test" consisting on the intake of 500 kcal was performed to a subset of 10 patients and 10 controls, in order to determine the postprandial curves of glucose, insulin, C-peptide, GLP-1 and GIP. Differences between patients and controls as well as the relationship of selected characteristics of the disease with the baseline and postprandial levels of incretins were analyzed using multivariate regression. During the meal test, areas under the curve (AUC), maximum concentrations and the minutes of response were compared between patients and controls. This study was approved by the Clinical Trial Committee of the University Hospital of the Canary Islands.

Results: Patients with RA showed, at baseline and after multivariate adjustment, higher levels of insulin (9.8±6.5 vs 13.0±13.4 U/ml, p=0.05), C-peptide (1.53±0.77 vs. 3.37±2.94 ng/ml, p=0.00), GLP-1 (0.49±1.28 vs. 0.71±0.22, p=0.00) and GIP (0.37±0.40 vs. 1.78±0.51, p=0.00). Similarly, IR indexes such as HOMA2-IR and HOMA2%B, built with insulin or Cpeptide, were higher in patients with RA compared to controls. Patients with RA, showed significantly lower levels of DPP-4 (811±459 vs. 696±301 ng/ml,p=0.02) after multivariate analysis. Amylin levels did not differ between patients and controls. Both C-reactive protein (beta coefficient 0.54,95% CI 0.16–0.96, p=0.013) and Erythrocyte Sedimentation Rate (beta coef. 0.01,0.00–0.01, p=0.033) showed a positive relationship with HOMA2%B and GIP levels, respectively. The presence of anti-cyclic citrullinated peptide antibody (beta coef. 157 CI 58–256, p=0.002) and the levels of disease activity measured by DAS28 (beta coef. 46,CI 6–87, p=0.026) and CDAI (beta coef 1.27 (0.28–2.26), p=0.012) showed a positive relationship with the levels of DPP-4. Patients with RA showed Pearson correlation coefficient of incretines, DPP-4 with insulin, C peptide and IR lower compared to control group. After the meal test patients with

RA exhibited an AUC of glucose and GIP greater than controls and a slower C-Peptide response time (75 vs. 30 minutes, p=0.029).
Conclusions: Incretins-insulin axis is altered in patients with RA compared to controls.

SAT0096 MYOCARDIAL FUNCTION IMPROVES IN RHEUMATOID ARTHRITIS PATIENTS TREATED ACTIVELY A MAGNETIC RESONANCE FOLLOW-UP STUDY

R. Koivuniemi[1], A. Kuuliala[2], S. Kivistö[3], M. Holmström[3], M. Leirisalo-Repo[1]. *[1]Rheumatology; [2]Bacteriology and Immunology; [3]Medical Imaging Center, Helsinki University Hospital and University of Helsinki, Helsinki, Finland*

Background: Rheumatoid arthritis (RA) patients are susceptible to development of heart failure (HF). Increased HF risk is not explained by increased prevalence of coronary heart disease (CHD) or traditional cardiovascular (CV) risk factors. Chronic inflammation is suggested to play an important role. In parallel with others (1, 2), we observed RA patients with active disease to have myocardial dysfunction and local myocardial late gadolinium enhancement (LGE) indicative of fibrosis or inflammation on cardiac magnetic resonance (cMR) (3).
Objectives: In our patients (3), we here studied the effects of disease modifying anti-rheumatic drugs (DMARDs) on the myocardium over one-year period.
Methods: Fifty-eight female patients with active RA (<70 years) and 22 fibromyalgia (FM) patients underwent cardiac magnetic resonance (cMR). Two RA groups existed: patients with untreated active early RA (ERA) starting conventional synthetic DMARDs (csDMARDs) or biological DMARDs (bDMARDs) and patients with chronic RA (CRA) who had inadequate response to csDMARDs and were candidates for bDMARDs. Patients with CHD, diabetes and smoking were excluded. CMR was performed to analyze LGE and ventricular function before and after one-year DMARD therapy
Results: Of 30 ERA patients, each started csDMARDs (77% as combination), two started also bDMARD. Of 28 CRA patients, each started bDMARD (one monotherapy).

Table 1. Patient charasteristics at baseline

	RA patients	FM patients	p-value
Age, years; mean ± SD	49±14	54±12	0.112
Rheumatoid factor positivity; n (%)	48 (84)		
Anti-citrullinated peptide antibody positivity; n (%)	51 (90)		
Extra-articular features; n (%)	19 (33)		
Erosions on radiographs; n (%)	26 (47)		
Body mass index, kg/m^2; mean±SD	25±4	27±5	0.012
Mean blood pressure, mmHg; mean±SD	113±17	114±15	0.814
Glycosylated hemoglobin A1C, mmol/mol; mean±SD	5.4±0.3	5.6±0.3	0.037
Low density lipoprotein, mmol/l; mean±SD	3.0±0.8	3.4±0.8	0.025

In RA patients, biventricular systo-diastolic function of the heart was impaired compared to FM (Table 2). Over the study-period, myocardial function improved (Table 2) and DAS28-CRP declined (3.5±1.1 vs 2.3±1.0; p<0.001). Only RA patients had LGE, with no improvement over time (67%).

Table 2. Cardiac magnetic resonance findings in RA and FM patients

RA patients	Baseline mean±SD	Follow-up mean±SD	p-value	FM vs RA patients at baseline	p-value
LV EF%	59±4	59±5	0.477	61±7	0.085
LV ESV, ml/m^2	34±6	33±8	0.449	29±8	0.011
LV EDV, ml/m^2	82±11	81±11	0.645	74±11	0.010
LV TPFR, ms	472±99	445±106	0.035	–	–
RV EF%	59±6	60±6	0.065	61±7	0.314
RV ESV, ml/m^2	34±9	32±8	0.009	29±7	0.043
RV EDV, ml/m^2	81±12	79±11	0.034	73±9	0.006

LV = left ventricle, RV = right ventricle, ESV = end-systolic volume, EDV = end-diastolic volume, EF = ejection fraction, TPFR = time to peak filling rate.

Conclusions: Myocardial function was impaired in RA patients with active RA compared to FM controls, although the latter group had worse classical CV risk factor profile. After one-year DMARD-treatment targeting to remission, myocardial function improved in parallel with decreasing RA activity. Inflammation seems to be deleterious to the myocardium. Tight control of RA activity may improve myocardial function.

SAT0097 FACTORS ASSOCIATED WITH ATHEROSCLEROSIS PROGRESSION IN PATIENTS WITH LOW-ACTIVE RHEUMATOID ARTHRITIS

A. Giollo[1], A. Dalbeni[2], A. Tagetti[2], S. Atanasio[2], G. Orsolini[1], G. Cioffi[3], F. Ognibeni[3], M. Rossini[1], C. Fava[2], O. Viapiana[1]. *[1]Rheumatology Unit, Department of Medicine; [2]General Medicine and Hypertension Unit, Department of Medicine, University of Verona, Verona; [3]Department of Cardiology, Villa Bianca Hospital, Trento, Italy*

Background: Longitudinal studies of the carotid intima-media thickness (IMT) change in RA suggested a role for inflammation in atherosclerosis progression. However, data on well controlled joint disease are scarce since most studies enrolled patients with very high disease activity.
Objectives: To estimate atherosclerosis progression and identify influencing factors in a cohort of longstanding and well controlled RA patients.
Methods: One hundred nine RA patients (females 80%, age 59±12 years, disease duration 15.6±10.6 years, mean Framingham 10-year CV disease risk score 16±12%) without previous cardiovascular (CV) events underwent carotid ultrasound (CUS) examination at baseline and after a mean time of 1.1±0.3 years. Atheromatous plaques and intima-media thickness (IMT) were assessed. Data on CV risk factors, inflammation markers, medications, and RA characteristics were collected.
Results: Overall, we observed a significant increase of IMT (0.03±0.10 mm, p=0.005) and plaques (+ 8%, p=0.035). The IMT progression rate was 0.027 mm/year (95% CI 0.007 - 0.046). Disease activity (DAS28-CRP) remained stable (2.68±1.01 vs 2.79±1.33, p=0.45). Anti-rheumatic, cardiovascular medications and the number of CV risk factors were substantially unchanged. In models of regression analysis sex, age, dyslipidemia, hypertension and use of corticosteroids were independently associated with the increase of IMT, whereas there were no confounding from use of biological therapies, seropositivity or disease duration. Patients with active disease (DAS28-CRP ≥2.6) had a significant increase in IMT (0.04±0.11 mm, p=0.009). Conversely, there was not a significant progression of patients in remission, who had also a lower prevalence of hypertension (40% vs 64%, p=0.027), dyslipidemia (43% vs 58%, p=0.044), and use of corticosteroids (37% vs 63%, p=0.007) and were receiving more frequently methotrexate (60% vs 40%, p=0.027).
Conclusions: In patients with established and controlled RA, the progression of atherosclerosis is mainly driven by traditional CV risk factors than disease activity. In addition, a remission state is associated with a lower prevalence of CV risk factors, which in turn could account for a slower progression of atherosclerosis in these patients. This study provides evidence that even in RA patients who achieve good disease control the treatment of CV risk factors should be optimized.

SAT0098 THE ASSOCIATION BETWEEN WORK DISABILITY AND MENTAL HEALTH IN RHEUMATOID ARTHRITIS

A. Houssien[1], S. Norton[2], E. Nikiphorou[2], F. Matcham[2], J. Galloway[2]. *[1]Academic Rheumatology Department, King's College London; [2]Academic Rheumatology, KCL, London, United Kingdom*

Background: Rheumatoid arthritis (RA) is characterised by joint inflammation, resulting in functional impairment. Consequently, it has long been recognised that work disability is common in RA. However, despite significant pharmacological advances in disease control, little is known about contemporary impact upon work. Depression has emerged in recent years as a key comorbidity in RA. In the general population, depression is strongly correlated with work disability
Objectives: To establish the extent to which depression associates with work ability in RA in a cross sectional study.
Methods: Our hospital routinely collects data via an electronic screening interface, which incorporates a series of validated questionnaires, which patients complete via an iPad while waiting for their appointment. The dataset is linked to the clinical record. For this study, cross sectional data were extracted on adults with RA. Question 2 of the Work and Social Adjustment Scale ("Because of my [RA] my ability to work is impaired") was used as a measure or work disability (scale 0–8). Mental health status was collected using the Patient Health Questionnaire-2 (PHQ), with a score≥3 considered a positive screen for depression.

Table 1

Characteristic	Whole Cohort N=385	PHQ2 score <3 n=263	PHQ2 score ≥3 n=122	p value
Age, mean (SD)	54 (15)	54 (15)	55 (14)	0.768
Female, n (%)	305 (79)	207 (79)	98 (80)	0.681
Seropositive, n (%)	261 (73)*	175 (72)*	86 (76)*	0.705
Disease duration, mean (SD)	6.6 (8.0)	6.0 (7.0)	8.0 (10.0)	0.118
DAS28, mean (SD)	4.0 (1.7)	3.6 (1.6)	4.7 (1.6)	<0.001
HAQ, mean (SD)	1.3 (0.9)	1.0 (0.8)	1.9 (0.7)	<0.001
Work ability, mean (SD)**	3.1 (2.9)	2.1 (2.4)	5.1 (2.6)	<0.001
Univariate regression				
Beta coefficient (95% CI)		Ref	2.94 (2.40 to 3.50)	<0.001
Multivariate regression***			1.40 (0.84 to 1.96)	<0.001

*Missing data on serostatus in 28 subjects. **Work ability on scale 0–8 from WSAS scale. ***Adjusted for age, gender, disease duration, HAQ and DAS score.

Results: Of 385 patients with RA were included in the analysis. Their demographics are shown in the Table.1 Patients scoring 3 or more on the PHQ had more severe RA (higher DAS/HAQ), but there was no significant difference in age, sex or disease duration. 124 (32%) reported no work disability, with the overall mean score 3.0. Patients screening positive for depression had a significantly lower work ability even after adjusting for available confounders.
Conclusions: There is a significant correlation between depression in RA and work ability, which persists even after accounting for disease severity. The magnitude of association observed was even greater than that seen between physical function and work. Although unmeasured confounding remains likely, these data confirm the link between depression and work in RA. It is likely that the relationship is bidirectional, between depression and work in RA. Beyond the importance of addressing work ability in RA, the results highlight the need for screening and targeting depression as part of routine clinical care beside the holistic approach of mangement.

SAT0099 POLYPHARMACY IS ASSOCIATED WITH AN INCREASED RISK OF ADVERSE OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS

A.D. Amarilla Vallejo[1], A. Rutherford[1], M. Filkova[2], M. Molokhia[3], E. Nikiphorou[1], S. Norton[1], K. Hyrich[4], J. Galloway[1]. *[1]Academic Department of Rheumatology, King's College London, London, United Kingdom; [2]Institute of Rheumatology and Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic; [3]Primary Care and Public Health Sciences, King's College London, London; [4]Arthritis Research UK. Epidemiology Unit, University of Manchester, Manchester, United Kingdom*

Background: In the general population, polypharmacy (PP) is associated with increased risk of adverse events. The relationship between adverse outcomes and PP in Rheumatoid Arthritis (RA) has not been studied in depth. The mantra of treatment in RA encourages PP through combination Disease Modifying Anti-Rheumatic Drugs (DMARD).
Objectives: To study the relationship between PP and serious adverse events in RA, including the influence of DMARDs within the PP count.
Methods: Data from the British Society for Rheumatology Biologics Register were analysed. PP was defined as number of drugs co-prescribed at baseline, with two models: (1) including DMARDs (2) excluding DMARDs from the medication count. PP was stratified by 0–5, 6–9 and >10. Patients were studied from initiation of 1st biologic until 1st serious adverse event (SAE), 3 years of follow up, or last available visit, whichever came first. A Cox-proportional hazard model was used, with adjustment for a priori selected cofounders.
Results: This study included 15,004 patients commencing biologics. The demographics are shown in table 1. Excluding DMARDs from the PP cohort, 7,115 (47%) of the patients were taking up to 5 drugs; 6,010 (40%) were taking 6 to 9 drugs; 1,870 (12%) were taking 10 or more medications. Higher levels of PP associated with older age, more severe disease, and longer disease duration. PP predictably associated with comorbidities; the relationship was not linear: comorbidity count appeared to show a ceiling effect. The overall incidence of SAEs was 25.5/100 person years (95% CI 24.7–26.3). The rate of SAEs increased across the PP counts (See Table 1). The relationship remained significant after adjusting for comorbidities. Including DMARDs within the PP count attenuated the association.
Conclusions: PP is common in patients with RA and is associated with adverse outcomes especially when patients are on >10 drugs. Including or excluding DMARDs from the PP model had negligible impact on findings. The relationship between PP and comorbidity is worthy of further research, as PP represents a potentially simple but valuable predictor of adverse outcomes, and a suitable surrogate for comorbidity in epidemiological analyses.

SAT0100 ACPA AND ABDOMINAL ADIPOSITY ARE INDEPENDENT PREDICTORS OF INCREMENTS IN BASAL INSULIN IN PATIENTS WITH RA

E. Gomez-Bañuelos[1], K. Arrona-Rios[2], S. Duran-Barragan[3], L. Gonzalez-Rosas[2], J. Aguilar-Arreola[2], F.D.J. Perez-Vazquez[1], G.-I. Diaz-Rubio[1], E. Chavarria-Avila[1], F. Corona-Meraz[1], A. Saldaña-Millan[1], R.-E. Navarro-Hernandez[1], M. Vázquez-Del Mercado[1,2]. *[1]Instituto de Invesgitación en Reumatología y del Sistema Musculoesquelético, Universidad de Guadalajara; [2]Servicio de Reumatología, División de Medicina interna, Pnpc 004086, CONACyT; [3]Instituto de Invesgitación en Reumatología y del Sistema Musculoesquelético, Hospital Civil de Guadalajara, "Juan I. Menchaca", Guadalajara, Mexico*

Background: Insulin resistance (IR) is a comorbidity found in about 40%of RA patients. Currently, there is little information regarding the role of antibodies against citrullinated proteins and IR development in RA. Patients positive for ACPA and/or RF may be at higher risk of IR since these group of patients has a higher expression pro-inflammatory citokines like TNFa and IL-6, both implicated in the pathogenesis of IR.
Objectives: To analyze the contribution of autoantibodies positivity (ACPA and/or RF) and their impact in the development of IR in patients with RA.
Methods: We retrospectively analyzed patients classified with RA per ACR 1987 and ACR/EULAR 2010 criteria with at least one year of follow-up in a cohort of RA patients without comorbidities from Hospital Civil "Juan I. Menchaca". DAS-28, basal insulin, HOMA-IR and anthropometric parameters: Body weight, body mass index (BMI), Sum 4 skinfold thicknesses (S4T), Waist to hip ratio (WHR), waist circumference (WC) and total fat mass (FM); were determined at current and baseline. Mean differences between the two time points were calculated. A multiple regression model was constructed considering mean insulin change as dependent variable.
Results: We studied 57 RA patients, 44% (25) with IR and 56% (32) without IR. Of these, 21% (12) developed IR during follow-up. BMI, FM and ST4 were higher at baseline in patients with current IR at baseline. Ptients who developed IR during follow-up had a mean increase of DAS-28 of 1.27 ($P<0.005$ vs. patients who improved or never developed IR). Patients positive for ACPA had a greater increase in IR during follow-up. Multivariate analysis revealed that ACPA, increments in WHR and ST4 were independent predictors of basal insulin increases during follow-up.
Conclusions: ACPA and abdominal adiposity (WHR) are independent predictors of IR development in RA

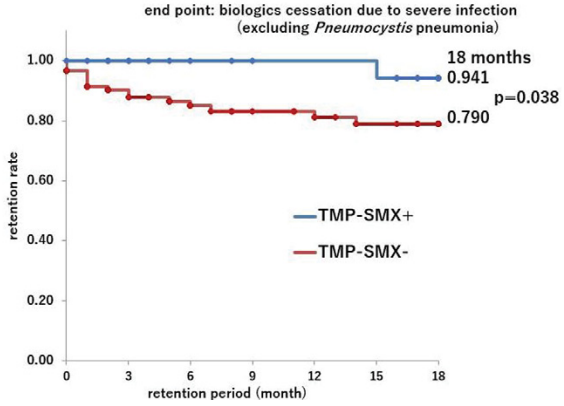
SAT0101 POSSIBILITY OF BACTERIAL INFECTION PROPHYLAXIS OF TRIMETHOPRIM-SULFAMETHOXAZOLE IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS UNDERGOING TREATMENT WITH BIOLOGICS: A SINGLE-CENTER, RETROSPECTIVE, CASE-CONTROL STUDY

E. Kikuchi, N. Aoki, T. Yoshioka, T. Okai. *Center for Rheumatology and Joint Surgery, Kawakita General Hospital, Tokyo, Japan*

Background: Trimethoprim-sulfamethoxazole (TMP-SMX) is widely used for the prophylaxis of *Pneumocystis jiroveci* pneumonia (PCP) in immunocompromised patients, but data about the prophylactic effect of TMP-SMX against bacterial infections are insufficient.
Objectives: To analyze the prophylactic effect of TMP-SMX against severe bacterial infections in elderly patients with rheumatoid arthritis undergoing treatment with biologics.
Methods: Data were retrospectively collected from the medical records of patients with rheumatoid arthritis at our center. We divided the elderly patients (65 years or above) who took biologic agents into two groups. The first group (TMP-SMX+) comprised patients who previously or concurrently started TMP-SMX with biologic

agents for the purpose of PCP prophylaxis and continued with it throughout the treatment with biologics. The second group (TMP-SMX−) comprised patients who were not prescribed TMP-SMX throughout the treatment with biologics. We analyzed the retention rate of each group by Kaplan-Meier curves and the Wilcoxon test. The primary end point was the 18-month retention rate of biologics without severe infection (defined as hospitalization or multiple days of intravenous antibiotic treatment in the clinic, including suspected cases).



Results: The TMP-SMX+ group included 30 patients with a mean age of 76.7±7.0 years. The rate of ACPA positivity was 80.0%, MTX use was 73.3%, oral steroid use was 43.3%, and bio-naive patients was 73.3%. The number of patients treated with abatacept, certolizumab pegol, etanercept, golimumab, infliximab, and tocilizumab was 13, 1, 7, 7, 1, and 1, respectively. The cumulative retention rates at 12 and 18 months were 1.000 and 0.941, respectively. Prophylactic doses of TMP-SMX were between TMX 20mg/SMX 100mg/day and TMX 91mg/SMX 457mg/day.

The TMP-SMX− group included 113 patients with a mean age of 73.6±5.6 years. The rate of ACPA positivity was 79.3%, MTX use was 70.8%, oral steroid use was 54.9%, and bio-naive patients was 80.5%. The number of patients treated with abatacept, adalimumab, certolizumab pegol, etanercept, golimumab, infliximab, and tocilizumab was 15, 15, 4, 41, 7, 18, and 13, respectively. The cumulative retention rates at 12 and 18 months were 0.812 and 0.790, respectively. There was a significant difference between the retention rates in the two groups (p =0.038, Wilcoxon test). Five patients were enrolled in both groups because another biologic agent was used in different periods.

In the TMP-SMX+ group, only one patient was hospitalized for probable bacterial pneumonia (causative bacteria not detected). In the TMP-SMX− group, nine patients were hospitalized for pneumonia, three for septic arthritis, two for urinary tract infection, and two for soft tissue infection. The causative bacteria were *Escherichia coli*, *Klebsiella oxytoca*, *Enterococcus faecalis* and others.

Furthermore, seven patients in the TMP-SMX− group were treated for PCP, whereas no patients contracted PCP in the TMP-SMX+ group.

The retention rates of biologics for elderly (≧65 years) RA patients

Conclusions: Prophylactic administration of TMP-SMX may reduce the risk of bacterial infection in elderly patients with rheumatoid arthritis undergoing treatment with biologics.

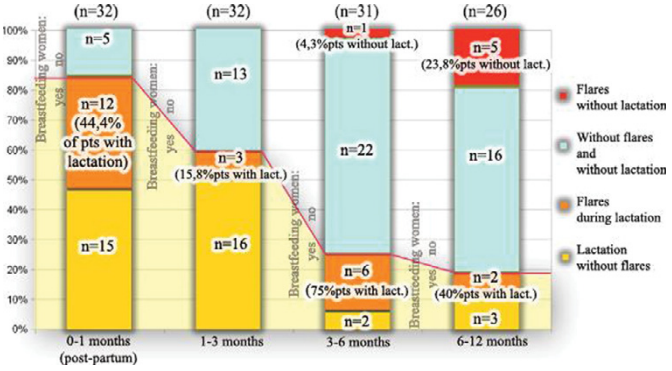
SAT0102 THE EFFECT OF LACTATION ON THE ACTIVITY OF RHEUMATOID ARTHRITIS

E. Matianova, N. Kosheleva. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation*

Background: It has been reported that rheumatoid arthritis (RA) onset in females is often associated with post-partum period and lactation. Moreover, flares of pre-existing RA occur in 33–91% of cases during post-partum and breastfeeding periods.

Objectives: To assess the effect of lactation on RA activity during the post-partum period.

Methods: Prospective study included 32 RA pts (ARA criteria, 1987) who were followed up and assessed at 30–34 weeks of pregnancy, and at 1, 3, 6 and 12 months post-partum. Pts' median age was 29 (20–37) years, disease duration 8 (1–28) years. RF (62,1%) and ACPA (58,6%) seropositive, of radiographic stage 2–3 (72,4%) and functional class 1–2 (86,2%) prevailed. At each control visit DAS28^{CRP} score and the number of between the visits flares were obtained among breastfeeding and non-breastfeeding women. RA flare was documented based on changes in DAS28^{CRP} score values vs the previous visit following EULAR recommendations.



Results: 6 pts were lost for follow up (FUP; the 1 after Mo 3?, 5 after Mo 5–6 post-partum). Lactation immediately after birth was suppressed in 5 (15,6%)pts. 27 (84,4%)pts were breast-feeding their babies for the period from 2 weeks to 16 months (Me=2,5 [1;6] months). All relevant data on the study population during the FUP is summarized in the Table1.

During the whole FUP the DAS28^{CRP} score was higher among breast-feeding females, although the difference was statistically significant only during the first month post-partum (p=0,01). During the first month post-partum, as well as at Mo3 post-partum RA flares were registered only in nursing mothers, i.e. in 12 out of 27, and in 3 out of 19, respectively. The number of nursing mothers after 3d month was reduced to 8. RA flares in these breast-feeding women were more frequent, than in non-breast-feeders during 3 to 6 months period of the FUP: 6 vs 1 (RR=10,3, 95% CI=2,6;40,1; p=0,0002).Only after 6 mo postpartum the rate of RA flares among nursing mothers did not statistically significant exceed the rate among non-feeders (in 2 out of 5 vs 5 out of 21, p>0,05) (Fig.1).

Assessment of RA flares at all 121 points during 12 months post-partum FUP (59 points during lactation, 62 – after termination of lactation) demonstrate that RA flares were documented in 23 (39%) lactating women and in 6 (9,7%) non-lactating women. Therefore, the risk of RA flare in lactating women was 4-fold higher vs the risk in non-lactating women (RR=4; 95% CI=1,8;9,2; p=0,0002).

Increased RA exacerbation rates among nursing mothers is partially explained by postponement of active therapy. The majority of pts refused initiation of therapy for the sake of breastfeeding.

Approaches to breastfeeding practices in RA mothers should be individual. Nursing is acceptable during RA remission or low disease activity given the patient continues on the recommended drugs, compatible with breast-feeding.

Conclusions: Lactation and breastfeeding is associated with 4-fold higher risk of RA exacerbation as compared to non-breastfeeding population (RR=4; 95% CI=1,8;9,2; p=0,0002)

SAT0103 NON-DIPPING STATUS IS ASSOCIATED WITH DIASTOLIC NOCTURNAL HYPERTENSION IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Troitskaya, S. Velmakin, S. Villevalde, Z. Kobalava. *Propaedeutics of internal disease, RUDN University, Moscow, Russian Federation*

Background: Rheumatoid arthritis is associated with increased cardiovascular risk. Nocturnal hypertension and non-dipping status are important determinants of cardiovascular mortality and morbidity. Little is known about their associations in patients with RA.

Objectives: The aim of the study was to assess the prevalence of nocturnal hypertension and its associations in patients with RA.

Methods: 62 patients with RA (EULAR 2010) without known cardio-vascular disease were examined (73% females, age 58,5±15,4 (M±SD) years, 13%

Abstract SAT0102 – Table 1. The mean DAS28^{CRP} scores in the groups

	III pregn trimester		1 month		3 month		6 month		12 month	
	n	DAS28^{CRP}	n	DAS28^{CRP}	n	DAS28^{CRP}	n	DAS28^{CRP}	n	DAS28^{CRP}
Nursing mothers	–	–	27	3,6±1,2*	19	3,4±1,2	8	3,7±1,1	5	3,2±1,5
Nonnursing mothers	32	3±1,2	5	3,1±1,4*	13	3,3±1,9	23	2,9±1,4	21	2,9±1,1

*p=0,01.

smokers, 61% with AH, 34% with dyslipidemia). Median duration of RA was 8 years (IQR 3–17). Seropositive RA was diagnosed in 69% of patients. Median CRP was 12,1 mg/dl (IQR 2,2–23,4 mg/dl), median rheumatoid factor (RF) was 32,5 IU/ml (IQR 8,3–173 IU/ml). All patients received disease-modifying antirheumatic drugs, 22 (38%) - biological treatment. Median duration of AH was 6,1 years (IQR 0–10 years. All patients with AH received antihypertensive treatment. 24-h peripheral and central BP monitoring was performed (BPLab Vasotens, "Petr Telegin"). Arterial stiffness was assessed by applanation tonometry (Sphygmocor, AtCor, Australia). $P<0.05$ was considered significant.

Results: Mean office BP was 130±15/80±10 mmHg. Mean pulse wave velocity (PWV) was 9,3±3,2 m/s. The dipping states were as follows: non-dipping in 39 (62,9%) patients, dipping – In 7 (11,3%), extreme dipping – in 5 (8,1%) and reverse dipping in 11 (17,7%). Median of nocturnal fall in systolic BP was 3,5% (IQR 0–9%). Isolated nocturnal AH was observed in 12 (19,4%) pts. Patients were divided into 2 groups according to nocturnal fall of BP: G1 (non-dipping - >10%) – 42 (67,7%) pts and G2 (dipping- <10%.) – 16 (32,3%) pts. Non-dippers were older (56,7±16,2 vs 49±12,5 years), more often were smokers (20 vs 0%), had higher BMI (25,4±6,0 vs 22,3±5,1 kg/m^2), median duration of AH (1,5; IQR 0–11 vs 0; min 0, max 1 years), median duration of RA (10; IQR 7–19 vs 2,5; IQR 2–6,5 years), PWV (8,6±2,8 vs 7,2±2,1 m/s), nocturnal BP (120,4±12,7/69,8±10,4 vs 103,8±8,8/59,4±4,4 mmHg), $p<0,05$ for trend. Spearmen analysis revealed significant correlations between nocturnal fall in SBP and RA duration (r=-0,3), central BP (r=0,2 for SBP and DBP), night SBP and DBP (r=-0,3 and -0,5 respectively), $p<0,05$ for trend. Multiple regression analysis showed that elevation of central office DBP and night DBP were significant predictors of non-dipping state (β=-3,7, p=0,008 and -0,7, $p<0,0001$ respectively).

Conclusions: The majority of patients with rheumatoid arthritis are characterized by non-dipping state. Diastolic nocturnal hypertension is a significant predictor of non-dipping in this patient population.

SAT0104 THE IMPACT OF DISEASE ACTIVITY ON PATIENT REPORTED COGNITIVE DYSFUNCTION ("BRAIN FOG") IN RHEUMATOID ARTHRITIS

G.W. Reed[1], L.R. Harrold[1], O. Pala[2], J.M. Kremer[3]. *[1]University of Massachusetts, Worcester; [2]University of Miami, Miami; [3]Albany Medical College and The Center for Rheumatology, Albany, United States*

Background: Rheumatoid arthritis (RA) is a systemic, inflammatory disease and its burden extends beyond joint disease. In recent years, there has been significant advances in treating joint disease but we need a greater understanding of physical and especially psychosocial comorbities to improve quality of life in RA patients. In particular, patients often report "brain fog" meaning a diminished ability to think, learn, remember and perform other mental tasks. Doctors have long recognized that patients with certain physical conditions can experience cognitive dysfunction. Limited information is available in the literature with regard to the prevalence of cognitive dysfunction and factors associated with the condtion in RA.

Objectives: To characterize the association of disease activity with patient reported cognitive dysfunction in patients with RA overall and stratified by age.

Methods: We identified patients with RA aged ≥18 years who were enrolled in the Corrona registry who were biologic naïve at their last follow-up visit (October 2010–June 2016). We compared those who reported cognitive dysfunction (responded "yes" to the question asking if they had "problems with thinking") to those who did not with respect to disease activity based on the Clinical Disease Activity Index (CDAI). Unadjusted and adjusted logistic regression models controlling for demographic (age, gender, race, education), comorbidity/lifestyle (diabetes, fibromyalgia, body mass index, smoking) and RA disease characteristics (disease duration, disability and prednisone dose) were conducted. We further examined whether the relationship between disease activity and cognitive dysfunction varied based on patients age (<55 vs. >55 years) testing the moderating effect using a likelihood ratio test.

Results: There were 10,401 patients who met inclusion criteria of whom 863 (8%) reported cognitive dysfunction. Those who reported cognitive dysfunction were more likely to be women (83% vs. 73%, $p<0.001$), younger (62 vs. 64 years, $p<0.001$), disabled (24% vs. 8%, $p<0.001$), with moderate/high disease activity based on the CDAI (51% vs. 31%, $p<0.001$). In adjusted models, the likelihood of cognitive dysfunction increased with higher levels of disease activity in the total population (Table). The impact was more pronounced in those age <55 (p=0.007; Table).

	Total population*	Age <55**	Age ≥55**
Disease activity OR (95% CI)*			
Remission	1	1	1
Low	2.70 (2.11–3.45)	3.97 (2.34–6.75)	2.42 (1.84–3.20)
Moderate	3.56 (2.75–4.61)	5.93 (3.45–10.19)	3.01 (2.24–4.05)
High	3.90 (2.92–5.21)	7.92 (4.49–13.98)	2.90 (2.04–4.12)

*Adjusted for age, gender, race, disability, education, smoking status, body mass index, diabetes, fibromyalgia, disease duration and prednisone dose. **Adjusted for gender, race, disability, education, smoking status, body mass index, diabetes, fibromyalgia, disease duration and prednisone dose.

Conclusions: Increasing disease activity is associated with a higher likelihood of reporting cognitive disfunction. The effect was more pronounced in younger as opposed to older RA patients.

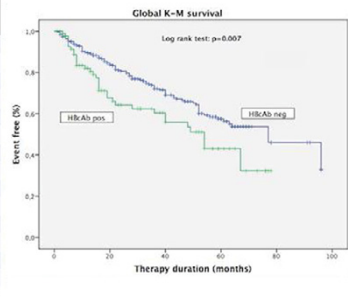
SAT0105 SURVIVAL IN FIRST LINE OF BIOLOGIC AGENTS IN AN APULIAN COHORT OF RHEUMATOID ARTHRITIS PATIENTS WITH OCCULT HEPATITIS B VIRUS INFECTION

G. Carlino[1], M. Fornaro[2], F. D'Onofrio[3], N. Maruotti[2], A. Semeraro[4], C. Zuccaro[5], L. Santo[6], A. Marsico[4], R. Bucci[7], L. Quarta[8], O. Casilli[8], P.C.F. Falappone[5], F. Iannone[2]. *[1]Rheumatology Service, ASL LECCE - DSS Casarano and Gallipoli, Casarano; [2]DETO – Rheumatology Unit, University of Bari, Bari; [3]UOC Reumatologia Universitaria, University of Foggia, Foggia; [4]O.U. of Rheumatology, ASL Taranto, Taranto; [5]Ambulatorio di Reumatologia, Ospedale di Brindisi, Brindisi; [6]O.U. of Rheumatology, ASL Barletta, Barletta; [7]Rheumatology Hospital Unit, A.O.U. Foggia, Foggia; [8]O.U. of Rheumatology, "V.Fazzi" Hospital, Lecce, Italy*

Background: The occurrence of hepatitis B virus (HBV) infection may be a concern during the treatment of patients with Rheumatoid Arthritis (RA). We wondered whether a state of HBV occult infection (anti-HBcAg-pos, HBsAg-neg, HBV-DNA-neg) might influence the effectiveness of biological drugs in RA patients in real-world settings.



Objectives: We performed a retrospective analysis to evaluate the survival on first line biologic drug of RA Apulian patients with HBV occult infection.

Methods: We analyzed longitudinal data of 384 consecutive RA patients starting a first biological drug in a time frame from 1st January 2008 to 31st December 2014. Demographic and disease related characteristics were collected at baseline and at last observation visit. Baseline serological markers of HBV infection and causes of discontinuation of treatment were also recorded. Primary endpoint was the influence of anti-HBcAg-pos on drug survival, estimated by Kaplan-Meier life table analysis. Estimates hazard ratios (HRs) of drug discontinuation or achievement of Clinical Disease Activity Index (CDAI) based remission at last visit, adjusted for disease characteristics, biological drug class and anti-HBcAg-pos were computed by Cox-regression models.

Results: No baseline demographic and disease characteristics difference between anti-HBcAg-pos and anti-HBcAg-neg RA patients were detected, except for DAS28 that was significantly higher in anti-HBcAg-pos group. Drug survival rate was significantly lower in anti-HBcAg-pos (57.6%, median survival time (95% CI) 54 months (38–69)) than in anti-HBcAg-neg patients (67.8%, median survival time (95% CI) 77 months (59–94)). Median survival time for ineffectiveness was 15 months (12–17) for anti-HBcAg-pos and 24 months (18–30) for anti-HBcAg-neg patients (p=0.04). Cox regression models showed a significant association between anti-HBcAg-neg (HR 0.60, 0.39–0.92) or RF/ACPA-neg (HR 1.69, 1.16–2.46) and drug discontinuation, while co-therapy with MTX (HR 2.14, 1.01–4.58) or with steroids (HR 0.38, 0.16–0.91), and RF/ACPA neg (HR 0.45, 0.21–0.95) were independently associated with the achievement of CDAI based remission.

	All (nr. 384)	Anti-HBc neg (nr. 298)	Anti-HBc pos (nr. 86)	P

Values are the mean ± SD unless otherwise indicated. *28 joints Disease Activity Score; CDAI = Clinical Disease Activity Index; RF =Rheumatoid Factor; MTX =Methotrexate.

Conclusions: HBV occult infection seems to influence negatively the effectiveness

of biological therapies in RA patients. However, being a real-life setting, unknown confounding factors might generate an apparent association or mask a true correlation between the HBcAb status and clinical outcomes.

SAT0106 FURTHER "WELLNESS" CAN BE ACHIEVED BY SURGICAL INTERVENTION IN THE IMPAIRED HAND EVEN FOR PATIENTS WITH WELL-CONTROLLED RHEUMATOID ARTHRITIS

H. Ishikawa[1], A. Abe[1], Y. Nomura[1], S. Ito[1], T. Kojima[2], M. Kojima[3], N. Ishiguro[2], A. Murasawa[1]. *[1]Rheumatology, Niigata Rheumatic Center, Shibata; [2]Orthopedic Surgery, Nagoya University Hospital; [3]Medical Education, Nagoya City University Hospital Graduate School of Medicine, Nagoya, Japan*

Background: The hand is the most frequently involved site in rheumatoid arthritis (RA). The treatment aim of RA is achieving and maintaining remission (REM) or low disease activity (LDA) via tight medical control. However, despite remarkable advances in medication, progressive deterioration and/or deformity of the hand, if adequate medication is not administered in the early stage. Surgical reconstruction is still required in hands with functional loss and/or a grotesque appearance caused by joint deterioration or tendon rupture. Recently, patients have expressed a desire to achieve functional REM with a higher quality of life (QOL) and improved mental wellness.

Objectives: The objective of this study was to clarify the systemic effects of surgical intervention in the impaired hand, even in patients with well-controlled disease who have achieved REM or LDA.

Methods: A prospective cohort study was performed in 119 hands of 119 patients with functional loss and/or a grotesque appearance due to RA who underwent primary elective surgery between October 2012 and September 2014. A total of 42 hands in 42 patients (males: 2, females: 40) had a disease activity of REM or LDA just before surgery. In the REM/LDA group, the average (range) age was 61 (29–82) years, and the average (range) disease duration was 15 (2–35) years. The procedures performed included Darrach procedure (ulnar head resection) in 17 hands, radiolunate arthrodesis in 10, extensor tendon reconstruction in 6, thumb/finger metacarpophalangeal joint arthroplasty (Swanson) in 14, proximal interphalangeal (interphalangeal) joint fusion in 4, and thumb CM joint arthroplasty (Thompson) in 4 and so on. The patient-reported outcome (PRO) was assessed using the Health Assessment Questionnaire-Disability Index (HAQ-DI), EuroQol-5 Dimensions (EQ-5D), Beck Depression Inventory-II (BDI-II), Patient's General Health using visual analogue scale of 100 mm (Pt-GH), and the Disabilities of the Arm, Shoulder and Hand (DASH). The 28-joint Disease Activity Score using C reactive protein (DAS28-CRP) and Grip power (GP) were also examined. All of these items were investigated just before surgery (baseline) and again at 6 and 12 months after surgery.

Results: On the whole, the physical function (HAQ-DI, DASH, GP), QOL (HAQ-DI, EQ-5D, Pt-GH), mental wellness (BDI-II, Pt-GH), and disease activity (DAS28-CRP) were significantly improved at 6 and 12 months after surgery compared to baseline ($p<0.05$)[1)]. In the REM/LDA group, a significant improvement was noted in the upper-extremity function (DASH), QOL (EQ-5D), and disease activity (DAS28-CRP) at 6 and 12 months after surgery; however, we did not observe any significant changes in any other items (Table1).

Table 1: Outcome of surgical intervention in the impaired hand for patients with rheumatoid arthritis

		HAQ-DI	EQ-5D	BDI-II	Pt-GH (mm)	DASH	GP (mmHg)	DAS28-CRP
Total n=119	baseline	1.07 (0.73)	0.72 (0.12)	13.4 (9.4)	35 (23)	42.1 (22.5)	126 (58)	3.1 (0.9)
	PO# 6mos.	0.97* (0.78)	0.76** (0.14)	11.7** (8.6)	24** (21)	36.7** (21.7)	135* (55)	2.4** (2.1)
	PO# 12mos	0.91** (0.78)	0.76** (0.14)	11.9** (9.1)	24** (20)	35.7** (23.0)	139** (60)	2.2** (0.8)
REM+LDA n=42	baseline	0.85 (0.63)	0.75 (0.14)	11.0 (8.1)	15 (13)	34.6 (21.8)	143 (61)	2.1 (0.5)
	PO# 6mos.	0.80 (0.68)	0.80** (0.15)	10.1 (8.1)	16 (18)	30.2** (19.6)	143 (57)	1.8** (0.6)
	PO# 12mos	0.81 (0.760)	0.79** (0.16)	10.8 (8.3)	14 (14)	30.1** (21.0)	151 (66)	1.8** (0.7)

Mean(SD) *: p<0.05 compared to baseline, **: p<0.01 compared to baseline

Conclusions: Achieving REM or LDA is not the ultimate goal of treatment for patients with functional loss and/or a grotesque appearance of their hands. Further "wellness" can be achieved by surgical intervention in the affected hand, even for patients with well-controlled RA. Such intervention can also ameliorate the disease activity.

SAT0107 FACTORS THAT INFLUENCE ON PAIN CONTROL DURING TREATMENT FOR RHEUMATOID ARTHRITIS PATIENT

I. Yoshii[1], T. Chijiwa[2]. *[1]Rheumatology, Yoshii Hospital, Shimanto City; [2]Rheumatology, Kochi Memorial Hospital, Kochi, Japan*

Background: Pain control is the most important theme for treatment of rheumatoid arthritis (RA) patient. For pain control, it is obviously important key to control disease activity control. However, patient status at start of treatment (BL), can be also important as well as disease activity control. Including these factors, keys that can reduce pain should be clarified.

Objectives: In this study, factors that affect on pain control were evaluated statistically from real clinical data.

Methods: In 685 RA patients who have been treated for more than 1 year, 500 patients were monitored their disease activity with parameters in 28-joints disease activity index with C-reactive protein (DAS28-CRP), pain score with using visual analogue scale (PS-VAS), modified Health Assessment Questionnaire Disability Index (mHAQ). Drugs administered for patient had been checked at the time of consult.

PS-VAS at consult was evaluated, as it demonstrated no more than 15mm, or decrease than last time more than 20mm was evaluated as "Pain Reduced". Patients sex, ACP, Sharp/van der Heijde Score (SHS), patients current age, history length, DAS28-CRP and its components, PS-VAS at BL, and followed consultation, drug usage and its dosage were evaluated for Pain Reduced statistically with Binary Logistic Regression Analysis. Significant level was set within 1%.

Results: 14,005 times from 495 patients were enrolled in this study. At BL, male patient, higher ACPA, younger age at onset and at BL, older age at following consultation, short following term, smaller SvdHS, greater tenderness joint count (TJC), swollen joint count (SJC), smaller patient's global assessment (PGA), evaluator's global assessment (EGA), great CRP, and smaller mHAQ and DAS28-CRP at BL demonstrated significant contribution on Pain Reduce. In following consult, smaller mHAQ, PS-VAS, and DAS28-CRP, in which smaller PGA and EGA, demonstrated significant contribution on Pain Reduce. In drugs, paraetamol/tramadol combination drug use, non-steroid anti-inflammation drug (NSAIDs) use, pregabalin use, tofacitinib use, and opioid use, and methotrexate dose decrease demonstrated significant contribution on Pain Reduce.

Conclusions: These results suggest that pain control for RA patient depends on patient's status at baseline. And followed disease activity control and activity in daily life (ADL) maintenance. In adding with these, drug selection is also important key. It is also suggested specific drugs have higher effect on pain control. Anti-chronic pain agent can be candidate for pain relief for the patient who complains remnant pain even after successful disease activity control and ADL maintenance.

SAT0108 CLINICAL SIGNIFICANCE OF ANTI-ACTIN ANTIBODIES IN AUTOIMMUNE INFLAMMATORY RHEUMATIC DISEASES

I. Ayadi, L. Laadhar, M. Kallel-Sellami. *Immunology, la Rabta Hospital, Tunis, Tunisia*

Background: Anti-actin antibodies (AAA) are well-described as the major component of smooth muscle autoantibodies (microfilament antibodies). They are specially detected in patients with chronic active hepatitis (CAH) and celiac disease (CD). AAA have also been found less frequently in various other autoimmune disorders including systemic lupus erythematosus (SLE), Sjogren's syndrome, and myasthenia gravis, as well as in primary biliary cirrhosis and alcoholic liver disease.

Objectives: to study clinicobiological characteristics of patients with AAA in autoimmune inflammatory rheumatic diseases (AIRD).

Methods: From January to December 2016, we have collected all cases of patients with AAA presenting for symtomatology of AIRD. The presence of AAA was detected fortuitously by indirect immunofluorescence (IIF) in accordance with its characteristic fluorescence pattern in HEp2 cells (BioRad©). The specificity for F-actin was confirmed by IIF on rat liver-kidney-stomach sections (Biosystem®) and/or Immunodot (Euroimmun®). Coeliac disease related antibodies were performed in all patients with AAA.

Results: Six patients were included: 5 women and a man with a mean age of 43.5 years. AIRD have been suspected in these patients and the mean clinical features were inflammatory polyarthralgia and fever. AIRD was diagnosed in three cases: One patient presented with SLE and two others with rheumatoid arthritis (RA). Hepatic function was disturbed with elevated serum ALT and AST activities in one case higly suspected of CAH. CD was diagnosed in one case. The sixth patient had positive antinuclear antibodies, hypocomplementemia and anti-Ro52, anti-SSB and anti-DFS antibodies associated with FR but didn't

fulfilled SLE criteria. The immunological tests showed anti-nuclear antibodies among all patients with high titre and anti-DNA antibodies in SLE and CAH patients respectively. One RA patient had anti-Ro60 antibodies.

Conclusions: During our study, AAA were found fortuitously in AIRD. This association is rarely described in the literature. Hepatic involvement can be seen during AIRD. Nevertheless, a CAH and CD associated shouldn't be disregarded.

SAT0109 QUANTITATIVE ESTIMATES OF DAMAGE AND DISTRESS, IN ADDITION TO INFLAMMATION, AND THE PROPORTION EACH OF THE 3 VARIABLES AFFECTS CLINICAL MANAGEMENT DECISIONS (TOTAL=100%) MAY CLARIFY ASSESSMENT OF CLINICAL STATUS IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA)

K.A. Gibson[1,2,3], I. Castrejon[4], T. Pincus[4]. *[1]Rheumatology, Liverpool Hospital; [2]ingham Research Institute, Liverpool; [3]University of New South Wales, Sydney, Australia; [4]Rheumatology, Rush University Medical Center, Chicago, United States*

Background: Quantitative assessment in rheumatoid arthritis (RA) is directed to inflammatory activity (INF) and not to joint damage (DAM) and distress (STR - seen as fibromyalgia, depression, etc.). However, DAM and STR may affect clinical management and outcomes of treatment in many RA patients. For example, an RA patient with well-controlled INF who has secondary fibromyalgia may have 0 swollen joints (SJC) and an ESR≥ of 15, but nonetheless have a DAS28 of 5.1, CDAI of ≥22, and RAPID3 of ≥16 (indicating high activity), based on 14/28 tender joints and a patient global assessment of 80/100. Therefore, quantitative estimates of DAM, and STR, as well as INF may clarify patient status and clinical management decisions.

Objectives: To analyze physician quantitative estimates for the proportion of management decisions attributed to INF, DAM, or STR (total=100%) in RA patients seen in routine care.

Methods: At one academic rheumatology center, the rheumatologist completes four 0–10 visual analog scales (VAS) for overall global assessment (DOCGL), INF, DAM, and STR. In patients with DOCGL ≥2, the proportion of management decisions are estimated as %INF+%DAM+%STR=100%. Cross-tabulations were computed for various phenotypes in 5 INF+DAM and INF+STR categories, 0, 1–20%, 21–40%, 42–60%, and 61–100%.

Results: Among the 77 RA patients, >40% of clinical management decisions were attributed to INF in only 31 (40%), versus >40% to DAM in 33 (43%), and >40% to STR in 17 (22%) (Table). No category of INF+DAM or INF+STR included more than 20% of the patients, and patients were found in 17 of 25 possible categories for combinations of INF+DAM and INF+STR. The 13 patients (17%) in whom INF was estimated to contribute 0% to management included 3 of 5 DAM and 5 of 5 STR categories (Table). The 23 patients with 1–20% of management attributed to INF included 4/5 DAM and 5/5 STR categories. The 10 with 21–40% INF included 4/5 DAM and 4 STR categories. The 16 with 41–60% attributed to INF included 3 DAM and 2 STR categories. Only 15 of the 77 patients (19%) had >60% attributed to INF.

Number among 77 RA patients with physician estimates of % inflammation, % damage and % distress (total=100%) in clinical management decisions (% is of all patients)

% Inflammation:	0	1–20%	21–40%	41–60%	61–100%	Total
N	13 (17%)	23 (30%)	10 (13%)	16 (21%)	15 (19%)	77
% Damage:						
0–20%	3 (4%)	8 (10%)	5 (6%)	3 (4%)	14 (18%)	33 (43%)
21–40%	0	0	2 (3%)	8 (10%)	1 (1%)	11 (14%)
41–60%	3 (4%)	4 (5%)	1 (1%)	5 (6%)	0	13 (17%)
61–80%	0	6 (8%)	2 (3%)	0	0	8 (10%)
81–100%	7 (9%)	5 (6%)	0	0	0	12 (16%)
% Distress:						
0–20%	7 (9%)	13 (17%)	3 (4%)	15 (19%)	15 (19%)	53 (69%)
21–40%	1 (1%)	2 (3%)	3 (4%)	1 (1%)	0	7 (9%)
41–60%	2 (3%)	2 (3%)	2 (3%)	0	0	6 (8%)
61–80%	1 (1%)	4 (5%)	2 (3%)	0	0	7 (9%)
81–100%	2 (3%)	2 (3%)	0	0	0	4 (5%)

Conclusions: Quantitative physician estimates of the proportion of clinical management decisions attributed INF, DAM, and STR may help clarify RA patient status and document a basis for clinical decisions. High levels of DAM and/or STR may explain in part why a target of RA remission often is not met in many patients seen in routine clinical care.[1]

SAT0110 THE IMPACT OF PUMMONARY INVOLVEMENT TO THE TREATMENT OF REUMATOID ARTHRITIS

K. Setoguchi[1], F.Y. Chen[1], S. Kamei[1], M. Ogawa[1], S. Kobayashi[2]. *[1]Systemic immunological diseases, Tokyo metropolitan Komagome Hospital; [2]Allergy and Rheumatology, Graduate school of medicine, The University of Tokyo, Tokyo, Japan*

Background: Standard treatment of patients with rheumatoid arthritis (RA) complicated with pulmonary involvements has not been clarified.

Objectives: To evaluate the influence of pulmonary involvement on immunological background and treatment of patients with RA.

Methods: A cross-sectional study was conducted, in which medical records of 479 RA patients who visited our hospital during September the first to November 31th, 2016 were reviewed. Pulmonary involvements were diagnosed by imaging including plain chest radiography or chest computed tomography findings. Patients were divided into two groups, with or without pulmonary involvement, and compared with immunological background (serum level of rheumatoid factor (RF), anti-CCP antibody and recent treatment.

Results: Among 479 patients, pulmonary involvements were diagnosed in 158 patients (female =116), mean age was 73.4 (standard deviation (SD) 9.0) year old, and mean disease duration was 143.3 (SD 125.9) months. Pulmonary involvements included interstitial pneumonia (N=52), organizing pneumonia (N=11), airway diseases (N=36), old tuberculosis (N=18), nontuberculous mycobacteria (N=13), pleurisy (N=5). Higher anti-CCP titers were found in RA with pulmonary involvement than RA only (medians 303.9±596.5 versus 163.5±256.1 U/mL, P<0.001), and the same result was found in RF (medians 322.5±437.2 versus 157.9±277.5 IU/mL, P<0.001). Methotrexate (MTX) was less frequently used (N=56, 35.4% versus N=205, 63.9%, P<0.001), but biological agents were more used (N=31, 19.6% versus N=49, 15.3%), especially abatacept (ABT) was highly used (N=15, 9.5% versus N=8, 2.5%).

Conclusions: RA patients with pulmonary involvements had high immunological response and were less prescribed MTX with may injure lungs and more used ABT. Association between pulmonary involvement and high titer of ACPA, and between positivity for RF or ACPA and good response of ABT were reported. ABT may be useful treatment for RA patients with pulmonary involvement.

SAT0111 CLARA CELL PROTEIN CC16 AND ITS PATHOGENIC ROLE IN BRONCHIAL OBSTRUCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

K.V. Nochevnaya[1], I.I. Nesterovich[2], Y.D. Rabik[2], A.A. Speranskaya[3], V.P. Zolotnitskaya[3], N.A. Amosova[3], V.I. Amosov[3], V.I. Trofimov[2], T.D. Vlasov[4]. *[1]Hospital Therapy Department, Department of Pathophysiology; [2]Hospital Therapy Department; [3]Radiology Department; [4]Department of Pathophysiology, Academician I.P. Pavlov First St. Petersburg State Medical University, Saint Petersburg, Russian Federation*

Background: Bronchial obstruction (BO) is a common manifestation of lung involvement in rheumatoid arthritis (RA) with high incidence from 60 to 80% of all cases. However the pathogenesis of BO in patients with RA remains unknown. Serum level of protein CC16 produced by Clara cells in terminal bronchioles has been reported to decrease in BO associated with bronchial asthma, chronic obstructive pulmonary disease and others. CC16 was considered to demonstrate anti-inflammatory effect via inhibition of interferon-gamma, tumor necrosis factor alpha, interleukin 1 beta, neutrophil elastase and other proinflammatory factors. Also it was shown that CC16 deficiency has a pathogenic effect in BO. In the same time the role of protein CC16 in the pathogenesis of autoimmune diseases (and RA) is not studied.

Objectives: We aimed to evaluate serum level of CC16 in patients with RA in dependence on the presence and severity of BO.

Methods: Serum levels of CC16 in 66 patients with RA and 13 healthy controls were measured by enzyme linked immunoadsorbent assay (ELISA). Patients with RA underwent survey, physical examination and pulmonary function tests (PFTs) including spirometry and bronchodilator test with inhalation of salbutamol (N=41) and body plethysmography (N=11). Statistical processing was carried out using Spearman correlation coefficient and Mann-Whitney test. P value <0.05 was considered as significant.

Results: More than 60% of participants with RA had BO in terminal bronchioles (small airway obstruction), which was revealed with changes of expiratory flows (forced expiratory volume in 1s (FEV1), forced expiratory flow (FEF) between 50% and 75% of forced vital capacity), residual volume (RV) and bronchial resistance (SGaw) in relation to proper values. Depression of post-bronchodilator $FEF_{75\%}$ lower than 70% was adopted as the main criterion of BO. There were no differences (p value >0,05) between serum levels of CC16 in patients with RA (20,14±1,49 ng/ml) and control group (22,70±2,13 ng/ml). However in patient group those with BO had significantly lower levels of CC16 (15,59±1,89 compared with 27,43±2,81 in patients without BO, p value <0,01). Lower CC16 was associated with decreased post-bronchodilator FEV1 and $FEF_{75\%}$ (r =0,345, p

value <0,05 and r =0,486, p value <0,01 respectively), depressed bronchial resistance SGaw (r =0,773, p value <0,01) and increased RV (r = -0,736, p value <0,01), which determined BO severity.

Conclusions: More than half of patients with RA have BO predominantly in terminal bronchioles. Accepting significant decrease of Clara cell protein CC16 in patients with RA having BO we suppose pathogenic relationship between functional depression of Clara cell anti-inflammatory activity and BO in this category of patients.

SAT0112 PREVALENCE AND INCIDENCE OVER 3 YEARS OF DIFFERENT COMORBIDITIES IN RHEUMATOID ARTHRITIS (RA): A 3 YEAR LONGITUDINAL STUDY IN 769 ESTABLISHED RA PATIENTS

L. Gossec, M. Soubrier, F. Foissac, F. Fayet, N. Balandraud, T. Bardin, C. Beauvais, G. Chales, I. Chary-Valckenaere, E. Dernis, L. Euller-Ziegler, R.-M. Flipo, M. Gilson, T. Marhadour, X. Mariette, G. Mouterde, S. Pouplin, P. Richette, A. Ruyssen-Witrand, T. Schaeverbeke, C. Sordet, M. Dougados. *COMEDRA working group, Paris, France*

Background: Comorbidities including cardiovascular (CV) risk, cancer and osteoporosis are frequent in RA.[1]

Objectives: To quantify at baseline and 3 years later, the prevalence (at baseline) and incidence (over 3 years) of some selected comorbidities.

Methods: This was an open long term (3 years) extension of the COMEDRA 6-month randomized controlled trial in which patients with definite, stable RA were visiting a nurse for comorbidity counselling.[2] Comorbidity status was assessed through face-to-face interviews and nurses provided advice on screening and management, at baseline and 3 years later. The frequency of comorbidities was assessed at both timepoints and incidence of new cases was assessed as overall % of patients and as relative increase in the given comorbidity.

Results: Of the 970 recruited patients, 776 (80%) were followed up at 2–4 years (15, 1.5%, had died) and 769 (79%) had available data for comorbidities at both timepoints: at baseline, mean (±SD) age 58 (±11) years, mean disease duration 14 (±10) years; 614 (80%) were women and 538 (70%) were receiving a biologic with a mean DAS28 of 3.1±1.3.

At baseline, the most frequent comorbidities were history of fracture (31.9%) and high blood pressure (30.9%) and at 3 years the comorbidity which had most increased (i.e., incidence) in this population aged around 60 years, was high blood pressure (4%) whereas smoking had decreased (Table).

Table: frequency of comorbidities at baseline and 3 years later

Comorbidity	COMEDRA study baseline (month 0 for group I and month 6 for group II)	Follow-up at 3 years	Absolute increase, % of 769 patients (relative increase, % of baseline prevalence)
Myocardial infarct	13 (1.7)	18 (2.3)	0.6 (38.4)
Angina	9 (1.2)	17 (2.2)	1.0 (88.9)
Stroke	16 (2.1)	29 (3.8)	1.7 (81.2)
Obliterating arteriopathy	8 (1.0)	14 (1.8)	0.8 (75.0)
Diabetes	39 (5.1)	50 (6.5)	1.4 (28.2)
High Blood Pressure	238 (30.9)	270 (35.1)	4.2 (13.4)
Hyperlipidemia	149 (19.4)	170 (22.1)	2.7 (14.1)
Obesity (BMI>=30)	114 (14.8)	124 (16.1)	1.3 (8.8)
Smoking	120 (15.6)	104 (13.5)	-2.1 (-13.3)
Colon cancer	2 (0.3)	2 (0.3)	0 (0)
Breast cancer	23 (3.0)	27 (3.5)	0.5 (17.4)
Lung cancer	1 (0.1)	2 (0.3)	0.2 (100.0)
Prostate cancer	3 (0.4)	4 (0.5)	0.1 (33.3)
Uterus cancer	7 (0.9)	7 (0.9)	0 (0)
Skin cancer (all types)	26 (3.4)	36 (4.7)	1.3 (27.8)
Lymphoma	2 (0.3)	3 (0.4)	0.1 (50.0)
History of fracture	245 (31.9)	256 (33.3)	1.4 (4.5)

Conclusions: Comorbidities are frequent in RA though screening does not always address the most frequent or severe comorbidities. Efforts must be pursued to improve comorbidity screening and prevention.

SAT0113 OBESITY AND METABOLIC SYNDROME INFLUENCE ON N-TERMINAL PRO-BRAIN NATRIURETIC PEPTIDE LEVELS IN RHEUMATOID ARTHRITIS PATIENTS

L. Kondratyeva, T. Popkova, I. Kirillova, D. Novikova, A. Novikov, E. Alexandrova, E. Nasonov. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

Background: N-terminal pro-brain natriuretic peptide (NT-proBNP) is a recognized myocardial injure marker, a known predictor of heart failure and cardiovascular death. Rheumatoid arthritis (RA) patients (pts) were shown to have higher than in general population NT-proBNP concentrations, positively correlating with IL-6 levels. Adipose tissue is considered be one of the sources of this pro-inflammatory cytokine. But on the other hand, metabolic syndrome (MS) and obesity, which also occur in RA pts, are usually associated with lower NT-proBNP levels in general population.

Objectives: To find out whether overweight/obesity or MS may modify NT-proBNP levels in RA pts.

Methods: A total of 68 early RA pts (72% females, 28% males) was enrolled in the study. Mean disease duration was 6 [4;8] months, and RA activity using DAS28 calculator was 5,6 [5,1;6,4] scores. The majority of pts had positive RF (87%) and ACPA (88%). All pts were glucocorticoids and disease-modifying antirheumatic drugs - naïve prior to inclusion. The overweight/obesity was determined by WHO criteria in patients with body mass index (BMI) ≥25 kg/m^2. National Cholesterol Education Program/Adult Treatment Panel III criteria were used to confirm MS. Serum levels of NT-proBNP (pg/mL) were measured using electrochemiluminescence test Elecsys proBNP II (Roche Diagnostics, Switzerland). NT-proBNP levels >125,0 pg/mL were considered as elevated.

Results: Overweight and obesity were established in 54,4% RA pts. Overweight/obese RA pts were older than pts with normal BMI (57 [53;61] years vs 48 [34;61] years, p=0,02), had higher DAS28 scores (5,85 [5,20;6,57] vs 5,28 [4,76;5,69], p<0,01), higher CRP (38,8 [14,3; 47,9] mg/L vs 12,8 [2,2;28,8] mg/L, p<0,01). Elevated NT-proBNP concentrations were found in 62,2% overweight/obese pts vs 29,0% pts with normal weight (p<0,01), median NT-proBNP concentrations were 153,4 [87,3;236,9] pg/mL vs 75,2 [40,2;147,4] pg/mL, respectively (p=0,02). MS was established in 62,2% pts with BMI ≥25kg/m^2 and in 25,8% pts with BMI<25kg/m^2 (p<0,01). Median NT-proBNP concentrations did not vary significantly in pts with and without MS, whether they were overweight/obese (p=0,75), or had normal BMI (p=0,27). Although higher rates of elevated NT-proBNP concentrations were documented in pts with MS (61,3% vs 35,1%, p=0,03). NT-proBNP levels positively correlated with waist circumference (r=0,33, p<0,01), ESR (r=0,25, p=0,04), and CRP (r=0,3, p=0,01).

Conclusions: Overweight and obesity in RA pts were associated with increased NT-proBNP levels. Abdominal obesity was identified as the only MS component, influencing NT-proBNP levels, presumably via up-regulation of the inflammatory process.

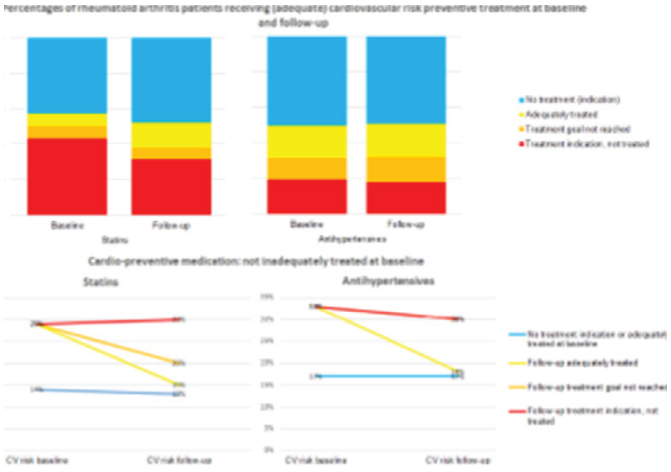
SAT0114 POOR CARDIOVASCULAR RISK MANAGEMENT IN RHEUMATOID ARTHRITIS PATIENTS DESPITE AN EXPLICIT CARDIOVASCULAR RISK MANAGEMENT PROGRAM

M. Heslinga[1], I. van den Oever[1], E. Griep[2], H. Griep-Wentink[2], Y. Smulders[3], W. Lems[1,4], M. Boers[1,4], A. Voskuyl[4], M. Peters[3], D. van Schaardenburg[1], M. Nurmohamed[1,4]. *[1]Amsterdam Rheumatology and immunology Center | Reade, Amsterdam; [2]Antonius Hospital Zuidwest Friesland, Sneek; [3]VU University Medical Center; [4]Amsterdam Rheumatology and immunology Center | VU University Medical Center, Amsterdam, Netherlands*

Background: In 2011, we started a cardiovascular (CV) risk management program for rheumatoid arthritis (RA) patients visiting Reade in the Netherlands. We previously reported the presence of under treatment of hypercholesterolemia and hypertension [1].

Objectives: To assess the effectiveness of our CV risk management program after one year.

Methods: CV risk screening was performed at baseline and we informed the general practitioner (GP) about the results, including advices regarding the initiation of cardio preventive drugs. In high risk patients, antihypertensives were recommended when systolic blood pressure >140 mm/Hg and statins were recommended when low-density lipoprotein >2.5 mmol/l. The decision to start preventive medication was left to the GP. CV risk screening was repeated after one year. Patients completed a questionnaire about the actions that were taken following the results of the initial screening.



Results: Of the 266 patients 202 (76%) were female, the mean age was 58±11 years. After one year, 88 out of 134 patients who received inadequate or no treatment at baseline were still untreated or undertreated. Of the 188 (71%) patients who were at high CV risk and who did have an indication to start therapy, only 7.5% was contacted by their GP and another 6.8% arranged an appointment themselves. While the 10-year CV risk did not decrease in the group as a whole, a risk reduction was found in the patients that started medication. Remarkably, 42% of patients reported lifestyle changes, including more exercise (20%), diet adaption (16%) and weight loss (9%).

Conclusions: It is striking that one year after the introduction of our CV risk

Table 1. Cardiovascular risk factors at baseline and after one year

	Baseline	Follow-up
CV disease history	20 (7.5)	23 (8.6)
CV risk <10%	43 (16.2)	52 (19.5)*
CV risk 10–20%	60 (22.6)	62 (23.3)
CV risk >20%	143 (53.8)	129 (48.5)*
SBP in mm/Hg	135±17	135±18
Body Mass Index in kg/m^2	26.4±5.0	26.3±4.8
TC in mmol/l	5.5±1.0	5.2±1.0**
Triglycerides in mmol/l	1.4±0.8	1.4±0.8
LDL-cholesterol in mmol/l	3.2±0.9	3.0±0.9**
HDL-cholesterol in mmol/l	1.6±0.5	1.6±0.5
TC/HDL-ratio	3.7±1.2	3.7±1.2**
Current smokers	60 (22.6)	53 (20.1)
Diabetes mellitus	12 (4.5)	12 (4.5)
SBP >140 mm/Hg	95 (35.7)	96 (36.2)
LDL >2,5 mmol/l	208 (78.8)	180 (68.4)**
TC ≥6.5 mmol/l	37 (13.9)	26 (9.8)
Antihypertensives	81 (30.5)	88 (33.1)
Statins	38 (14.3)	57 (21.4)**

CV = Cardiovascular, HDL = high-density lipoprotein, LDL = low-density lipoprotein, TC = total cholesterol, SBP = Systolic blood pressure. Results are presented as mean ± standard deviation or n, (%). *p<0.05, **p<0.01.

management program, only 14,3% patients with an indication for preventive treatment visited their GP and only 14% started with CV risk lowering drugs. This is mainly caused by the small percentage of high risk patients that contacted their GP. On the other hand, a high percentage reported the start of healthy lifestyle. These results underscore the need for a short-term follow-up, in close collaboration with primary care providers to ensure appropriate CV risk management. This is a future implementation project that will be initiated shortly.

SAT0115 EFFECT OF BIOLOGICAL DISEASE MODIFYING ANTI-RHEUMATIC DRUGS (BDMARDS) ON CARDIO VASCULAR DISEASE (CVD) RISK IN RA PATIENTS:THREE YEARS RESULTS FROM A CANADIAN COHORT

M. Khraishi[1], C. Molta[2], A. Lewis[3]. *[1]Rheumatology, Memorial University of Newfoundland, St. John's, Canada; [2]Rheumatology, MainLine Rheumatology Lankenau Medical Center, Philadelphia, United States; [3]Epidemiology, Memorial University of Newfoundland, St. John's, Canada*

Background: RA patients have a higher risk for developing CV Diseases (e.g. IHD and stroke) than the general population.We reported previously (ACR, EULAR) the results CV risk in our patients treated with bDMARDs for 1& 2 years.

Objectives: To assess the effect of bDMARDs treatment on 10-year CV disease risk in patients with RA after 36 months and evaluate the impact of their use on the incidence of CV events

Methods: A cohort of RA patients was followed prospectively.Demographics, disease activity parameters, inflammatory markers, CV events, CVD 10 year risk assessment [Framingham Risk Score (FRS)] were ascertained at the baseline and every six months, up to 36 months.Statistical analysis utilized SPSS (IBM version 24) software.

Results: 321 patients were included, of those 270 patients were followed for three years. Eight BDMARDs were included evaluating their effect on disease activity and CV risk in 233 patients who continued on their prospective biologic for the three years.

Significant overall reduction in disease activity in all groups was obtained as compared to baseline. The whole group DAS improved from 3.996 to 3.118. The HAQ also improved significantly (1.201 to 0.857) and the CRP improved significantly (12.91 mg/L to 7.3).

Overall, Total cholesterol (TC) changed from 5.195 mmol/L at baseline to 4.992 (P 0.001). High Density Lipoprotein Cholesterol (HDL-C) increased significantly at 36 months from 1.336 to 1.376. However, the Atherogenic Index (AI) for the whole cohort changed from 3.636 to 3.845. The overall 10 year risk of cardiovascular event increased from 12.878 to 13.8

The cohort included 321 patients. Eight bDMARDs were evaluated to assess their effect on disease activity and CVD risk. The outcomes in 233 patients who continued their prospective biologic for the three years were reported (table). 77% were females, median RA duration was 11 ys. Significant reduction in disease activity in all groups was achieved vs. baseline. The DAS improved from 3.996 to 3.118, the HAQ improved significantly (1.201 to 0.857) and the CRP also improved significantly (12.91 mg/L to7.3). Overall, Total cholesterol (TC) changed from 5.195 mmol/L at baseline to 4.992 (P 0.001). High Density Lipoprotein Cholesterol (HDL-C) increased significantly at 36 months from 1.336 to 1.376. The Atherogenic Index (AI) for the cohort changed from 3.636 to 3.845. The overall 10 year risk of cardiovascular event increased from12.878 to 13.8.

Table 1

	Rituximab n=40	Tocilizumab n=42	Golimumab n=24	Adalimumab n=42	Abatacept n=35	Etanercept n=39
DAS 28	4.3 vs 3.7 P 0.014	4.2 vs 2.8 P<0.001	4.1 vs 3.4 P 0.028	3.4 vs 2.8 P 0.011	4.3 vs 3.1 P<0.001	4.0 vs 2.8 P 0.0015
HAQ	1.3 vs 1.1	1.0 vs 0.9	1.2 vs 1.0	1.7 vs 0.5	1.2 vs 1.0	1.1 vs 0.7 P<0.001
Swollen Joint Count	3.8 vs 2.1 P 0.005	5.0 vs 1.8 P<0.001	5.3 vs 6.7	3.6 vs 1.7 P 0.010	3.7 vs 3.6	3.9 vs 1.7 P<0.001
AI	4.0 vs 3.7 P 0.045	4.7 vs 4.0	3.2 vs 3.94	3.8 vs 3.7	4.1 vs 3.9	4.2 vs 3.7
10 yr CV Risk	15.9 vs 17.9	13.5 vs 14.4	14 vs 15.7	10.1 vs 13.2 P 0.009	13.5 vs 14.1	11.2 vs 12.2

Conclusions: The bDMARDS studied were effective in controlling the disease activity of RA. Although the overall CVD risk was not reduced in the group as a whole at 36 months, bDMARDS may still play a role in reducing the CVD risk in these patients

SAT0116 PREVALENCE OF UNACCEPTABLE PAIN IN PATIENTS WITH LONG-STANDING RA

M.L. Andersson, K. Forslind, B. Svensson. *Department of Clinical Sciences, Section of Rheumatology, Lund University, Lund and Helsingborg, Sweden*

Background: Pain in patients with rheumatoid arthritis (RA) is the most common and troublesome symptom, occurs frequently in many sites in the muscular-skeletal system, causes fatigue and functional impairment. The origin of pain in RA may be inflammatory and/or other, such as increased sensitivity to pain, fibromyalgia and osteoarthritis.

Objectives: To study unacceptable pain in an inception cohort of patients with RA at 15 years follow-up

Methods: This study concerns 477 patients from the BARFOT inception cohort study, consisting of 839 patients with early RA, who have passed the pre-defined 15 year follow-up visit. Unacceptable pain (UP) was defined as ≥40 mm on a continuous VAS pain scale of 100 mm with the ends "no pain" and "worst possible pain" (1). ADL- function was assessed by the HAQ test, physical function by the SOFI test and joint damage by the van der Heijde modified Sharp method. Remission was defined as DAS28 ≤2.6.

The prevalence of UP over time as well as the relationship of UP with clinical variables were assessed. Baseline predictors of UP after 15 years were evaluated by logistic regression.

Results: The mean baseline VAS pain was 45 mm, decreased after 6 months to 29 and remained after that fairly stable through the years ending in 31 at 15 years. UP followed a similar course with 56% of the patients at baseline, which decreased to 30% after 6 months and then behaved stable until 15 years, 34%. Seventy-seven per cent of the patients with UP were not in remission at 15 years, while 23% had UP in spite of being in remission.

Patients with UP who were in remission at the 15 years visit had higher mean age (p=0.004), ESR (p=0.001) and SOFI (p=0.001) than patients without UP.

Patients with UP who were not in remission at this point in time were more often women (0.008) and had more tender joints (p=0.001) than patients who did not have UP.

In both remission groups the mean DAS28, patient global assessment and HAQ were higher in patients with UP compared with patients without.

The means of the x-ray joint damage scores - total score, erosion and joint space narrowing scores - were very similar among patients with or without UP, statistically not significant.

A logistic regression analysis of the ability of baseline variables to predict UP at 15 years was performed. It was shown that female gender and baseline pain independently predicted unacceptable pain at 15 years in patients not in remission while in patients in remission high age and ESR were independent predictors.

Conclusions: Pain is a frequent and relentless suffering during the long-term course of rheumatoid arthritis. In this study, 34% of the patients had unacceptable pain 15 years after diagnosis indicating unsatisfactory treatment. Unacceptable pain also occurred in patients in remission indicating that pain in RA is multifactorial. Therefore, the cause of pain should be identified and treatment initiated accordingly.

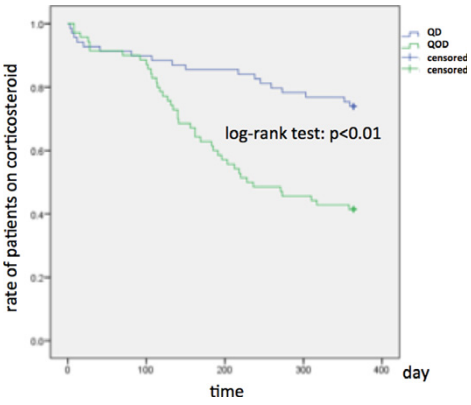
SAT0117 RETENTION RATES OF ADALIMUMAB, ETANERCEPT, AND INFLIXIMAB AS 1ST- OR 2ND-LINE BIOTHERAPY FOR RHEUMATOID ARTHRITIS PATIENTS IN DAILY PRACTICE IN AUVERGNE

M. Soubrier[1], B. Pereira[2], T. Frayssac[1], A. Fan[1], M. Couderc[3], S. Malochet-Guinamand[1], S. Mathieu[1], Z. Tatar[1], A. Tournadre[3], J.-J. Dubost[1]. *[1]Rheumatology, C.H.U. HÔPITAL GABRIEL MONTPIED; [2]DRCI, CHU Gabriel Montpied; [3]Rheumatology, CHU Hopital Gabriel Montpied, Clermont-Ferrand, France*



Background: The use of anti-tumor necrosis factor-alpha agents, or anti-TNFs, has greatly improved the treatment of rheumatoid arthritis (RA). The first three anti-TNFs available to us (infliximab, adalimumab, and etanercept) are the most widely used in treating RA. Their efficacy and safety, demonstrated in extensive randomized and controlled trials (RCTs), were not shown to vary significantly when compared indirectly based on randomized studies. Nevertheless, the randomized studies were of short duration and included a selected population that differed from patients treated in daily practice.
Objectives: To compare, in real-life conditions, the retention rates of the initial anti-TNF treatment (etanercept [ETN], adalimumab [ADA], and infliximab [IFX]) initiated as first-line biotherapy for rheumatoid arthritis (RA) and to evaluate, in case of failure, the switch to another anti-TNF or a non-anti-TNF biological.
Methods: Monocentric retrospective cohort including all patients with RA starting a first anti-TNF between 2001 and 2015.
Results: Among the 346 patients analyzed, 201 received ETN, 82 ADA, and 63 IFX. The first anti-TNF was interrupted in 151 cases. The retention rates were 82.8%, 67.6%, 46.5%, 28.1%, and 22.5% at 1, 2, 5, 10, and 15 years, respectively, with a median retention duration of 52.8 [18.9 -136.2] months (ETN: 59.3 [19.1-NA), ADA: 79.9 [19.3–136.2], and IFX: 37.2 [17.5–134.5], p=0.49). The predictive factors of discontinuation were active RA (DAS28-CRP HR: 1.22 [1.03–1.45]), inflammatory syndrome (ESR HR: 1.01 [1.0–1.02]; CRP HR: 1.00 [1.00–1.01]), absence of MTX treatment (HR: 0.60 [0.43–0.83]), and corticosteroid use (HR: 1.91 [1.31–2.78]). The patients who switched to another anti-TNF treatment had an inferior retention than those who switched to a non-anti-TNF treatment (HR: 0.39 [0.17 - 0.87], p: 0.02). p=0.02).
Conclusions: In real life, there was no difference in retention among the three anti-TNF agents, and 25% of patients continued them at 15 years. After failure of an anti-TNF, the switch to a non-anti-TNF biotherapy showed better retention.

SAT0118 SAFETY AND EFFICACY OF ALTERNATE-DAY CORTICOSTEROIDS AS ADJUNCTIVE THERAPY IN RHEUMATOID ARTHRITIS

M. Suda[1], S. Ohde[2], T. Tsuda[1], M. Kishimoto[1], M. Okada[1]. *[1]Immuno-Rheumatology Center, St. Luke's International Hospital; [2]Center for Clinical Epidemiology, St. Luke's International University, Tokyo, Japan*

Background: Corticosteroids are often used for treating rheumatoid arthritis. However, minimizing adverse events while maximizing efficacy remains challenging. An alternate-day corticosteroid dose is known to decrease adverse events.
Objectives: To investigate the safety and efficacy of an alternate-day corticosteroid dose for treating rheumatoid arthritis.
Methods: We have conducted a retrospective cohort study among patients over 18-year-old who started oral corticosteroids (prednisolone and methylprednisolone) as treatment of rheumatoid arthritis from 2005 to 2014 at St. Luke's International Hospital, a tertiary-level community teaching hospital in Tokyo, Japan. Patients were included if they met the American College of Rheumatology/European League Against Rheumatism 2010 classification criteria for rheumatoid arthritis, and had positive anti-cyclic citrullinated peptide antibody. They were excluded for a history of corticosteroid use for other diseases, or if they were lost to follow-up within 1 year after starting corticosteroids. We divided patients into a daily corticosteroid group (QD) and an alternate-day corticosteroid group (QOD). Patients who received both daily and alternate-day corticosteroids were assigned to the daily group. We investigated the percentage of patients without any infection within 1 year after starting corticosteroids. We have conducted multivariate logistic regression model analysis to calculate adjusted odds ratio for QD/QOD to the outcome. We also investigated the mean decrease in C-reactive protein (CRP) at 1 month as a marker of short-term effectiveness, and the percentage of patients free from corticosteroid at one year, using student's t-test.
Results: In total, 139 patients were analysed (69 in the QD group, 70 in the QOD group). The maximum dose of corticosteroid in one year was not significantly different in two groups (11.4±7.7 mg/day VS 10.1±5.3 mg/day; P=0.267), and the mean daily dose of corticosteroid in one year was significantly higher in the QD group (6.1±4.4 mg/day vs 3.9±1.7 mg/day; P<0.01).The percentage of patients without any infection was 49.2% in QD group, and 75.7% in QOD group. Univariate analysis showed QD group is significantly associated with higher incidence of infection (P=0.001). After multivariate analysis adjusted with age, gender, initial CRP value, mean daily dose of corticosteroid in one year, use of biologic DMARDs, and duration of rheumatoid arthritis, the odds ratio of QD for any infection in 1 year was 3.9 (95% confidence interval [CI], 1.7–8.8; P=0.001).The mean decrease of CRP at 1 month was 1.5 mg/dl in QD group, and 1.1 mg/dl in QOD group (P=0.435).The percentage of patients free from corticosteroids at one year was 26.1% in QD group, and 58.6% in QOD group (P<0.01). Kaplan-Meier plot showed that QD group patients are more difficult to become free from corticosteroid (log-rank test: p<0.01).

Conclusions: Alternate-day corticosteroid dose has a lower adverse event rate and is as effective as a daily corticosteroid dose for treating rheumatoid arthritis.

SAT0119 PREGNANCY OUTCOMES IN WOMEN WITH AND WITHOUT RHEUMATOID ARTHRITIS

M.E.B. Clowse, G. McDaniel, A.M. Eudy. *Rheumatology, Duke University Medical Center, Durham, United States*

Background: Prior studies have suggested higher rates of preterm birth in pregnancies to women with rheumatoid arthritis.
Objectives: We sought to identify differences in the pregnancy outcomes of women with and without RA, and pregnancies that occurred prior to and following RA diagnosis.
Methods: A cross-sectional survey was completed by 75 women with RA age-matched to 75 women without RA. Information collected about each prior pregnancy included: pregnancy outcome (spontaneous abortion, stillbirth, elective termination, ectopic pregnancy, or live birth); the timing of delivery; infant anomalies; methotrexate exposure in pregnancy; and whether the pregnancy was planned. Simple statistics were used to compare pregnancy outcomes between women with and without RA and pregnancies prior to and following RA diagnosis.
Results: The majority of women with RA (83%) and controls (64%) were white, and 11% of women with RA and 28% of controls were African American. About half of controls and 31% of women with RA had education beyond college. The average age at the time of the survey was 32 years (SD: 5) in both RA patients and controls, and the average age at RA diagnosis was 23 years (SD: 10). There were 76 pregnancies in 40 women with RA and 99 pregnancies in 33 healthy controls (see table). The overall rates of live birth, spontaneous abortion, and ectopic pregnancies were similar between groups; there were no stillbirths.
The rate of elective termination was significantly different, with 9% of RA and 30% of control pregnancies terminated (p=0.005). The large majority of the terminations in women with RA occurred prior to diagnosis. The higher frequency of unplanned pregnancy among the controls (38% unplanned RA vs 67% unplanned controls, p=0.0002) likely contributed to this higher termination rate. Of unplanned pregnancies, 45% were terminated in controls, 33% in pre-RA pregnancies, and 9% in post-RA pregnancies. No planned pregnancies were terminated. Three pregnancies in women with RA were exposed to methotrexate (2 unplanned, 1 planned) resulting in 2 spontaneous abortions and 1 live birth, born at term without any reported abnormalities.
The rates of preterm birth and infant abnormalities did not differ significantly between those with and without RA, though among women with RA, all preterm births and infant abnormalities occurred after RA diagnosis. Each of the RA preterm births was delivered between 31–34 weeks gestation. Preeclampsia

was more common in women with RA, but did not differ significantly between pregnancies prior to and after RA diagnosis.
A total of 41% of the post-RA pregnancies had an adverse pregnancy outcome (miscarriage, preterm delivery, or infant abnormality), compared to 13% of pre-RA pregnancies (p=0.01) and 20% of control pregnancies (p=0.01).

	Pregnancies in Healthy Controls	Pregnancies in women with RA	Pregnancies prior to RA	Pregnancies after RA
Number of Pregnancies	99	76	32	44
Live Births	53 (54%)	51 (67%)	20 (63%)	31 (70%)
Spontaneous Abortion	13 (13%)	15 (20%)	4 (13%)	11 (25%)
Ectopic Pregnancies	3 (3%)	3 (4%)	2 (6%)	1 (2%)
Elective Termination	30 (30%)	7 (9%)†	6 (19%)	1 (2%)
Preterm Birth	6/53 (11%)	5/51 (10%)	0	5/31 (16%)
Preeclampsia	1/53 (2%)	9/51 (18%)†	5/20 (25%)	4/31 (13%)
C-section	14/52 (27%)	15/51 (29%)	7/20 (35%)	8/31 (26%)
Abnormal Infant	3/54 (6%)*	3/51 (6%)	0	3/31 (10%)
Adverse Pregnancy Outcome	20 (20%)	22 (29%)	4 (13%)	18 (41%)‡

*one twin pregnancy in controls
†p<0.05, controls vs. RA pregnancies
‡p<0.05, pre- vs. post-RA pregnancies

Conclusions: Women with RA, overall, had similar rates of miscarriage, stillbirth, and ectopic pregnancy compared to healthy women, but pregnancies that occurred after RA diagnosis had higher rates of these adverse outcomes. More pregnancies in women with RA were planned, leading to a lower rate of elective termination.

SAT0120 EVALUATION OF THE RISK OF OVERALL MALIGNANCY AND MALIGNANT LYMPHOMA WITH METHOTREXATE AND BIOLOGICAL AGENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS BASED ON THE IORRA COHORT DURING A 14-YEAR OBSERVATION PERIOD

N. Sugimoto[1], E. Tanaka[1], E. Inoue[1,2], M. Kawano[1], M. Ochiai[1], Y. Shimizu[1], R. Yamaguchi[1], K. Ikari[1], A. Nakajima[1], A. Taniguchi[1], H. Yamanaka[1]. [1]*Institute of Rheumatology, Tokyo Women's Medical University;* [2]*Center for Clinical Research for Development, National Center for Child Health and Development, Tokyo, Japan*

Background: While dramatic progress has been made in this decade with treatments for rheumatoid arthritis (RA), such as methotrexate (MTX) and biological agents, concern about the safety, including the occurrence of malignancy, of these highly effective drugs still exists in daily clinical practice. There has not been an evident association between the use of biological agents and the occurrence of malignancy in most reports from clinical trials[1] and observational studies[2], although MTX use might be associated with the development of malignant lymphoma, called MTX-associated lymphoproliferative disorder[3], in patients with RA. In an analysis of risk factors for overall and site-specific malignancies in Japanese patients with RA, higher disease activity was identified to be a risk factor for overall malignancies (hazard ratio [HR] 1.10, 95% CI 1.02–1.19), suggesting that tight control of RA disease activity would reduce the occurrence of malignancies in patients with RA[4]. However, the risk of malignancies with RA treatments including MTX and biological agents was not assessed in that analysis.
Objectives: We investigated the association between the occurrence of malignancies (overall and malignant lymphoma) and drug use (MTX and biological agents) in a large observational cohort of Japanese patients with RA over a long-term period.
Methods: Among Japanese patients with RA enrolled in the Institute of Rheumatology, Rheumatoid Arthritis (IORRA) cohort from April 2000 to September 2013, data for all malignancies were extracted from patients' self-reports and confirmed by medical records. Data for malignancies occurring in patients who dropped out of the IORRA study during the subsequent three months were also collected from medical information from affiliated hospitals. We analysed whether MTX and biological agents were risk factors for overall malignancy and malignant lymphoma using a marginal structural Cox proportional hazards model[5] adjusted for age, gender, smoking history, body mass index, RA disease duration, rheumatoid factor positivity and disease activity (28-joint disease activity score).
Results: Among 11,106 Japanese patients with RA representing 68,483 person-years, 507 overall malignancies, including 68 malignant lymphomas, were confirmed. Neither MTX nor biological agent use was a significant risk factor for overall malignancy, with an HR (95% CI) of 1.18 (0.77–1.81) and 1.01 (0.65–1.57), respectively, or for malignant lymphoma, with an HR (95% CI) of 1.17 (0.55–2.48) and 1.26 (0.43–3.64), respectively.
Conclusions: The use of MTX and biological agents was not significantly associated with the occurrence of overall malignancy or malignant lymphoma during long-term longitudinal observation of Japanese patients with RA.

SAT0121 COMORBITIES AND DISEASE ACTIVITY ARE RELEVANT FOR FUNCTIONAL DISABILITY IN RHEUMATOID ARTHRITIS

N. Andrade[1], A.M. Kakehasi[2], C. Machado[2], K. Gomes[3], M.F. Guimarães[2], S. Krampe[1], C. Rodrigues[3], C. Brenol[1]. [1]*Federal University of Rio Grande do Sul, Porto Alegre;* [2]*Universidade Federal de Minas Gerais, Belo Horizonte;* [3]*University of Fortaleza, Fortaleza, Brazil*

Background: Health status in rheumatoid arthritis (RA), as measured by Health Assessment Questionnaire - Disability Index (HAQ-DI), has been established as a relevant quantitative measure to assess and monitor the disease (1). Current RA therapy has shown improvement in patient-reported outcomes, but more data on specific factors influencing health status are needed (2).
Objectives: To assess the relationship between functional disability and clinical factors in patients with RA, using the HAQ score.
Methods: Cross-sectional study in patients with RA according to the ACR classification criteria from three Brazilian University Hospitals. Demographic and comprehensive clinical data, including components of metabolic profile were collected. Blood pressure, weight and height were determined in the assessment visit and recent laboratory data were assessed from medical records. Disease activity was evaluated by the Disease Activity Score in 28 joints (DAS28) and functional disability was assessed by the HAQ-DI, considering an index>0.5 as disability. All analyses were performed using Stata for MAC 12.0 software. Variables that achieved a p–value<0.3 in the univariate analysis were considered as candidates to take part of a multivariate binomial logistic model, and in this model, variables were considered as statistically significant at the 0.05 significance level (3).
Results: 453 patients were included, 380 (83.9%) women, mean age 55.7 (±12) years, 356 (79.1%) Caucasian, and mean disease duration of 13.3 (±9) years. Methotrexate were used by 73.5% of the sample. Mean DAS28 was 3.9 (±1.4), mean HAQ score was 1.11 (±0.77), and 23.9% of the patients had HAQ score>0.5. Dyslipidemia, diabetes mellitus (DM), high blood pressure (HBP) and family history of premature cardiovascular disease occurred in 28.6%, 12.8%, 51% and 21.4% of the patients, respectively. Mean body mass index (BMI) was 27.1 (±4.9) kg/m^2. In multivariate analysis age, DAS28, tobacco use, and diabetes mellitus were independently associated with HAQ>0.5 (TABLE 1).

Table 1. Association between clinical parameters, disease activity, and functional disability (HAQ >0.5)

Parameters	OR (IC95%)	p
Age	1.01 (1.01;1.03)	<0.001
DAS28	2.74 (1.69;4,45)	<0.001
Tobacco use	1.37 (1.06;1.77)	0.016
Diabetes Mellitus	1.83 (1.82;1.83)	<0.001

DAS28 – disease activity score in 28 joints; BMI – body mass index; OR – odds ratio.

Conclusions: Our results depicted that distinct factors could reflect in the functional status response in RA patients. This is relevant since it may influence the clinicaly important difference when evaluating the HAQ response in populations with diverse cultural features and different comorbidities prevalence.

SAT0122 WHICH MULTIMORBID CONDITIONS ARE MORE PREVALENT AROUND THE TIME OF EARLY RA DIAGNOSIS AND HAVE THE GREATEST IMPACT ON TRAJECTORIES OF DISEASE ACTIVITY IN THE FIRST YEAR? RESULTS FROM THE CANADIAN EARLY ARTHRITIS COHORT

O. Schieir[1], S.J. Bartlett[2,3], C. Hitchon[4], J. Pope[5], G. Boire[6], B. Haraoui[7], E. Keystone[1], D. Tin[8], C. Thorne[8], V.P. Bykerk[1,9] on behalf of Canadian Early Arthritis Cohort Canada (CATCH) Investigators. *[1]University of Toronto, Toronto; [2]McGill University, Montreal, Canada; [3]Johns Hopkins University, Baltimore, United States; [4]University of Manitoba, Winnipeg; [5]Western University, London; [6]Universite de Sherbrooke, Sherbrooke; [7]Institut de Rhumatologie de Montreal, Montreal; [8]Southlake Regional Health Center, Newmarket, Canada; [9]Hospital for Special Surgery, New York, United States*

Background: Multimorbidity (MM) is highly prevalent in early RA (ERA), and higher counts of conditions are associated with poorer disease control[1]. It is important to understand the number of, and which specific conditions most affect disease presentation, early therapies and disease activity over time.
Objectives: To estimate the prevalence of MM conditions at the time of ERA diagnosis and associations with ERA clinical characteristics, early treatment, and trajectory of disease activity in the 1st year of follow up.
Methods: Data were from ERA patients (<1-year of symptoms) enrolled in CATCH (Canadian Early Arthritis Cohort) who met 1987 or 2010 RA criteria, and had at least two DAS28 measures in the first year. We examined baseline prevalence of: 1) cardiovascular disease (CVD), 2) diabetes, 3) cancer, 4) pulmonary disease, 5) bowel disease, 6) other rheumatic diseases, and 7) psoriasis, obtained from patient-reports of physician-diagnosed medical conditions, 8) obesity (BMI≥30), and 9) depressive symptoms (RAND-12 <42). We compared baseline demographic and clinical characteristics in ERA + each condition vs. ERA alone. We estimated adjusted effects of each condition on early use of RA therapies with logistic regression and adjusted effects of each condition on DAS28 trajectory over the first year of follow up with linear growth models.
Results: The sample included 1,595 patients, 1153 (72%) were female, with a mean (sd) age of 54 (15) years and 6 (3) months of symptoms. At baseline 1,434 (92%) were treated with conventional DMARDs (mostly methotrexate (76%)) and 33 (2%) with a biologic. More than 70% of ERA patients reported at least one MM, and over 30% reported 2+ MMs. Patients with MM were often older and had higher disease activity at baseline, with variations by condition. Patients with RA+CVD or depressive symptoms had a 60% and 90% higher adjusted odds of baseline steroid use, respectively (p<.001). In fully adjusted growth models, relative to patients with ERA only, patients with: a) diabetes, other rheumatic diseases or depressive symptoms had higher baseline DAS28 scores and less improvement over time, b) pulmonary disease, bowel disease, psoriasis or obesity had similar baseline DAS28 scores but less improvement over time; and c) CVD or cancer had higher baseline DAS28 scores but similar improvement over time (all p<0.05).
Conclusions: Multimorbidity is common in ERA patients seen in routine practice and associated with higher disease activity at baseline, less improvement over time, or both, and a greater likelihood of prescribing steroids for certain conditions. Integrating MM in to current RA care strategies may help achieve better patient outcomes.

SAT0123 MULTIDIMENSIONAL EVALUATION OF PAIN IN RHEUMATOID ARTHRITIS

P. Vergne-Salle[1], S. Pouplin[2], A. Bera-Louville[3], M. Soubrier[4], C. Richez[5], R.-M. Javier[6], S. Perrot[7], P. Bertin[1]. *[1]Rheumatology, University Hospital, Limoges; [2]Rheumatology, University Hospital, Rouen; [3]Rheumatology, University Hospital, Lille; [4]Rheumatology, University Hospital, Clermont-Ferrand; [5]Rheumatology, University Hospital, Bordeaux; [6]Rheumatology, University Hospital, Strasbourg; [7]Pain center, University Hospital, Paris, France*

Background: Although pain in rheumatoid arthritis (RA) is frequently thought to be inflammatory in nature, some studies reported clinically significant pain despite relatively low rheumatoid arthritis (RA) disease activity. Less than 50% of patients are satisfied by the management of pain.
Objectives: to report a recent multidimensional evaluation of pain in a large RA population.
Methods: Patients with RA were enrolled in 7 French Rheumatology Centers during a visit or a hospitalization in a transversal observational study. Socio-demographic data, previous and prescribed medications, disease duration, immunologic status, DAS28 score were assessed. Patients completed the multidimensional pain questionnaire from french health autority, the health assessment questionnaire (HAQ), the Beck depression scale and the anxiety scale STAI. Joint damage was evaluated by a simple erosion narrowing score.
Results: Of the 299 screened patients, 295 were included with a mean age of 58.4±11.7 years, 80.3% of female, a mean disease duration of 13.2±9.6 years, positivity of rheumatoid factors in 76.4%, anti-citrullin antibodies in 74% of cases. Concerning medications, 42.7% were treated by corticoids (mean dose=6.4 mg/d), 66% by analgesic drugs (64.1% with acetaminophen, 45.6% weak opioids, 7.1% strong opioids) and 24.4% with NSAIDs. The RA treatments were DMARDs in 69.1% and biotherapies in 82.7% of cases. The mean DAS-28 score was 3.1±1.3 with 38.7% of patients in remission and 15.4% in low disease activity. The verbal scale for satisfaction about pain management showed that a third of patients was very satisfied, the half satisfied, 16% weakly or not satisfied. The mean pain visual analogic scale (VAS) for the last 8 days was 33.6 mm ±26.5/100. 39% of patients had a pain VAS >40 mm/100. The Beck scale showed a moderate to severe depression in 34,3% of patients. Anxiety was present in 57.5%. The impacts of pain on daily behaviors were more important on work. The pain VAS for the 8 days was correlated with the score of depression et with the DAS-28 score (p<0.0001). The population with a pain VAS >40 mm had a significant more important Beck score, anxiety score, HAQ, DAS-28 score and had more impacts of pain on daily behaviors There was no association between pain and structural damage and disease duration. There was no difference between the populations with VAS>40 or <40 mm in terms of IL-6, IL-17 and IL-33 serum levels. The multidimensional evaluation of pain wasn't different between treatement groups (DMARDs, biotherapies) and between the different biotherapies. Multivariate analysis with principal component analysis

found statistically significant associations between pain VAS and depression score, impacts of pain on daily behaviors and between pain VAS and DAS-28.
Conclusions: Almost 40% of patients had moderate to severe pain in a population of severe RA followed in hospital centers and treated with biotherapies in more than 80% of cases. Therefore, pain is still a major outcome to consider in RA. But, the proportion of patients with moderate to severe pain is less important than that one published by Taylor et al. Pain is associated with the DAS-28 score, but also with the depression score.

SAT0124 HIGHER BMI AND SHORTER DISEASE DURATION ARE ASSOCIATED WITH "FIBROMYALGIC" RHEUMATOID ARTHRITIS – EVALUATION USING POWER DOPPLER ULTRASONOGRAPHY

P. Cheung, M. Lahiri. *Rheumatology, National University Hospital, Singapore, Singapore, Singapore*

Background: Power Doppler ultrasonography (PDUS) can differentiate RA patients who truly have active disease. Patients with persistent joint tenderness may not necessarily have true inflammation; yet composite disease activity indices remain high, leading to treatment escalation. These patients are often referred to having "fibromyalgic RA" where tender joints far exceed that of swollen joints.
Objectives: We evaluated the predictors of "fibromyalgic RA (FMRA)," defined as patient-reported tender joint count (TJC) at least 7 greater than PDUS joint count.
Methods: Consecutive RA patients were recruited in a tertiary rheumatology centre in Singapore. Patients self-assessed 28 joints for tenderness, followed by blinded PDUS assessment of the corresponding joints. Patients were grouped into either, (i) PDUS joint count > patient-reported TJC, (ii) PDUS joint count = patient-reported TJC (iii) patient-reported TJC > PDUS joint count, (difference <7) (iv) patient-reported TJC > PDUS joint count, (difference ≥7). Group (iv) is defined as FMRA. Predictors of FMRA were evaluated by multinomial logistic regression.
Results: Of the 101 patients, 81% were female, 72% Chinese, median age of 53.8 (IQR 48.1;62.4) and disease duration of 6.2 (1.9;8.8) years. Median BMI was 23.6 (20.8;27.0) and DAS28 was 3.2 (2.5;4.2). FMRA patients (15%) had a high median patient-reported TJC of 13 (10;18) but low median PDUS joint count of 1 (0;4). Compared to the other groups, they had higher median DAS28 of 4.6 (3.3;5.2), shorter mean disease duration of 2.3 (0.4;6.8) years, and higher median BMI of 26.9 (23.7;32.2). No differences in mean ESR or proportion of patients with seropositive disease were observed. Using Group (i) as the reference, patients with FMRA were more likely to have a higher BMI (adjusted OR=1.6, 95% CI 1.2; 2.1,p=0.001 for every unit increase) and shorter disease duration (adjusted OR=0.8, 95% CI 0.7;0.98,p=0.03 for every additional year). Age, gender, ethnicity, disease activity (PDUS score) and seropositivity were not significant predictors of FMRA.
Conclusions: Higher BMI and shorter disease duration were independent predictors of FMRA. Use of PDUS would be useful in this group, rather than basing treatment decisions on composite disease activity indices alone.

SAT0125 TENOSYNOVITIS IN RHEUMATOID ARTHRITIS: PREVALENCE AND DETERMINANTS OF TENOSYNOVITIS DETECTED IN THE SONAR-ULTRASOUND EXAMINATION IN THE SCQM COHORT

R. Micheroli[1], A. Scherrer[2], L. Brulhardt[3], H. Ziswiler[4], P. Zufferey[5], B. Möller[6], A. Ciurea[1], G. Tamborrini[7]. *[1]USZ; [2]SCQM, Zurich; [3]Hôpital Neuchâtelois, la Chaux-de-Fonds; [4]OsteoRheuma, Bern; [5]CHUV, Lausanne; [6]Inselspital, Bern; [7]Ultrasound Center Rheumatology, Basel, Switzerland*

Background: Tenosynovitis is one of the common features of rheumatoid arthritis (RA). The diagnosis of tenosynovitis is frequently made clinically but for the detection of tenosynovitis, ultrasound (US) is more sensitive. US and MRI detected tenosynovitis is a predictor for unstable remission and erosive progression in RA.
Objectives: The aim of this study was to assess the prevalence and determinants of TS detected in the SONAR (Swiss Sonography Group in Arthritis and Rheumatism) examinations in patients with Rheumatoid Arthritis in the SCQM Cohort.
Methods: The SONAR ultrasound examination consists of a semi-quantitative score employing both multiplanar gray scale (B-mode) and Doppler-mode (PwD) and a TS composite score (grade 0–3). Pathologic TS was defined as TS grade 2–3. Characteristics of patients with and without TS are shown using standard descriptive methods. In a longitudinal sub-group the change in TS from no TS to pathologic TS or vice versa and DAS28 over time was categorized as "worse" (ΔDAS28 ≥2.1), "same" and "better" (ΔDAS28 ≤-2.1) and the correlation between change DAS28 and in tenosynovitis was evaluated.
Results: 941 RA patients with TS score were available. 20% of included patients showed signs of TS. The presence of TS was associated with male gender and higher values of disease activity and physical function disability. Furthermore, 15% of patients in DAS28 Remission had sonographic TS. TS was less frequently observed in patients on biologic therapies (Table 1). The longitiudinal sub-group consisted of 348 patients. The correlation between change in DAS28 and change in TS was poor (polychoric correlation 0.28 [0.14, 0.43]).

Table 1. Patient Characteristics at first Tenosynovitis measurement

Parameter	Tenosynovitis		OR [95% CI]
	Yes (N=184)	No (N=757)	
Male gender, n (%)	59 (32)*	158 (21)*	1.8 [1.2, 2.5]*
Mean age in years	57	56	1.0 [0.99, 1.02]
Mean disease duration in years	5	3	0.98 [0.96, 1.00]
RF positive, n (%)	123 (68)	511 (70)	0.9 [0.7, 1.3]
Anti-CCP positive, n (%)	109 (65)	477 (70)	1.1 [0.6, 2.1]
DAS28 Remission, n (%)	24 (15)*	232 (38)*	0.3 [0.2, 0.5]*
Mean DAS28	3.9*	3.1*	1.6 [1.4, 1.8]*
Mean B-Mode SONAR Score	12.0*	8.0*	1.1 [1.04, 1.08]*
Mean PD-SONAR Score	2.0*	1.0*	1.0 [1.06, 1.12]*
Mean Physician Global Assessment	4.0*	2.0*	1.4 [1.3, 1.5]*
Mean HAQ Score	0.8*	0.5*	1.6 [1.1, 2.2]*
On biologic, n (%)	61 (33)*	399 (53)*	0.4 [0.3, 0.6]*
On synthethic DMARD, n (%)	110 (60)	500 (66)	0.8 [0.6, 1.1]*

*p<0.05.

Conclusions: In the SCQM RA cohort TS is associated with male gender and an overall higher disease activity. One should actively look for TS even in RA patients in DAS28 remission.

SAT0126 MENTAL HEALTH BENEFITS ASSOCIATED WITH REDUCTION IN DISEASE ACTIVITY AMONG RHEUMATOID ARTHRITIS PATIENTS: A SYSTEMATIC REVIEW OF THE LITERATURE

V. Strand[1], R. Rendas-Baum[2], M. Kosinski[2], D. Brooks[3], R. Ganguly[3]. *[1]Stanford University, Palo Alto, CA; [2]Optum, Inc., Eden Prairie, MN; [3]GlaxoSmithKline, Collegeville, PA, United States*

Background: The association between physical functioning and rheumatoid arthritis (RA) disease activity is well established. In randomized controlled trials (RCTs) of RA treatment, reductions in disease activity result in improved physical functioning. The mental health benefits associated with reductions in disease activity are less well recognized.
Objectives: Investigate the association between reductions in RA disease activity and measures of mental health status.
Methods: A systematic review of the published literature of RCTs in RA was conducted. The search was limited to those published in the last 10 years that included the Short-Form (SF)-36 Health Survey as an outcome measure.
Results: The search strategy yielded 77 articles of which 38 were excluded for the following reasons: not RCT (23); focus exclusively on early RA (9); psychometric evaluation (4); review study (1); and off topic (1). Of the 39 articles reporting mean changes in scores on the SF-36 mental health (MH) and role emotional (RE) domains by treatment group, 3 articles also presented these changes in association with reductions in RA disease activity measures.[1–3] In relation to American College of Rheumatology (ACR) response criteria, small to moderate (0.2–0.5 standard deviation [SD]) effect size changes in RE and MH domain scores were observed among RA patients whose ACR responses ranged from 20–49%. Moderate to large effect sizes (0.5–0.8 SD) were reported in RE and MH domain change scores among ACR50 responders. Similar changes in RE and MH domain scores were reported by patients with reductions in Simplified Disease Activity Index (SDAI) of ≥10 points.
Conclusions: The benefits of clinically meaningful reductions in disease activity among RA patients not only include improved physical functioning but also meaningful improvements in overall mental health status. The improvement in mental health is positively associated with reduction in disease activity, with only small to moderate improvements associated with less than ACR50 responses. Additional work is needed to investigate the incremental effects of RA therapies on mental health beyond the effects related to improvements in disease activity.
